A clear airway can be promoted with a room humidifier and oral fluids to reduce viscosity of secretions, as well as regular coughing and deep breathing exercises. A nagging, nonproductive cough can be treated with an **antitussive** as

antitussive: anti—against + tussive—cough

BOX 28-8 ETHICAL CONSIDERATION

Mr. David Hamill, 88 years old, is admitted to a room on the surgical unit. He has been diagnosed with a metastatic tumor of the lung but does not yet know the diagnosis. Dr. Lester and the family have discussed the diagnosis. Dr. Lester decided not to tell Mr. Hamill the diagnosis because he believes that Mr. Hamill would become upset and depressed. Dr. Lester has written an order saying that the patient should not be told his diagnosis.

Two days ago, Mr. Hamill was taken to surgery for a thoracotomy. Since then, he has been asking the nurses, staff, and his family what the physician found in surgery and what the results of the pathology reports were. Dr. Lester has visited Mr. Hamill several times but has avoided talking about the diagnosis by saying that all the laboratory tests were not back yet. The family has been avoiding visiting the patient so that he will not ask them about the diagnosis. The family often asks the nurse when Mr. Hamill will be told his diagnosis. They believe the physician should tell him.

This is an unusual situation. Some elderly patients may not believe that they have a right to question a physician or be fully informed and will simply agree to whatever is suggested. Most families will express their needs, but there are some geographic areas where traditional physician-patient relationships follow a very paternalistic model. This situation provides an opportunity to examine autonomy, paternalism, and veracity.

Most nurses would be uncomfortable in a situation in which both patient and family want information. Would it be different if the patient and family were not asking for information? Would it be different if the patient was Ms. Hamill instead of Mr. Hamill? What degree of "truth" is required? What about partial truths and white lies? Can it ever be beneficial to not tell the truth? What does *paternalism* mean, and why might the physician be taking such a position with this patient? Does the hospital have an ethics committee? Could such a committee help? What options are available to the nurse or for the nurse to suggest to the family? Use the decision-making model described in Chapter 2 to determine possible alternative actions for the nurse to take.

ordered by the physician. Instruct the patient to notify the physician if hemoptysis is persistent. Exposure to powders, tobacco smoke, and aerosols increases airway irritation and should be eliminated. Suctioning may be necessary if the patient becomes too weak to cough effectively.

Anorexia is common in the patient with cancer. Nutrition can be maintained by eating frequent small meals. Nutritional supplements that are high in calories but easy to eat or drink may be used. A dietitian consultation is helpful. Antiemetics before meals may help control nausea. Use of spices to enhance flavor of foods may be used as the patient prefers. Mints may help reduce the metallic taste left in the mouth by some chemotherapeutic medications. Good mouth care is essential. Total parenteral nutrition may be necessary late in the disease. (See Nutrition Notes Box 28–6.)

Pain is controlled by opioids and supportive noninvasive therapies. See Chapter 9 for more information on pain control. Use of opioids for pain control necessitates attention to

bowel function. Prevent constipation with the use of high-fiber foods and extra fluids if tolerated. If these conservative measures are ineffective, request an order for a bulk-forming agent, stool softener, or laxative.

Fatigue is battled with frequent rest periods and assistance with activities of daily living. Encourage the patient to identify and engage in those activities that are most important to him or her and to avoid unnecessary or undesirable activities.

The patient who is grieving should be allowed the opportunity to talk about his or her life and impending death and to express anger or sadness. You should be physically present but should not force verbalization unless the patient wishes to talk. Encourage the family to stay with the patient as much as the patient wishes. Contact a minister or spiritual counselor if the patient desires a referral.

Hospice care is available for the patient who has a terminal condition. This allows the family to have the support needed to care for the patient in his or her home or a home-like environment. Hospice nurses are knowledgeable in end-of-life care and are an invaluable resource to the family.

EVALUATION. Carefully consider the patient's individual goals when evaluating care. Is the patient comfortable and free from unnecessary dyspnea? Is the airway clear, and is nutrition maintained? Are medication side effects manageable? Have patients with terminal conditions come to terms with their impending death, and have they been able to do those things most important to them before their death?

► THORACIC SURGERY

A surgical incision made into the chest wall is called a **thoracotomy**. A thoracotomy may be performed for a number of reasons, including biopsy; removal of tumors, lesions, or foreign objects; to repair trauma following penetrating or crushing injuries; or to repair or revise structural problems. Open heart surgery also requires a thoracotomy and is discussed in Chapter 22.

Types of Thoracic Surgery

Pneumonectomy

A **pneumonectomy** is the surgical removal of a lung. This is usually done to treat lung cancer. It may also be used to treat severe cases of tuberculosis, bronchiectasis, or lung abscesses. Chest drainage is not usually used following a pneumonectomy, because once the lung is removed, the air in the thoracic cavity is absorbed and the cavity fills with serosanguineous fluid. At about 6 months after surgery, the fluid is coagulated and the thoracic cavity is stabilized.

Lobectomy

Lobectomy is the surgical removal of one lobe. This also may be done for lung cancer, tuberculosis, or another localized problem.

Resection

Resection refers to removal of a smaller amount of lung tissue; that is, less than one lobe. A segmental resection is the removal of one segment of a lobe; a wedge resection is removal of a small wedge of lung tissue.

Lung Transplantation

Lung transplant can benefit patients with a variety of serious pulmonary disorders, including pulmonary hypertension, emphysema, cystic fibrosis, and bronchiectasis. Either a single lung, both lungs, or heart and lungs have been successfully transplanted. Better criteria for selecting patients and donors, as well as advancements in surgical techniques, have improved outcomes for these patients.

► NURSING PROCESS: THE PATIENT UNDERGOING THORACIC SURGERY

Preoperative Nursing Care

Perform a thorough assessment before surgery, with a focus on the respiratory system. This gives a baseline against which to judge changes postoperatively. Routine preoperative teaching is done by the nurse and physician. The patient should understand that he or she will wake up in an intensive care environment. If at all possible, it is helpful to have the patient and family tour the intensive care unit before the surgery to decrease anxiety postoperatively. Prepare the patient for waking up after surgery with an endotracheal tube connected to a ventilator, oxygen, chest tubes, intravenous fluids, cardiac monitor, Foley catheter, and possibly an epidural catheter for pain control. Consult the surgeon for specific plans.

Advise the patient that position changes and early ambulation help prevent complications following surgery. Also instruct the patient in the use of an incentive spirometer and coughing and deep breathing techniques.

Postoperative Nursing Care

ASSESSMENT. Following thoracic surgery, patients initially are in an intensive care unit. Larger hospitals have special intensive care units specifically for surgical or thoracic patients. Here patients can be closely monitored for signs of complications. Frequent assessment of vital signs and hemodynamic stability; respiratory rate, depth, and effort; and lung sounds is performed. Remember that lung sounds are absent on the side of a pneumonectomy. An increase in pulse rate or a falling blood pressure may indicate internal bleeding and should be reported immediately. Oxygen saturation is monitored continuously. Often patients report an immediate improvement in breathing, because the pulmonary blood supply is no longer being routed to diseased lung tissue.

Assessment for tracheal deviation alerts you to the possible complication of mediastinal shift. The trachea is normally positioned straight above the sternal notch. If the trachea deviates from the midline position, the surgeon should

be notified immediately. Secretions are monitored and reported to the physician if they become thick, yellow or green, or foul smelling. Arterial blood gases are monitored closely. Chest tubes are usually present (except following pneumonectomy) and are monitored as in Chapter 26. Pain is assessed using a pain rating scale, and incision sites are monitored for redness, edema, or drainage. If the patient is mechanically ventilated, additional assessment of the endotracheal tube and ventilator settings will be necessary.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. After thoracic surgery, many respiratory diagnoses may be appropriate. Following are the most common.

Ineffective Airway Clearance. Regular suctioning is necessary while the patient is intubated to keep the airways free of secretions. Once extubated, the patient is reminded to cough and deep breathe regularly. Postoperative pain must be controlled for the patient to be able to cough effectively. Intravenous or oral fluids, humidified oxygen, and a room humidifier will help keep secretions thin.

Acute Pain. Pain control is important for the patient to be able to ambulate and deep breathe and cough effectively. Some institutions are successfully using epidural analgesia following thoracotomy. Because narcotics depress respirations, it is important to monitor respiratory rate before their administration. The patient is also taught to splint the incision while coughing.

Impaired Gas Exchange. Maintaining Fowler's position and use of an incentive spirometer following extubation encourage the patient to deep breathe and maximize oxygenation. Oxygen and bronchodilators are administered as ordered. Some authorities believe patients should be positioned with the operative side up, others with the operative side down. The surgeon should be consulted for specific positioning orders.

Impaired Physical Mobility. Range-of-motion exercises are performed to prevent contracture of the arm and shoulder on the affected side. This may be done passively at first, then actively when the patient is able. The patient is out of bed on the first or second postoperative day and ambulates as tolerated.

Risk for Infection. Sterile technique for suctioning and standard infection control precautions are used. The patient is extubated as soon as possible to reduce the risk of postoperative infection.

EVALUATION. The patient's airway should remain clear, and secretions should be easily coughed up. The patient should report an acceptable comfort level and be able to cough, deep breathe, and ambulate without excessive discomfort. The patient's breathing should be unlabored, with a respiratory rate of 12 to 20 per minute. The patient's affected arm and shoulder should maintain full range of motion. Signs of infection should be absent.

REVIEW QUESTIONS

- Which of the following assessment findings in the patient with pneumonia most indicates a need to remind the patient to cough and deep breathe?
 - The patient complains of chest pain.
 - The patient has removed her oxygen.
 - The nurse auscultates wheezes and crackles.
 - The nurse notes a fever of 101° F.
- The nurse is caring for a patient with tuberculosis who puts his light on because he needs to use the bathroom. There are green surgical masks in the isolation cabinet outside his room. What should the nurse do?
 - Fit the mask firmly to his or her face before going into the room.
 - Place two masks together and fit them firmly to the face.
 - Ask the patient to put on a mask before entering the room.
 - Ask the patient to wait while the nurse obtains a special high-efficiency mask.
- Which of the following assessment findings does the nurse expect in the patient with emphysema?
 - Purulent sputum
 - Diminished breath sounds
 - Generalized edema
 - Dull chest pain
- Which of the following assessment findings in the patient with pneumothorax does the nurse report immediately?
 - Positioning of the trachea toward the unaffected side
 - Frequent dry cough
 - Moderate pain at the chest tube site
 - Diminished breath sounds over the affected area
- As the nurse enters Mr. Jones's room, he notes that the patient has become confused and combative over the past hour. Which of the following actions is appropriate first?
 - Assess Mr. Jones; check to see if his oxygen is flowing correctly.
 - Page the physician stat.
 - Put up Mr. Jones's side rails and apply soft restraints.
 - Administer an oral sedative.

6. Which of the following interventions is most appropriate for the patient with an ineffective breathing pattern?
 - a. Encourage the patient to cough and deep breathe.
 - b. Encourage oral fluids.
 - c. Teach the patient controlled diaphragmatic breathing.
 - d. Allow the patient to rest between activities.
7. Mrs. Jackson had an abdominal hysterectomy yesterday. The nurse enters her room and finds her acutely short of breath, with a look of panic in her eyes. Which of the following additional symptoms is most important as the nurse decides what to do?
 - a. Mrs. Jackson complained of pain in her left leg earlier this morning.
 - b. Mrs. Jackson states that she also has a headache.
 - c. Mrs. Jackson has a recent history of an upper respiratory infection.
 - d. Mrs. Jackson has not eaten in 24 hours.

Answers to CRITICAL THINKING

Mr. Smith

1. A complete respiratory history is taken as described in Chapter 26. An open-ended question such as "What happened to bring you to the hospital?" elicits information about the incident. In addition, questions to determine mental status and ability to make decisions and function safely on his own are appropriate. If any concerns arise, a social service consultation might be helpful for discharge planning.
2. Mr. Smith should be instructed to always read label warnings before using any cleaning products in the future and to never mix bleach and ammonia!

Jim

1. Ask questions based on the WHAT'S UP? format:
Where (not applicable)
How does it feel? Does the coughing cause chest pain? Are you short of breath?
Aggravating and alleviating factors. What makes the cough worse? What seems to help? Do you use any techniques at home that are helpful?
Timing. How often do you cough during a day? Is it interfering with sleep and rest?
Severity. How bad is it on a scale of 0 to 10? How much sputum are you coughing up? What color is it?
Useful other data. Are you experiencing any other symptoms with your cough (such as shortness of breath, nausea, loss of appetite)?
Patient's perception. Is it better or worse than usual today? How can I help? (The patient with long-standing disease often knows what will help but is hesitant to ask.)
2. The most appropriate nursing diagnosis is ineffective airway clearance related to excessive secretions and ineffective cough.
3. Provide hydration with oral liquids and a room humidifier to liquefy secretions. Administer expectorants as ordered. Instruct the patient in coughing and deep breathing exercises to increase the effectiveness of his cough. Provide good oral care following expectoration of sputum to freshen the patient's mouth. Obtain an order for chest physiotherapy to help loosen and drain secretions.

4. $300 \text{ mg}/200 \text{ mg} \times 5 \text{ mL} = 7.5 \text{ mL}$
5. "Patient coughed up 200 mL of bright yellow, foul-smelling sputum. Lungs have scattered crackles and wheezes throughout after coughing episode. **Expectorant** given; fluids encouraged. Mouth care provided."

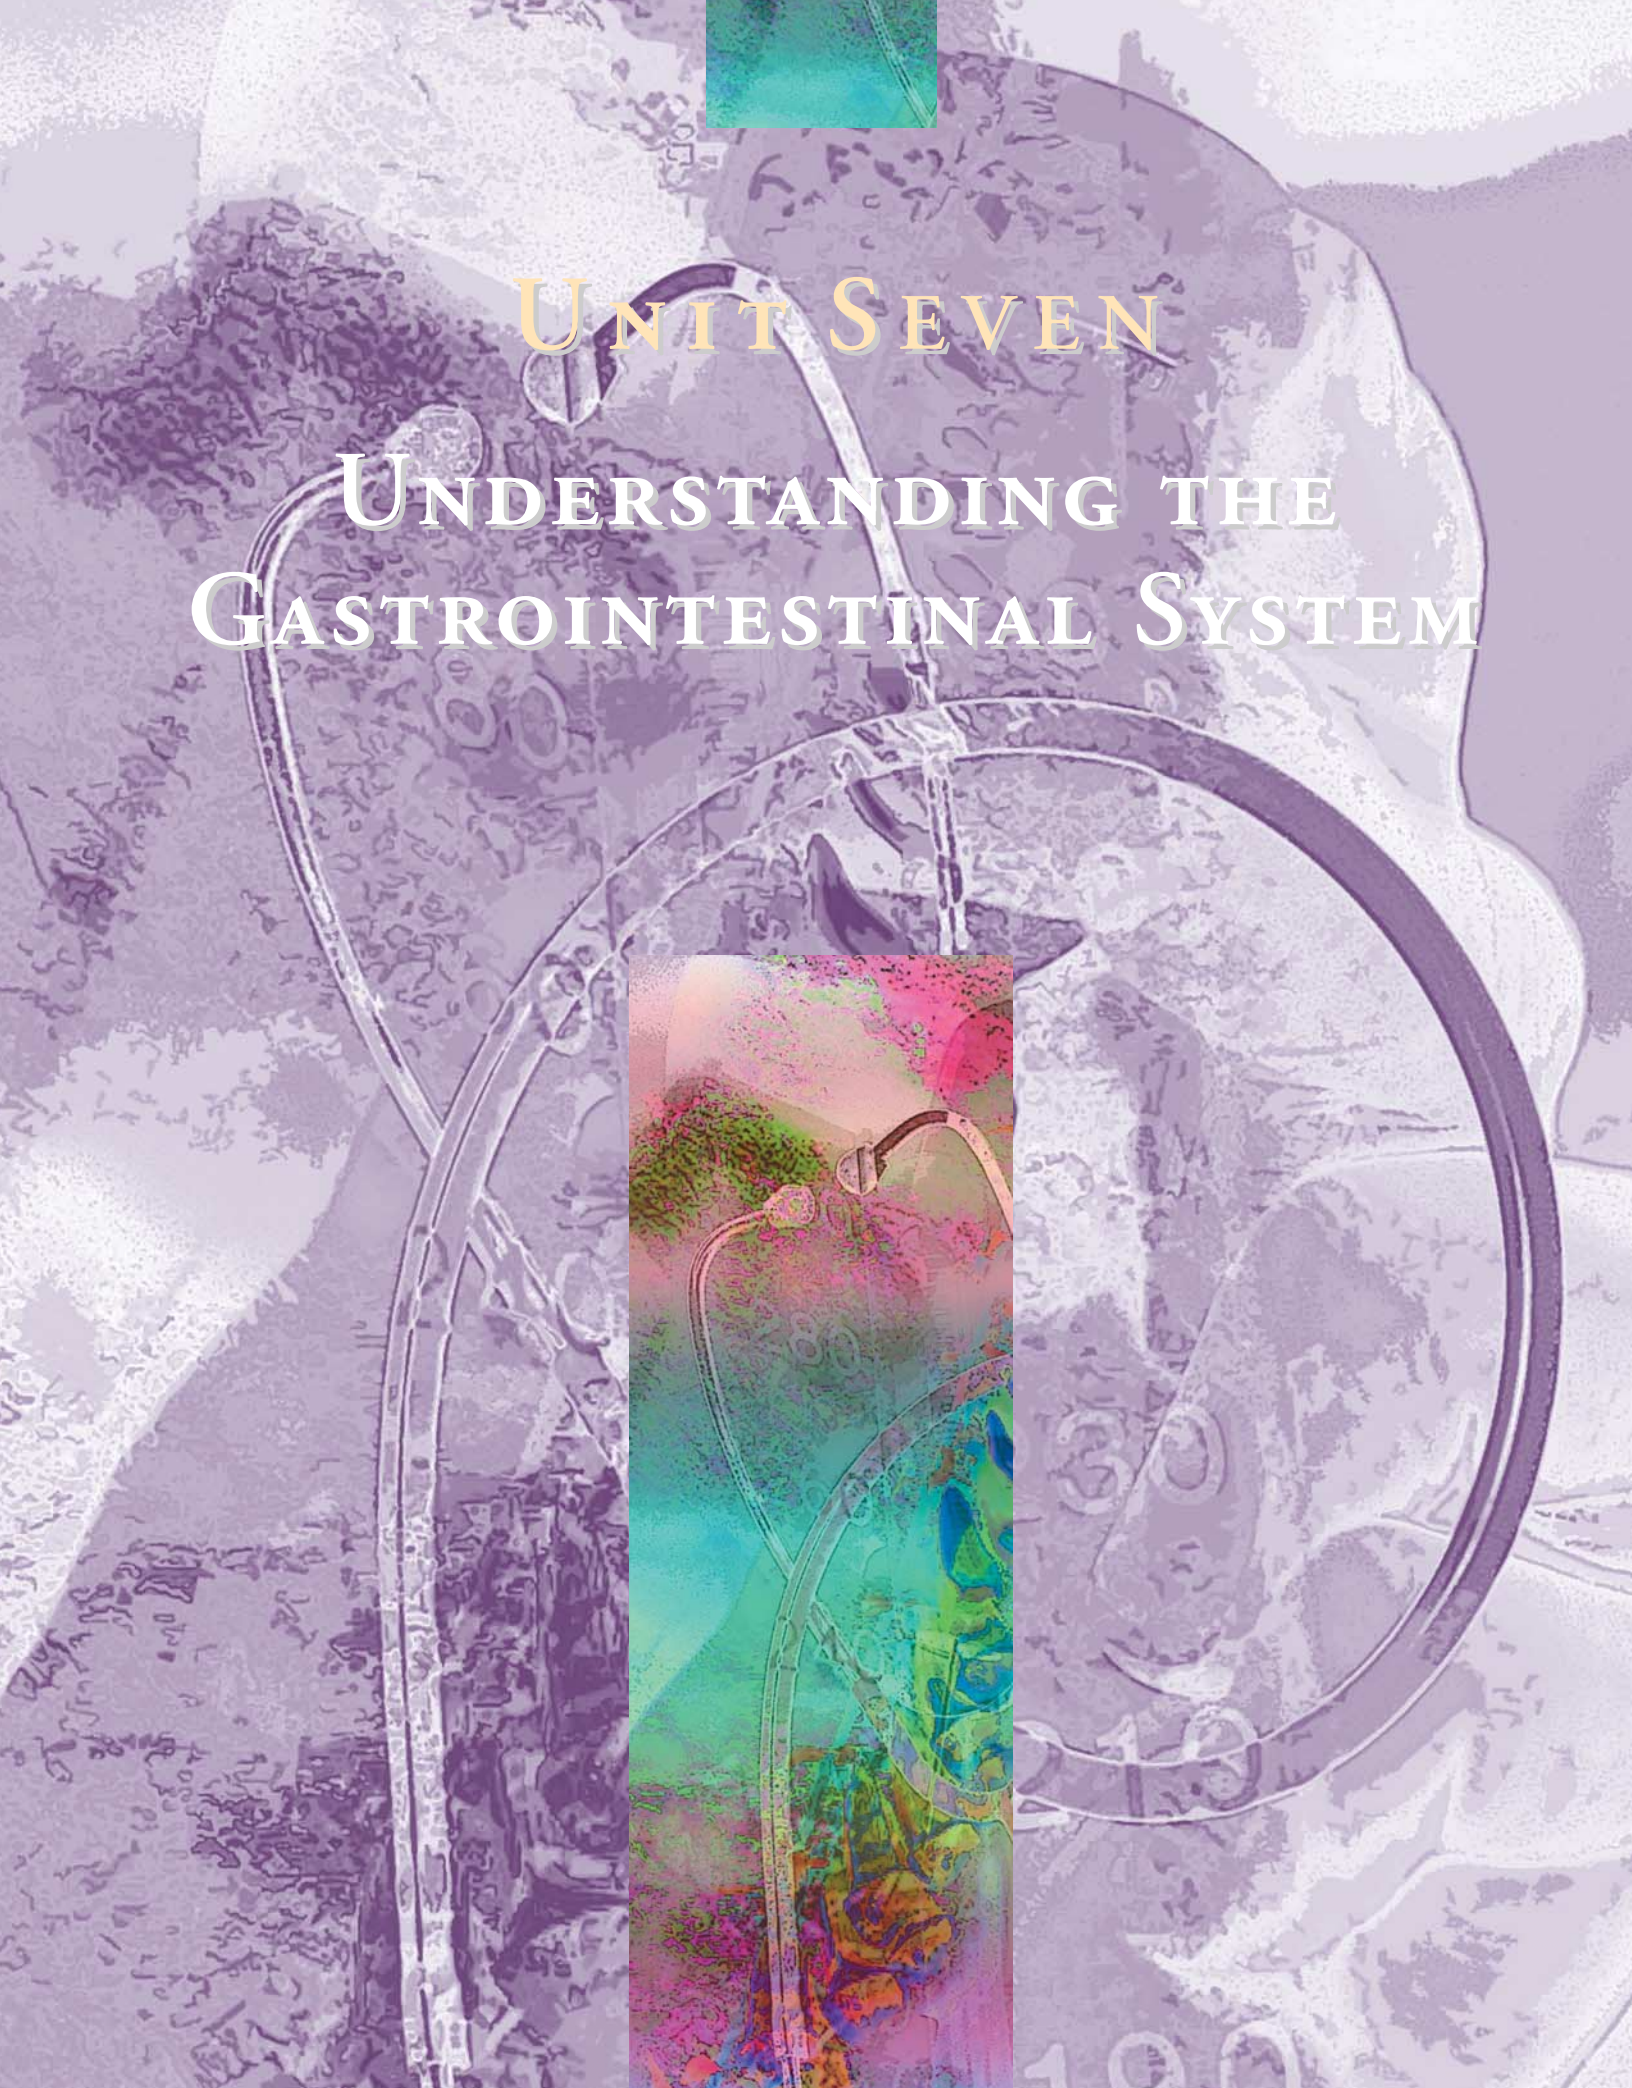

Mr. Franklin

1. You need to do several things at once. You will begin by speaking in a calm voice and trying to help Mr. Franklin to calm himself by doing pursed lip breathing. Assure him that you will help him and won't leave. At the same time, check his oxygen to make sure it is on the ordered number of liters and that his tubing is not kinked or disconnected. Grab the bedside table for him to lean on. Call for someone to page a respiratory therapist to do an NMT if ordered. Have someone bring a pulse oximeter to check his oxygen saturation. Also call for the registered nurse (RN) to administer IV morphine if ordered. All this should take about 1 minute! Once Mr. Franklin is a bit calmer, you can find out what happened. Did the exertion of moving to the bedside commode cause his dyspnea? Check his vital signs and lung sounds, and work with the RN to determine if this represents a change in Mr. Franklin's condition that should be reported to the physician.
2. Teach Mr. Franklin that he should probably stay on bedrest until his acute exacerbation is resolved. Once he is able to start moving around, he should call for help to get up. Review his controlled breathing exercises, which he can use during movement, and encourage rest between activities.
3. "3:00: Patient up on BSC, RR 36 and labored, color gray, appeared very apprehensive. O_2 on at 4 L per min per NC, assisted to lean on overbed table. Encouraged pursed lip breathing. VS 146/64, 102, 36, SaO_2 86%. RT paged; administered PRN NMT. LS diminished, no cough. At 3:15, patient appears much more calm, RR 24 and less labored, SaO_2 90%."

QUESTIONS TO GUIDE YOUR READING

1. What are the structures of the gastrointestinal system?
2. What are the functions of each organ of the gastrointestinal system?
3. How does age affect the gastrointestinal system?
4. How would you perform a gastrointestinal assessment on a patient with actual or potential problems of the mouth, esophagus, stomach, and intestines?
5. How would you prepare, teach, and provide follow-up care for patients having various diagnostic tests of the gastrointestinal tract?
6. What therapeutic interventions would you provide for patients with each type of gastrointestinal disease?

► REVIEW OF NORMAL GASTROINTESTINAL ANATOMY AND PHYSIOLOGY

The alimentary tube is part of the digestive system (Fig. 29–1). It extends from the mouth to the anus and consists of the oral cavity, pharynx, esophagus, stomach, small intestine, and large intestine (or colon). Digestion begins in the oral cavity and continues in the stomach and small intestine. Most absorption of nutrients takes place in the small intestine. The large intestine is where the majority of water is reabsorbed from digested food. Undigestible material, mainly cellulose, is then eliminated from the large intestine.

Oral Cavity and Pharynx

The boundaries of the oral cavity are the hard and soft palates superiorly, the cheeks laterally, and the floor of the

mouth inferiorly. Within the oral cavity are the teeth and tongue and the openings of the ducts of the salivary glands.

The teeth begin mechanical digestion, the physical breakup of food into smaller pieces to create more surface area for the chemical digestion brought about by enzymes. The roots of the teeth are in sockets in the jawbones (the mandible and maxillae). The gums, or gingiva, cover the jawbones and surround the bases of the crowns (tops) of the teeth. The tooth sockets are lined with a periodontal membrane that produces a bonelike cement to anchor the teeth.

The tongue is made of skeletal muscle innervated by the hypoglossal nerve (twelfth cranial nerve). The papillae on the upper surface of the tongue contain taste buds, innervated by the facial and glossopharyngeal nerves (seventh and ninth cranial). The tongue is important for chewing because it keeps food between the teeth. Elevation of the tongue is the first step in swallowing.

The three pairs of salivary glands are the parotid, submandibular, and sublingual glands. Their ducts carry saliva to the oral cavity. The presence of anything in the mouth increases the rate of secretion; this is a parasympathetic response mediated by the facial and glossopharyngeal nerves. Saliva is mostly water, which is used to dissolve food for tasting and moisten the food for swallowing. The only digestive enzyme in saliva is amylase, which digests starch to maltose. Usually, however, food does not remain in the mouth long enough for amylase to have any significant effect.

The pharynx is a muscular tube that is a passageway for food exiting the oral cavity and entering the esophagus. When a mass of food is pushed backward by the tongue, the constrictor muscles of the pharynx contract as part of the swallowing reflex. This reflex is regulated by the medulla.

Esophagus

The esophagus is about 10 inches long and carries food from the pharynx to the stomach. No digestion takes place in the esophagus. **Peristalsis** (rhythmic contraction of muscles) of the muscle layer in the wall of the esophagus is one-way; food reaches the stomach even if the body is upside down. At the junction with the stomach, the lumen of the esophagus is surrounded by the lower esophageal sphincter (LES; gastroesophageal sphincter, or cardiac sphincter), a circular smooth muscle. The LES relaxes to permit food to enter the stomach and then contracts to prevent the backup of stomach contents. Incomplete closure of the LES may allow gastric juice to splash up into the esophagus.

Stomach

The stomach is in the upper left abdominal quadrant, to the left of the liver and in front of the spleen. It is a saclike organ that extends from the esophagus to the duodenum of the small intestine. Some digestion takes place in the stomach, and it also serves as a reservoir for food so that digestion may take place gradually.

The parts of the stomach are shown in Figure 29–2. The LES provides the opening from the esophagus to the stom-

Figure 29-1 Anterior view of the digestive system. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 353, with permission.)

The author acknowledges the contribution to this chapter by Gary Sanders Lott.

Figure 29-2 Stomach: anterior view and partial section. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 359, with permission.)

ach. The fundus forms the upper curve of the stomach. The body of the stomach is the large, central portion, bounded laterally by the greater curvature and medially by the lesser curvature. The pylorus is adjacent to the duodenum, and the pyloric sphincter surrounds the junction of the two organs.

When the stomach is empty, the mucosa has folds called rugae. The rugae flatten out as the stomach fills and permit expansion of the lining. The mucosa contains gastric pits, the glands of the stomach that produce gastric juice. Gastric juice is mostly water and contains mucus, pepsinogen, and hydrochloric acid. Pepsinogen is an inactive enzyme that is changed to active pepsin by hydrochloric acid; pepsin begins the digestion of proteins to polypeptides. Hydrochloric acid creates the pH of 1 to 2 that is necessary for pepsin to function and to kill most microorganisms that enter the stomach.

Gastric juice is secreted at the sight or smell of food; this is a parasympathetic response. The presence of food in the stomach stimulates the secretion of the hormone gastrin by the gastric mucosa. Gastrin increases the secretion of gastric juice.

The stomach wall has three layers of smooth muscle: circular, longitudinal, and oblique. These provide for very effi-

cient mechanical digestion to change food to a thick liquid called chyme. The pyloric sphincter contracts when the stomach is churning food and relaxes at intervals to allow small amounts of chyme to pass into the duodenum, then contracts again to prevent the backup of intestinal contents into the stomach. Carbohydrates are most readily digested by the stomach, followed by proteins and fats.

Small Intestine

The small intestine is about 1 inch in diameter and approximately 20 feet long. Within the abdominal cavity, the coils of the small intestine are encircled by the colon. The small intestine extends from the stomach to the cecum of the colon. The duodenum is the first 10 inches and contains the hepatopancreatic ampulla (ampulla of Vater), the entrance of the common bile duct. The jejunum is about 8 feet long, and the ileum is about 11 feet in length.

Digestion is completed in the small intestine, and the end products of digestion are absorbed into the blood and lymph. Bile from the liver and enzymes from the pancreas function in the small intestine (Table 29-1). When chyme enters the

TABLE 29-1 DIGESTIVE SECRETIONS

Organ	Enzyme or Other Secretion	Function	Site of Action
Salivary glands	Amylase	Converts starch to maltose	Oral cavity
Stomach	Pepsin	Converts proteins to polypeptides	Stomach
	Hydrochloric acid	Changes pepsinogen to pepsin; maintains pH 1–2; destroys pathogens	Stomach
Liver	Bile salts	Emulsifies fats	Small intestine
Pancreas	Amylase	Converts starch to maltose	Small intestine
	Lipase	Converts emulsified fats to fatty acids and glycerol	Small intestine
	Trypsin	Converts polypeptides to peptides	Small intestine
	Peptidases	Converts peptides to amino acids	Small intestine
Small intestine	Sucrase, maltase, lactase	Converts disaccharides to monosaccharides	Small intestine

duodenum, the intestinal mucosa produces the enzymes sucrase, maltase, and lactase, which complete the digestion of disaccharides to monosaccharides, and the peptidases, which complete the digestion of proteins to amino acids.

The absorption of nutrients requires a large surface area, and the small intestine has extensive folds for this purpose. The circular folds (*plicae circulares*) are macroscopic folds of the mucosa and submucosa. Villi are folds of the mucosa, and microvilli are microscopic folds of the cell membranes on the free surface of the intestinal epithelial cells. Within each villus is a capillary network and a lymph capillary called a lacteal. Water-soluble nutrients (monosaccharides, amino acids, minerals, water-soluble vitamins) are absorbed into the blood in the capillary networks. Fat-soluble vitamins and fatty acids and glycerol are absorbed into the lymph in the lacteals.

Large Intestine

The large intestine extends from the ileum of the small intestine to the anus. It is about 5 feet long and 2.5 inches in diameter. The cecum is the first part, and at its junction with the ileum is the ileocecal valve, which prevents backup of colon contents into the small intestine. Attached to the cecum is the small, dead-end appendix, apparently a vestigial organ (an incompletely developed structure that was more developed in a previous stage of the species) for people, but one that may become a site of infection.

The other parts of the colon are the ascending, transverse, and descending colon, which encircle the small intestine; the sigmoid colon, which turns medially and downward; the rectum, which is about 6 inches long; and the anal canal, the last inch that surrounds the anus (clinically, the terminal end of the colon is usually referred to as the rectum).

Although no digestion takes place in the colon, its functions are important. The colon temporarily stores and then eliminates undigestible material. The mucosa absorbs significant amounts of water and minerals, as well as the vitamins produced by the normal bacterial flora.

Elimination of feces is accomplished by the defecation reflex, a spinal cord reflex over which voluntary control may be exerted. When peristalsis propels feces into the rectum, receptors in the smooth muscle layer detect the stretching and generate impulses to the spinal cord. The returning motor impulses cause contraction of the smooth muscle of the rectum and relaxation of the internal anal sphincter, which surrounds the anus. Surrounding the internal sphincter is the external anal sphincter, which is made of skeletal muscle and may be voluntarily contracted to prevent defecation.

Aging and the Gastrointestinal System

Many changes occur in the aging gastrointestinal (GI) system (Gerontological Issues Box 29–1). The sense of taste becomes less acute, and there is greater likelihood of periodontal disease and oral cancer. There may be difficulties with chewing if teeth have been lost. Secretions throughout the GI tract are reduced, and the effectiveness of peristalsis

BOX 29-1 GERONTOLOGICAL ISSUES

Age-related Changes in the Gastrointestinal System

Mouth

Tooth enamel becomes harder and more brittle.
Tongue atrophy results in less acute taste sensations.
Sweet taste sensation is lost to a greater degree than sour, salt, and bitter.
Saliva production decreases by 33%.

Esophagus

Esophageal motility decreases, the esophagus dilates, and emptying is slower.
Gag reflex is weaker.

Stomach

Decreased mobility of stomach results in decreased gastric emptying.
Gastric hydrochloric acid production is decreased.

Large and Small Intestines

Fat absorption is slower in the intestine.
Large and small intestine begin to atrophy.
Mucous secretions and elasticity of rectal wall are decreased.
Weakness of intestinal wall can result in diverticulosis.
Absorption of vitamins B₁ and B₁₂, calcium, and iron is faulty.

diminishes because of loss of muscle elasticity and slowed motility. Indigestion may become more common, especially if the LES loses its tone, and there is greater chance of peptic ulcer. In the colon, diverticula may form. Constipation may be a problem, as may hemorrhoids. The risk of colon cancer also increases with age.

► NURSING ASSESSMENT

Nursing assessment of the GI system includes a patient history and physical examination (Box 29–2).

BOX 29-2 Nursing Assessment of the Gastrointestinal System

1. Visually inspect the abdomen for size, shape, and color of skin.
2. Does the patient have bowel sounds? Are they heard in all four quadrants? How long do bowel sounds last in each quadrant? What do they sound like?
3. Is the abdomen hard or soft? Is it distended with fluid? Does the patient have pain in the abdomen? Are there any masses?
4. Has the patient had any nausea or vomiting in the preceding 24 hours?
5. What type of diet is the patient on? Is the diet tolerated?
6. Can the patient swallow without difficulty?
7. What is the patient's weight and height? Has the patient had any recent changes in weight?
8. What are the patient's bowel patterns? How often does the patient usually have a bowel movement? What is the color? What is the consistency? Does the patient have a colostomy? If so, what does the stoma look like?
9. What drugs are being prescribed? How do the drugs relate to the GI system? Are they working? How do you know?
10. What laboratory values relate to the patient's GI system? Are they normal or abnormal? What do the results mean?

Subjective Data

Health History

Demographic data is obtained, including travel history, which may help in diagnosing the cause of GI symptoms such as diarrhea. Assessment of current signs and symptoms includes asking the WHAT'S UP? questions: where it is, how it feels, aggravating and alleviating factors, timing, severity, useful data for associated symptoms, and perception by the patient of the problem. Also documented are the patient's normal bowel pattern; changes in bowel patterns or habits; a history of any gastrointestinal diseases, such as ulcers, cancer, Crohn's disease, or colitis; or an unexplained weight loss or gain. Information about previous GI surgeries is obtained. Signs or symptoms of disease, such as bloody or tarry stools, rectal bleeding, stomach pain, or abdominal pain, are also noted.

Medications

The patient is asked about medication use such as non-steroidal anti-inflammatory drugs (NSAIDs), aspirin, vitamins, laxatives, enemas, or antacids. Heavy use of medications that can cause irritation and bleeding in the GI tract, such as NSAIDs or aspirin, should be carefully noted. Elderly patients with arthritis often use these types of medications for pain control. The patient's knowledge of the side effects of these medications should be assessed to identify teaching needs. Elderly patients may use laxatives regularly and develop a dependence on them. Teaching may be needed on normal bowel patterns and laxative use.

CRITICAL THINKING

Mrs. Todd

Mrs. Todd, 74, has arthritis and takes eight aspirin daily for pain control. She is scheduled for an **esophagogastroduodenoscopy** (EGD) for suspected GI bleeding caused by unexplained anemia.

1. What is a likely cause of the GI bleeding?
2. What could you do to help prevent future bleeding episodes for Mrs. Todd?

Answers at end of chapter.

Nutritional Assessment

A diet history should include usual foods and fluids, allergies, appetite patterns, swallowing difficulty, and use of nutritional and herbal supplements (Cultural Consideration Box 29–3). A patient food diary can be used to provide more detailed information. Elderly patients may be on fixed incomes, which may limit their food budget and result in meal skipping or purchasing of inexpensive foods. The elderly patient's daily food intake should be explored, especially if malnutrition, financial limitations, or living alone is noted (Home Health Hints).

Also explored during a nutritional assessment are patterns of gastric acid reflux, indigestion, heartburn, nausea,

BOX 29-3 CULTURAL CONSIDERATION

Questions to ask when performing a cultural nutritional assessment:

1. What types of your cultural foods are available in your community?
2. What are your preferred foods over foods available and eaten?
3. Which foods do you most commonly consume?
4. How and where are your foods chosen and purchased?
5. Who prepares the food in your household?
6. Who purchases the food in your household?
7. How is your food stored for future use?
8. How is your food prepared before eaten?
9. How is any uneaten food discarded?
10. What foods do you eat to maintain your health?
11. What foods do you avoid to maintain your health?
12. What foods do you eat when you are ill?
13. What foods do you avoid when you are ill?

HOME HEALTH HINTS

- Be familiar with community nutritional support services: Women, Infant's, and Children (WIC) program, elderly nutrition sites, Meals on Wheels, school food programs, and government surplus food programs.
- Assess patient's food preparation facilities to ensure the patient's nutritional needs can be met. Some elderly patients may have outdated or spoiled food in their refrigerators or cupboards because they are unable to see dates or mold growing on foods.
- Ensure that patients are able to use appliances to heat food safely. Patients with limited vision may not see gas flames and can ignite their clothing. Confused patients might try to heat foods in the cardboard containers. If the patient is able to obtain and learn to use a microwave, it may be a safer cooking appliance.
- A feeding tube can be prevented from kinking by slipping a split straw lengthwise around the area that tends to kink and lightly taping over the split in the straw.
- Wire coat hangers make good hooks for enteral feeding solutions bags. They can be bent and hung over doorways or closet bars.
- If a 60-ml feeding syringe is not available for a bolus tube feeding or tube flushing, a measuring cup and funnel can be used.

vomiting, diarrhea, constipation, flatulence, and bowel incontinence, all of which may interfere with proper nutrition (Gerontological Issues Box 29–4). Acid reflux can be assessed by asking patients if they experience reflux with a bile taste or awaken with an unpleasant taste in their mouth.

Family History

Family history of close relatives with conditions that may influence the patient's GI status is assessed. Some GI problems such as colon cancer are thought to be hereditary.

BOX 29-4 GERONTOLOGICAL ISSUES

A complete bowel history should be obtained for older patients before beginning a bowel program. A bowel history includes the following:

- Normal bowel evacuation pattern
- Characteristics of stool
- Presence of any bleeding or mucus with the stool
- Use of products and medications to stimulate or slow bowel function
- Report of usual diet
- Amount of fluids—number and size of beverages glasses per day (beverages containing caffeine, such as coffee, tea, and sodas, do not count as fluids because of the diuretic effect of caffeine)
- Exercise and physical activity
- Rituals and practices related to bowel function

Cultural Influences

Many cultures have special dietary practices and restrictions (Cultural Consideration Box 29-5). Understanding these cultural influences, respecting them, and assisting the patient to maintain desired cultural practices is important for nutritional maintenance.

Objective Data**Height, Weight, and Body Mass Index**

When the GI system is assessed, the patient's height and weight are obtained for planning care. The patient's ideal body weight according to height is obtained using current reference charts. Body mass index (BMI) is calculated to measure body fat and used with waist circumference meas-

BOX 29-5 CULTURAL CONSIDERATION

Most societies of the world use various foods and herbs for maintaining health. With increased attention to herbal therapies in the United States, the U.S. National Institutes of Health is studying 40 foods that are thought to fight disease. Among them are garlic, carrots, soy, cranberry juice, licorice, and green tea. Green tea has been used in Japan and China for centuries as a means of maintaining health and preventing disease.

African-Americans

Obesity is seen as positive among many African-Americans. They often view individuals who are thin as "not having enough meat on their bones." One needs to have adequate meat on his or her bones so that when an illness occurs, one can afford to lose weight. Many African-American diets are high in animal fat and fried foods and low in fiber, fruits, and vegetables.

Appalachians

The diet of some Appalachians is deficient in vitamin A, iron, and calcium. The nurse working with this population needs to do a dietary assessment and teach patients food selections that include adequate vitamin A, iron, and calcium.

Arabs

Many Arabs eat food only with their right hand because it is regarded as clean. The left hand, commonly used for toileting, is considered unclean. Thus the nurse should feed the Arab patient with the right hand regardless of the nurse's dominant handedness. Additionally, some may not drink beverages with their meals because some individuals consider it unhealthy to eat and drink at the same meal. Likewise, mixing hot and cold foods may be seen as unhealthy.

Muslim Arabs may refuse to eat meat that is not Halal (slaughtered and prepared in a ritual manner). Because Muslim Arabs are prohibited from ingesting alcohol or eating pork, they may refuse medication that includes alcohol, such as mouthwashes, toothpaste, alcohol-based syrups and elixirs, and products derived from pigs, such as insulin, gelatin-coated capsules, and skin grafts. However, if no substitute is available, Muslims are permitted to use these preparations.

The condition of the alimentary tract has priority over all other body parts in the Arab's perception of health. Gastrointestinal complaints are the most common reason Arab-Americans seek care.

Asian Indians

Among Asian Indians, nutritional deficiencies are patterned from their region of emigration. For example, beriberi (thiamine deficiency) is found in people emigrating from rice-growing areas. Pellagra (niacin deficiency) causing skin and mental disorders and diarrhea is found in people emigrating from maize-millet areas. Thiamine deficiency is common among people mostly dependent on rice. Thorough milling of rice, washing rice before cooking, and allowing the cooked rice to remain overnight before consumption the following day result in the loss of thiamine.

Commitment to the sacred cow concept has an impact on Hindus by encouraging dairy and milk use. However, lactose intolerance affects more than 10% of adults. The adequacy or inadequacy to digest lactose may be due to genetic differences among Asian Indians.

Goiter is prevalent among some Asian Indian immigrants resulting from an iodine deficiency in food and water from their homeland. Fluorosis occurs in other parts of India resulting from drinking water high in fluoride. Osteomalacia is prevalent where diets are deficient in calcium and vitamin D. Endemic dropsy is prevalent among Asian Indians emigrating from West Bengal, resulting from using mustard oil for cooking. The nurse needs to be aware of these conditions and their causes when working with Hindus and Asian Indians and teach patients prevention.

Brazilians

There is an increase in gastrointestinal distress among Brazilians when they first come to the United States, partially because many have a lactose intolerance and partially because of different methods of milk pasteurization. The nurse can assist the patient in identifying alternative food sources for Brazilian patients to obtain needed calcium in their diet.

Jewish

Among Jews, the laws regarding food are commonly referred to as the laws of Kashrut or the laws of what foods are permissible in accordance with the religious law. The term *kosher* means fit for eating; it is not a brand or form of cooking.

Foods are divided into those that are permitted (clean) and forbidden (unclean). The kosher slaughter of animals prevents undue cruelty to the animal and ensures the animal's health for its consumer. Care must be taken that all blood is drained from the animal before eating it.

BOX 29-5 CULTURAL CONSIDERATION

Among the more conservative and Orthodox Jews, milk and meat may not be mixed together, whether in cooking, serving, or eating. This involves separating the utensils used to prepare foods and the plates used to serve them. To avoid mixing foods, religious Jews have two sets of dishes, pots, and utensils: one set for milk products and one for meat.

Cheeseburgers, meat lasagna, and grated cheese on meatballs and spaghetti are not acceptable. Milk cannot be used in coffee if served with a meat meal. Nondairy creamers can be used as long as they do not contain sodium caseinate, which is derived from milk.

Fish, eggs, vegetables, and fruits are considered neutral and may be used with either dairy or meat dishes. A U with a circle around it or a K is used on food products to indicate kosher.

When working in a Jewish person's home, the nurse should not bring food into the house without knowing whether the patient is kosher. If the patient is kosher, do not use any cooking items, dishes, or silverware without knowing which are used for meat and which are used for dairy. It is important for the nurse to understand the dietary laws so as not to offend the patient. The nurse should advocate for kosher meals if they are requested and plan medication times accordingly.

Although liberal Jews decide for themselves which dietary laws, if any, they follow, many still avoid pork and pork products out of a sense of tradition and symbolism. It would be insensitive to serve pork products to Jewish patients unless they specifically request it.

Kosher meals are available in hospitals and long-term care facilities. Even though the organization may not have a kosher kitchen, frozen kosher meals can be obtained from several organizations, most of which are located in large cities with large Jewish populations. The kosher kitchen closest to your organization can be obtained by calling the Jewish synagogue nearest the organization to

obtain the address and telephone number. Kosher meals arrive on paper plates with plastic utensils sealed in plastic. The nurse should not unwrap the utensils if the patient is able to do so or change the foodstuffs to another serving dish. Determining a patient's dietary preferences and practices regarding dietary laws should be done during the admission assessment.

Mexican-Americans

Good health to Mexican-Americans, which is largely a part of "God's will," can be maintained by dietary practices that keep the body in balance. To provide culturally competent care, the nurse must be aware of the hot-and-cold theory of disease when offering health teaching. Many diseases are thought to be caused by a disruption in the hot-and-cold balance theory of the body. Thus, by eating foods of the opposite variety, one may either cure or prevent specific hot-and-cold illnesses and conditions.

Examples of hot disease conditions include infection, diarrhea, sore throats, stomach ulcers, liver conditions, kidney problems, gastrointestinal upsets, and febrile conditions. Foods that are considered "cold" are therefore viewed as remedies for hot illness conditions. Cold foods include fresh fruits and vegetables, dairy products, barley water, fish, chicken, goat meat, and dried fruits. However, there are significant differences in what are considered hot and cold foods and illnesses among Mexican-American families depending on their native region in Mexico.

Examples of cold illness conditions include cancer, malaria, earaches, arthritis and related conditions, pneumonia and other pulmonary conditions, headaches, menstrual cramping, and musculoskeletal conditions. Hot foods used to treat these conditions typically include cheeses, liquor, beef, pork, spicy foods, eggs, grains other than barley, vitamins, tobacco, and onions.

urements to determine patient's health risk factors (Table 29-2). Excess waist circumferences (for women, more than 35 inches; for men, more than 40 inches) place people at greater risk for diabetes and cardiovascular disease.

Oral Cavity

Gastrointestinal assessment begins with the oral cavity. The lips are examined for lesions, abnormal color, and symmetry. With a penlight and tongue blade, the oral cavity is inspected for inflammation, tenderness, ulcers, swelling, bleeding, and discolorations. Any odor of the patient's breath is noted. A foul odor may indicate infection or poor oral care. The tongue should be pink with a rough texture and assessed for signs of dehydration such as dryness, cracks, or furrows. The patient's gums should be pink without swelling, redness, or irregularities. The teeth or dentures are examined for loose, broken, or absent teeth and the fit of the dentures or

dental work. Ill-fitting dentures can affect the patient's nutritional intake and obstruct the airway. Loose teeth can become dislodged and aspirated into the airway. Broken teeth can be a source of pain and contribute to poor nutritional intake. The patient's knowledge of dental and oral care is assessed. The ability of the patient to perform oral care is noted and included in the plan of care if there are deficits.

Abdomen

INSPECTION. To inspect the abdomen, patients are placed in a supine position with their arms at their sides. The abdomen is visually inspected to note the condition of the skin and the contour. The contour may be rounded, flat, concave, or distended, depending on the patient's body type. Irregularities in contour may be due to distention, tumors, hernia, or previous surgeries. Scars, wounds, tubes, and ostomy device type and location are noted.

TABLE 29-2 CALCULATING BODY MASS INDEX AND WAIST MEASUREMENT

To calculate body mass index:

Step 1. Multiply body weight (in pounds) by 703.

Step 2. Multiply height (in inches) by height.

Step 3. Divide answer in step 1 by answer in step 2.

To obtain waist measurement:

Step 1. Place measuring tape at the level of the top of the iliac crest.

Step 2. Pull snugly around the waist.

Step 3. Read measurement at end expiration.

AUSCULTATION. When auscultating the patient's abdomen, the upper right quadrant is auscultated first (Fig. 29–3). Then a clockwise direction is followed to listen to the other quadrants. The stethoscope is pressed lightly on the abdomen to listen for bowel sounds, which are soft clicks and gurgles that may be heard every 5 to 15 seconds. **Bowel sounds** at this rate are considered normal. Bowel sounds are produced when peristalsis moves air and fluid through the GI tract and are categorized as normal, hyperactive, hypoactive, or absent. Hyperactive bowel sounds are usually rapid, high pitched, and loud and may occur with hunger or gastroenteritis. Hypoactive bowel sounds are bowel sounds that are infrequent and can occur in patients with a paralytic ileus or following abdominal surgery. Bowel sounds are considered absent if no sounds are auscultated after listening to all four quadrants for a minimum of 5 minutes in each quadrant. With a bowel obstruction, a high-pitched tinkling sound that is proximal to the obstruction and absent distal to the obstruction may be heard. Abnormal or absent bowel sounds are important findings and should be documented and reported to the physician.

LEARNING TIPS

In a complete bowel obstruction, air and fluid are propelled forward by peristalsis proximal to the obstruction. This produces proximal high-pitched bowel sounds when the air and fluid create turbulence as they hit the obstruction and are unable to pass. Absent bowel sounds are heard distal to the obstruction.

PALPATION. Using the same quadrant approach as mentioned before, lightly depress the abdomen with the finger pads to check for distention. Note any pain, tenderness, or rigidity. Abdominal girth is measured by placing a tape measure around the patient's abdomen at the iliac crest. A mark can be made at the measurement site so that measurements obtained by others are made at the same location for comparison. Abdominal girth is increased in patients

Quadrants of the abdomen

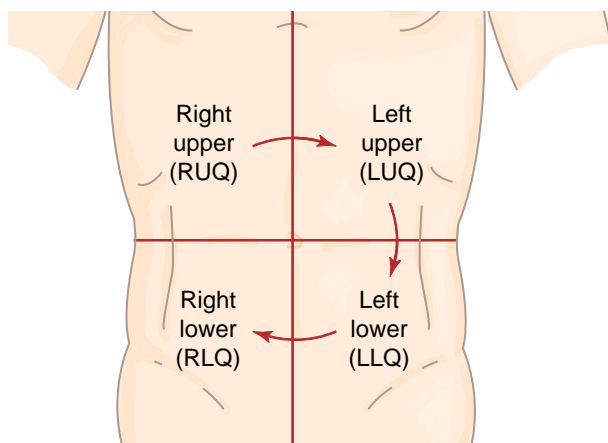

Figure 29-3 Abdominal quadrants are auscultated from the right quadrant in a clockwise manner.

with distention or conditions such as ascites (accumulation of fluid in the peritoneal cavity). Daily measurements should be obtained and recorded to monitor changes when abdominal girth is abnormal.

The advanced nurse practitioner or physician performs all other types of palpation. The liver is not normally palpable, but if enlarged, it may be felt below the right lower ribcage. Rebound tenderness is determined by pressing down on the abdomen a few inches and quickly releasing the pressure. If the patient feels a sharp pain during this procedure, appendicitis may be indicated.

PERCUSSION. Percussion produces a sound that identifies the density of the organs beneath and is performed by the physician or advanced nurse practitioner. Percussion is used to detect fluid, air, and masses in the abdomen and to identify size and location of abdominal organs (especially the liver and spleen). Tympanic high-pitched sounds indicate the location of air, and dull thuds indicate fluid or solid organs.

Diagnostic Tests

Commonly used tests associated with diseases of the GI tract include the following:

- Laboratory tests
- Radiographic tests
- Endoscopy
- Gastric analysis
- Cytological studies
- Magnetic resonance imaging

Observe standard precautions when obtaining specimens of body fluids, substances, or blood. Handwashing before and after the procedure, wearing gloves, and using goggles if splashing may occur are important.

Laboratory Tests

The complete blood cell count (CBC) reveals if anemia or infection are present (Table 29–3). Anemia may occur with GI bleeding or cancer. Electrolyte imbalances often occur with GI illness as a result of vomiting, diarrhea, malabsorption, or use of GI suction. **Carcinoembryonic antigen (CEA)** and carbohydrate antigen 19-9 are markers used to monitor GI cancer treatment effectiveness and detect recurrence. These markers are also found in patients with cirrhosis, hepatic disease, and alcoholic pancreatitis and in heavy smokers.

Stool Tests

Stool samples can be tested for **occult blood** (blood not seen by the naked eye). A series of three tests are usually done to increase the chances of detecting blood. False-positive occult blood results can occur with bleeding gums following a dental procedure; ingestion of red meat within 3 days before testing; ingestion of fish, turnips, or horseradish; and use of drugs, including anticoagulants, aspirin, colchicine, iron preparations in large doses, NSAIDs, and steroids.

Stool for ova (eggs) and parasites is collected to detect intestinal infections caused by parasites and their ova. The

TABLE 29-3 COMMON LABORATORY TESTS USED TO ASSESS GASTROINTESTINAL FUNCTION

Test	Normal	Significance of Abnormal Findings
Carcinoembryonic Antigen		
	Less than 5 ng/mL (nonsmokers)	Increased values indicate possible colorectal cancer and inflammatory bowel disease
Complete Blood Cell Count		
Red blood cell count	4.2–5.2 million/mm ³ (women) 4.5–6.2 million/mm ³ (men)	Decreased values indicate possible anemia or hemorrhage
Hemoglobin	12–16 g/dL (women) 14–18 g/dL (men)	Increased values indicate possible hemoconcentration, caused by dehydration
Hematocrit	38–46% (women) 42–54% (men)	
Electrolytes		
Calcium	8.0–10.5 mg/dL	Decreased values indicate possible malabsorption
Chloride	98–107 mEq/L	Decreased values indicate possible malabsorption
Potassium	3.5–5.0 mEq/L	Decreased values indicate possible GI suction, diarrhea, vomiting, intestinal fistulas
Sodium	135–145 mEq/L	Decreased values indicate possible malabsorption and diarrhea
Fecal Analysis		
Stool for occult blood	Negative	Presence indicates possible peptic ulcer, cancer of the colon, ulcerative colitis
Stool for ova and parasites	Negative	Presence indicates infection
Stool cultures	No unusual growth	Presence of pathogens may indicate shigella, salmonella, <i>Staphylococcus aureus</i> , or <i>Bacillus cereus</i> infections
Stool for lipids	2–5 g per 24 hours (normal diet)	Increased values indicate possible malabsorption syndrome or Crohn's disease

test usually requires a series of three stool specimens collected every second or third day. The stool specimen is collected using a tongue blade, placed in a container with a preservative, and sent immediately to the laboratory. The stool must be examined within 30 minutes of collection. False-negative results can occur as a result of urine in the specimen or if the specimen is not fresh.

Stool cultures (sterile collection technique) are done to determine the presence of pathogenic organisms in the GI tract. Stool can also be examined for lipids (fat). Excessive secretion of fecal fats (**steatorrhea**) may occur in various digestive and absorptive disorders. The stools are collected for 72 hours and stored on ice if necessary before being sent to the laboratory.

Radiographic Tests

Flat Plate of the Abdomen

A flat plate of the abdomen is an x-ray examination giving an anterior-to-posterior view. Radiographs visualize abdominal organs and can detect such abnormalities as tumors, obstructions, and strictures. For an x-ray examination, the patient should be dressed in a hospital gown without any metal such as zippers, belts, or jewelry. Pregnant patients or those thought to be pregnant should avoid x-ray examinations.

Upper Gastrointestinal Series (Barium Swallow)

An **upper gastrointestinal series** (UGI series) is an x-ray examination of the esophagus, stomach, duodenum, and je-

junum using an oral liquid radiopaque contrast medium (barium) and a **fluoroscope** to outline the contours of the organs. A UGI series is used to detect such things as strictures, ulcers, tumors, polyps, hiatal hernias, and motility problems.

The patient receives nothing by mouth (*nada per os* in Latin, abbreviated NPO) for 6 to 8 hours before the procedure. Usually the patient eats a clear liquid supper the night before the procedure and is then NPO until the procedure is done. Because smoking can stimulate gastric motility, the patient is discouraged from smoking the morning of the procedure. Patient teaching includes information about the patient's diet before and after the procedure, the barium ingestion, and the appearance of stools afterward.

During the procedure, the patient drinks the thick, chalky barium while standing in front of a fluoroscopy tube. X-ray films are taken at specific intervals to visualize the outline of the organs and to note the passage of the barium through the GI tract.

A laxative is usually ordered after the procedure to expel the barium and prevent constipation or a barium **impaction**. The patient is instructed to drink 12 8-oz glasses of water per day for several days to prevent dehydration, which can lead to constipation. The abdomen is assessed for distention and bowel sounds. The stool is monitored to determine whether the barium has been completely eliminated. Initially the barium causes the patient's stool to be white, but it should return to its normal color within 3 days. Constipation with distention indicates a barium impaction.

Lower Gastrointestinal Series

The **lower GI series** (barium enema) is performed to visualize the position, movements, and filling of the colon. Tumors, diverticula, stenosis, obstructions, inflammation, ulcerative colitis, and polyps can be detected. The patient is placed on a low-residue or clear liquid diet for 2 days before the test to empty the bowel. Laxatives, bowel cleansing solutions (such as GoLYTELY), and enemas may be administered the evening before the test. GoLYTELY is chilled and drunk full strength with no ice, 8 oz every 10 minutes for a total of 4 L. Inform the patient that a watery diarrhea will begin in about 1 hour and continue up to 5 hours as the bowel is cleared. This is necessary for adequate visualization during the procedure. Inadequate bowel prep may result in poor test results or test cancellation. (See Fig. 32–2.) The patient either receives a clear liquid diet the morning of the test or is NPO after midnight the night before. The area around the rectum should be clean before the patient is sent for the procedure. If the patient has active inflammatory disease of the colon or suspected perforation or obstruction, a barium enema is contraindicated. Active GI bleeding may also prohibit the use of laxatives and enemas.

During the procedure, barium is instilled rectally and x-ray films are taken with or without fluoroscopy. The procedure takes about 15 minutes, and the patient is allowed to use the bathroom immediately after the procedure.

The patient's stools are monitored after the procedure to note if all the barium is passed, as with the UGI. Constipation development is monitored. The patient is encouraged to drink at least one 8-oz glass of liquid per hour for the next 24 waking hours to help remove the barium. The patient is told to report any abdominal pain, bloating, or absence of stool, all of which could indicate constipation or bowel obstruction, as well as any rectal bleeding.

Computed Tomography

Computed tomography (CT) uses a beam of radiation to allow three-dimensional visualization of abdominal structures. Diluted oral barium or other contrast media may be used to distinguish normal bowel from abnormal masses. The patient may have a clear liquid diet the morning of the test. If a contrast medium is to be used, any allergies to iodine or shellfish are assessed, a consent form is signed, and the patient is NPO for 2 to 4 hours before the procedure.

Endoscopy

Endoscopy uses a tube and a fiberoptic system (endoscope) for observing the inside of a hollow organ or cavity. A consent form is signed for any endoscopic procedure.

Esophagogastroduodenoscopy

Esophagogastroduodenoscopy (EGD) visualizes the esophagus (esophagoscopy), the stomach (gastroscore), and the

esophagoscopy: oisophagos—esophagus + skopein—to examine

gastroscore: gaster—stomach + skopein—to examine

duodenum. Abnormalities such as inflammation, cancer, bleeding, injury, and infection can be seen.

The procedure is explained to the patient. To prevent aspiration of stomach contents into the lungs if vomiting occurs, the patient is NPO for 8 to 12 hours before the procedure. Sedatives such as diazepam (Valium), meperidine (Demerol), or midazolam (Versed) may be given before the procedure to help relax the patient. A local anesthetic in spray or gargle form is administered just before the scope is inserted to inhibit the gag reflex.

The patient is placed on the left side, and the flexible, fiberoptic endoscope tube is passed orally down the GI tract (Fig. 29–4). Photos or videotapes of the procedure can be made. Biopsy or cytology specimens can be obtained.

After the procedure vital signs are checked as ordered. Patients are placed on one side to prevent aspiration while sedation and the local anesthetic wear off. Patients are NPO until the gag reflex returns (usually within 4 hours). Patients are assessed for signs of perforation, which include bleeding, fever, and dysphagia. Midesophageal perforation can cause referred substernal or epigastric pain. Blood loss secondary to perforation can lead to hematoma formation, which in turn can result in cyanosis and referred back pain. Distal esophageal perforation may result in shoulder pain, dyspnea, or symptoms similar to those of a perforated ulcer. The patient may have a sore throat for a few days.

Lower Gastrointestinal Endoscopy

PROCTOSIGMOIDOSCOPY. Proctosigmoidoscopy is the examination of the distal sigmoid colon, the rectum, and the anal canal using a rigid or flexible endoscope (sigmoidoscope). Ulcerations, punctures, lacerations, tumors, hemorrhoids, polyps, fissures, fistulas, and abscesses can be detected. Malignancies at an early stage can be detected, so an annual examination for patients 40 years old and older is recommended.

Proctosigmoidoscopy requires the lower bowel to be cleaned out. The patient usually receives a clear liquid diet 24 hours before the test and a laxative the night before the test. The morning of the procedure a warm tap-water enema or sodium biphosphate (Fleet) enema is given. Bowel prepara-

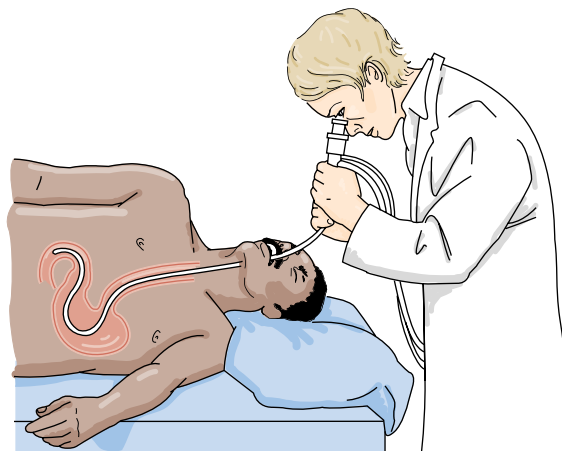

Figure 29–4 Gastroscopy.

ration may not be ordered for patients with bleeding or severe diarrhea.

The patient is positioned in a left lateral knee-to-chest position, which allows the sigmoid colon to straighten by gravity. A rigid proctoscope is used to visualize the rectum. A flexible scope is then used to permit visualization above the rectosigmoid junction. Patients are told they may feel pressure as though they are going to have a bowel movement. During the procedure, one or more small pieces of intestinal tissue may be removed (biopsy specimens). Rectal or sigmoid polyps are removed with a snare. An electrocoagulating current is used to cauterize sites to prevent or stop bleeding. Specimens are labeled and sent to the pathology laboratory immediately for examination.

After the procedure, the patient is allowed to rest for a few minutes in the supine position to avoid orthostatic hypotension when standing. Pain and flatus may occur from instilled air. The patient is observed for signs of perforation such as bleeding, pain, and fever.

COLONOSCOPY. Colonoscopy provides visualization of the lining of the large intestine to identify abnormalities through a flexible endoscope, which is inserted rectally. A biopsy specimen may be obtained or polyps be removed during the colonoscopy.

The patient receives a liquid diet 24 hours before the test and is NPO after midnight before the procedure. A bowel preparation solution such as GoLYTELY is given the night before the procedure. Drinking this solution can be unpleasant for the patient. In addition, a laxative, suppository (bisacodyl [Dulcolax]), or enema may be needed.

LEARNING TIPS

Elderly patients may experience fatigue and weakness during bowel preparation and may be unable to complete it. Monitor the patient for distress. Consult the physician if you note any patient distress during bowel preparation.

Conscious sedation (e.g., midazolam, meperidine) is used to relax and ease pain during the procedure. The patient is positioned on the left side with the knees bent. A small amount of air is instilled into the colon to help the physician visualize the bowel. The air causes pressure and may be uncomfortable for the patient. The patient is encouraged to relax and take slow deep breaths through the nose and out the mouth. Vital signs are monitored throughout the procedure to watch for a vasovagal response, which can lead to hypotension and bradycardia.

After the procedure, the patient is monitored until stable. Complications such as hemorrhage or severe pain are reported. When giving the patient discharge instructions, explain that flatus and cramping will occur for several hours after the test, that blood may be present in the stool if a

biopsy specimen was taken, and to report problems to the physician.

Gastric Analysis

Gastric analysis measures the secretions in the stomach. Diagnosis of duodenal ulcer, gastric carcinoma, pyloric or duodenal obstruction, and pernicious anemia are made. A diagnosis of pernicious anemia is ruled out by the finding of acid. A diagnosis of gastric carcinoma may be made by the presence of cancer cells in the gastric secretions. There are two tests performed in gastric analysis: the **basal cell secretion test** and the **gastric acid stimulation test**.

Before the basal cell secretion test, the patient should avoid taking any drugs that could interfere with gastric acid secretion, such as cholinergics and antacids. The patient is NPO after midnight the night before the test. For the procedure, a nasogastric (NG) tube is inserted and the contents of the stomach are suctioned out through the tube using a syringe. The NG tube is connected to wall suction, and stomach contents are collected every 15 minutes for 1 hour. The specimens are labeled according to the time they were collected and the order in which they were obtained. The gastric acid is tested for pH using indicator paper or a pH meter. The amount of gastric acid is also measured. Too much hydrochloric acid may indicate a peptic ulcer; too little could be a sign of cancer or pernicious anemia.

The gastric acid stimulation test measures the amount of gastric acid for 1 hour after subcutaneous injection of a histamine drug. If abnormal results occur, radiographic tests or endoscopy can be done to determine the cause.

Endoscopic Ultrasonography

Endoscopic ultrasonography is performed through the endoscope using sound waves. Tumors can be detected in various GI structures and organs. Pre- and postprocedure care is similar to endoscopic care. During the test the patient must lie still while a transducer with gel is moved back and forth over the abdomen to produce images.

THERAPEUTIC MEASURES

Gastrointestinal Intubation

Gastrointestinal intubation is the placement of a tube within the GI tract for therapeutic or diagnostic purposes (Fig. 29–5). When the GI tube is inserted from the nares into the stomach, it is referred to as a nasogastric tube. A nasointestinal tube is a tube inserted from the nares into the intestines. A variety of tubes are available, each designed for specific purposes (Table 29–4). Nasogastric and nasointestinal tubes are inserted for a variety of reasons, but the main purposes for their use include the following:

- To remove gas and fluids from the stomach or intestines (decompression)
- To diagnose GI motility and to obtain gastric secretions for analysis
- To relieve and treat obstructions or bleeding within the GI tract

colonoscopy: kolon—colon + skopein—to examine

Figure 29-5 Feeding tubes. (A) Nasogastric tube connected to tube feeding pump. (B) Feeding tube placement sites (esophagostomy, nasointestinal, gastrostomy, and jejunostomy). (C) Gastrostomy tube insertion site.

TABLE 29-4 GASTROINTESTINAL TUBES

Tube	Uses and Description	Nursing Considerations
Gastric		
<i>Levine tube</i>	Single lumen, may be used for gastric decompression, irrigations, lavages, and feedings	Tube is not vented, so use with low intermittent suction to prevent injury to stomach lining.
<i>Sump tube (Salem sump)</i> <i>Anderson tube</i>	Double lumen, "pigtail" acts as an air vent and prevents excess suction, which could damage stomach lining; used for decompression, irrigations, and lavages	May be used with low continuous suction because of air vent.
<i>Weighted, flexible feeding tubes with stylets (Nutriflex, Keofeed)</i>	Small-bore tubes for tube feedings only; less injury, remains in place for extended periods	Suction collapses tube. Use a 10-mL syringe or greater, because smaller syringe creates too much pressure and possible rupture of tube.
Intestinal		
<i>Miller-Abbott tube</i>	Double-lumen tube used to drain and decompress the small intestine in cases of partial or complete obstruction; one lumen for aspiration, the other to inflate the balloon with mercury so that the tube is weighted and moves by gravity and peristalsis into the small intestine	Rarely used, this tube is inserted by the physician or a specially trained nurse. Tube is not secured with tape, but passed through gauze taped to patient's forehead to allow tube to advance into intestines. Usually the tube advances 1–2 inches every 2 hours until it reaches small intestine; turning and ambulating the patient, if possible, facilitates tube's advancement.
<i>Cantor tube</i> <i>Harris tube</i>	Single-lumen tubes with distal mercury-filled balloons and proximal drainage ports.	

- To provide a means for nutrition (**gavage** feeding), hydration, and medication when the oral route is not possible or is contraindicated
- To promote healing after esophageal, gastric, or intestinal surgery by preventing distention of the GI tract and strain on the suture lines
- To remove toxic substances (**lavage**) that have been ingested either accidentally or intentionally and to provide for irrigation

Feeding tubes include esophagostomy, **gastrostomy**, or jejunostomy tubes. (See Fig. 29–5.) Nasogastric tubes are

gastrostomy: gaster—stomach + ostium—little opening

BOX 29–6 Nursing Care for Insertion and Maintenance of Nasogastric Tubes

1. Explain the procedure and reason for the tube to the patient. Inform the patient how he or she can help by swallowing when instructed to do so if able.
2. Assist patient into high Fowler's position (right side lying as an alternative) as able.
3. Measure tube for correct insertion length: Hold insertion end of tube from nose tip to earlobe to xyphoid process and mark tube with tape at this point.
4. Select naris that is straightest and from which patient breathes the easiest, because tube is inserted more easily in a straight naris.
5. Lubricate tube with water-soluble lubricant before insertion.
6. Insert tube as follows:
 - As tube is inserted, aim it along the floor of the naris and laterally. Rotate the tube gently if resistance is met.
 - Encourage patient to swallow to advance the tube. Drinking water with a straw or ice chips facilitates the swallowing process if patient is able.
 - If patient is unconscious, flex patient's head to bring chin toward chest to help prevent tube from passing into the trachea.
 - Observe for coiling of the tube in patient's mouth.
 - To assist in assessing correct placement, insert tube to level of carina tracheae and listen for air at end of tube. If air is present, remove tube. If no air is heard, advance tube to stomach.
 - If at any time the patient begins to cough uncontrollably, becomes cyanotic, or begins to experience any respiratory distress, remove the tube, allow rest time, and then reattempt insertion.
7. After tube is inserted to premeasured length, confirm gastric placement per institutional policy using the following methods¹:
 - Flexible feeding tubes should have x-ray confirmation.
 - Aspirate for gastric contents with a 30- or 60-mL catheter-tipped syringe:
 - Gastric fluid—green with sediment; colorless and clear with off-white or tan mucus; brown if digested blood is present.
 - Esophageal contents—scant fluid, aspirate is unreliable for confirmation.
 - Intestinal fluid—light to dark golden yellow to brownish green.
 - Respiratory secretions—off-white or tan mucus.
 - Pleural fluid (with stylet perforation)—watery, straw colored, may be blood-tinged from perforation.
 - Measure pH of secretions obtained to rule out respiratory placement:
 - Gastric pH range is acidic (1–5).
 - Respiratory and intestinal secretions are alkaline with pH > 6.
 - If any doubts about gastric placement exist, notify physician for x-ray order to confirm tube placement.
8. Secure tube in place with tape so that pressure is not put on the naris. Provide daily skin care to taped area to prevent skin breakdown. Slipknot a rubber band around tube and pin rubber band to patient's gown.
9. If suction is ordered, low intermittent suction is used with nonvented tubes (Levin); vented tubes (Anderson, Salem) may have continuous low suction.
10. If patient is NPO, provide frequent care to keep oral mucous membranes moist. When suction is used, prevent excessive intake of ice chips, if ordered, because electrolyte imbalances may result when the water is suctioned out along with electrolytes. Normal saline instead of water can be made into ice chips to help prevent imbalances.
11. Gastric placement is periodically confirmed, especially before instilling anything into the tube¹:
 - Review any recent chest or abdominal x-ray report with tube status.
 - Verify tube position marking is in original position. If not, reposition as necessary.
 - Bolus feedings/medications: 4 hours after last feeding, aspirate fluid for pH and appearance.
 - Continuous feedings: Assess tolerance. If normal along with correct tube marking and any confirming x-ray reports, continue feeding.
 - For patients at high risk of dislodgement (e.g., those who are vomiting or have severe coughing) with tube movement, consider x-ray examination.
12. The tube is flushed at intervals, every 2–4 hours, to maintain patency. When tube feedings are administered, residual feeding amounts are checked at specified intervals (hourly when begun, every 4 hours thereafter) to ensure the feeding is being absorbed.
13. After tube placement, record accurate intake and output, including drainage, vomitus, and irrigation solution instilled (use only normal saline to prevent electrolyte imbalance).

usually temporary and short term. Esophagostomy, gastrostomy, or jejunostomy tubes are generally used for longer-term nutrition delivery.

General nursing care measures for insertion and maintenance of GI tubes are given in Box 29–6. Provide emotional support and explanation to the patient and significant others to facilitate the process of tube insertion and maintenance. Assessing tube placement is essential to prevent complications or death from incorrect tube placement. Nasogastric tube placement must be assessed after insertion and then intermittently to ensure that it is in the correct position and not in the lungs (most common), esophagus, pleural space, or brain.

Gastrostomy or jejunostomy tube placement is verified by comparing current length with documented insertion length. The tube may not be in the desired position if the current and insertion tube lengths are different, so the physician should be consulted before using the tube.

Tube Feedings

A tube feeding supplies patients with nutrition when oral intake is not possible. Feedings can be given to the patient as a supplement or to provide the patient's total nutritional needs. If the esophagus and stomach need to be bypassed, tube feedings are delivered directly into the duodenum or proximal jejunum. Reasons for administering tube feedings include inability to swallow, severe burns or trauma to the face or jaw, debilitation, mental retardation, and oropharyngeal or esophageal paralysis. Complications associated with tube feedings are presented in Table 29–5. (See Home Health Hints.)

Tube Feeding Formulas

Tube feeding formulas are chosen by the physician based on the patient's nutritional needs, the consistency of the formula, the size and location of the tube, the method of delivery, and the convenience for the patient at home. Commercially prepared formulas are composed of protein, carbohydrates, and fats. When patients receive tube feedings, their daily water needs in addition to any water supplied by the feeding should be considered. Dietitians can help calculate the patient's water needs. The water used to flush the tube or administer medications can be considered as satisfying part of the patient's daily total water needs. Dehydration can occur if the patient's water needs are not met.

to 30 minutes. Intermittent feedings via a pump allow the stomach to rest at night and more closely simulate normal eating and nutrient absorption patterns. A continuous feeding administered 24 hours a day through a pump allows for small amounts to be given over a long period. Pumps are set at the specified rate to control the speed of the feeding being delivered to the patient.

When feedings are administered, patients must be positioned in a sitting or high Fowler's position to reduce the risk of aspiration. Monitor the rate carefully to avoid administering feedings too rapidly, and watch for signs that the feeding is not being absorbed. Abdominal distention, patient report of a feeling of fullness, and nausea or vomiting are indicators that the feeding is not being absorbed and should be stopped to prevent aspiration. A residual check to see how much feeding, if any, has not been absorbed is done hourly when the feeding is initiated, then every 4 hours or before giving any medications or adding more feeding for infusion. If there is more than 100 mL or the amount specified by the agency or physician, the feeding should be stopped to prevent vomiting or aspiration and the physician notified. Continuous or intermittent feedings reduce the risk of aspiration, distention, nausea, vomiting, and diarrhea.

If medications are administered during tube feedings, understand possible drug-nutrient interactions. Some medications cannot be given with certain substances. Other medications, such as enteric-coated or sustained-release medications, should not be crushed. Liquid medications should be used when possible to reduce clogging of the tube. Pharmacists and dietitians should be consulted for special considerations.

Gastrointestinal Decompression

Gastrointestinal decompression may be necessary when the stomach or small intestines become filled with air or fluid. Swallowed air and GI secretions enter the stomach and intestines and collect there if they are not propelled through the GI tract by peristalsis. Accumulating air or fluid causes distention, a feeling of fullness, and possibly pain in the abdomen. Gastric distention may occur after major abdominal surgery. Ambulating or turning the patient frequently can help prevent this. However, when GI decompression is necessary, a nasogastric tube or occasionally a nasointestinal tube may be inserted and suction applied. Nasointestinal tubes are more difficult and slower to place and may be uncomfortable, so they are not used often. The tube remains in place until full peristaltic activity (active bowel sounds and passage of flatus) has returned. The diet is then progressed as ordered and tolerated by the patient.

Total Parenteral Nutrition

Total parenteral nutrition (TPN, also known as intravenous hyperalimentation) is a method of supplying nutrients to the patient by an intravenous (IV) route. TPN solutions usually contain dextrose (sugar), amino acids (protein), vitamins, minerals, and fat (intralipid) emulsions. TPN solutions are designed to improve the patient's nutritional sta-

CRITICAL THINKING

Mrs. Wood
Mrs. Wood is receiving a tube feeding because of dysphagia, the cause of which is being investigated. Mrs. Wood is not receiving any medications. You note that Mrs. Wood's tongue is bright red with deep furrows. She states her mouth is very dry. Her skin remains tented when skin turgor is checked.

1. What do Mrs. Wood's assessment findings indicate?
2. How would you document your assessment findings?
3. Why might Mrs. Wood be exhibiting this condition?
4. What actions could you take for this condition?

Answers at end of chapter.

Method of Delivery

Feedings are administered either by gravity or by a controlled pump that delivers continuous volume through the feeding tube. Gravity feedings are placed above the level of the stomach and dripped in by gravity slowly or given as a bolus feeding over a few minutes. Intermittent feedings are defined as either being delivered by a pump that runs continuously throughout the day and is discontinued each night or as a 4- to 6-hour volume of feeding given over 20

TABLE 29-5

COMMON MECHANICAL GASTROINTESTINAL AND METABOLIC COMPLICATIONS OF TUBE-FED PATIENTS AND PREVENTION STRATEGIES

Complication	Prevention Strategies
<i>Mechanical</i>	
Tube irritation	Consider using a smaller or softer tube. Lubricate the tube before insertion.
Tube obstruction	Flush tube after use. Do not mix medications with the tube feeding formula. Use liquid medications if available. Crush other medications thoroughly (if not contraindicated to crush). Use an infusion pump to maintain a constant flow. (See Fig. 29-5.)
Aspiration and regurgitation	Feeding should not be started until tube placement is radiographically confirmed. Elevate head of the patient's bed more than or equal to 30 degrees at all times. Discontinue feedings at least 30 to 60 minutes before treatments requiring head to be lowered (e.g., chest percussion). If the patient has an endotracheal tube in place, keep the cuff inflated during feedings. Test pH of aspirate with pH paper or meter. <ul style="list-style-type: none"> a. pH of tracheobronchial secretions is alkaline, >7.4. b. pH of gastric secretions is acidic, <5.0. c. As the tube moves from the acid stomach to the alkaline duodenum, pH will change from acid to alkaline.
Tube displacement	Place a black mark at the point where the tube, once properly placed, exits the nostril. Replace tube and obtain physician's order to confirm with x-ray imaging.
<i>Gastrointestinal</i>	
Cramping, distention, bloating, gas pains, nausea, vomiting, diarrhea*	Practice good personal hygiene when handling any feeding product. Bring formula to room temperature before feeding. Initiate and increase amount of formula gradually. Change to a lactose-free formula. Decrease fat content of formula. Administer drug therapy as ordered (e.g., Lactinex, kaolin-pectin, Lomotil). Change to formula with a lower osmolality. Change to formula with a different fiber content. Evaluate diarrhea-causing medications the patient may be receiving (e.g., antibiotics, digitalis preparations).
<i>Metabolic</i>	
Dehydration	Assess the patient's fluid requirements before treatment. Monitor hydration status.
Overhydration	Assess the patient's fluid requirements before treatment. Monitor hydration status.
Hyperglycemia	Initiate feedings at a low rate. Monitor blood glucose. Use hyperglycemic medication if necessary. Select a low-carbohydrate formula.
Hypernatremia	Assess the patient's fluid and electrolyte status before treatment. Provide adequate fluids.
Hyponatremia	Assess the patient's fluid and electrolyte status before treatment. Restrict fluids. Supplement feeding with rehydration solution and saline. Diuretic therapy may be beneficial.
Hypophosphatemia	Monitor serum levels. Replenish phosphorus levels before refeeding.
Hypercapnia	Select a low-carbohydrate, high-fat formula.
Hypokalemia	Monitor potassium levels. Supplement feeding with potassium if necessary.
Hyperkalemia	Reduce potassium intake. Monitor potassium levels.

*The most commonly cited complication of tube feeding is diarrhea.

From Lutz, CA, and Przytulski, KR: Nutritional and Diet Therapy, ed 2. FA Davis, Philadelphia, 1997, p 280. Reprinted with permission.

tus, achieve weight gain, and enhance the healing process. The patient with conditions such as burns, trauma, cancer, acquired immunodeficiency syndrome (AIDS), malnutrition, anorexia nervosa, or fever and those undergoing major surgery may need TPN.

Usually, registered nurses are responsible for administering TPN. A filter must be used with TPN solutions but not with lipid solutions, which are given as a separate infusion along with TPN therapy. TPN is started slowly to give the pancreas time to adjust to increasing insulin production for

the high amounts of glucose in the TPN. The TPN rate is increased until the ordered rate, as tolerated by the patient, is reached. When TPN is discontinued, the patient must be gradually weaned to allow the pancreas to adjust to decreasing glucose levels. The patient, as ordered, is fed before the TPN is stopped to help prevent hypoglycemia. Signs of hypoglycemia include weakness, shakiness, sweating, and confusion.

It is important to monitor glucose levels as ordered and to look for signs of hyperglycemia in the patient receiving TPN. Refer to agency policy for obtaining glucose levels when a hyperglycemic reaction is suspected in the patient receiving TPN.

During TPN administration, the following laboratory values, as ordered, are usually monitored:

- Complete blood cell count (CBC)
- Albumin
- Glucose
- Electrolytes
- Magnesium
- Platelet count
- Prothrombin time (PT)

LEARNING TIPS

- Patients may respond to TPN with an elevated serum glucose level, even though they do not have diabetes. This is due to the high concentration of glucose used in TPN. These elevated serum glucose levels do not usually indicate that the patient who does not have diabetes has acquired the disease. After the TPN is discontinued, the serum glucose levels should return to baseline or normal levels.
- Regular insulin is given, as ordered, to control hyperglycemia during TPN therapy. The insulin is ordered either on a sliding scale (regular insulin given based on blood glucose levels measured at ordered intervals over 24 hours) or as an additive to the TPN solution.
- Administration of insulin according to a sliding scale requires a current blood glucose level. Based on the obtained glucose level, if it is elevated, specified regular insulin units may be ordered. Usually blood glucose is measured before meals, but for a patient who is not eating, as with most patients receiving TPN, there is no meal time. Instead, specified time intervals are ordered (typically every 6 hours).
- Insulin given on a sliding scale is always regular insulin. Can you figure out why? Regular insulin is rapid acting, which is what is needed to treat the current blood glucose level that was obtained to determine what insulin coverage was needed, if any.

TPN can be irritating to the peripheral veins because it is five or six times more concentrated than blood. Therefore TPN dextrose more than 12 percent is administered through a central venous catheter into a large vein such as the subclavian or internal jugular (see Fig. 6–8). The volume in the large vein dilutes the TPN solution, so it is less irritating.

Peripheral Parenteral Nutrition

Peripheral parenteral nutrition (PPN) is a method of supplying nutrients to the patient by an IV route that is not a central vein. PPN is used for less than 10 days when the patient does not need more than 2000 calories daily. PPN solutions can contain a mixture of dextrose (of less than 12 percent), amino acids, and lipids, in addition to electrolytes or water, which can be found in routine IV solutions. The all-in-one PPN system mixes dextrose, amino acids, and lipids all in one container, which causes less irritation of veins.

LEARNING TIPS

Patients with any of the following may need to be considered for TPN or PPN:

- Any significant weight loss (10 percent or more of healthy weight)
- A decrease of oral food intake for more than 3 days
- Any significant sign of protein loss: serum albumin levels below 3.2 g/dL
- Muscle wasting
- Decreased tissue healing
- Persistent vomiting and diarrhea

Answers to CRITICAL THINKING

Mrs. Todd

1. Daily aspirin use is the most likely cause of her bleeding.
2. Medication teaching including side effects can help Mrs. Todd prevent future bleeding episodes. Assessment of pain relief needs and consultation with the physician will also help.

Mrs. Wood

1. Assessment of Mrs. Wood indicates dehydration.
2. Document as follows: "1/20/03 0800 'Mouth very dry.' Tongue bright red with deep furrows, tented turgor. Tube feeding infusing. Physician notified. K. Ohno LVN."
3. Mrs. Wood's daily water needs are not being met. She is not receiving medications that would incidentally provide water during their administration.
4. Consult a dietitian or review Mrs. Wood's daily water needs. Divide the water needs over 24 hours and ensure that water is administered. Ensure tubing is flushed per agency policy, and calculate water used toward daily water needs. Monitor intake and output. Continue assessing Mrs. Wood's signs and symptoms, and report abnormal findings.

REVIEW QUESTIONS

1. The nurse is assessing a patient's bowel sounds. The nurse understands that bowel sounds heard at an irregular rate every 5 to 15 seconds should be documented as which of the following?
 - a. Abnormal
 - b. Hyperactive
 - c. Hypoactive
 - d. Normal
2. The nurse is planning care for a 78-year-old patient's elimination needs. Which of the following interventions should the nurse plan to reduce complications from the aging change of slowed motility?
 - a. Decrease ambulation.
 - b. Increase dietary fiber.
 - c. Increase dairy products.
 - d. Decrease fluid intake.
3. The nurse is caring for a patient after an EGD. Which of the following would best indicate to the nurse that it is safe for the patient to resume oral intake?
 - a. Vital signs are within normal limits.
 - b. Patient's gag reflex returns.
 - c. Patient is alert.
 - d. Patient has no nausea or vomiting.
4. The nurse is caring for a patient who is receiving a TPN infusion. Blood glucose monitoring every 6 hours is ordered to detect which of the following complications?
 - a. Hyponatremia
 - b. Hyperglycemia
 - c. Hypocalcemia
 - d. Hyperkalemia
5. Following a colonoscopy, the nurse is assisting the patient into bed and sees bright red blood on the sheets. Which of the following should be the nurse's first action?
 - a. Apply gauze dressing to perineum.
 - b. Bathe the patient.
 - c. Assess the patient's drainage.
 - d. Notify the physician immediately.

QUESTIONS TO GUIDE YOUR READING

1. What are anorexia, anorexia nervosa, and bulimia nervosa and their medical management and nursing care?
2. What is obesity, and what medical, surgical, and nursing management is used to treat it?
2. What nursing care would you give to a patient with stomatitis?
3. How would you care for patients with acute or chronic gastritis?
4. How would you explain the pathophysiology, signs and symptoms, and diagnostic testing for hiatal hernia, peptic ulcer disease, gastric bleeding, and gastric cancer?
5. What is the current pharmacological treatment for peptic ulcer disease?
6. What nursing care would you provide for patients with hiatal hernia, peptic ulcer disease, gastric bleeding, and gastric cancer?

► EATING DISORDERS

Anorexia

Anorexia, which is a lack of appetite, is a common symptom of many diseases and can be caused by noxious food odors, certain drugs (as an intended or side effect), emotional stress, fear, psychological problems, and infections. Prolonged anorexia with an inadequate nutritional intake can lead to serious electrolyte imbalances, which in turn can lead to cardiac dysrhythmias. Although eating is the preferred method of weight gain, other measures such as tube feedings and intravenous infusion can be used. Ask patients what causes them to lose their appetite and what improves it to plan care. Nursing actions for the patient with anorexia include documenting accurate intake and output; monitoring vital signs, electrolytes, and electrocardiograms; and monitoring the rate of the intravenous infusion and tube feeding.

Anorexia Nervosa

Anorexia nervosa is an eating disorder that is recognized by the American Psychiatric Association (Box 30–1). This disease most commonly occurs in females between the ages of 12 and 18 who are from the middle and upper classes of Western culture. Males account for less than 10 percent of the population with anorexia nervosa. Young women with low self-esteem seem to be at highest risk. Anorexia nervosa is thought to be psychological in origin. Patients may have a phobia of weight gain, are afraid of a loss of control, and are mistrusting.

Signs and Symptoms

Early signs and symptoms of anorexia nervosa include severe weight loss, low self-esteem, compulsive dieting, and an altered body image (patients imagine themselves as fat although they are within normal weight range). As the disease progresses, additional symptoms appear, including amenorrhea in females, electrolyte imbalance, cardiac dysrhythmias, constipation, dry skin, lanugo (downy hair covering body), bradycardia, hypothermia, hypotension, muscle wasting, and facial puffiness. Often patients with anorexia nervosa deny the existence of any problem. They may develop bizarre food rituals and sometimes weigh themselves several times a day. Anorexia nervosa sometimes overlaps with **bulimia nervosa** (compulsive eating with self-induced vomiting).

BOX 30-1 Diagnostic Criteria for Anorexia Nervosa

1. Refusal to maintain body weight over a minimum normal weight for age and height
2. Intense fear of gaining weight or becoming fat, even though underweight
3. Disturbance in the way in which one's body weight, shape, or size is experienced
4. In females, the absence of at least three consecutive menstrual cycles when otherwise expected to occur

Medical Management

The most important intervention for anorexia nervosa is the restoration of nutritional health; up to 18 percent of anorexia patients die as a result of the disease. During the crisis period, when severe weight loss, life-threatening electrolyte imbalances and dysrhythmias, or other symptoms occur, nutrition is supplied by intravenous infusions containing electrolytes. Tube feedings or oral feedings may also be given.

The patient's damaged self-image and self-esteem are underlying problems and must be addressed in conjunction with the nutritional aspect (Nutrition Notes Box 30–2). Both self-image and nutrition issues require treatment over a long period. Psychotherapy and behavior modification

BOX 30-2

Nutrition Notes

Supplying Nutrition in Upper Gastrointestinal Conditions

Anorexia Nervosa and Bulimia Nervosa

These eating disorders, which produce severe weight loss, require multidisciplinary treatment. Although correcting the nutritional consequences of these conditions is of major importance, to achieve a cure it is essential to treat the underlying psychological causes.

Obesity

Candidates for gastric banding or gastric bypass surgery should be carefully selected. The procedure should be viewed as one tool to assist with weight control, along with behavioral changes. It is not done to permit overeating, because in time the constructed pouch can be stretched, thus negating the surgery. Guidelines include eating three to six small balanced meals daily; chewing thoroughly and eating slowly; drinking most fluids between meals; exercising regularly; and taking a multivitamin-multimineral supplement. Potential complications of these surgeries include nausea, vomiting, bloating, heartburn, staple disruption, obstruction, dumping syndrome, and osteoporosis.

Gastroesophageal Reflux and Hiatal Hernia

Patients with gastroesophageal reflux and hiatal hernia may find symptoms alleviated by protein foods that tighten the cardiac sphincter. Substances that may be better avoided because they relax the sphincter include fat, caffeine, peppermint, spearmint, chocolate, alcohol, and nicotine. Pepper and decaffeinated coffee may be problematic because they stimulate gastric secretions. Acidic juices may be irritating as well.

Dumping Syndrome

The recommended meal pattern for patients with dumping syndrome includes six small meals per day, high in protein and low in simple sugars; fluids between rather than with meals; and reclining for half an hour after meals. Supplementation with the vitamins B₁₂, D, and folic acid and the minerals calcium and iron may be necessary to prevent deficiencies.

Gastric Cancer

If a patient has a poor prognosis following a total gastrectomy for cancer, dietary interventions should focus on symptoms the patient wishes to control. An overly restricted diet causing the patient discomfort or distress is inappropriate.

that includes participation of the patient’s significant others are often used to treat anorexia nervosa.

Nursing Care

Gaining the patient’s genuine cooperation by using therapeutic communication and setting realistic, mutual goals is important in establishing trust and preventing relapse. To work with patients with anorexia nervosa, a therapeutic relationship must be developed to facilitate effective interactions. Empathy, acceptance of the patient, trust, warmth, and being nonjudgmental is important. Caring for patients with anorexia nervosa is challenging. Nursing actions for these patients include obtaining vital signs, daily weights, and accurately documenting intake and output of food and fluids.

Bulimia Nervosa

Bulimia nervosa is compulsive eating with self-induced vomiting, which is commonly known as binge-purge. The bulimic patient typically eats massive amounts of food at one sitting and then purges the food by intentionally inducing vomiting so weight is not gained. Laxatives are also sometimes used by the bulimic patient to purge the body of food to avoid weight gain. Excessive exercise may also be used to control weight. As in anorexia nervosa, bulimic patients are extremely thin to the point of starvation. A high percentage of patients with bulimia are young women.

Signs and Symptoms

Patients with bulimia nervosa usually exhibit the same signs and symptoms as patients with anorexia nervosa, with a few exceptions. Bulimic patients often have enamel erosion of

the front teeth caused by the acid content of the emesis. They also spend a great deal of time locked in the bathroom vomiting, especially after meals. As the electrolyte imbalance worsens, they develop metabolic alkalosis as a result of the loss of gastric acid in the stomach contents.

Medical Management

The treatment for bulimia nervosa is essentially the same as for the patient with anorexia nervosa, as discussed earlier.

Obesity

Several methods can be used to diagnose a patient as overweight or obese, although there is no one definitive measure of either. Factors such as age, body frame size, and gender can influence these measurements:

- Height-weight chart: Weight 10 to 20 percent above ideal body weight is overweight; 20 percent or more above ideal body weight is obesity.
- Waist-to-hip ratio: Waist-to-hip ration is waist measurement divided by hip measurement. If the result is more than 1.0 in men or 0.8 in women, it indicates that the patient is overweight.
- Body mass index (BMI): BMI is one of the best methods for defining **obesity**. BMI increases with age. Generally a BMI of 25 to 29.9 kg/m² is defined as being overweight, with more than 30 kg/m² being obese (Fig. 30-1). BMI can be calculated using height-to-weight ratios:

$$BMI = \frac{\text{Weight (kg)}}{\text{Height (m)}^2}$$

$$\text{Example: } BMI = \frac{68 \text{ kg}}{1.67 \text{ m}^2} = \frac{68 \text{ kg}}{2.7889 \text{ m}^2} = \frac{24.38 \text{ kg}}{\text{m}^2}$$

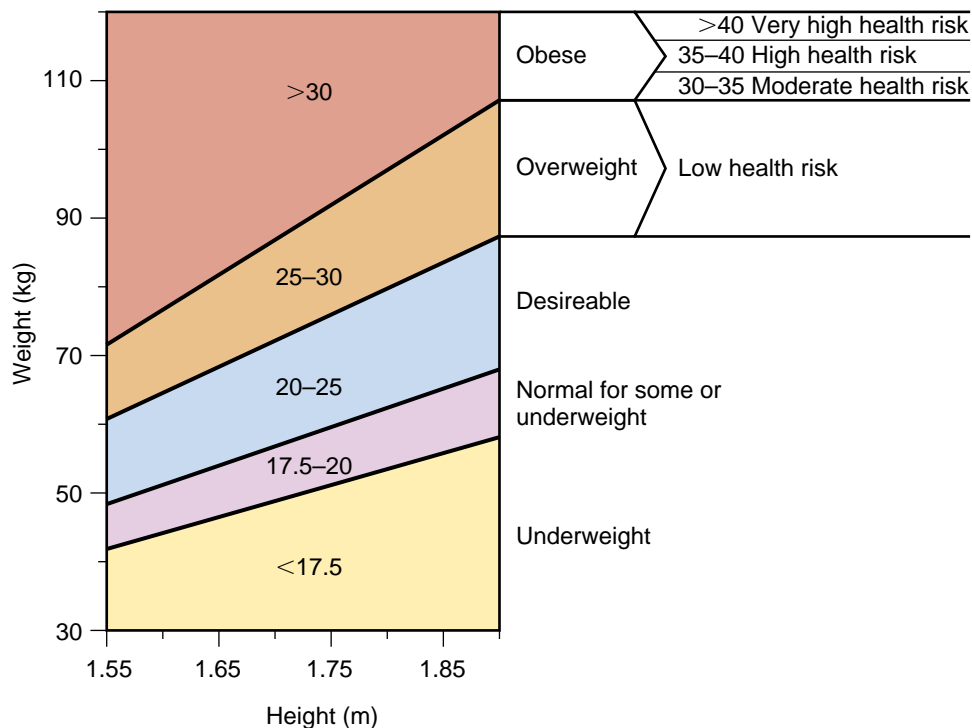

Figure 30-1 Body mass index ranges and associated level of health risk with obesity.

Obesity is caused by a caloric intake that exceeds energy expenditure. Only a small percentage of obesity is associated with a metabolic or endocrine abnormality within the body. Health risks can result from being overweight. Diseases that are associated with obesity are called comorbidities. Comorbidities include but are not limited to atherosclerosis, heart disease, diabetes mellitus, hypertension, sleep apnea, osteoarthritis, decreased mobility, lack of self-esteem, and depression. Obesity that interferes with activities of daily living, such as breathing or walking, is known as morbid obesity. Morbid obesity refers to people whose BMI is above 40, which is about 100 pounds overweight for men and about 80 pounds overweight for women. Surgery can be an option for people whose BMI is above 40 or for people whose BMI is between 35 and 40 and who have life-threatening obesity-related diseases such as severe sleep apnea or heart disease. For more information, go to the National Heart, Lung, and Blood Institute Web site at www.nhlbisupport.com/bmi, The American Obesity Association at www.obesity.org, or The North American Association for the Study of Obesity at www.naaso.org. For information about surgery, finding a surgeon, chat rooms, and more, visit www.obesityhelp.com.

Medical Management

Initial treatment for obesity is weight loss through exercise and calorie restriction. For weight loss to occur, it is essential that the patient cooperates and has sustained motivation. Support groups such as Take Off Pounds Sensibly (TOPS) and Weight Watchers can help patients be successful. Behavior modification methods that provide rewards for successful weight loss are often included in a weight loss plan. Short-term use of medications that suppress appetite or block fat absorption may also be used.

Surgical Management

Patients who do not respond to medical methods of weight loss or whose BMI is 40 or above may have surgery to reduce their weight if they meet established criteria for the surgery. Surgical techniques produce weight loss by restriction (limiting how much the stomach can hold), or malabsorption (decreased calorie and nutrient absorption). (See Nutrition Notes Box 30–2.) The field of obesity surgery is called bariatric surgery and is designed to treat severe obesity. The word *bariatric* comes from the Greek word *baros* which means “weight.” Various procedures have been used over the years, but complications have arisen with some, such as malabsorption, so they are no longer used. For a list of surgical obesity centers and surgical procedures, visit The American Society for Bariatric Surgeons at www.asbs.org.

GASTRIC BYPASS. The Roux-en-Y bypass is the most common gastric bypass surgery today (Fig. 30–2). In the first part of this two-step surgery, a small stomach pouch the size of a thumb is created with staples. This small pouch causes a quick satisfactory feeling of fullness during a meal, which is the key to the success of this procedure. Next, a Y-shaped section of the small intestine is attached to the pouch to al-

Figure 30-2 (A) Roux-en-Y gastric bypass. A staple line creates a small pouch at the top of the stomach, which is then attached to the jejunum. Food bypasses most of the stomach and the duodenum and goes into the jejunum. (B) Vertical banded gastroplasty for gastric bypass. A small stomach pouch is made with a staple line and a mesh band. A circular window made with staples allows the band to be placed around the pouch. The band restricts and slows food flow from the stomach pouch. As the small pouch fills, there is a feeling of fullness even with small meals.

low food to bypass the lower stomach and duodenum. Digestive juice flow is maintained, and food enters the jejunum within 10 minutes of eating. There is little malabsorption of food. This procedure has also been performed laparoscopically.

VERTICAL BANDED GASTROPLASTY. Vertical banded gastroplasty (VBG) is the most commonly used restrictive surgery for weight reduction and control today. (See Fig. 30–2.) There is little malabsorption of food with this procedure. About 30 percent of patients who have had VBG achieve normal weight. Other methods of gastric banding are currently under study.

COMPLICATIONS OF GASTRIC RESTRICTIVE SURGERIES.

A common side effect of restrictive surgery is vomiting caused by overeating or by not chewing food well. Severe side effects of VBG include erosion of the gastric tissue surrounding the band, breakdown of the staple line, and leaking of the stomach secretions into the abdomen. Leaking of the stomach secretions requires emergency surgery and can lead to peritonitis, a very serious infection of the peritoneum. Infection or death from any of these complications can occur.

POSTOPERATIVE CARE. Postoperative bariatric patients require care similar to that for most types of gastric surgeries. (See Nursing Management after Gastric Surgery later in this chapter.) The bariatric diet, however, is very different. Patients are started on a clear liquid diet because of the small stomach pouch that has been created. Then the diet progresses to full liquids, pureed foods, and finally, at about 6 weeks after surgery, regular foods as tolerated.

LEARNING TIPS

For the patient who is, it is often necessary to have on hand special equipment for patient care. Some items you may need include the following:

- Extra-large hospital bed
- Extra pillows to elevate the head of the bed to ease breathing
- Extra-large hospital gowns
- Extra-large blood pressure cuff
- Oversized wheelchair and walker
- Devices for securing for Foley catheters to prevent tugging on the catheter
- Abdominal binder for postoperative comfort and to reduce the occurrence of wound edge separation

▶ INFLAMMATORY DISORDERS**Stomatitis**

Stomatitis is the general term for inflammation of the oral cavity. There are many causes of stomatitis, such as an infection or a systemic disease. The most common types of stomatitis are **aphthous stomatitis** (canker sores) and herpes simplex virus type I (also known as cold sores or fever blisters).

Aphthous Stomatitis (Canker Sores)

Aphthous stomatitis appears as small, white, painful ulcers on the inner cheeks, lips, tongue, gums, palate, or pharynx and typically lasts for several days to 2 weeks. Self-induced trauma such as biting the lips and cheeks can cause these ulcers to develop, as well as stress or exposure to irritating foods. Application of topical tetracycline several times a day usually shortens the healing time. A topical anesthetic such as benzocaine or lidocaine provides pain relief and makes it possible to eat with minimal pain.

gastroplasty: gastro—stomach + plasty—repair
stomatitis: stoma—mouth + itis—inflammation

Herpes Simplex Virus Type I

Herpes simplex virus type I (HSV-I) may appear as painful cold sores or fever blisters on the face, lips, perioral area, cheeks, nose, or conjunctiva. These lesions recur over time but last only for a few days each time. The onset can be provoked by fever or stress, among other things. Acyclovir ointment can be used to ease the pain, but it does not cure the lesions. Oral acyclovir may reduce recurrences. These lesions are infectious and standard precautions should be used when ointment is applied or oral care is given.

▶ ORAL CANCER

Oral cancer can occur anywhere in the mouth or throat. If detected early enough, it is curable. Oral cancer is found most commonly in patients who use alcohol or any form of tobacco. The highest incidence of oral cancer is found in the pharynx (throat), with the lowest incidence on the lips. Any oral sore that does not heal in 2 weeks should be assessed by the patient's physician. Cancerous ulcers are often painless but may become tender as the cancer progresses. In the later stages the patient may complain of difficulty in chewing, swallowing, or speaking or may have swollen cervical lymph glands. Biopsy specimens are taken to determine the presence of cancer.

Oral cancer treatment varies depending on the individualized diagnosis. Radiation, chemotherapy, and surgery are used alone or in combination to treat oral cancer. Radical or modified neck dissection is performed if the cancer has metastasized to cervical lymph nodes (Fig. 30–3). The tumor is removed along with lymph nodes, muscles, blood vessels, glands, and part of the thyroid, depending on the extent of the cancer. Drains are inserted into the incision to prevent fluid accumulation. A tracheostomy is usually performed to protect the airway and prevent obstruction. The airway must be monitored and secretions controlled to prevent aspiration. Tube feedings are usually given to meet the patient's nutritional needs because swallowing is difficult.

▶ ESOPHAGEAL CANCER

As with oral cancer, esophageal cancer is associated with the use of tobacco or alcohol. Esophageal cancer is usually detected late because of its location near many lymph nodes that allow it to metastasize. As the cancer progresses, obstruction of the esophagus can occur, with possible perforation or fistula development that may cause aspiration. The appearance of signs and symptoms usually means that the cancer is in the late stages. Signs and symptoms may include difficulty swallowing, a feeling of fullness, pain in the chest area after eating, foul breath, or regurgitation of foods if there is obstruction.

Diagnosis of esophageal cancer is usually made by esophagogastroduodenoscopy (EGD) and biopsy. Mediastinoscopy (endoscopic examination of mediastinum) is used to determine whether the cancer has spread to the lymph nodes and surrounding structures. Treatment for esophageal cancer includes radiation, chemotherapy, and surgery alone or in combination. Surgical procedures include esophageal resection (esophagogastrectomy), Dacron esophageal replace-

Figure 30-3 Radical neck dissection with tracheostomy tube and drains inserted.

ment, or use of a section of colon to replace the esophagus (esophagoenterostomy). If the tumor is inoperable, esophageal dilation or stent placement can be done to relieve dysphagia and allow food to pass through the esophagus.

► HIATAL HERNIA

The esophagus passes through an opening in the diaphragm called the hiatus. A **hiatal hernia** is a condition in which the lower part of the esophagus and stomach slides up through the hiatus of the diaphragm into the thorax (Fig. 30-4). Hiatal hernia occurs most commonly in women and those who are older than age 60, obese, or pregnant. A small hernia may not produce any discomfort or require treatment. However, a large hernia can cause pain, heartburn, a feeling of fullness, or reflux, which can injure the esophagus with possible ulceration and bleeding. Hiatal hernias are diagnosed by x-ray studies and fluoroscopy.

Medical Management

Treatment for hiatal hernia includes antacids; eating small meals that pass easily through the esophagus; not reclining for 1 hour after eating; elevating the head of the bed 6 to 12 inches to prevent reflux; and avoiding bedtime snacks, spicy foods, alcohol, caffeine, and smoking. (See Nutrition Notes Box 30-2).

Surgical Management

Surgical procedures can be done to prevent the herniated portion of the stomach from moving upward through the hiatus. Fundoplication is the most common surgical procedure performed, in which the stomach fundus is wrapped

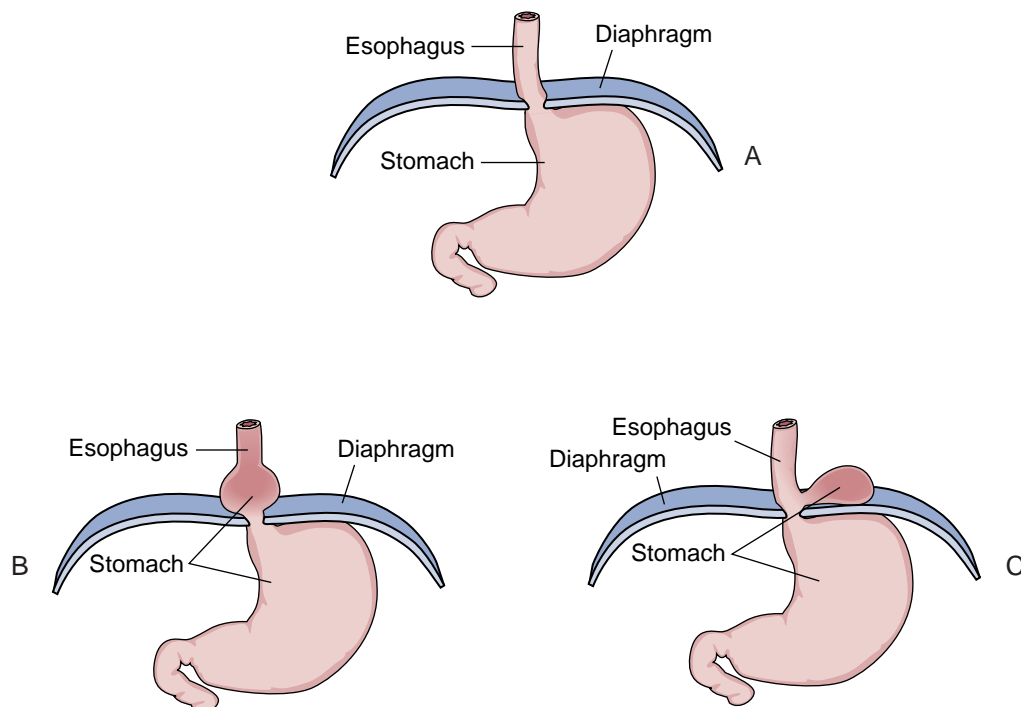

Figure 30-4 Hiatal hernia. (A) Normal esophagus and stomach. (B) Sliding hiatal hernia. (C) Rolling hiatal hernia.

Figure 30-5 Hiatal hernia repair. Nissen fundoplication wraps the stomach fundus around the esophagus and then sutures it onto itself to hold it in place.

around the lower part of the esophagus (Fig. 30-5). Following this repair, patients are assessed for dysphagia during their first postoperative meal. If dysphagia occurs, the physician should be notified because the repair may be too tight, causing obstruction of the passage of food.

▶ GASTROESOPHAGEAL REFLUX DISEASE

Gastroesophageal reflux disease (GERD) is a condition in which gastric secretions reflux into the esophagus. The esophagus can be damaged by acidic gastric secretions and exposure to digestive enzymes. GERD is caused primarily by conditions that affect the ability of the lower esophageal sphincter to close tightly, such as hiatal hernia. Signs and symptoms of GERD include heartburn, regurgitation, dysphagia, and bleeding. Aspiration is a concern. Scar tissue can develop from the inflammation. Diagnostic tests include a barium swallow, esophagoscopy, or pH monitoring of the normally alkaline esophagus. GERD often occurs in elderly people.

Medical Management

Interventions for GERD aim to decrease the reflux of gastric secretions into the esophagus. Medications used may include antacids, histamine (H_2) receptor antagonists, cytoprotective agents (sucralfate), and cholinergic drugs that improve gastric emptying and function of the lower esophageal sphincter. Obese patients are encouraged to lose weight. A low-fat, high-protein diet is recommended because fat causes decreased functioning of the lower esophageal sphincter. Caffeine, milk products, and spicy foods should be avoided. If surgery is necessary to alleviate symptoms, a fundoplication can be done.

Nursing Management

Patients need to be educated about medications and management of their condition. They are instructed to sleep with the head of the bed elevated 4 to 6 inches, eat small meals, and avoid lying down for 2 hours after eating. Smok-

ing and alcohol intake should be avoided because they decrease functioning of the lower esophageal sphincter. Foods that cause discomfort should be identified by the patient and avoided.

▶ GASTRITIS

Gastritis is inflammation of the stomach mucosa and can be acute or chronic. Causes are listed in Box 30-3. Gastritis results when the protective mucosal barrier is broken down and allows autodigestion from hydrochloric acid and pepsin to occur. Edema of the tissue and possible hemorrhage result. With severe gastritis, the gastric mucosa can become gangrenous and perforate, which can lead to peritonitis (infection of the peritoneum). Scarring may also occur, resulting in pyloric obstruction.

Symptoms and Medical Management

The major symptom of gastritis is abdominal pain, which is often accompanied by nausea and anorexia. Treatment is removal of the irritating substance and provision of a bland diet of liquids and soft foods along with antacids. With a bland diet, the patient usually recovers in about a day.

Chronic Gastritis Type A

Chronic gastritis occurs over time and is classified as type A or type B. Type A is often referred to as autoimmune gastritis and occurs in the fundus (body of stomach). Chronic gastritis type A is diagnosed by endoscopy, upper gastrointestinal (GI) x-ray examination, and gastric aspirate analysis. (See Chapter 29.) Type A gastritis is often asymptomatic. Patients with type A gastritis usually do not secrete enough intrinsic factor from their stomach cells and as a result have difficulty absorbing vitamin B_{12} , which leads to pernicious anemia (discussed later).

Chronic Gastritis Type B

Type B gastritis affects the antrum and pylorus (lower end of the stomach near the duodenum) and is associated with *Helicobacter pylori* bacterial infection. Signs and symptoms

gastritis: gastr—stomach + itis—inflammation

BOX 30-3 Causes of Gastritis

- Alcohol
- Helicobacter pylori*
- Medication
 - Aspirin
 - Nonsteroidal anti-inflammatory drugs
 - Corticosteroids
 - Reflux of bile
- Salmonella*
- Smoking
- Spicy foods
- Stress—physiological or psychological
- Trauma

include poor appetite, heartburn after eating, belching, a sour taste in the mouth, and nausea and vomiting. Type B gastritis can also be diagnosed by endoscopy, upper gastrointestinal x-ray examination, and gastric aspirate analysis. *H. pylori* infection is treated with antibiotics.

▶ PEPTIC ULCER DISEASE

Etiology

Until 1982 the cause of peptic ulcer was poorly understood and thought to be related to stress, diet, and alcohol or caffeine ingestion. However, research results found that **peptic ulcer disease** is primarily caused by infection with the gram-negative bacterium *H. pylori*. This bacterium is responsible for 80 percent of gastric ulcers and more than 90 percent of duodenal ulcers. Two-thirds of all people are infected with *H. pylori*, and it is most common in those who are elderly, Hispanic, African-American, or in lower socioeconomic groups in the United States. The discovery of *H. pylori* has led to changes in treating and curing peptic ulcers. It is not known how *H. pylori* is transmitted, although the oral-oral or fecal-oral routes are likely. Contaminated water may also play a role. Vaccines to prevent peptic ulcers are being developed.

Peptic ulcer development is also influenced by smoking, which increases the harmful effects of *H. pylori*, alters protective mechanisms, and decreases gastric blood flow. For more information on *H. pylori*, visit www.cdc.gov or call 1-888-MY-ULCER (1-888-698-5237).

LEARNING TIPS

Most peptic ulcers are caused by an infection (*H. pylori*) that can be cured with antibiotics.

Pathophysiology

Peptic ulcer disease (PUD) is a condition in which the lining of the stomach, pylorus, duodenum, or the esophagus is eroded, usually from infection with *H. pylori*. The erosion may extend into the muscle layers or the peritoneum. Peptic ulcers occur in the portions of the gastrointestinal tract that are exposed to hydrochloric acid and pepsin. The erosion is due to an increase in the concentration or activity of hydrochloric acid and pepsin. The damaged mucosa is unable to secrete enough mucus to act as a barrier against the hydrochloric acid. Some individuals have more rapid gastric emptying, which, combined with hypersecretion of acid, creates a large amount of acid moving into the duodenum. As a result, peptic ulcers occur more often in the duodenum. Ulcers are named by their location: esophageal, gastric, or duodenal. Duodenal ulcers are more common than gastric ulcers.

Signs and Symptoms

Symptoms vary with the location of the ulcer (Table 30–1). Symptoms, including pain, may not be experienced with

TABLE 30-1 PEPTIC ULCER DISEASE SUMMARY

Signs and symptoms	Gastric: Intermittent high left epigastric or upper abdominal burning or gnawing pain, increased 1–2 hours after meals or with food Duodenal: Intermittent midepigastric or upper abdominal burning or cramping pain, increased 2–4 hours after meals or in the middle of the night; relieved with food or antacids Anorexia Nausea/vomiting Bleeding (stomach secretions or stool positive for occult blood)
Diagnostic tests <i>H. pylori</i>	Urea breath test IgG antibody detection test for <i>H. pylori</i> Biopsy Culture
Peptic ulcer	Upper GI series (barium swallow) Esophagogastroduodenoscopy
Medical treatment	Antibiotics Proton pump inhibitors H ₂ antagonists Bismuth subsalicylate Sucralfate (Carafate) Antacids Bland diet Avoiding irritants, such as smoking, caffeine, alcohol
Complications	Bleeding Perforation Obstruction
Nursing diagnoses	Acute pain related to disruption of GI mucosa Risk for injury related to complications of peptic ulcer activity such as hemorrhage or perforation Deficient knowledge related to lack of exposure to peptic ulcer disease and its treatment

gastric or duodenal ulcers until complications such as hemorrhage, obstruction, or perforation develop. If pain does occur, patients with gastric ulcers commonly experience a burning and gnawing pain in the high left epigastric region. There may be more pain with food ingestion or 1 to 2 hours after a meal. Duodenal ulcers produce cramping or burning pain in the midepigastric or upper abdominal area. The pain occurs 2 to 4 hours after meals or in the middle of the night. This intermittent pain may be relieved by the ingestion of food or antacids. Anorexia and nausea and vomiting may also occur with either ulcer location. Bleeding may occur with massive hemorrhaging or slow oozing. Patients often have low hematocrit and hemoglobin levels, and gastric or fecal occult blood may be found, depending on where the ulcers are located.

Diagnosis

H. pylori can be diagnosed with several tests. The urea breath test is performed by having the patient drink carbon-labeled urea. The urea is metabolized rapidly if *H. pylori* is present, allowing the carbon to be absorbed and measured in exhaled carbon dioxide. An IgG antibody detection test for *H. pylori* identifies whether the patient is infected with *H. pylori*. These are both noninvasive detection tests. Biopsy specimens for the *Campylobacter*-like organism (CLO) biopsy urease test and a histological examination can be obtained during esophagogastroduodenoscopy (EGD). Biopsy is the most conclusive test for *H. pylori*. Cul-

tures of the biopsy specimen may also be done to determine antimicrobial susceptibility.

Peptic ulcers are diagnosed on the basis of symptoms, upper GI series (barium swallow), and EGD.

Medical Management

Several treatment options are used to cure *H. pylori* without recurrence (Table 30–2). The first antibiotic treatment for ulcer disease caused by *H. pylori* was approved by the Food and Drug Administration (FDA) in 1996. For better effectiveness, triple therapy with two antibiotics to decrease resistance of the bacteria and a proton pump inhibitor or H₂ antagonist is used. Treatment lasting 14 days has better eradication rates than 10-day treatments. Bismuth subsalicylate (Pepto-Bismol) may also be used for its antibacterial effects. Proton pump inhibitors are powerful agents that stop the final step of gastric acid secretion to reduce mucosa erosion and aid in healing ulcers (Table 30–3). H₂ antagonists block H₂ receptors to decrease acid secretion, although not as powerfully as gastric acid pump inhibitors. A bland diet may also be recommended, and foods known to cause discomfort to the patient, such as spicy foods, carbonated drinks, and caffeine, should be avoided until the ulcer heals.

Nursing Process

Assessment

The primary focus of nursing care for peptic ulcer disease is educating patients regarding the importance of this diagnosis, because ulcers may be caused by an infection that can be cured with antibiotics. Patients may still believe that all ulcers are caused by stress, lifestyle, or diet. Assessing the patient’s knowledge aids in providing accurate information to assist the patient in managing peptic ulcer disease. Data are also collected about the patient’s disease history. Identifying factors that trigger or relieve symptoms is important.

Nursing Diagnosis

Nursing Care Plan 30–4 discusses nursing diagnoses for peptic ulcer disease. The care plan should focus on the patient’s understanding of the importance of taking all medication as

LEARNING TIPS

Basic types of medications for the stomach include the following:

- Proton pump inhibitors such as omeprazole (Prilosec) or lansoprazole (Prevacid) inhibit gastric acid from forming.
- H₂ antagonists such as cimetidine (Tagamet), famotidine (Pepcid), and ranitidine (Zantac) reduce gastric acid secretion.
- Antacids such as Maalox and Mylanta neutralize gastric acid that has already formed.
- Sucralfate (Carafate) is like a band-aid for ulcers. Carafate forms a sticky paste that adheres to the ulcer surface, providing a protective barrier to allow healing.

TABLE 30–2 MEDICATION REGIMEN OPTIONS FOR *H. PYLORI* INFECTION

Type of Therapy	Examples of Therapy Options
<i>Triple therapy*</i> Two antibiotics + proton pump inhibitor	<ul style="list-style-type: none"> • Amoxicillin (Amoxil) + clarithromycin (Biaxin) + omeprazole (Prilosec) • Amoxicillin (Amoxil) + clarithromycin (Biaxin) + lansoprazole (Prevacid) (available as Prevpac, combined for convenience)
<i>Dual therapy</i> Antibiotic + proton pump inhibitor or Antibiotic + H ₂ antagonist	<ul style="list-style-type: none"> • Clarithromycin (Biaxin) + omeprazole (Prilosec) • Amoxicillin (Amoxil) + lansoprazole (Prevacid) • Clarithromycin (Biaxin) + ranitidine bismuth citrate (Tritec)
<i>Other therapy</i> Two antibiotics + bismuth subsalicylate + H ₂ antagonist	<ul style="list-style-type: none"> • Metronidazole (Flagyl) + tetracycline + bismuth subsalicylate (Pepto-Bismol) + H₂ antagonist

*Triple therapy has a better eradication rate.

TABLE 30-3 MEDICATIONS USED TO PROMOTE HEALING OF PEPTIC ULCERS

Medication	Action	Side Effects	Nursing Interventions
Hyposecretory Agents—H₂ Receptor Blocking Agents			
<i>Cimetidine</i> (<i>Tagamet</i>)	Inhibits gastric acid secretion by blocking H ₂ receptors on gastric parietal cells.	Fever, rash, headaches, dizziness, somnolence, confusion (especially in elderly), hypotension, diarrhea, neutropenia, gynecomastia, and impotence	Monitor mental status of elderly; do not take antacids within 1 hour of Tagamet; take with meals and at bedtime; interacts with theophylline, phenytoin, warfarin, and beta blockers; continue treatment for at least 8 weeks to ensure healing.
<i>Ranitidine</i> (<i>Zantac</i>)	Inhibits gastric acid secretion by blocking H ₂ receptors on gastric parietal cells.	All side effects rare, including nausea, constipation, bradycardia, increased liver enzymes, and headache	Give antacids at least 1 hour before or 2 hours after Zantac; can be given in single bedtime dose; use cautiously in patients with liver or renal disease; absorption not affected by food; interacts minimally with other drugs.
<i>Famotidine</i> (<i>Pepcid</i>)	Inhibits gastric acid secretion by blocking H ₂ receptors on gastric parietal cells.	Headache, diarrhea, constipation, nausea, flatulence, increased blood urea nitrogen and creatinine, and rash	Should not be taken longer than 8 weeks without physician's order; may be given with antacids; can be given in single bedtime dose; has no significant drug interactions.
<i>Nizatidine</i> (<i>Axid</i>)	Inhibits gastric acid secretion by blocking H ₂ receptors on gastric parietal cells.	Diarrhea, rash, bronchospasms, somnolence, joint pain, and sweating	Give as single bedtime dose or, if given twice a day, one dose at bedtime; assess for excessive drowsiness; monitor and record stools; do not give antacids within 1 hour of Axid; must be taken 4 to 8 weeks for ulcer healing; notify physician if somnolence or rash develops.
Proton Pump Inhibitor			
<i>Omeprazole</i> (<i>Prilosec</i>)	Binds to enzyme on gastric parietal cells to prevent final transport of hydrogen to block gastric acid secretion.	Abdominal pain, diarrhea, rash, chest pain, and weakness	Give before meal in morning; swallow capsule whole; assess for abdominal pain and bleeding; monitor complete blood cell count and liver enzymes; may give with antacids; must be taken 4 to 8 weeks for ulcer healing; notify physician if bleeding, diarrhea, headache, or abdominal pain develops.
<i>Lansoprazole</i> (<i>Prevacid</i>)	Binds to an enzyme in the presence of acidic gastric pH, preventing the final transport of hydrogen ions into the gastric lumen.	Dizziness, headache, diarrhea, abdominal pain, nausea, rash	Assess for epigastric or abdominal pain and for blood in stool, emesis, or gastric aspirate. Give before meals. Capsules may be opened and sprinkled on applesauce and taken immediately for patients with difficulty swallowing. Do not crush capsule. Tell patient not to chew capsule.
<i>Rabeprazole</i> (<i>Aciphex</i>)	Same as for lansoprazole	Headache	Tell patient to swallow tablets whole.
Antacids			
<i>Aluminum-magnesium combinations</i> (<i>Riopan</i> , <i>Maalox</i> , <i>Mylanta</i> , <i>Gelusil</i>)	Increases gastric pH to reduce pepsin activity; strengthens gastric mucosal barrier and esophageal sphincter tone.	Mild constipation or diarrhea	Do not give to patients with renal disease; monitor bowel movements and signs of hypermagnesemia; Riopan low in sodium; do not give within 1 to 2 hours of H ₂ receptor antagonists, tetracycline, or enteric-coated tablets.
<i>Calcium carbonate</i> (<i>Tums</i> , <i>Titralac</i>)	Increases gastric pH to reduce pepsin activity; strengthens gastric mucosal barrier and esophageal sphincter tone.	Constipation, gastric distention, rebound hyperacidity, hypercalcemia, and hypophosphatemia	Do not give with milk; monitor for symptoms of hypercalcemia and constipation; do not give within 1 to 2 hours of H ₂ receptor antagonists, tetracycline, or enteric-coated tablets.
Mucosal Barrier Fortifiers			
<i>Sucralfate</i> (<i>Carafate</i>)	In presence of mild acid condition, forms viscid and sticky gel and adheres to ulcer surface, forming a protective barrier.	Dizziness, constipation, sleepiness, nausea, and gastric discomfort	Take on an empty stomach, 1 hour before meals and at bedtime; monitor for constipation.

BOX 30-4 NURSING CARE PLAN FOR THE PATIENT WITH PEPTIC ULCER DISEASE**▶ Acute pain related to gastric mucosal erosion****PATIENT OUTCOMES**

Patient's pain is relieved as evidenced by no report of pain and absence of nonverbal pain cues.

EVALUATION OF OUTCOMES

Is pain relieved to patient's satisfaction?

INTERVENTIONS

Ask patient to rate pain level on scale of 0 to 10 every 3 hours and as needed. Assess location, onset, intensity, characteristics of pain, and nonverbal pain cues.

Assess for factors precipitating and relieving pain.

Ask patient to help identify techniques for pain relief

Administer antiulcer medications as ordered.

Provide small, frequent meals four to six times a day.

Encourage nonacidic fluids between meals.

RATIONALE

Prompt assessment can lead to timely intervention and relief of pain.

Peptic ulcer pain may be relieved by food, antacids, or other interventions.

Gaining the patient's cooperation increases compliance.

H₂ receptor antagonists reduce amount of gastric acid produced, and antacids neutralize gastric acid to help relieve pain.

Small, frequent meals dilute and neutralize gastric acid.

Nonacidic fluids decrease irritation to gastric mucosal.

EVALUATION

Does patient rate pain using scale and describe pain?

Is patient able to state precipitating and relieving pain factors?

Is patient willing to participate in planning how to relieve pain?

Do medications reduce patient's symptoms?

Does patient report relief of gastric pain between meals?

Does patient identify and drink nonacidic fluids?

▶ Risk for injury related to complications of peptic ulcer activity such as hemorrhage and perforation**PATIENT OUTCOMES**

Patient's vital signs will be maintained within normal limits and bleeding or hemorrhage will be promptly detected.

EVALUATION OF OUTCOMES

Are patient's vital signs within normal limits?

INTERVENTIONS

Assess for signs and symptoms of hemorrhage such as hematemesis (vomiting blood) and melena (blood in the stool).

Monitor vital signs: blood pressure, pulse, respirations, and temperature.

Maintain intravenous infusion as ordered.

Monitor hematocrit and hemoglobin levels as ordered.

RATIONALE

Rapid assessment can lead to prompt intervention.

Severe blood loss of more than 1 L per 24 hours may cause manifestations of shock such as hypotension; weak, thready pulse; chills; palpitations; and diaphoresis.

Normal fluid balance prevents hypovolemia and shock due to hemorrhage.

Decreased hematocrit and hemoglobin levels indicate a decrease in circulating blood volume and reduced oxygen-carrying capacity to the tissues.

EVALUATION

Does patient have any bleeding?

Are vital signs normal?

Are intake and output balanced?

Are hematocrit and hemoglobin levels normal?

directed, even if symptoms are gone. Patient noncompliance with treatment is a major cause of ulcer recurrence.

Stress Ulcers

A small number of patients who are critically ill may develop gastric or small intestinal stress ulcers from ischemia. The stress response to the illness causes reduced blood flow to the stomach and small intestine, resulting in ischemia and damage to the mucosa. The damaged mucous barrier allows acid secretions to create ulcers. Preventive treatment has dramatically reduced stress ulcers, which have a high

mortality rate because of the multiple bleeding ulcer sites. This treatment includes trauma care that quickly restores oxygen to the stomach, as well as early feeding within 24 hours of the trauma. Placement of a nasogastric (NG) tube allows testing of the gastric pH to ensure that it is higher than 5, as well as providing a means for enteral feeding. In addition, medications are given such as antacids, histamine blockers, and sucralfate (Carafate).

▶ GASTRIC BLEEDING

Gastric bleeding may be caused by ulcer perforation, tumors, gastric surgery, or other conditions. Bleeding peptic

ulcers are the most common cause of blood loss into the stomach or intestine. Blood loss can be hidden (occult) blood in the stool, observable vomited blood (hematemesis), or black tarry stools (melena). When blood mixes with hydrochloric acid and enzymes in the stomach, a dark, granular material resembling coffee grounds is produced. This material can be vomited or passed through the GI system and mixed with stools. Melena occurs from slow bleeding in an upper GI area.

Signs and Symptoms

With mild bleeding, the patient may experience only slight weakness or diaphoresis. Severe blood loss (more than 1 L in 24 hours) may result in hypovolemic shock, with signs and symptoms such as hypotension; a weak, thready pulse; chills; palpitations; and diaphoresis.

Medical Management

The goal of treatment for a massive GI bleed is to prevent or treat hypovolemic shock and prevent dehydration, electrolyte imbalance, and further bleeding. The patient is kept on nothing-by-mouth (NPO) status. An intravenous (IV) line is started to replace lost fluids and administer blood if necessary. A complete blood cell count is obtained to determine the amount of blood lost. A urinary catheter is inserted to monitor output. An NG tube is inserted to assess the rate of bleeding, decompress the stomach, monitor the pH of gastric secretions, and administer saline lavage if ordered. Oxygen therapy may be required if the patient has lost a large amount of blood. To prevent aspiration with vomiting, the head of the bed is elevated. The physician may perform endoscopy to help control the bleeding. Drugs may also be instilled into the GI tract by use of an endoscope. For severe cases, surgery may be needed to remove the bleeding area or ligate bleeding vessels. Drugs such as ranitidine (Zantac) are given to decrease the secretion of gastric acid.

► GASTRIC CANCER

Gastric cancer refers to malignant lesions found in the stomach. It is the second most common cancer in the world and is more common in men than in women. *H. pylori* infection plays a role in gastric cancer development. Studies are being done to see whether preventing *H. pylori* infection reduces the development of gastric cancer. Other factors that may be associated with gastric cancer development include pernicious anemia; exposure to occupational substances such as lead dust, grain dust, glycol ethers, or leaded gasoline; and a diet high in smoked fish or meats. A poor prognosis is often associated with gastric cancer, because most patients have metastasis at the time of diagnosis. (See Nutrition Notes Box 30–2.)

Signs and Symptoms

Gastric cancer is rarely diagnosed in its early stages because symptoms do not appear until late in the disease. In the early stages there may not be any symptoms at all, and

metastasis to another organ, such as the liver, may have already occurred. The symptoms of gastric cancer are often mistaken for peptic ulcer disease: indigestion, anorexia, pain relieved by antacids, weight loss, and nausea and vomiting. Anemia from blood loss commonly occurs, and occult blood in the stool may be present.

Diagnosis

Diagnosis of gastric cancer is made by upper gastrointestinal x-ray examination, gastroscopy, gastric fluid analysis, and measurement of serum gastrin levels.

Medical Management

Surgical removal of the cancer is the most effective treatment for gastric cancer. Most often the cancer has already metastasized, and surgery is performed only to relieve the symptoms. Chemotherapy and radiation are sometimes used in conjunction with surgery, although they are not very effective against the cancer. Biologic therapies, new cytotoxic agents, and new delivery methods are being studied for use with gastric cancer.

► GASTRIC SURGERIES

Subtotal Gastrectomy

Two types of surgical interventions are used to treat upper gastrointestinal diseases. The first type is the subtotal **gastrectomy**, which is used to treat cancer in the lower two-thirds of the stomach. *Subtotal gastrectomy* is a general term used to describe any surgery that involves partial removal of the stomach. There are two types of subtotal gastrectomies: the Billroth I procedure and the Billroth II procedure.

Billroth I Procedure (Gastroduodenostomy)

In the Billroth I procedure, also known as a **gastroduodenostomy**, the surgeon removes the distal portion (75 percent) of the stomach (Fig. 30–6). The remainder of the stomach is anastomosed (surgically attached) to the duodenum. This procedure is used to treat gastric problems.

Billroth II Procedure

The Billroth II procedure, **gastrojejunostomy**, involves removal of the distal 50 percent of the stomach and reanastomosis of the proximal remnant of the stomach to the proximal jejunum. Because it results in bypassing of the duodenum, the Billroth II procedure is used to treat duodenal ulcers. Pancreatic secretions and bile are necessary for digestion and continue to be secreted into the duodenum from the common bile duct even after the partial gastrectomy.

gastrectomy: gastr—stomach + ectomy—to remove

gastroduodenostomy: gastro—stomach + duoden—duodenum + ostomy—mouth or opening

gastrojejunostomy: gastro—stomach + jejeun—jejunum + ostomy—mouth or opening

Figure 30-6 Subtotal gastrectomy involves removing the distal portion of the stomach. The remaining portion of the stomach is then sutured (A) to the duodenum (Billroth I procedure) or (B) to the proximal jejunum (Billroth II procedure). Vagotomy may also be performed.

Total Gastrectomy

Total gastrectomy, the total removal of the stomach, is the treatment for extensive gastric cancer. This surgery involves removal of the stomach, with anastomosis of the esophagus to the jejunum (Fig. 30-7).

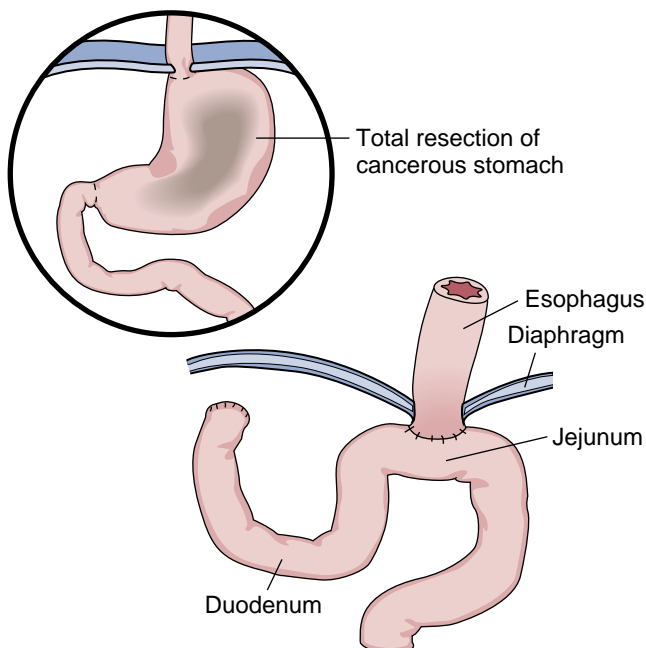

Figure 30-7 Total gastrectomy.

Vagotomy

A vagotomy, in which a section of the vagus nerve is cut, may be performed with gastric surgery. Vagotomy eliminates the vagal stimulation for hydrochloric acid and gastrin hormone secretion and slows gastric motility.

Nursing Management after Gastric Surgery

Patients' vital signs are monitored postoperatively as ordered. Respiratory status is carefully monitored because the high location of the surgical incision may cause pain, which interferes with deep breathing and coughing. Atelectasis or pneumonia can develop as a result of guarding and shallow breathing. The patient's pain is assessed and relieved, which also helps the patient's ability to deep breathe or cough without pain. The patient's IV site and infusion are monitored, and intake and output are recorded. The incisional site and dressings are observed for drainage and bleeding.

Bowel sounds are assessed. Patients may have an NG tube inserted during surgery. The nurse applies suction as ordered, which is usually low intermittent suction to prevent trauma to the gastric mucosa. The drainage from the NG tube is monitored for color and amount. If bleeding or excessive amounts of drainage are noted, they are reported to the physician. The nurse should not irrigate or reposition the NG tube following gastric surgery to prevent damaging the suture line. The patient should be assessed for abdominal distention. If distention occurs, abdominal girth should be measured and the physician notified.

It is important to teach patients how to assist in their recovery. This includes incisional care, activity or dietary restrictions, and information about prescribed medications. Patients are encouraged to ambulate early to promote a quicker recovery by improving respiratory and gastrointestinal function.

Complications of Gastric Surgery

Complications that can occur after gastric surgery include hemorrhage, acute gastric distention, nutritional problems, **steatorrhea** (fat in stools), pyloric obstruction, and dumping syndrome.

Hemorrhage

The incidence of hemorrhage after gastric surgery is very low and is most often caused by a dislodged clot at the surgical site or slippage of a suture. The patient experiencing hemorrhage exhibits restlessness, cold skin, increased pulse and respirations, and decreased temperature and blood pressure. In addition, the patient may vomit bright red blood. To prevent aspiration during vomiting, the patient is turned to one side and the head of the bed is elevated.

Following gastric surgery, patients usually have an NG tube that has been inserted in the operating room. The drainage from the tube should be assessed for color and amount. A small amount of pink or light red drainage may

steatorrhea: steatos—fat + rrhea—profuse flow

be expected for the first 12 hours, but moderate or excessive bleeding should be immediately reported to the physician. The abdominal dressing should also be assessed for any drainage or bleeding.

Gastric Distention

In the immediate postoperative period, distention of the stomach can occur if an inserted NG tube is clogged or if an NG tube has not been inserted. Symptoms of gastric distention include an enlarged abdomen, epigastric pain, tachycardia, and hypotension. The patient may complain of feeling full and may hiccup or gag repeatedly. These symptoms must be reported to the physician.

The physician usually inserts the NG tube during surgery so that the suture line is not damaged. If suction is desired, a physician's order is required. Irrigating or repositioning the NG tube is not performed by the nurse to prevent harm to the suture line. Any problems with distention or an improperly functioning NG tube are reported to the physician. The physician may need to reposition the NG tube to correct the problem. The patient's vital signs should be monitored until the patient's distention is relieved and the patient is stable.

CRITICAL THINKING

Mr. Wong

You are working the evening shift on a surgical unit. A patient, Mr. Wong, has had gastric surgery earlier that morning. He has an intravenous infusion of 1000 mL dextrose 5 percent in 0.45 normal saline running at 83 mL per hour and a nasogastric tube to low intermittent wall suction. Mr. Wong is restless and complaining of pain. His bowel sounds are absent, and his abdomen is distended. The suction canister contains no gastric output.

1. What nursing interventions in order of priority are needed to help Mr. Wong?
2. What equipment do you need to care for Mr. Wong?

Answers at end of chapter.

Nutritional Problems

Nutritional problems that commonly occur after removal of part or all of the stomach include B₁₂ and folic acid deficiency and reduced absorption of calcium and vitamin D. Also, rapid entry of food into the bowel often results in inadequate absorption of food.

Following gastric surgery, patients are NPO until bowel sounds return (usually 24 to 48 hours) or the physician orders a diet. Intravenous fluid provides hydration. However, if patients are to be NPO for a longer time, they may need additional nutritional intake provided by total parenteral nutrition (TPN) through a central line. TPN is an intravenous solution given to meet caloric needs and provide fluids lost in drainage or emesis. Many patients with gastric cancer are malnourished and may require several days of TPN therapy.

After the return of bowel sounds and the removal of the nasogastric tube, clear fluids may be ordered with progression

to full liquids, then soft foods as the patient tolerates. It is important to remember that foods and fluids must be introduced into the diet gradually following gastric surgery. If the patient eats too much or too fast, regurgitation may result.

PERNICIOUS ANEMIA. Vitamin B₁₂ deficiency can occur after some or all of the stomach is removed because intrinsic factor secretion is reduced or gone. Normally vitamin B₁₂ combines with intrinsic factor to prevent its digestion in the stomach and promote its absorption in the intestines. Lifelong administration of vitamin B₁₂ injections is required to prevent the development of pernicious anemia. The parenteral route must be used because oral vitamin B₁₂ cannot be absorbed. Vitamin B₁₂ is given daily initially, then monthly for life. Patients must be taught the importance of complying with this treatment for the rest of their lives to prevent pernicious anemia. Symptoms of pernicious anemia include anemia, weakness, sore tongue, numbness and tingling, and gastrointestinal upset.

Steatorrhea

Steatorrhea is the presence of excessive fat in the stools and is the result of rapid gastric emptying, which prevents adequate mixing of fat with pancreatic and biliary secretions. In most cases, steatorrhea can be controlled by reducing the intake of fat in the diet.

Pyloric Obstruction

Pyloric obstruction can occur after gastric surgery as a result of scarring, edema, or inflammation or a combination of these. The signs and symptoms are vomiting, a feeling of fullness, gastric distention, nausea after eating, loss of appetite, and weight loss. As the obstruction increases, it gradually becomes more difficult for the stomach to empty, and symptoms worsen. Conservative methods are used first, such as replacing fluids and electrolytes through intravenous fluids and decompressing the distended stomach using a nasogastric tube. Surgery may be necessary if conservative measures do not relieve the signs and symptoms. Pyloroplasty widens the exit of the pylorus to improve emptying of the stomach.

Dumping Syndrome

Dumping syndrome occurs with the rapid entry of food into the jejunum without proper mixing of the food with digestive juices. On entering the jejunum, the food draws extracellular fluid into the bowel from the circulating blood volume to dilute the high concentration of electrolytes and sugars. This rapid shift of fluids decreases the circulating

CRITICAL THINKING

Mrs. Lindsay

Mrs. Lindsay has had gastric surgery. You have taught her about dumping syndrome, and she is concerned about what she will eat. Create a 1-day meal plan for Mrs. Lindsay.

Answers at end of chapter.

blood volume and produces symptoms. The symptoms occur 5 to 30 minutes after eating and include dizziness, tachycardia, fainting, sweating, nausea, diarrhea, a feeling of fullness, and abdominal cramping. Additionally, the blood sugar rises, and excessive insulin is excreted in response. This release of insulin causes the patient to have symptoms of hypoglycemia about 2 hours later. Symptoms include weakness, sweating, anxiety, shakiness, confusion, and tachycardia. The patient should immediately eat some candy or drink juice containing sugar to relieve the symptoms.

The treatment for dumping syndrome includes teaching the patient to eat small, frequent meals that are high in protein and low in carbohydrates, especially refined sugars (see Nutrition Notes Box 30–2). The patient is also taught to avoid fluids 1 hour before, with, or for 2 hours after meals to prevent rapid gastric emptying. It is best for the patient to lie down after meals to delay gastric emptying. The patient is told that these symptoms may last for up to 6 months after gastric surgery but usually slowly subside over time.

REVIEW QUESTIONS

- Which one of the following is the most important intervention for anorexia nervosa?
 - Weigh the patient daily.
 - Restore nutritional health.
 - Assist with activities of daily living.
 - Document intake and output.
- Which of the following is the priority nursing diagnosis for a patient with peptic ulcer disease?
 - Activity intolerance related to epigastric pain
 - Deficient knowledge related to lack of information on ulcers
 - Acute pain related to epigastric erosion and acid buildup
 - Ineffective coping related to diagnosis of peptic ulcers
- Which of the following is the purpose of H₂ antagonists?
 - Neutralize gastric acid.
 - Form a protective paste.
 - Determine gastric pH levels.
 - Inhibit secretion of gastric acid.
- Which one of the following is primarily the cause of peptic ulcers?
 - Eating spicy foods
 - A stressful life
 - A bacterial infection
 - Excessive caffeine intake
- Which one of the following actions should the nurse take first for a patient who has just returned from surgery after a total gastrectomy and begins to vomit bright red blood?
 - Increase the IV rate.
 - Administer oxygen.
 - Place patient on side.
 - Irrigate nasogastric tube.

Answers to CRITICAL THINKING

Mr. Wong

- Prioritize your interventions:
 - Take Mr. Wong's vital signs to determine whether he is stable. Pain can sometimes increase the blood pressure and pulse rate. However, gastric distention can cause pain, and once the distention is relieved, the pain caused by distention subsides.
 - Listen to Mr. Wong's bowel sounds. Manipulation of internal organs during abdominal surgery can produce a loss of normal peristalsis for 24 to 48 hours. Expect to hear absent or hypoactive bowel sounds for the first 1 or 2 days.
 - Next, check placement of Mr. Wong's nasogastric tube by aspirating gastric contents and verifying pH of the contents as ordered. It is important to check for abdominal placement of Mr. Wong's nasogastric tube to make sure it is not misplaced in the lungs. After abdominal placement is determined, if there is a physician's order, the nasogastric tube can be connected to suction equipment, usually set on low intermittent suction.
 - Next check the suction equipment for ordered settings and to ensure that it is turned on. The suction setting normally is ordered to be on low. A whistling sound is heard when the tube is disconnected from the suction setup. The seals should be tight on the suction canister. When the tubing is hooked to

suction, gastric contents should be moving into the suction canister. It is important to make sure equipment is functioning properly to ensure patient safety.

- Check the nasogastric tube for clogs only if the physician orders aspiration or irrigation to be done. The tube is gently aspirated with a 60-mL catheter-tipped syringe. If the tube remains clogged, it is gently flushed as ordered with 10 to 20 mL of sterile normal saline.
 - After the gastric distention has been relieved, Mr. Wong's pain level is reassessed to determine if he needs pain medication. Considering that he is less than 1 day postoperative, he probably needs it.
- Necessary equipment includes stethoscope, 60-mL catheter-tipped syringe, gloves, goggles, and normal saline for irrigation.

Mrs. Lindsay

Although there are many variations, the following is an example of a 1-day meal plan for Mrs. Lindsay:

Breakfast: one egg, any style; ½ orange; one glass milk

Snack: one slice toast with apple butter, jelly, or jam

Lunch: 2 oz ham, ½ cup cottage cheese, four asparagus spears

Snack: ½ serving chicken salad on bed of lettuce

Dinner: 2 oz broiled fish, ½ serving corn, ½ serving broccoli

Snack: ½ cup yogurt or sherbet

QUESTIONS TO GUIDE YOUR READING

1. What are the causes, signs, and symptoms of constipation and diarrhea?
2. What nursing care and teaching do patients with constipation or diarrhea require?
3. What medical treatment, nursing care, and teaching are appropriate for patients with inflammatory and infectious disorders of the lower gastrointestinal tract?
4. How would you describe irritable bowel syndrome and the nursing care for this condition?
5. What signs and symptoms of abdominal hernias should be reported to the physician?
6. What nursing care and teaching do patients with absorption disorders require?
7. What are the causes signs and symptoms of intestinal obstruction?
8. What is the medical treatment and nursing care for intestinal obstruction?
9. What is the medical treatment and nursing care for lower gastrointestinal bleeding?
10. What nursing care and teaching does a patient with an ostomy require?

The lower gastrointestinal (GI) system includes the small and large intestines, rectum, and anus. Disorders associated with this system are discussed in this chapter.

► PROBLEMS OF ELIMINATION

Constipation

Pathophysiology

Constipation occurs when the fecal mass is held in the rectal cavity for a period that is not usual for the patient. When the feces are held for a prolonged time in the rectum, the amount of water absorbed increases, making the feces drier, harder, more difficult to pass, and sometimes painful to pass.

If a patient repeatedly ignores the urge to have a bowel movement, the musculature and rectal mucous membrane become insensitive to the presence of feces. Eventually a stronger stimulus is needed to produce the peristaltic rush required for defecation. Prolonged constipation is called **obstipation**.

Etiology

There are many causes of constipation. Rectal or anal conditions such as **hemorrhoids** or **fissures** may delay defecation because of the associated pain. Metabolic or neurological conditions such as diabetes mellitus, multiple sclerosis, lupus erythematosus, or scleroderma may interfere with normal bowel innervation and function. Colon cancer may cause an obstruction that prevents normal bowel function and leads to constipation. Medications such as narcotics, tranquilizers, and antacids with aluminum decrease motility of the large intestine and may contribute to constipation. Low intake of dietary fiber and fluids decreases the bulk of the feces and causes constipation. Decreased mobility, weakness, and fatigue, especially in the elderly, reduce the strength of the muscles used for defecation, increasing the likelihood of constipation. Chronic laxative use can also contribute to constipation because the laxative overrides the bowel's ability to recognize the urge to defecate.

Prevention

Regular exercise and a diet high in fiber and fluids are the best preventive measures for constipation. Laxatives should be used only occasionally.

Signs and Symptoms

Abdominal pain and distention, indigestion, rectal pressure, a sensation of incomplete emptying, and intestinal rumbling are indications of constipation (Table 31–1). The patient may also complain of headache, fatigue, decreased appetite, straining at stool, and elimination of hard, dry stool.

Complications

A variety of problems can result from constipation. Fecal **impaction** may result when the fecal mass is so dry it cannot be passed. Pressure on the colon mucosa from a mass of stool may cause ulcers to develop. Often, small amounts of liquid

TABLE 31–1 CONSTIPATION SUMMARY

<i>Symptoms</i>	Abdominal distention Indigestion Rectal pressure Feeling of incomplete emptying Straining at stool Hard, dry stool Intestinal rumbling
<i>Diagnostic tests</i>	History Physical examination
<i>Therapeutic management</i>	High-fiber diet 2–3 L fluid daily Strengthening of abdominal muscles Exercise Bulk-forming agents Stool softeners Education

stool ooze around the fecal mass and cause incontinence of liquid stools. The incontinence may be treated with an antidiarrheal medication, which will worsen the constipation, if a thorough assessment is not performed to rule out impaction. Straining to have a bowel movement (Valsalva's maneuver) can result in cardiac, neurological, and respiratory complications. If the patient has a history of heart failure, hypertension, or recent myocardial infarction, straining can lead to cardiac rupture and death. Grossly dilated loops of the colon, known as **megacolon**, can occur proximal to the dry fecal mass and obstruct the colon. Abdominal distention occurs, and in severe cases, loops of bowel can be palpated through the abdominal wall.

Chronic laxative abuse can lead to colonic mucosal atrophy, muscle thickening, and fibrosis. These conditions can result in perforation of the colon and necessitate an emergency **colectomy**.

Diagnostic Tests

Constipation is usually self-diagnosed or diagnosed by history and physical examination. If complications are suspected, a radiographic examination, sigmoidoscopy, and stool testing for occult blood may be necessary.

Medical Treatment

Treatment of constipation depends on the cause. Fiber should be added to the diet, and exercises to strengthen abdominal muscles should be done. Behavior changes can help establish a more normal bowel pattern. These changes include setting a daily defecation time, appropriately responding to the urge to defecate, and drinking 8 oz of warm water every morning and 2 to 3 L of water every day if it is not contraindicated for other reasons. Laxative abuse should be discontinued. Bulk-forming agents such as psyllium (Metamucil) or stool softeners such as docusate sodium (Colace) should be used instead of laxatives. Ene-

megacolon: mega—large + colon—colon

colectomy: col—pertaining to colon + ectomy—surgical excision

mas and rectal suppositories are used only in extreme cases and are discontinued when an acute episode is resolved.

Nursing Process

ASSESSMENT. The patient may feel self-conscious or embarrassed when interviewed about bowel habits and history. Consideration should be given to the patient's feelings by postponing the discussion until rapport has been established. The nursing history should include the onset and duration of constipation, past elimination pattern, current elimination pattern, occupation, lifestyle (stress, exercise, nutrition), history of laxative or enema use, medical-surgical history, and current medications being taken. The color, consistency, and odor of the stool, as well as any intestinal symptoms, are also important.

After the interview, the patient's abdomen should be auscultated for bowel sounds. Infrequent, absent, high-pitched, or gurgling bowel sounds should be noted. The abdomen is inspected and palpated for distention and symmetry. Inspection of the perianal area may reveal fissures, external hemorrhoids, or irritation.

NURSING DIAGNOSES. Major nursing diagnoses identified may include the following:

- Constipation
- Anxiety related to concern about irregular elimination pattern
- Perceived constipation for patients who abuse laxatives
- Deficient knowledge about health maintenance practices to prevent constipation.

PLANNING. The nurse and patient collaborate on plan of care goals and interventions. The family or caregiver is included in this process. If the patient is a resident of a nursing facility or uses home care services, a representative from the facility or home care agency that is providing care should be included in this phase of the nursing process.

IMPLEMENTATION AND PATIENT EDUCATION. Patient and family or caregiver education is one of the most important aspects of treatment of constipation. Prevention of constipation may be as simple as correcting the contributing factors. The patient should be taught the factors leading to constipation and the interventions necessary to prevent it. It is important to instruct the patient and family about the physiology of defecation and the reason for obeying the urge to defecate when it occurs. Setting a specific time for defecation, such as after a meal, may facilitate the urge reflex. To ensure the most appropriate posture during defecation, patients can place their feet on a footstool to promote flexion of the hips.

What the patient considers a normal diet may not be appropriate for the correction or prevention of constipation. If constipation is caused by decreased motility and muscle tone, the patient should eat a high-fiber, high-residue diet that includes fresh fruits and vegetables and whole grains. In the older patient, adding 2 g of bran to cereal daily can significantly increase bowel movements and therefore decrease the number of laxatives, enemas, or stool softeners required (Nutrition Notes Box 31-1). The patient who be-

BOX 31-1

Nutrition Notes

Treating Constipation with Food Formula

Constipation may be successfully treated with 1 to 2 oz of the following mixture taken with the evening meal: 1 cup applesauce, 1 cup All-Bran cereal, and ½ cup 100-percent prune juice. Mixture may be stored in the refrigerator for 5 days and then should be discarded. In all cases of constipation, especially when increased fiber is given, adequate fluid intake is essential.

lieves that a daily bowel movement is absolutely necessary needs information and reassurance. Assure the patient that having a daily bowel movement is not always necessary.

Instructions also should include the importance of increasing activity through a daily walking program and abdominal exercises designed to improve the muscle tone. These actions improve peristalsis, promoting more spontaneous defecation.

The dangers of regular laxative use should be stressed. By increasing exercise and fluid and fiber in the diet, the patient should be able to discontinue laxative use.

EVALUATION. The plan has been effective if the patient has established a regular bowel function pattern (Table 31-2), if increased physical activity results in report of less abdominal discomfort, and if the patient verbalizes understanding of self-care measures and express satisfaction with the outcomes.

CRITICAL THINKING

Mrs. Jessie Burns

Mrs. Burns is a 93-year-old nursing home resident. You see on her chart that she has not had a bowel movement in a week. What action would you take?

Answers at end of chapter.

Diarrhea

Diarrhea occurs when fecal matter passes through the intestine rapidly, resulting in decreased absorption of water, electrolytes, and nutrients and causing frequent, watery stools. Classification and severity of diarrhea are based on the number of unformed stools in 24 hours. Large-volume

diarrhea: dia—through + rhea—to flow

TABLE 31-2 CRITERIA FOR REGULAR BOWEL FUNCTION

1. A regular time for defecation is routine.
2. A regular exercise program is followed.
3. Laxative use is avoided.
4. Water consumption is 2 to 3 L per day.
5. High-fiber and high-residue foods are added to the diet.
6. Consistency of stools reported are soft and formed.
7. Frequency of stools is every 1 to 3 days.

diarrhea occurs when the volume of feces is increased. Small-volume diarrhea is caused by an increase in peristalsis, without an increase in fecal volume.

Pathophysiology and Etiology

The most common cause of acute diarrhea is a bacterial or viral infection. Bacteria (normal flora) are normally found in the intestines. If these bacteria grow out of control or if bacteria or viruses are ingested in contaminated food or water, infection results. Some bacteria release toxins that irritate the intestinal mucosa, causing an inflammatory response and an increase in mucus production. Hyperperistalsis occurs, which lasts until the irritants have been excreted. The most common infectious agents are *Escherichia coli*, *Campylobacter jejuni*, *Shigella* spp., *Clostridium difficile*, *Giardia* spp., and *Salmonella* spp.

Poor tolerance or allergies to certain foods may cause diarrhea. Foods that most commonly cause diarrhea are additives (such as nutmeg or sorbitol), caffeine, milk products, meats, wheat, and potatoes. Acute diarrhea usually resolves in 7 to 14 days.

Chronic diarrhea may result from inflammatory disease, osmotic agents, excessive secretion of electrolytes, or increased intestinal motility. Inflammatory diseases such as Crohn's disease or ulcerative colitis (discussed later) may impair absorption, resulting in frequent, watery stools. Osmotic diarrhea results from ingestion of laxatives or other agents that prevent absorption of water or nutrients in the intestine. Additional causes of malabsorption include surgical resection or disease of certain areas of the intestinal tract, such as the terminal ileum or pylorus. Radiation therapy for cancer also may induce a malabsorption syndrome. Enteral tube feedings commonly result in diarrhea, especially when malnutrition has caused edema in the gut wall, which decreases absorption.

Increased secretion of water and electrolytes by the intestinal mucosa associated with certain hormonal disorders results in high-volume fecal output. An irritable bowel or a neurological disorder may cause increased motility problems. Also, as described earlier, diarrhea can indicate fecal impaction.

Prevention

Proper handling, storage, and refrigeration of all fresh foods minimize contact with infectious agents. Milk and milk products must be kept refrigerated and protected. Handwashing and cleaning of the kitchen and food preparation or serving items are extremely important.

It is best to start enteral feedings slowly with full-strength formula and gradually increase the rate rather than dilute the formula, thus reducing the risk of contaminating the formula by adding to it.

Signs and Symptoms

Initial diarrhea stools are foul smelling and may have undigested food particles and mucus. The stools may also contain blood or pus. Diarrhea resulting from food poisoning usually has an explosive onset and may be accompanied by nausea and vomiting. Abdominal cramping, distention, anorexia, intestinal rumbling, and thirst are common. Fever indicates infection. Weakness and dehydration from fluid loss may occur (Gerontological Issues Box 31–2).

BOX 31-2 GERONTOLOGICAL ISSUES

Diarrhea can cause older people to quickly become dehydrated and hypokalemic because both fluid and potassium are lost in stools. The signs and symptoms of hypokalemia include muscle weakness, hypotension, anorexia, paresthesia, and drowsiness. It can also cause cardiac dysrhythmias, such as atrial and ventricular tachycardia, premature ventricular contraction, and ventricular fibrillation, which can be fatal.

If the older person has decreased mobility, quick access to the bathroom is important. Because of poor muscle control, older patients may be incontinent. This might embarrass patients or cause them to hurry, which increases chances of patients falling and causing other problems such as fracture, dislocation, or hematoma. Also, because older patients' skin is more sensitive resulting from poor turgor and a reduction in subcutaneous fat layers, perirectal skin excoriation can occur secondary to the acidity and digestive enzyme content of diarrheal stools.

Diagnostic Tests

The diagnosis of diarrhea is determined by the onset and progression of the disease, absence or presence of fever, laboratory examinations, and visual inspection of the stool. Evidence of bacteria, pus, and blood is checked. Diarrhea mixed with red blood cells and mucus is associated with cholera, typhoid, typhus, large-bowel cancer, or amebiasis. Diarrhea mixed with white blood cells and mucus is associated with shigellosis, intestinal tuberculosis, salmonellosis, regional enteritis, or ulcerative colitis. Bulky, frothy stool is seen in sprue and celiac disease. Pasty stools usually have a high fat content and may be associated with common bile duct obstruction, sprue, and celiac disease. "Butter stool" appearance is seen in patients with cystic fibrosis.

Medical Treatment

Replacing fluids and electrolytes is the first priority. This is done by increasing oral fluid intake, using solutions with glucose and electrolytes if ordered by the physician. Intravenous fluid replacement may be necessary for rapid hydration, especially in the very young or very old. An elimination diet can be tried to identify foods that may contribute to diarrhea. Foods known to cause diarrhea are eliminated to see if a change in bowel function occurs. Each food item is then added back into the diet, one at a time, to see which ones cause diarrhea. The patient is also encouraged to increase fiber and bulk in the diet.

If the patient has three or more watery stools per day, motility of the intestines can be decreased with the use of

drugs, such as diphenoxylate (Lomotil) and loperamide (Imodium). If diarrhea is thought to be caused by antibiotics that change the normal flora of the bowel, a *Lactobacillus* granules dietary supplement (Lactinex) may be used to restore the normal flora. Antimicrobial agents are prescribed if infectious agents have been documented.

Nursing Process

ASSESSMENT. Observation of the patient's behavior and symptoms assists in identifying the cause of diarrhea. Ask the patient to describe any symptoms, when they started, and how long they have been present. Questions should include "Is there any abdominal pain, urgency, or cramping?" and "What time of the day does it happen?" Stool consistency, color, odor, and frequency are documented.

The abdomen is inspected for distention and auscultated for hyperactive bowel sounds or rumbling. The patient's usual dietary habits and any changes or recent exposure to contaminated food or water is assessed. Find out if any medications contributed to the diarrhea. If the patient has traveled recently, discover the geographic location and whether exposure to an infected person or someone with similar symptoms occurred.

Assess for symptoms of dehydration, such as tachycardia, hypotension, decreased skin turgor, weakness, thready pulse, dry mucous membranes, and oliguria. Abnormal laboratory studies that may indicate dehydration include increased serum osmolality, increased specific gravity of urine, and increased hematocrit. Decreased serum potassium may result from intestinal loss of potassium.

NURSING DIAGNOSIS. Possible nursing diagnoses include the following:

- Diarrhea related to infection or possible ingestion of irritating foods
- Risk for deficient fluid volume related to frequent passage of stools and insufficient fluid intake
- Risk for infection related to fecal contamination
- Risk for impaired skin integrity related to passage of frequent liquid stools
- Anxiety related to uncontrolled elimination
- Acute pain related to increased peristalsis

PLANNING. Patient care planning includes settings goals. The chief goals include controlling diarrhea, preventing deficient fluid volume, avoiding the spread of infection, keeping skin intact, decreasing anxiety, and controlling pain.

IMPLEMENTATION. Measures to decrease diarrhea must be implemented. Caffeine intake must be limited because it stimulates intestinal motility. During acute diarrhea, the patient may have nothing by mouth (NPO) to promote bowel rest. Then clear liquids, such as water, juices, bouillon, and gelatin, are started, with progression to a low-residue diet (Nutrition Notes Box 31-3). Rest is also important because of the weakness associated with fluid and electrolyte loss. Intake and output (including diarrhea stools) are recorded to determine fluid balance. If output is greater than intake,

BOX 31-3

Nutrition Notes

Deciding When to Refer an Adult with Diarrhea for Medical Care

Most instances of diarrhea in healthy adults are self-limiting and resolve without treatment. Indications for medical consultation include the following:

- Large volumes of stool
- Severe abdominal pain
- Bloody stools
- Protracted duration
- Systemic symptoms such as fever or prostration
- Medical conditions for which fasting, dehydration, or infectious disease are hazardous

Healthy adults at minimal risk of electrolyte imbalance may institute self-treatment as follows:

- For the first 12 hours: Water or oral rehydration solutions at room temperature. Easily absorbed fluids maintain hydration. Hot or cold liquids are more likely to stimulate peristalsis.
- For the second 12 hours: Clear liquids, no caffeine or extremes of temperature. If more than 5 percent of body weight is lost, seek medical attention.
- For the third 12 hours: Full liquids. Experiment with milk in case temporary lactose intolerance has developed as a result of intestinal inflammation.
- For the fourth 12 hours: Soft diet. Include applesauce or banana for pectin and also rice, pasta, and bread without fat (digested by enzymes usually unaffected in gastroenteritis).
- By the 48th hour: Regular diet. If diarrhea has not resolved and regular diet is not tolerated, seek medical treatment.

intravenous fluid replacement may be ordered. Antidiarrheal medications are administered as directed. Control of diarrhea controls pain.

Potentially infected persons or contaminated foods must be identified to prevent the spread of infection. Thorough handwashing by patient, family, and nurse is essential. A private room to prevent infection transmission may be necessary. The perianal skin is protected from contact with liquid stools and their enzymes. This is accomplished by keeping the skin clean, dry, and protected with a moisture barrier, such as petrolatum or medicated ointment, after each bowel movement.

The patient's coping mechanisms can be increased by allowing the patient to express fear or anxiety regarding possible incontinence of liquid stools and the accompanying embarrassment. Adult disposable briefs may be used during acute episodes. Being understanding and tolerant also helps.

PATIENT EDUCATION. The patient must be taught the importance of identifying the source of diarrhea, such as foods or persons (family, neighbors) who may be infected. To prevent the spread of infection it is important to provide instruction in proper handwashing before and after handling foods and before and after toileting. The patient should also be educated about the signs and symptoms of dehydration to report.

EVALUATION. Goals have been met if fluid and electrolyte balance is achieved, frequency of diarrhea stools is de-

creased, skin integrity is maintained, and anxiety is controlled. Goals are also met if the patient reports an increase in comfort and verbalizes an understanding of measures to prevent reinfection.

▶ INFLAMMATORY AND INFECTIOUS DISORDERS

Many diseases of the lower GI tract are a result of inflammation in the bowel. Sometimes the inflamed areas become infected, resulting in a worsening of symptoms and necessitating antimicrobial therapy.

Appendicitis *Pathophysiology*

Appendicitis is the inflammation of the appendix, the small, fingerlike appendage attached to the cecum of the large intestine. Because of the small size of the appendix, obstruction may occur, making it susceptible to infection. The resulting inflammatory process causes an increase in intraluminal pressure of the appendix.

Signs and Symptoms

Signs and symptoms of appendicitis include fever, increased white blood cells, and generalized pain in the upper abdomen. Within hours of onset the pain usually becomes localized to the right lower quadrant at McBurney's point, midway between the umbilicus and the right iliac crest (Fig. 31-1). This is one of the classic symptoms of appendicitis. Nausea, vomiting, and anorexia are also usually present.

Physical examination reveals slight abdominal muscular rigidity (guarding), normal bowel sounds, and local rebound tenderness (intensification of pain when pressure is released after palpation) in the right lower quadrant of the abdomen. Sometimes there is pain in the right lower quadrant when the left lower quadrant is palpated (Rovsing's sign). The patient may keep the right leg flexed for comfort and experience increased pain if the leg is straightened.

Figure 31-1 Pain at McBurney's point is a symptom of appendicitis.

appendicitis: appendic—pertaining to appendix + itis—
inflammation

Complications

Perforation, abscess of the appendix, and peritonitis are major complications of appendicitis. With perforation, the pain is severe and the temperature is elevated to at least 37.7° C (100° F). An abscess is a localized collection of pus separated from the peritoneal cavity by the omentum or small bowel. This is usually treated with parenteral antibiotics and surgical drainage. An appendectomy is done about 6 weeks later. Management of **peritonitis** is discussed later in this chapter.

Diagnostic Tests

A complete blood cell count (CBC) reveals elevated leukocyte and neutrophil counts. Ultrasound or computed tomography (CT) scan reveals an enlargement in the area of the cecum.

Medical Treatment

The patient is kept NPO and surgery is done immediately unless there is evidence of perforation or peritonitis. If the appendix has ruptured, intravenous fluids and antibiotic therapy are started and surgery may be delayed for 8 hours or more. Laxatives and enemas are avoided because they may trigger or complicate a rupture. The use of a heating pad on the abdomen is avoided because the warmth may increase inflammation and risk of rupture. The patient may be discharged from the hospital on the day of surgery once the inflamed appendix is removed, pain is controlled, and the patient is afebrile. However, if there is evidence of rupture, the patient is hospitalized for 5 to 7 days to observe for signs of peritonitis or an ileus.

Nursing Care

The patient with suspected appendicitis is given nothing by mouth until a diagnosis is confirmed, in case surgery is necessary. Ice to the site of pain and maintaining semi-Fowler's position may help reduce pain while the diagnosis is being made. The patient is often readied for an appendectomy by emergency department staff, so time for preoperative teaching is limited.

After surgery the patient is NPO if no bowel sounds are present. If the appendix has ruptured, the postoperative patient may have a nasogastric tube until bowel sounds return to prevent abdominal distention and vomiting. After bowel sounds return, the diet initially consists of clear fluids and is advanced as tolerated by the patient. Vital signs and abdominal assessment are done to monitor for signs and symptoms of peritonitis. Early ambulation, coughing, deep breathing, and turning are encouraged to prevent respiratory complications. The patient may be taught to splint the incision while coughing and deep breathing to reduce pain and stress on the incision. Dressing changes are performed as ordered.

peritonitis: periton—pertaining to peritoneum + itis—
inflammation

Peritonitis

Pathophysiology and Etiology

Trauma, ischemia, or tumor perforation in any abdominal organ causes leakage of the organ's contents into the peritoneal cavity. The most common cause of peritonitis is a ruptured appendix, but it may also occur after perforation of a peptic ulcer, gangrenous gallbladder, intestinal diverticula, incarcerated **hernia**, or gangrenous small bowel. It may also be a complication of peritoneal dialysis. Peritonitis results from the inflammation or infection that is caused by the leakage. The tissues become edematous and begin leaking fluid containing increasing amounts of blood, protein, cellular debris, and white blood cells. Initially the intestinal tract responds with hypermotility, but this is soon followed by paralysis (paralytic ileus).

Signs and Symptoms

Generalized abdominal pain evolves into localized pain at the site of the perforation or leakage. The area of the abdomen that is affected is extremely tender and aggravated by movement. Rebound tenderness and abdominal rigidity are present. Decreased peristalsis results in nausea and vomiting. Infection causes fever, increased white blood cells, and an elevated pulse.

Complications

Complications of peritonitis are intestinal obstruction (discussed later), hypovolemia caused by the shift of fluid into the abdomen, and septicemia from bacteria entering the bloodstream. Shock and ultimately death may result. Wound dehiscence or evisceration can occur if the patient has had abdominal surgery.

Medical Treatment

The patient is NPO because of the impaired peristalsis. Fluid and electrolyte replacement is crucial to correct hypovolemia. Abdominal distention is relieved through insertion of a nasogastric tube with low intermittent suction. Antibiotics are used to treat or prevent sepsis. Depending on the cause of the peritonitis, surgery may be performed to excise, drain, or repair the cause. An ostomy may be formed to divert feces, allowing resolution of the infection. After surgery the patient usually has a wound drain, a nasogastric (NG) tube, and a Foley catheter. Pain control is essential to overall recovery. Severely compromised patients may receive total parenteral nutrition (TPN) to meet nutritional needs for increased immune function and healing.

Nursing Process

ASSESSMENT. Pain is assessed using the WHAT'S UP? format. Abdominal distention and bowel sounds are monitored and recorded. Vital signs are monitored for fever or signs of septic shock. Intake and output are monitored and recorded accurately so that appropriate fluid replacement therapy is ordered.

NURSING DIAGNOSIS. Nursing diagnoses for the patient with peritonitis include acute pain related to inflammatory

process, risk for deficient fluid volume related to fluid shifting from the circulation to the peritoneal cavity, risk for injury related to complications of peritonitis, and imbalance nutrition: less than body requirements related to nausea and NPO status.

PLANNING. Goals for the patient include pain control, stable fluid balance, early recognition and reporting of possible complications, and maintenance of adequate nutrition.

IMPLEMENTATION. Narcotics in conjunction with noninvasive measures such as position changes, diversion, and relaxation exercises are provided for pain. Semi-Fowler's position may reduce tension on the abdomen. Frequent mouth care is done if an NG tube is in place.

Reduced urinary output, dropping blood pressure, and rising pulse rate may indicate fluid volume deficit. If a fever is also present, the patient may be developing sepsis. All symptoms are reported to the physician promptly.

Respiratory complications can be prevented with coughing, deep breathing, and regular turning. Splinting the abdomen during coughing and moving may help reduce discomfort. Oxygen may be administered if the oxygen saturation is less than 95 percent. If the patient has had surgery, output from any drains is monitored. Documentation of the color, volume, odor, and consistency of all drainage is important. Care should be taken in moving the patient so that the drains are not dislodged.

If nausea occurs, the NG tube should be checked for patency. Antiemetics are administered as ordered. If the patient is to be NPO for a prolonged period (3 days or more), TPN should be considered to maintain nutritional status and prevent complications such as sepsis.

EVALUATION. A decrease in temperature and pulse rate indicate that the peritonitis is improving. The abdomen becomes less distended and softens with the return of normal bowel sounds and passing of flatus. Nursing care is effective if vital signs are stable, complications are prevented, nutritional status is maintained, and the patient reports that pain is controlled.

Diverticulosis and Diverticulitis

Pathophysiology

A diverticulum is a herniation or outpouching of the bowel mucous membrane caused by increased pressure within the colon and weakness in the bowel wall. **Diverticulosis** is a condition in which multiple diverticula are present without evidence of inflammation (Fig. 31–2). Many people have diverticulosis without knowing it because it develops gradually. When food and bacteria are trapped in a diverticulum, inflammation and infection develop. This is called **diverticulitis**.

diverticulosis: diverticul—blind pouch + osis—condition
diverticulitis: diverticul—blind pouch + itis—inflammation

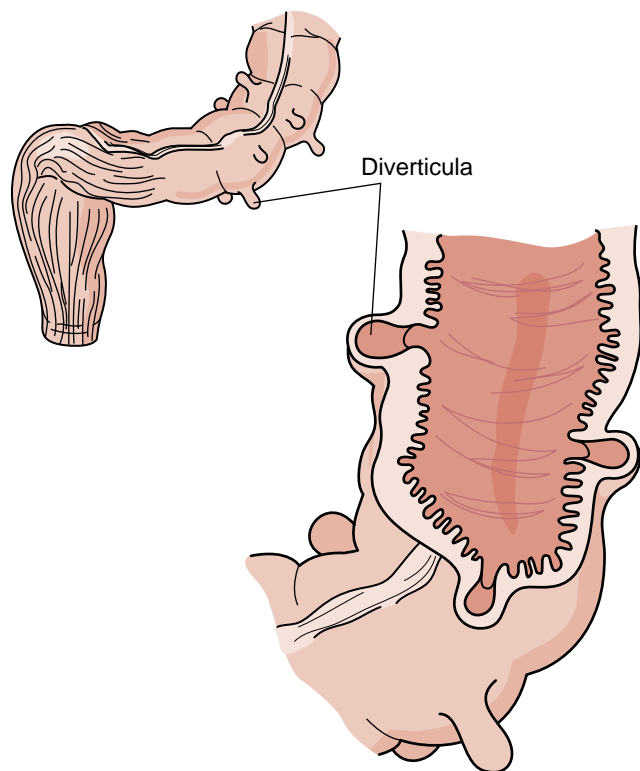

Figure 31-2 A diverticulum is a herniation or outpouching of the bowel mucous membrane. Multiple diverticuli are called diverticulosis. If they become inflamed or infected, the condition is called diverticulitis.

Etiology

Chronic constipation usually precedes the development of diverticulosis by many years. When the patient is chronically constipated, pressure within the bowel is increased, leading to development of diverticula. A major cause of the disease is a decreased intake of dietary fiber. Diverticulosis is most common in the sigmoid colon. A small percentage of patients with diverticulosis develop diverticulitis. People older than age 60 are the most common group to experience diverticulitis.

Prevention

Diverticulitis is prevented by increasing dietary fiber to prevent constipation and onset of diverticulosis.

Signs and Symptoms

The patient with diverticulosis is generally asymptomatic. When diverticulitis is present, the patient exhibits bowel changes, possibly alternating between constipation and diarrhea. Steady or crampy pain in the left lower quadrant of the abdomen is the most common symptom. As the condition worsens, bleeding may occur, along with weakness, fever, fatigue, and anemia. Guarding and rebound tenderness may be present. If an abscess develops, the diverticulum may rupture, leading to peritonitis (Gerontological Issues Box 31-4).

BOX 31-4 GERONTOLOGICAL ISSUES

With age-related weakness in the intestinal wall, approximately 40 percent of adults older than age 80 have diverticular disease. Clinical manifestation of this condition may include abdominal pain, rectal bleeding, nausea, and vomiting. Patients may not notice the abdominal pain until infection is present. Many times the symptoms are not reported early because patients fear it may be cancer. Due to impaired vision, the elderly may not recognize blood in the stool, which can be an indication of diverticulitis.

Diagnostic Tests

Diverticulosis is confirmed with sigmoidoscopy, colonoscopy, and barium enema. The diverticuli and specific areas of inflammation can be seen during a colonoscopy or sigmoidoscopy. If an abscess is suspected, a CT scan may be done. Barium enema may show irregular narrowing of the colon and thickened muscle walls. A stool specimen may show occult blood. An abdominal x-ray examination may be done to identify a perforated diverticulum.

Medical Treatment

Diverticulosis is managed by preventing constipation. With acute diverticulitis, the patient may be hospitalized for intravenous antibiotics and pain control. A nasogastric tube, intravenous fluids, and NPO status may be ordered until pain, nausea or vomiting, fever, and inflammation decrease. When the acute period is over, a progressive diet is started. Whether or not perforation occurs, surgical resection with anastomosis or a temporary **colostomy** (discussed later) may be done to allow the inflammation to subside and the diseased portion of the colon to rest.

Nursing Process

ASSESSMENT. The patient is assessed for signs and symptoms of diverticulitis (Table 31-3). Physical examination is done to assess for abdominal distention and tenderness. A firm mass may be palpated in the sigmoid area.

NURSING DIAGNOSIS. Constipation related to low-fiber dietary habits may be one nursing diagnosis. Others may include pain related to inflammation or infection and ineffective tissue perfusion: gastrointestinal related to infection secondary to perforation, peritonitis, or abscess.

PLANNING. Goals include normal bowel elimination (especially without straining), pain control, and prevention of risks related to infection and inflammation.

IMPLEMENTATION. Implement interventions that alleviate and prevent constipation. Unless contraindicated, fluid intake should be increased to 2 to 3 L per day. Dietary considerations for a patient with diverticulosis (without evidence of inflammation) include foods that are soft but high

colostomy: colo—pertaining to colon + stoma—mouth or opening

TABLE 31-3 SYMPTOMS ASSOCIATED WITH DIVERTICULITIS

W—Where is the pain?	Usually in the left lower quadrant
H—How does it feel? (Describe quality)	Tender, crampy
A—Aggravating and alleviating factors	Constipation and low-fiber diet may aggravate; treatment of constipation may alleviate
T—Timing (onset, duration, frequency)	Gradual onset, intermittent, gradual increase in frequency of pain events
S—Severity (0–10)	Usually 5–7
U—Useful other data/associated symptoms	Intermittent rectal bleeding; straining at stool; constipation alternating with diarrhea; elevated white blood cells and sedimentation rate; elevated temperature and pulse rate; and pus, mucus, and blood in stool
P—Patient's perception	Fear diagnosis of cancer

in fiber, such as prunes, raisins, and peas. Unprocessed bran can be added to soups, cereals, and salads to give added bulk to the diet. Fiber should be increased in the diet slowly to prevent excess gas and cramping. Some health care providers recommend avoiding nuts or foods with small seeds that can get caught in diverticuli, such as tomatoes and raspberries, but this has not been proven to help.

If the patient is experiencing pain, administer analgesics or antispasmodic drugs as prescribed. A diet low in fiber is recommended for the patient with acute pain. Monitor the patient closely and notify the physician immediately if pain increases, especially if associated with abdominal rigidity. Increased pain may indicate that the bowel has ruptured and peritonitis is developing.

PATIENT EDUCATION. Instruct the patient on dietary changes needed to alleviate constipation and to prevent future episodes of diverticulitis. Teach the patient that laxatives or enemas may increase motility and pressure in the bowel and cause further complications. Provide the patient with information about the signs and symptoms of diverticulitis that should be reported.

EVALUATION. The goals are met when the patient reports a normal pattern of bowel elimination, pain-free bowel movements, and less abdominal pain and cramping and there is no infection.

▶ INFLAMMATORY BOWEL DISEASE

Crohn's Disease (Regional Enteritis)

Pathophysiology

Crohn's disease, also known as regional **enteritis** or granulomatous enteritis, is an inflammatory bowel disease (IBD) that can involve any part of the intestine but most commonly the terminal portion of ileum. The inflammation extends through the intestinal mucosa, which leads to the for-

mation of abscesses, **fistulas**, and fissures. As the disease progresses, obstruction occurs because the intestinal lumen narrows with inflamed mucosa and scar tissue.

Etiology

Although the exact cause of Crohn's disease has not been identified, there is a familial tendency. Other possible influences are autoimmune processes and infectious agents. Crohn's disease is most often diagnosed between the ages of 15 and 30 and occurs more often in women. There are periods of remissions and exacerbations. Physical or psychological stress may trigger exacerbations (Cultural Consideration Box 31-5).

BOX 31-5 CULTURAL CONSIDERATION

Ulcerative colitis and Crohn's disease are more common in Caucasians, persons of Jewish descent, and upper-middle-class urban populations. The incidence of Crohn's disease is increasing rapidly in Western Europe and North America. These findings support possible hereditary or environmental risk factors for IBD.

Signs and Symptoms

Crampy abdominal pains (unrelieved by defecation), weight loss, and diarrhea occur. Because the crampy pains occur after eating, the patient often does not eat in order to avoid the pain. A lack of eating and poor absorption of nutrients results in weight loss and malnutrition. Chronic diarrhea contributes to fluid deficit and electrolyte imbalance. The inflamed intestine may perforate, leading to the formation of intra-abdominal or anal fissures, abscesses, or fistulas. Some nongastrointestinal symptoms may also occur, including arthritis, skin lesions, inflammatory disorders of the eyes, and abnormalities of liver function.

Complications

In addition to malnutrition, the development of fissures, abscesses, or fistulas is the most common complication of Crohn's disease. Fistulas may include enterovaginal (small bowel to vagina), enterovesicle (small bowel to bladder), enterocutaneous (small bowel to skin), enteroentero (small bowel to small bowel), or enterocolonic (small bowel to colon) (Fig. 31-3). Fistulas communicating with organs that then drain externally can cause tremendous skin irritation, as well as increased risk of developing infections. Fistulas are corrected surgically.

Diagnostic Tests

Endoscopy (colonoscopy and sigmoidoscopy), with multiple biopsies of the diseased colon and terminal ileum, is the most conclusive diagnostic test for Crohn's disease. Endoscopy identifies areas of normal to severely inflamed mucosa. Crohn's disease is confirmed by granulomas in the biopsy specimen. A barium enema shows a classic "cobblestoning" effect and, as the disease progresses, areas of narrowing in the intestine. An elevated sedimentation rate and

Figure 31-3 Fistulas are a common complication of Crohn's disease.

leukocytosis are present, and serum albumin levels may be low because of malnutrition or poor absorption of protein. Bowel sounds are hyperactive over the right lower quadrant, and a stool examination reveals fat content and occult blood.

Medical Treatment

Management of Crohn's disease is aimed at relieving symptoms, such as inflammation and diarrhea, and the effects of those symptoms, such as dehydration and malnutrition. Budesonide (Entocort EC), an oral steroid, is a new treatment that acts locally in the intestine to reduce inflammation. Because budesonide is not absorbed systemically, there are fewer steroid side effects (e.g., moon face and acne). Corticosteroids are used during an acute inflammation, then tapered and discontinued. Antidiarrheal medications such as loperamide (Imodium) reduce peristalsis. Sulfasalazine (Azulfidine) or mesalamine (Pentasa) is used long term to decrease inflammation. Antibiotics such as metronidazole (Flagyl) and ciprofloxacin (Cipro) are used if abscesses or peritonitis are present. In some cases, symptoms worsen. Immunosuppressants such as azathioprine (Imuran) and cyclosporine (Sandimmune) may be used to treat patients who have not responded to other treatments or those who require steroids.

Surgery may be indicated if obstruction, stricture, fistula, or abscess is present. Surgical procedures include resection of the affected area with anastomosis, colectomy with ileostomy, or colectomy with ileorectal anastomosis, depending on the area of bowel involved. See details regarding intestinal ostomies later in this chapter.

ileostomy: ileo—pertaining to ileum + stoma—mouth or opening

Because of the similarities between Crohn's disease and ulcerative colitis, the nursing processes for both are discussed together.

Ulcerative Colitis

Pathophysiology

Ulcerative colitis is similar to Crohn's disease. Crohn's disease, however, can occur anywhere in the gastrointestinal system, whereas ulcerative colitis occurs in the large colon and rectum. Multiple ulcerations and diffuse inflammation occurs in the superficial mucosa and submucosa of the colon. The lesions spread throughout the large intestine and usually involve the rectum. The patient with ulcerative colitis has increased risk of developing colorectal cancer.

Etiology

Several theories exist to explain the cause of ulcerative colitis. These include infection, allergy, and autoimmune response. Environmental agents such as pesticides, tobacco, radiation, and food additives may precipitate an exacerbation. At one time a psychological component was suggested in the etiology of ulcerative colitis. However, anyone who experiences chronic intestinal cramps and frequent, sometimes painful bowel movements is going to be discouraged, anxious, and depressed. These behaviors may be a result of the disease, not the cause. Psychological stress may trigger or worsen an attack of symptoms. Ulcerative colitis usually begins between ages 15 and 40.

Signs and Symptoms

Abdominal pain, diarrhea, rectal bleeding, and fecal urgency are common symptoms of ulcerative colitis (Table 31-4). Anorexia, weight loss, cramping, vomiting, fever, and dehydration associated with passing 5 to 20 liquid stools a day may also occur. Along with the potential for

TABLE 31-4 INFLAMMATORY BOWEL DISEASE SUMMARY

<i>Symptoms</i>	Abdominal pain or cramping Weight loss Diarrhea Fluid and electrolyte imbalance Fissures, fistulas, abscesses Arthritis and skin lesions Inflammatory eye disorders Abnormal liver function
<i>Diagnostic tests</i>	Endoscopy with biopsy Barium enema Laboratory examination Stool examination Absent bowel sounds
<i>Therapeutic management</i>	Medications: anti-inflammatories, antidiarrheal, antibiotics, immunosuppressants, corticosteroids Surgery if necessary Avoidance of offending foods Elemental formula or TPN if required Support and education

fluid and electrolyte imbalance, there is a loss of calcium. Anemia often develops as a result of rectal bleeding. Serum albumin may be low because of malabsorption. Like Crohn's disease, arthritis, skin lesions, inflammatory disorders of the eyes, and abnormalities of liver function may also occur. Symptoms are usually intermittent, with remissions lasting from months to years.

Complications

Malnutrition and its associated problems are complications of ulcerative colitis. Other complications include the potential for hemorrhage during an acute phase, bowel obstruction, perforation, and peritonitis. The risk for colon cancer is also increased in patients with ulcerative colitis. Symptoms outside the GI tract, such as arthritis, skin lesions, and inflammatory disorders of the eyes, may also occur.

Diagnostic Tests

Examination of stool specimens is done to rule out any bacterial or amebic organisms. The stool is positive for blood. Anemia is often present because of blood loss. Leukocyte levels and erythrocyte sedimentation rate are elevated because of the chronic inflammation. Electrolytes are depleted from chronic diarrhea. There is a protein loss because of liver dysfunction and malabsorption. Endoscopy and barium enema help differentiate ulcerative colitis from other diseases of the colon with similar symptoms. Biopsy specimens taken during sigmoidoscopy and colonoscopy typically show abnormal cells.

MEDICAL TREATMENT. Foods that cause gas or diarrhea are avoided. Because the offending foods may be different for each patient, foods are tried in small amounts if they are thought to cause symptoms. In general, high-fiber foods, caffeine, spicy foods, and milk products are avoided. Total

parenteral nutrition may be needed to meet nutritional needs during acute exacerbations.

As with Crohn's disease, antidiarrheal, anti-inflammatory, and immunosuppressant agents may be given. Corticosteroids are used if needed to reduce inflammation.

If medical treatment is ineffective, surgery is considered. Because ulcerative colitis usually involves the entire large intestine, the surgery of choice is total proctocolectomy with formation of an ileostomy. Ileostomies are discussed later in this chapter.

Nursing Process for the Patient with Inflammatory Bowel Disease

ASSESSMENT. A history obtained from the patient should include identification of symptoms, including the onset, duration, frequency, and severity. Ask if there has been any correlation between exacerbations of symptoms related to dietary changes or stress. Determine the presence any food allergies or intolerances, such as milk, because some may increase diarrhea. Also, note the daily and weekly intake of caffeine, nicotine, and alcohol, because all these stimulate the bowel and can cause cramping and diarrhea.

Assess the patient for nutritional status and signs of dehydration. The amount of weight loss in 2 months can be 10 to 20 pounds. Perianal skin should be assessed for irritation and excoriation.

Assessment of emotional status, coping skills, and verbal and nonverbal behaviors is essential. The patient may withdraw from family and friends because of frequent bowel movements. Anxiety, sleep disturbances, depression, and denial can be problems. If surgery involving an ileostomy is planned, the patient is at risk for problems with body image.

NURSING DIAGNOSIS. Nursing diagnoses for the patient with IBD may include the following:

- Diarrhea related to inflammatory process
- Ineffective nutrition, less than body requirements, related to anorexia and malabsorption
- Deficient fluid volume related to anorexia, nausea, and diarrhea
- Acute pain related to increased peristalsis and cramping
- Impaired skin integrity related to frequent loose stools
- Ineffective coping related to repeated episodes of diarrhea

PLANNING. Goals include achieving normal bowel elimination, maintenance of nutrition, prevention of deficient fluid volume, relief of abdominal pain and cramping, and effective coping with the disease.

IMPLEMENTATION. Document characteristics of stools, including color, consistency, amount, frequency, and odor. Ensure the patient has quick access to the bathroom, or provide a bedside commode. Keep the environment clean and odor free to help alleviate anxiety. Administer antidiarrheal medication as prescribed. Encourage bedrest to decrease peristalsis.

Teach the patient to avoid high-fiber foods such as whole grains and raw fruits and vegetables, as well as caffeine, al-

cohol, and nicotine, because they stimulate the GI tract. For severe symptoms a special liquid (elemental) formula that is absorbed in the upper bowel, allowing the colon to rest, may be given. If the patient is unable to tolerate oral intake, TPN may be necessary.

Signs of deficient fluid volume are documented and reported to the physician. Daily weight and intake and output (volume of stools, fistula drainage, vomitus, and urine) are accurately recorded so the physician can order adequate intravenous (IV) fluid replacement.

Document the onset, duration, and severity of pain, and medicate as prescribed. Describe the character of the pain (dull, cramping, burning) and if the pain is associated with meals or activity.

Perianal skin should be kept clean and dry to prevent excoriation from frequent stools. Sitz baths may be helpful. Protect the skin by applying a protective moisture barrier after each stool.

Anxiety should be reduced because it aggravates the symptoms of inflammatory bowel disease. Reducing anxiety can be done by answering questions, talking in a calm, confident manner, and actively listening to the patient. If surgery involving an ostomy is discussed, obtain a consultation with a wound ostomy continence nurse (WOCN) if available. Reinforce teaching by using basic terms and providing pamphlets or showing a video of ostomy management and a picture of a stoma and allowing the patient time to handle an ostomy appliance. Allow the patient to decide what teaching information is most important, and include the patient's family or significant other. More details about ostomy care are

provided later in this chapter. (See Nursing Care Plan Box 31–6 for the Patient with Inflammatory Bowel Disease.)

PATIENT EDUCATION. Information about IBD must be given in a way that promotes positive reinforcement and reassurance. Nutrition and dietary considerations need to be discussed. If the patient is on medications, instructions regarding the dose, when and how to take the drug, why it was ordered, and potential effects and side effects should be given. Patients on steroids will probably be weaned off them after surgery. The patient needs to know not to stop taking steroids suddenly to prevent adrenocortical insufficiency. Instructions in daily care are provided if the patient has an ileostomy or colostomy.

EVALUATION. After intervention, it is reasonable to expect a decrease in the frequency and amount of diarrheal stools. Nutritional status should improve, as evidenced by maintenance of ideal weight and a fluid and electrolyte balance within normal range. Other outcomes include less pain, intact skin, and the ability to cope with the disease and treatment.

CRITICAL THINKING

Judy Moore
 Judy Moore is an 18-year-old college student who has just been diagnosed with Crohn's disease. What can you do to help her adapt to this disease?
Answers at end of chapter.

BOX 31-6 NURSING CARE PLAN FOR THE PATIENT WITH INFLAMMATORY BOWEL DISEASE

▶ Ineffective coping related to inflammatory bowel disease

PATIENT OUTCOMES

Patient will identify strategies that will promote effective coping.

EVALUATION OF OUTCOMES

Is the patient able to state strategies for effective coping?

INTERVENTIONS

Assess knowledge of ulcerative colitis

Encourage the patient to express feelings about the disease and how it may affect his or her life.

Determine whether the patient would like to speak with a person of similar age from the Crohn's and Colitis Foundation of America.

Identify strategies for effective coping that are acceptable to the patient.

RATIONALE

Many people have little knowledge of a disease unless they know someone who has it. Inaccurate information must be corrected.

Expressing feelings about the disease and its perceived effect enables the patient to identify and talk about concerns. Once identified, these concerns can then be addressed by the health care team.

Speaking with someone close in age with the same disease lets the patient know that he or she is not the only person having to cope with this disorder. It can also help him or her learn some strategies for effectively coping with the disease.

Talking about concerns and possible solutions is a positive step. Coping strategies identified with the patient are more likely to be implemented.

EVALUATION

Does the patient verbalize information about ulcerative colitis and its effects on the body?

Does the patient talk about feelings regarding the potential impact of the disease on his or her life?

Does the patient show an interest in speaking with someone with the same disease?

Is the patient able to identify strategies for effective coping that he or she believes will work?

► IRRITABLE BOWEL SYNDROME

Pathophysiology and Etiology

Irritable bowel syndrome (IBS) is a disorder of altered intestinal motility and increased sensitivity to visceral sensations. The bowel mucosa is not changed by IBS. Symptoms may be exacerbated by psychological stress or food intolerances. IBS is more common in women and in those who are young to middle aged.

Signs and Symptoms

IBS is characterized by complaints of gas, bloating, constipation, diarrhea, or alternating constipation and diarrhea. The patient also has feelings of abdominal bloating, with or without visible abdominal distention. This sensation of bloating is from increased sensitivity to visceral sensations. Other symptoms include the rectal passage of mucus, a feeling of incomplete evacuation, abdominal pain relieved by defecation, depression, anxiety, and palpitations.

Diagnostic Tests

Diagnosis of IBS is made based on history and physical examination. Stool examination, barium enema, upper GI series, and sigmoidoscopy may be done to rule out other disorders. Avoiding mild products for a time may be advised to rule out lactose intolerance.

Medical Treatment

IBS is a chronic condition, but symptoms can generally be controlled. Bran or bulk-forming laxatives such as psyllium (Metamucil) may be used to normalize stools. Foods causing gas formation are avoided. Antidepressants and relaxation exercises may help decrease stress and anxiety. Medication to decrease or increase intestinal motility (as needed) and reduce pain may also be given.

► ABDOMINAL HERNIAS

Pathophysiology and Etiology

A hernia is an abnormal protrusion of an organ or structure through the wall of the cavity normally containing it, which in this case is the abdominal wall. Hernias are caused by a weakness in the abdominal wall along with increased intra-abdominal pressure, such as the pressure from coughing, straining, and heavy lifting. Obesity, pregnancy, and

poor wound healing are also risk factors. The hernial sac is formed by the peritoneum protruding through the weakened muscle wall. Contents of the hernia can be small or large intestine or the omentum. Indirect hernias are caused by a defect of structural closure. Direct hernias are acquired and arise from a weakness in the abdominal wall, usually at old incisional sites.

There are many types of hernias (Fig. 31-4). Inguinal hernias are located in the groin where the spermatic cord in males or the round ligament in females emerges from the abdominal wall. This common hernia is an example of an indirect hernia and is usually seen in males.

Umbilical hernias are seen most often in obese women and in children. They are caused by a failure of the umbilical orifice to close. Ventral (incisional) hernias usually result from a weakness in the abdominal wall following abdominal surgery, especially if a drainage system was used, the patient experienced poor wound healing, the patient received inadequate nutrition, or the patient is obese.

Prevention

Improving abdominal musculature is the best way to prevent hernias. Those who do heavy lifting, tugging, or pushing should wear a support binder.

Signs and Symptoms

Unless complications occur, there are very few symptoms associated with hernias. An abnormal bulging can be seen in the affected area of the abdomen, especially when straining or coughing. It may disappear when the patient lies down. If the intestinal mass easily returns to the abdominal cavity or can be manually placed back in the abdominal cavity, it is called a reducible hernia. When adhesions or edema occur between the sac and its contents, the hernia becomes irreducible or incarcerated, meaning that the herniated bowel is trapped and cannot be returned to the abdomen.

Complications

An incarcerated hernia may become strangulated if the blood and intestinal flow are completely cut off. Incarceration leads to an intestinal obstruction and possibly gangrene and bowel perforation. Symptoms are pain at the site of the strangulation, nausea and vomiting, and colicky abdominal pain. Treatment is emergency surgery.

Figure 31-4 Types of hernias.

Medical Treatment

Hernias are diagnosed by physical examination. Surgery is indicated if there is strangulation or the threat of obstruction. Surgical procedures include herniorrhaphy and hernioplasty. Herniorrhaphy (surgery of choice) involves making an incision in the abdominal wall, replacing the contents of the hernial sac, and then closing the opening. Hernioplasty involves replacing the hernia into the abdomen and reinforcing the weakened muscle wall with wire, fascia, or mesh. Bowel resection or a temporary colostomy may be necessary if the hernia is strangulated. A patient who is not a good surgical candidate may be directed to use a truss or binder once the hernia is manually reduced. A truss is an external restraining device held in place with a belt used to push the hernia into the abdomen.

Nursing Care

If surgery is not planned, the patient is instructed to avoid activities that increase intra-abdominal pressure, such as lifting heavy objects. The patient is taught to recognize signs of incarceration or strangulation and the importance of notifying the physician immediately. If a truss has been ordered, the patient is taught to apply it before arising from bed each morning, while the hernia is not protruding. Special attention should be paid to maintenance of skin integrity beneath the truss.

PREOPERATIVE CARE. A simple herniorrhaphy is generally done as outpatient surgery. The patient is instructed in routine preoperative deep breathing and coughing techniques. Holding the abdomen with a splint, such as a pillow, helps support the weakened abdominal muscles during coughing and moving.

POSTOPERATIVE CARE. Care following inguinal hernia repair is similar to any postoperative care. The male patient may experience swelling of the scrotum. Ice packs and elevation of the scrotum may be ordered to reduce the swelling. Intake and output are monitored. The patient is observed for difficulty with voiding, which is not uncommon following hernia surgery, and voids before discharge. Bowel sounds are monitored, and the patient is instructed to report discomfort or distention because peristalsis may stop temporarily following surgery. Because most patients are discharged the same day as surgery, they are taught to change the dressing and report signs and symptoms of infection, such as redness, incisional drainage, or fever. The patient is also instructed to avoid lifting for 2 to 6 weeks. Specific activity limitations are provided by the surgeon. Most patients can return to work within 2 weeks.

► ABSORPTION DISORDERS

The process of digestion reduces nutrients to a liquid form that can be absorbed through intestinal mucosa into the portal bloodstream. Most of the more than 8000 mL of liquid with nutrients and electrolytes are absorbed proximal to the ileocecal valve.

Pathophysiology and Etiology

Malabsorption occurs when the GI system is unable to absorb one or more of the major nutrients (carbohydrates, fats, or proteins). Some causes of malabsorption are ileal dysfunction, jejunal diverticula, parasitic disease, celiac disease, enzyme deficiency, and inflammatory bowel diseases such as Crohn's disease and ulcerative colitis. The primary malabsorption disorders are tropical sprue, adult celiac disease, and lactose intolerance.

The cause of tropical sprue has not been specifically identified but is thought to be related to bacterial infection of the intestine. In adult celiac disease (sometimes called nontropical sprue), a sensitivity to gluten is thought to cause malabsorption of protein. Gluten is a protein found in wheat, barley, oats, and rye (Nutrition Notes Box 31–7).

A deficiency in lactase, an enzyme that breaks down lactose (milk sugar), causes lactose intolerance. When lactose is not digested, a high concentration of it occurs in the intestines, causing an osmotic retention of water and watery stools (Nutrition Notes Box 31–8).

Signs and Symptoms

Weight loss, weakness, and general malaise resulting in malnutrition are associated with malabsorption disorders. Signs and symptoms of sprue include frequent loose, bulky, foul stools that are gray in color and have an increased fat content. (Increased fat in stool is called steatorrhea.) Lactose intolerance causes abdominal cramping, excessive gas, and loose stools after eating milk products.

BOX 31-7

Nutrition Notes

Treating Celiac Disease

Celiac disease, or gluten-sensitive enteropathy, requires permanent elimination of wheat, rye, oats, and barley from the diet. Careful selection of prepared foods is mandatory because of the widespread use of these grains as thickeners. If a patient with celiac disease ingests gluten, damage to the intestine continues even in the absence of symptoms. Instruction from and follow-up by a dietitian are indicated to ensure adequate nutritional intake despite the many dietary limitations.

BOX 31-8

Nutrition Notes

Managing Lactose Intolerance

Patients with lactose intolerance control their conditions through trial and error, because the degree of lactose intolerance varies greatly among patients. Moderate amounts of many lactose-containing foods can be digested when taken with a mixed meal. A dietitian's services may be advised to begin dietary management after diagnosis. Ingredients to avoid include milk, milk solids, lactose, and whey. Low-lactose foods (up to 2 grams per serving) include sherbet, cheese aged longer than 90 days, processed cheese, and milk treated with lactase enzyme. In cheese-making the whey containing most of the lactose is removed, so that hard, ripened cheeses such as blue, brie, cheddar, Colby, gouda, parmesan, and Swiss are classified as low lactose. Some brands of yogurt, a high-lactose food, may be tolerated because they contain bacterial lactase.

Complications

Vitamin K deficiency and resulting hypoprothrombinemia can increase the risk of bleeding. Calcium deficiency can be severe enough to cause bone pain and neuromuscular hyperirritability, including tetany. Folic acid, vitamin B₁₂, and iron deficiencies can result in glossitis, stomatitis, anemia, and dry, rough skin.

Diagnostic Tests

See Table 31–5 for the diagnostic studies used to identify malabsorption diseases.

Medical Treatment

Folic acid, broad-spectrum antibiotics, and a high-calorie, high-protein, low-fat diet are ordered for patients with tropical sprue. Adults with celiac disease are ordered a high-calorie, high-protein, gluten-free diet to relieve the symptoms and improve nutritional status. However, because gluten is used as a filler or binder in many products, even those labeled “wheat free,” diligence in identifying potentially offending foods is essential.

Lactose intolerance is treated by removing foods from the diet that contain lactose, such as milk and milk products. Some fermented milk products, such as cheese and yogurt, may be lower in lactose and better tolerated. Lactaid is an over-the-counter lactase substitute that can be taken when milk products cannot be avoided. It can be added to milk in liquid form or taken as a tablet before eating foods containing lactose. Lactaid digests about 70 percent of the lactose in foods, making them more tolerable.

TABLE 31–5 DIAGNOSTIC TESTS FOR DISORDERS OF MALABSORPTION

Diagnostic Test	Test Result and Associated Malabsorption Syndrome
Hemoglobin and hematocrit	Decreased if anemia is present.
Mean corpuscular volume	Decreased values are found with malabsorption of vitamin B ₁₂ .
Upper GI series	Thickening of the intestinal mucosa, narrowed mucosa of the terminal ileum, or a change in fecal transit time are indicative of malabsorption syndrome.
D-Xylose absorption test	Decreased excretion of xylose after 5 hours is indicative of malabsorption.
Sudan stain for fecal fat	Malabsorption can be distinguished from maldigestion if this test shows abnormally large numbers of fat droplets.
72-hour stool collection for fat	Stool fat greater than 5 g per 24 hours after ingestion of 80 g of fat in 2 days implies a fat digestion disorder.

Nursing Care

Nursing care involves monitoring fluid and electrolyte balance, nutritional status, and skin integrity. Daily weight and intake and output help determine if fluid loss is occurring. Intake of electrolyte-rich fluids is encouraged to replace losses. Antidiarrheal agents are given if ordered. Electrolyte levels, especially potassium, are monitored as ordered. The patient is instructed in dietary limitations. Nutritional supplements may be ordered if necessary. Perianal skin is kept clean and dry, and barrier ointments are used as needed to protect the skin from excoriation.

▶ INTESTINAL OBSTRUCTION

Intestinal obstructions occur when the flow of intestinal contents is blocked. There are two types of intestinal obstruction, mechanical and paralytic, which can be either partial or complete.

Mechanical obstruction occurs when a blockage occurs within the intestine from conditions, causing pressure on the intestinal walls such as adhesions, twisting of the bowel, or strangulated hernia. Paralytic obstruction occurs when peristalsis is impaired and the intestinal contents cannot be propelled through the bowel. Paralytic obstruction is seen following abdominal surgeries, trauma, mesenteric ischemia, or infection. The severity of the obstruction depends on the area of bowel affected, the amount of occlusion within the lumen, and the amount of disturbance in the blood flow to the bowel (Table 31–6).

Small-Bowel Obstruction

Pathophysiology

When obstruction occurs in the small bowel, a collection of intestinal contents, gas, and fluid occurs proximal to the obstruction. The distention that results stimulates gastric secretion but decreases the absorption of fluids. As distention

TABLE 31–6 BOWEL OBSTRUCTION SUMMARY

<i>Symptoms</i>	Abdominal pain Blood and mucus per rectum Feces and flatus cease Visible peristaltic waves in thin person Possible fecal vomiting Bowel sounds high-pitched and tinkling or absent Abdominal distention Fluid and electrolyte imbalance
<i>Diagnostic tests</i>	Abdominal x-ray examination CT scan CBC and electrolytes
<i>Therapeutic management</i>	NPO status Frequent mouth care Nasogastric tube Fluid and electrolyte replacement Medications: antibiotics, antiemetics, analgesics Surgery Education

worsens, the intraluminal pressure causes a decrease in venous and arterial capillary pressure, resulting in edema, necrosis, and eventually perforation of the intestinal wall.

Etiology

Following abdominal surgery, loops of intestine may adhere to areas in the abdomen that are not healed. This may cause a kink in the bowel that occludes the intestinal flow. These adhesions, or bands of scar tissue, are the most common cause of small bowel obstruction and are usually acquired from previous abdominal surgery or inflammation. Hernias and neoplasms are the next most common causes, followed by inflammatory bowel disease, foreign bodies, strictures, **volvulus**, and **intussusception**. A volvulus occurs when the bowel twists, occluding the lumen of the intestine. Intussusception occurs when peristalsis causes the intestine to telescope into itself (Fig. 31-5). These conditions are mechanical obstructions. Paralytic, or adynamic, ileus is a non-mechanical obstruction that occurs when the intestinal peristalsis decreases or stops because of a vascular or neuromuscular pathological condition. Box 31-9 lists causes of nonmechanical obstructions.

Signs and Symptoms

The patient initially complains of wavelike abdominal pain and vomiting. Initially, flatus and feces that is low in the

Figure 31-5 Mechanical bowel obstructions. (A) Intussusception. (B) Volvulus.

intussusception: intus—within + suscept—to receive

BOX 31-9 Causes of Nonmechanical Obstruction

- Pneumonia
- Spinal injuries
- Hypokalemia
- Myocardial infarction
- Peritonitis
- Vascular insufficiency

bowel and blood and mucus may be passed, but this stops as the obstruction becomes worse. The symptoms progress as the obstruction worsens or becomes complete. As the obstruction becomes more extreme, peristaltic waves reverse, propelling the intestinal contents toward the mouth, eventually leading to fecal vomiting. Peristaltic waves may be visible in a thin person. Pain that is sharp and sustained may indicate perforation. In mechanical obstructions, high-pitched, tinkling bowel sounds are heard proximal to the obstruction and are absent distal to it. If the obstruction is nonmechanical, there is an absence of bowel sounds.

Loss of fluid and electrolytes leads to dehydration, with its associated symptoms of extreme thirst, drowsiness, aching, and general malaise. The lower in the gastrointestinal tract the obstruction is, the greater the abdominal distention. An uncorrected obstruction can lead to shock and possibly death.

Diagnostic Tests

Dilated loops of bowel are evident in radiographic studies and CT scans. If strangulation or perforation occurs, leukocytosis is evident. Hemoglobin and hematocrit are elevated if the patient is dehydrated, and serum electrolyte levels are decreased.

Medical Treatment

In most cases the patient is kept NPO and the bowel is decompressed using a nasogastric (or rarely an intestinal) tube, which relieves symptoms and may resolve the obstruction. An IV solution with electrolytes is initiated to correct the fluid and electrolyte imbalance. Sometimes IV antibiotics are begun. Complete mechanical obstruction requires surgical intervention, such as removal of tumors, release of adhesions, or bowel resection with anastomosis.

Large-Bowel Obstruction

Pathophysiology

Obstruction in the large bowel is less common and not usually as dramatic as small-bowel obstruction. Dehydration occurs more slowly because of the colon's ability to absorb fluid and distend well beyond its normal full capacity. If the blood supply to the colon is cut off, the patient's life is in jeopardy because of bowel strangulation and necrosis.

Etiology

Most large-bowel obstructions occur in the sigmoid colon and are caused by carcinoma, inflammatory bowel disease, diverticulitis, or benign tumors. Impaction of stool may also cause obstruction.

Signs and Symptoms

Symptoms of large-bowel obstruction develop slowly and depend on the location of the obstruction. If the obstruction is in the rectum or sigmoid, the only symptom may be constipation. As the loops of bowel distend, the patient may complain of crampy lower abdominal pain and abdominal distention. Vomiting, if it occurs, is a late sign and may be fecal. High-pitched tinkling bowel sounds may be heard. A localized tender area and mass may be felt on palpation. Large-bowel obstructions, if not diagnosed and treated, can lead to gangrene, perforation, and peritonitis (discussed earlier).

Medical Treatment

Radiological examination reveals a distended colon. If impaction is present, enemas and manual disimpaction may be effective. Other mechanical blockages may require surgical intervention.

Surgical resection of the obstructed colon may be necessary. A temporary colostomy may be indicated to allow the bowel to rest and heal. Sometimes an ileoanal anastomosis is done. A patient who is a poor surgical risk may have a cecostomy (an opening from the cecum to the abdominal wall) to allow diversion of stool.

Nursing Process

ASSESSMENT. Each quadrant of the abdomen is auscultated for 5 minutes before documenting the absence of bowel sounds. Palpation for distention, firmness, and tenderness is done. The amount and character of stool, if any, is documented. Pain is assessed using the institution's pain scale and described according to location and character, such as crampy or wavelike. Daily weight and intake and output are monitored. Skin turgor is assessed for fluid deficit. If a nasogastric tube is in place, the amount, color, and character of drainage is documented. Vital signs are monitored for signs of infection or shock.

NURSING DIAGNOSIS. Possible diagnoses include acute pain related to abdominal distention and ineffective tissue perfusion and deficient fluid volume related to collection of fluid in the intestine and vomiting.

PLANNING. Goals for the patient include pain control and prevention of dehydration and electrolyte imbalance.

IMPLEMENTATION. The nasogastric tube is maintained on low intermittent suction to relieve discomfort from distention. NPO status is maintained to rest the bowel, and frequent mouth care is provided. Medication for pain is administered as ordered. Opioids are given cautiously because they may mask symptoms of perforation and decrease intestinal motility. The patient is placed in semi-Fowler's position to reduce tension on the abdomen.

Careful monitoring of intake and output is critical. The type and amount of IV fluid replacement ordered is based on NG output. Ice chips may be given if ordered by the physician but must be used sparingly. When melted ice mixed with electrolytes and hydrochloric acid are removed from the stomach by suction, electrolyte imbalance and metabolic alkalosis occur. If surgery is anticipated, care for abdominal surgery is implemented.

EVALUATION. Goals have been met if the patient states that pain is controlled and if fluid is balanced and electrolytes are within normal limits.

CRITICAL THINKING

Mrs. Loos
Mrs. Loos is admitted for abdominal pain. You note that she has a history of diabetes mellitus. As you do your morning assessment, you find her abdomen large, firm, and tender to touch. She states that she feels nauseated. What do you do? What do you think is happening?
Answers at end of chapter.

▶ ANORECTAL PROBLEMS

Hemorrhoids

Hemorrhoids are varicose veins in the anal canal. They are caused by an increase in pressure in the veins, often from increased intra-abdominal pressure. Internal hemorrhoids occur above the internal sphincter, and external hemorrhoids occur below the external sphincter. Most hemorrhoids are caused by straining during bowel movements. They are common during pregnancy. Prolonged sitting or standing, obesity, and chronic constipation also contribute to hemorrhoids. Portal hypertension related to liver disease may also be a factor.

Internal hemorrhoids are usually not painful unless they prolapse. They may bleed during bowel movements. External hemorrhoids cause itching and pain when inflamed and filled with blood (thrombosed). Inflammation and edema occur with thrombosis, causing severe pain and possibly infarction of the skin and mucosa over the hemorrhoid.

Preventing constipation, avoiding straining during defecation, and good personal hygiene relieve hemorrhoid symptoms and discomfort. Astringents, such as witch hazel, can be used for symptom relief. Sitz baths increase circulation to the area and aid in comfort and healing. Stool softeners can be used to reduce the need for straining. Other anti-inflammatory medications may be tried, such as steroid creams or suppositories. Alternating ice and heat helps relieve edema and pain with thrombosed hemorrhoids.

If hemorrhoids are prolapsed and are no longer reduced by palliative measures, more aggressive measures may be used. Sclerotherapy involves the injection of a sclerosing agent into the tissues around the hemorrhoids, causing them to shrink. Rubber band ligation uses rubber bands placed on the hemorrhoids until the tissue dies and sloughs off. Cryosurgery uses cold to freeze the hemorrhoid tissue.

Surgical hemorrhoidectomy involves surgical removal of hemorrhoids and is used in severe cases.

The patient should be instructed to consume a high-fiber diet and 2 to 3 L of fluid a day to promote regular bowel movements. The effects and side effects, proper dosage, and frequency of local or topical treatments should be explained. If the patient has surgery, analgesics should be given as needed because the many nerve endings in the anal canal can cause severe pain. Comfort measures such as a side-lying position and fresh ice packs should also be used to relieve pain. After the first postoperative day, sitz baths may be ordered. Unfortunately, a side effect of opioid analgesics is constipation, which needs to be avoided, especially in the immediate postoperative period. Because the first bowel movement can be painful and anxiety provoking, stool softeners are given and analgesics administered before the first bowel movement.

Anal Fissures

Anal fissures are cracks or ulcers in the lining of the anal canal. They are most commonly associated with constipation and stretching of the anus with passage of hard stool, although Crohn's disease or other factors may also play a role. The patient may experience bright red bleeding. Pain may be so severe that the patient delays defecation, leading to further constipation and worsening symptoms. Treatment of anal fissures involves measures to ensure soft stools, allowing fissures time to heal. Sitz baths may be used to promote circulation to the area to aid in healing. Anesthetic suppositories and nonopioid analgesics may be ordered for comfort. If conservative measures are not helpful, surgical excision may be necessary.

Anorectal Abscess

An anorectal abscess is a collection of pus in the rectal area. Common causative organisms include *E. coli*, *Proteus* spp., staphylococci, or streptococci. Symptoms include pain, redness and swelling, fever, and sometimes drainage.

Abscesses are treated with antibiotics and surgical incision and drainage of pus. The area may be left open to drain, with packing placed to assist with drainage and healing. Nursing care includes dressing or packing changes as ordered. Sitz baths are used to keep the area clean and promote healing, especially after bowel movements. The patient is instructed in the importance of keeping the area clean and dry. Other postoperative care is similar to care following hemorrhoidectomy.

► LOWER GASTROINTESTINAL BLEEDING

Etiology

Major causes of lower gastrointestinal bleeding are diverticulitis, polyps (growths in the colon), anal fissures, hemorrhoids, inflammatory bowel disease, and cancer. Bleeding may also occur in the upper GI tract. (See Chapter 30.)

Signs and Symptoms

Bleeding from the GI tract is evident in the stools. When blood has been in the GI tract for more than 8 hours and

has come in contact with hydrochloric acid, it causes **melena**, or black and tarry stools. The presence of melena indicates bleeding above or in the small bowel. Bleeding from the colon or rectum is usually bright red (**hematochezia**).

Significant blood loss causes hypotension, light-headedness, nausea, and diaphoresis. The patient is pale and has cool skin. The onset of tachycardia and worsening hypotension indicate hypovolemic shock and should be reported to the physician immediately.

Diagnostic Tests

A thorough history is necessary to determine underlying disorders that may be causing the bleeding. Decreased hemoglobin and hematocrit result from blood loss. Blood urea nitrogen (BUN) may be elevated as a result of breakdown of proteins in the blood by the GI tract. Stool can be tested for occult blood if it is not evident on inspection. Digital examination, colonoscopy, or sigmoidoscopy may be done by the physician.

A new diagnostic test to find bleeding in the small intestine is being used by researchers. After an 8-hour fast, a pill-sized camera is swallowed to look inside previously inaccessible areas of the small intestine. The swallowed camera transmits two images per second via radiofrequencies to a recorder on a belt the patient wears. The patient can drink liquids after 2 hours and eat after 4 hours. After 8 hours the patient returns the recorder and belt to the doctor to download the images into a computer.

Medical Treatment

Treatment depends on the cause of the bleeding. Mild bleeding may resolve with conservative measures. If bleeding continues, surgery to correct diverticulosis, inflammatory bowel disease, or cancer may be considered.

Nursing Care

Stools are checked for the presence and amount of blood. Vital signs are monitored for signs of shock. Declining blood pressure and rising heart rate are reported to the physician immediately. The patient is prepared for diagnostic tests and nursing care for the underlying disorder is provided.

► COLON CANCER

Colon cancer is one of the most common types of internal cancer in the United States. People with a family history of colon cancer or ulcerative colitis are at higher risk of developing it themselves. The American Cancer Society estimated 135,400 new cases and 56,700 deaths from colorectal cancer in 2001.¹

Pathophysiology and Etiology

Colon cancer originates in the epithelial lining of the colon or rectum and can occur anywhere in the large intestine. People with a personal or family history of ulcerative colitis, colon cancer, or polyps of the rectum or large intestine are at higher risk for developing cancer. Colon cancer has also been linked with previous gallbladder removal and di-

hematochezia: hemat—blood + chezia—in stool

etary carcinogens. A major causative agent is lack of fiber in the diet, which prolongs fecal transit time and in turn prolongs exposure to possible carcinogens. Also, bacterial flora is believed to be altered by excess fat, which converts steroids into compounds having carcinogenic properties.

Signs and Symptoms

Manifestations of colon cancer vary according to the type of tumor and the location (Fig. 31–6). A change in bowel habits is the most common symptom (Table 31–7). Blood or mucus in stools may occur. Although all tumors cause varying degrees of obstruction, those in the descending colon and rectum do not cause anemia, weight loss, nausea, or vomiting.

Complications

Complications include complete obstruction of the colon, perforation, peritonitis, and extension of the tumor to adjacent organs. Colorectal cancer can metastasize to the lymphatic system and liver.

TABLE 31–7 COLON CANCER SUMMARY

<i>Symptoms</i>	Change in bowel habits Blood or mucus in stools Abdominal or rectal pain Weight loss Anemia Obstruction
<i>Diagnostic tests</i>	Colonoscopy with biopsy Sigmoidoscopy with biopsy Proctosigmoidoscopy Barium enema Abdominal and rectal examination Fecal occult blood
<i>Therapeutic management</i>	Surgery, possibly colostomy Radiation Chemotherapy and/or radiation Medications: analgesics TPN as necessary Support and education

Diagnostic Tests

Most colorectal cancers are identified by biopsy done at the time of endoscopy (proctosigmoidoscopy, sigmoidoscopy, or colonoscopy). In addition to abdominal and rectal examination, other tests include fecal occult blood testing and barium enema. Carcinoembryonic antigen (CEA), a blood test, is used to assess response to treatment of GI cancer. CEA is present when epithelial cells rapidly divide and provides an early warning that the cancer has returned.

Medical Treatment

Small localized tumors may be excised and treated during endoscopy or laparoscopy. These procedures can also be used as palliative care for patients with advanced tumors who cannot tolerate major surgery.

Surgery is performed to either resect larger tumors and anastomose the remaining bowel or divert the feces by forming a colostomy. In rectal cancer an abdominal perineal (A & P) resection is done with the formation of a permanent end colostomy (Fig. 31–7). With an abdominal perineal resection, the anus, rectum, and part of the sigmoid colon are removed. A perineal wound, often with a drain inserted, is left where the anus was. Medical management includes radiation therapy and chemotherapy. When both are used, along with surgery, increased survival rates have been demonstrated.

LEARNING TIPS

Three incisional areas are created in an abdominal perineal resection:

1. An abdominal incision
2. A perineal incision
3. A stoma

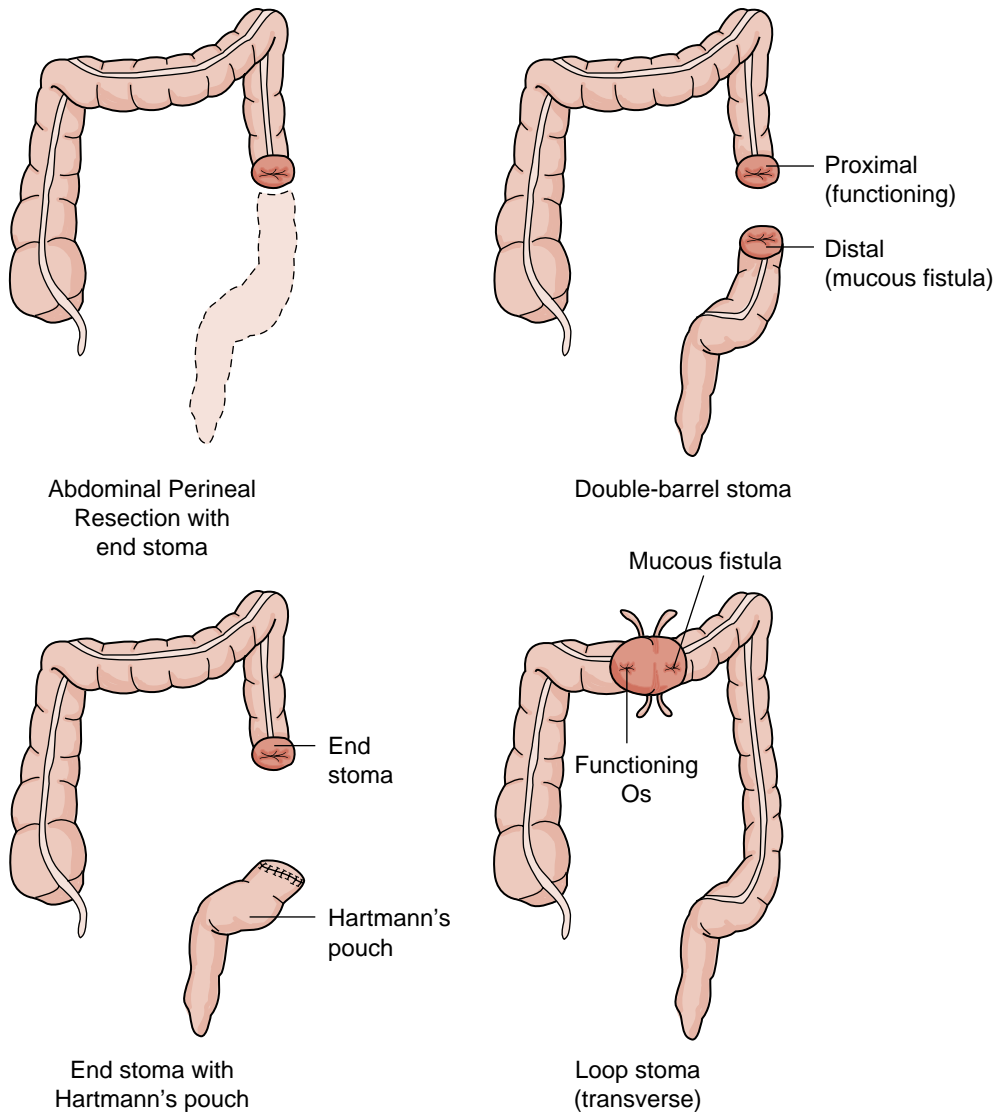

Figure 31-7 Types of stomas.

Nursing Process

ASSESSMENT. Risk factors for colon or rectal cancer are identified by asking questions about the patient’s personal and family history: Is there a history of inflammatory bowel disease? What were the patient’s dietary habits? What foods were usually eaten, and how much fluid was usually consumed? Prior to diagnosis, did the patient experience constipation or diarrhea? Has there been a change in bowel habits? Has mucus or blood been noted in the stools? What social habits does the patient have? Did the patient smoke, drink alcoholic beverages, exercise? Has there been a recent weight loss? How much and in what time frame? Does the patient admit to unusual fatigue or insomnia? Stool should be checked for mucus or blood.

NURSING DIAGNOSIS. Nursing diagnoses identified, based on the assessment data, may include acute pain related to tissue compression from the tumor, anxiety related to diagnosis of cancer, imbalanced nutrition: less than body requirements related to nausea and anorexia, and deficient knowledge related to surgery and postoperative care.

PLANNING. Goals include relief from pain, alleviation of anxiety, achievement of optimum nutritional status, and understanding of self-care following surgery.

IMPLEMENTATION. Set aside time to allow the patient who so desires to talk, cry, or ask questions about the diagnosis and planned surgery. Postoperatively, administer analgesics as prescribed. Provide a quiet, relaxing atmosphere to help alleviate anxiety, and limit visitors and telephone calls if the patient prefers. Postoperative care includes monitoring vital signs, the stoma, and the return of bowel sounds and flatus, indicating peristalsis has resumed, and ambulation, coughing and deep breathing, and dressing changes as ordered. Dressings are observed for drainage. Large amounts of drainage or bleeding are reported. If a drain is inserted, often in the perineal wound, moderate amounts of serosanguineous (light pink) drainage are expected. Frequent dressing reinforcements or changes are needed to keep the area dry.

Total parenteral nutrition may be necessary to provide depleted vitamins, minerals, and nutrients if the patient has

been anorexic for any length of time or has had a significant weight loss. After bowel sounds return, provide the patient with a high-protein, high-calorie diet, as ordered, that is low in residue to decrease excessive peristalsis and minimize cramping. If the patient is anemic, blood transfusions may be necessary.

EVALUATION. Expected outcomes are that the patient verbalizes less anxiety and control of pain, attains an optimum level of nutrition, and verbalizes understanding of the disease and treatment. If the patient has a colostomy, the stoma is observed by the patient and a return demonstration of the appliance change should be done before discharge.

► OSTOMY MANAGEMENT

An ostomy is a surgically created opening that diverts stool or urine to the outside of the body through an opening on the abdomen called a **stoma**. A stoma is the portion of bowel that is sutured onto the abdomen. The types of abdominal ostomies include ileostomy, colostomy, and urostomy. (Urinary ostomies are discussed in Chapter 35.) The stomas can be end, loop, or double barrel. See Figure 31–7 for types of ostomies.

Ileostomy

An ileostomy is an end stoma formed by bringing the terminal ileum out to the abdominal wall following a total colectomy. Two types of ileostomies can be formed: a conventional ileostomy and a continent ileostomy, such as a Kock pouch (Fig. 31–8). A conventional ileostomy is a small stoma in the right lower quadrant that requires a pouch at all times because of the continuous flow of liquid effluent.

Figure 31-8 Surgical formation of continent ileostomy (Kock pouch). (A) Loop of terminal ileum. (B) Both limbs of ileum are brought together and sutured into a U shape. (C) Pouch created with nipple valve. (D) Pouch sutured to abdominal wall.

A continent ileostomy is formed by taking a portion of the terminal ileum to construct an internal reservoir with a nipple valve. The stoma is usually flush to the skin and located near the suprapubic area. The patient is taught to insert a catheter into the stoma three or four times a day to empty the reservoir. A continent ileostomy surgery takes longer and requires additional instruction for the patient to be able to do self-care.

The patient who is opposed to having an ileostomy may have an ileoanal anastomosis done to connect the ileum to the anus, avoiding a stoma (Fig. 31–9). This is usually a two-step procedure. During the first surgery, the diseased bowel is removed. A reservoir (called a J pouch or an S pouch) is then formed from part of the ileum and connected to the anus. A temporary ileostomy is also formed to divert stool while the reservoir heals. After 2 to 3 months, the ileostomy is reversed and the patient can have bowel movements from the anus. Problems with perianal skin irritation resulting from frequent liquid stools may occur. An ileorectal anastomosis can also be performed, but this may not be a curative procedure for a patient with ulcerative colitis, because the rectum may still be diseased.

Colostomy

A colostomy is named according to where in the bowel it is formed: It may be an ascending, transverse, descending, or sigmoid colostomy. The type of effluent is dependent on the location of the bowel used (Table 31–8).

TABLE 31-8 LOCATION OF STOMA AND TYPE OF EFFLUENT

Location of Stoma	Type of Effluent
Ileostomy	Liquid to mushy
Cecostomy, ascending colostomy	Liquid to mushy, foul odor
Right transverse colostomy	Mushy to semiformed
Left transverse colostomy	Semiformed, soft
Descending or sigmoid colostomy	Soft to hard formed

Figure 31-9 Ileal J pouch–anal anastomosis. The two-loop ileal pouch is simple to construct, provides adequate storage capacity, and is evacuated spontaneously and fully.

LEARNING TIPS

As stool travels through the colon, water is absorbed and the stool becomes firmer. Therefore an ileostomy produces the most liquid effluent, followed by an ascending colostomy. A descending or sigmoid colostomy produces the firmest stool. Those with an ileostomy are at increased risk for dehydration due to greater water loss.

End Stoma

An end stoma is formed when the proximal end of the bowel is brought to the outside abdominal wall. If an abdominal perineal resection is done (usually for low rectal cancer), the rectum is removed and the proximal sigmoid or descending colon is brought out as a stoma. Another procedure that may be done involves removing the segment of diseased or injured bowel and using the proximal portion to form the stoma. The remaining limb of bowel is sutured closed and left in the peritoneal cavity so that the rectum is intact. This is called a Hartmann's pouch, or mucous fistula, and may be permanent or temporary depending on the diagnosis. Because the rectum is intact, the patient may feel the urge to defecate. This is normal because the colon continues to produce mucus. As the rectal stump fills with mucus, the sphincter is triggered and alerts the patient as if it were stool.

Loop Stoma

To create a loop stoma, a loop of bowel, usually the transverse colon, is pulled to the outside abdominal wall and a bridge is slipped under the loop to hold it in place. An incisional slit is made in the top of the exposed colon to allow stool to exit. The entire loop of bowel is not cut through.

Double-barrel Stoma

With a double-barrel stoma, the bowel is completely dissected and both ends of the colon are brought to the outside abdominal wall to form two separate stomas. The proximal stoma is the functioning stoma that expels stool. The distal stoma is called a mucous fistula because mucus produced by the bowel passes from it. A double-barrel stoma is often temporary, allowing the bowel to rest during healing after trauma or surgery.

Preoperative Care

A wound ostomy continence nurse should be consulted before surgery. The WOCN can help prepare the patient both emotionally and physically for the surgery. In addition, the WOCN has expertise in marking the stoma site for the surgeon. This involves observing the abdomen as the patient assumes different positions and noting how clothing is worn, such as where the belt rides. The site for the stoma can then be chosen so it is visible to the patient for self-care, avoids skin or fat folds, and is where clothing will not interfere with the appliance. Properly planned stoma placement can prevent agony over inability to perform self-care

and uncomfortable, leaking, or poorly fitting appliances postoperatively.

Routine preoperative instruction, including the importance of coughing and deep breathing, splinting, and early ambulation, is provided. Orders for cleansing of the bowel are performed to reduce the risk for infection following surgery. Unless the patient has chronic diarrhea related to IBD, an oral agent to cleanse the bowel (Go-LYTELY) is given. Oral and intravenous antibiotics are given as ordered.

Nursing Process

ASSESSMENT. The patient with a new ostomy has many nursing care needs. In addition to routine postoperative assessment, the stoma should be inspected at least every 8 hours. The stoma should be pink to red, moist (similar to the inside of the mouth), and well attached to the surrounding skin (Fig. 31–10). A bluish stoma indicates inadequate blood supply; a black stoma indicates necrosis. Either complication should be reported to the physician immediately for treatment, which may require that the patient return to surgery. Initially the stoma is swollen. The stoma size gradually decreases over the first few weeks following surgery. This is explained to the patient.

Skin is assessed for irritation around the pouch and under the pouch each time it is changed. Ostomy discharge (effluent) is monitored and documented. Unexpected changes, such as liquid stool from a descending ostomy, are reported.

NURSING DIAGNOSIS. A sample care plan is shown for a nursing diagnosis of disturbance in body image related to new ostomy care. (See Nursing Care Plan Box 31–10 for the Patient with an Intestinal Ostomy.)

PLANNING. The goal for the ostomy patient is to perform the self-care measures necessary for safe discharge home. The physical, emotional, psychosocial, economic, and rehabilitative aspects must be considered, and teaching must be provided to assist the patient to live with his or her ostomy. Collaborative discharge planning should include the social worker, dietitian, pharmacist, home health nurse, and WOCN. Some communities have an ostomy club that sends trained visitors with ostomies to visit with patients with new ostomies to help them adjust.

IMPLEMENTATION

Deficient Knowledge Related to New Ostomy. Recognizing patient readiness and ability to learn and perform self-care is of primary importance. The patient experiencing pain, nausea, or vomiting is not likely to be ready to look at the ostomy or learn about ostomy care. A patient who is blind, deaf, or has a language barrier requires special instructional methods. Patients with severe arthritis or other physical conditions that limit ability to perform self-care may require a specific type of ostomy appliance.

If the patient is not ready or able to learn, it is important that a family member or caregiver be included in the teaching. With short hospital stays, teaching time frames are limited and must begin soon after surgery. A home care nurse

BOX 31-10 NURSING CARE PLAN FOR THE PATIENT WITH AN INTESTINAL OSTOMY

Disturbed body image related to new ostomy

PATIENT OUTCOMES

Patient will verbalize acceptance of intestinal ostomy before discharge.

EVALUATION OF OUTCOMES

Is the patient able to verbalize acceptance of the ostomy?

INTERVENTIONS

Assess knowledge of self-care of ostomies.

Encourage patient to verbalize feelings about the stoma.

Explain the normal characteristics of the stoma before the patient's first look.

Demonstrate ostomy appliance change and daily care and encourage patient participation.

RATIONALE

Many people have misconceptions regarding ostomies. Identification of misconceptions and "hearsay" knowledge is important to clarify or correct.

Allowing the patient to express his or her feelings provides opportunity to identify and verbalize concerns, which then can be addressed by health care providers.

Helping the patient understand what to expect will help relieve anxiety. Being available to answer questions immediately also relieves anxiety.

When the patient observes and participates in self-care, his or her self-concept improves.

EVALUATION

Does the patient verbalize appropriate knowledge of ostomy care?

Does the patient discuss his or her feelings regarding the stoma to the nurse or significant other?

Does the patient look at the stoma without hesitation?

Is the patient participating in self-care? Has the patient performed return demonstration of appliance change and emptying of pouch?

often continues the teaching in the patient's home. A WOCN or equipment supplier can suggest appliances suited to individual patients' needs. Figure 31–11 shows types of appliances.

Appliance change. Depending on the type of appliance used, the appliance will need to be changed as often as every 3 days or rarely every 10 to 14 days. If leakage occurs, the appliance should be changed as soon as possible to avoid **peristomal** skin irritation. The skin barrier that is placed over the stoma on the skin should fit within one-sixteenth to one-eighth inch of the base of the stoma to prevent skin contact with stool. The stoma should be measured with each appliance change for as long as the stoma remains edematous. Because most stomas are not round, a pattern should be traced to teach the patient proper size and shape. An open-ended or drainable pouch should be used for all colostomies or ileostomies, especially during the first 8 weeks after surgery. See Figure 31–12 for the pouch application procedure.

If the patient has a left-sided (descending or sigmoid) colostomy, the bowel can be regulated either by diet or by regular irrigation of the stoma. Once bowel regulation has been achieved, the patient may use a closed-end pouch or a stoma cap.

Daily care and hygiene. The patient is instructed to empty the pouch when it is one-third to one-half full. The amount of effluent and the frequency of emptying depends on the location of the stoma in the bowel. If the pouch is allowed to get more than half full of stool, the weight of the effluent will pull on the pouch and weaken the seal of the skin bar-

rier. Once the pouch is emptied, the inside of the tail of the pouch must be cleaned and dried before the clamp is replaced to help control odor. If a two-piece system is used, the pouch can be taken off, washed out, and replaced. The patient can bathe or shower with the appliance in place but needs to check the seal and retape or change it if it is loosening. Spray deodorants or chlorophyll tablets can be placed in the pouch for odor control. Chlorophyll is more effective if taken by mouth.

Dietary considerations. The patient needs to be aware of foods that contribute to odor and gas. If foods that are known to cause odor or gas are eaten, the patient should know to empty the pouch of flatus more often and to be aware that more odor is probable. It is important that the patient know the foods that contribute to and control diarrhea and what to do for constipation. A list of foods that may contribute to ileostomy blockage must be given to the ileostomy patient (Table 31–9, Nutrition Notes Box 31–11).

Colostomy irrigation. Colostomy irrigation is rarely done to regulate an ostomy anymore. However, it may be done as bowel preparation for procedures. Irrigation is performed in a manner similar to an enema, except that special equipment is used to instill fluid into the bowel via the stoma. Because the stoma does not have a sphincter, specially designed tubing with a cone at the end is used to irrigate the ostomy. The cone blocks the fluid that is being instilled from flowing back out the stoma.

Disturbed Body Image. Altered body image, fear of the unknown, and concerns regarding acceptance by significant

others can take control of the patient with an ostomy. Overcoming those concerns is crucial to patient adjustment. The idea of feces being expelled from the abdomen can make the patient feel dirty and abnormal. The spouse or significant other should be encouraged to view the stoma with the patient and be allowed to ask questions and participate in care. The attitude and behavior of nursing staff caring for the patient with an ostomy can significantly affect his or her ability to adapt, either positively or negatively. A trained visitor with an ostomy can help the patient see that there is hope for a normal life. (Check the local phone directory for The United Ostomy Association or ostomy club.)

One of the most common fears expressed by patients with ostomies is the fear of gas and odor. Because the stoma does not have a sphincter, flatus is expelled unexpectedly. It is helpful to inform the patient that when he or she is wearing clothes, rather than a loose hospital gown, the noise is usually muffled. The quality of appliances also allows for control of odor. The patient needs to know that if an odor is noticeable, something is wrong, and that the following questions need to be considered: (1) Was the pouch just emptied of feces or “burped” of air? (2) Is there feces on the drainage spout of the pouch? (3) Are there signs of leakage under the skin barrier? (4) If a two-piece system is used, is the pouch snapped onto the skin barrier correctly?

If leakage occurs in a public place, such as the grocery store, church, or a friend’s house, the patient may be reluctant to go out again. Advise the patient to be prepared for an emergency pouch change because leakage of an appliance can occur at any time. Encourage him or her to always carry an extra appliance and to determine the cause of the leakage. Also teach the patient measures to decrease the chance of leakage and to consult a WOCN if leakage is a continuous problem.

Sexual Dysfunction. Feared change in body image can also lead to sexual dysfunction. If the male patient had an abdominal perineal resection for cancer of the rectum, there is a chance that he will be impotent. This impotence may be transient, depending on the severity of nerve damage or edema associated with the surgery. If the patient is impotent, a urologist may be consulted for interventions. Encourage patients to discuss any concerns regarding sexuality with his or her spouse or sexual partner. This may help them work through any fears or embarrassment. Attractive pouch covers can be purchased and worn to help disguise the pouch and its contents. Alternative sexual positions can also be suggested.

Ineffective Therapeutic Regimen Management. The patient may have difficulty carrying out self-care measures for a variety of reasons. The cost and availability of ostomy supplies is problematic for many patients. Most insurers, including Medicare, pay for ostomy supplies, although some limit the type of appliance and number allowed per month. Each state-funded Medicaid system is different. The type of appliance needed to eliminate leakage may not always be covered, requiring the patient to either pay the difference or wear what the insurance company will provide. If the

BOX 31-11

Nutrition Notes

Anticipating Dietary Management of Ostomies

Ostomy patients receive a soft diet initially, progressing to a general diet as the surgeon prescribes. Stringy, high-fiber foods are avoided initially. These include celery, coconut, corn, cabbage, coleslaw, membranes on citrus fruits, peas, popcorn, spinach, dried fruit, nuts, sauerkraut, pineapple, seeds, and skins of fruits and vegetables. Some patients avoid fish, eggs, beer, and carbonated beverages because they produce excessive odor. Dietary restrictions are usually based on individual tolerance.

Patients with ostomies should be encouraged to do the following:

- Eat at regular intervals.
- Chew food well to avoid blockage at the stoma site.
- Drink adequate amounts of fluid.
- Avoid foods that produce excessive gas, loose stools, offensive odors, and undesirable bulk.
- Avoid excessive weight gain.

patient has no insurance, costs can be high. Some patients find they have to choose whether to purchase ostomy appliances or prescriptions with their limited funds. Fortunately, the pouches in most two-piece systems can be washed out and reused to save money (Home Health Hints). In some areas the availability of supplies may be limited. However, supply sources continue to increase. Local retail pharmacists and internet and mail-order companies are available.

HOME HEALTH HINTS

Ostomy bag deodorizers can increase the cost of care. Alternatives include the following: (1) Place tissue or cotton balls saturated in almond or vanilla extract inside the appliance and replace as needed. (2) Put mouthwash in the water that is used to rinse the appliance. (3) Spray a light coat of cooking spray inside the clean bag to make later cleanup easier.

Risk for Injury. Complications related to ostomies include skin and stomal problems. If there are any complications associated with the care of the ostomy, the WOCN should be consulted if available. A WOCN has had specialized instruction in caring for the stoma and peristomal skin and has a wealth of information to offer.

Peristomal skin irritation. The skin around the stoma may become irritated if the opening in the skin barrier around the stoma is cut too large and exposes skin to the GI effluent. Prolonged contact with effluent can lead to a reaction similar to a chemical burn. Tape and adhesive removal, especially if done frequently, can lead to skin shearing. Occasionally, allergic dermatitis from a sensitivity to the adhesive may develop. To prevent irritation, a skin barrier such as stomahesive should be used. Pouches are left on for several days or until leakage occurs to prevent skin shearing from frequent removal.

Peristomal hernia. Hernias may develop around the stoma as a result of weakened abdominal muscles. This can pose a problem with appliance leakage caused by the change in body contours associated with the hernia. A more flexible ostomy appliance may be helpful.

Stomal prolapse. Sometimes the weakened abdominal muscles contribute to the falling down (or out) of the intestinal mucosa. This is called a prolapse and most commonly occurs in the elderly. Pouching a prolapsed stoma can be difficult. A prolapsed stoma should be reported to the physician.

Stomal necrosis. Stomal necrosis occurs when there is circulatory compromise. This may arise as a result of vascular collapse, blockage in the mesentery of the intestines, or edema in the intestine from obstruction proximal to the stoma. The onset of necrosis should be reported to the physician immediately. Usually, necrotic tissue occurs only at the very end of the stoma and will eventually slough off, revealing viable mucosa. Odor from the necrotic tissue may be a problem.

Ileostomy blockage. It is essential that the patient with an ileostomy be taught the signs and symptoms of a blockage and how to manage one should it occur. The patient with

an ileostomy may have a blockage if bowel movements are absent or a large quantity of hot liquid is passed through the stoma and is associated with abdominal cramping. With blockage, the stoma becomes edematous and the color may turn pale or dusky. Once signs and symptoms are recognized, the patient needs to consider what was eaten in the past 24 hours because certain foods are considered to cause stomal blockage. (See Table 31–9.)

Once the problem is identified, the patient should get into a tub of warm water (not too hot or cold), get into a knee-to-chest position, and sip on warm liquid, such as coffee, tea, bouillon, broth, or hot chocolate. If the blockage is partial, relief will occur fairly soon after these measures are taken. If the blockage is complete, an ileostomy lavage must be performed by a physician or WOCN.

EVALUATION. The plan of care has been effective if the patient or caregiver is able to competently care for the ostomy, the patient is able to accept the change in body image, and self-care measures to prevent or treat complications can be described by the patient or caregiver.

REHABILITATIVE NEEDS. One of the goals of care for the ostomy patient is to assist the patient to return to activities of daily living. In addition to the WOCN, a home care nurse may be able to assist the patient in becoming comfortable with self-care. Being able to perform the ostomy appliance change and daily care is vital, but ensuring that the patient returns to work or civic activities as before is also important.

The patient can generally perform any activity he or she was able to do before the ostomy. Resources available, as needed, include the United Ostomy Association, the Crohn's and Colitis Foundation of America, and the American Cancer Society (Table 31–10).

REVIEW QUESTIONS

- A patient has ulcerative colitis. Which foods should he be taught to avoid in his diet?
 - Fresh fruits
 - White bread
 - Sweet desert
 - Meat
- The nurse is listening to a patient's abdomen and determines that bowel sounds are absent. To make this determination, the nurse would listen for which of the following time frames?
 - 2 minutes in each quadrant
 - 5 minutes in each quadrant
 - 7 minutes in each quadrant
 - 10 minutes in each quadrant
- The nurse is caring for a patient who has a sudden onset of diarrhea. Which of the following terms should the nurse use to document the patient's black, tarry stool?
 - Melena
 - Hematochesia
 - Hematemesis
 - Steatorrhea
- The nurse is developing a teaching plan for a patient who is interested in lifestyle changes to help prevent colon cancer. Which of the following of the patient's dietary habits does the nurse understand may increase the risk for development of colon cancer?
 - High fat, low fiber intake
 - High intake of milk and milk products
 - Low meat and protein intake
 - Low fat, high carbohydrate intake
- A patient with Crohn's disease is to receive sulfasalazine, 500 mg oral suspension qid. The oral suspension is available as 250 mg/5 mL. How many milliliters should the nurse give for the 0800 dose?
 - 5 mL
 - 10 mL
 - 20 mL
 - 50 mL

REFERENCES

- 2001 Facts and Figures. American Cancer Society: <http://www.cancer.org>, July 20, 2001.

Answers to CRITICAL THINKING

Mrs. Jessie Burns

You need to assess the situation before intervening. First, ask Mrs. Burns or her caregivers if she had a bowel movement that was inadvertently not charted. Next, ask Mrs. Burns if she feels constipated or if she has abdominal discomfort. Assess Mrs. Burns's abdomen for distention and presence or absence of bowel sounds. A digital examination may be necessary to determine if a fecal impaction is present. If simple constipation appears to be the problem, the medical record should be checked for as-needed laxative or enema orders. Once Mrs. Burns has had a bowel movement, laxatives should be discontinued and preventive measures such as regular fluids, fiber, and exercise should be instituted.

Judy Morrow

You need to further assess how Judy perceives that Crohn's disease will affect her lifestyle. What does she know about Crohn's disease? What is she concerned about? How has Crohn's disease affected her ability to sleep, what she eats, her participation in sports, and her relationships with other people?

Convey a caring manner to Judy by being accepting of her, listening actively to her concerns, and helping her to find acceptable ways of resolving them. Provide her with information that she needs about Crohn's disease. Arrange to have a well-adapted person of approximately the same age from the Crohn's and Colitis Foundation of America meet with her to share coping strategies with her.

Mrs. Loos

- You need to further assess Mrs. Loos before deciding what to do. Begin by asking the WHAT'S UP? questions, including exactly where the pain is occurring, how it feels, if there is anything that aggravates or alleviates the pain, when it started, how bad it is on a scale of 0 to 10, whether there are associated symptoms, and if Mrs. Loos has some insight regarding the cause of her problem. Listen for bowel sounds for 5 minutes in each quadrant. Find out when her last bowel movement was. Because of her history of diabetes, you suspect that neuropathy may be causing a nonmechanical bowel obstruction. If assessment findings confirm the possibility, the physician should be contacted. Because of the nausea and the potential obstruction, withhold food and fluids until the physician can be contacted.
- When documenting, answer the questions what, why, when, where, who, how (either explicitly or implicitly by professional knowledge, in narrative or flow sheet format) for completeness.
 - What = Patient is experiencing large, firm, tender to touch abdomen with nausea (additional assessment data should be included).
 - Why = Unknown, physician notified
 - When = Current date and time
 - Where = Abdomen
 - Who = J. Morgan, LPN

The background of the slide is a detailed anatomical illustration of the human torso, focusing on the abdominal region. The liver is shown in a light purple hue, with its characteristic lobulated surface. The gallbladder is depicted as a pear-shaped sac tucked under the right lobe of the liver. The pancreas is shown as a long, flat, yellowish organ extending across the front of the abdominal cavity. The biliary and pancreatic ducts are clearly visible, showing their complex branching and confluence. A central vertical inset provides a colorized view of the same anatomical structures, with the liver in shades of green and blue, and the gallbladder and pancreas in red and orange tones. The text is overlaid on the upper portion of the illustration.

QUESTIONS TO GUIDE YOUR READING

1. What is the normal anatomy of the liver, gallbladder, and pancreas?
2. What are the normal functions of the liver, gallbladder, and pancreas?
3. What are the effects of aging on the liver, gallbladder, and pancreas?
4. Which data should you collect when caring for a patient with a disorder of the liver, gallbladder, or pancreas?
5. What are the techniques used in a physical examination of the abdomen conducted for a patient with possible liver, gallbladder, or pancreas disease?
6. What nursing care should you provide for patients undergoing common diagnostic tests for liver, gallbladder, or pancreatic disease?

► REVIEW OF NORMAL ANATOMY AND PHYSIOLOGY

The liver, gallbladder, and pancreas are called accessory organs of digestion because they produce or store digestive secretions but are not sites of the digestive process, which takes place in parts of the alimentary tube.

Liver

The liver fills the right and center of the upper abdominal cavity just below the diaphragm. The two main lobes of the liver are called the right and left lobes.

The blood supply of the liver differs from that of other organs. The liver receives oxygenated blood by way of the hepatic artery. By way of the portal vein, blood from the abdominal digestive organs and the spleen is brought to the liver before being returned to the heart. This special pathway is called hepatic portal circulation and permits the liver

to regulate blood levels of nutrients or to remove potentially toxic substances such as alcohol from the blood before the blood circulates to the rest of the body.

The only digestive function of the liver is the production of bile by the hepatocytes (liver cells). Bile flows through small bile ducts, then through larger ones, and leaves the liver by way of the hepatic duct (Fig. 32–1), which joins the cystic duct of the gallbladder to form the common bile duct, which carries bile to the duodenum.

Bile is mostly water and has an excretory function in that it carries bilirubin and excess cholesterol to the intestines for elimination in feces. The digestive function of bile is accomplished by bile salts, which emulsify fats in the small intestine. Emulsification is a type of mechanical digestion in which large fat globules are broken into smaller globules but are not chemically changed. Production of bile is stimulated by the hormone secretin, which is produced by the duodenum when food enters the small intestine.

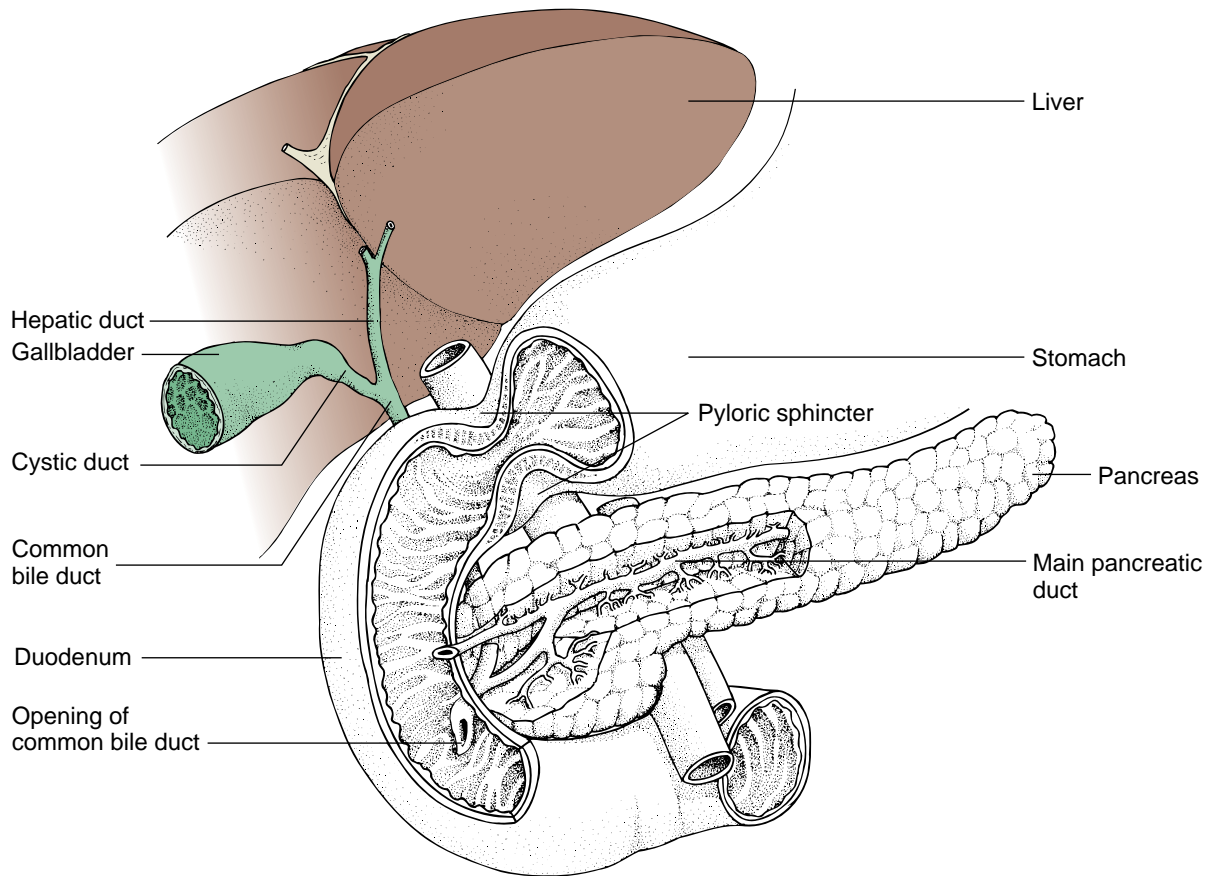

Figure 32-1 The liver, gallbladder, pancreas, and duodenum.

Functions of the Liver

The liver is involved in a great variety of metabolic functions, most of which involve the synthesis of specific enzymes. For the sake of simplicity, these functions may be grouped into categories.

CARBOHYDRATE METABOLISM. The liver regulates the blood glucose level by storing excess glucose as glycogen and changing glycogen back to glucose when the blood glucose level is low. The liver also changes other monosaccharides such as fructose and galactose to glucose, which is more readily used by cells for energy production.

AMINO ACID METABOLISM. The liver regulates the blood levels of amino acids based on tissue needs for protein synthesis. Of the 20 amino acids needed for the production of human proteins, the liver is able to synthesize 12, called the nonessential amino acids, by the process of transamination. The other eight amino acids, which the liver cannot synthesize, are called the essential amino acids. Essential amino acids are required in the diet.

Excess amino acids (those not needed for protein synthesis) undergo the process of deamination in the liver; the amino group is removed and the remaining carbon chain is converted to a simple carbohydrate that is used for energy production or converted to fat for energy storage. The amino groups are converted to urea, a nitrogenous waste

product that is removed from the blood by the kidneys and excreted in urine.

LIPID METABOLISM. The liver forms lipoproteins for the transport of fats in the blood to other tissues. The liver also synthesizes cholesterol and excretes excess cholesterol into bile to be eliminated in feces.

The liver is also the main site of the process called beta oxidation, in which fatty acid molecules are split into two-carbon acetyl groups. These acetyl groups may be used by the liver to produce energy, or they may be combined to form ketones to be transported to other cells for energy production.

SYNTHESIS OF PLASMA PROTEINS. The liver synthesizes albumin, clotting factors, and globulins. Albumin, the most abundant plasma protein, helps maintain blood volume by pulling tissue fluid into capillaries. Clotting factors produced by the liver include prothrombin and fibrinogen, which circulate in the blood until needed for chemical clotting. The globulins synthesized by the liver become part of lipoproteins or act as carriers for other molecules in the blood.

PHAGOCYTOSIS BY KUPFFER CELLS. The fixed macrophages of the liver are called Kupffer cells; they phagocytize pathogens that circulate through the liver. Many of the bacteria that get to the liver come from the

colon, after being absorbed as the colon absorbs water. These bacteria are normal flora of the colon but would be very harmful elsewhere in the body. Portal circulation brings this blood to the liver first, however, and the bacteria are phagocytized by Kupffer cells.

FORMATION OF BILIRUBIN. The fixed macrophages of the liver phagocytize old red blood cells (RBCs) and form bilirubin from the heme portion of their hemoglobin. The liver also removes from the blood the bilirubin formed in the spleen and red bone marrow and excretes it into bile to be eliminated in feces.

STORAGE. The liver stores the minerals iron and copper; the fat-soluble vitamins A, D, E, and K; and the water-soluble vitamin B₁₂.

DETOXIFICATION. The liver synthesizes enzymes that change harmful substances to less harmful ones. Alcohol and medications are examples of potentially toxic chemicals. The liver also converts ammonia from the colon bacteria to urea, a less toxic substance.

Gallbladder

The gallbladder is a muscular sac about 3 to 4 inches long located on the undersurface of the left lobe of the liver. Bile in the hepatic duct from the liver flows through the cystic duct (see Fig. 32–1) into the gallbladder, which stores bile until it is needed in the small intestine. The gallbladder also concentrates bile by absorbing water.

When fatty foods enter the duodenum, the duodenal mucosa secretes the hormone cholecystokinin. One function of cholecystokinin is to stimulate contraction of the smooth muscle of the wall of the gallbladder. Contraction of the gallbladder forces bile into the cystic duct, then into the common bile duct, which empties into the duodenum.

Pancreas

The pancreas is about 6 inches long, between the curve of the duodenum and the spleen in the upper right abdominal quadrant (see Fig. 32–1). The digestive secretions of the pancreas are produced by exocrine glands called acini. The small ducts of these glands unite to form larger ducts and finally the main pancreatic duct (there may be an accessory duct also), which emerges from the medial side, or head, of the pancreas and joins the common bile duct.

The pancreatic digestive enzymes are involved in the digestion of all three food types. The enzyme amylase digests starch to maltose; lipase converts emulsified fats to fatty acids and glycerol. Trypsinogen is an inactive enzyme that is changed to active trypsin in the duodenum. Trypsin digests polypeptides to shorter chains of amino acids.

The pancreas also produces a bicarbonate juice, which is alkaline because of its high sodium bicarbonate content. The function of bicarbonate juice is to neutralize the hydrochloric acid in gastric juice as it enters the duodenum from the stomach. The pH of duodenal chyme is raised to about 7.5, which prevents corrosive damage to the mucosa.

Secretion of pancreatic juice is stimulated by the hormones of the duodenal mucosa. Secretin stimulates the production of bicarbonate pancreatic juice, and cholecystokinin stimulates secretion of the pancreatic enzyme juice.

Aging and the Liver, Gallbladder, and Pancreas

The liver usually continues to function well into old age, unless damaged by pathogens such as the hepatitis viruses or by toxins such as alcohol. There is a greater tendency for gallstones to form, sometimes necessitating removal of the gallbladder. In the absence of specific pathological conditions, the pancreas usually functions well, although acute pancreatitis of unknown cause is somewhat more common in the elderly.

► NURSING ASSESSMENT

When assessing the patient with disease of the liver, pancreas, or gallbladder, use the same systematic approach as when assessing other organ systems. Make the patient as comfortable as possible before beginning the assessment process.

Nursing History

Obtain a patient history (Table 32–1). Elements of the patient history include a complete description of any abdominal pain or tenderness. Ask the patient which events cause or provoke pain; what actions, if any, relieve or palliate the pain; the quality of the pain, such as sharp, dull, boring, or burning; the location of the pain; the severity of the pain; and the timing, or when the pain occurs. Using the WHAT'S UP? model presented in Chapter 1 will help you remember all the elements that need to be included in a complete symptom assessment.

Ask the patient about any nausea, vomiting, or abdominal distention. Information about the timing or other common triggers of episodes of nausea or vomiting may help the practitioner identify their cause. Such information may also help determine appropriate treatment for any future nausea or vomiting. Abdominal distention in the presence of nausea and vomiting may indicate intestinal obstruction. Patients with liver, gallbladder, or pancreatic disease may also complain of feeling bloated, of having gas or belching frequently, or of right upper quadrant (RUQ) tenderness.

Question the patient about any observed changes in bowel elimination. Diarrhea may be caused by irritation of the bowel. Constipation may indicate decreased water intake or excessive water loss. Observe the patient's stool for evidence of bacteria (a foul smell), fat (stool floats on the water surface and appears greasy), pus, blood, or mucus. Patients with liver or gallbladder disease may have pale or clay-colored stools.

Patients with disease of the liver, pancreas, or gallbladder commonly have changes in appetite such as anorexia or alterations in eating preferences. Ask the patient about any abnormal weight loss or unexpected weight gain and changes in food tolerance, including the type or amount of

TABLE 32-1 QUESTIONS ASKED DURING ASSESSMENT OF THE LIVER, GALLBLADDER, AND PANCREAS

Question	Rationale
Do you have abdominal pain? (Use WHATS UP? to further assess.) Do any foods cause pain? Have you experienced nausea and vomiting?	Pain can be associated with disease of the liver, gallbladder, or pancreas. Fatty foods can cause pain related to gallbladder disease. These are generalized symptoms that may be associated with disease of the liver, gallbladder, or pancreas.
Does your abdomen feel distended or full? What do your stools look like?	Fluid in the abdomen, or ascites, occurs with liver disease. Clay-colored stools indicate liver or gallbladder disease. Black stools may indicate bleeding, which can be related to liver disease. Fatty stools occur with pancreatic disease.
Has your appetite or weight changed?	Anorexia and weight loss accompany many liver, gallbladder, and pancreatic disorders.
Does anyone in your family have liver, gallbladder, or pancreatic disease or alcoholism?	These disorders tend to run in families.
How much alcohol do you drink each day?	Excess alcohol intake is associated with liver disease and pancreatitis.
Do you bruise or bleed easily?	Bleeding is associated with liver disease, because clotting factors are made in the liver.
Do you use any over-the-counter drugs or herbal remedies? What is your occupation?	Many drugs and herbs are toxic to the liver. Some occupations are associated with exposure to substances that can be toxic to the liver.

offending foods. For example, patients with gallbladder disease may report that they feel nauseated or bloated after eating fried or greasy foods.

The patient's history should note whether there is a family history of liver, pancreas, or gallbladder diseases, such as diabetes mellitus, alcoholism, cancer, heart disease, or bleeding tendencies. These diseases have a high incidence within families.

Obtain a social history. Determine whether the patient ingests alcohol or uses other recreational drugs. If the patient does acknowledge using alcohol or other drugs, record the type, frequency, and amount used. You also need to ask the patient what medications are being taken with or without a physician's prescription. Many people do not consider over-the-counter preparations and herbal or natural products that they purchase without a prescription important enough to report and must be asked specifically to do so. Remember to ask specifically about the use of antacids, laxatives, vitamins, or pain relievers such as aspirin or nonsteroidal anti-inflammatory drugs (NSAIDs). See also Gerontological Issues Box 32-1.

BOX 32-1 GERONTOLOGICAL ISSUES

With increasing age, the liver decreases in volume, mass, and blood flow. These changes are significant because the liver acts to metabolize many drugs. If a patient has impaired liver function, there may be toxic levels of a drug present in the blood. It is important to assess liver function tests and perform a medication review to determine those that are metabolized by the liver. Older patients may require reduced doses of many drugs.

Ask about the patient's usual work activities and work setting. Document exposure to chemicals such as paint fumes, industrial dyes, acids, farm pesticides, or other liver-toxic substances.

Investigate the patient's activities other than work. Document reports of fatigue along with information about when

the fatigue occurs. Ask the patient about stressors such as financial concerns, problems dealing with the health care environment, and any family or personal problems. Attempt to determine what coping mechanisms the patient usually employs to deal with stressors.

Physical Assessment

Be prepared to assist with a thorough physical assessment of the patient. Instead of following the usual inspect-palpate-percuss-auscultate (IPPA) format, assess the abdomen starting with inspection, then auscultation, percussion, and palpation. This is to prevent palpation from changing other assessment findings.

Inspection

Assessment begins with inspection of the patient's skin for scars, **striae** (light silver-colored or thin red lines on the abdomen), bruising, **caput medusae** (bluish-purple swollen vein pattern extending out from the navel), and **spider angiomas** (thin reddish-purple vein lines close to the skin surface). The patient's abdomen is observed for any visible masses, visible movement or peristalsis, or **jaundice** (also called **icterus**, a yellowing of the skin and the sclera of the eye).

JAUNDICE. Jaundice is a cardinal symptom of liver or gallbladder disease and red blood cell disorders. Old red blood cells are cleared from the circulatory system by phagocytes in the spleen, liver, lymph nodes, and bone marrow. In the process, the compound heme (part of hemoglobin) is split into iron and another substance that is metabolized to bilirubin. The liver is then responsible for converting bilirubin to a water-soluble compound that can be excreted in bile. If the liver is unable to convert or conjugate bilirubin to a water-soluble compound, or if bile drainage is obstructed, serum bilirubin is elevated and pigments are deposited in body tissues.

When serum bilirubin levels elevate, the patient's skin color changes to yellow. The yellow color varies from pale yellow to a striking golden orange. The color intensity is directly related to the amount of elevation of the serum bilirubin. Jaundice can be seen in nearly every body tissue and fluid where there is any amount of albumin. Pigment may occasionally be seen in cerebrospinal fluid or joint fluid. Pigment is not seen in saliva or tears. Urine becomes dark, and if bile flow to the bowel is obstructed, stools will be a light clay color (Cultural Consideration Box 32–2). Describe any abnormal finding completely in the patient's record, and report your findings promptly.

BOX 32-2 CULTURAL CONSIDERATION

The nurse should be aware of the variations of assessing for jaundice among people of color. To assess for jaundice in a dark-skinned patient, look at the sclera, conjunctiva, palms of hands, soles of feet, and in the buccal mucosal for patches of bilirubin pigment.

Auscultation

Inspection should be followed with auscultation of bowel sounds with a stethoscope. Auscultate all four quadrants for at least 1 minute in each quadrant. Normal bowel sounds are heard every 5 to 15 seconds. Bowel sounds are considered normal if they occur within a range of 5 to 30 per minute and sound like soft gurgles or clicking. If the patient has recently had surgery, bowel sounds may be absent or occur less frequently than five per minute. High-pitched, frequent sounds may indicate hypermotility of the bowel or early bowel obstruction. It may be possible to hear circulatory sounds if the stethoscope is placed over the abdominal aorta. Patients with chronic liver failure may have a humming sound over their liver. This finding usually indicates overloaded venous circulation in the liver.

Percussion

The experienced practitioner may percuss the abdomen to determine the presence of masses, fluid, or air in the abdominal cavity. The normal sounds heard during percussion of the abdomen are tympany (musical drumlike sound over hollow air-filled space) or dull (a soft thudding sound over solid organs such as the liver). If an abnormal amount of fluid has collected in the peritoneal cavity, a sloshing sound may be heard when the patient turns from side to side or shifts position.

Palpation

Light palpation of the abdomen concludes the physical assessment. Depress the abdomen not more than $\frac{1}{2}$ to 1 inch during the palpation. Note any muscle tension, rigidity, masses, or expressions of pain. Deep palpation of the abdomen is done only by physicians and highly skilled nurses such as nurse practitioners.

▶ DIAGNOSTIC STUDIES

Laboratory Tests

Laboratory tests and normal values listed in Table 32–2 are the common tests performed to detect problems with the liver, gallbladder, and pancreas. Bilirubin is an excellent measure of liver and gallbladder functioning. In addition, certain enzymes such as alanine aminotransferase (ALT, formerly called serum glutamic pyruvic transaminase [SGPT]), aspartate aminotransferase (AST, formerly called serum glutamic oxaloacetic transaminase [SGOT]), and lactic dehydrogenase (LDH) are released by damaged liver cells. Elevations in these blood values in the absence of known trauma or heart muscle damage such as a heart attack are excellent indicators of liver damage.

Radiology

A flat-plate x-ray examination of the abdomen is usually the first diagnostic radiological procedure the physician orders. The flat-plate radiograph may show abdominal structures, abnormal masses, or blockage of normal bowel action. There is no patient preparation required.

Upper Gastrointestinal Series

An upper gastrointestinal (GI) series is usually ordered for patients complaining of nausea, vomiting, weight loss, or abdominal pain. These complaints are common for patients with liver, gallbladder, or pancreas disorders. The patient is allowed nothing by mouth (NPO) after midnight (or at least 8 hours) before the test. You should answer any patient concerns and explain that the patient will be asked to swallow a large amount of barium (a substance that is opaque on radiographs) during the procedure. The patient will be placed on an x-ray table, and radiographs will be taken in various positions and at various times during the procedure. The patient should understand that the procedure may take several hours depending on the rate at which the barium moves through the patient's gastrointestinal tract. A laxative such as Milk of Magnesia may be given after the procedure to aid in the evacuation of the barium.

Lower Gastrointestinal Series

A barium enema (BE, or lower GI series) may be ordered if the patient has reported any changes in bowel function, such as diarrhea or constipation, or blood or mucus in the stool. The patient is asked to eat a low-residue diet for 2 days before the scheduled procedure, then a clear liquid meal the night before. Fluids should be increased to prevent dehydration related to the preparation. The patient is made NPO after midnight before the test. Further, the patient is asked to use a powerful laxative such as bisacodyl (Dulcolax) or magnesium citrate (Citrate of Magnesia) to cleanse the bowel for more accurate x-ray views (Fig. 32–2). Enemas may also be ordered. Individual institutions' preparations may vary. Older patients may find the preparation routine especially taxing. Observe the patient often because defecation urgency, especially in unfamiliar surroundings, may create a fall risk.

TABLE 32-2 LABORATORY TESTS FOR LIVER, GALLBLADDER, AND PANCREAS DISORDERS

Test	Normal Range	Significance
Blood		
Alanine aminotransferase (ALT)	5–35 IU/dL	↑ in chronic liver failure and hepatitis
Albumin	3.1–4.3 g/dL	↓ in liver disease
Amylase	53–123 U/L	↑ in pancreatitis, gallstones
Ammonia	12–55 mol/L	↑ in chronic liver failure, hepatitis
Aspartate aminotransferase (AST)	8–20 units/L	↑ in chronic liver failure, viral hepatitis, acute pancreatitis
Bilirubin		
Total serum	0.1–1.0 mg/dL	↑ in liver and gallbladder disease with red blood cell destruction
Conjugated (direct)	0.0–0.4 mg/dL	↑ in gallbladder obstruction
Unconjugated (indirect)	0.1–1.0 mg/dL	↑ with red blood cell destruction or liver disease
Calcium	9–10.5 mg/dL	↓ with acute pancreatitis, liver disease, or malabsorption
Cholesterol	150–200 mg/dL	↑ in pancreatitis, gallbladder disease; ↓ may indicate severe liver disease
Lactic dehydrogenase (LDH)	110–250 IU/L	↑ in liver disease
Potassium	3.5–5.0 mEq/L	↓ with diarrhea, intestinal fistulas, vomiting, suctioning
Prothrombin time	11–12.5 s	↑ in liver disease, vitamin K deficiency
Urine		
Urine amylase	Depends on test	↑ in acute pancreatitis
Urine bilirubin	Negative	↑ in chronic liver failure, hepatitis, biliary obstruction
Urobilinogen	0.3–1.0 Ehrlich units in 2 h	↑ with destruction of red blood cells, hepatitis, chronic liver failure, obstructive jaundice
Feces		
Fecal fat	Negative	↑ in pancreatic disease
Occult blood	Negative	Positive in cancer, bleeding tendencies from ↓ vitamin K

Figure 32-2 (A) An image of a patient who was poorly prepared for a barium enema. (B) An image of a patient who was adequately prepared for a barium enema. (Courtesy Dr. Russell Tobe.)

During the procedure, barium is given by enema and the patient is asked to retain the barium while radiographs are taken. The patient may experience some abdominal cramping and an urge to have a bowel movement during the procedure. The patient is told to take slow, deep breaths and to tighten the anal sphincter. The rate of flow of the barium is slowed until the cramping diminishes.

After the procedure, instruct the patient to drink plenty of fluids. Administer a mild laxative as ordered to eliminate the barium, because barium left in the bowel tends to harden and become difficult to evacuate. The stool should be observed for complete evacuation of the barium to prevent an impaction. Stools will change from clay colored or white to their normal brown color when the barium is gone.

CRITICAL THINKING

Mrs. Pearl

Mrs. Pearl is a 95-year-old woman undergoing a lower GI series for complaints of abdominal pain. As her nurse, what concerns might you have for Mrs. Pearl as she undergoes this test? How can you address them?

Answers at end of chapter.

Oral Cholecystogram

An oral cholecystogram (gallbladder series) may be ordered if the physician suspects gallstones. The patient is asked to ingest a radiopaque dye that collects in bile in the gallbladder. The dye then shows up when the patient has an x-ray examination, showing the gallbladder, ducts, and any gallstones.

In preparation, the patient is asked to eat a high-fat diet for 2 days before the test, then a low-fat diet the day before the examination. Depending on agency protocol, the patient takes radiopaque tablets (usually six), the evening before the examination. Some agencies ask the patient to take the pills for two nights before the examination. The patient takes them with water about 5 minutes apart. The patient then has nothing by mouth after midnight before the examination. The radiopaque tablets contain iodine, so be sure to ask patients about any allergies to iodine or shellfish (which contain iodine). Also advise the patient that the tablets may cause diarrhea. The procedure will take about half an hour in the x-ray department.

Computed Tomography

A computed tomography (CT) scan may be ordered for any suspected abnormalities of liver, gallbladder, or pancreas functioning. The computer-enhanced radiographs may be taken with or without contrast medium. No patient preparation is necessary. Patients are told that they will be on a narrow, hard x-ray table that is closely surrounded by a noisy metal shell. Patients with fear of closed spaces may have to make arrangements for a CT scan at an “open” scanner. There are no follow-up care requirements.

Angiography

Intravenous cholangiography may be ordered for patients with symptoms of biliary obstruction or after a cholecystectomy. This examination permits the radiologist to see the gallbladder and biliary ducts by intravenously injecting a contrast medium, which then collects in these structures. The injection of contrast medium is done about 1 hour before the examination. Radiographs are taken about every 20 minutes for 1 hour or until the structures are readily viewed. The radiopaque material is iodine based, so ask the patient about any allergies to iodine. There are no follow-up care requirements after the procedure.

Liver Scan

A liver scan involves injecting a slightly radioactive medium that is taken up by the liver. An instrument is

passed over the liver that records the amount of material taken up by the liver and forms a composite “picture” of the liver. The physician may be able to determine tumors, masses, and abnormal size and patterns of blood vessel. The procedure takes a short time.

Endoscopy

The physician may order an endoscopic examination of the gastrointestinal tract for patient complaints such as bleeding or if cancer or obstruction is suspected. Endoscopic examination permits the physician to directly view the structures of portions of the gastrointestinal tract with an instrument that contains flexible optic fibers. In addition to viewing the structures, the physician can also remove polyps, take biopsy specimens, or coagulate bleeding sites that are identified.

Esophagogastroduodenoscopy

An **esophagogastroduodenoscopy** (EGD) is an endoscopic procedure that allows the physician to view the esophagus, stomach, and duodenum. The patient is asked not to take anything by mouth after about 8 P.M. the night before the examination. Because this is an invasive procedure, patients may be asked to sign an operative consent form, and a preoperative checklist may be necessary, depending on institution policy. Just before the procedure, the patient is asked to remove dentures. At the start of the procedure, the patient is given medication such as midazolam hydrochloride (Versed) or diazepam (Valium) for relaxation. Doses of the medications may be given at intervals during the procedure to keep the patient relaxed. The patient may be given atropine sulfate to dry secretions in the mouth. The physician usually sprays the back of the throat with a topical anesthetic to ease passage of the endoscope through the mouth and into the GI tract.

Follow-up care includes placing side rails up until the patient is fully alert. The patient is not given anything by mouth for up to 2 hours or until the gag reflex returns. The nurse checks the vital signs and gag reflex and observes the patient for any bleeding, complaints of pain, or signs of perforation such as abdominal pain, tenderness, or guarding.

Endoscopic Retrograde Cholangiopancreatography

Endoscopic **retrograde cholangiopancreatography** (ERCP) permits the physician to visualize the liver, gallbladder, and pancreas (Fig. 32–3). The procedure allows both direct viewing and use of contrast medium. An endoscope is passed through the esophagus to the duodenum, where dye is injected that outlines the pancreatic and bile ducts.

esophagogastroduodenoscopy: esophago—esophagus + gastro—stomach + duoden—duodenum + oscopy—to examine

retrograde cholangiopancreatography: retro—backward + grade—step + chol—bile + angio—via the vessels + pancreat—pancreas + ography—writing

Figure 32-3 Endoscopic retrograde cholangiopancreatography. (Modified from Watson, J, and Jaffe, S: *Nurse's Manual of Laboratory and Diagnostic Tests*, ed 2. FA Davis, Philadelphia, 1995, p 525, with permission.)

The patient is prepared for an ERCP in the same manner as for an EGD, with nothing by mouth after 8 P.M. the night before the examination. In addition, the patient is asked about allergies to iodine. Ensure that any ordered laboratory studies, such as a prothrombin time, have been done before the procedure and that the patient has removed dentures. Follow-up care is similar to an EGD. In addition, the nurse is alert to patient complaints such as increased right upper quadrant pain, fever, or chills, which may indicate infection. Hypotension, tachycardia or rapid heart rate, increasing RUQ pain, nausea, or vomiting may indicate perforation or the onset of pancreatitis. Report such findings immediately.

Ultrasonography

The use of high-frequency sound waves through the abdomen allows the physician to view soft-tissue structures. The sound waves reflect varying images based on the density of the soft tissues in the abdomen. The patient is asked not to take anything by mouth after midnight on the day of the examination. A clear gel is applied to the abdomen and to the transducer on the sonograph. The gel improves the conduction of sound waves and thus improves the images obtained. The transducer is placed on the skin and moved

over the abdomen while the technician views the sonograph screen and takes periodic pictures. The procedure takes about half an hour and requires no follow-up care.

Percutaneous Liver Biopsy

If less invasive tests do not aid in diagnosis of liver disease, a liver biopsy may be done. This may be done to identify cancer, cirrhosis, hepatitis, or other causes of liver disease. The physician generally inserts a needle through the skin and into the liver to withdraw a small sample for examination. This procedure places the patient at risk for bleeding, because the liver is highly vascular and because many patients with liver disease have faulty clotting ability.

Before the biopsy, ensure that the patient understands the procedure and that a consent has been signed if required by institution policy. You should also ensure that laboratory tests, such as a complete blood cell count and coagulation studies, have been completed and reviewed as ordered. The patient may be ordered nothing by mouth for 6 to 8 hours before the procedure. Baseline vital signs are taken, and a sedative is given if ordered.

During the procedure the nurse assists the physician to position the patient on his or her back or left side and assists the patient to hold very still while the needle is being introduced. The physician may also ask the patient to exhale and hold his or her breath during the needle insertion.

After the biopsy, the patient should remain on bedrest for 24 hours. The patient lies on the right side for the first 2 hours with a small pillow or rolled towel under the biopsy site to provide pressure and prevent bleeding. Vital signs and the site are monitored for signs of bleeding. The patient is advised to avoid coughing or straining. Analgesics are offered for comfort if ordered.

CRITICAL THINKING

Mr. Wozynski
 Mr. Wozynski is admitted with chronic liver failure and jaundice. What specific laboratory value can you expect to be elevated related to his jaundice? Mr. Wozynski's physician orders a liver biopsy. Why is it important for you to check Mr. Wozynski's laboratory reports before the procedure?
Answers at end of chapter.

REVIEW QUESTIONS

- Which of the following is a function of the liver?
 - Synthesis of plasma proteins
 - Elimination of carbohydrates
 - Concentration of bile
 - Secretion of cholecystokinin
- Which food is most likely to stimulate the release of bile?
 - Green beans
 - French fried potatoes
 - Coffee
 - Poached egg
- The enzymes of the pancreas are involved in the digestion of which foods?
 - Starch and fat
 - Starch, fat, and protein
 - Fat and protein
 - Starch and protein
- Which of the following complications should the nurse monitor for after a liver biopsy?
 - Nausea
 - Muscle twitching
 - Bleeding
 - Hypoventilation
- Which of the following nursing measures is most important after an upper or lower GI series?
 - Offer a laxative as ordered.
 - Place pressure on the puncture site.
 - Check for return of a gag reflex.
 - Keep the patient in semi-Fowler's position.
- Mr. Sikmiller returned an hour ago from an EGD and is asking for a glass of water. Which of the following responses is best?
 - "I'm sorry, Mr. Sikmiller, you will need to wait 4 hours before drinking anything."
 - "I can't give you any water; would you like some ice chips?"
 - "I will bring you some water and a laxative."
 - "Let me check your gag reflex first to make sure it is safe to drink water."

Answers to CRITICAL THINKING**Mrs. Pearl**

Mrs. Pearl is at risk for dehydration and electrolyte loss as a result of the laxative and enema preparation and NPO status. This risk is increased because of her age. Her fluid and electrolyte status should be monitored closely.

Mrs. Pearl will likely have a concern about "making it" to the bathroom during the preparation and should have a bedside commode placed within easy reach. Her call light should be answered promptly. If enemas are ordered "until clear," Mrs. Pearl will be at greater risk for fluid and electrolyte loss. If more than two or three enemas are required, the physician should be notified.

Elderly patients can become very fatigued during testing and test preparation. Mrs. Pearl should be allowed plenty of rest before and after the test. She may also have a concern about being able to hold the barium in her bowel during the test without having an "acci-

dent." She should be assured that the barium is held in with a balloon on the end of the enema catheter and that bathrooms are nearby.

Mr. Wozynski

You can expect to find that Mr. Wozynski's serum bilirubin is elevated because his liver is unable to convert or conjugate bilirubin into a water-soluble compound that can be eliminated in feces. Mr. Wozynski is at risk for bleeding because the liver is highly vascular and prone to bleed when a biopsy specimen is taken. In addition, he may not be manufacturing the necessary amount of prothrombin needed for blood clotting and is less likely to stop bleeding once the biopsy has been performed. It will be especially important to check his coagulation studies and report any elevations to the physician before the biopsy.

QUESTIONS TO GUIDE YOUR READING

1. How would you explain the causes, risk factors, and pathophysiology of the various types of viral hepatitis?
2. What is current medical treatment for patients with viral hepatitis?
3. What nursing care should you provide for the patient experiencing viral hepatitis?
4. What are the causes, risk factors, and pathophysiology of acute and chronic liver failure?
5. What is current medical treatment for acute and chronic liver failure?
6. What nursing care would you provide for patients with acute or chronic liver failure?
7. What are five common complications of chronic liver failure?
8. What is current medical treatment of patients with cancer of the liver?
9. What nursing care would you provide for patients with cancer of the liver?
10. What are the causes, risk factors, and pathophysiology of acute and chronic pancreatitis?
11. What is current medical treatment for acute and chronic pancreatitis?
12. What nursing care would you provide for patients with acute or chronic pancreatitis?
13. How would you explain the causes, prevention, medical and nursing treatment of cancer of the pancreas?
14. What are the causes, risk factors, and pathophysiology of cholecystitis and cholelithiasis?
15. What is current medical treatment for cholecystitis and cholelithiasis?
16. What nursing care would you provide for patients with cholecystitis and cholelithiasis?
17. What are the causes, prevention, complications, and medical treatment of cancer of the gallbladder?

► DISORDERS OF THE LIVER

Hepatitis

Hepatitis is an inflammation of the cells of the liver, usually caused by a virus. Less commonly, hepatitis may be caused by certain drugs or occasionally by bacteria. Symptoms of hepatitis range from nearly no symptoms to life-threatening symptoms from liver necrosis or death of liver tissue.

Pathophysiology

Hepatitis is usually caused by one of six viruses:

- Hepatitis A virus (HAV), sometimes called infectious hepatitis
- Hepatitis B virus (HBV), sometimes called serum hepatitis
- Hepatitis C virus (HCV), sometimes called non-A, non-B (NANB) hepatitis
- Hepatitis D virus (HDV)
- Hepatitis E virus (HEV)
- Hepatitis G virus (HGV)

The viral agents vary by mode of infection, incubation period, symptoms, diagnostic tests, and preventive vaccines (Table 33–1). The infecting organism causes inflammation of the liver, with resulting damage to liver cells and loss of liver function. If damage involves the bile canaliculi, obstructive jaundice will occur. If complications do not occur, cells regenerate and normal liver function eventually resumes.

There are approximately 60,000 new cases of hepatitis in the United States each year. The incidence of HAV increased nearly 27 percent in the mid-1980s and is the most common cause of hepatitis. HAV has a low mortality rate. However, HBV is more common among some groups, including health care workers and intravenous drug users; it has a mortality rate of about 5 percent. Hepatitis G virus is a recently discovered virus that is transmitted by blood transfusions and unprotected sex. It is not known to cause hepatitis.

Prevention

The hepatitis viruses are very resistant to a wide range of anti-infective measures, such as drying, heat, ultraviolet light exposure, freezing, and bleach and other disinfectants. At least 30 minutes in boiling water is required to guarantee their destruction. The best methods for preventing the transmission of the hepatitis viruses are careful attention to cleanliness and the use of vaccines such as immune serum globulin (ISG) or vaccines to HBV and HAV. Health care workers must use standard precautions at all times. Infection control precautions should reflect the usual mode of transmission of the particular hepatitis virus.

Immune serum globulin is a temporary, passive, nonspecific immunity to hepatitis. Permanent, active immunity is acquired from the body's own antibodies in response to ac-

tual viral infection. The active immunity is to the specific virus to which the body has developed antibodies. Vaccines to HBV are available and provide permanent, active immunity to HBV. Health care workers are strongly encouraged to be vaccinated for HBV. A vaccine for HAV has also been developed.

Public health measures such as health education programs, licensing and supervision of public facilities, screening of blood donors, and careful screening of food handlers are general measures to prevent the transmission of hepatitis viruses.

Signs and Symptoms

Hepatitis usually shows a typical pattern of loss of liver function. There are generally three stages in hepatitis:

1. The prodromal, or preicteric (prejaundice), stage lasts about 1 week. The patient complains of flulike symptoms of malaise, headache, anorexia, low-grade fever, and possibly dull right upper quadrant (RUQ) pain.
2. The icteric stage lasts 4 to 6 weeks. The patient complains of more severe fatigue, anorexia, nausea, vomiting, and malaise. The patient is also likely to have jaundice or noticeable yellowing of the skin, sclera of the eyes, and other mucous membranes. The liver is usually enlarged and tender on examination.
3. The posticteric, or convalescent, stage lasts from 2 to 4 weeks to months. The patient usually feels well during this time, but full recovery as measured by the return to normal of all liver function tests may take as long as 1 year.

Hepatitis is considered a reversible process if the patient complies with a medical regimen of adequate rest, good nutrition, and abstinence from alcohol or other liver-toxic agents. See Chapter 32 for a more complete discussion of jaundice.

Complications

Hepatitis may lead to fulminant or acute liver failure (see the following). About 5 percent of hepatitis patients progress to chronic liver failure. Some patients become asymptomatic carriers of the virus; HBV-infected carrier patients have a greater risk of developing cancer of the liver.

Diagnostic Tests

Serum liver enzymes are elevated. Serum bilirubin and urobilinogen may be elevated. The erythrocyte sedimentation rate is usually elevated from the inflammatory process. In patients with severe hepatitis, prothrombin time may be elevated (Table 33–2). Serological tests may be ordered to determine the specific virus causing the hepatitis. Each virus has specific antigen markers that serological study can reveal. The antigen markers can be further used to determine the degree of healing from the hepatitis. Abdominal x-ray examination may show an enlarged liver.

Medical Treatment

Medical treatment is aimed at providing rest and adequate nutrition for healing. There are no specific drugs or other

TABLE 33-1 COMPARISON OF TYPES OF VIRAL HEPATITIS

	Hepatitis A Virus	Hepatitis B Virus	Hepatitis C Virus	Hepatitis D Virus	Hepatitis E Virus
Mode of transmission	Oral-fecal contamination of water, shellfish, eating utensils, or equipment	Blood or body fluids such as saliva, semen, and breast milk; equipment contaminated by blood	Blood transfusions, IV drug use, unprotected sex	Blood or body fluids as with HBV; strongly linked as a coinfection with HBV	Usually, contaminated water
Incubation period	3–7 weeks	2–5 months	1 week to months	Same as HBV	2–9 weeks
Symptoms	Early (prodromal): fatigue, anorexia, malaise, nausea, or vomiting Icteric: jaundice, pale stools, amber or dark urine, RUQ pain	May have no early symptoms Early (prodromal): 1–2 months of fatigue, malaise, anorexia, low-grade fever, nausea, headache, abdominal pain, muscle aches Icteric: jaundice, rashes	Same as HBV, usually less severe	Similar to HAV and to HBV but more severe	Similar to HAV
Diagnostic tests	Elevated serum liver enzymes (ALT, AST), elevated serum bilirubin, HAV antigen	Elevated serum liver enzymes (ALT, AST), elevated serum bilirubin, HBV antigen	Elevated serum liver enzymes (ALT, AST), elevated serum bilirubin, HCV antigen	Elevated serum liver enzymes (ALT, AST), elevated serum bilirubin, HDV antigen	Elevated serum liver enzymes (ALT, AST), elevated serum bilirubin
Preventive vaccine	Immune globulin	Immune globulin or HBIG	None	HBIG	None
Groups at risk	Individuals in military or day care	IV drug abusers, homosexuals, healthcare workers, transplant and hemodialysis patients	Same as HBV	Same as HBV	Travelers to endemic areas

ALT = alanine aminotransferase; AST = aspartate aminotransferase; HBIG = hepatitis B immune globulin; IV = intravenous; RUQ = right upper quadrant.

TABLE 33-2 LABORATORY TESTS FOR HEPATITIS

Test	Normal Range	Significance
Alanine aminotransferase	5–35 IU/mL	Found in high concentration in liver cells; released with death of liver cells
Aspartate aminotransferase	8–20 U/L	Found in high concentrations in liver cells; released with death of liver cells
Erythrocyte sedimentation rate	Adult: Women, 1–20 mm/h Men, 1–13 mm/h	Increased with inflammation and tissue damage
Prothrombin time	8.8–11.6 s	Liver can no longer make prothrombin
Serological tests	Negative titer	Indicates exposure and probable infection with virus
Anti-HAV	Negative titer	Indicates exposure and probable infection with virus
Anti HBV	Negative titer	Indicates exposure and probable infection with virus
Anti-HCV		

medical therapies for hepatitis. Interferon therapy and antiviral medication may be used for hepatitis B or C, but they may not be effective. With proper rest and nutrition, the liver should recover.

Patients are restricted from any alcohol or drugs that are known to be toxic to the liver (Box 33-1). In addition, patients are generally placed on limited activity with bathroom privileges. Because the patient usually experiences malaise, fatigue, and anorexia, rest is advised. As the patient improves, activity may be increased if the patient does not become fatigued.

Nursing Process

ASSESSMENT. Assess the patient for subjective complaints such as malaise, fatigue, pruritus (itching), nausea, anorexia, and RUQ abdominal pain. Objective data, such as vomiting, pale stools, amber or dark-colored (tea-colored) urine, and jaundice, are recorded. The patient's vital signs are taken, and a low-grade fever or any abnormal bruising or bleeding is reported immediately.

BOX 33-1 Common Hepatotoxic Substances

Ethyl alcohol
 Acetaminophen (Tylenol)
 Acetylsalicylic acid (aspirin)
 Anesthetic agents
 Halothane (Fluothane)
 Diazepam (Valium)
 Erythromycin estolate (Ilosone)
 Isoniazid (INH)
 Methyldopa (Aldomet)
 Oral contraceptives
 Phenobarbital (Luminal)
 Phenytoin (Dilantin)
 Tranquilizers
 Chlorpromazine (Thorazine)
 Industrial chemicals
 Carbon tetrachloride
 Trichloroethylene
 Toluene

NURSING DIAGNOSIS. Common nursing diagnoses for the patient with viral hepatitis are as follows:

- Imbalanced nutrition, less than body requirements related to anorexia, nausea, or vomiting
- Risk for impaired skin integrity related to itching secondary to bilirubin pigment deposits in skin
- Pain related to inflammation and enlargement of the liver
- Risk for ineffective management of therapeutic regimen related to lack of knowledge of hepatitis and its treatment.

PLANNING. Major goals for the patient with viral hepatitis include that the patient will have adequate nutrition, describe pain and other discomforts as tolerable, and be able to self-manage the treatment regimen for viral hepatitis.

IMPLEMENTATION

Imbalanced Nutrition. The usual ordered diet is a high-calorie, high-protein, high-carbohydrate, low-fat diet. There are no restrictions on what the patient may eat, but the focus is to provide a well-rounded, nutritious diet. Give the patient antiemetic drugs as ordered. Provide larger meals earlier in the day because nausea tends to increase during the day. Place the patient in an upright or sitting position for meals to decrease abdominal discomfort. Serve meals in a quiet, pleasing environment without unpleasant noise or odors that may decrease appetite.

Risk for Impaired Skin Integrity. The physician may order an antihistamine to decrease the itching related to bilirubin pigment deposits in skin. Encourage the patient not to scratch, but to press firmly on the itching area. Encourage the patient to keep fingernails trimmed short so that vigorous scratching does not tear the skin. Maintain room temperature at a comfortable level to decrease perspiration, which may increase itching.

Pain. The physician may order analgesics to decrease the pain related to inflammation and enlargement of the liver. The analgesics are administered as ordered. The patient is evaluated frequently for abdominal pain and the extent of any RUQ tenderness.

Risk for Ineffective Management of Therapeutic Regimen. Teach the patient the necessity of proper home cleanliness, including handwashing after toileting and using soap and hot water to clean eating utensils, cookware, and food preparation surfaces. (See Home Health Hints.) Teach patients how hepatitis affects their body and the importance of adequate rest and proper nutrition. Teach the importance of avoiding alcohol and other liver-toxic drugs.

HOME HEALTH HINTS

- For patients with hepatitis, home health nurses are concerned with proper treatment to prevent transmission in the community and to prevent permanent liver damage to the patient.
- If possible, the patient should have a separate bedroom and bathroom. The person cleaning the bathroom should wear disposable gloves or rubber gloves and then clean the gloves with a 10-percent bleach solution. The family is advised to use liquid soap instead of bar soap.
- Contaminated linens should be washed separately from household laundry, in hot water. One cup of bleach should be added with the detergent to each load. Rubber gloves should be worn to wash the patient's laundry.
- Patients with abdominal ascites need a hospital bed at home so the patient can be positioned to aid in breathing. A physician's order must be obtained.
- The measurement of abdominal girth should be taken at each visit and recorded in the nurse's notes. The patient should weigh on the same scale, first thing in the morning, and record the weight so the nurse can document the findings.

EVALUATION. Management of the patient with hepatitis has been successful if the patient demonstrates the following:

- Maintenance of body weight to within 2 pounds of preillness weight
- No breaks, cuts, or tears on skin
- Abdominal pain or other discomfort reported as not greater than 2 on a 5-point scale
- The effects of hepatitis and the necessity of adequate rest, proper nutrition, and necessary sanitation measures can be stated

For more information, visit Hepatitis Foundation International at www.hepfi.org and the American Liver Foundation at www.liverfoundation.org.

Fulminant Liver Failure

Fulminant (acute) liver failure is an uncommon but gravely serious complication of liver disease and has a mortality rate as high as 50 percent.

Pathophysiology

Acute liver failure results from the sudden massive loss of liver tissue, or necrosis. The cause of liver damage is usually drug toxicity or HBV in the presence of HDV. The outcome

CRITICAL THINKING

Carl

Carl, a 23-year-old man, is admitted to a medical-surgical nursing unit. During the admission process, Carl talks about his trip to an African country as a missionary. He returned to this country 4 weeks ago. During his trip he sustained a serious laceration that required many sutures. Carl also mentions his fondness for seafood and that he has had several "feasts" that have included raw oysters. Carl states that since his return he has lost nearly 8 pounds, is nauseated, has frequent headaches, and tires easily. Carl also tells you that he is very irritable, which is different from his usual easygoing manner.

1. What information might lead you to suspect hepatitis A? Hepatitis B?
2. What precautions should be instituted for Carl until a diagnosis is made?
3. What nursing actions might you implement to help Carl improve his nutrition?
4. What medications should Carl avoid?
5. What information should be included in a discharge teaching plan for Carl?

Answers at end of chapter.

of the disease may be decided within 48 to 72 hours of diagnosis. Possible outcomes are reversal, need for transplantation, or death.

Etiology

Patients are usually admitted to the hospital with a diagnosis of viral hepatitis. Some patients are admitted through the emergency department with a diagnosis of drug toxicity.

Prevention

Acute liver failure may be avoided by eliminating exposure to hepatitis B or hepatotoxic, liver-damaging substances. Hepatitis B can be transmitted through body fluids, such as blood or semen from unprotected sex; intravenous drug use; and dialysis. See Box 33-1 for a list of hepatotoxic substances.

Signs and Symptoms

Signs and symptoms of the disorder include hepatic **encephalopathy**, or central nervous system dysfunction (discussed in detail in the section on chronic liver failure). The patient may suddenly lapse into extremely serious illness, starting with confusion and progressing to coma. In a matter of hours the liver shows a rapid reduction in size, a typical sign of onset of acute liver failure. In addition, there is a sudden elevation of liver enzymes, bilirubin, and prothrombin time. Marked elevation in the prothrombin time is an ominous sign.

Diagnostic Tests

Early diagnosis of acute liver failure is essential so that the process of organ procurement may begin. An otherwise

encephalopathy: encephalo—brain + pathy—disease

healthy patient may be a priority organ recipient depending on age and whether or not the patient is alcohol dependent.

Laboratory tests include the serum liver enzymes alanine aminotransferase (ALT) and aspartate aminotransferase (AST). Levels of ALT and AST may rise from 1000 mU/mL to as high as 4000 mU/mL. The serum bilirubin level is more than 2.5 mg/dL. Urobilinogen levels may be elevated. Serum potassium levels drop below 3.5 mEq/L. Blood glucose drops below 70 mg/dL. The prothrombin time is elevated above 25 seconds.

An abdominal x-ray examination may document the change in size of the liver.

Medical Treatment

Medical treatment is directed toward stopping and reversing the damage to the liver. An attempt is made to put the liver completely at rest. The patient is put on complete bedrest. All drugs are eliminated. Dialysis may be ordered if the liver damage is a result of an overdose of a hepatotoxic substance. The patient is ordered a high-calorie, low-sodium, low-protein diet. Lactulose, neomycin, magnesium citrate, or sorbitol may be given to decrease ammonia levels, but they are not always effective. (For information on how these drugs work, see the section on medical treatment for chronic liver failure.) The patient needs intensive amounts of supportive care. It may be possible to support the patient long enough to stabilize him or her for transplantation.

Complications

The patient with acute liver failure experiences metabolic alkalosis, hypokalemia, hypoglycemia, disruption of blood clotting, and possibly sepsis. Metabolic alkalosis is related to disruption of the urea production cycle and the resulting accumulation of bicarbonate. Patients with acute liver failure also experience electrolyte imbalances. The patient's kidneys excrete potassium rather than hydrogen ions in an attempt to correct the alkalosis. The patient usually has hypoglycemia from loss of glycogen stores in the damaged liver, impaired gluconeogenesis (the manufacture of glucose from other nutrients), and an elevated insulin level caused by the stress response. Further, blood clotting disorders that can lead to disseminated intravascular coagulation (DIC) develop when prothrombin time elevates.

Finally, the patient is at risk for sepsis because of poor white blood cell migration and other responses to infection. Sepsis, abscess formation, endocarditis, and meningitis account for nearly a quarter of the deaths from acute liver failure. Renal failure accounts for about 30 percent of deaths. Respiratory problems and hypotension also contribute to the deaths from acute liver failure. The patient progresses through encephalopathy to coma and death.

Nursing Process

Nursing care of the patient with acute liver failure is essentially the same as for the patient with terminal chronic liver failure, discussed next.

Chronic Liver Failure

Chronic liver failure is also called Laënnec's **cirrhosis**, or portal, nutritional, or alcoholic liver disease. Chronic liver failure is the tenth leading cause of death among the total population and is more common among men than women (Cultural Consideration Box 33–2).

BOX 33-2 CULTURAL CONSIDERATION

The incidence of liver disease is more common among Mexican-Americans. Risk factors include working in occupations such as mining, factories using chemicals, and farming using pesticides. Additionally, the use of alcohol is increased with the machismo of society, and cigarette smoking is common.

Egyptian-Americans may suffer from schistosomiasis, known as bilharziasis in Egypt. Schistosomiasis can lead to cirrhosis, liver failure, portal hypertension, esophageal varices, bladder cancer, and renal failure. Thus the nurse may need to screen newer Egyptian-American immigrants for this disease.

Alcohol use and abuse is common among African-American communities. For many it is a socially accepted behavior and carries little or no stigma. The mortality rate from cirrhosis of the liver among African-Americans is nearly twice that of European-Americans. The nurse needs to provide counseling, teaching the detrimental effects of alcohol, and work with African-American churches and community leaders to help prevent the detrimental effects of alcohol abuse.

Etiology

Chronic liver failure may be caused by chronic excessive alcohol ingestion, especially when excess alcohol is combined with a lack of dietary protein. Additional types of liver failure include postnecrotic, biliary, and cardiac.

- Postnecrotic liver failure may result from massive exposure to hepatotoxins or viral hepatitis.
- Biliary liver failure is caused by chronic inflammation and obstruction of the gallbladder and bile ducts.
- Cardiac liver failure is caused by chronic severe congestion of the liver from heart failure. The liver congestion causes death of liver cells from lack of nutrients and oxygen.

Pathophysiology

Chronic liver failure is a progressive disease. Healthy liver cells respond to toxins such as alcohol by becoming inflamed. The liver cells are infiltrated with fat and white blood cells and are then replaced by fibrotic tissue. As the disease progresses, more and more liver cells are replaced by fatty and scar tissue. The lobes of the liver are disrupted and the liver becomes hardened and lumpy. Early in the disease, the liver is enlarged, firm, and hard from the inflammatory process. Later, the liver shrinks and is covered with gray connective tissue.

cirrhosis: cirrh—orange yellow + osis—condition

Prevention

Chronic liver failure may be prevented by abstinence from alcohol, eating a balanced diet with adequate amounts of protein, and avoiding exposure to infections or hepatotoxic chemicals. Patients are advised that total abstinence from alcohol should be a lifelong goal.

Signs and Symptoms

Signs and symptoms of impaired liver function include malaise, anorexia, indigestion, nausea, weight loss, diarrhea or constipation, and dull, aching RUQ pain. The liver may be enlarged, firm, and tender. Bruising of the skin, bleeding gums, anemia, and jaundice, also known as icterus, may be present. Jaundice is a common finding with hepatitis. The patient's skin may be dry or contain abnormal pigmentation. The patient may complain of severe pruritus (itching). Laboratory values reflect progressive loss of liver function. As chronic liver failure progresses, signs and symptoms of increasing loss of liver function and complications related to the increasing loss of function develop.

Complications

Complications of chronic liver failure include **hepatorenal syndrome**, blood clotting defects, **ascites**, **portal hypertension**, and hepatic encephalopathy. Hepatorenal syndrome occurs in about one-third of liver failure patients. Symptoms of hepatorenal syndrome include oliguria without detectable kidney damage, reduced glomerular filtration rate (GFR) with essentially no urine output or less than 200 mL per day, and nearly total sodium retention. Hepatorenal syndrome is considered an ominous sign.

Figure 33-1 Portal hypertension. Obstruction of normal blood flow through the liver causes blood to back up into the venous system, leading to esophageal varices, splenomegaly, hemorrhoids, and caput medusae.

hepatorenal syndrome: hepato—liver + renal—kidneys + syndrome—group of symptoms

Blood clotting defects may develop because of impaired prothrombin and fibrinogen production in the liver. Further, the absence of bile salts prevents the absorption of fat-soluble vitamin K, which is essential for some blood clotting factors. Patients with chronic liver failure have a tendency to bruise easily and may progress to DIC or hemorrhage.

Ascites is an accumulation of serous fluid in the abdominal cavity. The fluid accumulates primarily because of low production of albumin by the failing liver. An insufficient amount of protein in the capillaries causes plasma to seep into the abdominal cavity. The accumulated fluid causes a markedly enlarged abdomen. The fluid may cause severe respiratory distress as a result of elevation of the diaphragm.

Portal hypertension is a persistent blood pressure elevation in the portal circulation of the abdomen. Liver damage causes a blockage of blood flow in the portal vein. Increased resistance from delayed drainage causes enlargement of the visible abdominal veins around the umbilicus (caput medusae), rectal hemorrhoids, enlarged spleen, and esophageal **varices** (Fig. 33-1). The most serious result of portal hypertension is bleeding esophageal varices (dilated veins). The walls of the esophageal veins are thin and tear easily. Varices usually develop from the fundus of the stomach upward and may extend into the upper esophagus. The blood-filled, thin-walled varices may tear easily from sudden excessive pressure, such as the intra-abdominal pressure that results from coughing, lifting, or straining, causing severe bleeding.

Hepatic encephalopathy is caused by the accumulation of noxious substances in the circulation. The failing liver is unable to make the toxic substances water soluble for excretion in the urine. Ammonia, a byproduct of protein metabolism, is most commonly the substance causing symptoms. Signs and symptoms of hepatic encephalopathy include progressive confusion; **asterixis**, or flapping tremors in hands caused by toxins at peripheral nerves; and **fetor hepaticus**, or foul breath caused by metabolic end products related to sulfur. Stages of hepatic encephalopathy are *early*, *stuporous and confused*, and *comatose*. Signs and symptoms of the stages are as follows:

- **Early:** The patient exhibits subtle changes in personality, fatigue, drowsiness, and changes in handwriting (the best assessment for the early stage).
- **Stuporous and confused:** The patient is often belligerent and irritable and develops asterixis, muscle twitching, and marked confusion.
- **Comatose:** The patient gradually loses consciousness and becomes comatose.

If toxic levels can be decreased and managed, the patient gradually regains consciousness. Hepatic encephalopathy represents end-stage liver failure and has a mortality rate as high as 90 percent once coma begins.

Diagnostic Tests

Liver serum enzymes, serum bilirubin, urobilinogen, serum ammonia, and prothrombin times are elevated (Table 33-3). Abdominal radiographs of patients with chronic liver failure

may be expected to show ascites and enlargement of the liver. An upper gastrointestinal (UGI) series may reveal esophageal varices or evidence of gastric inflammation or ulcers. If the patient is bleeding, other arterial radiological examinations may be done to locate the specific source of bleeding.

Liver scans may be done to show abnormal liver masses or thickening. The physician may order an esophagogastro-duodenoscopy (EGD) to detect any bleeding and to directly observe the esophagus, stomach, and duodenum. Small surface vessels that are bleeding can be treated by injection sclerotherapy during the EGD. The procedure uses sclerosing agents, which are chemical substances that cause the veins to inflame and scar shut.

The physician may do a liver biopsy to determine the extent and nature of the liver damage. Patients with chronic liver failure undergoing a liver biopsy need careful observation for bleeding after the procedure. (See Chapter 32.)

Medical Treatment

Medical treatment for chronic hepatic failure seeks to remove or to treat the underlying causes of the disease. In addition, medical treatment seeks to support liver regeneration and to treat the complications of liver failure.

Ascites is treated with diuretics, albumin infusions, and sodium restriction. Paracentesis is sometimes considered as

an emergency measure to remove accumulated abdominal fluid. Paracentesis is not commonly done because it removes serous fluid, which contains a large amount of albumin that the liver cannot easily replace. Ascites may be treated by the nonsurgical placement of a shunt between the portal and systemic venous systems, called a **transjugular intrahepatic portosystemic shunt (TIPS)**.

The purpose of the shunt is to sidetrack venous blood around the liver to the vena cava. Shunts are used for patients with severe respiratory compromise and are not as successful as originally hoped. Surgical shunts, sometimes called portacaval shunts, may be used to relieve portal hypertension (Fig. 33-2). When shunts are used, less venous blood circulates through the liver and fewer protein end

Figure 33-2 Transjugular intrahepatic portosystemic shunt. A stent is placed to shunt blood from the portal vein to the systemic circulation to divert blood flow around the diseased liver.

LEARNING TIPS

For complications of chronic liver failure, remember the mnemonic **CHEAP**:

- C—clotting disorders
- H—hepatorenal syndrome
- E—encephalopathy
- A—ascites
- P—portal hypertension

TABLE 33-3 LABORATORY TESTS FOR CHRONIC LIVER FAILURE		
Test	Normal Range	Significance
Blood		
Alanine aminotransferase	5–35 IU/mL	Found in high concentrations in liver cells; released with death of liver cells
Albumin	3.5–5.5 g/dL	Decreased because of impaired protein synthesis; edema and ascites may result
Ammonia	15–19 µg/dL	Increased because liver cannot metabolize protein end product; contributes to hepatic encephalopathy
Bilirubin	0.3–3.0 mg/dL	Increased from increased breakdown of red blood cells
Aspartate aminotransferase	8–20 U/L	Found in high concentrations in liver cells; released with death of liver cells
Prothrombin time	Adult: Women, 1–20 mm/h Men, 1–13 mm/h	Liver can no longer make prothrombin; patient bleeds easily
Urine		
Urobilinogen	<4.0 mg/24 h	Increased urine because of filtration of excessive bilinogen in blood

asterixis: a—not + sterixis—fixed position
fetor hepaticus: fetor—offensive odor + hepat—liver + icas—related to

transjugular intrahepatic portosystemic shunt: trans—across + jugular—jugular vein + intra—within + hepatic—liver + porto—portal (liver circulation) + systemic—systemic (circulation) + shunt—to divert

products are metabolized. For this reason, patients are put on a low-protein diet.

The medical goals for managing bleeding from esophageal varices are as follows:

- Stop the bleeding.
- Treat the fluid volume deficit caused by the bleeding.
- Prevent further fluid loss.
- Maintain fluid and electrolyte balance.

Bleeding varices are treated with vasoconstrictors such as vasopressin, with tamponade (direct pressure on the bleeding veins), or with emergency sclerotherapy to close the veins.

Tamponade is usually a temporary measure and is done with a multilumen esophagogastric tube such as the Sengstaken-Blakemore tube (Fig. 33–3). Other multilumen tubes such as the Minnesota tube may be used. The Sengstaken-Blakemore tube is inserted through the nose or mouth to the stomach. First the gastric balloon is inflated with 200 mL of air to secure the tube in its proper location. The esophageal tube is then inflated with 50 mL of air to produce tamponade. One to two pounds of traction may be applied to the tube. Occasionally the patient may wear a football helmet so that the tube can be secured to the face guard rather than putting pressure on the patient's nose. The Sengstaken-Blakemore tube is then connected to nasogastric suction.

Complications that may occur from the use of esophagogastric tamponade include (1) aspiration, (2) erosion of esophageal gastric mucosa, and (3) suffocation. With the balloons inflated, the patient cannot swallow saliva. Oral suction with a Yankauer catheter should be available. Sometimes a Salem sump tube is placed in the upper esoph-

agus before the esophageal balloon is inflated to drain secretions.

Inflation pressure of the esophageal balloon should be maintained between 20 and 25 mm Hg. Agency procedures should clearly state how long the tube may remain in place and how often (and for how long) the esophageal balloon should be deflated. The gastric balloon remains inflated at all times until the procedure is stopped.

If the gastric tube dislodges into the esophagus, the patient can be suffocated. Keep a pair of scissors at the bedside when esophagogastric tamponade is in progress. If the gastric balloon dislodges, cut the inflation ports of the gastric and esophageal balloons to allow quick release of air.

Unfortunately, recurrence of bleeding occurs in about 20 to 60 percent of patients after successful tamponade. With each new bleeding episode, the risk of mortality increases. Sclerotherapy may be undertaken to prevent recurrence of bleeding. Sclerotherapy can be done without general anesthesia, which is an advantage for the patient with a severely damaged liver. The procedure is usually done as part of an EGD while the patient is sedated with diazepam (Valium) or midazolam hydrochloride (Versed). A topical anesthetic is used. The varices are injected with a sclerosing agent that causes thickening and closing of the dilated vessels. The procedure usually takes about an hour. After the procedure the patient may complain of chest pain for up to 72 hours. Give the prescribed analgesics and monitor the patient for pain relief. Report severe pain unrelieved by the prescribed analgesic immediately because the patient may be experiencing an esophageal perforation or ulceration, which are complications of sclerotherapy.

Hepatic encephalopathy is treated by trying to remove the toxic waste material. Saline or magnesium sulfate ($MgSO_4$) enemas may remove some of the toxic waste. The enemas may be given to cleanse the bowel of the noxious substances. Neomycin, an intestinal antibiotic, may be given by mouth, nasogastric tube, or enema. The antibiotic inhibits ammonia formation by reducing colonic bacteria that change ammonium to ammonia. Lactulose may be given by mouth to reduce the pH of the intestine and to “trap” ammonia, allowing it to be excreted in the stool. Hepatic encephalopathy is also treated by restricting or eliminating dietary protein. In severe cases, dialysis may be considered to remove ammonia (Nutrition Notes Box 33–3).

Nursing Process for Acute and Chronic Liver Failure

ASSESSMENT. A complete history and physical assessment are done. Be alert to subjective symptoms of liver slowdown such as malaise, anorexia, indigestion, nausea, severe itching, and dull, aching RUQ pain. Assess the patient for objective evidence of liver problems, such as weight loss, diarrhea or constipation, and an enlarged, firm, and tender liver. Observe the patient for dryness and bruising of the skin, bleeding gums, anemia, jaundice, and any evidence of alterations in thought processes, such as confusion, disorientation, or inability to make decisions. Figure 33–4 shows a mind map for assessing a patient with chronic liver failure.

Figure 33-3 Balloon tamponade for bleeding esophageal varices. An esophageal balloon compresses bleeding vessels.

BOX 33-3

Nutrition Notes

Supplying Nutrients To Patients with Liver Disease

A registered dietitian may modify the diet daily for patients with liver disease. Usually these patients suffer from severe anorexia, often displaying their best appetites for breakfast. For early or mild disease, protein is encouraged to support healing; later in liver disease, protein is restricted. For esophageal varices, foods are soft, in addition to other restrictions. For liver failure, the following dietary considerations are necessary:

- Protein is restricted according to individual’s ability to metabolize it.
- Complete protein foods are selected to provide all the essential amino acids.
- Homogenized milk and eggs are offered because the fat is already emulsified, requiring less bile for digestion.
- Adequate carbohydrates are given to prevent the use of tissue protein for energy.

- Fluid and sodium are likely to be restricted if ascites is present.

Hepatic encephalopathy is associated with increased serum levels of ammonia and aromatic amino acids. Foods producing high ammonia levels may be restricted (e.g., chicken, salami, ground beef, ham, bacon, gelatin, peanut butter, potatoes, onions, lima beans, egg yolk, buttermilk, blue and cheddar cheeses). Vegetable proteins and special enteral feeding formulas (e.g., Hepatic-Aid II and Travasorb-Hepatic) containing branched-chain amino acids may be given in place of foods containing aromatic amino acids that interfere with formation of dopamine and norepinephrine.

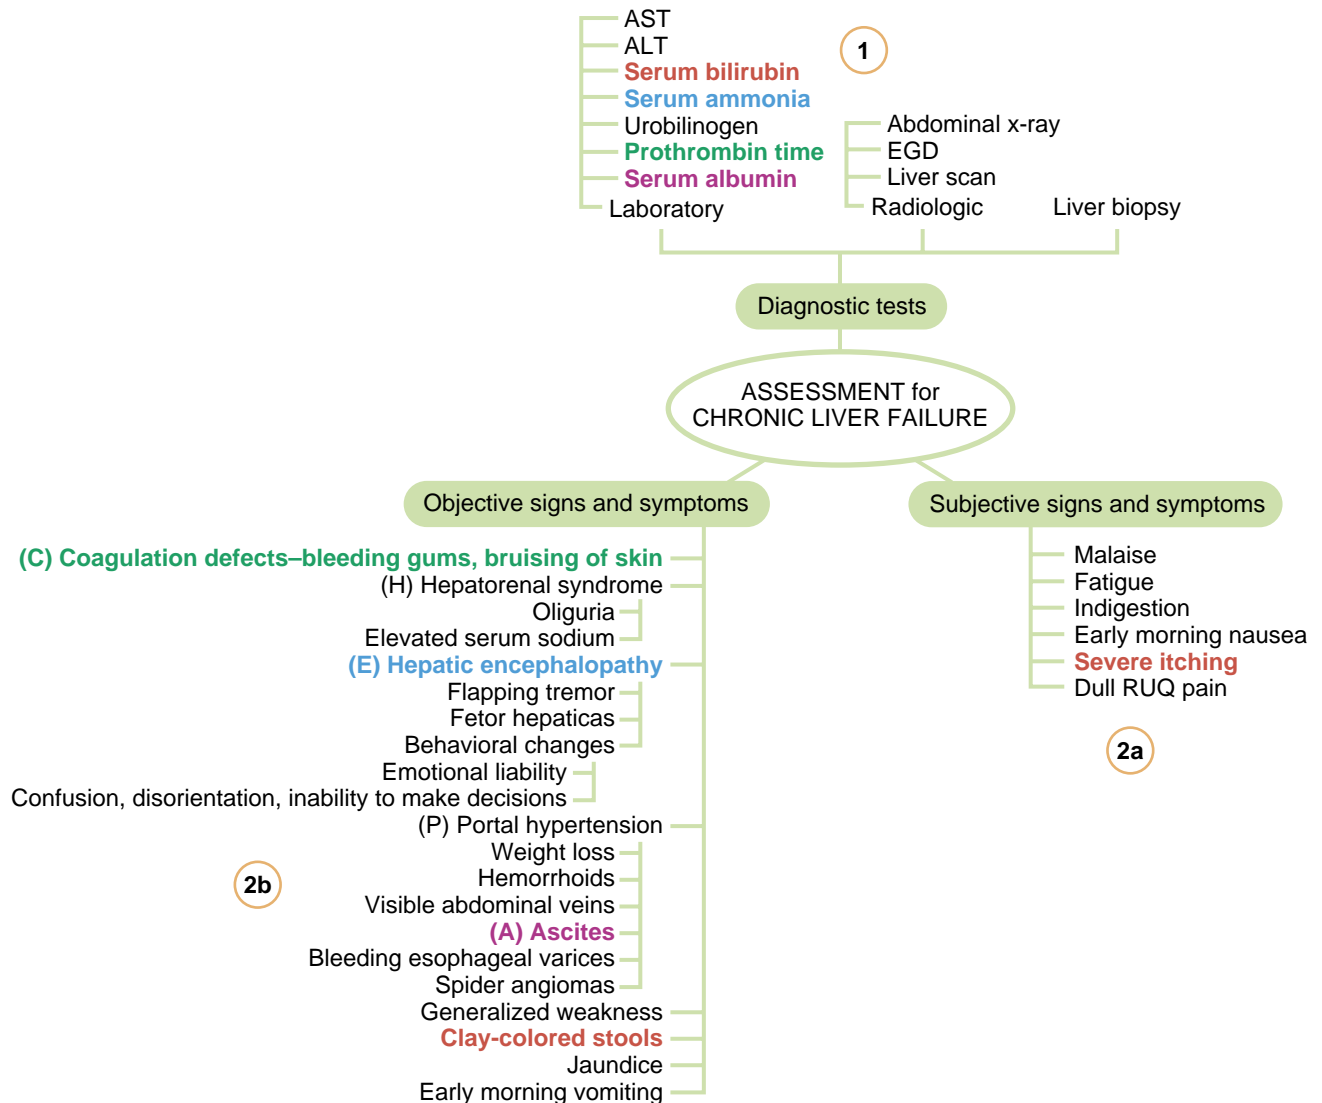

Figure 33-4 Mind map: Assessment of the patient with chronic liver failure.

NURSING DIAGNOSIS. Common nursing diagnoses for chronic liver failure include the following:

- Fluid volume excess related to portal hypertension (ascites)
- Imbalanced nutrition: less than body requirements related to disinterest in food
- Pain related to abdominal pressure
- Risk for disturbed thought processes related to elevated ammonia levels
- Risk for ineffective breathing pattern related to abnormal amounts of fluid in the abdomen
- Risk for deficient fluid volume related to bleeding (esophageal varices, clotting disorders)
- Risk for infection related to impaired immune responses

PLANNING. Major goals for the patient with liver failure include that the patient will experience no fluid excess or deficit, have adequate nutrition, be able to think clearly, breathe effectively, and be free of infection.

IMPLEMENTATION

Fluid Balance. Weigh the patient on admission to obtain a baseline weight. Measure and record the patient's weight and abdominal girth or circumference daily. Mark the place where you measured so the same site will always be measured during subsequent assessments. Report any weight gain or increase in girth promptly. Monitor the patient's low-sodium diet and maintain any ordered fluid restrictions. If intravenous fluids or albumin have been ordered, the assist in careful monitoring of the rate of infusion. Check the patient's vital signs every 4 hours, and report any evidence of difficulty breathing or changes in mental status promptly. Administer ordered diuretics as scheduled. Assist with a paracentesis as required.

Nutrition. The patient with chronic liver failure usually experiences anorexia in addition to impaired metabolism of needed nutrients. Assess the patient's bowel sounds, abdominal distention, and evidence of bleeding at least once every 8 hours. Report weight loss of more than half a pound from previous measurement. Monitor the patient's diet to ensure that any ordered protein restriction is carried out. Offer the patient frequent, small, high-calorie meals. If total parenteral nutrition (TPN) or tube feedings have been ordered, assist with the treatment and monitor the patient's response closely. Make sure that odors and other unpleasant stimuli are eliminated to prevent further worsening of appetite. Offer frequent mouth care. Administer vitamins or other medications as ordered.

Altered Thought Processes. Assess the patient's level of consciousness, speech, behavior, and neuromuscular function frequently. Neuromuscular function can be assessed by asking the patient to hold his or her arms out straight in front and steady. If asterixis, or liver flap, is present, the patient's hands will unwillingly dip and return to the horizontal position in a flapping motion. Look for changes in the patient's handwriting. Give lactulose, neomycin, magnesium citrate, or sorbitol as scheduled to decrease serum ammonia

levels. Be aware that lactulose causes loose stools, and do not hold the medication when the patient develops diarrhea. Question giving medications such as sedatives, narcotics, and tranquilizers that may increase the serum ammonia levels. Reorient the patient to time and place frequently. Give simple, clear explanations of care to the patient and give the patient time to understand the explanation. Provide a safe environment for the confused or unsteady patient.

Ineffective Breathing Pattern. Assess the patient's respiratory rate, rhythm, chest movement, and skin color frequently. Assist the patient in using an incentive spirometer and in coughing gently every 2 to 4 hours. Elevate the head of the patient's bed so that the patient's lungs have maximum room for expansion. Reposition the patient at least every 2 hours. Avoid suctioning the patient if possible because bleeding may occur. Make sure that oxygen and respiratory treatments are carried out as ordered, and that the patient is responding to the treatments as desired. Assist with a thoracentesis if required. Carry out patient care in an unhurried, quiet manner. Time care to allow the patient to rest and to avoid fatigue.

Safety. The patient with chronic liver failure is at risk for hemorrhage from bleeding esophageal varices, gastrointestinal bleeding, and lack of blood clotting factors. Assess gastric secretions, stool, and urine for blood at least every 8 hours. Monitor blood clotting laboratory studies such as the prothrombin time and report any abnormal values. Caution the patient to use a soft-bristle toothbrush and an electric rather than straight razor to avoid injury. Use a small-gauge needle for injections and apply direct pressure to all puncture sites to avoid bleeding. The patient should not eat hot, spicy, or irritating foods. The patient also should not cough or blow the nose forcefully, strain, vomit, or gag if at all possible. If bleeding occurs, assist with monitoring the patient receiving blood, blood products, and fluids. You may need to assist with esophagogastric tubes if needed. Administer vasopressin and vitamin K as ordered.

Infection. Observe the patient carefully for evidence of infection. Report any rise in temperature or sudden increase in pulse and respiratory rate. Carefully evaluate laboratory studies such as the white blood cell count. The white blood cell count may not elevate or may elevate slowly because the white cell activity is impaired. The earliest warning signs of infection may be subtle changes in the patient's behavior, such as sudden restlessness, an increase in confusion, or irritability.

PATIENT EDUCATION. Teach patients how chronic liver failure is affecting their bodies. In particular, patients need to know about portal system hypertension and hepatic encephalopathy. Patients and their families need to observe for and report any confusion, tremors, or personality changes. Teach patients to get adequate rest and to avoid strenuous activity. Instruct patients about a diet high in calories, low in sodium, and high in protein if hepatic encephalopathy has not developed. Patients should know to avoid narcotics, sedatives, and tranquilizers. Patients and

their families should know to promptly report any bleeding; any sign of low potassium, such as muscle cramps, nausea, or vomiting caused by diuretics; changes in mental status, such as confusion or personality changes; changes in weight; and any increase in current symptoms. The patient and the family should know that the patient must avoid alcohol. The patient should also know the importance of frequent follow-up care and laboratory studies.

EVALUATION. Successful management of the patient with chronic liver failure can be claimed if the patient demonstrates the following:

- No weight gain or increase in abdominal girth
- Maintenance of body weight
- Alert and oriented demeanor
- Respiratory rate between 16 and 20 respirations per minute with no cyanosis or changes in level of consciousness
- No bleeding, infection, or injuries
- Accurate knowledge of chronic liver failure and proper disease management requirements

CRITICAL THINKING

Mary

Mary, a 76-year-old retired business woman, has lived alone for the past 20 years, since the death of her husband. She has a long history of poor nutritional habits but does not use alcohol. During a recent visit to her physician, she was diagnosed with early chronic liver failure.

1. What risk factors does Mary have for chronic liver failure?
2. What symptoms would you expect Mary to exhibit with early chronic liver failure?
3. What values do you expect to see for serum albumin? Prothrombin time?
4. What are the two greatest concerns with portal hypertension?
5. What is the usual treatment for ascites?
6. What complication of esophageal tamponade requires that a pair of scissors be at the bedside at all times while tamponade is in progress?

Answers at end of chapter.

Transplantation

Patients with liver disease who do not respond well to medical or surgical treatment may be candidates for a liver transplant. Patients who have chronic liver failure from hepatitis or biliary disease, metabolic disorders, or hepatic vein obstruction may be evaluated for a liver transplant. In general, patients who have cancer are not considered for liver transplantation; the drugs used to suppress tissue rejection by the immune system may cause the cancer cells to grow at an increased rate.

The patient with end-stage liver failure who does not have hypertension, bleeding esophageal varices, infection, or severe cardiac disease is placed on a national list as a potential liver recipient. The patient must be as physically and

emotionally stable as possible (Cultural Consideration Box 33–4).

BOX 33-4 CULTURAL CONSIDERATION

Jewish law views organ transplantation from the recipient, the living donor, the cadaver donor, and the dying donor. If the recipient's life can be prolonged without considerable risk, transplant is ordained. For a living donor to be approved, the risk to the life of the donor must be considered. One is not obligated to donate a part of himself or herself unless the risk is small. This includes kidney and bone marrow donations. The use of a cadaver for transplant is usually approved if it is saving a life. The use of skin for burns is acceptable, although there is no agreement on the use of cadaver corneas. The nurse may need to help the Jewish patient contact a rabbi when making a decision regarding organ donation or transplantation.

After the surgical implantation of a donor liver, the patient must be closely observed for evidence of donor organ rejection. The patient is placed on drugs such as cyclosporine (Cyclosporin A), azathioprine (Imuran), and prednisone (Deltasone) to suppress the immune system responses to foreign protein or tissue rejection. Observe the patient for the following signs of impending rejection:

- Pulse greater than 100 beats per minute
- Temperature greater than 101° F (38° C)
- Complaints of RUQ pain
- Increased jaundice
- Decrease in bile from the T-tube or change in bile color

In addition, laboratory studies may show increased serum transaminases (ALT and AST), serum bilirubin, alkaline phosphatase, and prothrombin time. Symptoms of acute tissue rejection usually develop between the fourth and tenth postoperative days.

The patient who has received an organ transplant needs extended medical follow-up. Teach the patient to promptly report to the physician any symptoms of infection, bleeding episodes, or RUQ pain (Ethical Consideration Box 33–5).

Cancer of the Liver

Cancer of the liver is usually the result of metastasis from a primary cancer at a distant location. The liver is a likely area of involvement if cancer originated in the esophagus, lungs, breast, stomach, or colon. Patients with malignant melanoma may also have liver involvement. For some patients, liver cancer is the primary tumor site. Patients with a history of chronic hepatitis B, nutritional deficiencies, or exposure to hepatotoxins may develop cancer of the liver.

Symptoms of cancer of the liver include encephalopathy, abnormal bleeding, jaundice, and ascites. Laboratory tests show an elevated serum alkaline phosphatase. Radiological examinations may include abdominal radiographs or radioisotope scans, which show tumor growth. Liver cancer is definitively diagnosed with a positive needle biopsy combined with an ultrasonogram of the liver.

BOX 33-5 ETHICAL CONSIDERATION**Organ Transplantation**

Despite widespread public and medical acceptance of organ transplantation as a highly beneficial procedure, ethical questions remain. Whenever a human organ is transplanted, a large number of people are involved, including the donor, the donor's family, and medical and nursing personnel, as well as the recipient and the recipient's family. Society in general could also be added to this mix because of the high cost of organ transplantation that is usually borne directly by tax monies or indirectly in the form of increased insurance premiums. Each one of these persons or groups has rights that may conflict with others' rights.

Most institutions that perform transplants and organizations that are involved in obtaining organs, have developed elaborate, detailed, and involved procedures to help deal with the ethical and legal issues involved in transplantation. Despite these efforts, there are still some ethical issues that should be considered whenever the issue of organ transplantation is raised.

Despite the best efforts of the medical and legal community to establish criteria for death, there are still some ethical questions about when a person is really dead. Does brain death, the most widely accepted criterion for death, really indicate that a person no longer exists as a human being? Or are there other criteria that should be examined? Such organs as hearts, lungs, and liver must come from a donor with a beating heart. Might there not be the tendency to declare brain death before it actually occurs?

One of the most difficult ethical issues involved in organ transplantation is the selection of recipients. There are many fewer organs available than there are people who need them. Many potential ethical dilemmas arise from this fact. Should someone

receive an organ because he or she is rich or famous or knows the right people? The national organ recipient list attempts to list and rank all persons who need organs in a nondiscriminatory manner. Some of the important criteria include need, length of time on the list, potential for survival, prior organ transplantation, value to the community, and tissue compatibility.

Nurses can be and often are involved in some aspect of the organ donation process. Many states have passed laws that require health care workers to ask family members of potential organ donors if they have ever thought about organ donation for their dead or dying loved one. Many nurses, particularly nurses in critical care units, provide care for patients who are potential organ donors. Nurses in operating rooms may help in the surgical procedures that remove organs from a cadaver and that transplant them into a recipient's body. Many floor nurses provide postoperative care for patients who have received a transplanted organ. Home health care nurses provide follow-up care for these patients at home.

Nurses working with organ transplantation need to be sensitive to the potential for manipulation. Most people who are seeking organ transplantations are desperately ill or near death. They, and their families, can be very easily manipulated or can be very manipulating. On the other side, the families of potential organ donors are usually emotionally distraught because of the sudden and traumatic loss of a loved one. They too are very vulnerable to manipulation. As a general rule, neither the donor nor the donor's family should play any part in the selection of a recipient. Nurses must avoid making statements or giving nonverbal indications of approval or disapproval of potential recipients.

The patient with liver cancer may be a candidate for surgical removal of the affected portion of the liver. Care of the postsurgical patient is similar to other abdominal surgery patients. If surgery is not an option, the patient may receive chemotherapeutic drugs by injection directly into the affected lobe of the liver or into the hepatic artery. Intra-arterial injection of chemotherapeutic drugs has the advantage of being less toxic to the rest of the body. (See Chapter 10 for care of the patient receiving chemotherapy.)

► DISORDERS OF THE PANCREAS**Pancreatitis**

Pancreatitis is an inflammation of the pancreas; it may be mild or severe, acute or chronic. The two forms of pancreatitis have different courses and are considered two different disorders.

Acute Pancreatitis**Pathophysiology**

Inflammation of the pancreas appears to be caused by a process called autodigestion. For reasons not fully understood, pancreatic enzymes are activated while they are still within the pancreas and begin to digest the pancreas. In addition, large amounts of the enzymes are released by inflamed cells. As the pancreas digests itself, chemical cascades occur. Trypsin destroys pancreatic tissue and causes

vasodilation. As capillary permeability increases, fluid is lost to the retroperitoneal space, causing shock. In addition, trypsin appears to set off another chain of events that causes the conversion of prothrombin to thrombin, so that clots form. The patient may develop DIC. (See Chapter 24.)

Etiology

Pancreatitis is most commonly associated with excessive alcohol consumption. Alcohol appears to act directly on the acinar cells of the pancreas and the pancreatic ducts to irritate and inflame the structures. Biliary disease such as **cholelithiasis** (gallstones) or cholangitis (inflammation of the bile ducts) may also trigger pancreatitis. Gallstones may plug the pancreatic duct and cause inflammation from excessive fluid pressure on sensitive ducts. The irritant effect of bile itself may cause inflammation. Blunt trauma to the abdomen or infection may trigger the process by causing ischemia, inflammation, and activation of the pancreatic enzymes. Drugs such as thiazide diuretics (HydroDiuril), estrogen, and excessive serum calcium from hyperparathyroidism are less common causes of pancreatitis.

Elderly patients and patients with a first diagnosis of pancreatitis have a higher mortality rate. In addition, patients

cholelithiasis: chole—bile + lith—stone + iasis—condition

who have pancreatitis associated with biliary disease have a higher mortality rate than patients with alcohol-related pancreatitis.

Prevention

Caution patients who drink alcohol to stop. Patients with biliary disease need to seek medical treatment for these conditions so that pancreatitis does not develop as a complication. Monitor patients, especially the elderly, for any abdominal complaints when they are placed on a thiazide diuretic or estrogen therapy (Cultural Consideration Box 33–6).

BOX 33-6 CULTURAL CONSIDERATION

Pancreatic disease is more common among Mexican-Americans and Chinese-Americans. Risk factors include working in occupations such as mining, factories using chemicals, and farming using pesticides. The high use of alcohol and cigarette smoking add to the risk of pancreatic disease.

Signs and Symptoms

Patients with acute pancreatitis are very ill, with dull abdominal pain, guarding, rigid abdomen, hypotension or shock, and respiratory distress from accumulation of fluid in the retroperitoneal space. The abdominal pain is generally located in the midline just below the sternum, with radiation to spine, shoulders, or low back. The location and degree of pain indicate the area of the pancreas involved and to some extent the amount of involvement. For example, if the patient complains primarily of RUQ pain, the head of the pancreas is most likely involved. Respirations are likely to be shallow as the patient attempts to splint painful areas.

The patient may have a low-grade fever, dry mucous membranes, and tachycardia. If the primary cause is biliary, the patient may complain of nausea and vomiting, and jaundice may be evident. The islets of Langerhans in the terminal one-third of the pancreas are usually not impaired.

Complications

It may be useful to think of pancreatitis as a chemical burn to the organ. As with other severe burns, death is likely to occur from secondary causes. From the onset of symptoms, cardiovascular, pulmonary (including acute respiratory distress syndrome), and renal failure are the most likely causes of death. Hemorrhage, peripheral vascular collapse, and infection are also major concerns for patients with pancreatitis. A purplish discoloration of the flanks (Turner's sign) or a purplish discoloration around the umbilicus (Cullen's sign) may occur with extensive hemorrhagic destruction of the pancreas.

Diagnostic Tests

Serum amylase (normal: 56 to 190 IU/L) and serum lipase (normal: 0 to 110 U/L) may be elevated 5 to 40 times normal. The levels usually begin to drop within 72 hours.

Urine amylase elevates and stay elevated longer. Glucose, bilirubin, alkaline phosphatase, lactic dehydrogenase, ALT, AST, cholesterol, and potassium are all elevated. Decreases are measured in serum albumin, calcium, sodium, and magnesium.

X-ray examination may show pleural effusion from local inflammatory reaction to pancreatic enzymes, pulmonary infiltrates, or a change in the size of the pancreas. Computed tomography and ultrasonography can provide more complete information about the pancreas and surrounding tissues.

Medical Treatment

Medical treatment of acute pancreatitis depends on the intensity of the symptoms. Treatment is concerned with the maintenance of life support until the inflammation resolves. The physician orders intravenous fluids, such as crystalloid, electrolyte, or colloid (such as albumin) solutions, if the patient experiences hypovolemic shock. Blood or blood products may also be ordered if the patient has massive blood loss from hemorrhage.

The patient may be given antianxiety agents to decrease oxygen demand. The patient may require supplemental oxygen if abdominal pressure, pleural effusion, or acidosis cause a severe decrease in circulating oxygen.

The physician usually orders meperidine hydrochloride (Demerol) for pain. Pain and anxiety increase pancreatic secretion by stimulating the autonomic nervous system. Morphine sulfate, long thought to be contraindicated as an analgesic because it was believed to cause smooth muscle spasm in the biliary and pancreatic ducts, may also be ordered.

The patient is usually ordered to have nothing by mouth (NPO) to rest the gastrointestinal tract. Further, the patient may need to have a nasogastric tube inserted into the stomach and attached to low suction to empty gastric contents and gas. The physician usually orders histamine (H_2) antagonists such as ranitidine hydrochloride (Zantac) to prevent stress ulcers and to decrease acid stimulation of pancreatic secretion. If the NPO therapy is prolonged or if the patient is malnourished, the patient will receive TPN (Nutrition Notes Box 33–7).

BOX 33-7

Nutrition Notes

Nourishing the Patient with Pancreatitis

For acute pancreatitis the patient may be given ice chips made with electrolyte solutions to minimize gastric secretions and subsequent loss through the nasogastric tube. Nourishment is provided intravenously via TPN. If enteral feedings are started, an elemental formula that has been “predigested” may be selected.

In chronic pancreatitis the meal pattern is six small meals per day, beginning with clear liquids and progressing to a high-carbohydrate, low-fat diet. Medium-chain triglyceride (MCT) oil may be used because of its direct absorption. Vitamin supplements, including parenteral B_{12} , are commonly administered. An increase in serum amylase levels may necessitate the return to a more restricted diet.

Additional typical drug orders include sodium bicarbonate to reverse the acidosis caused by shock, electrolytes such as calcium and magnesium to replace losses, regular insulin to combat hyperglycemia, and antibiotics to treat sepsis.

Nursing Process

ASSESSMENT. Frequently measure and record vital signs (especially blood pressure and pulse), skin color and temperature, and urinary output. Monitor nausea and vomiting. Observe the patient for evidence of respiratory distress, such as restlessness, irritability, use of accessory muscles for breathing, or dyspnea. Evaluate the patient frequently for pain.

NURSING DIAGNOSIS. The most common nursing diagnoses for the patient with acute pancreatitis are as follows:

- Pain related to edema and inflammation
- Imbalanced nutrition: less than body requirements related to vomiting, pain, NPO, gastric suction
- Risk for ineffective breathing pattern related to abdominal pain and pressure
- Risk for injury related to disturbed blood clotting mechanisms and fluid and electrolyte imbalances

PLANNING. The nurse, the patient, and other members of the health team need to work together to develop a plan for achieving pain control, adequate nutrition, and prevention of cardiorespiratory complications.

IMPLEMENTATION

Pain. Administer analgesics as ordered. Evaluate the patient for pain at least every 2 hours initially. Advise the patient to sit in an upright or slightly forward-leaning position to decrease abdominal discomfort. Space nursing care activities to allow the patient to rest. Keep the patient's immediate surroundings quiet, restful, and free from anxiety-producing stimuli.

Imbalanced Nutrition: Less than Body Requirements. Weigh the patient regularly and evaluate laboratory tests such as serum albumin (normal: 3.5 to 5.5 g/dL) and other pancreatic function tests. If the serum albumin level drops below 3.2 g/dL, the physician may order intravenous albumin as replacement. Assess the patient at least every 8 hours for bowel sounds, nausea, and vomiting.

Monitor TPN therapy, including daily blood sugar results. Patients may be ordered to have blood glucose monitoring done every 6 hours. Administer regular insulin as ordered for elevated blood sugars.

Give histamine antagonists and antacids as ordered. If the patient has a nasogastric tube, record the amount and character of the drainage every 8 hours or according to agency policy.

The patient is usually slowly progressed to solid foods, starting with carbohydrate supplements through the nasogastric tube, then tube feedings with protein and fats as they are tolerated. Finally, bland, soft foods are ordered. Report any nausea, vomiting, or increase in complaints of abdominal discomfort immediately. Patients who progress too quickly may have a relapse of the pancreatitis.

Risk for Ineffective Breathing Pattern. Carefully observe the patient for signs of respiratory distress such as tachypnea, tachycardia, dyspnea, use of accessory muscles, or presence of abnormal breath sounds or crackles. Report evidence of poor oxygenation, including changes in mental status (e.g., irritability, confusion, or increasing sleepiness) promptly. Administer supplemental oxygen as ordered. Position the patient in an upright or slightly forward-leaning position. Good pain control enables the patient to breathe more effectively.

Risk for Injury. Assess the patient for evidence of disturbed electrolyte balance. Monitor laboratory values for sodium, potassium, calcium, and magnesium daily. Evidence of hypokalemia includes muscle weakness, diminished bowel sounds, apathy, and hypotension. Evidence of hypocalcemia includes nausea, vomiting, irritability, abdominal pain, and neuromuscular irritability. Neuromuscular irritability can be determined by Chvostek's sign. (See Chapter 5.) Assess the patient for evidence of abnormal bleeding. Observe the abdomen for Turner's and Cullen's signs. Evaluate the patient's vital signs for tachycardia, tachypnea, and hypotension, which may indicate bleeding. Initially, urinary output is measured hourly using a urometer. Urine output should be greater than 30 mL/h. Report any evidence of bleeding, such as a urinary output of less than 30 mL/h or frank bleeding, promptly. Assist with monitoring the administration of volume replacement solutions or blood infusions as ordered.

PATIENT EDUCATION. Teach the patient about pancreatitis. The patient needs to know the treatment regimen and the reason for slow dietary progression from NPO to a normal diet. Teach that rest is a vital part of the treatment plan and that gradual progression to full activities is normal. The patient must exercise moderation in food, exercise, and alcohol ingestion to decrease the risk of future episodes of pancreatitis.

If the pancreatitis is the result of chronic excessive alcohol ingestion, arrange to have the patient counseled about abstinence from alcohol. Refer the patient and family to support organizations such as Alcoholics Anonymous. For more information, visit Alcoholics Anonymous at www.alcoholics-anonymous.org.

EVALUATION. The plan of care for the patient with acute pancreatitis has been successful if the patient demonstrates the following:

- Pain of 2 or less on a scale of 0 to 5
- Weight loss of less than 5 percent of total body weight
- Respirations 16 to 20, unlabored, regular
- No elevated temperature
- No abnormal bruising
- No restlessness
- Urinary output greater than 30 mL/h
- Blood pressure within 5 percent of baseline

See Nursing Care Plan Box 33–8 for the Patient with Acute Pancreatitis.

BOX 33-8 NURSING CARE PLAN FOR THE PATIENT WITH ACUTE PANCREATITIS**Pain related to edema and inflammation****PATIENT OUTCOME**

Patient experiences an increase in comfort as evidenced by statement of pain level less than 2 on a scale of 0 to 5.

EVALUATION OF OUTCOME

Does patient state pain level is less than 2 on a pain scale of 0 to 5?

INTERVENTIONS

Assess the patient every 2 hours for pain by

Asking the patient to rate pain on a scale of 0 to 5.

Observing the patient for acute pain behaviors such as grimacing, irritability, reluctance to move, or inability to lie quietly.

Administer analgesics as ordered.

Assist the patient to a position of comfort, usually high Fowler's or leaning forward slightly.

Keep the environment free from excessive stimuli.

Teach the patient alternative pain control strategies such as guided imagery and relaxation techniques.

RATIONALE

Intense pain is likely to occur with acute pancreatitis.

A pain scale allows for a consistent and individual evaluation of pain.

Observation of acute pain behaviors, such as reluctance to move, shallow respirations, grimacing, or irritability, may be a reliable indicator of pain. Some patients with pain may deny their discomfort. However, the patient in pain may have no observable pain behaviors. Analgesics are most effective if given before pain becomes too great.

Upright position keeps abdominal organs from pressing against the inflamed pancreas.

Quiet, restful, anxiety-free atmosphere permits the patient to relax and may decrease pain perception.

Successful use of pain control strategies may decrease the amount of analgesics needed and give the patient a greater sense of control.

EVALUATION

Does patient state that pain is less than 2 on a pain scale of 0 to 5, where 0 = no pain and 5 = worst possible pain?

Does patient exhibit pain behaviors that differ from his or her report of pain?

Are analgesics effective?

Does positioning promote comfort?

Does patient state atmosphere is relaxing?

Are alternative strategies effective?

Altered nutrition: less than body requirements related to pain, medical restrictions (NPO), and treatment (suction)**PATIENT OUTCOME**

Patient will experience improved nutrition as evidenced by stable weight, albumin greater than 3.5 g/L.

EVALUATION OF OUTCOME

Is weight stable? Is albumin level greater than 3.5 g/L?

INTERVENTIONS

Assess the patient's nutritional status by

Weighing the patient every other day.

Checking serum albumin levels on laboratory studies.

Auscultating for bowel sounds.

Observing for nausea or vomiting.

Monitoring blood sugar at least every 6 hours if the patient is on TPN.

Observing for diarrhea, bloating, or steatorrhea (fatty stools).

Administer nutritional supplements, including pancreatic enzymes, as ordered.

Teach the patient to avoid alcohol.

Teach the patient and family the signs and symptoms of diabetes mellitus.

RATIONALE

A loss of 1 lb of body weight occurs when the body uses 3500 calories more than is taken in.

Serum albumin of 3.5–5.5 g/L indicates normal protein metabolism in the absence of liver or renal disease.

Nausea, vomiting, and pain are risk factors for inadequate intake.

Patients on TPN are more likely to have high blood glucose.

Diarrhea, bloating, or fatty stools may indicate malabsorption syndrome.

Provides adequate nutrition.

Alcohol may trigger another episode of pancreatitis.

Patients with pancreatitis are at great risk for developing diabetes mellitus, which also causes high blood glucose levels.

EVALUATION

Has patient lost less than 5% of total baseline body weight? Is patient's albumin below 3.5 g/dL?

Does patient have sufficient energy and strength to carry out activities of daily living?

Does patient take any supplements?

Does patient verbalize understanding of importance of avoiding alcohol?

Does patient verbalize signs and symptoms of diabetes to report?

Continued

BOX 33-8 NURSING CARE PLAN FOR THE PATIENT WITH ACUTE PANCREATITIS—CONT'D

Teach the patient and family to self-monitor for symptoms of malabsorption syndrome, such as fatty stools, weight loss, dry skin, or bleeding.

Absence of pancreatic enzymes causes problems with digestion of fats, carbohydrates, and proteins.

Does patient verbalize understanding of symptoms of malabsorption to report?

Risk for ineffective breathing pattern related to abdominal pressure and pain

PATIENT OUTCOME

Patient has an effective breathing pattern as evidenced by unlabored respirations, 16–20 per minute.

EVALUATION OF OUTCOME

Are respirations unlabored, 16–20 per minute?

INTERVENTIONS

Assess the patient's breathing patterns:

- Observe respirations for depth, regularity, and rate.
- Observe respiratory effort.

Observe for evidence of respiratory distress, such as use of accessory muscles, use of intercostal muscles, and rapid or difficult breathing.

Administer oxygen as ordered.

Place the patient in an upright or slightly forward-leaning position.

Prepare the patient's food by opening cartons and lids. Cut food into bite-size portions.

Teach the patient to move slowly and to take frequent rests.

RATIONALE

Abdominal pressure from inflammation and tissue damage under the diaphragm may cause the patient to take shallow, rapid respirations, which can tire the patient.

Abdominal pressure can force the use of additional muscles to aid in breathing.

Oxygen can decrease the amount of effort the patient must expend to breathe.

Relieves pressure on the diaphragm.

Decreases the demand for oxygen.

Helps decrease the demand for oxygen.

EVALUATION

Are patient's respirations 16–20 per minute, unlabored, and regular? Is patient alert and oriented? Has there been a change in the level of patient's arousal?

Does patient exhibit signs of distress?

Does oxygen help patient breathe easier?

Is positioning effective?

Does patient accept assistance with food preparation?

Does patient tolerate activity?

Risk for injury related to disturbed blood clotting mechanisms, fluid, and electrolyte imbalances

PATIENT OUTCOME

Patient experiences no injury.

EVALUATION OF OUTCOME

Is there evidence of injury? Are signs and symptoms of impending injury recognized and reported early?

INTERVENTIONS

Assess the patient's fluid, electrolyte, and blood clotting mechanisms by

- Monitoring laboratory values of sodium, potassium, calcium, and magnesium daily.
- Evaluating neuromuscular status by checking Chvostek's sign.
- Monitoring the patient's hematocrit, hemoglobin, and blood clotting times frequently.
- Observing abdomen and flanks for Cullen's and Turner's signs.
- Weighing the patient daily.
- Measuring and recording intake and output every shift.
- Observing for nausea and vomiting.

RATIONALE

Sodium, potassium, calcium, and magnesium need to be replaced.

Patients are likely to bleed.

Patients may lose fluids because of nausea, vomiting, diarrhea, and hemorrhage.

EVALUATION

Does patient have any abnormal bruising, bleeding gums, or pink urine? Is urinary output greater than 30 mL/h? Is patient's blood pressure within 5% of baseline? Do laboratory studies show that patient's electrolyte, hemoglobin, hematocrit, and blood clotting values are within acceptable ranges?

BOX 33-8 NURSING CARE PLAN FOR THE PATIENT WITH ACUTE PANCREATITIS—CONT'D

Report any drop in blood pressure greater than 5% of the patient's baseline.	May indicate severe fluid loss.	Are vital signs stable?
Monitor TPN and report any difficulties.	TPN must not be stopped abruptly. Patient's blood glucose may drop sharply.	Are blood glucose levels stable?
Teach the patient to report any weakness or muscle twitching.	May indicate electrolyte imbalance.	Does patient verbalize understanding of signs and symptoms of electrolyte imbalance to report?

CRITICAL THINKING**Mrs. Samuels**

Mrs. Samuels, an 85-year-old retired librarian, is admitted to the nursing unit from the emergency department with severe mid-epigastric pain that radiates to her back. On admission, she is noted to have guarding of the abdomen, and the abdomen is full and tense. Her medical record documents that she had an endoscopic retrograde cholangiopancreatograph 2 days ago for recurrent episodes of RUQ abdominal pain. She has no history of excessive alcohol intake.

1. What is the most common cause of acute pancreatitis? Does Mrs. Samuels fit the description?
2. Why do patients such as Mrs. Samuels have difficulty breathing?
3. Why is Mrs. Samuels at risk for hemorrhage?
4. What laboratory test is most likely to be abnormal in early acute pancreatitis?
5. Why are narcotics commonly ordered for acute pancreatitis?
6. Why does the physician usually order a histamine antagonist?

Answers at end of chapter.

Chronic Pancreatitis

Chronic pancreatitis is continuing pancreatic cellular damage and decreased pancreatic enzyme functioning usually following repeated occasions of acute pancreatitis.

Pathophysiology

Chronic pancreatitis is a continuous, progressive disease that replaces functioning pancreatic tissue with fibrotic tissue as a result of inflammation. Toxins from alcohol irritate the pancreatic ducts. The ducts become obstructed, dilated, and finally atrophied. The acinar or enzyme-producing cells of the pancreas ulcerate in response to inflammation. The ulceration causes further tissue damage and tissue death, and it may cause cystic sacs filled with pancreatic enzymes to form on the surface of the pancreas. The pancreas becomes smaller and hardened, and progressively smaller amounts of the enzymes are produced.

Etiology and Incidence

The major cause of chronic pancreatitis in men is excessive alcohol ingestion that causes repeated attacks of acute pancreatitis. The major cause in women is chronic obstructive biliary disease that leads to persistent inflammation of the pancreatic ducts. Other conditions known to cause chronic pancreatitis are prolonged malnutrition, cancer of the pancreas or duodenum, and prolonged use of enteral feedings, which can cause atrophy of the pancreas. The usual age for chronic pancreatitis to develop is between ages 45 and 60. The patient's mean life span is 25 years after the diagnosis of chronic pancreatitis is made. Death is often not related to pancreatic failure.

Prevention

Advise patients with an episode of acute pancreatitis from excessive alcohol ingestion that abstinence could prevent recurrence of the pancreatitis and prevent the possibility of chronic pancreatitis. Advise all patients with obstructive biliary disease to seek medical treatment for their condition to prevent the progression from acute to chronic pancreatitis. Carefully monitor patients who are unable to feed themselves for nutritionally adequate diets. Monitor routine laboratory values. Report any trend toward reduced functioning of the pancreas.

Signs and Symptoms

The signs and symptoms of chronic pancreatitis are less severe than acute pancreatitis but more long term. The patient's history will show a pattern of remissions and exacerbations over a period of years. The patient will complain of epigastric or LUQ pain, weight loss, and anorexia. Malabsorption and fat intolerance occur late in the disease. Usually the islets of Langerhans function until late stages of the disease, so diabetes mellitus is a late-occurring symptom.

Complications

Complications of chronic pancreatitis include the development of abscesses or fistulas, malabsorption syndrome, and diabetes mellitus. Abscesses and fistulas may develop when cysts filled with pancreatic enzymes burst into the abdominal cavity, causing severe inflammation and tissue necrosis. Pleural effusion may develop from inflammation just under the diaphragm. Malabsorption syndrome with fatty stools and diarrhea may develop in response to the

limited amount of pancreatic enzymes produced. In addition, biliary obstruction may further complicate fat absorption. Pancreatic enzymes are essential for normal absorption of nutrients from the intestines. As the terminal third of the pancreas becomes involved and the islets of Langerhans are destroyed, the patient exhibits the classic pattern of insulin-dependent diabetes mellitus (discussed in Chapter 38).

Diagnostic Tests

Serum amylase (normal: 59 to 190 U/L) and serum lipase (normal: 0 to 110 U/L) levels are lower than normal. Fecal fat analysis shows higher than normal amounts of fat.

Both computed tomography and ultrasonography show characteristic pancreatic structural changes such as masses, calcification of ducts, cysts, and change in pancreatic size. Endoscopic retrograde cholangiopancreatography (ERCP) can locate specific obstructions and detect ductal leaks.

Medical Treatment

Medical treatment is aimed at promoting comfort and maintaining adequate nutrition. Pain is managed with analgesics. Nutrition is improved with the careful replacement of pancreatic enzymes and specially prepared nutritional supplements.

Surgery may be necessary to repair fistulas, drain cysts, or repair other damage. In some cases, ducts or sphincters may be surgically repaired. In other instances, part or all of the pancreas may be removed.

Nursing Process

ASSESSMENT. Perform frequent thorough assessments for pain. Weigh the patient frequently. Monitor laboratory values to determine the adequacy of nutrition, including serum albumin (normal: 3.5 to 5.5 g/dL) and blood glucose levels.

NURSING DIAGNOSIS. Common nursing diagnoses for the patient with chronic pancreatitis include the following:

- Pain related to edema and inflammation
- Imbalanced nutrition: less than body requirements related to inability to absorb nutrients

PLANNING AND IMPLEMENTATION

Pain. Determine with the patient what events and patterns cause or help the pain. Attempt to determine how pain is affecting the patient's eating habits and lifestyle. Administer analgesics as ordered. The patient may have chronic pain with periodic episodes of severe acute pain. The possibility exists that the patient may develop dependence on the analgesic agent. The nurse can best help by careful assessment of the patient so that medication regimens can be tailored to the patient's need.

Imbalanced Nutrition: Less Than Body Requirements. Weigh the patient daily. Administer nutritional supplements, including pancreatic enzymes, as ordered. Administer histamine antagonists or antacids as ordered. Monitor

the patient's blood sugar and observe the patient carefully for evidence of diabetes mellitus. The patient with less than adequate amounts of insulin exhibits excessive thirst, frequent urination, hunger, and weight loss. (See Chapter 38 for management of the patient with diabetes mellitus.) Further, observe the patient for diarrhea, bloating, or **steatorrhea** (fatty stools). Report any evidence of continuing difficulty with digestion immediately.

PATIENT EDUCATION. Counsel the patient to avoid alcohol. Give the patient and family the warning signs and symptoms of diabetes mellitus. Teach the patient to monitor for malabsorption syndrome. The patient should check for fatty stools, report any weight loss, and report any evidence of vitamin A, D, E, or K deficiencies. Vitamin A deficiency may be evidenced by dry, scaly skin or changes in skin pigment. Vitamin D deficiency may be detected by patient complaints of bone pain. Vitamin E deficiency may be associated with anemia. Vitamin K deficiency can be detected from abnormal bruising or bleeding and prolonged clotting time. The patient should know that sudden increases in abdominal pain, increased difficulty breathing, or radiating back pain may indicate development of pancreatic cysts, abscesses, or fistulas and should be reported promptly.

EVALUATION. The plan of care for the patient with chronic pancreatitis is successful if the patient exhibits the following:

- Pain that is no more than 2 on a pain scale of 0 to 5
- No weight loss or gain of more than half a pound per week
- No diarrhea or steatorrhea
- Ability to state signs and symptoms of diabetes mellitus to report
- Ability to state signs and symptoms of pancreatic cysts, abscesses, or fistulas to report

Cancer of the Pancreas

Cancer of the pancreas is the fifth leading cause of cancer death in the United States, killing more than 20,000 people each year. More than 25,000 new cases of cancer of the pancreas are diagnosed yearly; it most often affects people between ages 65 and 79. About 70 percent of cancers of the pancreas occur in the head of the pancreas. About 30 percent of cancers are located in the body and tail of the pancreas.

Pathophysiology

Most primary tumors of the pancreas are ductal adenocarcinomas and occur in the exocrine parts of the pancreas. The tumors in the head and body of the pancreas tend to be large. Cancer of the pancreas spreads rapidly by direct extension to the stomach, gallbladder, and duodenum. Cancer located in the body of the pancreas usually spreads further and more rapidly than do masses in the head. Cancer of the pancreas may spread by the lymphatic system and through the vascular system to distant organs and lymph nodes.

Etiology

The cause of cancer of the pancreas is not known. Cancer of the pancreas has been associated with chemical carcinogens such as high-fat diets and cigarette smoking, diabetes mellitus, excessive alcohol intake, and chronic pancreatitis. It may also occur as a result of metastasis from a primary cancer of the lung, breast, kidney, or thyroid gland or malignant melanomas of the skin.

Signs and Symptoms

The patient with cancer of the pancreas usually complains of vague symptoms early in the disease process. Weight loss, pain, anorexia, nausea, vomiting, and weakness are among the vague early symptoms. Detection is often difficult because of the nonspecific complaints offered by the patient. The patient may complain of abdominal pain that is often worse at night. The pain is described as gnawing or boring, and it radiates to the back. The pain may be lessened by a side-lying position with the knees drawn up to the chest or by bending over when walking. The pain becomes increasingly severe and unrelenting as the cancer grows.

The patient may complain of a bloated feeling or fullness after eating. If the cancer obstructs the bile duct, the patient may have jaundice, dark urine, pruritus, and light-colored stools. The patient often complains of fatigue and depression. The patient's health history may include a recent diagnosis of diabetes mellitus.

Complications

Complications may occur before or after surgical treatment. Preoperative complications include malnutrition, spread of the cancer, and gastric or duodenal obstruction. Postoperative complications include infection, breakdown of the surgical site, fistula formation, diabetes mellitus, and malabsorption syndrome. If the patient has chemotherapy or radiation therapy, complications specific to those therapies may also occur.

Thrombophlebitis is a common complication of cancer of the pancreas. As the tumor grows, byproducts of the tumor growth appear to increase the levels of thromboplastic (clotting) factors in the blood, making clotting easier. The potential for thrombophlebitis increases if the patient is confined to bed or has surgery.

Diagnostic Tests

Serum amylase, lipase, alkaline phosphatase, and bilirubin levels are elevated. Blood coagulation tests, such as clotting time, may be done. Carcinoembryonic antigen (CEA) may be ordered to confirm the presence of cancer (normal: less than 5 ng/mL).

Abdominal radiographs may be ordered to determine the size of the pancreas and the presence of masses. Computed tomography and ultrasonography may be done to more precisely locate any masses in the pancreas. ERCP may be done to visualize the common ducts and to take tissue samples for microscopic analysis.

A tissue sample may be obtained by needle aspiration during ultrasonography. This procedure may cause seeding of the tumor along the needle pathway.

Medical Treatment

Medical treatment depends on the staging of the cancer. If diagnosed early, treatment may be aimed at cure. If the patient's cancer has progressed to distant involvement of other organ structures and lymph nodes, treatment is directed at easing symptoms, thus making the patient more comfortable.

Surgery may include a total or partial **pancreatectomy** or removal of all or part of the pancreas. Whipple's procedure is done to remove the head of the pancreas, parts of the stomach nearby, the lower portion of the common bile duct, and the duodenum (Fig. 33-5). Sometimes the gallbladder is also removed. Potential postoperative problems after Whipple's procedure include failure of the suture lines to hold, causing leakage of pancreatic enzymes and bile into the abdomen; pneumonia or atelectasis from shallow breathing because the incision line is directly under the diaphragm; paralytic ileus; gastric retention or ulceration; wound infection; fistula formation; unstable diabetes mellitus; and renal failure.

Other surgical procedures may remove the entire pancreas, stomach, gallbladder, duodenum, and regional lymph nodes, or merely the distal portion of the pancreas and the spleen for smaller, more localized tumors. Postoperative complications similar to those that occur after Whipple's procedure may develop.

pancreatectomy: pancreat—pancreas + ectomy—excision

Figure 33-5 Pancreatoduodenectomy (Whipple's procedure) for cancer of the head of the pancreas.

Relief of biliary obstruction can sometimes be accomplished by implanting a stent or plastic tube in the common bile duct during an endoscopic procedure. Pain can be reduced by surgical removal of a portion of the greater splanchnic nerve.

Surgery may be followed by chemotherapy and radiation therapy. In some instances, either radiation therapy or chemotherapy may be used for relief of symptoms if the cancer has become too widespread for surgery. (See Chapter 10 for care of the patient with radiation or chemotherapy.)

Nursing Process

ASSESSMENT. Observe the patient with cancer of the pancreas for evidence of malnutrition and fluid imbalance, including weight loss, inelastic skin turgor, vomiting, fatty stools, and complaints of anorexia or nausea. Review laboratory tests, especially blood glucose, liver function studies, and clotting time. Evaluate the patient every 2 to 4 hours for pain, including what triggers and what helps relieve the pain. Observe the skin for bruising, scaling, and yellowing, and question the patient about itching. Evaluate the patient's mental status for evidence of depression.

NURSING DIAGNOSIS. The common nursing diagnoses for the patient with cancer of the pancreas include the following:

- Imbalanced nutrition: less than body requirements related to inability to digest food, anorexia, nausea, and vomiting
- Pain related to pancreatic tumor or surgical incision
- Risk for deficient fluid volume related to nasogastric tube drainage or hemorrhage
- Risk for impaired skin integrity related to malabsorption, leakage of pancreatic or bile drainage postoperatively

PLANNING. The patient and health team plan to ensure that the patient has adequate nutrition, remains free of excessive pain, and does not develop complications from treatment.

IMPLEMENTATION

Altered Nutrition: Less Than Body Requirements. Frequently assess the patient for nausea or vomiting. Auscultate bowel sounds every 4 to 8 hours. Carefully monitor TPN if ordered. Assess blood glucose levels by finger stick every 6 hours when TPN is administered. Administer regular insulin as ordered.

Administer nasogastric tube feeding or other enteral feedings (gastrostomy or jejunostomy), as scheduled. Observe the patient for evidence of intolerance to feedings, such as diarrhea, nausea, or vomiting. Give pancreatic enzyme replacements as ordered. Steatorrhea (fatty stools) may indicate that the enzyme replacement doses are not meeting the patient's needs. Report steatorrhea immediately.

Pain. The pain associated with pancreatic cancer is intense. Evaluate the patient for pain every 2 to 4 hours and give analgesics as ordered. Opioids such as meperidine hydrochloride or morphine sulfate are usually ordered. For ad-

equate pain relief, dosages of analgesics may need to be very high. Dependence on opioid analgesics is not usually a concern because the outcome of the disease is so poor. Administer other medications, such as antidepressants, as ordered.

Place the patient in the position that provides the most comfort. The usual position is semi-Fowler's, so that the diaphragm has the most expansion room. However, if the patient is more comfortable in a side-lying position with legs drawn up, support him or her in that position. Additional methods of pain relief, such as guided imagery, distraction, or massage, may assist the patient to greater comfort.

Risk for Fluid Volume Deficit. Monitor the patient's intake and output carefully. Tachycardia, tachypnea, and low blood pressure may indicate excessive fluid loss. Monitor laboratory values, especially serum sodium, potassium, calcium, and chloride levels. If electrolyte values are low, the physician may order intravenous replacement solutions. Serum albumin should be between 6 and 8 g/dL. Report a low albumin level and assist with monitoring intravenous albumin therapy if ordered.

Coagulation studies may reveal a lowered clotting time from vitamin K deficiency. Carefully observe the patient for abnormal bruising, bleeding gums, or pink-tinged urine. Inspect the patient's abdomen and flanks for Cullen's sign (bluish discolorations around the umbilicus) and Turner's sign (bluish discolorations on the flanks), which are indications of bleeding into the retroperitoneum. If the patient has tubes or drains, carefully inspect around the incision sites and the drainage tubing for any bleeding. Teach the patient to use a soft-bristle toothbrush. Encourage use of an electric razor rather than a straight razor. The physician may order vitamin K.

High Risk for Impaired Tissue Integrity. Assess the patient for any complaints of itching. Help the patient keep fingernails short, provide frequent skin care with products free of soap or alcohol, and protect skin around drains with skin-protective barrier products and ostomy bags. Products such as calamine lotion may be ordered to decrease itching.

Exercise special care of any drains to prevent unnecessary tension that may cause the sutures to give way. Keep all drains patent, and keep drainage tubing and bags free from kinks. If the nasogastric tube must be irrigated, 10 to 20 mL of normal saline or air may be gently instilled, unless agency policy calls for a different procedure. Place the patient in semi-Fowler's position to help with gravity drainage.

PATIENT EDUCATION. Teach the patient and family self-care measures such as blood glucose monitoring, insulin administration, signs and symptoms of hyperglycemia and hypoglycemia (see Chapter 38), and the regimen for pancreatic enzyme replacement. Instruct the patient on how to manage dressing changes if he or she is to be discharged with tubes or drains. The patient and family should know the signs and symptoms of hemorrhage, gastric ulceration, infection, and fistula formation. Arrange to have the patient referred to the appropriate community health care agency for assistance with pain management. Offer a referral for hospice care.

EVALUATION. The plan of care for the patient with pancreatic cancer is successful if the patient exhibits the following:

- Maintains body weight within 5 percent of normal body weight and experiences no nausea or vomiting
- States that pain remains at 2 or less on a pain scale of 0 to 5
- Has urinary output greater than 40 mL/h, skin turgor is elastic, mucous membranes are moist, and pulse and blood pressure remain within 10 percent of patient's baseline
- Has no complaints of sudden, excessive abdominal pain or rigidity; incisions healed at the expected rate
- Can demonstrate the appropriate self-care procedures for tubes, drains, dressings, and medication administration and states the signs and symptoms of complications that are to be reported immediately

For more information, visit the National Pancreas Foundation at www.pancreasfoundation.org.

► DISORDERS OF THE GALLBLADDER

Cholecystitis, Cholelithiasis, and Choledocholithiasis

Gallstones and inflammations of the gallbladder and common bile duct are the most common disorders of the biliary system. These disorders are also common health problems for people in the United States: Nearly 25 million people have gallstones, and about 1 million new cases are diagnosed each year.

Pathophysiology

Cholecystitis is an inflammation of the gallbladder. It is most often a response to obstruction of the common bile duct resulting in edema and inflammation. Often bacteria invade the bile and add to the inflammation and irritation of the gallbladder. Chronic cholecystitis may be the result of repeated attacks of acute cholecystitis or chronic irritation from gallstones. The gallbladder becomes fibrotic and thickened and does not empty easily or completely.

Cholelithiasis, or stones in the gallbladder, are most often composed primarily of cholesterol. **Choledocholithiasis** refers to gallstones in the common bile duct. Although the exact cause of gallstones is unknown, one theory suggests that cholesterol may supersaturate the bile in the gallbladder. After a time, the supersaturated bile crystallizes and begins to form stones. Another type of gallstone is a pigment stone. Pigment stones appear to be composed of calcium bilirubinate, which occurs when free bilirubin combines with calcium.

cholecystitis: chole—bile + cyst—bladder + itis—
inflammation

choledocholithiasis: chole—bile + docho—duct + lith—
stone + iasis—condition

Etiology and Incidence

Pooling, or stasis, of bile within the gallbladder appears to contribute to the formation of stones. Stasis may be caused by a decreased gallbladder emptying rate or a partial obstruction in the common duct. Excessive cholesterol intake combined with a sedentary lifestyle is linked with an increased incidence of cholelithiasis.

Some low-fat diets have been linked to cholelithiasis because the diet appears to free cholesterol from body tissues; the cholesterol then crystallizes in the gallbladder before it is excreted. Further, a family history of cholelithiasis, obesity, diabetes mellitus, pregnancy, some hemolytic blood disorders, and bowel disorders such as Crohn's disease have also been linked to a higher incidence of cholelithiasis.

Cholelithiasis is responsible for about 90 percent of the cases of cholecystitis, or inflammation of the gallbladder. Women between ages 20 and 50 are about three times more likely to have gallstones than men. After age 50, the rate of gallstones is about the same for men and women (Cultural Consideration Box 33–9). Cholelithiasis is responsible for nearly 800,000 hospital admissions at a cost of more than \$2 billion dollars every year. The incidence of gallstones increases with age.

BOX 33-9 CULTURAL CONSIDERATION

Gallbladder disease is more common among Mexican-Americans. Risk factors include working in occupations such as mining, factories using chemicals, and farming using pesticides.

Native-Americans have an increased incidence of pancreatic and gallbladder disease. It is unknown how much increased dietary risk factors may contribute to gallbladder disease. The nurse can positively affect the nutritional status of Native-Americans by teaching food preparation practices that use less fat.

Signs and Symptoms

Signs and symptoms of cholecystitis and cholelithiasis are similar. Objective symptoms include evidence of inflammation, such as an elevated temperature, pulse, and respirations; vomiting; and jaundice. Subjective symptoms include patient complaints of epigastric pain, RUQ tenderness, nausea, and indigestion. The patient may have a positive Murphy's sign, which is the inability to take a deep breath when an examiner's fingers are pressed below the liver margin.

The epigastric pain caused by cholelithiasis may also be called biliary **colic**. The pain is a steady, aching, severe pain in the epigastrium and RUQ that may radiate back to behind the right scapula or to the right shoulder. The pain usually begins suddenly after a fatty meal and lasts for 1 to 3 hours. If the pain is caused by a stone in the common bile duct (choledocholithiasis), the pain may last until the stone has passed into the duodenum. Jaundice is more commonly

colic: colic—spasm

present with acute choledocholithiasis because the common bile duct is blocked or inflamed.

The biliary colic caused by cholecystitis typically lasts 4 to 6 hours. The pain is made worse with movement such as breathing. The patient usually has nausea, vomiting, and a low-grade fever with the pain.

Patient complaints of heartburn, indigestion, and flatulence are more common with chronic cholecystitis. Patients often report a medical history that suggests repeated attacks of acute cholecystitis (Table 33–4).

Family history of either cholecystitis or cholelithiasis; dietary habits such as high fat intake or a recent low-fat diet; and complaints of flatulence (gas), eructation (belching), nausea, vomiting, or abdominal discomfort after a high-fat meal are common evidence of a gallbladder disorder.

Complications

Complications of cholecystitis include inflammation of the bile ducts (cholangitis), necrosis or perforation of the gallbladder, empyema (a collection of purulent drainage in the gallbladder), fistulas, and adenocarcinoma of the gallbladder. A major complication of choledocholithiasis is acute pancreatitis if the pancreatic duct is obstructed.

Diagnostic Tests

The patient may have an elevated white blood cell count (normal: 5,000 to 10,000 cells per mm³). The serum amylase levels may be elevated (normal: 59 to 190 IU/L) if the pancreas is involved or if there is a stone in the common duct.

An abdominal x-ray examination is done to determine whether the gallstone is primarily calcium. Calcium-based stones are less responsive to medical treatments. Cholesterol stones are highly responsive to medical therapy. Further radiological examinations may include an oral cholecystography. The patient is given a contrast medium either by mouth or intravenously. Radiographs then show the presence of gallstones. Cholesterol stones usually float to the top of the bile. Patients are given a high-fat meal, and the radiologist can see the gallbladder contract and empty.

Oral cholecystography is not used with patients who are jaundiced because the liver cannot transport the contrast medium to the obstructed gallbladder.

Sonograms can detect stones and may be able to determine whether the walls of the gallbladder have thickened.

An ERCP can be done to directly visualize the pancreatic ducts and bile ducts to determine the presence of stones in the common duct and occasionally to remove stones from the common duct.

Medical Treatment

Medical management for an acute episode of cholecystitis centers on pain control, prevention of infection, and maintenance of fluid and electrolyte balance. Pain control is achieved by using opioid analgesics. The analgesic agent most often ordered is meperidine hydrochloride because morphine sulfate is believed to cause spasms of the gallbladder, biliary ducts, and the sphincter of Oddi. Antispasmodics or anticholinergic drugs such as propantheline bromide (Pro-Banthine) and dicyclomine hydrochloride (Bentyl) may be ordered to decrease the biliary colic. If the patient has nausea and vomiting, an antiemetic such as prochlorperazine (Compazine) may be ordered. Patients are placed on high-protein, low-fat diets after the nausea and vomiting subside (Nutrition Notes Box 33–10).

Treatment for cholelithiasis usually involves surgical removal of the gallbladder. The surgical procedure may be cholecystectomy via **laparoscopy** or a traditional cholecystectomy. A laparoscopic cholecystectomy may be done with a laparoscope through four small puncture wounds in the abdomen. A traditional cholecystectomy is done through a long, transverse, right subcostal incision. The patient has a T-tube inserted into the common duct for several days postoperatively to ensure that bile drainage is not obstructed

laparoscopy: laparo—pertaining to flank + scopy—to examine

TABLE 33–4 SYMPTOMS OF GALLBLADDER DISORDERS

	Acute Cholecystitis	Chronic Cholecystitis	Cholelithiasis and Choledocholithiasis
Biliary colic	Lasts 4–6 hours Worse with movement	Only during acute attack	Sudden onset
Jaundice	✓ (if common bile duct is inflamed or blocked)	✓	Lasts 1–3 hours Radiates to right scapula or shoulder
Low-grade fever	✓	✓	✓
Nausea, vomiting	✓	Only during acute attack	✓
Repeated attacks		✓	
Heartburn, indigestion, and flatulence		✓	
Complications	Cholangitis Necrosis or perforation Fistulas	Empyema Fistulas Adenocarcinoma	Acute pancreatitis

✓ = Usually present or commonly found on assessment.

BOX 33-10

Nutrition Notes

Modifying the Diet for Patients with Gallbladder Disease

During an acute attack of cholecystitis, a full liquid diet with minimal fat is usually allowed. For treatment of chronic cholecystitis, the patient is instructed to do the following:

- Correct obesity.
- Avoid troublesome and gas-forming foods.
- Decrease dietary fat each day by (1) selecting skim-milk dairy products, (2) limiting fats or oils to 3 teaspoons, and (3) consuming no more than 6 ounces of very lean meat.

Cholelithiasis has been associated with a long overnight fast that permits concentrated bile to remain in the gallbladder for an extended period.¹ Eating a light bedtime snack or drinking two glasses of water on arising if breakfast is delayed alter this risk factor.

1. Sichiare, R, Everhart, JE, and Roche, H: A prospective study of hospitalization with gallstone disease among women: Role of dietary factors, fasting period, and dieting. *Am J Public Health* 81:880, 1991.

(Fig. 33-6). The patient with a traditional cholecystectomy has incisional pain that creates difficulty with coughing and deep breathing postoperatively because deep breathing causes the diaphragm to press on the operative site. Patients are hospitalized for 2 to 3 days with a traditional cholecystectomy and 24 hours or less with a laparoscopic cholecystectomy.

Some patients are poor surgical risks and have stones in the gallbladder or biliary duct that cannot be removed easily by other methods. Such patients may have a cholecystostomy, which is an incision directly into the gallbladder to remove a stone. If the stone is in the biliary ducts, a choledocholithotomy may be done. The patient usually has a T-tube in place for several days to help remove bile from swollen structures.

Other methods of treatment include **choledochoscopy**, **extracorporeal shock-wave lithotripsy (ESWL)**, oral drugs to dissolve stones, and direct-contact dissolving drugs. The procedure for a choledochoscopy involves the use of an endoscope to explore the common bile duct and in some instances to snare and remove any stones found.

Extracorporeal shock-wave lithotripsy uses shock waves as a noninvasive method to destroy stones in the gallbladder or biliary ducts. Patients who are considered poor surgical risks and who have few cholesterol stones that are not calcified are the most likely candidates for ESWL. The patient lies face down on a water bag over a lithotripter (Fig. 33-7). A conductive gel is placed between the patient and the water bag. Ultrasound is used to locate the stone or

Figure 33-6 T-tube. A T-tube is used to drain bile after a cholecystectomy until swelling of the duct subsides.

Figure 33-7 Extracorporeal shock-wave lithotripsy. Shock waves are transmitted through water to break up gallstones. (A) Position for stones in gallbladder. Patient is lying on a fluid-filled bag. (B) Position for stones in common bile duct. Patient is in a water bath.

stones and to monitor the destruction of the stones. The patient requires sedation and strong analgesics during the procedure to reduce the pain and discomfort of the shock waves. After ESWL, the patient is usually put on a course of oral dissolution drugs to ensure complete removal of all stones and stone fragments.

Dissolution of stones with drugs may be attempted with chenodeoxycholic acid (chenodiol) or ursodeoxycholic acid (ursodiol). Patients who are poor surgical risks because of advanced age or severe health problems and who have cholesterol stones may be given oral dissolution drugs. The major disadvantages to the use of these drugs are that abnormal liver function studies and diarrhea are common side effects. Patients may also have an increase in serum choles-

choledochoscopy: chole—bile + docho—duct + scopy—to examine

extracorporeal shock-wave lithotripsy: extra—outside + corporeal—body + litho—stone + tripsy—rub or crush

terol while taking the drugs. Treatment with the dissolution drugs may take from 4 months to 2 years. Patients may need to take cholesterol-lowering drugs such as cholestyramine (Questran) in addition to the dissolution drugs to lower serum cholesterol and to decrease the probability of stones reforming.

Direct-contact dissolution drugs are administered directly into the gallbladder through a percutaneous trans-hepatic catheter. The physician inserts a catheter through the wall of the abdomen into the gallbladder and then injects and aspirates the dissolution agent repeatedly during the treatment. Candidates for this procedure are patients who are poor surgical risks and whose gallbladder can be seen during oral cholecystography. Disadvantages of the procedure include abnormal liver function studies, pain at the catheter site, nausea, and elevations in the white blood cell count.

Nursing Process

ASSESSMENT. Assess the patient frequently for pain, including location, intensity, and relieving and intensifying events. Take the patient's vital signs, particularly the temperature and pulse, frequently to monitor for signs of infection. Weigh the patient and inspect mucous membranes, skin turgor, and urinary output for signs of dehydration. Measure intake and output, including any emesis or drainage from nasogastric tubes or T-tubes. Observe stools and urine for color and consistency. Obstruction of bile flow may result in stools that are clay colored or have a foul, greasy appearance or urine that is dark amber or tea colored. Report either finding immediately. Evaluate laboratory studies for elevation in the white blood cell count or abnormalities in electrolytes or serum bilirubin levels.

NURSING DIAGNOSIS. Common nursing diagnoses for the patient with cholecystitis include the following:

- Pain related to biliary colic
- Risk for deficient fluid volume related to anorexia, nausea, vomiting, or excessive tube drainage

Additional nursing diagnoses for the patient with cholelithiasis who has a surgical procedure include the following:

- Risk for impaired skin integrity related to surgical incision and T-tube drainage
- Risk for ineffective breathing pattern related to abdominal incision

PLANNING. Goals for the patient with cholecystitis or cholelithiasis include pain management so that biliary colic is tolerable, management of the nausea and vomiting to prevent excessive fluid loss, management of the surgical incision to prevent infection or tissue damage from drainage, and close monitoring to detect and treat any infection.

IMPLEMENTATION

Pain. Assess the patient frequently for pain. The pain should be controlled at not more than 2 on a pain scale of

0 to 5. Give the patient meperidine hydrochloride as ordered. Give antispasmodics or anticholinergics as ordered. Place the patient in a position of comfort and provide support.

Risk for Fluid Volume Deficit. Assist with administration of intravenous fluids and electrolytes as ordered while the patient is on restricted oral intake. Give antiemetics as needed if the patient experiences nausea and vomiting. After surgery, a nasogastric tube may be inserted to prevent an ileus from developing. Frequently assess for the return of bowel sounds and passage of flatus. After the nasogastric tube is removed, the patient is slowly reintroduced to a solid diet, usually high protein and low fat. Monitor T-tube drainage. About 250 to 500 mL of yellowish-green bile is common within the first 24 hours after surgery. The amount of bile diminishes over the next several days. Carefully observe the T-tube drainage unit to prevent kinking of the tubing. Pressure in the biliary drainage system from poor drainage may greatly increase the patient's pain and the risk for infection.

Risk for Impaired Skin Integrity. Change the patient's position frequently. Encourage the patient to stay in a low semi-Fowler's position as much as possible. Inspect the cholecystectomy incision frequently for excessive drainage or evidence of infection such as redness, edema, or warmth. Change dressings frequently to protect the skin around the incision site. Montgomery straps prevent skin irritation from repeated or prolonged exposure to adhesive bandages. Protect the skin with a skin barrier product or bag such as those used with colostomies if bile is leaking around the T-tube site. An enterostomal therapist can be consulted for the best choice of dressing if the facility has such a specialist. Inspect the patient's skin and the sclera of the eyes frequently for jaundice. Report patient complaints of excessive itching.

Risk for Ineffective Breathing Pattern. Deep breathing and coughing after any surgical procedure help prevent respiratory tract infections and atelectasis. Patients with high abdominal incisions are particularly reluctant to cough and deep breathe. Instruct the patient in the proper techniques before surgery and give the opportunity to practice. After surgery, encourage the patient to cough and deep breathe at every encounter. If the patient is reluctant to cough because of pain, the pain medication regimen may need to be evaluated. Assist the patient with splinting and encourage the patient to walk when permitted.

PATIENT EDUCATION. Patient education focuses on diet. Patients are put on high-protein, low-fat diets. Encourage obese patients to lose weight. After a cholecystectomy, there is a slow reintroduction of fat in the diet. Once the duodenum becomes accustomed to constant infusion of bile, the patient's individual tolerance for fat becomes the only restriction for diet.

EVALUATION. The plan of care for a patient with cholecystitis or cholelithiasis is successful if the patient exhibits the following:

- Reports pain not greater than 2 on a pain scale of 0 to 5 or pain that is tolerable
- No weight loss, urinary output greater than 50 mL/h, moist mucous membranes, elastic skin turgor, and no complaints of excessive thirst
- Intact skin with no warmth, redness, swelling, or purulent drainage at the wound site; no jaundice or complaints of itching
- Clear breath sounds and a normal white blood cell count

CRITICAL THINKING

Donna

Donna, a 23-year-old woman, is diagnosed with possible acute cholecystitis. She is 5-feet, 6-inches tall and weighs 138 pounds. She has recently stopped following an extremely low-fat diet after losing nearly 70 pounds. Her physician wishes to delay surgery until her inflammation has subsided.

1. What risk factors does Donna have for cholecystitis?
2. What diagnostic tests might be ordered to confirm Donna's diagnosis of cholecystitis?

3. What medications can you anticipate that the physician will order for Donna?
4. What type of diet will Donna need to eat after discharge?
5. When the diagnosis of cholecystitis is confirmed, what type of surgical treatment might be ordered?

Answers at end of chapter.

REVIEW QUESTIONS

1. The patient with altered thought processes related to liver failure most likely has which of the following laboratory findings?
 - a. Low bilirubin
 - b. Low amylase
 - c. High hematocrit
 - d. High ammonia
2. Jack, a patient with chronic liver failure, has an episode of bleeding. Which of the following conditions placed Jack at risk for bleeding?
 - a. Portal hypertension
 - b. Low vitamin K
 - c. Elevated liver enzymes
 - d. High-fiber diet
3. Most gallstones are composed of which of the following?
 - a. Lipase
 - b. Cholesterol
 - c. Sodium
 - d. Potassium
4. John develops jaundice and dark, amber-colored urine. Which of the following is the most likely cause?
 - a. Encephalopathy
 - b. Pancreatitis
 - c. Bile duct obstruction
 - d. Cholecystitis
5. Jeff is a 26-year-old health care worker who is diagnosed with hepatitis C virus. Which of the following questions is most important to ask Jeff?
 - a. "Have you eaten any raw seafood recently?"
 - b. "Have you experienced a needle stick?"
 - c. "Have you made beds or handled clothing such as slippers without gloving?"
 - d. "Has anyone coughed into your face when you weren't wearing a mask?"
6. Jim, age 43, is admitted to your unit with chronic pancreatitis. You recognize that an elevation in which diagnostic test indicates chronic pancreatitis?
 - a. Serum bilirubin
 - b. Serum calcium
 - c. Serum albumin
 - d. Serum amylase
7. In planning care for the newly admitted patient with acute pancreatitis, you assign the highest priority to which patient outcome?
 - a. Patient expresses satisfaction with pain control.
 - b. Patient verbalizes understanding of medications for home.
 - c. Patient increases activity tolerance.
 - d. Patient maintains normal bowel function.

Answers to CRITICAL THINKING

Carl

1. Foreign travel within the past 2 months, fatigue, nausea, and irritability suggest hepatitis A virus. Recent possible exposure to materials contaminated with blood or body fluids, fatigue, headache, and nausea suggest hepatitis B virus.
2. Careful handwashing and standard precautions when handling any body fluids or feces should be instituted.
3. The nurse should plan to give an antiemetic if Carl is nauseated. Larger meals should be given early in the day, with Carl in an upright or sitting position. The nurse should also ensure that the environment is free of noxious stimulants such as unpleasant odors. The diet should be high calorie, high protein, high carbohydrate, and low fat.
4. Any medication that is known to be hepatotoxic, such as acetaminophen, aspirin, and diazepam (Valium), should be avoided.
5. Carl should be reminded that cleanliness, especially with food preparation, is essential. He should also be reminded that frequent handwashing is crucial. Carl needs to know that alcohol and other liver-toxic substances should be avoided.

Mary

1. Mary has a history of poor nutrition. Her age also puts her at risk.
2. Mary may report that she has malaise, nausea, weight loss, a change in bowel habits, and dull, aching RUQ pain.
3. Serum albumin is usually less than 3.2 g/dL. Her prothrombin time will probably be greater than 25 seconds.
4. Esophageal varices and ascites are the two greatest concerns for the patient with portal hypertension.
5. The physician will usually order diuretics, intravenous albumin infusions, and a sodium-restricted diet.
6. The possibility of suffocation from having the gastric tube dislodge into the esophagus requires that scissors be kept at the bedside at all times during tamponade.

Mrs. Samuels

1. The most common cause of acute pancreatitis is excessive alcohol intake. Mrs. Samuels denies alcohol consumption, but

- she does have the risk factor of having a recent ERCP, which may have dislodged a gallstone or irritated the pancreatic duct.
2. Respiratory distress may result from excess fluid accumulation in the retroperitoneal space and from shallow respirations that seek to decrease pressure from the diaphragm on the inflamed pancreas and surrounding tissues.
 3. Pancreatitis is similar to a chemical burn and may cause erosion of major blood vessels in surrounding tissue.
 4. Serum amylase may be elevated as much as 40 times more than normal early in acute pancreatitis.
 5. Narcotics are ordered because pain is intense, and pain with anxiety stimulates the autonomic nervous system, which may stimulate greater production of pancreatic enzymes.
 6. Stomach acid stimulates the production of pancreatic enzymes. Histamine antagonists decrease stomach acidity.

Donna

1. Some low-fat diets have been linked to the development of cholesterol gallstones, which then irritate the gallbladder and cause inflammation.
2. Donna's physician might order a white blood cell count, which will be elevated if she has cholecystitis. In addition, the physician may order a cholecystogram to visualize the gallbladder and its contents and the common bile duct.
3. You can anticipate that the physician will order an antibiotic, a narcotic such as meperidine hydrochloride, and possibly a antispasmodic such as the anticholinergic propantheline bromide.
4. Donna will need to eat a low-fat diet after discharge. Eventually she may be able to add more fats to her diet as her body adjusts.
5. Donna will probably have a laparoscopic cholecystectomy unless her surgeon decides that she needs a traditional cholecystectomy.

UNDERSTANDING
THE RENAL AND
URINARY SYSTEM

34

URINARY SYSTEM FUNCTION, ASSESSMENT, AND THERAPEUTIC MEASURES

Betty J. Ackley

KEY TERMS

cystoscopy (sis-**TAHS**-koh-pee)
dysuria (dis-**YOO**-ree-ah)
hematuria (HEM-uh-**TYOOR**-ee-ah)
percutaneous (PER-kyoo-**TAY**-nee-us)
pyelogram (**PIE**-loh-GRAM)
uremia (yoo-**REE**-mee-ah)

QUESTIONS TO GUIDE YOUR READING

1. What is the normal anatomy of the urinary system?
2. What is the normal function of the urinary system?
3. What are the effects of aging on the urinary system?
4. What is normal and oliguric 24-hour urinary output?
5. What data should you collect when caring for a patient with a disorder of the urinary system?
6. How do you collect a midstream, clean-catch urine specimen and 24-hour creatinine clearance specimen?
7. What is the meaning of an elevated serum creatinine, blood urea nitrogen, and uric acid level?
8. What is the preparation and aftercare for diagnostic tests of the urinary system?
9. Which nursing actions can be taken to decrease the risk of infection in catheterized patients?
10. What nursing care should be given to patients who are incontinent?

► REVIEW OF ANATOMY AND PHYSIOLOGY

The urinary system consists of two kidneys, two ureters, the urinary bladder, and the urethra. The kidneys form urine, and the rest of the system eliminates urine. The purpose of urine formation is the removal of potentially toxic waste products from the blood; however, the kidneys have other equally important functions as well:

- Regulation of the blood volume by the excretion or conservation of water
- Regulation of the electrolyte balance of the blood by the excretion or conservation of minerals
- Regulation of the acid-base balance of the blood by the excretion or conservation of ions such as hydrogen or bicarbonate
- Regulation of all of the above in tissue fluid

The process of urine formation thus helps maintain the normal composition, volume, and pH of blood and tissue fluid.

Kidneys

The two kidneys are located in the upper abdominal cavity behind the peritoneum on each side of the vertebral column. The upper portions of both kidneys rest on the lower surface of the diaphragm and are enclosed and protected by the lower ribcage. The kidneys are cushioned by surrounding adipose tissue, which is in turn covered by a fibrous connective membrane called the renal fascia; both help hold the kidneys in place. On the medial side of each kidney is an indentation called the hilus, where the renal artery enters and the renal vein and ureter emerge. The renal artery is a branch of the abdominal aorta, and the renal vein returns blood to the inferior vena cava. The ureter carries urine from the kidney to the urinary bladder.

Internal Structure of the Kidney

A frontal section of the kidney shows three distinct areas (Fig. 34–1). The outermost area is the renal cortex, which contains the parts of the nephrons called renal corpuscles and convoluted tubules. The middle area is the renal medulla, which contains loops of Henle and collecting tubules. The renal medulla consists of wedge-shaped pieces called renal pyramids; the apex, or papilla, of each pyramid points medially. The third area is a cavity called the renal pelvis; it is formed by the expansion of the ureter within the kidney at the hilus. Funnel-shaped extensions of the renal pelvis, called calyces, enclose the papillae of the renal pyramids. Urine flows from the pyramids into the calyces, then to the renal pelvis, and finally into the ureter.

Nephron

The nephron is the structural and functional unit of the kidney. Urine is formed in the approximately 1 million nephrons in each kidney. The two major parts of a nephron are the renal corpuscle and the renal tubule; these and their subdivisions and blood vessels are shown in Fig. 34–2.

A renal corpuscle consists of a glomerulus surrounded by a Bowman's capsule. The glomerulus is a capillary network that arises from an afferent arteriole and empties into an efferent arteriole. The diameter of the efferent arteriole is smaller than that of the afferent arteriole, which helps maintain a fairly high blood pressure in the glomerulus. Bowman's capsule is the expanded end of a renal tubule; it encloses the glomerulus. The inner layer of Bowman's capsule has pores and is highly permeable; the outer layer has no pores and is not permeable. The space between the inner and outer layers contains renal filtrate, the fluid that is

formed from the blood in the glomerulus and that will eventually become urine.

The renal tubule continues from Bowman's capsule and consists of the proximal convoluted tubule, the loop of Henle, and the distal convoluted tubule. The distal convoluted tubules from several nephrons empty into a collecting tubule. Several collecting tubules then unite to form a papillary duct that empties urine into a calyx of the renal pelvis. All the parts of the renal tubule are surrounded by the peritubular capillaries, which arise from the efferent arteriole and receive the materials reabsorbed by the renal tubules.

Blood Vessels of the Kidney

The pathway of blood flow through the kidney is an essential part of the process of urine formation. Blood from the abdominal aorta enters the renal artery, which branches extensively within the kidney into smaller arteries. The smallest arteries give rise to afferent arterioles in the renal cortex. From the afferent arterioles, blood flows into the glomeruli (capillaries), to efferent arterioles, to peritubular capillaries, to veins in the kidney, to the renal vein, and finally to the inferior vena cava. In this pathway are two sets of capillaries—that is, two sites of exchanges between the blood and the surrounding tissues (in this case, the parts of the nephrons). The exchanges that take place in the capillaries of the kidneys form urine from blood plasma.

Formation of Urine

The formation of urine involves three major processes: glomerular filtration in the renal corpuscles, tubular reabsorption, and tubular secretion.

Glomerular Filtration

Filtration is the process by which blood pressure forces plasma and dissolved materials out of capillaries. In glomerular filtration, blood pressure forces plasma, dissolved substances, and small proteins out of the glomeruli and into Bowman's capsules. This fluid is then called renal filtrate.

The blood pressure in the glomeruli is relatively high, about 60 mm Hg. The pressure in Bowman's capsule is low, and its inner layer is permeable, so that approximately 20 to 25 percent of the blood that enters glomeruli becomes renal filtrate in Bowman's capsules. The larger proteins and blood cells are too large to be forced out of the glomeruli; they remain in the blood. Waste products such as urea and ammonia are dissolved in plasma, so they pass to the renal filtrate, as do dissolved nutrients and minerals. Renal filtrate is similar to blood plasma except that there is far less protein and no blood cells are present.

The glomerular filtration rate (GFR) is the amount of renal filtrate formed by the kidneys in 1 minute; it averages 100 to 125 mL. The GFR may change if the rate of blood flow through the kidney changes. If blood flow increases, the GFR increases, more filtrate is formed, and urinary output increases. If blood flow decreases, the GFR decreases, less filtrate is formed, and urinary output decreases.

Figure 34-1 Frontal section of the left kidney. (From Scanlon, V, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 405, with permission.)

Figure 34-2 A nephron and its associated blood vessels. (From Scanlon, V, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 406, with permission.)

Tubular Reabsorption

Tubular reabsorption is the recovery of useful materials from the renal filtrate and their return to the blood in the peritubular capillaries. Approximately 99 percent of the renal filtrate formed is reabsorbed, and normal urinary output is 1000 to 2000 mL per 24 hours. Most reabsorption takes place in the proximal convoluted tubules, whose cells have microvilli that greatly increase their surface area. The distal

convoluted tubules and collecting tubules are also important sites for the reabsorption of water. The mechanisms of reabsorption are active transport, passive transport, osmosis, and pinocytosis.

Active transport requires energy in the form of adenosine triphosphate (ATP); the cells of the renal tubule use energy to transport useful materials such as glucose, amino acids, vitamins, and positive ions back to the blood. For many of these substances there is a threshold level of

reabsorption—that is, a limit to how much the renal tubules can remove from the filtrate. The level of a substance in the renal filtrate is directly related to its blood level. If the blood level of a substance such as glucose is normal, the filtrate level is normal, the threshold level cannot be exceeded, and no glucose appears in the urine.

Passive transport is the mechanism by which negative ions are reabsorbed. They are returned to the blood after the reabsorption of positive ions, because unlike charges attract.

The reabsorption of water is by osmosis following the reabsorption of minerals, especially sodium. The conservation of water is very important to maintain normal blood volume and blood pressure. The hormones that influence the reabsorption of water or minerals are summarized in Table 34–1.

Small proteins in the filtrate are reabsorbed by pinocytosis; the proteins become adsorbed to the membranes of the tubule cells and are engulfed and digested. Normally, all proteins in the filtrate are reabsorbed and none are found in urine.

Tubular Secretion

In tubular secretion, substances are actively secreted from the blood in the peritubular capillaries into the filtrate in the renal tubules. Waste products, such as ammonia and creatinine, and the metabolic products of medications may be secreted into the filtrate to be eliminated in urine. Hydrogen ions may be secreted by the tubule cells to help maintain the normal pH of the blood.

In summary, tubular reabsorption conserves useful materials, tubular secretion may add unwanted substances to the filtrate, and most waste products simply remain in the filtrate and are excreted in urine.

TABLE 34–1 EFFECTS OF HORMONES ON THE KIDNEYS

Hormone (Gland)	Function
<i>Aldosterone (adrenal cortex)</i>	Promotes reabsorption of sodium ions from the filtrate to the blood and excretion of potassium ions into the filtrate. Water is reabsorbed following the reabsorption of sodium.
<i>Antidiuretic hormone (posterior pituitary)</i>	Promotes reabsorption of water from the filtrate to the blood.
<i>Atrial Natriuretic hormone (atria of heart)</i>	Decreases reabsorption of sodium ions, which remain in the filtrate. More sodium and water are eliminated in the urine.
<i>Parathyroid hormone (parathyroid glands)</i>	Promotes reabsorption of calcium ions from the filtrate to the blood and excretion of phosphate ions into the filtrate.

Source: Scanlan, V, and Sanders, T. *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 410, with permission.

The Kidneys and Acid-Base Balance

The kidneys are the organs most responsible for maintaining the normal pH range of blood and tissue fluid. They have the greatest ability to compensate for or correct the pH changes that are part of normal body metabolism or the result of disease.

At its simplest, this function of the kidneys may be described as follows: If body fluids are becoming too acidic, the kidneys secrete more hydrogen ions into the renal filtrate and return more bicarbonate ions back to the blood. This helps raise the pH of the blood back to normal. In the opposite situation, when the body fluids become too alkaline, the kidneys return hydrogen ions to the blood and excrete bicarbonate ions in urine. This helps lower the pH of the blood back to normal.

Other Functions of the Kidneys

Some functions of the kidneys are not related to the formation of urine. These include the secretion of renin, activation of vitamin D, and production of erythropoietin. The production of renin influences urine formation and is considered first.

When blood pressure decreases, the juxtaglomerular cells in the walls of the afferent arterioles secrete the enzyme renin. Renin then initiates the renin-angiotensin-aldosterone mechanism, which results in the formation of angiotensin II. (See Chapter 15.) Angiotensin II stimulates vasoconstriction and increases the secretion of aldosterone, both of which help raise blood pressure.

Vitamin D exists in several structural forms, which are converted to calciferol, the most active form, by the kidneys. Vitamin D is important for the efficient absorption of calcium and phosphate from food in the small intestine.

Erythropoietin is a hormone secreted by the kidneys during states of hypoxia; it stimulates the red bone marrow to increase the rate of red blood cell (RBC) production. With more RBCs in circulation, the oxygen-carrying capacity of the blood is greater and the hypoxic state may be corrected.

Elimination of Urine

The ureters, urinary bladder, and urethra do not change the composition or volume of urine but are responsible for its elimination.

Ureters

The ureters are behind the peritoneum of the dorsal abdominal cavity. Each ureter extends from the hilus of a kidney to the lower, posterior side of the urinary bladder. The smooth muscle in the wall of the ureter contracts in peristaltic waves to propel urine toward the urinary bladder. As the bladder fills, it expands and compresses the lower ends of the ureters to prevent backflow of urine.

Urinary Bladder

The urinary bladder is a muscular sac below the peritoneum and behind the pubic bones. In women the bladder is infe-

rior to the uterus; in men the bladder is superior to the prostate gland. The functions of the bladder are the temporary storage of urine and its elimination.

Urethra

The urethra carries urine from the bladder to the exterior. Within its wall is the external urethral sphincter, which is made of skeletal muscle and is under voluntary control.

In women the urethra is 1 to 1.5 inches long and is anterior to the vagina. In men the urethra is 7 to 8 inches long and extends through the prostate gland and penis. The male urethra carries semen, as well as urine.

The Urination Reflex

Urination is a spinal cord reflex over which voluntary control may be exerted. The stimulus is the stretching of the detrusor muscle as urine accumulates in the bladder. Sensory impulses travel to the sacral spinal cord, and motor impulses return along parasympathetic nerves to the detrusor muscle, causing contraction. At the same time, the internal urethral sphincter relaxes. If the external urethral sphincter is voluntarily relaxed, urine flows into the urethra and the bladder is emptied.

Characteristics of Urine

Amount

Normal urinary output is 1000 to 2000 mL per 24 hours. Any changes in fluid intake or other fluid output (such as sweating) changes this volume.

Color

The color of urine is often referred to as straw or amber. Dilute urine is a lighter color (straw) than is concentrated urine. Freshly voided urine is clear. Cloudy urine may indicate an infection.

Specific Gravity

The usual range of specific gravity of urine is 1.010 to 1.025; this is a measure of the dissolved materials in urine. (The specific gravity of distilled water is 1.000.) The higher the specific gravity, the more dissolved material is present. Specific gravity of urine is a measure of the concentrating ability of the kidneys; the kidneys must excrete the waste products that are constantly formed in as little water as possible.

pH

The pH range of urine is 4.6 to 8.0, with an average of 6.0. Diet has the greatest influence on urinary pH. A vegetarian diet results in a more alkaline urine; a high-protein diet results in a more acidic urine.

Constituents

Urine is approximately 95 percent water, which is the solvent for waste products and salts. Nitrogenous wastes include urea, creatinine, and uric acid. Urea is formed by liver cells when excess amino acids are deaminated to be used for energy production. Creatinine comes from the metabolism

of creatine phosphate, an energy source in muscles. Uric acid comes from the metabolism of nucleic acids—that is, the breakdown of DNA and RNA.

Aging and the Urinary System

With age, the number of nephrons in the kidneys decreases, often to half the original number by age 70 or 80. The GFR also decreases; this is in part a consequence of arteriosclerosis and diminished renal blood flow. The urinary bladder decreases in size, and the tone of the detrusor muscle decreases. This may result in the need to urinate more frequently or in residual urine in the bladder after voiding. Elderly people are also more subject to infections of the urinary tract, and the changes of aging may influence medication therapy for elderly people (Gerontological Issues Box 34–1).

BOX 34-1 GERONTOLOGICAL ISSUES

Age-related Renal Changes

Certain changes typically occur in the renal system as people age. They include the following:

- The renal mass becomes smaller.
- Renal flow decreases by 50 percent, with subsequent decreased glomerular filtration rate.
- Tubular function and the exchange of substances decrease.
- Bladder muscles weaken and bladder capacity decreases, leading to increased frequency and nocturia.
- The voiding reflex is delayed.

Also, keep in mind that most drugs are excreted through the kidneys. Consequently, changes in renal function become a serious consideration for older adults who need drug therapy. Decreased renal function could slow the excretion of some drugs, keeping them in the body longer. This can increase the risk of adverse drug reactions, such as toxicity and overdose. It is important to monitor kidney function (such as creatinine and blood urea nitrogen levels) in an older person receiving drug therapy.

► NURSING ASSESSMENT

Health History

When recording a patient's health history, the following minimum information should be obtained:

- History of renal or urinary problems
- Family history of urinary disorders, diabetes, or hypertension (diabetes and hypertension are major contributing factors to renal failure)
- Presence of pain or burning either with voiding or over the kidney
- Voiding pattern
- New onset of symptoms of edema, shortness of breath, weight gain, abdominal fullness, or other symptoms of renal failure (see Chapter 35)
- Current medications, including over-the-counter medications and herbs
- Functional ability to take care of toileting needs

- Fluid intake and diet
- Age

LEARNING TIPS

To find your kidneys, put your hands on your hips with your thumbs pointing back and upward. Your thumbs are pointing to the bottom of the kidneys. This is called the flank area. Pain in this area is called flank pain.

Any symptoms should be further assessed using the WHAT'S UP? format found in Chapter 1.

If the patient has impaired kidney function or is in kidney failure, a complete head-to-toe assessment is needed, because kidney failure (renal failure) affects every system of the body. (See Chapter 35.)

Physical Assessment

The nurse first inspects the skin for color and texture. A patient with chronic renal failure may have a yellow or gray cast to the skin. The presence of crystals on the skin is called uremic frost and is a late sign of waste products building up in the blood (**uremia**). When the wastes are not filtered by the kidneys, they can come out through the skin and look like a coating of frost.

Palpation and percussion of the kidneys is done by physicians and advance practice nurses. Gentle palpation and percussion of the bladder may be done by the licensed practical nurse/licensed vocational nurse (LPN/LVN) if urine retention is suspected. If the patient has a feeling of fullness but is unable to urinate, the nurse gently palpates the suprapubic area for a full bladder. Normally the bladder is not palpable. The bladder may also be percussed. The percussion note sounds dull over a fluid-filled bladder.

Most assessment of the urinary system is done using indirect measures. Assessment of vital signs, lung sounds, edema, daily weights, and intake and output can provide valuable data related to urinary function.

Vital Signs

If renal disease is suspected, blood pressure should be assessed and documented while the patient is lying, sitting, and standing. An increase in blood pressure is commonly seen with renal disease. A drop in blood pressure accompanied by a rise in pulse rate as the patient rises to sitting or standing positions is called orthostatic or postural hypotension and may indicate fluid deficit. (See Chapter 15 for a more complete discussion of orthostatic hypotension.) A rapid respiratory rate may indicate fluid retention in the lungs.

uremia: ur—urine + emia—blood

Lung Sounds

If the patient retains more fluid than the heart can effectively pump, fluid may be retained in the lungs. This is manifested as crackles, which are popping sounds heard on inspiration and sometimes on expiration when the chest is auscultated. Wheezes may also be present. New-onset crackles and wheezes should be reported to a physician. (See Chapter 26 for assessment of the respiratory system.)

Edema

Fluid retention may be manifested as edema (excess fluid in tissues). The nurse assesses and documents the degree and location of edema. Edema may be generalized in renal failure. The nurse also looks for edema in the area around the eyes (periorbital edema). Assessment of edema is discussed in detail in Chapter 15.

Daily Weights

Weight is the single best indicator of fluid balance in the body. Patients with renal disease often have fluid imbalances. The patient should be weighed at the same time each day, in the same or similar clothing. The nurse is careful not just to document the weight, but also to look at trends in weight gain or loss. If the patient's weight is steadily increasing, fluid retention is suspected and should be reported. A patient undergoing diuresis is expected to have decreasing weights.

Intake and Output

All patients with renal disease should have careful measurement of intake and output. Individual voidings are analyzed for amount and recorded. The nurse measures and records all liquids taken in, including oral, intravenous, irrigation, tube feeding, and other fluids. Output includes urine, emesis, nasogastric effluent, wound drainage if it is copious, and any other drainage. As part of measuring output, the nurse should examine the urine for any abnormalities. Often problems show up readily in the urine, with changes such as **hematuria**, cloudiness, and foul odor seen with infection or concentrated dark-amber urine seen with dehydration.

Intake and output totals are analyzed and recorded every 8 or 12 hours or more often for unstable patients. As with daily weights, the nurse notes trends in retention or loss of fluid and reports significant changes to the physician. Ac-

CRITICAL THINKING

Mr. Nolan

It is the end of the shift. As you empty Mr. Nolan's indwelling catheter bag, you find that it has only 50 mL of concentrated urine in it. What do you do?

Answer at end of chapter.

hematuria: hemat—blood + uria—urine

curate documentation is vital, because the physician may base medication and intravenous fluid orders on intake and output results.

▶ DIAGNOSTIC TESTS OF THE RENAL SYSTEM

Laboratory Tests

Urine Tests

URINALYSIS. A urinalysis (urine analysis) is a commonly performed diagnostic test for the renal system. The results of the urinalysis give information regarding kidney function and various body functions. Table 34-2 lists normal and abnormal findings on a urinalysis.

To collect a voided specimen for urinalysis, the nurse has the patient wash the perineum using soap and water or a special towelette from a clean-catch midstream urine collection kit. Women should be directed to wash from the front to the back of the perineum. The patient is instructed to begin to void into the toilet, and then move the collection container under the stream, and then finish voiding into the toilet. This is called a clean-catch midstream specimen. It is used to obtain the cleanest possible specimen. Female patients should be told to separate the labia with one hand and keep it separated while washing and collecting the specimen to decrease the risk of contamination of

the specimen. If the female patient is menstruating, this should be specified on the laboratory form. A tampon may be used to prevent contamination of the specimen. The uncircumcised male patient should be directed to retract the foreskin with one hand and keep it retracted while cleansing and voiding. At least 10 mL of urine should be collected.

If a urinalysis is ordered for a patient with a urinary catheter, the nurse obtains the urine specimen. This specimen is considered sterile because it is coming directly from the bladder into the urinary catheter tubing. To obtain the specimen, wear clean gloves and use an alcohol swab to clean the sample port on the catheter tubing. Insert the needle of a syringe (usually 10 mL) into the port and withdraw urine from the tubing into the syringe. Then empty the urine from the syringe into a collection container and safely dispose of the syringe.

URINE CULTURE. A urine culture is done to determine the number of bacteria present in the urine and to identify the organism causing infection in the urine. The urine should be collected before antibiotic treatment is begun to avoid affecting results. The midstream clean-catch system is used to obtain voided specimens. A physician may order a catheterized specimen if there is a risk of contamination from the vagina, if a female patient is menstruating, or if the patient is incontinent. As a general rule, a bacterial count

TABLE 34-2 URINALYSIS RESULTS

Test	Normal Results	Abnormal Results and Significance
<i>Color of urine</i>	Pale yellow to amber	Dark-amber urine suggests dehydration. Yellow-brown to green urine indicates excessive bilirubin. Cloudiness of freshly voided urine indicates infection. Nearly colorless urine is seen with a large fluid intake or diabetes insipidus.
<i>Odor of urine</i>	Aromatic	With infection, urine becomes foul smelling. In diabetic ketoacidosis, the urine has a fruity odor. Urine that has been standing for a while develops a strong ammonia smell.
<i>pH</i>	4.6–8.0	The pH is greatly affected by the food eaten. pH below 4.6 is seen with metabolic and respiratory acidosis. pH above 8.0 is seen when urine has been standing or with infection because bacteria decompose urea to form ammonia.
<i>Specific gravity</i>	1.010–1.025	Low specific gravity indicates excessive fluid intake or diabetes insipidus. High specific gravity is seen with dehydration. A specific gravity fixed at 1.010 indicates kidney dysfunction.
<i>Protein</i>	0–18 mg/dL	Persistent proteinuria is seen with renal disease from damage to the glomerulus. Intermittent protein in the urine can result from strenuous exercise, dehydration, or fever. As a general rule, protein in the urine is a significant sign of renal problems.
<i>Glucose</i>	None	Glucose in the urine indicates diabetes mellitus, excessive glucose intake, or low renal threshold for glucose reabsorption.
<i>Ketones</i>	None	Ketones in the urine indicate diabetes mellitus with ketonuria or starvation from breakdown of body fats into ketones.
<i>Bilirubin</i>	None	Bilirubin in the urine indicates liver disorders causing jaundice. Bilirubin may appear in the urine before jaundice is visible.
<i>Nitrite</i>	Negative	Nitrites in the urine indicate infection in the urine. Bacteria in the urine convert nitrate to nitrite, which gives a positive reading.
<i>Leukocyte esterase</i>	Negative	A positive leukocyte esterase in the urine indicates infection in the urine. It determines the presence of an enzyme released by WBCs in the urine.
<i>Red blood cells</i>	0–4/hpf	Blood in the urine may be caused by kidney stones, infection, cancer, renal disease, or trauma.
<i>White blood cells</i>	0–5/hpf	WBCs in the urine indicate infection or inflammation in the urinary tract.
<i>Casts</i>	None to occasional hyaline cast	Casts are formed when abnormal urine contents settle into molds of the renal tubules and may be made of protein, WBCs, RBCs, or bacteria. A few hyaline casts may be found in normal urine. The presence of casts generally indicates renal damage or infection.

hpf = high-power field; WBC = white blood cells.

of 100,000 or more per milliliter of urine indicates a urinary tract infection. An amount less than that may result from contamination during specimen collection. The urine is cultured to grow and identify the kind of bacteria present. Often a sensitivity test is also ordered to determine what kind of antibiotic will be most effective in eradicating the offending bacteria.

Renal Function Tests

A number of blood tests reflect kidney function. If the kidneys are not functioning adequately, these test results will be elevated.

SERUM CREATININE. Creatinine is a waste product from muscle metabolism and is released into the bloodstream at a steady rate. Creatinine levels are a very good indicator of kidney function (normal: 0.6 to 1.5 mg/dL). A serum creatinine level above 1.5 mg/dL means there is kidney dysfunction. The higher the creatinine level, the more impaired the kidney function.

BLOOD UREA NITROGEN. Urea is a waste product of protein metabolism. The blood urea nitrogen (BUN; normal: 8 to 25 mg/dL) is not as sensitive an indicator of kidney function as the creatinine level. This is because it is readily affected by increased protein intake, dehydration, and other factors in the body. An elevated BUN level can be caused by the following factors:

- Kidney dysfunction or failure
- Decreased kidney blood supply, such as when the patient is in a state of shock or in severe heart failure
- Dehydration, because the loss of water makes the blood more concentrated (decreased BUN level is seen with overhydration)
- High-protein diet, because urea formation increases
- Gastrointestinal bleeding, because blood is absorbed as protein and converted into urea
- Steroid use, because steroids increase the rate of protein breakdown in the body

URIC ACID. Uric acid is an end product of purine metabolism and the breakdown of body proteins. The uric acid is not as diagnostic as creatinine because many factors can cause an elevated uric acid level (normal: 2 to 7 mg/dL). An elevated uric acid level can be caused by the following:

- Kidney disease
- Gout (patients with gout metabolize uric acid abnormally)
- Malnutrition
- Leukemia
- Use of thiazide diuretics (because of impairing uric acid clearance by the kidney)

CREATININE CLEARANCE. The creatinine clearance test measures the amount of creatinine cleared from the blood in a specified period by comparing the amount of creatinine in the blood with the amount of creatinine in the urine. It is an excellent indicator of renal function.

To carry out the test, urine is collected for a 24-hour period, and a sample for serum creatinine is collected some-

time during the 24 hours. The following procedure should be followed:

1. When the test is begun, the patient is directed to void and discard that urine.
2. Urine is collected for 24 hours, keeping the urine in a large container provided by the laboratory. The container is kept on ice.
3. Twenty-four hours after the test was begun, the patient is instructed to void again. This urine is added to the collection container.
4. The laboratory collects a serum creatinine during this 24-hour period.

The creatinine clearance is computed in the laboratory and is expressed in volume of blood that is cleared of creatinine in 1 minute. Normal is 85 to 125 mL. A minimum creatinine clearance of 10 mL per minute is needed to live without dialysis.

LEARNING TIPS

A handy approximation to determine kidney function is to equate the creatinine clearance result to percent of renal function. For example, a creatinine clearance of 100 mL per minute = 100 percent renal function, 30 mL per minute = 30 percent renal function, and 5 mL per minute = 5 percent renal function.

Radiological Studies

Kidney-Ureter-Bladder

A kidney-ureter-bladder (KUB) is an x-ray examination of the named structures. This test is also known as a flat plate of the abdomen. It displays the outline of the renal structure and can show tumors, swollen kidneys, and calcium-based kidney stones. No special care is necessary for this test.

Intravenous Pyelogram

The intravenous **pyelogram** (IVP) is a common test. During the test, a radiopaque dye is injected into a large vein. The dye is cleared from the blood by the kidneys. Because the x-rays cannot penetrate the dye, the dye outlines the renal structures. Radiographs are taken at frequent intervals to see the dye filling the renal pelvis and going down the ureters into the bladder (Fig. 34–3).

In preparation for an IVP, the patient takes laxatives to cleanse the bowel the day before the test, following agency policy. The patient is allowed nothing by mouth (NPO) after midnight the evening before the test. As with all contrast studies, the patient should be questioned for allergies to iodine and shellfish before the test. The dye can cause allergic and anaphylactic reactions in people who are allergic to these substances, although this problem is less common since the introduction of a newer radiopaque dye. The patient should also be warned about a warm, flushing sensa-

pyelogram: pyelo—pelvis of the kidney + gram—radiograph

Figure 34-3 Intravenous pyelogram.

tion up the arm and sometimes all over the body when the dye is injected. A strange taste may occur as well.

Aftercare for an IVP includes having the patient drink a large amount of fluids to help clear the dye from the kidneys. On rare occasions, people can develop acute renal failure because the dye is highly concentrated and can obstruct the kidney tubules.

Renal Angiography

A renal angiogram is a test to visualize the renal arteries. The femoral artery is pierced with a needle, and a catheter is threaded up through the femoral and iliac arteries into the aorta and then the renal artery. A contrast agent is injected to make the renal arterial supply visible on x-ray examination. Iodine or shellfish allergies should be determined before the study. Angiography is done in the x-ray department with the patient awake during the procedure. The test helps the physician see blood flow to the kidneys to determine the cause and treatment of kidney disease.

Before the procedure, the patient should be NPO for 4 to 8 hours. Patient care following angiography includes bedrest for up to 12 hours to prevent bleeding at the injection site. The extremity is immobilized with a sandbag, and a pressure dressing is applied. The patient is instructed not to bend the leg, and the head of the bed is not raised more than 45 degrees. The nurse monitors vital signs, dressing, and pulses in the affected extremity frequently. Institution policy is consulted for specific care guidelines.

Endoscopic Procedures

Cystoscopy and Pyelogram

A **cystoscopy** and pyelogram (C&P) is a minor surgical procedure that involves a rigid or fiberoptic instrument (cystoscope) inserted into the bladder through the urethra. A

cystoscopy: cysto—bladder + scopy—to examine

light at the end of the instrument allows a physician to visualize the interior of the bladder. Commonly a pyelogram is done as well. This involves insertion of a ureteral catheter into the pelvis of the kidney. Radiopaque dye is injected through the catheter and radiographs are taken. A C&P is done for both diagnostic and therapeutic reasons. As part of the diagnosis, a physician can do the following:

- Inspect the inside of the bladder.
- Collect a urine specimen from either kidney.
- Visualize the renal structure with x-rays.
- Biopsy any suspicious growths in the bladder or ureter.

Therapeutic interventions that can be done during a C&P include the following:

- Removal of small bladder tumors
- Removal of stones from the bladder
- Removal of stones from the ureters
- Dilation of the ureters

The preparation for a C&P is the same as for any surgery. Care following a C&P includes measuring urine to make sure the patient has not developed urinary retention from swelling of the urinary meatus and encouraging fluid intake. The patient should expect some **dysuria** for 24 hours following a C&P, and the first one or two voidings may be blood tinged. Complications that can result include urinary tract infection, urinary retention, and perforation of the bladder.

Ultrasound Examination of the Kidneys

Renal Ultrasound

A renal ultrasound, also known as ultrasonography, is a noninvasive study using sound waves to examine the anatomy of the urinary tract. A transducer is passed over the skin, which has been covered with a conductive gel. Structures of the urinary system can be visualized on a screen. A renal ultrasound is used to help diagnose tumors of the kidney and to look for enlargement of the kidneys, kidney stones, and changes of renal structures with chronic infection. There is no special preparation or aftercare, and there are no known complications.

Renal Biopsy

A renal biopsy may be done to diagnose or gain more information about kidney disease. Most renal biopsies are **percutaneous** (done with a needle through the skin), though some are open (done through a surgical incision). A percutaneous biopsy may be done in the operating room, the radiology department, or the patient's room. A computed tomography (CT) scan or ultrasound is done first to locate the kidney for biopsy. The patient is in a prone position, usually with a sandbag under the abdomen, and the biopsy is taken through the flank area. The physician obtains a sample of tissue, which is examined in the laboratory.

dysuria: dys—difficult or painful + uria—urination
percutaneous: per—through + cutaneous—skin

Before the biopsy, the patient is NPO for 6 to 8 hours and a mild sedative is given. The patient should not take anticoagulants before the biopsy because of the risk of bleeding. A complete blood cell count and coagulation studies are performed. For a percutaneous biopsy, a local anesthetic is used.

Following the biopsy, the patient is observed closely for bleeding, because the kidney is highly vascular. A pressure dressing is applied to prevent bleeding, and the patient is maintained on bedrest for 24 hours. A sandbag may be used under the flank to place additional pressure on the biopsy site. Urine is inspected for blood with each voiding. Vital signs are monitored frequently for 24 hours according to agency policy. Grossly bloody urine, falling blood pressure, and rising pulse are signs of bleeding and are reported immediately. Fluids are encouraged if not contraindicated.

► THERAPEUTIC MEASURES

Management of Urinary Incontinence

Urinary incontinence is defined as the involuntary passing of urine and is very common. It is estimated that 10 million Americans (mostly women) suffer from incontinence. Most patients do not seek treatment. At times, urinary incontinence can be prevented by patient teaching or physician intervention. Incontinence that cannot be prevented is managed by the use of padding and absorptive products worn by the patient. With all kinds of incontinence, it is helpful for the nurse or patient to keep a urinary diary for at least several days to determine when incontinence occurs and to look for any predisposing events. The patient should be referred to a urologist specializing in the area of incontinence for a careful examination to determine the cause and identify potential medical or surgical treatment. Some areas of the country have continence clinics, which can be helpful for patients with this problem. There are several types of incontinence, discussed next.

Stress Incontinence

Stress incontinence is the involuntary loss of urine associated with increasing abdominal pressure during coughing, sneezing, laughing, or other physical activities. Stress incontinence is commonly seen in women following childbirth and after menopause.

Urge Incontinence

Urge incontinence is the involuntary loss of urine associated with an abrupt and strong desire to void. The patient typically complains of being “unable to make it to the bathroom in time.” Patients with stress incontinence or urge incontinence can be taught Kegel exercises to increase perineal muscle tone. Box 34–2 explains how to teach patients to perform Kegel exercises.

Functional Incontinence

Functional incontinence is caused by chronic impairment of physical function or ability to think, leaving the patient unable to get to the toilet in time to maintain continence. This is a common cause of incontinence in the elderly.

BOX 34-2 Patient Education for Kegel Exercises

The purpose of Kegel exercises is to decrease the incidence of incontinence by strengthening the pubococcygeal muscle, which supports the pelvic organs. By increasing the tone of this muscle, the patient has an increased ability to tighten the muscle that encircles the urinary meatus and stop the flow of urine. This exercise can also help prevent uterine prolapse, enhance sensation during sexual intercourse, and hasten postpartum healing. It may be used by the elderly male patient to control dribbling.

1. Establish awareness of pelvic muscle function by instructing the patient to “pull in” the muscles in the perineum as if to control urination or defecation. The muscles of the buttocks, inner thigh, and abdomen are not used to do Kegel exercises.
2. To help identify the correct muscles to tighten, ask the patient to tighten the muscles that control urination. It can be helpful to use an analogy of an elevator: start squeezing at the bottom floor and then squeeze upward to the top floor.
3. Instruct the patient to tighten the pelvic muscles for 10 seconds, followed by at least 10 seconds of relaxation.
4. Advise the patient to perform these exercises 30 to 80 times per day. Help the patient determine cues to remind the patient to perform the exercises, such as stopping the stream of urine 10 times each time the patient urinates.

Source: Adapted from Urinary Incontinence in Adults: Clinical Practice Guideline. Agency for Health Care Policy and Research, Public Health Service, US Department of Health and Human Services (AHCPR Pub No 92-0038), Rockville, MD, 1992.

Total Incontinence

Total incontinence is a continuous and unpredictable loss of urine. Bladder training has been tried and proven ineffective. Often the patient with total incontinence is neurologically impaired. In these situations the nurse’s priority is to keep the patient clean and dry using absorptive products. For the male patient, an external condom catheter can be effective in some situations.

NURSING PROCESS. The medical diagnoses of stress and urge incontinence are also nursing diagnoses. Many nursing interventions can be helpful to decrease these kinds of incontinence. See Nursing Care Plan Box 34-3 for the Patient with Stress Incontinence or Urge Incontinence and Nursing Care Plan Box 34-4 for the Patient with Functional Incontinence.

Management of Urine Retention

Urine retention can be caused by many factors. It can be acute, with a sudden onset of retention and no urine output, or chronic, with a slower onset of retention of urine and some urine being expelled. Acute retention often results from surgeries and is caused by anesthesia, medications, or local trauma to the urinary structures. Acute retention can be a medical emergency causing extreme pain, a large bladder, and the possibility of bladder rupture or acute renal failure. Chronic urine retention may be related to an enlarged prostate gland, a medication effect, strictures, or other causes of obstruction of the urinary tract.

BOX 34-3**NURSING CARE PLAN FOR THE PATIENT WITH STRESS INCONTINENCE OR URGE INCONTINENCE****▶ Stress incontinence or urge incontinence related to decreased tone of perineal muscles****PATIENT OUTCOMES**

Patient will be continent of urine. Patient will state three actions that can be taken to decrease incidence of stress or urge incontinence.

EVALUATION OF OUTCOMES

Is the patient continent? Is the patient able to state three actions that can be taken to decrease the incidence of stress or urge incontinence?

INTERVENTIONS

Assess history of incontinence; have patient keep a voiding journal.
Instruct patient on how to perform Kegel exercises (see Box 34-2).
Work with the patient to incorporate Kegel exercises into normal activities of daily living (e.g., do 10 pelvic muscle contractions with each voiding).
Encourage patient to drink at least 2000 mL of fluid per day, preferably 3000 mL per day unless medical reason for fluid restriction.

RATIONALE**STRESS INCONTINENCE AND URGE INCONTINENCE**

A journal helps identify the severity and timing of incontinence.

Kegel exercises increase perineal muscle tone and help prevent incontinence.

An excellent time to perform Kegel exercises is when voiding because the correct muscles are used.

Concentrated urine is irritating to the urinary tract and can increase the incidence of urge incontinence and dribbling.

EVALUATION

Does patient complete the voiding journal?

Does patient explain how to perform Kegel exercises?

Does patient perform Kegel exercises when voiding or at other cued times during the day?

Is urine dilute?

Encourage patient to avoid alcohol and caffeine.
 Discuss use of and provide small adhesive peripads to wear in underclothing.
 Refer patient to a continence clinic or to a physician specializing in incontinence.
 Refer patient to supportive and educational groups such as Help for Incontinent People (HIP).

Alcohol serves as a diuretic, and caffeine is irritating to the urinary tract.
 Peripads provide protection in case of incontinence.

Specialists in the area of incontinence can use medical or surgical interventions to decrease the incidence of incontinence.
 Support groups can help patients deal with the embarrassment of incontinence and learn methods and resources to prevent incontinence.

Does patient explain the need to avoid alcohol and fluids containing caffeine?
 Does patient have and use peripads if desired?

Does patient know resources available to further assist with treatment of incontinence?

Does patient know the names and addresses of support groups to help with incontinence?

URGE INCONTINENCE

Teach patient to void at frequent intervals (every 2 hours), then gradually increase length of time between voidings.
 Teach urge inhibition techniques (distraction), such as counting back from 100 by sevens and relaxation breathing.

By emptying the bladder at frequent intervals, the incidence of urge incontinence can be decreased.

These distraction techniques can help patients reach the bathroom in time to prevent incontinence.

Does patient follow a frequent voiding schedule?

Do distraction techniques help patient prevent incontinence?

Functional urinary incontinence related to interference with rapid voiding

PATIENT OUTCOMES

Patient will be continent of urine. Patient will state three measures to increase continence.

EVALUATION OF OUTCOMES

Is the patient continent of urine? Is the patient able to state three measures to increase continence?

INTERVENTIONS

Assess history of incontinence. Keep a voiding log of when patient is incontinent.
 Determine any acute causes of incontinence, including new onset of urinary tract infection, constipation or impaction, medication effect, or poor fluid intake.
 Determine if clothing is inhibiting timely voiding. If necessary, Velcro fasteners can be appropriate, or sweat shirts and sweat pants.
 Determine if there are any obstacles to reaching appropriate urine receptacle, such as poor lighting, busy bathroom, lack of assistive devices.
 Provide appropriate urinary receptacles, such as a three-in-one commode, female or male urinal, or no-spill urinal.
 Initiate a voiding schedule of every 2 hours, or base schedule on voiding log. Always assist patient to the toilet when patient first awakens and before sleep. Use prompted voiding techniques: check patient regularly, provide positive reinforcement if dry, prompt patient to toilet, praise patient after toileting, return patient to toilet in a specified time.
 Teach patient to set up schedule of voiding using environmental cues such as meals, bedtime, and television shows.

RATIONALE

A voiding log helps demonstrate when incontinence is most likely to occur and can help determine the cause of incontinence. These may be readily treatable causes of incontinence.
 Clothing can be difficult to remove for the elderly, resulting in voiding before the clothing can be removed. Clothing can be modified so that it comes off quickly.
 Obstacles can make it impossible for the patient to reach the voiding receptacle in time to prevent incontinence.
 Assistive devices can be helpful for the patient to increase continence.
 Frequent scheduled voiding using prompting techniques can increase continence.
 Environmental cues help the patient remember when it is time to void.

EVALUATION

Does the patient cooperate so that a voiding log can be kept?
 Does the patient have any easily treatable causes of incontinence?
 Does the patient have easy-to-remove clothing?
 Does the patient have ready access to a voiding receptacle?
 Does the patient need and have access to an appropriate assistive device?
 Does the patient receive help to do bladder training with prompted voiding?
 Can the patient indicate cues throughout the day that prompt voiding?

To assess for urinary retention, urine output is determined and the lower abdomen is palpated. An enlarged bladder can be palpated, and the dull percussion notes may extend up to and beyond the umbilicus.

A newer technique called a bladder scan is used to assess the volume of urine in the bladder (Fig 34-4). This technique uses sound waves to estimate the amount of urine in the bladder. It is painless, noninvasive, and requires no patient preparation. The nurse performs this scan at the bedside. It helps guide the need for catheterization, thereby reducing unnecessary catheterizations and associated risks. The bladder scan may be used instead of catheterization (the gold standard for determining urine retention) after the patient urinates to determine the amount of urine remaining in the bladder. Normally the bladder contains less than 50 mL after urination. A residual volume of 150 to 200 mL of urine indicates the need for treatment for urinary retention.

Urinary Catheters

Indwelling Catheters

Indwelling urinary catheters (Foley catheters) may be inserted into hospitalized patients for various justifiable reasons such as shock or urinary tract obstruction. As a general rule, catheters should be avoided if possible. Urinary incontinence is not justification for insertion of a catheter. Urinary catheters result in infection of the urinary tract in up to 44 percent of patients within 72 hours of catheterization, and up to 90 percent of patients who have indwelling catheters for 17 days develop significant bacterial infection.¹

Bacteria enter the bladder mainly in one of two ways with an indwelling catheter: (1) through the outlet at the end of the drainage bag contaminating the urine, which is then inadvertently drained back into the bladder; or (2) around the catheter up the urethra and into the bladder. It has been demonstrated that the incidence of infection is decreased when intermittent straight catheterization is used instead of indwelling Foley catheters. Box 34-5 outlines

Figure 34-4 A bladder scan can be used to determine the volume of urine in a patient's bladder.

BOX 34-5 Guidelines for Care of the Patient with an Indwelling Catheter

1. Maintain a closed system. Do not separate the catheter from the tubing of the bag. Instead, collect specimens and irrigate through the sample port in the tubing.
2. Keep the catheter securely taped or fastened to the leg. This decreases traction on the catheter with back-and-forth movement of the catheter that can help bacteria enter the bladder.
3. Encourage fluids to internally irrigate the catheter, if fluids are not contraindicated because of heart or kidney disease.
4. Use good aseptic technique when emptying the drainage bag by handwashing, wearing clean gloves, and using a container designated for that patient only to collect the urine.
5. Wash the perineum with soap and water at least once a day, and again if there is any bowel incontinence.
6. Keep the tubing coiled on the bed and positioned to allow free flow of urine. *Keep the catheter bag below the level of the bladder at all times.*
7. Do not clamp catheters. Clamping a catheter results in obstruction, which increases infection. Periodic clamping has not been found to be effective in bladder retraining.
8. Remove indwelling catheters as soon as possible.

guidelines that should be followed to decrease infection in the patient with a catheter (Home Health Hints).

After an uncircumcised male is catheterized, it is essential that the foreskin is properly positioned over the glans penis and not left retracted to prevent injury. If left retracted,

HOME HEALTH HINTS

- The home health nurse should always have a sterile specimen container. This provides a quick way to get a specimen to the physician's office without the nurse having to obtain the container, saving time and money.
- When catheters plug and irrigation fails, families can be taught to take the catheter out. A syringe for removing water from the balloon should be left in the home for this purpose. The family is instructed to avoid cutting the valve stem. The family should contact the nurse to reinsert the catheter, but in the meantime, the patient's bed or chair can be padded with towels or diapers. Garbage or cleaners' bags can be used to line the mattress. The family must be instructed to notify the nurse immediately if the catheter is plugged or has been removed.
- Not all homes have adequate lighting, which is a must for inserting a catheter. If lighting is inadequate, a caregiver can be asked to hold a flashlight while the nurse inserts the catheter. The nurse should always have a flashlight with him or her. Having two catheters and catheter trays is also wise in case of a defect or contamination.
- Urinary drainage bags and leg bags should be changed a minimum of every 2 weeks in the home setting to prevent infection. The family is instructed not to clean and reuse the bags.
- To encourage fluid intake, the patient should keep a large container of water (1 to 2 quarts) next to the place the patient sits most of the day. The goal is to drink 2 quarts of water by the end of the day, unless contraindicated by other medical problems. This also simplifies measuring intake. A sport bottle helps to keep water at hand while moving about the home.

subsequent swelling may make it impossible to pull the foreskin over the glans penis later. This can then cause ischemia of the glans penis, which is an emergency. A physician must be notified immediately and may need to perform an emergency circumcision if the foreskin cannot be properly positioned. Always make sure that the foreskin is positioned properly following catheterization or perineal care.

Intermittent Catheterization

For the patient who is unable to void, the best intervention is intermittent catheterization. A postoperative patient or a patient with a neurological disorder or urine retention may benefit from intermittent catheterization. It reduces the risk of infection as long as the bladder is not allowed to overflow. A full bladder stretches the muscle fibers, which in turn reduces circulation to the bladder and increases the risk of infection.

Intermittent catheterization involves the use of a straight plastic or rubber catheter that is inserted into the urethra every 3 hours or more to empty the bladder. Once the bladder is empty, the catheter is removed. Patients may be taught to do intermittent self-catheterization (ISC) at home. Patients doing ISC may be taught to wash and reuse the same catheter repeatedly when they are in their own environment. In the hospital, however, sterile technique is used.

Suprapubic Catheter

After some surgeries of the urinary tract and in some long-term situations, a suprapubic catheter may be used. This is

an indwelling catheter that is inserted through an incision in the lower abdomen directly into the bladder.

Nursing care of a suprapubic catheter involves keeping the area clean and dry, changing the dressing when the site is new, and keeping the catheter taped to prevent tension. A skin barrier such as Stomahesive may help protect the skin from urine leakage. All other care is the same as for any indwelling catheter.

Answers to CRITICAL THINKING

Mr. Nolan

You should realize that 50 mL of concentrated urine after 8 to 12 hours is not normal. Further investigation is necessary to determine the cause and seriousness of the problem. Some items to assess follow.

1. Consider Mr. Nolan's diagnosis. Is he in renal failure? Is he severely dehydrated and retaining water?
2. Ask if anyone emptied Mr. Nolan's bag earlier in the shift.
3. Look at the trends in Mr. Nolan's intake and output record. Has his output been decreasing? Is this a change?
4. Has Mr. Nolan been taking in enough fluids?
5. Look at trends in daily weights. Is Mr. Nolan's weight increasing? Is this an expected finding?
6. Listen to Mr. Nolan's lung sounds. Check for edema. Do findings indicate fluid retention?
7. Palpate Mr. Nolan's bladder. Is it distended? Maybe the catheter is blocked.
8. If a problem is identified, the physician should be contacted.

REVIEW QUESTIONS

1. A home health nurse visits a patient who is 82 years old. He uses a cane and is not incontinent. Which one of the following interventions should be included in the plan of care, based on an understanding of normal age-related changes of the urinary system, to promote his safety?
 - a. Encourage fluids after 6 P.M.
 - b. Limit fluids to 1000 mL per day.
 - c. Provide a nightlight in the bathroom.
 - d. Provide adult briefs to prevent dribbling.
2. Which of the following is the most accurate assessment of fluid balance in the patient with renal failure?
 - a. Voiding pattern
 - b. Daily weight
 - c. Laboratory studies
 - d. Skin turgor
3. A physician has ordered a midstream urine specimen for culture and sensitivity. Which of the following should be included in patient teaching for collecting this specimen?
 - a. A second voided specimen is preferred.
 - b. A 24-hour urine specimen is needed.
 - c. As soon as the urine starts to flow, it should be collected in a sterile container.
 - d. Women should keep the labia separated while voiding.
4. Which of the following is the most important nursing action that the nurse should take to prevent urinary tract infection in the catheterized patient?
 - a. Force fluids to 4000 mL every 24 hours.
 - b. Empty the Foley bag every 4 hours around the clock.
 - c. Maintain a closed catheter system.
 - d. Wash the perineum every 8 hours.
5. A patient is experiencing stress incontinence with frequent involuntary loss of urine. Which of the following directions would be most appropriate when teaching her how to perform Kegel exercises?
 - a. "Tighten your rectum at frequent intervals throughout the day."
 - b. "Keep your abdominal muscles tightened; do this every time you stand up."
 - c. "Do at least 20 sit-ups per day."
 - d. "When urinating, stop and start the stream of urine by tightening the perineal muscles."

QUESTIONS TO GUIDE YOUR READING

1. What are the predisposing causes, symptoms, laboratory abnormalities, and treatment of urinary tract infections?
2. What are the predisposing causes, symptoms, and treatment of kidney stones?
3. What should you teach patients with kidney stones?
4. What are symptoms of cancer of the bladder and cancer of the kidneys?
5. How do you give care to a patient with an ileal conduit or continent reservoir?
6. How would you explain the pathophysiology associated with diabetic nephropathy, nephrosclerosis, hydronephrosis, and glomerulonephritis?
7. What is the nursing care for patients with diabetic nephropathy, nephrosclerosis, hydronephrosis, and glomerulonephritis?
8. What are common nephrotoxic substances?
9. What is the difference between acute renal failure versus chronic renal failure?
10. What are common symptoms experienced by the patient in renal failure?
11. What nursing care should be given to patients in renal failure and with a hemodialysis blood access site?
12. How does hemodialysis and peritoneal dialysis work to replace the function of the kidney?

Disorders of the urinary tract include a variety of problems involving the kidneys, ureters, bladder, and urethra. These problems may arise from infection, obstructions, cancer, hereditary disorders, or chronic diseases. Some may lead to renal failure if not treated or controlled. Infection may be found in three different anatomic parts of the urinary tract: the urethra, resulting in **urethritis**; the bladder, with a diagnosis of **cystitis**; or the kidneys, with a diagnosis of **pyelonephritis**.

► URINARY TRACT INFECTIONS

Urinary tract infection (UTI), a general term, refers to invasion of the urinary tract by bacteria.

Predisposing Factors for Urinary Tract Infections

Urinary tract infections are almost always caused by an ascending infection, starting at the external urinary meatus and progressing toward the bladder and kidneys. Predisposing factors for UTIs include the following:

- Stasis of urine in the bladder can be caused from obstruction such as a clamped catheter or simply from not voiding frequently enough. Urine overdistends the bladder, decreasing the blood supply to the wall of the bladder, which keeps white blood cells (WBCs) from fighting contamination that may have entered the bladder. The standing urine then serves as a culture medium for bacterial growth.
- Contamination in the perineal and urethral area can be from fecal soiling, from intercourse in which bacteria are massaged into the urinary meatus, or from infection in the area, such as vaginitis, epididymitis, or prostatitis.
- Instrumentation, or having instruments or tubes inserted into the urinary meatus. The most common cause is urinary catheterization. Bacteria ascend around or within the catheter, causing infection. Many patients develop a UTI within 2 weeks of placement of an indwelling catheter.
- Reflux of urine from the urethra to the bladder or the bladder to the ureter because of faulty valves to maintain one-way flow. Reflux can be congenital, or it may be acquired as a result of previous infections.
- Previous UTIs are thought to provide a reservoir of persistent bacteria that causes reinfection.

Female patients are more likely to develop UTIs because of the shorter length of the urethra and the closer proximity of the anal orifice. The majority of UTIs are caused by the bacteria *Escherichia coli*, which is commonly found in stool. Elderly men are predisposed to infection because an enlarged prostate causes obstruction of urine flow.

urethritis: urethr—urethra (canal that discharges urine from bladder) + itis—inflammation

cystitis: cyst—closed sac containing fluid + itis—inflammation

pyelonephritis: pyelo—pelvis + nephro—kidney + itis—inflammation

Symptoms

UTIs are characterized by common symptoms of dysuria, urgency, frequency, and cloudy, foul-smelling urine.

Urethritis

Urethritis is inflammation of the urethra that may be due to a chemical irritant or bacterial infection or can be sexually transmitted. Bubble bath and bath salts are common irritants and should not be used by anyone with a history of UTIs. Urethritis can also be caused by spermicidal agents. Gonorrhea and chlamydia are sexually transmitted diseases that can cause urethritis in men. It is common to have some degree of urethritis in association with bladder or prostatic infections.

Symptoms of urethritis include urinary frequency, urgency, and dysuria. The male patient may have discharge from the penis. A urinalysis or urine culture is done to diagnose urethritis.

The treatment of urethritis is removal of the cause if it is caused by a chemical irritant. If urethritis is caused by a bacteria, an antibiotic is prescribed based on the results of a culture. Phenazopyridine (Pyridium), a urinary analgesic, is often used to treat dysuria. The patient should be forewarned that urine will turn orange while on phenazopyridine. If urethritis is sexually transmitted, it is important that the sexual partner also be treated.

Cystitis

Cystitis is inflammation and infection of the bladder wall. Symptoms include dysuria, frequency, urgency, and cloudy urine. Cystitis infection acquired outside the hospital is diagnosed with a routine urinalysis collected as a clean-catch midstream specimen. Changes seen in the urinalysis include cloudy urine and the presence of WBCs, bacteria, and sometimes red blood cells (RBCs) in the specimen. Nitrites are usually positive. Some laboratories also examine for leukocyte esterase, which is positive if infection is present in the urine. For the complicated UTI, such as one acquired in the hospital or a repeat infection, a urine culture and sensitivity should be done. Hospital-acquired UTIs are often caused by bacteria that are resistant to the usual antibiotics used for UTIs. A sensitivity test can identify which antibiotics will be effective against the offending organism.

The treatment of uncomplicated cystitis is most often a combination sulfa medication, such as sulfamethoxazole and trimethoprim (Bactrim, Septra). Complicated cystitis is often treated with ciprofloxacin (Cipro). Other antibiotics may be prescribed depending on the results of the urine culture and sensitivity. The patient is told to take all medications until gone, force fluids unless contraindicated, and return in a week for a follow-up urinalysis or culture to ensure that the infection is gone.

Pyelonephritis

PATHOPHYSIOLOGY. Pyelonephritis is infection of the kidneys. Pathophysiology includes formation of small abscesses throughout the kidney and gross enlargement of the

kidney. The cause is usually an ascending bacterial infection. On occasion, kidney infection is caused by bacteria spreading from a distant site through the bloodstream and entering the kidney through the glomerulus.

SIGNS AND SYMPTOMS. Symptoms include urgency, frequency, dysuria, flank pain, fever, and chills. The urine is cloudy with increased WBCs, bacteria, casts, RBCs, and positive nitrites. In contrast to cystitis, the patient with pyelonephritis is much sicker and shows signs of systemic disease.

DIAGNOSTIC TESTS. Several tests are helpful to differentiate pyelonephritis from cystitis. With kidney infection, the urinalysis will show casts. Casts are microscopic particles formed in the kidney from abnormal constituents in the urine such as WBCs, RBCs, or pus. The presence of casts always indicates a problem in the kidneys. The complete blood cell count (CBC) will show an elevated WBC count. The patient will also have costovertebral (flank) tenderness.

MEDICAL MANAGEMENT. Treatment of pyelonephritis includes antibiotics based on the results of the culture and sensitivity. With severe gram-negative infections, the patient is hospitalized for intravenous (IV) antibiotics. The patient with acute pyelonephritis generally heals completely after treatment and has no lasting kidney damage.

COMPLICATIONS. Repeated kidney infections can result in scarring and loss of kidney function, leading to renal failure. Septicemia may occur from bacteria invading the bloodstream. When septicemia results from a urinary cause is called **urosepsis**. In the elderly, urosepsis can be the cause of new onset confusion. The elderly or immunocompromised patient may develop septic shock from infection in the urinary tract that has invaded the bloodstream, which may result in death.

Nursing Process: The Patient with a Urinary Tract Infection

Assessment

The patient is asked about pain on urination, flank pain, or general symptoms of infection such as fever, chills, and malaise. The urine is examined for cloudiness, blood, or foul odor. The presence of a catheter, recent instrumentation, or other predisposing factor is determined. Urinalysis and culture results are examined.

It is important to listen to the patient's concerns about the diagnosis. There can be acute embarrassment and feelings of shame associated with the diagnosis of a UTI.

Nursing Diagnosis

Possible nursing diagnoses include acute pain: dysuria and flank pain; hyperthermia; impaired urinary elimination:

dysuria, frequency, urgency, or incontinence; and risk for repeat infection.

Planning

The plan for the patient focuses on promotion of comfort, treatment of symptoms of infection, and educating the patient to prevent future infections.

Implementation

Discomfort may be treated with urinary or other analgesics. Fever is treated with acetaminophen. Fluids are encouraged to help flush bacteria from the bladder. Assistance to the bathroom is provided promptly when the patient requests help to avoid incontinence related to urgency. A bedside commode may be helpful in preventing incontinence.

Patient Education

It is very important that patients be advised to take all the prescribed antibiotic until it is gone. Commonly patients take medication for several days until they no longer have symptoms and then stop. This allows the infection to continue, and it may become chronic and resistant to antibiotics.

Patients who have one UTI commonly develop repeat infections. It is important that they receive health teaching to prevent repeated infections of the urinary tract (Box 35-1 and Nutrition Notes 35-2).

BOX 35-1 Patient Teaching to Prevent Urinary Tract Infection

1. Void frequently—at least every 3 hours while awake.
2. Drink up to 3000 mL of fluid a day if there are no fluid restrictions from the physician. Preferably drink water.
3. Drink one glass of cranberry juice (10 ounces) per day.
4. Take showers; avoid tub baths.
5. Wipe perineum from the front to the back after toileting.
6. Urinate after intercourse.
7. Avoid bubble bath and bath salts, perfumed feminine hygiene products, synthetic underwear, and constricting clothing such as tight jeans.
8. Take prescribed medication for UTIs until it is all gone.
9. If UTI is associated with another source of infection such as vaginitis or prostatitis, ensure that both infections are treated.

BOX 35-2

Nutrition Notes

Urinary Tract Infections

Instructions to increase fluid intake should specify amounts to consume or amount of urine resulting. Patients have developed electrolyte imbalances by overenthusiastically forcing fluids.

An effective intervention for urinary tract infections is increasing fluid intake (with the precaution cited above), both for its flushing effect and to excrete urinary drugs. Daily intake of cranberry juice to prevent UTI has reduced bacteriuria.

urosepsis: uro—urine + sepsis—infection in the blood

Evaluation

Goals have been met if the patient states that pain, urgency, and frequency are relieved and fever is controlled. It is also important to have the patient restate what was taught to ensure that correct learning occurred.

CRITICAL THINKING

Mrs. Milan

Mrs. Milan is a 25-year-old woman who recently spent a 3-day weekend getaway with her husband. On Monday she notices that she has symptoms of dysuria, frequency, and urgency. She visits her family practitioner and is diagnosed with a UTI.

1. What could have predisposed Mrs. Milan to developing a UTI?
2. What should Mrs. Milan be taught to prevent further occurrences of a UTI?
3. What urinalysis findings would you expect for Mrs. Milan?

Answers at end of chapter.

UROLOGICAL OBSTRUCTIONS

Obstruction of urine flow in the urinary tract is always significant. When urine does not drain normally from the kidney, the resulting backup of urine eventually destroys the kidney by compressing the kidney structures. The causes of urological obstructions include strictures, stones, and tumors.

Urethral Strictures

A urethral stricture is a narrowing of the lumen of the urethra caused by scar tissue. A common cause of stricture is urethral injury resulting from insertion of catheters or surgical instruments. Strictures can also be caused by trauma from straddle injuries, a result of direct application of force to the perineal area, as well as untreated gonorrhea and congenital abnormalities.

The patient with a urethral stricture has a diminished urinary stream and is prone to develop UTIs because of obstruction of urine flow. Urethral strictures are often seen in elderly men. The problem becomes more apparent when attempts to insert a urinary catheter are unsuccessful because of the narrowed lumen.

Initially the treatment of a urethral stricture is mechanical dilation by a urologist, by inserting instruments to stretch open the urethra and then inserting a urinary catheter. If the stricture continues to be a problem after dilation, the area can be surgically repaired (**urethroplasty**).

The dilation process is often done at the bedside when the patient is awake. This is a painful experience for the patient, and it is helpful and caring to encourage the urologist to order pain medication before the procedure. The nursing diagnosis of acute pain is very relevant. An indwelling catheter is generally inserted after the dilation, so the nurs-

ing diagnosis of risk for infection is also present. Patients need teaching on how to prevent UTIs (see Box 35-1).

Renal Calculi

Renal **calculi** (kidney stones; one stone is a calculus) are hard, generally small stones that form somewhere in the renal structures. When stones are found in the kidneys, the condition is called nephrolithiasis (Fig. 35-1).

Pathophysiology

Normally the dissolved substances in urine, including urinary salts, are diluted and readily excreted from the body. Calculi are formed when urinary salts are concentrated enough to settle out; there is often a nucleus around which the salts collect and deposit. Substances that can serve as a nucleus include pus, blood, dead tissue, a catheter, and crystals. Following are common urinary salts that make up renal calculi, arranged in order of frequency:

1. Calcium oxalate
2. Calcium phosphate
3. Magnesium ammonia
4. Uric acid
5. Cystine

The majority of renal calculi contain calcium, either in the form of calcium oxalate or calcium phosphate, but it is also possible to have combination stones.

Etiology

Causes of calculi formation include a family history of stones, chronic dehydration (causing more concentrated urinary salts), and infection, because it provides a nucleus

Figure 35-1 Location of calculi in the urinary tract.

urethroplasty: urethro—urethra + plasty—surgical repair

for stone formation. Additional causes of calcium stones include dietary factors (see Nutrition Notes Box 35–2). Excessive amounts of calcium in the water in some geographic areas may also be a factor. Immobility causes stone formation because of the resulting urinary stasis; in addition, calcium leaves the unstressed bones during immobility, so more calcium is in the blood that is then filtered through the kidneys.

Signs and Symptoms

Symptoms of renal calculi include excruciating flank pain and renal colic; when the stone is lodged in the ureter, it is common to have pain radiate down to the genitalia. The pain results when the stone prevents urine from draining. Additional symptoms include hematuria from irritation by the stone, dysuria, frequency, urgency, and enuresis. The patient may also have costovertebral tenderness. Some patients develop nausea, vomiting, and diarrhea because of the proximity of the gastrointestinal structures.

Diagnostic Tests

The diagnosis of renal calculi may be made initially by doing a kidney-ureter-bladder (KUB; flat plate of the abdomen) examination or an intravenous pyelogram.

Medical Management

Renal calculi are treated medically if possible. Most stones are urinated out of the body. Patients can urinate stones if they are 5 mm or smaller; larger stones do not pass. If patients experience severe renal colic, they are admitted to the hospital. Intravenous fluids are administered to hydrate the patient and help flush the stone out of the body. All urine is strained to detect passage of stones, and pain medication such as morphine is given. If the patient is unable to pass the stone and infection, impaired renal function, or severe pain continues, intervention is needed.

LITHOTRIPSY. Lithotripsy therapy is used to break the stones into smaller parts that can then be removed or urinated out. Forms of lithotripsy include extracorporeal shock-wave lithotripsy (ESWL), electrohydraulic lithotripsy, laser lithotripsy, and percutaneous ultrasonic lithotripsy. With ESWL, the patient is immersed in a tub of water and ultrasonic shock waves are used to break up the stone into sand particles (Fig. 35–2), which are then urinated out. The patient is anesthetized for the procedure. After the procedure, the patient is usually discharged home after being told to increase fluid intake to help flush the sand out and to notify the urologist if there are any problems. Blood in the urine is common after lithotripsy.

SURGERY FOR RENAL CALCULI. For some patients, surgery may be necessary. The surgical procedure depends on the location of the stone. With any of these surgical procedures, postprocedure bleeding is a concern. Endoscopic procedures or open surgery can be used. Endoscopic procedures for the bladder include a cystoscopy for small stones and a cystolitholapaxy for larger stones. For cystolitholapaxy an instrument is inserted through the urethra to the bladder to crush the stone; the stone is then washed out with an irrigating solution. If the stone is lodged in a ureter, the urologist may insert an instrument into the ureter through a cystoscope to crush the stone or use an ultrasonic lithotripsy instrument to break the stone into fragments. Postoperative care following these procedures is similar to care following any cystoscopy. (See Chapter 34.) The open surgery procedure for stones in the bladder is a cystotomy and for the ureter is a ureterolithotomy.

For kidney stones, a percutaneous **nephrolithotomy** is performed, in which a scope is inserted through the skin

nephrolithotomy: nephro—kidney + lith—stone + otomy—incision

Figure 35-2 Extracorporeal shock-wave lithotripsy.

into the kidney to aid in breaking up the stone and to irrigate the renal pelvis. If the stone is very large, it may be necessary to do a nephrolithotomy, which is a surgical incision into the kidney to remove the stone. A pyelolithotomy is done to remove stones lodged in the renal pelvis.

Prevention of Renal Calculi

The patient may be advised to avoid foods that increase the risk of recurrent calculus development. Nutrition Notes Box 35–3 discusses foods that may contribute to calculi. (See also Cultural Consideration Box 35–4.) It should be noted that a low-calcium diet is generally no longer prescribed. Consult with the physician and dietitian to determine which foods should be avoided, depending on the type of stone found.

Complications of Renal Calculi

The presence of renal calculi increases the risk for UTIs because of obstruction of free flow of urine. Untreated ob-

struction of a stone in a ureter or the urethra can also result in retention of urine and damage to the kidney. This process is called **hydronephrosis** (discussed later).

Nursing Process

ASSESSMENT. Patients with stones are often in extreme pain and should be assessed routinely for pain. Nursing care of a patient with a renal calculus always involves careful measurement of intake and output and observation of the urine for abnormalities such as hematuria, pyuria, or passage of a stone. Temperature is monitored for onset of fever, which would indicate infection. A special strainer is used to strain all urine for stones. If a stone is found, it is saved for analysis in the laboratory. The patient is also asked about a recent history of infection, dietary or activity changes, or other risk factors for renal calculi. If the cause can be identified, teaching can be done to help prevent recurrent calculi.

NURSING DIAGNOSIS. Acute pain is a priority nursing diagnosis for any patient with renal calculi. Risk for impaired urinary elimination resulting from obstruction may be a priority issue. Risk for injury or infection from urine retention and recurrent calculi are also concerns. Deficient knowledge related to prescribed therapeutic regimen must also be addressed.

PLANNING. Planning should focus on pain relief, prevention of injury and infection, and teaching to prevent recurrent calculi.

IMPLEMENTATION. Analgesics are given to relieve pain. Fluids are encouraged to facilitate passage of the stone and to prevent dehydration if nausea and vomiting are present. Antipyretics and antibiotics may be used if infection is present. The physician is notified immediately if gross hematuria, **oliguria**, or **anuria** develops. The patient is instructed about the importance of maintaining a large fluid intake for the rest of their lives, activity increase, and diet changes if ordered.

EVALUATION. Patient outcomes are met if pain is controlled, fever and other complications are recognized and reported promptly, and the patient verbalizes understanding of self-care measures to prevent recurrent stones.

Hydronephrosis

Hydronephrosis is a condition that results from untreated obstruction in the urinary tract. It is usually treatable once the condition is detected. The obstruction of urine flow can be from a stricture in a ureter or the urethra, from kidney stones, from a tumor, or from an enlarged prostate. Because of the unrelieved obstruction, urine backs up and distends the ureters and then progresses to the kidney (Fig. 35–3). This enlargement of the kidney can be either unilateral or

BOX 35–3

Nutrition Notes

Renal Calculi

Sufficient fluid to produce 2000 mL of urine per day should be ingested to prevent concentrated urine, which enhances precipitation of crystals.

About 80 percent of kidney stones are composed of calcium oxalate, which led to early prescriptions of low-calcium diets. A large prospective study correlated higher calcium intake with fewer kidney stone occurrences, possibly because a high calcium intake inhibits gastrointestinal absorption of oxalate and consequently decreases the amount to be excreted in urine. Tables of nutritive composition of foods often are incomplete regarding oxalates; thus implementing a low-oxalate diet is problematic but recommended. Additionally, in the Curhan study, known high-oxalate foods (e.g., chocolate, nuts, tea, and spinach) were not associated with risk of kidney stones; however, intake of animal protein was directly associated and potassium and fluid intakes inversely associated with the risk of kidney stones.

Uric acid kidney stones can be a complication of gout, which is a disorder of purine metabolism. Purines are end products of digestion of certain proteins and are present in some medications. High-purine foods include organ meats, anchovies, herring, sardines in oil, meat extracts, consommé, and gravies. Low-purine foods include fruits, milk, cheese, eggs, refined grains, sugars, coffee, tea, carbonated beverages, tapioca, yeast, and vegetables (except asparagus, beans, cauliflower, mushrooms, peas, and spinach).

BOX 35–4 CULTURAL CONSIDERATION

Recurrent Calculus Development

Filipino immigrants are at high risk for developing renal stones, hyperuricemia, and gout. A shift from a traditional Filipino diet to a U.S. diet increases the occurrence of hyperuricemia, with some older Filipinos developing gout. The nurse may need to assist Filipino patients to identify food choices that will help prevent these conditions.

hydronephrosis: hydro—pertaining to water + nephrosis—degenerative change in kidney
oliguria: olig—small + uria—urine
anuria: an—without + uria—urine

Figure 35-3 Hydronephrosis. Progressive thickening of bladder wall and dilation of ureters and kidneys results from obstruction of urine flow.

bilateral. The unrelieved pressure on the kidneys from the urine causes the kidneys to become bags filled with urine instead of functioning kidneys.

If the onset of obstruction is gradual, the patient initially may be asymptomatic. Patients often develop UTIs because of the obstruction of urine flow and may have symptoms of frequency, urgency, and dysuria. As the disease progresses, flank and back pain may occur. Eventually the patient develops symptoms of renal failure (discussed later).

The treatment of hydronephrosis always involves relieving the obstruction. Initial removal of the obstruction may be done by insertion of an indwelling urinary catheter. Long-term correction of the obstruction depends on the cause and includes treatments and surgeries to relieve obstruction from strictures, stones, tumor, or an enlarged prostate. At times the obstruction cannot be relieved because a stone is too large or removal of tumor growth would result in death of the patient. In these situations, **stents**, which are tiny tubes, may be placed inside the ureters during a cystoscopy and pyelogram (C&P) to hold them open or a **nephrostomy** tube may be inserted directly into the kidney pelvis to drain urine. A nephrostomy tube exits through an incision in the flank area and allows urine to drain into a collecting bag, so that function of the kidney can be maintained. Figure 35-4 shows a stent in place in a ureter and a nephrostomy tube.

nephrostomy: nephr—pertaining to the kidney + ostomy—surgically formed artificial opening to the outside

Figure 35-4 (A) Ureteral stents. (B) Nephrostomy tube inserted into renal pelvis; catheter exits through an incision on flank.

Complications associated with hydronephrosis include increased incidence of UTIs because of obstruction of urine flow and kidney failure from unrelieved pressure on the kidneys.

Intake and output is carefully measured. Urine retention can worsen the condition and must be recognized and reported promptly. If the patient has a nephrostomy tube, ensure that it is draining adequately and prevent kinking or clamping of the tube. Kinking of the tube results in continuation of the hydronephrosis, and the resulting pressure will destroy kidney function. If both a nephrostomy tube and urinary catheter are present, output from each should be measured and documented separately.

► TUMORS OF THE RENAL SYSTEM

Cancer of the Bladder

Cancer of the bladder is the most common kind of cancer of the urinary tract. It is more commonly seen in men ages 50 to 70.

Etiology

There is a strong correlation between smoking and bladder cancer. Exposure to industrial pollution such as aniline dyes, benzidine and naphthylamine, leather finishings, metal machinery, and petroleum processing products also increases the incidence.

Pathophysiology

Cancer of the bladder often starts as a benign growth on the bladder wall that undergoes cancerous changes. Common sites for metastasis include the liver, bones, and lungs.

Diagnostic Tests

Diagnosis of cancer of the bladder is made with a cystoscopy and biopsy, as well as from laboratory tests such as a urinalysis. An intravenous pyelogram (IVP) may also be done. The patient is also examined for metastasis to other parts of the body utilizing bone scans and x-ray examinations.

Signs and Symptoms

Cancer of the bladder usually causes painless hematuria. Blood in the urine is one of the seven warning signs of cancer from the American Cancer Society. Initially the bleeding is intermittent, which often results in people's delaying seeking treatment. As the disease progresses, the patient experiences frank hematuria, bladder irritability, urinary retention from clots obstructing the urethra, and fistula formation (an opening between the bladder and an adjoining structure such as the vagina or bowel).

Medical Management

Treatment depends on the kind of bladder cancer and the severity. For small, confined tumors, chemotherapy is instilled into the bladder through a urinary catheter, allowed to dwell, and then removed along with the catheter. Treatments are given at intervals. Systemic chemotherapy is also used and can be helpful to prolong life when other treat-

ments are no longer indicated. The bacille Calmette-Guérin (BCG) vaccine may be instilled into the bladder to prevent recurring tumors.

Photodynamic therapy may be used, in which drugs are given that make tumors sensitive to light. When light is applied to the tumor area, cancer cells are killed.

Surgical treatment of cancer of the bladder includes a number of procedures. A cystoscopy and pyelogram with fulguration (destruction of tissue with electrical current) may be done to burn off cancerous tissue. An alternate method is use of a laser to destroy tumor tissue.

INCONTINENT URINARY DIVERSION. If it has been determined that the patient has a potentially curable disease with significant bladder involvement, complete removal of the bladder and creation of a urinary diversion may be done. A urinary diversion means that urine leaves the body in a different manner. A common incontinent surgery for urinary diversion is called an ileal conduit, an involved surgery in which a section of the ileum or colon is removed and used as a conduit for urine. The remaining portions of the bowel are stitched back together. The surgeon is careful to keep the blood and neurological supply intact to the section of bowel that has been removed. The isolated section of bowel is closed off on one end, the ureters are stitched into it, and the other end is brought out as a stoma on the abdomen that almost continuously drains urine (Fig. 35-5). The urine from an ileal conduit contains mucus because it comes through the ileum, which normally secretes mucus. The patient must wear an ostomy appliance at all times over the stoma to collect urine. Box 35-5 explains how to apply an appliance to an ileal conduit stoma.

CONTINENT URINARY DIVERSION. Several newer continent urinary diversion surgeries are being done for patient convenience. One version is the Kock pouch (continent internal ileal reservoir), which is created from a segment of ileum that has been made into a reservoir for urine (see Fig. 35-5). The ureters are implanted into the side of the reservoir. A special nipple valve is constructed and is the passageway through which the patient inserts a catheter at 4- to 6-hour intervals to drain urine. Another type of this surgery is the Indiana pouch (see Fig. 35-5). A reservoir is created using a portion of the ascending colon and terminal ileum, making a larger pouch than the Kock pouch. Additional versions of this type of surgery use other parts of the bowel and include the Mainz pouch or Florida pouch.

ORTHOTOPIC BLADDER SUBSTITUTION. The newest surgery is formation of an orthotopic bladder, using a section of the intestines to make a neobladder (neo = new) and implanting both the ureters and the urethra into the neobladder.

Different types of orthotopic bladder substitution surgery include the Studer pouch, hemi-Kock pouch and ileal W-neobladder. After this surgery the patient can void through the urethra, though incontinence may be a problem and intermittent catheterization may be needed.

Figure 35-5 Urinary diversion surgery. (A) Ileal conduit. (B) Kock pouch. (C) Indiana pouch.

Nursing Management

Nursing care of the postoperative patient is similar to care following any major surgical procedure. (See Chapter 11.) It is important to ensure that there is adequate urinary output and to detect and report any obstruction of urine drainage early to prevent complications. The patient will

BOX 35-5 Application of a Disposable Pouch to an Ileal Conduit

1. Gather all supplies: a washcloth and towels and water, a pouch to apply with a stomahesive flange, and wicks such as Kerlix gauze to absorb urine. The nurse should wear clean gloves.
2. Empty the old pouch.
3. Gently remove soiled pouch by pushing down on skin while lifting up on the flange. Discard soiled pouch and flange.
4. Place a towel around the stoma to catch urine.
5. Cut an opening in the flange that is only $\frac{1}{16}$ to $\frac{1}{8}$ inch larger than the stoma. Once stomal shrinkage is complete, a presized pouch can be used that fits the stoma.
6. Remove paper backing from the stomahesive and set the flange to one side.
7. Clean the skin around the stoma with water. Pat dry. Immediately wrap the stoma in wicks to absorb urine. Otherwise urine will leak onto the skin, and the flange will not adhere.
8. Center the flange over the stoma, remove the wick, and immediately apply the flange. Then snap the pouch onto the flange. **NOTE:** The flange and pouch may be snapped together before application to the stoma.
9. Use the heat of your hand to compress the flange to ensure a good seal.
10. Ensure that the bottom of the pouch is closed off, or connect to a urinary catheter bag for nighttime or for the patient in bed most of the time.

Source: Adapted from Hampton, BG, and Bryant, RA: *Ostomies and Continent Diversions: Nursing Management*. Mosby, St Louis, 1992.

need instruction on how to care for the urinary diversion after surgery, either by frequent draining with a catheter or by wearing an appliance. Be sensitive to the patient's anxiety about caring for the urinary diversion. Body image disturbance may occur because of the change in body function. A consultation with a nurse who specializes in wound and ostomy care or an ostomy support group may be helpful both before and after surgery.

Cancer of the Kidney Pathophysiology and Etiology

Cancer of the kidney is rare but serious. Risk factors include smoking and exposure to industrial pollution. Males have twice the incidence of females. Often the cancer has metastasized before it is diagnosed, because the kidney has such a large volume of circulating blood, which increases the risk for spread of the tumor. In addition, there are few early symptoms of the disease.

Signs and Symptoms

The three classic symptoms of kidney cancer are hematuria, dull pain in the flank area, and a mass in the area. Symptoms of metastasis may be the first manifestation of kidney cancer and include weight loss and increasing weakness.

Diagnostic Tests

A number of diagnostic tests will be done, including an IVP, cystoscopy and pyelogram, ultrasound examination of the kidneys, computed tomography (CT) scans, and magnetic resonance imaging (MRI). A definitive diagnosis is made with a renal biopsy.

Medical Management

A radical **nephrectomy** is the preferred treatment for cancer of the kidney. The kidney is removed, along with the adrenal gland and other surrounding structures, including fascia, fat, and lymph nodes, in the area. Radiation therapy, immunotherapy, or chemotherapy may be used following surgery.

Nursing Management

Nursing care of the nephrectomy patient is similar to postoperative care following any major surgery. (See Chapter 11.) Because the kidney is highly vascular, it is essential that the nurse observe for onset of bleeding and any signs of hypovolemic shock. Urine output is monitored. Changes in urine amount or color, bleeding, and signs of infection are reported.

► RENAL SYSTEM TRAUMA

There are many causes of trauma to the kidney, ureters, and bladder, such as motor vehicle accidents, sports injuries, falls, gunshot, and stabbing. Young males are at greatest risk for renal system trauma. Diagnostic tests include urinalysis, IVP, ultrasound, CT, and MRI. Flank pain and hematuria may be present. Treatment depends on the extent of the injury and ranges from bedrest to surgical intervention. Nursing care includes measuring intake and output, monitoring vital signs, and providing IV fluids and pain relief.

► POLYCYSTIC KIDNEY DISEASE

Polycystic kidney disease is a hereditary disorder that can result in renal failure. The disease is characterized by formation of multiple cysts in the kidney that can eventually replace normal kidney structures. The cysts are grape-like and contain serous fluid, blood, or urine. The patient generally first shows signs of the disease in adulthood. The initial symptoms include a dull heaviness in the flank or lumbar region and hematuria. As the disease progresses, the patient develops symptoms of renal failure (discussed later).

There is no treatment to stop the progression of polycystic kidney disease. Complications such as urinary tract infections are treated as needed. As the disease progresses, treatment for hypertension and eventual renal failure may be necessary. Because polycystic disease is hereditary, patients should be counseled about the risks of children inheriting it.

► CHRONIC RENAL DISEASES

Diabetic Nephropathy

Diabetic **nephropathy** is the most common cause of renal failure. It is a long-term complication of diabetes mellitus in which the effects of diabetes result in damage to the small blood vessels in the kidneys. Renal damage shows up approximately 15 to 20 years after onset of type 1 diabetes (insulin dependent), but it may also be a complication of type 2 diabetes (non-insulin dependent). Careful control of blood glucose levels reduces the risk of nephropathy in patients with diabetes.

Pathophysiology

Multiple factors contribute to diabetic nephropathy. Widespread atherosclerotic changes occur in the blood vessels of patients with diabetes, decreasing the blood supply to the kidney. Abnormal thickening of glomerular capillaries damages the glomerulus, allowing protein to leak into the urine. Patients with diabetes also commonly develop pyelonephritis and renal scarring. Another complication of diabetes, neurogenic bladder, causes incomplete bladder emptying. This results in retention of urine, which can cause infection or obstruction of urine, further damaging the kidneys.

Initially patients lose only small amounts of protein in their urine (microalbuminuria); this disease can be detected only with careful watching by the physician, utilizing frequent examinations of the urine. As the disease progresses, high-output renal failure (nonoliguria) can develop, in which a large amount of diluted urine is excreted without the usual amounts of waste product dissolved in the urine. The patient can lose large amounts of protein in the urine and may develop nephrotic syndrome, which causes massive edema because of low levels of albumin in the blood. As renal function decreases, the patient needs smaller doses of insulin because the kidney normally degrades insulin. Because the kidney is no longer able to break down insulin and excrete it, small doses of insulin circulate in the body for long periods.

Symptoms

As diabetic nephropathy progresses, urine output decreases, toxic wastes accumulate, and the patient develops chronic renal failure. Symptoms of chronic renal failure are found in Figure 35–6.

Diagnostic Tests

Diabetic nephropathy is diagnosed by careful watching of the patient with diabetes for onset of protein spillage in the urine, which is an early sign of the disease. Serum creatinine levels and 24-hour creatinine clearance tests are then done to confirm the presence and extent of diabetic nephropathy.

nephrectomy: nephro—kidney + ectomy—excision

nephropathy: nephro—pertaining to the kidney + pathy—disease

Figure 35-6 Symptoms of chronic renal failure.

Medical Management

In the early stages of diabetic nephropathy, strict control of blood glucose levels and blood pressure and a restricted-protein diet can help slow the progress of the disease and reduce symptoms. As the disease progresses to renal failure, the patient needs dialysis to maintain life. Unfortunately, other complications related to diabetes cause patients to tolerate dialysis less well than patients with renal failure from other causes. Kidney or kidney-pancreas transplant, when available, is the treatment of choice for the patient with diabetic nephropathy and often improves the patient's chance for a healthier life.

Complications

Patients with diabetic nephropathy often have a guarded prognosis because they are vulnerable to all the complications of long-term diabetes in addition to kidney disease. (See Chapter 38.)

Nephrotic Syndrome

Nephrotic syndrome may occur as a result of other disease processes (Table 35-1). In nephrotic syndrome, large amounts of protein are lost in the urine from increased glomerular membrane permeability. As a result, serum albumin and total serum protein are decreased. Normally, albumin and other serum proteins maintain fluid within the vascular space. When levels of these proteins are low, fluid leaks from the blood vessels into tissues, resulting in edema. With very low levels of protein, ascites and massive widespread edema (anasarca) occur. In response to the low protein levels, the liver produces lipoproteins. As a result, serum cholesterol, low-density lipoproteins, and triglyceride levels are elevated.

TABLE 35-1 CAUSES OF NEPHROTIC SYNDROME

- Primary nephrotic syndrome
- Glomerulonephritis
- Diabetes
- Systemic lupus erythematosus
- Infections: streptococcal, human immunodeficiency virus (HIV), hepatitis, malaria
- Cancer: leukemia, Hodgkin's disease
- Drugs: nonsteroidal anti-inflammatory drugs (NSAIDs), penicillamine, captopril

Treatment is focused on the cause and symptoms of nephrotic syndrome. To control edema, sodium intake is restricted. A low to moderate protein intake is ordered to prevent buildup of nitrogen wastes (nitrogen wastes result from protein metabolism) from impaired kidney function. Protein intake is based on the severity of urinary protein loss. Diuretics may be used. Lipid-lowering drugs may be tried. Anticoagulants are given for thrombosis. In some cases, corticosteroids may be used.

Complications of nephrotic syndrome include impaired immune function, nutritional imbalances, and most importantly increased blood coagulation. Nursing care focuses on the edema and preventing infection. For edema, daily weights, careful intake and output measurement, and abdominal girth measurement are performed and documented. Edematous tissue must be protected from injury. Preventing malnutrition is challenging but important in maintaining normal body functions.

Nephrosclerosis

Hypertension damages the kidneys by causing sclerotic changes, such as arteriosclerosis with thickening and hardening of the renal blood vessels (**nephrosclerosis**). The arteriosclerotic changes in the kidney blood vessels result in a decreased blood supply to the kidney (ischemia of the kidney) and can eventually destroy the kidney. Symptoms of nephrosclerosis include proteinuria, hyaline casts in the urine, and, as it progresses, symptoms of renal failure.

The treatment of nephrosclerosis is treatment of hypertension. The patient is placed on antihypertensive medications or, if already on these, changed to stronger antihypertensive medications. The patient is placed on a low-sodium diet. If the patient develops renal failure, dialysis will be used to maintain life.

The prognosis is often poor because by the time the patient has developed nephrosclerosis, there is widespread arteriosclerosis throughout the body. Arteriosclerosis makes the patient prone to myocardial infarctions or cerebrovascular accidents.

The major nursing diagnosis that is relevant when the patient develops nephrosclerosis is impaired health mainte-

nephrosclerosis: nephro—pertaining to the kidney + sclerosis—hardening

nance. The priority is to help the patient learn as much about the control of hypertension as possible. The patient should also be taught the symptoms of renal failure. Once the patient has lost renal function, the nursing care plan for renal failure is appropriate.

CRITICAL THINKING

Mr. White
Mr. White is a 35-year-old African-American gentleman admitted to the intensive care unit with uncontrolled hypertension. His blood pressure is controlled by intravenous medication. His lab tests show protein and hyaline casts in the urine. He is diagnosed with nephrosclerosis.

1. What should the nurse assess as part of the morning evaluation of the patient's condition?
2. What other renal function tests are appropriate for the nurse to check?
3. What teaching does Mr. White need when his condition is more stable?

Answers at end of chapter.

► GLOMERULONEPHRITIS

Pathophysiology

Glomerulonephritis is an inflammatory disease of the glomerulus. Inflammation occurs as a result of the deposition of antigen-antibody complexes in the basement membrane of the glomerulus or from antibodies that specifically attack the basement membrane. The resulting immune reaction in the glomerulus causes inflammation, which in turn causes the glomerulus to be more porous, allowing proteins, white blood cells, and red blood cells to leak into the urine.

Etiology

Acute Poststreptococcal Glomerulonephritis

Glomerulonephritis can be caused by a variety of factors but is most commonly associated with a group A beta-hemolytic streptococcus infection following a streptococcal infection of the throat or skin. This is the most common cause in children and young adults. Antibodies form complexes with the streptococcal antigen and are deposited in the basement membrane of the glomerulus. Glomerulonephritis generally develops about 6 to 10 days after the preceding infection. Other kinds of bacteria and viruses can also be the offending infectious agent.

Goodpasture's Syndrome

Occasionally glomerulonephritis is caused by an autoimmune response, in which the person for some unknown reason forms antibodies against his or her own glomerular

basement membrane. Glomerulonephritis caused by an autoimmune response usually progresses rapidly and often leads to renal failure.

Chronic Glomerulonephritis

Chronic glomerulonephritis occurs over years as a result of glomerular inflammatory disease. It is often discovered during an examination for another concern. Ultrasound, CT scan, or renal biopsy is used to diagnose the cause.

Symptoms

The symptoms of glomerulonephritis include fluid overload with oliguria, hypertension, electrolyte imbalances, and edema. Edema may begin around the eyes (periorbital edema) and face and progress to the abdomen (ascites), lungs (pleural effusion), and extremities. Flank pain may be present. Blood urea nitrogen (BUN) and creatinine levels may be elevated. Urinalysis shows red blood cells, white blood cells, albumin, and casts. The urine is dark or cola colored from old red blood cells and may be foamy because of proteinuria.

Medical Management

Most cases of acute glomerulonephritis resolve spontaneously in about a week, but some progress to renal failure. Treatment is primarily symptomatic. Sodium and fluid restrictions may be ordered along with diuretics to treat fluid retention. Medications may be given to control hypertension. If associated with a streptococcus infection, antibiotics are given to treat any remaining infection. If fluid overload is severe, dialysis may be done.

Complications

The prognosis is good for acute glomerulonephritis acquired in childhood, and the majority of children recover completely. Adults who develop glomerulonephritis may recover renal function or progress to chronic glomerulonephritis. Some patients develop rapidly progressive glomerulonephritis, which can quickly lead to renal failure. Chronic glomerulonephritis is a slow process characterized by hypertension, gradual loss of renal function, and eventual renal failure, discussed next.

Nursing Management

Nursing care for a patient with glomerulonephritis focuses on symptom relief. Vital signs are monitored because the patient may be critically ill. During the acute phase, rest is encouraged. Edema is controlled with fluid and sodium intake restrictions. Protein intake may be limited if the kidneys are not filtering protein waste products (as seen by increased serum BUN and creatinine levels). Other care is discussed in the section on chronic renal failure. Teaching the patient about preventing glomerulonephritis is important. Antibiotics for diagnosed streptococcal throat infections should be taken for prevention.

glomerulonephritis: glomerulo—glomerulus + nephro—kidney + itis—inflammation

► RENAL FAILURE

Renal failure, also called kidney failure, is diagnosed when the kidneys are no longer functioning adequately to maintain normal body processes. This results in dysfunction in almost all other parts of the body as a result of imbalances in fluid, electrolytes, and calcium levels, as well as impaired RBC formation and decreased elimination of waste products. Renal failure can be acute, with sudden onset of symptoms, or chronic, occurring gradually over time. For more information on kidneys, visit the American Kidney Fund at www.akfnc.org, the National Kidney Foundation at www.kidney.org, and the American Association of Kidney Patients at www.aakp.org.

Acute Renal Failure

Acute renal failure (ARF) occurs when loss of kidney function is sudden, with a rapid onset of hours to days.

Pathophysiology and Etiology

In acute renal failure, rapid damage to the kidney causes waste products to accumulate in the bloodstream, resulting in the symptoms of renal failure. The patient becomes oliguric, with urine output decreasing to less than 20 mL per hour. Many patients with acute renal failure recover completely with treatment directed toward correcting the cause, supporting the patient with dialysis, and prevention of complications that may lead to permanent damage. Approximately 50 percent of patients die as a result of complications of infection, pneumonia, or septicemia.

Three categories of causes can lead to acute renal failure. Each category is associated with the location of the cause in the kidney.

PRERENAL FAILURE. Prerenal (before the kidney) failure is associated with a decrease or interruption of blood supply to the kidneys. The causes may include a decrease in blood pressure as a result of dehydration, blood loss, shock, or trauma to or blockage in the arteries that carry blood to the kidneys. When the nephrons receive an inadequate blood supply, they are unable to make urine and the waste products are not adequately removed.

Prerenal failure can be diagnosed by evaluating possible causes. An arteriogram of the renal arteries is helpful to determine if the blood supply to the kidneys is decreased or blocked; angioplasty may be used to open the blockage.

INTRARENAL FAILURE. Intrarenal failure (inside the kidney) occurs when there is damage to the nephrons inside the kidney. The most common causes are from infectious processes leading to glomerulonephritis, trauma to the kidney, exposure to **nephrotoxins** (Table 35–2), allergic reactions to radiograph dyes, and severe muscle injury, which releases substances that are harmful to the kidneys.

TABLE 35–2 COMMON NEPHROTOXINS

Antibiotics
Aminoglycosides
Tetracyclines
Cephalosporins
Sulfonamides
Vancomycin
Amphotericin B
Analgesics

Arsenic
Copper
Gold
Lithium
Contrast Dyes
Contrast media used for diagnostic testing such as intravenous pyelograms, cardiac catheterizations
Organic Solvents
Gasoline
Glycols
Kerosene
Turpentine
Tetrachloroethylene
ACE = angiotensin-converting enzyme.

A number of substances can be toxic to the kidneys (nephrotoxic) when they enter the body. Kidney damage is most likely to occur when these substances enter the body in high concentrations or when there is preexisting kidney damage for some other reason. Environmental nephrotoxins, such as insecticides and lead paint, may be ingested by children. Many commonly administered medications can be nephrotoxic. Aminoglycosides are nephrotoxic antibiotics; when they are administered, blood levels of the drugs are carefully monitored to avoid toxic levels.

Contrast media used during tests such as intravenous pyelograms and CT scans can cause kidney damage when the patient is dehydrated or has preexisting renal damage. The medium can precipitate out in the tubules, damaging the kidney. It is important for the patient to be adequately hydrated after any diagnostic test using a contrast medium to decrease the incidence of toxicity.

LEARNING TIPS

To protect patients' kidneys, be aware of the following:

- The patient's renal function status: Serum BUN and creatinine levels will tell you this.
- Nephrotoxic substances:
 - Diagnostic contrast media (dyes) in presence of dehydration or renal impairment
 - Medications—IV aminoglycosides (gentamicin, tobramycin, amikacin), cisplatin
 - Chemicals—arsenic, carbon tetrachloride, lead, mercuric chloride
- Preventive measures:
 - Before administering nephrotoxic dyes or medications, check serum BUN and creatinine levels.
 - Make sure peak and trough drug levels of nephrotoxic drugs are obtained on an ongoing basis per institutional policy.
 - After contrast media (dye) tests, encourage fluids to dilute and flush, flush, flush the dye away!

POSTRENAL FAILURE. Postrenal (after the kidney) failure is associated with an obstruction that blocks the flow of urine out of the body. In this case the blood supply to the kidneys and nephron function initially may be normal, but urine is unable to drain out of the kidney, resulting in

backup of urine and impaired nephron function. Common causes are kidney stones, tumors of the ureters or bladder, and an enlarged prostate that blocks the flow of urine.

Diagnosis of causes of postrenal failure can be done with x-ray examination of the kidneys, ureters, and bladder. Cystoscopy will show presence of tumors, stones, or prostate enlargement. Surgical intervention may be needed to correct the problem.

Medical Management

Acute renal failure is treated by relieving the cause. The care of the patient with acute renal failure is similar to care of the patient with chronic renal failure, as explained in the next section.

CONTINUOUS RENAL REPLACEMENT THERAPY. Temporary dialysis or continuous renal replacement therapy (CRRT) may be necessary to treat renal failure and to prevent permanent renal damage (Fig. 35-7). Temporary **hemodialysis** is indicated for severe symptoms of **uremia**. He-

hemodialysis: hemo—blood + dialysis—passage of a solute through a membrane

uremia: ur—urea + emia—in the blood

Figure 35-7 Continuous renal replacement therapy: continuous arteriovenous hemofiltration.

modialysis is intermittent, but CRRT can be used to remove fluid continuously along with the hemodialysis. CRRT is also used alone to remove fluid and solutes in a controlled, continuous manner in unstable patients with fluid overload, as in acute renal failure or pulmonary edema. CRRT is done in a variety of ways that depend on arterial or venous access of a central artery or vein. A pump is required to move the blood when venous access is used. CRRT is not as complex as hemodialysis and can be done for more than a month if needed.

During CRRT, a permeable hemofilter is attached to the vascular access. Blood flows through the hemofilter and excess fluids and solutes move into a collection bag. The remaining blood returns to the patient via the venous access. If desired, replacement fluid and electrolytes can be given through the vascular access. Monitoring intake and output, fluid and electrolytes, daily weights, hourly vital signs, and vascular access is important.

Chronic Renal Failure

Chronic renal failure (CRF) affects approximately 290,000 people in the United States. It occurs with a gradual decrease in the function of the kidneys over time. This loss of function is not reversible.

Etiology

The causes of chronic renal failure are numerous; common ones include diabetes mellitus resulting in diabetic nephropathy, chronic high blood pressure causing nephrosclerosis, glomerulonephritis, and autoimmune diseases.

Pathophysiology

When a large proportion of the nephrons are damaged or destroyed because of acute or chronic kidney disease, renal failure occurs. As the nephrons die off, the undamaged ones increase their work capacity and take over the work previously done by the dead ones, so the patient may experience significant kidney damage without showing symptoms of renal failure.

Chronic renal failure is a progressive disease process. In the early, or silent, stage the patient is usually without symptoms, even though up to 50 percent of nephron function may have been lost. This stage is often not diagnosed.

The renal insufficiency stage occurs when the patient has lost 75 percent of nephron function and some signs of mild renal failure are present. Anemia and the inability to concentrate urine may occur. The BUN and creatinine levels are slightly elevated. These patients are at risk for further damage caused by infection, dehydration, drugs, heart failure, and use of diagnostic x-ray dyes. The goal of care is to prevent further damage if possible by good control of blood sugar levels and blood pressure.

End-stage renal disease (ESRD) occurs when 90 percent of the nephrons are lost. Patients at this stage experience chronic and persistent abnormal kidney function. The BUN and creatinine levels are always elevated. These patients may make urine but not filter out the waste products,

or urine production may cease. Dialysis or a kidney transplant is required to survive.

Uremia (urea in the blood) is present in chronic renal failure. Patients eventually develop problems in all body systems. Table 35–3 shows the effect of renal failure on body systems. If left untreated, the patient with uremia dies, often within weeks.

Symptoms of Renal Failure and Nursing Interventions

Patients in either acute or chronic renal failure have multiple symptoms. Some of the more common symptoms associated with renal failure are explained next (see Fig. 35–6).

Disturbance in Water Balance

Patients with renal failure experience disturbances in the removal and regulation of water balance in the body and show signs of fluid accumulation. An early symptom is edema (swelling) of the extremities, sacral area, and abdomen. Patients may complain of being short of breath. Crackles and wheezes may be present on auscultation of the lungs, which are signs of fluid accumulation in the lungs. The blood vessels in the neck may be distended, and the patient may be hypertensive. These patients may produce a large amount of dilute urine (**polyuria**), small amounts of urine (oliguria), or no urine (anuria).

Nursing care for disturbances in water balance involves monitoring the patient's weight at the same time each day. The patient who is retaining fluid will have an increase in weight. Intake and output are measured, and a fluid restriction will be ordered by the physician, generally 1000 mL per 24 hours. Lung sounds are monitored for crackles and wheezes. Symptoms of fluid retention are reported.

Disturbance in Electrolyte Balance

As kidney function decreases, the kidneys lose their ability to absorb and excrete electrolytes. Important electrolytes are sodium, potassium, and magnesium. When the kidneys are unable to maintain normal amounts of electrolytes in the blood, these substances accumulate at high levels and may be life threatening.

When the kidneys are unable to regulate sodium levels adequately, the patient may show signs of hypernatremia, an excessive sodium level in the blood, which causes water retention, edema, and hypertension. Hyponatremia, too little sodium, may occur when too much sodium is lost. This can occur when the patient has experienced prolonged episodes of vomiting or diarrhea or is urinating large amounts of diluted urine. Patients with hyponatremia may show signs of confusion.

Hyperkalemia (high level of potassium) presents a life-threatening situation. The patient may exhibit signs of dysrhythmia and cardiac arrest if the potassium level is too high. Patients complain of muscle weakness, abdominal cramping, and diarrhea. The nurse may identify that the pa-

polyuria: poly—much + uria—urine

TABLE 35-3 EFFECTS OF RENAL FAILURE ON BODY SYSTEMS

Body System	Disease Process
Cardiovascular	Hypertension due to fluid overload and accelerated arteriosclerosis Congestive heart failure/pulmonary edema due to fluid overload, increased pulmonary permeability, left ventricular failure Angina due to coronary artery disease, anemia Dysrhythmias due to electrolyte imbalance, coronary artery disease Edema due to fluid overload and a decrease in osmotic pressure Pericarditis due to presence of waste products in the pericardial sac
Pulmonary	Pleurisy/pleural effusion due to waste products in the pleural space causing inflammation with pleurisy pain and also collection of fluid resulting in effusion
Hematopoietic	Anemia due to impaired synthesis of erythropoietin, a substance needed by the bone marrow to stimulate formation of RBCs; also due to decreased life span of RBCs due to uremia and interference in folic acid action Bleeding tendency due to abnormal platelet function from effects of uremia Prone to infection due to a decrease in immune system function from uremia; renal patients can rapidly become septic and die from septic shock
Integumentary	Dry, itchy, inflamed skin due to calcium-phosphate deposits in the skin and urochrome, and a pigment of uremia, which causes the skin to be pale gray, yellow bronze; skin will have an odor of urine because skin is an organ of excretion and the body attempts to remove toxins; there is also a decrease in function of oil and sweat glands
Gastrointestinal	Stomatitis due to fluid restriction, presence of waste products in the mouth, secondary infections Anorexia, nausea, vomiting due to uremia Gastritis/gastrointestinal bleeding due to urea decomposition in gastrointestinal tract releasing ammonia that irritates and ulcerates the stomach or bowel; patient is also under stress, increasing ulcer formation, and may have platelet dysfunction Constipation due to electrolyte imbalances, decrease in fluid intake, decrease in activity, phosphate binders Diarrhea, hypermotility due to electrolyte imbalance
Neurological	Confusion due to uremic encephalopathy from an increase in urea and metabolic acids Peripheral neuropathy due to effects of waste products on neurological system Cerebrovascular accidents due to accelerated atherosclerosis
Skeletal	Bone disease due to renal osteodystrophy from hyperphosphatemia and hypocalcemia
Reproductive	Loss of libido, impotence, amenorrhea, infertility due to a decrease in hormone production

tient is confused or demonstrates disinterest in care. Hyperkalemia exists when the potassium level exceeds 5 mEq/L. These patients should be placed on a cardiac monitor and observed for cardiac dysrhythmias. A potassium level above 7 mEq/L may be life threatening. A high potassium level in the patient with renal failure may be caused by a diet high in potassium-rich foods, injuries, or blood transfusions. Nursing care should include monitoring daily laboratory values, restricting potassium intake, and reporting abnormalities. Insulin or sodium bicarbonate may be used as a temporary measure to drive excess potassium into the cells. Sodium polystyrene sulfonate (Kayexalate) may be given either orally or as a retention enema; it causes the potassium to be eliminated through the bowels. The definitive treatment for hyperkalemia is hemodialysis to remove potassium from the body. Dietary education is extremely important. The patient is instructed to avoid foods that are high in potassium (Box 35-6).

BOX 35-6 Foods High in Potassium

Citrus fruits and juices
Bananas
Salt substitutes
Potatoes, sweet and white
Excessive dairy products
Excessive meats
Chocolate

Calcium levels decrease because the kidneys are unable to produce the hormone that activates vitamin D, the vitamin that is necessary for the absorption of calcium. Hypocalcemia exists when the calcium level falls below 8.5 mg/dL. Also associated with a low calcium level is hyperphosphatemia, a phosphorous level above 5 mg/dL. These imbalances cause the bones to release calcium, causing patients to be prone to fractures. These patients should ambulate regularly to prevent further calcium loss from the bone.

Phosphates are supplied by some foods. The increase in phosphorus levels may result in severe itching, and patients may have open sores as a result of scratching, placing them at risk for infections. Patients complain of muscle cramps and aches. Medications to bind phosphate are given to patients with high phosphate levels. Tums and Caltrate (calcium carbonate) or PhosLo (calcium acetate) are examples of commonly ordered phosphate binders. These must be given to the patient with meals, so that the medicines can bind with the phosphates in the bowel and be eliminated.

Disturbance of Removal of Waste Products

When the kidneys are unable to remove the waste products of metabolism, **azotemia** occurs. This is an increase in the serum urea level (measured by BUN); creatinine levels are often elevated as well. These substances are the

azotemia: azo—nitrogenous waste products + temia—blood

result of protein metabolism. The patient may show signs of weakness and fatigue, confusion, seizures, twitching movements of extremities (asterixis), nausea, vomiting, and lack of appetite and may complain of a bad taste in the mouth. The nurse may smell urine on the patient's breath. The patient may have yellowish-pale skin and complain of itching.

Nursing care for patients with azotemia includes monitoring laboratory results and treating and reporting symptoms. Adequate nutrition is important; the dietitian should be consulted to recommend the appropriate low-protein diet to decrease formation of these waste products.

Good oral care and skin care is important for these patients. The nurse should offer mouth care frequently and inspect the mouth for sores. Lotion is used for itching, and the skin is observed for open areas and signs of infection. The patient is protected from injury if confusion or seizures occur. Dialysis to remove the excessive waste products in the blood is the only treatment of the underlying causes of these symptoms.

Disturbance in Maintaining Acid-Base Balance

Renal failure affects hydrogen ion excretion, causing a disturbance in acid-base balance that results in metabolic acidosis. Patients may complain of a headache, fatigue, weakness, nausea, vomiting, and lack of appetite. As the acidosis progresses, the patient shows signs of lethargy, stupor, and coma. Respirations become fast and deep as the lungs attempt to blow off carbon dioxide to correct the acidosis. See Chapter 5 for a more detailed discussion of acid-base balance.

Disturbance in Hematological Function

Failing kidneys do not produce adequate erythropoietin, the hormone that stimulates red blood cell production. Nutritional deficiencies and blood loss during dialysis also contribute to anemia. Regular injections of epoetin (Epogen, Procrit), a synthetic form of erythropoietin, helps restore RBC production and prevent anemia.

Impaired white blood cell and immune functions contribute to an increased risk for infection. The patient should be protected from potential sources of infection.

Impaired platelet function creates a risk for bleeding. The patient should be protected from injury, and signs of bleeding, such as blood in stool or emesis, should be reported.

Medical Management of Renal Failure

Renal insufficiency and early renal failure are treated symptomatically with restricted diet and fluids, medications, and careful monitoring for onset of serious problems that warrant initiation of dialysis. In later stages, dialysis is necessary to replace lost kidney function. A kidney transplant, when available, may return the patient to a nearly normal state of health.

Diet

Dietary recommendations are individualized by the dietitian and physician, based on the patient's needs. Calories are high to maintain weight and energy needs. Protein is usually restricted to limit nitrogen intake but may be increased for the patient on dialysis, because protein is lost during the dialysis process. Sodium is restricted to minimize sodium and fluid retention. Potassium is restricted, especially later in the disease when the kidneys are unable to eliminate it. Calcium is increased or supplemented because of poor absorption related to faulty vitamin D activation. Phosphorus is restricted because of high blood levels related to hypocalcemia. Saturated fat and cholesterol are restricted for patients with hyperlipidemia. Fluids are restricted to prevent overload. Most patients are given iron, vitamins, and minerals to supplement the restricted diet (Nutrition Notes Box 35–7).

BOX 35-7

Nutrition Notes

Understanding Dietary Changes in Renal Disease

Patients with impaired renal function require careful coordination of diet with current physiological status, which may change frequently. Six National Renal Diets have been developed for patients with renal sufficiency who are being treated with hemodialysis or peritoneal dialysis. Different diets are used for patients with and without diabetes. The following principles are offered as general guidelines.

- Caloric intake is maintained to avoid catabolism of tissue for energy. Simple carbohydrates and monounsaturated and polyunsaturated fats are given freely because their end products, carbon dioxide and water, are less likely than protein to burden the kidney. Patients with diabetes and uremia may receive higher amounts of sugar than usual because treatment of the uremia may take precedence over the diabetes. Patients with type IV hypertriglyceridemia may have to limit carbohydrates.
- Protein may be restricted when the patient's kidneys are failing but increased when the patient is treated with dialysis to compensate for losses in the dialysate. Sometimes proteins of high biologic value (e.g., eggs, meat, and dairy products) are prescribed because they are more easily converted to body protein than those of low biologic value. In other situations, vegetarian diets may be given, with the plant proteins carefully selected to manage potassium and phosphorus serum levels.
- Sodium may be restricted, depending on blood pressure, edema, and laboratory findings.
- Potassium may be restricted for patients with oliguria. Salt substitutes are often potassium compounds that are to be avoided. Potassium content in foods varies with processing and preparation methods. Patients should choose from prescribed foods only.
- Fluid restriction may be altered daily according to output. Renal insufficiency patients may receive 500 mL plus the amount of the previous day's output.

Figure 35-8 Hemodialysis.

Because restrictions are complex, the diet is a source of frustration for many patients. The nurse should assist the patient to identify foods that are palatable yet within the diet plan. The dietitian should be consulted for instruction and assistance.

Medications

Early in the disease, diuretics are given to increase output, and angiotensin-converting enzyme (ACE) inhibitors, calcium channel blockers, or beta-blocking agents may be used to control hypertension. Phosphate binders are given with meals to reduce phosphate levels. Calcium and vitamin D supplements are used to raise calcium levels. Agents to lower potassium levels are used if necessary. All drug therapy is closely monitored because diseased kidneys are unable to effectively remove medications from the body.

Dialysis

Dialysis is started when the patient develops symptoms of severe fluid overload, high potassium levels, acidosis, or symptoms of uremia that are life threatening.

HEMODIALYSIS. Hemodialysis involves the use of an artificial kidney to remove waste products and excess water from the patient's blood. The blood flows from the patient's body through tubes into an artificial kidney called a dialyzer. The artificial kidney has specialized chambers that allow the patient's blood to flow through while the waste products and excess fluids pass into a dialysate solution that circulates around the chambers. The dialysate solution carries the waste products away, and the cleansed blood is returned back into the patient's body through another tube (Fig. 35-8). A hemodialysis treatment takes 3 to 4 hours and is done three or four times a week. Hemodialysis is done at a hemodialysis center (Fig. 35-9) or in the hospital if the patient develops a complication and needs hospitalization.

Hemodialysis provides a rapid and efficient way to remove waste products from the blood. It is also an excellent

means to correct excessive fluid-overloaded states such as occur in heart failure.

Hemodialysis is not without side effects. Following a treatment, the patient normally feels weak and fatigued, sometimes even too tired to eat. Sudden drops in blood pressure may cause the patient to become weak, dizzy, and nauseated. Cardiac dysrhythmias and angina may occur. Fluid and electrolyte levels drop rapidly and cause the patient to feel lethargic and have muscle cramps. Patients are given large amounts of heparin, an anticoagulant used to keep the blood from clotting while it is in the artificial kidney; this may cause bleeding from the puncture sites, gastrointestinal tract, nose, or other sites if injury occurs.

The hemodialysis patient requires a surgically placed access site that allows the blood to be removed from the body and replaced back into the body at the time of dialysis. An access is made by joining an artery and a vein together under the skin. There are two kinds of permanent access. An arteriovenous graft (AV graft) uses a piece of special material (e.g., Gore-Tex or the new Vectra VAG, which reduces

Figure 35-9 Patient undergoing hemodialysis at dialysis center.

the waiting period after surgical implantation and decreases postdialysis bleeding time) that is sewn to an artery and then attached to a vein. An AV fistula is made by sewing the vein and the artery together (Fig. 35–10). The graft and the fistula are both placed in the arm when possible. Both types of access sites take 1 to 2 weeks to mature once the surgical procedure is completed. This allows the new site to receive the high-pressure blood from the dialyzer following the treatment.

A temporary access is used for patients requiring hemodialysis before the graft or fistula is placed or is usable. This is a special hemodialysis catheter that is placed in the subclavian vein or the jugular vein in the neck or the femoral vein in the groin.

Special care of the access site must be taken because this is the patient's only way to eliminate waste products (Box 35–8). It is important that the site be carefully monitored per institution policy to detect any clotting or problems at the site. Early detection of clotting allows the surgeon an opportunity to save the access by performing a declotting procedure, rather than a total revision. Box 35–9 describes care of the patient during hemodialysis.

PERITONEAL DIALYSIS. Peritoneal dialysis provides continuous dialysis treatment and is done by the patient or family in the home. The peritoneal membrane is used as a semi-permeable membrane across which excess wastes and fluids move from blood in peritoneal vessels into a dialysate solution that has been instilled into the peritoneal cavity. A peritoneal catheter is placed into the patient's peritoneal space between the two layers of the peritoneum below the waistline. This catheter is used to perform an exchange. The exchange process has three steps: filling, dwell time, and draining.

peritoneal dialysis: peritoneal—peritoneum + dialysis—passage of a solution through a membrane

Figure 35-10 Hemodialysis access sites. (A) Arteriovenous fistula. (B) Arteriovenous vein graft.

BOX 35-8 Care of Blood Access Graft or Fistula

1. Watch for signs of bleeding or infection at the site.
2. Listen for a bruit at the site by placing the diaphragm of a stethoscope gently on the site. A bruit is a swishing sound made as the blood passes through the access site.
3. Gently palpate the site for a thrill, which is a buzzing or pulsing feeling that indicates good blood flow through the access site.
4. Do not take blood pressure, use a tourniquet, draw blood, or start any intravenous lines in the affected arm. Injections should be avoided if possible.
5. Many hospitals have the patient wear a red arm bracelet to signify that the arm should be protected. A sign above the bed may also be helpful.
6. Teach the patient to avoid wearing constrictive clothing or jewelry over the site.
7. Teach the patient to avoid prolonged bending or sleeping on the arm with an access.
8. Notify the physician if signs of bleeding or reduced circulation through the access site occur.

BOX 35-9 Nursing Care of the Patient Receiving Hemodialysis

1. Consult with the physician about medications to hold before hemodialysis. Some medications, such as antihypertensives, can be harmful when they become effective during dialysis and can reduce blood pressure to dangerously low levels. Other medications are water soluble and will be dialyzed out and thus are not effective.
2. Ensure that the patient is weighed both before dialysis in the morning and after dialysis to document weight loss as a result of fluid removal.
3. If the patient has lab tests ordered and blood needs to be drawn, coordinate this process with the dialysis nurse, who can obtain the blood samples and save the patient unnecessary needle sticks.
4. Try to get morning care done early and breakfast given before dialysis. After dialysis, patients are often exhausted and need rest.
5. When the patient returns from dialysis, weigh the patient, assess the access site for bleeding, and make sure the vital signs are stable. Administer medications that were held if not contraindicated and vital signs are stable.
6. Protect the patient's dialysis access as outlined in Box 35–4. *No dialysis access site should be utilized for any purpose other than dialysis.*

The fill step involves instilling a bag of sterile dialyzing solution (dialysate) into the patient's peritoneal cavity through the catheter. The amount of solution is usually 1500 to 2000 mL. The solution is left to dwell in the abdomen for several hours, allowing time for the waste products from the blood to pass through the peritoneal membrane into the dialysate solution (Fig. 35–11).

The solution is then drained out of the body and discarded. This process is repeated three or four times a day and is continuous for the patient. Several different treatment plans use this exchange process; the treatment plan

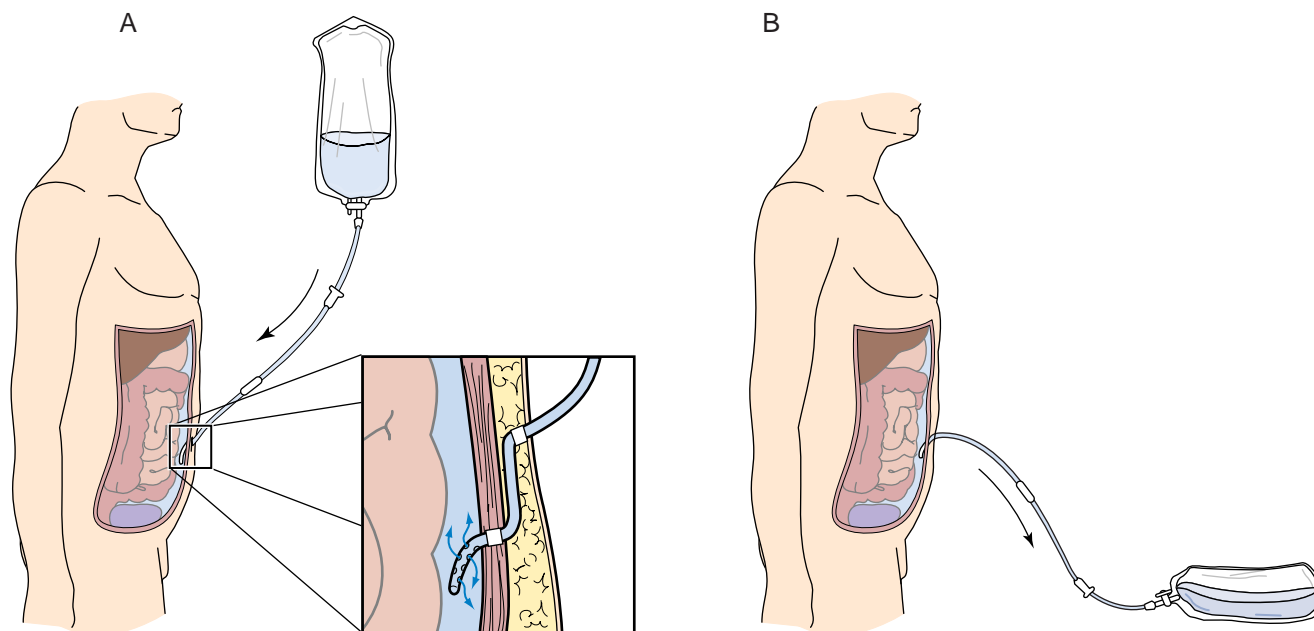

Figure 35-11 (A) Peritoneal dialysis works inside the body. Dialysis solution flows through a tube into the abdominal cavity, where it collects waste products from the blood. (B) Periodically the used dialysis solution is drained from the abdominal cavity, carrying away waste products and excess water from the blood.

that best suits the patient's needs is determined by the patient and the dialysis team.

Continuous ambulatory peritoneal dialysis (CAPD) is the most commonly used treatment plan. Usually three exchanges are done during the day and one before bedtime. Other treatment plans allow for the use of a computerized machine called a cycler to regulate the exchanges during sleeping hours. Sometimes medications are added to the dialyzing solutions, such as heparin to prevent clotting of the catheter, insulin for the patient with diabetes, or antibiotics if there is infection.

Patient and family education is extremely important for peritoneal dialysis to be successful. The patient must be taught, and be able to demonstrate that he or she is able, to do a successful exchange. Sterile technique while performing the exchanges is imperative, and the exchanges should be done in a clean environment. A major complication is peritonitis (infection of the peritoneum), which can be life threatening. The major cause of peritonitis is poor technique when connecting the bag of dialyzing solution to the peritoneal catheter. The first sign of peritonitis is usually abdominal pain. Refer to Chapter 31 for additional signs and symptoms of peritonitis. If any symptoms of peritonitis occur, the patient must contact the physician immediately, so that antibiotic treatment can begin. The patient should be taught to care of the exit site (the site where the catheter comes out of the abdomen) and the need to inspect both the site and the dialysate solution for any signs of infection.

Dietary education is also important. A dietitian can assist the patient in making appropriate choices for adequate calories, protein, and potassium intake. The peritoneal dialysis patient generally has fewer dietary and fluid restrictions than the patient on hemodialysis, because dialysis is continuous.

LEARNING TIPS

Differences between hemodialysis (HD), peritoneal dialysis (PD) and continuous renal replacement therapy include the following:

Equipment: HD requires a specialized complex dialyzer. PD and CRRT do not require the specialized dialyzer.

Training: HD requires skilled HD nurse. CRRT can be done by a non-HD nurse. PD can be done by the patient.

Timing: HD is intermittent. PD and CRRT are continuous.

Solute removal: HD and PD use the principles of osmosis and diffusion, which require a dialysate solution. CRRT uses convection, so no dialysate is needed.

Cardiovascular effects: HD may cause hypotension, which is a risk in the unstable patient. PD and CRRT have few cardiovascular effects. CRRT can be used on the unstable patient.

Kidney Transplantation

Another treatment for renal failure is kidney transplantation. A kidney transplant is a procedure in which a donor kidney is placed in the abdomen of a patient with chronic renal failure (Fig. 35-12). This healthy transplanted kidney functions as a normal functioning kidney does. The donated kidney can come from a family member; a living, non-related donor; or a cadaver donor. Tissue and blood types must match so that the body's immune system does not reject the donated kidney. Patients receive special drugs to help prevent rejection; these drugs must be taken for the rest of the patients' lives. Sometimes even with these drugs, the body rejects the kidney and the patient needs to go back on dialysis (Cultural Consideration Box 35-10 and Patient Perspective Box 35-11). For more information, visit the Transplant Society at www.a-s-t.org.

Figure 35-12 A transplanted kidney is placed in the abdomen. The patient's kidneys are usually left in place.

BOX 35-11 Patient Perspective

Kidney Transplantation: Pat

My experience with a kidney transplant spans three decades, but my overall renal illness experience also spans several years of illness and dialysis before the transplant. I think the biggest changes I have seen over the years are the involvement of patients in their own care options, as well as increased technical advances that allow transplantation to be much more successful. Some of the feelings experienced before transplantation are fear, uncertainty, and—if awaiting a donor—the guilt of knowing someone must die before you can live.

Thirty years ago there were no support groups and no one to talk to except family and doctors. Today there are many support mechanisms in place for patients and families both before and after transplantation. As a nurse, you can help patients by knowing these support resources for referral. After a transplant, it is wonderful to feel better, almost immediately. However, as wonderful as transplantation is, the side effects of the antirejection medications may be immediately felt, while other problems take years to develop. Unfortunately no patients escape the side effects of the medications. I have had breast cancer, osteoarthritis, cataracts, ulcers, skin cancer, anemia, weight gain, and other side effects of Prednisone and Imuran. However, I can assure you that this is much better than the alternative of dialysis.

Nursing Process

See Nursing Care Plan Box 35-12 for the Patient with Renal Failure for a summary of nursing care.

BOX 35-10 CULTURAL CONSIDERATION

Renal Function and Assessment

Because many Vietnamese people believe that the body must be kept intact, even after death, they may object to removal of body parts or organ donation.

Jewish law views organ transplantation from the recipient, the living donor, the cadaver donor, and the dying donor differently. If the recipient's life can be prolonged without considerable risk, transplant is ordained. For a living donor to be approved, the risk to the life of the donor must be considered. One is not obligated to donate a part of himself or herself unless the risk is small. The use of a cadaver for transplant is usually approved if it is saving a life. The nurse may need to assist the Jewish patient contact a rabbi when making a decision regarding organ donation or transplantation.

CRITICAL THINKING

Mrs. Jackson

Mrs. Jackson is a 56-year-old woman with a 20-year history of type 1 diabetes. She is now in chronic renal failure. She is admitted to a medical unit for beginning treatment of renal failure. She has severe edema, oliguria, and cardiac dysrhythmias.

1. What should the nurse assess as part of the morning evaluation of the patient's condition?
2. What laboratory tests are essential for the nurse to check?
3. What should the nurse assess related to Mrs. Jackson's understanding of self-care?

Answers at end of chapter.

BOX 35-12 NURSING CARE PLAN FOR THE PATIENT WITH RENAL FAILURE

Excess fluid volume related to kidneys' inability to excrete water

PATIENT OUTCOMES

Fluid volume will be stable as evidenced by stable weight, absence of edema, lung sounds clear, and blood pressure within patient's normal parameters.

EVALUATION OF OUTCOMES

Is weight stable? Is edema absent? Are lungs clear? Is blood pressure within patient's normal parameters?

NURSING INTERVENTIONS

Monitor weight daily at same time; report gain of greater than 2 pounds.

RATIONALE

Weight gain represents retention of fluid.

EVALUATION

Is weight stable? Should physician be notified of change?

BOX 35-12 NURSING CARE PLAN FOR THE PATIENT WITH RENAL FAILURE—CONT'D

<p>Monitor intake and output. Assess for and report shortness of breath, tachycardia, crackles in lungs, frothy sputum, heart irregularities, hypotension, cold clammy skin. Watch for new onset of neck vein distention with patient's head raised to 30- to 45-degree angle. Monitor vital signs, including orthostatic blood pressure. Monitor for edema. Monitor activity tolerance. Monitor serum protein and albumin levels. Maintain sodium and fluid restrictions as ordered. Develop a plan with specific allotted amounts of fluid at each meal and for medications. Teach client importance of each.</p>	<p>This monitors degree of fluid retention. These are symptoms of heart failure that may accompany fluid overload.</p> <p>Fluid overload causes right-sided heart failure resulting in distended neck veins.</p> <p>Blood pressure changes reflect fluid volume.</p> <p>Edema is a symptom of fluid overload. Reduced activity tolerance may indicate heart failure related to fluid retention. Low serum protein and albumin levels contribute to edema. Sodium and fluids cause fluid retention in the patient with renal failure.</p>	<p>Is output less than intake? Is this a change? Are symptoms of heart failure present?</p> <p>Are neck veins distended? Is this a new finding?</p> <p>Is blood pressure increased?</p> <p>Is edema present? Is this a change? Is patient's tolerance of activity stable? Worsening? Are levels within normal limits?</p> <p>Does patient understand and maintain sodium and fluid restriction?</p>
---	--	---

▶ Activity intolerance related to anemia secondary to impaired synthesis of erythropoietin by the kidneys

PATIENT OUTCOMES

Patient will be able to perform activities important to him or her.

EVALUATION OF OUTCOMES

Does patient state satisfaction with level of activity tolerance?

INTERVENTIONS

Assess for pale mucous membranes and skin color, dyspnea, chest pain.
Monitor hemoglobin (Hgb), hematocrit (Hct).
Watch for signs of bleeding.
Administer erythropoietin as ordered. Assist with blood transfusion as necessary.
Have patient space activities with rest periods.

RATIONALE

These are signs and symptoms of anemia.

Low hemoglobin and hematocrit indicate anemia.
Bleeding will worsen anemia.
Erythropoietin stimulates production of red blood cells by bone marrow.

Rest periods decrease demand for oxygen.

EVALUATION

Does patient exhibit symptoms of anemia?

Are Hgb and Hct within normal limits?

Are signs of bleeding present?
Are Hgb and Hct rising with use of erythropoietin?

Is patient able to tolerate activities with rest periods?

▶ Risk for injury related to bleeding tendency from platelet dysfunction and use of heparin during dialysis, and tendency for gastrointestinal bleeding

PATIENT OUTCOMES

Patient will not experience bleeding. If bleeding occurs, it will be recognized and stopped quickly.

EVALUATION OF OUTCOMES

Are signs and symptoms of bleeding absent or recognized and reported quickly?

INTERVENTIONS

Observe for and report blood in stool or emesis, easy bruising, bleeding from mucous membranes or puncture sites and report immediately if present.
Monitor Hgb, Hct, clotting studies, and platelets and report results.
Monitor vital signs.

Avoid giving injections if possible. If bleeding, apply gentle pressure to site if possible.

RATIONALE

Bleeding must be recognized quickly to prevent complications.

Declining Hgb and Hct indicate blood loss.
Declining platelet count or rising clotting times indicates increased risk for bleeding.
Falling blood pressure and rising pulse may indicate volume deficit from bleeding.
Injections can cause bleeding into tissue.
Pressure promotes hemostasis.

EVALUATION

Does patient exhibit signs of bleeding?

Are lab results stable?
Are vital signs stable?

Can medications be given by another route?

Does pressure stop bleeding?

BOX 35-12 NURSING CARE PLAN FOR THE PATIENT WITH RENAL FAILURE—CONT'D

Teach patient to prevent injury to self and symptoms of bleeding to report.

Injury can cause bleeding.
Understanding of symptoms of bleeding encourages early reporting.

Does patient verbalize understanding of instruction?

 **Risk for infection related to impaired immune system function**

PATIENT OUTCOMES

Patient will not develop infection as evidenced by WBCs and temperature within normal limits, no signs and symptoms of infection.

EVALUATION OF OUTCOMES

Are WBCs and temperature within normal limits?

INTERVENTIONS

Monitor for signs and symptoms of infection and report promptly to physician.
Protect patient from any source of infection, including infected roommates, visitors, or nursing staff.
Maintain skin integrity.
Staff and patient practice good handwashing technique.
Culture any suspected site of infection as ordered by physician.
Consult with physician about influenza and pneumonia vaccines.
Teach patient and family signs and symptoms of infection to report to physician.

RATIONALE

Early recognition of infection and prompt treatment help prevent complications.
Exposure to pathogens increases risk for infection.
Intact skin protects against infection.
Handwashing helps control spread of infection.
A culture identifies pathogens and guides treatment.
Patients with impaired immune function are at risk for influenza and pneumonia.
Early reporting of symptoms allows for prompt initiation of treatment.

EVALUATION

Does patient exhibit symptoms of infection?
Does anyone in contact with the patient have an infection?
Is skin intact?
Is good handwashing being practiced?
Is a culture necessary?
Has the patient been vaccinated?
Do patient and family verbalize understanding of symptoms to report?

 **Impaired nutrition, less than body requirements related to restricted diet, anorexia, nausea, and vomiting, and stomatitis secondary to effect of excessive urea on the gastrointestinal system**

PATIENT OUTCOMES

Patient will maintain ideal weight. Serum protein and albumin levels are within normal limits.

EVALUATION OF OUTCOMES

Are weight and lab values at desired levels?

INTERVENTIONS

Monitor weekly weight and serum protein and albumin levels.
Initiate a calorie count—consult dietitian for assistance.
Provide frequent oral care.
Offer frequent small feedings and dietary supplements.
Offer medications ordered for nausea before meals.
Ensure bowel movement daily or according to patient's usual pattern.

RATIONALE

Weight and lab results provide information about nutrition status.
A calorie count can provide information about the adequacy of the patient's diet.
Oral care enhances appetite.
Smaller feedings are better tolerated and reduce risk of nausea.
Nausea reduces appetite and must be controlled.
Constipation can interfere with appetite.

EVALUATION

Are weight and lab values stable?
Is patient receiving adequate calories?
Does oral care enhance appetite?
Does patient tolerate small feedings?
Are antiemetics effective?
Are patient's bowels functioning normally for him or her?

REVIEW QUESTIONS

1. A patient is admitted to the nursing unit with a diagnosis of urinary tract infection. When teaching the patient about preventing urinary tract infections, which of the following information is most important for the nurse to include?
 - a. Void frequently and after sexual intercourse.
 - b. Drink large amounts of citrus juices.
 - c. Eat large amounts of vegetables.
 - d. Wash the perineum every 8 hours.
2. A patient has an ileal conduit for treatment of his cancer. While changing the pouch at the stoma site, the nurse notes that the stoma is constantly spilling urine. Which of the following actions should the nurse take?
 - a. Notify the physician of the constant spillage.
 - b. Continue changing the pouch.
 - c. Remove the overflow of urine with a straight catheter.
 - d. Irrigate the stoma with a sterile solution of normal saline.
3. A patient has a graft inserted into his left arm to provide a blood access for hemodialysis treatments. Which of the following interventions should the nurse do to determine patency of the graft?
 - a. Observe the tubing for bright red blood.
 - b. Feel for a brachial pulse on both arms.
 - c. Feel for a thrill over the graft.
 - d. Assess blood pressure in the affected arm.
4. A patient with renal failure who is on hemodialysis asks for a snack in the afternoon. His potassium level remains high. Which of the following foods would be contraindicated?
 - a. Banana
 - b. Gelatin dessert
 - c. Clear carbonated beverage
 - d. Cranberry juice
5. The nurse is caring for a patient with glomerulonephritis. Which of the following interventions would the nurse recommend be included in the patient's plan of care?
 - a. Increase fluid intake
 - b. Decrease sodium intake
 - c. Increase potassium intake
 - d. Decrease carbohydrate intake

Answers to CRITICAL THINKING**Mrs. Milan**

1. Sexual intercourse can be a predisposing factor to UTI, especially if the patient does not urinate after intercourse.
2. Mrs. Milan should be cautioned to always urinate after intercourse. See also Box 35-1.
3. The urinalysis will show WBCs, bacteria, RBCs, and positive nitrites.

Mr. White

1. Weight, intake and output, blood pressure, and lab tests should be assessed as part of the morning evaluation.
2. BUN, serum creatinine, and potassium levels should also be checked.

3. Mr. White should be taught that he needs to take antihypertensive medications, keep his follow-up visits to his physician, follow a low-sodium diet, and restrict fluids if ordered.

Mrs. Jackson

1. Assess Mrs. Jackson's weight and intake and output to monitor fluid balance. A cardiovascular system assessment should be done to see how she is tolerating the dysrhythmia.
2. BUN, serum creatinine, serum potassium, hemoglobin and hematocrit, and blood sugar are monitored.
3. Assess Mrs. Jackson's understanding of what renal failure is, how it is treated, how to follow the renal diet and fluid restrictions, and the action and importance of medications.

UNIT TEN

UNDERSTANDING THE
ENDOCRINE SYSTEM

36

ENDOCRINE SYSTEM FUNCTION AND ASSESSMENT

Paula D. Hopper

KEY TERMS

affect (**AF**-fect)
exophthalmos (ECKS-off-**THAL**-mus)

QUESTIONS TO GUIDE YOUR READING

1. What are the glands of the endocrine system?
2. What is the function of each of the hormones in the endocrine system?
3. What are the effects of aging on endocrine system function?
4. What data should you collect when caring for a patient with a disorder of the endocrine system?
5. What nursing care should you provide for patients undergoing testing for an endocrine disorder?

► NORMAL ANATOMY AND PHYSIOLOGY

The endocrine system consists of the endocrine, or ductless, glands, which secrete chemicals called hormones. Unlike other organ systems, the glands of the endocrine system are anatomically separate (Fig. 36–1). Their hormones, however, are involved in all aspects of metabolism: growth, energy production, regulation of fluid and electrolyte balance and pH, resistance to stress, and reproduction. Each hormone is secreted in response to a particular and specific stimulus, is circulated by the blood throughout the body, and exerts its effects on certain target organs or tissues that have receptors for that hormone. The effects of the hormone often reverse the stimulus and ultimately lead to decreased secretion of the hormone. This is called a negative feedback mechanism; the secretion of many hormones is regulated this way. Some hormones are secreted in response to hormones from other endocrine glands.

Pituitary Gland

The pituitary gland is also called the hypophysis; it hangs by a short stalk from the hypothalamus in the brain. The two major parts are the posterior pituitary (neurohypophysis) and anterior pituitary (adenohypophysis).

Posterior Pituitary Gland

The posterior pituitary gland stores antidiuretic hormone (ADH, sometimes called vasopressin) and oxytocin, which are actually produced by the hypothalamus. Their release is stimulated by nerve impulses from the hypothalamus.

Antidiuretic hormone increases the amount of water reabsorbed by the kidney tubules, which decreases urinary output. The water is reabsorbed back into the blood, thereby maintaining normal blood volume and normal blood pressure. The stimulus for secretion of ADH is a decrease in the water content of the body—that is, dehydration. When body water is lost and not replaced, specialized cells in the hypothalamus called osmoreceptors detect the increased salt concentration of body fluids and transmit impulses to the posterior pituitary to secrete ADH to prevent the further loss of water in urine. In cases of great fluid loss, as in severe hemorrhage, the large amount of ADH secreted causes vasoconstriction, which also contributes to maintenance of a normal blood pressure.

Oxytocin causes contraction of the smooth muscle in the uterus and mammary glands. At the end of pregnancy, stretching of the cervix generates sensory impulses to the hypothalamus, which then transmits impulses to the posterior pituitary for the release of oxytocin. Oxytocin causes strong contractions of the myometrium to bring about

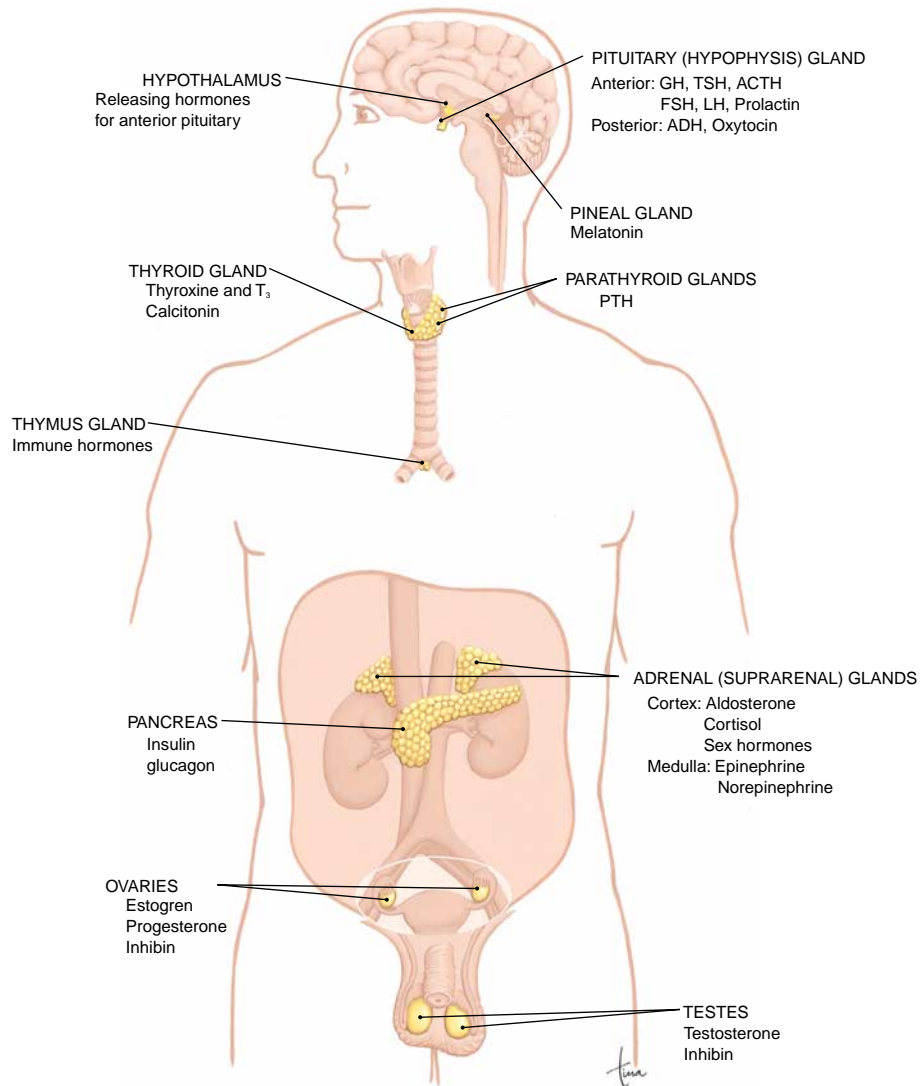

Figure 36-1 Glands of the endocrine system. (From Scanlon, V, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 211, with permission.)

delivery of the baby and the placenta. This is an example of a positive feedback mechanism. The placenta also produces oxytocin, but its precise role in labor and delivery has not yet been determined.

During breast-feeding, the sucking of the baby generates sensory impulses from the mother's nipple to the hypothalamus. The subsequent release of oxytocin causes contraction of the smooth muscle cells around the mammary ducts. This release of milk is sometimes called "milk ejection" or the "milk letdown" reflex.

Anterior Pituitary Gland

The anterior pituitary gland secretes its hormones in response to releasing hormones from the hypothalamus. The anterior pituitary secretes growth hormone, thyroid-stimulating hormone, adrenocorticotropic hormone, prolactin, follicle-stimulating hormone, and luteinizing hormone.

Growth hormone (GH, or somatotropin) increases cell division in those tissues capable of mitosis, which is one of

the ways it is involved in growth. It also increases the transport of amino acids into cells and their use in protein synthesis. Growth hormone also increases the release of fat from adipose tissue and the use of fats for energy production; this is important even after growth in height has ceased. The secretion of GH is regulated by growth hormone-releasing hormone (GHRH) and by growth hormone-inhibiting hormone (GHIH, or somatostatin), both from the hypothalamus. GHRH is produced during hypoglycemia or when there is a high blood level of amino acids (to be turned into protein). GHIH is secreted during hyperglycemia, when carbohydrates are available for energy production and the mobilization of fat is not necessary.

Thyroid-stimulating hormone (TSH, or thyrotropin) has only one target organ: the thyroid gland. TSH stimulates growth of the thyroid and the secretion of two of its hormones, thyroxine (T_4) and triiodothyronine (T_3). The secretion of TSH is stimulated by thyrotropin-releasing hormone (TRH) from the hypothalamus when metabolic rate decreases and there is a need for thyroxine.

Adrenocorticotropic hormone (ACTH) stimulates the secretion of cortisol and related hormones from the adrenal cortex. Corticotropin-releasing hormone (CRH) from the hypothalamus stimulates the release of ACTH. CRH is produced during any type of physiological stress situation, such as injury, disease, exercise, or hypoglycemia.

Prolactin initiates and maintains milk production by the mammary glands. The hypothalamus produces both prolactin-releasing hormone (PRH) and prolactin-inhibiting hormone (PIH); prolactin is not secreted until pregnancy is over and the levels of estrogen and progesterone (from the placenta) have dropped.

Follicle-stimulating hormone (FSH) is a gonadotropic hormone; that is, its target organs are the ovaries or testes. In women, FSH initiates growth of ova in ovarian follicles and secretion of estrogen by the cells of those follicles. In men, FSH initiates sperm production in the seminiferous tubules of the testes. FSH is secreted in response to gonadotropin-releasing hormone (GnRH) from the hypothalamus. Another hormone called inhibin (from the ovaries or testes) decreases the secretion of FSH.

Luteinizing hormone (LH) is another gonadotropic hormone whose secretion is increased by GnRH from the hypothalamus. In women, LH causes ovulation and stimulates the ruptured ovarian follicle to become the corpus luteum and begin secreting progesterone, as well as estrogen. In men, LH stimulates the secretion of testosterone by the interstitial cells of the testes.

Thyroid Gland

The thyroid gland consists of two lobes connected by a middle piece called the isthmus; the gland is located on the front and sides of the trachea just below the larynx. Three hormones are produced by the thyroid gland. T_4 and T_3 are produced in the thyroid follicles, require iodine (T_4 has four iodine atoms, T_3 has three iodine atoms), and have the same functions. Calcitonin is the third hormone; it is produced by parafollicular cells.

T_4 and T_3 regulate normal energy production and protein synthesis. They increase the rate of cell respiration of all food types (carbohydrates, fats, and excess amino acids), which increases the metabolic rate—that is, energy and heat production. They also increase the rate of protein synthesis in cells. These hormones are the most important day-to-day regulators of metabolic rate; their activity is reflected in the functioning of the heart, brain, muscles, and virtually all other organs. They are essential for normal physical growth, mental development, and reproductive maturation.

The direct stimulus for secretion of T_4 and T_3 is TSH from the anterior pituitary. The sequence of events is as follows: A decrease in metabolic rate (energy production) is detected by the hypothalamus, which secretes TRH. TRH stimulates the anterior pituitary to secrete TSH, which stimulates the thyroid to increase secretion of T_4 and T_3 , which increase energy production to raise the metabolic rate. As the metabolic rate rises, negative feedback decreases the secretion of TRH from the hypothalamus until the metabolic rate drops again.

The third thyroid hormone, calcitonin, has bones as its target and seems to be of greater importance in childhood when bones are growing than in maturity when bone growth has ceased. Calcitonin decreases the reabsorption of calcium and phosphate from the bones to the blood, thereby lowering the blood levels of these minerals as they are retained in bones. This one function of calcitonin has two important results: the maintenance of normal blood levels of calcium and phosphate and the maintenance of a strong, stable bone matrix.

LEARNING TIPS

An easy way to remember the function of calcitonin is to remember *calciTONin TONes down serum calcium.*

The stimulus for secretion of calcitonin is hypercalcemia, a high blood calcium level. When the blood calcium level rises, increased calcitonin ensures that no more will be removed from bones until there is a real need for more calcium in the blood.

Parathyroid Glands

There usually are four parathyroid glands, two on the back of each lobe of the thyroid gland. The hormone they produce is called parathyroid hormone (PTH), which is an antagonist to calcitonin for the maintenance of normal blood levels of calcium and phosphate. Besides bone, the target organs of PTH are the small intestine and kidneys.

PTH increases the reabsorption of calcium and phosphate from the bones to the blood, which raises their blood levels. Absorption of calcium and phosphate from food in the small intestine is also increased by PTH through its action of activating vitamin D (calcitriol) in the kidneys. PTH also increases the reabsorption of calcium by the kidneys and the excretion of phosphate (more than is obtained from bones). Therefore the overall effect of PTH is to raise the blood calcium level and lower the blood phosphate level.

Secretion of PTH is stimulated by hypocalcemia, a low blood calcium level, and is inhibited by hypercalcemia. In adults, PTH is probably the most important regulator of the blood calcium level. Calcium ions in the blood are essential for normal excitability of neurons and muscle cells and for the process of blood clotting.

Adrenal Glands

The two adrenal (also called suprarenal) glands are located one on top of each kidney. Each adrenal gland consists of an inner adrenal medulla and an outer adrenal cortex.

Adrenal Medulla

The cells of the adrenal medulla are called chromaffin cells. They secrete epinephrine and norepinephrine, which are collectively called catecholamines and are sympathomimetic

(mimicking the sympathetic nervous system). Secretion of both hormones is stimulated by sympathetic impulses from the hypothalamus in stressful situations. The functions of the catecholamines mimic and prolong those of the sympathetic nervous system, which enable the individual to respond physiologically to stress situations.

Of the two hormones, epinephrine is secreted in larger amounts (approximately four times that of norepinephrine) and has many effects. It increases the heart rate and force of contraction, stimulates vasoconstriction in skin and viscera and vasodilation in skeletal muscles, dilates the bronchioles, decreases peristalsis, stimulates the liver to convert glycogen to glucose, increases the use of fats for energy, and increases the rate of cell respiration. The most significant function of norepinephrine is to cause vasoconstriction in the skin, viscera, and skeletal muscles, thereby raising blood pressure.

Adrenal Cortex

The adrenal cortex secretes three types of steroid hormones: sex hormones, mineralocorticoids, and glucocorticoids. The sex hormones are small amounts of male androgens and even smaller amounts of female estrogens. Their function is not known with certainty, though they may contribute to the growth spurt that often occurs just before puberty and to the libido (sex drive) in adult women.

LEARNING TIPS

An easy way to remember the hormones of the adrenal cortex is to remember *salt, sugar, and sex*. Mineralocorticoids promote salt retention, glucocorticoids affect sugar (carbohydrate) metabolism, and androgens and estrogens are sex hormones.

Aldosterone is the most abundant of the mineralocorticoids, and its target organs are the kidneys. Aldosterone increases the reabsorption of sodium ions and the excretion of potassium ions by the kidney tubules. This means that sodium ions are returned to the blood and potassium ions are eliminated in urine. This function of aldosterone has important consequences. As sodium ions are reabsorbed, hydrogen ions may be excreted in exchange; this is one mechanism to prevent the accumulation of hydrogen ions that would lead to acidosis. Also as sodium ions are reabsorbed, water and negative ions such as bicarbonate follow and are thus returned to the blood. Although the reabsorption of water is an indirect effect of aldosterone, it is important for the maintenance of normal blood volume and blood pressure.

Secretion of aldosterone may be stimulated in several ways: a low blood sodium level, a high blood potassium level, or loss of blood or dehydration that lowers blood pressure. Low blood pressure activates the renin-angiotensin mechanism of the kidneys, which culminates in the formation of angiotensin II. One function of angiotensin II is to increase secretion of aldosterone. The hormone called atrial natriuretic peptide (ANP), secreted by the atria of the heart

when blood pressure or blood volume rises, seems to inhibit secretion of aldosterone (and renin) and thereby promotes elimination of sodium ions and water by the kidneys.

Cortisol is the most abundant of the glucocorticoids and has many target tissues. Cortisol stimulates the liver to change glucose to glycogen (glycogenesis) for storage. It increases the conversion of excess amino acids to carbohydrates (gluconeogenesis) for energy production and increases the use of fats for energy. By providing these secondary energy sources to most cells, cortisol ensures that whatever glucose is present will be available for the brain (the glucose-sparing effect).

Cortisol also has an anti-inflammatory effect because it blocks the effects of histamine and stabilizes the lysosomes in cells. Normal cortisol secretion seems to limit the inflammation process to what is useful for tissue repair and to prevent excessive tissue destruction. Excess cortisol has damaging effects, however: It raises blood glucose levels, decreases the immune response, and delays healing of damaged tissue.

The direct stimulus for cortisol secretion is ACTH from the anterior pituitary gland. Cortisol is also a “stress” hormone, and any type of physiological stress (injury, disease, malnutrition) stimulates the hypothalamus to secrete CRH. CRH increases the secretion of ACTH by the anterior pituitary, which increases cortisol secretion by the adrenal cortex.

Pancreas

The pancreas is located in the upper left abdominal quadrant and extends from the curve of the duodenum to the spleen. The endocrine portions of the pancreas are called islets of Langerhans (pancreatic islets); they contain alpha cells, which produce glucagon, and beta cells, which produce insulin. Delta cells in the islets secrete somatostatin, which inhibits secretion of both insulin and glucagon.

The functions of glucagon are all related to energy production. Glucagon stimulates the liver to change glycogen to glucose (glycogenolysis) and to increase the use of fats and excess amino acids for energy production. The overall effect, therefore, is to raise the blood glucose level and to make all types of food available for cell respiration.

The secretion of glucagon is stimulated by hypoglycemia, a low blood glucose level. Such a state may occur during physiological stress situations such as exercise or simply being between meals.

Insulin increases the transport of glucose from the blood into cells by increasing the permeability of cell membranes to glucose (brain and liver cells, however, are not dependent on insulin for glucose intake). Inside cells, glucose is broken down in cell respiration to release energy. The liver and muscles are also stimulated by insulin to change glucose to glycogen (glycogenesis) to be stored for later use. Insulin also enables cells to take in fatty acids and amino acids to use in the synthesis of lipids and proteins (not energy production). Insulin, therefore, decreases the blood glucose level by increasing the use of glucose for energy, promoting the storage of excess glucose, and decreasing energy production from other food sources.

Secretion of insulin is stimulated by hyperglycemia, a high blood glucose level. This state occurs after meals, especially those high in carbohydrates. It should be apparent that insulin and glucagon function as antagonists and that normal secretion of both hormones ensures a blood glucose level that fluctuates within normal limits. Table 36–1 reviews endocrine hormone function.

Aging and the Endocrine System

Most of the endocrine glands decrease their secretions with age, but normal aging usually does not lead to serious hor-

mone deficiencies. There are decreases in adrenal cortical hormones, for example, but the levels are usually sufficient to maintain homeostasis of water, electrolytes, and nutrients. The decreased secretion of growth hormone leads to a decrease in muscle mass and an increase in fat storage. A lower basal metabolic rate is common in elderly people as the thyroid slows its secretion of thyroxine. Although insulin secretion declines somewhat, for most elderly people with a decreased glucose tolerance the cause is a decrease in the cells' sensitivity to insulin. Unless specific pathological conditions develop, the endocrine system usually continues to function adequately in old age.

TABLE 36-1 REVIEW OF ENDOCRINE FUNCTION

Hormone	Function(s)	Regulation of Secretion
Hormones of the Posterior Pituitary Gland		
<i>Oxytocin</i>	Promotes contraction of myometrium of uterus (labor)	Nerve impulses from hypothalamus, the result of stretching of cervix or stimulation of nipple
	Promotes release of milk from mammary glands	Secretion from placenta at the end of gestation—stimulus unknown
<i>Antidiuretic hormone</i>	Increases water reabsorption by the kidney tubules (water returns to the blood)	Decreased water content in the body (alcohol inhibits secretion)
Hormones of the Anterior Pituitary Gland		
<i>Growth hormone</i>	Increases rate of mitosis Increases amino acid transport into cells Increases rate of protein synthesis Increases use of fats for energy	GHRH (hypothalamus) stimulates secretion GHIH—somatostatin (hypothalamus) inhibits secretion
<i>Thyroid-stimulating hormone</i>	Increases secretion of thyroxine and T ₃ by thyroid gland	TRH (hypothalamus)
<i>Adrenocorticotropic hormone</i>	Increases secretion of cortisol by the adrenal cortex	CRH (hypothalamus)
<i>Prolactin</i>	Stimulates milk production by the mammary glands	PRH (hypothalamus) stimulates secretion PIH (hypothalamus) inhibits secretion GnRH (hypothalamus)
<i>Follicle-stimulating hormone</i>	<i>In women:</i> Initiates growth of ova in ovarian follicles Increases secretion of estrogen by follicle cells <i>In men:</i>	
<i>Luteinizing hormone</i>	Initiates sperm production in the testes <i>In women:</i> Causes ovulation Causes the ruptured ovarian follicle to become the corpus luteum Increases secretion of progesterone by the corpus luteum <i>In men:</i> Increases secretion of testosterone by the interstitial cells of the testes	GnRH (hypothalamus) GnRH (hypothalamus) GnRH (hypothalamus)
<i>Melanocyte-stimulating hormone (MSH)</i>	Stimulates production of melanin by melanocytes	CRH (hypothalamus)
Hormones of the Thyroid Gland		
<i>Thyroxine and triiodothyronine</i>	Increase energy production from all food types Increase rate of protein synthesis	TSH (anterior pituitary)
<i>Calcitonin</i>	Decreases the reabsorption of calcium and phosphate from bones to blood	Hypercalcemia
Hormones of the Parathyroid Glands		
<i>Parathyroid hormone</i>	Increases the reabsorption of calcium and phosphate from bone to blood Increases absorption of calcium and phosphate by the small intestine Increases the reabsorption of calcium and the excretion of phosphate by the kidneys	Hypocalcemia

TABLE 36-1 REVIEW OF ENDOCRINE FUNCTION — CONT'D

Hormone	Function(s)	Regulation of Secretion
Hormones of the Pancreas		
<i>Glucagon</i>	Increases conversion of glycogen to glucose in the liver Increases the use of excess amino acids and of fats for energy	Hypoglycemia
<i>Insulin</i>	Increases glucose transport into cells and the use of glucose for energy production Increases the conversion of excess glucose to glycogen in the liver and muscles Increases amino acid and fatty acid transport into cells and their use in synthesis reactions	Hyperglycemia
<i>Somatostatin</i>	Inhibits glucagon, insulin, and growth hormone secretion	Increased levels
Hormones of the Adrenal Medulla		
<i>Norepinephrine</i> <i>Epinephrine</i>	Causes vasoconstriction in skin, viscera, skeletal muscles Increases heart rate and force of contraction Dilates bronchioles Decreases peristalsis Increases conversion of glycogen to glucose in the liver Causes vasodilation in skeletal muscles Causes vasoconstriction in skin and viscera Increases use of fats for energy Increases the rate of cell respiration	Sympathetic impulses from the hypothalamus in stress situations
Hormones of the Adrenal Cortex		
<i>Aldosterone</i>	Increases reabsorption of Na ⁺ ions by the kidneys to the blood	Low blood Na ⁺ level Low blood volume or blood pressure
<i>Cortisol</i>	Increases excretion of K ⁺ ions by the kidneys in urine Increases use of fats and excess amino acids for energy Decreases use of glucose for energy (except for the brain) Increases conversion of glucose to glycogen in the liver Anti-inflammatory effect: stabilizes lysosomes and blocks the effects of histamine	High blood K ⁺ level ACTH (anterior pituitary) during physiological stress
<i>Androgens and estrogens</i>	May be involved in growth spurt at puberty Contribute to libido Source of sex hormones for women after menopause	ACTH

K⁺ = potassium; Na⁺ = sodium.

► NURSING ASSESSMENT

Health History

When performing a health history, a number of questions can be asked to determine whether an endocrine problem exists. Often, however, you might be aware of a history of an endocrine disorder, such as diabetes or hypothyroidism. When a disorder exists or is suspected, you can do a more focused assessment. Assessment of individual disorders is provided in Chapters 37 and 38. Table 36-2 offers general questions that can help you identify new problem areas. If the assessment reveals abnormalities, they should be reported to a registered nurse or physician.

Physical Assessment of the Patient with an Endocrine Disorder

Physical assessment starts with height, weight, and vital signs. These should always be compared with the patient's baseline assessment if available. Table 36-3 includes common endocrine-related causes of physical assessment abnormalities.

Inspection

Observe the patient for mood and **affect** (emotional tone) throughout the physical assessment. Inspect the neck for thyroid enlargement. Look for eyes that bulge (**exophthalmos**). Note posture, body fat, and presence of tremor. Observe skin and hair texture and moisture. Note the presence of a moonlike face or “buffalo hump” on the upper back. Observe the lower extremities for skin and color changes that might indicate circulatory impairment. See Table 36-3 for rationales for these observations.

LEARNING TIPS

Some patients call diabetes mellitus “sugar.” So instead of asking if anyone in their family has diabetes, you may need to ask if anyone has “sugar.”

exophthalmos: exo—outward + ophthalmos—eye

TABLE 36-2 QUESTIONS ASKED DURING ASSESSMENT OF THE ENDOCRINE SYSTEM

Question	Rationale
Have you noticed a change in your energy level?	Lack of energy may be associated with uncontrolled diabetes, hypothyroidism, hyperthyroidism, Addison's disease, or pituitary disorders.
Have you noticed muscle spasms or twitching?	These symptoms may be associated with excessive antidiuretic hormone secretion (SIADH) or calcium depletion resulting from hypoparathyroidism.
Do you have numbness, tingling, or pain in your feet, legs, or hands?	These may be associated with neuropathy resulting from diabetes mellitus. Numbness and tingling may also indicate hypocalcemia related to hypoparathyroidism.
Have you gained or lost weight without trying?	Actual weight gain may be associated with hypothyroidism. Weight gain due to water retention may result from Cushing's syndrome, or SIADH. Weight loss may result from uncontrolled diabetes or hyperthyroidism.
Have you noticed excessive thirst or urination?	Weight loss due to dehydration may be related to Addison's disease. Excessive thirst and urination are classic symptoms of diabetes mellitus and diabetes insipidus.
Do you generally tolerate changes in environmental temperature?	Hypothyroidism can cause cold intolerance. Hyperthyroidism can cause heat intolerance.
Have you noticed a change in your mood or memory?	Mental function may be dull with hypothyroidism. Mood swings may occur with Cushing's syndrome. Agitation or confusion may result from hypoglycemia in a person with diabetes.
Does anyone in your family have a thyroid problem or diabetes?	These may be hereditary.

SIADH = syndrome of inappropriate antidiuretic hormone.

TABLE 36-3 ENDOCRINE-RELATED CAUSES OF ABNORMAL PHYSICAL ASSESSMENT FINDINGS

Assessment Finding	Possible Causes
Inappropriate mood or affect	Depressed mood or affect from hypothyroidism Nervousness related to hyperthyroidism
Weight change	Agitation related to low blood sugar Gain due to decreased metabolic rate in hypothyroidism, fluid excess Loss due to increased metabolic rate in hyperthyroidism; uncontrolled diabetes, dehydration
Poor skin turgor	Dehydration due to water loss in Addison's disease, diabetes mellitus, diabetes insipidus
Hyperpigmentation of skin	Addison's disease
Dry, scaly skin	Hypothyroidism
Change in pulse or temperature	Elevated due to increased metabolic rate in hyperthyroidism Decreased due to slowed metabolic rate in hypothyroidism
Elevated blood pressure	Increased catecholamine release in pheochromocytoma or fluid retention in Cushing's syndrome
Decreased blood pressure	Sodium and water loss in Addison's disease
Weak peripheral pulses, dusky lower extremities	Circulatory changes in diabetes mellitus
Tremor	Hyperthyroidism or pheochromocytoma
Exophthalmos (bulging eyes)	Fat deposits and edema behind the eyes in Graves' disease
Fat pads on neck and shoulders ("buffalo hump"), round face	Accumulation of fat in Cushing's syndrome
Enlarged thyroid gland	Excessive stimulation by TSH in hypothyroidism or hyperthyroidism

Palpation

The thyroid gland is the only palpable endocrine gland. The LPN/LVN may assist a physician or nurse practitioner to palpate the thyroid gland. The practitioner stands behind or in front of the seated patient and palpates the gland while the patient swallows a sip of water (Fig. 36-2). You may assist with positioning the patient, providing water, and instructing the patient to take a sip of water and hold it in his or her mouth until told to swallow. The thyroid gland

should never be palpated in a patient with uncontrolled hyperthyroidism, because this may stimulate secretion of additional thyroid hormone.

Palpate all peripheral pulses. The posterior tibial and dorsalis pedis pulses may be diminished in patients with circulatory impairment. Palpate skin turgor by gently pinching a small piece of skin. If a "tent" remains, the patient may be dehydrated as a result of water loss, as in ADH deficiency.

Figure 36-2 Thyroid palpation.

Auscultation and Percussion

Auscultation and percussion are not usually part of an endocrine assessment.

▶ DIAGNOSTIC TESTS

Hormone Tests

Serum Hormone Levels

Many hormones can be measured from a simple blood specimen. This is useful in diagnosing hypofunctioning or hyperfunctioning gland states. See Table 36-4 for some commonly measured hormones.

Stimulation Tests

Stimulation tests may also help determine endocrine gland function. For this type of test, a substance is injected to attempt to stimulate a gland. The hormone secreted by that gland is then measured in the blood to determine how well it responded to the stimulation. For example, in a TSH

TABLE 36-4 COMMON ENDOCRINE-RELATED LABORATORY TESTS

Test	Normal Values*	Significance
Thyroid Tests		
Thyroid-stimulating hormone	0.5–5.0 U/mL	↑ in primary hypothyroidism ↓ in primary hyperthyroidism
Triiodothyronine	75–195 ng/100 mL	↓ in hypothyroidism ↑ in hyperthyroidism
Thyroxine	4–12 µg/100 mL	↓ in hypothyroidism ↑ in hyperthyroidism
Parathyroid Tests		
Parathyroid hormone	<25 pg/mL	↑ in primary hyperparathyroidism ↓ in primary hypoparathyroidism, parathyroid trauma during thyroid surgery
Calcium	8.5–10.5 mg/100 mL	↑ in some cancers, hyperparathyroidism ↓ in hypothyroidism
Phosphorus	2.4–4.7 mg/dL	↑ in hypoparathyroidism ↓ in hyperparathyroidism
Pituitary Tests		
Growth hormone	<5 ng/mL	↑ in acromegaly ↓ in small stature
Antidiuretic hormone	2.3–3.1 pg/mL	↑ in SIADH ↓ in diabetes insipidus
Urine specific gravity	1.010–1.025	↓ in diabetes insipidus
Adrenocorticotropic hormone	<120 pg/mL at 6–8 A.M.	↑ in Addison's disease ↓ in Cushing's syndrome, long-term corticosteroid therapy
Adrenal Tests		
Cortisol	5–25 µg/100 mL	↑ in Cushing's syndrome, stress ↓ in Addison's disease, steroid withdrawal
Vanillylmandelic acid (VMA; Urine Test)	0.7–6.8 mg/24 h	↑ in pheochromocytoma
Pancreas Tests		
Fasting blood sugar (FBS)	70–110 mg/100 mL	↑ in diabetes mellitus, stress, Cushing's syndrome ↓ in hypoglycemia, Addison's disease
Oral glucose tolerance test	Blood glucose returns to normal within 3 h	Any two values over 140 diagnose diabetes mellitus
Two-hour postprandial glucose	<120 mg/dL <140 mg/dL in elderly	↑ in diabetes mellitus ↓ in hypoglycemia, gastrointestinal malabsorption
Glycosylated hemoglobin	4–7%	↑ in poor diabetes control

SIADH = syndrome of inappropriate antidiuretic hormone.
*All normal values are for a fasting test.

stimulation test, TRH is injected. If the pituitary gland responds appropriately, TSH is secreted. If the thyroid gland responds appropriately to the TSH, T_3 and T_4 levels rise. Failure of the TRH to stimulate TSH and thyroid hormone indicates a pituitary or thyroid condition. Further studies might be done to determine the cause.

Suppression Tests

Suppression tests are the opposite of stimulating tests. For this type of test, a substance is injected that is expected to suppress a hormone's release. For example, if dexamethasone (a steroid hormone) is injected, cortisol release is expected to be suppressed via the negative feedback mechanism. If the cortisol level is not suppressed, adrenal cortex dysfunction is suspected.

Urine Tests

Sometimes it is helpful to measure the amount of hormone or hormone byproduct excreted in the urine during a 24-hour period. Examples are cortisol and vanillylmandelic acid, a product of catecholamine metabolism.

To collect a 24-hour urine specimen, it is necessary to obtain a special urine container from the laboratory. It is usually an opaque container that protects the specimen from light; it may have preservative in it. Check with the laboratory to find out whether the specimen needs to be kept on ice during the test and whether the patient needs to be on a special diet before or during the test. To keep a specimen on ice, a bath basin is filled with ice and the container is placed in the basin. The ice must be refilled every few hours to keep the specimen cold. When initiating the test, ask the patient to urinate and discard the urine. The time of this first discarded voiding is considered the start of the test. Any urine collected from this time forward for 24 hours is saved. At the end of the 24-hour period, the patient is again asked to urinate, but this time the urine is saved. The entire collection is then labeled and sent to the laboratory. Instruct the patient how to do the test, place a sign on the toilet with the start and stop time of the test, and remind all staff to save the urine.

If the patient is incontinent or otherwise unable to participate in the test, a catheter may need to be inserted. If the patient already has an indwelling catheter, a new bag and tubing should be attached before the start of the test. The lab should be consulted to determine the need for a preservative or ice. Preservative can be added to the catheter bag if necessary. If ice is necessary, the bag should be kept in a basin of ice rather than hanging on the side of the bed. If the specimen must be protected from light, the bag can be covered with dark plastic or foil.

CRITICAL THINKING

Mrs. Trombley

Mrs. Trombley is having a 24-hour urine test done. You begin the test at 0600, and it progresses well until you learn that the nursing assistant helped her up to void in the toilet at noon, forgetting to save her urine.

1. What do you do?
2. How can you prevent this from happening again?
3. How would you document this incident?

Answers at end of chapter.

Other Laboratory Tests

Some laboratory tests may indirectly reflect the function of an endocrine gland. For example, a serum calcium level helps indicate PTH or calcitonin secretion, and a blood glucose level reflects insulin secretion.

Nuclear Scanning

A thyroid scan may be done to determine the presence of tumors or nodules. For this test, a radioactive material is injected or radioactive iodine is taken orally. The material is attracted by the thyroid gland. After a specified time, the thyroid gland is scanned with a scintillation camera. The scan will show "hot spots," which are nodules that are not malignant, or "cold spots" (areas that do not take up the radioactivity), which indicate malignancy. Cold spots may then be biopsied to confirm a diagnosis. Because such a small amount of radioactive material is used, there is no risk to the patient. The patient should be aware that the test takes approximately 30 minutes to complete.

Radiographic Tests

A computed tomography (CT) scan or magnetic resonance imaging (MRI) may be done to locate a tumor or identify hypertrophy of a gland.

Ultrasound

Ultrasound may be done of the thyroid or parathyroid glands to determine if they are enlarged or to find masses.

Biopsy

Biopsy is done to obtain tissue to examine for possible cancerous cells. The thyroid gland can be biopsied either by needle aspiration under local anesthesia or using a surgical incision.

REVIEW QUESTIONS

1. The posterior pituitary gland secretes the following hormone:
 - a. Antidiuretic hormone
 - b. Thyroid-stimulating hormone
 - c. Growth hormone
 - d. Luteinizing hormone
2. When the effects of a hormone suppress further secretion of the hormone, which of the following types of feedback has occurred?
 - a. Positive feedback
 - b. Negative feedback
 - c. Rhythm feedback
 - d. Stimulus feedback
3. The functions of T_4 and T_3 include which of the following?
 - a. Retention of salt and water
 - b. Maintenance of blood sugar
 - c. Maintenance of blood pressure
 - d. Regulation of energy production
4. Strong bones are maintained by the action of which hormone?
 - a. ADH
 - b. Insulin
 - c. Calcitonin
 - d. TRH
5. When collecting a 24-hour urine specimen for hormone measurement, the nurse should do which of the following to begin the test?
 - a. Discard the first voided urine.
 - b. Save the first voided urine.
 - c. Discard the last voided urine.
 - d. Save the first and last voided urine.
6. When explaining a thyroid scan to a patient, which of the following statements is correct?
 - a. "You will take a special pill, and then an ultrasound will be taken of your neck."
 - b. "You will receive an injection of radioactive material, and then a special camera will take pictures of your thyroid gland."
 - c. "You will be placed into a special machine, and x-rays will be taken of your neck. It may be noisy."
 - d. "You will be given a special drink, and then magnetic energy is used to visualize the thyroid area."

Answers to CRITICAL THINKING

Mrs. Trombley

1. The specimen must include all urine for a 24-hour period. Restart the test from noon.
2. To prevent this from happening again, try placing an incontinence pad or other large item directly over the toilet as a reminder to the patient. Be sure there is a sign posted above the toilet or on the toilet handle, and communicate with the nursing assistant why the urine needs to be saved.
3. "Patient voided in toilet at 1200. 24-hour urine test restarted; importance of saving urine explained to patient. RN notified." Note that it is not appropriate to "blame" the nursing assistant for making a mistake.

QUESTIONS TO GUIDE YOUR READING

1. What are the disorders caused by variations in the hormones of the pituitary, thyroid, parathyroid, and adrenal glands?
2. How would you explain the pathophysiology of each of the endocrine disorders presented?
3. What are the etiologies, signs, and symptoms of each of the disorders?
4. What is current medical and surgical treatment of each of the selected endocrine disorders?
5. What data would you collect when caring for patients with each of the endocrine disorders discussed?
6. What nursing care will you provide for patients with each of the disorders?
7. How will you know if your nursing interventions have been effective?

A variety of disorders can be found within the endocrine system. Although the causes vary, the pathophysiology usually involves either too little or too much hormone activity. Insufficient hormone activity may be the result of hypofunction of an endocrine gland or insensitivity of the target tissue to its hormone. Excessive hormone activity may be the result of a hyperactive gland, **ectopic** hormone production, or self-administration of too

much replacement hormone (Table 37–1). If you can remember the function of each hormone in the body, understanding the problems involved with an altered amount of each hormone becomes easier.

Most endocrine disorders are either primary or secondary. A primary disorder is a problem within the gland that is out of balance. Secondary disorders are caused by problems outside the gland, such as an imbalance in a tropic hormone, certain drugs, trauma, surgery, or a problem in the feedback mechanism.

ectopic: ec—away from normal + topic—place

LEARNING TIPS

If you can remember what each hormone does in the body, it will be easier to remember what results from imbalances of that hormone. Most symptoms of hormone hyperactivity are the opposite of symptoms of that hormone's hypoactivity.

TABLE 37-1 CAUSES OF ENDOCRINE PROBLEMS

Insufficient Hormone Activity	Excess Hormone Activity
Gland hypofunction	Gland hyperfunction
Lack of tropic or stimulating hormone	Excess tropic or stimulating hormone
Target tissue insensitivity to hormone	Ectopic hormone production
	Self-administration of too much replacement hormone

► PITUITARY DISORDERS

Pituitary disorders often involve several hormone imbalances caused by general hypopituitarism or hyperpituitarism. Problems involving all the pituitary hormones at once are rare. For simplicity, imbalances are considered separately here.

Disorders Related to Antidiuretic Hormone Imbalance

Antidiuretic hormone (ADH, also called vasopressin) is synthesized in the hypothalamus and stored and secreted by the posterior pituitary gland. A decrease in ADH activity results in diabetes insipidus (DI). An increase in ADH activity is called syndrome of inappropriate antidiuretic hormone (SIADH). Table 37-2 compares DI and SIADH. Note how symptoms of too little ADH (water loss) are opposite from symptoms of too much ADH (water retention).

Diabetes Insipidus

PATHOPHYSIOLOGY. Diabetes insipidus is caused by a deficiency of ADH. Recall that ADH is responsible for reabsorption of water by the distal tubules and collecting ducts in the kidneys. If ADH is lacking, adequate reabsorption of water is

TABLE 37-2 COMPARISON OF ANTIDIURETIC HORMONE DISORDERS

	Insufficient ADH	Excess ADH
<i>Disorder</i>	Diabetes insipidus	SIADH
<i>Signs and symptoms</i>	Polyuria, polydipsia, hypernatremia, dehydration	Fluid retention, weight gain, hyponatremia
<i>Usual treatment</i>	Synthetic ADH replacement	Treat cause
<i>Priority nursing diagnoses</i>	Risk for fluid volume deficit	Risk for fluid volume excess

prevented, leading to diuresis. In **nephrogenic** diabetes insipidus, there is enough ADH but the kidneys do not respond to it. Patients may urinate from 3 to 15 L per day. This leads to increased serum **osmolality** (concentrated blood) and dehydration. The increased osmolality and decreased blood pressure normally trigger ADH secretion, which causes water retention and dilutes the blood; in patients with DI, this does not occur. Increased osmolality also leads to extreme thirst, which usually causes the patient to drink enough fluids to maintain fluid balance. In an unconscious patient or a patient with a defective thirst mechanism, however, dehydration may quickly occur if the problem is not recognized and corrected. For more information, check out the Nephrogenic Diabetes Insipidus Foundation at www.ndif.org.

ETIOLOGY. The primary causes of diabetes insipidus are tumors or trauma to the pituitary gland. Surgery in the area of the pituitary and certain drugs, such as glucocorticoids or alcohol, may also cause DI. Occasionally the cause is **psychogenic**: The patient drinks large quantities of water in the absence of true disease. Nephrogenic DI may be inherited or acquired and is diagnosed when the kidneys do not respond to ADH. It can be triggered by certain drugs or neoplasms or by damage to the kidneys from pyelonephritis, polycystic disease, or other causes.

SIGNS AND SYMPTOMS. The patient with DI urinates frequently (**polyuria**), and nighttime urination (**nocturia**) is present. This results in high serum osmolality and low urine osmolality. Urine specific gravity is decreased (the urine is diluted and light in color).

The patient experiences extreme thirst (**polydipsia**), and large volumes of water are consumed. Often patients crave ice-cold water. If urine output exceeds fluid intake, dehydration occurs, with characteristic symptoms of hypotension, poor skin turgor, and weakness. **Hypovolemic** shock occurs if fluid balance is not restored. Dehydration and electrolyte imbalances result in a decrease in level of consciousness and death if the problem is not corrected.

The patient with DI may develop an enlarged bladder and kidney damage from constantly trying to “hold” too much urine.

DIAGNOSTIC TESTS. Diagnosis is based initially on a history of risk factors and reported symptoms. Urine specific gravity is less than 1.005 (normal: 1.010 to 1.025), and can be monitored by laboratory tests or by using reagent strips at the bedside. Plasma osmolality is measured. The actual amount of sodium in the blood may be normal, but it appears elevated in relation to the decreased amount of water. Computed tomography (CT) scan or magnetic resonance imaging (MRI) may show a pituitary tumor.

nephrogenic: nephro—kidney + genic—to produce

psychogenic: psycho—related to the mind + genic—to produce

polyuria: poly—much + uria—urine

nocturia: noct—night + uria—urine

polydipsia: poly—much + dipsia—thirst

hypovolemic: hypo—deficient + vol—volume + emic—blood

A water deprivation test may be done. For this test, the patient is deprived of water for up to 8 hours. Body weight and urine osmolality are tested hourly. If the urine continues to be diluted, even though the patient is not drinking and is losing weight as a result of volume depletion, DI is suspected. In the second stage of the test, the patient receives an injection of ADH, with a final urine test done 1 hour later. If the DI is nephrogenic, the kidneys do not respond to the injected ADH.

MEDICAL TREATMENT. If a pituitary tumor is involved, treatment usually involves removal of the pituitary gland (**hypophysectomy**). Medical treatment of DI involves replacement of ADH. In acute cases, vasopressin, a synthetic form of ADH, is given by the intravenous or subcutaneous route, along with intravenous fluid replacement. In patients who require long-term therapy, such as those who have had a hypophysectomy, synthetic ADH (desmopressin, or DDAVP) in the form of a nasal spray is used. Desmopressin's action lasts 18 to 24 hours. Other drugs, such as chlorpropamide (Diabinese), stimulate ADH secretion in patients with partial DI. Thiazide diuretics may be ordered to treat nephrogenic DI.

NURSING PROCESS

Assessment. When doing a nursing assessment of a patient with DI, place special attention on fluid balance. Daily weights are the most reliable method for monitoring the amount of fluid that is being lost. Accurate intake and output measurement is also helpful. Skin turgor will be poor and mucous membranes will be dry and sticky if the patient is becoming dehydrated. Monitor skin integrity because dehydration increases risk of breakdown. Monitor vital signs for signs of shock. Use a reagent strip (dipstick) or urimeter to measure urine specific gravities. Monitor serum electrolytes and osmolality as ordered, and watch for changes in level of consciousness. Assess the patient's understanding of his or her disease and treatment. Once treatment is initiated, observe the patient for fluid overload.

Nursing Diagnosis. Priority nursing diagnoses include deficient fluid volume related to failure of regulatory mechanisms and deficient knowledge related to lack of exposure to information about self-care of diabetes insipidus.

Planning and Implementation. Give the patient oral fluids if the DI is not psychogenic. If the patient's thirst mechanism is not intact, give the patient fluids every hour. Hypotonic intravenous (IV) fluids such as 0.45 percent saline may be ordered to replace intravascular volume without adding excessive sodium. IV fluids are especially important if the patient is unable to take oral fluids. Report a significant drop in blood pressure and a rising pulse to the registered nurse or physician because these may be signs of shock. If the patient is able, he or she may participate in maintaining intake and output records.

hypophysectomy: hypophysis—pituitary + ectomy—surgical removal

Patient Education. Teach the patient the basic pathophysiology of the disease and how to administer medications and monitor their effectiveness. Teach the patient how to measure urine specific gravity and the significance of results. Include signs and symptoms of dehydration and fluid overload. Stress the importance of daily weights; losses or gains of greater than 2 pounds in a day should be reported to the physician. Advise the patient to wear identification, such as a medical alert bracelet, that identifies the disorder.

Evaluation. If treatment has been effective, signs of dehydration will be absent and weight and vital signs will be stable. The patient should be able to explain what is happening in the disease, symptoms to report, and how to manage self-care.

Syndrome of Inappropriate Antidiuretic Hormone

PATHOPHYSIOLOGY. Syndrome of inappropriate antidiuretic hormone (SIADH) results from too much ADH in the body. This causes excess water to be reabsorbed by the kidney tubules and collecting ducts, leading to decreased urine output and fluid overload. As fluid builds up in the bloodstream, osmolality decreases and the blood becomes diluted. Normally a decreased serum osmolality inhibits release of ADH. In SIADH, however, ADH continues to be released, adding to the fluid overload.

ETIOLOGY. Bronchogenic lung cancer, duodenal cancer, or pancreatic cancer may be ectopic sites of production of an ADH-like substance. Certain drugs, such as tricyclic antidepressants and general anesthetics, may increase ADH secretion. Head trauma or surgery or a brain tumor affecting pituitary function may also cause SIADH. It may be a complication of treatment of diabetes insipidus.

SIGNS AND SYMPTOMS. Symptoms of SIADH include symptoms of fluid overload, such as weight gain (usually without edema) and dilutional hyponatremia (Box 37-1). The actual amount of sodium in the blood may be normal, but it appears low because of the diluting effect of the retained fluid. Serum osmolality is less than 275 mOsm/kg. The urine is concentrated because water is not being excreted. Muscle cramps and weakness may occur because of electrolyte imbalance. Because the osmolality of the blood is low, fluid may leak out of the vessels and cause brain

BOX 37-1 Manifestations of Dilutional Hyponatremia

Bounding pulse
Elevated or normal blood pressure
Muscle weakness
Headache
Personality changes
Nausea
Diarrhea
Convulsions
Coma

swelling. If untreated, this results in lethargy, seizures, coma, and death.

DIAGNOSTIC TESTS. Serum and urine sodium levels and osmolality are measured. A water load test may be done, which involves administering a specific amount of water, then measuring blood and urine sodium and osmolality hourly for 6 hours. The patient with SIADH retains the water instead of excreting it. Additional testing may be done to diagnose and locate an ADH-secreting tumor.

MEDICAL TREATMENT. Treatment is aimed at eliminating the cause. If a tumor is secreting ADH, surgical removal may be indicated. Symptoms may be alleviated by restricting fluids to 800 to 1000 mL per 24 hours. Normal or hypertonic saline fluids may be administered intravenously to maintain the serum sodium level. If the cause is inoperable cancer, drugs such as furosemide (Lasix) and demeclocycline (Declomycin) are used to block the action of ADH in the kidney.

NURSING PROCESS

Assessment. Fluid overload with hyponatremia is the primary concern for the patient with SIADH. To monitor fluid balance, assess vital signs, daily weights, intake and output, urine specific gravity, skin turgor, edema, and lung sounds. The patient's ability to maintain a fluid restriction is determined. Assess level of consciousness and neuromuscular function. (See Chapter 45.) Monitor laboratory tests, including serum sodium level, as ordered by the physician. Assess the patient's understanding of the disease process and treatment.

Nursing Diagnosis. Priority nursing diagnoses include risk for excess fluid volume related to compromised regulatory mechanism and knowledge deficit related lack of exposure to information about self-care of SIADH.

Planning and Implementation. Explain the importance of maintaining the fluid restriction to the patient. Hard candy may help alleviate thirst. Ice chips may also help and are counted as half the volume of fluid; that is, 100 mL of ice chips equal approximately 50 mL of water. Providing calibrated cups can help the patient maintain the restriction independently if able. To increase compliance, allow the patient to participate in planning the types and times of fluid intake. Fluids high in sodium, such as broth, cola, or tomato juice, may help correct dilutional hyponatremia. Report a change in level of consciousness immediately, and monitor the patient for seizures.

Patient Education. Instruct the patient to report any weight gain greater than 2 pounds in one day, a change in urine output, or acute thirst. Use of medical alert bracelet or other identification should be encouraged.

Evaluation. Weight should stabilize at the preillness level once treatment is begun. Serum sodium level should be within normal limits. Patients should be able to verbalize the cause of their symptoms and demonstrate self-care, including ability to maintain a fluid restriction if necessary.

CRITICAL THINKING

Mrs. Jackson
 You are caring for Mrs. Jackson, a 78-year-old woman who has just returned to your unit following hip surgery. During the next 2 days, you notice that her weight increases from 118 to 124 pounds and she seems lethargic, but the nurse in report didn't seem concerned about it. You check her ankles and sacrum for edema but find none. In the afternoon, her son rushes out of the room and tells you she is becoming confused, adding that this is not like her at all.

1. What could be happening?
2. What assessment can you do to gather further data to support your suspicions?
3. What will you do?

Answers at end of chapter.

Disorders Related to Growth Hormone Imbalance

Growth hormone (GH), also called somatotropin, is responsible for normal growth of bones, cartilage, and soft tissue. GH is synthesized and secreted by the anterior pituitary gland. An excess or deficiency of GH may be related to a more generalized problem with the pituitary gland. Excess GH results in gigantism or acromegaly. A deficit of GH results in dwarfism (Fig. 37-1).

Figure 37-1 Gigantism and dwarfism.

Dwarfism

PATHOPHYSIOLOGY. Dwarfism, also called short stature, occurs when growth hormone is deficient in childhood. A deficiency of GH in adults does not affect growth but is responsible for a variety of other symptoms.

ETIOLOGY. Growth hormone may be deficient as a result of a pituitary tumor or failure of the pituitary to develop. It may be the result of infection or other trauma to the pituitary gland. It may also be deficient in some cases of neglect or severe emotional stress, causing psychosocial dwarfism. Sometimes the cause is not known (Cultural Consideration Box 37-2).

BOX 37-2 CULTURAL CONSIDERATION

Dwarfism, mostly related to a limited gene pool, often occurs among Amish communities. Ellis-van Creveld syndrome is prevalent among the Amish of Lancaster County, Pennsylvania. This syndrome is characterized by short stature and an extra digit on each hand, with some individuals having a congenital heart defect and nervous system involvement resulting in a degree of mental handicap.

SIGNS AND SYMPTOMS. Children may grow to only 3 to 4 feet in height but have normal body proportions. Sexual maturation may be slowed, related to involvement of additional pituitary hormones. Dwarfism in children is sometimes accompanied by mental retardation. In adults, symptoms include weakness, hypoglycemia, sexual dysfunction, skin changes, and increased risk for cardiovascular and cerebrovascular disease. Headaches, mental slowness, and visual disturbances may also occur.

DIAGNOSTIC TESTS. Growth hormone levels in the blood are measured by a routine laboratory test. A growth hormone stimulation test may be done by measuring GH response to induced hypoglycemia. Radiographic studies help determine the presence of a pituitary tumor and may also be used to determine bone age.

MEDICAL TREATMENT. Treatment of dwarfism in a child is administration of growth hormone. In the past, GH was derived from human pituitary glands, so treatment was expensive. Now GH can be made in a laboratory using genetic engineering, and it is more readily available to those who need it. It is administered by injection. Surgery may be indicated if a tumor is the cause.

NURSING PROCESS

Assessment. Assessment of the adult with dwarfism includes mental status, ability to cope with the effects of the disorder, and understanding of the treatment plan.

Nursing Diagnosis. Possible priority nursing diagnoses include disturbed body image, ineffective coping, and deficient knowledge. If the adult with dwarfism has accepted and coped well with the condition, diagnosis and treatment by a nurse may not be indicated.

Planning and Implementation. Approach patients with dwarfism with an attitude of acceptance and caring. Provide an opportunity to verbalize their feelings. An occupational therapist may be able to provide techniques to assist patients to adapt to an environment that is geared toward people of average height. Information about support groups may be provided to patients.

Evaluation. The goal has been achieved if the patient is able to express his or her feelings of acceptance of the disorder, demonstrate adaptive techniques, and verbalize understanding of treatment.

CRITICAL THINKING

Adoption

Three siblings were adopted to a loving home after having been in several foster homes. After a year in their new home, each child suddenly grew 6 to 8 inches. What do you think happened?

Answer at end of chapter.

Acromegaly

Acromegaly is a rare excess of growth hormone that affects adults, usually in their thirties or forties. If a GH excess occurs in children, the condition results in gigantism.

PATHOPHYSIOLOGY. Acromegaly occurs as a result of oversecretion of GH in an adult. Bones increase in size, leading to enlargement of facial features, hands, and feet. Long bones grow in width but not length, because the epiphyseal disks are closed. Subcutaneous connective tissue increases, causing a fleshy appearance. Internal organs and glands enlarge. Impaired tolerance of carbohydrates leads to elevated blood glucose.

ETIOLOGY. Excess secretion of growth hormone can be caused by pituitary **hyperplasia**, a benign pituitary tumor, or hypothalamic dysfunction.

SIGNS AND SYMPTOMS. Often the first symptom noticed is a change in hat or shoe size. The nose, jaw, brow, hands, and feet enlarge (Fig. 37-2). The teeth may be displaced, causing difficulty chewing, or dentures may no longer fit. The tongue becomes thick, causing difficulty in speaking and swallowing. Vertebral changes may lead to kyphosis. Visual disturbances may occur because of tumor pressure on the optic nerve. Headaches are a result of tumor pressure on the brain. Diabetes mellitus may develop because GH increases blood glucose and causes an increased workload for the pancreas. (See Chapter 38.) Osteoporosis and arthritis may occur. Erectile dysfunction may occur in men and **amenorrhea** in women. With treatment, soft tissues reduce in size, but bone growth is permanent.

hyperplasia: hyper—excessive + plasia—formation or deviation

amenorrhea: a—not + men—month + orrhea—flow

Figure 37-2 Patient with acromegaly. From Tamparo, CD, and Lewis, MA: *Diseases of the Human Body*, ed 2. FA Davis, Philadelphia, 1995, p. 270.

DIAGNOSTIC TESTS. Serum growth hormone levels are measured, and radiographs show abnormal bone growth.

MEDICAL TREATMENT. Treatment is aimed at the cause. Bromocriptine (Parlodel) or octreotide (Sandostatin) may decrease GH levels. Hypophysectomy or radiation may be indicated if a tumor is the cause. If the pituitary is removed, lifelong replacement of thyroid hormone, corticosteroids, and sex hormones is important to maintain homeostasis.

NURSING PROCESS

Assessment. The nurse caring for the patient with acromegaly is concerned with the patient's response to the disease. Assess safety in relation to impaired eyesight, chewing, and swallowing. Monitor serum glucose levels for onset of diabetes mellitus. Assess knowledge and acceptance of the disease. If hypophysectomy is planned, assess the patient for anxiety related to the surgery and perform a preoperative baseline neurological assessment. (See Chapter 45 and Care of the Patient Undergoing Hypophysectomy later in this chapter.)

Nursing Diagnosis. Possible nursing diagnoses include disturbed body image, risk for injury related to poor eyesight and **dysphagia**, deficient knowledge, pain, and disturbed sensory perception. Additional diagnoses are identified if diabetes mellitus or other problems exist.

Planning and Implementation. Allow the patient to verbalize feelings related to the disease. A care plan for safety is implemented if vision or swallowing is disturbed. If pain is present, comfort measures are provided.

Patient Education. Teach the patient and significant others about the disease and treatment. If the patient is having a hypophysectomy, be sure he or she understands that some symptoms will be relieved but that bone growth and visual changes may not reverse. Stress the need for lifelong hormone replacement after surgery.

Evaluation. The patient who is effectively treated will have some soft tissues return to normal size. Injuries related to poor eyesight and difficulty swallowing will be avoided. The patient should be able to accurately describe self-care requirements.

Pituitary Tumors

Most tumors of the pituitary gland are benign adenomas. However, even benign tumors in the brain can cause many symptoms, including visual disturbances, symptoms of increased pressure in the brain, and symptoms related to hormone imbalances, as described earlier. Treatment for pituitary tumors is usually hypophysectomy (surgical removal of the pituitary gland). Radiation may be used alone or as an adjunct to surgery.

Care of the Patient Undergoing Hypophysectomy

Removal of the pituitary gland is called hypophysectomy. Figure 37-3 shows the transsphenoidal approach to the gland. Some tumors may necessitate removal via a transfrontal craniotomy (entry through the frontal bone of the skull).

Preoperative Care

Ensure that the patient understands the physician's explanation of surgery. Perform and document a baseline neurological assessment. Prepare the patient for what to expect following surgery. Instruct the patient to avoid any actions that increase pressure on the surgical site, such as coughing, sneezing, nose blowing, straining to move bowels, or bending from the waist. Because coughing can raise intracranial pressure and is therefore contraindicated, instruct the patient in deep breathing exercises or use of an incentive spirometer.

Postoperative Care

Perform routine neurological assessments to monitor for neurological damage. Also be sure to check urine for specific gravity, because diabetes insipidus may occur following pituitary surgery. If patients have had transsphenoidal surgery, they will have nasal packing and a "mustache dressing," which is placed under the nose to collect drips. These are left in place and not removed unless ordered by the physician. Monitor the dressing for signs of cerebrospinal fluid (CSF) leakage. CSF contains glucose, so glucose testing strips can be used to determine if drainage is actually CSF or just nasal discharge. Remind the patient to avoid any actions that increase pressure on the surgical site. Obtain orders for stool softeners and antitussives as needed. Tooth brushing is avoided until the incision line is healed. The patient may use floss and mouth rinses. The patient is placed on hormone replacement therapy following hypophysectomy. Pituitary hormones are difficult to replace, so target hormones are generally given. These may include thyroid hormone, glucocorticoids, intranasal desmopressin, and sex hormones. Instruct the patient in how to administer the hormones, as well as side effects to report.

dysphagia: dys—bad + phagia—swallowing

Figure 37-3 Transsphenoidal approach to pituitary gland for hypophysectomy.

► DISORDERS OF THE THYROID GLAND

Triiodothyronine (T_3) and thyroxine (T_4) are secreted by the thyroid gland. These hormones may be collectively referred to as thyroid hormone (TH). Deficient secretion of these hormones results in hypothyroidism; excess TH results in hyperthyroidism. For more information on disorders of the thyroid gland, visit the American Thyroid Association at www.thyroid.org.

Hypothyroidism

Hypothyroidism occurs primarily in women 30 to 60 years old. If hypothyroidism occurs in an infant, the result is cretinism. Hypothyroidism that develops in an adult is called **myxedema**.

PATHOPHYSIOLOGY. Primary hypothyroidism occurs when the thyroid gland fails to produce enough TH even though there is enough thyroid-stimulating hormone (TSH) being secreted by the pituitary gland. The pituitary responds to the low level of TH by producing more TSH. Secondary hypothyroidism is caused by low levels of TSH or thyrotropin-releasing hormone (TRH, secreted by the hypothalamus), which fail to stimulate release of TH. Most cases of hypothyroidism are primary (Table 37-3).

Because thyroid hormones are responsible for metabolism, low levels of these hormones result in a slowed metabolic rate, which causes many of the characteristic symp-

TABLE 37-3 THYROID HORMONE ABNORMALITIES

	Hyperthyroidism	Hypothyroidism
<i>Primary</i>	TH \uparrow TSH \downarrow	TH \downarrow TSH \uparrow
<i>Secondary (pituitary cause)</i>	TH \uparrow TSH \uparrow	TH \downarrow TSH \downarrow

toms of hypothyroidism. Other symptoms are related to myxedema, which refers to a nonpitting type of edema that occurs in connective tissues throughout the body.

ETIOLOGY. Primary hypothyroidism may be a result of a congenital defect, inflammation of the thyroid gland, iodine deficiency, or thyroidectomy. Hashimoto's thyroiditis is an **autoimmune** disorder that eventually destroys thyroid tissue, leading to hypothyroidism. Secondary hypothyroidism may be caused by a pituitary or hypothalamic lesion or by postpartum pituitary necrosis, a rare disorder in which the pituitary is destroyed following pregnancy and delivery. Peripheral resistance to TH may also occur.

SIGNS AND SYMPTOMS. Manifestations primarily are related to the reduced metabolic rate and include fatigue, weight gain, bradycardia, constipation, mental dullness, feeling cold, shortness of breath, and dry skin and hair (Table 37-4). Heart failure may occur because of decreased pumping strength of the heart. Altered fat metabolism causes hyperlipidemia. Myxedema causes water retention, with puffiness

myxedema: myx—mucus + edema—swelling

autoimmune: auto—pertaining to self + immune—exempt

TABLE 37-4 SYMPTOMS OF THYROID DISORDERS

	Hypothyroidism	Hyperthyroidism
Cardiovascular	Bradycardia, decreased cardiac output, cool skin, cold intolerance	Tachycardia, palpitations, increased cardiac output, warm skin, heat intolerance
Neurological	Lethargy, slowed movements, memory loss, confusion	Fatigue, restlessness, tremor, insomnia, emotional instability
Pulmonary	Dyspnea, hypoventilation	Dyspnea
Integumentary	Cool, dry skin; brittle, dry hair	Diaphoresis; warm, moist skin; fine, soft hair
Gastrointestinal	Decreased appetite, weight gain, constipation, increased serum lipid levels	Increased appetite, weight loss, frequent stools, decreased serum lipid levels
Reproductive	Decreased libido, erectile dysfunction	Decreased libido, erectile dysfunction, amenorrhea

in the face, eye area, and feet. Fluid may also accumulate around the heart, causing altered cardiac function.

COMPLICATIONS. If the metabolic rate drops so low that it becomes life threatening, the result is called myxedema coma. This can be triggered by stress, such as infection, trauma, or exposure to cold. The patient becomes hypothermic, with a temperature less than 95° F, and has a decreased respiratory rate and blood pressure. Depressed mental function and lethargy may occur. Blood glucose drops. Death may occur as a result of respiratory failure. If you note changes in mental status or vital signs, the physician should be contacted immediately. Treatment of myxedema coma involves intubation and mechanical ventilation. The patient is slowly rewarmed with blankets. Intravenous levothyroxine (Synthroid) is given.

DIAGNOSTIC TESTS. T₃ and T₄ levels are low, and TSH may be high or low, depending on the cause. If the pituitary is functioning normally, TSH is elevated in an attempt to stimulate an increase in TH. Serum cholesterol and triglycerides are elevated. Antibodies are usually present in autoimmune disease.

MEDICAL TREATMENT. Hypothyroidism is easily treated with thyroid replacement hormone. Some patients still use TH from animal thyroids. Most patients now take synthetic thyroid hormone (levothyroxine). Doses are started low and are slowly increased to prevent symptoms of hyperthyroidism or cardiac complications.

NURSING PROCESS. See Nursing Care Plan 37-3 for nursing care of the patient with hypothyroidism.

BOX 37-3 NURSING CARE PLAN FOR THE PATIENT WITH HYPOTHYROIDISM

▶ Activity intolerance related to fatigue

PATIENT OUTCOMES

(1) Patient reports lessening fatigue after treatment initiated. (2) Patient is able to carry out usual activities of daily living (ADLs).

EVALUATION OF OUTCOMES

(1) Does patient report lessening fatigue? (2) Is patient able to carry out ADLs?

INTERVENTIONS

Assist patient with self-care activities.

Allow for rest between activities.

Slowly increase patient's activities as medication begins to be effective.

RATIONALE

Patients with fatigue may have difficulty carrying out activities independently.

Rest periods will enable patient to conserve energy for activities.

As thyroid replacement therapy becomes effective, patient's fatigue will subside.

EVALUATION

Are patient's self-care needs being met? Is assistance needed?

Does patient state rest is adequate?

Does patient tolerate increases in activity?

GERIATRIC

When getting elderly patients up, watch for orthostatic hypotension.

Orthostatic hypotension is common in elderly and may cause falls.

Does patient's blood pressure drop when changing positions?

▶ Constipation related to slowed gastrointestinal motility

PATIENT OUTCOMES

(1) Soft, formed stool passed at preillness frequency. (2) Patient identifies measures to prevent constipation in future.

EVALUATION OF OUTCOMES

(1) Are bowels moving according to patient's preillness pattern? (2) Does patient verbalize measures to prevent constipation?

BOX 37-3 NURSING CARE PLAN FOR THE PATIENT WITH HYPOTHYROIDISM—CONT'D

INTERVENTIONS	RATIONALE	EVALUATION
Monitor and record bowel movements.	A record helps determine if a problem exists.	Does record show a problem?
Help patient follow usual preillness pattern (e.g., after morning coffee).	A schedule allows bowel movement to occur before stool becomes hard and dry.	Is patient able to identify and implement usual self-care for bowels?
Increase fluids to eight 8-ounce glasses of water daily if cardiovascular status stable.	Adequate fluid intake helps prevent hard, dry stools.	Does patient take adequate fluids?
Add fiber to diet: fresh fruit, vegetables, bran.	Fiber helps increase the number of bowel movements.	Does patient tolerate fiber? Is it effective?
Encourage regular ambulation.	Activity increases peristalsis.	Is patient able to ambulate or engage in other activity?
Use bedside commode or bathroom rather than bedpan.	The sitting position aids in evacuation.	Is sitting position effective?
Obtain physician order for stool softener if needed.	Soft stools are passed more easily.	Is stool softener needed? Effective?
If stool is impacted, break up stool digitally and gently remove.	Breaking up stool eases evacuation.	Is stool impacted? Is digital disimpaction effective?
Avoid use of enemas.	Enemas can cause fluid and electrolyte imbalances and can damage mucosa.	Does patient understand need to avoid enemas?

▶ Impaired skin integrity related to dry skin, inactivity**PATIENT OUTCOMES**

(1) Skin is soft and moist. (2) Skin remains intact.

EVALUATION OF OUTCOMES

(1) Is skin soft and moist? (2) Is skin intact?

INTERVENTIONS	RATIONALE	EVALUATION
Assess skin daily for breakdown.	Skin lesions are more effectively treated when identified early.	Is breakdown present?
Avoid use of soap on dry areas. Try bath oil.	Soap is drying to skin.	Does use of bath oil help?
Use nondrying lotion following bath.	Lotion helps trap moisture in skin. Some lotions contain alcohol, however, which is drying.	Does patient state relief with use of lotion?
Encourage/assist with position changes at least every 2 hours.	Changing position enhances circulation to the skin, promoting healing and preventing breakdown.	Does patient change position at least every 2 hours? Are pressure areas prevented?

Altered nutrition, more than requirements, related to decreased metabolic rate**PATIENT OUTCOMES**

(1) Patient will return to preillness weight. (2) Patient will verbalize understanding of dietary recommendations.

EVALUATION OF OUTCOMES

(1) Is patient approaching preillness weight? (2) Is patient able to explain dietary recommendations and how they will be implemented?

INTERVENTIONS	RATIONALE	EVALUATION
Weigh weekly and record.	Weekly weights record progress without the frustration of daily fluctuations.	Is patient losing or maintaining weight?
Consult dietitian for therapeutic diet until hypothyroidism is controlled.	The dietitian can provide food choices for gradual weight loss if necessary.	Does patient verbalize understanding of and ability to follow diet?
Encourage regular exercise within limits of fatigue.	Exercise promotes weight control.	Does patient verbalize understanding of and ability to follow exercise plan?
Counsel patient that weight should normalize once hypothyroidism is controlled.	Thyroid replacement hormone increases the metabolic rate, allowing to return to normal weight.	Does patient verbalize understanding of instruction?

GERIATRIC

Allow patient to help determine acceptable diet modifications.	Older patients may have long-standing dietary habits that are hard to change.	Is patient satisfied with weight loss plan?
--	---	---

PATIENT EDUCATION. Instruct the patient in the importance of consistent use of thyroid replacement medication and regular blood tests to monitor the levels of TH. The patient needs to be aware that too much thyroid hormone will cause symptoms of hyperthyroidism. Such symptoms should be reported to the physician immediately.

CRITICAL THINKING

Mae
Mae is a 59-year-old woman who is tired all the time and has gained 16 pounds during the past year. Her physician does some blood tests and prescribes levothyroxine PO. Lab results show low T_3 and T_4 and elevated TSH.

1. Why is Mae's TSH elevated?
2. What will happen to Mae's caloric requirements as she begins treatment? Why?
3. Why should you teach Mae to check her pulse?

Answers at end of chapter.

Hyperthyroidism

Hyperthyroidism is most often diagnosed in young women. Graves' disease, which is one cause of hyperthyroidism, is more common in young women. Multinodular goiter is more common in older women.

PATHOPHYSIOLOGY. Hyperthyroidism results from excessive amounts of circulating thyroid hormone (thyrotoxicosis). Primary hyperthyroidism occurs when a problem within the thyroid gland causes excess hormone release. Secondary hyperthyroidism occurs because of excess TSH release from the pituitary or excess TRH from the hypothalamus, which overstimulate the thyroid. A high level of thyroid hormone increases the metabolic rate. It is also believed to increase the number of beta-adrenergic receptor sites in the body, which enhances the activity of norepinephrine. The resulting fight-or-flight response is the cause of many of the symptoms of hyperthyroidism.

ETIOLOGY. A variety of disorders can cause hyperthyroidism. Graves' disease is the most common cause; it is thought to be an autoimmune disorder, because thyroid-stimulating antibodies are present in the blood of these patients.

Multinodular goiter, in which thyroid nodules secrete excess TH, is sometimes associated with hyperthyroidism. A pituitary tumor may secrete excess TSH, which overstimulates the thyroid gland. A thyroid tumor may secrete TH. Patients taking thyroid hormone for hypothyroidism may take too much. Each of these problems can cause excess circulating TH and symptoms of hyperthyroidism.

SIGNS AND SYMPTOMS. Many signs and symptoms are related to the hypermetabolic state, such as heat intolerance, increased appetite with weight loss, and increased frequency of bowel movements. Nervousness, tremor, tachycardia, and palpitations are caused by the increase in sympathetic nervous system activity. Heart failure may oc-

cur because of tachycardia and the resulting inefficient pumping of the heart. See additional signs and symptoms in Table 37-4. If treatment is not begun, the patient may become manic or psychotic. Additional signs that occur only with Graves' disease include thickening of the skin on the anterior legs and exophthalmos (bulging of the eyes; Fig. 37-4) caused by swelling of the tissues behind the eyes.

Be especially alert to the elderly patient, who may not exhibit the typical signs and symptoms of hyperthyroidism. These patients may present with heart failure, atrial fibrillation, fatigue, apathy, and depression.

COMPLICATIONS

Thyrotoxic Crisis. Thyrotoxic crisis (also called thyroid storm) is a severe hyperthyroid state that can occur in hyperthyroid individuals who are untreated or who are experiencing another illness or stressor. It may also occur following thyroid surgery in patients who have been inadequately prepared with antithyroid medication. Thyrotoxic crisis can result in death in as little as 2 hours if untreated. Symptoms include tachycardia, high fever, hypertension (with eventual heart failure and hypotension), dehydration, restlessness, and delirium or coma.

If thyrotoxic crisis occurs, treatment is first directed toward relieving the life-threatening symptoms. Acetaminophen is given for the fever. Aspirin is avoided because it binds with the same serum protein as T_4 , freeing additional T_4 into the circulation. Intravenous fluids and a cooling blanket may be ordered to cool the patient. A beta-adrenergic blocker, such as propranolol, is given for tachycardia. If the patient is short of breath because of cardiac dysfunction, oxygen is administered and the head of the bed is elevated. Once symptoms are controlled and the patient is safe, the underlying thyroid problem is treated.

Figure 37-4 Exophthalmos caused by Graves' disease. From Tamparo, CD, and Lewis, MA: *Diseases of the Human Body*, ed 2. FA Davis, Philadelphia, 1995, p 275, with permission.)

Hypothyroidism. Another complication of hyperthyroidism can be hypothyroidism. This can occur as a result of long-term disease or as a result of treatment. Patients with a history of hyperthyroidism should be monitored for recurrent hyperthyroidism or the onset of hypothyroidism.

DIAGNOSTIC TESTS. Serum levels of T₃ and T₄ are elevated. TSH is low in primary hypothyroidism or high if the cause is pituitary. A TRH stimulation test may be done. A thyroid scan can be done to locate a tumor.

MEDICAL TREATMENT. Several medications can be used to treat hyperthyroidism. Propylthiouracil (PTU) and methimazole (Tapazole) inhibit the synthesis of TH. Propranolol (Inderal) is a beta-blocking medication that relieves the sympathetic nervous system symptoms. Radioactive iodine (¹³¹I) may be used to destroy a portion of the thyroid gland. Oral iodine suppresses the release of thyroid hormone.

Sometimes medications alone control hyperthyroidism. If this does not occur, surgery is planned. If surgery is the treatment chosen, antithyroid medications are given to calm the thyroid before surgery. They help slow the heart rate and reduce other symptoms, making surgery safer. Iodine also reduces the vascularity of the thyroid gland, decreasing the risk of bleeding during surgery. Adequate preparation of the patient is important, because a **euthyroid** state helps prevent a postoperative thyrotoxic crisis. Nursing care of the patient undergoing a thyroidectomy is discussed later in this chapter.

NURSING PROCESS

Assessment. Monitor the patient with hyperthyroidism closely until normal thyroid activity is restored. Monitor vital signs and report any increases in pulse and blood pressure to the registered nurse or physician. Monitor lung sounds, because crackles may indicate heart failure. Assess level of anxiety and ability to cope with symptoms. Monitor weight and bowel function. Assess eyes for risk for injury caused by exophthalmos, and note degree of muscle weakness. Never palpate the thyroid gland of a patient with hyperthyroidism, because palpation may stimulate release of thyroid hormone and precipitate a thyrotoxic crisis.

Nursing Diagnosis. Priority nursing diagnoses include risk for injury related to hypermetabolic state and exophthalmos, hyperthermia, diarrhea, imbalanced nutrition, disturbed sleep pattern, and anxiety.

Planning and Implementation. Report changes in vital signs to the physician. The patient with exophthalmos may benefit from lubricating eye drops and dark glasses. The eyes may be gently taped shut with nonallergic tape for sleeping. Elevation of the head of the bed and a low-sodium diet may decrease edema behind the eyes. If routine measures for hyperthermia are ineffective, a cooling blanket may be ordered. Diarrhea may be lessened with a low-fiber diet. A high-calorie diet with six meals a day may be necessary to meet caloric requirements. A restful environment and a

mild sleeping aid may assist the patient to fall asleep. Assure the patient that proper treatment will correct symptoms.

Patient Education. Teach the patient about the disease and symptoms of hyperthyroidism or hypothyroidism to report. Also teach the patient how to take antithyroid medication if ordered.

Evaluation. If the plan of care is effective, the patient will remain free from complications or injury related to the hypermetabolic state. Eyes will be comfortable and free from injury. Body temperature will be kept within normal limits. Diarrhea will be controlled, and complications of diarrhea such as skin breakdown and dehydration avoided. The patient's weight should remain stable. The patient should report that he or she is rested on awakening and that anxiety is controlled.

CARE OF THE PATIENT RECEIVING RADIOACTIVE IODINE.

If radioactive iodine is used, it is usually given orally in one dose. If the dose is high, such as for the patient with thyroid cancer, the patient is hospitalized. Patients receiving lower doses may be treated as outpatients. You should limit time spent with the patient and maintain a safe distance when providing direct care. The nurse who is pregnant should avoid caring for patients receiving radioactive iodine. Urine, vomitus, and other body secretions are contaminated and should be disposed of according to hospital policy. Many hospitals direct nurses to flush the toilet twice following disposal of contaminated material. The radiation safety officer and hospital policy should be consulted for specific precautions.

At home, the patient is instructed to avoid close contact with family members for about a week and to use careful handwashing after urinating. Oral contact with others should be avoided, and eating utensils should be washed thoroughly with soap and water. Hospital teaching protocols should be used for specific patient teaching. If the treatment is being administered for hyperthyroidism, inform the patient that symptoms will subside in about 6 to 8 weeks. In addition, the patient should be aware of symptoms of hypothyroidism to be reported, because hypothyroidism may occur up to 15 years after the treatment.

Goiter

PATHOPHYSIOLOGY AND ETIOLOGY. Enlargement of the thyroid gland is called a goiter. The thyroid gland may enlarge in response to increased TSH levels. TSH is elevated in response to low TH; iodine deficiency; pregnancy; or viral, genetic, or other conditions. When a goiter is caused by iodine deficiency or other environmental factors, it is called an endemic goiter.

A goiter may be associated with a hyperthyroid, hypothyroid, or euthyroid state. Once the cause of the goiter is removed, the gland usually returns to normal size.

Some foods and medications are **goitrogens**. These substances interfere with the body's use of iodine and include

euthyroid: eu—normal, healthy + thyroid

goitrogenic: goitro—goiter + genic—producing

BOX 37-4

Nutrition Notes

Relating Nutrition to Thyroid Disorders**Iodine Deficiency**

Inland areas of all continents have iodine-poor soils. People in developing countries with only local food sources are still subject to endemic goiter; however, fortification of salt with iodine has significantly reduced the occurrence of endemic goiter in developed countries.

Most goitrogens compete with iodide for active transport into thyroid cells but are not thought to cause endemic goiter. At particular risk of iodine deficiency are strict vegetarians who consume sea salt, which contains virtually no iodine, rather than iodized salt. In a study of a group of North American vegans, 12 percent developed hypothyroidism.

Iodine Excess

Saltwater fish, shellfish, and seaweed are naturally high in iodine. Iodine toxicity has occurred in Japan. Excessive iodine can be manifested as either hyperthyroidism or hypothyroidism, sometimes producing “iodine goiter.”

Remer, T, Neubert, A, and Manz, F: Increased risk of iodine deficiency with vegetarian nutrition. *Br J Nutr* 81:45, 1999.

such foods as turnips, cabbage, broccoli, horseradish, cauliflower, and carrots (Nutrition Notes Box 37-4). Some goitrogenic medications include propylthiouracil, sulfonamides, lithium, and salicylates.

SIGNS AND SYMPTOMS. The thyroid gland is enlarged, with swelling apparent at the base of the neck (Fig. 37-5). The patient may have a full sensation in the neck. If the goiter is large, it may interfere with swallowing or breathing. Symptoms of hypothyroidism or hyperthyroidism may be present.

DIAGNOSTIC TESTS AND MEDICAL TREATMENT. A thyroid scan shows an enlarged thyroid gland. Serum T_3 and T_4 levels are measured to determine thyroid function. Treatment is aimed at the cause. If goitrogens are suspected, the patient is given a list of foods to be avoided. If iodine deficiency is a problem, it is added to the diet with supplements or iodized salt. A thyroidectomy may be necessary if the gland is interfering with breathing or swallowing.

NURSING CARE. Be careful to assess the effect of the goiter on breathing and swallowing. Stridor, a whistling sound, may be heard if the airway is obstructed. Stridor is an ominous sign and should be reported to the physician immediately. If the patient experiences difficulty swallowing, notify the physician and collaborate with the dietitian to provide soft foods or liquid nutrition. A swallowing study might be ordered, which can assist a speech pathologist or other expert to make specific recommendations for safe swallowing.

Cancer of the Thyroid Gland

Although thyroid cancer is rare, it is the most common cancer of the endocrine system (Cultural Consideration Box 37-5). Women are affected more often than men. Most tumors of the thyroid gland are not malignant.

Figure 37-5 Patient with goiter.

BOX 37-5

CULTURAL CONSIDERATION

Because of the Chernobyl nuclear disaster in Russia in 1988, Russian immigrants are at exceptionally high risk for developing pituitary, thyroid, and parathyroid disorders and cancers. The proximity of Estonia, Latvia, Lithuania, Poland, and other Eastern European countries to Russia places immigrants and long-term visitors from these countries at risk also. The nurse needs to be alert for endocrine disorders among these populations and assist patients to arrange genetic counseling for those who desire it.

ETIOLOGY. Thyroid hyperplasia may lead to thyroid cancer. Other causes include exposure to radiation, iodine deficiency, and prolonged exposure to goitrogens.

SIGNS AND SYMPTOMS. A hard, painless nodule may be palpable on the thyroid gland. Difficulty breathing or swallowing or changes in the voice may occur if the tumor is near the esophagus and trachea. Most patients with cancer of the thyroid have normal TH levels.

DIAGNOSTIC TESTS. A thyroid scan shows a “cold” nodule. This is because malignant tumors of the thyroid do not take up the radioactive iodine administered for the scan. A fine-needle aspiration biopsy confirms the diagnosis. A “hot” nodule indicates a benign tumor.

MEDICAL TREATMENT. A partial or total thyroidectomy may be done. Chemotherapy or radioactive iodine therapy may also be used, alone or following surgery.

NURSING CARE. Nursing care is determined by the symptoms the patient is experiencing. See Chapter 10 for care of the patient with cancer.

NURSING CARE OF THE PATIENT UNDERGOING THYROIDECTOMY. Patients may undergo thyroidectomy for cancer of the thyroid, hyperthyroidism, or a goiter that is causing dyspnea or dysphagia. See Chapter 11 for general care of a patient having surgery.

A total thyroidectomy is usually performed if cancer is present. After a total thyroidectomy, lifelong replacement

hormone must be taken. A subtotal (partial) thyroidectomy may be done for hyperthyroidism, leaving a portion of the thyroid gland to secrete TH.

Before undergoing a thyroidectomy, the patient should be in a euthyroid state. This is accomplished with the use of antithyroid medication. Saturated solution of potassium iodide (SSKI) may also be administered to decrease the size and vascularity of the gland, reducing the risk of bleeding during surgery.

PREOPERATIVE CARE

Assessment. Assess the patient for symptoms related to an enlarged thyroid, including difficulty swallowing or breathing. Monitor TH levels. Assess nutritional status and drug history, and monitor vital signs. Assess the patient's understanding of the procedure and level of anxiety.

Nursing Diagnosis. Possible diagnoses include anxiety, deficient knowledge related to lack of exposure to information about surgery, and risk for injury.

Planning and Implementation. Reassure the patient that symptoms will be relieved after surgery. Allow the patient time to express fears and ask questions. Approach the patient slowly and calmly, because the hyperthyroid state increases the patient's feelings of anxiety. Report changes in vital signs, ensure that the patient's nutritional needs have been addressed, and verify that antithyroid drugs have been administered as ordered.

Patient Education. Explain what the patient can expect before, during, and after surgery and clarify misconceptions. (See Chapter 11.) Before surgery, teach the patient how to perform gentle range-of-motion exercises of the neck, how to support the neck during position changes, and how to use an incentive spirometer after surgery.

Evaluation. The patient will state that anxiety is controlled and that questions related to surgery have been answered. Risk for injury will be minimized by verifying that the patient is in a euthyroid state before surgery.

POSTOPERATIVE CARE

Assessment. Monitor vital signs and dressings every 15 minutes initially, progressing to every 4 hours, as ordered. Decreased blood pressure with increased pulse should alert you to the possibility of shock related to blood loss. Tachycardia and fever, along with mental status changes, may indicate thyrotoxic crisis. Check the back of the neck for pooling of blood. Because of the location of the surgery, observe for signs of respiratory distress, including an increase in respiratory rate, dyspnea, or stridor. Ask the patient to speak to detect hoarseness of the voice, which may indicate trauma to the recurrent laryngeal nerve. Monitor the patient for evidence of **tetany** (discussed later in this chapter). Report any abnormal findings to the physician immediately.

Nursing Diagnosis. Possible diagnoses include risk for injury (complications), pain related to surgical procedure, risk for imbalanced nutrition, and ineffective airway clearance due to edema at surgical site.

Planning and Implementation. Notify the physician of changes in vital signs, respiratory distress, or excessive bleeding from the surgical site. Keep a tracheostomy set at the bedside for emergency use if edema causes respiratory obstruction. Semi-Fowler's position helps reduce edema and promotes comfort. Implement routine interventions to prevent postoperative pain. Pillows or sandbags may be used to support the head. The patient should be assisted with gentle range-of-motion exercises, avoiding hyperextension of the neck, which can cause strain on the incision line. Remind the patient to do coughing and deep breathing exercises every hour. Encourage the patient to use the incentive spirometer to assist with deep breathing. When the patient's swallowing and gag reflexes are intact, clear liquids are ordered. A dietitian may be consulted to assist the patient with potential dietary changes needed following surgery. With correction of metabolic alterations, dietary needs may be significantly altered.

Patient Education. Teach the patient the importance of follow-up care, and how to administer replacement hormone if indicated. Also teach the patient or significant other how to change the dressing and to report bleeding or signs of infection at the site. Because the threat of thyrotoxic crisis may continue after discharge, the patient or significant other should be taught to immediately report unusual irritability, fever, or palpitations.

Evaluation. If the plan has been effective, complications caused by surgery will not occur or will be recognized and reported early. Pain will be prevented or controlled, and the patient will demonstrate understanding of dietary modifications and postoperative self-care.

COMPLICATIONS

Thyrotoxic Crisis. Thyrotoxic crisis may result from manipulation of the thyroid gland during surgery, with the subsequent release of large amounts of thyroid hormone. This is a rare complication because the use of antithyroid drugs before surgery has become routine. For more information on thyrotoxic crisis, see the section on hyperthyroidism earlier in this chapter.

Tetany. Tetany is caused by low calcium levels and is characterized by tingling in the fingers and perioral area (around the mouth), muscle spasms, twitching, and cardiac dysrhythmias. Muscle spasms in the larynx can lead to respiratory obstruction. Watch carefully for symptoms of tetany and report them immediately if they occur, because if the problem is not recognized quickly, death can result.

Tetany can occur if the parathyroid glands are accidentally removed during thyroid surgery. Because of the proximity of the parathyroid glands to the thyroid, it is sometimes difficult for the surgeon to avoid them. In the absence of parathyroid hormone, serum calcium levels drop and tetany results.

Intravenous calcium gluconate is given to treat acute tetany. To provide temporary relief while medications are being prepared, have the patient breathe into a paper bag. This causes mild acidosis, which increases ionization of

calcium in the blood. A respiratory therapist can assist with this procedure.

▶ DISORDERS OF THE PARATHYROID GLANDS

Recall that the parathyroid glands secrete parathyroid hormone (PTH) in response to low serum calcium levels. PTH raises serum calcium levels by promoting calcium movement from bones to blood and by increasing absorption of dietary calcium. Decreased PTH activity is called hypoparathyroidism. Increased PTH activity is called hyperparathyroidism.

Hypoparathyroidism

PATHOPHYSIOLOGY. A decrease in PTH causes a decrease in bone resorption of calcium. This means that calcium stays in bones instead of being moved into the blood. The result is a decreased serum calcium level, called hypocalcemia. As calcium levels fall, phosphate levels rise.

ETIOLOGY. The most common causes of hypoparathyroidism are heredity and the accidental removal of the parathyroid glands during thyroidectomy. Because of the proximity of the glands to the thyroid, it is sometimes difficult to avoid removing them. Hypoparathyroidism also occurs following purposeful removal of the parathyroid glands for hyperparathyroidism. Another cause is hypomagnesemia, which impairs secretion of PTH. Hypomagnesemia can occur with chronic alcoholism or certain nutrition problems.

SIGNS AND SYMPTOMS. Calcium plays an important role in nerve cell stability. Hypocalcemia causes neuromuscular irritability. In acute cases, tetany may occur (see previous section on tetany), with numbness and tingling of the fingers and perioral area, muscle spasms, and twitching. (See Table 37–5.) Positive Chvostek’s and Trousseau’s signs are early indications of tetany. (See Figs. 5–4 and 5–5 in Chapter 5.) To check Chvostek’s sign, tap on the patient’s facial nerve just in front of the ear. Spasm of the face is a positive result, indicating hypocalcemia. To elicit Trousseau’s sign, place a sphygmomanometer on the patient’s arm and pump it to above the patient’s systolic pressure. Spasm of the thumb and fingers occurs within 3 minutes if the patient has hypocalcemia.

LEARNING TIPS

To remember which test is which, remember *CHvostek’s sign is done near the CHEek*.

In chronic hypoparathyroidism, the patient is lethargic and experiences muscle spasms. Calcifications may occur in the eyes and brain, leading to psychosis. Bone changes are evident on x-ray examination. Convulsions may occur. Death can result from laryngospasm if treatment is not provided.

DIAGNOSTIC TESTS. Chvostek’s and Trousseau’s signs are present. Laboratory studies show decreased serum calcium and PTH levels and increased serum phosphate. Magnesium levels may be low. Radiographs show bone changes.

MEDICAL TREATMENT. Acute cases of hypoparathyroidism are treated with intravenous calcium gluconate. Long-term treatment includes a high-calcium diet (Box 37–6), with oral calcium and vitamin D supplements. Thiazide diuretics may also be used because they reduce the amount of calcium excreted in the urine. Magnesium is given if hypomagnesemia is present.

NURSING PROCESS

Assessment. The patient at risk for hypoparathyroidism should be closely monitored for symptoms of tetany. If you suspect tetany, check for Chvostek’s and Trousseau’s signs. Monitor respirations closely for stridor, a sign of laryngospasm.

Nursing Diagnosis. A priority nursing diagnosis is risk for injury related to tetany. In chronic hypoparathyroidism, the patient should be assessed for knowledge deficit related to self-care of hypoparathyroidism.

Planning and Implementation. If the patient exhibits signs of tetany, you should recognize a potential emergency and notify the registered nurse and physician immediately. A tracheostomy set, endotracheal tube, and intravenous calcium are kept at the bedside for emergency use. Ensure that the patient with chronic hypoparathyroidism has knowledge of home medications and dietary recommendations. Consult the dietitian for diet instruction.

BOX 37-6 Dietary Sources of Calcium

Milk
Cheeses
Yogurt
Sardines
Oysters
Salmon
Cauliflower
Green leafy vegetables

TABLE 37-5 COMPARISON OF PARATHYROID DISORDERS

	Insufficient PTH	Excess PTH
Disorder	Hypoparathyroidism	Hyperparathyroidism
Signs and symptoms	Hypocalcemia, neuromuscular irritability, tetany	Hypercalcemia, fatigue, pathological fractures
Usual treatment	Calcium replacement; high-calcium, low-phosphorus diet	Calcitonin, parathyroidectomy
Priority nursing diagnoses	Risk for injury related to tetany	Risk for injury related to bone demineralization

Evaluation. Injury is prevented through early recognition and reporting of signs and symptoms of tetany. The patient should be able to describe correct treatment for this disease.

Hyperparathyroidism

PATHOPHYSIOLOGY. Overactivity of one or more of the parathyroid glands causes an increase in PTH, with a subsequent increase in the serum calcium level (hypercalcemia). This is achieved through movement of calcium out of the bones and into the blood, absorption in the small intestine, and reabsorption by the kidneys. PTH also promotes phosphate excretion by the kidneys.

ETIOLOGY. Hyperparathyroidism is usually the result of hyperplasia or a benign tumor of the parathyroid glands, or it may be hereditary. Some cancers can also make a substance that mimics PTH and causes hypercalcemia. Secondary hyperparathyroidism occurs when the parathyroids secrete excessive PTH in response to low serum calcium levels. Serum calcium may be reduced in kidney disease because of the kidneys' failure to activate vitamin D, which is necessary for absorption of calcium in the small intestine.

SIGNS AND SYMPTOMS. Signs and symptoms of hyperparathyroidism are caused primarily by the increase in serum calcium level, although many patients are asymptomatic. Symptoms include fatigue, depression, confusion, increased urination, anorexia, nausea, vomiting, kidney stones, and cardiac dysrhythmias. The increased serum calcium level also causes gastrin secretion, resulting in abdominal pain and peptic ulcers. Because calcium is being removed from bones, joint pain and pathological fractures may occur. With severe hypercalcemia, the result may be coma and cardiac arrest.

DIAGNOSTIC TESTS. Laboratory studies include serum calcium, phosphate, and PTH levels. Radiographs may show decreased bone density.

MEDICAL TREATMENT. The patient should be monitored for bone changes and decline in renal function. Hydration with intravenous normal saline lowers the calcium level by dilution. Furosemide is given to increase renal excretion of calcium. Pamidronate (Aredia) or calcitonin may be given to prevent calcium release from bones. Mithramycin may be used to lower serum calcium levels, although its toxicity limits use to two or three doses. If hypercalcemia is severe or if the patient is at risk for bone or kidney complications, surgery to remove the diseased parathyroid glands is performed. If possible, some parathyroid tissue is left intact to continue to secrete PTH.

NURSING PROCESS

Assessment. Assess the patient for symptoms related to hypercalcemia, including muscle weakness, lethargy, bone pain, anorexia, nausea, vomiting, behavioral changes, and renal insufficiency. Monitor serum calcium levels as ordered.

Nursing Diagnosis. Nursing diagnoses depend on assessment findings. Risk for injury (fracture) related to bone

demineralization, imbalanced nutrition related to nausea and vomiting, activity intolerance related to fatigue, and disturbed thought processes related to hypercalcemia are some possible diagnoses.

Planning and Implementation. The patient should be protected from injury. Treat nausea so nutritional status can be maintained while the underlying problem is being treated. Allow for adequate rest periods. Report changes in mental status immediately. If surgery is planned, preoperative and postoperative care is similar to that of the patient undergoing thyroid surgery.

Evaluation. If the plan is effective, symptoms of hypercalcemia will be recognized and reported quickly, nausea and vomiting will be controlled, and complications and injury will be prevented.

► DISORDERS OF THE ADRENAL GLANDS

Adrenal disorders may involve the adrenal medulla or the adrenal cortex. Hypersecretion of epinephrine from the adrenal medulla is associated with a rare tumor called a **pheochromocytoma**. Hyposecretion of epinephrine is rare and generally causes no symptoms. Hypersecretion of cortisol from the adrenal cortex results in Cushing's syndrome. Hypofunction of the adrenal cortex results in Addison's disease.

Pheochromocytoma

PATHOPHYSIOLOGY. A pheochromocytoma is an uncommon tumor that arises from the chromaffin cells of the adrenal medulla. Occasionally a pheochromocytoma occurs outside the adrenal gland. The tumor autonomously secretes catecholamines (norepinephrine and sometimes epinephrine) in excessive amounts. Ninety percent of pheochromocytomas are benign.

ETIOLOGY. The cause of pheochromocytoma is unknown. About 5 percent of cases are hereditary.

SIGNS AND SYMPTOMS. Because norepinephrine is the fight-or-flight hormone, patients with a pheochromocytoma have exaggerated fight-or-flight symptoms. These might be fairly constant, or occur in "attacks." Manifestations include hypertension, tachycardia (with heart rate greater than 100), palpitations, diaphoresis, feeling of apprehension, elevated blood glucose, and severe pounding headache. Nausea and vomiting are occasionally present. Blood glucose may increase because catecholamines inhibit insulin release from the pancreas. The most prominent characteristic, however, is intermittent unstable hypertension. Diastolic pressure may be greater than 115 mm Hg. If hypertension is uncontrolled, the patient is at risk for stroke, vision changes, and organ damage. It is estimated that about 0.1 percent of cases of hypertension are caused by a pheochromocytoma.

pheochromocytoma: pheo—dark + chromo—color + cyt—cell + oma—tumor

DIAGNOSTIC TESTS. Patients with a suspected pheochromocytoma have a 24-hour urine test for metanephrines and vanillylmandelic acid (VMA). These are end products of catecholamine metabolism. The patient should avoid caffeine and medications for 2 days before and during the test. Check institution policy for other dietary restrictions. If results are elevated, a CT scan or MRI is done to locate the tumor.

MEDICAL TREATMENT. Treatment for pheochromocytoma is surgical removal of one or both adrenal glands. However, the patient must be stabilized before surgery. Alpha-blocking medications such as phentolamine (Regitine) or phenoxybenzamine (Dibenzylin) dilate blood vessels to control acute hypertension. Beta-blocking medication may be added to block beta-adrenergic receptors in the heart and lungs, reducing other fight-or-flight symptoms.

NURSING CARE. Patients with pheochromocytoma are at risk for very high blood pressure and related complications. Monitor vital signs closely and report increases in blood pressure or pulse to the registered nurse or physician.

Because of the unstable hypertension and fight-or-flight state, patients are often quite anxious. Stress may precipitate a hypertensive episode. Approach the patient calmly and maintain a quiet environment. Teach the patient how the medications will reduce symptoms, and the importance of avoiding foods and beverages containing caffeine.

Adrenocortical Insufficiency

Adrenocortical insufficiency (AI) is the insufficient production of the hormones of the adrenal cortex. Primary AI is called Addison's disease.

PATHOPHYSIOLOGY. Adrenal insufficiency is associated with reduced levels of cortisol, aldosterone, or both hormones. A deficiency in androgens may exist but usually does not cause symptoms. In primary disease, ACTH levels may be elevated in an attempt to stimulate the adrenal cortex to synthesize more hormone. In secondary disease, deficient ACTH fails to stimulate adrenal steroid synthesis. In most cases the adrenal glands are atrophied, small, and misshapen and are unable to produce adequate amounts of hormone.

ETIOLOGY. Addison's disease is thought to be autoimmune; that is, the gland destroys itself in response to conditions such as tuberculosis, fungal infection, infection related to acquired immunodeficiency syndrome (AIDS), or metastatic cancer. It may also be associated with other autoimmune diseases, such as Hashimoto's thyroiditis. Adrenalectomy also results in adrenal insufficiency.

Secondary AI may be caused by dysfunction of the pituitary or hypothalamus. In addition, prolonged use of corticosteroid drugs may depress ACTH and corticotropin-releasing hormone production, which in turn reduces steroid hormone production. A patient receiving long-term corticosteroid therapy is particularly at risk for AI if the drugs are abruptly discontinued. Because the pituitary has been suppressed for a prolonged period, it may take up to a

year before ACTH is produced normally again. Therefore corticosteroid therapy should be slowly tapered, never abruptly discontinued.

SIGNS AND SYMPTOMS. The most significant sign of Addison's disease is hypotension. This is related to the lack of aldosterone. Remember that aldosterone causes sodium and water retention in the kidney and potassium loss. If aldosterone is deficient, sodium and water are lost and hypotension and tachycardia result. Low cortisol levels cause hypoglycemia, weakness, fatigue, confusion, and psychosis. In primary AI, increased ACTH may produce hyperpigmentation of the skin, causing the patient to have a tanned or bronze appearance. Anorexia, nausea, and vomiting may also occur, possibly as the result of electrolyte imbalances.

COMPLICATIONS. If a patient is exposed to stress, such as infection, trauma, or psychological pressure, the body may be unable to respond normally with secretion of cortisol and an adrenal crisis can occur. Loss of large amounts of sodium and water and the resulting fluid volume deficit cause profound hypotension, dehydration, and tachycardia. Potassium retention can cause cardiac dysrhythmias. Hypoglycemia may be severe. Coma and death result if treatment is not initiated. Treatment of adrenal crisis involves rapidly restoring fluid volume and cortisol levels. Intravenous fluids, glucocorticoids, and mineralocorticoids are administered.

DIAGNOSTIC TESTS. Serum and urine steroids are measured. These include cortisol, aldosterone, and 17-ketosteroids. Blood glucose is low. Blood urea nitrogen (BUN) and hematocrit levels may appear to be elevated because of dehydration. An ACTH stimulation test may help determine whether the adrenal glands are functioning. Serum sodium and potassium levels are monitored.

MEDICAL TREATMENT. Treatment consists of replacement of glucocorticoids (hydrocortisone) and mineralocorticoids (fludrocortisone). Patients will need hormone replacement therapy for the rest of their lives. Hormones are given in divided doses, with two-thirds of the daily dose given in the morning and one-third in the evening to mimic the body's own diurnal rhythm. Remember that steroid hormones are our natural stress hormones and so are naturally elevated during times of stress. Therefore, during times of stress or illness, doses need to be increased to two to three times normal. The patient may also be placed on a high-sodium diet.

NURSING PROCESS

Assessment. The patient with Addison's disease should be assessed for understanding of and compliance with the treatment regimen. Daily weights or intake and output measurement help monitor fluid volume. Monitor serum glucose levels and symptoms of hyperkalemia and hyponatremia. Report changes in mental status. If the patient is in crisis, monitor vital signs closely and report any signs of fluid volume deficit such as orthostatic hypotension or poor skin turgor to the physician immediately.

Nursing Diagnosis. Priority diagnoses include risk for deficient fluid volume and deficient knowledge related to lack of exposure to information about self-care of Addison's disease.

Planning and Implementation. Nursing actions for the patient with adrenal insufficiency primarily involve assessment and education. Monitor fluid balance carefully, and notify the physician if symptoms of fluid volume deficit occur.

Patient Education. Teach the patient the importance of hormone replacement. Explain the need to increase medication dosage during times of stress or illness according to the physician's instructions. Help the patient identify the causes and symptoms of stress. Medical alert identification is recommended. If ordered by the physician, teach the patient and significant other how to use an emergency intramuscular hydrocortisone injection kit.

Evaluation. The patient and family should be able to describe proper self-care of Addison's disease. If the plan is successful, complications will be prevented or recognized and reported promptly.

Cushing's Syndrome

Cushing's *disease* is characterized by excess cortisol secretion resulting from secretion of too much adrenocorticotropic hormone (ACTH) by the pituitary. Cushing's *syndrome* refers to symptoms of cortisol excess caused by other factors. See Table 37-6 for a comparison of adrenal insufficiency and Cushing's syndrome.

PATHOPHYSIOLOGY. Recall that cortisol, aldosterone, and androgens are the three steroid hormones secreted by the adrenal cortex. Cortisol is essential for survival and is normally secreted in a diurnal rhythm, with levels increasing in the early morning. Secretion is increased during times of stress. In Cushing's syndrome, cortisol is hypersecreted without regard to stress or time of day. When levels of cortisol are very high, effects related to excess aldosterone and androgens are also seen.

TABLE 37-6 COMPARISON OF ADRENAL CORTEX HORMONE IMBALANCES

	Hypofunction	Hyperfunction
<i>Disorder</i>	Adrenocortical insufficiency, Addison's disease	Cushing's syndrome
<i>Signs and symptoms</i>	Sodium and water loss, hypotension, hypoglycemia, fatigue	Weight gain, sodium and water retention, hyperglycemia, buffalo hump, moon face
<i>Usual treatment</i>	Glucocorticoid and mineralocorticoid replacement	Alter steroid therapy schedule; surgery if tumor
<i>Priority nursing diagnoses</i>	Risk for fluid volume deficit	Risks for fluid volume excess, glucose intolerance, infection

LEARNING TIPS

Remember from Chapter 36, an easy way to remember the hormones of the adrenal cortex is to think *salt, sugar, and sex*. Aldosterone promotes salt retention, cortisol affects sugar (carbohydrate) metabolism, and androgens are sex hormones.

ETIOLOGY. Cushing's disease is caused by the hypersecretion of ACTH by the pituitary. This is most often the result of a pituitary adenoma. Sometimes ACTH is produced by a tumor in the lungs or other organs. The high levels of ACTH cause adrenal hyperplasia, which in turn increases production and release of cortisol.

The most common cause of Cushing's syndrome is prolonged use of glucocorticoid medication (e.g., prednisone) for chronic inflammatory disorders such as rheumatoid arthritis, chronic obstructive pulmonary disease, and Crohn's disease.

SIGNS AND SYMPTOMS. Most signs and symptoms of Cushing's syndrome are related to excess cortisol levels. Weight gain, truncal obesity with thin arms and legs, buffalo hump, and moon face result from deposits of adipose tissue at these sites (Fig. 37-6). Cortisol also causes insulin resistance and stimulates gluconeogenesis, which result in glucose intolerance. Some patients develop secondary diabetes mellitus. (See Chapter 38.) Muscle wasting and thin skin with purple striae occur as a result of cortisol's catabolic effect on tissues. Catabolic effects on bone lead to osteoporosis, pathological fractures, and back pain. Because cortisol has anti-inflammatory and immunosuppressive actions, the patient is at risk for infection. Hyperpigmentation of the skin may occur. Approximately 50 percent of patients experience mental status changes, from irritability to psychosis (sometimes referred to as steroid psychosis). Sodium and water retention are related to the mineralocorticoid effect. As sodium is retained, potassium is lost in the urine, causing hypokalemia. (See Chapter 5 to review these electrolyte imbalances.) Androgen effects include acne, growth of facial hair, and amenorrhea in women.

DIAGNOSTIC TESTS. Suspicion of Cushing's syndrome may initially be based on a cushingoid appearance. Plasma and urine cortisol and plasma ACTH are measured. A dexamethasone suppression test may be done.

MEDICAL TREATMENT. If a pituitary or other ACTH-secreting tumor is present, surgical removal or radiation therapy to the pituitary may be employed. If the adrenals are the primary cause of the problem, radiation or removal of the adrenal gland or glands may be performed. Drugs such as ketoconazole block production of adrenal steroids.

If the cause of Cushing's syndrome is administration of steroid medication, an every-other-day schedule or once-a-day dosing in the morning may reduce side effects. Usually steroids are prescribed as a last resort for chronic disorders that are unresponsive to other treatment. The patient and physician must weigh the risks and benefits of continuing

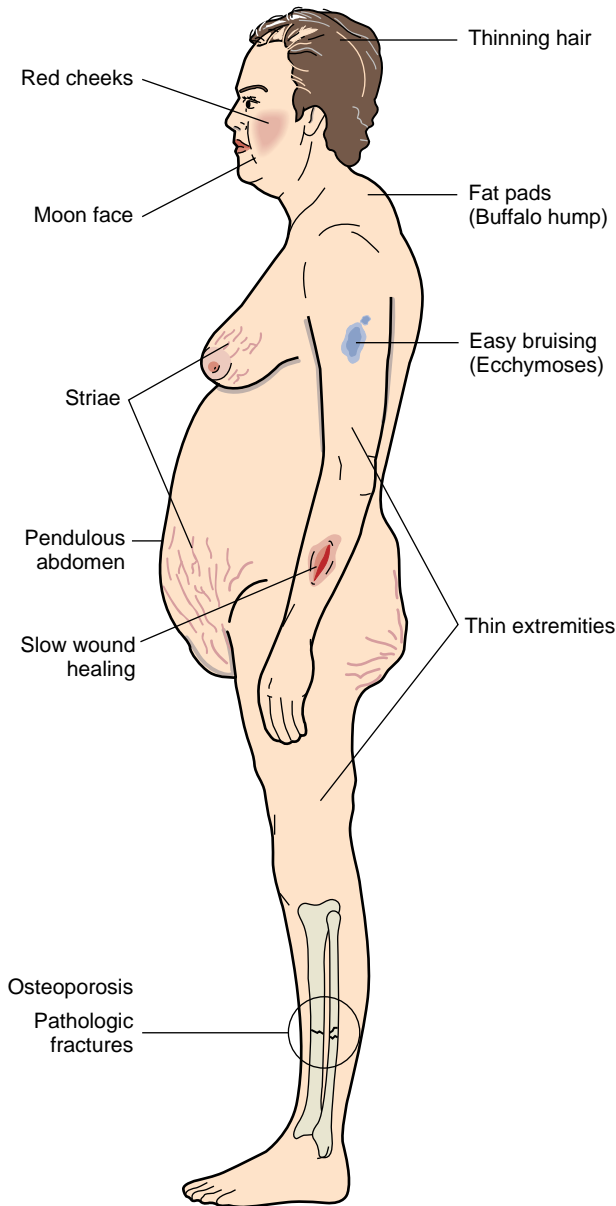

Figure 37-6 Physical manifestations seen in Cushing's syndrome.

the medication. The physician may order a high-potassium, low-sodium, high-protein diet. Potassium supplements may be ordered. If the patient has high blood sugar, appropriate nutrition therapy for diabetes should be instituted. (See Chapter 38.)

NURSING PROCESS

Assessment. When caring for the patient with Cushing's disease or syndrome, assess the patient's drug history. Monitor vital signs and complications related to fluid and sodium excess. Auscultate the lungs for crackles, and assess extremities for edema. Assess skin integrity, and monitor capillary glucose as ordered by the physician. Watch for signs of infection.

Nursing Diagnosis. Possible diagnoses include excess fluid volume related to sodium and water retention, risk for impaired skin integrity, risk for infection, and risk for injury re-

lated to impaired glucose tolerance. Disturbed body image is common as a result of the cushingoid appearance.

Planning and Implementation. Report signs of fluid overload to the physician. Take care to protect the skin. Protect the patient from infection and instruct to avoid others who are ill. You and other health care workers should use good handwashing technique. If glucose intolerance occurs, be prepared to administer insulin, because oral hypoglycemics are not usually effective. Patients who are to receive long-term insulin therapy should be referred to diabetes education classes. Consult a dietitian for diet counseling. If surgery is planned, the patient is prepared for an adrenalectomy or hypophysectomy, depending on the cause of the disorder.

Evaluation. If care has been effective, complications of fluid overload will be recognized and treated early. The patient will have intact skin and be free from signs of infection. The patient will demonstrate skill in self-care of diabetes if indicated.

NURSING CARE OF THE PATIENT UNDERGOING ADRENALECTOMY

Preoperative Care. Monitor the patient for electrolyte imbalance and hyperglycemia. Abnormalities must be corrected before surgery. To prevent adrenal crisis, glucocorticoids are administered, because removal of the adrenals causes a sudden drop in adrenal hormones.

Postoperative Care. Following surgery, the patient receives routine postoperative care. In addition, the patient is closely monitored for changes in fluid and electrolyte balance and adrenal crisis. Patients who undergo bilateral adrenalectomy must take replacement glucocorticoid and mineralocorticoid hormones for the remainder of their life. If only one adrenal gland is removed, the remaining gland should eventually produce enough hormone to enable the patient to discontinue replacement hormone.

See Table 37-7 for a summary of endocrine disorders.

CRITICAL THINKING

Mrs. Tercini
Mrs. Tercini is a 62-year-old woman admitted to your unit in Addisonian crisis. She is lethargic, with a blood pressure of 86/58, pulse 112, and respirations 18. While interviewing her daughter, you learn that Mrs. Tercini has a history of Cushing's syndrome treated with bilateral adrenalectomy 25 years ago. She has been taking 150 mcg fludrocortisone (Florinef) and 200 mg hydrocortisone daily ever since. Three days ago she developed the flu.

1. Why is an adrenalectomy done to treat Cushing's syndrome?
2. What is the most effective schedule for Mrs. Tercini's medication?
3. What precipitated this Addisonian crisis?
4. Why is Mrs. Tercini's blood pressure low?
5. How could this crisis have been prevented?
6. Fludrocortisone is available as 0.1 mg tablets. How many should you administer?

Answers at end of chapter.

TABLE 37-7 SUMMARY OF ENDOCRINE PROBLEMS

Hormone	Hypofunction	Hyperfunction
Antidiuretic hormone	Diabetes insipidus—water loss	SIADH—water retention
Growth hormone	Dwarfism—short stature	Acromegaly, gigantism—bone and tissue overgrowth
Thyroid hormone	Hypothyroidism—slow metabolism	Hyperthyroidism—increased metabolism
Epinephrine	Rare	Pheochromocytoma—hypertension
Parathyroid hormone	Hypoparathyroidism—low serum calcium, osteoporosis, tetany	Hyperparathyroidism—high calcium, weakness
Cortisol	Addison's disease—sodium and water loss	Cushing's syndrome—sodium and water retention, hyperglycemia; see text

REVIEW QUESTIONS

- When assessing a patient with diabetes insipidus, which of the following findings is expected?
 - Edema
 - Polyuria
 - Heat intolerance
 - Diarrhea
- Which of the following expected outcomes is most appropriate for the patient with SIADH?
 - Patient will verbalize relief from excessive thirst.
 - Patient will verbalize understanding of importance of increasing fluid intake.
 - Patient's daily weights will be stable.
 - Patient will state pain is relieved.
- Which action by the nurse is most important following hypophysectomy?
 - Performing a routine neurological assessment
 - Encouraging the patient to cough and deep breathe
 - Monitoring for tracheal edema
 - Maintaining strict intake and output
- Which of the following statements by the patient with hypothyroidism indicates to the nurse that the plan of care has been effective?
 - "I feel so much better now that my energy is returning."
 - "I'm really glad the diarrhea has stopped."
 - "I'm so glad I won't have to take medication for very long."
 - "My fingers aren't tingling any more."
- Which of the following nursing assessments is most important in the patient with hyperthyroidism and risk for thyrotoxic crisis?
 - Intake and output q2h
 - Patient's understanding of dietary restrictions
 - Bowel sounds each shift
 - Frequent vital signs
- Which symptom in the patient with a goiter should the nurse report to the physician immediately?
 - Weight gain of 2 pounds
 - Stridor
 - Excessive thirst
 - Nausea
- Following a total thyroidectomy, which of the following instructions from the physician will the nurse reinforce?
 - "You will be taking thyroid replacement hormone for the rest of your life."
 - "You must weigh yourself daily and report any gain or loss of more than 1 pound."
 - "You will need to return to the physician's office for a weekly blood pressure check."
 - "You will need to restrict your sodium and potassium intake."
- Which of the following nursing interventions will be most helpful for the patient with acute hypertension related to pheochromocytoma?
 - Offer the patient pain medication every 4 hours.
 - Provide a calm, quiet environment.
 - Assist the patient to elevate the legs.
 - Encourage increased fluid intake.

Answers to CRITICAL THINKING

Mrs. Jackson

1. Her weight gain is most likely caused by fluid retention, which can be a result of heart failure or SIADH, among other things.
2. Assess edema, lung sounds, and vital signs. Check intake and output during the past 2 days. Monitor mental status and level of consciousness. Check recent lab work to see if her serum sodium is low. You also check a book on the unit and recall that anesthetics and morphine are possible causes of SIADH. Morphine can also cause confusion.
3. Notify the registered nurse of your findings and your suspicions. Be prepared to place Mrs. Jackson on a fluid restriction. Reassure her son that the physician is being notified of the changes he noted.

Adoption

The children's growth hormone secretion was probably suppressed because of psychosocial stress. Once they felt secure in a loving environment, growth hormone levels returned to normal.

Mae

1. Mae's TSH is elevated because her pituitary gland is working overtime to try to stimulate the underactive thyroid gland.
2. Mae's metabolism has been slow, so she has been burning fewer calories. When she starts on thyroid replacement hormone, her metabolic rate will return to normal and she will need more calo-

ries. Intake of calories should be balanced with the possible need for weight loss.

3. If Mae receives too much thyroid hormone, she will have symptoms of hyperthyroidism, including an increased pulse rate. She should know how to check her pulse and to call her physician if it is elevated.

Mrs. Tercini

1. Cushing's syndrome is caused by too much cortisol. The adrenal cortex is responsible for secreting cortisol.
2. Mrs. Tercini should take two-thirds of her daily dose of hydrocortisone and fludrocortisone in the morning and one-third in the evening. This most closely mimics the body's natural corticosteroid secretion.
3. The flu probably triggered this crisis. Illness is a stressor, and normally the body secretes steroids during stress. Because Mrs. Tercini's body is unable to produce steroids, she experiences symptoms of hypoadrenalism during stressful times.
4. Mrs. Tercini's blood pressure is low because she has insufficient circulating mineralocorticoids. Without aldosterone, sodium and water are lost and blood pressure drops.
5. Mrs. Tercini should have taken extra medication when she became ill.
6. You should give her 1.5 tablets; remember that 1 mg = 1000 mcg.

38

NURSING CARE OF PATIENTS WITH DISORDERS OF THE ENDOCRINE PANCREAS

Paula D. Hopper

KEY TERMS

diabetes mellitus (DYE-ah-BEE-tis mel-LYE-tus)
 endogenous (en-DAH-jen-us)
 gastroparesis (GAS-troh-puh-REE-sus)
 glycosuria (GLY-kos-YOO-ree-ah)
 hyperglycemia (HIGH-per-gligh-SEE-mee-ah)
 hypoglycemia (HIGH-poh-gligh-SEE-mee-ah)

 retinopathy (RET-i-NAH-puh-thee)

QUESTIONS TO GUIDE YOUR READING

1. What is the pathophysiology of type 1 and type 2 diabetes mellitus?
2. What are the causes and risk factors for type 1 and type 2 diabetes mellitus?
3. What are the signs and symptoms of diabetes mellitus?
4. What are the causes, signs and symptoms, and treatment of high and low blood glucose levels?
5. Why are persons with diabetes prone to complications such as heart disease, blindness, and kidney failure? How can you help your patients prevent these complications?
6. What diagnostic tests are used to diagnose and monitor diabetes mellitus and its complications?
7. What types of diets are available to help patients with diabetes control their blood glucose levels?
8. How does exercise affect diabetes and blood glucose levels?
9. How do the different insulins and oral hypoglycemic agents lower blood glucose levels? What should you know when administering these medications?
10. How would you apply the nursing process to the patient with diabetes mellitus?
11. Why can surgery be especially risky for a patient with diabetes? What measures can be taken to increase the safety of the patient undergoing surgery?
12. What is reactive hypoglycemia? How is it diagnosed and treated?

▶ DIABETES MELLITUS

Diabetes mellitus (be careful not to confuse it with diabetes insipidus) is a group of metabolic diseases in which defects in insulin secretion or action result in high blood sugar (**hyperglycemia**). Approximately 16 million people in the United States have diabetes mellitus, and 5 million of those

diabetes: diabetes—passing through
hyperglycemia: hyper—excessive + glyc—glucose + emia—in the blood

don't know it. The direct and indirect cost (such as lost work time) of diabetes in the United States is about \$98 billion per year.¹ The incidence of diabetes mellitus varies by race and ethnicity. In the United States, Native-Americans have the highest rate of diabetes of all ethnic and racial groups. African-Americans, people of Mexican heritage, Puerto Ricans, and Japanese-Americans have a higher rate of diabetes than do white ethnic groups.

Diabetes is a serious disease that can cause complications such as blindness, kidney failure, heart attacks, and strokes.

It is a leading cause of lower limb amputations in the United States. With good education and self-care, patients with diabetes can prevent or delay these complications and lead full and productive lives. A major role of the nurse is helping the patient learn to care for himself or herself effectively.

Pathophysiology

Body tissues, and the cells that compose them, use glucose for energy. Glucose is a simple sugar provided by the foods

we eat. When carbohydrates are eaten they are broken down into glucose, which is then absorbed into the bloodstream. Carbohydrates provide most of the glucose used by the body; proteins and fats provide smaller amounts of glucose. Glucose is able to enter the cells only with the help of insulin, a hormone produced by the beta cells in the islets of Langerhans of the pancreas (Fig. 38–1). When insulin comes in contact with the cell membrane, it combines with a receptor that allows activation of special glucose transporters in the membrane.

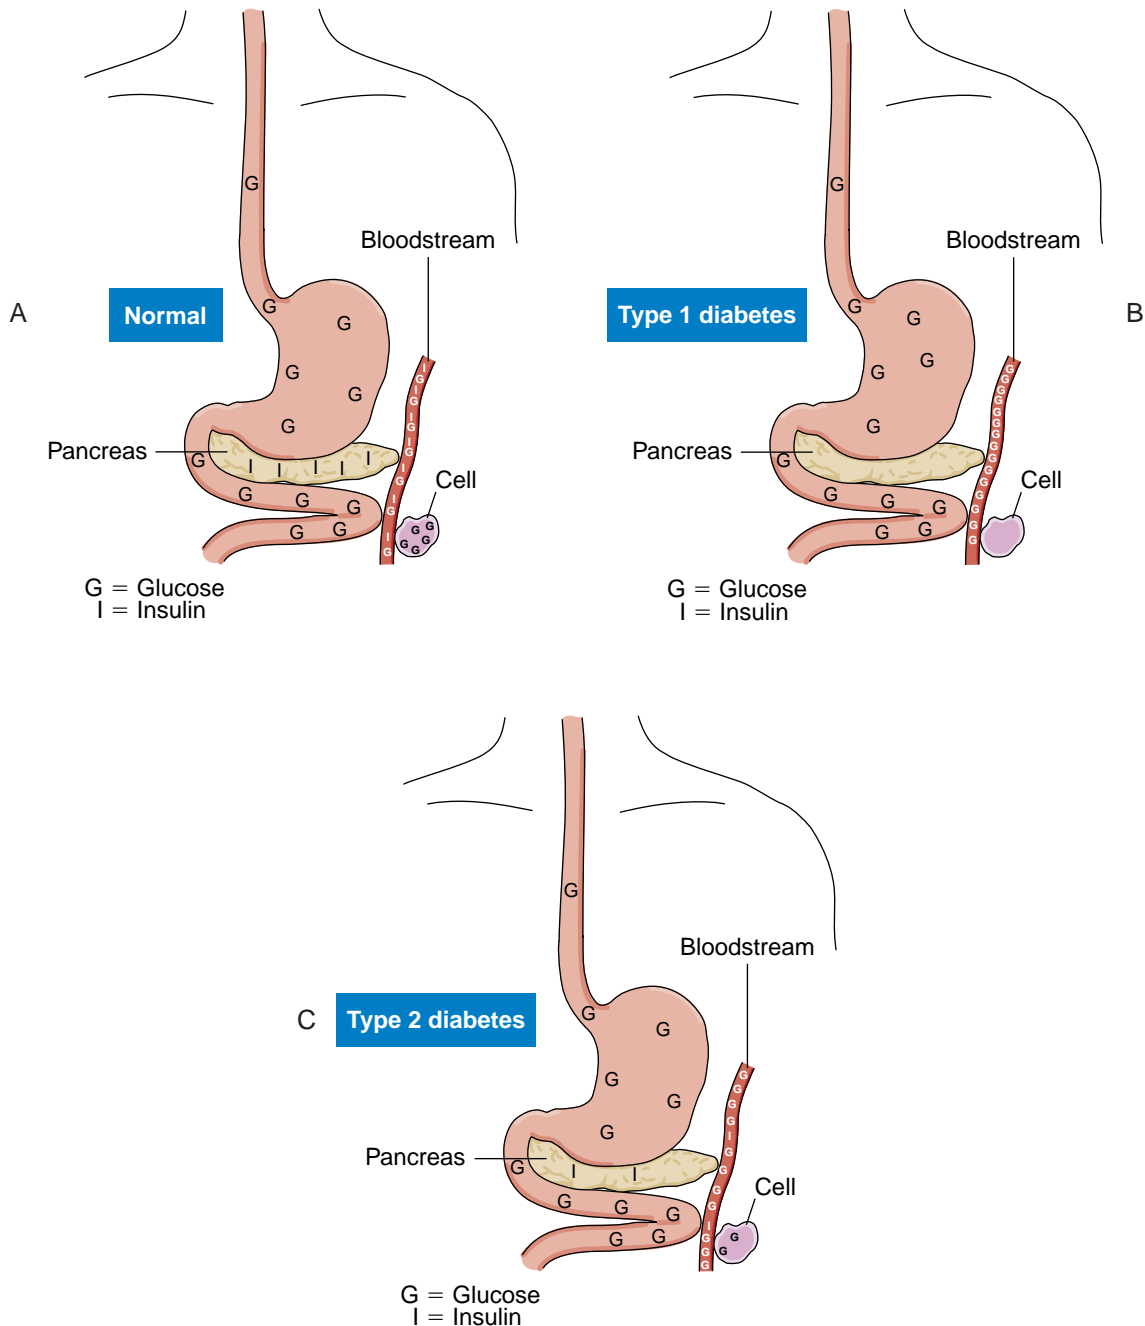

Figure 38-1 Maintenance of blood glucose levels. (A) Normal physiology: Foods (especially carbohydrates) are broken down into glucose, which is absorbed into the bloodstream for transport to the cells. Insulin, produced by the beta cells of the islets of Langerhans in the pancreas, is needed to “open the door” to the cells, allowing the glucose to enter. (B) In type 1 diabetes mellitus the pancreas does not produce insulin. Because glucose is unable to enter the cells, it builds up in the bloodstream, causing hyperglycemia. (C) In type 2 diabetes mellitus, insulin production is reduced. Less glucose enters the cell, and hyperglycemia results. In some cases, enough insulin is produced but cells are resistant to it.

By helping glucose enter the body's cells, insulin lowers the glucose level in the blood. Insulin also helps the body to store excess glucose in the liver in the form of glycogen. Another hormone, glucagon, is produced by the alpha cells in the islets of Langerhans. Glucagon raises the blood glucose when needed by releasing the stored glucose from the liver and muscles. Insulin and glucagon work together to keep the blood glucose at a constant level.

Diabetes results from faulty production of insulin by the beta cells in the pancreas or from inability of the body's cells to use insulin. When glucose is unable to enter body cells, it stays in the bloodstream; hyperglycemia results, and the cells are denied their energy source.

Types and Causes

Type 1 Diabetes Mellitus

Type 1 diabetes (formerly called juvenile diabetes mellitus, insulin-dependent diabetes mellitus, or IDDM) is caused by destruction of the beta cells of the pancreas. When the beta cells are destroyed, the pancreas produces no insulin at all. Insulin must be injected for the body to use food for energy. See Patient Perspectives Box 38-1 for Dave's story about having type 1 diabetes.

It is believed that the pancreas may attack itself following a viral infection (this is called an autoimmune re-

sponse). Almost 85 percent of patients newly diagnosed with type 1 diabetes have islet cell antibodies in their blood. Other times, the cause of type 1 diabetes is unknown, or idiopathic. From 10 to 30 percent of type 1 diabetes cases are hereditary. The patient with type 1 diabetes is usually young and thin and is prone to develop **ketoacidosis** when blood glucose is elevated. (See Table 38-1 for a comparison of

ketoacidosis: keto—ketones + acid—acidic + osis—condition

TABLE 38-1 COMPARISON OF TYPE 1 AND TYPE 2 DIABETES

	Type 1 (IDDM)	Type 2 (NIDDM)
Onset	Rapid	Slow
Age at onset	Usually < 40	Usually > 40
Risk factors	Virus, autoimmune response, heredity	Heredity, obesity
Body type	Lean	Obese
High blood glucose complication	Ketoacidosis	Hyperosmolar Hyperglycemic Nonketotic syndrome
Treatment	Diet, exercise; must have insulin to survive	Diet, exercise; may need oral hypoglycemics or insulin to control blood glucose level

BOX 38-1 Patient Perspective

Dave

I was diagnosed with type 1 diabetes mellitus at age 3. I remember being left in a children's ward of the hospital with the nuns (who were nurses) in their habits and looking into the parking lot as my parents got in the car and drove away. I remember the fear and horror of being left alone. Later, I remember my doctor teaching my mother and me about the diet and monitoring my urine for glucose and ketones. This was all we had in those days (the early 1960s). I was supposed to test my urine before meals and at bedtime, just like we monitor blood glucose today. Every time I saw my doctor he would review and change my treatment based on the results. Insulin then was extracted from pig and cow cadavers.

I remember my life being pretty normal except at holidays. When my brothers and sisters were getting Halloween candy and Christmas candy canes I felt odd and left out. My mom was really tough and observant and I had to be sneaky to get away with stealing a treat or two left momentarily unobserved by those around me. I was thrilled when sugarless candy became available around age 10 or so and I could have my own candies to hoard for myself.

Hypoglycemic reactions were always a trauma-filled event at our house. They came at unexpected times and my mom sometimes blamed herself. I can honestly say that my mom deserves more credit than I have ever given her for my good fortune with my diabetes. She did not have glucometers, glycohemoglobin tests, or even diabetes specialists and educators; she just had the desire of a mother who did everything she could to make sure I had and did everything right as far as she knew.

In my late teens I took everything my doctor and my mom had done for me and trashed them. I lived with reckless abandon: I did what I wanted, ate what I wanted, and didn't even think about the disease I lived with until I was about 30. I worked hard

those years in construction, and the physical activity probably delayed the complications that might otherwise have occurred.

At age 35 I began to experience the inevitable effects of long-term hyperglycemia. I developed diabetic retinopathy, the leading cause of adult-onset blindness in the United States. My vision was restored in my left eye with laser surgery. It would take another surgery (vitrectomy) to bring the vision in my right eye back to the 20/60 it is now from the 20/2000 it was before the surgery.

About that time I was referred to an endocrinologist who specialized in diabetes, and my treatment took a remarkable turn for the better. The endocrinologist began to aggressively change my medications, insulin regimen, exercise program, and diagnostic testing, all with the purpose of controlling blood glucose and preventing the onset and advancement of diabetes complications. This aggressive plan of action was taught to me by a registered nurse certified diabetes educator who worked with my doctor. I must also give enormous credit to the office staff nurses who were an integral part of the team, supporting me throughout the whole experience. The doctors and nurses made my education both understandable and pertinent. They basically put the ball in my court, and then it was up to me to take control of my own life. My wife was more than supportive throughout this time period too, and sacrificed much for the new array of medications and doctor's appointments that took a huge chunk out of our family finances.

I have mentioned briefly those involved in my life with diabetes. I take no credit for any of the results though; I believe it was God who made these choices available and miraculously reversed the effects of disease in my body. To the amazement of medical professionals, He continues to bless me with good health. It is because of all I have gone through with diabetes that I have recently completed my nursing degree and hope to become a diabetes educator myself.

type 1 and type 2 diabetes.) Diabetic ketoacidosis is discussed later in this chapter. Exciting research is currently being done on a new drug that may block the development of type 1 diabetes when administered early in the disease process.

Type 2 Diabetes Mellitus

In type 2 diabetes mellitus (formerly called adult-onset diabetes mellitus, non–insulin-dependent diabetes mellitus, or NIDDM), some insulin is still made by the pancreas, but in inadequate amounts. Sometimes the amount of insulin is normal or even high, but the tissues are resistant to it and hyperglycemia results.

Heredity is responsible for up to 90 percent of cases of type 2 diabetes. Obesity is also a major contributing factor. Many experts are concerned about the growing number of obese children in the United States because of their increased risk for diabetes, heart disease, and other obesity-related problems. Often the patient with a new diagnosis of type 2 diabetes is obese, relates a family history of diabetes, and has had a recent life stressor such as the death of a family member, illness, or loss of a job.

Gestational Diabetes

Gestational diabetes mellitus (GDM) may develop during pregnancy, especially in women with the risk factors for type 2 diabetes. The extra metabolic demands of pregnancy trigger the onset of diabetes. Blood glucose usually returns to normal after delivery, but the mother has an increased risk for type 2 diabetes in the future. If she is overweight, she should be counseled that weight loss and exercise will decrease her risk of later developing diabetes. Mothers with GDM require specialized care and should be referred to an expert in this area.

Prediabetes

Prediabetes (*impaired glucose tolerance* [IGT]) refers to blood glucose levels that are above normal but do not meet the criteria for diagnosing diabetes. An IGT diagnosis is made after an oral glucose tolerance test shows a glucose level between 140 and 200 mg/dL after 2 hours. A diagnosis of impaired fasting glucose (IFG) is made when the fasting glucose level is between 110 and 126 mg/dL.

SYNDROME X. A newer finding is the link between diabetes and a condition called metabolic syndrome, or syndrome X. This is a group of disorders commonly found together, including insulin resistance, glucose intolerance, low HDL cholesterol, high triglycerides, hypertension, abdominal obesity, a tendency to form clots, and high levels of c-reactive protein, a risk factor for heart attack. Any patient who fits this profile should be monitored closely for the onset of diabetes and should be encouraged to adopt a healthy lifestyle.

Other Causes of Diabetes

Secondary diabetes may develop as a result of another chronic illness such as pancreatitis or cystic fibrosis. Pro-

longed use of some drugs, such as steroids, phenytoin (Dilantin), thiazide diuretics, and thyroid hormone, may also impair insulin action and raise blood glucose. Less common causes include pancreatic trauma, certain genetic defects, and other endocrine disorders. One genetic defect is called maturity-onset diabetes of the young (MODY), which is an inherited impairment of insulin secretion that usually occurs before the age of 25.

Signs and Symptoms

Classic symptoms of diabetes mellitus include **polydipsia** (excessive thirst), **polyuria** (excessive urination), and **polyphagia** (excessive hunger). Because glucose is unable to enter the cells, the cells starve, causing hunger. The large amount of glucose in the blood causes an increase in serum concentration, or osmolality. The renal tubules are unable to reabsorb all the excess glucose that is filtered by the glomeruli, and **glycosuria** results. Large amounts of body water are required to excrete this glucose, causing polyuria, **nocturia**, and dehydration. The increased osmolality and dehydration cause polydipsia. High blood glucose may also cause fatigue, blurred vision, abdominal pain, and headaches. Ketones may build up in the blood and urine of patients with type 1 diabetes (ketoacidosis).

LEARNING TIPS

Remember the classic symptoms of diabetes by the 3 Ps: *polydipsia, polyuria, and polyphagia.*

Diagnostic Tests

FASTING BLOOD GLUCOSE. Diagnosis of diabetes mellitus is based on blood glucose levels measured by a laboratory. A normal blood glucose level ranges from 60 to 110 mg/dL, although different laboratories may have slightly different normal values. When the fasting blood glucose (drawn after at least 4 hours without eating) is above 126 mg/dL on two separate occasions, diabetes is diagnosed.

ORAL GLUCOSE TOLERANCE TEST. Another test to diagnose diabetes is the oral glucose tolerance test (OGTT). An OGTT measures blood glucose at intervals after the patient drinks a concentrated carbohydrate drink. Diabetes is diagnosed when the blood glucose level is 200 mg/dL or higher after 2 hours.

GLYCOHEMOGLOBIN. The glycohemoglobin test (also called glycosylated hemoglobin, or HbA_{1c}) is used to gather baseline data and to monitor progress of diabetes control. Glucose in the blood attaches to hemoglobin in the red

polydipsia: poly—many or much + dipsia—thirst

polyuria: poly—many or much + uria—urine

polyphagia: poly—many or much + phagia—to eat

glycosuria: glyc—glucose + uria—urine

nocturia: noc—by night + uria—urine

blood cells. Red blood cells live about 3 months in the body. When the glucose that is attached to the hemoglobin is measured, it reflects the average blood glucose level for the previous 3 months. Results should be approximately 4 to 7 percent, depending on the laboratory. This is a helpful measurement when blood glucose levels fluctuate and a single measurement would be misleading. It also assists in determining the degree of effectiveness of a patient's treatment plan. Newer methods allow this test to be done in a physician's office while the patient waits. Glycohemoglobin testing might be inaccurate in some people, such as those with anemia. These individuals may have a glycated serum protein test, which is a similar test that indicates glucose levels over a period of 1 to 2 weeks instead of 3 months.

ADDITIONAL TESTS. Because diabetes affects so many body systems, additional tests recommended to gather baseline data include a lipid profile, serum creatinine and urine microalbumin levels to monitor kidney function, urinalysis, and electrocardiogram.

CRITICAL THINKING

Mr. McMillan
Mr. McMillan is a 50-year-old patient brought into the emergency department with extreme fatigue and dehydration. After the physician sees him, you ask Mr. McMillan some additional questions. Based on the patient's answers, you request that the physician add a glucose level to the laboratory tests ordered. The result is 1400 mg/dL.

1. What questions would you ask Mr. McMillan if you suspected diabetes?
2. Why was Mr. McMillan fatigued?
3. Why was he dehydrated?

Answers at end of chapter.

Treatment

The only cure for diabetes is a pancreas transplant. However, diabetes can be controlled. Treatment begins with diet and exercise. Insulin is added in patients with type 1 diabetes and insulin or oral hypoglycemia medication as needed in those with type 2 diabetes. Blood glucose monitoring and education are also important to good diabetes control.

Type 2 diabetes can be prevented or delayed in some cases. In patients with a family history of diabetes, a healthy diet, exercise, and moderate weight loss are advised, along with regular blood glucose screening.

To monitor the effectiveness of treatment, patients should have regular health care follow up visits. See Figure 38–2 for American Diabetes Association recommendations for follow-up visits.

Goals of Treatment

The American Diabetes Association recommends that patients maintain a fasting plasma glucose level of less than 120 mg/dL and glycohemoglobin level of less than 7 percent

to prevent or delay complications. These goals may be adjusted in individual circumstances. For example, the patient who does not feel symptoms of **hypoglycemia** might have a higher goal of preventing undetected hypoglycemic episodes.

Medical Nutrition Therapy

The goal of medical nutrition therapy (MNT) is to achieve and maintain blood glucose and lipid levels as near to normal as possible to prevent long-term complications. For some, especially those with type 2 diabetes, weight loss and blood pressure control may be additional goals.

Because the patient with diabetes has a limited amount of insulin, either **endogenous** (from within the body) or injected, it is important to eat an amount of food that will not exceed the insulin's ability to carry it into the cells. The meal plan should include consistent amounts of carbohydrates, proteins, and fats each day (Nutrition Notes Box 38–2). Because carbohydrates contribute most to the blood glucose level, it is most important that carbohydrates are consistent from one day to the next. If a patient eats a small amount of carbohydrate one day and a large amount the next, the blood glucose fluctuates, leading to complications. It is possible to relax nutrition restrictions somewhat if the patient is willing to test blood glucose frequently at home and adjust treatment accordingly. This requires in-depth instruction by a diabetes educator.

In the past the commonly prescribed meal plan was the American Diabetes Association (ADA) diet, which was based on a basic plan with lists of amounts of foods that could be exchanged to vary the menu. The ADA no longer recommends a single meal plan, but rather advocates a complete assessment by a specially trained dietitian and individualized nutrition therapy recommendations and teaching.

A variety of meal plans are now available, as shown in Table 38–2. Because diabetes increases the risk of high serum cholesterol and triglycerides, all plans limit fat intake. Patients who use fat replacers (in foods such as fat-free baked goods or ice cream) should be aware that they still have food value and calories, so they cannot be considered “free” foods. Sodium intake is limited in individuals with hypertension. Most plans also encourage the use of complex carbohydrates such as grains, pastas, vegetables, and fruits. Simple sugars, which may cause the blood glucose to rise more rapidly, are used less but are not prohibited as they were in the past. Any meal plan should be chosen to fit the patient's lifestyle and food preferences. Preferences of patients based on their ethnic background should also be considered (Cultural Consideration Box 38–3).

The success of MNT is evaluated by monitoring glucose levels, HbA_{1c}, lipids, weight, blood pressure, and kidney function.

hypoglycemia: hypo—deficient + glyc—glucose + emia—in the blood

endogenous: endo—within + genous—to produce

The American Diabetes Association

suggests these goals for most people with diabetes. You may have different goals. You can record your goals and your results in the spaces provided below.

Every Diabetes Visit	ADA Goals	My Goals	My Results Date	Date
Review blood sugars before meals	80–120			
at bedtime	100–140			
Check blood pressure	below 130/80			
Review meal plan				
Review activity level				
Check weight				
Discuss questions or concerns				
At Least Every 6 Months				
Hemoglobin A _{1c}	below 7			
At Least Every Year

I Have Diabetes

I may be having a low blood sugar reaction to insulin or a diabetes pill.

If I cannot be awakened or cannot swallow, do not try to give me anything to drink. Call 911.

If I'm awake but acting strangely, give me some regular soft drink, juice, milk, hard candy, or some sugar. If I do not get better within 15 minutes, call 911 or get me to a hospital.

My name _____

Emergency contact _____

Diabetes care provider _____

Telephone _____

Diabetes medicines _____

Allergies _____

Your diabetes care team and you work together for good diabetes care. You decide what and how much to eat, when to take your medicine, when to check your blood sugar, and how to be active. Remember, you're the leader of your diabetes care team. Review the diabetes care list on the back of this card. Ask to see your "numbers."

Individualizing Medical Nutrition Therapy in Diabetes Mellitus

A certified diabetes educator can use many approaches in the nutritional management of diabetes. This permits a meal plan based on the patient's abilities and commitment. Several meal-planning approaches are described in Table 38-2. Overall goals and strategies differ for the two types of diabetes. In general, a patient with type 1 diabetes needs to prevent wide swings in blood glucose levels through careful timing of meals and snacks in relation to insulin therapy and activity. A patient with type 2 diabetes uses diet modifications to maintain near-normal glucose, blood pressure, and lipid levels and to lose weight as necessary.

Using ADA Exchange Lists

A food guide called the *ADA Exchange Lists*, published jointly by the American Dietetic Association and the American Diabetes Association, is used by some patients with diabetes and also by patients who are attempting to achieve a healthier body weight. This system is composed of six lists of foods plus a "free food" list. Foods in each list contain similar energy nutrients (carbohydrate, protein, and fat). For example, corn is on the starch list rather than the vegetable list because it is closer in composition to a slice of bread than to green beans. Individual food items within an exchange list are essentially equal to each other in nutrient composition and can thus be exchanged or "swapped" for each other. Exchanges were designed to be approximately equal in nutrients, not in volume; therefore, portion sizes may vary. For instance, one fruit exchange is equal to 1 $\frac{1}{4}$ cup of whole strawberries but to only three dates. To correctly use this method of meal planning, patients must choose the prescribed number of items from each appropriate list: starch, fruit, milk, vegetable, meat, and fat.

A specific meal plan should be given to the patient with the exchange lists. A meal plan is a food guide that shows the number of choices or exchanges the patient should eat at each meal and snack. A meal plan based on exchange lists allows patients

a variety of food choices yet requires minimal calculation. Even experienced users of the exchange list system should be advised to weigh or measure their portions several times per week to avoid portion inflation.

Using Carbohydrate Counting

Carbohydrate counting is a three-level approach to teaching meal planning that focuses on only carbohydrates, but patients are told to eat about the same amount of protein each day and to choose low-fat foods. With this system the patient keeps track of the units or exchanges of carbohydrate eaten throughout the day to keep carbohydrates and insulin balanced. Carbohydrate counting is based on classifying carbohydrates together, whether from starch, fruit, or milk. For example, one slice of whole wheat bread, one orange, and 8 ounces of skim milk are each equivalent to one carbohydrate unit or exchange. This method offers more flexible food choices within a day's meal plan than the exchange list system and may achieve better control of blood glucose. However, it may entail weighing and measuring food, keeping food records, monitoring blood sugar before and after eating, and controlling body weight. Mastery of level III of carbohydrate counting permits adjusting short-acting insulin dosage using insulin-to-carbohydrate ratios and is often a prerequisite for receiving insulin pump therapy.

Using the Glycemic Index

All carbohydrates are not metabolized the same. Foods containing equal amounts of carbohydrate impact blood glucose levels differently. The glycemic index is a classification of foods according to the speed and degree of change in blood glucose levels. Compared with a standard of 100 for white bread, glucose has a glycemic index of 138, sucrose (table sugar) 83, and fructose 26. Baked russet potatoes and corn flakes have higher glycemic indices than sucrose, whereas sweet potato has a lower one. Because most meals contain a combination of nutrients, the glycemic index is rarely used in clinical practice except with highly motivated and educated patients.

TABLE 38-2 MEAL-PLANNING APPROACHES FOR DIABETES

Approach	Comments	Availability
Food Pyramid	Initial phase of teaching Provides a basic foundation in normal nutrition. Does not emphasize meal consistency.	A colorful version is available from the National Dairy Council, 10255 West Higgins Road, Suite 900, Rosemont, IL 60018-4233 1-708-803-2000
Dietary Guidelines	Initial phase of teaching Provides a basic foundation in normal nutrition, 40 pages in length. Does not emphasize meal consistency.	United States Department of Agriculture Home & Garden Bulletin #232, Local Cooperative Extension Office
The First Step in Diabetes Meal Planning	Initial phase in teaching Combines Food Pyramid and Dietary Guidelines, and provides information on meal consistency in a simplified format.	The American Dietetic Association, 216 West Jackson Boulevard, Suite 800, Chicago, IL 60606-6995 1-800-366-1655
CHO Counting	Progressive teaching tool that leads to maximum control of blood glucose and lipid levels. Decreased emphasis on balance and variety.	The American Dietetic Association, 216 West Jackson Boulevard, Suite 800, Chicago, IL 60606-6995 1-800-366-1655
Month-O-Meals	Each book contains 28 complete and interchangeable menus for breakfast, lunch, dinner, and snacks. Excellent approach for the client who "just wants to be told what and when to eat."	The American Dietetic Association, 216 West Jackson Boulevard, Suite 800, Chicago, IL 60606-6995 1-800-366-1655
Exchange Lists of the American Dietetic and the American Diabetes Associations	Allows the health-care educator to distribute all of the energy nutrients. More emphasis on the importance of eating a balanced diet than the CHO counting approach. Time consuming to learn and teach	The American Dietetic Association, 216 West Jackson Boulevard, Suite 800, Chicago, IL 60606-6995 1-800-366-1655

BOX 38-3 CULTURAL CONSIDERATION

The diabetic diet for ethnic individuals may need a significant adjustment from the U.S. menu. An exchange list of foods for these patients will not be followed because their food choices are different. The patient may be labeled noncompliant, when in reality the health care worker has been culturally insensitive.

The nurse can consult the American Diabetes Association in Washington, D.C. (1-800-342-2383) to obtain meal plans for ethnic individuals such as Asians, Hispanics, African-Americans, and Native-Americans.

Exercise

Exercise is an important factor in controlling blood glucose and lipid levels. Exercise lowers blood glucose, both immediately and for approximately 24 hours after the exercise. Insulin is not needed for glucose to enter exercising muscle cells. Exercise also improves blood lipid levels and circulation, which is important for the person with diabetes, who already has an increased risk of cardiovascular disease. Patients are instructed to exercise on a regular basis, ideally 30 minutes on most days of the week, to keep blood glucose levels stable and promote health.

Some patients with complications of diabetes must be careful in their exercise choices. For example, a patient with **retinopathy** should not do anything that causes straining. (See Long-Term Complications later in this chapter.) A patient with **neuropathy** or foot problems should limit weight-bearing exercise. A physician or exercise physiologist should be consulted for an individualized exercise plan.

Persons with diabetes should always carry a quick source of sugar when exercising in case the blood glucose drops too low. Individuals on intermediate-acting insulin are taught to avoid exercising at the time of day when their blood glucose is at its lowest point (i.e., when insulin or medication is peaking) and to have a carbohydrate snack before exercising if blood glucose is less than 100 mg/dL. Exercising at similar times each day also helps prevent blood glucose fluctuations.

Patients should be cautioned to avoid exercise when their glucose level is higher than 250 mg/dL and ketones are present in the urine or if glucose is more than 300 mg/dL without ketones. This indicates that insufficient insulin is available and glycogen may be released during exercise, further increasing the serum glucose.

Medication

INSULIN. The individual with type 1 diabetes has no endogenous insulin and therefore must inject insulin daily. At this time, insulin cannot be taken by mouth, because it is a protein and is therefore digested. Researchers are trying to find ways that insulin can be given without injections—either by inhaling it intranasally or by taking it in an oral

form that is not digested. For now, it is generally given subcutaneously, although regular insulin may be ordered via the intramuscular or intravenous route in urgent situations. There are several types of insulin and schedules by which it may be given. The type and schedule are determined by the physician, in collaboration with the patient, based on his or her lifestyle and willingness to spend time on injections. In general the more frequent the injections, the better the glucose control.

Insulin injections should be given in a different subcutaneous site each time to avoid injury to the tissues. A sample rotation chart is shown in Figure 38–3. Because each area absorbs insulin at a slightly different rate, it is advisable to use one area for a week, then move on to the next area. Within that area, each injection should be spaced at least 1 inch from the previous injection. Most experts recommend using primarily the torso (abdomen and buttocks) to provide more uniform absorption. Aspirating for blood before injection and rubbing the site following injection are not recommended with insulin injections.

A newer development in diabetes care is the insulin pump (Fig. 38–4). This is a small device that delivers subcutaneous insulin continuously in small (basal) amounts. The patient can then add a bolus of insulin before meals or snacks. This provides insulin administration more closely matched to a person without diabetes. It allows for tighter control of blood glucose levels and a more flexible lifestyle for the patient.

Most insulin is now synthetically produced in a laboratory and is identical to human insulin. Some patients may still use insulin from beef or pork sources. It is important that the physician include the insulin source in the prescription. Be careful to check the source when preparing insulin for injection, because insulins from different sources may act slightly differently. Some individuals may be aller-

Rotation sites for injection of insulin.

Figure 38-3 Sample insulin rotation chart.

retinopathy: retino—nervous tissue of the eye + pathy—illness

neuropathy: neuro—nervous system + pathy—illness

BOX 38-4 CULTURAL CONSIDERATION

Muslims and Jewish people do not eat pork. Therefore they should not be prescribed pork insulin.

The cow is sacred in India. Therefore the Hindu patient should not be prescribed beef insulin.

insulin, insulin glargine (Lantus AE), is now available and provides a basal insulin dose. A person who does not have diabetes is always secreting a little insulin, called a basal rate—about 1 unit per hour. When Lantus is injected at bedtime, it provides a very slow basal absorption rate for 24 hours, without a peak. The patient then injects short-acting insulin before meals during the day. This allows for more normal insulin and blood glucose levels in the body.

It is important for the individual with diabetes and the nurse to be aware of the onset, peak, and duration of any insulin given. This assists in making decisions such as when to give insulin, when to exercise, and when to be alert to low blood glucose symptoms.

LEARNING TIPS

The Evens-and-Odds Rule: To remember the onset, peak, and duration of intermediate-acting insulin, think *evens*—2, 12, and 24 hours. To remember short-acting insulin, think *odds*—1, 3, and 5 hours. These times are not exact, but they are a great memory booster when you need to think fast.

gic to beef or pork preparations or may refuse them based on cultural practices (Cultural Consideration Box 38-4).

Once insulin is injected, a period elapses before it begins to lower blood glucose. This time is called the onset of action. The peak action time occurs when the insulin is working at its hardest and the blood glucose is at its lowest point. It is during this peak time that the patient is most at risk for an episode of low blood glucose. Duration is the length of time the insulin works before it is used up. Onset, peak, and duration are determined by whether the insulin is short-, intermediate-, or long-acting (Table 38-3). A newer type of

In the past, most patients with diabetes used an injection of an intermediate-acting insulin before breakfast and possibly a second injection before supper. Many patients are now choosing to take more frequent injections of short-acting insulin before meals or a combination of short- and intermediate- or long-acting insulins to achieve better, “tighter” control. These patients are often taught to adjust their insulin dose based on blood glucose level and the amount of carbohydrates eaten.

When two insulins need to be given at the same time, they can often be mixed together to prevent having to give more than one injection. See Box 38-5 for how to mix insulins in one syringe. Preset mixtures of intermediate- and short-acting insulins are available for patients who have difficulty learning to mix insulins.

TABLE 38-3 ONSET, PEAK, AND DURATION OF INSULINS

Insulin Type	Example	Brand Name	Onset	Peak	Duration
Very short acting	lispro	Humalog	15 min	30–90 min	≤5 h
	aspart	NovoLog	Rapid	1–3 h	3–5 h
Short acting	regular	Humulin R, Novolin R	½–1 h	2–5 h	5–8 h
Intermediate acting	NPH	Humulin N, Novolin N	1–3 h	6–12 h	18–26 h
	Lente	Humulin L, Novolin L			
Long acting	Ultra Lente	Humulin U Ultralente	4–6 h	14–24 h	26–36 h
	Insulin glargine	Lantus AE	Unknown	No peak	24 h
Premixed insulins	70% NPH and 30% regular	Humulin 70/30	30 min	4–8 h	Up to 24 h
	or 50% NPH and 50% regular	Humulin 50/50			

LEARNING TIPS

When mixing insulin, remember *clear to cloudy*. Always draw up the clear insulin first. This involves injecting air into the cloudy vial first. This is because if the clear is drawn up last, the vial may be contaminated by the cloudy insulin, altering the action of the clear insulin. If cloudy insulin is unknowingly contaminated by clear insulin, the clear will become cloudy and its effect will be diminished.

BOX 38-5 How to Mix Insulin

1. Assemble equipment: insulins, syringe (be sure it is large enough to hold the entire insulin dose), alcohol swab, physician's order.
2. Check physician's order to confirm correct insulin types and doses of regular (clear) and an intermediate-acting (cloudy) insulin.
3. Roll the bottle of cloudy insulin to mix. Do not shake, because this will cause bubbles.
4. Wipe tops of both vials with alcohol swab.
5. Draw up and inject an amount of air equal to the dose of intermediate-acting insulin into the cloudy vial. Remove syringe from vial.
6. Draw up and inject an amount of air equal to the dose of intermediate-acting insulin into the cloudy vial. Remove syringe from vial.
7. Draw up the correct amount of clear insulin. Double-check amount with another nurse if this is the institution's policy.
8. Remove the syringe and insert into the cloudy vial. Carefully draw up the correct amount of insulin. If too much insulin is accidentally drawn into the syringe, the syringe must be discarded and the process repeated. Double-check again with another nurse.

NOTE: Some insulins cannot be mixed. Check a drug reference before mixing.

During times of stress or illness, some patients are placed on "sliding-scale" insulin. This involves determining each dose of short-acting insulin based on blood glucose results, usually before meals and at bedtime. For example, an order might read, "For blood glucose < 200, no insulin; 201–250, 2 units regular insulin; 251–300, 4 units regular insulin; 301–350, 6 units regular insulin; >350 call physician."

Problems with Insulin Therapy. Two problems that can occur with glucose control are the Somogyi effect and the dawn phenomenon. The Somogyi effect may be at fault when the patient's blood glucose seems to be rising in spite of increasing insulin doses. If insulin levels are too high, the blood glucose may drop too low, stimulating release of counterregulatory hormones (epinephrine, glucagon, corticosteroids, growth hormone) that then elevate the blood glucose. The low sugars often occur during the night, and the patient may report night sweats or morning headaches. The high morning glucose is then interpreted as hyperglycemia, and the insulin dose may be further increased, compounding the problem.

Dawn phenomenon is thought to occur because of the natural release of growth hormone and cortisol during the

early morning hours. This causes hyperglycemia on arising in the morning.

The patient might be asked to monitor blood sugar between 2 and 4 A.M. in addition to bedtime and morning testing to assess whether Somogyi effect or dawn phenomenon is occurring. Correction of the Somogyi effect involves reducing the insulin dose. Dawn phenomenon is treated with careful adjustment of meals and insulin; moving the evening insulin dose to bedtime may cause the insulin to peak when the blood glucose is highest.

ORAL HYPOGLYCEMIC MEDICATION. The patient with type 2 diabetes may be able to control blood glucose levels with medical nutrition therapy and exercise alone. Oral hypoglycemic medication or insulin may also be prescribed. Oral hypoglycemics are not insulin pills. Remember that if insulin is ingested, it is digested, because it is a protein. Because most oral hypoglycemics depend on at least a partially functioning pancreas, most are not useful for patients with type 1 diabetes.

CRITICAL THINKING

Mrs. Evans

Mrs. Evans is a 68-year-old woman with type 2 diabetes who resides in an assisted living facility. She is on Lente insulin every morning.

1. If Mrs. Evans eats her breakfast at 8:00 every morning, when should she take her insulin?
2. At what time of day should she be alert for symptoms of low blood sugar?
3. What could happen if Mrs. Evans has a busy day and misses her lunch?

Answers at end of chapter.

Older oral hypoglycemic agents, called first-generation drugs, have many side effects. It is believed that they may increase the risk of death from cardiovascular disease. Second-generation drugs are more effective and have fewer side effects. Many new oral hypoglycemic agents have recently been developed (Table 38–4).

Most insulins and oral hypoglycemics should be administered before meals (check individual drugs for specific timing). Care should be taken to prevent passage of more than 30 minutes between medication administration and the meal, because this may result in a hypoglycemic episode.

If blood glucose levels are not controlled with oral hypoglycemic agents, insulin may be necessary for the person with type 2 diabetes. This does not mean the person has type 1 diabetes. Insulin may be necessary to control blood glucose, but it is not necessary to sustain life, as it is for the person with type 1 diabetes.

Self-Monitoring of Blood Glucose

The ability to test blood glucose levels at home has been a major advance in diabetes care. Blood glucose can be better controlled because of the availability of monitoring at any time, in any place. A variety of blood glucose monitors are

TABLE 38-4 ORAL HYPOGLYCEMIC AGENTS

Generic Name	Trade Names	Action	Usual Dosage	Nursing Considerations
Insulin Stimulators				
<i>First-generation sulfonylureas</i>				
Tolbutamide	Orinase	Stimulates insulin secretion from pancreas, increases insulin receptor sensitivity. May be given with other classes of oral agents.	500–2000 mg per day	May cause weight gain. Monitor for hypoglycemia. Teach patient to avoid alcohol. May result in cardiovascular events. Rarely used.
<i>Second-generation sulfonylureas</i>				
Chlorpropamide	Diabinese		250–500 mg per day	
Glipizide	Glucotrol	Stimulates insulin secretion from pancreas, increases insulin receptor sensitivity. May be given with other classes of oral agents.	2.5–40 mg per day	May cause weight gain. Monitor for hypoglycemia. Teach patient to avoid alcohol. Cheapest class. Give Glucotrol 30 minutes before meals.
Glimepiride	Amaryl		1–8 mg per day	
Glyburide	Micronase Diabeta Glynase Pres-Tabs		2.5–20 mg per day 2.5–20 mg per day 1.5–12 mg per day	
<i>Meglitinides</i>				
Repaglinide	Prandin	Stimulates insulin secretion from pancreas, increases insulin receptor sensitivity. May be given with other classes of oral agents.	0.5–4 mg with meals	Dosed with meals to improve postprandial hyperglycemia. Multiple dosing less convenient. Hold dose if patient skips meal.
Nateglinide	Starlix		60–240 mg with meals	
Insulin Sensitizers				
<i>Biguanides</i>				
Metformin	Glucophage Glucophage XR	Increases insulin-stimulated glucose transport in skeletal muscle, reduces production of glucose by liver. Reduces LDL cholesterol, triglycerides, and blood pressure. May be given with other classes of oral agents.	500 mg–2.5 g per day	Give with meals. May cause GI side effects; may enhance weight loss. Withhold if patient is having tests involving contrast dye. Contraindicated in renal and hepatic disease and CHF. Notify physician of early symptoms of lactic acidosis: hyperventilation, myalgia, malaise.
<i>Combination agent</i>				
Metformin/glyburide	Glucovance	Combines actions of metformin and glyburide	1.25/250–5/500 mg	See metformin and glyburide
<i>Thiazolidinediones (glitazones)</i>				
Pioglitazone	Actos	Reduces insulin resistance in muscles. Improves blood lipids; may lower blood pressure and improve cardiovascular risk. May be given with other classes of oral agents.	15–45 mg per day	Give with meal. Side effects include nausea, weight gain, and fluid retention. Works well with obese patients. Avoid with liver disease; monitor liver enzymes. May alter effectiveness of some birth control pills.
Rosiglitazone	Avandia		4–8 mg daily as single dose or divided	
Troglitazone	Rezulin		200–600 mg per day	Off market in 2000 because of deaths from liver failure.
Absorption Delayers				
<i>Alpha-glucosidase inhibitors (AGIs)</i>				
Acarbose	Precose	Lowers postprandial glucose by reducing rate of carbohydrate digestion and absorption. May be given with other classes of oral agents.	25–100 mg before each meal (tid)	Give at start of each meal. May cause diarrhea, flatulence, and abdominal pain. No weight gain or hypoglycemia risk. Multiple dosing less convenient. If used in combination with another drug and hypoglycemia occurs, treat with milk or glucose tablets, not table sugar.
Miglitol	Glyset		25–75 mg before each meal (tid)	

CHF = congestive heart failure; LDL = low-density lipoprotein.

on the market at a reasonable price (Fig. 38–5). Most of the cost involved in monitoring is in the test strips that must be used. Health insurance programs sometimes cover this cost.

Self-monitoring of blood glucose (SMBG) is generally done before meals and at bedtime by the individual on insulin who wishes to maintain tight control of blood glucose. Less frequent schedules may be prescribed for patients who are unable or unwilling to test four times a day or for patients not on insulin. Some may test before breakfast and supper, and some may vary testing times from day to day. Patients are also often recommended to periodically test 2 hours after meals. New noninvasive devices are being developed, such as a monitoring device that resembles a wrist watch. It is worn on the arm, and it checks glucose levels by extracting fluid from the arm every 20 minutes. An excellent test for long-term monitoring is the HbA_{1c}, described earlier. It is usually done every 3 to 4 months.

The physician should be consulted for desirable blood glucose ranges, because these may differ for each patient. For example, a patient whose type 2 diabetes is controlled by nutrition therapy and exercise alone may have a goal of 80 to 120 mg/dL. Patients who are prone to insulin reactions (hypoglycemia) or small children or the elderly may have higher goal ranges, such as 100 to 150 mg/dL. Lower blood glucose levels for these populations could increase the risk of hypoglycemia.

Urine Glucose and Ketone Monitoring

Urine may also be tested for glucose and for ketones. Urine glucose testing was done routinely before the development of SMBG. A variety of dipsticks and tape products are available for urine testing. If glucose appears in the urine, the patient is warned that the blood glucose is elevated, but the actual level is unknown. Most people have glucose in their urine when their blood glucose is more than 180 mg/dL. It is difficult to base treatment on urine glucose levels, and so routine urine testing for glucose is no longer recommended.

Figure 38-5 OneTouch Ultra glucose monitor. (Courtesy LifeScan.)

Urine should be tested for ketones during acute illness or stress, when blood glucose levels are consistently above 300 mg/dL, during pregnancy, or when symptoms of ketoacidosis are present. If ketones are present, the patient knows an insulin deficiency is present and should notify the physician. Patients with type 1 diabetes are most at risk for developing ketoacidosis; however, it is wise for the patient with type 2 diabetes to test for ketones if risk factors are present.

An important aspect of blood or urine monitoring is the interpretation of results. Monitoring is useless if the results are not used to improve blood glucose control. The patient should be instructed to keep a diary of blood glucose levels (Fig. 38–6). Some patients have computer software that graphs results. The patient may be taught by a diabetes educator to interpret the trends in the results, or the diary may be taken on a regular basis to the health care provider for interpretation and adjustment of the treatment plan.

See Box 38–6 for a summary of diabetes symptoms, diagnosis, and treatment.

Pancreas Transplant

If the patient is unable to control blood sugar levels with conventional treatment, a pancreas transplant may be considered. This is especially beneficial in the patient with kidney disease, who can receive both a kidney and pancreas transplant at the same time. An experimental but exciting development is the use of pancreatic islet cell transplants.

Acute Complications of Diabetes

The individual with diabetes is at risk for a variety of complications. Acute complications related to high and low blood glucose levels are treatable and can often be prevented with appropriate care.

BOX 38-6 Diabetes Summary

Symptoms

- Polyuria
- Polydipsia
- Polyphagia
- Fatigue
- Blurred vision
- Headache
- Abdominal pain

Diagnostic Tests

- Fasting blood glucose
- HbA_{1c} (glycosylated hemoglobin)
- Oral glucose tolerance test

Management

- Diet
- Exercise
- Insulin
- Oral hypoglycemic medication
- Self-monitoring of blood glucose levels
- Education

Day		Breakfast	Lunch	Supper	Bedtime	Urine Ketones	Notes

Hyperglycemia

When calories eaten exceed insulin available or glucose used, high blood glucose (hyperglycemia) occurs. The most common cause of hyperglycemia is eating more than the meal plan prescribes. Another major cause is stress. Stress causes the release of counter-regulatory hormones, including epinephrine, cortisol, growth hormone, and glucagon. These hormones all increase the blood glucose level. In a person without diabetes, this is an adaptive function. However, the patient with diabetes is unable to compensate for the increased blood glucose with increased insulin secretion, and hyperglycemia occurs.

Patients must be able to recognize signs and symptoms of high blood glucose levels and know what to do if they occur (Table 38-5). For many patients, these are similar to the symptoms they experienced when they were first diagnosed with diabetes. Chronic high blood glucose levels may lead to long-term complications (discussed later in this chapter).

Hypoglycemia

Low blood glucose, or hypoglycemia, occurs when there are not enough calories available in relation to circulating insulin. This is sometimes referred to as an insulin reaction. Hypoglycemia is usually defined as a blood glucose level below 50 mg/dL, although some patients have symptoms at higher glucose levels. Occasionally symptoms occur as a result of a rapid drop in blood glucose, even though the actual glucose level is normal or high. Causes of hypoglycemia may include skipping a meal, exercising more than usual, or ac-

cidental administering too much insulin. An occasional hypoglycemic episode, treated promptly, should not lead to chronic complications. Repeated or extremely low blood glucose levels may cause neurological damage. It is therefore important to teach patients how to prevent and treat low blood sugar.

CRITICAL THINKING

Jeff
 Jeff is a 16-year-old who is having trouble with repeated insulin reactions. He says he has not had this trouble before, and it is interfering with his new job. What questions might you ask as you do your assessment to help him figure out how to prevent future reactions?
Answers at end of chapter.

Symptoms of low blood glucose include hunger, sweating, pallor, tremor, palpitations, and headache. These symptoms are caused by activation of the sympathetic nervous system. As hypoglycemia progresses, the brain is deprived of glucose and neurological symptoms such as irritability, confusion, seizures, and coma may occur.

If you find a patient with symptoms of an altered blood glucose but are unable to identify whether it is high or low, do a blood glucose test. However, if the patient is exhibiting neurological symptoms, treat low blood glucose immediately. The blood glucose may then be checked and further treatment provided as indicated.

TABLE 38-5 COMPARISON OF HIGH AND LOW BLOOD GLUCOSE LEVELS

	Hyperglycemia	Hypoglycemia
<i>Causes</i>	Overeating Stress Illness Too little insulin or medication	Undereating, skipping a meal Too much insulin or medication Exercise
<i>Symptoms</i>	Polyuria Polydipsia Polyphagia Blurred vision Headache Lethargy Abdominal pain Ketonuria (if type I) Coma	Hunger Sweating Blurred vision Tremor Headache Irritability Confusion Seizures Coma
<i>Treatment</i>	Confirm hyperglycemia with glucose meter; if greater than 300 mg/dL, check urine for ketones and increase fluid intake. Assess cause of hyperglycemia, teach prevention. Return to prescribed treatment plan if applicable. Call physician for medication adjustment if indicated or if blood glucose is >200 mg/dL for 2 days. Call physician if patient is ill or vomiting.	Confirm hypoglycemia with glucose meter (if patient is not acutely ill). Administer 15 g fast-acting carbohydrate. Recheck glucose in 15 minutes; if still low, readminister carbohydrate. Continue checking glucose and administering fast sugar until hypoglycemia subsides; if symptoms worsen, call physician or emergency help. Glucagon subcutaneously or dextrose 50% IV may be administered if ordered. Assess cause of hypoglycemia, teach prevention.

To treat low blood glucose, administer a “fast sugar”—15 grams of carbohydrate that will enter the bloodstream quickly. This may be 4 ounces of orange juice, commercially available glucose tablets, or another quickly available source of sugar (Box 38-7). If the patient is not alert or is unable to safely swallow, contact the registered nurse (RN) for administration of intravenous (IV) glucose according to agency policy. Recheck glucose in 15 minutes. If the blood glucose does not return to normal, repeat the procedure every 15 minutes until relief occurs. Do not overtreat hypoglycemia with too much sugar, because this may cause hyperglycemia and rebound hypoglycemia. Many nurses added sugar to orange juice in the past. This is no longer recommended.

If the next meal is more than 1 hour away, follow the treatment with a protein and complex carbohydrate snack, such as crackers with cheese or peanut butter, or half of a sandwich. If symptoms worsen, the physician should be contacted. Intravenous glucose or subcutaneous glucagon may be given in emergency situations. Check hospital or agency policy for specific protocol for treating hypoglycemic episodes.

BOX 38-7 Fast Sugars

4 oz orange juice
6 oz regular (not diet) soda
Miniature box of raisins
3 glucose tablets
6–8 Life Savers

Some elderly patients with poor autonomic nervous system function or patients taking beta-adrenergic blocking medication (such as propranolol or atenolol) may not feel the symptoms of hypoglycemia. These patients should check glucose levels more frequently and keep the levels in a safe range to prevent hypoglycemic episodes.

Individuals with diabetes should be instructed to keep a fast sugar in their purse or pocket at all times. Fast sugars may also be stored in bedside tables, cars, and desks at work.

Diabetic Ketoacidosis

PATHOPHYSIOLOGY. Diabetic ketoacidosis (DKA) occurs when blood glucose levels become very high and insulin is deficient. This most commonly occurs in individuals with type 1 diabetes. DKA is often the reason a person with undiagnosed type 1 diabetes first seeks help. It may also be the result of stress or illness in a person with previously diagnosed type 1 diabetes. When there is insufficient insulin to allow glucose into cells, the cells starve. The body then breaks down fat to be used for energy. The fat breakdown releases an acid substance called ketones. As ketones build up in the blood, ketoacidosis occurs.

The body attempts to reduce acidosis by deepening respirations, thereby blowing off excess carbon dioxide. (See the section on metabolic acidosis in Chapter 5.) The deep, sighing respiratory pattern is called **Kussmaul’s** respirations. The expired air has a fruity odor caused by the ketones and may be mistaken for alcohol. Some nurses have likened the odor to Juicy Fruit gum.

With such high blood glucose and the accompanying polyuria, the body becomes dehydrated very quickly. Tachycardia, hypertension, and shock can result. High blood glu-

cose also causes potassium to leave the cells and accumulate in the blood (hyperkalemia). The combination of dehydration, hyperkalemia, and acidosis causes the patient to develop flulike symptoms, including abdominal pain and vomiting. The patient loses consciousness and death occurs if DKA is not treated. The mortality rate for DKA is about 5 percent.

TREATMENT. Treatment includes IV fluids, IV insulin, and blood glucose monitoring. Assist with monitoring blood glucose levels closely and notify the RN or physician when the desired level is reached. Glucose should be added to the IV when the blood glucose drops to 250 mg/dL to avoid hypoglycemia. Potassium should also be monitored, because the serum potassium level drops rapidly as it reenters the cells. The cause of the DKA should be identified and treated.

Prevention of ketoacidosis involves careful monitoring of blood glucose levels at home. If the blood glucose rises above 300 mg/dL, the patient should use a urine dipstick made to detect ketones. If ketones are present, the physician should be notified. Patients should be instructed to never stop their insulin without a physician's supervision.

Hyperosmolar, Hyperglycemic, Nonketotic Syndrome

PATHOPHYSIOLOGY. Hyperosmolar, hyperglycemic, nonketotic (HHNK) syndrome occurs primarily in type 2 diabetes, when blood glucose levels are high as a result of stress or illness. Because the person with type 2 diabetes has some insulin production, cells do not starve and DKA usually does not occur. It occurs more often in the elderly.

As the blood glucose rises (hyperglycemic), polyuria causes profound dehydration, producing the hyperosmolar (concentrated) state. Blood glucose may rise as high as 1500 mg/dL. Because ketoacidosis is not present, the patient may not feel as physically ill as the patient with DKA and may delay seeking treatment. Symptoms of HHNK develop slowly and include extreme thirst, lethargy, and mental confusion. Shock, coma, and death occur if HHNK is left untreated. The mortality rate for HHNK is about 15 percent.

TREATMENT. Treatment includes IV fluids and insulin, and glucose monitoring. The cause should be identified and treated. HHNK syndrome can be prevented with careful monitoring of glucose levels at home. Patients should be instructed to drink plenty of fluids if blood glucose levels are beginning to rise, especially in times of stress and illness. They should also know when to call their physician with high blood glucose results.

Long-Term Complications

Over time, chronic hyperglycemia causes a variety of serious complications in persons with diabetes. These involve the circulatory system, eyes, kidneys, and nerves. Most of the complications involve either the large blood vessels in the body (macrovascular complications) or the tiny blood ves-

sels, such as those in the eyes or kidneys (microvascular complications). The Diabetes Control and Complications Trial (DCCT), a large research study completed in 1993, showed that individuals with type 1 diabetes who maintain tight control of blood glucose experience fewer long-term complications than individuals who take traditional care of their diabetes. Similarly, the United Kingdom Prospective Diabetes Study (UKPDS), completed in 1998, showed that individuals with type 2 diabetes who maintain an HbA_{1c} below 7 percent can significantly reduce complications. In fact, for every percent of decrease in HbA_{1c}, there were 25 percent fewer deaths from diabetes-related complications.⁴ Unfortunately, even tight control does not guarantee the prevention of all complications.

Macrovascular Complications

CIRCULATORY SYSTEM. Individuals with diabetes develop atherosclerosis and arteriosclerosis faster than the general population. They are more likely to have hypertension and elevated low-density lipoprotein (LDL) cholesterol and triglyceride levels. High blood glucose may also affect platelet function, leading to increased clotting. These problems lead to a higher incidence of strokes, heart attacks, and poor circulation in the feet and legs. The risk of cardiovascular disease and strokes is two to four times more common in persons with diabetes than in the general population.

Blood glucose and blood pressure control is vital to help prevent these deadly complications. Patients should also avoid smoking, and maintain normal weight. Aspirin therapy to reduce platelet aggregation is recommended for patients older than 21 years of age with diabetes.

Microvascular Complications

EYES. Small blood vessels may become diseased, eventually leading to retinopathy in most patients with diabetes. Retinopathy involves damage to the tiny blood vessels that supply the eye. Small hemorrhages occur, which can cause blindness if not corrected. Diabetic retinopathy causes 12,000 to 24,000 new cases of blindness each year.⁵ Newer laser surgery techniques may help improve vision after hemorrhages occur. Diabetes is also associated with a high incidence of cataracts. Patients with diabetes should have a yearly dilated eye examination.

KIDNEYS. **Nephropathy** is caused by damage to the tiny blood vessels within the kidneys. From 20 to 30 percent of patients with diabetes develop some degree of nephropathy. Native-Americans, Hispanics, and African-Americans have the highest risk. A primary risk factor for diabetic nephropathy is poor control of blood glucose. If nephropathy occurs, the kidneys are unable to remove waste products and excess fluid from the blood. Diabetes is the leading cause of end-stage renal (kidney) disease (ESRD). When the kidneys have lost most of their function, patients may have their blood cleansed artificially, by either hemodialysis

nephropathy: nephro—of the kidney + pathy—illness

or peritoneal dialysis. (See Chapter 35.) The only cure for ESRD is a kidney transplant.

Patients should be taught the importance of blood glucose control in the prevention or delay of kidney disease. Angiotensin-converting enzyme (ACE) inhibitor medications such as enalapril (Vasotec) have also been shown to slow the development of kidney problems in patients with diabetes. Patients who have both diabetes and hypertension should be placed on an ACE inhibitor. Routine urine tests are done to check for microalbuminuria (tiny amounts of protein in the urine) or microalbumin-to-creatinine ratios. If microalbuminuria occurs, a low-protein diet may help delay further development of nephropathy. A trained renal dietitian should work with the patient and physician in determining the best diet for the patient.

Nerves

Another complication of diabetes is neuropathy, which is damage to nerves as a result of chronic hyperglycemia. Neuropathy can cause numbness and pain in the extremities, erectile dysfunction (impotence) in males, **gastroparesis** (delayed stomach emptying), and other problems. Unfortunately, pain caused by neuropathy is difficult to treat with traditional analgesics. Some antidepressant and anticonvulsant drugs may be helpful, and in some cases local injections of anesthetics may be used. Improved control of blood glucose levels may also help.

Infection

Persons with diabetes are prone to infection for several reasons. If injuries occur, healing may be slow because of impaired circulation. There may not be enough blood supply to heal the wound or fight an infection. For the same reason, it may be difficult for IV antibiotics to reach an infected site, and topical antibiotics may be preferable. In the presence of hyperglycemia, white blood cells become sluggish and ineffective, further reducing the body's ability to fight infection.

The incidence of periodontal (gum) disease, caused by bacteria in plaque, is also increased in individuals with diabetes. Patients must be taught to maintain good oral hygiene and make regular visits to the dentist.

Foot Complications

The combination of vascular disease, neuropathy, and risk for infection makes patients with diabetes prone to foot problems. Consider patients who have no feeling in their feet because of neuropathy. If they step on a tack, they may not feel it right away. Vascular disease prevents a good blood supply from promoting healing. If infection sets in, it is slow to resolve. Pressure points on the feet may also break down (Fig. 38-7). Neuropathy can lead to deformities of the feet, further increasing the risk for injuries.

For these reasons, diabetes is the leading cause of amputation of the lower extremities. Patients should be taught to

Figure 38-7 Diabetic foot ulcer. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA Davis, Philadelphia, 1997, p 438, with permission.)

protect their feet at all times by wearing well-fitting shoes and by washing, drying, and inspecting their feet daily (Box 38-8). If any sores are noted, the patient should not delay in seeking treatment. During routine visits to the physician, the patient should be sure to remove shoes and socks so the feet can be thoroughly examined. The physician or diabetes specialist can test sensation in the feet with tiny filaments. Loss of protective sensation is an early risk factor for amputation, so any reduction in sensation is a warning sign that extra care must be taken. A podiatrist (foot doctor) can be consulted if problems occur. Specialized wound treatment centers have new healing techniques that have prevented many amputations (Ethical Consideration Box 38-9).

Special Considerations for the Patient Undergoing Surgery

Surgery is a stressor. The counter-regulatory hormones released during stress cause the blood glucose to rise, even if the patient has been fasting. High blood glucose levels interfere with healing and may promote an environment for infection. Blood glucose should be well controlled before elective surgery. Check the physician's orders for changes in

BOX 38-8 Foot Care Tips

Wash and dry feet every day. Use warm (not hot) water. Apply lotion that does not contain alcohol, avoiding areas between toes.

Inspect feet for sores or red areas daily (have a family member help if necessary).

Report any abnormalities immediately.

Wear leather shoes and cotton socks.

Never go barefoot.

Avoid garters and tight socks.

Avoid crossing legs.

Cut toenails to natural shape of nail—not into corners.

See a podiatrist for calluses or problem toenails (avoid “bathroom surgery”).

Have feet checked at least once a year, preferably 3–4 times a year, for loss of sensation.

gastroparesis: gastro—stomach + paresis—partial paralysis

CRITICAL THINKING

Mr. Jones

Mr. Jones is a 54-year-old banker with type 2 diabetes admitted to your unit with a tiny red area on his right heel. His admitting blood glucose is 360 mg/dL. The lesion is so small you wonder what the fuss is about. While doing his assessment, you find that he wore a new pair of shoes to work all day about a month ago and has been avoiding seeing his physician about the resulting red area. He is placed on bedrest and IV antibiotics, and within 3 days the red area has broken open and has yellow drainage. He is sent home with topical antibiotics, to be followed by a visiting nurse. The wound takes 6 months to fully heal.

1. List three risk factors for foot problems.
2. Why did the sore take so long to heal?
3. Why was bedrest important?
4. Why might topical antibiotics work better than IV antibiotics?
5. The nurse documents the following description of Mr. Jones' wound: "Small red open area on heel, with yellow drainage on dressing." What is wrong with this charting? How can you improve it?

Answers at end of chapter.

insulin orders. Often patients are placed on intravenous infusions of glucose and insulin during and immediately after surgery. Monitor blood glucose levels every 2 to 4 hours or as ordered, and monitor carefully for signs and symptoms of hypoglycemia or hyperglycemia.

Patients who were not previously on insulin may be placed on insulin during surgery and postoperatively. They can generally return to their presurgical treatment plan after the stress of surgery is past.

Nursing Process

Assessment

A complete history and physical assessment should be carried out because diabetes affects every body system. Some areas on which to focus are shown in Table 38–6. It is especially important to assess each patient's knowledge of diabetes and its care, so that appropriate teaching can be done.

Nursing Diagnosis

Because diabetes affects so many different areas, nearly any nursing diagnosis may be appropriate. It is important to assess each patient as an individual and choose diagnoses

BOX 38–9 ETHICAL CONSIDERATION

Mr. Mann is 55 years old and has had diabetes for more than two decades. He has not managed his diabetes well and has subsequently suffered many complications. Mr. Mann does not regularly test his blood sugar, so he does not always get the appropriate amount of insulin. Also, he does not eat properly. He picks up fast-food during his lunch break and he binges on various snack foods before he eats his dinner, or instead of eating his dinner. He is not aware of the importance of taking care of himself to prevent long-term complications of diabetes. His present situation is the result of a neglected leg ulcer. He tried to treat it at home with over-the-counter remedies, but it did not improve.

The leg ulcer grew and became infected. Currently part of the foot is gangrenous and an amputation is recommended. The first time the surgery was mentioned, Mr. Mann became outraged and was adamant about the unacceptability of the proposed treatment. He was not going to "leave this earth" without all his parts. After further discussions with Mr. Mann, it was clear that he understood the consequences of his condition. He was more annoyed by the drainage from the ulcer than worried about the progressive gangrene.

Can Mr. Mann be treated without his permission? Should action be taken to have someone else named as Mr. Mann's guardian, despite his apparent competence? Does disagreement with the medical establishment in itself denote incompetence? Does the level of risk if treatment is refused make any difference in the health professional's response? What if Mr. Mann's refusal was based on religious beliefs or was related to some cultural tradition? How does the application of ethical theories help to sort out the critical elements when this case is examined?

based on assessment findings. A sample care plan is shown for a diagnosis of risk for ineffective health maintenance, because patients with diabetes must learn to care for themselves to maintain their health. The actual presence of the defining characteristics should be confirmed with the patient before choosing any nursing diagnosis. (See Nursing Care Plan Box 38–10 for the Patient with Diabetes Mellitus.)

Planning and Implementation

Once diagnoses have been identified, planning takes place. This should be done with the patient and family. Diabetes affects not only the person with the disease, but the entire family as well. The desired outcome for the plan of care is that the patient is knowledgeable about and able to care for

TABLE 38–6 ASSESSMENT OF THE PATIENT WITH DIABETES MELLITUS

BOX 38-10 NURSING CARE PLAN FOR THE PATIENT WITH DIABETES MELLITUS**Risk for ineffective health maintenance related to knowledge deficit in the patient with newly diagnosed diabetes mellitus****PATIENT OUTCOMES**

Blood glucose levels within parameters negotiated with health care provider. Patient states satisfaction with understanding of diabetes self-care.

EVALUATION OF OUTCOMES

Are blood glucose levels within parameters negotiated? Does patient state satisfaction with understanding of diabetes self-care?

INTERVENTIONS

Assess knowledge of diabetes self-care.

Assist patient to collaborate with health care provider to determine appropriate blood glucose levels and action to be taken if glucose levels are too high or too low.

Teach patient to assess glucose levels before meals and at bedtime or as ordered by health care provider. Ensure that patient knows how to obtain glucose monitor and instruction for home use.

Teach patient to administer insulin or oral hypoglycemic agent 30 minutes before meals (<15 minutes if patient is using Lispro). Ensure that meal is begun within 30 minutes of medication. Replace any uneaten foods to prevent hypoglycemia.

Teach technique for administering insulin if indicated.

Observe for symptoms of hypoglycemia and hyperglycemia and treat as necessary. Teach causes, prevention, recognition, and treatment of hypoglycemia and hyperglycemia.

Consult with dietitian for nutrition therapy instruction.

Consult with social worker as needed.

Provide patient with information regarding comprehensive diabetes education. Remind patient that only survival skills have been taught during initial instruction.

Assist patient to obtain medical alert card or tag that identifies diabetes.

Assess ability to see and manipulate syringe, glucose monitor, and other equipment. Obtain assistive devices as needed.

RATIONALE

Teaching should be initiated only if a knowledge deficit exists.

Appropriate blood glucose levels are different for each patient and should be determined on an individualized basis. The patient should know what blood glucose levels require notification of the health care provider.

Good blood glucose control depends on knowledge of glucose levels and trends.

The onset of most diabetes medication is about 30 minutes (see Table 38-4 for specific times). If more than 30 minutes passes before a meal, the patient might experience hypoglycemia.

The patient and family should be familiar with the injection procedure.

If the patient has a good understanding of hypoglycemia and hyperglycemia, most episodes can be prevented. If hypoglycemia or hyperglycemia does occur, prompt treatment is essential to prevent complications.

The dietitian is trained to provide in-depth meal plan instruction.

Some patients may not have the resources to carry out effective self-care.

Instruction provided in the hospital usually is not comprehensive. Outpatient diabetes classes can provide additional self-care and health promotion information.

If the patient is ever unresponsive for any reason, the health care provider would need to be aware of diabetes.

The elderly patient may have poor eyesight or other sensory deficits.

EVALUATION

Does patient exhibit knowledge of diabetes self-care?

Are blood glucose levels within parameters negotiated with health care provider?

Does patient state satisfaction with knowledge of diabetes self-care?

Does patient state appropriate blood glucose levels and action to take if glucose is high or low?

Does patient demonstrate correct use of glucose monitor or state how monitor and instruction will be obtained?

Does patient state correct meal and medication schedule?

Does patient demonstrate correct injection technique?

Does patient state causes, prevention, symptoms, and treatment of hypoglycemia?

Is patient able to state plan for obtaining appropriate meals?

Does patient state availability of adequate resources for self-care at home?

Does patient state plan for obtaining further diabetes education after discharge?

Does patient state plan to carry or wear identification at all times?

Is patient able to manipulate equipment to safely care for self?

GERIATRIC

his or her disease. Consult the dietitian, social worker, certified diabetes educator (CDE), home care nurse, outpatient education programs, and other resources as needed. (See Home Health Hints.)

HOME HEALTH HINTS

- Some home glucose monitoring devices have a memory that the nurse can access on the visit. It gives the date, time, and blood glucose result. This is a good indication of compliance with self-monitoring performed by patient or caregiver.
- The nurse should remember to call the patient the day before performing a venipuncture for a fasting blood sugar and remind the patient not to eat after midnight.
- Older patients tend to skip meals. Assist them to identify easy but nutritious meals, such as frozen dinners. Meals-on-Wheels is another option.
- Prefilled syringes should be stored in the refrigerator flat or with needles pointing up. This prevents crystals from settling and clogging the needle.
- The patient can discard used syringes and needles in a hard plastic container such as a Clorox bottle with a screw top.
- If the patient has a visual or dexterity problem, suggest getting a syringe magnifier. A pharmacist or occupational therapist may be able to assist with obtaining one.
- The patient can use a mirror to look at the bottom of the feet or have a family member examine the patient's feet. The patient should remove shoes and socks at each physician visit for a thorough foot inspection. Catching a "red spot" early is the goal.
- Due to decreased skin sensation in some persons with diabetes, hot water heaters should be set below 120° F.
- Even if patients have had diabetes for many years, observe them preparing and injecting their insulin. This provides an opportunity to praise good technique or correct bad habits.

Unless the patient demonstrates thorough knowledge, implementation of the care plan should include teaching. As each phase of the plan is carried out, explain to the patient and family what is being done and why. Appointments should be made to sit down with the patient and family to discuss new information and allow time for questions. Provide the patient ample time to demonstrate any newly learned skills. You should be familiar with agency policy regarding licensed practical nurse/licensed vocational nurse (LPN/LVN) responsibilities for diabetes education. Many institutions have written teaching plans that are helpful. Additional information about patient education is presented later in this chapter. Two Web sites that might be helpful to both you and your patients are www.diabetes.org and www.lifeclinic.com/focus/diabetes/resources.asp.

Evaluation

The best indicator of the success of a care plan for diabetes is controlled blood glucose and glycohemoglobin levels. The patient should also be without symptoms of hypoglycemia or hyperglycemia and be able to state what to do

if they do occur. Long-term complications should be minimized. Another important indicator is the patient's statement of satisfaction and comfort with the plan and his or her ability to carry it out on a daily basis.

Patient Education

The individual with diabetes must be taught self-care if at all possible. No amount of care from a physician or nurse can replace the self-care required of the person with diabetes. The involvement of family or significant others is also important for the success and well-being of the person with diabetes.

If the patient is hospitalized at diagnosis, the initial instruction is done in the hospital. However, with hospital stays becoming shorter, you must not waste any time. Begin teaching as soon as the patient is feeling physically well enough to learn. This is usually the responsibility of the primary or registered staff nurse, although aspects of the instruction may be delegated to the LPN/LVN. Some hospitals have a certified diabetes educator who provides classroom or bedside instruction. The dietitian should be contacted to provide meal plan instruction.

Most hospitals have policies or management plans describing the instruction to be provided by the nurse. Generally this encompasses "survival skills," which include the basic information the patient needs initially to survive at home. Survival skills include medication administration, glucose monitoring, meal plan basics, and what to do if high or low blood glucose levels occur. A variety of helpful aids, such as pamphlets and videos, are available. Diabetes equipment suppliers provide kits that are full of samples and information. These are a significant help when you are teaching a patient. Also advise the patient to purchase a medical alert bracelet or necklace.

It is difficult to know how to operate and teach glucose monitoring with the variety of glucose monitors available. Many drugstores and medical supply stores not only sell the monitors but also provide training for the patient and family. You can obtain this information by calling local medical suppliers or by contacting the diabetes educator.

After discharge, the patient is referred to outpatient diabetes classes for further instruction. If classes are unavailable or if the patient is unable to leave home, a referral to a visiting nurse should be given. It is usually advisable to have a nurse present for the patient's first insulin injection at home.

Because many people with diabetes are elderly, it is important to be aware of their special needs (Gerontological Issues Box 38-11).

BOX 38-11 GERONTOLOGICAL ISSUES

Diabetes care can be a challenge for many elderly patients. Syringe magnifiers and talking glucose meters are available for those with impaired vision. Family members may be taught to draw up a week's supply of insulin for the patient. Home meal programs may help ensure an adequate diet. Elderly patients should also have an emergency call system in their home and regular contact with family members or other support people.

▶ REACTIVE HYPOGLYCEMIA

Reactive hypoglycemia occurs when the blood glucose drops below a normal level, usually below 50 mg/dL. Hypoglycemia is most often a complication of diabetes treatment, but at times it may occur without the presence of diabetes. It may be a warning sign of impending diabetes.

Pathophysiology

Low blood glucose may occur as an overreaction of the pancreas to eating. The pancreas senses a rising blood glucose and produces more insulin than is necessary for the use of that glucose. As a result, the blood glucose drops to below normal. Some experts believe that this is a rare condition and that many “hypoglycemic” episodes are due to activation of the sympathetic nervous system for other reasons, without true hypoglycemia.

Signs and Symptoms

Low blood glucose causes release of epinephrine, which in turn causes the blood glucose to rise. Epinephrine release

causes a fight-or-flight reaction, which may produce shaking, sweating, and palpitations. Headache, chills, and confusion may also occur.

Diagnosis

Diagnosis is often based on a 5-hour glucose tolerance test, with below-normal readings between 2 and 5 hours. However, with the availability of home glucose monitors, it is now preferable for patients to monitor blood glucose levels at home. Readings should be taken in the morning on arising, 2 hours after each meal, at bedtime, and during symptoms of hypoglycemia. These results may then be taken to the physician for interpretation.

Treatment

Treatment includes frequent small meals and avoidance of fasting. Simple sugars are avoided, because they may aggravate symptoms. A high-protein, low-carbohydrate diet is stressed. See Table 38–7 for a sample diet.

TABLE 38–7 SAMPLE MEAL PLAN FOR HYPOGLYCEMIC DIET

Exchange Group	Sample Menu	Exchange Group	Sample Menu
<i>Morning</i>	½ cup unsweetened orange juice	<i>Mid-afternoon</i>	
1 fruit	¾ cup whole-grain cereal	1 meat	1 oz low-fat cheese

REVIEW QUESTIONS

- Which of the following is the best definition of diabetes mellitus?
 - It is a group of metabolic diseases in which high blood sugar results from defective insulin secretion or action.
 - It is a disease that causes polyuria and polydipsia.
 - It is a disease characterized by macrovascular and microvascular complications.
 - It is a complex disease of protein and fat metabolism.
- Which of the following is a risk factor for type 2 diabetes mellitus?
 - Cardiovascular disease
 - Obesity
 - Age younger than 40 years
 - Smoking
- Diabetes is diagnosed when the fasting blood glucose is greater than ____ on two occasions?
 - 70 mg/dL
 - 126 mg/dL
 - 140 mg/dL
 - 200 mg/dL
- Which of the following symptoms is most commonly associated with hyperglycemia?
 - Tremor
 - Flank pain
 - Sweating
 - Polyuria
- Protein in the urine is a sign of which long-term complication of diabetes?
 - Nephropathy
 - Neuropathy
 - Retinopathy
 - Gastroparesis
- What is the best way for patients to avoid long-term complications of diabetes?
 - See the doctor for a complete check up every 6 months.
 - Check feet daily.
 - Maintain blood sugar levels under 120 mg/dL.
 - Follow a strict 1500 calorie diet.
- For which of the following blood glucose results would the nurse administer a fast sugar?
 - 48
 - 80
 - 126
 - 223
- Which meal plan is best for the patient with reactive hypoglycemia?
 - High-carbohydrate meals
 - Small, frequent meals
 - Avoidance of fats and proteins
 - Three medium to large meals daily

Answers to CRITICAL THINKING

Mr. McMillan

1. "Have you been eating or drinking more than usual? Have you been urinating more than usual? Do you get up at night to urinate?"
2. Fatigue occurs because the glucose is unable to enter the cells without insulin, so they are starving.
3. Mr. McMillan is dehydrated because he is losing excessive amounts of urine as his kidneys excrete extra glucose.

Mrs. Evans

1. Mrs. Evans should take her insulin at 7:30 A.M.
2. She should be alert for low blood sugar at midafternoon to just before supper. Although her insulin peaks between 1:30 and 7:30 P.M., her chances of having a hypoglycemic episode are slim once she has eaten her supper.
3. If she misses a meal, her blood sugar will drop further, increasing her risk of a hypoglycemic episode.

Jeff

What kind of new job is it? Is it more physically strenuous than his previous job? Does it interfere with his usual meal schedule?

Mr. Jones

1. Poor circulation, neuropathy, and slow wound healing place Mr. Jones at risk for problems.
2. Circulation to the foot may be poor, and white blood cells are sluggish if the blood glucose is high.
3. Any pressure on the foot while walking may further impair circulation.
4. If circulation to the area is poor, IV antibiotics may not reach the sore.
5. "Small red open area on right posterior heel, 1 cm × 1.5 cm, 2 mm deep. 2 cm area of yellow drainage on dressing." In addition, many agencies are now taking instant photos of wounds to include in the chart. If no camera is available, a drawing of the size and shape is helpful.

QUESTIONS TO GUIDE YOUR READING

1. What is the normal anatomy of the reproductive system?
2. What are the normal functions of the reproductive system?
3. Which data should you collect when caring for a patient with a disorder of the reproductive system?
4. Which diagnostic tests are commonly performed to diagnose disorders of the reproductive system?
5. What nursing care should you provide for patients undergoing each of the diagnostic tests?
6. Which therapeutic measures are commonly used for patients with disorders of the reproductive system?

▶ REVIEW OF NORMAL ANATOMY AND PHYSIOLOGY

The male and female reproductive systems produce gametes (sperm and egg cells) and ensure the union of gametes in fertilization following sexual intercourse. In women the uterus provides the site for the developing embryo/fetus until birth.

Female Reproductive System

The female reproductive system consists of the paired ovaries and fallopian tubes, the single uterus and vagina, and the external genital structures (Fig. 39–1). The mammary glands may be considered accessory organs to the system.

Ovaries

The ovaries are a pair of oval structures about 1.5 inches long on either side of the uterus in the pelvic cavity (Fig. 39–2). The ovarian ligament extends from the medial side of the ovary to the uterine wall, and the broad ligament is a fold of the peritoneum that covers the ovaries. These ligaments help keep the ovaries in place.

The ovaries produce egg cells by the process of meiosis, more specifically called oogenesis, which begins at puberty and ends at **menopause**, between the ages of 45 and 55. This process is cyclical in that usually one mature ovum is

menopause: men—month + pause—stop

produced every 28 days and is under hormonal control (covered in the section on the menstrual cycle). The follicles of the ovary produce the hormone estrogen and later, as the corpus luteum, secrete progesterone as well.

Fallopian Tubes

Each fallopian, or uterine, tube is about 4 inches long; the lateral end with its fringed-like fimbriae encloses the ovary on its side, and the medial end opens into the uterus. The lining of a fallopian tube is ciliated epithelium; in the wall is smooth muscle. The sweeping of the cilia and the peristaltic contractions of the smooth muscle usually ensure that the ovum (or the zygote after fertilization), which has no means of self-locomotion, will reach the uterus. Fertilization usually takes place within the fallopian tube, and the zygote is swept into the uterus within 4 to 5 days.

Uterus

The uterus is about 3 inches long and 2 inches wide, superior to the urinary bladder and medial to the ovaries in the pelvic cavity. Ligaments help keep the uterus in place, tilted forward over the top of the bladder. During pregnancy the uterus increases greatly in size, contains the placenta to nourish the embryo (later called the fetus), and expels the baby at the end of gestation.

The fundus of the uterus is the upper portion above the entry of the fallopian tubes, and the body is the large central portion. The cervix is the narrow, lower end, which

Figure 39-1 Female reproductive system in a midsagittal section. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 446, with permission.)

Figure 39-2 Female reproductive system in a anterior view and a longitudinal section. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 447, with permission.)

opens into the vagina. The outermost layer of the uterine wall is the epimetrium, a fold of the peritoneum. The myometrium is the smooth muscle layer; during pregnancy these cells increase in size to accommodate the growing fetus, and they contract for labor and delivery at the end of gestation.

The lining of the uterus is the endometrium, a highly vascular mucous membrane, part of which is lost and regenerated with each menstrual cycle. During pregnancy, the endometrium forms the maternal side of the placenta.

Vagina

The vagina is a muscular tube about 4 inches long that extends from the cervix to the vaginal orifice in the perineum. It is between the urethra and the rectum. The functions of the vagina are to receive sperm from the penis during sexual intercourse, to serve as the exit for menstrual blood flow, and to serve as the birth canal at the end of pregnancy.

After puberty, the vaginal mucosa is relatively resistant to infection. The normal bacterial flora of the vagina creates an acidic pH that helps inhibit the growth of most pathogens.

External Genitals

Also called the vulva, the female external genital structures are the clitoris, labia majora and minora, and Bartholin's glands. The clitoris is a small mass of erectile tissue anterior to the urethral orifice. Its function is sensory; it responds to

sexual stimulation, and its vascular sinuses become filled with blood.

The mons pubis is a pad of fat over the pubic bones, covered with skin and pubic hair. Extending posteriorly from the mons are the lateral labia majora and the medial labia minora; these are paired folds of skin. The area between the labia minora is the vestibule; it contains the openings of the urethra and vagina. The labia cover these openings and prevent drying of their mucous membranes. Bartholin's glands, also called vestibular glands, are within the floor of the vestibule; their ducts open into the mucosa at the vaginal orifice. Their secretion keeps the mucosa moist and lubricates the vagina during sexual intercourse.

Mammary Glands

Enclosed within the breasts and surrounded by adipose tissue, the mammary glands produce milk after pregnancy. The milk enters the lactiferous ducts, which converge at the nipple. The skin around the nipple is a pigmented area called the areola. The formation of milk is under hormonal control. During pregnancy, high levels of estrogen and progesterone prepare the glands for milk production. Prolactin from the anterior pituitary causes the actual synthesis of milk after pregnancy. The sucking of the infant on the nipple stimulates the release of oxytocin from the posterior pituitary gland, which in turn stimulates the release of milk.

The Menstrual Cycle

The menstrual cycle depends on follicle-stimulating hormone (FSH) and luteinizing hormone (LH) from the anterior pituitary gland and estrogen and progesterone from the ovaries. These hormones bring about changes in the ovaries and uterus. A cycle may be described in terms of three phases: menstrual phase, follicular phase, and luteal phase.

The menstrual phase involves the loss of the endometrium in menstruation, which may last 2 to 8 days, with an average of 3 to 6 days. At this time, secretion of FSH is increasing and several ovarian follicles, each with a potential ovum, begin to develop. Table 39–1 includes a summary of these hormones.

During the follicular phase, FSH stimulates growth of ovarian follicles and secretion of estrogen by the follicle cells. The secretion of LH is also increasing, but more slowly. FSH and estrogen promote the growth and maturation of the ovum, and estrogen stimulates the growth of blood vessels to regenerate the endometrium. This phase ends with ovulation, when a sharp increase in LH causes rupture of a mature ovarian follicle.

During the luteal phase, LH causes the ruptured follicle to become the corpus luteum, which begins to secrete progesterone in addition to estrogen. Progesterone stimulates further growth of blood vessels in the endometrium and promotes the storage of nutrients such as glycogen. As progesterone secretion increases, LH secretion decreases, and if the ovum is not fertilized, the secretion of progesterone also begins to decrease. Without progesterone, the endometrium cannot be maintained and begins to slough off in menstruation. FSH secretion begins to increase (as estrogen and progesterone decrease), and the cycle begins again. Although an average cycle is 28 days, cycles of 23 to 35 days may also be considered normal.

Male Reproductive System

The male reproductive system consists of the testes and a series of ducts and glands. Sperm are produced in the testes

and are transported through the reproductive ducts: epididymis, ductus deferens, ejaculatory duct, and urethra (Fig. 39–3). The reproductive glands are the seminal vesicles, prostate gland, and bulbourethral glands, all of which produce secretions that become part of semen.

Testes

The testes are located in the scrotum between the upper thighs, where the temperature is slightly lower than body temperature, which is necessary for the production of viable sperm. Each testis is about 1.5 inches long and 1 inch wide and contains the seminiferous tubules in which spermatogenesis (meiosis) takes place. In contrast to oogenesis, once started at puberty, spermatogenesis is a constant rather than cyclical process and usually continues throughout life. Also in the testes are specialized cells that produce the hormones testosterone and inhibin. Spermatogenesis is initiated by FSH from the anterior pituitary. LH from the anterior pituitary stimulates the secretion of testosterone, which contributes to the maturation of sperm. The secretion of inhibin is stimulated by testosterone; inhibin decreases the secretion of FSH, which helps keep the rate of spermatogenesis fairly constant. The functions of these hormones are summarized in Table 39–2.

A sperm cell consists of the head, which contains the 23 chromosomes; a flagellum, which provides motility; and the acrosome on the tip of the head, which contains enzymes to digest the membrane of the egg cell. Sperm from all the seminiferous tubules of a testis passes through tubules leading to the epididymis.

Epididymis, Ductus Deferens, and Ejaculatory Ducts

The epididymis is a tube about 20 feet long that is coiled on the posterior side of a testis. Smooth muscle within its wall propels sperm into the ductus deferens.

Also called the vas deferens, the ductus deferens extends from the epididymis in the scrotum through the inguinal

TABLE 39–1 HORMONES OF FEMALE REPRODUCTION

Hormone	Secreted By	Functions
<i>Follicle-stimulating hormone</i>	Anterior pituitary	Initiates development of ovarian follicles Stimulates secretion of estrogen by follicle cells
<i>Luteinizing hormone</i>	Anterior pituitary	Causes ovulation Converts ruptured ovarian follicle into corpus luteum
<i>Estrogen</i>	Ovary (follicle) Placenta	Stimulates secretion of progesterone by corpus luteum Promotes maturation of ovarian follicles Promotes growth of blood vessels in endometrium Initiates development of secondary sex characteristics
<i>Progesterone</i>	Ovary (corpus luteum) Placenta	Promotes growth of duct system of mammary glands Promotes further growth of blood vessels in endometrium Inhibits contractions of the myometrium during pregnancy
<i>Inhibin</i>	Ovary (corpus luteum)	Promotes growth of secretory cells of mammary glands
<i>Prolactin</i>	Anterior pituitary	Decreases secretion of FSH toward end of cycle
<i>Oxytocin</i>	Posterior pituitary	Promotes production of milk after birth Promotes release of milk

canal and into the abdominal cavity. The inguinal canal is an opening in the abdominal wall for the spermatic cord, a connective tissue sheath that contains the ductus deferens, testicular blood vessels, and nerves. Within the abdominal cavity, the ductus deferens extends over the top of the urinary bladder, then down the posterior side to join the ejaculatory duct on its own side.

Each of the two ejaculatory ducts receives sperm from the ductus deferens and the secretion of the seminal vesicle on its own side. Both ejaculatory ducts empty into the urethra.

Seminal Vesicles, Prostate Gland, and Bulbourethral Glands

The paired seminal vesicles are posterior to the urinary bladder. Their secretion is alkaline to enhance sperm motility and contains fructose to nourish the sperm. The duct of a seminal vesicle joins the ductus deferens on its side to form the ejaculatory duct.

The prostate is a muscular gland that surrounds the first inch of the urethra as it emerges from the urinary bladder. The secretion of the prostate is alkaline and contributes to sperm motility. The smooth muscle of the prostate contracts during **ejaculation**, causing the expulsion of semen from the urethra.

The bulbourethral glands are located below the prostate gland and empty into the urethra. Their alkaline secretion coats the interior of the urethra just before ejaculation, which neutralizes any acidic urine that might be present.

The alkaline secretions of the male reproductive glands ensure that sperm remain viable in the acidic environment of the vagina. The normal bacterial flora of the vagina create an acidic pH there, but the pH of semen is about 7.4 and permits sperm to remain motile.

Urethra and Penis

The urethra is the last of the male reproductive ducts, and its longest portion is within the penis. The penis is an external genital organ; its distal end is called the glans penis and is covered with a fold of skin called the prepuce or foreskin. Within the penis are three masses of erectile or cavernous tissue. Each consists of a framework of smooth

muscle and connective tissue that contains blood sinuses, which are large, irregular vascular channels.

When blood flow through these sinuses is minimal, the penis is flaccid (soft). Sexual stimulation causes the arteries to the penis to dilate; the sinuses fill with blood, and the penis becomes erect and firm. This is brought about by parasympathetic impulses. The culmination of sexual stimulation is ejaculation, which is brought about by peristalsis of the reproductive ducts and contraction of the prostate gland.

Aging and the Reproductive System

For women there is a definite end to reproductive capability; this is called menopause and usually occurs between the ages of 45 and 55. Estrogen secretion decreases, and ovulation and menstrual cycles become irregular and finally cease. The decrease in estrogen has other effects as well. Loss of bone matrix may lead to osteoporosis and fractures; an increase in blood cholesterol makes women more likely to develop coronary artery disease; and drying of the vaginal mucosa increases susceptibility to vaginal infections.

For most men, testosterone secretion continues throughout life, as does sperm production, although both diminish with advancing age. Perhaps the most common reproductive problem for older men is enlargement of the prostate gland, called prostatic hypertrophy. As the urethra is compressed, urination may become difficult. Prostatic hypertrophy is usually benign, but cancer of the prostate is one of the more common cancers in elderly men.

▶ FEMALE ASSESSMENT

Assessment of women's reproductive health can seem challenging because of the complex relationship of physical and psychosocial factors. Hormones not only affect a multitude of body functions, they also can influence moods and mental functioning. Reproduction involves not only physical processes, but also relationships, role identifications, and self-esteem issues.

Normal Function Baselines

Knowing about expected functioning of the reproductive system is the nurse's best preparation for nursing assessment. Regular, relatively pain-free shedding of an appropriate amount of the lining of the uterus is expected from puberty through midlife or later. Intercourse is normally expected to be free of pain and infection, to occur when desired by both partners, to be satisfying, and generally to result in pregnancy over a reasonable period (unless precautions are taken). Pregnancies are expected to last approximately 40 weeks and to produce a healthy child. Physical and psychological sexual characteristics and function including **libido** are expected to be adequately maintained by hormones. Sexual functioning, desire, and fertility are expected to change throughout the process of aging. Although individ-

uals may vary somewhat from these expected descriptions, these serve as a baseline for assessment of possible disorders. Chapter 40 further defines specific reproductive system disorders.

Much of what happens in female reproductive system disorders occurs inside the body and may not show external signs. Skill in asking appropriate questions, documenting patient statements, and describing observations is essential. Descriptions of symptoms should be thorough and follow the WHAT'S UP? format described in Chapter 1. Short quotes of the patient's own words to describe change that you have noticed may add valuable information, but be careful to use critical thinking skills when interviewing and documenting, rather than just quoting indiscriminately. Because many signs and symptoms of reproductive system disorders occur in a cyclic fashion, the patient may be asked to keep an accurate written record of occurrences, noting times and dates to identify patterns.

History

The nurse is often responsible for recording initial history and physical assessment data. Breast history questions include breast-feeding history; knowledge and practice of breast self-examination; discomforts; breast changes; and presence of any lumps, thickening, or nipple discharge.

Menstrual history questions include age of **menarche** (beginning of menstrual periods) and age of menopause (if applicable), length of cycles, length of menses, menstrual regularity, amount of bleeding, presence of clots, discomforts, and measures taken to relieve discomforts.

Obstetrical history includes number of pregnancies, pregnancy outcomes, and complications. These are generally documented using abbreviations of Latin words: G = pregnancies (from the Latin word *gravida*); P = births, whether alive or stillborn (from the Latin word *para*); A = abortions, whether spontaneous or therapeutic (from the Latin word *abortus*; a spontaneous abortion is sometimes called a miscarriage); and Roman numerals following the letter to specify the number of each. For example, three pregnancies, twins, one single birth, and one spontaneous abortion, are recorded as GIII, PIII, AI. This may also be written as G₃P₃A₁. Note, however, that some hospitals use different notation, further delineating history, such as, number of premature or full term births, number of living children, and number of therapeutic abortions. If uncertain of how to document, check your institutional history forms or ask the person in charge.

Medical intervention history includes any testing, operations, or treatments done on the reproductive organs and excretory system. Medications the patient is taking (for whatever reasons), height-to-weight ratio, and marked changes in weight may also provide significant data for diagnostic and care planning purposes concerning reproductive system disorders.

LEARNING TIPS

Remember the word *gravid*a by thinking of gravity and that one is generally heavier when pregnant.

Sexual history questions include whether the patient is sexually active, sexual preference, number of partners, history of sexually transmitted disease (STD), knowledge and practice of STD risk reduction, history of participation in high-risk sexual activities, birth control knowledge and practice, and whether their level of sexual functioning is satisfactory. Many nurses feel awkward asking these questions, and patients may also feel some uneasiness with this line of questioning. A matter-of-fact attitude, an assurance of confidentiality, and an adequate explanation about why the information is needed tend to encourage patient comfort and cooperation.

LEARNING TIPS

There are many things to remember when asking health history questions. Making up an index card for your pocket or purchasing a prepared one from a medical bookstore can provide a handy reference.

Breast Assessment

Palpation

Palpation is the most important assessment technique for breast examination, because it can be used to identify alterations from normal consistency, to confirm the presence of lumps, and to locate areas of tenderness. Even mammograms are not sensitive enough to detect a small percentage of masses that can be felt by the patient or health care provider.

Breast Self-Examination

Self-palpation during breast self-examination (BSE), if done regularly and thoroughly, may be even more sensitive than physician or nurse palpation, because the patient becomes so familiar with her own breasts that she is more likely to notice subtle changes that an infrequently visited health practitioner might overlook. BSE is one of the most important health protection skills that nurses can teach to women. The few moments spent monthly on this activity may mean the difference between life and death or comfort and extreme suffering for women.

Patient Teaching

The examination procedure is simple. BSE should be done regularly once per month. One week after the beginning of the menstrual period is a good time to do BSE because some women's breasts become swollen and feel lumpier around

the beginning of menses. For women who no longer have a regular menstrual period, any regular monthly schedule is fine. Although most women's breasts are not exactly the same size, marked differences between the breasts or a change in the size of one breast should be checked with a health care provider. Puckering or dimpling of skin, asymmetrical movement, and different pointing position of the nipples should also be reported to a health care provider. Whether the breasts are examined in parallel lines, a spiral formation or a wedge pattern is probably insignificant. It is important, however, to encourage that the examination be methodical and cover all areas of the breast, the tail of Spence, and the axilla (Fig. 39-4).

LEARNING TIPS

Some women do BSE the day their telephone bill arrives each month, because it is a dependable monthly reminder.

Figure 39-4 Breast self-examination. (From Venes, DJ (ed): *Taber's Cyclopedic Medical Dictionary*, ed 19. FA Davis, Philadelphia, 2001, with permission.)

Diagnostic Tests of the Breasts

Ultrasound and Mammography

Further assessment of the breast may be done by several methods. Ultrasound examination is done by bouncing high-frequency sound waves off the tissues within the breast to determine the density of the tissues and to map the breast structures (Fig. 39–5). This is mainly useful for distinguishing fluid-filled (**cystic**) lumps from solid tumors but may also be used to guide a needle for fine needle aspiration of fluid or core needle biopsies.

Mammography is a radiographic (x-ray) examination of the breast. A special machine is used that spreads and flattens the breast tissue to a thin layer to more effectively show benign and malignant growths, which might be hidden by breast structures on typical chest examination. (See Chapter 10.) Generally at least two radiographs are taken of each breast, with the machine compressing the breast top to bottom and side to side to give comparison views of any lumps from more than one angle. If suspicious or unclear spots are seen, additional views may be taken. The American Cancer Society recommends from age 20 throughout life that women do monthly BSE, from ages 20 to 39 that they add a breast examination by a health professional every 3 years, and from age 40 that they have a yearly mammogram and breast examination by a health professional. Those who experience breast symptoms or have a strong family history of breast cancer may be advised to have more frequent examinations.

cystic: baglike

mammography: mammo—breast + graphy—recording

PATIENT TEACHING. Patients preparing for mammography should be advised to bathe and not to apply deodorant, powder, or any other substance to the upper body because these may cause false shadows on the test. They should be instructed that if a shadow is seen on a mammogram, further testing will be done to determine the reason for the shadow.

Thermography, Tomography, and Magnetic Resonance Imaging

There are several other less commonly used methods for diagnosis of breast disorders. Thermography is a method of mapping the breast using photographic paper, which records temperature variations throughout the tissue in different colors. Tomography takes very precise x-ray pictures of the breast, layer by layer, as it would look if it were in thin slices, and then stores these pictures in a computer. This allows for precise measurement of the position of tumors without the displacement caused by flattening the breast for a mammogram. Tomography, however, is much more expensive than mammography, so it is not a practical method to use for general screening of all women to detect possible breast cancers. Magnetic resonance imaging (MRI) uses radiofrequency radiation and magnetic fields to map the breast tissue. The equipment needed for this method is expensive, and it is unavailable in some areas.

PATIENT TEACHING. Ask patients preparing for MRI whether they have any metal inside their bodies, such as orthopedic wires, metal sutures, or artificial joint replacements, because heat is generated by the MRI and the procedure may be contraindicated.

Figure 39-5 Diagnostic testing by ultrasound. (Modified from Cavanaugh, BM: Nurse's Manual of Laboratory and Diagnostic Tests, ed 3. FA Davis, Philadelphia, 1999, p 687, with permission.)

Biopsy

If suspicious lumps or lesions are found in the breast by any of these methods, they may be checked using one of the other methods and then further assessed by biopsy. This procedure involves removing a small portion of tissue, fluid, or cells from the breast or lymph nodes for microscopic examination. This may be done by surgically removing a portion of tissue or by aspirating fluid or cells through a needle that is placed into the lump or lesion. Needle biopsies are often done with local anesthetic and may take place in a clinic or physician's office. More extensive biopsies may require a general anesthetic. A frozen section examination may be done in the laboratory by moistening and rapidly freezing a section of tissue, slicing it very thinly, and immediately examining it by microscope. This allows for diagnosis to be made during the course of an operation, so that the patient is spared an additional later operation for removal of cancerous tissue.

Nursing Care

As with any surgical intervention, be prepared to set out the sterile equipment and supplies needed for the procedure and ensure that a signed consent has been obtained. Following the biopsy, assess the patient for excessive bleeding and instruct about signs of impairment of healing processes. It is important that biopsy samples be clearly labeled, packaged appropriately for transport to laboratory facilities, and delivered promptly. Consult the laboratory for information about the transport container and whether a cell fixative is required in the container.

Assessment of the patient's psychological condition during breast diagnosis procedures is essential. Most women know someone who has had breast cancer. Although breast cancer screening procedures can seem routine to health care workers, they may be a cause of much anxiety for patients and their families. An understanding and calm nurse who can explain the procedures can help the assessment phase to be less traumatic.

Additional Diagnostic Tests of the Female Reproductive System

There are many tests to assess reproductive system function; this is presently an area of rapid change. The names of the individual procedures may also vary among institutions or according to particular methods used (e.g., a **salpingoscopy** is also called a fallopscopy, and a laparoscopy is the same as a peritoneoscopy). For this reason, this chapter is limited to general descriptions of categories of medical and surgical assessment procedures rather than attempting to name all tests.

Hormonal Tests

Hormonal tests are commonly used to assess functioning of the endocrine system as it relates to reproduction. They

may be used to measure potential fertility, to find reasons for abnormal menses, to assess hormone-producing tumors, and to determine whether treatments to adjust hormone levels have been effective. Several hormones may be assessed at any one time. Some hormonal tests are time specific, and the samples can be useless if not gathered within a certain time range.

NURSING CARE. Consult institution policy for specific instructions for each test. Explain the procedure to the patient and provide support. Women who are undergoing hormonal tests may feel embarrassed, worried about their femininity and potential fertility, and depressed because of repeated tests, often with little positive result. Some may fear loss of their spouse's love (and perhaps relationship) if they are diagnosed as infertile.

Pelvic Examination

The pelvic examination allows visual inspection of the vagina and cervix, as well as sampling of mucus, discharge, cells, and exudates. Palpation of portions of the reproductive system and some treatments may also be done as part of the procedure.

NURSING CARE. Be prepared to assist the health care provider with the examination. Explain the procedure as you set out the supplies. Vaginal specula range from tiny vaginal sizes to extra large (Fig. 39–6). The appropriate size is related to the size of the woman's (or child's) pelvis and whether she has had children or not. For a small child a nasal speculum may be used. A sterile basin of warm tap water to warm the sterile speculum and a small amount of surgical lubricant should be placed near but not on the speculum (because some tests may be affected by water or lubricant). Two clean gloves for the examiner should be placed nearby, and a light should be adjusted to illuminate the area. Other equipment may be set out according to the tests or treatments that will be carried out during the pelvic examination.

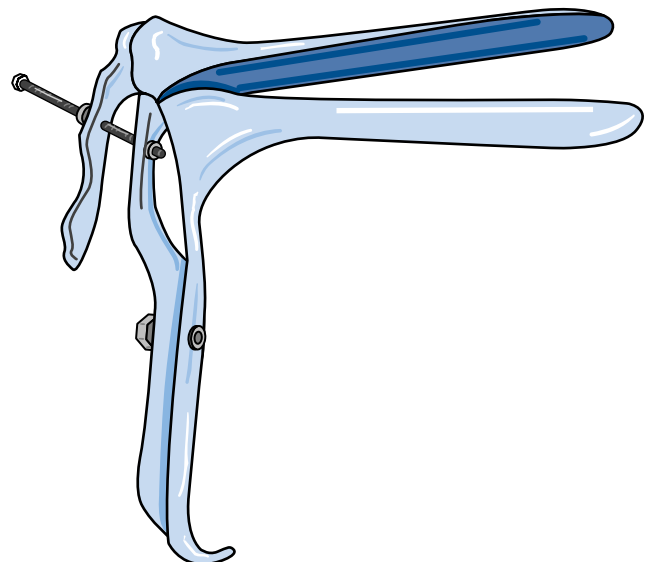

Figure 39-6 Vaginal speculum.

salpingoscopy: salpingo—tube + scopy—looking

Instruct the patient to empty her bladder before the examination. Place the patient in a gown (without underwear) either on her back with her arms resting down at her sides to aid relaxation of abdominal muscles or in a side-lying position, according to the health care provider's preference. Provide a sheet turned so that there is plenty of room for the legs to spread while the sheet still covers the patient on the sides.

Bimanual Palpation

Because much of the reproductive system is not visible even with a speculum, **bimanual** palpation is often done during a pelvic examination. One hand is placed on the abdomen and the other gloved hand is inserted deeply into the vagina. The uterus and **adnexa** are moved about between the two hands to feel the size, shape, and consistency of the uterus and adnexa and to check for any abnormal growths.

NURSING CARE. Explain the procedure and support the patient. Some women may be fearful, embarrassed, or tense and may find the procedure uncomfortable. Active relaxation strategies may decrease discomfort.

CRITICAL THINKING

Reproductive Assessment

How might the age of the patient change your approach, plans, and teaching for patients who have disorders of the reproductive system? Consider your approach, plans, and teaching for each of the following scenarios.

1. A 2-year-old child is brought into the clinic by her mother because she has a foul smell coming from her perineal area and a slight yellowish discharge from her vagina.
2. A 19-year-old woman comes to the doctor's office where you work for renewal of her yearly birth control pill prescription. Your employer enforces regular checks for cervical changes by renewing the prescription only after a Papanicolaou (Pap) smear is done. As you start setting out the Pap smear materials, your patient expresses some reluctance to have a Pap smear today because she is so sore already.
3. Your 56-year-old patient comes in to "get things checked out" because she hurts every time that she and her husband have intercourse.

Answers at the end of chapter.

Cytology

Cytology is the study of cells taken as biopsies. There are several ways that cells from the reproductive system may be removed for microscopic examination. During a Pap smear, one or more small samples of cells are gently scraped away from the surface of the cervical canal using a small wooden spatula, tiny cylindrical brush, or long cotton-tipped applicator, and then they are smeared or rolled onto microscopic

slides for viewing. Cells may also be collected by **conization**, which involves removing a small cone-shaped sample from the cervical canal, or by punch biopsy, which removes a small core of cells. Endometrial biopsy specimens are samples of cells taken from the lining of the uterus by scraping with a small spoon-shaped tool called a **curet**, which is inserted through the cervix. Small biopsy specimens may also be taken by cutting or removing a suspicious lesion. Cells may be observed for changes indicative of hormonal secretion, cellular maturation, or abnormalities such as are seen with viral growths and cancerous or precancerous conditions.

NURSING CARE. Add appropriate sample collection materials and fixatives to the pelvic examination supplies according to the type of cytological examination being done. For a Pap smear, this usually includes one or two clear glass slides labeled with the woman's name, fixative spray, cytobrush or wooden cervical spatula, and transport box for the slides. For larger cell samples, a sterile biopsy collection container labeled with the name and site of biopsy and a bottle of fixative solution should be placed close to the pelvic examination supplies. The procedure manual or health care provider is consulted concerning the types of instruments to put out for biopsies other than Pap smears. Cells die and degrade rapidly once removed from the patient, so they must be packaged securely (generally in a preservative solution or sprayed with a fixative) for transport to laboratory facilities.

Prepare the patient by explaining the procedure and providing support. The woman may be fearful of cancer or other abnormality. Removal of the sample may cause pain, bleeding, swelling, or, later, inflammation, so the patient is monitored after the procedure and alerted to watch for and report these complications if they occur. Document the woman's status after the procedure on the chart and record that the sample was sent to the laboratory.

Swabs and Smears

Swabs and smears are done to determine which microorganisms are causing disease and which antibiotics should be used.

NURSING CARE. Add sample collection materials, including swabs, slides, and a chlamydia collection kit, to pelvic examination equipment if symptoms of vaginal infection are present. It is important to place samples of discharge into culture media that support growth. Clear media are required for some and charcoal media for others, so both types should be set out. Viral swabs require a special collection kit. Chlamydia samples are especially difficult to transport to laboratories, and special kits are available for this pathogen. Some microorganisms, such as yeasts and *Trichomonas*, can be identified well from smears on slides. Wet

bimanual: bi—two + manual—hands
adnexa: ad—together + nexa—to tie (usually refers to ovaries and tubes)

conization: coniz—cone-forming + ation—process
curet: scoop

mounts are smears of discharge spread onto a slide. These must be taken to the microscope immediately after they are obtained. Sodium chloride and potassium hydroxide are dropped onto individual wet mount slides before they dry to aid in identification of some microorganisms. Support the patient, who may be anxious about possible sexually transmitted diseases and effects on relationships.

Sonography

Ultrasound assessment (also called sonography) may be done to determine size, shape, development, and density of structures associated with the female reproductive system, as well as fetal measurements and some types of prenatal diagnoses. This procedure is especially useful for differentiating cysts from solid tumors, as well as locating **ectopic** pregnancies and intrauterine devices. Ultrasound may also be used to guide needles for obtaining samples of fluid or cells. Either external or vaginal transducers may be used to send and receive the signals for this procedure. Vaginal transducers are placed in a plastic sheath before insertion into the vagina. A full bladder may be required for some ultrasound tests.

NURSING CARE. Explain the procedure and support the patient. The pressure of the transducer on the skin may be painful if the underlying structures are inflamed or swollen or if the bladder is very full.

Radiographic Procedures

Several radiographic procedures may be used for diagnosis of reproductive system problems. Computed tomography (CT) scanning and MRI are used to locate tumors of the reproductive system. Structures of the female reproductive system may also be outlined by taking x-ray pictures of cavities that have been filled with a radio-opaque substance.

During a **hysterosalpingogram**, dye is injected into the uterus until it comes out the ends of the fallopian tubes. This test is useful for identifying congenital abnormalities in the shape of the uterus and blockages of the fallopian tubes.

NURSING CARE. Prepare the patient for this test according to the x-ray department manual protocol and the physician's orders (they may include a laxative, suppository, or enema). Ensure that the patient understands the procedure and that appropriate consents are signed if required. Ask about allergies to iodine or shellfish, because contrast media may contain iodine. Notify the charge nurse immediately if the patient reports an allergy. After the procedure, assess for nausea, light-headedness, and signs of allergy and promote comfort, because some cramping may occur. Discharge teaching should include signs of infection and advice that the x-ray dye may stain clothing, so a pad should be worn until any vaginal drainage stops.

Endoscopic Examinations

Several types of endoscopic examinations are done to visually inspect internal areas to diagnose (and sometimes treat) reproductive system disorders. The names of the tests vary according to the area inspected, but all these generally make use of a fiberoptic light and lens system, which is inserted through a tube called a cannula into a small incision. A laparoscopy is done to view the abdominal cavity and is useful for identifying problems such as endometriosis (Fig. 39-7). A salpingoscopy is performed to see the inside of the fallopian tubes and a **hysteroscopy** to see the inside of the

hysterosalpingogram: hystero—womb + salpingo—tube + gram—record

hysteroscopy: hystero—womb + scopy—looking

uterus. A binocular microscope is used with an endoscope that is introduced into the vagina to closely study lesions of the cervix during a **colposcopy**. During **culdoscopy**, an endoscope is introduced into the vagina and through a small incision in the vagina into the cul-de-sac of Douglas, a cavity behind the uterus (Fig. 39–8).

NURSING CARE. Preoperatively the patient is prepared for an endoscopic examination according to institutional protocol. This generally involves asking the patient whether she has fasted as instructed, assessing vital signs, recording the time of last voiding, helping the patient into the operating room gown, and obtaining a signature on the consent form. General anesthesia may be given for some endoscopic procedures. Explain what to expect and provide support for the woman. The patient may be anxious about possible disorders.

Postoperatively, provide comfort measures. These procedures produce almost no blood loss. The woman may experience pain in the neck, shoulders, and upper back if carbon dioxide (CO₂) gas was pumped into the body compartment being examined. Called **insufflation**, this is done to increase the distance between structures, so that it is easier for the physician to see and diagnose possible disorders. The CO₂ remaining after completion of the examination travels to the highest level of the body before being absorbed, so lying flat for a few hours after the examination may decrease discomfort. If incisions were made through the abdominal wall for insertion of the endoscope and for insufflation, these are tiny and a Band-Aid or small dressing is applied.

colposcopy: colpo—vagina + scopy—looking

culdoscopy: culdo—cul de sac + scopy—looking

insufflation: in—in + suffl—to blow + ation—process

PATIENT TEACHING. Advise the patient to observe the sites for redness, bleeding, or any drainage, returning to the physician promptly if these occur and otherwise approximately 1 week later for suture removal (according to physician preference). If the endoscopic procedure was done transvaginally, advise the patient to wear a perineal pad until the drainage stops, to report any bright bleeding after the operative day, and to report any fever or foul-smelling discharge.

Further detail about some specific forms of the tests that have been described in this chapter are included with the disorders to which they apply in Chapters 40 and 42.

► MALE ASSESSMENT

As with the female reproductive system, the male reproductive system is a complex interaction of both physical and psychosocial factors. Unlike women, however, men may find it much more difficult in our society to talk about or admit to having problems related to reproductive health. From toilet training through adulthood, men are expected to have behaviors associated with maleness. Unfortunately, by the time some boys reach manhood, their male identity is defined by the successful functioning of their sex organs.

One of the important first steps in obtaining a male reproductive assessment is providing a comfortable, nonjudgmental, confidential atmosphere for discussion. This means you must first be knowledgeable and comfortable with sexual issues. Nurses do not hesitate to ask female patients about their menstrual history and should be equally comfortable in asking men about their **erection** or ejaculation history. Be open and straightforward with all questions and answers. It may be necessary at times to use more commonly expressed sexual words instead of medical terminology. You will discover that many men do not know the function of their prostate gland or the difference between ejaculation

Figure 39-8 Culdoscopy. (Modified from Cavanaugh, BM: Nurse's Manual of Laboratory and Diagnostic Tests, ed 3. FA Davis, Philadelphia, 1999, p 566, with permission.)

and **orgasm**. Use the assessment as an opportunity to teach men the facts about their own sexual functioning.

History

There are some basic questions to ask a male patient during an assessment of sexual functioning. These include the following:

1. “Are you having any problems getting or keeping an acceptable erection?” Additional questions might be whether the patient can have an erection anytime (with or without a sex partner); if erection problems occur when he is under stress or taking medication; or if he is involved in substance abuse. “Do you have erections first thing in the morning or during sleep?” If the patient is able to get an erection, is it straight and firm enough for penetration? Does the erection last long enough for him to reach orgasm?
2. “Are you able to ejaculate during orgasm? Do you have any painful sensations related to the experience? Does any fluid come out during the ejaculation process, and if so, is it a small, moderate, or large amount, and is it clear, cloudy, or brown in color?” The amount and color may de-

pend on whether the patient has had recent sexual activity or genitourinary surgery or may indicate a congenital anomaly or infection.

3. For patients younger than 40 years old: “Do you practice monthly testicular self-examinations?” Men younger than age 40 should be encouraged to perform monthly testicular examinations as a cancer prevention measure.
4. For patients older than 40 years: “When was the last time you had a prostate examination?” A digital rectal examination (DRE) should be a regular part of a man’s routine physical after age 40. Prostate cancer is treatable when detected early.

A more complete male sexual history not only includes information about sexual practices but also medical information. A variety of assessment data may affect a man’s current and future sexual functioning (Table 39–3).

Physical Examination

The physical examination is generally performed by a physician or someone trained in physical assessments. The examination begins with the patient’s general appearance. He

TABLE 39-3 MALE SEXUAL ASSESSMENT GUIDELINES

Subject	Data to Collect	Possible Impact
Medication	Prescribed or over-the-counter medications that affect sexual desire, erection, or ejaculation (refer to Table 41-3)	Loss of sexual desire, erection, ejaculation, orgasm, or fertility
Family history	Any genetically transmitted diseases (e.g., heart problems, hypertension, diabetes), mother’s use of DES during pregnancy	High risk for circulation problems that interfere with erections, congenital anomalies of reproductive organs
Personal habits	Tobacco use, caffeine intake, substance abuse/recreational drugs, steroid use, frequent use of hot tubs, long-distance driving or bike riding	Decreased blood flow to penis, loss of erection; decreased testosterone (male hormone) interferes with erection and fertility; excessive heat decreases sperm production
Personal health history	Mumps during adolescence, recent infection or fever	Decreased sperm production
Mental health	Stressful personal problems or job situation, problems with sexual partner, performance anxiety or depression	Decreased sexual desire and ability to have an erection
Circulatory/respiratory	Heart problems/surgery, high blood pressure, sickle cell disease, lung disease, sleep apnea	Decreased circulation—unable to have usable erection; decreased respiratory—activity intolerance, loss of erection, congenital anomalies of reproductive organs
Gastrointestinal	Liver infection/disease, surgery, bowel problems/surgery	Liver—decreased testosterone and increased estrogen, loss of erection; gastrointestinal/bowel—pain, loss of desire; surgery—loss of blood or nerve flow
Musculoskeletal	Painful joints, back injury/surgery, pelvic/lower back nerve damage	Pain, loss of desire; limited movement/positions, loss of erection, ejaculation, and orgasm
Neurological	Stroke, multiple sclerosis, Parkinson’s disease	Limited movement/positions, loss of sensations, loss of control
Metabolic/endocrine	Diabetes, obesity, thyroid problems	Diabetes mellitus—circulation problems, retrograde ejaculation, nerve damage; obesity—decreased male hormones, excess female hormones
Genitourinary	Congenital deformity of penis/testicles, prostate problems/surgery, erection/ejaculation problems, sexually transmitted diseases	Difficulty with penetration, erection problems, retrograde ejaculation, infertility
Sexual practices	Frequency of intercourse (including positions, timing with female ovulation cycle), masturbation, use of lubricants or birth control methods, problems with erectile dysfunction or premature ejaculation	Decrease in quality and quantity of sperm that reach the female egg

DES = diethylstilbestrol.

is observed for male patterns of hair growth on the head, face, chest, arms, and legs. Normal male pubic hair pattern is “triangle up,” hair growth up toward the umbilicus. The patient’s height and muscle mass are noted. Men are commonly taller than 5-feet 6-inches tall, weigh more than 135 pounds, and have shoulders that are broader than their hips. The presence of excess breast tissue may indicate **gynecomastia**, an excess of female hormones. Abnormal findings in either hair patterns or muscle mass often indicate a hormone imbalance.

The penis, scrotum, and testes (testicles) are examined by observation and palpation. On observation, the penis is normally flaccid (soft) and hanging straight down. The size can vary greatly and should not be a concern unless it is unusually small (microphallus) or edematous. The left testis generally hangs slightly lower in the scrotum than the right.

The penis is examined for warts, sores (evidence of sexually transmitted diseases), swelling, curves, or lumps along the shaft. The examiner also makes sure the urethral opening is at the tip of the penis and not on the underside of the shaft (**hypospadias**). If the man is not **circumcised**, the foreskin should be pulled back carefully and the area inspected for signs of inflammation or foul-smelling discharge. The practitioner should be sure to replace the foreskin in the forward position after the examination is completed.

The scrotum and testes are carefully examined and palpated. Both testes should be present and a normal size (approximately 2 cm × 4 cm). The testes are egg shaped and should feel smooth and rubbery when lightly palpated between the thumb and fingers. The epididymis can be felt along the top edge and posterior section of each testis. The testes and scrotum are palpated for any lumps, cysts, or tumors. If a fluid-filled mass (**hydrocele**) is found, further evaluation should be done. A simple noninvasive test called **transillumination** is used to determine if the mass is fluid filled or solid. With the room lights out, a flashlight is held behind the scrotum. If the mass is fluid, a red glow appears; if it is solid, it appears opaque. The spermatic cord (made up of veins, arteries, lymphatics, nerves, and the vas deferens) is palpated and should feel firm and threadlike. If a condition called a **varicocele** is present, the area feels like a bag of worms. A varicocele, which is swelling of the veins of the spermatic cord, is one of the most common problems associated with male infertility.

The male patient is also examined for inguinal hernias by pressing up through the scrotum into each of the inguinal rings while asking him to cough or bear down. Each side is examined separately while he is in the standing position. A hernia feels like a pulsation against the examining fingertips.

A digital rectal examination may be done by an experienced practitioner. During DRE, the prostate gland is palpated by inserting a gloved, lubricated finger into the rectum

while the man is in a knee-to-chest position. The entire posterior lobe of the gland can be felt this way. The gland should feel slightly firm and without any lumps. If the prostate gland feels very hard or soft, enlarged, or contains any lumps, a rectal ultrasound with needle biopsy is often ordered. A swollen, painful prostate generally indicates that an infection is present. Remind all men older than age 40 that unless they have had a complete removal of the prostate gland they still need a DRE performed every year. Many men are under the impression that any prostate surgery means the gland has been completely removed. When simple surgery is performed, prostate tissue is left in the body and will begin to regrow over time. This prostatic tissue can become cancerous and needs to be monitored with a yearly DRE.

Testicular Self-Examination

All men after puberty should do monthly testicular self-examination (TSE) to detect any tumors or other changes in the scrotum. See Box 39–1 for instructions that can be used to teach a man how to examine his testicles. Refer also to Figure 39–9.

Breast Self-Examination

Although breast cancer in men is rare, it can occur. Men, like women, should perform monthly breast self-examination.

Diagnostic Tests of the Male Reproductive System

Ultrasound

An ultrasound may be done to diagnose or evaluate a variety of male reproductive or genitourinary problems. A transrectal ultrasound may be done to diagnose prostate cancer. For this procedure, a rectal probe transducer is inserted into the rectum and sound waves are used to evaluate the

BOX 39-1 Guidelines for Monthly Testicular Self-Examination

The examination is easiest during or right after a warm shower or bath, when the scrotum is relaxed and the testicles are hanging low. Choose one day a month to always do the examination.

1. Raise the penis up out of the way and look for any difference in size or shape of each side of the scrotum (sac). The left side usually hangs a little lower than the right.
2. Using both hands, hold the scrotum in the palms. Begin, one at a time, to gently roll each testicle between the thumb and first three fingers, feeling for any lumps or hard spots.
3. Identify the parts. The testicles should feel round, smooth, and egg shaped. The epididymis along the top and back side should feel soft and a little bit tender. The spermatic cord is a tube that runs from the epididymis and usually feels firm, smooth, and movable.
4. See your doctor immediately if you feel any lumps or unusual changes.

gynecomastia: gyneco—female + mastia—breast

transillumination: trans—across + illumin—light + ation—process

Figure 39-9 Testicular self-examination.

prostate gland. An enema may be ordered before the procedure. No special aftercare is necessary.

Pelvic or scrotal ultrasound helps evaluate and locate masses. Ultrasound may also be done to guide the needle during a fine needle biopsy.

Cystourethroscopy

Cystourethroscopy may be done to evaluate the degree of obstruction by an enlarged prostate gland. For this procedure, a Foley catheter is inserted and a dye is injected into the bladder. Radiographs are taken with the dye in the bladder and while voiding after the catheter has been removed.

NURSING CARE. The procedure is explained to the patient, and possible allergic reaction to dyes is assessed and communicated to the physician as necessary. The patient is instructed to void before the procedure. A sedative or analgesic may be ordered to help the patient relax during the procedure.

After the procedure, intake and output are measured for 24 hours and alteration from the patient's normal pattern or absence of urination are reported to the physician. Fluids are encouraged to promote excretion of the dye.

Laboratory Tests

PROSTATE-SPECIFIC ANTIGEN. Normal value of prostate-specific antigen (PSA) is less than 4 ng/L. PSA is a glycoprotein produced by prostate cells. An elevated level indicates prostatic hypertrophy or cancer.

PROSTATIC ACID PHOSPHATASE. Normal value of prostatic acid phosphatase (PAP) is less than 3 ng/mL. PAP is an

enzyme that normally affects metabolism of prostate cancer cells. An elevated level indicates prostate cancer.

OTHER TESTS. If prostate cancer is suspected or diagnosed, additional tests may be done. Acid phosphatase may be elevated in metastatic prostate cancer. Alkaline phosphatase and serum calcium levels may be elevated if metastasis to the bone has occurred.

Tests for Infertility

Various hormone levels may be measured, including FSH, LH, testosterone, and adrenocorticotrophic hormone (ACTH) to help determine causes of infertility in male patients.

Semen analysis may be done to provide information about infertility or to evaluate whether a vasectomy has been effective. Semen may be analyzed for sperm count, motility, and shape. Other tests determine whether the semen contains adequate nutrients to support sperm, whether antibodies to the sperm are present, and the ability of the sperm to penetrate an ovum.

NURSING CARE. The patient is instructed to refrain from ejaculation for 3 days before collecting the semen sample to avoid altering findings. Generally specimens are collected on three separate occasions over a period of 4 to 6 days. Masturbation and ejaculation directly into a sterile container are recommended to avoid loss of semen. Condoms and lubricants should be avoided. The sample should be taken to the laboratory within 1 hour of collection. Additional tests of the male reproductive system are discussed in Chapter 41.

REVIEW QUESTIONS

- Which male reproductive duct carries sperm into the abdominal cavity?
 - Urethra
 - Epididymis
 - Ductus deferens
 - Ejaculatory duct
- Which of the following is the usual site of fertilization?
 - Ovary
 - Uterus
 - Vagina
 - Fallopian tube
- According to the American Cancer Society, what is most effective method for detecting breast cancer?
 - BSE
 - Mammogram
 - Clinical breast examination
 - One or more of the above according to age guidelines
- Which of the following items should be placed out in preparation for a Pap smear?
 - Syringe
 - Vaginal speculum in water
 - Dry, sterile vaginal speculum
 - Vaginal speculum with lubricant
- Which of the following techniques is recommended for male patients younger than age 40 to detect prostate cancer early?
 - Yearly DRE
 - Monthly STE
 - Yearly PSA
 - Bimonthly bimanual examination
- Anna Brown has just had a laparoscopy to investigate the causes of her infertility. The nurse should instruct her to lie flat in the bed for a few hours for which of the following reasons?
 - She will rip out the stitches in her 4-inch long abdominal incision.
 - Her blood pressure will be extremely low because of blood loss.
 - The carbon dioxide left over from the test will travel upward and cause pain.
 - Her uterus needs to be at the same level as her heart to prevent excessive swelling.

Answers to CRITICAL THINKING

Reproductive Assessment

- Calm fears. Explain simply. Allow the parent to stay with the child if appropriate. Consider whether the child has possibly been abused. (If so, evidence needs to be collected and a report filed with the appropriate child protection authorities.) Place a nasal speculum out for examination. Place a forceps out for removal of a possible foreign body (not uncommon at this age). Teach that this is a normal part of the body that is to be protected and taken care of.
- Assess knowledge and maturity. Set out supplies for a Pap smear and for swabs and smears. Teach while getting supplies ready. Explain that vaginal soreness generally needs to be treated and that the doctor must know more about the problem to do so effectively. Explain that inflammations can interfere with Pap smear results, so it may have to be repeated later after treatment. Explain culture and sensitivity testing. Teach about risk reduction and inform that oral contraceptives do not offer a barrier.
- Try to put the woman at ease through general conversation. Set out supplies for a Pap smear (if needed) and for swabs and smears. Teach while getting supplies ready. Discuss aging and the effects of decreased estrogen in general and specifically on vaginal tissues. Inform that there are several ways to deal with the problems resulting from decreased estrogen, such as oral hormonal replacements, water-soluble vaginal lubricants, vaginal creams, estrogen patches, and estrogen receptor modulator medication.

6. What nursing care will you provide for patients with each of the covered disorders?
7. How will you know if your nursing interventions have been effective?

Reproductive system disorders can be frightening, irritating, frustrating, embarrassing, and in some cases fatal. They involve not just body parts but also roles, relationships, and sense of identity and purpose in life. Nurses can play an important role in helping women with these disorders. Women's health is an area where much research is being done. The Nurses' Health Study, conducted at Harvard Medical School, is a large ongoing study on many topics related to women's health. Learn about it at www.nurseshealthstudy.org.

► BREAST DISORDERS

Benign Breast Disorders

Much has been done in recent years to educate the general public concerning breast cancer. It is the leading cause of death among women ages 35 to 54; the mortality rate has not changed significantly since 1930.¹ Heightened awareness of the risks of breast cancer, however, sometimes results in excessive anxiety among women with benign breast conditions. The following section covers benign, or noncancerous, breast disorders.

Cyclic Breast Discomfort

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. The most common breast symptoms result from cyclic variations in hormone levels. Swelling, tenderness, and sometimes pain (**mastalgia**) can be related to hormone-mediated changes within the breast tissues that prepare them for their potential role of breast-feeding.

TREATMENT. If persistent or severe, these symptoms may be treated with medications that modify hormone levels. Explaining that cyclic discomfort is temporary and not from a disease helps to allay fears.

Fibrocystic Breast Changes

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. Overresponsiveness of cells to hormonal stimulation may cause long-term changes resulting in replacement of normal tissue with fibrous tissue, **ectasia** (overdevelopment) of cells, and blockage of ducts so that cysts form around trapped fluid. This makes the breasts feel somewhat hard and lumpy.

TREATMENT. Generally no treatment is necessary. Although **fibrocystic** changes are not cancerous, more frequent mammography or ultrasound may be advised because the fibrocystic changes may make it more difficult to feel early cancerous lumps during breast self-examination (BSE) and some types of breast cysts are associated with a higher cancer risk.²

mastalgia: mast—breast + algia—pain

ectasia: extension

fibrocystic: fibro—fibrous + cystic—saclike

Mastitis

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. Breast infection with inflammation (**mastitis**) occurs as a result of injury and introduction of bacteria into the breast. This condition most commonly occurs while breast-feeding. The breast becomes swollen, hot, red, and painful and may form an abscess.

TREATMENT. Mastitis may be treated either with antibiotics or by incision and drainage (I & D) of the abscessed area. The location and type of infection determine whether breast-feeding should be continued.

NURSING CARE AND TEACHING. You may assist with an I & D by setting out the equipment: a wrapped sterile sharp-pointed scalpel blade, a blade handle, clean gloves, and dressing materials. A dressing may be applied over the I & D site to absorb drainage. Application of warm, moist packs may also increase comfort and promote healing for patients with mastitis.

Patient teaching should include instructions to wash hands carefully to prevent the spread of infection and to wear a supportive bra to relieve some of the discomfort.

Malignant Breast Disorders

Etiology

Research has identified factors that increase the risk of development of breast cancer: increasing age, personal or family history of breast cancer, high-fat diet, high alcohol intake, treatment with estrogens (especially when used without progestins), early menarche, late menopause, late first pregnancy, and no pregnancies.

Prevention

Exercising moderation in fat and alcohol consumption, using nonhormonal methods of birth control, and managing menopausal symptoms can reduce risk of breast cancer. However, there are many factors that cannot be controlled, so the importance of early detection cannot be overemphasized. Recent research has discovered genes (BRCA1 and BRCA2) that are linked with susceptibility to breast cancer. These findings offer the possibility of very early identification of women at the most risk of developing breast cancer (and also ovarian cancer for those with BRCA1). They can then be monitored closely for any changes and receive early treatment if cancer develops.³

Diagnostic Tests

Breast self-examination and clinical breast examinations are important parts of identification of cancer. Cancerous growths tend to be harder, less movable, more irregularly shaped, with less clearly defined borders than benign growths. The prognosis is good for women who have breast

mastitis: mast—breast + itis—inflammation

cancers removed in the early stages but gets worse with time. Teaching and encouraging the regular use of BSE and appropriate use of mammography can save lives. Refer to Chapter 39 for more about BSE and for explanations about diagnostic tests used to assist in determining whether tumors of the breast are malignant.

Staging

The spread (metastasis) of cancerous cells from the primary site to other areas of the body by way of the blood or lymph is denoted by staging classifications. (See Chapter 10.) The lower numbers indicate less cancer spread.

Treatment and Complications

There are five main treatment options for breast cancer: radiation therapy, chemotherapy, hormonal therapy, modification of biologic response, and surgery. These options may be used separately or in combination depending on the condition of the patient and the stage of the disease.

The possibility of metastases necessitates drastic treatment of the whole body in many cases to prevent secondary cancer growth at other sites. Both radiation and chemotherapy generally combat cancer by destroying rapidly reproducing cells. This treatment is effective against cancer but also tends to destroy normal body cells that reproduce rapidly, such as hair and the cells lining the mouth, vagina, and gastrointestinal tract. Interventions to help preserve these tissues and maintain nutrition can be helpful.

Hormonal therapy may be undertaken to deprive cancer cells of hormones that stimulate their growth. Because breast cancer cells are often estrogen sensitive, this may be accomplished by decreasing circulating estrogen levels with

drugs or by blocking the use of estrogen by cancer cells as occurs with use of the drug tamoxifen citrate. Interference with estrogen levels, however, may produce menopausal symptoms and increase the risk of osteoporosis and heart disease.

Substances that modify the body’s biologic responses may be given to intensify positive responses of the body (e.g., stimulate the immune system) or to decrease negative body responses. Some examples of biologic response modifiers are interferons, tumor necrosis factor, interleukins, and various experimental immunotherapy formulations. This is an area of much research and is likely to expand greatly during the next few years.

Breast surgeries to remove cancerous tissue can be disfiguring and have profound effects on the patient’s self-concept. The amount of tissue removed varies depending on the size, nature, and invasiveness of the cancer. A lumpectomy removes just the tumor and a margin around it. A **mastectomy** may be partial (removing only part of the breast), simple (removing only breast tissue), or radical (removing breast tissue, underlying muscle, and surrounding lymph nodes). Recently, surgical practice has shifted from mainly radical mastectomies to more breast-conserving surgeries with radiation therapy, with similar survival rates demonstrated.⁴

Nursing Care and Teaching

See Nursing Care Plan Box 40–1 for care of the patient undergoing a mastectomy.

mastectomy: mast—breast + itis—inflammation

BOX 40-1 NURSING CARE PLAN FOR THE PATIENT UNDERGOING MASTECTOMY

Risk for anxiety related to uncertainty about diagnosis, prognosis, and treatments

PATIENT OUTCOMES

Patient will verbalize a decrease in anxiety.

INTERVENTIONS

Teach what to expect about to the surgical experience based on patient’s understanding, concerns, and willingness to learn.
Support the physician’s explanations, answer questions, and refer to knowledgeable sources.

RATIONALE

Knowledge dispels unreasonable fears and helps patient to prepare to cope with stressors.

EVALUATION

Does patient express satisfaction with amount and type of information?
Does patient evidence adequate understanding of the procedure and what to expect afterward?
Do patient’s vital signs, verbal, and nonverbal demeanor suggest anxiety?

Risk for ineffective breathing pattern related to pain with chest movement

PATIENT OUTCOMES

Effective breathing pattern with clearance of mucus from air passages.

INTERVENTIONS

Medicate to relieve pain as necessary.
Encourage deep breathing and coughing each hour.
Encourage use of an incentive spirometer each hour when awake.

RATIONALE

Pain may inhibit deep breathing efforts. This helps to loosen secretions and to prevent atelectasis, pneumonia, and inadequate oxygenation of tissues.

EVALUATION

Does patient evidence pain or guarding during chest movement?
Does chest sound clear?
Are skin color and oxygen saturation adequate?

BOX 40-1 NURSING CARE PLAN FOR THE PATIENT UNDERGOING MASTECTOMY—cont'd**Risk for impaired tissue perfusion and integrity related to damage to blood and lymph vessels and tension at surgical incision site****PATIENT OUTCOMES**

Incision will heal by primary intention without excessive bleeding or swelling.

INTERVENTIONS

Monitor vital signs, oxygen saturation, and peripheral vascular status according to hospital policy and as necessary.
 Avoid use of the affected arm for blood pressure, venipunctures, and injections.
 Check for bleeding, amount and color of drainage if a drain device is used, and swelling.
 Measure circumference of arms daily and compare.
 Elevate affected arm if swelling occurs.
 Place items where patient may easily reach them.
 Encourage reasonable exercise of the affected arm following post-mastectomy exercises that are approved by the institution.

RATIONALE

Vital signs, oxygen saturation, and peripheral vascular signs reflect circulatory status.
 Restrictive and invasive procedures might further compromise tissue integrity of the affected arm.
 Excessive bleeding and swelling may further compromise tissue perfusion.
 Swelling causes an increase in circumference.
 Gravity aids fluid return to the heart.
 Excessive movement of the arm may exert tension on incision and increase bleeding.
 Reasonable exercise promotes circulation, preserves muscle and joint function, and increases self-care ability.

EVALUATION

Are vital signs stable and within normal range?
 Is dressing dry?
 Is arm protected?
 Does incisional area look swollen, smooth, or shiny? Is drainage amount and color appropriate?
 Is affected arm larger than unaffected arm?
 Does elevation prevent swelling?
 Can patient reach items without abducting the arm over 90 degrees?
 Is patient moving the arm appropriately and gradually increasing range of motion and self-care ability?

Risk for ineffective coping related to cancer threat and body image disturbance**PATIENT OUTCOMES**

Patient verbalizes ability to cope; seeks help and support appropriately.

INTERVENTIONS

Maintain an open and trusting therapeutic relationship.
 Allow grieving to take place.
 Encourage patient to express feelings and concerns.
 Encourage active problem solving.
 Help patient remember previous successes in coping and strategies used.
 Refer to appropriate agencies for further support as needed (e.g., American Cancer Society, Reach for Recovery, local support groups,

RATIONALE

Effective communication is based on trust.
 Loss of a breast disturbs many aspects of body image, and cancer threatens one's sense of security and reasonableness of life.
 Active problem solving promotes self-efficacy and combats depression.
 Memory of prior success can encourage hope for future success.
 Social support can assist individuals to meet their needs while developing effective coping skills and strategies.

EVALUATION

Is patient talking about concerns?
 Is patient willing to look at incision area?
 How are family members interacting with patient?
 How is patient responding to family members and friends?
 Is grief being expressed?
 Is patient planning for the future?
 Is patient taking an active interest in her personal appearance?
 Does patient have sufficient coping skills or supports available to promote healthy living?

Alternative therapies are also available for many cancers. See Chapter 4 for information about helping patients evaluate alternative and complementary therapies. The American Cancer Society and cancer treatment centers also have people who can answer questions about experimental and alternative therapies and discuss research findings. For more information about breast cancer, visit the American Cancer Society at www.cancer.org.

Breast Modification Surgeries

Mammoplasty is surgical modification of the breast. This may be done to restore a normal shape after removal of cancerous tissues. Many women, however, undergo mammoplasty electively to reduce or increase the size or improve

mammoplasty: mamm(o)—breast + plasty—to mold

the shape of their breasts. A caring and nonjudgmental attitude is essential. Because nurses are very aware of the dangers involved with surgery, psychosocial issues may seem to be a trivial reason to voluntarily assume such risks to life and health. However, body image is an important component of quality of life. Patients' informed decisions should be respected if they choose this surgery.

Breast Reduction and Mastopexy

Generally in breast reduction operations the nipple is separated from the surrounding tissue except for a small section with the blood vessels and nerves that supply it (Fig. 40-1). A large wedge of tissue is removed from the bottom of the breast, the edges are sewn together, and the nipple is reimplanted in a higher position. This not only decreases the overall size of the breast, which may help with back, neck, and head pain, it also corrects excessive sagging—a common problem for women with large breasts.

A **mastopexy** involves the removal of some skin and fat with subsequent resuturing so that the breast tissues are held higher on the chest to correct sagging breasts. This procedure usually does not remove as much tissue as a breast reduction.

Figure 40-1 Breast reduction. (Modified from Love, SM: Dr. Susan Love's Breast Book, ed 3. Perseus Publishing, Cambridge, Mass. 2000.)

Augmentation and Reconstruction Mammoplasty

Augmentation is a surgery to increase the size of the breasts. An implant—either a bag containing saline solution or silicone gel or a transplanted portion of the patient's own body tissues from another area—is inserted through an incision and positioned either under or over the pectoral muscles (Fig. 40-2).

For reconstructive mammoplasty, use of the patient's own tissues is generally safer than use of artificial implants, because no foreign material is introduced into the body. For situations in which significant amounts of tissue are needed for reconstruction, a portion of tissue may be moved from one area of the body to another as a **pedicle** graft. Pedicle literally means "little foot" because the graft remains attached to a stalk (containing the blood vessels and nerves) somewhat resembling a little leg with a foot (the graft) attached. Figure 40-3 shows two options for mastectomy graft repair—using the latissimus dorsi muscle and overlying tissue on the side of the chest or using the rectus abdominis muscle of the abdomen with its overlying tissue. For both these procedures, a portion of muscle is separated from its usual attachment. Tissues overlying a part of the muscle are excised and left attached to the muscle. This segment of tissue is then pulled under the skin and superficial layers to an incision at the mastectomy site. There it is brought to the surface and attached to reconstruct a breast shape. Tissue from the buttock area or the abdomen may also be grafted onto a mastectomy site without a pedicle.

pedicle: ped—foot + icle—little

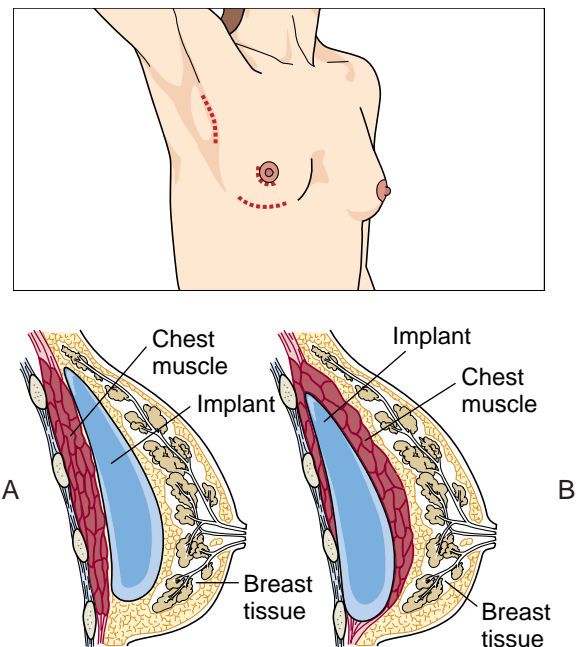

Figure 40-2 Breast implants. (A) Implant over muscle. (B) Implant under muscle. (Modified from Love, SM: Dr. Susan Love's Breast Book, ed 3. Perseus Publishing, Cambridge, Mass. 2000.)

Figure 40-3 Mastectomy reconstruction. (Modified from Love, SM: Dr. Susan Love’s Breast Book, ed 3. Perseus Publishing, Cambridge, Mass, 2000.)

Complications

Any of these surgeries may be complicated by infection or impaired healing. The use of silicone implants has been less than satisfactory for many women. Some women have experienced hardening of breast tissues and others have developed serious autoimmune disease problems after receiving silicone gel implants. Although actual etiology of all the problems is uncertain, many surgeries have been undertaken recently to remove silicone implants and saline implants are now used more often.

Nursing Care and Teaching

Carefully assess the healing process when changing dressings and explain to the patient how to assess healing, because not all tissues successfully attach at the new site and failure of attachment can require surgical revision. Signs of poor attachment include unnatural color of the incision, graft, or surrounding tissues; swelling; drainage; gaping of incision lines; and sloughing of the graft or edges of the site.

► MENSTRUAL DISORDERS

Flow and Cycle Disorders

Pathophysiology, Etiologies, and Signs and Symptoms

There are many types of menstrual abnormalities (Table 40-1). Causes can include stress, pregnancy, hormonal imbalances, metabolic imbalances (such as obesity, anorexia nervosa, and loss of too much body fat through excessive exercise), tumors (both benign and malignant), infections, organ diseases (such as liver, kidney, or thyroid disease), blood or bone marrow abnormalities, and the presence of foreign bodies in the uterus (such as intrauterine devices). Menstrual abnormalities can be distressing and can result in anemia, persistent fatigue, and sexual dysfunction. Establishment of a comfortable and open professional relationship is essential for communication about such concerns.

Diagnostic Tests

Appropriate testing to determine the cause of menstrual abnormalities can involve a thorough medical history and physical examination, swabs of vaginal discharge, a Papanicolaou (Pap) smear, pregnancy testing, urine testing, and extensive blood testing to screen for any of the disorders that may influence the menstrual cycle and flow. Generally health care providers initially test to rule out the most likely causes and then begin to test for more obscure disorders until the cause of the disorder is identified. For example, reproductive hormone levels are likely to be tested before kidney or liver function, unless the latter disorders are evident in the initial history and physical examination.

Treatment

Medical treatment of menstrual disorders generally involves manipulation of hormone levels. Surgical treatment of

TABLE 40-1 MENSTRUAL FLOW DISORDERS

Disorder	Description
Amenorrhea	Menses absent for more than 6 months or three of previous cycles Called primary amenorrhea when menarche has not occurred by age 17 Called secondary amenorrhea when menses are absent after menarche
Oligomenorrhea	Menstrual cycles of more than 35 days
Hypomenorrhea	Less than the expected amount of menstrual bleeding
Menorrhagia	Passing more than 80 mL of blood per menses
Hypermenorrhea	Menses lasting longer than 7 days
Polymenorrhea (also called metrorrhagia)	Menses more frequently than 21-day intervals
Menometrorrhagia (also called metromenorrhagia)	Overly long, heavy, and irregular menses

menstrual disorders can involve **dilation and curettage** (D & C), **laser ablation** of endometrial tissue, and **hysterectomy**. During D & C the cervix is first dilated (opened wider) and then curets—sharp, spoonlike instruments—are inserted through the cervix and used to scoop out the inner lining of the uterus. Laser ablation involves targeted burning of endometrial tissue so that scar tissue that does not bleed forms. Hysterectomy (removal of the uterus), a last resort treatment, is described later in this chapter.

Nursing Care and Teaching

Estimation of the amount of blood lost during menses may be difficult because pad counts can vary widely depending on the frequency of pad changes and the portion of the pad that contains blood. The only accurate way to estimate menstrual flow is by weighing the pads (sealed in a biohazard bag) and then subtracting the weight of the original pads. A 1-g increase in pad weight equals approximately 1 mL of blood loss. You can document what the patient says for blood loss, but be sure to quote it and in parentheses place “patient estimate” after the quote.

Dysmenorrhea

Pathophysiology, Etiologies, and Signs and Symptoms

Painful menstruation, or **dysmenorrhea**, is a common problem of women, although few find it to be incapacitating. Primary dysmenorrhea is not pathological and is caused mainly by the action of endogenous prostaglandins, which stimulate uterine contractions producing cramping pain. Secondary dysmenorrhea occurs after normal menses without discomfort has been established and may be caused by some pathological condition such as endometriosis, pelvic infection, **retroversion** of the uterus, or tumors.

Diagnostic Tests

Hormonal tests may be required for primary dysmenorrhea, but laparoscopic examination, biopsies, and other various reproductive function tests (explained later in the chapter) may be required for investigation of secondary dysmenorrhea.

Treatment

Primary dysmenorrhea may be treated with drugs that inhibit prostaglandin synthesis, such as aspirin and nonsteroidal anti-inflammatory drugs (NSAIDs). Correction of secondary causes of dysmenorrhea may include such measures as hormonal adjustment, dilation and curettage, and other surgical procedures.

dilation and curettage: dilat(e)—to widen + ation—the process of + curet—scoop + tage—doing

laser ablation: laser—light amplification by stimulated emission of radiation + ab—away + lat—to carry + ion—the process

hysterectomy: hyster—womb + ec—away + tomy—cutting

dysmenorrhea: dys—painful + men(o)—month + rhea—flow

retroversion: retro—back + version—turning

Nursing Care and Teaching

Several nonprescription preparations are available for treatment of dysmenorrhea, but patients should be advised to read the labels carefully, because aspirin and NSAIDs (the main component of many of the drugs) may be bought less expensively. Other added drugs in these compounds, such as diuretics, may not be necessary. If dysmenorrhea is related to uterine retroversion, assuming a knee-to-chest position may relieve the discomfort. Sudden development of dysmenorrhea in a woman with no previous menstrual discomfort should always be investigated.

Premenstrual Syndrome

Pathophysiology, Etiologies, and Signs and Symptoms

Premenstrual syndrome (PMS) is a recurrent problem for many women and may involve water retention; headaches; discomfort of joints, muscles, and breasts; changes in affect, concentration, and coordination; and sensory changes. Few women find PMS serious enough to interfere with work or relationships. The impact of ovarian hormones, aldosterone, and neurotransmitters such as monoamine oxidase and serotonin on PMS is not well understood, and further research is needed.

Medical Treatment

A variety of drugs have been given to combat PMS with varying degrees of success. Some commonly used PMS medications include drugs that affect prostaglandin production, hormonal balance, and neurotransmitter production and reuptake, as well as diuretics and supplements of calcium, magnesium, vitamin E, and vitamin B₆. Patients should be warned, however, that dosages of vitamins should not be increased without professional advice, because vitamins are medications (as well as nutrients) and high doses of some vitamins can lead to physiological damage.⁵

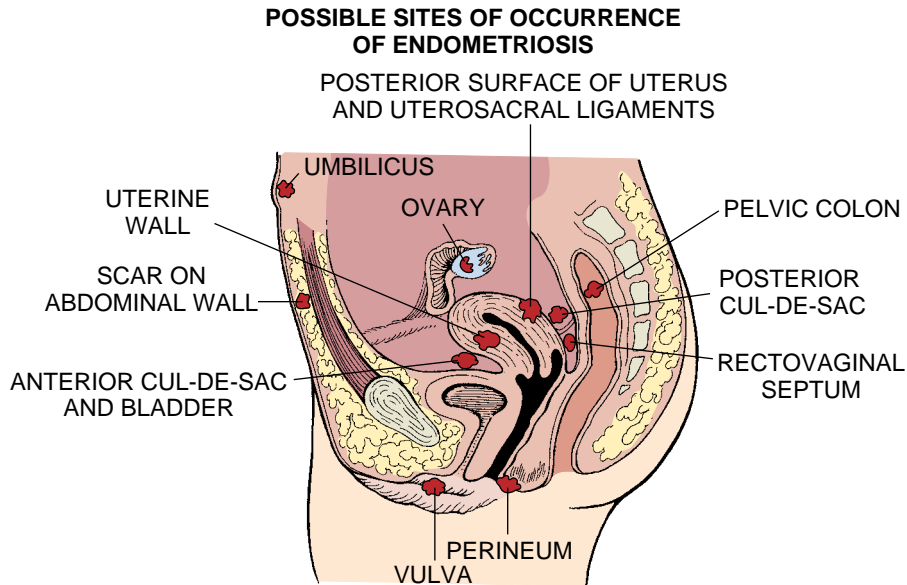

Nursing Care and Teaching

Being understanding and nonjudgmental is especially important, because some women who suffer from severe PMS may have been treated as if they are psychologically unbalanced because of the interaction of hormones and neurotransmitters and because of outdated ideas concerning PMS. You can help by providing educational materials on lifestyle measures, such as restriction of alcohol, caffeine, nicotine, salt, and simple sugars; participation in regular exercise; and development of stress management skills that can help women to who have a tendency to experience PMS.

Endometriosis

Pathophysiology, Etiologies, and Signs and Symptoms

Endometriosis is a condition in which functioning endometrial tissue is located outside the uterus (Fig. 40–4). Several theories have been proposed to explain development of en-

ometriosis, including faulty developmental differentiation of cells, transport of endometrial cells via blood and lymph to other parts of the body, and **retrograde** menstruation—a backward leakage of blood and tissue out through the fallopian tubes during the menstrual period.

Endometriotic cells grow in areas of sufficient blood supply—extending into other tissues such as intestinal walls, ovaries, and other abdominal structures. On a cyclic basis, mediated by ovarian hormones, these cells build up and slough just as they would in the uterus, but the sloughing and bleeding occur in the enclosed abdominal cavity or into the tissues that they have invaded. The buildup of the blood and cells can result in pain, swelling, damage to abdominal organs and structures, scar tissue development, and infertility. Ectopic endometrial tissue also produces complement component 3 and prostaglandins, increasing capillary permeability, adhesion development, and cramping.

Treatment

Surgical intervention may be required, especially if scar tissue develops into tight bands, which can cause strangulation of sections of bowel or ureters. Reduction of estrogen and prevention of ovulation either with medications or by surgical removal of the ovaries can be very effective but result in infertility and menopausal symptoms. Analgesics may be required.

Nursing Care and Teaching

The severity and persistence of the pain of endometriosis may lead to overuse of pain medication, so it is important to teach patients alternative pain relief strategies such as relaxation exercises and application of heat to the abdomen or back.

Menopause

Pathophysiology and Signs and Symptoms

Menopause is the permanent cessation of menstrual cycles resulting from decreased hormone production. This is a natural part of aging, but it is placed within this section because several related uncomfortable symptoms and conditions can occur. The climacteric (perimenopause) is the period of gradual decline in hormone production before the permanent end of menses and may last from months to several years. **Perimenopausal** physical symptoms vary widely and may include erratic menses, atrophy of urogenital tissues with a marked decrease in the amount of natural lubrication, a pH shift toward alkalinity (encouraging yeast overgrowth), and vasomotor instability (resulting in hot flashes and night sweats).

Estrogen protects women against several disease processes; the risk of heart disease and osteoporosis increase with declining estrogen production. Mental changes may also occur because of the complex interplay of reproductive hormones and neurotransmitters. It is important to acknowledge mental symptoms such as irritability, anxiety, insomnia, memory problems, and mild depression as a normal, temporary part of hormonal changes, so that perimenopausal women do not doubt their sanity.

Treatment

Hormone replacement therapy (HRT) is a controversial treatment for perimenopausal symptoms. Medications such as conjugated estrogens (Premarin), estradiol, and medroxyprogesterone acetate (Provera) may be prescribed. The National Heart, Lung, and Blood Institute of the National Institutes of Health conducted a major research project to study the risks and benefits of combined estrogen and progestin therapy for

retrograde: retro—backward + grade—step

perimenopausal: peri—around + men(o)—month + pausal—stopping

healthy women. However, the project was halted in July, 2002, 3 years early, because of very worrisome results. Positive findings with HRT included a one-third reduction in hip fractures, a 24% reduction in total fractures, and a 37% decrease in colorectal cancer. Disturbing findings included a 26% increase in breast cancer, a 41% increase in strokes, a 29% increase in heart attacks, doubling of venous thromboembolism rates, and an overall 22% increase in cardiovascular disease. It is uncertain what to make of this data because there was no difference in total mortality when comparing women treated with HRT and those given a placebo. Long-term results will continue to be examined, but for now, the risks of HRT have been deemed too great to continue the study.⁶

Prevention of osteoporosis begins in early adulthood. Fair-skinned, Caucasian women are at greatest risk for bone loss. Throughout life, adequate intake of calcium and vitamin D (preferably from foods) and regular weight-bearing exercise help to maximize bone mass. At menopause, some women may receive HRT or intensive treatment with bone-building medications to retard bone loss.

Complications

It is important to note that resumption of vaginal bleeding after menstruation has finally ceased can be a sign of disorder of the cells of the endometrium caused by either benign changes, such as polyps, or malignant changes and should always be investigated.

Nursing Care and Teaching

Patients who are perimenopausal often ask nurses about how to cope effectively with symptoms. Planning ahead for hot flashes by dressing in clothing that may be removed or applied in layers for comfort makes adjustment easier. Not allowing hot flashes to interrupt activities is an important strategy, as is engaging in satisfying and calming activities that contribute to a sense of serenity. Treatment of vaginal symptoms with a water-soluble moisture restorer or lubricant or with an estrogen cream (following prescription directions) can help. Eating a healthy diet that is light in caffeine, sugar, and alcohol can help women better control their bodies and minds. Looking forward to new challenges rather than toward the past may help to counteract depressive tendencies occurring with hormonal changes. It is important to remind perimenopausal women that they may still be fertile unexpectedly after several months of **amenorrhea**. To prevent conception, they need to continue to practice birth control until they receive confirmation from their physician that menopause is complete.

► IRRITATIONS AND INFLAMMATIONS OF THE VAGINA AND VULVA

Several causative agents can irritate the vulva and the vagina. Signs and symptoms are often similar, but there are some differences in the discharge produced in response to the disorders. See Table 40-2 for common vaginal irrita-

tions and inflammations that are not generally sexually transmitted. See Chapter 42 for information on sexually transmitted diseases.

Pathophysiology, Etiologies, and Signs and Symptoms

The normal vaginal environment is a balanced ecosystem with a pH of less than 4.2 as a result of lactic acid and hydrogen peroxide production by cells in the vagina. This acidic pH protects against the growth of many pathogenic microorganisms. A variety of normal resident microorganisms coexist relatively harmoniously unless the ecological balance is destroyed. Candidiasis, bacterial **vaginosis**, and **cytolytic** vaginitis are all instances of overgrowth of normally present, nonpathogenic microorganisms. Trichomoniasis also is included here because it can be transmitted nonsexually (on fomites, such as toilet seats), as well as sexually, and it grows well when the vaginal environment is disturbed.

Several conditions can predispose patients to an overgrowth of resident microbes: poor nutrition (especially diets high in simple sugars), inconsistent control of blood glucose levels in patients with diabetes, stress, pregnancy, marked hormonal fluctuations, pH changes, prolonged overheating of the genital area with little aeration (as happens with sitting still for long periods in overly restrictive clothing), and changes in the balance of vaginal flora types because of antibiotic treatment. Patients who have a compromised immune system may experience frequent overgrowths of resident microbes, and, conversely, vaginal infections can make women more susceptible to infection with sexually transmitted diseases, such as gonorrhea and human immunodeficiency virus (HIV). Frequent and persistent yeast infections may be one sign of HIV. Vaginosis (overgrowth) and vaginitis (inflammation) can sometimes produce irritation and inflammation in the male sexual partner as well and may lead to urethritis, **balanitis**, excoriation, and sores on the penis. If the male partner is not treated also, he may reactivate the problem for the woman. Therefore several types of medication come in “partner packs” for both partners to use. (See Table 40-2.)

Nursing Care and Teaching of the Patient Undergoing Diagnostic Testing

The patient may feel embarrassed to speak about what is bothering her. A safe question to begin with for most patients is, “Hello. What can I write on your chart as the reason for your visit today?” If embarrassment is evident, a comment that you need to know a bit about what materials to put out for examination purposes often defuses an uncomfortable situation. As you set up materials for a pelvic examination, swabs, and cultures, you can explain that some information is needed to determine how to treat the

amenorrhea: a—without + men(o)—month + rhea—flow

vaginosis: vagin—vagina + osis—condition

balanitis: balan—acorn (shape of glans penis) + itis—
inflammation

TABLE 40-2 COMMON VAGINAL IRRITATIONS AND INFLAMMATIONS

Disorder and Etiology	Signs and Symptoms	Discharge/ Examination	Diagnostic Tests	Usual Treatment
Candidiasis: <i>Candida albicans</i> , <i>glabrata</i> or <i>tropicalis</i> , overgrowth	Burning, itching, redness of vulva; burning on urination	White, cottage cheese appearance	Wet mount slides (yeasts look like tiny, budding tree branches); may be cultured	Antifungals (drugs mostly ending in <i>-azole</i>)
Bacterial vaginosis: <i>Gardnerella vaginalis</i> , <i>Mycoplasma</i> , or anaerobe overgrowth	None or vulvar or vaginal irritation	White or gray, homogeneous, foul-smelling discharge; pH higher than 4.5	Wet mount slides show “clue cells” or release fishy odor when potassium hydroxide is applied	Drugs such as metronidazole or clindamycin
Trichomoniasis: <i>Trichomonas vaginalis</i> (may be transmitted by inanimate objects or sexually)	Itching, irritation, foul odor, redness, dysuria	Discharge may be frothy; pH higher than 4.5; “strawberry cervix” resulting from petechiae	Wet mount slides treated with normal saline show motile cells with flagella (like tiny whips); may also be cultured	Metronidazole, 2-g single dose
Cytolytic vaginosis: Lactobacilli overgrowth, stress, some medications	Burning, irritation, pain with intercourse	Nonodorous, thick, white, pasty, or dry and flaking	Lower than normal pH as tested with pH indicator tape (or litmus strip); may be cultured	Depends on cause; alkaline douches may be prescribed
Contact vulvovaginitis: contact with allergens or irritating chemicals such as contraceptive creams or bubble baths	Itching, burning, redness	Generally no change from normal discharge, though may be increased	History and physical information, recent contact with chemicals	Avoidance of the offending substance; warm sitz baths or application of hydrocortisone cream
Atrophic vaginitis: estrogen levels too low to support estrogen-sensitive vaginal tissues	Vulvovaginal irritation, less lubrication, dyspareunia, increased tendency for resident microbe overgrowth	May have little or increased discharge; discharge may be watery, yellow, or green; may be blood-tinged	Maturation index may be determined during Pap test to identify atrophic cellular changes, but diagnosis is usually by history and physical information only	HRT (oral, patch, or vulvovaginal cream) or water-soluble lubricant replacing vaginal lubricants

problem. (See Chapter 39.) Often this is a good time to ask about the discharge and other signs and symptoms using the WHAT'S UP? format. (See Chapter 1.) Allow the patient privacy while she changes into a gown. Return to the room if requested as a chaperone, assistant, and support for the woman. NOTE: If any wet mount slides were made, these must be taken to the laboratory immediately while still wet. Use standard precautions to transport samples. Although swabs may be taken for culture, the health care provider may prescribe medication before the results of the swabs return because such irritations are so uncomfortable.

Nursing Care and Teaching of the Patient Undergoing Treatment

Vaginal inflammations and infections may require local application of medication either in cream, suppository, or medicated douche form. Depending on the practice standards in the area, the nurse may apply this for patients who are unable to do this for themselves or may teach patients to self-administer. Anatomically the vagina slopes back toward the sacrum for approximately the length of an adult finger (though it can stretch longer). Application is easiest when the patient is lying down ready to sleep, because vagi-

nal medications tend to run out because of gravity when the patient stands or sits. Medicated douches may be administered with the patient sitting on a bedpan with the bed in semi-Fowler's position or, if self-administered, while sitting on a toilet. Most vaginal medications come with an applicator that either injects a dose of creamy medication or pushes a firmer, shaped dose of medication off the end of the tube when the plunger is depressed. Consult instructions supplied with the medication. Patients should be instructed to use all the medication as prescribed and to wear an absorbent pad to prevent possible staining of clothing.

Toxic Shock Syndrome Pathophysiology, Etiologies, and Signs and Symptoms

Toxic shock syndrome (TSS), first identified in 1978, is primarily associated with superabsorbent tampon use during menstruation but can also occur with use of nasal packings and in individuals who are not menstruating and who have no packing at all. It is a severe systemic infection with strains of *Staphylococcus aureus*, which produce an epidermal toxin. The effect of the toxin on the liver, kidneys, and

circulatory system makes this a life-threatening condition. A streptococcal infection can cause a similar syndrome.

Individuals with TSS may experience a sudden high fever with sore throat, headache, dizziness, confusion, redness of the palms and soles of the feet, skin rashes, blisters, and petechiae followed by peeling of the skin. Muscle weakness and pain and gastrointestinal upset also have been reported. Signs and symptoms such as these should be reported to the health care provider immediately.

Prevention

Tampon makers have removed the highly absorbent fibers that were most often associated with the syndrome from their product lines, and TSS is now rare. Women can also reduce their risk of developing TSS by substituting sanitary pads for tampons at least part of the time (nighttime use may work well), changing tampons every 4 hours, washing hands carefully before inserting anything into the vagina, not leaving female barrier **contraceptives** in place for longer than needed, and not using tampons or female barrier contraceptives in the first 12 weeks after giving birth.

Nursing Care and Teaching

All menstruating women should be taught measures to prevent TSS. They should also be taught to recognize symptoms of TSS, because early identification and treatment can save lives.

► DISORDERS RELATED TO THE DEVELOPMENT OF THE GENITAL ORGANS

Pathophysiology, Etiologies, and Signs and Symptoms

Several types of congenital malformations of the genital organs may affect the health of female patients. Genetic or environmental factors during pregnancy may cause these, and they may require medical or surgical treatment at some point in life. **Agenesis** of structures means that they never developed. **Hypoplasia** of reproductive tract portions means that they are underdeveloped. **Imperforate** means that expected openings do not exist. Blind pouches exist where cavities should meet but do not. The uterus can form in several different configurations, including a double uterus.

Many malformations are discovered during childhood or early adolescence, but some are identified when patients seek medical help because of dysmenorrhea, **dyspareunia** (pain with intercourse), infertility, or repeated spontaneous abortions (miscarriages).

contraceptive: contra—against + ceptive—taking in (conceiving)

agenesis: a—without + genesis—production

hypoplasia: hypo—little + plasia—shape (or form)

imperforate: im—not + perforate—pierced

dyspareunia: dys—painful or abnormal + pareunia—mating

Diagnostic Tests

Procedures such as ultrasonography, hysterosalpingography, computed tomography (CT), magnetic resonance imaging (MRI), and endoscopic examinations may be used to determine the type and extent of developmental defects.

Treatment

Some defects can be repaired surgically, but others cannot. Depending on the type and location of the defect, surgeries may be done by endoscopy or by surgical incision. Absence of hormone-producing tissue may be overcome by hormone supplements.

Nursing Care and Teaching

Patients who have these problems may struggle with self-esteem issues, such as feeling that they are somehow incomplete or have been cheated of something they desire. You can show that you are willing to listen if and when the patient wishes to talk while allowing her as much privacy as she desires.

Displacement Disorders

Pathophysiology, Etiologies, and Signs and Symptoms

The pelvic organs are suspended within the pelvis by ligaments and supported by muscles and fascia. The pubococcygeal muscle runs from the pubis to the coccyx and supplies support from below. Pregnancies (especially those producing large babies) and rapid or traumatic deliveries may result in stretching and injury of the supporting structures, which can cause displacement of the uterus, vagina, bladder, or bowel from their normal positions. The observation that some children have defective muscle support of the pelvic organs and that prolapse is more prevalent in some families seems to suggest that congenital defects and genetic inheritance may also influence displacement disorders even without pregnancy. Scarring from sexually transmitted diseases also may cause some displacement of the pelvic organs. Aging generally increases the problem because the effects of gravity over time contribute to stretching, and lower estrogen levels weaken estrogen-dependent supportive tissues. Chronic constipation, obesity, and lack of exercise also worsen these problems.

Nursing Care and Teaching

Teach patients to eat a healthy diet to avoid obesity and constipation and how to do Kegel exercises to keep the pubococcygeal muscle strong to support the organs in the pelvic cavity. There are several variations of such exercises. The important idea is that the appropriate muscles are exercised adequately to strengthen and build up ability to control muscle contractions.

1. To find the pubococcygeal muscle, tighten while urinating so that the flow of urine stops.
2. Squeeze the muscle that stopped urinary flow tightly, holding for 10 seconds, and totally relaxing the muscle afterward. Repeat 15 times per day.

- Practice controlling the muscle by contracting and relaxing it to move the pelvic floor upward and downward very slowly. Thinking of an elevator helps some women. Repeat this 15 times per day.

These exercises can be done anywhere and are not apparent to anyone watching.

LEARNING TIPS

Teach patients to do Kegel exercises while waiting in lines to use otherwise wasted time to promote their health. Another suggestion is to plan specific times of day or activities that would include Kegel exercises, such as while in a car or working at a computer.

Treatment

A pessary is a supportive (usually ring-shaped) device that is placed in the proximal end of the vagina to help support the pelvic organs. These are usually removed daily at bedtime for cleaning, but some types are designed to remain in the vagina for months at a time. When pessary use is begun, it is important that the woman return to the physician for a recheck after an initial period of use to determine whether the pessary is causing pressure damage to tissues. Because the pessary is a foreign object in the vagina, increased vaginal discharge may be expected. Discharge should not be pink, bloody, or purulent.

Cystocele

Pathophysiology, Etiologies, and Signs and Symptoms

Cystocele occurs when the bladder sags into the vaginal space because of inadequate support (Fig. 40-5). A feeling of pelvic pressure and stress incontinence are common with this condition.

Treatment

Kegel exercises or the use of a pessary may help. If these measures are ineffective, anterior **colporrhaphy**, which is a surgical repair of the anterior portion of the vagina, may be necessary to correct this problem. Another possible surgical treatment involves resuspending the bladder.

Rectocele

Pathophysiology, Etiologies, and Signs and Symptoms

Rectocele occurs when a portion of the rectum sags into the vagina because of inadequate support (see Fig. 40-5). A feeling of pelvic pressure, as well as fecal incontinence, constipation, and hemorrhoids, may result.

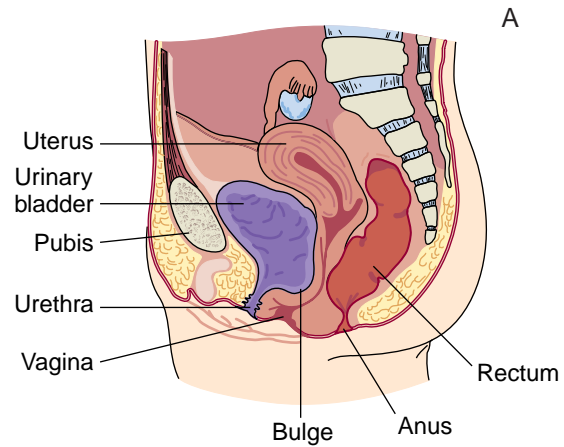

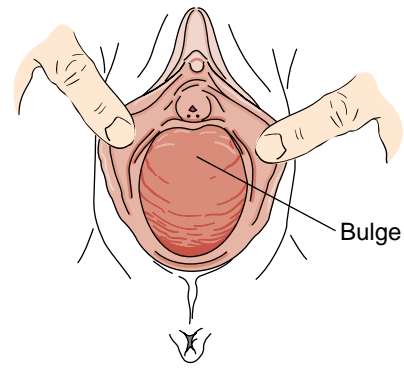

Figure 40-5 (A) Cystocele. (B) Rectocele.

cystocele: cysto—bag (bladder) + cele—hernia
colporrhaphy: colpo—vagina + rrhaphy—suture
rectocele: recto—rectum + cele—hernia

Treatment

Kegel exercises may help strengthen the supporting muscles. The patient should maintain bowel regularity with a high-fiber diet to avoid further discomfort and sagging from bowel overdistention. Posterior colporrhaphy may be necessary to correct this problem.

Uterine Position Disorders

Pathophysiology, Etiologies, and Signs and Symptoms

The most common variations of position of the uterus are **anteversion**, **anteflexion**, retroversion, and **retroflexion** (Fig. 40–6). In anteversion the uterus lies too far forward, and in retroversion it lies too far backward. In anteflexion the upper portion of the uterus bends forward, and in retroflexion it bends backward.

Symptoms that may result from these uterine displacements include painful menstruation and intercourse, infertility, and repeated spontaneous abortion.

anteversion: ante—front + version—turning
anteflexion: ante—front + flexion—bending
retroflexion: retro—back + flexion—bending

Treatment

A pessary may correct some positional problems. If infertility or recurrent spontaneous abortion is involved or the condition is very painful, surgery to correct the condition may be undertaken.

Uterine Prolapse

Pathophysiology, Etiologies, and Signs and Symptoms

Uterine prolapse occurs when the uterus sags into the vagina (Fig. 40–7). The amount of sagging can vary and may increase over time as a result of the effects of gravity, poor pelvic support, and excessive lifting or straining. In first-degree prolapse, less than half the uterus sags into the vagina. In second-degree prolapse, the entire uterus sags into the vagina. In third-degree prolapse, the uterus sags outside the body.

Uterine prolapse can be very uncomfortable, resulting in back pain, pelvic pain, pain with intercourse (or inability to have intercourse), urinary incontinence, constipation, and the development of hemorrhoids. The pressure on the uterus also may compromise circulation, resulting in tissue necrosis. NOTE: Vaginal vault prolapse may also occur in women who have had a hysterectomy, so that the vagina turns inside out and sags downward with similar signs and

Figure 40-6 Uterine positions. (A) Anteversion. (B) Anteflexion. (C) Retroversion. (D) Retroflexion.

Figure 40-7 Uterine prolapse. (A) Normal uterus. (B) First-degree prolapse: Descent within the vagina. (C) Second-degree prolapse. (D) Third-degree prolapse: The vagina is completely everted.

symptoms. This condition generally requires surgical resuspension.

Treatment

Some of the more minor uterine displacements may be treated with use of a pessary. Kegel exercises may be more effective in prevention of uterine prolapse than in treatment, because once the tissues become stretched sufficiently for the uterus to sag into the vagina, the continued weight of the uterus prevents adequate contraction of the muscles. Surgery may be done to correct this problem. Although the uterus may be resuspended by shortening the muscles and fascia, hysterectomy is the more common treatment unless further childbearing is desired.

► FERTILITY DISORDERS

Infertility is a complicated problem that must be considered according to the causative factors. Some couples with infertility may have multiple reproductive problems. Both male and female partners should be examined. (See Chapter 41 for greater detail on male reproductive system disorders.) Often the woman sees the health care provider first and may be given a specimen container and advised to give this to her partner to provide a semen sample for analysis. See Table 40-3 for a summary of fertility disorders and diagnostic tests.

Nursing Care and Teaching of the Patient Undergoing Fertility Testing

An understanding attitude is very important, because infertility can be a cause of low self-esteem, as well as relationship problems. Patients who have been undergoing diagnostic testing or treatment for infertility can become very discouraged with the process and the expense, especially if it has been ineffective. Having to plan your sexual activity around a health care provider's directions can compromise feelings of spontaneity, enjoyment, and privacy. Extensive questioning by nurses can aggravate the situation, but avoiding conversation may convey a lack of caring. A friendly "Which test shall I help you get ready for today?" may well be enough to get the needed information. Many women undergoing infertility testing are very well informed about the test they will be having and can tell you so that you know which equipment to set out.

On the first infertility investigation visit, the nurse may teach or give a handout to the patient about keeping a precise record of her oral temperatures with a basal thermometer each morning on awakening, before any other activity. The first day of her menses is day 1 on the temperature chart. Changing levels of hormones result in slight temperature changes, which can be used to identify when ovula-

TABLE 40-3 FERTILITY DISORDERS

Disorder	Pathophysiology/Etiology	Diagnostic Tests
Male	Possible anatomic abnormalities, hormonal factors, genetic defects, inflammatory conditions, immune system disorders, difficulties with sexual function or technique, psychological factors, or exogenous influences such as drug use, radiation or chemical exposure, trauma, and excessive testicular temperatures (as may occur with prolonged hot tub use or too tight clothing)	Semen analysis of number, condition, and movement of the sperm and composition of seminal fluid using various tests
Female: Ovulation	Possible anatomic and physiological abnormalities of ovaries; hormonal balance problems related to hypothalamus, thyroid, or adrenal glands; or polycystic ovary syndrome	Basal body temperature charting, midluteal serum progesterone blood levels, luteinizing hormone levels blood or urine testing, ultrasound monitoring of a follicle for evidence of release of ovum, endometrial biopsy, observation of male hair distribution, and other hormone testing as indicated
Tubal	Possible obstruction of the fallopian tubes resulting from anatomic variations, scarring, or adhesions; prior surgeries; and inflammatory processes involving other abdominal tissues	Hysterosalpingography (described in Chapter 39), laparoscopy
Uterine	Possible abnormalities in shape or blockages within the uterus (rare cause of infertility but a potential cause of pregnancy loss before maturity), menstrual disorders involving the endometrium	Hysteroscopy (described in Chapter 39), removal of tissue samples using curet or endoscope
Other sources of infertility	Possible reproductive environmental factors such as destructive antigen-antibody responses, inappropriate pH of seminal fluid for maximal sperm motility, or substances in female partner's genital tract fluids that disable sperm	Postcoital test: couple is advised to have intercourse when luteinizing hormone and estrogen levels are high, then a specimen of cervical mucus is taken from the woman 2–12 hours later for analysis of reproductive environment

tion seems to be occurring and when particular hormone levels should be tested. Because many factors may influence temperature and cycles, explain that it may take a few months of recording to clearly identify her own pattern.

You may assist with office procedures such as endometrial biopsy, which may be done during a pelvic examination 2 or 3 days before menses is expected. A pregnancy test should be done before this procedure to avoid interfering with a pregnancy. Consult your procedure manual, laboratory manual, or health care provider for what materials to set up. The woman may receive pain medication and paracervical block anesthesia for the procedure. Assess pulse and blood pressure. A vasovagal reaction treatment kit containing epinephrine (or atropine, according to the health care provider's choice), a tourniquet, and a syringe should be kept handy for injection if a vasovagal reflex occurs during the procedure. Vasovagal reflex is a reflex stimulation of the vagal nerve that can happen when the cervix, larynx, or trachea is manipulated and results in slowing of the heart rate and decreased cardiac output, so that the blood pressure drops markedly.

Treatment

Treatment of infertility is designed to ensure that an adequate amount of sperm and an ovum can be in close proximity in the most conducive environment for fertilization. Removal of barriers such as scar tissue may require surgery.

Depending on the results of blood tests and the **postcoital** test (described in Table 40-3), adjustments of environmental factors may involve such actions as sperm washing to avoid destructive antigen-antibody responses, changing the pH of the seminal fluid to encourage sperm motility, treating the female partner to prevent substances in her genital tract fluids from disabling the sperm, or adjusting her hormone levels. The number of sperm or ova available may be increased through use of such fertility drugs as clomiphene citrate or various hormone preparations. Infertility treatments are quite complicated and expensive and change periodically as a result of ongoing research. In-depth coverage of these treatments is beyond the scope of this book.

Various methods may be used to bring the gametes into close proximity. If the problem involves inability to get the sperm close enough to the ovum (as may happen with ejaculatory problems), the physician may place a semen sample from the male partner closer to the ovum via a small catheter. **In vitro fertilization** (IVF) involves bringing ova and sperm together outside the bodies of the participants. Ova may be harvested using a long needle or an endoscope after hormonal preparation of the woman. Sperm may be obtained through masturbation; intercourse with a nonlu-

postcoital: post—after + coital—pertaining to intercourse
in vitro fertilization: in—inside + vitro—glass + fertiliz—fruitful + ation—process

bricated, nonpermeable condom; or electrical stimulation of ejaculation for patients with spinal cord injuries.

For those whose sperm is unable to successfully penetrate the ovum, procedures involving gamete micromanipulation may be done. Under a microscope, an ovum from the female partner is partially opened by removing a portion of the outer covering to facilitate sperm penetration, or sperm may be injected into the ovum. This fertilized ovum is then reinserted into the woman's body.

When measures to improve the chances of conception using the partners' own gametes are unsuccessful, gametes from donors may be utilized. Artificial insemination by injecting another man's sperm into the genital tract of the female patient is the simplest of the donor procedures. Ova also may be harvested from a donor woman and used for in vitro fertilization using the male partner's sperm if possible. Both these procedures allow for genetic inheritance from one member of the couple. If genetic inheritance is not possible or desirable (as with familial disease carriers), both donor sperm and ova may be used for in vitro fertilization to be transferred into the female patient. Surrogacy is a situation in which an embryo from one couple is placed into a "host" mother for growth of a baby for the couple and is a topic of much ethical debate.

Nursing Care and Teaching of the Patient Undergoing Treatment

Patients who are undergoing infertility treatment may experience many upsetting and distressing feelings. Feelings of inadequacy, frustration, depression, and anger are common. If the infertility was caused by something the patient perceives as avoidable, such as sexually transmitted disease, guilt feelings may add to the psychological discomfort. Any or all of the previously described tests may be completed and some repeated many times without identification of reasons for the infertility, resulting in repeated disappointments. Some patients cling to the hope that new tests and treatments are being developed that may help them, whereas others feel that they are being used as a "guinea pig" for development of new strategies. The beginning of menses may signal a time of mourning for these couples. Depression may result after failed IVF attempts. Strained relationships may develop between marriage partners, especially if there is disagreement about the value of testing or the importance of having children.

Usually more than the desired number of embryos are implanted because it is expected that not all will survive and because this is more cost-effective with less physical risk for the mother. However, this requires heart-wrenching decisions of whether to "reduce" (abort) extra pregnancies or to risk having more than the desired number of children at once as a result of the fertility treatments.

Offer a listening ear while being careful not to give advice about treatment modalities. There are many ongoing debates among researchers and practitioners as to the value of particular procedures; consequently, strategies may vary widely from one health care provider to another. Encourage

open communication among the patient, the health care provider, and the patient's significant other, and encourage decision making that is informed and based on the patient's values.

Many varieties of assistive reproductive technology are available, and the number is increasing with research. Most of the procedures are called by acronyms (names developed by using first letters of each descriptor). For example, *GIFT* means "gamete intrafallopian transfer" (putting the gametes together in the fallopian tube). Acronyms can be a useful shortcut but can be confusing. Most nurses probably do not need to know all acronyms of infertility treatments unless they work in a gynecologist's office or infertility clinic. Knowing that words in all capital letters are generally acronyms helps understanding of many procedures.

► REPRODUCTIVE LIFE PLANNING

Reproductive life planning is a more comprehensive term than *contraception* and implies reasoned decisions related to pregnancy timing and whether or not to have children. Nurses can contribute to the overall health and quality of life for women and families by assisting them to find the information they need to make wise choices.

There are many different types of birth control available, and several additional types are in developmental and testing stages. General categories of agents are discussed in this chapter. General knowledge of how the different types of contraceptives work can assist the nurse in answering patients' questions or helping patients find additional information. This section is not intended to be a substitute for discussion with the health care provider or for information supplied with individual products.

No numerical statements of effectiveness are included here because several different sets of statistics are currently in use. It seems likely that as products improve, hormone dosages are changed, or more data come in from users, the numbers will be adjusted. Methods are introduced in the order of general effectiveness from most to least effective (with the exception that experimental methods are discussed at the end regardless of their efficacy). Consult your clinic or health care provider for an approved, current comparison list of methods for distribution.

For some patients, the distinction of whether the birth control method actually prevents conception or only interferes with implantation or maintenance of a pregnancy is an important factor in their decision. If a patient believes life begins at conception, any action other than prevention of conception would be considered equivalent to abortion (Fig. 40-8).

Oral Contraceptives

Oral contraceptive medications are among the most widely used forms of birth control in North America. Most contain an estrogen and a progestin in combination, although some (minipills) contain only a progestin. Some work to prevent conception by inhibiting ovulation or changing the environment of the reproductive tract so that activity of the sperm is inhibited. Others do not prevent conception but

Figure 40-8 A variety of birth control methods are available.

make implantation less likely and hasten the breakdown of the corpus luteum so that pregnancy-sustaining hormones are not produced. Many of the adverse effects that occurred in the past have been overcome by adjustment of dosage levels.

Oral contraceptives may also be used in some instances to regulate irregular menses or to decrease dysmenorrhea. There is much debate about whether hormonal contraceptive agents may offer some protection against some sexually transmitted diseases based on lower statistical rates of STDs among oral contraceptive users. However, cellular changes of the cervix seen with hormonal contraceptive use actually tend to be associated with higher rates of some sexually transmitted diseases.⁷ Unless some specific mechanism of prevention is demonstrated by research, it seems irresponsible to suggest that oral contraceptives alone offer protection against anything other than pregnancy. Therefore women should still be advised about the risks of contracting sexually transmitted diseases while taking an oral contraceptive.

Advantages, Disadvantages, Side Effects, and Risks

Oral contraceptives are very effective. Improvement of dysmenorrhea, increased regularity of menses, and decrease in menstrual flow may occur; however, some women experience menstrual changes such as amenorrhea, irregular or prolonged menses, and intermenstrual spotting. They require a great deal of commitment because irregular use decreases effectiveness. To encourage regular use, oral contraceptives are generally dispensed in containers labeled with the days of the week, and some companies include unmedicated pills in the package to be taken during the time of hormone cessation for menses, so that the woman only has to remember to take a pill every day.

Some women experience side effects such as acne, fluid retention, headaches, breast swelling and discomfort, mid-cycle bleeding, and sometimes depression. Use of an oral contraceptive also has some risks. Higher rates of blood clot formation, strokes, high blood pressure, heart attacks, and worsening of diabetes are rare occurrences with some hormonal contraceptives and are generally related to preexist-

ent disease entities. Women who smoke or have diabetes, high blood pressure, heart disease, or a history of thrombophlebitis should receive counseling about the risks of oral contraceptives and education about alternative methods of contraception.

Oral contraceptives decrease the risk of endometrial and ovarian cancer, but there is debate about risk of breast cancer, and cervical **dysplasia** (cell changes that may become cancerous) sometimes occurs among oral contraceptive users. Women should definitely be advised to have regular annual (or more frequent if abnormalities develop) Pap smears while taking oral contraceptives.

Many medications can alter the effectiveness of oral contraceptives, and women should be warned always to alert health care providers and pharmacists that they are on an oral contraceptive whenever a new medication is to be started or a regular medication is discontinued. Use of hormonal contraceptives increases the risk of vitamin B deficiencies, so a healthy diet with good sources of B vitamins is advisable.

Contraceptive Implants

Contraceptive implants involve one or more small permeable tubes that are surgically implanted through a small incision under the skin of the upper arm. These tubes slowly release medication such as levonorgestrel (Norplant) and provide rapid and continued contraceptive effects for 5 years. Three-year replacement may be recommended for larger women.

Advantages, Disadvantages, Side Effects, and Risks

Long-term contraceptive effect without having to remember to take daily medication is the main advantage of implants. Improvement of dysmenorrhea and decrease in menstrual flow may occur; however, some women experience menstrual changes such as amenorrhea, irregular or prolonged menses, and breakthrough bleeding (especially in the first year of use).

Women older than 30 years of age may experience some delay of fertility after removal of the implants. Use of these implants is contraindicated for women with history of jaundice or liver disease. If redness, swelling, or inflammation occurs at the insertion site, the patient should return to the health care provider. Change or removal is done through another small incision. Some fibrosis develops around the insertion sites.

Depot Medications

Medroxyprogesterone and norethindrone are two types of contraceptive agents available in a slow-release (depot) form that can be injected intramuscularly. Medication is continuously released for 3 months. Some other depot contraceptives require monthly injections.

dysplasia: dys—painful or abnormal + plasia—shape or form

Advantages, Disadvantages, Side Effects, and Risks

The main advantage of depot medications is that there is no requirement to take medication daily. Disadvantages are that the medication is not immediately effective, so another method is necessary for the first 2 weeks after the initial injection, and that fertility may not return for several months to 1 year after cessation of injections.

Alterations in menstrual flow, especially amenorrhea, are the most commonly noted side effects. Other side effects and risks are similar to those encountered with oral contraceptive use.

Estrogen-Progestogen Contraceptive Ring

An estrogen-progestogen contraceptive ring has been very effective in trials.⁸ It works in much the same manner as other hormonal contraceptives by slowly releasing hormones. The user inserts it into the vagina around the cervix much in the manner of a diaphragm, but it does not provide a barrier over the cervix, so there is less risk of infection than with a diaphragm or cervical cap. It is left in place for 3 weeks and then removed for 1 week for menses to occur.

Advantages, Disadvantages, Side Effects, and Risks

Not having to remember daily medication can be an advantage to the contraceptive ring, but failing to remove it at the right time may disrupt the regularity of the menstrual cycles. Further research is necessary to determine the seriousness of any side effects and risks, but these would be likely to resemble other low-dose hormonal contraceptives.

Transdermal Contraceptive Patch

A transdermal patch has been tested in the United States and Canada. It is worn weekly for 3 weeks and is then removed for 1 week.⁹

Advantages, Disadvantages, Side Effects, and Risks

The contraceptive patch has been found to be similar to oral contraceptives in effect without having to remember to take a pill each day. Bathing, swimming and other activities can continue with the patch in place.

Barrier Methods

Barrier methods of birth control alone are less effective in preventing pregnancy than most of the previously mentioned methods. Barriers are intended to prevent sperm from reaching the ovum. There are several forms of barrier contraceptives. Effectiveness of all the barrier methods may be increased by use of a spermicidal preparation with them. Spermicidal preparations may be purchased without a prescription.

Condoms

Condoms are to be used once and then discarded into an appropriate waste receptacle. They should be stored in a cool, dry place before use and should not be stored tightly pressed, because heat and continued pressure can weaken them. Storage in a wallet or glove compartment is not advisable. Petroleum-based substances, such as Vaseline, can also weaken condoms, so use of water-soluble lubricants (preferably spermicides) should be advised.

ADVANTAGES, DISADVANTAGES, SIDE EFFECTS, AND RISKS OF MALE CONDOMS.

Male condoms have long been used for contraception because they are a relatively inexpensive, totally reversible method that men can control at the time of intercourse. They provide some barrier protection against transmission of sexually transmitted disease organisms as well. An electron microscope study of a sample of nonlubricated latex condoms, however, found that the majority of those viewed had surface abnormalities, including cracking and melted areas.¹⁰ Patients should be informed that barrier methods can reduce risk but do not absolutely prevent transmission of STDs, especially in areas of contact not covered by the barrier. The main disadvantages of condom use are interruption of foreplay for application, decreased sensation, and the possibility of slippage or breakage during intercourse. These disadvantages may be overcome by incorporating application of the condom by the female partner as a part of foreplay; using thinner, lubricated, or textured condoms to increase sensation; using the correct size condom with a reservoir or applied with approximately half an inch at the tip of the condom loose enough to serve as a reservoir for the semen (Fig. 40-9); and removal from the vagina before relaxation of the erection.

ADVANTAGES, DISADVANTAGES, SIDE EFFECTS, AND RISKS OF FEMALE CONDOMS.

Female condoms are a more recent innovation that allows female initiation of contracep-

Figure 40-9 Correct application of a condom.

tion, as well as some barrier protection against infection with sexually transmitted diseases. Coverage of the labia by the condom may provide more of a barrier than male condoms (Fig. 40–10). Disadvantages are greater expense than male condoms, decreased sensation, the necessity to apply before

intercourse, and the possibility of flaws in the condom material. As of the writing of this book, there had been relatively little controlled research on this type of condom.

Diaphragms, Cervical Caps, Sponges, and Lea’s Shield

ADVANTAGES, DISADVANTAGES, SIDE EFFECTS, AND RISKS. Diaphragms, cervical caps, and sponges all work in the same manner by blocking the entry of sperm through the cervix. The barrier effect is enhanced by a spermicide. The sponge comes presaturated with a spermicide and generally needs to be moistened slightly with water and inserted with the indentation toward the cervix. The diaphragm and cervical cap require application of spermicide to the edges and a small amount in the cup before application. Lea’s Shield is a silicone bowl-shaped barrier that may be purchased without prescription in some countries. It may offer improvements over the traditional diaphragm because it has a loop for ease of removal, fits closer to the cervix with less pressure exerted toward the urethra, and requires less spermicide than a traditional diaphragm. Little research was available on it at the time of the writing of this book.

All these methods are relatively inexpensive, are female initiated, and work without systemic medication. Diaphragms and cervical caps require initial fitting and a prescription to buy them, may need to be refitted after childbirth and the loss or gain of weight, and can last for years. These devices should be replaced periodically as the manufacturer recommends or whenever there is any evidence of hardening, cracking, or thin spots. They need to be washed with soap and water, dried, and stored in a case away from heat and sunlight between uses. Sponges do not require fitting, but they are more expensive than the other two methods and are used only once and then discarded.

Women and their partners may experience irritation or allergic reaction to the spermicide or the contraceptive device material, which would require changing birth control methods. All these methods require that the device be inserted before intercourse and left in place for several hours after intercourse. (See package insert for recommendations.) An increase in incidence of urinary tract infection has been reported with use of the diaphragm, and risk of toxic shock syndrome increases with prolonged uninterrupted use of cervical barriers. Adequate fluid intake, voiding shortly after intercourse, and removal of the device when 8 hours have passed since intercourse all help to prevent these potential problems. If urinary tract infections are recurrent using the diaphragm, changing to a cervical cap or a shield may decrease the occurrence because there is less pressure against the bladder side of the vagina.

Spermicides

Spermicidal agents also may be used alone, although use in combination with a barrier method is much more effective. They come in a variety of forms, such as creams, gels, foams, and suppositories, which kill or disable sperm so that fertilization does not occur.

Figure 40-10 Female condom application. (A) Inner ring is squeezed for insertion. (B) Sheath is inserted similar to a tampon. (C) Inner ring is pushed up as far as it can go with index finger. (D) Condom in place.

Advantages, Disadvantages, Side Effects, and Risks

Spermicidal preparations are relatively inexpensive and can be male or female initiated. They do not produce systemic effects, and no hormones are involved. They are less effective alone than the previously described methods. Spermicides require application before each act of intercourse and are considered by some patients to be somewhat messy. Many contain the same ingredient—nonoxynol 9. If genital irritation or a rash occurs with spermicides, the patient should read the labels carefully to avoid contact with the same ingredient.

Intrauterine Devices

The presence of a foreign object in the uterus is thought to alter the environment, so that implantation is less likely to occur. Intrauterine devices (IUDs) are generally made of some form of plastic and may contain copper wire or a supply of a progestin that is slowly released into the system to further alter the environment, so that fertilization or implantation are hindered.

Advantages, Disadvantages, Side Effects, and Risks

The main advantage of use of an IUD is continued contraception without the necessity of remembering to take medication and without the side effects associated with medications. The disadvantages are changes in menstrual bleeding (especially increases in bleeding), cramping, and increased risk of pelvic inflammatory disease. Rarely an IUD has caused a uterine perforation. IUDs are contraindicated for women who have never been pregnant, those with uterine abnormalities, and those who have a history of anemia or heavy menstrual flow. Expulsion or displacement of the IUD can occur, so women should be taught to feel for the string before intercourse.

Insertion Procedure

Insertion of an IUD is generally done as a physician's office procedure with a nurse assisting. Usually this is done during the first 7 days of the menstrual cycle because the cervix is generally slightly dilated at this time. You will need to put out a vasovagal reaction treatment kit, an IUD insertion kit containing one or more uterine "sounds" and a tenaculum (a special long forceps) for grasping the cervix, and the IUD package. The IUD is generally inserted into the vagina through a tube that comes packaged with the IUD, which temporarily holds the IUD flat or folded so that it requires less room for insertion. When the IUD is pushed out the end of the tube, it springs into a shape that helps to keep it inside the uterus. One potential danger associated with IUD insertion is vasovagal reflex stimulation (previously described in association with endometrial biopsy). You periodically assess pulse or blood pressure during the procedure and notify the health care provider of slowing of the heart rate or a decrease in blood pressure.

Natural Family Planning

Periodic abstinence, or natural family planning, is less effective than the previously described methods. It is a method by which couples control their fertility by restricting intercourse to "safe periods" in which risk of conception is low. Many signs may be assessed to determine "safe" days, including temperature changes, cervical consistency and mucus changes, calendar timing, and awareness of symptoms of fertility.

Slight body temperature changes can indicate ovulation. During the first half of the menstrual cycle the temperature remains low, with a marked drop just before ovulation occurs. With ovulation the temperature rises and stays higher for the last half of the cycle. Women who use this assessment method should use a basal body temperature thermometer when they awaken, before doing anything else, and record it on a chart.

Cervical consistency and mucus changes may also help pinpoint ovulation. As hormone levels change, the consistency of cervical mucus changes. As ovulation approaches, there is an increase in the amount of mucus and the mucus becomes more clear, thin, slippery, and stretchable than at other times of the month. Around the time of ovulation the cervix becomes softer to touch and more open than at other times of the cycle.

Following the calendar can work fairly well if a woman's menstrual periods are regular, but becoming aware of her pattern may take time. Symptoms such as breast tenderness and midcycle discomfort (mittelschmerz) may also help identify ovulation. Users of this method should be advised to abstain for approximately 3 days before ovulation and 3 to 4 days after, because the sperm and ovum can survive for a long period in the female genital tract.

Advantages and Disadvantages

The advantages of this method are that it is inexpensive, it requires no medication, and it is the only birth control method presently approved by the Catholic church. The disadvantages are that it requires the cooperation of both partners and may interfere with spontaneity of sexual expression. It is generally not very effective as a means of birth control. It may be difficult to be accurate about ovulation times because infectious and inflammatory processes may affect temperature readings, infections and feminine hygiene products may affect cervical mucus, and irregularity of flow and symptoms may make prediction difficult.

Less Effective Methods

Coitus Interruptus

Coitus interruptus involves removal of the penis from the vagina before ejaculation occurs.

ADVANTAGES, DISADVANTAGES, AND RISKS. Although this method requires no expense or preparation, it is not very effective. Excellent control of ejaculation is required, and even the small amount of sperm that may be present in pre-ejaculatory fluid may result in pregnancy.

Postcoital Douching

The intended purpose of postcoital douching is to wash sperm out of the reproductive tract or to kill or immobilize sperm that the douche solution contacts.

ADVANTAGES, DISADVANTAGES, AND RISKS. This is relatively inexpensive and female initiated, but it is not very effective. Sperm move very rapidly once deposited, and douching may actually push the sperm upward.

Breast-Feeding

Breast-feeding is sometimes used as a method of birth control because the high blood levels of prolactin that occur with breast-feeding may suppress ovulation.

ADVANTAGES, DISADVANTAGES, AND RISKS. This method costs nothing but is not very effective. Prolactin levels can vary widely, and ovulation may resume at any time without any noticeable signs, resulting in pregnancy before even experiencing a menstrual period after the previous birth.

Ongoing Research: Future Possibilities for Contraceptive Choices

Several contraceptive agents are presently in developmental stages. A single contraceptive implant containing norgestrel acetate (Uniplant) implanted under the skin of the upper arm or gluteal region has been tested in clinical trials and found to be effective for 1 year. This method, however, will probably be further refined and tested as a result of menstrual cycle irregularities among women using it.

Many researchers have tried to develop effective and reversible male contraceptives. A plant called *Tripterygium*, used in Chinese herbal medicine, when taken orally yields substances that can limit numbers and mobility of sperm, but it also has active ingredients that suppress immunity somewhat, so further investigation is necessary. Reversible injection procedures to block the seminal vas deferens are also being investigated, as are reversible injection procedures to block the fallopian tubes. Reversible birth control vaccines are also being investigated for both men and women with the goal of causing an immune response to occur at some vital point in the process of conception.

Some questions related to contraceptive vaccines include the unknown long-term repercussions of stimulating the body to respond with immunity to itself and whether governments could use vaccines as a means to control populations without their consent. Another frightening possibility is that with further removal of the threat of pregnancy even fewer people would use barrier methods and STDs would increase even more dramatically.

Sterilization Actions

Permanent sterilization can be accomplished by either interrupting the fallopian tubes (tubal ligation) or vas deferens (vasectomy) or by removing the uterus and suturing the

CRITICAL THINKING

Jessica

You have just observed a patient who looks to be about 13 years old announce loudly at the clinic reception desk that she is “ready to be a responsible adult” and would like some birth control.

1. What information needs to be gathered from her?
2. What do you think she needs to know?
3. How can contraceptive teaching capitalize on her desire to be a responsible adult?

Answers at end of chapter.

proximal end of the vagina closed. Tubal interruption may be done by tying a suture or placing a ring or clip around each fallopian tube, by coagulating a section of the tubes, or by surgically removing a portion of the tube and suturing the ends. These procedures are usually done by laparoscope.

Advantages, Disadvantages, Side Effects, and Risks

Although this method is not absolutely certain to be permanent, the failure rate is low and has been decreasing recently with newer surgical methods. Tubal repair is sometimes requested at a later time to reestablish fertility. This requires microsurgery with anesthesia and has a poor success rate.

Patient Teaching

Patients should be advised by their surgeon about the complications of the surgery and of reversal before they sign a consent for sterilization. If any uncertainty about the surgery is evident, the physician should be notified promptly.

► PREGNANCY TERMINATION

Termination of pregnancy (abortion) is a difficult topic. Discussions about it are often highly charged with emotion. Both pro-life and pro-choice advocates argue on the basis of human rights—the former based on supposed rights of the fetus and the latter on supposed rights of the mother—because of the humanity of each party. There are very few people on either side of the philosophical argument, however, who would describe abortion as a healthy medical intervention. Most agree that abortion is a problematic solution to a difficult situation. There are instances in which carrying a pregnancy to term threatens the life of the mother. There are also many more instances in which a pregnancy is inconvenient or undesired. Although a discussion of the ethical issues surrounding abortion is encouraged, it is beyond the scope of this book to thoroughly address all the issues (Ethical Consideration Box 40–2).

Nursing Care, Teaching, and Patient Advocacy

Ethically an individual nurse should not be required to assist in any treatment that demands that he or she act in a way that contradicts personal moral beliefs—this would vi-

BOX 40-2 ETHICAL CONSIDERATION

The famous case of *Roe versus Wade* (1973) changed the legal status of therapeutic abortion in the United States but added a great deal of confusion to its ethical and moral status. A careful reading of the *Roe versus Wade* decision reveals that the court made no decision about the ethics or morality of elective (therapeutic) abortion. Rather, the court said that according to the U.S. Constitution, all people, including women, have a right to determine what they can do with their bodies (right to self-determination) and a right to privacy. Therefore during the first trimester a woman and her physician may decide to terminate a pregnancy without interference from the state. During the second trimester, the state may regulate the circumstances under which an abortion may occur to protect the woman's health. Once the fetus is viable, the state may also prohibit abortion. Although a woman may have a right to obtain an abortion, there is not a right to require the death of the fetus should a viable fetus be identified after the abortion procedure. Pro-choice groups put the right to self-determination and privacy central to their concerns. Pro-life groups generally believe that abortion is fundamentally killing and therefore abortion is wrong.

One of the central issues in the debate is the status of the fetus. Is the fetus considered a person with individual rights separate from those of the woman who is pregnant? Another central question is, When does human life begin? Is abortion at any stage of pregnancy morally acceptable? Each fertilized egg contains the essential genetic material for the development of a unique individual. However, many fertilized eggs never successfully implant in the uterus in the natural process of conception. Does such a factor make the timing of the procedure a critical element? Related to this problem is the status of frozen embryos created through in vitro fertilization. They too contain the essential, unique genetic material for the development of a human person. If every embryo should be respected as potential human life, what moral obligation do we have toward those embryos?

olate the nurse's rights. However, there is also an ethical duty to provide care to patients for whom the nurse is responsible. Therefore it is wise for nurses who have moral objections to abortion to carefully choose their work setting. For example, choosing to work in day surgery in a hospital that performs abortions and refusing to care for abortion patients is not a legitimate option. One way that nurses can positively influence the abortion situation is by teaching about family planning, which may lower the number of requests for abortions. Another way might be to become involved with agencies that help pregnant women to have viable alternatives to abortion.

Therapeutic Abortion for Ectopic Pregnancy

An ectopic pregnancy is the implantation of a fertilized ovum in an area other than the uterus. It may occur because of an abnormally shaped uterus or fallopian tubes that are obstructed as a result of abnormal development, scarring from STDs or other inflammatory processes, or for unknown reasons. This is a life-threatening situation for the mother, and currently abortion is the only treatment.

Therapeutic Abortion for Prenatal Abnormalities

Development of a variety of prenatal testing methods has introduced the possibility of knowing many things about a baby before birth. Prenatal testing may be done using ultrasound, samples of fluid taken from the amniotic sac or the placental villi, or blood samples from the mother. From these tests, several genetic diseases and congenital deformities can be identified. After anomalies are diagnosed, some patients choose to abort the baby. This is a very difficult decision to consider even in instances in which the baby has a fatal defect that will not allow it to live outside the uterus. Information about alternatives to abortion and possible treatments for their child are important for patients who have a serious prenatal diagnosis. No one should feel pressured to make the decision quickly to abort, but legal requirements and increasing risk for the mother may limit the time to decide. Abortion because of fetal abnormality may result in much grieving for the patient and her family.

Methods of Abortion

Several methods are available. The method is determined primarily by the length of the gestation and the goal of inflicting as little trauma to the mother's reproductive system as possible while still inducing pregnancy loss. Periods for the different abortion methods and the allowable reasons for legal abortion vary according to the laws of the state, province, or country.

Chemical Agents

The "morning after pill," or emergency contraceptive treatment, consists of postcoital administration of sufficient estrogen or an estrogen/progestin combination to cause sudden sloughing of the endometrial lining of the uterus, preventing implantation of a possibly fertilized ovum. For this to be effective, the initial dose is generally given within 72 hours of intercourse. This treatment is used in case of unexpected unprotected sexual intercourse (as with sexual assault) or unexpected risk of conception (as with condom failure). Nausea and cramping may accompany the shedding of the uterine lining, and an antiemetic may be taken to manage nausea. No advance planning before intercourse is required, so this can be abused as a casual form of birth control. These patients may need education about appropriate birth control methods.

Another example of postcoital contraception is the drug RU-486, which is a progestin antagonist. It prevents the binding of progestins at their receptors, resulting in a chemically induced abortion up to the 10th week of pregnancy. Nausea and cramping may accompany expulsion of uterine contents. There is much debate about whether RU-486 should be used at all or should be used only within specific guidelines. The United States Food and Drug Administration approved RU-486 in 2000 in an accelerated drug ap-

proval process, but legislative bills have been introduced and reintroduced to stipulate regulations for health care providers prescribing RU-486. Undoubtedly RU-486, as well as methotrexate (a cancer medication) and misoprostol (a medication to prevent stomach ulcers), all of which can stimulate abortion, will be the subject of much debate over the next few years.

Abortion Methods for Early Pregnancy

Early in a pregnancy (during approximately the first 13 weeks) there are three primary means of pregnancy termination—menstrual extraction, vacuum aspiration, and D & C. Menstrual extraction is removal of the endometrial lining by manual suction and can be done during the first 7 weeks following the last menstrual period (LMP). This can be done without anesthesia and without cervical dilation by inserting a small cannula into the cervix and aspirating with a large syringe. Vacuum aspiration is a similar process that is used from confirmation of pregnancy through the first 13 weeks. It requires cervical dilation and is generally done with local anesthesia. The patient returns home 1 to 4 hours after the procedure. D & C may also be used during the first 13 weeks. In this procedure the cervix is dilated and the uterine contents are scooped away with a curet rather than being removed by suction.

Abortion Methods for Later Pregnancy

During the second trimester the fetus is much larger, so more dilation is required. A dilation and evacuation (D & E) may be performed, in much the same manner as a D & C. Generally, dried laminaria (a type of seaweed) or some other absorbent substance is placed inside the cervical canal. This absorbs fluid and swells, thus gradually dilating the cervix. Prostaglandin may be administered either by suppository into the vagina or by injection into the amniotic sac; this usually induces uterine contractions and results in delivery a few hours later. Unfortunately, a live fetus too premature to survive may be born by this method and continue to breathe for a time until death.

An induction with either a saline or urea injection may be used for pregnancies beyond 16 weeks. A portion of amniotic fluid is removed and replaced with concentrated saline or urea solution, which kills the fetus and stimulates contractions. Sometimes saline and prostaglandins are used in combination to terminate a pregnancy.

Hysterotomy involves removal of the uterine contents through an abdominal incision in the same manner as a cesarean section. This procedure is rarely done for pregnancy termination.

Risks and Complications

Abortion involves risks. Some are the same risks inherent in childbirth, such as possible hemorrhage or introduction of infection, but there are additional risks related to inter-

ruption of natural processes and the aggressiveness with which the products of conception are removed during abortion. During an uncomplicated childbirth the uterine lining is not scraped or forcefully emptied by suction. Natural hormonal preparation for term childbirth contributes to uterine contraction after the birth, which decreases blood loss, but no such preparation occurs for abortion. Artificial dilation of the cervix may cause injury, as may introduction of the instruments used for abortion. Injured tissues are more likely to become sites for growth of microorganisms than are intact tissues. Finally, the possibility of infertility as a result of complications related to abortion, although relatively uncommon, is a risk.

Some possible physical complications following therapeutic abortion are injuries to the uterus or cervix, excessive bleeding, infection, retention of some products of conception, and possible failure of abortion. Rarely, second trimester abortions can be complicated by amniotic fluid embolism, in which amniotic fluid is absorbed into the uterine circulation because of disruption of placental attachments with instruments. Amniotic fluid in the mother's circulatory system can result in circulatory collapse and disseminated intravascular coagulation (DIC). DIC is a serious derangement of the body's blood clotting controls and, though rare, can be fatal. Clotting mechanisms are overstimulated, so that the blood begins to form clots in vessels all over the body. In response to this hypercoagulation, fibrinolytic mechanisms are overstimulated and the patient may suffer severe and widespread bleeding. Treatment of this disorder is difficult because the normal mechanisms for both sides of this clotting/clot dissolving equation are hypersensitive.

Nursing Care and Teaching

Aftercare is very important. Abortion patients rarely stay overnight, and complications may occur after they are discharged. They should be carefully assessed after the procedure for signs of bleeding. Instruct that bleeding should not exceed that of a heavy period, that the passage of clots larger than a quarter may be a sign of complications, and that the discharge should not become foul smelling. Patients should be given a phone number (available 24 hours per day, seven days per week) to call if fever, chills, excessive bleeding, or any signs of infection occur. The patient should be advised to abstain from sexual intercourse for the time specified by the health care provider (usually about 3 weeks). A grief response may occur after a pregnancy termination, even if the baby was definitely unwanted and the patient does not have strong beliefs against abortion. There is much debate about frequency of postabortion syndrome or whether such a condition exists. However, loss and trauma have occurred in any case, and reorganization of the self takes time. Availability of psychological counseling for women after abortion is very important. Women should be given a number to call if they experience psychological discomforts. The need for birth control should be assessed.

hysterotomy: hystero—womb + tomy—cutting

► TUMORS OF THE REPRODUCTIVE SYSTEM

Benign Growths

Fibroids

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. Fibroids or **leiomyoma** (singular form is leiomyomata) are benign tumors made up of endometrial cells that have implanted on or within the walls of the uterus. These can grow very large and may cause pain or menstrual disorders, exert pressure on the bladder or bowel, cause necrosis because of pressure on the blood supply to tissues, and interfere with fertility.

TREATMENT. Because fibroids are estrogen sensitive, medical treatment may involve hormone suppression. Surgical treatment may involve **myomectomy** or hysterectomy. Myomectomy is removal of only the fibroid tumor and may be chosen to preserve fertility. Myomectomy may be done surgically through an abdominal or vaginal incision or with a laser introduced through a laparoscope. Hysterectomy may be necessary for very large fibroids or those that cause severe bleeding or discomfort.

Polyps

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. Polyps are generally benign growths that grow inside the uterus or on the cervix and may bleed after intercourse or between menstrual cycles. These are generally teardrop shaped and are attached by a stalk. Polyps develop most often after the age of 40.

TREATMENT. Polyps are generally removed vaginally or transcervically by separating the stalk from the uterus and then stopping the bleeding by use of chemical, electrical, or laser **cautery**. Removal of polyps in the vagina may be done without anesthetic in a physician's office. Removal of polyps transcervically requires cervical dilation and is more likely to be done in a hospital with anesthesia.

Reproductive System Cysts

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. Several types of cysts may affect women's health. Cysts of the ovaries may develop associated with incomplete ovulation, **hypertrophy** of the corpus luteum after ovulation, or inflammation of the ovary. Most ovarian cysts eventually spontaneously shrink and merely cause discomfort for a time. Chocolate cysts are formed when endometrial cells bleed into an enclosed space, as occurs with endometriosis. These are called chocolate cysts because they

are filled with old blood, which has become chocolate colored. Cystadenomas are benign growths that can sometimes undergo cellular transformation and become cancerous. Any pelvic mass in a postmenopausal woman has a high potential for malignancy and should be investigated.

TREATMENT. Most cysts are not surgically removed, but excessive size, interference with fertility, and high cancer potential may make needle drainage, biopsy, laparoscopic surgery, or **laparotomy** advisable. If cysts are painful, application of heat to the abdomen or back may help promote comfort.

Polycystic Ovary Syndrome

PATHOPHYSIOLOGY AND ETIOLOGY. Polycystic ovary syndrome (PCOS) is a complex abnormality of endocrine balance of unknown etiology. Multiple cysts on the ovaries are a sign that was discovered early and for which the disease was named, but they are not present in all cases. There seem to be strong genetic links with such family history as too much or too little hair (especially for women), severe acne, diabetes, irregular menses, and infertility. Many of the symptoms of PCOS are a result of excessive levels of insulin in the blood because of insulin resistance. Excess insulin in turn stimulates secretion of androgens.

SIGNS AND SYMPTOMS. Women with PCOS often present with infertility, obesity, and menstrual disturbances. They may also exhibit masculinization because of the excess androgen secretion. They have a higher risk for diabetes mellitus, elevated blood pressure, coronary artery disease, and endometrial cancer.

DIAGNOSTIC TESTS. Diagnostic tests may include blood tests to rule out other causes of endocrine abnormality, tests to determine whether ovulation is occurring (such as midluteal progesterone levels and basal body temperature graphing), endometrial biopsies to determine the level of proliferation and to check for endometrial cancer, and blood tests to determine lipid levels and glucose tolerance.

MEDICAL TREATMENT. Medical treatments may involve blood pressure medications, lipid control medications, and oral hypoglycemics. Diet and exercise may be recommended for weight reduction, control of lipid levels and cardiac health. Oral contraceptives may be used to normalize hormone levels and protect the endometrium for those not desiring to conceive. Ovulation-inducing medication may be used for those women who desire to conceive. If masculinization is a problem, antiandrogen medications may be prescribed. In severe cases, gonadotropin-releasing hormone (GnRH) agonists may be used to produce medical suppression of the ovaries, with results similar to removal of the ovaries. This is followed 6 months later with an estrogen/progestin combination to protect the bones from development of osteoporosis.

leiomyoma: leio—smooth + myom(a)—fibroid
myomectomy: myom(a)—fibroid + ec—away + tomy—cutting
cautery: branding iron
hypertrophy: hyper—too much + trophy—nourishment (growth)

laparotomy: laparo(o)—abdominal wall + tomy—cutting

Bartholin's Cysts

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. Bartholin's cysts are actually infected or obstructed Bartholin's glands at either side of the vaginal opening. Excessive swelling of Bartholin's glands results in pain with sitting and with intercourse.

TREATMENT. Incision and drainage may alleviate the discomfort. If Bartholin's cyst formation occurs often, **marsupialization**—the surgical formation of a pouch around an opening made into a gland to facilitate drainage—may be necessary. Sitz baths may be ordered to cleanse the area and to promote comfort and healing.

Dermoid Cysts

PATHOPHYSIOLOGY, ETIOLOGIES, SIGNS AND SYMPTOM. Rarely, for unknown reasons, a **dermoid** cyst (also called a cystic **teratoma**) may develop from a germinal cell of an ovary. This cell divides and differentiates into various tissue types such as skin, teeth, bones, hair, and even extremities in a disordered arrangement. This type of cyst may grow quite large and may occur on both ovaries at the same time.

TREATMENT. Dermoid cysts are removed by laparoscopy or laparotomy. If the cyst contained glandular tissue that was secreting hormones, adjustment of hormone levels to normal may take some time. Although most teratomas are benign, some are malignant, especially in postmenopausal women, so a biopsy is generally done on the tissue.

NURSING CARE AND TEACHING. Growth of a dermoid can be a frightening experience for a woman. Reassurance that this is merely a disordered group of cells identical to the other cells in her body, rather than a monster or deformed baby, is important.

Malignant Disorders

It is sometimes difficult to distinguish benign growths from malignant growths without biopsy results, and some benign growths can become cancerous. Malignancies can occur in all parts of the reproductive system and can occur at all ages. Although reproductive system cancers are more common in older age groups, ovarian tumors can occur even in young children. Both male and female children of women who were given diethylstilbestrol (DES) to prevent premature delivery in high-risk pregnancies have experienced a high incidence of developmental defects and cancers of the reproductive organs.

Many different types of genital cancer are possible, and discussion of every type in detail is beyond the focus of this book. This section presents a general overview of the most common cancers. Cancerous changes often can be observed or noticed, and if investigated and treated early enough, cure is often complete.

marsupialization: marsupial—pouch + ization—process of making

dermoid: derm—skin + oid—form

teratoma: terat—monster + oma—growth

LEARNING TIPS

Three C changes that may indicate cancer are changes in *color*, *contour*, and *consistency* of a tissue.

Vulvar Cancer

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. Although vulvar cancer is not a common, alertness to changes of visible parts of the reproductive system such as the vulva can result in early diagnosis and requirement of less drastic treatment with more positive results. Persistent itching of the vulva or appearance of white or red patches, rough areas, skin ulcers, or wart-like growths on the vulva should not be ignored; these can be signs of precancerous or cancerous changes. Risk factors for development of vulvar cancer are an STD of any type, precancerous or cancerous changes of the anus or any of the genitalia, immune system depression, and smoking.

DIAGNOSTIC TESTS. Regular Pap smears and physical examinations can identify lesions. Biopsy of suspicious lesions is necessary to diagnose vulvar cancer.

TREATMENT. If discovered early, vulvar cancer may be treated with removal or destruction of cancerous cells. If not diagnosed early, it may require surgical removal of the entire vulva and associated lymph nodes (a radical vulvectomy) with subsequent skin grafting from other areas of the body for repair.

Cervical Cancer

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. Changes in the cells of the cervix (called cervical intraepithelial neoplasia, or CIN) can progress to cervical cancer. Dysplastic cells (those with dysplasia) are generally less differentiated or less ordered than expected for their cell type.

Some identified risk factors for development of cervical cancer include starting sexual activity at an early age, having multiple sexual partners, having several pregnancies, smoking, and being infected with human papillomavirus or herpes simplex virus type II (HSV-II).¹¹ Use of oral contraceptives for several years may also increase a woman's risk of developing cervical cancer, although part of the difference in incidence may be because women using oral contraceptives may not be using barrier protection against STDs. Although some women experience slight spotting or a serosanguineous discharge with cervical cancer, many are asymptomatic until the cancer is widespread.

DIAGNOSTIC TESTS. Pap smears are the best method of screening for cervical cancer presently available, but some work is being done on self-tests that women can collect. A Pap smear determines the degree of cellular change, or dysplasia. Ranking systems vary, but Pap smear results are usually presented in categories that range from no atypical cells seen to invasive cancer evident (0 to IV). This procedure

has significantly reduced the incidence of invasive cervical cancer over the years since its introduction, because cellular changes can be identified early enough for treatment before the cells become cancerous. Schiller's test may be done if a patient has an abnormal Pap smear. This involves painting the cervix with iodine. Dysplastic cells stain differently than normal ones. Biopsy is done to confirm a cancer diagnosis. Recommendations for frequency of screening vary, but most recommend that Pap smears begin at either age 18 or with the start of sexual activity and be done yearly unless abnormalities develop. After a period of normal Pap smears, some health care providers advocate longer intervals for low-risk people.

TREATMENT. Treatments for preinvasive neoplasia include **cryotherapy** (freezing), laser therapy (burning), and surgical removal of the involved area with a loop excision instrument or by conization (Fig. 40–11). All these procedures are done through the vagina, so there are no external incisions. After any of these treatments the patient is advised not to douche, use tampons, or have intercourse for approximately 2 weeks to allow for healing to take place. She should be advised to report immediately if fever or bloody or foul vaginal discharge occurs. For invasive cancers, hysterectomy, radiation implant, or chemotherapy may be done.

cryotherapy: cryo—cold + therapy—treatment

Figure 40-11 Conization.

Endometrial Cancer

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. Endometrial cancer is the most common type of uterine cancer. Most develop in response to relative estrogen excess. Abrupt changes in bleeding patterns, especially bleeding in a menopausal woman, may indicate endometrial cancer development. Estrogen excess can develop for many reasons. Estrogen levels fluctuate widely in the perimenopausal period. Obesity results in increased estrogen production that is not balanced by progestins. Estrogen replacement therapy for menopausal symptoms without the addition of progestins also has been associated with an increase in endometrial cancer, but addition of a progestin may decrease the risk of endometrial cancer to less than that of untreated women. Whether alcohol consumption increases the risk of endometrial cancer by interfering with estrogen metabolism is still a matter of debate. Some endometrial cancer, however, is unexplained by any presently known risk factors.

DIAGNOSTIC TESTS. Diagnosis is generally done by endometrial biopsy, but MRI may be used to evaluate invasiveness and involvement of lymph nodes.

TREATMENT. Depending on the stage of endometrial cancer and metastasis, treatment with hysterectomy, radiation, or chemotherapy may be used.

Ovarian Cancer

PATHOPHYSIOLOGY, ETIOLOGIES, AND SIGNS AND SYMPTOMS. Ovarian cancer is an especially insidious killer because cellular changes in the ovaries often are

asymptomatic until the cancer is quite advanced. Little is known about what prompts these cells to undergo malignant changes. Risk factors are not definitely identified, but some proposed factors include low fertility and number of children, late menopause, a family history of reproductive or colon cancers, and a diet rich in animal fats. Use of hormonal contraception may help prevent this, because it results in less ovulation during the woman's lifetime.

DIAGNOSTIC TESTS. Identification of abnormal growths on the ovaries may begin with bimanual examination, so it is important for women, especially in the older age groups, to continue to have regular pelvic examinations even if they are not sexually active and even if they have had a hysterectomy. Various blood tests measuring tumor marker substances, ultrasonography, CT scanning, and MRI may also be used to assist in diagnosis.

TREATMENT. Treatment may involve surgical removal of the ovaries by laparoscopy or laparotomy. Sometimes the ovaries are removed to prevent the disease in women who have a high familial risk. Radiation and combination chemotherapy may also be used.

Nursing Care and Teaching of Patients with Malignant Disorders

Radiation therapy for cancers of the reproductive system may involve the placement of radioactive implants into the patient's body for 24 to 72 hours. Avoid prolonged contact with the patient and perform care with as much of the patient's body between you and the implant as possible (e.g., for cervical implants, stand at the head of the bed rather than at the foot). Prevent inappropriate radiation of the patient's other body parts by such actions as maintaining patency of a urinary catheter to avoid unnecessary exposure of the bladder. Follow institutional guidelines for radiation precautions. Do not give care to patients with radioactive implants if you are pregnant. A foul-smelling vaginal discharge is expected after radiation by implant because of tissue destruction caused by the radiation; document the amount and character of the discharge. Chemotherapy treatments often cause severe nausea, as well as anorexia and sores of the mouth, vagina, and anus. See Chapter 10 for care of patients receiving chemotherapy.

► GYNECOLOGICAL SURGERY

Endoscopic Surgeries

Many of the surgeries performed on the reproductive system may be done using an endoscope. The scopes used contain not only magnifying lenses and a light source but may also include tiny tools for performing surgery, for removal of small areas of diseased tissue and samples, for suction, and for cauterization of bleeding vessels. Because endoscopic surgeries require tiny incisions (usually less than 1 inch long), there is less tissue disruption and very little bleeding when compared with traditional surgical techniques. Smaller incisions also present less risk of infection than traditional methods, and recuperation is generally more rapid

with fewer complications. Overall the danger to the patient is generally low for endoscopic surgeries; however, not all surgical situations may be satisfactorily handled in this way. The size of the cannula restricts the size of tissues that can be removed, unless they can be divided into smaller sections and then pulled out through the cannula. If affected areas are widespread, the scope may not be able to reach all sites. Traditional surgery still may have to be done when endoscopic surgery has been ineffective, and this can be frustrating to patients. Information gained through the prior endoscopic surgery may decrease the time required for the traditional surgery, however.

Laparoscopies are the most common type of endoscopic surgical procedure employed for women's reproductive system surgeries. This method can be used for access to the abdominal cavity and the anterior portions of the reproductive organs. Tubal ligations, tubal repairs, removal of ectopic pregnancy implantations, removal of small tumors, removal of endometriotic sections of tissue, and aspiration of fluid-filled cysts can all be done by this method.

Culdoscopies may be done to access the area at the back of the uterus. A **culdotomy**, which is an incision into the upper posterior portion of the vagina, is necessary to insert the cannula. A **culdocentesis**, which is the removal of fluid from the cul de sac of Douglas, may be done during a culdосcopy. Aftercare is much the same as for laparoscopy, although the patient should be informed that a small amount of vaginal spotting may be expected from the incision but heavy, purulent, or foul-smelling discharge could indicate infection. (See Chapter 39.)

Colposcopies are generally used to screen, diagnose, or treat problems of the cervix. The binocular microscope attached to the scope cannula, which is introduced into the vagina, allows the physician to examine dysplastic cells while they are still in their normal place and to treat cervical dysplasia as previously described. Hysteroscopy may be used to treat problems within the uterus. Removal of polyps and other growths, modification of congenital malformations such as septa (walls of tissue where there should be none), and laser ablation of endometrial tissue may all be done during hysteroscopy. The endoscope may be inserted further into the fallopian tubes to perform a salpingoscopy, allowing surgical or laser opening of blocked tubes.

Nursing Care and Teaching

Postoperative care involves careful assessment for signs of possible excessive internal bleeding, including checks of vital signs, skin color and temperature, and pain. Measures to reduce the discomfort produced by residual carbon dioxide from insufflation may include instruction to lie flat for a few hours, massaging of the back and shoulders, and administration of pain medication. Instruction about possible danger signs, any medications, and when and where to go for suture removal complete the discharge teaching.

culdotomy: culdo—cul de sac + tomy—cutting

culdocentesis: culdo—cul de sac+ centesis—puncturing

Hysterectomy

Removal of the uterus (hysterectomy) may be done for a variety of reasons, including abnormally heavy or painful menstruation, large fibroids or other benign tumors, severe uterine prolapse, and cancer of the uterus. It should not be done merely as a sterilization procedure, because the risks involved in hysterectomy surgery are much greater than risks associated with tubal ligation. The surgery is usually performed through an abdominal incision, but it may be done vaginally in some cases. The vagina is left intact except for suturing of the proximal end, which had been attached to the uterus, forming a blind pouch. Although less vaginal lubrication is present after hysterectomy, nerve routes are maintained and satisfactory sexual intercourse is expected to continue.

The uterus alone may be removed, and in some cases the tubes and ovaries may also be removed—a procedure called total abdominal hysterectomy with **bilateral salpingo-**

oophorectomy (TAH-BSO), or **panhysterectomy**. If the ovaries are removed, the woman undergoes immediate menopause and may suffer from symptoms associated with menopause, including the increased risks of cardiovascular disease and osteoporosis. Because removal of the ovaries is usually done because of the presence of estrogen-dependent cancer, estrogen replacement is not usually feasible in these cases, and extra care, comfort, and explanation from nurses are necessary. (See Nursing Care Plan 40–3 for the Patient Undergoing Hysterectomy. In addition to the nursing diagnoses covered, also assess for anxiety related to surgery and resulting body image changes and for ineffective coping.)

bilateral salpingo-oophorectomy: bi—two + lateral—sided + salpingo—tubal + oophor—ovary + ec—from + tomy—cutting

panhysterectomy: pan—all + hyster—uterus + ec—from + tomy—cutting

BOX 40-3 NURSING CARE PLAN FOR THE PATIENT UNDERGOING HYSTERECTOMY

▶ Risk for impaired tissue integrity related to surgical incision and removal of the uterus (and possibly the ovaries)

PATIENT OUTCOMES

Incision(s) will heal by primary intention without excessive bleeding.

INTERVENTIONS

Monitor vital signs and oxygen saturation according to hospital policy and as necessary.

Check for bleeding or other discharge on perineal pad and on abdominal dressing (if applicable).

Assess wound healing twice a day (bid) and report any evidence of infection or inadequate healing promptly.

RATIONALE

Vital signs and oxygen saturation reflect tissue perfusion status.

Excessive bleeding may compromise tissue perfusion and slow healing. Vaginal discharge gives clues to healing of incision at the proximal end of the vagina.

Early treatment of inadequate wound healing decreases postoperative complications.

EVALUATION

Are vital signs stable and within normal range?

Is pad or dressing dry? Is discharge foul smelling?

Is incisional area swollen, reddened, or draining purulent material?

▶ Risk for impaired urinary elimination related to manipulation of the bladder and ureters during surgery, anticholinergic drugs, fluid intake changes, and fear of pain

PATIENT OUTCOMES

Patient will have urinary output 30 mL/h or more without difficulty.

INTERVENTIONS

Assess urinary output after surgery. Report if less than 30 mL/h or unable to void.

Assess bladder fullness using Doppler monitoring or scratch test (listening with a stethoscope, lightly scratch abdomen as you move downward from xiphoid until you hear change in sound indicating top of the bladder).

Medicate for pain on a fixed schedule for operative day and first postoperative day (unless patient declines pain medication).

RATIONALE

Inadequate urinary output can be an evidence of dehydration, low glomerular perfusion, kidney dysfunction, damage to ureter, or urinary retention.

Urinary retention can cause damage to kidneys, ureters, and bladder. Scratch test and Doppler monitoring cause less discomfort and pressure to an abdominal incision area.

Maintenance of a consistent blood level of medication in the immediate postoperative period provides relief of pain and promotes voiding without fear of discomfort.

EVALUATION

Is output adequate?

Is patient able to void without discomfort?

Does patient feel she is emptying fully when voiding?

Does Doppler indicate residual urine after voiding?

Where is level of sound change with scratch test?

Does patient state that she is comfortable?

BOX 40-3 NURSING CARE PLAN FOR THE PATIENT UNDERGOING HYSTERECTOMY—cont'd

Risk for constipation and gas related to manipulation of the bowel during surgery, opioid analgesics and anticholinergic drugs, diet changes, less exercise than usual, and fear of pain when passing stool

PATIENT OUTCOMES

Patient will pass soft formed stool without excessive gas discomfort by third postoperative day.

INTERVENTIONS

Assess for active bowel sounds in all four abdominal quadrants before giving anything orally.

Encourage high fluid intake, and graduate diet toward a high-fiber, regular diet as soon as patient is able to tolerate if (or doctor's orders prescribe).

Encourage adequate exercise.

Control pain with analgesics, especially before administering suppository or enema.

Give stool softeners, laxatives, suppositories, or enemas as ordered (check bowel protocol or standing orders).

RATIONALE

Manipulation of the bowel during surgery or anesthetics and other medications may interfere with bowel function.

Adequate fluid and fiber in the diet softens the stool for easy passage.

Reasonable exercise promotes peristalsis and relieves gas discomfort.

The presence of pain may inhibit defecation.

Soft stool is easier to pass.

EVALUATION

Are bowel sounds sluggish, active, or hyperactive?

Are bowel sounds present in all four quadrants?

Is patient drinking well?

Is patient ready for more normal foods, as well as liquids?

Has patient dangled at bedside the day of surgery and then walked increasing amounts each day following?

Is patient passing intestinal gas without difficulty?

Does patient express satisfaction with pain control?

Has patient passed soft formed stool by the third day after surgery?

REVIEW QUESTIONS

- Which of the following is the least effective form of contraception?
 - Douching
 - Condom with spermicide
 - Diaphragm with spermicide
 - Oral contraceptive medication
- Following a hysterectomy, what should the nurse teach the patient to expect?
 - Heavy bleeding for a week
 - Symptoms of menopause
 - Painful intercourse for approximately 6 months
 - Monthly cramping but no menstrual flow
- During an endometrial biopsy, the nurse observes for which of the following signs and symptoms of vasovagal response?
 - Pain in the chest and abdomen
 - Cramping and diaphoresis
 - High blood pressure and tachycardia
 - Bradycardia and falling blood pressure

4. Which of the following can be used to treat vasovagal response during gynecologic procedures?
 - a. Atropine
 - b. Morphine
 - c. Epinephrine
 - d. Norepinephrine
5. Which response by the nurse is most appropriate when a 60-year-old neighbor, who has been menopausal for several years, relates that she has begun having vaginal bleeding again?
 - a. "Ignore it—it is perfectly normal."
 - b. "I guess you were not really menopausal yet."
 - c. "You should see a doctor to have that checked as soon as possible."
 - d. "Give it time—bleeding after menopause usually goes away within a month."
6. If a mastectomy patient has a Hemovac drain in place postoperatively, nursing actions should include which of the following?
 - a. Leave the drainage in the bag until the Hemovac is removed from the patient.
 - b. Stop the drain by clamping it.
 - c. Empty the bag as ordered and note the amount and color of drainage.
 - d. No action is necessary.

Answers to CRITICAL THINKING

Jessica

1. Some important information from Jessica would include her true age (laws vary concerning birth control for minors), her intentions, her family situation, whether she is already sexually active, and what information she wants.
2. She needs to know that being sexually active involves more risks than just pregnancy. Discussion of STDs is vital. Discussion of violence, potential for abuse, long-term effects, and psychological suffering, which may accompany early sexual activity, may also be important. The choices of birth control should be explained, including the risks, effectiveness, disadvantages, and advantages of each method.
3. Although focusing on her desire to be a responsible adult is an admirable attitude, potential scenarios can be presented for her

"responsible" consideration, such as the following: What would she do if contraceptive failure resulted in a pregnancy? How would she feel if she contracted an incurable or permanently damaging sexually transmitted disease that she might pass on to someone else? How would she react now to being "dumped" by someone she cares for who is less responsible and mature? Asking about her goals and plans in life may be significant. Counseling that evidences concern for the individual at this stage may do a lot to postpone sexual activity until the patient is more mature. It is important for her to realize that choosing to delay sexual activity at this time may be the most responsible and health-promoting life decision she can make.

QUESTIONS TO GUIDE YOUR READING

1. How would you explain the pathophysiologies associated with male genitourinary and reproductive disorders?
2. What are the etiologies, signs and symptoms, and treatments of prostate problems?
3. What disorders of the penis can interfere with normal function?
4. What are disorders of the testes and how do they impact sexual function?
5. What are some physical and emotional causes of erectile dysfunction?
6. What are the medical, surgical, and psychological treatment options for erectile function?
7. What is the nurse's role in helping men cope with the loss of sexual function?
8. What are male factors that interfere with fertility?
9. What are the treatment options for male infertility?

Problems affecting the male genitals and urinary system are generally difficult areas for both the patient and the nurse to deal with because of the sexual nature of the male anatomy. It is important to realize that sexuality is a natural part of each of us as human beings and should not be avoided when we provide care to patients. Very often the nurse is in an ideal position to provide important sexual health care teaching to patients. If the patient is approached in a confident, confidential manner, it can be a positive learning experience for both the patient and the nurse.

► PROSTATE DISORDERS

The prostate gland sits at the base of the bladder and wraps around the upper part of the male urethra like a doughnut. It is traditionally divided into lobes: anterior, posterior, median, and lateral. The primary purpose of the prostate is to provide alkaline secretions to semen and to aid in ejaculation. The prostate does not contain any hormones; however, many men fear that prostate problems and treatment will cause problems with their erections or their “nature” (sexual activities).

Prostatitis

Pathophysiology

Prostatitis, or inflammation of the prostate gland, can occur any time after puberty. The problem may be chronic or a single, acute episode. The inflammation causes the prostate gland to swell, resulting in pain, especially when standing. It eventually may lead to difficulty in passing urine as a result of an inward squeezing of the urethra that causes a mild obstruction.

Etiology

There are three basic types of prostatitis: acute bacterial, chronic bacterial, and nonbacterial. Bacterial prostatitis is most common in older men. It results in edema and inflammation of all or part of the prostate gland.

The bacteria primarily responsible for the infection are gram-negative organisms such as *Escherichia coli*; however, gram-positive and gonococcal bacteria may also play a part. The prostate gland may become infected by the following:

- Bacteria ascending the urethra
- Infected urine refluxing from the bladder into the prostatic ducts
- Bacteria in the blood or lymph supply to the gland
- Surgical instrumentation or other forms of urethral trauma.

Prevention

Ways to avert prostatitis are regular and complete emptying of the bladder to prevent urinary tract infection (UTI), avoiding excess alcohol (more than 2 to 3 ounces per day—alcohol is a bladder irritant), and avoiding certain high-risk sexual practices. Avoiding contamination of the urinary tract and factors that produce congestion of the prostate gland are the best preventive measures.

Signs and Symptoms

The most common symptoms are the same ones that occur with any UTI: complaints of urgency, frequency, hesitancy, and dysuria. Because of the location and role of the prostate gland, the patient may complain of low back, perineal, and postejaculation pain; he may also have a fever and chills.

Complications

One complication of acute bacterial prostatitis is urinary retention. If the prostate is extremely swollen, it prevents complete bladder emptying. For most men, the most troublesome complication may be a temporary problem with erections. Ascending infections, prostatic abscess, **epididymitis**, and prostatic calculi (stones) are some of the more serious and rare complications of prostatitis.

Diagnostic Tests

The first test performed is a careful, gentle, digital rectal examination (DRE) of the prostate. The prostate gland is examined by the health care provider by insertion of a gloved finger into the rectum. The examiner may find a warm, irregular, swollen, painful prostate gland. A urine culture generally is positive for bacteria. The examiner may also gently massage the prostate gland and order an expressed prostatic secretion (EPS) test that reveals bacteria and a large number of white blood cells.

Medical Treatment

Acute bacterial prostatitis is usually treated medically with antibiotic therapy. The preferred treatment is trimethoprim and sulfamethoxazole (Bactrim, Septra) for 30 days. Other antibiotics may be used for chronic prostatitis.

Other forms of treatment may include anti-inflammatory agents, warm sitz baths, prostatic massage, and diet changes such as decreasing spicy foods and alcohol. In some cases, prostate surgery is necessary to remove the obstruction.

Nursing Process

ASSESSMENT. Begin the assessment by asking the patient to describe signs and symptoms that indicate evidence of a UTI, such as sudden fever, chills, and complaints of urgency, frequency, hesitancy, dysuria, and nocturia. In addition, the patient may have complaints of pain in the lower back, in the perineum, or after ejaculating. Ask if the patient has ever had a UTI or prostate infection in the past. Care must be taken to assess urinary retention resulting from obstruction. Obtain a urine culture and assist with collection of the EPS specimen, if requested, as part of the patient assessment.

NURSING DIAGNOSIS. The nursing diagnoses for patients with prostatitis may include impaired urinary elimination, and ineffective health maintenance: knowledge deficit related to causes, treatment, and prevention of prostatitis, particularly for those with their first acute episode. Because of the alteration in comfort, a diagnosis related to pain should be included. Because the prostate gland is so closely associated with sexual activity, a diagnosis of anxiety related to sexual concerns should be considered for most patients.

PLANNING. Because of the nature of prostatitis and its accompanying discomfort, the patient's sexual partner is often included in the plan of care. If the bacteria causing the problem is a sexually transmitted organism such as *Chlamydia* or *Gonococcus*, both partners should be treated with antibiotics; sexual intercourse should be avoided during treatment. Scheduled medications and frequent sitz baths may require adjustments in work or normal routines. If a urinary catheter is required, provide catheter care and monitor fluid intake and output every 8 hours.

INTERVENTIONS. Take special care to maintain privacy and sensitivity when discussing treatment with the patient. Emphasize preventive measures that will help the patient

prostatitis: prostat—prostate gland + itis—inflammation

epididymitis: epi—upon + didym—testis + itis—inflammation

avoid future infection. An area of special concern is reinfection resulting from not taking antibiotics until the medicine is completely gone. Many patients take antibiotics only until the symptoms disappear and need to be reminded to carefully follow directions for taking their medications.

EVALUATION. A clean urine culture with complete disappearance of signs and symptoms of prostatitis is the desired outcome. Prevention of chronic prostatitis can generally be achieved with patient education.

PATIENT EDUCATION. Teach the patient the causes, prevention, and treatment of prostatitis. Include risk factors such as the use of indwelling urinary catheters, poor hygiene or sexual practices, excessive intake of bladder irritants, ignoring signs and symptoms of UTIs, and poor compliance with the antibiotic treatment plan.

Encourage the patient to wash his hands and sitz bath equipment before and after each treatment. Fluids such as water and cranberry juice should be encouraged up to 2500 to 3000 mL per day unless contraindicated. Bladder irritants in the form of caffeine products (e.g., coffee, tea, cola, and chocolate), citrus juices, and alcohol should be taken in very limited amounts. Encourage the patient to empty his bladder every 2 to 3 hours even if he does not feel the urge to urinate.

Encourage the patient to discuss possible complications and questions about sexual practices with his health care provider. In some cases, sexual intercourse is encouraged as a means of relieving prostatic congestion; in other situations it may be contraindicated.

Benign Prostatic Hyperplasia

Enlargement of the prostate gland is a normal process in older men. It begins at about age 50 and happens in 75 percent of men older than age 70. Benign prostatic hyperplasia (BPH) is a nonmalignant growth of the prostate that gradually causes urinary obstruction. According to current studies, BPH does not increase a man's risk of developing cancer of the prostate.

Pathophysiology

There is a slow increase in the number of cells in the prostate gland, generally the results of aging and the male hormone dihydrotestosterone. As the size of the prostate gland increases, it begins to compress or squeeze the urethra shut. The narrowing of the urethra means the bladder must work harder to expel the urine. More effort and a longer time is required to empty the bladder. Eventually the narrowing causes an obstruction and may lead to urinary retention or eventually distention of the kidney with urine (hydronephrosis).

It is the location of the enlargement, not the amount, that causes the problem. A small growth in the prostate gland closest to the urethra may cause more problems with urination than a growth the size of an orange in the outer portion of the gland.

Etiology

There is no known cause of BPH other than normal aging. Some men think they may have caused the problem by certain sexual practices; however, there is no scientific proof at this time. Some factors that are being investigated in research studies are high-fat diet, ethnic background, and lifestyle issues.

Prevention

Because there is no known cause, there is no proven method to prevent enlargement of the prostate gland. There are many new treatments that are aimed at slowing down the enlargement process. One such treatment that is being researched is the herbal supplement saw palmetto.

Signs and Symptoms

Symptoms of BPH are usually identified in two ways (Table 41-1). A prostate symptom index score sheet has been developed, and health care providers are asking their older patients the questions as a way of assessing the seriousness of their symptoms and determining treatment options.

Complications

When BPH is untreated and obstruction is prolonged, serious complications may occur. Urine that sits in the bladder for too long can back up into the kidneys and cause hydronephrosis, renal insufficiency, or **urosepsis**; it can also damage the bladder walls, leading to bladder dysfunction, recurrent UTIs, or calculi (stones).

Diagnostic Tests

The first step is a medical history, including specific questions about the patient's symptoms. A DRE of the prostate is then conducted by the health care provider to assess for enlargement and whether the gland is hard, lumpy, or "boggy." Additional diagnostic tests are listed in Table 41-1.

Medical Treatment

If the patient has no symptoms or only mild ones, the most current medical approach is "watchful waiting." The health care provider watches for any increase in symptoms or signs that the urethra is becoming obstructed. Treatment of symptoms may include use of a catheter (indwelling or intermittent), encouraging oral fluids, and antibiotics for UTI.

Conservative medical treatment includes the use of medication to either relax the smooth muscles of the prostate and bladder neck or block the male hormone to prevent or shrink tissue growth. Alpha blockers are medications that relax the smooth muscles and include prazosin (Minipress), terazosin (Hytrin), and doxazosin (Cardura). These medications are also used to treat high blood pressure, and patients need to work closely with their health

urosepsis: uro—urine + sepsis—systemic infection

TABLE 41-1 BENIGN PROSTATIC HYPERPLASIA SUMMARY

Symptoms	
<i>Related to obstruction</i>	Decrease in size and force of urinary stream Difficulty in starting stream or pushing to start Dribbling at the end of urination Interrupted stream, starting and stopping stream Urinary retention—feeling bladder is not empty Overflow incontinence—leaking more
<i>Related to irritation</i>	Nocturia Dysuria Urgency
Diagnostic Tests	
<i>Primary</i>	Urinalysis BUN and serum creatinine Prostate-specific antigen
<i>Secondary</i>	Urodynamic flow studies Transrectal ultrasound of the prostate Cystoscopy
Therapeutic Management	
<i>Conservative</i>	Alpha blockers Testosterone blockers
<i>Nonsurgical (experimental) options</i>	Transurethral microwave antenna (TUMA), which involves heat applied directly to the gland Prostatic balloon, which dilates the urethra by stretching or compressing Prostatic stents, which open the passageway for urine to flow
<i>Transurethral options</i>	Transurethral incision of the prostate (TUIP), in which surgical incisions are made into the gland to relieve obstruction Transurethral ultrasound-guided laser-induced prostatectomy (TULIP), in which incisions are made by laser to relieve obstruction
<i>Open prostatectomy</i>	Transurethral resection of the prostate (TURP), in which a resectoscope is used to remove small pieces of tissue Suprapubic resection, which involves making an abdominal incision and removing the gland through the bladder Retropubic resection, which involves making an abdominal incision and removing the gland through the prostate capsule Perineal resection, which involves making an incision between the scrotum and anus and removing the gland and low pelvic mass

BUN = blood urea nitrogen.

urodynamic: uro—urine + dynamic—force

care providers to avoid overdose or the negative side effects of postural hypotension. The most commonly used medication to block the action of the male hormone in the prostate gland is finasteride (Proscar). All these medications must be taken on a long-term, continuous basis to achieve results. Conservative measures are used initially unless there are recurring infections, repeated gross hematuria, bladder or kidney damage, evidence of cancer, or unsatisfactory lifestyle changes. (See Table 41-1.)

Nonsurgical invasive treatments, some of which are experimental, are available in some areas of the country in addition to surgical options. (See Table 41-1.)

Surgical Treatment

TRANSURETHRAL RESECTION OF THE PROSTATE. During the past 50 years, transurethral resection of the prostate (TURP) has been the surgical treatment used most often to relieve obstruction caused by an enlarged prostate (Fig. 41-1). The patient is anesthetized and the surgery is performed using an instrument called a resectoscope. The resectoscope is inserted into the urethra and the prostate gland is “chipped” away a piece at a time. Special surgical

instruments are now being used that “vaporize” or “microwave” the pieces and cut down on the amount of bleeding during surgery. During routine TURP, the “chips” are flushed out using an irrigating solution and are sent to the laboratory to be analyzed for possible evidence of cancer. The prostate gland is not completely removed but peeled away like the rind of an orange. The prostate tissue that is left eventually grows back and can cause obstruction again at a later time. Patients need to be reminded to continue having yearly prostate examinations.

As the tissue is removed during TURP, bleeding occurs. A Foley catheter is left in place with 30 to 60 mL of sterile water inflating the balloon. The balloon is overfilled and may be secured to the leg or abdomen to **tamponade** (compress) the prostate area and stop the bleeding. Irrigation solution generally flows continuously; manual irrigation may be done for the first 24 hours to help maintain catheter patency by removing clots and chips. The health care provider removes the Foley catheter after the danger of hemorrhage has passed.

Complications associated with prostate surgery depend on the type and extent of the procedure performed. The

Figure 41-1 Transurethral resection of the prostate.

main medical complications include clot formation, bladder spasms, and infection. Less common complications may be urinary incontinence, hemorrhage, and erectile dysfunction (Nursing Care Plan Box 41-1).

Retrograde ejaculation is a common side effect of prostate surgery. When any of the prostate gland is removed, there is a decrease in the amount of semen produced and a part of the ejaculatory ducts may be removed. The result is that less semen is pushed outside the body, and instead it “falls back” into the bladder. This causes no harm; the semen is simply passed during the next urination.

It is important to understand that erection, ejaculation, and **orgasm** are all separate actions. Erection means the penis becomes hard, ejaculation is the release of semen, and orgasm is felt as pulsations along the urethra. Unless additional problems are present, the patient continues to have

retrograde: retro—backward + grade—step

BOX 41-1 NURSING CARE PLAN FOR THE POSTSURGICAL PATIENT HAVING TRANSURETHRAL RESECTION OF THE PROSTATE FOR BENIGN PROSTATIC HYPERPLASIA

▶ Acute pain related to bladder spasms, obstruction, or surgical process

PATIENT OUTCOMES

(1) Patient states pain has decreased. (2) Patient identifies at least two comfort measures.

EVALUATION OF OUTCOMES

(1) Does patient state that pain is decreased? (2) Is patient able to identify at least two measures that will help relieve pain?

INTERVENTIONS

Monitor pain every 2 to 4 hours using a pain scale for first 48 hours. Monitor for signs of bladder spasm, such as facial grimaces, irrigation solution that does not flow into bladder, urinating around catheter, multiple clots. Give prescribed medication (analgesics, antispasmodics) and monitor response. Irrigate catheter as ordered. Teach relaxation, deep breathing techniques.

RATIONALE

A pain scale is a more accurate measure of pain. Relief of spasms promotes comfort, rest, and healing. Medications relieve symptoms. Removal of clots reduces spasms and pain. Relaxation calms spasms and relieves pain.

EVALUATION

Does patient verbalize pain as increasing or decreasing on the scale? Is number of spasms increasing or decreasing? Does patient state relief when medications are given? Does irrigating solution go in and out easily? Are clots being removed? Is patient able to relax?

▶ Urge incontinence related to poor sphincter control

PATIENT OUTCOMES

(1) Patient identifies at least two methods to achieve dryness. (2) Patient verbalizes satisfactory control of dribbling.

EVALUATION OF OUTCOMES

(1) Does patient identify ways to prevent incontinence? Do they help? (2) Does patient verbalize satisfaction with outcome?

INTERVENTIONS

Teach Kegel (pelvic floor) exercises (see Chapter 40)—to be practiced every time patient urinates and throughout the day.

RATIONALE

Strengthens muscle tone to hold urine after catheter is removed.

EVALUATION

Is patient able to start and stop his urine stream?

BOX 41-1**NURSING CARE PLAN FOR THE POSTSURGICAL PATIENT HAVING TRANSURETHRAL RESECTION OF THE PROSTATE FOR BENIGN PROSTATIC HYPERPLASIA—CONT'D**

Discuss use of condom catheter or penile pads.

Instruct patient to continue drinking 2000 to 4000 mL of non-caffeinated, nonalcoholic beverages each day.

Encourage patient to discuss long-term (>6 months) incontinence problems with physician. National incontinence support groups are available.

Specific urine control devices are available for men.

Adequate nonirritating fluid intake is important for healing and preventing UTI.

Patient may need to learn self-catheterization or try medication.

Increased abdominal pressure can cause healing tissue to break apart in the prostate capsule, and excessive bleeding occurs.

Does patient indicate an informed choice of incontinence products?

Does patient drink adequate fluids even though he dribbles?

Does patient verbalize understanding of what to do if incontinence continues?

Is patient able to identify activities that would cause risk for excessive bleeding?

 **Ineffective management of therapeutic regimen related to lack of knowledge of postoperative restrictions and care**

PATIENT OUTCOMES

(1) Patient avoids activities that increase intra-abdominal pressure resulting in excessive bleeding. (2) Patient verbalizes understanding of how to prevent postoperative infection.

EVALUATION OF OUTCOMES

(1) Does patient verbalize understanding of how to prevent bleeding? (2) Is infection prevented?

INTERVENTIONS

Teach patient to avoid lifting heavy objects (>10 lb), stair climbing, driving, strenuous exercise, constipation, straining during bowel movements, and sexual activities until approved by physician (about 6 weeks).

Instruct patient on proper catheter care using verbal, written, and demonstration techniques (many are sent home before catheter is removed). Include the following information:

- Keep catheter bag secured to abdomen or thigh and below bladder.
- Wash catheter/meatal junction with soap and water once daily.
- Use clean technique to change from leg bag to night drainage bag.
- Report signs and symptoms of UTI to physician immediately.
- Encourage oral fluids.

RATIONALE

Urinary tract infections are extremely dangerous and can cause death following genitourinary surgery in an elderly patient.

EVALUATION

Can patient give a return demonstration of proper catheter care? Is patient free from signs and symptoms of infection?

 **Anxiety related to concerns over loss of sexual functioning**

PATIENT OUTCOME

(1) Patient verbalizes normal sexual changes that happen after prostate surgery. (2) Patient identifies support systems if needed.

INTERVENTIONS

Explain to patient that he will probably have retrograde ejaculation into bladder after surgery. It is not harmful and semen will come out when he urinates.

Instruct patient to talk with urologist if erection problems occur.

RATIONALE

Removal of the prostate gland often results in retrograde ejaculation.

Urologists who specialize in treatment of erectile dysfunction can be helpful.

EVALUATION

Does patient understand what will happen when he ejaculates?

Is patient aware of local support services?

erections and orgasmic sensations but decreased or no ejaculation.

OPEN PROSTATECTOMY. When the prostate gland is very large, is causing obstruction, or is cancerous, an open prostatectomy is performed (Fig. 41–2). In the **suprapubic** approach, an incision is made through the lower abdomen into the bladder. The gland is removed, and the urethra is reattached to the bladder. The **retropubic** approach is similar except there is no incision into the bladder. A **perineal** prostatectomy procedure is rarely done because of the increased risk of contamination of the incision (close to the rectum), urinary incontinence, erectile dysfunction, or injury to the rectum.

An open prostatectomy means a longer hospital stay compared with other BPH surgeries. A suprapubic catheter and care for an abdominal incision increase the length of stay and the risk for complications. Follow-up home care for wound dressing changes and catheter care is an important aspect of nursing interventions for these patients.

Nursing Process

ASSESSMENT. Begin by asking the patient if he has ever had treatment or surgery for prostate trouble. Assess amount and type of fluid intake per day and whether the patient has noticed any of the symptoms of BPH.

NURSING DIAGNOSIS. Nursing diagnoses for patients with mild or no symptoms are directed at knowledge deficits related to prevention of UTIs, knowing when to report an increase in symptoms to the health care provider, and taking medication exactly as the health care provider orders. For patients scheduled for prostate surgery, the preoperative nursing diagnoses might include the following:

- Impaired urinary elimination related to obstruction of urethra
- Ineffective health maintenance related to insufficient knowledge of condition, surgery, and postsurgical activities
- Body image disturbance related to loss of normal urination
- Anxiety related to insufficient knowledge of preoperative and postoperative routines and sensations
- Pain related to urinary retention
- Disturbed sleep pattern related to frequency of urination

Nursing care after TURP follows standard guidelines for routine care (see Nursing Care Plan Box 41–1). In addition, each patient experiences individual responses and needs. Individualized care plans are often necessary, because the majority of these patients are elderly and have secondary medical problems such as cardiovascular disease.

PLANNING. Planning should include use of educational materials to discuss the expected surgical outcomes with both the patient and his family whenever possible. It is important that they know about bladder spasm sensations and that the treatment option may be a belladonna and opium (B & O) suppository. If you ask the patient if he wants a suppository for pain, the answer may be no, because he does not realize it is not for his bowels but to relieve the spasms.

Seeing the catheter bag filled with bloody drainage may also be upsetting to a patient or his family. Tell them it is normal to have this type of drainage and that what they see is actually a little blood mixed with a large amount of irrigating solution. It is important to closely monitor the urinary output in terms of amount, color, and presence of clots at least every hour for the first 24 to 48 hours postoperatively. Careful monitoring and documentation of vital signs and fluid intake and output can help prevent major complications.

prostatectomy: prostat—prostate gland + ectomy—excision
suprapubic: supra—above + pubic—pubic bone

A. Suprapubic prostatectomy B. Retropubic prostatectomy C. Perineal prostatectomy

Figure 41-2 (A) Suprapubic prostatectomy. (B) Retropubic prostatectomy. (C) Perineal prostatectomy.

INTERVENTIONS. Special care should be taken to control bladder spasms, prevent excessive bleeding, and prevent infection. Encourage the patient to ask for medication before pain becomes severe. Often men are reluctant to ask for pain medication, so it is important to monitor closely for evidence of pain. Routinely offer the patient pain medication if he does not ask on his own.

Ambulation and other activity levels should be limited based on the characteristics of the drainage in the catheter bag. If the drainage is bright red or has large clots, the patient should be encouraged to lie down in bed until the color lightens and the clots are diminished. Interventions to clear the catheter require increasing either the continuous or manual irrigation process.

The risk for catheter-induced infections is very high unless sterile technique is used when the catheter is opened for irrigation. If the patient is being discharged home with a catheter, careful written instructions regarding catheter care and the need for increased fluid intake to prevent UTI are an important part of discharge planning. Patients are routinely placed on antibiotics during the operation and sometimes postoperatively to prevent infection.

EVALUATION. A patient should be discharged home with a minimum of bladder discomfort, light pink to clear urine, and no evidence of UTI. Home care nursing may be required if the patient lives alone or does not have the capacity to provide for meals, toileting, or transportation for the follow-up visit.

PATIENT EDUCATION. Prevention of complications such as postoperative bleeding and infections are critical to these patients' recovery. Encourage patients to drink up to 2500 mL per day (unless contraindicated by other medical conditions) of water, noncitrus juices (e.g., prune juice to prevent straining from constipation and cranberry juice to reduce risk of UTI), and other noncaffeinated, nonalcoholic beverages. Activities should be limited to short periods of sitting or walking followed by rest. Climbing stairs should be limited to once a day, which may mean keeping a urinal handy if a bathroom is unavailable on the level where the kitchen and television are located. The patient should not drive or engage in sexual intercourse until after he is seen for a final checkup with his health care provider (usually 4 to 6 weeks). Heavy lifting must also be avoided during this time (limited to 10 pounds or less).

CRITICAL THINKING

Mr. Atkinson

Mr. Atkinson is a 68-year-old African-American farmer with an enlarged prostate. He lives on a 75-acre farm with his wife and one son. He is scheduled for a TURP the beginning of March.

1. What postoperative instructions should he be given in light of his occupation?
2. What should you tell him if he asks about how the surgery will affect his "nature" (sexual activities)?

Answers at end of chapter.

Cancer of the Prostate

Cancer of the prostate is the second most common cause of cancer death in American men older than 60 years of age. Chances are that, unless a cause other than age is found, the numbers will continue to increase in the years to come as more men live longer.

Pathophysiology

Prostate cancer depends on testosterone to grow. The cancer cells are usually slow growing and begin in the posterior (back) or lateral (side) part of the gland. The cancer spreads by one of three routes. If it spreads by local invasion, it will move into the bladder, seminal vesicles, or peritoneum. The cancer may also spread through the lymph system to the pelvic nodes and may travel as far as the supraclavicular nodes. The third route is through the vascular system to bone, lung, and liver. Prostate cancer is staged or graded based on the growth or spread.

Etiology

Age is the primary risk factor. Prostate cancer is found most often in men older than age 65 and is rare in men younger than age 40. Other risk factors are higher levels of testosterone, high-fat diet, and immediate family history.

Prostate cancer rates are highest in African-American men and lowest in Japanese men. Occupational exposure to cadmium (e.g., welding, electroplating, alkaline battery manufacturing) has been identified as an added risk factor.

Signs and Symptoms

Symptoms are rare in the early stage (stage A) of prostate cancer. Later stages (stages B and C) include symptoms of urinary obstruction, hematuria, and urinary retention. In the advanced (metastatic) stage (stage D), symptoms may be bone pain in the back or hip, anemia, weakness, weight loss, and overall tiredness.

Complications

Early complications of prostate cancer are related to bladder problems, such as difficulty in urinating, and bladder or kidney infection. As the cancer metastasizes, the patient may develop problems such as pain, bone fractures, weight loss, and depression; eventually death may occur if treatment is not successful.

Diagnostic Tests

A routine DRE of the prostate is the first test; often the examiner finds a hard lump or hardened lobe. A blood test looking for high levels of prostate-specific antigen (PSA) or prostatic acid phosphatase (PAP) is done to detect prostate cancer. When there is a palpable tumor, the health care provider may order a transrectal ultrasound and biopsy to help confirm the diagnosis. Bone scans and other tests may be ordered to determine if the cancer has spread outside the prostate gland.

Medical Treatment

Prostate cancer in stage A may be treated with testosterone-suppressing medications, such as leuprolide (Lupron) or goserelin (Zoladex); surgery, such as TURP or open prostatectomy; or a combination of medication and radiation therapy. In stages B and C the treatment is usually a radical prostatectomy, radiation therapy, or implantation of radioactive “seeds” into the prostate (brachytherapy). In stage D, prostate cancer treatment involves relief of symptoms or blocking testosterone by bilateral **orchietomy**, estrogen therapy (diethylstilbestrol [DES]), administration of antiandrogen (flutamide [Eulexin]), or use of agents such as leuprolide and goserelin. Sometimes chemotherapy is used to help relieve symptoms from the cancer spread.

Brachytherapy, external-beam radiation therapy, and radical prostatectomy combinations are showing favorable results in the treatment of advanced cancer. Gene therapy, vaccine, and immune-based interventions are the latest medical treatment options under investigation in the war against prostate cancer. Nontraditional prostate cancer prevention using vitamin E and selenium is currently being investigated in a 5-year nationwide study.

RADICAL PROSTATECTOMY. The radical prostatectomy procedure is generally reserved for patients with cancer of the prostate or when the gland is too large to resect using the TURP method.

The patient returns from surgery with a large indwelling catheter in the urethra and may also have a suprapubic catheter. Often there is a Penrose or sump drain in place to remove fluids from the abdominal cavity and allow the wound to heal from the inside outward. Special care must be taken to keep the incision and drain sites clean and dry. Dressings should be changed according to institution policy using sterile technique.

There are more complications associated with radical prostatectomy than any other treatment option. The major complications are hemorrhage, infection, loss of urinary control, and erectile dysfunction.

Patient Education

All men older than age 40 should be encouraged to have a yearly DRE of the prostate. Prevention and early detection are the best ways to fight prostate cancer.

► PENILE DISORDERS

Problems of the penis, aside from sexually transmitted diseases, are fairly rare but may cause great concern and worry for the patient. Most men have difficulty seeking help for a “private” problem. It is important to be sensitive when assessing or providing care for these patients.

Peyronie’s Disease

Peyronie’s disease often gives the penis a curved or crooked look when it is erect. Fibrous bands or plaques form mainly

on the dorsal (top) part of the layer of tissue that surrounds one of the corpora cavernosa of the penis. The plaque may be caused by injury or inflammation of the penile tissue, or it may come and go spontaneously. If the plaque is thick enough, it can cause curvature, painful erection, difficulty in vaginal penetration, and erectile dysfunction. When conservative treatments such as vitamin E, steroids, or ultrasound do not work, surgery may be needed to remove the plaque. Patients need to be reassured that the problem is not life threatening and can be treated.

Priapism

Priapism is a painful erection that lasts too long. Anytime an erection lasts for longer than 4 to 6 hours it can become a medical emergency. The small veins in the corpora cavernosa spasm, so the blood cannot drain back out of the penis as it should. When the blood cannot drain, the tissue of the penis does not get oxygen and there can be permanent tissue damage. There may be a complete loss of erection ability after the priapism episode. Prolonged priapism can also prevent the patient from passing urine, which can lead to painful bladder and kidney problems. Some causes of priapism are prolonged sexual activity, sickle cell anemia, leukemia, widespread cancer, spinal cord injury or tumors, and use of crack cocaine or certain other drugs. Treatment in the emergency department may include ice packs, sedatives, analgesics, injection of medications directly into the penis to relax the vein spasms, needle aspiration, and irrigation of the corpora. If all else fails, surgery is done to drain the blood out of the penis.

Phimosis and Paraphimosis

Phimosis is the term used to describe a condition in which the foreskin of an uncircumcised male becomes so tight it is difficult or impossible to pull back away from the head of the penis. It may make it impossible to clean the area underneath. Smegma, a cottage cheese–like secretion made by the glands of the foreskin, becomes trapped under the foreskin and is an excellent place for the growth of bacterial and yeast infections. Treatment usually begins with antibiotics and warm soaks to the area. The physician may then cut a small slit in the foreskin to relieve the pressure and treat the infection. A full circumcision may be recommended to the patient if the problem continues or if a condom catheter is necessary for urine drainage. Phimosis is generally prevented by teaching uncircumcised males to pull the foreskin back carefully, wash with mild soap and water daily, and replace the foreskin to its normal position.

Paraphimosis occurs when the uncircumcised foreskin is pulled back, during intercourse or bathing, and not immediately replaced in a forward position. This causes constriction of the dorsal veins, which leads to edema and pain. Moderate to severe paraphimosis is a medical emergency and requires immediate care by a physician. The longer the problem continues, the greater the risk of circulation problems and possible gangrene. Again, prevention through daily cleaning and replacing the foreskin in its normal place is important.

Cancer of the Penis

Cancer of the penis has been found in men who were not circumcised as babies or have acquired the human papillomavirus (HPV). The tumor looks like a small, round, raised wart. It is one form of cancer that may be spread to the sex partner. Several research studies have found a link between cancer of the penis and cancer of the uterine cervix. Cancer of the penis may be treated with minor surgery such as a circumcision or laser removal of the growth. If the cancer has spread, the treatment may mean cutting away part or all of the penis, radiation, or chemotherapy. Finding and treating any wartlike tumor in its earliest stages is an important part of patient education.

▶ TESTICULAR DISORDERS

Cryptorchidism

Cryptorchidism (undescended testes) is a congenital condition in which a baby boy is born with one or both of his testes not in the scrotum. The testes normally drop down (descend) into the scrotum in the last 1 to 2 months before the boy is born. Many times the testes descend into the scrotum on their own by 2 years of age. If they do not descend by the age of 2, surgery should be done to correct the problem. Testes that are not brought down into the scrotum decrease a man's chances of producing a child, usually because excessive body heat damages sperm production in the testes. Studies have shown that the chances of testicular cancer are also higher if the condition is not corrected before the child reaches his teen years. If normal male sex characteristics do not develop during puberty because the testosterone level is too low, extra testosterone medication may be given. Testosterone can be administered in the form of a daily pill or long term by injection or patch.

Hydrocele

A **hydrocele** is a collection of fluid in the scrotal sac. Hydroceles are not dangerous and generally do not cause any pain. The cause is not known, and it can happen at any point during the lifetime. No treatment is necessary unless the hydrocele is so large that it causes discomfort or embarrassment or is a threat to the blood supply to the testes. If treatment is needed, the health care provider aspirates, or surgically drains, the fluid.

Varicocele

A varicocele is a condition sometimes called varicose veins of the scrotum. The main blood supply to the testes travels along the spermatic cord. The veins become dilated, and when the man is standing, the area in the scrotum begins to feel like a "bag of worms." The patient may complain of a pulling sensation, a dull ache, or scrotal pain. The sensations are most often felt when standing up. Most varicoceles

occur on the left side because of the way the scrotal vein enters at a sharp angle from the left renal vein.

A varicocele is often not discovered until a couple tries to have a baby and is unable to conceive. It is believed that the varicose veins may increase the temperature of the testes and cause damage to the sperm. The most successful treatment is surgical repair of the varicose veins.

Epididymitis

The epididymis is a small tube along the back of the testes where sperm is matured for its last 10 to 12 days before it is ready to be ejaculated. Epididymitis is inflammation or infection of the epididymis that may be caused by bacteria, viruses, parasites, chemicals, or trauma. Epididymitis may be facilitated by sexual or nonsexual contact, a complication of some urological procedures, or reflux (backflow) of urine. The problem may also be associated with prostate infections and is usually painful, with the scrotal skin being tender, red, and warm to the touch.

Epididymitis is treated with antibiotics; the partner is also treated if it was sexually transmitted. Depending on the severity of the pain, the patient may be placed on bedrest with the scrotum elevated, possibly on ice packs, and also given analgesics. The pain and tenderness usually go away in about a week, although the swelling may last for several weeks. Complications may include chronic epididymitis, abscess formation, and sterility.

Orchitis

Orchitis is a rare inflammation or infection of the testes. The problem may be caused by trauma or surgical procedures; chemical substances; infection from epididymitis; UTI; or systemic diseases such as influenza, infectious mononucleosis, tuberculosis, gout, pneumonia, or mumps (after puberty). The patient has swollen, extremely tender testes; red scrotal skin; and a fever. Interventions are basically the same as for epididymitis and include bedrest, scrotal support, antibiotics, and medication to relieve pain and fever. Complications such as sterility from mumps orchitis can be prevented by giving boys the mumps vaccine at an early age.

Cancer of the Testes

Pathophysiology and Etiology

Cancer of the testes is the most common solid tumor in men 15 to 40 years of age and peaks between 20 and 34 years of age. The etiology of testicular cancer is unknown. Some of the known risk factors are cryptorchidism, family history, mother's use of DES (an estrogen preparation once used to prevent spontaneous abortion) while pregnant, white race, and high socioeconomic status. The tumors are mostly a germ cell type of cancer formed during normal embryo development.

cryptorchidism: crypt—hidden + orchid—testis + ism—condition

hydrocele: hydro—water + cele—swelling

orchitis: orch—testis + itis—inflammation

Prevention

The best prevention is monthly testicular self-examination (TSE). The procedure is simple and easy to learn and should be taught to males between ages 15 and 40. See Chapter 39 for instructions on TSE.

Signs and Symptoms

Early warning signs of cancer may include a small, painless lump on the side or front of the testes. The patient may also notice that the scrotum is swollen and feels heavy. Late symptoms of back pain, shortness of breath, difficulty swallowing, breast enlargement, and changes in vision or mental status indicate metastasis of the cancer.

Complications

Emotional complications can range from fear of cancer and death to feelings of loss of masculine body image and sexual function. Physical complications may involve dealing with pain and the effects of metastasis to areas such as the lungs, abdomen, or lymph nodes. Other less common areas of cancer spread are the liver, brain, and bone. Treatments such as surgery, chemotherapy, and radiation therapy can all have negative side effects on the patient and require special care.

Diagnostic Tests

When a tumor is found, several laboratory and radiographic tests are done. An ultrasound of the testes is done first. If the test shows cancer, a chest x-ray examination is done to look for spread to the lungs. A scan of the lymph nodes, liver, brain, and bones may also be ordered. Blood is drawn to look for what are called tumor markers. An example of a tumor marker for testicular cancer is beta human chorionic gonadotropin (bHCG). An exploration, biopsy, and removal of the testes is done to decide the stage of the tumor.

Testicular tumors may be staged or classified in several ways. The simplest way to stage a testicular tumor is as follows:

- Stage I—tumor only in the testes
- Stage II—tumor spread to groin lymph nodes
- Stage III—tumor spread past lymph nodes, usually to the lungs

Medical Treatment

Intervention depends on the stage of the cancer. All treatment begins with complete removal of the cancerous testes, spermatic cord, and local lymph nodes. Stage I tumor treatment then includes radiation to the groin area lymph nodes. Treatment for stage II involves chemotherapy. Stage III or metastatic cancer is treated with both radiation and chemotherapy. If the cancer is found in the beginning stages, the chances for complete recovery are about 75 percent. All patients should have regular follow-up testing.

Nursing Care

Nursing care is directed first at prevention, by teaching young men to practice monthly testicular self-examination

and to see their health care provider if they notice any changes. If a diagnosis of cancer has been made, provide emotional support for the patient. If the patient wants to have children, he should be encouraged to make deposits in a sperm bank before any surgery or treatment is started. The patient and his partner may have many questions about sexual activities as they go through treatment. They should be encouraged to talk with their health care provider or a sex therapist about ways to express love and tenderness toward one another. Helping the patient deal with pain and the side effects of chemotherapy or radiation therapy are also important nursing interventions for these men.

CRITICAL THINKING

Mr. Cunningham
Mr. Cunningham is a 23-year-old white college student engaged to be married next spring. While taking a shower one day he discovers a lump on his left testes.

1. What should he do?
2. What are the treatment options if Mr. Cunningham has cancer of the testes?
3. How can you help Mr. Cunningham cope with the diagnosis?

Answers at end of chapter.

SEXUAL FUNCTIONING

Vasectomy

A **vasectomy** is the surgical cutting and sealing off of the vas deferens to prevent sperm from reaching the outside of the body. This 15- to 30-minute surgery is performed most often as a permanent birth control method but may also be performed on some men during prostate gland removal. The male patient should carefully discuss the surgery with his physician, so there is a clear understanding of the results following the procedure.

The testes continue to produce the male hormone testosterone and sperm. The prostate gland, along with the seminal vesicles, still ejaculate semen, but the semen does not contain sperm. There should be no major change in the way the ejaculate looks or feels following the procedure. The patient should be encouraged to continue using another birth control method for about 6 weeks after surgery to be sure there are no sperm left in the tract above the surgical site. The sperm continue to be produced in the testes but are absorbed by the body.

There are times when the man may decide he wants to have more children and asks to have the vasectomy “undone.” The surgical procedure to reverse a vasectomy is called a vasovasotomy. Using microscopic instruments, the surgeon reconnects the two pieces of the vas deferens. During the surgery the physician generally tries to determine whether the testes are still producing good sperm. If the vasectomy was done less than 10 years before, the fertility

vasectomy: vas—vas deferens + ectomy—excision

success rate is higher. A vasovasotomy is generally not an option if the vasectomy procedure is more than 10 years old.

Erectile Dysfunction

Problems with getting or keeping an erection can happen at any age and have been a concern of men and their partners for centuries. It is a unique problem because it affects not only the man but his sex partner as well. Most men experience a temporary erection problem at some time during their life. It is often caused by stress, illness, fatigue, or an excessive use of alcohol or drugs. When the problem becomes persistent, as it does for more than 30 million men in the United States, it is time to seek medical help.

Before the 1980s, 90 percent of men who went to their physicians for help were told the problem was emotional, not physical. Through improved testing methods, it is now believed that 80 to 90 percent of erection problems have a physical cause. For more information, visit the National Library of Medicine at www.nlm.nih.gov/nih/cdc/www/91txt.html and www.medlineplus.nlm.nih.gov/medlineplus/drug-info/.

Pathophysiology

The term *impotence* means powerlessness. This term is being replaced with the more accurate term **erectile dysfunction** (ED), which describes a physical condition. Erectile dysfunction means that a man cannot get or keep a usable erection that is firm enough and long-lasting enough for satisfactory sexual intercourse. For a man to have a usable erection, several conditions must be met.

1. *Circulatory system.* The blood supply coming into the penis from the arteries must be sufficient to fill the corpora cavernosa (spongy erectile tissue inside the penis), causing the penis to become rigid. The diameter of these vessels is about the size of pencil lead. The veins in the penis must then be able to constrict (narrow down) to trap the blood in the corporal bodies to keep the penis erect. The most common cause of erectile dysfunction is failure in the circulatory system.
2. *Nervous system.* Both the sympathetic and parasympathetic nerves are involved in the erection, ejaculation, orgasm, and resting phases of the penile response cycle. There are many nerve receptors and transmitters in the spinal cord and the penis that must be intact for a usable erection. Spinal cord injuries are the most common neurological cause of erection problems. The remarkable fact about spinal cord injuries is that higher cord injuries (cervical or thoracic) have less negative impact on erections than those in the lumbar or sacral area.
3. *Hormonal system.* There are three basic male hormones involved with an erection. The most important hormone, testosterone (normal: 350 to 1000 ng/dL), affects a man's sex drive and desire. The testosterone level is highest when a man is in his late teens and begins to decline in middle age. Luteinizing hormone (LH; normal: 5 to 18 mIU/mL) stimulates the production of testosterone, and prolactin (less than 15 ng/mL) in large amounts may block testosterone.
4. *Limbic system.* This is the center in the brain that affects how we feel emotionally. It works with our five senses to stimulate the desire for sex.

All these systems can be influenced by physical, emotional, and chemical factors. A good assessment is important to determine the cause of erectile dysfunction.

Etiology

The psychological causes of erectile dysfunction usually come from stress or anxiety. Marital problems, financial worries, job frustration, or even fear of not being able to perform resulting from an isolated incidence of erection problems may lead to sexual dysfunction. Even when the cause is physical, there are psychological (emotional) side effects. Fear of failure, ridicule, or rejection by the partner lead to a lack of self-esteem or self-confidence.

The list of physical causes is long because it includes anything that may interfere with the flow of blood, the nerve supply, the balance of hormones, or the effects of emotions (Table 41–2). There are many medications and chemicals

TABLE 41–2 CAUSES OF ERECTILE DYSFUNCTION

Psychogenic	Surgical	Vascular	Cardiorespiratory	Neurological
Excessive stress in family, work, or interpersonal relationships; depression; fatigue; fear of failure to perform	Coronary artery bypass Abdominal-perineal resection Cystectomy Radical prostatectomy Pelvic lymphadenectomy Renal transplant Sympathectomy TURP	Aortic aneurysm Arteriosclerosis Aortofemoral bypass Cerebrovascular disease/accident Pelvic steal syndrome Venous leak Hypertension	Angina pectoris Myocardial infarction COPD Coronary insufficiency Congestive heart failure	Electroshock therapy Multiple sclerosis Parkinson's disease Cerebral palsy Myasthenia gravis Peripheral neuropathy Sympathectomy Tumors/transection of spinal cord Trauma to spinal cord Head injuries Spina bifida

COPD = chronic obstruction pulmonary disease.

that can interfere with desire, blood supply, or nerve transmission and cause problems with erections (Table 41–3). The most common types of medications that cause problems are high blood pressure and cardiovascular medications.

Diagnostic Tests

Assessment of erectile dysfunction has now been divided into primary and secondary diagnostic studies according to guidelines developed by the National Institutes of Health. The first step begins with a careful history that is especially designed to focus on the medical-surgical history, medications including any substance abuse, lifestyle patterns, and sexual history. The main areas to investigate are those that indicate vascular, neurological, endocrine, and psychological factors. A physical examination looks for evidence of abnormal genital disorders, hormonal imbalance (such as hair patterns or enlarged breasts), surgical interventions, decreased circulation, and lack of nerve sensations. Blood is taken to look at glucose levels; testosterone; evidence of liver, heart, or kidney disorders; signs of infection; or blood disorders. The health care provider may also order specific blood tests if other problems exist that may have an impact on erections. Some physicians are also using intracorporeal injection of vasoactive medications that can create an erection to test the blood flow in the penis. A psychological evaluation is recommended to rule out any serious issues in the sexual relationship or emotional problems that may contribute to erectile dysfunction or affect the treatment outcome.

Secondary level of testing may involve the use of sophisticated vascular flow studies to locate areas where either the blood vessels are narrowed or the veins allow the blood to drain out of the penis too rapidly. Another area of testing may be related to sleep tumescence and apnea studies. These studies are based on the physiological process of erections during rapid eye movement (REM) sleep. A “normal” man has erections every 60 to 70 minutes while he sleeps.

Because of the expense of vascular flow studies and sleep studies, they are used on a limited basis.

Medical Treatment

One of the most important treatment options begins with the couple’s being able to share intimate communication. No matter what may be causing the problem, if the patient and his partner are not touching, talking, and sharing feelings with one another, any treatment option is going to have limited success.

When the problem has clearly been identified as psychological, counseling therapy is the treatment of choice. If long-term therapy has been tried with only limited success, the addition of oral medication or even intracorporeal injection therapy may be added to provide a boost in confidence and self-esteem. Medical treatment for physical erection problems begins with conservative, nonsurgical treatment and then progresses to surgical options if necessary.

MEDICATION CHANGES. Sometimes all that is needed to correct the problem is a change in medication. There are many prescription, over-the-counter, and street drugs that can cause erection problems. (See Table 41–3.) It is important for the patient to talk with the health care provider before discontinuing any medication. Some men have been known to stop taking their blood pressure medication and risk a stroke or heart attack because the medication interfered with their sexual activity.

HORMONE TREATMENT. If the testosterone level is low and it is not the result of a pituitary tumor or thyroid problem, replacement hormone may be needed. The health care provider should first examine the patient carefully for any evidence of prostate cancer, because testosterone treatment can cause the cancer to grow and spread. Testosterone treatment works best when it is given by intramuscular (IM) injections. It may take several weeks to raise the hormone level high enough to see any benefits. If after about 6 to 8 weeks of treatment there is no increase in the number or quality of erections, a different treatment should be tried.

YOHIMBINE. Most men are looking for a magic pill or potion to correct the problem. Some health care providers prescribe a pill called yohimbine (Yocon, Yohimex), which is thought to be a mild aphrodisiac and vasodilator. When the cause may be psychological or mildly physical, the medication may be helpful in restoring confidence and erections.

INTRACORPOREAL MEDICATIONS. The use of vasoactive or smooth muscle relaxant medication is the latest nonsurgical treatment option. The medication (papaverine, prostaglandin E, phentolamine, or sildenafil) causes the arterioles and cavernous tissue to relax, allowing more blood to flow in and lowering peripheral resistance, trapping blood in the cavernous bodies to maintain the erection. There are now four methods of administering the medication: direct injection into the corporeal bodies, transurethral suppository pellet, transdermal patch, and pill.

Antianxiety agents	Glucocorticoids
Antidepressants	H ₂ antagonists
Antihistamines	Major tranquilizers
Antineoplastic agents	Muscle relaxants
Blood-pressure medications	Commonly abused drugs
ACE inhibitors	Alcohol
Beta-blocking agents	Amphetamines
Others	Barbiturates
Diuretics	Caffeine
Drugs for Parkinson’s disease	Cocaine
Estrogens	Marijuana
	Nicotine
	Opiates

ACE = angiotensin-converting enzyme; H₂ = histamine.
NOTE: Not all drugs in a category cause erectile dysfunction.

Injection Method. After careful evaluation, the patient or his partner is taught how to inject the medication into the penis using a 26- or 27-gauge needle on a tuberculin syringe or a prefilled autoinjector. The injections are nearly painless and produce a natural erection in 10 to 15 minutes. The erection may last 1 to 2 hours, and patients are generally limited to a maximum of three injections per week. The dosage is regulated on an individual basis. The most serious side effect is priapism, which requires immediate reversal in a physician's office or emergency room. When the patient is taught and monitored carefully, the risk of complications is minimal.

Transurethral Suppository. The patient is instructed to urinate first to disperse the medicated pellet and help promote absorption of the medication. A tiny pellet (microsuppository) is inserted into the urethra using a specialized single-dose applicator. The medication usually begins to work in 5 to 10 minutes, and the effects last for approximately 30 to 60 minutes. The most common side effect has been pain in the penis when high dosages were used.

Transdermal Patch. A skin patch containing the vasoactive medication may be applied to the penis. Special care must be taken with some forms, so that the partner does not absorb the medication. This can be prevented by having the male wear a condom over the patch.

Oral Pill. Oral medications are now the first line of therapy used to treat ED. The most widely prescribed pill is sildenafil (Viagra). The pill is usually taken 30 to 60 minutes before sexual intercourse. It provides an easy way to administer the medication and has a success rate of between 40 and 80 percent, depending on the cause of the problem. Men using nitrate medication (antianginal agents) should avoid using the pill because it is vasoactive. It can also cause abnormal visual problems for some men.

Other forms of ED medication being evaluated are an oral form of phentolamine (Vasomax), apomorphine (Uprima, an older drug used to treat Parkinson's), and pentoxifylline

(improves oxygen delivery to the penis). Investigative work using genetically designed agents and regeneration of penile nerves involving proteins called immunophilins is showing promise as a treatment option.

Other Nonsurgical Treatments

SEXUAL DEVICES AND TECHNIQUES. There are a variety of sexual aids, such as vibrators and dildos (hollow penises), that may be alternatives for patients who do not want or cannot afford expensive medical treatment. They should be encouraged to talk with a health care provider or qualified sex therapist before trying these alternatives.

Suction devices are another nonsurgical treatment option. This is an external cylinder vacuum device that fits over the penis and draws the blood up into the corporeal bodies, causing an erection. A penile ring is then slipped onto the base of the penis. Once the cylinder is removed, sexual intercourse can begin. Special care must be taken to remove the penile ring within 15 to 20 minutes to prevent tissue damage. The suction device may be used alone or with intracorporeal injection therapy for patients who have difficulty keeping an erection. The companies that manufacture the suction devices provide free videotapes and written patient instruction booklets.

Surgical Treatments

PENILE IMPLANTS (PROSTHESIS). Penile implants are a pair of solid or fluid-filled chambers that are surgically placed into the corporeal bodies in the penis to produce an erection. This treatment option has been used successfully for more than 25 years. There are two basic types of implants—noninflatable and inflatable (Fig. 41-3). The noninflatable type is economical, can be surgically implanted in less than an hour, and provides firmness for penetration. The inflatable device contains a sterile saline solution that fills the cylinders using a manual pumping action. When activated, the inflatable implant provides both firmness and an increase in diameter of the penis. Although the inflatable device is more expensive and has a

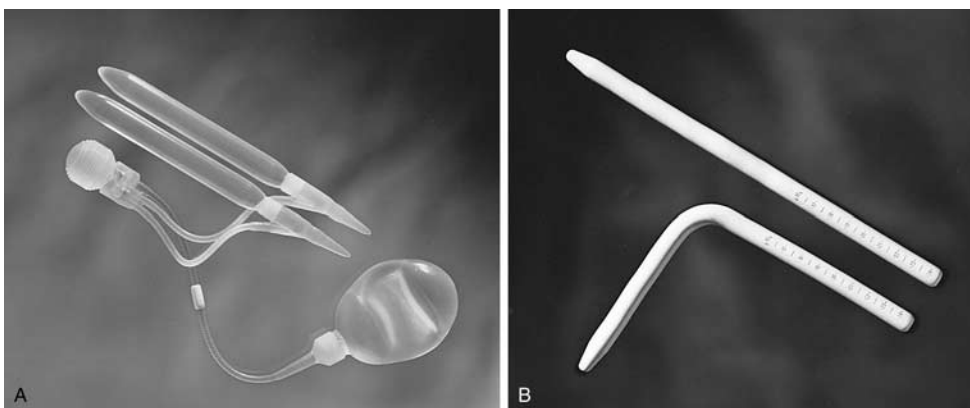

Figure 41-3 Penile implants. (A) Inflatable penile implant. Inflatable cylinders are implanted in the penis, the small hydraulic pump in the scrotum, and the fluid-filled reservoir in the lower abdomen. Sterile radiopaque saline from the reservoir fills the cylinders to provide an erection. (Alpha-1 implant photo courtesy Mentor Urology.) (B) Malleable penile implant. Malleable rods are implanted into the penis. The penis is always firm, but the rods can be bent close to the body when erection is not desired. (Acu-Form implant photo courtesy Mentor Urology.)

greater risk of mechanical failure, it provides a more natural appearing and functioning erection than the noninflatable implant.

Penile implants are considered secondary treatment options because they have a risk of complications such as mechanical failure, infection, and erosion. Patients at greatest risk for complications are those with uncontrolled diabetes and those with severe circulation problems. Patients should be taught that an implant will not restore ejaculation or orgasm if these functions have been lost before the surgery. Surgery recovery time varies from 4 to 6 weeks; the patient must receive approval from the health care provider before having sexual intercourse.

VASCULAR SURGERY. If a younger man (younger than age 35) has an erection problem caused by poor blood flow into the penis or from blood leaking out of the penis, rapidly causing the loss of the erection, corrective surgery may be performed. A bypass graft may be done to increase the blood flow into the penis or to go around a blockage (e.g., Peyronie's disease). If the blood leaves the corporeal bodies too fast, a procedure to ligate (tie off) the leaking veins may be successful. Neither surgery works well in older men because the bypass graft rapidly becomes obstructed and the natural tendency of the older body is to form collateral circulation around the veins that are tied off.

Nursing Process

ASSESSMENT. Before the assessment begins, it is important to provide privacy and ensure confidentiality. A complete sexual history, often conducted by a nurse, is taken, with special focus on factors related to the circulatory, nervous, and endocrine systems. The questions cover the following:

- Medical problems
- Surgical treatments that might interfere with blood flow or nerve supply to the groin or spine
- Genitourinary problems
- A complete list of medications used, including over-the-counter drugs and any evidence of substance abuse
- General lifestyle patterns, including stress factors, depression, and excessive use of caffeine or nicotine (causing vasoconstriction)
- Sexual patterns and practices

A physical examination is performed by the physician or health practitioner to assess for any evidence of congenital deformities, hormonal imbalance, decreased circulation, or nerve damage. Throughout the assessment process it is important to observe for any signs of psychological or emotional distress.

NURSING DIAGNOSIS. Because of the nature of the problem, it is important to recognize nursing concerns related to anxiety, fear, powerlessness, knowledge deficit, and issues related to ineffective role performance or family dynamics. The present nursing diagnosis of sexual dysfunction is very broad and does not focus on specific aspects of male erectile dysfunction.

PLANNING. Planning generally involves not only the male patient but also his sexual partner. Treatment success rates are much higher when the support person is included in the decision-making process.

Unrealistic expectations are common in the beginning period of restoration. The patient must be encouraged to communicate with his partner through both talk and touch. Restoration of an erection cannot repair a bad relationship, and often counseling is an important part of the treatment plan.

IMPLEMENTATION. Special care should be taken in selecting the treatment option that will work best for the patient and his partner. They should be encouraged to ask questions of their physician and other health care professionals involved in their care. Where available, support groups that are focused on men and their partners have provided excellent resources and information on treatment options. Conservative treatment options are tried first, with surgical interventions reserved as a last resort. Nursing care focuses both on the emotional and physical discomfort associated with the diagnosis and treatment options.

EVALUATION. The best indicator of a positive outcome is restoration of erectile function with a verbal account of satisfaction. Sometimes the physical problem is easier to correct than the emotional scars that the problem has created. It is important to evaluate both the physiological and emotional outcomes of treatment.

PATIENT EDUCATION. The nurse plays an important role in public education related to erectile dysfunction. Men need to know that they are not alone with their problem. More than 20 million men in the United States experience ongoing problems with erections. The majority of the causes are physical, and help is available through health care providers who specialize in treating erectile dysfunction.

Treatment may be as simple as a change in lifestyle or in medication. Men need to be encouraged to seek help from appropriate health care providers and recognize that erectile dysfunction is a treatable condition with positive outcomes.

Infertility

A growing number of couples in the United States are having difficulty conceiving children. Several factors can interfere with a man's ability to father a child.

Physiology

Eight fundamental male physiological factors are necessary for normal conception to occur:

- Proper endocrine function between the hypothalamus, pituitary gland, and testes
- At least one testes that produces quality sperm
- An epididymis, or storage place, to mature the sperm
- A duct system to transport sperm from the testes to the outside of the body

- Glands that secrete the right type and amount of seminal fluid to nurture and transport the sperm
- An intact nervous system that helps provide an erection and ejaculation
- Semen that meets the following criteria: volume 1.5 to 5 mL, a concentration of more than 20 million sperm per milliliter, 50 to 60 percent of the sperm classified as grade 2 mobility, 60 to 80 percent of sperm with a normal shape, pH is between 7.2 and 7.8, a small amount of fructose (sugar, a food supply), and sperm (semen) that first coagulate and then liquefy
- A basic knowledge of sexual practices, along with a willing partner.

Etiology

The factors related to infertility are divided into three general categories: pretesticular, testicular, and posttesticular.

PRETESTICULAR (ENDOCRINE) FACTORS. The first factor involves the proper functioning of the hypothalamus, the pituitary gland, and the testes. These endocrine functions are complex and are a rare (3 percent) cause of infertility. Examples of endocrine causes might be pituitary or adrenal tumors, thyroid problems, or uncontrolled diabetes.

TESTICULAR FACTORS. The two most common causes of male infertility are a varicocele (40 to 50 percent) and idiopathic causes (40 percent). It is believed that a varicocele lowers sperm count by raising the blood flow and temperature in the testes. Sperm cannot live if the temperature is too high or too low.

Congenital anomalies such as Klinefelter's syndrome (a chromosome defect) or cryptorchidism result in absent or damaged testes. Failure of a part of the male reproductive system to develop as a result of the mother's use of DES or other drugs during pregnancy may also result in fertility problems.

Certain disease or inflammatory processes may cause damage to the storage area (epididymitis) or to the testes themselves (mumps orchitis). Any high fever or viral infection can interfere with the production of sperm for up to 3 months.

Medications, radiation, substance abuse, environmental hazards, and lifestyle practices have all been identified as possible factors that can interfere with spermatogenesis (sperm production). Medications such as cimetidine (Tagamet), sulfasalazine (Azulfidine), anabolic steroids (testosterone), anticancer drugs (cyclophosphamide [Cytosan], methotrexate), recreational drugs (cocaine, marijuana), and antihypertensives (methyldopa) have all been identified as possible causes of infertility. Radiation damage, whether as treatment for cancer or job related, tends to depend on the dosage received. A small amount of radiation causes temporary loss of sperm. Permanent sterility occurs with large doses or prolonged treatment. The relation between use of drugs such as cocaine and marijuana and infertility has been documented in several studies, but there is no clear indication of the amount or length of time it takes for these substances

to cause infertility problems. Environmental hazards such as pesticides, Agent Orange, and lead poisoning have been listed as possible causes of infertility and are still under investigation. Excessive use of hot tubs and saunas, wearing tight jeans, and long-haul truck driving have all been identified as raising the temperature level in the scrotum to the extent that the sperm production is decreased.

POSTTESTICULAR FACTORS. The most common factor in posttesticular infertility is the result of surgery or injury along the pathway from the testes to the outside of the man's body. Examples of surgical causes are vasectomy, bladder neck reconstruction, pelvic lymph node removal, or any surgery that causes retrograde ejaculation. Congenital anomalies and various types of infections may also cause infertility problems.

Prevention

Prevention involves possible lifestyle changes to avoid excessive heat to the scrotum, substance abuse, exposure to toxins, and environmental hazards. Problems related to medication or infections should be discussed with the health care provider.

Signs and Symptoms

A couple is considered infertile if they have been unsuccessful at becoming pregnant after at least 1 year of unprotected intercourse. If pregnancy has occurred during the year but there was no delivery, the problem is generally considered a female rather than a male factor.

Diagnostic Tests

Diagnosis begins with a detailed history and physical examination that looks for known male causes of infertility.

History

SEXUAL PRACTICES. Assessment includes frequency of intercourse, positions, timing (according to ovulation cycle), use of contraceptives, problems with premature ejaculation, and erection problems.

LIFESTYLE PRACTICES. Weight lifting or use of steroids, hot tubs, or saunas; tight jeans; use of nicotine, caffeine, alcohol, or marijuana; and the strength of desire for children on the part of the man are all assessed.

OCCUPATION. High stress, long periods of sitting, and exposure to environmental toxins are determined.

MEDICAL-SURGICAL HISTORY. Assessment includes any sexually transmitted viruses or diseases, endocrine problems, congenital urinary problems, serious illnesses or groin injuries, cancer, and treatment with chemotherapy or radiation.

Physical Examination

Observe for normal hair pattern and growth, muscle development, size of testes, and any evidence of a varicocele or hydrocele.

Diagnostic Tests

A semen analysis is done after collecting several specimens following a special collection technique. It is analyzed to see if it contains the right amount and type of healthy sperm needed for a pregnancy. There are several other tests that may be done, depending on the level of desire and the financial resources of the couple. Many insurance companies do not pay for the tests or treatment options for infertility.

Medical Treatment

Treatment may be as simple as making a change in sexual or lifestyle practices. If the couple is able to handle the emotional and financial strain, they may try male surgery to correct a varicocele or a variety of in vitro fertilization procedures. The success rates for in vitro fertilization range from 8 to 60 percent and generally cost several thousand dollars each time an attempt is made. Another possible option that should be presented to the couple is adoption.

You can play an important role in the emotional support a couple needs during infertility studies. It is important that the couple feel comfortable in communicating their feelings and frustrations with one another and their health care provider. You may need to be the communication link, explaining various tests and cost factors and discussing how long the couple may want to continue trying the various treatment options. It may also help them to talk with other couples or attend a support group designed for couples experiencing infertility. For more information, visit the following Websites:

Answers to CRITICAL THINKING

Mr. Atkinson

1. Mr. Atkinson should be instructed not to lift anything heavier than 10 pounds for the first 6 weeks, and he will not be able to plow or drive for the first 6 weeks. It is important that his son understand his father's limitations and how important it is for him or someone else to help out with the farm chores.
2. Mr. Atkinson will notice a change in his ejaculation (either very little or none at all). If he could get an erection before surgery, the chances are very good that he will continue to be able to have intercourse; however, he will not ejaculate.

Mr. Cunningham

1. Mr. Cunningham should be encouraged to see his health care provider immediately for an evaluation to rule out cancer of the testes.
2. Depending on the stage of the cancer, he will have the cancerous testes, cord, and lymph nodes removed. He may need chemotherapy or radiation treatments as well.
3. Mr. Cunningham should be encouraged to make deposits at a certified sperm bank before any treatments. It is also important to include his future wife and his family in the decision-making process and encourage them to share their feelings and concerns with one another. Cancer support groups may also be helpful to Mr. Cunningham.

REVIEW QUESTIONS

1. Which test is encouraged annually for every man older than age 40?
 - a. Prostate ultrasound
 - b. Serum creatinine
 - c. Digital rectal examination
 - d. Acid phosphatase
2. Which of the following is the greatest risk factor for prostate cancer?
 - a. Smoking
 - b. Aging
 - c. Drug use
 - d. History of STDs
3. Which of the following is the most commonly used surgical treatment for BPH?
 - a. TUIP
 - b. TUMA
 - c. TURP
 - d. TULIP
4. You are caring for Mr. Frank following transurethral resection of the prostate. He says he is having pain in his bladder, and you notice urine leakage around his catheter. Which of the following responses is best?
 - a. "Bladder spasms are common after your surgery. Take some deep breaths while I get a B & O suppository."
 - b. "You should not be experiencing spasms. I will notify the RN right away."
 - c. "Spasms can be very painful. Would you like an injection of Demerol?"
 - d. "Your catheter is leaking; we will need to replace it right away."
5. Mr. Jackson is discharged following prostate surgery. As you are doing his discharge teaching, he asks if he can return to work delivering water softener salt to homes. Which response is best?
 - a. "Certainly, returning to work is a good way to get your mind off your surgery."
 - b. "You should spend your time off looking for a job that involves less lifting."
 - c. "It is okay to drive, but you should not lift heavy objects for 6 weeks."
 - d. "You should not drive for 4 to 6 weeks or lift anything heavier than 10 pounds."
6. Which of the following is the most common cause of erectile dysfunction?
 - a. Endocrine problems
 - b. Circulatory problems
 - c. Excessive stress
 - d. Excessive alcohol use

QUESTIONS TO GUIDE YOUR READING

1. How would you explain the pathophysiology of each of the common sexually transmitted diseases (STDs)?
2. What are the etiologies, signs, and symptoms of each of the common STDs?
3. What care would you provide for patients undergoing tests for STDs?
4. What is current treatment for the common STDs?
5. What data should you collect when caring for patients with STDs?
6. What nursing care will you provide for patients with STDs?
7. How will you know if your nursing interventions have been effective?

Sexually transmitted diseases (STDs) are infections that can be transmitted through intimate contact with the genitals, mouth, or rectum of another individual. Some may also be spread by other routes such as blood or body fluids. A nurse's best protection against catching diseases from blood and body fluids from patients is the strict practice of standard precautions and maintaining your own healthy, intact skin.

Physically, STDs may cause tremendous suffering through pain, scarring of genitourinary structures, damage to other body organs, infertility, birth defects, nervous system damage, development of cancer, and even death of infected adults and sometimes their children. Psychologically and socially, these diseases also have profound effects on individuals, families, and relationships. Guilt about passing on an incurable disease to a loved one or feelings of betrayal because of being infected as a result of someone else's choices are only part of the emotional consequences of STDs.

Changing sexual mores have been associated with increasing incidence of almost all types of sexually transmitted diseases, including some previously rare diseases related to anal intercourse. Coexistence of more than one STD in an individual is also occurring more often. There are more than 50 diseases and syndromes associated with sexually transmitted diseases; the more common ones are discussed here. Human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS) are discussed separately in Chapter 54.

Symptoms, diagnostic techniques, and treatment regimens vary for different geographic areas. Availability of equipment for diagnosis, experience with patients who are atypical or antibiotic resistant, and health care provider preferences are responsible for much of the variety that is documented in the literature. As an introduction for practical/vocational nurses, general overviews are presented. Attempts have been made to present consensus from a variety of the available health care literature.

► DISORDERS AND SYNDROMES RELATED TO SEXUALLY TRANSMITTED DISEASES

Vulvovaginitis is an inflammation of the vulva and vagina and can be asymptomatic or involve redness, itching, burning, excoriation, pain, swelling of the vagina and labia, and discharge. A variety of sexually transmitted and nonsexually transmitted infectious agents can cause vulvovaginitis. The odor, consistency, and color of the discharge varies with the different microbes involved. Nonsexually transmitted vaginitis, vulvovaginitis, and vaginosis are described in Chapter 40. Some microorganisms may be acquired either by sexual or nonsexual routes, so they are also mentioned in this chapter. Bartholin's glands may develop ab-

scences as a result of infection with nonsexually transmitted microbes or STDs such as gonorrhea and chlamydia.

Both STDs and nonsexually transmitted microorganisms can cause **urethritis** in men and women. In men, inflammation of the urethra, prostate, and epididymis can result in difficult, painful, and frequent urination and a urethral discharge, which may be clear, cloudy, or yellow. Partners of men with urethritis may also suffer from urethritis, but they may also develop **mucopurulent cervicitis** (MPC) and a variety of other symptoms of the particular infection. Some causative agents for urethritis include *Neisseria gonorrhoeae*, *Chlamydia trachomatis*, *Ureaplasma urealyticum*, *Trichomonas vaginalis*, *Candida albicans*, and herpes simplex. Often this disease category is divided into gonococcal urethritis caused by *N. gonorrhoeae* (GU) and nongonococcal urethritis (NGU).

MPC is an inflammation of the cervix that can produce a mucopurulent yellow exudate on the cervix or may have no noticeable symptoms. MPC during pregnancy can result in **conjunctivitis** and pneumonia in newborn babies, as well as **puerperal** fever of the mother. MPC can be caused by such organisms as *C. trachomatis*, *N. gonorrhoeae*, *T. vaginalis*, *C. albicans*, and herpes simplex.

MPC may spread to become pelvic inflammatory disease (PID), a chronic inflammation of the lining of the uterus (**endometritis**) and the fallopian tubes (**salpingitis**), resulting in scarring, infertility, and increased risk of ectopic pregnancy (because scar tissue may block the fallopian tubes). Two of the most common causative agents of PID are *C. trachomatis* and *N. gonorrhoeae*, often in combination, which requires treatment for both.

Proctitis is inflammation of the rectum and anus that may be due to either nonsexually transmitted microbes or to STDs. This is especially prevalent among those who practice anal intercourse, both heterosexual and homosexual. Enteritis, which is inflammation of the lining of the intestine, may occur as a result of contamination during anal intercourse. Infection with *Campylobacter* spp., *Shigella* spp., and *Giardia lamblia* can be a problem for homosexual men. Care of patients who have gastrointestinal disorders is discussed in Unit 7.

Genital ulcers are formed when papules or macules erode and leave often painful raw, pitted, or excoriated areas on or around the genitals. Not all genital ulcers are caused by STDs—injury, some non-STD viruses, some types of drug reactions, radiation, and some forms of cancer can also pro-

salpingitis: salping—tube + itis—inflammation

proctitis: proc—anus + itis—inflammation

vulvovaginitis: vulvo—vulva + vagin—vagina + itis—inflammation

duce genital ulcers. However, several STDs can produce genital ulcers, including syphilis, herpes, chlamydia, chancroid, granuloma inguinale, and HIV. Genital ulcers from one type of disease may increase the risk of infection with other STDs during sexual activity, because the open areas present an easy portal of entry for the infecting organism.

Cellular changes can also be caused by STDs, including **condylomatous** (wartlike) growths and dysplasia or neoplasia, which may result in precancerous or cancerous conditions. Herpes viruses, HIV, and human papillomavirus (HPV) have all been linked to the development of cancer.

Chlamydia

Etiology and Signs and Symptoms

Chlamydia is the most common STD in the United States.¹ It can be transmitted sexually and by blood and body fluid contact. There are several serotypes of the bacteria *C. trachomatis*. Chlamydia is often asymptomatic in women, but urethritis, MPC, and conjunctivitis may result from this infection. Fitz-Hugh–Curtis syndrome, a surface inflammation of the liver, can also be caused by *C. trachomatis*. This inflammation may cause nausea, vomiting, and sharp pain at the base of the ribs that sometimes refers to the right shoulder and arm. A large proportion of cases of PID can be attributed to chlamydia, and it can lead to infertility and much greater risk of ectopic pregnancy. The infection can be passed from mother to baby during birth, resulting in neonatal pneumonia and conjunctivitis.

Lymphogranuloma venereum (LGV) is also caused by some serotypes of *C. trachomatis* but is more commonly seen in tropical climates or among people who emigrated from these areas. This disease also causes urethritis and proctitis, and it inflames lymph nodes that drain the pelvic area, resulting in draining sores and fistula development. Scarring from this disease can complicate vaginal deliveries.

Diagnostic Tests

There are several tests for chlamydia. Samples for culture are gathered in a special collection tube to send to a laboratory for microscopic examination. However, culturing is difficult and expensive and generally requires 2 to 6 days for results, depending on the availability of a fluorescence microscope. Research on some serological tests has shown some specificity problems, but some first-void urine samples, cervical samples, and urethral samples are being tested using RNA amplification. Because this disease is so common, it is wise to set out an unopened chlamydia collection kit within easy reach of the health care provider for each pelvic examination.

Treatment

Antibiotics ending in *-cycline* and *-mycin* are generally given to treat chlamydia in adults. The latter type is given during pregnancy because tetracyclines can deposit in de-

veloping bones and teeth. Eye drops of tetracycline or erythromycin may be given to babies shortly after birth for the prevention of conjunctivitis. Institutional policies and state regulations determine the type of eye drops to be used and whether administration of the drops requires specific consent of the parents.

Gonorrhea

Etiology and Signs and Symptoms

Almost 325,000 cases of gonorrhea were reported to the U.S. Center for Communicable Disease in 1997 (the most recently available complete statistics), but it is estimated that a true picture of the number of people who contract the disease yearly is around 800,000 and that the cost of care and treatment in the United States is approximately \$1.1 billion.² The causal bacteria, *N. gonorrhoeae*, may be transmitted vaginally, rectally, orally, and through contact with blood and body fluids and can produce a variety of symptoms. Men may be asymptomatic or may have urethritis with a yellow urethral discharge. Women who have gonorrhea may have either no noticeable symptoms or have a sore throat, MPC, urethritis, or abnormal menstrual symptoms such as bleeding between periods. Many cases of PID are caused by gonorrhea. Intercourse with an infected partner during menstruation may be especially risky for development of PID, because removal of the cervical mucous barrier can promote the growth of the gonococcus in the higher reproductive tract. Gonorrhea can also cause Fitz-Hugh–Curtis syndrome. Fever, nausea, vomiting, and lower abdominal pain may be present. Gonorrhea may also infect the throat and the rectum and may cause disseminated gonococcal infection, resulting in inflammation of the joints, skin, meninges, and lining of the heart.

Newborns born to mothers who have gonorrhea can develop **ophthalmia neonatorum**, which involves inflammation of the conjunctiva and deeper parts of the eye and can result in blindness. The newborn may also experience disease at other sites of infection with gonorrhea at birth. Abscesses may develop where fetal scalp monitors were attached during labor, and infection of the nose, lungs, and rectum may occur.

Diagnostic Tests

Diagnosis is done by microscopic examination of smears and cultures of the discharge or identification of bacterial DNA in the urine. More than one test may be done to verify the diagnosis.

Treatment

Development of antibiotic resistance by *N. gonorrhoeae* and co-infection with other microorganisms, such as *C. trachomatis*, is making treatment more complicated. At the time of the writing of this book, ceftriaxone, cefixime,

condylomatous: condyl—rounded projection + oma(t)—growth + ous—like

ophthalmia neonatorum: ophthalmia—eye disease + neonatorum—of the newborn

ciprofloxacin, and ofloxacin generally are recommended (but the latter two should not be given to people younger than 18 or to pregnant women).³ Ophthalmia neonatorum may be prevented by use of antibiotic eye drops such as erythromycin or tetracycline in the newborn at birth. Institutional policies and state regulations determine the type of eye drops to be used and whether administration of the drops requires specific consent of the parents.

Syphilis

Etiology and Signs and Symptoms

Syphilis is an ancient disease that has not disappeared, although it is overshadowed by more commonly occurring diseases such as chlamydia. The primary stage of syphilis begins with the entry of the *Treponema pallidum* spirochete through the skin or mucous membranes. Between 3 and 90 days later a papule develops at the site of entry; this sloughs off, leaving a painless, red, ulcerated area called a **chancre** (Fig. 42-1). Chancres may also develop in other areas of the body at this time. Chancre formation is generally the only symptom of this stage of syphilis. The chancre eventually heals, but the spirochete remains active in the infected individual and can be passed on to others. Secondary syphilis begins 2 to 8 weeks later and affects the body more generally, causing such problems as flulike symptoms, joint pain, hair loss, skin rashes (primarily on the soles of the hands and feet), mouth sores, and condylomatous growths in moist areas of the body.

Serious damage can occur if syphilis is untreated in the early stages. The disease may not progress to the tertiary (or late) stage for 3 to 15 years. At this stage it can involve any organ system of the body. In the tertiary stage the spirochete may form **gummas**, which are tumors of a rubbery consistency that can break down and ulcerate, leaving holes in body tissues. The gummas can damage the heart, circulatory system, and nervous system (neurosyphilis). Ulceration of gummas may destroy areas of vital tissue and lead to mental and physical disability or early death.

gummas: from the word meaning “rubber”—rubber tumors

Syphilis can be passed on to the unborn children of women who carry the spirochete, resulting in **hepatosplenomegaly**; increase in bilirubin; destruction of red blood cells; birth defects, especially of the face; **lymphadenopathy**; and a baby who can transmit the spirochete through nasal drainage. If left untreated, syphilis during pregnancy may cause lesions in various organs of the unborn baby and result in higher rates of spontaneous abortion, stillbirth, and premature birth.

Diagnostic Tests

Several tests for syphilis exist, and different tests may have to be used at different stages of the disease for accurate diagnosis. The organism is difficult to grow in culture and is so tiny that it cannot be seen with a light microscope. Dark-field microscopy of material from a chancre may show the organism but may also be negative in spite of definite symptoms of systemic syphilis infection. **Serological** (blood) tests are categorized as nontreponemal and treponemal. Some nontreponemal tests include the Venereal Disease Research Laboratory (VDRL) test, the rapid plasma reagin (RPR) test, and the automated reagin test (ART). These tests indirectly check for syphilis by detecting the presence of antibodies that the body forms in response to treponema and, unfortunately, in response to some other disorders, so false-positive results can occur. Treponemal tests are much more specific for syphilis but, unfortunately, can remain positive long after the disease has been effectively treated, so a combination of testing methods may be used to determine whether a patient truly has syphilis. Diagnosis of neurosyphilis is even more difficult because some testing of cerebrospinal fluid may result in false-negative results. Treponemal enzyme-linked immunosorbent assay (ELISA), fluorescent treponemal antibody absorption (FTA-ABS), and polymerase chain reaction (PCR) tests for treponemal DNA are some new methods being introduced to improve specificity.⁴

Treatment

Probenecid is added to penicillin to prolong the action to treat syphilis of nonpregnant, pregnant, and newborn patients. For those who are allergic to penicillin, doxycycline is one choice. However, when HIV and syphilis are seen in the same individual, symptoms of neurosyphilis are more likely and ceftriaxone is one recommended medication.⁵

Trichomonas

Etiology and Signs and Symptoms

Trichomoniasis is generally a sexually transmitted disease, but it may be transmitted through nonsexual contact with infected articles, because it can survive for quite a long time

hepatosplenomegaly: hepato—liver + spleno—spleen + megaly—enlargement

lymphadenopathy: lymph—lymph nodes + adeno—node + pathy—disorder

serological: sero—blood + logical—science

outside the body. (Therefore it was included in the chart of vaginal irritations and inflammations in Chapter 40.) Carriers of *T. vaginalis* may be asymptomatic for years until changes in vaginal or urethral conditions encourage an outbreak of the disease. A decrease in acid-producing resident bacteria, injuries to the vaginal tissues, and development of lesions from some other STDs or from some forms of cancer may activate the organism. Redness, swelling, itching, and burning of the genital area; pain with intercourse and voiding; and a frothy and foul-smelling discharge are seen with this infection.

Diagnostic Tests

The organisms can be identified by their motility and whip-like flagella when wet-mount slides of the discharge are viewed under a microscope. Trichomonas may produce abnormal Papanicolaou (Pap) smear readings, which require that more frequent Pap smears be done to provide adequate surveillance of cellular changes.

Treatment

The drug treatment of choice is metronidazole, except during the first trimester of pregnancy, when a 2-percent clindamycin vaginal cream is recommended. Some strains of *Trichomonas* may exhibit resistance but generally succumb to much higher doses of the drug. Because some people carry the organism without symptoms, sexual partners should also be treated regardless of symptoms.

Herpes

Etiology and Signs and Symptoms

Herpes infection is caused by the herpes simplex viruses types I and II (HSV-I and HSV-II). Herpesviruses have an affinity for tissues of the skin and nervous system and can lie dormant in nervous system tissues and then reactivate periodically when the body undergoes stress, fever, or immune system compromise. HSV-II can cause “fever blisters” of the mouth, as well as genital lesions. HSV-II causes a more severe genital version. After infection, vesicles develop, spontaneously rupture, and produce painful ulceration of the underlying skin tissues. However, some patients are totally asymptomatic and can still transmit the disease. Asymptomatic latent periods are generally interspersed between the **vesicular** outbreaks, but the virus may still be transmitted even during latent periods.

Initial infection with herpes may produce a flulike condition. Urethritis, cystitis, and MPC with vaginal discharge may also be evident. Infection of the spinal nerve roots by HSV may result in **sacral radiculopathy**, causing retention of urine and feces. Although rare, disseminated herpes infection can result in inflammation of the spinal cord, meninges, nerve pathways, and lymph nodes. Urethral

strictures and increased risk for development of cervical cancer in women are also consequences of herpes.

Transmission may occur from a mother to her child during pregnancy and delivery and through breast-feeding. It is estimated that one in five of all pregnant women carry herpes, although most of their babies do not develop **herpetic** disease. If infected, the baby’s skin, eyes, mucous membranes, and nervous system may be involved and death from disseminated herpes infection may occur. Active lesions or asymptomatic viral shedding increase risk of transmission.

Diagnostic Tests

Testing for HSV requires special viral collection kits for swabbed or scraped specimens from lesions. Follow the directions on the viral collection kit. Blood tests are improving; the Western blot assay can determine whether the person has HSV-I or HSV-II antibodies.

Treatment

There is presently no known cure for herpes infection, although antiviral medications such as acyclovir, valacyclovir, and ganciclovir may be given to decrease the severity of symptoms. (Only acyclovir may also be given during pregnancy, a treatment that may reduce the risk of transmission to the baby).⁶ Cesarean section delivery may also decrease the risk of transmission of the disease from the mother to the baby if there are active, open lesions at the time of delivery. See also Nursing Care Plan Box 42–1 for the Patient with Genital Herpes.

Genital Warts

Signs and Symptoms

Condylomata acuminatum (genital warts) are the most common sexually transmitted viral disease, and their incidence is increasing rapidly. Infection with human papillomavirus (HPV) produces the condylomata—soft, raised, **verrucous** fleshy tumors, which may also have fingerlike projections (Fig. 42–2). Some people remain asymptomatic, but they can still transmit the infection. More than 100 types of HPV have been identified, and several have been closely linked to development of cancers of the reproductive organs and anus in both males and females. There may be a long latent period of as much as 3 years’ duration from the time of exposure to development of the warts.

HPV can be passed on from a pregnant woman to her fetus, resulting in the growth of genital warts on the baby, HPV infection of the baby’s respiratory tract, and a possible increased risk of cancer development. HPV infection during pregnancy can cause particularly difficult problems. Genital warts tend to grow more rapidly in pregnant women

vesicular: vesicul—blister + ar—type

sacral radiculopathy: sacral—sacrum + radiculo—root + pathy—disorder or disease

herpetic: herpet—herpes + ic—pertaining to

condylomata acuminatum: condyl—rounded projection + oma—growth + ta—pluralizes the word (singular form is condyloma) + acuminatum—genital growths

verrucous: verruc—wart + ous—like

BOX 42-1 NURSING CARE PLAN FOR THE PATIENT WITH GENITAL HERPES**Pain related to inflammation, skin lesions****PATIENT OUTCOMES**

The patient will express pain relief and will rest and move well.

EVALUATION OF OUTCOME

Does patient state relief of pain?

INTERVENTIONS

Assess pain using the WHAT'S UP? format.

Recommend pain relief measures appropriate to the type and location of the pain (both alternative measures, such as heat, ice, and change of position, and medication may be offered).

Document results of pain relief measures.

Instruct patient about self-care for pain and STD treatment at home.

RATIONALE

Assessment of the characteristic of the pain assists the nurse in providing appropriate relief measures.

Not all types of pain respond well to the same treatment.

Documentation alerts other caregivers about what works and does not work, thus providing more consistent, effective pain relief.

Most STDs are treated at home.

EVALUATION

Can patient describe the pain characteristics?

Does patient express satisfactory relief of pain?
Does patient move and rest without evidence of pain?

Have you gained sufficient information from patient to document results?

Does patient verbalize understanding of self-care measures?

Risk for transmission of infection to others related to lack of knowledge about transmission, symptoms, and treatment**PATIENT OUTCOME**

Patient will verbalize understanding of measures to prevent transmission to others.

EVALUATION OF OUTCOME

Does patient verbalize understanding of transmission prevention? Does patient practice preventive behaviors?

INTERVENTIONS

Assess patient's understanding of transmission, symptoms, complications, and treatment of STDs.

Assess whether patient is engaging in high-risk behaviors.

Use universal precautions and strict aseptic technique for *all* procedures involving blood and body fluids.

Instruct patient in appropriate strategies to reduce risk of infecting others:

- Abstinence
- Monogamy (if no active infection)
- Use of barrier methods and spermicides
- Adherence to treatment regimen

Teach patient signs and symptoms of STDs to report immediately.

RATIONALE

New instruction should be based on patient's previous knowledge.

If patient is continuing to engage in high-risk behaviors, the risk for infection of others is high.

The health team, in addition to other patient contacts, must be protected.

These measures may help prevent transmission of infection to others.

Prompt treatment of patient and partners further reduces risk of transmission of infection.

EVALUATION

Is patient's current understanding accurate? What teaching is necessary?

Is patient protecting self and others appropriately?

Are universal precautions observed?

Does patient verbalize understanding of methods to prevent transmission and intent to practice them?

Does patient verbalize understanding of signs and symptoms to report?

Fear related to diagnosis of an incurable illness and effects on sexual relationships and reproduction**PATIENT OUTCOME**

Patient will verbalize realistic and accurate information about disease process and relate control of excessive fear.

EVALUATION OF OUTCOME

Does patient relate accurate knowledge? Is fear manageable?

BOX 42-1 NURSING CARE PLAN FOR THE PATIENT WITH GENITAL HERPES—CONT'D

INTERVENTIONS	RATIONALE	EVALUATION
Assess patient's fears.	Fear is a normal response and may be appropriate.	What does patient fear?
If fear is based on misconceptions, provide factual information.	When fear is based on misconceptions, they should be corrected.	Are fears based on factual information?
Allow patient to verbalize feelings. Be empathetic, but do not offer false hope.	Sharing fears may help patient gain insight into dealing with them.	Is patient able to verbalize feelings?
Explain all procedures and treatments.	Unfamiliar procedures or treatments may contribute to fear.	Does patient understand procedures and treatments?
Help patient identify support systems and coping strategies that have worked in the past.	Methods that have worked for patient before are likely to be helpful again.	Does patient have effective coping skills and support systems?

and to bleed more easily with injury than in nonpregnant women.

Diagnostic Tests

Diagnosis may be made by applying dilute acetic acid (vinegar) to the skin of the external genital area, vagina, cervix, and anus and then closely examining with a colposcope the areas that turn a lighter color. Biopsy specimens of the suspicious areas can be sent for further study of the cells. Other tests to diagnose HPV include an antigen test and the Southern and dot blot tests, which use radioactive probes. Cancerous changes stimulated by this virus may be identified on Pap smears.

Treatment

There is presently no known cure for papillomavirus infection. The warts may be treated by freezing, burning, or chemically destroying them or by manipulating the patient's immune system to attack the virus. Cryotherapy (freezing) of the warts may be done by touching each wart with a cryoprobe or a liquid nitrogen-soaked swab. Warts may also be burned, or **electrocoagulated** with an **electro-**

cautery or a laser. Heat causes the proteins to coagulate, resulting in death of the wart tissue. Podophyllin, trichloroacetic acid (TCA), and fluorouracil (also called 5FU) are some of the chemical agents that may be applied topically to the warts.⁷ Some options are not appropriate for use during pregnancy because of their **cytotoxic** effects, which might damage the fetus, but cryosurgery and laser destruction of the wart tissue may be done during pregnancy. All treatments may require multiple applications and generally result in a great deal of discomfort as the warts degenerate, ulcerate, and slough over a long period.

Various types of immunotherapy have been used against HPV. Interferons are proteins produced by the body that can inhibit viral growth. Several types of interferon have been used to combat HPV. These substances may be applied topically, injected into the condyloma, or administered systemically. Interferons can produce side effects of flulike symptoms, a drop in the number of white blood cells, and changes in liver function. Systemic interferon treatment, however, may offer the advantage of being able to attack warts all over the body at the same time, rather than individually as with topical treatments, thus speeding the process of treatment. Research to develop vaccines against HPV strains is ongoing, but the multitude of varieties makes this difficult. Widespread destruction of tissue in the most sensitive areas of the body can cause severe discomfort. More conservative treatments, however, may not keep pace with the growth of new warts.

Home Care

Patients who have genital warts (condylomata acuminatum) burned off need to recuperate at home. If the burns (there may be multiple areas treated) are near the urethra or rectum, the patient may need a Foley catheter inserted to avoid contamination. Also, the patient is instructed to increase dietary roughage and fluids to prevent constipation. The health care provider is consulted for orders on care of burns. Sterile technique is used for dressing changes. The patient is premedicated for pain control if necessary for dressing changes.

electrocoagulated: electro—electrical + coagul—curdled or hardened + ated—process completed

electrocautery: electro—electrical + cautery—branding iron

cytotoxic: cyto—cell + toxic—poison

Hepatitis B

Etiology and Signs and Symptoms

There are several main hepatitis viruses, but this section deals only with hepatitis B virus (HBV), which is generally considered within the STD category because it can be transmitted through sexual contact with blood and body fluids. Early signs of hepatitis are loss of appetite, rashes, malaise, muscle and joint pain, headaches, nausea, and vomiting. As the virus affects the liver, the urine may darken and the stool color lighten (as a result of changes in bile excretion), liver enzymes may rise, and jaundice may appear. Enlargement of the spleen, enlargement and tenderness of the liver, necrosis of liver cells, cirrhosis, coma, and death may follow if the disease is severe. Chronic asymptomatic carrier status may follow hepatitis virus infection, with an increased risk of liver cancer.

During pregnancy, hepatitis B virus may be transmitted to the unborn baby, which can result in acute hepatitis and the possibility of becoming a chronic carrier of HBV.

Diagnostic Tests

Diagnosis of hepatitis is generally made using a variety of blood tests based on antigen and antibody responses.

Treatment

Supportive medical care with avoidance of drugs that require liver metabolism may help the patient through the active stage of the disease. Treatment of the disease may involve injection of serum immune globulins to confer passive immunity. It is recommended that all babies of HBV-positive mothers receive a 0.5-mL dose of HBV immune globulin less than 12 hours after birth and then be immunized with HBV vaccine 1 week, 1 month, and 6 months after birth. See Chapter 33 for more information. Interferon alpha is also available for patients with chronic hepatitis B.⁸

Prevention

Prevention is better than treatment and may be accomplished by using HBV vaccine. This is especially recommended for health care workers who come in contact with blood and body fluids. Standard precautions should be used when contact with any body fluids is expected.

Genital Parasites

Etiology and Signs and Symptoms

Genital parasites are not a true STD, but they may be transmitted during close body contact. The two most commonly seen parasites are pubic lice (*Phthirus pubis*, commonly called “crabs” because of the shape of the lice) and scabies (*Sarcoptes scabiei*). These parasites cause itching, redness, and, for scabies, tracks under the skin where the females burrow to lay their eggs.

Diagnostic Tests

Direct visual or magnified view of the parasites aids in diagnosis.

Treatment

Parasites are treated with topical insecticides. Advise the patient to refer to package inserts for application instructions and precautions to avoid reinfection.

Pediatric Sexually Transmitted Diseases

Not all STD patients are adults. Unfortunately, childhood sexual abuse does occur. You can play an important role in providing explanations in simple terms for procedures and in comforting and supporting the child. Fortunately, not all STDs grow well in immature genital tracts. However, chlamydia, syphilis, herpes, and genital warts are sometimes seen in young children. It is very important that child sexual abuse be reported and investigated. For this to occur effectively, evidence must be gathered. The health care provider may request an evidence kit from the local police for use during the examination.

Accusations of sexual abuse have sometimes been wrongly filed and have produced a great deal of trauma in children and families. Some forms of STDs may have been transmitted at or before birth and later have presented symptoms. It is probably wisest to report suspicions with documentation of evidence to a supervisor if the patient is seen in a health care setting. In the community, child welfare agencies may be contacted. Depending on the state, province, or country, the nurse may be required by law to report directly to a child protection agency any suspicion of child abuse. Children who frequently scratch their genital areas or who have a foul smell emanating from the genital area may be victims of sexual abuse or may have put a foreign object into the vagina. Examination of a small child may be done with a nasal speculum rather than a vaginal speculum. Further content on care and examination of children is addressed in pediatrics texts. Teenagers and the elderly are also at risk for STDs (Gerontological Issues Box 42–2).

BOX 42-2 GERONTOLOGICAL ISSUES

Older adults remain sexually active even though society often views them as asexual. Do not assume that because an older adult is single or widowed he or she is not sexually active. Older adults who have enjoyed active and fulfilling sex lives with a spouse or partner seek that in new relationships. Older adults who engage in high-risk sexual behaviors (multiple partners, genital-anal sex, no use of barriers during sexual intercourse) are also at risk for sexually transmitted diseases.

▶ REPORTING OF SEXUALLY TRANSMITTED DISEASES

You may also facilitate the reporting and public health follow-up of STDs by filling in patient information on the STD reporting form and placing the form in the patient's chart for completion by the health care provider. The requirements for reporting STDs may vary for different states, provinces, and countries. In some areas, laboratories are also

required to submit a report form for positive reportable STD tests. Laboratory reports that are not followed by a health care provider's report may result in investigation of the situation by an STD investigator. Generally the report form has spaces for listing of sexual contacts who should be notified of possible STD exposure. Depending on the laws of the state, province, or country, the patient may notify contacts or have the health care provider do so or contacts may be notified by a public health authority that they have been listed as a sexual contact by an anonymous person who has tested positive for a particular STD.

► NURSING CARE AND TEACHING

STDs are usually diagnosed and treated in health care provider's offices and clinics. Hospitalization related to STDs generally occurs only in conjunction with infertility investigations, **perinatal** difficulties caused by STDs, or serious long-term complications resulting from STDs, such as AIDS. If the complication is, for instance, meningitis caused by a herpesvirus, the plan of care will be similar to the plan for any other type of meningitis, with the consideration that psychosocial concerns may differ somewhat because of the source of the infection. The nurse's role in the care of patients with STDs includes observation and documentation of signs and symptoms and providing education and patient support during times of diagnosis and treatment.

You may be expected to set out supplies for pelvic examinations and swabs and smears and to be present during the examination as a chaperone or patient support person. (See Chapter 39.) Some patient teaching may take place as the supplies are readied. Explanation of what to expect during the examination and collection of test samples may help decrease patient anxiety. Information about possible risk reduction strategies may also be needed. Pamphlets or other reading materials may be available to provide to the patient. Clarify with your employer the type and depth of information patients should be given, so that teaching is not duplicated, confused, or omitted.

Sometimes patients visit clinics or health care providers' offices for stated reasons other than STDs, yet their real concern is an STD. A female patient may state that she needs a Pap smear, when her real concern is the possibility of STDs. After the patient has been placed in an examining room, asking the date of the last Pap smear and whether she is presently experiencing any irritation, pain, or unusual growths or discharges in her private areas may clarify the request without being considered too intrusive. Explaining to the patient the need to know what examination supplies to set out for the health care provider may further help put the patient at ease. Some people misunderstand the purpose of Pap smears and believe that any problems of the reproductive organs can be diagnosed through this test. If appropriate questioning does not determine the real needs of the patient, she may believe that she has received testing for

infection that in reality was not done. If she is asymptomatic by visual inspection and does not tell the health care provider about her concerns, a Pap smear may be all that is done. Furthermore, the results for Pap smears that are done when there is an active infection may read "inflammatory changes present, repeat Pap smear after resolution of the inflammation." Although this may eventually alert the health care provider that there was an infection at the time of the Pap smear, the infective agent is not identified, another pelvic examination is probably be required, and the diagnosis is delayed needlessly (during which time the infection may have been transmitted to others).

Nursing diagnoses that may be identified for the patient with an STD may include pain related to inflammation or skin lesions, risk for transmission of infection to others, ineffective sexuality pattern related to illness and risk for transmission, and fear related to diagnosis of possible incurable illness. Your plan of care should include measures to increase patient comfort, instruction on safer sex practices and how to prevent transmission of the disease, and identification of coping behaviors that help reduce fear. Ensure that the patient understands self-administration of analgesics and other prescribed treatments, as well as signs of possible complications and how to report them, and knows that the pain will subside with effective treatment of the infection.

It has been said that the only sure prevention of sexually transmitted diseases is abstinence. Lifelong monogamy of both sexual partners in a relationship also provides excellent protection. Having a sexual relationship with someone is the **epidemiological** equivalent of engaging in sexual activity with all of that person's previous partners. Ignorance of the serious repercussions of some STDs may explain some of the apathy surrounding risk reduction.

Many myths about sexual activity are sincerely believed by some patients (Table 42-1). Assessing the patient's health beliefs and correcting misconceptions is part of the job of a nurse. It is vitally important for patients to know the sexual and lifestyle history of any potential partner before sexual activity has occurred and before emotional issues may cloud judgment. Development of a healthy relationship in which honest communication can occur generally takes time and effort.

When teaching patients, the terms *safe sex* and *STD prevention* are misnomers. You should more accurately refer to information about barrier methods as *safer sex practices*, which may decrease the risk of (but not absolutely prevent) transmission of STDs (Table 42-2).⁹

One of the most common contributing factors for infection with an STD is the consumption of alcohol or other psychoactive drugs. Patients should be advised that reduction of inhibitions and changes in judgment may result in unintended sexual encounters, which can transmit STDs. Avoiding or limiting alcohol and other drug consumption

perinatal: peri—around + natal—birth

epidemiological: epi—on + demio—people + logical—pertaining to

TABLE 42-1 COMMON MYTHS ABOUT SEXUALLY TRANSMITTED DISEASES

Myth	Factual Data
People who have STDs are easily identifiable.	Inspection of the potential partner's genitals before sexual activity may decrease the risk (if one does not participate in sexual activity with a person who has visible lesions), <i>but . . .</i> <ul style="list-style-type: none"> • Not all people who are infected have visible symptoms. • There is no standard personality or physical profile for people who can be infected with STDs—<i>anyone</i> can be infected.
Avoiding persons who have a history of casual sex, intravenous drug use, homosexual activity, bisexual activity, or a previous sexual relationship with persons who engage in these high-risk practices effectively protects one from infection with STDs.	Avoiding people with these types of history may decrease risk, <i>but . . .</i> <ul style="list-style-type: none"> • Not everyone is honest when responding to questions about sexual history. • Not everyone is aware of their previous partners' histories or the histories of others with whom their previous partners have had sexual relationships. • Asking these kinds of questions is difficult and may be postponed at times until emotional factors complicate such communication.
STDs never happen the first time.	Only one contact with one microorganism is necessary for infection.
Intact genital skin is impervious to the germs (and gentle sexual activity does no harm).	Intact skin is the body's first line of defense, <i>but . . .</i> <ul style="list-style-type: none"> • Some microorganisms can be transmitted without a noticeable tissue injury. • Minor injuries can occur during many types of sexual activity, including vaginal intercourse.
Condoms prevent the spread of all STDs.	Condoms can greatly decrease the risk of STDs, <i>but . . .</i> <ul style="list-style-type: none"> • Condoms can have tiny channels in the rubber (or other elastic material), which can allow microorganisms to pass through. • Condoms can break, slip off, or be applied improperly. • Petroleum-based lubricants may weaken latex condoms. • Condoms do not provide a barrier for any area other than the penis and most of the vagina (or anus). Some STDs may still be transmitted by contact of surrounding uncovered tissues.
The female condom prevents all transmissions of STDs.	It does cover more surface area, but it may have similar problems to male condoms (see previous).
Manual, oral, and anal stimulation cannot transmit STDs.	Contact of hands to genitals can allow for transmission of microorganisms through breaks in the skin. Oral sex can transmit some STD-causing microorganisms. Anal intercourse is a very high-risk activity for transmission of STDs because anal tissues are easily injured and the gastrointestinal tract can be a reservoir for many microorganisms.
Nonoxynol-9 spermicide kills all STD germs.	Nonoxynol-9 can reduce the risk of transmission of STDs, <i>but . . .</i> <ul style="list-style-type: none"> • Nonoxynol-9 is <i>not</i> guaranteed to kill all microorganisms.
People get AIDS only by homosexual sexual activity or by blood transfusion. A woman cannot transmit HIV to a man. A man cannot transmit HIV to a woman.	Homosexual activity may result in a higher incidence of transmission of human immunodeficiency virus, <i>but . . .</i> <ul style="list-style-type: none"> • HIV can be transmitted during heterosexual activity. • The gender of the individual does not protect him or her from being infected with HIV.
Sexual activity during menstruation is less likely to result in STDs.	Sexual activity during menstruation is more likely to result in transmission of some microorganisms that cause STDs because of the vulnerability of the lining of the uterus caused by sloughing of the outer layers of cells and because blood and cellular debris may serve as a nutritious medium for growth of microorganisms.
Lesbian sexual activity cannot transmit STDs.	Transmission of microorganisms can occur by contact with mouth, anal, or genital tissues or fomites (inanimate objects, such as vibrators and other sex paraphernalia) that have been contaminated with microorganisms from an infected individual—regardless of the original source of the infection.
Individuals who have not been infected after sexual activity with several people are naturally immune to STDs.	There is no known natural immunity to STDs. The individual may not yet have had contact with someone with an active STD.
Those who have had an STD and have been cured of it by taking medicine are now immune to that disease.	Infection that has been eradicated by medication does not confer immunity.
People can be certified free of all STDs by having a blood test and taking a simple medication if an infection is present.	Testing of those who suspect they may have contracted an STD and treatment (if possible) may decrease the spread of STDs, <i>but . . .</i> <ul style="list-style-type: none"> • No one test identifies all STDs. Some are identified by examination, and not all infected people show symptoms. • Some STDs do not show positive test results for long periods yet may be transmitted by the individual while the tests are still negative. • People may be infected with more than one causative agent at a time and each must be treated (if possible). One STD may obscure the symptoms of other concurrent STDs, so that one or more types may go unnoticed and untreated or may not be evident until other STDs have been treated. • There are no known cures for some STDs.
Oral contraceptive (OC) pills give protection against STDs.	OC preparations are <i>not</i> an antibiotic—they provide only some protection against conception. Use of a barrier method with spermicide along with the OC can decrease risk of STDs, as well as pregnancy.

TABLE 42-2 BARRIER METHODS FOR SAFER SEX

Barrier	Related Information
Male condoms	<p>Latex condoms are less likely to break during intercourse than other types.</p> <p>Lubrication decreases the chances of breakage during use, but only water-soluble lubricants should be used, because substances such as petroleum jelly (Vaseline) may weaken the condom.</p> <p>Condoms should never be inflated to test them, because this can weaken them.</p> <p>Condoms should be applied only when the penis is erect.</p> <p>Either condoms with a reservoir tip or regular condoms that have been applied while holding approximately ½ inch of the closed end flat between the fingertips allow room for expansion by the ejaculate without creating excessive pressure, which might break the condom.</p> <p>The penis should be withdrawn after ejaculation before the erection begins to subside while holding the top of the condom securely around the penis to avoid spillage.</p> <p>Condoms should never be reused and should be discarded properly after use so that others will not come in contact with the contents.</p>
Female condoms	<p>Female condoms should be applied before any penetration occurs (even preejaculation fluid can contain microorganisms).</p> <p>Lubrication decreases the chances of breakage during use, but only water-soluble lubricants should be used, because substances such as petroleum jelly may weaken the condom.</p> <p>Female condoms should never be reused and should be discarded properly after use so that others will not come in contact with the contents.</p>
Cervical caps or diaphragms	<p>These may provide some protection for the cervix only. They are not effective barriers against STD infection.</p>
Rubber gloves, rubber dental dams, split (opened) male condoms	<p>These may provide some barrier protection for manual and oral sexual activity. Although some groups suggest that male condoms may be split down one side and opened or rubber dental dam material may be taped over areas that have lesions to avoid direct contact with blood and body fluid, especially during sadomasochistic sexual activity, this <i>very high-risk behavior</i> is not recommended.</p>
Double condoms	<p>Anal intercourse is a <i>very high-risk activity</i> for transmission of many types of STDs, as well as many intestinal organisms, and is not recommended. Homosexual networks advise wearing double condoms and using water-soluble lubricants, preferably containing nonoxynol-9, to decrease risk somewhat if engaging in this type of sexual activity.</p>

when with potential partners may help prevent STD infection from occurring.

For those who choose to be sexually active with more than one person (or with a person who has been sexually active with others) and for those who choose to practice high-risk behaviors, barrier protection may decrease the chances of developing an STD. Information on how to use barrier methods effectively is essential. Ensure that the patient has access to these methods. For more information on STDs, visit <http://www.niaid.nih.gov/factsheets/stdstats.htm> and <http://www.ashastd.org/>.

Evaluation

Goals have been met if the patient does the following:

- States that pain is controlled
- Verbalizes understanding of and intent to follow recommendations for prevention of infection transmission
- Describes safer sexual practices
- Relates accurate information and reduction in fear

CONCLUSION

Neighbors, friends, or family members may seek information from you because they know nurses are educated about health issues. Such questions may be stated in indirect terms, such as, “I have a friend who is having a problem. . . .” It is often wisest to identify broad areas of information that people seem to be seeking without going into details that may be embarrassing. Suggesting that the concerned person see a health care provider or contact the local STD clinic for further investigation or information is wise. Emphasize the serious consequences of untreated STDs and the impossibility of effective self-treatment. Avoid stating that there is no cure for a particular type of STD, because research is ongoing and sometimes cures are developed and tested before the general medical community becomes aware of them.

STD diagnosis is a complicated process. Individual pathogens may affect the body in a variety of ways, and infection with more than one pathogen may further complicate the picture. Some signs and symptoms that are seen with STDs may also be caused by non-sexually transmitted infection or overgrowth of the body’s resident microorganisms. General awareness of common signs and symptoms of STDs, however, is important for nurses. Some patients

CRITICAL THINKING

Stephanie

As you seat a young woman in an examining room of the clinic where you work, she comments, “I am new to this area and I’ve heard that there are three guys in this town who have syphilis and are spreading it around. Is that true?”

1. What are some concerns this question might reflect?
2. You find out that Stephanie knows very little about syphilis. List in outline form a teaching plan that includes the information that is important for Stephanie to know about syphilis.

Answers at end of chapter.

admitted for other diagnoses may be unaware that they have STDs as well. Nurses are often the ones who bathe and given perineal care to patients. Unusual discharges, redness, blisters, swollen areas, ulcers, and evidence of parasites in the genital area may be observed during patient care. STD awareness can sensitize you to the possible significance of patient complaints such as persistent pelvic pain, dysuria, discharges, and rectal soreness. Such problems should be accurately documented and reported, so that further investigation and possible treatment can take place.

One of the most important ways you can help those who experience STDs is by being kind, polite, nonjudgmental, and sensitive to the patient's communication. Keeping the arms crossed over the chest or other closed postures may be interpreted as evidence of a judgmental attitude regardless of your feelings. Maintaining an open posture and eye contact that is appropriate for the patient's culture relays a sense of openness and willingness to talk and preserves the possibility of continuing health promotion with these individuals in the future.

REVIEW QUESTIONS

- Medication may be put in newborns' eyes to protect them against which of the following disorders?
 - Hepatosplenomegaly
 - Neonatal pneumonia
 - Ophthalmia neonatorum
 - Becoming a chronic carrier of HBV
- Which of the following pathogens causes syphilis?
 - Treponema pallidum*
 - Chlamydia trachomatis*
 - Human papillomavirus
 - Human immunodeficiency virus
- Which of the following has been linked to cancerous changes in cervical cells?
 - Syphilis
 - Gonorrhea
 - Chlamydia
 - Human papillomavirus
- Which is the most accurate term to use when teaching patients about STD prevention?
 - Safe sex strategies
 - Safer sex strategies
 - Risk elimination strategies
- Lisa comes into the clinic where you work and is diagnosed with an STD. She says, "How could I have an STD? I only have sex with my boyfriend. I don't sleep around!" Which of the following responses is best?
 - "You are right, that should have kept you safe. There just are no guarantees."
 - "If your boyfriend is not infected, then obviously you have had sex with someone else."
 - "Your boyfriend could be infected from his past sexual encounters. He should be tested."
 - "Even lifelong monogamy cannot prevent many STDs."
- What is the worst possible outcome of an STD?
 - Pain
 - Death
 - Scarring
 - Infertility

Answers to CRITICAL THINKING

Stephanie

- Concerns might include (a) a wish to speak with a health care worker; (b) uncertainty about whether patient information will be kept confidential (give assurance that if you knew about anyone with syphilis, it would be your professional responsibility to keep it confidential); (c) fear that she might have become infected through heterosexual contact; (d) a desire to protect herself by avoiding those who have this problem; and (e) a desire for information about syphilis and its transmission routes.
- The teaching plan might include information about (a) the spirochete that causes syphilis; (b) signs and symptoms; (c) diagnostic tests; (d) means of transmission; (e) strategies for risk reduction; (f) treatment; (g) research; and (h) rights and responsibilities of those who have the disease.

QUESTIONS TO GUIDE YOUR READING

1. What is the normal structure and function of the musculoskeletal system?
2. What major changes occur in the musculoskeletal system when a person ages?
3. Why is it important to inspect, palpate, and determine range of motion in a patient with a musculoskeletal problem?
4. What areas are reviewed when performing a neurovascular assessment?
5. What psychosocial problems do you assess for when caring for patients with musculoskeletal problems?
6. How would you describe diagnostic tests for musculoskeletal problems?
7. What nursing care would you provide for each musculoskeletal diagnostic test?

► REVIEW OF NORMAL ANATOMY AND PHYSIOLOGY

The skeletal and muscular systems may be considered one system because they work together to enable the body to move. The skeleton is the framework that supports the body and to which the voluntary **muscles** are attached. The skeletal framework includes the **joints** or articulations between **bones**. Contraction of a muscle pulls a bone and changes the angle of a joint. It is important to remember that movement would not be possible without the proper functioning of the nervous, cardiovascular, and respiratory systems. Voluntary muscles require nerve impulses to contract, a continuous supply of blood provided by the circulatory system, and oxygen provided by the respiratory system.

► SKELETAL SYSTEM TISSUES AND THEIR FUNCTIONS

The tissues that make up the skeletal system are bone tissue; cartilage, which covers most joint surfaces; and fibrous connective tissue, which forms the ligaments that connect one

bone to another and also form part of the structure of joints. The tissues of the muscular system are skeletal (also called striated or voluntary) muscle; fibrous connective tissue, which forms the tendons that connect muscle to bone; and the fasciae, the strong membranes that enclose individual muscles.

Besides its role in movement, the skeleton has other functions. It protects organs from mechanical injury. For example, the brain is protected by the skull and the heart and lungs are protected by the ribcage. Flat and irregular bones contain and protect the red bone marrow, one of the hematopoietic (blood-forming) tissues. The bones are also a storage site for excess calcium, which may be removed from bones to maintain a normal blood calcium level. Calcium in the blood is necessary for blood clotting and for the proper functioning of nerves and muscles.

Although the primary function of the muscular system is to move the skeleton, the voluntary muscles collectively contribute significantly to heat production, which maintains normal body temperature. Heat is one of the energy products of cell respiration, the process that produces

adenosine triphosphate (ATP), the direct energy source for muscle contraction. Another important function of the muscular system is that it aids in returning blood from the legs through muscular compression on the leg veins.

Bone Tissue and Growth of Bone

Bone tissue is composed of bone cells, called osteocytes, within a strong nonliving matrix made of calcium salts and the protein collagen. In compact bone the osteocytes and matrix are in precise arrangements called haversian systems. Compact bone is very dense and to the unaided eye appears solid. In spongy bone the arrangement of cells and matrix is less precise, giving the bone a spongy appearance. Compact bone forms the diaphyses (shafts) of the long bones of the extremities and covers the spongy bone that forms the bulk of short, flat, and irregular bones.

A living bone is covered by a fibrous connective tissue membrane called the periosteum, which is the anchor for tendons and ligaments because the collagen fibers of all these structures merge to form connections of great strength. This membrane also contains the blood vessels that enter the bone itself (most bone has a very good blood supply) and bone-producing cells called osteoblasts that are activated to initiate repair when bone is damaged.

The growth of bone from fetal life until a person attains final adult height depends on many factors. Proper nutrition provides the raw material to produce bone matrix: calcium, phosphorous, and protein. Vitamin D is essential for the efficient absorption of calcium and phosphorous from food in the small intestine. Vitamins A and C do not become part of bone but are needed for enzymes involved in the production of bone matrix (a process called calcification or ossification). Hormones directly necessary for growth include growth hormone (GH) from the anterior pituitary gland, thyroxine from the thyroid gland, and insulin from the pancreas. Growth hormone increases mitosis and protein synthesis in growing bones; thyroxine also increases protein synthesis, as well as increasing energy production from food. Insulin is essential for the efficient use of glucose to provide energy. If a child is lacking any of these hormones, growth is much slower and the child does not reach his or her genetic potential for height.

Bone is not a fixed tissue, even when growth in height has ceased. There is a constant removal and replacement of calcium and phosphate (usually the rates are equal) to maintain normal blood levels of these minerals. Parathyroid hormone secreted by the parathyroid glands increases the removal of calcium and phosphate from bones; the hormone calcitonin from the thyroid gland promotes the retention of calcium in bones, although its greatest effects may be during childhood.

Osteoblasts produce bone matrix during normal growth, to replace matrix lost during normal turnover and to repair fractures. Other cells called osteoclasts reabsorb bone matrix when more calcium is needed in the blood and during normal growth and fracture repair when excess bone must be removed as bones change shape.

The sex hormones, estrogen from the ovaries or testosterone from the testes, are important for the retention of calcium in adult bones. For women after menopause, more calcium may be removed from bones than is replaced, leading to a thinning of bone tissue and the possibility of spontaneous fractures.

Structure of the Skeleton

The 206 bones of the human skeleton are in two divisions: the axial skeleton and the appendicular skeleton. The axial skeleton consists of the skull, vertebral column, and ribcage; all are flat or irregular bones and contain red bone marrow. The appendicular skeleton consists of the bones of the arms and legs and the shoulder and pelvic girdles, by which the extremities attach to the axial skeleton (Fig. 43–1).

The long bones of the limbs are those of the arm, forearm, hand, and fingers and those of the thigh, leg, foot, and toes. All long bones have the same general structure: a central diaphysis or shaft with two ends called epiphyses. The diaphyses of long bones contain yellow bone marrow, which is mostly fat—that is, stored energy. The bones of the wrist and ankle are short bones, and those of the shoulder and pelvic girdles are considered flat bones. These bones contain red bone marrow.

Skull

The skull consists of 8 cranial bones and 14 facial bones and also contains the 3 auditory bones found in each middle ear cavity. The cranial bones that enclose and protect the brain are frontal, two parietal, two temporal, occipital, sphenoid, and ethmoid (Fig. 43–2). All the joints between cranial bones and those between most of the facial bones are immovable joints called sutures. The mandible is the only movable facial bone; the temporomandibular joint is a condyloid joint (Table 43–1). The maxillae are the upper jaw bones, which also form the front of the hard palate. The rest of the facial bones are shown in Fig. 43–2.

Vertebral Column

The vertebral column (or spinal column) is made of individual bones called **vertebrae** (see Fig. 43–1). From top to bottom there are 7 cervical, 12 thoracic, 5 lumbar, 5 sacral fused into 1 sacrum, and 4 or 5 coccygeal vertebrae fused into 1 coccyx.

The first cervical vertebra, the atlas, articulates with the occipital bone of the skull and forms a pivot joint with the axis, the second cervical vertebra. The thoracic vertebrae articulate with the posterior ends of the ribs. The lumbar vertebrae are the largest and strongest. The sacrum permits the articulation of the two hip bones, the sacroiliac joints. The coccyx is the remnant of tail vertebrae, and some muscles of the perineum are attached to it.

The vertebrae as a unit form a flexible backbone that supports the trunk and head and contains and protects the spinal cord. The joints between vertebrae are symphysis joints in which a disk of fibrous cartilage serves as a cushion and permits slight movement.

Figure 43-1 The full skeleton in anterior view. (Modified from Scanlon, VC, and Sanders, T: *Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 106, with permission.)

Ribcage

The ribcage consists of the 12 pairs of ribs and the sternum, or breastbone. All the ribs connect posteriorly with the thoracic vertebrae. The seven pairs of true ribs articulate directly with the sternum by means of costal cartilages; the three pairs of false ribs join indirectly with the sternum, and the two pairs of floating ribs do not connect to the sternum at all.

The ribcage protects the heart and lungs, as well as upper abdominal organs such as the liver and spleen, from me-

chanical injury. During breathing, the flexible ribcage is pulled upward and outward by the external intercostal muscles to expand the chest cavity and bring about inhalation.

Appendicular Skeleton

The bones of the appendicular skeleton are shown in Fig. 43-1. The important joints of the appendicular skeleton are summarized in Table 43-1.

Figure 43-2 Anterior (*upper*) and lateral (*lower*) views of the skull. (Modified from Scanlon, VC, and Sanders, T: Anatomy and Physiology, ed 3. FA Davis, Philadelphia, 1999, p 107, with permission.)

TABLE 43-1 JOINTS OF THE APPENDICULAR SKELETON

Type of Joint and Description	Examples
Symphysis—disk of fibrous cartilage between bones	Between vertebrae Between pubic bones
Ball and socket—movement in all planes	Scapula and humerus (shoulder) Pelvic bone and femur (hip)
Hinge—movement in one plane	Humerus and ulna (elbow) Femur and tibia (knee) Between phalanges (fingers and toes)
Condyloid—hinge with some lateral movement	Temporal bone and mandible (lower jaw)
Pivot—rotation	Atlas and axis (neck) Radius and ulna (distal to elbow)
Gliding—side-to-side movement	Between carpals (wrist)
Saddle—movement in several planes	Carpometacarpal of thumb

Adapted from Scanlon, VC, Sanders, T: Essentials of Anatomy and Physiology, ed 3. FA Davis, Philadelphia, 1999, p. 120, with permission.

Structure of Synovial Joints

All freely movable joints (this excludes sutures and symphyses) are synovial joints in that they share similarities of structure (Fig. 43-3). On the joint surface of each bone is the **articular** cartilage, which provides a smooth surface. The joint capsule is similar to a sleeve. It is made of fibrous connective tissue and forms a strong sheath that encloses the joint. Lining the joint capsule is the synovial membrane, which secretes synovial fluid into the joint cavity. Synovial fluid prevents friction as the bones move.

Many synovial joints also have **bursae**, which are small sacs of synovial fluid between the joint and the tendons that cross over the joint. Bursae permit the tendons to slide easily as the joint moves.

Figure 43-3 Longitudinal section through a typical synovial joint. (Modified from Scanlon, VT, and Sanders, T: Workbook for Essentials of Anatomy and Physiology, ed 3. FA Davis, Philadelphia, 1999, p 121, with permission.)

MUSCLE STRUCTURE AND ARRANGEMENTS

One muscle is made of thousands of muscle cells (fibers), which are specialized for contraction. When a muscle contracts, it shortens and pulls on a bone. Each muscle fiber receives its own motor nerve ending, and the number of fibers that contract depend on the job the muscle has to do. Muscles are anchored to bones by tendons, which are made of fibrous connective tissue. A muscle usually has at least two tendons, each attached to a different bone. The more stationary a muscle's attachment to its origin, the more movable the attachment to its insertion. The muscle itself crosses the joint formed by the two bones to which it is attached, and when the muscle contracts it pulls on the insertion and moves the bone in a specific direction.

The more than 600 muscles in the body are arranged to bring about a variety of movements (Fig. 43-4). The two general types of arrangements are the opposing antagonists and the cooperative synergists.

Antagonistic muscles have opposite functions; such arrangements are necessary because muscles can only pull, not push. If the biceps brachii, for example, flexes the forearm, an antagonist, the triceps brachii, is needed to extend the forearm. Other examples of antagonists are the quadriceps femoris and hamstring groups, the pectoralis major and the latissimus dorsi, and the tibialis anterior and gastrocnemius.

Synergistic muscles have similar functions or work together to perform a particular function. The brachioradialis is a synergist to the biceps brachii for flexion of the forearm; the sartorius is a synergist to the quadriceps group for flexion of the thigh. Synergists are necessary to provide slight differences in angles when joints are moved.

ROLE OF THE NERVOUS SYSTEM

Skeletal muscles are voluntary muscles in that nerve impulses are essential to cause contraction. Such nerve impulses originate in the motor areas of the frontal lobes of the cerebral cortex. The coordination of voluntary movement is a function of the cerebellum. The cerebellum also regulates muscle tone, the state of slight contraction usually present in muscles. Good muscle tone is important for posture and for good coordination.

Neuromuscular Junction

Each of the thousands of fibers in a muscle has its own motor nerve ending; the neuromuscular junction is the termination of the motor neuron on the muscle fiber. (See Fig. 47-2). The axon terminal is the enlarged tip of the motor neuron. It contains sacs of the neurotransmitter acetylcholine. The membrane of the muscle fiber, called the sarcolemma, contains receptor sites for acetylcholine and also the inactivator cholinesterase. The synaptic cleft is the small space between the axon terminal and the sarcolemma.

When a nerve impulse arrives at the axon terminal, it causes the release of acetylcholine, which diffuses across the

Figure 43-4 Major muscles. (A) Anterior view. (B) Posterior view. (Modified from Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, pp 140-141, with permission.)

synaptic cleft and bonds to the acetylcholine receptors on the sarcolemma. This makes the sarcolemma permeable to sodium ions, which rush into the cell and generate an electrical impulse (an action potential) along the entire sarcolemma. This electrical change triggers a series of reactions in the internal units of contraction called sarcomeres. Put simply, filaments of the protein actin slide over filaments of another protein called myosin, and the sarcomere shortens. All the thousands of sarcomeres in a muscle fiber shorten, and the entire cell contracts. If a muscle has little work to do, few of its many muscle fibers contract, but if the muscle has more work to do, more of its muscle fibers contract.

▶ AGING AND THE MUSCULOSKELETAL SYSTEM

The amount of calcium in bones depends on several factors. Good nutrition is certainly one factor, but age is another, especially for women. One function of estrogen or testosterone is the maintenance of a strong bone matrix. For women after menopause, bone matrix loses more calcium than is replaced. Weight-bearing joints are also subject to damage after many years. Often the articular carti-

lage wears down and becomes rough, leading to pain and stiffness.

Muscle strength declines with age as the process of protein synthesis decreases. Such loss of strength need not be drastic because aging muscles benefit from regular exercise, which has been shown to increase strength and reduce falls and accidents (Gerontological Issues Box 43-1).

BOX 43-1 GERONTOLOGICAL ISSUES

Age-related Changes in the Older Adult

Age-related changes can lead to impaired mobility, an increased risk for falls, and pain. Common age-related musculoskeletal changes include the following:

- Muscle mass and strength decline.
- Number of muscle cells decrease and are replaced by fibrous connective tissue.
- Elasticity of ligaments, tendons, and cartilage decrease, resulting in weaker bones.
- Intervertebral spaces decrease from loss of water.
- Posture and gait change. (Men develop a wider stance and take smaller steps; women have a narrow stance and walk with a waddling gait.)

► NURSING ASSESSMENT OF THE MUSCULOSKELETAL SYSTEM

The initial assessment begins with a history that includes the effects the condition is having on the patient's life. It then proceeds to a physical and psychosocial assessment (Table 43–2). Frequent neurovascular assessments may be needed if there is a risk of circulation impairment, such as if the patient has a fracture or musculoskeletal surgery (Table 43–3).

Subjective Data

History

The patient's history should include the following:

- If there was an injury, how it happened and when it happened
- Occupation and activities, including sports and other physical activities
- Risk factors for musculoskeletal problems and family history of musculoskeletal problems (to detect hereditary problems)
- Current health status, including ongoing or chronic medical conditions (such as heart disease, diabetes, lung conditions)
- Diet history (including whether calcium and vitamin D intake are adequate to ensure proper bone and muscle maintenance and repair)
- Information specific to the patient's musculoskeletal problems

Patients with musculoskeletal problems frequently report pain or related stiffness and tenderness as a major concern. The pain may be acute or chronic and may limit the patient in everyday life. Assessment includes previous diagnoses, pain severity, medications, treatments, and procedures the patient uses to alleviate the pain. The WHAT'S UP? model can be used to assess the patient's pain. (See Chapter 1.)

Physical Assessment

Three areas of musculoskeletal assessment are important: inspection, palpation, and range of motion (ROM). If the patient is able to walk, inspect the patient's posture and gait, noting poor posture or alterations in movement, such as limping. Note the use of mobility aids, such as a cane or walker. Document other gross deformities, such as unequal limbs, malalignment, or contractures. Spinal deformities are especially significant because they can compromise breathing and balance. Inspect the joints and muscles of the arms, hands, legs, and feet for deformity, redness, swelling, increased temperature, or **crepitation** (grating sound as joint or bone moves). Also note the patient's general nutritional status (e.g., normal, obesity, emaciated).

After inspection, gently palpate for warmth, swelling, and tenderness in the areas of swelling; redness; and areas where the patient reported pain (being careful to minimize the pain this may cause). For example, reddened joints should be palpated for **synovitis** (swollen synovial tissue

synovitis: synovia—joint + itis—inflammation

TABLE 43–2 NURSING ASSESSMENT OF MUSCULOSKELETAL SYSTEM

History	Significance
Age, gender, socioeconomic status	Increased age, being female, and lower socioeconomic status increases risk of musculoskeletal injury/problems.
History of the injury (if there was one)	Provides information that helps in the diagnosis of the problem, as well as making you aware of possible complications of the injury.
Occupation	Enables you to begin planning for discharge teaching if the patient has to alter his or her employment.
Activities patient participates in	Provides information regarding the level of activity the patient had before the concern.
Risk factors for musculoskeletal problems	Smoking and a sedentary lifestyle are risk factors for musculoskeletal problems.
Family history	Some musculoskeletal conditions have genetic and familial tendencies.
Current health status	Coexisting illnesses or conditions may affect the patient's care.
Diet history	Dietary intake such as calcium and vitamin D influence some musculoskeletal disorders.
Allergies	Prevents exposure to medication or compounds used in diagnostic tests, treatments, and therapies.
Pain	Provides information about severity of the condition and effectiveness of the treatment and therapy.
Physical Assessment	Possible Abnormal Findings
Inspect, palpate, and observe range of motion of affected areas	Altered gait, tone, size, shape, posture, contractures, deformities, range of motion, pain, activities of daily living, nerve function, sensation, movement, and weakness can be determined.
Psychosocial Assessment	Significance
Assess for deformities, changes in body image, self-concept, socialization, employment.	The patient may need assistance with strategies to cope with the stress of a possible chronic musculoskeletal condition. Some musculoskeletal conditions require lifestyle alterations that can cause increased stress and difficulties in coping.

TABLE 43-3 NEUROVASCULAR ASSESSMENT

Assess For	Note and Report
Color	Pallor, cyanosis, redness, or discoloration
Temperature	Unusual coolness or warmth
Pain	Pain that is worse on passive motion, pain that no longer responds to analgesics
Movement	Alterations in movement
Sensation	Alterations in feeling, tingling or paresthesias
Pulses	Diminished or absent distal pulses
Capillary refill	Nailbed that does not blanch in 3–5 seconds

within the joint) or the presence of bony nodes. In some cases, joints and muscles may seem healthy but are tender when palpated.

Next assess joint mobility. Stabilize the body area proximal to the joint being moved. Observe the patient's ROM for performing independent activities of daily living. Pay particular attention to the hands and observe movement in finger joints. For a quick and easy assessment of range of motion in the hands, ask the patient to touch each finger, one by one, to the thumb (known as opposition) and then to make a fist.

Also assess the size, shape, strength, and tone of muscles. Evaluate bilateral muscle strength by asking the patient to grip your hands. This enables you to feel the strength and equality. Pushing an extremity against your hand provides a general indication of muscle strength. More specific evaluation is performed by a physical therapist (PT) or an occupational therapist (OT). Using a scale of 0 to 5 (0 = paralysis and 5 = moving a muscle against resistance), the PT or OT measures the strength of each muscle group and rates it as a fraction. For example, 5/5 means that the patient reached a 5 out of 5 possible on the muscle strength scale.

Psychosocial Assessment

Deformities resulting from arthritis or other musculoskeletal disorders can affect a patient's body image and self-concept. (See Chapter 44.) Chronic pain may keep the patient from socializing or from working. Many work days are lost as a result of both acute and chronic musculoskeletal problems. Patients often avoid social events and tend to withdraw from people. Data collection should include questions related to the psychological effects of the musculoskeletal disorder.

Patients may experience a tremendous amount of psychological stress resulting from the pain, loss of income, and withdrawal from friends and family. The nurse assesses the patient's ability to cope, asking what coping strategies have been used in the past for other life stressors. Support systems for the patient need to be identified, especially spiritual and social systems. As needed, consult the appropriate member of the health care team (social work, clergy, support groups) to ensure that the patient's psychosocial needs are being met.

CRITICAL THINKING

Mr. Smith

Mr. Smith, age 80, is brought to the emergency department with a fractured left hip. He is positioned for comfort while you collect data.

1. What information should you obtain in Mr. Smith's history?
2. What should be assessed in Mr. Smith's physical examination?

Answers at end of chapter.

▶ DIAGNOSTIC TESTS

Diagnosis of musculoskeletal problems is assisted by laboratory tests and diagnostic imaging (including x-ray examinations and nonradiological tests). Specific tests for patients with connective tissue diseases are described in Chapter 44.

Laboratory Tests

Serum Calcium and Phosphorus

Bone disorders commonly cause changes in calcium and phosphorus (or phosphate) levels. When a person is healthy, calcium and phosphorus have an inverse relationship. This means that when serum calcium increases, serum phosphorus decreases, and vice versa. Some disorders, however, cause an increase in both values or a decrease in both values. Calcium and phosphorus levels are regulated by calcitonin from the thyroid gland and parathyroid hormone from the parathyroid glands. When these glands are not functioning properly, alterations in calcium and phosphorus levels can occur.

Serum calcium tends to decrease in patients with osteoporosis or in people who consume inadequate amounts of calcium in their diets. Serum calcium levels increase in patients with bone cancer, particularly those with metastatic disease.

Alkaline Phosphatase

Alkaline phosphatase (ALP) is an enzyme that increases when bone or liver tissue is damaged. In metabolic bone diseases and bone cancer, ALP increases to reflect osteoblast (bone-forming cell) activity.

Serum Muscle Enzymes

When muscle tissue is damaged, a number of serum enzymes are released into the bloodstream, including skeletal muscle creatine kinase (CK-MM [CK3]), aldolase (ALD), aspartate aminotransferase (AST), and lactate dehydrogenase (LDH). These enzymes increase in certain muscle diseases such as muscular dystrophy, polymyositis, and dermatomyositis.

Radiographic Tests

Standard X-rays

The skeleton and dense or inflamed tissues surrounding joints can be visualized on standard x-ray examination. Radiographs can readily detect bone abnormalities and defor-

mities. An x-ray examination can determine bone density, texture, changes in alignment and bone relationship, erosion, swelling, and intactness. In addition, x-ray examinations can be useful in identifying certain soft tissue damage (e.g., ligaments and tendons) because of alterations in bone position and spacing.

Although there is no special nursing care associated with x-ray examinations, you should inform patients that they will have to lie still during the examination and that the x-ray table will be cold and hard.

Computed Tomography

Tomograms radiographs that produce a clearer image by focusing on a particular slice of bone or soft tissue, such as ligaments and tendons. Computed tomography (CT) is especially helpful for diagnosing problems of the joints or vertebral column (Fig. 43-5). It may be used with or without a contrast medium (similar to a dye), which is given orally or intravenously. If a contrast medium is used, check that the patient is not allergic to iodine or shellfish (which contains iodine) because some contrast mediums have an iodine base. Because of the possibility of allergic responses or nausea from the contrast medium, the patient should be given nothing by mouth (NPO) for at least 4 hours before the test.

Inform patients that they must lie completely still during the test and that they will be surrounded by the scanner during the test. Headphones are worn for communication with the technician and to listen to soothing music of the patient's choice. Reports of claustrophobia and annoying clicking sounds made by the scanner while it is rotating are common.

Figure 43-5 Computed tomography scan of fifth cervical vertebra showing a burst fracture of the vertebral body (*top arrow*) and both laminae (*bottom arrows*). (From McKinnis, LN: *Fundamentals of Orthopedic Radiology*. FA Davis, Philadelphia, 1997, p 23, with permission.)

Arthrography

An x-ray examination of any synovial joint can be performed for patients with suspected joint trauma. The most common joints tested are the knee and shoulder. For this test, a contrast medium or air is injected into the joint to help visualize the soft tissues. Inform the patient that the test may be temporarily uncomfortable while the contrast medium is injected. After the procedure, the joint is usually swollen for several days. Ice and elevation help diminish swelling. Strenuous physical activity should be avoided for 12 to 24 hours.

Myelogram

During a myelogram, a contrast medium is injected into the subarachnoid space so that the spine and spinal cord can be visualized for disk herniation or other abnormalities. Inform patients that they may be positioned head down for a short period to allow the contrast medium to flow up to the level of the neck. After the procedure, assess the patient for headache (a possible complication of the procedure) or nausea. The patient must lie in bed with the head raised to a maximum 45-degree angle for at least 3 hours or as ordered by the physician.

Other Diagnostic Tests

Magnetic Resonance Imaging

Magnetic resonance imaging (MRI), with or without contrast media, is a commonly performed test to diagnose musculoskeletal problems, especially those involving soft tissue (Fig. 43-6). MRI uses electromagnets and is more accurate than CT for diagnosing many problems of the vertebral column. If the patient has had previous spinal surgery, a contrast medium is used.

The image is produced by interaction of magnetic fields and radio waves. For very large patients or those who are claustrophobic, the open MRI offers a comfortable

Figure 43-6 Magnetic resonance image of a normal cervical spine. (A) Cerebellum. (B) Spinal cord. (C) Marrow of C2 vertebral body. (D) C45 intervertebral disk. (From McKinis, LG: *Fundamentals of Orthopedic Radiology*. FA Davis, Philadelphia, 1997, p 26, with permission.)

alternative to the traditional machine (Patient Perspective Box 43–2).

The use of an electromagnet in the machine necessitates the removal of anything metal or with metal components from the patient's body. Pacemakers, surgical clips, and any other internally implanted metal device or apparatus are contraindications for MRI (Box 43–3).

Nuclear Medicine Scans

Several tests are performed using radioactive material to help visualize bone and other tissues. A bone scan allows visualization of the entire skeleton. It is used primarily for detecting metastatic bone disease, osteomyelitis (bone infection), and unexplained bone pain. The patient is injected with a radioisotope 2 to 3 hours before the scan. The radioisotope is attracted to bone and therefore travels to bone tissue. Reassure patients that this substance is not harmful.

For an accurate test, the patient must be able to lie still for 30 to 60 minutes during scanning. Patients who are elderly, restless, agitated, or in pain may therefore find this test

BOX 43-2 Patient Perspective

Undergoing an MRI

I was told that the MRI scanner was small and could cause feelings of claustrophobia. When asked if I was claustrophobic, I said no and so was not offered an antianxiety medication before the procedure. I really am not claustrophobic, but I decided to keep my eyes closed during the test to make sure to prevent these feelings. As the table I was lying on moved into the scanner, my heart began beating fast. I shut my eyes and imagined myself walking on the beach, which is a favorite place for me. The cool air that was blowing in the machine I imagined to be the wind blowing. That air really is essential in keeping you cool and the claustrophobic feeling away. I had on headphones through which the music I had brought with me was playing. I focused on the music and sang along to myself as I “walked on the beach.” I felt calmer as I did this. Through the headphones the technician kept me informed of how much longer the test would be and when the loud pounding noise would start. This really helped and I did not mind the noise. I knew that I had to be very still for the test, so I gave myself pep talks. “Okay, only 10 more minutes. Just lie still and this will be over soon.”

Then, halfway through the MRI, I accidentally opened my eyes for an instant. “Uh, oh.” I quickly shut them again with my heart racing and a feeling of panic rising. The wall of the MRI machine was only inches from my face. I quickly focused on the music again, told myself I could get through this, and focused on calming myself down by “going back to the beach.” Before I knew it, the test was over and I was told that because I held so still it was a great test that went more quickly than usual. I sure was glad to hear that! My personal coping techniques really helped me through the MRI. Without them I would have panicked and been unable to complete the test. The information the nurse gave me helped me know what to expect during the procedure so I could prepare myself to cope with the test. Providing information to your patients on what to expect during the test, as well as coping methods to use, can help them successfully complete an MRI.

BOX 43-3 Preparing the Patient for Magnetic Resonance Imaging

- Is the patient pregnant?
- Does the patient have magnetic metal fragments or implants, such as an aneurysm clip?
- If the patient has an IV catheter, can it be converted to a saline lock temporarily?
- Is the patient claustrophobic?
- Does the patient have a pacemaker or electronic implant?
- Can the patient be without supplemental oxygen for an hour?
- Can the patient tolerate the supine position for 20 to 30 minutes?
- Can the patient lie still for 20 to 30 minutes?
- Does the patient need life support equipment?
- Can the patient communicate clearly and understand verbal communication?

Source: Ignatavicius, DD, Workman, ML, and Mishler, MA: *Medical-Surgical Nursing: A Nursing Process Approach*, ed 2, WB Saunders, Philadelphia, 1995, Chart 49–3, with permission.

uncomfortable. Sedatives or analgesics may have to be administered before or during the procedure. The physician looks for “hot spots,” indicating areas where the radioactive substance is concentrated. These hot spots indicate abnormal bone metabolism, a sign of bone disease.

LEARNING TIPS

Hot spots are created because increased circulation occurs in abnormal bone areas, resulting in increased amounts of the radioactive substance being transported to the abnormal area.

Gallium/Thallium Scans

A gallium or thallium scan is similar to a bone scan but is more specific and sensitive as a diagnostic test. Gallium not only migrates to bone but also to brain and breast tissue and is therefore used to diagnose problems in these tissues as well.

Traditionally used for heart problems, thallium is now used for evaluation of bone cancers. Thallium is best for detecting osteosarcoma. Like the bone scan, these scans are not harmful to the patient.

Arthroscopy

An arthroscope is a tubular instrument that allows the surgeon to directly visualize a joint. The knee and shoulder are the joints most often evaluated. Because **arthroscopy** is an invasive procedure performed under local or light general anesthesia, the patient is treated as a surgical candidate.

arthroscopy: arthro—joint + scopy—to examine

Arthroscopy is done in same-day surgery settings. The surgeon makes several small incisions and distends the joint with injected saline. The scope is inserted and the joint is visualized from different angles. The joint is moved through range of motion, so tears, defects, or other soft tissue damage can be repaired through the scope using special instrumentation. Depending on the extent of the surgery, a bulky or small dressing wrapped with an elastic bandage may be applied.

The nurse in the postanesthesia care unit (PACU) assesses the neurovascular status of the surgical foot and leg frequently. (See Table 43–3.) If the patient had a diagnostic arthroscopy and no surgical repair, the PACU nurse encourages the patient to exercise the leg, including straight-leg raises. A mild analgesic usually relieves pain, and the patient returns to regular activities in 24 to 48 hours. If a surgical repair was performed, the patient may have activity restriction and need a stronger analgesic, such as oxycodone with acetaminophen (Tylox, Percocet).

Although complications are not common, the nurse monitors and teaches the patient to watch for and report to the physician the following:

- Thrombophlebitis (blood clot and vein inflammation)
- Infection (fever or warmth, pain, redness, swelling at surgical site)
- Increased joint pain

If a repair was done during the surgery, the patient is seen by the physician in 1 week to check for complications and progress. The patient may need crutches for the first week to limit weight bearing, depending on the surgical procedure performed. Physical or occupational therapy may be ordered (Home Health Hints).

HOME HEALTH HINTS

- Patients are considered homebound if (1) they are bedbound or require the maximum assistance to ambulate while using a walker or to transfer; (2) they can ambulate with only moderate assistance while using a cane to negotiate uneven surfaces; or (3) they can leave home only for periods of relatively short duration or for need of medical treatment.
- When testing strength, extend two or three fingers and ask the patient to squeeze the fingers.
- Observe patients moving around a room or bed. If they are clumsy or have involuntary movement, make efforts during that visit and subsequent visits to protect them from potential injury. Research has shown that pain or fear of falling may prevent a patient from moving and functioning to maximum potential.
- Encourage patients to wear flat, sturdy, rubber-soled shoes to prevent slipping, tripping, or spraining an ankle.
- Use sand or cat box filler on icy steps to increase traction, preventing slips and falls.
- Patients who use walkers can get pressure ulcers on their palms. One way to relieve the pressure is to wear padded cycling gloves that leave the fingers free.

CRITICAL THINKING

Mrs. Jones

Mrs. Jones was walking down the street when, without warning, she suddenly fell to the ground with extreme pain in her left leg. She was taken to the hospital, where it was determined that the greater trochanter of her left femur was fractured.

1. What information should you obtain from Mrs. Jones?
2. What possible condition may be the cause of her fracture?
3. What tests may be performed to identify the condition creating her problem?

Answers at end of chapter.

CRITICAL THINKING

Mr. Allan

Mr. Allan, age 45, comes to emergency with extreme pain in his lower back. The pain radiates down his right buttock and down the back of his leg to his knee. He tells you that he hurt his back picking up a box in the warehouse where he works.

1. What other information should you obtain from Mr. Allan?
2. What is a probable cause of Mr. Allan's pain?
3. What tests, procedures, and treatments may be done for Mr. Allan's condition?
4. How might this injury impact Mr. Allan's life?
5. Mr. Allan is to receive morphine 10 mg by intramuscular injection. You have available morphine 15 mg/mL. How many milliliters will you give?

Answers at end of chapter.

Bone or Muscle Biopsy

Bone or muscle tissue can be surgically extracted for microscopic examination to confirm cancer, infection (bone biopsy), inflammation, or damage (muscle biopsy). Muscle can also be biopsied to diagnose malignant hyperthermia, a genetic disorder. (See Chapter 11). Two techniques are used to retrieve muscle tissue: a needle (closed) biopsy or an incisional (open) biopsy.

A closed biopsy can be performed in the patient's room or special procedures area. After local or general anesthesia, the physician inserts a long needle into the tissue for extraction of a sample.

The open biopsy is performed in the operating suite under general anesthesia. A small incision is made and a section of bone or muscle is removed. A sterile pressure dressing is applied because bone is highly vascular.

The nurse inspects the biopsy site for bleeding, swelling, and hematoma formation. Increased pain that is unresponsive to analgesic medication may indicate bleeding in the soft tissue. The area is not moved for 8 to 12 hours to prevent bleeding. Vital signs and neurovascular assessments are monitored. (See Table 43–3.)

Ultrasonography

Sound waves are used to detect osteomyelitis (bone infection), soft tissue disorders, traumatic joint injuries, and surgical hardware placement. For this noninvasive procedure,

the technologist first applies a jellylike conducting substance over the area to be tested. A transducer is moved over the area while the ultrasound machine records the images. No special patient instructions are needed for this test.

Arthrocentesis

Arthrocentesis is a diagnostic or therapeutic procedure where synovial fluid is aspirated from a joint for analysis or to relieve pressure (pain) from effusion. Analysis of the synovial fluid aids in the diagnosis of noninflammatory conditions, septic arthritis, crystal detection, and **hemarthrosis** (blood in the joint cavity). Using aseptic technique, the physician provides local anesthetic and then uses a needle to aspirate the contents of the joint space. After the procedure

is complete, the physician can instill anti-inflammatory medications such as a corticosteroid. The site is covered with a sterile dressing. The main nursing intervention is to monitor the patient and teach the importance of observing for infection or hemarthrosis.

Nerve Conduction Studies

Electromyography (EMG) measures a muscle's electrical impulses. This aids in the diagnosis of muscle diseases or nerve damage. There are no special nursing actions related to this procedure other than informing the patient what will occur. Occasionally, slight discomfort occurs at the site where the study occurred. Warm compresses or mild analgesics can be offered for pain relief.

REVIEW QUESTIONS

- Which of the following is the function of synovial fluid in joints?
 - Exchange nutrients
 - Prevent friction
 - Absorb water
 - Wear away rough surfaces
- Which of the following assessments is included in neurovascular checks of the lower extremities?
 - Radial pulses
 - Checking for clubbing
 - Femoral pulses
 - Biceps reflex
- A patient has undergone an arthroscopy. Two hours after the procedure his pedal pulses are diminished from the previous assessment. What should the nurse do?
 - Take his vital signs.
 - Notify the physician.
 - Perform a neurovascular assessment.
 - Change the dressing and rewrap the elastic wrap.
- A patient has been diagnosed with a musculoskeletal disease that causes decreased bone density. Which assessment question is most appropriate by the nurse?
 - "Do you have any broken bones?"
 - "Has your doctor informed you to not exercise in case you break a bone?"
 - "What forms of physical activity are you able to participate in?"
 - "Do any of your spouse's relatives have problems with their bones?"
- A patient is scheduled for an MRI of his pelvis. Which of the following would the nurse do if during data collection the nurse found out that he had had previous heart surgery?
 - Ask the patient if he has any metal in his body.
 - Order a chest x-ray examination to identify if he has any metal objects in his body.
 - Cancel the MRI.
 - Inform the physician.

Answers to CRITICAL THINKING

Mr. Smith

1. You should determine if Mr. Smith has any allergies, how and when the injury occurred, if he has had any previous surgeries, what medications he takes, his medical history, and any past problems with anesthesia (in Mr. Smith or his family).
2. You should assess his left leg compared with his right leg, including limb length, deformity, pain, loss of range of motion, edema, and ecchymosis, and perform neurovascular checks, including movement, sensation (numbness/tingling), presence of pulses, skin temperature, color, and capillary refill.

Mrs. Jones

1. You should assess Mrs. Smith's age, her diet (does she have a low-calcium or vitamin D-deficient diet?), what she was doing at the time of the break, whether anything like this has happened before, whether anything similar has happened to any of her relatives, her pain level, when she ate last, her medications, her medical history, whether she smokes, and whether she has any allergies.
2. There is a possibility that Mrs. Jones has osteoporosis and that she has experienced a pathological fracture from decreased bone density. This is a common occurrence in postmenopausal women.

3. X-ray examinations, bone scans, bone density tests, and laboratory tests such as serum calcium, phosphorus, acid phosphatase, thyroid, and vitamin D levels are tests that might be performed.

Mr. Allan

1. You should determine what occurred, when it occurred, how it happened, if the pain was immediate, where exactly the pain is, whether anything makes it better or worse, if any kind of treatment was started, what kind of job Mr. Allen has, whether he has had any back problems in the past, what medications he is on, and whether he has any allergies.
2. Mr. Allan may have ruptured a disk in his vertebral column, which is a common occurrence with improper lifting or trying to lift something too heavy.
3. Test might include x-ray examination, myelogram, MRI, bone scan, and CT scan. Conservative treatment will be attempted first but ultimately a discectomy may be necessary.
4. Many back injuries result in lifelong chronic pain. Depending on the severity of the injury and the effectiveness of therapy, Mr. Allan may have to limit his physical and social activities. He may also have to find another type of employment.
5.
$$\frac{\text{Desired dose}}{\text{Dose on hand}} \times \text{vehicle} = \frac{10 \text{ mg}}{15 \text{ mg}} \times 1 \text{ mL} = 0.67 \text{ mL}$$

 vasculitis (VAS-kue-**LIGH**-tis)

QUESTIONS TO GUIDE YOUR READING

1. How would you differentiate between the care for osteoarthritis and rheumatoid arthritis?
2. What are the pathophysiology of and treatment for gout?
3. Which nursing interventions are appropriate when caring for patients with systemic lupus erythematosus, progressive systemic sclerosis, and polymyositis?
4. What would you include when preparing a plan of care for the patient undergoing a total joint replacement?
5. What patient education would be included for a patient with a lower extremity amputation and prosthesis?
6. What are the signs and symptoms of fractures?
7. Which nursing interventions are appropriate when caring for a patient in a cast or traction?
8. What would you include in a plan of care for a patient with a fractured hip?
9. What are the common causes of osteomyelitis?
10. What are the risk factors for the development of osteoporosis?
11. What signs and symptoms may be seen in patients with Paget's disease?
12. What are the characteristics of and treatments for patients with primary and metastatic bone tumors?

► CONNECTIVE TISSUE DISORDERS

Connective tissue disorders comprise a group of more than 100 diseases in which the major signs and symptoms result from joint involvement. Some connective tissue diseases affect only one part of the body; others affect many body organs and systems. Several of the most common disorders are

discussed here, including osteoarthritis, rheumatoid **arthritis**, gout, systemic lupus erythematosus, progressive systemic sclerosis, and **polymyositis**.

arthritis: arthr(on)—joint + itis—inflammation
polymyositis: poly—many + myo—muscle + itis—inflammation

Osteoarthritis

Osteoarthritis (OA) is the most common type of connective tissue disorder, affecting more than 20 million people in the United States. The term *arthritis* means inflammation of the joint, but OA is not a primary inflammatory process. Therefore some health care providers may refer to this disorder as *degenerative joint disease*. This term better reflects its pathophysiology.

Pathophysiology

Osteoarthritis occurs when the articular cartilage and bone ends of joints slowly deteriorate (Table 44-1). The joint space narrows, bone spurs develop, and the joint may become somewhat inflamed. The repair process is not able to overcome the rapid loss of cartilage and bone, eventually resulting in joint deformities, pain, and immobility, leading to the patient's functional decline. Weight-bearing joints (hips and knees), hands, and the vertebral column are most often affected (Fig. 44-1).

Causes and Types

The most common type of OA is primary (idiopathic) osteoarthritis. The cause of OA is unknown, but several risk factors have been identified. Aging, obesity, and physical activities that create mechanical stress on joints are major risks. Each of these factors cause prolonged or excessive "wear and tear" on synovial joints. The majority of people older than 60 years of age have some degree of symptomatic joint degeneration. Native-Americans are affected more often than other groups, but the reason for this is unknown.

Patients with secondary osteoarthritis develop their joint degeneration as a result of trauma, sepsis, congenital anomalies, certain metabolic diseases (such as Paget's disease), or systemic inflammatory connective tissue disorders such as rheumatoid arthritis.

Signs and Symptoms

The patient usually seeks medical attention when joint pain and stiffness become severe or the patient has problems

TABLE 44-1 COMPARISON OF OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS

	Osteoarthritis	Rheumatoid Arthritis
<i>Pathophysiology</i>	Articular cartilage and bone ends deteriorate Joint is inflamed	Inflammatory cells cause synovitis Synovium become thick and fluid accumulates, causing swelling and pain Joint becomes deformed
<i>Etiology</i>	Primary (idiopathic): –Cause unknown –Risk factors include age, obesity, activities causing joint stress Secondary: –Causes include trauma, sepsis, congenital abnormalities, metabolic disorders (Paget's disease), rheumatoid arthritis Joint pain and stiffness Alterations in ADLs Pain increases with activity and decreases with rest Nodes on joints of fingers (Heberden's nodes, Bouchard's nodes)	Autoimmune disease Can occur at any age (including juvenile rheumatoid arthritis) Cause unknown Familial history possible Symptoms vary according to disease process Early symptoms: –Bilateral and symmetrical joint inflammation –Redness, warmth, swelling, stiffness, pain –Stiffness after resting (morning stiffness) –Activity decreases pain and stiffness –Low-grade fever, weakness, fatigue, anorexia (mild weight loss) –Organ system involvement Late symptoms: –Joint deformity –Secondary osteoporosis
<i>Treatment</i>	Medication: –NSAIDs –Acetaminophen –Muscle relaxants –Cox-2 inhibitors Balanced rest and exercise Splinting of joint to promote rest Heat and cold Diet for weight loss Complementary therapies Surgery for total joint replacement	Medication: –Salicylates –NSAIDs –Gold treatment –Methotrexate –Prednisone Heat and cold Balanced rest and activity Surgery for total joint replacement

ADLs = activities of daily living.

Figure 44-1 Common joints affected by osteoarthritis and the changes that result in the joint.

with everyday activities. One or more joints may be affected, most commonly in the hands, hips, knees, spine, and feet. Joint pain intensifies after physical activity but lessens following rest. If the vertebral column is involved, the patient complains of radiating pain and muscle spasms in the extremity innervated by the area affected.

About half of patients with OA have bony nodes on the joints of their fingers, called Heberden's and Bouchard's nodes. Women tend to have them more often than men, and they may or may not be painful. The nodes have a familial tendency and are often a cosmetic concern to female patients.

Diagnostic Tests

X-ray examinations are useful in outlining joint structure and detecting bone changes. A computed tomography (CT) scan or magnetic resonance imaging (MRI) may be used to diagnose various joint involvement. Analysis of synovial fluid can aid in the diagnoses of OA while ruling out other pathological conditions of the joint.

Treatment

There is no curative therapy currently available for OA. Management of patients with OA centers on pain control, which is accomplished by drug therapy, other pain relief

CRITICAL THINKING

Mr. Dennis

Mr. Dennis is a 59-year-old overweight carpenter who visits his physician with complaints of knee and wrist pain. He has noticed that it is becoming increasingly difficult to climb a ladder or use a hammer. The physician suspects osteoarthritis.

1. What questions will the physician most likely ask Mr. Dennis?
2. What risk factors does he have?
3. What other signs and symptoms might he have?

Answers at end of chapter.

measures, or ultimately surgery. An interdisciplinary approach is needed to prevent decreased mobility and preserve joint function.

Synvisc is a newer therapy that is injected directly into osteoarthritic knees and acts like healthy, cushioning synovial fluid. Pain is relieved and flexibility restored when the knee joint is again lubricated and cushioned. For more information about this therapy, visit www.synvisc.com.

MEDICATION. Drug therapy, often used in combination with other therapies to reduce pain, is commonly used for patients with OA. The most typically used drugs are non-steroidal anti-inflammatory drugs (NSAIDs) (Table 44-2).

TABLE 44-2 COMMON DRUGS USED TO TREAT CONNECTIVE TISSUE DISEASES: OSTEOARTHRITIS, RHEUMATOID ARTHRITIS, AND OTHERS

	Type	Drug: Generic (Trade)	
NSAIDs	Nonselective cyclooxygenase (COX-1 and COX-2) inhibitors	Acetylsalicylic acid (aspirin)	
		Diclofenac sodium (Voltaren)	
		Diflunisal (Dolobid)	
		Etodolac (Lodine; osteoarthritis only)

		Immunosuppressives	
	Antimalarials		

These drugs have analgesic and anti-inflammatory effects but may cause side effects if not carefully monitored. Common side effects include gastrointestinal (GI) distress; bleeding tendencies, which can be severe; and sodium and fluid retention. Newer NSAIDs called COX-2 inhibitors are effective for short-term treatment of the pain of OA. The benefit of COX-2 inhibitors (e.g., celecoxib [Celebrex] and rofecoxib [Vioxx]) is minimal GI effects and decreased likelihood of bleeding problems. COX-2 inhibitors are indicated for those at high risk of developing GI problems. Elderly patients receiving NSAIDs on a routine basis should be carefully monitored for congestive heart failure or high blood pressure as a result of fluid retention.

REST AND EXERCISE. Joint pain from OA tends to decrease with rest; therefore pain is less severe in the morning. Activities should be scheduled at this time. A severely inflamed joint may be splinted by the occupational or physical therapist to promote rest to a selected joint. However, rest must be balanced with exercise to prevent muscle atrophy from disuse. Exercise has been identified as a means to maintain general health, range of motion, and muscle strength, while decreasing anxiety and depression. To minimize muscle atrophy, patients should be encouraged to perform exercises to strengthen their quadriceps if they have OA of the knee.

Joints should always be placed in their functional position—that is, a position that does not lead to contractures. For example, only a small pillow should be placed under the head when sleeping to prevent excessive neck flexion.

HEAT AND COLD. The patient with OA usually prefers heat therapy unless the joint is acutely inflamed. Hot packs, warm compresses, warm showers, moist heating pads, and paraffin dips provide sources of heat for the patient. Cold therapy minimizes inflammation while altering cutaneous pain receptors, thereby decreasing pain. Cold packs should be applied for no longer than 20 minutes at a time.

DIET. The obese or overweight patient benefits from losing weight to decrease joint stress, on weight-bearing joints, thereby reducing pain. If the patient is on medications that can alter fluid volumes (corticosteroids), a diet low in sodium may be appropriate.

COMPLEMENTARY THERAPIES. The popularity of complementary therapies to reduce pain and stress has grown tremendously. Imagery, music therapy, acupressure, acupuncture, and other holistic modalities that foster the mind–body–spirit connection work well for many people. Homeopathic therapies such as glucosamine and chondroitin have been suggested to improve OA. Recent studies have demonstrated that these two therapies are effective in OA therapy; however, further research must be conducted before they become an accepted and recommended therapy for OA.

SURGERY. If the patient's pain is not successfully managed, a total joint replacement (TJR) may be indicated. A TJR is the most common type of **arthroplasty**. (See Musculoskeletal Surgery.)

arthroplasty: arthro—joint + plasty—creation of

Nursing Process

ASSESSMENT. The patient's complaint of pain is assessed and the joints observed for signs of inflammation or deformity. Also assessed are function, alterations in activities of daily living (ADLs), and mobility. (See Chapter 43.)

NURSING DIAGNOSIS. The primary nursing diagnoses for the patient with OA include but are not limited to the following:

- Activity intolerance
- Chronic pain
- Chronic sorrow
- Disturbed body image
- Impaired physical mobility
- Ineffective health maintenance
- Risk for spiritual distress
- Deficient self-care

PLANNING. The goal of all the disciplines for all therapies related to joint conditions is to decrease suffering, increase quality of life, and decrease morbidity, all in a cost-effective manner. Collaboration with the interdisciplinary health team, especially the physician and physical or occupational therapist, is done to meet the goals of pain management, to improve mobility, and to minimize further joint destruction. For patients who need weight reduction, the dietitian is an important resource. The social worker, discharge planner, or case manager can help make arrangements for home care if needed. A home care aide may be necessary to help the patient with ADLs and mobility.

IMPLEMENTATION. Interventions focus on pain management, joint preservation, enhanced quality of life, and education.

EVALUATION. After pain management modalities are implemented, it is especially important to note the patient's response to these interventions. The best indicator of whether the plan of care was successful for the patient with OA is the patient's report of pain. If pain subsides or decreases, the plan was successful. If the pain worsens, surgery may be needed. Another important outcome is the patient's satisfaction with his or her ability to perform ADLs.

Patient Education

A vital function of each member of the health care team is health teaching. The patient with OA is seldom admitted to the hospital for treatment of OA unless surgery is scheduled. However, many patients with OA are admitted for other reasons, and their arthritis needs must also be considered in the comprehensive plan of care. Most patients residing in nursing homes also have OA, which can affect their participation in recreational activities, as well as their ADLs.

In any setting, including the home, patients can be taught ways to protect their joints and conserve energy. Nurses need to teach patients and their families how to promote health. Box 44-1 lists tips for joint protection and en-

BOX 44-1 Energy Conservation for the Patient with Arthritis

- Balance activity with rest. Take one or two naps each day.
- Pace yourself; do not plan too much for one day.
- Set priorities. Determine which activities are most important, and do them first.
- Delegate responsibility and tasks to your family and friends.
- Plan ahead to prevent last-minute rushing and stress.
- Learn your own activity tolerance and do not exceed it.

ergy conservation. For information on educational materials and self-help courses, visit the Arthritis Foundation at www.arthritis.org.

Rheumatoid Arthritis

Rheumatoid arthritis (RA) is a chronic, progressive, systemic inflammatory disease that destroys synovial joints and other connective tissues, including major organs. It affects women three times more often than men and Native-Americans more often than other ethnic groups. Rheumatoid arthritis can occur at any age; when it occurs in children it is called juvenile RA (JRA). The peak onset of RA is 30 to 60 years of age, and it affects 1 to 3 percent of the population in the United States. The etiology of RA is still unknown; however, there are indications that genetic predisposition and the environment play a role in triggering its development.

Pathophysiology

Inflammatory cells and chemicals cause **synovitis**, an inflammation of the synovium (the lining of the joint capsule). As the inflammation progresses, the synovium becomes thick and fluid accumulation causes joint swelling and pain. A destructive pannus (new synovial tissue growth infiltrated with inflammatory cells) erodes the joint cartilage and eventually destroys the bone within the joint (Fig. 44-2). Ultimately the pannus is converted to bony tissue, resulting in loss of mobility. Joint deformity and bone loss are common in late RA. (See Table 44-1.)

Synovial joints are not the only connective tissues involved in RA. Any connective tissue may be affected, including blood vessels, nerves, kidneys, pericardium, lungs, and subcutaneous tissue. The result of body system involvement is malfunction or failure of the organ or system. Death can occur if the disease does not respond to treatment.

Many patients experience spontaneous remissions and exacerbations (flare-ups) of RA. The symptoms of the disease may disappear without treatment for months or years. Then the disease may exacerbate just as unpredictably. Exacerbations usually occur when the patient experiences physical or emotional stress, such as surgery or infection.

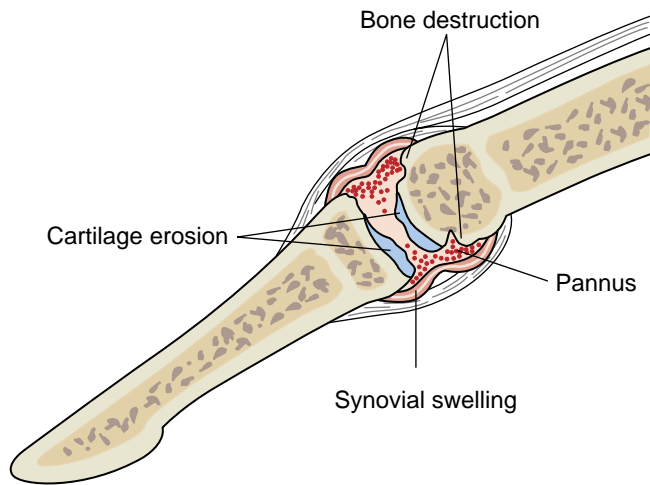

Figure 44-2 Rheumatoid arthritis.

Etiology

The exact cause of RA is unknown. An autoimmune response occurs that affects the synovial membrane of the joints; it is unknown what triggers the initial response. Antibodies (called rheumatoid factor) are often found in patients with RA. It is suggested that these antibodies join with other antibodies and form antibody complexes. These complexes lodge in synovium and other connective tissues, causing local and systemic inflammation, and may be responsible for the destructive changes of RA in body tissues.

The origin of the rheumatoid factor is not clear, but a genetic predisposition is likely. RA affects people with a family history of the disease two to three times more often than the rest of the population.

Signs and Symptoms

Signs and symptoms vary because the disease progresses in different patterns and rates from person to person. In general the signs and symptoms can be divided into early and late manifestations (Table 44-3).

The typical pattern of joint inflammation is bilateral and symmetrical. The disease usually begins in the upper extremities and progresses to other joints over many years (Fig. 44-3). Affected joints are slightly reddened, warm, swollen, stiff, and painful. The patient with RA often has morning stiffness lasting for up to an hour, and those with severe disease may complain of stiffness all day. Generally activity decreases pain and stiffness.

Because of the systemic nature of RA, the patient may have a low-grade fever, malaise, depression, lymphadenopathy, weakness, fatigue, anorexia, and weight loss. As the disease worsens, major organs or body systems are affected. Joint deformities occur as a late symptom, and secondary osteoporosis (bone loss) can lead to fractures.

Several associated syndromes are seen in some patients with rheumatoid arthritis. For example, Sjögren's syndrome is an inflammation of tear ducts (causing dry eyes) and salivary glands (causing dry mouth). Felty's syndrome is less common and is characterized by an enlarged liver and spleen and leukopenia (decreased white blood cell count).

Figure 44-3 Joint abnormalities in hands of patient with rheumatoid arthritis.

Diagnosis

No specific diagnostic test confirms RA, but several laboratory tests help support the diagnosis. An increase in white blood cells and platelets is typical, unless the patient has Felty's syndrome. A group of immunologic tests are usually performed, and typical findings for patients with RA include the following:

- Presence of rheumatoid factor (RF) in serum
- Decreased red blood cell (RBC) count
- Decreased C4 complement
- Increased erythrocyte sedimentation rate (ESR)
- Positive antinuclear antibody (ANA) test
- Positive C-reactive protein (CRP) test

RF can indicate the aggressiveness of the disease. However, it is not specific to RA and can also be found in systemic lupus erythematosus, connective tissue disease, and myositis. The ESR is also obtained to evaluate the effectiveness of treatment. If the disease responds to treatment, the ESR decreases. The higher the ESR, the more active the disease process.

LEARNING TIPS

The ESR is a general screening test for inflammation. It measures the amount of time it takes for RBCs to settle to the bottom of a test tube. In the presence of inflammation, RBCs settle faster in the tube. Therefore the ESR increases with the presence of inflammation.

X-ray examination and MRI detect joint damage and bone loss, especially in the vertebral column. A bone or joint scan assesses the extent of joint involvement throughout the body. For some patients, an **arthrocentesis** may be performed; the synovial fluid is cloudy, milky, or dark yellow with inflammatory cells present.

Medical Treatment

Like patients with osteoarthritis, patients with RA experience chronic joint pain. Pain can interfere with mobility or the ability to perform ADLs. Drug therapy is often needed to relieve or reduce pain as well as to slow the progression of the disease.

MEDICATION. Treatment for RA includes disease-modifying antirheumatic drugs (DMARDs), which can prevent joint destruction, deformity, and disability with early single or combination drug use; NSAIDs; and corticosteroids. (See Table 44–2.) Newer DMARDs such as leflunomide (Arava) and etanercept (Enbrel) are used to slow the progression of RA. Leflunomide taken orally has antiproliferative and anti-inflammatory properties. Etanercept inhibits tumor necrosis factor, which is involved in the inflammatory process, and is given subcutaneously twice a week. Low-dose methotrexate (MTX) or gold therapy is given to induce disease remission. NSAIDs such as aspirin, ibupro-

fen, and COX-2 inhibitors are prescribed for pain and stiffness, although they do not slow the disease process. Prednisone is a corticosteroid used to induce disease remission. Many of these medications have potentially serious side effects that must be monitored carefully.

Complementary therapies that may help decrease inflammation or pain include capsaicin cream, fish oil, magnetic therapy, and antioxidants such as vitamin C, vitamin E, and betacarotene. (See Chapter 4.)

HEAT AND COLD. Heat applications or hot showers help decrease joint stiffness and make exercise easier for the patient. For acutely inflamed, or “hot,” joints, cold applications are preferred. As for patients with osteoarthritis, a program that balances rest and exercise later in the day is most beneficial for the patient.

SURGERY. If nonsurgical approaches are not effective in relieving arthritic pain, the patient may have a total joint replacement (discussed later). In general, patients with RA who have surgery are not as successful when compared with patients with osteoarthritis. The presence of a systemic disease predisposes patients with RA to more postoperative complications.

Nursing Process

ASSESSMENT. A thorough history and physical assessment are needed for the patient with RA because the disease can involve every system of the body. In addition to assessing physical signs and symptoms, assess the patient for psychosocial, functional, and vocational needs.

Body changes resulting from joint deformity may lead to poor self-esteem and body image. Patients may feel helpless as they lose control over a disease process that is affecting many parts of their body. Chronic pain and suffering negatively affect the quality of one's life, and the patient may experience depression.

After having the disease for approximately 15 years, fewer than half of RA patients are totally independent in their ADLs. These limitations may place a burden on family members, who must be included in the care of the patient with RA.

Many patients with the disease are young or middle aged. RA can impair their ability to work, depending on the type of job they have. Chronic fatigue requires frequent rest periods that may not fit into a day's work schedule. The health care team assesses the patient's work skills to determine the need for changes in the workplace or a need to train for a new type of work.

NURSING DIAGNOSIS. The nursing diagnoses depend on the severity of the disorder and whether or not organs or systems are involved. All patients with RA typically experience but are not limited to the following:

- Acute pain
- Disturbed body image
- Fatigue
- Deficient self-care
- Impaired physical mobility

PLANNING. The plan of care for the patient with RA must be interdisciplinary, involving many members of the health team. For most patients, the physical therapist, occupational therapist, and social worker or case manager are vital in successfully meeting patient outcomes and improving quality of life. Family and significant others should be an integral part of the planning process.

IMPLEMENTATION. Each patient's plan of care is individualized. A major intervention is patient teaching. In addition, the interdisciplinary plan of care is carried out.

EVALUATION. The expected outcomes for the patient are relief of pain, disease remission, and improved ability to carry out ADLs. Medications are adjusted to control pain as well as to decrease the inflammatory process. ESR is used as an indicator of how well the treatment plan worked because its value decreases as inflammation subsides.

CRITICAL THINKING

Mrs. Summers

Mrs. Summers is a 48-year-old nurse who has had upper extremity joint pain and swelling for about 4 years. She was recently diagnosed with Rheumatoid arthritis (RA) but has no systemic involvement other than extreme fatigue at this time. She is concerned that she will have to give up providing direct patient care on a busy medical unit in the local hospital.

1. What questions might you ask her at this time about her illness?
2. What should you teach her about pain management?

Answers at end of chapter.

Patient Education

The patient with RA needs extensive patient education regarding the disease process, medication management, and the comprehensive plan of care. Many fads and myths published in popular tabloids are available, and some publicized "cures" can actually be harmful to the patient.

In collaboration with health team members, help the patient plan a daily schedule that balances rest and exercise. (See Box 44-1.) Child care responsibilities and other day-to-day activities need to be scheduled. A vocational counselor may be necessary for job training if the patient needs to pursue a different occupation. Patients who are unable to work may be able to qualify for disability benefits through the Social Security program.

Inform the patient about community resources. For example, the local chapter of the Arthritis Foundation provides support groups, information, and other resources for patients with RA and other types of connective tissue disorders. (See the Web Link in the Osteoarthritis section of this chapter.)

Gout

Gout (sometimes referred to as gouty arthritis) is an easily treated systemic connective tissue disorder. Men, especially

those middle aged and older, are affected more than women. Patients with gout are seldom hospitalized for their disease.

Pathophysiology

Uric acid is a waste product resulting from the breakdown of proteins (purines) in the body. Urate crystals, formed because of excessive uric acid (**hyperuricemia**) build up and are deposited in joints and other connective tissues, causing severe inflammation. When an "attack" of gout occurs, the patient unexpectedly has severe pain and inflammation in one or more small joints, usually the great toe. The inflammation may resolve in several days with or without treatment. Months or years may pass between attacks, and the patient may have no signs or symptoms of joint inflammation between episodes. Urate deposits may appear under the skin (tophi) (Fig. 44-4) or in the kidneys or urinary system, causing stone (calculi) formation. (See Chapter 35.)

Causes and Types

The causes and types of gout are well known. Primary gout is the most common and is caused by an inherited problem with purine metabolism. Uric acid production is greater than the kidneys' ability to excrete it. Therefore the amount of uric acid in the blood increases. About 25 percent of patients have a family history of primary gout. Acute attacks of gout may be triggered by stress, alcohol, illness, trauma, dieting, or certain medications.

Patients with secondary gout also experience hyperuricemia, but the increase is the result of another health problem, such as renal insufficiency, or medications, such as diuretic therapy and certain chemotherapeutic agents.

Signs and Symptoms

ACUTE GOUT. Patients with acute gout have one or more severely inflamed joints, usually small joints, often in the joint of the great toe. The joint is swollen, red, hot, and usually too painful to be touched.

Figure 44-4 Gout: subcutaneous nontender lesions near joints. (From Goldsmith, LA, et al: *Adult and Pediatric Dermatology*. FA Davis, Philadelphia, 1997, p 405, with permission.)

hyperuricemia: hyper—excessive + uric—uric acid + emia—in blood

CHRONIC GOUT. Patients with chronic gout may not have obvious signs and symptoms. Tophi, small urate deposits under the skin, are not commonly seen today because management of patients with gout has improved. If they are present, they tend to appear most often on the outer ear. Renal stones develop in about 20 percent of patients with gout. Various diagnostic tests may be needed to determine stone formation.

Diagnostic Tests

Diagnosis of gout is based on the serum uric acid level. The level at which uric acid levels become pathological are controversial because of normal variations within a patient, as well as different normal range values for men, women, and children. Any result above the maximum normal level of 7.5 mg/dL should be further evaluated. Joint fluid aspiration analysis can identify uric acid crystals in the synovial fluid, further confirming the diagnosis of gout. Urinary uric acid levels may also be assessed. To determine if kidney damage has occurred, renal function tests such as blood urea nitrogen (BUN) and serum creatinine are evaluated. Radiographs of the kidney determine the presence of calculi.

Treatment

MEDICATION. The treatment of secondary gout is management or removal of the underlying cause. Drug therapy is the first-line treatment for primary gout. When the patient has an acute gout episode, the physician usually prescribes either colchicine or an NSAID, which interferes with the white blood cell (WBC) inflammatory response to urate crystals. The patient usually takes these medications until joint inflammation subsides.

Uricosuric agents (medications used to decrease uric acid) are the drug of choice when trying to decrease serum levels. Allopurinol (Zyloprim) is the preferred drug for chronic gout. Allopurinol decreases uric acid production, necessitating several weeks of therapy before the medication becomes effective. The patient must take it every day to keep the uric acid level within the normal range. Probenecid (Benemid) may also be used temporarily to increase renal excretion of uric acid. The patient's serum uric acid level is monitored periodically.

DIET. There is no special therapeutic diet for patients with gout; however, certain foods should be avoided or consumed in moderation (Box 44–2). The patient should be instructed to avoid all forms of aspirin and diuretics because

BOX 44-2 Health Promotion for Patients with Gout

- Avoid high-purine (protein) foods, such as organ meats, shellfish, and oily fish (e.g., sardines).
- Avoid alcohol.
- Drink plenty of fluids, especially water.
- Avoid all forms of aspirin and drugs containing aspirin.
- Avoid diuretics.
- Avoid excessive physical or emotional stress.

they can trigger an attack. Increasing daily fluid intake is also important to help prevent kidney stones.

Systemic Lupus Erythematosus

The word *lupus* comes from the Latin word for wolf and refers to the masklike facial rash that patients with lupus may develop. The rash is red, and thus the word *erythematosus*, meaning reddened, was added to describe the disease.

Most patients with lupus have the systemic type, but a small percentage have the type that affects only the skin, a condition called discoid lupus erythematosus. Discoid lupus is not life threatening; systemic lupus erythematosus (SLE) can be life threatening because it is a progressive, systemic inflammatory disease that can cause major body organ and system failure. Although this definition seems similar to the definition of RA, one distinct difference exists. Patients with SLE typically have more body organ development earlier in their disease than do patients with RA.

Pathophysiology

SLE is an autoimmune disease characterized by spontaneous remissions and exacerbations. Production of abnormal antibodies (antinuclear antibodies [ANA]), immune complex formation, and complement system activation results in autoimmune effects on the patient's healthy connective tissue. Many of the manifestations result from recurring injuries to the patient's vascular system. The immune complexes that result lodge in the blood and organs, leading to inflammation, damage, and possibly death. The cause of SLE is unknown, but the disorder tends to occur in families. Identified chromosomal markers indicate a genetic link.

The mortality rate for patients with the disease has improved greatly during the past 30 years. The leading causes of death are kidney failure, heart failure, and central nervous system involvement. Lupus most often affects women between ages 15 and 40, at a rate 8 to 10 times more often than for men. African-American women are at a greater risk for the disease than women of other racial or ethnic backgrounds; however, there is also an increased risk in Asian and Chinese populations.

Signs and Symptoms

Unfortunately there is no classic textbook description of patients with SLE. Some patients have a very mild form of the disease in which the skin and joints are affected. Others have devastating signs and symptoms when the disease affects multiple body systems at the same time.

The classic feature of lupus is the characteristic butterfly rash, although only half of patients develop it. It is a raised, reddened rash over the bridge of the nose that extends to both cheeks (Fig. 44–5). The rash is usually dry and may itch. It commonly is photosensitive, tends to worsen during an exacerbation, and can be triggered by exposure to sun or ultraviolet light or by physical stressors, such as pregnancy or infection. Instead of the butterfly rash, some patients have discoid (coinlike) skin lesions on other parts of the

Figure 44-5 Lupus erythematosus: red papules and plaques in butterfly pattern on face. (From Goldsmith, LA, et al: *Adult and Pediatric Dermatology*. FA Davis, Philadelphia, 1997, p 230, with permission.)

body. During flare-ups, a fever develops. Fatigue, arthralgia, myalgia, malaise, weight loss, mucosal ulcers, and alopecia are other possible signs and symptoms of SLE. Table 44-4 lists other possible signs and symptoms of SLE.

Diagnostic Tests

Skin lesions can be biopsied and examined microscopically for signs of inflammation. Patients with suspected SLE are evaluated using the same immunologically based laboratory tests that are used to assess patients with rheumatoid arthritis. These tests include ESR (to detect systemic inflammation) and ANA titers (to detect the presence of abnormal antibodies, sometimes called LE cells). A new blood test has been developed that aids in the diagnosis of SLE. Systemic lupus erythematosus patients make antibodies against serine/arginine rich (SR) proteins (which are important in cell division). Seventy percent of SLE patients react positively to the SR proteins. This new diagnostic tool should help in identifying those SLE patients who do not produce some of the other antibodies looked for in the diagnosis of SLE. Although no laboratory test confirms a diagnosis of lupus, the results of the immunologic tests may support the diagnosis.

Treatment

Treatment of SLE focuses on decreasing inflammation and preventing life-threatening organ damage. At present, the therapy of choice includes medications to treat the symptoms or the body systems affected. Research is ongoing regarding the possible cause of SLE. Researchers have found the general location of a gene that is believed to predispose a person to lupus. Identifying the genetic cause of lupus will

CNS = central nervous system.

enable researchers to develop new methods of therapy, including gene therapy.

MEDICATION. Depending on the area of the body affected, medications are prescribed according to the patient's needs. NSAIDs, acetaminophen, corticosteroids, antimalarials, and immunomodulating drugs may all be part of the medication regimen. Topical cortisone preparations may help reduce skin inflammation and promote fading of skin lesions. For some patients with discoid or systemic lupus, the antimalarial drug chloroquine (Aralen) may be prescribed.

Patients who experience joint inflammation are usually placed on a NSAID. Patients with organ or major body system involvement are given more potent drugs that suppress the immune process, including oral steroids such as prednisone or chemotherapeutic agents such as azathioprine (Imuran). These drugs have serious side effects, and patients receiving them are monitored very carefully. In addition to monitoring for a variety of side effects, patients must be taught to avoid people with infections because they are immunocompromised while taking any of these medications.

Nursing Process

ASSESSMENT. Assess the patient to determine the extent and severity of signs and symptoms, such as pain, fatigue,

skin lesions, and fever. The plan of care for the patient is individualized because every patient who has SLE is unique.

NURSING DIAGNOSIS. The major nursing diagnoses related to SLE include but are not limited to the following:

- Acute pain
- Chronic sorrow
- Fatigue
- Disturbed body image
- Ineffective coping
- Ineffective health maintenance
- Powerlessness
- Risk for impaired skin integrity
- Deficient self-care

PLANNING. Collaborate with other health care team members as needed to promote or maintain function. For joint involvement, physical therapy is beneficial for exercise. Identify coping strategies that the patient has used in the past and wishes to use again. Young patients are often concerned about issues related to sexuality, pregnancy, and child rearing. These lifestyle concerns must be addressed with the appropriate health care professional.

IMPLEMENTATION. One of the most important nursing roles is coordination of care and patient education. The health of the patient with SLE can vary from seemingly healthy to severely ill in a critical care unit. These extremes can cause anxiety and concern about whether the patient may die from disease complications. Emotional support is offered to both the patient and family. Ensuring that the patient's medication regimen is administered appropriately and monitoring for side effects and potential complications of therapy are important nursing interventions.

EVALUATION. The expected outcome of care is that the patient can function daily without severe pain or fatigue and can avoid exacerbations of the disease.

Patient Education

Teach the patient about skin care and ways to prevent disease exacerbations. The patient should avoid prolonged exposure to sunlight or other forms of ultraviolet light, which can precipitate a flare-up of the illness. In addition, teach the patient how to care for the skin using mild soap and nondrying substances. Box 44–3 lists guidelines for skin protection and care for the patient with lupus.

It is also important to teach preventative measures to reduce exacerbations. Exercise can prevent muscle weakness and fatigue. The patient should be encouraged to be immunized against specific infections. Methods of stress reduction should be identified and utilized.

The Arthritis Foundation and the Lupus Foundation are national organizations that can provide information, assistance, and community support groups for patients diagnosed with lupus. For more information visit the Lupus Foundation of America at www.lupus.org.

BOX 44–3 Skin Protection and Care for Patients with Lupus Erythematosus

- Cleanse skin with a mild soap.
- Dry skin thoroughly by patting rather than rubbing.
- Apply lotion liberally to dry skin areas.
- Avoid powder and other drying agents, such as rubbing alcohol.
- Use cosmetics that contain moisturizers.
- Avoid direct sunlight and any other type of ultraviolet lighting (including tanning beds).
- Wear a large-brimmed hat, long sleeves, and long pants when in the sun.
- Use a sun-blocking agent with at least a sunburn protection factor (SPF) of 30.
- Inspect skin daily for open areas and rashes.

Source: Ignatavicius, DD, Workman, ML, and Mishler, MA: *Medical-Surgical Nursing: A Nursing Process Approach*, ed 3. WB Saunders, Philadelphia, 1998, with permission.

Scleroderma

Scleroderma is similar to SLE in that it can affect multiple organs and other connective tissues. Scleroderma is not as common as SLE but has a higher mortality rate. There are two types of scleroderma: localized and systemic. As the name implies, systemic scleroderma can affect any part of the body. Among other names for systemic scleroderma are diffuse and progressive systemic scleroderma (PSS).

Pathophysiology

Scleroderma is characterized by inflammation that ultimately develops into fibrosis (scarring) and then sclerosis (hardening) of tissues. The disease is an autoimmune response to the body's normal tissues. Like some of the other systemic connective tissue diseases, abnormal antibodies damage healthy tissue, resulting in inflammation, which then triggers overproduction of collagen, which is deposited in the skin.

PSS affects women three to four times more often than men, usually between ages 30 and 50. The disease tends to progress rapidly and does not respond well to treatment. Spontaneous remissions and exacerbations can occur.

Signs and Symptoms

When discussing the signs and symptoms of scleroderma, it is appropriate to discuss PSS because PSS can affect any body system. Although arthritis and fatigue are commonly seen, the most obvious sign of PSS is scleroderma, which is manifested at first by pitting edema, starting in the upper extremities. The skin is taut, shiny, and without wrinkles. If occurring as part of PSS, the swelling is replaced by tightening, hardening, and thickening of skin tissue. The skin then loses its elasticity, range of motion is decreased, and skin ulcers may appear. As the disease progresses, the patient loses range of motion and becomes contracted.

scleroderma: sclero—hardening + derma—skin

The same pathophysiological process affects certain body systems, especially the kidneys, lungs, heart, and gastrointestinal tract. If any of these systems is affected, the corresponding signs and symptoms are present. For example, gastrointestinal tract involvement usually manifests as esophagitis, dysphagia (difficulty swallowing), and decreased intestinal peristalsis caused by decreased smooth muscle elasticity.

The prognosis is thought to be worse when the patient has CREST syndrome, a group of signs and symptoms occurring at the same time:

- Calcinosis (calcium deposits)
- Raynaud's phenomenon (severe vasospasms of the small vessels in the hands and feet)
- Esophageal dysmotility (decreased activity)
- Sclerodactyly (scleroderma of the finger digits)
- Telangiectasia (spiderlike skin lesions)

Diagnosis

The patient's clinical history and physical manifestations aid in the diagnosis of scleroderma. Laboratory tests, pulmonary function tests, or x-ray examinations are used to determine the severity of organ involvement or if other diagnostic testing is not helpful in diagnosing this condition.

Treatment

The goal of medical management is to slow the progression of the disease. Systemic steroids, such as prednisone, and immunosuppressant drugs are used in large doses and in combination during a flare-up of PSS.

Other care approaches are directed toward symptom management. Skin protective measures can help minimize the chance of ulcerations or irritation. Box 44-3 is also appropriate for PSS. For example, teach the patient to use mild soaps and lotions to moisturize the skin.

If the patient has esophageal involvement, small, frequent, bland meals are better tolerated than large, spicy ones. Difficulty swallowing may necessitate cutting the food into smaller, more manageable portions or by providing food that is pureed (thicker liquids are easier to swallow than thin liquids). Medications to treat esophageal reflux, such as antacids and histamine blockers, may be prescribed.

Patients who have Raynaud's phenomenon or other types of **vasculitis** usually experience severe pain when small blood vessels constrict. Joints may also be painful. Pain management is a priority in the care of patients with PSS. A bed cradle or footboard keeps bed covers away from skin. Socks and gloves may keep the fingers and toes warm, thus diminishing pain. Minimizing exposure to cold and avoiding stressful situations, stopping smoking, and taking certain medications, such as calcium channel blockers, antiadrenergic agents, and angiotensin-converting enzyme (ACE) inhibitors, can all help promote circulation or minimize the likelihood of an attack. Research has suggested

that antioxidant therapy may provide another approach to treating PSS.

Rehabilitative therapy may be needed to help the patient be as independent as possible with activities of daily living and mobility. Collaborate with other members of the interdisciplinary team to individualize care.

Polymyositis

Polymyositis is a disease with an unknown cause that results in diffuse inflammation of skeletal muscle, leading to weakness, atrophy, and degeneration. When a rash is present with muscle inflammation, the disease is called dermatomyositis. The disease is progressive; however, remissions and exacerbations are common. Women are affected more than men, especially in their middle-aged years.

The shoulder and pelvic girdle muscles (proximal muscles) are most commonly affected. The patient may have associated conditions such as arthritis, fatigue, and possibly Raynaud's phenomenon (spasms and constriction of small vessels in the hands and feet). Patients with dermatomyositis also have the classic heliotrope (lilac) rash and periorbital (around the eyes) swelling. Malignant tumors occur in patients with these diseases more often than in the rest of the population.

Patients are treated symptomatically, using an interdisciplinary approach, to maintain optimum function. The drug of choice is high doses of prednisone. Side effects, such as immunosuppression, can occur with prednisone.

Muscular Dystrophy

Muscular dystrophy (MD) is a group of disorders resulting in loss of muscle tissue and progressive muscle weakness. A number of the disorders are diagnosed in childhood (e.g., Duchenne's MD is most common in children); however, other forms of MD, such as myotonic MD, are most common in adults. In addition, individuals with MD are now living longer into adulthood as a result of advances in treatment.

Pathophysiology and Etiology

Muscular dystrophy has a genetic origin. However, the exact cause is unknown. Skeletal (voluntary) muscle fibers degenerate and atrophy. This loss of muscle tissue results in muscle weakness and wasting. Muscle tissue is replaced by connective tissue. These changes in muscle tissue result in increasing disability and deformity. Life expectancy after diagnosis depends on the type of MD.

Signs and Symptoms

Signs and symptoms usually become apparent in childhood. Difficulty walking and muscle weakness in the arms, legs, and trunk are indicators of MD. Individuals with MD may have difficulty raising their arms above their heads or climbing stairs. Other signs and symptoms include frequent falls, developmental delays involving muscle skills, drooping eyelids (ptosis), drooling, intellectual retardation (only in some types of MD), contractures, and skeletal deformities.

Diagnosis

An increase in serum creatinine phosphokinase (CPK) caused by muscle atrophy is present in MD. Electromyography (EMG) and muscle biopsy can be used for diagnosis. Lactic dehydrogenase (LDH) and the isoenzymes, myoglobin (urine or serum), creatinine (urine or serum), CPK isoenzymes, and aspartate aminotransferase (AST) levels may also be altered in patients with MD.

Medical Treatment

Goals include supportive care and prevention of complications. Treatment regimens focus on controlling symptoms and maximizing quality of life. Keeping the patient as active as possible is a priority in the planning of care. Exercise programs (e.g., range of motion, physical therapy) help prevent muscle tightness, contractures, and atrophy. Splints and braces provide support during ADL. Surgery may be done to correct deformities. The potential benefit of gene therapy is currently being investigated. Some of the current research indicates that gene therapy could prove effective with some types of MD.

Nursing Process

ASSESSMENT. Assess for muscle weakness, noting areas of the body are affected and the severity of the weakness. Asking the patient and family what activities can be done with and without assistance helps determine the plan of care.

PLANNING. The patient and family should be involved in all aspects of care. The goal for impaired physical mobility is to maintain activity or to use adaptive equipment. The goal for ineffective breathing pattern is to maintain arterial blood gases within normal limits.

NURSING DIAGNOSIS. Priority diagnoses are impaired physical mobility related to muscle weakness and ineffective breathing pattern related to muscle weakness.

IMPLEMENTATION. Providing assistive devices (e.g., braces, splints, wheelchair) increases mobility. Range-of-motion exercises and other physical therapy prevent contractures and improve muscle strength. Encouraging the patient to do as much as possible increases independence and helps maintain muscle function. Respiratory rate and effort should be monitored every 4 hours. Measures to prevent skin breakdown need to be instituted, such as frequent turning or repositioning and teaching patients to shift their weight if able every 15 minutes while sitting or lying.

PATIENT EDUCATION. The patient and family need to understand the importance of physical therapy in maintaining function and preventing complications. National organizations and support groups provide information, resources, and emotional support. Family members need to encourage the patient to have activity and rest periods. As with any neuromuscular condition, the patient needs to avoid exposure to the cold and persons with infections. For more information on muscular dystrophy, visit www.mdausa.org or www.mdac.ca.

EVALUATION. The patient's goals are met if the patient maintains muscle function and desired level of activity; no evidence of skin breakdown, contractures, or injury is present; and the patient maintains or improves pulmonary status.

MUSCULOSKELETAL SURGERY

Some health problems cannot be managed conservatively and require surgery. Other disorders are initially treated medically but may need surgery if treatment is unsuccessful. The most common surgeries are discussed here.

Total Joint Replacement

Total joint replacement is most often performed for patients who have some type of connective tissue disease in which their joints become severely deteriorated. TJR may also be done for patients on long-term steroid therapy, such as patients with SLE or asthma. Long-term use of steroids and complications of joint replacement can cause **avascular necrosis (AVN)**, a condition in which bone tissue dies (usually the femoral head) as a result of impaired blood supply. Advanced AVN is very painful and usually does not respond to conservative pain relief measures. The primary goal of total joint replacement is to relieve severe chronic pain and improve ability to carry out ADLs when no other treatment is successful.

The most common surgeries are the total hip replacement (THR) and total knee replacement (TKR), although any synovial joint can be replaced. Another term used for joint replacement is *arthroplasty*. The replacement devices, sometimes referred to as prostheses, are made of metal, ceramic, plastic, or a combination of these materials. Some prostheses are held in place by cement. Others are secured by the patient's bone as it grafts and connects to the prosthesis. Bone substitutes, also called biologics, are being used more often when the amount of available bone is insufficient to provide a good base of support for the replacement devices. Bone glues and fillers such as Osteoset or Proosteon and bone stimulants such as Allomatrix help in providing better support for the prosthetics used.

Total Hip Replacement

A total hip replacement uses a two-piece device consisting of an acetabular cup that is inserted into the pelvic acetabulum and a femoral component that is inserted into the femur to replace the femoral head and neck (Fig. 44–6). The average life span of a cemented THR is about 10 years. Noncemented prostheses used in younger patients may last longer.

PREOPERATIVE CARE. Total joint surgery is an elective procedure and scheduled far enough in advance to allow ample time for preoperative teaching and screening. A case manager (registered nurse or social worker) may be assigned to assess the patient's needs and the support systems that are

avascular necrosis: a—without + vascular—blood + necrosis—death

Figure 44-6 Total hip arthroplasty of arthritic right hip. (From McKinnis, LN: *Fundamentals of Orthopedic Radiology*. FA Davis, Philadelphia, 1997, with permission.)

available postoperatively. It is important for the patient to have a caregiver who can assist the patient after surgery.

The patient is taught about the surgery and what to expect postoperatively. Some patients are scheduled to meet with the physical therapist to learn postoperative exercises and how to ambulate with a walker or crutches. Some institutions have total joint education programs, which are a series of educational sessions designed to make the recovery process smoother and more effective for the patient.

Depending on the amount of blood loss during surgery, some patients receive postoperative blood transfusions. Because total joint surgery is an elective procedure, the physician may order autologous blood donation by the patient. The patient donates blood before surgery per guidelines (e.g., time frames specified, hemoglobin levels normal), which is then available for reinfusion postoperatively as needed. This predeposited blood donation is cost effective and reassures patients who are concerned about receiving blood from other donors.

Patients are admitted to the hospital the morning of surgery (or occasionally, if there is a coexisting medical condition, the day before surgery) and are usually transferred to a surgical or medical-surgical unit after recovery in the postanesthesia care unit (PACU). The patient's length of stay on this unit varies from 3 to 5 days, depending on the patient's age and progress.

POSTOPERATIVE CARE. In addition to providing the general postoperative care that all patients undergoing general or epidural anesthesia require, plan and implement interventions to help prevent the following common complications of THR. (See Chapter 11.)

Hip Dislocation. The most common postoperative complication for the patient having a THR is subluxation (partial dislocation) or total dislocation. Dislocation occurs when the femoral component becomes dislodged from the acetab-

ular cup. The patient experiences increased hip pain, shortening of the surgical leg, and possibly rotation of the surgical leg. If any of these signs and symptoms occur, notify the surgeon immediately and keep the patient in bed. Additional analgesics may be ordered until the patient can be taken to the operating room. Under anesthesia, the surgeon manipulates the hip back into alignment and immobilizes the leg until healing occurs.

Prevention of dislocation is a major nursing responsibility. Correct positioning of the surgical leg is critical. The primary goals are to prevent hip adduction (across the body's midline) and hyperflexion (bending forward more than 90 degrees). To accomplish these goals, place the patient returning from PACU in a supine position with the head slightly elevated. A trapezoid-shaped abduction pillow (sometimes called a triangular pillow), splint, wedge, or regular bed pillows may be used between the legs to prevent adduction (Fig. 44-7). The patient is turned to the side specified by the physician, with hip adduction avoided. The patient is turned with adductor pillow or three regular pillows (one proximal and two distal) in place between the legs. When turning, it is important to turn the hip and legs simultaneously to minimize the chance of dislocation.

Figure 44-7 Abductor pillow is used to prevent adduction and hip dislocation.

To prevent hyperflexion, some surgeons initially allow the patient to sit at no more than a 60-degree angle in a reclining chair. The patient's position is progressed to 90 degrees, the maximum allowed to prevent hyperflexion (Fig. 44–8). While the patient is on bedrest, the use of a fracture (also called a slipper) pan when toileting the patient is recommended to minimize discomfort and to prevent the possibility of dislocation.

Skin Breakdown. Because most patients having total joint replacements are elderly, skin breakdown is a major concern as part of postoperative care. Turning the patient at least every 2 hours and keeping the heels off the bed are the key nursing interventions to prevent pressure ulcers. Heels and the sacrum are vulnerable and can break down in 24 hours. A reddened area that does not blanch is a stage 1 pressure ulcer and must be treated aggressively to prevent progression to other stages. Prophylactic application of DuoDerm dressing pads, as well as heel Poseys, help to decrease the chance of skin breakdown of the heels.

Patients who are incontinent must be kept clean and dry. Toileting the patient every 2 hours, using a protective barrier cream, and avoiding the use of diapers also help prevent skin problems related to incontinence. Box 44–4 describes additional nursing interventions that meet the needs of postoperative patients recovering from THR.

Infection. Orthopedic surgery patients are at an increased risk for infection because of the nature of the surgery and because the patients are often elderly, with an already increased risk for postoperative complications. The surgeon may order a prophylactic intravenous antibiotic preoperatively, often administers antibiotics intraoperatively, and may continue antibiotics for 24 hours postoperatively.

Once the initial surgical dressing is removed, observe the incision routinely for signs and symptoms of infection. Monitor temperature carefully. An elderly patient may not experience a fever but may appear confused instead.

BOX 44-4 Total Hip Replacement

- Use an abduction pillow or splint to prevent adduction after surgery.
- Protect the patient's heels while on bedrest to prevent pressure sores.
- Do not rely on fever as a sign of infection; elderly patients often have infection without fever. Decreasing mental status typically occurs when the patient has an infection.
- When assisting the patient out of bed, move the patient slowly to prevent orthostatic (postural) hypotension.
- Encourage the patient to deep breathe and cough and use the incentive spirometer every 2 hours to prevent atelectasis and pneumonia.
- As soon as permitted, get the patient out of bed to prevent complications of immobility.
- Anticipate the patient's need for pain medication, especially if the patient is unable to verbalize the need for pain control.
- Expect a temporary change in mental state immediately after surgery as a result of the anesthesia and unfamiliar sensory stimuli. Reorient the patient frequently.

Source: Ignatavicius, DD, Workman, ML, and Mishler, MA: *Medical-Surgical Nursing: A Nursing Process Approach*, ed 3, WB Saunders, Philadelphia, 1998, with permission.

Infection may not occur during the patient's hospital stay but can occur 1 or more years later. If this late infection does not respond to antibiotics, the prosthesis may be removed and replaced. To prevent infection, antibiotics are often instilled directly into the wound during surgery as beads, as part of the cement mixture, or as an irrigating solution.

Depending on the institution's policies, the surgeon may or may not remove the initial dressing. Regardless of who removes the dressing, meticulous aseptic care of the surgical wound is important to minimize the chance of infection. Care of the incision, as well as exit sites for drains, needs to be performed aseptically.

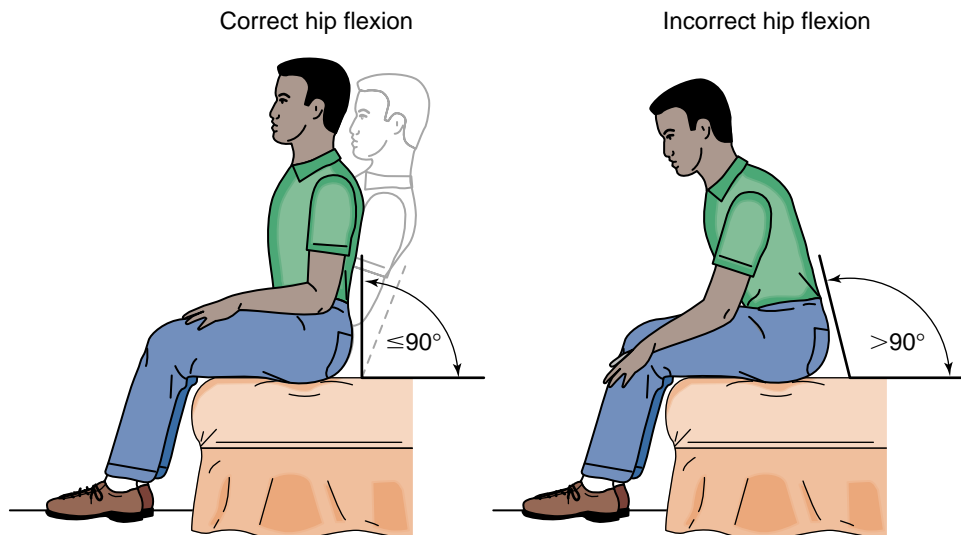

Figure 44-8 Hip flexion after total hip replacement should be 90 degrees or less to prevent dislocation.

Bleeding. Like any surgical wound, some bleeding is expected. In joint replacement surgery, up to two-thirds of the blood loss can occur postoperatively. The patient has at least one surgical drain (e.g., Hemovac or Jackson-Pratt) that is emptied every 8 to 12 hours and as required for the first day or two. On the second or third postoperative day, the patient's hemoglobin and hematocrit may decrease to the point that blood transfusion is needed. The patient may receive the preoperatively donated autologous blood or may receive salvaged operative or postoperative blood. Using a cell saver (sometimes called an orthopat, which stands for orthopedic patient autotransfusion) during surgery, about 50 percent of blood that is lost can be recovered and saved for reinfusion into the same patient. Postoperatively, blood can be replaced by collecting shed blood via suction into a reservoir, then filtering and reinfusing it within 6 hours of collection using the orthopat. Monitoring for blood loss and signs of shock are important nursing considerations.

Neurovascular Compromise. For any musculoskeletal surgery or injury, frequent neurovascular assessments for color, warmth, circulation, and movement are performed when vital signs are checked. The procedure and significance of these assessments are described in Chapter 43.

Pain. Because patients undergoing THR are in chronic pain preoperatively, some patients report that they have less pain postoperatively than they had before surgery. Initially pain is typically managed by epidural analgesia, patient-controlled analgesia (PCA), or injections with analgesics. After the first postoperative day, the patient usually progresses to oral opioid analgesia with a drug such as Percocet or Tylenol with codeine.

Ambulation. Care for the patient having a THR is interdisciplinary. The patient usually gets out of bed and into a chair the night of surgery or early the next day. Ensure that the patient does not adduct or hyperflex the surgical hip during transfer to the chair. The chair should have a straight back and be high enough to prevent excessive flexion. The toilet seat should also be raised for the same purpose. Permitted amounts of weight bearing depend on the type of prosthesis that is used. In general, weight bearing to tolerance or full weight bearing is used for cemented prostheses. If an uncemented device is used, the patient may be restricted to toe-touch, or partial, weight bearing or featherweight bearing.

Early ambulation helps prevent postoperative complications such as atelectasis and deep vein thrombosis (DVT). The physical therapist works with the patient for ambulation with a walker or crutches. Crutches are reserved for young patients. After 4 to 6 weeks, the patient is progressed to a cane. The patient does not need an ambulatory device if there is no limping.

Thromboembolic Complications. Patients having hip surgery are at greatest risk for DVT or pulmonary embolus (PE). Elderly patients are especially at risk because of compromised circulation. Obese patients and those with a history of thromboembolic (TE) problems are also at an exceptionally high risk for potentially fatal problems.

Thigh-high elastic stockings and sequential compression devices (SCDs) may be used while the patient is hospitalized. (See Chapter 11.) The surgeon orders an anticoagulant medication to help prevent clot formation, including subcutaneous low-molecular-weight heparin (enoxaparin [Lovenox]) or warfarin (Coumadin). Occasionally, heparin is still used, and if so, it is important to monitor for heparin-induced thrombocytopenia, which can occur as early as 3 days after the start of heparin therapy. The ordered daily dosage of these drugs is determined by coagulation studies. Partial thromboplastin times are monitored for patients on heparin. Prothrombin time and international normalized ratio (INR) are monitored when giving warfarin.

LEARNING TIPS

When giving enoxaparin, follow manufacturer's instructions for administration. The air bubble should not be removed from the prefilled syringe before administration to ensure the whole dose is given.

Because most DVT occur in the lower extremities, leg exercises are started in the immediate postoperative period and continued until the patient is fully ambulatory. The physical therapist teaches the patient how to perform foot and ankle exercises such as heel pumping, foot circles, and straight-leg raises (SLRs). The patient also performs quadriceps-setting exercises (quad sets) by straightening the legs and pushing the back of the knees toward the bed. Remind the patient to do several sets of these exercises each day to improve muscle tone and to help prevent blood clots in the leg.

Self-care. Because of restrictions in hip flexion, patients are instructed not to bend forward to tie shoes or put on pants. The occupational therapist provides adaptive or assistive devices, such as dressing sticks and long-handled shoe horns, to assist the patient in being independent in activities of daily living.

If the patient is medically stable, he or she is discharged home for rehabilitation or to a subacute care unit, rehabilitation unit, or nursing home for short-term rehabilitation, lasting a week or less. The rehabilitation program that began in the hospital continues after discharge until the patient is independent in ambulation and self-care.

Before hospital discharge, the interdisciplinary team provides patient education for home care, including hip precautions that need to be used until the surgeon reevaluates the patient at the 6- to 8-week follow-up visit (Box 44-5 and Home Health Hints).

Total Knee Replacement

The knee is the second most commonly replaced joint. Compared with the hip, it is a much more complicated joint and requires three components for replacement: a femoral component, a tibial component, and a patellar button (Fig. 44-9).

BOX 44-5 Patient Education for Total Hip Replacement**Hip Precautions**

- Do not sit or stand for prolonged periods.
- Do not cross legs beyond midline of body.
- Do not bend hips more than 90 degrees.
- Use an ambulatory aid, such as a walker, when walking.
- Use assistive/adaptive devices for dressing, such as for putting on shoes and socks.
- Resume sexual intercourse as usual, but when doing so, use the hip precautions learned in the hospital.

Source: Ignatavicius, DD, Workman, ML, and Mishler, MA: *Medical-Surgical Nursing: A Nursing Process Approach*, ed 3. WB Saunders, Philadelphia, 1998, with permission.

**HOME HEALTH HINTS**

If equipment or modifications to the home are needed following hospitalization for an orthopedic problem, it is best if they can be arranged or obtained before discharge.

Peak incidents of DVT after hip or knee surgery is highest by the fifth postoperative day and that risk persists for up to 12 weeks. Be alert for signs of DVT: warmth, redness, edema, Homans' sign, and protective behavior of the affected leg.

Research has shown that pain or fear of falling may prevent a patient from moving and functioning to maximum potential. Encourage patients to wear flat, sturdy, rubber-soled shoes to prevent slipping, tripping, or turning an ankle.

Patients who use walkers can get pressure ulcers on their palms. One way to relieve the pressure is to wear padded cycling gloves that leave the fingers free.

A patient on crutches can use the crutch to prop a casted leg or foot.

Care for the patient with a TKR is similar to that required for a patient with a hip replacement. Although precautions to prevent dislocation are not applicable for the patient with a knee replacement, other medical complications described for THR, such as deep vein thrombosis, may be seen in the patient undergoing knee replacement. (See Box 44-4.)

Most surgeons order a continuous passive motion machine (CPM) for the leg that is to be operated on. This motorized machine has a flexible extremity rest (for either the leg or arm) that glides back and forth on a track (Fig. 44-10). The CPM is set at the degree of flexion and speed ordered by the physician and is usually begun in the PACU. The CPM can be applied by a nurse, physical therapist, or technician and is used either intermittently, up to 8 to 12 hours a day, or continuously while the patient is in bed. The purpose of CPM is to keep the knee joint mobile. Nursing care associated with the use of the machine is summarized in Box 44-6.

Figure 44-9 Knee joint replacement. (From Richardson, JK, and Iglarsh, ZA: *Clinical Orthopaedic Physical Therapy*. WB Saunders, Philadelphia, 1994, p 651, with permission.)

Figure 44-10 A continuous passive motion machine is used following knee or elbow (as shown here) joint replacement to increase joint mobility and enhance recovery. The CPM machine slowly moves along the track at the set degree of flexion and speed.

Amputation

Simply defined, an amputation is the removal of a body part, which can be as limited as removing part of a finger or as devastating as removing nearly half the body. Amputations may be surgical as a result of disease or traumatic as a result of an accident. Surgical amputations are the most common type and are most often scheduled as elective surgery.

BOX 44-6 Using a Continuous Passive Motion Machine

- Ensure that the joint being moved is properly positioned on the machine.
- Ensure that the machine is well padded with sheepskin or other similar material.
- Check the cycle and range-of-motion settings at least once per shift (every 8 hours).
- If the patient is confused, place the controls to the machine out of the patient's reach.
- Assess the patient's response to the machine.
- Turn off the machine while the patient is having a meal in bed.
- When the machine is not in use, do not store it on the floor.

Source: Ignatavicius, DD, Workman, ML, and Mishler, MA: *Medical-Surgical Nursing: A Nursing Process Approach*, ed 3, WB Saunders, Philadelphia, 1998, with permission.

SURGICAL AMPUTATIONS. The main indication for surgical amputations is ischemia from peripheral vascular disease in the elderly. The rate of lower extremity amputation is much greater in the diabetic patient than in the nondiabetic patient. (See discussion of diabetes in Chapter 38.) Surgical amputations may also be done for bone tumors, thermal injuries (frostbite), congenital problems, or infections.

TRAUMATIC AMPUTATIONS. Traumatic amputations occur from accidents, often in young and middle-aged adults. Industrial machinery, motor vehicles, lawn mowers, chain saws, and snow blowers are common causes of accidental amputation.

Because in these patients the amputated part is usually healthy, attempts at **replantation** may occur. One of the most common replantations is one or more fingers. The current recommendation for prehospital care of the severed body part is to wrap it in a cool, slightly moist cloth and place it in a sealed plastic bag. The bag may be submerged in cold water until the body part is transported to the hospital.

The surgical procedure is performed by specialists who operate using a microscope. Nerves, vessels, and muscle must be reattached. These procedures are generally performed at large tertiary care centers that have specialty practitioners and equipment for replantation.

LEVELS OF AMPUTATION. The most common surgical amputation is part of the lower extremity. The loss of any or all of the small toes presents little problem. However, the loss of the great toe is more important because balance and gait are affected. Midfoot amputations are preferred over below-the-knee amputations (BKAs) for peripheral vascular disease. For the Syme amputation, the surgeon removes most of the foot but leaves the ankle intact for ambulation and weight bearing.

If the lower leg is amputated, a BKA is preferred over an above-the-knee amputation (AKA) to preserve joint function. The higher the level of amputation, the more energy is required for ambulation. Hip disarticulation (removal through the hip joint) and **hemipelvectomy** (removal through part of the pelvis) are reserved for young patients who have cancer or severe trauma. Rarely, a hemicorporectomy (hemipelvectomy plus a translumbar amputation) is performed as a last resort for young patients with cancer. This radical surgery removes nearly half of the body and requires both bowel and urinary diversion surgeries (ostomies) as well.

Upper extremity amputations are usually more significant than lower extremity amputations and more often result from trauma. The arms and hands are necessary for performing activities of daily living. Early replacement with a prosthesis is crucial for the patient with an upper extremity amputation.

PREOPERATIVE CARE. Patients who are scheduled for elective amputations have the advantage of time for preoperative teaching, prosthesis fitting, and adjustment to the loss of part of their bodies. Preoperative teaching is started in the surgeon's office. Postoperative and rehabilitative care are reviewed with the patient and family or significant other.

Preoperatively the patient should be referred to a certified prosthetist-orthotist (CPO) to begin plans for replacing the removed body part with a prosthesis.

Disturbed body image is a common nursing diagnosis for the patient having an amputation. If possible, it is helpful for the preoperative patient to meet with a rehabilitated amputee. Assess the patient's reaction to having an amputation with the expectation that the patient will experience many of the stages of loss and grieving. Support systems and coping mechanisms are identified that can help the patient through the surgery and postoperative period.

POSTOPERATIVE CARE. In addition to the general postoperative care, plan and implement interventions to help prevent postoperative complications. (See Chapter 11.)

Hemorrhage. When a patient loses part of the body, either by surgery or trauma, blood vessels are severed or damaged. The patient returns from surgery with a large pressure dressing that is secured with an elastic wrap. Assess the closest proximal pulse between the heart and the amputated body part for strength and compare findings with the nonsurgical extremity. Assess the bulky dressing for bloody drainage. If blood is on the dressing when the patient is admitted to the PACU or the surgical unit, circle, date, and time the drainage. The area is closely monitored for enlargement. If bleeding continues, the surgeon is notified immediately. A tourniquet should be readily available in the event that severe hemorrhage occurs.

replantation: re—again + plant—to plant + ation—process

hemipelvectomy: hemi—half + pelv—pelvis + ectomy—removal of

After the dressing is removed, observe for adequate perfusion to the skin flap at the end of the residual limb, referred to as the stump. The skin should be pink in a light-skinned patient and not discolored (lighter or darker than other skin pigmentation) in a dark-skinned patient. The residual limb should be warm but not hot.

Infection. Infection of the wound can be problematic, especially if the infection enters the bone (**osteomyelitis**). Inspect the wound for intense redness or drainage. If temperature is elevated, it could indicate a wound or other type of infection.

Pain. In addition to the usual incisional pain that is expected following a surgical procedure, phantom limb pain occurs in as many as 80 percent of all amputees. The patient complains of severe pain where the removed body part was located. The pain may be described as either intense burning, a crushing sensation, or cramping. This type of pain is not common in patients who have traumatic amputations.

Phantom limb pain can be triggered by touching the residual limb, feeling fatigued, or experiencing emotional stress. Although it occurs most often in the immediate postoperative period, phantom limb pain may occur at any time during the first postoperative year. The cause is not clear.

Never doubt that the patient is experiencing phantom limb pain. Treat the pain aggressively with medications and complementary therapies. The surgeon prescribes medication based on the type of pain sensation the patient experiences. For example, anticonvulsants, such as phenytoin (Dilantin), are used for knifelike pain. Beta-blocking agents, such as propranolol (Inderal), are appropriate for burning sensations, and gabapentin (Neurontin) or amitriptyline (Elavil) can be used for nerve pain. To complement traditional therapy, a number of therapies may be useful, including biofeedback, massage, imagery, hypnosis, acupuncture, acupressure, and distraction.

Mobility and Ambulation. To reduce surgical swelling, cold application may be ordered. Alternately, the residual limb may be elevated on a pillow for 24 hours or less. Continued use of a pillow for elevation can lead to flexion contractures, especially for patients with a BKA or an AKA. If the hip becomes contracted, using a prosthesis will not be possible because the patient will not be able to walk. Check the limb periodically to ensure that it lies completely flat on the bed. The patient should avoid positions of flexion such as sitting for long periods. If the patient is able, lying prone (on stomach) for 30 minutes four times daily helps prevent contracture.

Postoperative care of the patient experiencing an amputation is interdisciplinary, often requiring an extensive rehabilitation program in a subacute unit, nursing home, or on an ambulatory basis. The physical therapist teaches the patient muscle-strengthening exercises that help with ambulation and transfers and prevent flexion contractures.

A trapeze and overhead bed frame aid in strengthening the upper extremities and help the patient move around in the bed.

Prosthesis. The residual limb must be prepared for wearing the prosthesis. A temporary prosthesis may be worn until the swelling subsides.

The residual limb is wrapped at least every 8 hours using an elastic wrap (Ace or tensor) in a figure-of-eight fashion (Fig. 44-11). It is important to perform neurovascular checks and assess the residual limb for infection and alterations in tissue integrity at each rewrapping. Begin with the most distal portion and proceed proximally until the bandage is secured to the most proximal joint. The bandage should be tighter at the distal end.

The prosthesis requires special care and attention. Box 44-7 summarizes discharge teaching for the amputee with a prosthesis.

Figure 44-11 Application of elastic wraps on an above-the-knee amputation helps mold the stump for a prosthesis.

Lifestyle Adaptation. The patient may feel that life will be markedly changed as a result of the amputation. With the technological advances in prostheses, most patients who worked before surgery are able to return to their jobs after surgery. If the discharge planner or case manager thinks it is needed, a job analysis may be conducted by a vocational analyst or specialized case manager. Many patients with amputations are able to bowl, ski, hike, and experience all the recreational hobbies that they were able to do before surgery.

A supportive family or significant other is vital to help the patient adjust to body image change. Consider the need for a sexual counselor or psychologist if indicated. For any patient with an amputation, help the patient set realistic expectations.

For the patient who is not a candidate for a prosthesis, home adaptations for a wheelchair may be needed. The patient must have access to toileting facilities and areas necessary for self-care. Structural changes in the living environment may be necessary before the patient can be discharged from rehabilitation.

A small percentage of amputees return to their nursing home environment without prostheses. These patients need rehabilitation to ensure that they can be as independent as possible.

► BONE AND SOFT TISSUE DISORDERS

The musculoskeletal system is the second largest system in the body. A variety of injuries and diseases can affect bone, soft tissue, or both. The most common problems are discussed in this section.

Strains

A strain is a soft tissue injury that occurs when a muscle or tendon is excessively stretched. Causes of strains include falls, excessive exercise, and lifting heavy items without using proper body mechanics. Back and ankle injuries are common. Strains can be mild, moderate, or severe. A mild strain causes minimal inflammation; swelling and tenderness are present. A moderate strain involves partial tearing of the muscle or tendon fibers. Pain and inability to move the affected body part result. The most severe strain occurs when a muscle or tendon is ruptured, with separation of muscle from muscle, tendon from muscle, or tendon from bone. Severe pain and disability result from this injury.

RICE is an acronym for rest, ice, compression, and elevation. These four components are the basis of therapy for strain injuries. Immediately after a strain, ice should be applied to decrease pain, swelling, and inflammation. Applying an elastic bandage (compression) and elevating the affected area (if appropriate) provide support and minimize swelling. Once inflammation subsides, heat application (15 to 30 minutes four times a day) brings increased blood flow to the injured area for healing. Activity is limited (depending on the severity of the injury, casting may even be required for immobilization) until the soft tissue heals, and anti-inflammatory drugs are prescribed. Muscle relaxants may be used for muscle pulls as well. Exercise may begin as

early as 2 to 5 days after the injury (depending on the severity of the injury), but it may take 1 to 3 weeks of immobility before exercise can begin. For more severe strains, surgery to repair the tear or rupture may be needed. These procedures are done on an ambulatory, same-day-surgery basis.

Sprains

A sprain is excessive stretching of one or more ligaments that usually results from twisting movements during a sports activity, exercise, or fall. Like strains, sprains also vary in severity. A mild sprain involves tearing of just a few ligament fibers and causes tenderness. In a moderate sprain, more fibers are torn but the stability of the joint is not affected. A moderate sprain is uncomfortable, especially with activity. A severe sprain causes instability of the joint and usually requires surgical intervention for tissue repair or grafting. Pain and inflammation prevent mobility.

For mild sprains, RICE is again used as a therapy method. Rest, ice applications, and a compression (elastic) bandage and elevation are used for several days until swelling and pain diminish. Anti-inflammatory drugs are also used to decrease inflammation and control pain. Moderate sprains may need immobilization with a brace or cast until healing occurs.

Carpal Tunnel Syndrome

Pathophysiology

Carpal tunnel syndrome results in the compression of the median nerve within the carpal tunnel when swelling in the tunnel occurs. This swelling can result from edema, trauma, rheumatoid arthritis, or repetitive hand movements (repetitive motion injury) as used in some occupations such as typing or cash register operation.

Signs and Symptoms

Carpal tunnel syndrome usually results in slow-onset finger, hand and arm pain, and numbness. Painful tingling and paresthesias may also be present. Eventually, fine motor deficits and then muscle weakness may develop.

Diagnosis

Diagnosis is based on signs and symptoms, along with the patient's history. A positive Phalen's test (numbness with wrist flexion) is indicative of carpal tunnel syndrome. EMG can also be used to detect nerve abnormalities.

Medical Management

Medical treatment focuses on relieving the inflammation and resting the wrist. A splint is often ordered for the patient to wear. Medications to reduce pain and inflammation are ordered, such as aspirin and NSAIDs. Cortisone may be injected into the carpal tunnel to decrease pain and inflammation.

For some patients, surgery may be necessary. The surgeon may use an open incision or may perform an endoscopy. The median nerve is released from compression during the

surgery, thus correcting the problem of the nerve and the surrounding area becoming inflamed. Physiotherapy helps in the recovery of function.

Nursing Management

Educate the patient on methods to prevent carpal tunnel syndrome, such as frequent short breaks during the work day, interspersing ongoing tasks with repetitive movements throughout the day, and using ergonomically appropriate devices to minimize the pressure placed in the area of the wrist.

Provide pain relief as ordered, and if surgery is performed, provide routine preoperative and postoperative care. Postoperatively elevate the patient's hand and use a splint as ordered for up to 2 weeks. Lifting is restricted for several weeks. The patient is taught to report signs and symptoms of neurovascular compromise, such as numbness and tingling, coolness, lack of pulse, pale skin or nailbeds, or limited movement. The patient may need family assistance with ADLs.

Fractures

A fracture is a break in a bone and can occur at any age and in any bone. Some fractures are minor and are treated on an

ambulatory basis; others are more complex and require surgical intervention with hospitalization and rehabilitation.

Pathophysiology

Bone is a dynamic, changing tissue. When it is broken, the body immediately begins to repair the injury (Fig. 44–12). For an adult, within 48 to 72 hours after the injury a hematoma (blood clot) forms at the fracture site, because bone has a rich blood supply. Various cells that begin the healing process are attracted to the damaged bone. In about a week or so, a nonbony union called a callus develops and can be seen on x-ray examination. As healing continues, osteoclasts (bone-destroying cells) resorb any necrotic bone and osteoblasts (bone-building cells) make new bone as a replacement. This process is sometimes referred to as bone remodeling. Young, healthy adult bone completely heals in about 6 weeks; however, it can take up to a year before the whole process of remodeling is complete. An older person takes longer to heal, and children tend to heal more quickly.

Causes and Types

The major reason for a fracture is trauma, usually from either a fall or a motor vehicle accident. Bone disease, such as osteoporosis and metastatic bone cancer, malnutrition, and

Figure 44-12 Fracture healing phases.

regular drinking of soda pop can lead to fractures as well. Fractures resulting from any of these diseases are referred to as pathological fractures. One of the most common types of fractures is the hip fracture, which occurs in middle-aged and elderly women who have osteoporosis (irreversible bone loss), a condition discussed later in this chapter.

Fractures can be classified in several ways: by the extent of the fracture, the extent of the associated soft tissue damage, or the configuration of the bone after it breaks. A fracture that is complete, breaking the bone into two separate pieces, is called a displaced fracture. An incomplete fracture does not divide the bone into two pieces; it may also be referred to as a nondisplaced fracture. Complete fractures have the potential to be life threatening because sharp bone fragments can sever blood vessels and nerves.

LEARNING TIPS

The risk of developing a hip fracture in men or women can be dramatically reduced with the use of hip protectors. Hip protectors are pads sewn into underwear or worn on top of clothing with a belt. The pad directs a fall's energy away from the hip area to prevent a fracture. For more information on some brands of hip protectors that are available or are being studied, visit www.safehip.com, www.hipsaver.com, and www.hipguard.net.

Inform patients and families of the benefits of purchasing a hip protector if your institution does not provide them. (Present research findings supporting increased patient safety and decreased legal fracture risk for the institution to encourage your administrators to provide hip protectors.) Hip protector patient teaching should include the following:

- With time the patient will become used to wearing the protectors.
- The patient should wear the protectors at night for trips to the bathroom (a high-risk time for falls).
- The protector will not show under loose clothing.
- The protector can be laundered.
- Styles are available for incontinence care and easy changing.

The cost in hip fracture care (\$33,000) and quality-of-life savings make this a valuable tool in fracture risk reduction. (Up to 24 percent of persons older than age 50 who suffer hip fracture die within 1 year; up to 40 percent need extended care.)

A fracture may also be classified as open or closed. In an open (or compound) fracture, the bone breaks the skin. A closed fracture does not disrupt the skin. Open fractures are more likely to become infected than closed fractures.

Another way to describe fractures is by the way that the bone breaks, such as in a spiral or oblique fashion (Fig. 44-13). These fractures may be open or closed, complete or incomplete. Table 44-5 describes the types of fractures.

Signs and Symptoms

This section focuses on fractures of upper and lower extremities. If the patient sustains a hairline (microscopic) fracture, the signs and symptoms are not readily observable. The patient may complain of tenderness over the site of the

injury or more severe pain when moving the affected part of the body. The patient with a hip fracture usually complains of pain either in the groin area (the hip is a deep joint) or at the back of the knee (referred pain). If the fracture is displaced, the limb is often shortened because of contraction of the muscles pulling on the bone sections.

In addition to pain, patients with more complex fractures experience limb rotation or deformity and shortening of the limb (if a limb bone is broken). Range of motion is decreased. If the affected part is moved, a continuous grating sound (crepitation) caused by bone fragments rubbing on each other may be heard. The extremity should not be moved (to try and reposition the bone alignment) if crepitation is present.

Inspect the skin for intactness. A patient with a closed fracture may have ecchymosis (bruising) over the fractured bone from bleeding into the soft underlying tissue. Ecchymosis may not develop for several days after the injury. Swelling may also be present and can impair blood flow, causing marked neurovascular compromise. In an open fracture, one or more bone ends pierce the skin, causing a wound.

Diagnostic Tests

An x-ray examination usually visualizes bone fractures, showing bone malalignment or disruption. Computed tomography may be needed to help detect fractures of complex areas, such as the hip and pelvis. Magnetic resonance imaging is useful in determining the extent of associated soft tissue damage.

For patients experiencing moderate to severe bleeding, a hemoglobin and hematocrit level is obtained. If extensive soft tissue damage is present, the ESR is usually elevated, indicating the expected inflammatory response. The physician may order a serum calcium level to determine baseline values because bone repair requires a sufficient amount of calcium and other minerals.

Emergency Treatment

A patient with a suspected fracture often has injuries elsewhere in the body. Assess the patient for respiratory distress, bleeding, and head or spine injury. If any of these problems occur, emergency treatment is provided before concern is given to extremity or other fractures.

The treatment of fractures depends on the type and extent of the injury. Emergency treatment is essential to prevent possible life-threatening complications. Box 44-8 describes the emergency interventions for the patient with an extremity fracture.

LEARNING TIPS

For emergency care of a suspected fracture, do not try to reposition the limb. Splint it as it lies.

Figure 44-13 Types of fractures.

TABLE 44-5 TYPES OF FRACTURES

Fracture Type	Description
<i>Avulsion</i>	Piece of bone is torn away from the main bone while still attached to a ligament or tendon.
<i>Comminuted</i>	Bone splintered or shattered into numerous fragments. Often occurs in crushing injuries.
<i>Impacted</i>	Bone is forcibly pushed together, resulting in bone being pushed into bone.
<i>Greenstick</i>	Bone is bent and fractures on the outer arc of the bend. Often seen in children.
<i>Interarticular</i>	Fracture involves bones within a joint
<i>Displaced</i>	Bone pieces are out of normal alignment. One or both pieces may be out of alignment.
<i>Pathological (also called neoplastic)</i>	Caused by bone's being weakened either by pressure from a tumor or an actual tumor within the bone.
<i>Spiral</i>	Fracture curves around the shaft of the bone.
<i>Longitudinal</i>	Fracture occurs along the length of the bone.
<i>Oblique</i>	Fracture occurs diagonally or at an oblique angle across the bone
<i>Stress</i>	Results in the bone being fractured across one cortex. This is an incomplete fracture.
<i>Transverse</i>	Bone fractured horizontally.
<i>Depressed</i>	Bone pushed inward. Often seen with skull and facial fractures.

BOX 44-8 Emergency Care of the Patient with an Extremity Fracture

1. Remove the patient's clothing (cut if necessary) to inspect the affected area.
2. Apply direct pressure on the area if there is bleeding and pressure over the proximal artery nearest the fracture.
3. Keep the patient warm and in a supine position.
4. Check the neurovascular status of the area distal to the extremity: temperature, color, sensation, movement, and capillary refill. Compare affected and unaffected limbs.
5. Immobilize the extremity by splinting; include joints above and below the fracture site.
6. Cover the affected area with a clean cloth (e.g., a handkerchief).

Source: Ignatavicius, DD, Workman, ML, and Mishler, MA: *Medical-Surgical Nursing: A Nursing Process Approach*, ed 3. WB Saunders, Philadelphia, 1998, with permission.

Fracture Management

The two goals of fracture management are reduction, or realignment of bone ends, and immobilization of the fractured bone with bandages, casts, traction, or a fixation device. These interventions prevent further injury, reduce pain, and promote healing.

CLOSED REDUCTION. Closed reduction is the most common treatment for simple fractures. While manually pulling on the bone (limb), the physician manipulates the bone ends into realignment. Analgesia is typically used before the procedure. An x-ray examination is done to confirm that the bone ends are aligned before the area is immobilized.

BANDAGES AND SPLINTS. For some areas of the body, such as the clavicle or wrist, an elastic or muslin bandage or a splint may be used to immobilize the bone during the healing phase. Splints can be used when the fracture has some associated soft tissue damage that needs care or if there is an expectation of swelling. It is important that the splint be well padded, thereby preventing skin breakdown or unnecessary pressure. Perform neurovascular assessments to ensure adequate blood flow to the area. (See Chapter 43.)

CASTS. Casts provide a strong support for fractured bones, thereby aiding in early mobility and decreased pain. They are also used to correct deformities and to support weak joints while restricting movement. The type of cast used depends on the reason the cast applied. For more extensive fractures or for weight-bearing areas, a more rigid and durable cast is used for immobilization. Once the need for the cast is resolved (e.g., when bone healing is complete), the cast is removed.

Several types of materials are used for casts, including the traditional plaster of paris (anhydrous calcium sulfate) and a variety of synthetic products such as fiberglass. The plaster cast is used for large casts and for weight-bearing areas. Because of a chemical reaction that occurs when the plaster is wet, the cast feels hot when applied for about 30

minutes and then feels cool, taking anywhere from 24 to 72 hours to completely dry. The cast is dry when it feels hard and firm, is odorless, and is shiny white. Keep the wet cast open to air to aid in drying. A wet cast should be handled with the palms of the hand ("palming the cast") to prevent indentations or a change in the shape of the cast (Fig. 44-14). This prevents the possibility of pressure points forming inside of the cast. Unlike plaster of paris, synthetic material casts such as fiberglass harden quickly and dry in less than 2 hours.

A casted limb is elevated for 24 to 48 hours, and ice can be applied above and below the cast to reduce swelling. Assess the cast for dryness, tightness, drainage, and odor. A serious complication of a cast being too tight is compartment syndrome (discussed later). If the cast becomes too tight, the physician orders it to be cut (bivalved) with a cast cutter to relieve pressure and prevent pressure necrosis of the underlying skin (Fig. 44-15). If a wound is present or an odor is detected, the physician cuts a window opening into the cast to treat the underlying skin problem, often an infected area. The cast window should always be taped in

Figure 44-14 A wet plaster cast is moved with the palms of the hand to prevent making indentations in the plaster that could become pressure points.

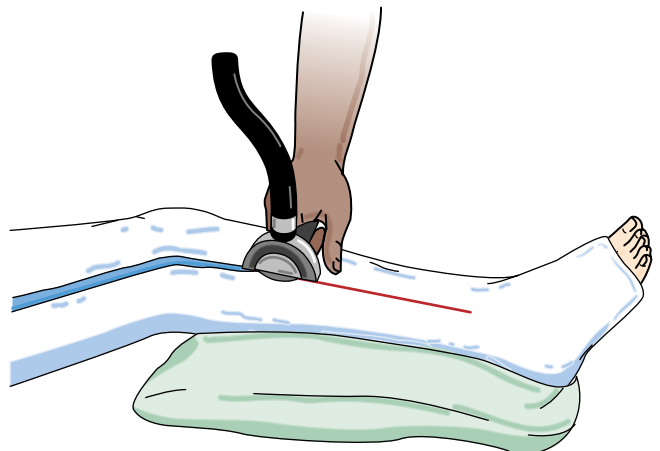

Figure 44-15 Bivalving a cast with a cast saw.

place when wound care is not being provided to prevent the skin from “popping up” through the window and developing pressure points and ischemia. Box 44–9 lists important nursing interventions when caring for a patient who has a cast.

TRACTION. Casts can be worn in or out of a hospital setting, but traction for fracture treatment usually requires that the patient be hospitalized. As a general definition, traction is the application of a pulling force to a part of the body to provide fracture reduction, alignment, or pain relief. Although still used in certain situations, improvements in surgical techniques and orthopedic devices have decreased the use of traction.

Traction is classified as either continuous or intermittent. Continuous traction is required for fracture management; intermittent traction, although not commonly used,

may be applied for patients experiencing muscle spasm. Most traction is either the “skin” or skeletal type. Skin traction typically involves the use of a Velcro boot (Buck’s traction), sling (Russell’s traction, or knee sling), belt (pelvic), or halter, which is secured around a part of the body (Fig. 44–16). This type of traction does not promote bone alignment or healing but is used instead for relief of painful muscle spasms that often accompany fractures. Buck’s traction is indicated for patients with hip fractures. The weight applied is between 5 and 10 pounds (2.2 to 4.5 kg). Skeletal traction, also called balanced suspension, involves the use of pins (Steinmann), screws, wires (Kirschner), or tongs (Gardner-Wells, Crutchfield), which are surgically inserted into the bone for the purpose of alignment while the fracture heals (Fig. 44–17). From 20 to 40 pounds (9 to 18 kg) of weight are usually applied for skeletal traction, depending on the physician’s order.

Balanced suspension maintains the traction while allowing the patient some mobility in bed. A Thomas (or T) splint with Pearson’s attachment can be used to provide balanced suspension for the lower extremity. The patient’s leg rests on a suspended sheepskin-covered splint.

Caring for the patient in traction includes frequently monitoring neurovascular status for impaired blood flow, checking the equipment to ensure proper functioning, and monitoring skin condition for pressure points or irritation from equipment. Traction must be maintained at all times for fractures. All knots, ropes, weights, and pulleys are inspected every 8 to 12 hours for any loosening and intactness. Weights are to hang unobstructed and should never touch the floor or be removed or lifted. The patient’s feet should not rest against the end of the bed. Assistance should be obtained to reposition the patient in bed to prevent lifting injuries, especially with heavy weights in use.

For patients in skeletal traction, pin sites are observed for redness and drainage. Clear, odorless drainage is expected. Some agencies or physicians advocate special solutions or ointments for the skin around the pins (pin care). Others recommend no cleaning to maintain skin integrity. Follow agency policy or physician’s order for pin care. Depending on the type of pin used, the pin ends may be covered to protect the patient (and health care workers) from being injured.

Patients who have traction are immobilized for an extended period and often experience problems associated with immobility. For example, pressure ulcers on heels are common among elderly patients in traction. Another common concern is the person’s psychosocial health. Ensure that the patient does not become socially isolated because of the need for extended bedrest.

OPEN REDUCTION WITH INTERNAL FIXATION. An open reduction with internal fixation (ORIF) is a treatment reserved for patients who cannot be managed by casts or traction. One of the most common indications for this surgical procedure is fractured hips. Fractures of the hip involve the proximal femur and affect the elderly more than any other

Figure 44-16 Types of skin traction. (A) Russell's traction. (B) Buck's (boot) traction.

age group. ORIF of the hip allows early mobilization while the bone is healing.

As the name implies, the bone ends are realigned (reduced) by direct visualization through a surgical incision. The bone ends are held in place by internal fixation (IF) devices such as metal plates and screws or by a prosthesis with

a femoral component similar to that for total joint replacement (Fig. 44-18). For hip surgery, the IF device is not removed after the fracture heals. For ankle or long bone surgery, the hardware may need to be removed after healing to prevent it from loosening over time (Nursing Care Plan Box 44-10).

Figure 44-17 Balanced suspension and skeletal traction for femur fracture.

CRITICAL THINKING

Mrs. Brown

Mrs. Brown, a long-time resident of Happy Hills Care Center, was found lying in the dayroom on her left side, moaning and holding her leg at 10 A.M. (1/4/03). She cried out with any movement and said she fell and broke her leg. The supervisor notified the paramedics and Dr. Jones. Her vital signs are blood pressure 150/84, pulse 100, respirations 20. The licensed practical nurse (LPN) remained with Mrs. Brown and instructed her not to move until help arrived. The LPN got blankets and a pillow for her head. The paramedics arrived quickly and took Mrs. Brown to nearby Grace Hospital by ambulance, where she was diagnosed as having a nondisplaced femoral neck (hip) fracture. Dr. Jones ordered 5 pounds of Buck's traction. Mrs. Brown is restless and picking at her bedcovers when you assess her at the beginning of your shift.

1. How would you document the incident of Mrs. Brown's fall?
2. What is the purpose of Buck's traction for Mrs. Brown?
3. What are your nursing responsibilities while caring for Mrs. Brown?
4. What might explain her restlessness?

Answers at end of chapter.

Figure 44-18 Internal fixation. (A) Intertrochanteric fracture of the hip with fracture fixation via a side plate and screw combination device. (B) Side plate and screw fixation of radial fracture. (From McKinnis, LN: Fundamentals of Orthopedic Radiology. FA Davis, Philadelphia, 1997, with permission.)

CRITICAL THINKING

Tommy Martin

Tommy, 18, was in a motor vehicle accident, resulting in a fractured pelvis. He is to be in pelvic traction for about 8 to 10 weeks.

1. Identify three nursing diagnoses related to Tommy's physical or emotional well-being.
2. What are some of the nursing interventions related to these diagnoses?

Answers at end of chapter.

EXTERNAL FIXATION. An alternative treatment for some fractures is external fixation. External fixation is used when there has been severe bone damage, such as in crushed or splintered fractures, or if there have been numerous fractures along the bone. After the fracture is reduced, the physician surgically inserts pins into the bone; the pins are held in place by an external metal frame to prevent bone movement (Fig. 44-19). External fixation is ideal for the patient who has an open fracture with soft tissue damage

BOX 44-10**NURSING CARE PLAN FOR THE PATIENT AFTER OPEN REDUCTION WITH INTERNAL FIXATION (ORIF) OF THE HIP****Pain related to surgical wound****PATIENT OUTCOME**

Patient states that pain relief is satisfactory.

EVALUATION OF OUTCOME

Does patient state that pain is absent or at tolerable level (pain rated 0 to 2 on pain assessment scale)?

INTERVENTION

Give pain medication as needed; anticipate need for pain medication.

Give pain medication before activity (e.g., session with physical therapist).

Use nondrug pain relief measures, such as distraction, guided imagery, other relaxation techniques. Use fracture bedpan.

RATIONALE

Pain medication relieves pain, especially if given before pain is severe.

Increased activity can cause pain.

Analgesic therapy is enhanced with complementary pain relief measures.

Fracture bedpans are more comfortable and easier to position for patients.

EVALUATION

Does patient state pain is relieved?

Is patient restless or agitated during activity?

Does patient report pain relief is enhanced with music or relaxation?

Is patient able to use fracture pan with comfort?

Impaired physical mobility related to hip precautions and surgical pain**PATIENT OUTCOME**

Patient will maintain desired level of activity.

EVALUATION OF OUTCOME

Does patient maintain activity desired?

INTERVENTION

Reinforce transfer and ambulation techniques.

Place overhead frame and trapeze on bed; teach patient how to use it. Assess patient for and take measures to prevent complications of immobility: turn patient every 2 hours and check skin; keep heels off bed; teach patient to deep breathe and cough q2h; teach use of incentive spirometer.

- Apply thigh-high elastic stockings or sequential compression device to unaffected limb as ordered.
- Give anticoagulants as ordered.
- Get patient out of bed as soon as ordered.
- Ambulate patient as early as possible.
- Remind patient to practice leg exercises.

RATIONALE

Activity is restricted due to hip precautions and weight-bearing limitations.

Patient mobility is increased and pain decreased with use of trapeze for movement.

Immobility complications can occur if preventive measures are not used.

EVALUATION

Does patient transfer and ambulate as instructed by physical therapist?

Does patient use overhead frame and trapeze for movement in bed with less pain?

Does patient experience complications of immobility?

that needs to be treated at the same time. Like skeletal traction, the patient with this device is at risk for pin site infection. Pin care may or may not be required, but pin sites are observed frequently for signs and symptoms of infection. See Nursing Care Plan Box 44-11.

NONUNION MODALITIES. Although most bones heal properly with the correct treatment, some patients experience malunion (malalignment of healed bone) or nonunion

LEARNING TIPS

If you have to move an extremity that has an external fixation device, grasp the device and lift, raise, or move the limb as needed. By grasping the device, there is less movement of the healing bone and therefore less trauma to the site of healing and less pain with movement. Care must be taken not to loosen any fasteners holding the pins in place.

Figure 44-19 External fixation for complex fractures and wound care.

(delayed or no healing). A number of variables influence how a bone heals, including age, nutritional status, and the presence of other diseases that alter the healing process, such as diabetes mellitus.

Several methods for treating nonunion are available, including electrical bone stimulation and bone grafting. For selected patients, bone stimulation may be effective in promoting healing; the exact mechanism of action is not known. Bone grafting involves adding packed bone to the fracture site in an attempt to facilitate healing. Bone stimulating compounds such as Osteoset, Proosteon or Allomatrix are being used to promote bone growth in patients. These compounds are used during surgical procedures as glue, cement, or filler.

Another fracture healing method is low-intensity pulsed ultrasound (also called Exogen therapy). Ultrasound treatment has provided excellent results for slow-healing fractures, as well as for new fractures. The patient applies the treatment for about 20 minutes each day.

Complications of Fractures

Monitor for possible complications and implement interventions to prevent them. The most common complications include hemorrhage, infection, and thromboembolic

BOX 44-11

NURSING CARE PLAN FOR THE PATIENT WITH EXTERNAL FIXATION OF THE LOWER EXTREMITY

▶ Risk for infection related to skin integrity impairment

PATIENT OUTCOMES

Patient does not develop an infection.

EVALUATION OF OUTCOME

Does patient remain free from infection?

INTERVENTIONS

Inspect dressings, wounds, pin sites for signs and symptoms of infection.

Monitor color of and measure wound drainage.

Change dressings or provide wound and pin care per facility policy using aseptic technique.

Monitor vital signs frequently.

RATIONALE

Signs and symptoms of infection could include warmth, redness, heat, swelling, drainage, pain.

Wound drainage color and amount can indicate severity of infection.

Use of aseptic technique minimizes chance of infection. Pin wound sites should be free of crusting, which promotes infections because of decreased skin integrity.

Alterations in vital signs can indicate infection.

EVALUATION

Are any wounds infected?

Does wound have large amount of purulent drainage?

Are pin sites clean with no crusting?

Are vital signs within baseline findings?

▶ Impaired physical mobility related to the external fixation (EF) device

PATIENT OUTCOMES

Patient will maintain desired level of mobility/activity.

EVALUATION OF OUTCOME

Has patient maintained desired level of mobility and activity?

INTERVENTIONS

Reinforce transfer and ambulation techniques.

RATIONALE

Depending on severity of fracture and size of EF device, there may be special needs to transfer and ambulate.

EVALUATION

Does patient transfer and ambulate as instructed?

BOX 44-11

NURSING CARE PLAN FOR THE PATIENT WITH EXTERNAL FIXATION OF THE LOWER EXTREMITY—cont'd

Place overhead frame and trapeze on bed; teach patient how to use them.	Patient mobility is increased and pain decreased with use of trapeze for movement.	Does patient use overhead frame and trapeze for movement with less pain?
Teach patient how to move limb using EF device.	Providing patient with instruction on moving the extremity promotes independence and minimizes pain.	Does patient move the extremity using EF device?
Assess patient for and take measures to prevent complications of immobility. Promote early ambulation to minimize complications. Include other disciplines such as the physiotherapist in promoting and teaching about ambulation.	Immobility complications can occur if preventative measures are not used.	Does patient have any complications of immobility?
	EF devices allow for earlier ambulation. Physiotherapy can provide initial or reinforce the education needed to promote ambulation (e.g., with crutch walking).	Has patient used information learned from other disciplines to aid ambulation?

 **Disturbed body image related to external fixation device**

PATIENT OUTCOMES

Patient will not experience disturbed body image while EF device is in place.

EVALUATION OF OUTCOME

Does patient experience disturbed body image resulting from EF device?

INTERVENTIONS

If possible, explain to patient preoperatively what EF device will look like.
Reinforce the idea that EF device will decrease discomfort and allow for earlier ambulation.
Provide psychological support and an environment of acceptance.

RATIONALE

Preparing patient for what to expect postoperatively increases likelihood of acceptance and minimizes the unknown.
Promoting early ambulation and increased comfort enhance acceptance.
Accepting your patient and allowing for discussion of concerns promotes a sense of well-being and acceptance of EF device.

EVALUATION

Was patient able to verbalize why device is to be used and what device will look like?
Did patient understand benefit of EF device allowing for early ambulation and increased comfort?
Did patient feel comfortable in expressing concerns related to body image?

complications. These problems are discussed in more detail in other parts of this text. Although they do not occur often, acute compartment syndrome and fat embolism syndrome (more common with fractures of long bones) can be life-threatening complications seen with fractures.

HEMORRHAGE. Bone is highly vascular, and damage or surgery to bone can cause bleeding. Assess for bleeding and monitor vital signs carefully. Hypovolemic shock may result from severe hemorrhage. (See Chapter 8.)

INFECTION. Trauma predisposes the body to infection, especially when the skin, the body's first line of defense, is disrupted. Wound infections, pin site infections, and osteomyelitis (bone infection) are common. Hospital-acquired infections, such as pneumonia or urinary tract infection, can occur in elderly patients who are immobilized for extensive periods while their fractures heal.

THROMBOEMBOLIC COMPLICATIONS. Deep vein thrombosis or pulmonary embolus (PE) also develop in patients who are immobile because of trauma or surgery. Thromboembolic complications are the most common problems of lower extremity surgery or trauma and the most fatal complication of musculoskeletal surgery, particularly in the elderly. Leg exercises, early ambulation, and anticoagulant therapy, usually using low-molecular-weight heparin

such as dalteparin (Fragmin) or enoxaparin (Lovenox), help prevent these problems.

ACUTE COMPARTMENT SYNDROME. Compartments are sheaths of fibrous tissue that support and partition nerves, muscles, and blood vessels, primarily in the extremities (Fig. 44-20). There are several compartments within each extremity. Acute compartment syndrome (ACS) is a serious problem in which the pressure within one or more extremity compartments increases, causing massive circulation impairment to the area. An external device such as a cast or bulky dressing can increase pressure when there is tissue swelling or compression in the area. The early symptom of ACS is the patient's report of severe, increasing pain that is not relieved with narcotics and occurs more on active movement than passive movement. Decreased sensation follows before ischemia becomes severe. In severe ACS, the patient has the six Ps:

- Pain (severe, unrelenting, and increased with passive stretching)
- Paresthesia (painful tingling or burning)
- Paralysis (late symptom)
- Pallor (but there may be warmth or redness over the area)
- Pulselessness (late and ominous sign)
- Poikilothermia (temperature matches environment; i.e., the extremity is cool to touch)

Figure 44-20 (A) Lower leg compartments. Each compartment contains muscles, an artery, a vein, and a nerve. (B) Compartment syndrome. Increased pressure in a compartment compresses structures within the compartment.

Relief of pressure is the goal. It may be accomplished by removing the source of pressure, such as bivalving a cast, or by performing a **fasciotomy**, which is an incision into the fascia that encloses the compartment. This incision allows the compartment tissue room to expand and relieves the pressure. If more than one compartment has increased pressure, multiple fasciotomies are required. These surgical wounds remain open until the pressure decreases. Then they are closed and may require skin grafting. If this condition continues without pressure relief, tissue necrosis, infection, extremity contracture, or renal failure may result. Renal failure is a potentially fatal complication of ACS.

CRITICAL THINKING

Mr. Andrews

Mr. Andrews has suffered a nondisplaced fracture of his right femur. He has a cast on from his groin to the middle of his foot. An hour ago he received 10 mg of morphine intravenously (IV) and he is complaining of continuing and increasing pain.

1. What nursing assessment should now be performed?
2. What might be happening with Mr. Andrews?
3. What interventions may be necessary?

Answers at end of chapter.

FAT EMBOLISM SYNDROME. Fat embolism syndrome (FES) is another serious complication in which small fat globules are released from yellow bone marrow into the bloodstream. The globules then travel to the lung fields,

causing respiratory distress. This process most often occurs when long bones (especially the femoral shaft) are fractured or when the patient has multiple fractures. The elderly patient with a fractured hip is also at a high risk for FES. This condition can occur up to 72 hours after the initial injury or procedure.

The earliest manifestation of FES is altered mental status resulting from a low arterial oxygen level. The patient then experiences tachycardia, tachypnea, fever, high blood pressure, and severe respiratory distress (shortness of breath). Most patients also have a measleslike rash, called petechiae, over the upper body. Even when aggressively treated, patients with FES often die from the pulmonary edema that typically develops. Note early FES signs and symptoms and report them to the physician immediately. If a fat embolism is suspected, the following actions should be taken:

- Promote oxygenation by administering oxygen at 2 L per minute via nasal cannula.
- Maintain bedrest and keep movement of extremity to a minimum.
- Prepare patient for a chest x-ray examination or lung scan.
- Administer intravenous fluids as ordered.
- Administer corticosteroids as ordered.
- Provide emotional support and calm environment.

Nursing Process

Caring for the patient with a fracture may require an interdisciplinary approach, especially for complex or multiple fractures. Coordinate care with other health team members.

ASSESSMENT. The most important aspect of assessment for the patient with a fracture is frequent monitoring of neu-

fasciotomy: fascia—fibrous tissue + otomy—opening into

rovascular status distal to the fracture site. As mentioned earlier, acute compartment syndrome is a potentially limb- or life-threatening complication that results when blood flow is impaired. Chapter 43 describes the procedure for this assessment and its significance.

Pain is managed by both medications and complementary therapies. Bone pain can be excruciating and must be treated aggressively. For the patient who cannot report pain, particularly a confused or comatose patient, ensure that pain relief is maintained.

LEARNING TIPS

A confused or comatose patient may not be able to report pain, the most reliable indicator of pain. Nonverbal indicators (e.g., grimacing, restlessness, elevated blood pressure and heart rate) are not reliable for pain assessment and should not be used to determine pain absence. You owe it to your patients to prevent their pain by anticipating it and treating it in advance. You can do this by recognizing causes of pain and understanding that the effects of mild but repetitive pain (as in turning several times a day) can adversely affect the patient (such as by leading to exhaustion). Causes of pain include conditions or diseases (such as fractures, surgery, trauma, or cancer), procedures (such as turning or wound care), and biomedical devices (such as orthopedic fixation devices, wound drains, Foley catheters, nasogastric tubes, and chest tubes).

With few patients medicated before painful procedures, some of which may be done several times a day (turning), confused or comatose patients are at greater risk for lack of pain relief. Provide analgesics before painful procedures and on a regular basis when pain is assumed to be present to keep your patients comfortable. For anticipated pain, the acronym APP (assume pain present) is used instead of a pain rating scale. Use accepted clinical practice guidelines as a rationale for providing your patients the best possible pain relief. Share pain research findings with administrators in your institution to establish policies that support proactive pain management for all patients.

NURSING DIAGNOSIS. The common nursing diagnoses for the patient with a fracture may include the following:

- Acute pain
- Impaired physical mobility
- Impaired walking
- Ineffective health maintenance
- Risk for peripheral neurovascular dysfunction
- Risk for ineffective tissue perfusion
- Risk for ineffective skin integrity

PLANNING. The plan of care is derived from the nursing diagnoses and risk for medical complications. Patients with uncomplicated fractures are treated on an outpatient basis. Patients with multiple or more complex fractures, especially involving soft tissue injury, are admitted to the hospital for care. To ensure continuity of care, the case manager involves the various disciplines involved in the patient's care from the time of admission through the continuing care phase.

IMPLEMENTATION. The most common fracture that leads to hospitalization is the hip fracture. Nursing Care Plan 44–10 highlights the most important aspects of care for the patient with a fractured hip.

EVALUATION. The expected outcomes for the patient are relief of pain, healing without complications, and return to or improvement in their previous level of functioning. The interdisciplinary team evaluates care to ensure that it is directed toward meeting these outcomes.

Patient Education

If the patient has a cast, review the appropriate instructions for cast care. Teach the patient not to insert objects (e.g., pencils, sharp objects) into the cast to scratch an itchy area. Health teaching is also important for care of the extremity after cast removal (Box 44–12). The patient may also have a wound including pin site care that will be managed at home. Teach the patient and caregiver how to assess and dress the wound and when to report changes such as signs and symptoms of infection.

Nutritional education is also essential. The body needs adequate protein, calories, vitamins, and minerals for healing to occur. Unless otherwise contraindicated, milkshakes and instant breakfast preparations are good sources of additional protein and calories, as well as a source of calcium.

Osteomyelitis

Osteomyelitis is an infection of bone that can be either acute or chronic. A bone infection lasting less than 4 weeks is considered acute; one that lasts more than 4 weeks is chronic.

Pathophysiology

Regardless of type, osteomyelitis results from invasion of bacteria into bone and surrounding soft tissues. Inflammation occurs, followed by ischemia (decreased blood flow) (Fig. 44–21). Bone tissue then becomes necrotic (dies), which retards healing and causes more infection, often as a bone abscess.

BOX 44-12 Care of the Extremity After Cast Removal

- Remove scaly, dead skin carefully by soaking—do not scrub.
- Move the extremity carefully. Expect discomfort, weakness, and decreased range of motion.
- Support the extremity with pillows or your orthotic device until strength and movement return.
- Exercise slowly as instructed by your physical therapist.
- Wear support stockings or elastic bandages to prevent swelling (for lower extremity).

Source: Ignatavicius, DD, Workman, ML, and Mishler, MA: Medical-Surgical Nursing: A Nursing Process Approach, ed 3. WB Saunders, Philadelphia, 1998, with permission.

Figure 44-21 Sequence of osteomyelitis development. (A) Infection begins. (B) Blood flow is blocked in the area of infection. An abscess with pus forms. (C) Bone dies within the infection site, and pus formation continues.

Pathogens enter bone in several ways. Direct inoculation means that an injury to the body allows the offending microbes direct access to bone tissue. An open fracture is an example of that process. Contiguous spread occurs when surrounding soft tissue becomes infected. An example is the patient with cellulitis whose infection then spreads to underlying bone. In hematogenous spread, an infection beginning in another part of the body migrates to bone. For instance, a patient with a total hip replacement may get osteomyelitis from a urinary tract infection.

Causes and Types

Penetrating trauma leads to acute osteomyelitis by direct inoculation. The most common pathogen is *Pseudomonas aeruginosa*. The leading cause of contiguous spread is a slow-healing foot ulcer in the patient who has diabetes mellitus or peripheral vascular disease. Multiple organisms may be present in the wound and subsequently the bone. Hematogenous spread results from bacteremia (infection of the blood), underlying disease, or nonpenetrating trauma. Long-term intravenous catheters are primary sources of infection.

Signs and Symptoms

The patient with acute osteomyelitis has fever, as well as local signs of inflammation, such as tenderness, redness, heat, pain, and swelling. Pain may be the only apparent complaint. Ulceration, drainage, and localized pain are typical signs and symptoms of chronic osteomyelitis.

Diagnostic Tests

The patient with osteomyelitis typically has an elevated leukocyte (white blood cell) count, an elevated erythrocyte sedimentation rate, and positive bone biopsy for infection. Some patients also have a positive blood culture. MRIs, x-ray examinations, and CT scans can show areas of infection.

Treatment

Long-term antibiotic therapy is the treatment of choice for patients with bone infection. Infection in bone tissue is difficult to resolve and may require weeks to months of medication. Patients often administer their intravenous antibiotics at home rather than have a costly stay in a hospital. Central venous access devices, such as Hickman, Broviac, or Groshong catheters, as well as peripherally inserted central catheters (PICC), are used for intravenous drug administration. Teach the patient and caregiver about the side effects, toxicity, interactions, and precautions for antibiotic therapy. A home care nurse may be needed to assist the patient.

If a soft tissue wound is present, irrigations and dressing changes are performed by the home health nurse or taught to the patient and family. Teach the patient about the importance of handwashing and how to avoid the spread of pathogens. Some patients are placed on standard precautions or other isolation precautions, depending on the offending organism.

Antibiotic therapy alone may not resolve the infection. Patients with chronic osteomyelitis may require surgery to remove necrotic bone tissue or replace it with healthy bone tissue. Amputations are reserved for patients who have massive infections that have not responded to one or more of the conventional treatments.

Osteoporosis

Osteoporosis is a common metabolic disorder in which the bone loses its density, resulting in fragile bones and possibly fractures. The wrist, hip, and vertebral column are most commonly involved.

Pathophysiology

Bone is dynamic, constantly building new tissue and resorbing (breaking down) old tissue. Bone density (mass) peaks between 30 and 35 years of age. After these peak years, the rate

of bone breakdown exceeds the rate of bone building. The result is irreversible bone loss that worsens with aging. Trabecular (cancellous) bone is lost first, followed by a loss of cortical (compact) bone. As a result, more than 1.5 million fractures occur each year in people older than age 45. Hip fractures are among the most common, accounting for more than 250,000 per year. The mortality rate for hip fractures is about 50 percent during the first year after the fracture. For postmenopausal women, decreased estrogen appears to slow down the absorption of calcium, resulting in an increased bone loss.

Cause and Types

Osteoporosis is either primary or secondary. Primary osteoporosis is the most common and is not associated with another disease or health problem. Risk factors for primary osteoporosis include the following:

- Caucasian or Asian heritage, postmenopausal, female (less estrogen available to protect bone)
- Sedentary lifestyle
- Decreased calcium intake
- Lack of vitamin D (to absorb calcium)
- Excessive alcohol consumption
- Cigarette smoking
- Excessive caffeine intake
- Petite body build

Secondary osteoporosis results from an associated medical condition, such as hyperparathyroidism; long-term drug therapy, especially steroids; and prolonged immobility, such as that seen with patients who have a spinal cord injury.

Signs and Symptoms

Most women do not realize they have osteoporosis until they fracture a bone. During the late middle years, the classic “dowager’s hump,” or kyphosis of the spine, is usually present. The patient’s height decreases and back pain may be present. The patient may be embarrassed by the change in body image and may have curtailed social activities. Some patients have difficulty finding clothes that fit comfortably.

Diagnostic Tests

X-ray examination of the bone is not helpful in diagnosing bone loss in its early stages. Computed tomography and quantitative CT scans detect early spine changes and measure bone density. Ultrasound can also be used to screen bone mass. Dual-energy x-ray absorptiometry (DXA) is used as a screening tool to measure bone mineral content. This test is noninvasive and is currently the most widely used technique to measure bone density.

Serum calcium and vitamin D levels may be decreased, and serum phosphorus may be increased. With severe bone loss, alkaline phosphatase levels may be elevated, confirming bone damage.

Treatment

The cornerstone of treatment for osteoporosis is medication and avoidance of modifiable risk factors to prevent bone loss.

MEDICATION. Medication may be used for prevention or treatment purposes. The current drugs of choice calcium supplements, vitamin D, and biophosphonates, such as alendronate (Fosamax) and risedronate (Actonel).

Calcium is also important to prevent bone loss. If serum calcium falls below normal levels, the parathyroid glands stimulate the bone to release calcium into the bloodstream. The result is demineralized bone. Therefore calcium supplements are an important aspect of treatment. Teach the patient to drink plenty of fluids to prevent calcium-based urinary stones. Vitamin D supplementation, to aid calcium absorption, may also be necessary for patients who have inadequate sunlight exposure (institutionalized people) or who cannot metabolize vitamin D.

Alendronate and risedronate are used to prevent or slow the progress of osteoporosis. They suppress osteoclast activity to prevent the breakdown of bone. Although side effects are not common, serious cases of esophagitis and esophageal ulcers have been reported. Therefore teach the patient to take the drug early in the morning and follow it with a full glass of water. The patient should not lie down for at least 1 hour after taking the drug.

The newest drug class for osteoporosis is the selective estrogen receptor modulator (SERM). Recently approved for use, raloxifene (Evista) increases bone mass 2 to 3 percent each year. SERM drugs are designed to mimic estrogen in some parts of the body while blocking its effects elsewhere.

Other drugs that may be used include testosterone (the male hormone that helps build bone), calcitonin (nasal spray, injection), and sodium fluoride. All these medications have major disadvantages and are consequently not commonly given. Any drug used to prevent or control osteoporosis must be administered under the supervision of a physician including supplements.

DIET. Increasing calcium and fluids are the main dietary considerations for women. Teach patients what foods are high in calcium, such as dairy products and dark green, leafy vegetables. If the patient consumes excessive caffeine or alcohol, teach about the need to avoid these substances. For more information, visit the National Osteoporosis Foundation at www.nof.org.

EXERCISE. Weight-bearing exercise, especially walking, stimulates bone building. The patient should wear well-supporting, nonskid shoes at all times and avoid uneven surfaces that could contribute to falls. Resistance exercise such as weight training or the use of some of the equipment available at fitness centers is also beneficial.

FALL PREVENTION. Osteoporotic bone may cause a pathological fracture in which the hip breaks before the fall. For other patients, a fall can cause a hip or other fracture. Therefore fall prevention programs in hospitals and nursing homes are important.

In collaboration with the physical or occupational therapist, case manager, or discharge planner, assess the patient’s home environment. The patient and family are taught how to create a hazard-free environment, such as avoiding

scatter rugs and slippery floors. Walking paths in the home must be kept free of clutter to prevent falls. If needed, a walker or cane provides additional support.

Paget's Disease

Paget's disease, also called osteitis deformans, is a metabolic bone disease in which increased bone loss results in large, disorganized bone deposits throughout the body. It is primarily a disease of the elderly.

Pathophysiology

Three phases of the disorder have been described: active, mixed, and inactive. A prolific increase in osteoclasts (cells that break down bone) causes massive bone deformity and destruction. Osteoblasts (bone-building cells) then react to form new bone. However, the result is disorganized in structure. Finally, when osteoblastic activity exceeds the osteoclastic activity, the inactive phase occurs. The newly formed bone becomes sclerotic with increased vascularity.

Paget's disease can affect one or multiple bones. The most common areas involved are the femur, skull, vertebrae, and pelvis.

Causes and Types

The exact cause of this disease is not known, but it tends to run in families. Paget's disease may be the result of a latent viral infection contracted in young adulthood. It is more common in Europe than in the United States.

Signs and Symptoms

Most patients with Paget's disease have no obvious symptoms, particularly when the disorder is confined to one bone. For patients with more severe disease, signs and symptoms are varied and potentially fatal. Table 44-6 lists the key features of this disease.

Diagnostic Tests

Diagnosis may be made solely on x-ray findings. Radiographs of pagetic bone show punched-out areas indicating increased bone resorption. The overall mass of bone may be

enlarged, depending on the phase of the disorder. Deformities, fractures, and arthritic changes are not uncommon. Bone scans can also be used to help in the diagnosis.

The primary laboratory findings are an increased alkaline phosphatase (ALP) and an increase in urinary hydroxyproline. Pylilinks and Osteomark are urine tests that can be used in place of the urinary hydroxyproline test. ALP reflects bone damage. Urinary hydroxyproline indicates an increase in bone turnover. The higher the level, the more severe the disease. Calcium levels in both blood and urine are elevated as damaged bone releases calcium into the bloodstream.

Treatment

Nonsurgical management is employed to relieve pain and promote a reasonable quality of life for the patient. For mild disease, NSAIDs are given.

MEDICATION. The purpose of drug therapy for the patient with Paget's disease is to relieve pain and decrease bone loss. Calcitonin (Calcimar) is a thyroid hormone that is often effective in initiating a remission of the disease. It appears to decrease bone loss while also decreasing pain. If effective, the ALP level decreases. The usual duration of therapy is 6 months, followed by 6 months of etidronate disodium (Didronel) or another biphosphate drug. Its action is similar to that of calcitonin, and it must be taken on an empty stomach.

Plicamycin (Mithramycin, Mithracin) is a potent anti-cancer drug and antibiotic that is reserved for patients with severe hypercalcemia or severe disease with neurological involvement. This drug suppresses both osteoclastic and osteoblastic activity within days, but it has serious adverse effects. As with all drugs, observe for toxic effects such as liver and kidney failure. Platelet count is monitored because the drug can decrease platelet production. When liver enzymes become too high, the drug is temporarily discontinued until they return to baseline.

Alendronate is a bone resorption inhibitor and calcium regulator. Intravenous dosing for 5 days may initiate a disease remission.

OTHER TREATMENT. Additional management for Paget's disease depends on the clinical manifestations. For example, if the patient has osteogenic sarcoma, the appropriate treatment for bone tumors is initiated.

Bone Cancer

Bone tumors may be benign or malignant. Malignant tumors may be either primary (originating in the bone) or metastatic, originating from another location and migrating to bone. Primary bone tumors tend to develop in people under 30 years of age and account for only a small percentage of bone cancers. Metastatic lesions are much more common and most often affect the elderly.

Pathophysiology

The pathophysiology depends on the type of bone cancer. The cause of bone cancer is not known.

Primary Malignant Tumors

Osteosarcoma, or osteogenic sarcoma, is the most common primary malignant bone tumor. It is a fairly large tumor that typically metastasizes to the lung within 2 years of diagnosis and treatment. More than 50 percent of osteosarcomas occur in the distal femur in young men. Older patients with Paget's disease may also develop these lesions.

Ewing's sarcoma is the most malignant bone tumor. In addition to local pain and swelling, systemic signs and symptoms, including low-grade fever, leukocytosis, and anemia, are common. The pelvis and lower extremity are most often affected in children and young men.

Patients with a chondrosarcoma (cancer of cartilaginous cells) have a better prognosis than those with the previously described types of bone cancer. This type of cancer occurs in middle-aged and older people.

METASTATIC BONE DISEASE. Primary malignant tumors that occur in the prostate, breast, lung, and thyroid gland are called bone-seeking cancers because they migrate to bone more than any other primary cancer. Once cancer has metastasized, multiple bone sites are typically seen. Patho-

logical fractures and severe pain are major concerns in managing metastatic disease. See Chapter 10 regarding caring for patients with cancer.

Signs and Symptoms

Primary tumors cause local swelling and pain at the site. A tender, palpable mass is often present. Metastatic disease is not as visible, but the patient complains of diffuse severe pain, eventually leading to marked disability.

Diagnostic Tests

Diagnosis of bone cancer is made by x-ray examination, computed tomography, bone scan, bone biopsy, or MRI. Chapter 43 discusses these tests in detail.

The patient with metastatic disease has an elevated ALP level and possibly an elevated erythrocyte sedimentation rate, indicating secondary tissue inflammation.

Treatment

Management of bone cancer depends on the type and extent of the tumor. The treatment of primary bone tumors is usually surgery, often combined with chemotherapy or radiation. The surgeon attempts to salvage the limb and performs a resection of the tumor. For patients with Ewing's sarcoma or early osteosarcoma, external radiation may be the treatment of choice to reduce tumor size and pain.

Care of the postoperative patient is similar to that for any patient undergoing musculoskeletal surgery. Monitoring neurovascular status of the limb to be operated on is a vital nursing intervention. (See Chapter 43.) Other general postoperative care is discussed in Chapter 11.

For metastatic bone disease, surgery is not appropriate. External radiation is given primarily for palliation. The radiation is directed toward the most painful sites in an attempt to shrink them and provide more comfort for the patient.

Nursing care for the patient with bone cancer is not unlike that for patients with any other type of cancer. Help the patient adjust to the diagnosis and refer the patient to resources such as the American Cancer Society and its various support groups. Chapter 10 describes the nursing care associated with chemotherapy and radiation therapy. For more information, visit the American Cancer Society at

www.cancer.org.

REVIEW QUESTIONS

1. A patient has osteoporosis and is scheduled for a right total hip replacement. The nurse should include which of the following postoperative leg positions in the preoperative teaching plan?
 - a. Maintain legs in adduction.
 - b. Maintain legs in abduction.
 - c. Maintain internal leg rotation.
 - d. Maintain more than 90-degree hip flexion.
2. A patient has a 36-hour-old fractured femur. He had morphine 5 mg intramuscularly 1 hour ago and is reporting severe unrelieved pain. Which nursing action is most appropriate?
 - a. Give pain medication.
 - b. Adjust the traction.
 - c. Bivalve the cast.
 - d. Notify the patient's physician.
3. The nurse is caring for a patient who just had a plaster cast applied. Which action should the nurse take to facilitate cast drying?
 - a. Cover the cast with blankets to provide extra warmth.
 - b. Turn the patient every 2 hours.
 - c. Increase the room temperature.
 - d. Apply a heating pad.
4. A patient has Paget's disease. A priority nursing diagnosis for the patient includes which of the following?
 - a. Pain
 - b. Deficient knowledge
 - c. Excess fluid volume
 - d. Deficient fluid volume
5. A patient who had a total knee replacement is to receive Toradol 15 mg intramuscularly q6h as needed for pain. The Toradol comes as 30 mg/mL. How many milliliters should the nurse give?
 - a. 0.05 mL
 - b. 0.15 mL
 - c. 0.5 mL
 - d. 1.5 mL

Answers to CRITICAL THINKING

Mr. Dennis

- The physician would ask Mr. Dennis the following questions:
 - “What is your typical day on the job like?”
 - “Do certain activities increase joint pain?”
 - “When is your pain worse—after activity or after rest?”
 - “How long have you experienced joint pain?”
 - “What relieves the joint pain?”
- Risk factors include that he is overweight, is in late middle age, and has a physically demanding job.
- Other signs and symptoms may include bony nodules on his fingers (such as Heberden’s nodes) and secondary inflammation causing joint swelling.

Mrs. Summers

- Ask Mrs. Summers about the following:
 - The nature of her pain
 - If it is worse after activity or rest
 - If she experiences joint stiffness and, if so, when

Follow the WHAT’S UP? method of pain assessment.

- Teach her to do the following:
 - Balance rest with exercise.
 - Use ice for very hot, swollen joints.
 - Use heat to decrease stiffness.

Mrs. Brown

- When documenting, answer (either explicitly or implicitly by professional knowledge, in narrative or flow sheet format) what, why, when, where, who, and how, for completeness.
 What = Mrs. Brown was found on the floor lying on her left side, moaning and holding her leg, crying out with any movement.
 Why = Fell
 When = 10 A.M. on January 4, 2003
 Where = Dayroom
 Who = I. Smith, LPN
 1/4/03 1000 Found patient on floor in dayroom lying on her left side, moaning and holding her leg, crying out with any movement. Stated, “I fell. I think my leg is broken.” Supervisor immediately notified, and paramedics and Dr. Jones called. Vital signs 150/84, 100, 20. Remained with patient and instructed not to move until paramedics arrive. Blankets applied and pillow placed under head for comfort. 10:30 Paramedics transported by ambulance to Grace Hospital.

I. Smith, LPN

- The purpose of the traction is to reduce the muscle spasms that often accompany fractures and to increase comfort.
- Nursing responsibilities include the following:
 - Check neurovascular status frequently.
 - Check equipment, including rope, pulleys, knots, and weights.

- Do not allow the weights to rest on the floor.
- Assess the patient’s skin often for areas of potential breakdown.
- Remove and rewrap the elastic bandages, maintaining the traction, at least every shift. Provide skin care during this time.

- Her restlessness is most likely the result of pain. She may be unable to state that she is in pain. Evaluate behaviors such as restlessness and other nonverbal cues to evaluate pain management needs. She may also be experiencing shock as a result of blood loss from the fracture. Assess vital signs, and check the area of the fracture for increased signs of bruising or swelling.

Tommy Martin

- Possible nursing diagnoses include but are not limited to the following:
 - Potential for social isolation related to extended need for immobilization
 - Potential for complications of inactivity related to extended need for traction
 - Potential for boredom related to extended need for bedrest
- Nursing interventions related to the diagnoses include the following:
 - To address social isolation, encourage Tommy’s friends to come visit; have an occupational therapist assess Tommy’s needs; and alternate family visitors.
 - To avoid complications of inactivity, ensure Tommy does the exercises recommended by occupational and physical therapists; reposition him every 2 to 3 hours; ensure Tommy’s diet is appropriate for good bone healing; have trapeze set up for Tommy to use; assess for signs and symptoms of skin breakdown; and assess for signs and symptoms of pulmonary embolism.
 - To alleviate boredom, encourage Tommy to listen to music; encourage visitors; and ensure access to hobbies, videos, books, magazines, and comics.

Mr. Andrews

- Nursing assessments should include the following:
 - Perform a neurovascular check.
 - Perform a further pain assessment.
 - Ask Mr. Andrews to move his limb and see if the pain worsens.
 - Take his vital signs.
 - Assess for the 6 Ps (pulselessness, paresthesia, paralysis, pallor, pain, poikilothermia).
- He might be experiencing compartment syndrome.
- Interventions may include the following:
 - Bivalving cast
 - Possible fasciotomy

QUESTIONS TO GUIDE YOUR READING

1. What is the normal anatomy of the nervous system?
2. What is the normal function of the nervous system?
3. What data should you collect when caring for a patient with a disorder of the nervous system?
4. What are the effects of aging on the nervous system?
5. What are the diagnostic tests commonly performed to diagnose disorders of the nervous system?
6. What nursing care should you provide for patients undergoing each of the diagnostic tests for disorders of the nervous system?
7. What are common therapeutic measures used for patients with disorders of the nervous system?

► REVIEW OF NORMAL ANATOMY AND PHYSIOLOGY

The nervous system is one of the body's control systems; by means of electrochemical impulses we are able to detect changes and feel sensations, initiate appropriate responses to changes, and organize and store information for future use. Some of this is conscious activity, but much of it is reflexive in nature and happens without our awareness.

The nervous system has two divisions. The central nervous system (CNS) consists of the brain and spinal cord. The peripheral nervous system (PNS) consists of cranial nerves

and spinal nerves, which include the nerves of the autonomic nervous system (ANS).

Nerve Tissue

Nerve tissue consists of neurons and specialized supporting cells. There are many kinds of neurons (nerve cells or nerve fibers), but they all have the same general structure (Fig. 45–1). The cell body contains the nucleus and is essential for the continued life of the neuron. All neuron cell bodies are found in the brain or spinal cord or within the trunk of the body; in these locations they are protected by bone. A

Figure 45-1 Structure of sensory and motor neurons. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 155, with permission.)

neuron may have one or many dendrites, which are extensions that carry impulses toward the cell body. A neuron has one axon that transmits impulses away from the cell body. It is the cell membrane of the dendrites, cell body, and axon that carries the electrical nerve impulse.

In the peripheral nervous system, axons and dendrites are wrapped in specialized cells called Schwann cells. The concentric layers of cell membrane of a Schwann cell form the myelin sheath. Myelin is a phospholipid that electrically insulates neurons from one another. The spaces between adjacent Schwann cells are called nodes of Ranvier (neurofibril nodes); only these parts of the neuron cell membrane depolarize when an electrical impulse is transmitted, which makes impulse conduction rapid. The nuclei and cytoplasm of Schwann cells are outside the myelin sheath and form the neurolemma. If a peripheral nerve is severed and reattached, the individual axons and dendrites

may regrow through the tunnels provided by the neurolemma. Growth factors produced by the Schwann cells are also believed to contribute to such regeneration.

In the central nervous system, the myelin sheaths (but not a neurolemma) are formed by oligodendrocytes, one of the neuroglia, the specialized cells found only in the brain and spinal cord. See Table 45–1 for the names and functions of the other neuroglial cells.

Synapses

When the axon of a neuron must transmit an impulse to the dendrite or cell body of another neuron, the impulse must cross a small gap called a synapse. An electrical impulse is incapable of crossing this microscopic space, and at synapses impulse transmission becomes chemical. The end of the axon (the presynaptic neuron) is called the synaptic knob and contains a chemical neurotransmitter that is released

TABLE 45-1 NEUROGLIA	
Name	Function
Oligodendrocytes	Produce the myelin sheath to electrically insulate neurons of the CNS
Microglia	Capable of movement and phagocytosis of pathogens and damaged tissue
Astrocytes	Contribute to the blood-brain barrier, which prevents potentially toxic waste products in the blood from diffusing out into brain tissue; disadvantage: some useful medications cannot cross it, which becomes important during brain infection, inflammation, or other disease
Ependyma	Line the ventricles of the brain; many of the cells are ciliated; involved in the circulation of cerebrospinal fluid

into the synapse by the arrival of the electrical impulse. The neurotransmitter diffuses across the synapse and combines with specific receptor sites on the postsynaptic membrane (Fig. 45-2). At excitatory synapses, the neurotransmitter makes the postsynaptic membrane more permeable to sodium ions, which rush into the cell, initiating an electrical impulse on the membrane of the postsynaptic neuron. The neurotransmitter is then inactivated to prevent continuous impulses. For example, the neurotransmitter acetylcholine is inactivated by the chemical called cholinesterase; each transmitter has its own specific inactivator.

Some synapses are inhibitory synapses in that the neurotransmitter makes the postsynaptic membrane more permeable to potassium ions, which leave the cell and make the

membrane resistant to the electrical change required for an impulse. Thus the electrical impulse is stopped. Inhibitory synapses are important for things such as slowing the heart rate or balancing the excitatory impulses transmitted to skeletal muscles, which prevents excessive contraction and is important for coordination.

At synapses, impulse transmission is one-way only because the neurotransmitter is released only by the presynaptic neuron; the impulse cannot go backward. This is important for the normal activity of the functional types of neurons. The relative complexity of synapses also makes them a potential target for the actions of medications.

Types of Neurons

A useful classification of neurons is a functional one; a neuron is either a sensory neuron, a motor neuron, or an interneuron. Sensory (afferent) neurons transmit impulses from receptors to the central nervous system. Receptors are specialized to detect external or internal changes and then generate electrical impulses. Sensory neurons from receptors in the skin, skeletal muscles, and joints are called somatic; those from receptors in internal organs are called visceral sensory neurons.

Motor (efferent) neurons transmit impulses from the central nervous system to effectors—that is, muscles and glands. Motor neurons to skeletal muscle are called somatic; those to smooth muscle, cardiac muscle, and glands are called visceral. Sensory and motor neurons make up the peripheral nervous system. Visceral motor neurons form the autonomic nervous system, a specialized part of the PNS.

Figure 45-2 Structure of a synapse, and the effect of a neurotransmitter such as acetylcholine. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 157, with permission.)

LEARNING TIPS

To remember the difference between afferent and efferent, try these clues:

Afferent: *A* is for affect or sense.

Efferent: *E* is for effect or action.

or

A before E: You have to feel or sense (afferent) a stimulus before you can take action (efferent).

Interneurons (or association neurons) are found entirely within the central nervous system. Each is specialized to transmit sensory or motor impulses or to integrate these functions. Such integration is involved in thinking and learning.

Nerves and Nerve Tracts

A nerve is a group of peripheral axons, dendrites, or both, with blood vessels and connective tissue. Most peripheral nerves are mixed; that is, they contain both sensory and motor neurons. An example of a purely sensory nerve is the optic nerve for vision; the autonomic nerves are purely motor nerves.

A nerve tract is a group of neurons within the central nervous system; such tracts are often called white matter because the myelin sheaths of the individual neurons are white. A nerve tract within the spinal cord carries either sensory or motor impulses; those within the brain may have sensory, motor, or integrative functions.

Nerve Impulse

A nerve impulse, which may also be called an action potential, is an electrical change brought about by the movement of ions across the neuron cell membrane. When a neuron is not carrying an impulse, it is in a state of polarization with a positive charge outside the membrane and a relatively negative charge inside the membrane. Sodium ions are more abundant outside the cell, and potassium and negative ions are more abundant inside the cell. A stimulus makes the membrane very permeable to sodium ions, which rush into the cell, making the inside positive and the outside relatively negative. This reversal of charges is called depolarization and spreads from the point of the stimulus along the entire neuron membrane.

Immediately following depolarization, the membrane becomes very permeable to potassium ions, which rush out of the cell. This is called repolarization and restores the positive charge outside and the negative charge inside. The sodium and potassium pumps return the sodium ions back outside and the potassium ions inside, and the neuron is polarized again and ready to respond to another stimulus. A neuron is capable of transmitting hundreds of impulses per second, and at great speed, many meters per second.

Spinal Cord

The spinal cord transmits impulses to and from the brain and is the integrating center for the spinal cord reflexes.

The spinal cord is within the vertebral canal formed by the vertebrae and extends from the foramen magnum of the occipital bone to the disk between the first and second lumbar vertebrae. The spinal nerves emerge from the intervertebral foramina.

In cross section the spinal cord is round or oval; internally it has an H-shaped mass of gray matter surrounded by white matter (Fig. 45–3). The gray matter is the cell bodies of motor neurons and interneurons. The white matter is the myelinated axons and dendrites of the interneurons. These nerve fibers are arranged in tracts based on their functions; ascending tracts transmit sensory impulses to the brain, and descending tracts transmit motor impulses from the brain to motor neurons. The central canal of the spinal cord is a small tunnel that is continuous with the ventricles of the brain; it contains cerebrospinal fluid (CSF).

Spinal Nerves

There are 31 pairs of spinal nerves, named according to their respective vertebrae: 8 cervical pairs, 12 thoracic pairs, 5 lumbar pairs, 5 sacral pairs, and 1 very small coccygeal pair. These nerves are often referred to by letter and number: the second cervical nerve is C2, the tenth thoracic is T10, and so on.

In general the cervical nerves supply the back of the head; the neck, shoulders, and arms; and the diaphragm (the phrenic nerves). The first thoracic nerve also contributes to nerves in the arms. The remaining thoracic nerves supply the trunk of the body. The lumbar and sacral nerves supply the hips, pelvic cavity, and legs. The small coccygeal pair (Co1) supplies the area around the coccyx.

Each spinal nerve has two roots, which are neurons entering or leaving the spinal cord. The dorsal root is made of sensory neurons that carry impulses into the spinal cord. The dorsal root ganglion is an enlargement of this root that contains the cell bodies of these sensory neurons. The ventral root is the motor root; it is made of motor neurons that carry impulses from the spinal cord to muscles or glands (their cell bodies are in the gray matter of the spinal cord). When the two roots merge, the nerve thus formed is a mixed nerve.

Spinal Cord Reflexes

A reflex is an involuntary response to a stimulus, an automatic reaction triggered by a specific change. Spinal cord reflexes are those that do not depend directly on the brain, although the brain may inhibit or enhance them.

Reflex Arc

A reflex arc is the pathway nerve impulses travel when a reflex is elicited. There are five parts:

1. **Receptors** detect a change (the stimulus) and generate impulses.
2. **Sensory neurons** transmit impulses from receptors to the CNS.
3. **The central nervous system** contains one or more synapses and the interneurons that may be part of the pathway.

Figure 45-3 Spinal cord in cross section, with nerve roots and meninges. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 158, with permission.)

4. **Motor neurons** transmit impulses from the CNS to an effector.
5. **Effector** performs its characteristic action.

The spinal cord reflexes include stretch reflexes and flexor reflexes. In a stretch reflex, a muscle that is stretched automatically contracts; an example is the familiar patellar, or knee-jerk, reflex, but all skeletal muscles have such a reflex. The purpose of these reflexes is to keep us upright (because gravity exerts a constant pull on the body) without our having to think about it. Flexor reflexes may also be called withdrawal reflexes; the stimulus is something painful and the response is to pull away from it. Again, this occurs without the need for conscious thought; the brain is not directly involved.

The clinical testing of certain spinal cord reflexes provides a way to assess the functioning of their reflex arcs. If the patellar reflex, for example, were absent, the problem might be in the quadriceps femoris muscle, the femoral nerve, or the spinal cord itself. If the reflex is present, however, it indicates that all parts of the reflex arc are functioning normally.

Brain

The brain consists of many parts, which function as an integrated whole. The major parts are the medulla, pons, and

midbrain (the brainstem); the cerebellum; the hypothalamus and thalamus; and the cerebrum (Fig. 45-4).

Ventricles

The ventricles are four cavities within the brain: two lateral ventricles within the cerebral hemispheres, the third ventricle within the thalamus and hypothalamus, and the fourth ventricle between the medulla and cerebellum. Each ventricle contains a capillary network called a choroid plexus, which forms cerebrospinal fluid (the tissue fluid of the CNS) from blood plasma.

Medulla

The medulla is anterior to the cerebellum, extends from the spinal cord to the pons, and regulates our most vital functions. Within the medulla are cardiac centers that regulate heart rate, respiratory centers that regulate breathing, and vasomotor centers that regulate the diameter of blood vessels and therefore blood pressure. Also in the medulla are reflex centers for coughing, sneezing, swallowing, and vomiting.

Pons

The pons is anterior to the upper portion of the medulla. Within the pons are two respiratory centers that work with those in the medulla to produce a normal breathing rhythm.

Figure 45-4 The brain's midsagittal section; medial surface of the right cerebral hemisphere. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 165, with permission.)

Midbrain

The midbrain extends from the pons to the hypothalamus and encloses the cerebral aqueduct, a tunnel that connects the third and fourth ventricles. Primarily a reflex center, the midbrain regulates visual reflexes (coordinated movement of the eyes), auditory reflexes (turning the ear to a sound), and righting reflexes that keep the head upright and contribute to balance.

Cerebellum

The cerebellum is posterior to the medulla and pons, separated from them by the fourth ventricle; it is overlapped by the occipital lobes of the cerebrum. The functions of the cerebellum are concerned with the involuntary aspects of voluntary movement: coordination, regulation of muscle tone, the appropriate trajectory and endpoint of movements, and the maintenance of posture and balance or equilibrium. For the maintenance of balance, the cerebellum (and midbrain) uses sensory information provided by the receptors in the inner ear that detect movement and changes in position of the head.

Hypothalamus

The hypothalamus is located above the pituitary gland and below the thalamus. It has many diverse functions:

1. Production of antidiuretic hormone (ADH) and oxytocin; these hormones are then stored in the posterior pituitary gland. ADH increases the reabsorption of water by the kidneys and thus helps maintain blood volume. Oxytocin

causes contractions of the myometrium of the uterus to bring about labor and delivery.

2. Production of releasing hormones that stimulate secretion of the hormones of the anterior pituitary gland. An example is growth hormone–releasing hormone (GHRH), which stimulates the anterior pituitary to secrete growth hormone.
3. Regulation of body temperature by promoting responses such as shivering in a cold environment or sweating in a warm environment.
4. Regulation of food intake; the hypothalamus is believed to respond to changes in blood nutrient levels or chemicals secreted by adipose tissue and bring about feelings of hunger or fullness.
5. Integration of the functioning of the autonomic nervous system, which is covered in a later section.
6. Stimulation of visceral responses in emotional situations, such as increased heart rate when angry or afraid. The neurological basis of emotions is not well understood, but the hypothalamus brings about bodily changes by way of the autonomic nervous system.

Thalamus

The thalamus is above the hypothalamus and below the cerebrum; its functions are concerned with sensation. Sensory pathways (except olfactory ones) to the brain converge in the thalamus, which begins to integrate sensations, which in turn permits more rapid interpretation by the cerebrum. The thalamus is also capable of suppressing unimportant sensations, permitting the cerebrum to concentrate without the distraction of minor sensations.

Cerebrum

The two cerebral hemispheres form the largest part of the human brain. The right and left hemispheres are connected by the corpus callosum, a band of about 200 million nerve fibers that allows each hemisphere to know what is going on in the other.

The cerebral cortex is the surface of the cerebrum; it is gray matter that consists of the cell bodies of neurons. The cerebral cortex is folded extensively into convolutions (or gyri) that permit more space for neurons. The grooves between the folds are called fissures or sulci. Interior to the gray matter is white matter, myelinated axons and dendrites that connect the parts of the cerebral cortex to one another and the cerebrum to other parts of the brain. The cerebral cortex is divided into lobes, whose functions have been extensively mapped.

The frontal lobes contain the motor areas that generate the impulses that bring about voluntary movement. Each motor area controls movement on the opposite side of the body. Also in the frontal lobe, usually only the left lobe, is Broca's motor speech area, which controls the movements involved in speaking.

The parietal lobes contain the general sensory areas for the cutaneous senses and conscious muscle sense. This is where these sensations are felt and interpreted.

The temporal lobes contain sensory areas for hearing, smell, and taste. Also in the temporal and parietal lobes, usually only on the left side, are speech areas involved in the thought that precedes speech.

The occipital lobes contain the visual areas that receive impulses from the retinas of the eyes; they "see" and interpret what is being seen.

In all lobes of the cerebral cortex are association areas that enable us to learn, remember, and think and probably give us our individual personalities. These have not yet been as precisely mapped as the sensory and motor areas.

Deep within the white matter of the cerebral hemispheres are masses of gray matter called the basal ganglia. Their functions are concerned with certain subconscious aspects of voluntary movement: regulation of muscle tone, inhibiting tremor, and use of accessory movements such as gestures when speaking.

Meninges and Cerebrospinal Fluid

The meninges are the three layers of connective tissue that cover the central nervous system. The outermost is the dura mater, made of thick, fibrous connective tissue. The middle layer is called the arachnoid membrane, which has a web-like appearance, and the inner layer is the pia mater, very thin connective tissue on the surface of the brain and spinal cord. Between the arachnoid membrane and the pia mater is the **subarachnoid** space, which contains cerebrospinal fluid.

subarachnoid: sub—below + arachnoid—middle layer of the meninges

Each of the four ventricles of the brain contains a choroid plexus, a capillary network that forms cerebrospinal fluid from blood plasma. This is a continuous process, and the cerebrospinal fluid then circulates from the ventricles to the central canal of the spinal cord and to the subarachnoid spaces around the brain and spinal cord. From the cranial subarachnoid space, cerebrospinal fluid is reabsorbed back to the blood through arachnoid villi that project into the cranial venous sinuses, large veins between the two layers of the cranial dura mater. The rate of reabsorption usually equals the rate of production.

As the tissue fluid of the CNS, cerebrospinal fluid permits the exchanges of nutrients and wastes between the blood and CNS neurons. It also acts as a cushion or shock absorber for the CNS. The pressure and constituents of cerebrospinal fluid may be determined by means of a lumbar puncture (spinal tap) and may be helpful in the diagnosis of diseases such as meningitis.

Cranial Nerves

The 12 pairs of cranial nerves emerge from the brainstem or other parts of the brain; some are purely sensory nerves, whereas others are mixed nerves. The impulses for sight, smell, hearing, taste, and equilibrium are all carried by cranial nerves to their respective sensory areas in the brain. Other cranial nerves carry motor impulses to muscles of the face or to glands. The functions of all the cranial nerves are summarized in Table 45-2.

Autonomic Nervous System

The ANS is part of the peripheral nervous system in that it consists of the motor portions of some cranial and spinal nerves. These are the visceral motor neurons to visceral effectors—that is, smooth muscle, cardiac muscle, and glands. The ANS has two divisions, sympathetic and parasympathetic; often they function in opposition to each other, and their activity is integrated by the hypothalamus.

An autonomic nerve pathway from the CNS to a visceral effector consists of two motor neurons that synapse in a ganglion outside the CNS (Fig. 45-5). The first neuron is called the preganglionic neuron, from the CNS to the ganglion. The second neuron is called the postganglionic neuron, from the ganglion to the visceral effector. The ganglia are actually the cell bodies of the postganglionic neurons.

Sympathetic Division

The cell bodies of the sympathetic preganglionic neurons are in the thoracic and some of the lumbar segments of the spinal cord. The axons of these neurons extend to the sympathetic ganglia, most of which are in two chains just outside the spinal column. Within the ganglia are the synapses between the preganglionic and postganglionic neurons; the axons of the postganglionic neurons then go to the visceral effectors. One preganglionic neuron often synapses with many postganglionic neurons to many effectors; this permits widespread responses in many organs.

TABLE 45-2 CRANIAL NERVES

Number	Name	Function
I	Olfactory	Sense of smell
II	Optic	Sense of sight
III	Oculomotor	Movement of eyeball; constriction of pupil for bright light or near vision
IV	Trochlear	Movement of eyeball
V	Trigeminal	Sensation in face, scalp, and teeth; contraction of chewing muscles
VI	Abducens	Movement of eyeball
VII	Facial	Sense of taste; contraction of facial muscles; secretion of saliva
VIII	Vestibulocochlear	Sense of hearing; sense of equilibrium
IX	Glossopharyngeal	Sense of taste; secretion of saliva; sensory for cardiac, respiratory, and blood pressure reflexes; contraction of pharynx
X	Vagus	Sensory in cardiac, respiratory, and blood pressure reflexes; sensory and motor to larynx (speaking); decreases heart rate; contraction of alimentary tube (peristalsis); increases digestive secretions
XI	Accessory	Contraction of neck and shoulder muscles; motor to larynx (speaking)
XII	Hypoglossal	Movement of the tongue

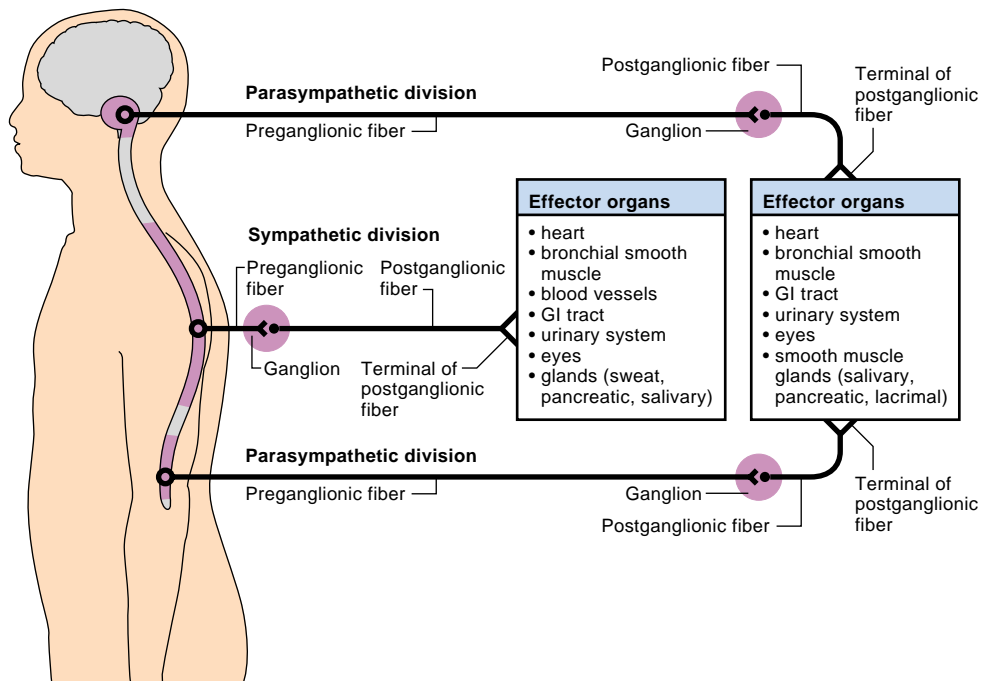

Figure 45-5 Autonomic nervous system. (Modified from Morton, PG: Health Assessment on Nursing, ed 2. FA Davis, Philadelphia, p 467, with permission.)

The sympathetic division is dominant in stressful situations such as fear, anger, anxiety, and exercise, and the responses it brings about involve preparedness for physical activity, whether or not it is actually needed. (Table 45-3 summarizes both ANS divisions.) The heart rate increases, vasodilation in skeletal muscles supplies them with more oxygen, the bronchioles dilate to take in more air, and the liver changes glycogen to glucose to provide energy. Relatively unimportant activities such as digestion are slowed, and vasoconstriction in the skin and viscera permits greater blood flow to more vital organs such as the brain, heart, and muscles.

The neurotransmitters of the sympathetic division are acetylcholine and norepinephrine. Acetylcholine is released by sympathetic preganglionic neurons; its inactivator is cholinesterase. Norepinephrine is released by most sym-

pathetic postganglionic neurons at the synapses with the effector cells; its inactivator is catechol O-methyltransferase.

Parasympathetic Division

The cell bodies of the parasympathetic preganglionic neurons are in the brainstem and the sacral segments of the spinal cord. The axons of these neurons are in cranial nerve pairs 3, 7, 9, and 10 and in some sacral nerves, and they extend to the parasympathetic ganglia. These ganglia are close to or actually in the visceral effector and contain the postganglionic cell bodies, with very short axons to the cells of the visceral effector. One preganglionic neuron synapses with just a few postganglionic neurons to only one effector. This permits localized responses.

The parasympathetic division dominates during relaxed, nonstressful situations to promote normal functioning of

TABLE 45-3 FUNCTIONS OF THE AUTONOMIC NERVOUS SYSTEM

Organ	Sympathetic Response	Parasympathetic Response
Heart (cardiac muscle)	Increase rate	Decrease rate (to normal)
Bronchioles (smooth muscle)	Dilate	Constrict (to normal)
Iris (smooth muscle)	Pupil dilates	Pupil constricts (to normal)
Salivary glands	Decrease secretion	Increase secretion (to normal)
Stomach and intestines (smooth muscle)	Decrease peristalsis	Increase peristalsis for normal digestion
Stomach and intestines (glands)	Decrease secretion	Increase secretion for normal digestion
Internal anal sphincter	Contract to prevent defecation	Relax to permit defecation
Urinary bladder (smooth muscle)	Relax to prevent urination	Contract for normal urination
Internal urethral sphincter	Contract to prevent urination	Relax to permit urination
Liver	Change glycogen to glucose	None
Sweat glands	Increase secretion	None
Blood vessels in skin and viscera (smooth muscle)	Constrict	None
Blood vessels in skeletal muscle (smooth muscle)	Dilate	None
Adrenal glands	Increase secretion of epinephrine and norepinephrine	None

several organ systems. Digestion proceeds normally, with increased secretions and peristalsis; defecation and urination may occur, and the heart beats at a normal resting rate. (See Table 45-3.)

LEARNING TIPS

Sympathetic—S for STRESS RESPONSE: The autonomic nervous system is a primitive response that affected early humans automatically and involuntarily, thus increasing the likelihood of surviving in the wilderness. It is often referred to as the fight-or-flight response. When you think of the sympathetic nervous system, think about getting away from a man-eating lion: You need dilated pupils to see the path better; copious production of sweat to provide the body lubrication in case you need to run between two tight trees or stones; increased rate and force of heartbeat to ensure that enough blood gets to the extremities so you can run faster; dilated bronchioles to get more oxygen to your muscles; decreased digestion so you won't get hungry while you are trying to get away from the lion; decreased urine output so you won't have to stop for the restroom; and increased mental alertness so you are always aware of where the lion is.

Parasympathetic—P for PARACHUTE or PEACEFUL: The parasympathetic nervous systems brings the body back to balance and rest. It is sometimes referred to as the rest-and-digest response. Think, *I just got away from a man-eating lion, now my body can go back to normal and start digesting and urinating again!*

This is a great way to remember the responses, rather than an accurate description of the physiology involved.

Acetylcholine is the neurotransmitter at all parasympathetic synapses, both preganglionic and postganglionic; it is inactivated by cholinesterase.

Aging and the Nervous System

With age the brain loses neurons, but this is only a small percentage of the total and is not the usual cause of mental impairment in the elderly; far more common causes are depression, malnutrition, hypotension, and the side effects of medications. Some forgetfulness is to be expected, however, as is a decreased ability for problem solving. Voluntary movements become slower, as do reflexes and reaction time (Table 45-4).

► NURSING ASSESSMENT OF THE NEUROLOGICAL SYSTEM

The focus of the nursing neurological assessment is to establish the present function of the patient's neurological system and to detect changes from previous assessments. A complete neurological assessment, intended to determine the existence of neurological disease, is typically performed by a physician or nurse practitioner. A baseline neurological assessment should be performed on every patient admission (Table 45-5). In addition to giving valuable information about the current functioning of the patient's neurological system, the assessment provides a basis for comparison. This is especially important if the patient has

TABLE 45-4 AGE-RELATED CHANGES AND CLINICAL IMPLICATIONS

Age-Related Change	Clinical Implications
Decreased blood flow to the brain	Increased risk of syncope, changes in some mental functions
Deposition of the aging pigment lipofuscin in nerve cells and amyloid in blood vessels	Impairment in cognition, reasoning, judgment, and orientation
Altered sleep patterns	Less sleep required and sleeping for shorter periods of time; increased sleep disturbances
Decreased vibratory sense	Equilibrium altered, leading to impaired gait
Decreased postural stability	Accidents and falls
Decreased reaction time	Greater time needed for patient responses and task performance
Progressive loss of dendrites with progression to fragmentation and cell death	Failing short-term memory

TABLE 45-5 BASIC NEUROLOGICAL ASSESSMENT

1. Assess level of consciousness (patient’s response to verbal or tactile stimulation) and orientation.
2. Obtain vital signs (specifically blood pressure, pulse, and respirations).
3. Check pupillary response to light.
4. Assess strength and equality of hand grip and movement of extremities.
5. Determine ability to sense touch or pain in extremities.

chronic neurological deficits on admission. One example is a patient, admitted for placement of a prosthetic hip, who has had a previous **cerebrovascular** accident resulting in **paresis** of the right arm. A complete neurological assessment would document that the right arm is weaker than the left. If during the postoperative course the assessment demonstrates that both arms are equal in strength, the patient would be evaluated for possible causes of weakening of the left arm.

The results of the baseline assessment are invaluable in planning and implementing safe care. For example, patients who give a history of seizure activity need careful monitoring, and all staff members who interact with such patients should be aware of how to respond to a seizure. Patients with **dysphagia** (difficulty swallowing) may need to have restrictions placed on the types of food or fluids they can have. This information must be consistently communicated to all staff who are involved in the patient’s care.

The patient’s admitting diagnosis, the presence of any chronic neurological disorders, and the current functioning of the patient’s neurological system all influence how often neurological assessments should be done. Physician or nurse

cerebrovascular: cerebro—brain + vascular—vessels
paresis: partial paralysis
dysphagia: dys—difficult + phagia—eating

practitioner orders for neurological assessments may vary from every 15 minutes for an acutely ill or injured patient, to every 8 hours for a patient who is close to being discharged, to every 24 hours for a resident living in long-term care. It is always appropriate to assess a patient more often than ordered, based on observed changes in the patient’s condition, and to communicate the findings of those assessments to the physician or nurse practitioner. The changes noted while assessing the patient may indicate changes in the central nervous system. Rapid detection and intervention may mean the difference between chronic dysfunction or recovery or even between life and death for the patient.

Subjective Data

To understand the patient’s neurological problems, ask about past and current symptoms; use of prescribed and over-the-counter medications; use of recreational drugs; surgeries; treatments; and risk factors such as family history, diet, exercise, sedentary lifestyle, caffeine intake, and recent stressors. Assessment of symptoms, as with other body systems, includes asking the **WHAT’S UP?** questions: *where* it is, *how* it is, *aggravating* and *alleviating* factors, *timing*, *severity*, *useful data* related to associated symptoms, and *perception* of the problem by the patient.

Health History

The nurse obtains a history of the patient’s general health and then focuses on the neurological symptoms. Symptoms of neurological disorders vary in type, location, and intensity. It is important to remember that some neurological disorders can affect the patient’s ability to think, remember, speak, or interpret stimuli. It may be necessary to question significant others about duration and severity of symptoms. Some patients may not be able to recognize their own neurological deficits. In these cases the significant other usually initiates contact with the health care system and provides the medical and social history. See Table 45–6 for sample questions to ask if the patient has a neurological problem.

TABLE 45-6 NEUROLOGICAL HEALTH HISTORY

Questions	Rationale
Assessment of a Symptom: WHAT’S UP? Format	
Where is the symptom, sensation, or lack of sensation? Does it radiate? Is it unilateral or bilateral?	Location of the symptom helps determine its cause.
How does it feel? Painful, achy, tingly, or numb? Some patients may use phrases such as “pins and needles in my arm” or “it feels like my leg is asleep” to describe paresthesia. Nerve pain may be described as “shooting” or “burning.”	These symptoms may be associated with strokes, spinal cord injury, neuromuscular disorders, or other neurological problems.
Aggravating/alleviating factors: Does exercise or fatigue make it worse? Does rest help? Do applications of ice or heat help relieve symptoms? Do changes in the weather have an impact?	Paresis or tremors are more pronounced if the patient is fatigued. Patients with multiple sclerosis may have exacerbations of symptoms in extreme weather.
Timing: How long has the patient had symptoms? Have the symptoms changed? Have they moved or spread to another part of the body? Are particular times of the day better or worse?	Patients with multiple sclerosis may experience symptoms that change in location or intensity. Patients with back or neck pain may complain of stiffness in the morning or increased pain after exertion.
Severity: How severe are the symptoms on a scale of 0 to 10? How do the symptoms affect the patient’s lifestyle, job, community service, and ability to carry out ADLs?	Elderly patients may be severely compromised by relatively mild deficits. Patients may be unable to stand up and walk long enough to shop for groceries or clean their house.

TABLE 45-6 NEUROLOGICAL HEALTH HISTORY — CONT'D

Questions	Rationale
Assessment of a Symptom: WHAT'S UP? Format	
Useful other data: Is the patient on medication? Does the patient have any other illnesses?	Some medications may cause neurological symptoms. Some neurological disorders can be complications of other illnesses, such as diabetic neuropathy.
Patient's perception: How do symptoms affect personal relationships and family obligations? What is the impact of the disorder on the patient's significant others, especially if they are the patient's caregivers?	Patients may need encouragement to discuss the impact of hemiparesis on sexual function or the effect of memory impairment on family relationships and roles. Patients with cognitive deficits may fear that they have Alzheimer's disease or are "going crazy."
Level of Consciousness (LOC)	
What is the patient's LOC based on the Glasgow Coma Scale?	The GCS determines the patient's level of responsiveness to stimuli. Changes in LOC can result from a variety of central nervous system problems.
Mental Status	
Ask: What is your name? What is the month? Year? Where are you now? Why are you here?	Disorientation is often an initial sign of a neurological disorder.
Are the patient's appearance and behavior, including dress, grooming, posture, gestures, facial expression, and motor activity, appropriate?	Appearance and behavior may be inappropriate to the situation in some neurological disorders.
Intellectual Function	
Can the patient count backward from 100 or subtract 7 from 100, then 7 from that answer, and so on (serial 7s)?	Most people with intact neurological function can complete serial 7s in about 1½ minutes.
Can the patient to interpret a proverb, such as "People who live in glass houses shouldn't throw stones"?	Ability to interpret a proverb indicates abstract reasoning ability. An answer such as "You might break a window" indicates concrete thinking.
Thought Content	
Are the patient's thoughts spontaneous, clear, relevant and coherent? Does the patient have any fixed ideas, illusions, or preoccupations? What are the patient's insights into these thoughts?	Preoccupation with death or morbid events, evidence of hallucinations, and paranoid ideation are all important and require further evaluation.
Emotional Status	
Are mood and affect natural and even, or irritable, angry, anxious, apathetic, or euphoric? Are they appropriate to the situation? Does the patient's mood fluctuate normally, or does it swing from joy to sadness during the interview? Is affect appropriate to words and thought content? Is verbal communication consistent with nonverbal cues?	Emotional lability may be indicative of stroke, decreased LOC, brain tumor, or other neurological disorders.
Perception	
Can the patient identify objects correctly or identify objects functions? For example, have patient identify a pencil and what it is used for.	Agnosia (inability to interpret or recognize familiar objects) can occur in cerebral vascular accidents and brain lesions.
Motor Ability	
Can the patient throw a ball, move a chair, walk in a straight line? Is the patient's motor strength equal bilaterally and appropriate? Can the patient move all extremities?	Failure to perform these tasks suggests cerebral dysfunction. Paralysis (inability to move extremity) may suggest stroke or spinal cord injury.
Language Ability	
Does the patient answer questions appropriately? Can the patient read a sentence from a newspaper and explain its meaning? Can the patient write his or her name?	Different types of aphasia can result from injury to different parts of the brain.

hemiparesis: hemi—divided in half on a vertical plane + paresis—weakness

In addition to using these questions, the nurse observes the patient during the health history. Is he or she shifting positions and exhibiting signs of discomfort? Is the patient able to change position and move about easily? Is he or she able to carry on a coherent conversation?

Physical Assessment

The physical assessment of the patient begins when you first meet the patient and make an overall evaluation of the patient's mental and physical status. The neurological system is assessed using inspection, palpation, and percussion (with

a reflex hammer). When conducting the mental status and cognitive portions of the assessment, be aware that fatigue or illness may alter findings. When interpreting findings consider the patient's age, educational background, and cultural orientation.

Level of Consciousness

The level of consciousness exists along a continuum from full wakefulness, alertness, and cooperation, to unresponsiveness, to any form of external stimuli. A fully conscious patient responds to questions spontaneously. As consciousness becomes impaired, a patient may show irritability, a shortened attention span, or an unwillingness to cooperate. The level of consciousness should be the first thing assessed during a neurological examination because the information obtained can be used to modify the remainder of the examination if necessary. Keep in mind that a decrease in the level of consciousness can be caused by hypoxia, hypoglycemia, intoxication, or other problems, as well as dysfunction of the neurological system.

Many health care institutions use the Glasgow Coma Scale (GCS), which is an international scale used to assess level of consciousness (LOC) and document findings (Table 45-7). The GCS is based on simple and clearly defined parameters of patient responses that provide for consistent assessment data. It is used to evaluate patients who have a potential for rapid deterioration in consciousness. The GCS assesses three parameters of consciousness: eye opening, verbal response, and motor response.

The first section of the GCS evaluates the stimulus needed to get patients to open their eyes. Individuals with normal neurological function open their eyes spontaneously (score of 4). People with mildly decreased LOC require verbal stimuli, such as calling out the patient's name or asking the patient to open his or her eyes (score of 3). The nurse should not confuse this response with patients who open their eyes to any loud noise. That is a reflex and indicates a lower level of consciousness. A lower level of consciousness is indicated by eye opening in response to painful stimuli (score of 2). Pressure on the nailbed or trapezius muscle are

two common ways of providing a painful stimulus. Care must be taken not to damage or bruise the skin or underlying tissue. Only enough pressure to elicit a response should be used. If no response is noted, the patient receives a score of 1 for this section of the GCS.

Some patients may be unable to open their eyes because of facial trauma or swelling. This should be recorded as "C," indicating eyes closed, rather than "1" for no response. Physical inability to open the eyes does not indicate a decreased level of consciousness.

The second section of the GCS addresses verbal response to the examiner. Orientation refers to the patient's cognitive awareness. Patients are often referred to as being oriented to person, place, and time, or "oriented times 3." Some clinicians include a fourth category, situation, indicating whether the patient understands what is happening to her or him. A patient who is fully oriented receives a score of 4 on the GCS. Assessment of orientation should not be superficial. Typical questions include "What is your name? Where are you? What day is it?" (Keep in mind that we all forget the date from time to time!) Patients may be able to recall the name of the hospital and the day but have no idea why they are in the hospital. Remember, a resident of a nursing home may consider the facility his or her home and is not necessarily considered disoriented. Be sure your question is appropriate to the patient's living conditions and lifestyle. If the patient is unable to speak because of a stroke (expressive **aphasia**), do not rule out the possibility that the patient is oriented. Give expressively aphasic patients yes-or-no questions such as "Are you in a grocery store? Are you in a bowling alley? Are you in a hospital?" and "Is the month June? Is it September?" Patients can answer with a shake of the head or blinks or hand squeezes, as instructed. Patients who are unable to understand what is being said to them are referred to as **receptively aphasic**. These patients may be able to match a spoken name with a picture of a family member.

Confusion and **disorientation** are terms that are sometimes used interchangeably. If the patient is confused, it is helpful to determine the extent of the confusion. Patients who have been in a hospital or long-term care facility for an extended period may lose track of the date but still be oriented to person and place. A patient who can tell the nurse the year and who is president but not the precise date is less confused than someone who thinks it is 1945 and Franklin Roosevelt is president. Patients who are acutely disoriented should have the correct information reinforced for them frequently. A calendar in an easily visible place, telling patients about current events in the family, and telling patients the date and why they are in the hospital or long-term care facility all reinforce orientation. Patients with short-term memory deficits may understand the information they are told but be unable to retain it long enough to use it.

TABLE 45-7 GLASGOW COMA SCALE

Eye Opening	Spontaneous	4
	To verbal stimulus	3
	To painful stimulus	2
	No response	1
Verbal Response	Spontaneous	5
	Confused conversation	4
	Inappropriate words	3
	Incomprehensible sounds	2
Motor Response	No response	1
	Obeys commands	6
	Localizes pain	5
	Withdraws from pain	4
	Abnormal flexion	3
	Abnormal extension	2
No response	1	

aphasia: a—absence + phasia—speech

LEARNING TIPS

A resident or patient who is chronically disoriented should not be continually reoriented because he or she may become frustrated, anxious, or angry.

A GCS score of 3 is given to patients who are not able to carry on a conversation and are limited to using words inappropriately. This includes those patients who spontaneously call out words that do not have meaning in that situation or who merely call out profanities at random. Incomprehensible sounds are those vocalizations that are not recognizable as words, and these patients are given a score of 2. Again, a score of 1 is given for no response. Patients who are intubated or have a tracheostomy should not automatically be scored as having no response. Head nodding, mouthing words, or using a picture board are all ways for intubated patients to respond to questions and have their orientation status assessed.

Typically, motor response is scored based on the best arm function that can be elicited. For some patients this part of the examination must be modified. A patient who is paralyzed may be able only to blink. If the patient can blink on command, that is scored as “6, obeys command.” Patients may be unable to use their arms but have voluntary movement of their legs. If these patients follow commands with their legs, they receive a score of 6.

Localizing pain indicates that the patient has an adequate level of consciousness to recognize where the pain is

coming from and to attempt to push it away. An example is the patient who pushes against the your hand when pressure is applied to the patient’s nailbed. The ability to localize pain is scored as a 5. Withdrawal from pain indicates less function of the cerebral cortex. In this case the patient is able to recognize the source of the painful stimuli but withdraws from it instead of trying to push the source away. This withdrawal is rated as a 4. Abnormal flexion posturing, characterized by flexion of the arms at the elbow, bringing the hands up toward the chest with the legs extended (**decorticate** posturing; Fig. 45–6A), indicates significant impairment of the cerebral functioning. A score of 3 is given to patients who exhibit abnormal flexion posturing. Abnormal extension posturing, or **decerebrate** posturing, indicates damage in the area of the brainstem (Fig. 45–6B). In this case, both the upper and lower extremities are extended and the arms are internally rotated. Abnormal extension posturing is scored as a 2. As with the other categories, no response is rated as 1.

The total possible score on the GCS ranges from 3 to 15. A score of less than 7 indicates a comatose patient and a score of 15 indicates the patient is fully alert and oriented. When used to score the effects of a head injury, a score of 13 or 14 indicates mild head injury, 9 to 12 indicates moderate injury, and any score of 8 or below indicates severe head injury. For all the categories of the GCS, the type of painful stimuli required to elicit a response should be documented. Deterioration in the patient’s condition (i.e., a lowering of the GCS score) should be reported to the physician promptly. Changes in GCS are often used as an indication of the need for intracranial pressure monitoring.

A. Decorticate posturing

B. Decerebrate posturing

Figure 45-6 Abnormal posturing.

Mental Status

You can learn a great deal about a patient's mental capacities and emotional state by simply interacting with the patient. The mental status examination consists of observing the patient's verbal and nonverbal responses to questions and specific requests. Behavior, moods, hygiene, grooming, and choice of dress reveal pertinent information about mental status. Question the patient to determine the patient's cognitive functioning, thought processes, and perceptions.

Assessment of the Eyes

Assessment of pupillary response is an important part of the recurrent neurological assessment, as well as the cranial nerve evaluation. The size of the pupils at rest is documented. Many institutions use a millimeter gauge for measuring pupils. This allows an objective description of the size. If the patient's pupils are unusually large or small, you should determine if the patient has had any eyedrops instilled or has taken any medications that might affect the size of the pupils. Approximately 17 percent of people have unequal pupils (**anisocoria**) without any underlying pathological condition. If the patient's pupils are unequal in size, without a correlating diagnosis or symptoms, ask the patient or his or her significant others if this is the patient's normal state. Development of unequal pupils in a patient who previously had equal pupils is an emergency and should be reported to the physician immediately. Any deviation from the normal round shape of the pupils is documented.

Once the resting size of the pupils has been noted, the next step is to assess their response to light. In a darkened room, a light source (such as a flashlight) is directed at the pupil from the lateral aspect of the eye. This allows the examiner to see the direct and the consensual response. A consensual response means that when one pupil is exposed to direct light the other pupil also constricts. Absence of a consensual response may indicate a pathological condition in the area of the optic chiasm. Typically the speed of light reaction is rated as brisk, sluggish, or absent. Differences in the speed or size of constriction between the two pupils should be reported to the practitioner.

Accommodation refers to the patient's ability to focus on an object as it moves closer. Ask the patient to watch the your finger as you hold it about 18 inches in front of the patient's face. As you move the finger toward the patient's face, the patient's eyes should turn toward the midline and the pupils should constrict. It is important to remember that only patients who can follow commands can be assessed for accommodation.

The eyes are evaluated for limitations in range of motion and for smoothness and coordination of movements. Eyes that move in the same direction in a coordinated manner are said to have a conjugate gaze. Conversely, a dysconjugate gaze is movement of the eyes in different directions. Some patients may be unable to move one or both eyes in a

specific direction; this is called ophthalmoplegia. It is often documented as "limited extraocular movements." Always document what the limitation is (e.g., "Patient is unable to look laterally with left eye"). This allows colleagues to compare their findings with yours and detect any changes.

Nystagmus is involuntary movement of the eyes. Nystagmus varies in the speed of the movement and the direction. Horizontal nystagmus is the most common. Common causes of nystagmus are phenytoin (Dilantin) toxicity and injury to the brainstem.

Assessment of Muscle Function

After assessment of level of consciousness, mental status, and pupillary response, prepare to evaluate muscle function. Muscle groups are compared for symmetry of size and strength. Compression of a specific nerve root may cause atrophy and weakness of the corresponding muscle (e.g., C5–6 compression leading to atrophy and weakness of the biceps).

Assess muscle groups systematically in the upper extremities and then the lower extremities, comparing right to left. The patient's age and general physical condition should be kept in mind when evaluating muscle strength. One does not expect the same amount of strength from a 75-year-old woman as from a 20-year-old man. If the patient has chronic neurological deficits, ask if the results of the assessment are different from his or her usual functioning.

Many health care providers use a 5-point scale to document muscle strength. A score of 5 indicates a patient who is able to move the extremity against gravity and the resistance of the examiner, displaying normal muscle strength. If the examiner is able to provide more resistance than the patient can overcome with active movement, the score is 4. If the patient is able to move the extremity only against gravity, but not resistance, the score is 3. If gravity must be eliminated by having the examiner support the extremity to allow the patient to move the extremity, the score is 2. A score of 1 is given if there is no active movement of the extremity, but a minimum muscular contraction can be palpated. If the examiner is unable to detect any muscular function, a score of 0 is given.

To test the deltoids, ask the patient to raise his or her arms at the shoulder. Have the patient resist as you push down on the upper arms. The biceps are tested by having the patient flex the arm at the elbow and bring the palm toward the face, then resist as you attempt to straighten the arm by pulling on the forearm. Tell the patient to "make a muscle." With the arm similarly flexed, ask the patient to straighten the arm while you resist the movement.

Hand grasps are tested by having the patient squeeze your fingers. Remember to cross your index and middle fingers to prevent the patient from hurting your fingers. If the patient does not release the grasp when told to, it is a reflex grasp, not a response to command. A reflex palmar grasp may indicate a pathological condition of the frontal lobe.

Assess the patient for arm drift by asking the patient to hold both arms straight in front with the palms upward while keeping the eyes closed. A downward drift of the arm,

or rotation so that the palm is down, indicates impairment of the opposite side of the brain. If a pathological condition is present, arm drift may be apparent before differences in muscle strength can be detected.

Assessment of leg muscle strength begins with the iliopsoas muscle. Place your hand on the patient's thigh and ask the patient to raise the leg, flexing at the hip. Hip adductors are tested by having the patient bring his or her legs together against your hands. The hip abductors and gluteus medius and minimus are tested by having the patient move the legs apart against resistance. Hip extension by the gluteus maximus is tested by placing the hand under the thigh and having the patient push down with the leg. The quadriceps femoris extends the knee and is tested by having the patient attempt to straighten the leg at the knee. The hamstrings are responsible for knee flexion and are evaluated by having the patient attempt to keep the heel of the foot against the bed or chair rung. Dorsiflexion is tested by having the patient pull the toes toward the head. Plantar flexion is tested by having the patient push against the examiner's hand with the ball of the foot.

Babinski's reflex is tested by stroking the sole of the foot. Normal response is flexion of the great toe. If the great toe extends and the other toes fan out, neurological dysfunction should be suspected if the patient is more than 6 months old. Deep tendon reflexes are not usually part of the nursing neurological assessment. The patient's gait should be assessed to detect any neurological dysfunction and also to assess ability to ambulate safely. Patients who stagger, weave, or bump into objects may need assistance when out of bed.

Romberg's test is performed by having the patient stand with feet together and eyes closed. Be sure to stand close to the patient, especially if he or she is an older adult, to prevent falling. A negative Romberg's test means that the patient experiences minimal swaying for up to 20 seconds. A patient who experiences swaying or who leans to one side is said to have a positive Romberg's test. A positive Romberg's test may be seen in cerebellar dysfunction.

LEARNING TIPS

A positive Romberg's test in an older adult is expected as a result of the normal aging changes of the cerebellum.

Assessment of Cranial Nerves

The cranial nerves are usually not examined in depth during routine bedside neurological assessment. The following recommendations assume a patient who is able to cooperate with the examiner and are intended to give a superficial assessment of cranial nerve function. The olfactory nerve can be tested by asking the patient to identify common scents such as coffee or cinnamon. The optic nerve can be assessed by asking the patient to read something, identify a picture, or tell you how many fingers you are holding up. Check the pupils for consensual reaction to light, indicating function

of the oculomotor nerve. Evaluate extraocular movements by asking the patient to follow your finger while it is moved in front of the patient's eyes. Extraocular movements are controlled by the oculomotor, trochlear, and abducens nerves. Lightly touching different parts of the face with a tissue tests the trigeminal nerve for decreased sensation. Evaluate the face for symmetry at rest and during movement. Asking the patient to frown, smile broadly, and wrinkle the forehead tests the facial nerve. Conversing with the patient gives a basic evaluation of the auditory portion of the vestibulocochlear, or acoustic, nerve. Dysfunction of the acoustic nerve may also cause difficulties with balance, which may be observed as the patient ambulates. Typically the glossopharyngeal and vagus nerves are tested together by assessing the gag reflex and by asking the patient to say "Ah." The spinal accessory nerve is assessed by asking the patient to shrug the shoulders against resistance. Ask the patient to stick out the tongue and move it from side to side. Evaluate for symmetry of size and movement as an indication of function of the hypoglossal nerve.

LEARNING TIPS

The cranial nerves are easier to remember when a mnemonic device is used:

On	Olfactory
Old	Optic
Olympus	Oculomotor
Towering	Trochlear
Top	Trigeminal
A	Abducens
Finn	Facial
And	Acoustic
German	Glossopharyngeal
Viewed	Vagal
Some	Spinal accessory
Hops	Hypoglossal

In all cases the findings of the neurological examination should be correlated with the remainder of the assessment findings. A decreased level of consciousness, coupled with a decreased oxygen saturation on pulse oximetry, point to hypoxia as a cause. Correlation of vital signs with neurological

CRITICAL THINKING

Tim Thompson

You are caring for Tim, a 78-year-old man admitted with heart problems. As you enter his room with his afternoon medications, you find him confused. He thinks he is at home, that the year is 1968, and does not understand who you are or why you are there. He recognizes his wife, who is at his bedside, and knows his own name.

1. How would you describe and document his mental status?
2. What additional data do you need to decide how to proceed?
3. What may have contributed to his confusion?

Answers at end of chapter.

signs is particularly important. Bradycardia, increasing systolic blood pressure, and widening pulse pressure, commonly referred to as Cushing's response, are late indications of increasing intracranial pressure. These findings, in conjunction with a unilateral dilated pupil, may indicate impending herniation of the brain (discussed further in Chapter 46).

► DIAGNOSTIC TESTS

Laboratory Tests

Specific diagnostic blood tests do not exist for neurological disorders. Measurement of erythrocyte sedimentation rate (ESR) and white blood cell (WBC) count may indicate an infection, such as meningitis. Hormone levels, such as prolactin or cortisol, may indicate dysfunction of the pituitary gland related to a brain tumor.

Lumbar Puncture

Cerebrospinal fluid may be obtained via lumbar puncture and evaluated for glucose and protein levels, presence of bacteria and white blood cells, levels of immunoglobulin, and culture and sensitivity. Cerebrospinal fluid samples should be sent to the laboratory immediately following the procedure.

LEARNING TIPS

The idea of a needle being introduced into the spinal canal is frightening to many people. Give simple, clear directions to the patient; help the patient maintain his or her position; and provide emotional support throughout the procedure.

Typically the lumbar puncture needle is placed at the level of L3–4 or L4–5 in an adult. Because the spinal cord ends at the L1 level, this placement prevents damage to the cord by the needle. If there is any difficulty inserting the needle, this may be done under fluoroscopy to help guide needle placement.

Nursing Care

Informed consent is obtained prior to the procedure. Assist the patient into a side-lying position with his or her back as close to the edge of the bed nearest the practitioner as possible. Depending on the patient's condition, you may need to help the patient flex his or her knees up to the chest (Fig. 45–7). This position maximizes the space between the vertebrae, which makes it easier for the physician or nurse practitioner to insert the needle. An alternative position is to have the patient sit with the back perpendicular to the edge of the bed. Leaning over a bedside table may help the patient maintain the position.

After the lumbar puncture is completed, instruct the patient to remain on bedrest with the head of the bed flat for 6 to 8 hours, as ordered by the physician, and to increase oral intake of fluids. Keeping the head flat decreases the likelihood of leakage of cerebrospinal fluid from the puncture site, which can result in a severe headache. Increasing fluid intake promotes replacement of the fluid that was removed. Check the puncture site for leakage of cerebrospinal fluid and report any leakage to the physician or nurse practitioner. Assess the patient for headache and if necessary obtain an order for analgesia. Label and send the specimens to the laboratory as ordered.

Figure 45-7 Position for lumbar puncture.

X-ray Examination

Spinal x-ray examinations are done to determine the status of individual vertebrae and their relationship to one another. If the patient experiences pain with certain movements, he or she may be asked to flex and extend the area of the spine being examined while the radiographs are taken. This allows detection of abnormal movement of the vertebrae. If the patient has possibly sustained trauma to the spine, particularly the cervical spine, radiographs are taken before immobilizing devices are removed. Skull radiographs may be taken to detect skull fractures or foreign bodies. No special nursing care is required.

Computed Tomography

A computed tomography (CT) scan is commonly the test ordered if the patient initially consults a general practitioner. CT scans for the purpose of diagnosing neurological disorders can be performed on the brain or the spine. Some of the disorders that can be detected by CT are tumors, skull fractures, and abscesses. The scan may be performed with or without radiopaque contrast material to enhance the clarity of the images that are recorded. If contrast material is used, a series of images is filmed and then the contrast material is given intravenously and another series of images is filmed. The patient should be questioned about any allergies to contrast material, iodine, or shellfish. The blood urea nitrogen (BUN) and creatinine levels should be checked before administration of contrast material because it is excreted through the kidneys. Patients with elevated BUN and creatinine or known renal disease may be unable to tolerate the contrast material. Contrast material is most commonly used if a tumor is suspected or following surgery in the area to be scanned. CT scans are commonly used in emergency evaluations because they can be done quickly, an important consideration if the patient is ventilated or unstable.

Nursing Care

During the CT scan, the patient must lie still on a moveable table. Noncontrast scans take approximately 10 minutes; contrast scans take between 20 and 30 minutes. Patients who are receiving dye should be warned that they may feel a sensation of warmth; warmth in the groin area may make them feel as though they have been incontinent of urine. Nausea, diaphoresis, itching, and difficulty breathing may indicate allergy to the dye and should be reported immediately to the physician or nurse practitioner. Sedation may be required for patients who are agitated or disoriented. Patients who are in pain may require pain medication before the examination.

Magnetic Resonance Imaging

Magnetic resonance imaging (MRI) gives a more detailed picture of soft tissue than a CT scan. It is not as useful when looking for bony abnormalities. MRI is a longer procedure and commonly requires transportation to distant areas of

the hospital, which may be problematic for unstable, disoriented, or ventilated patients. As with a CT scan, the MRI can be done with or without contrast material. Some facilities have the capability to perform magnetic resonance angiograms (MRA). This test allows visualization of blood vessels and assessment of blood flow without being as invasive as a traditional angiogram.

Nursing Care

Because of the magnetic fields being used, there are restrictions placed on patients undergoing an MRI and the health care personnel who work within the MRI facility. Individuals with pacemakers or any type of metallic prosthesis are not able to undergo MRI or be in the room when one is performed. This is because the magnetic field is so strong that it could dislodge the prosthesis or pacemaker. Patients are asked to remove all metal objects, such as jewelry or hair clips, before the procedure. Individuals who may have accidentally acquired metallic foreign bodies (e.g., metal slivers in the eye or shrapnel that was not removed) may need an x-ray examination to determine the presence or absence of such objects. Carefully question patients or their significant others regarding any possible contraindications. MRI is commonly used when herniated intravertebral disks are suspected. It may be difficult for the patient to lie in one position for a prolonged period. The patient's need for pain medication should be assessed before the procedure. Use of pillows for positioning may improve comfort. The narrow, tunnel-like structure of the MRI unit causes claustrophobia in some patients; some patients may require use of sedatives or open MRI units. Encourage the use of deep breathing, guided imagery, and other relaxation techniques.

Angiogram

Angiogram is an x-ray study of blood vessels that is used when an abnormality of cerebral or spinal blood vessels is suspected or to obtain information about blood supply to a tumor. Following injection of a local anesthetic, a catheter is inserted through the femoral artery and advanced until contrast material can be injected into the cerebral vessels. The dye then shows the vessels on the radiograph and provides information about the structure of specific vessels, as well as overall circulation to the area.

Nursing Care

Before an angiogram, the patient receives a clear liquid diet and has an intravenous needle in place. Informed consent must be obtained. BUN and creatinine levels are evaluated because the contrast material is excreted through the kidneys. Potential for bleeding is assessed by prothrombin time and partial thromboplastin time tests because a puncture is being made in a large artery. Typically the patient receives some type of sedation before being transported to the angiography suite. During the injection of the contrast material, the patient may complain of severe heat sensations and a metallic taste in the mouth. The patient must lie still

while the radiographs are being taken and so should be told about the sensations he or she may experience. Patients who are disoriented or agitated may require sedation to complete the test.

Following the procedure, pressure is maintained on the catheter insertion site and the patient is kept flat in bed for 6 to 8 hours to prevent bleeding from the insertion site. The patient may turn from side to side but must keep the affected leg straight. In addition to assessing vital signs, the nurse evaluates the catheter insertion site and the presence and quality of the popliteal and pedal pulses in the affected leg. Decrease or loss of the pedal pulse may indicate a clot in the femoral artery and should be reported to the physician immediately. Patients should be encouraged to increase oral intake in addition to the intravenous fluids that are administered to aid in the excretion of the contrast material.

Myelogram

A **myelogram** is an x-ray examination of the spinal canal and its contents. Following a lumbar puncture, cerebrospinal fluid is removed and sent for laboratory analysis. Contrast material is then injected into the subarachnoid space. The patient is moved into various positions and radiographs are taken. Compression of nerve roots, herniation of intravertebral disks, and blockage of cerebrospinal fluid circulation may all be detected by myelogram.

Nursing Care

Following the procedure the patient is kept on bedrest with the head elevated. This lessens the possibility of the contrast material getting into the cerebral cerebrospinal fluid circulation. The contrast material used for myelograms can lower the seizure threshold in some patients. Any patient with a known seizure disorder should have serum levels of anticonvulsants evaluated and be carefully observed for signs of seizures.

Because of their invasive nature, a separate informed consent form is normally required for angiogram, lumbar puncture, and myelogram. The physician performing the test explains the risks, benefits, and possible complications of the examination. Patients who need these diagnostic procedures, particularly lumbar puncture and angiogram, may have cognitive deficits; therefore it may be necessary to obtain consent from the legal next of kin.

Electroencephalogram

Evaluation of the electrical activity of the brain is obtained through an **electroencephalogram** (EEG). Electrodes are attached to the scalp with an adhesive. Electrical activity is transmitted through the electrodes to a tracing. Analysis of the tracing can identify areas of abnormality, such as seizure focus or areas of slowed activity.

myelogram: myelo—referring to the spinal cord + gram—picture

electroencephalogram: electro—electrical activity + encephalo—referring to the brain + gram—picture

Nursing Care

Before the test, make sure that the patient's hair is clean and dry. The physician may write orders to withhold any sedatives to prevent interference with the EEG, and patients may be weaned from their anticonvulsants if the goal of the test is to identify the seizure focus during a seizure. These patients must be very carefully monitored and protected from harm. Typically they undergo videotaping while the EEG is performed. Following the procedure, the adhesive must be washed from the hair. Assist the hospitalized patient to do this as soon as possible, before it becomes hardened and difficult to remove.

► THERAPEUTIC MEASURES

Moving and Positioning

Patients who have pain may need help in changing positions and ambulating. Use of heat, cold, or analgesics may allow the patient to be more independent in mobility. Patients with paresis, paralysis, or **paresthesias** may be partially or completely dependent in moving and positioning. Care should be taken to maintain the body in functional positions when routine position changes are made. If the patient experiences sensory loss, the person assisting with position changes must ensure that no part of the body is inadvertently compressed (e.g., a hand caught under a hip or the scrotum compressed between the legs). Collaboration with the physical therapist may yield positioning techniques that maximize the chance of useful recovery.

Contractures and footdrop are complications that are often associated with neurological disorders. Contractures are permanent muscle contractions with fibrosis of connective tissue that occur from lack of use of a muscle or muscle group. They cause permanent deformities and prevent normal functioning of the affected part. Footdrop occurs when the feet are not supported in a functional position and become contracted in a position of plantar flexion (Fig. 45–8). Some of the interventions used to prevent footdrop are foot boards, high-top tennis shoes, and splints. Splints are commonly used to prevent contractures of the upper and lower extremities and to keep the affected part in a functional position. If splints are used, the patient must be evaluated for discomfort and skin breakdown at the splint site.

Mobilization should be begun as soon as the patient is medically stable. Initially this may involve the use of a cardiac chair if the patient is unable to bear weight. Transfer of the patient to a bedside chair or use of ambulation aids may require a multidisciplinary approach. The nurse must recognize any physical or cognitive deficits that may affect safety and adjust the environment to protect the patient. This includes communicating any safety concerns to unlicensed personnel who interact with the patient.

Activities of Daily Living

The effects of neurological disorders on activities of daily living (ADLs) may range from an inconvenience to com-

paresthesia: para—beside + athesia—sensations

plete dependence. Patients may have trouble bending over to put on their shoes and socks, lifting a full cooking pot, or caring for an infant. A high-level quadriplegic may be completely unable to perform ADLs but can be taught to direct his or her own personal care. Patients should be encouraged to use strategies learned in occupational or physical therapy.

Assessment should include a discussion of the strategies the patient normally uses to accomplish ADLs. Every attempt should be made to continue to use these strategies. This is particularly true if the patient is admitted to a long-term care facility. Patients who have normal cognitive function should be included in care planning and encouraged to work collaboratively with caregivers. If the strategies the patient uses during ADLs must be changed, the rationale for the changes should be explained to the patient and significant others. An example is if the patient is using a transfer technique that is unsafe for the patient or caregivers. If patients have impaired cognitive function, try to maintain a specific routine that is as close to their normal environment as possible. Normalizing routines may help patients adapt to a change in environment and maximize their ability to function.

Communication

The communication problems associated with neurological disorders have a variety of etiologies. Some neurological disorders cause difficulty speaking (**dysarthria**). Dysfunction of the lips, tongue, or jaw makes speech difficult or impossible to understand. When dysarthric individuals know what they want to say but cannot be understood, the frustration level is high. This frustration is compounded if the patients are treated as if they have cognitive deficits merely because they have difficulty communicating.

Patients who have had a stroke can experience different types of aphasia. Expressive aphasia is difficulty or inability to verbally communicate with others. The patient may be able to speak in sentences but inappropriately substitute

words, such as “The sky is dish.” Word-finding difficulty is another type of expressive aphasia. These patients may tell you “I want a . . .” and then be unable to complete the sentence. In severe cases of aphasia the patient may make sounds that resemble words or may only utter sounds. For individuals with no intelligible speech or with word-finding difficulty, a picture board with commonly used items may facilitate communication. (See an example of a picture board in Chapter 46.) Keep in mind that patients with expressive aphasia may answer yes to all questions, rather than just those for which yes is correct. The same is true of answering no. This is one reason why a nurse should never ask a patient, “Are you Mrs. Gonzalez?” An aphasic patient may say yes even if that is not her name. Instead, ask the patient to state her name. If she cannot state her name, check her identification band.

For patients who substitute words, simply correct the substitution and continue the conversation. Patients with expressive aphasia are often very aware of and frustrated by their difficulty communicating. Give them time to try to express themselves. If you cannot understand them, offer possibilities based on the situation. If the patient is sitting in the chair, ask if he or she wants to go back to bed or wants to use the bathroom. If the patient is restless, ask if he or she is in pain.

Some patients use the same word in response to all questions, and for some patients that word is a profanity. This is very difficult for significant others to deal with, particularly if swearing is not something the patient normally did. Make it clear to the family that you understand that this behavior is part of the patient’s illness.

Receptive aphasia affects the patient’s ability to understand spoken language. Again, the severity of the aphasia varies. Some patients may understand simple directions such as “sit down” or “squeeze my fingers.” In other cases the nurse may need to pantomime the action the nurse wants the patient to perform, such as showing the patient pills and then mimicking taking the pills and drinking water.

LEARNING TIPS

If the patient has receptive aphasia, assume that he or she cannot understand or follow safety instructions, such as “Do not stand up until I get back.” Even going to the bathroom to get a towel can give a patient enough time to try to stand up and subsequently fall.

Nutrition

Alterations in ability to maintain an adequate nutritional intake can have many causes. The level of consciousness may be depressed enough that the patient does not recognize that she or he is hungry or thirsty. Decreased level of consciousness or cranial nerve dysfunction may impair the patient’s ability to swallow safely. Severe weakness may limit the patient’s ability to take in enough food to meet the body’s requirements. These conditions are often compounded by the increased metabolic rate that accompanies neurological injury or illness.

dysarthria: *dys*—dysfunctional + *arthria*—movement of the joints used in speech

If there is any question of the patient's ability to swallow, a swallowing evaluation should be performed by a speech therapist. Food coloring can be added to food or fluids and the patient watched until the food is swallowed. If respiratory secretions are the same color as the food coloring, the patient has aspirated and is not able to safely swallow the food or fluid. Some institutions use a radiological examination to evaluate the ability to swallow. A small amount of barium is added to the food or fluid, and fluoroscopy is used while the patient swallows. This allows visualization of the path of the food or fluid. Patients with swallowing difficulty (dysphagia) may have better success with foods or thick liquids rather than thin fluids. Liquids may be thickened with special thickening agents to allow easier swallowing. All patients should be positioned as upright as possible while eating or drinking, and patients who have difficulty swallowing should be monitored during eating.

If weakness or fatigue is the cause of decreased nutritional intake, several modifications are possible. Serving small portions of food frequently can increase intake. Using high-protein, high-calorie foods and supplements increases the nutritional content of small amounts of foods.

For patients who are unable to swallow or who cannot swallow enough food, enteral tube feedings may be required. If enteral feedings are anticipated to be for a short duration,

a nasogastric tube may be used. The disadvantages of nasogastric tubes include impairment of the integrity of nasal skin and the risk of aspiration. The risk of aspiration in neurologically impaired patients who have cognitive impairments is increased because these patients may pull out the nasogastric tube because they do not understand its purpose. If long-term enteral feedings are anticipated, a gastrostomy tube may be placed directly through the abdominal wall into the stomach. This feeding method has the advantage of eliminating the risks of aspiration and nasal skin breakdown.

Answers to CRITICAL THINKING

Tim Thompson

1. He is alert but confused, oriented to person only.
2. The nurse should ask his wife if this has ever happened before; check his medical history for any disorders that may contribute to neurological dysfunction; do a quick neurological assessment to determine if any additional deficits exist; check vital signs and pulse oximetry if available; and notify the physician immediately if the symptoms are a new finding.
3. Some possible explanations to explore include hypoxemia, stroke, worsening heart problems causing inadequate flow of blood to the brain, hypoglycemia, or even confusion related to a sudden transition from home to an unfamiliar environment.

REVIEW QUESTIONS

1. Which of the following are neurons that carry impulses from the CNS to effectors?
 - a. Mixed
 - b. Motor
 - c. Afferent
 - d. Sensory
2. Which of the following is a symptom of increasing intracranial pressure?
 - a. Constricted pupils
 - b. Decreasing level of consciousness
 - c. Narrowing pulse pressure
 - d. Bradypnea
3. Which of the following actions by the nurse is the best way to determine if a patient with expressive aphasia is oriented?
 - a. Ask yes-or-no questions.
 - b. Ask the patient to name the family member in the room.
 - c. Ask the patient who the current president is.
 - d. Have the patient count backward from 10.
4. Asking the patient to stick out his or her tongue evaluates the function of which cranial nerve?
 - a. IV—trochlear
 - b. Vtrigeminal
 - c. IX—glossopharyngeal
 - d. XIIhypoglossal
5. Which of the following nursing interventions can help prevent footdrop?
 - a. Positioning the patient in the left lateral position
 - b. Providing daily foot massage
 - c. Using high-top tennis shoes
 - d. Maintaining an upright position as much as possible
6. Which of the following activities should be encouraged when a patient returns from a CT scan using a contrast medium?
 - a. Ambulation
 - b. Drinking fluids
 - c. Turning side to side
 - d. Coughing and deep breathing
7. When observing a patient's gait, the nurse is checking the integrity of what?
 - a. Cerebellum
 - b. Brainstem
 - c. Diencephalon
 - d. Cerebrum
8. Which of the following areas of the brain controls speech?
 - a. Left occipital lobe
 - b. Broca's area
 - c. Midbrain
 - d. Brainstem

QUESTIONS TO GUIDE YOUR READING

1. What are the causes, risk factors, and pathophysiology of major disorders of the central nervous system?
2. What is the appropriate plan of care for a patient with a major disorder of the central nervous system?
3. What are the primary treatments for the major disorders of the central nervous system, including surgery, intracranial pressure monitoring, medication, and rehabilitation?
4. What are the causes, risk factors, and pathophysiology of traumatic injuries to the brain and spinal cord?
5. What is the appropriate plan of care for a patient with a traumatic injury to the brain or spinal cord?
6. What are the causes, risk factors, and pathophysiology associated with degenerative neuromuscular disorders?
7. What is the appropriate plan of care for a patient with degenerative neuromuscular disorders?
8. What are the causes, risk factors, pathophysiology, and progression of symptoms seen in patients with Alzheimer's disease?
9. What are the steps in the nursing process in meeting the diverse needs of patients with Alzheimer's disease and their families?

Disorders of the central nervous system (CNS) include problems originating in the brain and spinal cord. Because the CNS is the control center for the entire body, disorders in this system can cause symptoms in any part of the body, ranging from pain to paralysis, confusion, and coma. This chapter presents nursing care of patients with these disorders.

► CENTRAL NERVOUS SYSTEM INFECTIONS

Infectious agents may enter the central nervous system via a variety of routes (Table 46–1). Anything that depresses the patient’s immune system, such as steroid administration, chemotherapy, radiation therapy, and malnutrition, can make the patient more vulnerable to infection.

Meningitis

Meningitis is a purulent infection caused by bacterial or viral invasion of the pia mater, arachnoid, and subarachnoid space surrounding the brain and spinal cord. The membranes react to the infection with an inflammatory response. Bacterial meningitis is more common than viral. Occasionally meningitis is caused by a noninfectious irritant, such as dye from a myelogram.

Pathophysiology and Etiology

The most common organisms causing meningitis include meningococcus, pneumococcus, and *Haemophilus influenzae*. In the United States, as of the late 1990s—more than 10 years after the introduction of the *H. influenzae* serotype b vaccine (HIB)—the most common agents are *Neisseria meningitidis* and *Streptococcus pneumoniae*. During the early 1990s, about 25,000 cases occurred annually in the United States, with 70 percent identified among children age 5 or younger. Each year more than 2000 deaths were attributed to bacterial meningitis. The infection generally begins in another area, such as the upper respiratory tract, enters the blood, and invades the CNS, especially if the immune system is not functioning effectively. Bacterial invasion leads

to a rapidly increased blood supply to the meninges with massive neutrophil migration. The neutrophils then engulf the bacteria and disintegrate, causing purulent material to form. Exudate from tissue destruction also contributes to this purulent material. The purulent material causes the meninges to become inflamed, and intracranial pressure increases. Cranial nerve function may be transiently or permanently affected by meningitis. Some of the effects are listed in Table 46–2.

A common endocrine disorder associated with meningitis is a cycle of increased intracranial pressure leading to excessive release of antidiuretic hormone (ADH). ADH acts by inhibiting urination. This in turn leads to water retention, oliguria (reduced urination), hypervolemia (excess blood volume), hyponatremia (low serum sodium), and further increases in intracranial pressure. (See Increased Intracranial Pressure later in this chapter.)

Prevention

Vaccines are available against *H. influenzae* and *S. pneumoniae*. These are especially recommended for immunocompromised patients. Other vaccines are being developed.

Signs and Symptoms

The initial symptom of meningitis is a severe headache, caused by tension on blood vessels and irritation of the pain-sensitive dura mater. Fever is commonly 101° to 103° F or higher. If the meningitis is not resolved, pressure on the brainstem may elevate the temperature to 105° F or higher during the terminal phase. **Photophobia** may be present. The patient with meningococcal meningitis has a petechial rash on the skin and mucous membranes.

Nuchal rigidity (pain and stiffness when the neck is moved) is caused by spasm of the extensor muscles of the neck. Kernig’s sign and Brudzinski’s sign are often seen in patients suffering from meningitis. Both signs are caused by inflammation of the meninges and spinal nerve roots. Brudzinski’s sign is positive when flexion of the patient’s neck causes the hips and knees to flex. To elicit Kernig’s sign the examiner flexes the patient’s hip to 90 degrees and tries to extend the patient’s knee. The sign is positive if the patient experiences pain and spasm of the hamstring (Fig. 46–1). The nausea and vomiting associated with meningitis are caused by direct irritation of brain tissue and by increased intracranial pressure (ICP).

TABLE 46–1 ROUTES OF ENTRY FOR CENTRAL NERVOUS SYSTEM INFECTIONS

Route of Entry	Examples
Bloodstream	Insect bite Otitis media
Direct extension	Fracture of frontal or facial bones
Cerebrospinal fluid	Dural tear Poor sterile technique
Nose or mouth	Meningococcus meningitis
In utero	Contamination of amniotic fluid Rubella Vaginal infection

TABLE 46–2 CRANIAL NERVES AFFECTED BY MENINGITIS

Cranial Nerve Affected	Manifestation
III, IV, VI	Ocular palsies Unequal and sluggishly reactive pupils
VII	Facial weakness
VIII	Deafness and vertigo

meningitis: mening—membranous covering of the brain + itis—inflammation

photophobia: photo—light + phobia—fear or intolerance

Figure 46-1 (A) Kernig's sign. (B) Brudzinski's sign.

Encephalopathy refers to the mental status changes seen in patients with meningitis. These are manifested as short attention span, poor memory, disorientation, difficulty following commands, and a tendency to misinterpret environmental stimuli. Late signs of meningitis include lethargy and seizures.

Acute Complications of Meningitis

Hydrocephalus can occur when purulent material interferes with circulation and reabsorption of cerebrospinal fluid. The patient may begin to improve following the initiation of treatment and then experience neurological deterioration as hydrocephalus develops. Careful and frequent neurological assessments allow for the detection of subtle changes.

Irritation of the cerebral cortex makes patients prone to seizures. Seizure precautions should be in place for all patients with meningitis (Table 46-3). An oral airway should be used only if the patient's mouth is open. Never attempt

to insert something into the mouth of a seizing patient if the jaws are clenched.

As with all patients with neurological disorders, frequent assessment of respiratory function is necessary. Inflammation and edema may place pressure on the respiratory center and result in hypoxia. Hypoxia causes vasodilation, which increases intracranial pressure. If the patient experiences significant neurological and respiratory impairment, intubation and mechanical ventilation may be necessary.

Long-Term Complications

Resolution of meningitis depends on how quickly and effectively the disease is treated. Some individuals experience no lasting effects. Other patients have permanent neurological deficits. Cranial nerve damage may leave the patient blind or deaf. Seizures may continue to occur even after the acute phase of the illness has passed. Cognitive deficits ranging from memory impairment to profound learning disabilities may occur.

Diagnostic Tests

A lumbar puncture is the most informative diagnostic test for a patient with suspected meningitis. (See Chapter 45.) Viral meningitis is characterized by clear cerebrospinal fluid with normal glucose level and normal or slightly increased protein level. No bacteria are seen, but the white blood cell count is usually increased. In contrast, the cerebrospinal fluid of an individual with bacterial meningitis is **turbid**, or cloudy, because of the massive number of white blood cells. Bacteria are identified by Gram's stain and culture. The bacteria utilize the glucose normally found in cerebrospinal fluid (CSF), thereby lowering the glucose level. The amount of protein in the cerebrospinal fluid is elevated.

Medical Treatment

Meningitis can be fatal if not promptly treated. Broad-spectrum antibiotics are administered intravenously. After a culture and sensitivity test is done on CSF, the antibiotic may be changed. Antibiotics are not effective in the treatment of viral meningitis.

Symptom management is the same for viral or bacterial meningitis. Antipyretics such as acetaminophen are used to control the fever. A cooling blanket may also be used. Care

TABLE 46-3 INTERVENTIONS FOR SEIZURES

Seizure Precautions

- Pad side rails of hospital bed with commercial pads or bath blankets folded over and pinned in place.
- Keep call light within reach.
- Assist patient when ambulating.
- Keep suction and oral airway at bedside.

Nursing Care during a Seizure

- Stay with patient.
- Do not restrain patient.
- Protect from injury (move nearby objects).
- Loosen tight clothing.
- Turn to side when able to prevent occlusion of airway or aspiration.
- Suction if needed.
- Monitor vital signs when able.
- Be prepared to assist with breathing if necessary.
- Observe and document progression of symptoms.

encephalopathy: encephalo—brain + pathy—illness
hydrocephalus: hydro—water + cephalus—head

should be taken to avoid cooling the patient too much and causing shivering, because this increases the metabolic demand for oxygen and glucose. A quiet, dark environment lessens the stimulation to a patient who has a headache or photophobia (sensitivity to light) and who may be agitated, disoriented, or at risk for seizures.

Pain medications are given to lessen head and neck pain. Opioids are rarely used because of the risk of masking neurological changes. Codeine products are preferred because they are less sedating than other opioids and do not affect pupil response. Nausea and vomiting are controlled by administering antiemetic medications. The patient with meningococcal meningitis should be placed in isolation, because it can be transmitted to others.

Patients may become agitated and attempt to leave the hospital because they do not comprehend or remember how ill they are. An important aspect of nursing care focuses on keeping patients from harming themselves. It is very upsetting to families to see a loved one acting agitated or disoriented. It is important to teach the family about symptoms and treatment goals for the patient (Box 46–1).

Encephalitis

Pathophysiology

Encephalitis is inflammation of brain tissue. Nerve cell damage, edema, and necrosis cause neurological findings localized to the specific areas of the brain affected. Hemorrhage may occur in some types of encephalitis. Increased intracranial pressure may lead to herniation of the brain.

BOX 46-1 Meningitis Summary

Symptoms

Nuchal rigidity
Positive Kernig's sign
Positive Brudzinski's sign
Fever
Photophobia
Petechial rash on skin and mucous membranes
Encephalopathy

Diagnostic Tests

Lumbar puncture with CSF analysis

Therapeutic Management

Antimicrobials (if bacterial)
Seizure precautions
Symptom management
Antipyretics
Pain management
Reduction of environmental stimuli
Education

Etiology

Viruses are the most common cause of encephalitis. They may be specifically related to a particular time of year or geographic location. Some viruses, such as West Nile virus, are carried by ticks or mosquitoes. Others are systemic viral infections, such as infectious mononucleosis or mumps, that spread to the brain. Parasites, toxic substances, bacteria, vaccines, and fungi are other potential causes of encephalitis.

Herpes simplex is the most common non-insect-borne virus to cause encephalitis. The majority of individuals harbor herpes simplex virus type 1 in a dormant state. This is the virus responsible for cold sores on the oral mucous membranes. Infectious diseases, fever, and emotional stress are possible reasons for the virus becoming active, but the exact mechanism is not known.

Signs and Symptoms

As with meningitis, headache and fever are common presenting symptoms. The patient may also complain of nausea and vomiting and general malaise. These symptoms usually develop over a period of several days.

The viruses cause nuchal rigidity, confusion, decreased level of consciousness, seizures, sensitivity to light, **ataxia**, and tremors. The patient may have **hemiparesis** and exhibit abnormal deep tendon reflexes.

The patient with herpes encephalitis develops edema and necrosis (sometimes associated with hemorrhage), most commonly in the temporal lobes. This significant cerebral edema causes increased ICP and can lead to herniation of the brain. If the patient becomes comatose before treatment is begun, the mortality rate may be as high as 70 to 80 percent. The first 72 hours, when cerebral edema is worst, is the most likely time for death to occur.

Long-Term Complications of Encephalitis

Patients who have had encephalitis are often left with cognitive disabilities and personality changes. Ongoing seizures, motor deficits, and blindness may also occur. Deterioration in cognition and personality control are particularly stressful for significant others. The patient's behavioral control is a major factor in determining discharge plans. Assist significant others to realistically assess the patient's functional level and the family's ability to care for the patient. In-home care, outpatient therapy, and adult day care are options to explore. For some severely impaired individuals, custodial care may be the only feasible and safe discharge option.

Diagnostic Tests

Computed tomography (CT) scan, lumbar puncture to obtain cerebrospinal fluid, and electroencephalogram (EEG) are used to diagnose encephalitis. Cerebrospinal fluid analysis typically reveals increased white blood cell count and protein level and normal glucose levels. Breakdown of blood after cerebral hemorrhage results in yellow CSF.

encephalitis: encephalo—brain + itis—inflammation

hemiparesis: hemi—one side + paresis—partial paralysis

Treatment

No specific treatment is currently available for insect-borne encephalitis. Careful neurological assessment and a symptomatic approach to care help prevent complications and improve survival. Medications to reduce pain and fever and anticonvulsant medication are often administered. Significant others need emotional support and ongoing teaching.

Acyclovir (Zovirax) is given intravenously to treat herpes simplex encephalitis. Therapy should be instituted as soon as possible after diagnosis. The most favorable outcomes are noted when acyclovir is administered before the Glasgow Coma Scale (GCS) score is less than 10. Even with prompt treatment, only 38 percent of patients with herpes simplex encephalitis regain normal function.

▶ INCREASED INTRACRANIAL PRESSURE

Pathophysiology and Monitoring

Any patient with an intracranial pathological condition is potentially at risk for increased intracranial pressure. ICP is the pressure exerted within the cranial cavity by its components (blood, brain, and cerebrospinal fluid). The normal ICP is 0 to 15 mm Hg. This pressure fluctuates with normal physiological changes, such as arterial pulsations, changes in position, and increases in intrathoracic pressure (e.g., coughing or sneezing). Common causes of increased ICP include brain trauma, intracranial hemorrhage, and brain tumors. Prompt detection of changes in neurological status indicating increased intracranial pressure allows intervention aimed at preventing permanent brain damage.

The Monro-Kellie doctrine states that the skull is a rigid compartment containing three components: brain, blood, and cerebrospinal fluid. If an increase in one component is not accompanied by a decrease in one or both of the other components, the result is increased intracranial pressure

(ICP). The consequences of increased ICP depend on the degree of elevation and the speed with which the ICP increases. Patients with slow-growing tumors may have significantly increased intracranial pressure before they develop symptoms. Conversely, patients with a subarachnoid hemorrhage may sustain a sudden sharp increase in intracranial pressure.

The normally functioning body has several methods of compensating for increased intracranial pressure. Cerebrospinal fluid can be shunted into the spinal subarachnoid space. Hyperventilation may trigger constriction of cerebral blood vessels, decreasing the amount of blood within the cranial vault. These compensatory mechanisms are temporary and not particularly effective if the increase in ICP is sudden and severe.

Signs and Symptoms

Increased ICP may first be manifested by restlessness, irritability, and decreased level of consciousness, because cerebral cortex function is impaired. If not intubated, the patient may hyperventilate, causing vasoconstriction as the body attempts to compensate. As the pressure increases, the oculomotor nerve may be compressed on the side of the impairment. Compression of the outermost fibers of the oculomotor nerve results in diminished reactivity and dilation of the pupil. As the fibers become increasingly compressed, the pupil stops reacting to light. If the compression continues, both pupils become fixed and dilated.

Vital sign changes are a late indication of increasing intracranial pressure. Cushing's response is a classic late sign of increased ICP. Cushing's response is characterized by bradycardia and increasing systolic blood pressure while diastolic blood pressure remains the same, resulting in widening pulse pressure (Fig. 46-2). By the time these symptoms appear, the intracranial pressure is significantly increased and interventions may not be successful.

Figure 46-2 Cushing's response. Changes in vital signs that accompany increased intracranial pressure.

Monitoring

ICP monitoring has been the standard of care for patients with severe head injury for several years. ICP monitoring allows for early detection of the pressure on the brain before changes in symptoms can be seen. Intracranial monitoring is indicated when the patient demonstrates development of unequal pupils. Other reasons for monitoring include a CT scan demonstrating midline shift and the decision to use neuromuscular blocking agents and sedatives. The most common methods of monitoring ICP in adults are external ventricular drain, subarachnoid bolt, and intraparenchymal monitor. All three methods involve anesthetizing the scalp and drilling a burr hole in the skull. Patients who are rest-

less or agitated may require sedation for the procedure to be completed safely. Informed consent must be obtained, but in some emergent cases the monitor is inserted without consent.

Placement of a catheter into one of the lateral ventricles is referred to as external ventricular drainage (Fig. 46-3). Drainage of cerebrospinal fluid reduces intracranial pressure, which can be therapeutic, as well as a way of monitoring pressure. Disadvantages to this method include difficulty in locating the ventricle for insertion of the catheter and clotting of the catheter by blood in cerebrospinal fluid.

To allow communication with the subarachnoid space, a subarachnoid bolt is tightly screwed into the burr hole after the dura has been punctured (Fig. 46-4). The advantage to

Figure 46-3 Ventricular drain. A catheter into the ventricle allows ICP monitoring and CSF drainage.

Figure 46-4 Subarachnoid bolt monitor.

a subarachnoid bolt is ease of placement. Disadvantages include occlusion of the sensor portion of the bolt with brain tissue and inability to drain CSF. An intraparenchymal monitor is placed directly into brain tissue. Some physicians believe that this most accurately reflects the actual situation within the skull. These monitors cannot be used to drain CSF and may become occluded by brain tissue.

Patients with ICP monitors are cared for in an intensive care unit (ICU) and require aggressive nursing care to prevent complications. These patients are often mechanically ventilated and may be pharmacologically paralyzed and sedated. They may be completely dependent for all care. In addition to meeting the patient's physiological needs and preventing complications, provide education and emotional support to the significant others. Patients who require intracranial pressure monitoring are seriously ill, and their significant others need frequent honest communication regarding the clinical situation and prognosis.

Nursing Process: The Patient with an Infectious or Inflammatory Neurological Disorder

ASSESSMENT. Collaborate with the registered nurse (RN) to obtain a complete history from the patient, if feasible, and from significant others. Particular attention is paid to exposure to risk factors and symptoms of generalized malaise. The physical assessment must include all body systems because neurological impairment affects the entire person. Following the initial assessment, serial neurological assessments continue to be important to detect and report changes promptly. Pupil response, level of consciousness (LOC), and vital signs are monitored for signs of increased intracranial pressure (Box 46–2). Headache is monitored on a pain scale. The Glasgow Coma Scale, presented in Chapter 45, is a valuable tool to monitor level of consciousness.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Plan to meet the physical needs of the patient, as well as the emotional needs of the patient and significant others, during the acute phase of illness. Whenever possible, the goal is to support the patient and prevent long-term complications. This requires careful monitoring and timely reporting of changes in neurological status. Possible nursing diagnoses and interventions for the patient with a central nervous system infection include the following:

BOX 46–2 Signs and Symptoms of Increased Intracranial Pressure

Vomiting
Headache
Dilated pupil on affected side
Hemiparesis or hemiplegia
Decorticate then decerebrate posturing
Decreasing level of consciousness
Increasing systolic blood pressure
Increasing then decreasing pulse rate
Rising temperature

Decreased Intracranial Adaptive Capacity Related to Infectious or Inflammatory Process. Decreased adaptive capacity refers to the patient's inability to maintain normal intracranial pressure. Measures such as avoiding Valsalva's maneuver during bowel movements, avoiding rectal temperatures, and avoiding flexion of the neck when positioning the patient help prevent increases in ICP. The patient with increased ICP is usually cared for in an intensive care setting, and the licensed practical nurse/licensed vocational nurse (LPN/LVN) collaborates with the registered nurse in implementing care. See Table 46–4 for additional measures to prevent increased ICP.

Pain Related to Headache and Nuchal Rigidity. Headache and other alterations in comfort are difficult to treat. Opioid analgesics (with the possible exception of codeine) are usually avoided because they mask neurological symptoms and make detection of changes difficult. If they are used, monitor the patient carefully for changes in level of consciousness or other neurological changes. Assist patient to whatever position is most comfortable. A dark, quiet room with few distractions may also reduce headache.

Hyperthermia Related to Infectious Process. Control fever with acetaminophen or aspirin because a high temperature can increase the risk for seizures. A cooling mattress and tepid sponge baths may be necessary but are uncomfortable for the patient. Comfort can be increased and shivering reduced by cooling the patient gradually and wrapping extremities in bath blankets during cooling mattress therapy.

TABLE 46–4 INTERVENTIONS TO PREVENT INCREASED INTRACRANIAL PRESSURE

Action	Rationale
Keep head of bed elevated 30 degrees unless contraindicated.	Head elevation reduces ICP in some patients.
Avoid flexing the neck; keep head and neck in midline position.	Neck flexion may obstruct venous outflow.
Administer antiemetics or antitussives as necessary to prevent vomiting and cough.	Coughing and vomiting can increase ICP.
Administer stool softeners.	Straining for bowel movement can increase ICP.
Minimize suctioning. If absolutely necessary, oxygenate first and limit suction passes to one or two.	Suctioning can increase ICP.
Avoid hip flexion.	Hip flexion can increase intra-abdominal and thoracic pressure, which can increase ICP.
Prevent unnecessary noise and startling the patient.	Noxious stimuli can increase ICP in some patients.
Space care activities to provide rest between each disturbance.	Clustering care activities may increase ICP.

Risk for Injury Related to Seizures Or Falls. Maintain patient safety with seizure precautions (see the section on seizures later in this chapter), use of side rails, and reminders not to get up without help if indicated. Having a family member stay with the patient can help the patient feel more secure and prevent falls if the patient's ability to remember instructions is impaired.

Disturbed Sensory Perception Related to Cranial Nerve Involvement. Sensory problems can increase risk of injury. Monitor the patient closely for changes in level of consciousness. See Chapters 48 and 49 for specific interventions for patients with sensory problems.

Impaired Physical Mobility Related to Long-Term Complications of the Disease. Physical mobility should be maintained as much as possible. Encourage the patient to move and turn in bed and ambulate when able. Long-term mobility problems such as hemiparesis may be reduced with the help of a physical therapy consultation. Measures to prevent impaired skin integrity should be implemented.

EVALUATION. Successful nursing management of a patient with an infectious or inflammatory neurological disorder is evidenced by a patient who is comfortable and with no preventable complications such as pressure ulcers or **contractures**. This increases the possibility that the patient with a neurological deficit will benefit from rehabilitation and improve his or her level of functioning.

Patient Education

The nature and focus of teaching depend on the patient's level of consciousness and cognitive status. When appropriate, both the patient and significant others should be included in the education process. If the patient is not able to participate, the significant others become the focus of teaching.

Describing the brain as in control of body functions may help significant others to understand some of the symptoms of neurological disorders. The spinal cord can be compared to a telephone cord, with hundreds of tiny individual wires (nerves) making up the cord. The specific wires affected by disease determine the symptoms the patient experiences.

CRITICAL THINKING

Mr. Chung

Mr. Chung is an 18-year-old Asian college student. He comes to the emergency department complaining of headache, stiff neck, and fever. On physical assessment you notice a petechial rash on his legs and torso. The physician diagnoses meningococcal meningitis.

1. What tests are likely to be performed?
2. How should patient education be planned for Mr. Chung?
3. What infection control practices should be instituted?
4. What comfort measures might you offer to Mr. Chung?
5. What concerns do you have about how Mr. Chung contracted his illness?

Answers at end of chapter.

► HEADACHES

As mentioned throughout this chapter, headache is a common symptom of neurological disorders. However, most headaches are transient events and do not indicate a serious pathological condition. If headaches are recurrent, persistent, or increasing in severity, the patient should undergo a neurological evaluation.

Because the causes, signs and symptoms, pathophysiology, and treatment of headaches vary based on the type of headache experienced, these subjects are discussed separately for each type of headache.

Types of Headaches

Tension or Muscle Contraction Headaches

Persistent contraction of the scalp, facial, cervical, and upper thoracic muscles can cause tension headaches. A cycle of muscle tension, muscle tenderness, and further muscle tension is established. This cycle may or may not be associated with vasodilation of cerebral arteries. Headaches of this type may be associated with premenstrual syndrome or psychosocial stressors such as anxiety, emotional distress, or depression. Symptoms typically develop gradually. Radiation of pain to the crown of the head and base of the skull, with variations in location and intensity, is common. *Pressure, aching, steady, and tight* are some of the words patients use to describe the pain of tension headaches.

Care must be taken to thoroughly rule out physical causes before attributing the headache to psychosocial origins. Symptom management may include the use of relaxation techniques, massage of the affected muscles, rest, localized heat application, nonnarcotic analgesics, and appropriate counseling.

Migraine Headaches

A number of theories have been proposed to explain migraine headaches. It is believed that cerebral vasoconstriction followed by vasodilation is a major factor. This response may be triggered by the trigeminal nerve, which in turn stimulates release of substance P, a pain transmitter, into the vessels. Serotonin is another neurotransmitter that may play a role in migraine pain. The tendency to develop migraine headaches is often hereditary. Migraine episodes can be triggered by a variety of factors, including noise, bright light, alcohol, and stress. Some patients can identify specific foods that trigger the headache.

Symptoms include a **prodromal** period, in which the patient may experience several hours to days of changes in mood and appetite, drowsiness, or frequent yawning. Some patients experience additional neurological symptoms, such as visual changes (e.g., an aura), immediately before the pain begins. Many patients report seeing flashing lights. The headache that follows is often accompanied by nausea and sometimes vomiting and may last for hours to days. Commonly used descriptors of migraine pain include *throbbing, boring, viselike, and pounding*. It is usually on one side of the head. Noise and light tend to exacerbate the headache, leading the patient to rest in a dark, quiet environment.

Treatment of migraine may be prophylactic or directed at an acute episode. Prophylactic treatment is usually reserved for those patients experiencing one or more headaches per week. Dietary restrictions may be helpful if precipitating foods or beverages can be identified. Nifedipine (a calcium channel blocker), amitriptyline (a tricyclic antidepressant), and propranolol (a beta-adrenergic blocker) are prophylactic treatments that may be effective. Propranolol and nifedipine should be used cautiously because of the potential for lowering blood pressure (BP). This is particularly true of young, slender females, who may normally have a low blood pressure. Amitriptyline may cause drowsiness, dry mouth, and weight gain. None of these medications should be stopped abruptly after long-term use.

Several types of medications are available to treat the acute migraine headache. Ergot (Cafergot), a vasoconstrictor, is effective only if taken before the vessel walls become edematous, usually within 30 to 60 minutes of headache onset. Sumatriptan (Imitrex) and zolmitriptan (Zomig) are newer medications available for migraine relief. These drugs work at the serotonin receptor sites and have a vasoconstricting action. Sumatriptan is available in both intramuscular and oral forms. The potentially additive nature of multidrug medications and opioids requires careful monitoring.

Cluster Headaches

Vascular disturbance, stress, anxiety, and emotional distress are all proposed causes of cluster headaches. As indicated by the name, these headaches tend to occur in clusters during a time span of several days to weeks. Months or even years may pass between episodes. Alcohol consumption may worsen the episodes.

The patient may state that the headache begins suddenly, typically at the same time of night. *Throbbing* and *excruciating* are often the adjectives used by the patient. The headache tends to be unilateral, affecting the nose, eye, and forehead. A bloodshot, teary appearance of the affected eye is common.

Because of the brief nature of cluster headaches, treatment is difficult. A quiet, dark environment and cold compresses may lessen the intensity of the pain. Nonsteroidal anti-inflammatory drugs (NSAIDs) or tricyclic antidepressants may be prescribed.

Diagnosis

Most headaches are diagnosed based on the patient's history and symptoms, after other causes have been ruled out. Magnetic resonance imaging (MRI), CT, or other testing may be done to make sure that a brain tumor or other structural problem is not causing the headaches.

Nursing Care

Assessment

The WHAT'S UP? mnemonic is particularly useful in helping the patient provide useful information regarding the headache.

W—Where is the pain? Does it remain in one place or radiate to other areas of the head? Does the headache consistently start in one place?

H—How does the headache feel? Is it throbbing, steady, dull, bandlike, or does it have other qualities?

A—Aggravating or alleviating factors should be assessed. Some aggravating factors include red wine, caffeine, chocolate, and foods containing nitrates. Other factors include particular stages of the menstrual cycle, emotional stress, and tension. Alleviating factors might include lying down in a dark room, cold compresses, and over-the-counter medications.

T—Timing may be a factor for a patient who experiences headaches just before or during her menstrual period. For other patients, there may be no predictive timing. Also ask how long the headache lasted.

S—Ask the patient to rate the severity on a scale of 0 to 10. Is the severity consistent or does it vary from headache to headache?

U—Are there associated symptoms, such as nausea, vomiting, or bloodshot eyes?

P—Determine the patient's perception of the headache. Does it interfere with the patient's life? If so, how? Has the patient had a previous evaluation of headaches?

Patient Education

The first step in patient education is to help the patient identify and reduce or eliminate aggravating factors. This can be accomplished by keeping a headache diary for a time, recording the time of day the headache occurs, foods eaten or other aggravating factors, description of the pain, identification of associated symptoms such as nausea or visual disturbances, and other factors related to headache symptoms. This can help the patient lessen the frequency and intensity of attacks and provides a sense of control over his or her illness. Similarly, encouraging the patient to use alleviating techniques such as biofeedback or stress reduction helps the patient participate in the treatment of the headache. Relaxation exercises or warm, moist compresses may be helpful for tension headaches. A dark room and rest are essential during a migraine headache.

Education regarding medications, appropriate dosage, expected action, side effects, and consequences of misuse is essential. Depending on the patient's learning ability and interest, information may be given orally or in written format. Drawings, diagrams, and commercially prepared drug information are potential teaching aids.

► CEREBROVASCULAR DISORDERS

Transient Ischemic Attack

Transient ischemic attack (TIA) is a temporary impairment of the cerebral circulation causing neurological impairment. It is characterized by focal neurological deficits, typically minutes to hours in duration. Symptoms resolve completely within 24 hours. Symptoms that last longer than 24 hours but do not cause permanent neurological changes are called reversible ischemic neurological deficits (RIND).

Pathophysiology

Cerebral function is dependent on oxygen and glucose delivery to neurons. Interruption of blood flow to the brain deprives neurons of needed glucose and oxygen. The particular vessel or vessels involved determine the area of the brain affected and therefore the symptoms observed. The duration of ischemia determines whether the symptoms are transient or permanent. A transient ischemic attack may be a warning of an impending cerebrovascular accident.

Etiology

Atherosclerosis resulting in narrowing of arterial diameter is the most common cause of a transient ischemic attack. Although any vessel may be involved, the bifurcation of the common carotid artery into the internal and external branches is the most common location for cerebral occlusion. Emboli may lodge in cerebral vessels, resulting in occlusion, ischemia, and infarct. Emboli may break off of arterial plaque or be released into the circulation during atrial fibrillation.

Signs and Symptoms

Symptoms depend on the area of the brain affected. Common symptoms include visual disturbances, difficulty with speech, weakness or paralysis on one side of the body, and transient confusion. They can last a few minutes to a few hours and subside within 24 hours. See Table 46–5 for symptoms associated with occlusion of specific arteries.

Diagnostic Tests

Carotid Doppler testing can determine if stenosis of the carotid arteries exists. This noninvasive test involves bouncing sound waves off the carotid arteries to determine the velocity and turbulence of blood flow.

Patients may undergo an echocardiogram to determine the presence of heart disease that may increase risk of thrombus formation. CT scan or MRI may be used to assess for previous, possibly asymptomatic, infarctions. A cerebral angiogram may be done to determine the patency of cerebral vessels and the status of any collateral circulation. Refer to Chapter 45 for a description of this examination.

Treatment

MEDICAL MANAGEMENT. Medical management focuses on controlling the cause of the transient ischemic attack. Medications are used to control atrial fibrillation or hypertension. Warfarin (Coumadin) may be prescribed for patients prone to clot development. Education regarding

safety precautions is essential for these patients. They should be instructed to use electric razors to minimize nicks and to be careful to avoid any injury that might cause bleeding. The possible development of a cerebral hematoma following a fall or blow to the head must be stressed to the patient and significant others. Additional precautions are found in Chapter 24.

Antiplatelet drugs such as ticlopidine (Ticlid) or aspirin are often prescribed for patients experiencing transient ischemic attacks. Decreasing platelet aggregation lessens the likelihood of thrombus formation. If aspirin is prescribed for its antiplatelet properties, the patient should be instructed not to use aspirin or products containing aspirin for pain relief. Because ticlopidine is metabolized by the liver, it may elevate liver enzymes and regular blood tests are required.

SURGICAL MANAGEMENT. If carotid stenosis of greater than 70 percent is detected, a carotid **endarterectomy** may be performed. During this surgical procedure, the carotid artery is opened and the plaque removed. Nursing care focuses on careful neurological assessment for signs of deterioration related to ischemia. The incision is monitored for hematoma development and bleeding. Development of a hematoma can compromise the patient's airway. Bleeding at the suture line, particularly of bright red blood, may indicate failure of the sutures. This emergency situation requires prompt response to prevent massive blood loss. Balloon angioplasty for carotid stenosis is being investigated as a potential treatment in large facilities.

Acute Complications

By definition, a transient ischemic attack is an event that results in no permanent neurological deficit. However, patients can experience complications from events that occur during a transient ischemic attack. Falls may result in broken bones, abrasions and lacerations, or cerebral hematomas, particularly if the patient is on anticoagulants. Motor vehicle accidents may occur if the patient experiences visual or cognitive impairments. Hemiparesis can cause patients to burn or cut themselves if cooking or operating power tools. There are no long-term complications of transient ischemic attacks.

Cerebrovascular Accident

Cerebrovascular accident (CVA, also known as a stroke) is the infarction (death) of brain tissue caused by the disruption of blood flow to the brain. It is characterized by focal neurological deficits specific to the area of the brain involved. Although CVAs are most commonly associated with elderly patients, they affect approximately 500,000 people of all ages each year. A newer term for CVA is *brain attack*. This reminds us that, like a heart attack, CVA is an urgent condition that can be treated if medical care is sought immediately. Exciting new treatment developments may now allow patients to be deficit free if help is sought in time.

Pathophysiology

Infarction of brain tissue happens when there is inadequate blood flow to an area of the brain. When blood flow is severely compromised or absent, the oxygen and glucose needed to meet the brain's metabolic needs are not available. The brain has no capability to store oxygen or glucose, so it relies on a constant supply of these nutrients. If the supply of oxygen and glucose is stopped, the brain tissue dies. In contrast to TIA, a brain attack can cause permanent damage if it is not reversed with timely treatment.

Causes and Types

A brain attack can either be ischemic (from deficient blood supply to the brain) or hemorrhagic (from bleeding into the brain). An ischemic brain attack is either thrombotic or embolic. Thrombosis or atherosclerosis can narrow or completely occlude a vessel. People with diabetes and hypertension have an increased risk for atherosclerosis and stroke. Emboli can lodge in a cerebral vessel, stopping the blood flow to that area of the brain. Emboli can occur as a result of endocarditis, atrial fibrillation, or valvular disease but can be dissolved with **thrombolytic** medication if treatment is sought quickly.

Rupture of a cerebral blood vessel can result in a hemorrhagic brain attack. The most common cause of an intracerebral hemorrhage is poorly controlled hypertension. Another cause is a ruptured aneurysm. These hemorrhages tend to occur deep within the brain tissue. This type of infarct has the slowest rate of recovery and the highest probability of leaving the patient with extensive neurological deficits. There is no medication to reverse the effects of this type of brain attack.

The most common etiology of brain attack in younger patients is illicit drug usage. PCP, crack, cocaine, amphetamines, and heroin have all been associated with cerebrovascular accident from subarachnoid or intracerebral hemorrhage, because these drugs raise the blood pressure and increase pressure within the cerebral vessels.

Prevention

Incidence of CVA can be lessened by reduction of risk factors. Risk factors include hypertension, smoking, atherosclerosis, diabetes, and cardiac problems that cause emboli to form. Keeping hypertension and diabetes controlled can go a long way in preventing strokes. Emboli can be prevented with warfarin in individuals with high risk. Aspirin or ticlopidine may also be used. If atherosclerosis is a concern, a carotid endarterectomy may be done.

It is important to educate all patients about new treatments for stroke and the potential for reversal of symptoms with the use of thrombolytic agents. Patients must be aware of symptoms of stroke and the importance of emergency treatment to maximize the potential for prevention of neurological deficits. *Too often patients ignore early symptoms or delay calling for help. This delay can mean the difference between leading a normal life and permanent disability.*

Signs and Symptoms

As with transient ischemic attacks, the signs and symptoms of a cerebrovascular accident relate to the specific vessel involved. (See Table 46–5.) There are some symptoms common to cerebrovascular accidents of different etiologies. These may include changes in level of consciousness, fever, headache, vomiting, and seizures. Other common symptoms include numbness, weakness, or paralysis of one side of the face and one arm or leg; trouble understanding language or speaking coherently; vision changes; and impaired coordination or balance. Additional short-term and long-term manifestations are discussed next.

SHORT-TERM EFFECTS

Neurological Deterioration. Patients suffering from a CVA develop increased intracranial pressure, which further adds to brain damage. Patients are also vulnerable to repeated cerebrovascular accidents. Careful serial neurological assessments are needed to promptly detect and report changes.

Respiratory Compromise. Respiratory compromise may occur related to an increase in intracranial pressure. Patients with CVA are prone to aspiration because of decreased level of consciousness or impaired swallowing ability. Patients should be suctioned as needed to keep the airway clear. If the patient vomits, he or she should be turned to the side to reduce the risk of aspiration. Oral feedings should be begun carefully and progressed slowly only after the patient is alert and the ability to swallow safely has been determined by an appropriate swallowing evaluation.

LONG-TERM EFFECTS

Motor Function. The side of the body opposite the side of the cerebral infarct is affected, because nerve fibers cross over as they pass from the brain to the spinal cord (Fig. 46–5). The affected extremities may be weak or totally paralyzed (**hemiplegia**). An extremity that has no muscle tone

thrombolytic: thrombo—clot + lytic—causing breakdown

hemiplegia: hemi—one side + plegia—paralysis

Figure 46-5 The side opposite the infarct is affected in a brain attack.

or movement at all is called **flaccid**. Depending on the artery affected, the arm may be weaker than the leg or vice versa. These patients are particularly prone to contractures, which cause permanent immobility of a muscle or joint from fibrosis of connective tissue. Adaptation or assistance with activities of daily living (ADLs) is required. Sensory changes may prevent the patient from being aware of injuries to the affected side. Patients should be mobilized within 24 to 48 hours if possible to prevent complications of immobility. Physical and occupational therapy are provided to maximize functioning, and the patient must be taught to be aware of and protect the involved limbs.

Motor involvement often affects swallowing, control of urination, and bowel function. Difficulty swallowing (dysphagia) is a major problem for patients after a stroke and can cause aspiration pneumonia, which can lead to death.

Aphasia. If the infarct is on the dominant side of the brain, the speech center will probably be affected. Aphasia may be expressive, receptive, or global. Persons with expressive aphasia know what they want to say but are unable to speak in a way that can be understood. They may be able to say words but are not able to form coherent speech, such as the patient who picks up a fork but calls it a comb. A patient with receptive aphasia does not understand what is said to him or her. In this situation it is easy to attempt to speak louder to try to help the patient understand. Remember that it is not the patient's hearing that is affected. Global aphasia is a combination of expressive and receptive disturbance.

Emotional Lability. Emotional lability, or instability, is a common consequence of cerebrovascular accident. Patients may move rapidly from profound sadness to an almost euphoric state and back again. Laughing or crying may have

no relationship to the patient's situation at any given moment. Families can be upset by this behavior, because they do not understand why a once happy person is now crying all the time or why the patient laughs inappropriately. You can help by explaining that these responses probably do not reflect how the patient is feeling, but rather are a manifestation of the stroke damage.

Impaired Judgment. Patients who have had a CVA, particularly those with right-sided lesions, present safety risks. Patients may have poor understanding of their own limitations and believe that they are capable of performing tasks they did before the CVA. Precautions must be taken to protect the patient from injury.

If the frontal lobes are involved, learned social behaviors may be lost. The patient may undress in public, use profanity, or make inappropriate sexual advances. These behaviors are extremely difficult for significant others to cope with. Education and emotional support of the significant others are essential. Allowing them to vent their frustration and anger may facilitate coping. Distracting the patient from inappropriate behavior may help. The patient should never be reprimanded or punished, because he or she no longer has the cognitive ability to control the behaviors.

Unilateral Neglect. The phenomenon of unilateral neglect is seen predominantly in patients who have right hemisphere infarcts. These individuals do not acknowledge the left side of their environment. In severe cases the patient may forget to dress the left side of the body. Initially these patients should be approached from the right side. Essential items such as the call light and telephone are placed on the patient's right side. Position the bed so that the patient's right side is toward the door. Gradually the health team can begin teaching the patient to focus on the left side. This in-

volves teaching the patient to purposefully check where the left limbs are positioned and to look for safety risks. The patient can learn to turn his or her head and scan the environment. Patients may need reminders to turn their plates during meals to recognize the food on the left side of the plate.

Homonymous Hemianopsia. Some patients experience a loss of visual field in the same side of each eye. This is called homonymous hemianopsia, and it can cause the patient to ignore one side of a dinner tray or neglect to care for one side of the body.

LEARNING TIPS

When preparing a room for a patient with CVA, the caretaker should choose a room in which the patient can have the unaffected side toward the door if at all possible.

Diagnostic Tests

A CT scan can help determine the size and location of the infarct and whether the cause is hemorrhagic or occlusion of the artery. An EEG, arteriogram, or MRI may be done. If an embolism is suspected, cardiac tests may be done to determine the source.

Treatment

MEDICAL MANAGEMENT. Thrombolytic therapy is a recent development in the treatment of ischemic brain attack. Intracerebral hemorrhage must be ruled out before thrombolytic therapy is instituted. The goal of thrombolytic agents is to actually break down the thrombus causing the occlusion, which can potentially prevent or completely reverse the symptoms of stroke. Plasmin is the enzyme that causes thrombi to break down. Thrombolytic agents accomplish thrombus lysis by causing the conversion of plasminogen to plasmin. Commonly used thrombolytic agents are streptokinase, urokinase, and tissue-type plasminogen activator (TPA). Newer thrombolytics such as tenecteplase are faster and easier to administer. Cerebral hemorrhage is a major complication of thrombolytic therapy. Patients treated effectively with thrombolytic therapy may be able to leave the hospital within 1 or 2 days with no residual effects.

To be effective, thrombolytic therapy must be administered within 3 hours of the onset of symptoms. This time frame has clear implications for nurses. Patients with neurological symptoms who are seen in the emergency department must be assessed and stabilized promptly. A CT scan and, if an ischemic cause is suspected, an angiogram are performed quickly. Some people may be surprised to learn that there are treatments available for brain attack. Because of time constraints, individuals may be asked to make treatment decisions before other family members are able to arrive. This places a significant burden on people who are al-

ready experiencing stress. You can help ease this burden by explaining the time factor, repeating information as needed, and ensuring that the individuals involved have the opportunity to ask questions.

LEARNING TIPS

Time is brain. This means the faster the patient with CVA receives treatment, the more brain (and brain function) may be saved.

Management of the airway and control of hypertension if present are vital for the patient. Care is taken not to lower the blood pressure too quickly or too far. If the patient has long-standing hypertension, lowering the blood pressure to a “normal” level may actually cause further ischemia. Current recommendations are to not lower blood pressure more than 10 percent from baseline at one time. Vasoactive drugs must be used carefully and blood pressure monitored frequently. If the patient experiences neurological deterioration, the physician may adjust treatment to increase the blood pressure. Some physicians believe that the blood pressure should not be lowered because chronically hypertensive patients require a higher BP to maintain adequate cerebral perfusion. As soon as the patient is stabilized, a CT scan is performed to identify any cerebral hemorrhage. Further treatment is dependent on the presence or absence of hemorrhage.

If a CVA is caused by an embolism, anticoagulants may be prescribed. Treatment begins with intravenous heparin sodium. When the clotting studies reach a therapeutic level, oral warfarin is begun. The heparin can be stopped when the warfarin level is therapeutic. Patients need monitoring of prothrombin time (PT) and international normalized ratio (INR) and adjustment of warfarin dosage as long as they are on warfarin. These patients must be instructed to inform all health care providers, including dentists, that they are taking warfarin. The warfarin dosage needs to be adjusted before any invasive procedures are performed. Antiplatelet drugs may be used to lessen platelet aggregation.

SURGICAL MANAGEMENT. Surgical treatment to prevent a cerebrovascular accident was discussed earlier in the section on transient ischemic attacks. Occasionally a **craniotomy** is performed to remove an embolus or thrombus or to repair an aneurysm. Endarterectomy or balloon angioplasty may be performed if the attack is due to carotid blockage. Surgery must be performed within a few hours of the ischemic event if there is to be any possibility of preventing permanent neurological deficits (Box 46-3). For more information, visit the National Stroke Association at www.stroke.org.

craniotomy: crani—skull + otomy

BOX 46-3 Cerebrovascular Accident Summary**Symptoms**

 Speech therapy

Nursing Care

See Nursing Process: The Patient with a Cerebrovascular Disorder. Also see Nursing Care Plan Box 46-4.

Cerebral Aneurysm and Subarachnoid Hemorrhage

A cerebral aneurysm is a weakness in the wall of an artery. It may be congenital, traumatic, or the result of disease. If the aneurysm ruptures, a subarachnoid hemorrhage results. It is unknown what causes the formation of congenital aneurysms or what causes them to rupture. Unruptured aneurysms are typically asymptomatic. The exception to this is very large aneurysms, which can cause symptoms similar to brain tumors. Aneurysms often affect young, otherwise healthy adults.

Pathophysiology and Etiology

Aneurysms can occur in any of the cerebral arteries. Eighty percent of cerebral aneurysms occur in the circle of Willis. The most common site is at the bifurcation of an artery. It is theorized that increased turbulence at the bifurcation causes an outpouching of a congenitally weak arterial wall.

Subarachnoid hemorrhage is the collection of blood beneath the arachnoid mater following aneurysm rupture. Rupture of an arteriovenous malformation (Fig. 46-6) or

BOX 46-4 NURSING CARE PLAN FOR THE PATIENT WITH CEREBROVASCULAR ACCIDENT (STROKE)**Self-care deficit related to immobility and muscle weakness****PATIENT OUTCOMES**

Patient will increase tolerance and endurance for therapies, avoid complications of immobility, and become as independent as possible in activities of daily living.

EVALUATION OF OUTCOMES

Does patient demonstrate techniques and behaviors that enable resumption of activities? Is there absence of contractures and footdrop? Does patient perform self-care activities within level of own ability?

INTERVENTIONS

Assess ability to perform ADLs.
 Encourage early mobilization (bedside commode, chair).
 Avoid doing things patient can do for self, but provide assistance as necessary.
 Allow patient sufficient time to accomplish tasks. Alternate rest with activity.
 Teach family techniques to care for patient. Encourage family to attend therapy sessions.

RATIONALE

Assessment is essential to plan appropriate care.
 Early mobilization prevents complications of bedrest.
 Independence increases self-esteem and motivation.
 Too much activity without rest tires patient and may cause frustration.
 The family will be caring for patient at home unless patient is placed in a nursing home.

EVALUATION

What can patient do? What will patient need help with?
 Is patient able to move with increasing independence? Are complications prevented?
 Is patient becoming more independent?
 Are tiring and frustration avoided?
 Are family members able to demonstrate care activities?

Impaired verbal communication related to aphasia**PATIENT OUTCOMES**

Patient will use strategies to effectively communicate needs.

EVALUATION OF OUTCOMES

Is patient able to communicate needs?

BOX 46-4 NURSING CARE PLAN FOR THE PATIENT WITH CEREBROVASCULAR ACCIDENT (STROKE)**INTERVENTIONS**

Assess type and degree of dysfunction.
Request consult with speech therapist.
Maintain a calm, quiet, unhurried atmosphere.
Use alternative methods of communication as necessary (e.g., writing, communication board, gestures).

RATIONALE

Assessment helps determine strategies that will best help patient.
A speech therapist will assist with assessment and recommendations for communication.
Distractions can be frustrating to the patient and make communication more difficult.
Alternative methods may help patient communicate needs.

EVALUATION

Does patient understand what is being said?
Does patient make self understood?
Are recommendations helpful?

Does patient become frustrated when trying to communicate needs?
Is patient able to use alternative methods to effectively communicate needs?

▶ Disturbed sensory perception related to paresthesias, visual changes**PATIENT OUTCOMES**

The patient will adapt to sensory perceptual changes in vision, sensation, and proprioception and be free from related injury.

EVALUATION OF OUTCOMES

Is patient able to compensate for changes in ability and presence of residual deficits? Is patient free from injury?

INTERVENTIONS

Assess patient's sensory awareness (sensation, vision).

Arrange environment in a consistent manner.
Teach patient to scan the environment.
Assist patient to reposition at least every 2 hours, making sure to prevent areas of pressure.
Keep call light within reach on patient's good side.

RATIONALE

Diminished sensory awareness can place patient at risk for injury.

A familiar environment enhances safety.

Scanning compensates for a visual deficit.

Patient may not be able to reposition self and may not feel excess pressure that can cause skin breakdown.
Patient may not be able to find call light on affected side.

EVALUATION

Can patient differentiate between hot and cold, dull and sharp? Differentiate position of body parts? Feel pressure?
Can patient locate needed items?

Does scanning help patient to locate items?

Is skin free from breakdown?

Is patient able to use call light when needed?

▶ Impaired nutrition: less than body requirements related to motor and swallowing dysfunction**PATIENT OUTCOMES**

Patient will eat and drink foods and fluids without aspiration and maintain usual or attain ideal body weight.

EVALUATION OF OUTCOMES

Is patient able to consume adequate foods and fluids? Is patient at ideal or usual body weight?

INTERVENTIONS

Assess patient's ability to chew and swallow. Assess height and weight.

Request swallowing study/dietitian consult if indicated.

Institute swallowing safety measures. (See Nutrition Notes Box 46-5.)
Teach patient to chew on unaffected side. Check affected cheek for pocketing of food.

RATIONALE

Patient should not be fed until ability to swallow safely is determined. Aspiration can cause pneumonia and death.
A swallowing study can detect risk for aspiration. A dietitian can provide foods that are easily swallowed.
These interventions help prevent aspiration.

Patient may not be aware of foods on affected side.

EVALUATION

How well can patient swallow? Are height and weight within normal limits?

Does study show safe swallowing? Are appropriate foods provided?

Does patient swallow without aspiration?

Does patient pocket food?

head trauma may also result in subarachnoid hemorrhage. The presence of blood outside the blood vessels is very irritating to brain tissue. It is believed that irritation from blood breakdown is the major cause of vasospasm, a common complication of subarachnoid hemorrhage.

It is unclear what causes an aneurysm to rupture at a given time. Some individuals experience a subarachnoid hemorrhage while performing Valsalva's maneuver, engaging in sexual activity, or physically exerting themselves. For other patients the aneurysm ruptures during a quiet, nonactive pe-

Figure 46-6 Arteriovenous malformation. Note tangled vessels.

riod. If the aneurysm rupture is associated with a particular activity, the patient may be very frightened of engaging in that activity again. This may have a negative effect on the patient's interpersonal relationships if the associated activity was sexual in nature. The patient's partner may feel guilty or responsible for the hemorrhage. Emotional support and confidentiality regarding associated events help both the patient and significant other.

Signs and Symptoms

Some patients experience a small hemorrhage before diagnosis of subarachnoid hemorrhage. This leakage of blood may cause a mild headache, vomiting, or disorientation. The symptoms may be attributed to a flulike syndrome. Patients may dismiss the symptoms and not seek medical care.

The most common presentation of rupture of an aneurysm is sudden onset of severe headaches. Typically patients state, "I have never had a headache this bad in my life." Patients may hold their heads and moan or cry in pain. Sensitivity to light is a common finding. This may make patients reluctant to cooperate with pupil checks.

Level of consciousness varies based on the severity of the hemorrhage. Patients may be alert and coherent, may lose consciousness immediately, or may gradually become less responsive. The decreased level of consciousness is caused by increased ICP and impairment of cerebral blood flow. Patients may experience generalized seizures.

Blood in the subarachnoid space causes meningeal irritation. The patient may complain of nuchal rigidity. The most commonly affected cranial nerves are III and VI. This is manifested as an enlarged pupil or disconjugate gaze. Motor dysfunction may involve one or both limbs on the side opposite the hemorrhage.

Diagnostic Tests

Because of the severe nature of the symptoms, patients with subarachnoid hemorrhage almost always come to the emergency department rather than seeking care from routine

health care providers. A CT scan is done to identify the presence and location of a hemorrhage. Precise diagnosis of an aneurysm requires a cerebral angiogram. The contrast material will fill the aneurysm if one exists. For a patient with a severe headache and facing a life-threatening illness, this test can be very frightening. If the patient's neurological status does not allow him or her to cooperate, sedation may be required before and during the examination.

Treatment

SURGICAL MANAGEMENT. There is no cure for subarachnoid hemorrhage. Treatment consists of correcting the cause of the hemorrhage if possible. Preventing or managing complications and providing supportive care are important aspects of nursing care. Definitive treatment of the aneurysm involves performing a craniotomy and exposing the aneurysm. If the aneurysm has a neck (berry aneurysm), it is identified and clamped with a metal clip (Fig. 46-7). An aneurysm without a neck may be wrapped with very fine sterile muslin. This provides stability to the aneurysm walls, lessening the chance of rupture. In some situations it is possible to clamp the artery on either side of the aneurysm, removing that portion of the vessel, and the aneurysm, from the circulation.

MEDICAL MANAGEMENT. Nonsurgical intervention may be provided for aneurysms that are inoperable because of size, configuration, or the patient's medical status. A foreign material such as a tiny metallic coil or fibrin glue may be introduced into the aneurysm. A thrombus develops around the foreign body and, if the treatment is successful, occludes the aneurysm. The goal is to fill the aneurysm enough to prevent blood flowing into it without causing rupture.

Patients experiencing a subarachnoid hemorrhage are cared for in an intensive care unit setting. They typically have an arterial line and a central venous pressure monitoring catheter. The blood pressure is carefully monitored, because high pressures increase the risk of rerupture of the aneurysm and low pressures may be associated with ischemia. Values outside parameters identified by the physician

Figure 46-7 Surgical management of aneurysms.

are reported. Typically the systolic blood pressure is kept between 120 and 160. Vasoactive drugs may be required to maintain blood pressure within the prescribed parameters.

Acute Complications

REBLEEDING. Recurrent rupture of cerebral aneurysm carries significant morbidity and mortality rates. Patients are at risk for rebleeding until the aneurysm is surgically repaired. If the aneurysm is wrapped or embolized, there is a risk of rebleeding, but it is much less than if the aneurysm is left untreated.

HYDROCEPHALUS. Blood within the ventricular system interferes with the circulation, and reabsorption of CSF and hydrocephalus may develop. Early in the course of subarachnoid hemorrhage an external ventricular drain may be used to treat hydrocephalus (discussed earlier).

Approximately 25 percent of patients with subarachnoid hemorrhage require placement of a ventriculoperitoneal shunt to treat their hydrocephalus (Fig. 46–8). This surgical procedure involves placement of a ventricular catheter. This catheter is then connected to a valve, which regulates the rate of cerebrospinal fluid drainage. Another catheter connects to the valve and is passed down to the peritoneal cavity. The cerebrospinal fluid drains out of the peritoneal catheter and is absorbed into the peritoneal cavity.

VASOSPASM. Vasospasm is responsible for the majority of long-term complications of subarachnoid hemorrhage. Vasospasm is the narrowing of a blood vessel diameter. Although it typically begins in the vessel giving rise to the aneurysm, vasospasm may spread to other vessels. This ex-

plains why the ischemia or infarct caused by vasospasm can be so widespread and devastating.

The long-term complications of subarachnoid hemorrhage are similar to those of cerebrovascular accident.

Nursing Process: The Patient with a Cerebrovascular Disorder

ASSESSMENT. Patients with cerebrovascular disorders require careful serial assessments of their neurological status, as described in Chapter 45. Subtle changes in orientation, level of consciousness, or motor strength may indicate ischemia or increasing intracranial pressure. By detecting and reporting such changes quickly, you can improve the likelihood of a successful outcome for the patient. In addition to assessing for changes in status, determine the patient's ability to use the call light. Assess swallowing ability before offering food or drink to prevent aspiration. This may involve radiological swallowing studies. The patient should not be fed if swallowing ability is in question. Determine the patient's ability to move and need for assistance with turning in bed. The patient and family can also provide information about the patient's previous level of functioning.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Goals during the acute phase of the CVA include prevention of complications and recurrent CVA. Discharge planning should be initiated as soon as possible after admission, though it may be difficult to anticipate needs until the extent of the patient's deficits are known. Most patients require some rehabilitation to reach an optimum level of function. Consultation with the patient, significant others, and social worker or discharge planner should be ongoing. Possible nursing diagnoses and interventions during the acute phase of illness include the following.

Ineffective Tissue Perfusion Related to Increased ICP. Patients are at risk for increased intracranial pressure following a CVA. The patient in intensive care may have an intracranial pressure monitor. Any activities or interventions that increase ICP should be avoided, such as repeated suctioning, coughing, and vigorous turning. (See Table 46–4.)

Risk for Injury Related to Seizure or Repeat CVA. Precautions should be taken to prevent injury in the event of a seizure. (See Table 46–3.) If the patient has had a seizure, anticonvulsant medications may be ordered. Patients who have had a CVA are also at risk for a repeat CVA. Changes in neurological status should be reported immediately to the physician. Patients are also at risk for falls because of motor and sensory deficits and impaired judgment. Patients should be assisted with transfers and ambulation. Because many falls occur as patients are attempting to get up to use the bathroom, assisting the patient to the bathroom or bedside commode on a routine basis can help. Care should be taken to keep the patient's path unobstructed. Family members should be instructed in fall prevention if the patient is going home.

Imbalanced Nutrition Related to Impaired Swallowing and Motor Deficits. If the patient has difficulty swallowing

Figure 46-8 A ventriculoperitoneal shunt drains cerebrospinal fluid into the peritoneal cavity.

or is unable to self-feed, altered nutrition is a concern. The physician may order a swallowing study to determine the extent of the problem. A speech-language pathologist assesses the patient and makes recommendations for safe swallowing techniques. Measures to prevent aspiration generally include staying with the patient during meals, having the patient in a chair or high Fowler's position for meals, avoiding straws, using a thickening agent for thin liquids, and having the patient swallow twice after each bite. Check the patient's mouth after each bite, because patients may pocket food on the affected side of the mouth. See Nutrition Notes Box 46-5 for additional interventions. Some patients may require a feeding tube. Advance directives should be consulted before a feeding tube is placed.

Impaired Mobility Related to Motor Deficits. The patient with hemiplegia has difficulty turning or repositioning. If the patient has sensory deficits, pain or pressure are not noticed and injury may occur. Careful and frequent repositioning is essential to prevent skin, respiratory, and musculoskeletal complications. Pillows can be used to maintain the body in good alignment and promote comfort. Skin should be inspected each time the patient is repositioned. Range-of-motion exercises should be begun within 24 hours of admission to help prevent contractures. Splints may be used for some patients to maintain a functional position of extremities. Some patients experience injury to the shoulder of an affected arm. Care should be taken to support the arm on pillows when it is in a dependent position. Use a lift sheet to reposition the patient in bed, rather than pulling on the arms. A physical therapist can be consulted to assess the patient and make specific recommendations related to mobility.

BOX 46-5*Nutrition Notes***Feeding Patients with Swallowing Disorders**

Suggestions for persons who have difficulty swallowing include the following:

- Eat slowly.
- Avoid distractions while eating.
- Do not talk while eating.
- Sit up straight while eating.
- Use a regular teaspoon, taking only half a teaspoonful at a time.
- Swallow completely between bites or sips.

Possible nursing interventions to aid a person with a swallowing disorder include the following:

- Remove loose dentures.
- Position the head correctly. A speech therapist can help determine the optimum head position. A hemiplegic patient often benefits from turning the head toward the weak side.
- When spoon feeding a patient with hemiplegia, place the food on the unaffected side of the tongue.
- Consult a dietitian concerning appropriate textures. Often thicker substances are better managed than liquids. Although infant cereal can be an effective thickener, it may be rejected on a psychological basis in favor of instant potato flakes, unflavored gelatin, or a commercial thickener.

Impaired Verbal Communication Related to Aphasia.

Aphasia can cause great frustration to the patient, family, and caregivers. Care depends on whether the aphasia is receptive or expressive. If you have determined that the patient's responses are valid, asking yes/no questions may be helpful. Gestures and visual aids may be tried. Contact a speech or occupational therapist to acquire a picture board for the patient. This board has pictures on it that the patient can point to, such as a glass of water, tissue, toilet, hungry, too hot, and others (Fig. 46-9). Some patients can relearn language skills with the help of a speech therapist. It is important that staff and family continue to speak to the patient, because he or she may understand what is being said but may be unable to respond.

Deficient Knowledge Related to Diagnosis and Treatment.

The patient and significant other are likely to be very frightened of what is happening. Correct information about what a CVA is, tests and procedures, and rationale for care activities help reduce anxiety. Information should be presented in small amounts and as simply as possible. Orientation to the ICU or other setting and the constant monitoring provided helps reassure the patient and significant others that he or she is receiving competent care. If the patient is unable to communicate, do not assume that he or she cannot hear and understand. Every effort should be made to speak to the patient and to keep conversation appropriate when it is within the patient's range of hearing.

Risk for Caregiver Role Strain Related to New Responsibilities.

Cerebrovascular accidents, even those that leave relatively mild residual effects, have a significant impact on psychosocial functioning. Patients and their significant others may experience changes in roles, responsibilities, finances, and intimacy. Significant others should be encouraged to assess how the patient's functional level will affect their lives. Encourage them to identify support systems and make use of community resources. Assumption of roles or responsibilities previously fulfilled by the patient may be very stressful to significant others. The nurse and social worker can help them identify priorities and plan ways of adapting to change. (See Nursing Care Plan 46-4 for the Patient with a Cerebrovascular Accident.)

EVALUATION. As with all neurological disorders, the goal is to return the patient to his or her previous level of functioning. If this is not feasible, success is measured by the patient's lack of preventable complications and readiness for rehabilitation.

Rehabilitation

If the patient is able to tolerate intensive therapy, discharge from the hospital may be to a rehabilitation center. With rehabilitation, most patients can learn to walk, some with a walker or cane. Speech therapy can help the patient learn to communicate. Many patients can learn to take care of themselves. Some may be able to drive again and even have a job.

CRITICAL THINKING

Mrs. Washington

Mrs. Washington is a 68-year-old African-American retired office worker. She was admitted to your unit following a right-sided intracerebral hemorrhage. Her daughter states that Mrs. Washington has taken antihypertensive medication for the last 20 years. However, she states that her mother has been “forgetful” lately and that there are five more pills in the medicine bottle than expected. On admission Mrs. Washington is oriented only to person and has hemiparesis.

1. What may have precipitated Mrs. Washington’s CVA?
2. On which side are Mrs. Washington’s extremities affected?
3. List two safety concerns and strategies to promote patient safety.
4. List at least two educational needs for Mrs. Washington and her daughter.

Answers at end of chapter.

SEIZURE DISORDERS

Seizures

A seizure is defined as an abnormal electrical discharge within the neuronal structure of the brain. A seizure may be a symptom of epilepsy or of other neurological disorders such as a brain tumor or brain attack. Epilepsy is a chronic neurological disorder characterized by recurrent seizure activity.

Pathophysiology

The normal stability of the neuron cell membrane is impaired in individuals with epilepsy. This instability allows for abnormal electrical discharges to occur. These discharges cause the characteristic symptoms seen during a seizure.

Seizures can be classified as partial or generalized. Partial seizures begin on one side of the cerebral cortex. In some cases the electrical discharge spreads to the other hemisphere and the seizure becomes generalized. Generalized seizures are characterized by involvement of both cerebral hemispheres.

Etiology

Epilepsy may be acquired or idiopathic. Causes of acquired epilepsy include traumatic brain injury and anoxic events. No cause has been identified for idiopathic epilepsy. The most common time for idiopathic epilepsy to begin is before age 20. New-onset seizures after this age are most commonly caused by an underlying neurological disorder.

Signs and Symptoms

Symptoms of seizure activity correlate with the area of the brain where the seizure begins. Some patients experience an aura or sensation that warns the patient that a seizure is about to occur. An aura may be a visual distortion, a noxious odor, or an unusual sound. Patients who experience an aura may have enough time to sit or lie down before the seizure starts, thereby minimizing the chance of injury.

PARTIAL SEIZURES. Repetitive, purposeless behaviors, called automatism, are the classic symptom of partial seizures. The patient appears to be in a dreamlike state while picking at his or her clothing, chewing, or smacking his or her lips. Patients may be labeled as mentally ill, particularly if automatism include unacceptable social behaviors such as spitting or fondling themselves. Patients are not aware of their behavior or that it is inappropriate. If the patient does not lose consciousness, the seizure is labeled as simple partial and usually lasts less than 1 minute. Older terms for simple partial seizures include *jacksonian* and *focal motor*. If consciousness is lost, it is called a complex partial seizure or psychomotor seizure. It may last from 2 to 15 minutes.

Partial seizures arising from the parietal lobe may cause paresthesias on the side of the body opposite the seizure focus. Visual disturbances are seen if the occipital lobe is the originating site. Involvement of the motor cortex results in involuntary movements of the opposite side of the body. Typically movements begin in the arm and hand and may spread to the leg and face.

GENERALIZED SEIZURES. Generalized seizures affect the entire brain. Two types of generalized seizures are absence seizures and tonic-clonic seizures. Absence seizures, sometimes referred to as petit mal seizures, occur most often in children and are manifested by a period of staring that lasts several seconds.

Tonic-clonic seizures are what most laypeople envision when they think of seizures. They are sometimes called grand mal seizures or convulsions. Tonic-clonic seizures follow a typical progression. Aura and loss of consciousness may or may not occur. The tonic phase, lasting 30 to 60 seconds, is characterized by rigidity, causing the patient to fall if not lying down. The pupils are fixed and dilated, the hands and jaws are clenched, and the patient may temporarily stop breathing. The clonic phase is signaled by contraction and relaxation of all muscles in a jerky, rhythmic fashion. The extremities may move forcefully, causing injury if the patient strikes furniture or walls. The patient is often incontinent. Biting the lips or tongue may cause bleeding. An oral airway can be used to prevent self-injury if the patient’s mouth is open. Never attempt to force an airway or anything else into the patient’s mouth if the jaws are clenched.

The **postictal** period is the recovery period after a seizure. Following a partial seizure the postictal phase may be no more than a few minutes of disorientation. Patients who experience a generalized seizure may sleep deeply for 30 minutes to several hours. Following this deep sleep, patients may complain of headache, confusion, and fatigue. Patients may realize that they had a seizure but not remember the event itself.

Diagnostic Tests

An EEG is the most useful test for evaluating seizures. An EEG can determine where in the brain the seizures start, the

postictal: post—after + ictal—seizure

frequency and duration of seizures, and the presence of subclinical (asymptomatic) seizures. Sleep deprivation and flashing light stimulation may be used to evaluate the seizure threshold. See Chapter 45 for more information on EEG.

Medical Management

If an underlying cause for the seizure is identified, treatment focuses on correcting the cause. If no cause is found or if the seizures continue despite treatment of concurrent disorders, treatment focuses on the seizure activity.

Numerous anticonvulsant medications are available, each with specific actions, therapeutic ranges, and potential side effects (Table 46-6). Typically the patient is started on one drug and the dosage is increased until therapeutic levels are attained or side effects become troublesome. If seizures are not controlled on a single drug, another medication is added. Most anticonvulsants require periodic blood tests to monitor serum levels and kidney and liver function. If seizures continue despite anticonvulsant therapy, surgical intervention may be considered.

Surgical Management

The success of surgical intervention for epilepsy depends on identification of an epileptic focus within nonvital brain tissue. If no focus is identified or if it is in a vital area such as the motor cortex or speech center, surgery is not feasible. The surgeon attempts to resect the area affected to prevent spread of seizure activity. In some cases, seizures may be cured, but in others the goal is to reduce the frequency or severity of the seizures.

The preoperative assessment for epilepsy surgery is an extensive multistage process. Thorough assessment and teaching are essential. To adequately identify seizure foci, the patient is weaned off anticonvulsant therapy. Increasing the frequency of seizures is anxiety provoking to patients and significant others.

Emergency Care

The prime objective in caring for a patient experiencing a seizure is to prevent injury. Side rails should be padded to prevent injury if the patient strikes his or her extremities

against them. If the patient falls to the floor, move furniture out of the way. A small pillow should be placed under the patient's head to prevent striking it on the floor, taking care that the airway does not become occluded. If possible, turn the patient on his or her side to prevent aspiration if vomiting occurs. An oral airway and suction should be readily available. Do not force an airway in once the seizure has begun. The individual should not be restrained, because this may increase the risk of injury. Observe and document eye deviation, incontinence, which part of the body was first involved, and progression of the seizure (Patient Perspective Box 46-6).

Status Epilepticus

Status epilepticus is characterized by at least 30 minutes of repetitive seizure activity without a return to consciousness. This is a medical emergency and requires prompt intervention to prevent irreversible neurological damage. Abrupt cessation of anticonvulsant therapy is the usual cause of status epilepticus.

Seizure activity precipitates a significant increase in the brain's need for glucose and oxygen. This metabolic demand is even greater during status epilepticus. Irreversible neuronal damage may occur if cerebral metabolic needs cannot be fulfilled. Adequate oxygenation must be maintained, if neces-

BOX 46-6 Patient Perspective

I have had seizures for 35 years and as a result of falling during seizures have experienced cuts, bruises, and a broken bone. I usually have an aura that lets me know a seizure is about to occur. This is helpful if I can get myself to a safe place to prevent falling or being injured. When a patient is having a seizure you can best help by using padding such as pillows or blankets for protection, talking calmly, and using gentle touch to prevent injury. You should not sit on or hold down someone during a seizure. I have had the frightening experience of waking up with a nurse sitting on me and holding down my arms. After you have protected the patient, let them come out of the seizure on their own. When the seizure is over, I usually want to sleep because seizures are exhausting and uncomfortable. I will rest better knowing you are watching over me to keep me safe.

TABLE 46-6 SELECTED ANTICONVULSANT MEDICATIONS

Medication	Action	Side Effects/Comments
Phenytoin (Dilantin)	Limits seizure propagation; may also be used for some cardiac dysrhythmias and some types of nerve pain	May cause gingival hyperplasia, nausea, ataxia, rash; regular dental care essential; therapeutic level is 10–20 $\mu\text{g}/\text{mL}$
Phenobarbital (Luminal)	CNS depressant; raises seizure threshold	Causes drowsiness; often given with phenytoin
Carbamazepine (Tegretol)	Decreases synaptic transmission in CNS; may be used for some types of neuralgias	Common side effects: drowsiness and ataxia; used if other drugs ineffective; therapeutic level 6–12 $\mu\text{g}/\text{mL}$
Valproic acid (Depakote)	Increases GABA, an inhibitory neurotransmitter in CNS	Causes GI upset, nausea, vomiting; therapeutic level 50–100 $\mu\text{g}/\text{mL}$
Clonazepam (Klonopin)	CNS sedative; may also be used for neuralgia or restless leg syndrome	Side effects: drowsiness, ataxia, changes in behavior; therapeutic level 20–80 ng/ml
Gabapentin (Neurantin)	Unknown	Causes fatigue, dizziness. May cause leukopenia.

GABA = gamma-aminobutyric acid.

sary by intubating and mechanically ventilating the patient. These patients are also at significant risk for aspiration.

Intravenous diazepam (Valium) or lorazepam (Ativan) is given to stop the seizures. Because both these drugs may cause respiratory depression, careful airway management is required. After obtaining serum drug levels, anticonvulsant therapy is adjusted to achieve therapeutic levels.

If seizures remain resistant to treatment, a barbiturate coma may be induced with intravenous pentobarbital. The last line of treatment for status epilepticus is general anesthesia or pharmacological paralysis. Both these therapies require intubation, mechanical ventilation, and management in an ICU setting. Continuous EEG monitoring is used to verify that the seizures have actually stopped. A patient treated with neuromuscular blockade drugs may still be seizing but have no visible manifestations. For more information, visit the Epilepsy Foundation of America at www.effa.org.

Nursing Management of Seizures

Assessment

Perform a general neurological assessment of the patient with a history of seizures. Determine the type of seizure manifestations and type of aura if any. Assess the patient's knowledge of the disease and its treatment. It is important to assess whether the patient has the resources to purchase prescribed anticonvulsant medications and whether the medication regimen is adhered to. Drug levels may help determine degree of compliance with therapy.

Nursing Diagnosis, Planning, and Implementation

The goal is for the patient and significant others to be able to manage the treatment effectively to prevent seizures. If seizures occur, the goal is to prevent injury. Priority nursing diagnoses for the patient at risk for seizures include the following.

RISK FOR INJURY RELATED TO SEIZURE ACTIVITY. Instruct the patient to recognize the aura and to get to safety if it occurs. This may mean lying down away from furniture or other objects that may cause harm. For the patient admitted to a health care institution, seizure precautions are instituted. If a seizure does occur, the patient's safety is maintained. See Table 46-3 for precautions and interventions for seizures. Encourage all patients to wear medical alert jewelry or other identification to alert others to the presence of seizure disorder.

Some patients can identify conditions that trigger seizures. Hypoglycemia, hypoxia, and hyponatremia are all potential triggers of hypersensitive neurons. Teach the patient the importance of a consistent schedule of eating and sleeping.

RISK FOR INEFFECTIVE MANAGEMENT OF THERAPEUTIC REGIMEN RELATED TO COMPLEX REGIMEN AND POSSIBLE LACK OF RESOURCES. Patients with seizures may have several medications to take several times each day. This

makes compliance difficult at best. Medication teaching is vital. Patients need to understand dosing, potential side effects, possible interactions with alcohol and other medications, and the importance of regular blood tests. If finances are a concern, the patient may be unable to obtain prescriptions. Patients must understand the risk for seizures and status epilepticus if medications are stopped abruptly. A nurse or social worker can help the patient apply for assistance to pay for medications if necessary.

ANXIETY RELATED TO RISK FOR SEIZURES. Epilepsy is a chronic disorder with significant impact on lifestyle. Patients may be ashamed to acknowledge their condition and may try to hide it from others. Provide the patient with current, accurate information and help him or her identify coping strategies to maximize independence. Support groups may also be helpful.

INEFFECTIVE ROLE PERFORMANCE RELATED TO POSSIBLE DISABLING DISORDER. Finances can be a major concern to these patients. Some patients with epilepsy experience hiring discrimination, or they may not qualify for some jobs in which safety is a concern. Remind patients that falsifying information on job applications may be grounds for dismissal. Refusal of health insurance coverage can create financial hardships for patients on long-term medications. Most patients whose seizures are controlled can work and lead productive lives. You can help patients explore options for financial assistance if necessary.

Patients with poorly controlled seizures should not operate motor vehicles. In our society a driver's license is a sign of adulthood and independence, and patients who cannot drive may experience lowered self-esteem. Job opportunities may be limited for patients who depend on public transportation. Encourage the patient to obtain a state identification card. This can be used in place of a driver's license for identification.

Patients may limit interpersonal relationships out of fear of having a seizure. The involuntary movements, sounds, and possible incontinence that occur with seizures are embarrassing to patients and can be frightening to laypeople. Role playing may help the patient determine when and how to confide in others.

Evaluation

Successful care of a patient with epilepsy is manifested by a decrease in seizures to the lowest possible frequency. Patient verbalization of understanding of needed lifestyle changes is another indication of success. Patients should be able to state measures to prevent injury if a seizure should occur and should verbalize understanding of all medications and their administration schedules. Therapeutic drug levels may be measured to evaluate compliance with the medication regimen.

► TRAUMATIC BRAIN INJURY

Traumatic brain injury is a major cause of death and disability in adults. Young males make up a large proportion of brain injury victims. The use of alcohol and illicit drugs is often associated with brain injury.

Pathophysiology

Traumatic brain injury is a complex phenomenon with results ranging from no detectable effect to persistent vegetative state. Trauma can result in hemorrhage, contusion or laceration of the brain, and damage at the cellular level. In addition to the primary insult, the brain injury may be compounded by cerebral edema, hyperemia, or hydrocephalus.

Etiology

Motor vehicle accidents account for the largest percentage of traumatic brain injuries. Violent assaults are increasing in frequency and may be accompanied by penetrating brain injuries. Falls and sports-related injuries are also common causes of traumatic brain injury.

The brain is susceptible to several types of injury. *Acceleration injury* is the term used to describe a moving object hitting a stationary head. An example of this type of injury is a patient who is hit in the head with a baseball bat. A deceleration injury occurs when the head is in motion and strikes a stationary surface. This type of injury is seen in patients who trip and fall, hitting their head on furniture or the floor.

A combination of acceleration-deceleration injury occurs when the stationary head is hit by a mobile object and the head then strikes a stationary surface. A soccer player who sustains a blow to the head and then hits the ground with his or her head may sustain an acceleration-deceleration injury.

Rotational injuries have the potential to cause shearing damage to the brain, as well as laceration and contusions. Rotational injuries may be caused by a direct blow to the head or may occur during a motor vehicle accident in which the vehicle is struck from the side. Twisting of the brainstem can damage the reticular activating system, causing loss of consciousness. Movement of the brain within the skull may result in bruising or tearing of brain tissue where it comes in contact with the inside of the skull.

Types of Brain Injury and Signs and Symptoms

CONCUSSION. Cerebral concussion is considered a mild brain injury. If there is a loss of consciousness, it is for 5 minutes or less. Concussion is characterized by headache, dizziness, or nausea and vomiting. The patient may complain of amnesia of events before or after the trauma. On clinical examination there is no skull or dura injury and no abnormality detected on CT or MRI.

CONTUSION. Cerebral contusion is characterized by bruising of brain tissue, possibly accompanied by hemorrhage. There may be multiple areas of contusion, depending on the causative mechanism. Severe contusions can result in diffuse axonal injury. The symptoms of a cerebral contusion depend on the area of the brain involved.

Brainstem contusions affect level of consciousness. The decreased level of consciousness may be transient or permanent. Respirations, pupil reaction, eye movement, and motor response to stimuli may also be affected. The autonomic

nervous system may be affected by edema or by hypothalamic injury, causing rapid heart rate and respiratory rate, fever, and diaphoresis.

HEMATOMA. Subdural hematomas are classified as acute or chronic based on the time interval between injury and onset of symptoms. Acute subdural hematoma is characterized by appearance of symptoms within 24 hours following injury. The bleeding is typically venous in nature and accumulates between the dura and arachnoid membranes (Fig. 46–10). Approximately 24 percent of patients who sustain a severe brain injury develop an acute subdural hematoma. Damage to the brain tissue itself may cause an altered level of consciousness. Therefore it can be difficult to recognize a subdural hematoma based only on clinical examination. As the subdural hematoma increases in size, the patient may exhibit one-sided paralysis of extraocular movement, extremity weakness, or dilation of the pupil. Level of consciousness may deteriorate further as ICP increases.

Elderly and alcoholic individuals are particularly prone to chronic subdural hematomas. Atrophy of the brain, common in these populations, stretches the veins between the brain and the dura. A seemingly minor fall or blow to the head can cause these stretched veins to rupture and bleed. Often there are no other injuries associated with the trauma. Because a chronic subdural hematoma can develop weeks to months after the injury, the patient may not remember an injury occurring.

The patient with a chronic subdural hematoma may be forgetful, lethargic, or irritable or may complain of a headache. If the hematoma persists or increases in size, the

Figure 46-10 (A) Subdural hematoma is usually venous and forms between the dura and the arachnoid membranes. (B) An epidural hematoma is usually from an arterial bleed and forms between the dura mater and the skull.

subdural: sub—below + dural—pertaining to the dura mater

patient may develop hemiparesis and pupillary changes. The patient or significant other may not associate the symptoms with a previous injury and therefore may delay seeking medical care.

Approximately 10 percent of patients with severe brain injuries develop **epidural** hematomas. This collection of blood between the dura mater and skull is usually arterial in nature and is often associated with skull fracture. (See Fig. 46–10.) Arterial bleeding can cause the hematoma to become large very quickly. Patients with epidural hematoma typically exhibit a progressive course of symptoms. The patient loses consciousness directly after the injury; he or she then regains consciousness and is coherent for a brief period. The patient then develops a dilated pupil and paralyzed extraocular muscles on the side of the hematoma and becomes less responsive. If there is no intervention, the patient becomes unresponsive. Seizures or hemiparesis may occur. Once the patient exhibits symptoms, the deterioration may be rapid. Airway management and control of ICP must be instituted immediately. If ICP is not controlled, the patient will die.

Diagnostic Tests

CT scan is usually the first imaging test performed on the brain-injured patient. It is faster and more accessible than MRI. This is particularly important for unstable patients or those with multiple injuries. It is easier to identify skull fractures on CT than on MRI. MRI may be used later to identify damage to the brain tissue.

Neuropsychological testing can be useful in assessing the patient's cognitive function. This information helps direct rehabilitation placement, discharge planning, and return to work or school. Neuropsychological testing identifies problems with memory, judgment, learning, and comprehension. Compensation strategies can be suggested to the patient and significant others based on the results.

Treatment

SURGICAL MANAGEMENT. Surgical treatment of hematomas is discussed under intracranial surgery later in this chapter.

MEDICAL MANAGEMENT. Medical management of traumatic brain injury involves control of ICP and support of body functions. Brain-injured patients may be partially or completely dependent for maintenance of respiration, nutrition, elimination, movement, and skin integrity.

A variety of techniques are used to control intracranial pressure in the patient with moderate or severe brain injury. The first step is to insert an ICP monitor to allow determination of the ICP. Refer to the section on increased ICP earlier in this chapter for further information.

If ICP remains elevated despite drainage of cerebrospinal fluid, the next step is use of an osmotic diuretic. The most commonly used drug is intravenous mannitol (Osmitol). Mannitol utilizes osmosis to pull fluid into the intravascular

space and eliminate it via the renal system. Serum osmolarity and electrolytes must be carefully monitored when mannitol is being administered. Some patients experience a rebound increase in ICP after the mannitol wears off.

Mechanical hyperventilation is the next step if the patient is still experiencing increased ICP. Hyperventilation is effective in lowering ICP because it causes vasoconstriction. This allows less blood into the cranium, thereby lowering ICP. Research has demonstrated, however, that aggressive hyperventilation, particularly within the first 24 hours after injury, may induce ischemia in the already compromised brain. Therefore hyperventilation is now reserved for increased ICP that does not respond to other treatments.

High-dose barbiturate therapy may be used to induce a therapeutic coma, which reduces the metabolic needs of the brain during the acute phase following injury. These patients are completely dependent for all their needs and care. They will be mechanically ventilated and cared for in an ICU setting. Vasopressors may be required to maintain blood pressure, and the patient's temperature should be kept as normal as possible.

If none of these interventions is successful, the patient may experience uncontrolled edema or herniation of brain tissue (Fig. 46–11). Herniation is displacement of brain

Figure 46-11 Herniation of the brain. (A) Normal brain. (B) Herniation of brain tissue into tentorial notch.

epidural: epi—above + dural—pertaining to the dura mater

tissue out of its normal anatomic location. This displacement prevents function of the herniated tissue and places pressure on other vital structures, most commonly the brainstem. Herniation usually results in brain death.

Patients who experience brain death may be suitable organ donor candidates. For some significant others, the opportunity to donate their loved one's organs provides some sense of purpose in the death (Box 46–7).

Acute Complications of Traumatic Brain Injury

DIABETES INSIPIDUS. Edema or direct injury affects the posterior portion of the pituitary gland or hypothalamus. Inadequate release of antidiuretic hormone results in polyuria and, if the patient is awake, polydipsia. Fluid replacement and intravenous vasopressin are used to maintain fluid and electrolyte balance.

ACUTE HYDROCEPHALUS. Cerebral edema can interfere with cerebrospinal fluid circulation, causing hydrocephalus. Initial treatment is with an external ventricular drain, followed by a ventriculoperitoneal shunt if necessary.

LABILE VITAL SIGNS. Direct trauma to or pressure on the brainstem can cause fluctuations in blood pressure, cardiac rhythm, or respiratory pattern. Treatment is aimed at control of intracranial pressure.

Long-Term Complications

POSTTRAUMATIC SYNDROME. Patients who sustain a concussion may experience ongoing, somewhat vague symptoms. They complain of headache, fatigue, difficulty concentrating, depression, or memory impairment. Symptoms may be severe enough to interfere with work, school, and interpersonal relationships. Neuropsychological testing may provide objective evidence of cognitive dysfunction and establish the need for cognitive rehabilitation. Symptoms may take 3 to 12 months to resolve.

COGNITIVE AND PERSONALITY CHANGES. Alterations in personality and cognition may be the most difficult

long-term complication for patients and significant others to adjust to. The patient may have significant short-term memory impairment. This limits his or her ability to learn new information and may interfere with ability to function at work or school. Impaired judgment can make the patient a safety risk to self or others. It also affects social functioning.

Emotional lability, loss of social inhibitions, and personality changes may occur. These consequences of traumatic brain injury have a profound effect on the patient and significant others. Spouses may state, “This is not the person I married.” If behavior is violent, bizarre, or profane, children may be unwilling to bring their friends home and may become socially isolated. Young children, in particular, have difficulty understanding why the parent is behaving so differently. Disintegration of relationships is not uncommon following traumatic brain injury.

Neuropsychological testing objectively identifies problems. These deficits can then be addressed with cognitive rehabilitation. Individual and family counseling may be of benefit. Support groups for patients and significant others are often helpful.

Motor and speech impairment are additional possible long-term complications of traumatic brain injury. Intensive rehabilitation provides the best opportunity for maximizing recovery. For more information, visit the Brain Injury Association at www.biausa.org.

Nursing Process: The Patient with Traumatic Brain Injury Assessment

After stabilization in the emergency department, care of the patient with a traumatic brain injury is in the intensive care setting, where ICP can be carefully monitored. Neurological status is assessed frequently, including Glasgow Coma Scale score, pupil responses, muscle strength, and vital signs. Review Box 46–2 for signs of increased ICP. Once the patient is stabilized, neurological damage is assessed. Identification of deficits guides nursing care. Assessment of discharge needs should also begin as soon as possible. The patient may require extensive rehabilitation, and early referral may speed transfer to an appropriate facility.

Nursing Diagnosis, Planning, and Implementation

The patient with a traumatic brain injury may have many nursing problems. The goals of care are to prevent further injury or complications while the patient stabilizes and then to provide rehabilitation to maximize functioning. Assessment and rapid reporting of changes is an important intervention in maximizing recovery potential. Common diagnoses include the following.

INEFFECTIVE CEREBRAL TISSUE PERFUSION RELATED TO INCREASED ICP. If assessment reveals signs of increased ICP, the physician is notified. See Table 46–4 for interventions to prevent increased ICP.

BOX 46–7 Traumatic Brain Injury Summary

Signs and Symptoms

Loss of consciousness (note total time)
Loss of memory before or after the injury
Increased ICP

Diagnostic Tests

CT scan
Neuropsychological testing

Therapeutic Management

Control ICP
Maintain respiratory function
Maintain diet/nutrition
Maintain skin integrity
Prevent complications
Education

INEFFECTIVE BREATHING PATTERN RELATED TO PRESSURE ON RESPIRATORY CENTER. Respiratory rate and depth are closely monitored. Arterial blood gases help determine effectiveness of respiration. Mechanical ventilation may be necessary.

INEFFECTIVE AIRWAY CLEARANCE RELATED TO REDUCED COUGH REFLEX AND DECREASED LEVEL OF CONSCIOUSNESS. Monitor airway and breath sounds. If the patient is unable to cough effectively, suctioning may be necessary. Suction passes should be limited to one or two at a time to prevent increased ICP.

PAIN RELATED TO TISSUE DAMAGE. The only sign of pain in the unconscious patient may be restlessness or a change in vital signs. Opioids are avoided because they further depress LOC and may mask changes in neurological status. Codeine may be ordered because it has less effect on LOC and pupils.

IMPAIRED PHYSICAL MOBILITY RELATED TO DECREASED LOC. Mobility is maintained with range-of-motion exercises at least three times a day and position changes every 1 to 2 hours (if ICP is not elevated). Monitor skin closely for breakdown. Position the patient in functional body alignment to prevent contractures that can interfere with function after recovery. Physical and occupational therapy can be instituted once the patient is stable.

SELF-CARE DEFICIT RELATED TO DECREASED LOC. Initially the patient may be totally dependent for routine care. Activities should be spaced to allow for rest because clustered activities may increase ICP. Monitor bowel and bladder function carefully. A bowel program may be necessary to maintain regular bowel movements. An indwelling catheter may be used immediately following the injury to monitor fluid balance. Long-term catheterization is avoided, however, because of risk of infection.

SENSORY-PERCEPTUAL DISTURBANCE RELATED TO CRANIAL NERVE DAMAGE. The patient may not have a normal corneal reflex and may not be able to protect his or her eyes. Lubricating eye drops and taping the eyes shut help protect the eyes. See Chapters 48 and 49 for interventions for specific sensory problems.

RISK FOR INJURY RELATED TO DECREASED LOC, RISK FOR SEIZURES. If the patient is at risk for injury, routine safety precautions are instituted. Seizure precautions are instituted. (See Table 46–3.)

DISTURBED THOUGHT PROCESSES RELATED TO DECREASED LOC AND BRAIN DAMAGE. Confusion increases risk for injury. The confused patient is reoriented as needed. A calendar, clock, family photos, and other familiar items in the patient's room may help promote orientation. You may wish to ask a family member or significant other to stay with the patient to prevent the need for restraints to maintain safety.

INEFFECTIVE ROLE PERFORMANCE RELATED TO LONG-TERM EFFECTS OF INJURY. The effects of a head injury can

have a profound impact on the patient and family; provide emotional support as needed. The entire health team is needed to coordinate discharge to a safe environment. A social worker consult can help assess specific needs and identify resources for physical care and financial assistance if necessary.

Evaluation

The plan of care has been successful if the patient shows no unexpected worsening of neurological function and injuries and complications are prevented. The airway is clear. The patient is kept comfortable, and self-care needs are met.

Rehabilitation

Once the patient is stabilized, evaluation for discharge to a rehabilitation facility is done. The patient must be able to physically tolerate the rehabilitation program. The patient is taught to function as independently as possible. The family must be prepared for changes in the patient's ability to function and possible changes in personality. It may take months to years before the patient reaches his or her maximum potential. In some cases of severe brain damage or continued comatose state, rehabilitation is not feasible and the patient is discharged to home or a long-term facility for custodial care.

► BRAIN TUMORS

Brain tumors are neoplastic growths of the brain or meninges. They may be characterized by vague symptoms such as headache or visual changes or by focal neurological deficits such as hemiparesis or seizures.

Pathophysiology and Etiology

Brain tumors cause symptoms by either compressing or infiltrating brain tissue. Tumors may arise from central nervous system cells or may metastasize from other locations in the body. Primary brain tumors rarely metastasize. If they do metastasize, it is to the spine.

There is no established cause for primary brain tumors. It is unclear what causes the cells to begin reproducing in an uncontrolled fashion. Brain tumors can be classified in several different ways. The traditional distinction of benign and malignant is less applicable when discussing brain tumors. A benign tumor in the brainstem may be fatal, whereas a malignant tumor in the frontal lobe may not. Location of the tumor can be just as important a factor in outcome as the cell type.

Primary tumors are those arising from cells of the central nervous system. From 80 to 90 percent of brain tumors are primary in nature. Secondary tumors are those that metastasize from primary malignancies elsewhere in the body (Fig. 46–12). Intra-axial tumors are those that arise from the glial cells within the cerebrum, cerebellum, or brainstem. These tumors infiltrate and invade brain tissue itself. Extra-axial tumors arise from the skull, meninges, pituitary gland, or cranial nerves. These tumors have a compressive effect on the brain.

Figure 46-12 Metastatic brain tumor. This patient’s primary cancer was in the lung.

Approximately 10 to 20 percent of brain tumors are metastatic from a primary malignancy elsewhere in the body. These tumors commonly spread via the arterial system. If untreated, they cause increased ICP. This may be the cause of the patient’s death, rather than the primary malignancy.

Signs and Symptoms

The symptoms of a brain tumor are directly related to the location of the tumor in the brain and to the rate of growth. Slow-growing types of tumors such as meningiomas (a tumor arising from the meninges; Fig. 46-13) can get to be

Figure 46-13 Meningioma.

quite large before becoming symptomatic. Conversely, glioblastoma multiforme or metastatic tumors may abruptly cause seizures or hemiparesis. Other types of tumors include oligodendroglioma, astrocytoma, and acoustic neuroma. The suffix *-oma* refers to tumor. The prefix denotes the type of cell the tumor arose from.

Symptoms can include seizures, motor and sensory deficits, headaches, and visual disturbances. If the pituitary gland is involved, additional symptoms such as abnormal growth or fluid volume changes are related to changes in hormone secretion.

LEARNING TIPS

The phrase *P.T. Barnum loves kids* can be used to help remember the locations of tumors that most commonly metastasize to the brain:

P	Prostate
T	Thyroid
Barnum	Breast
Loves	Liver
Kids	Kidney

Diagnostic Tests

MRI gives the clearest images of a brain tumor. Many health care providers order a CT scan first because it is cheaper. If the tumor appears to be highly vascular or in close proximity to major blood vessels, an angiogram may be performed. It is now possible to do magnetic resonance angiograms. This involves the intravenous administration of contrast material and is much less invasive than a traditional angiogram. If the tumor is in the region of the pituitary gland, serum hormone levels are evaluated.

Treatment

Surgical treatment involves removal of the tumor or as much of the tumor as possible. Care of the patient undergoing intracranial surgery is discussed later in this chapter.

Medical Management

Medical treatment consists of controlling symptoms and administering additional therapies. Patients who have a seizure are placed on anticonvulsants. If significant cerebral edema is noted on the CT or MRI or if the patient is suffering from headaches, dexamethasone (Decadron) may be prescribed to lessen the edema. Typically these patients do not require narcotics for pain relief.

Radiation Therapy

External beam radiation therapy is standard treatment for many patients with a brain tumor. The therapy is typically given 5 days a week for 6 weeks. Some clinicians use a hyperfractionated schedule, in which the patient has therapy twice a day for less time. Brachytherapy is a means of delivering radiation therapy directly to the tumor. Small catheters are implanted in the tumor and then tiny ra-

radioactive particles are inserted into the catheters. The treatment typically takes 3 to 5 days. During this time the patient is confined to a private room and interaction with visitors and staff is kept to a minimum because of radioactivity. This therapy is not appropriate for confused individuals because they may not be able to cooperate with restrictions.

Stereotactic radiosurgery is a technique that utilizes small amounts of radiation directed at the tumor from different angles. A metal frame is affixed to the patient's skull, and the tumor is visualized within the framework on a CT or MRI. A computer plan is generated to direct the radiation. Because multiple small sources are used, the normal brain tissue receives very little radiation while the majority of the radiation accumulates in the tumor.

Chemotherapy

The blood-brain barrier is a protective mechanism that prevents many injurious substances from reaching brain tissue. Unfortunately, it is also effective in preventing chemotherapeutic agents from reaching the brain. To penetrate the blood-brain barrier, very large doses of chemotherapy may be required. These doses may not be well tolerated by other body systems. New treatments are currently being investigated. Some clinicians place chemotherapeutic substances in the cavity left by surgical resection. Others disrupt the blood-brain barrier with mannitol and then deliver intra-arterial chemotherapy under general anesthesia. Gene therapy is also being used in an effort to kill malignant cells.

Complementary Therapies

The rate of success for treatment of brain tumors is not as high as treatment of other neoplasms. Patients may be drawn to nontraditional therapies both as cures and for treatment of symptoms. Encourage patients to look at each option in a rational manner. Some questions they should ask themselves include the following:

- Will this interfere with any of my other treatments or medications?
- What is the cost?
- What are the side effects?
- Is there any objective information (research) available?
- What does my physician think of this?

Additional information on evaluation of complementary therapies is found in Chapter 4.

Acute and Long-Term Complications

It is difficult to distinguish between symptoms of a brain tumor and complications of treatment. Seizures, headaches, memory impairment, cognitive changes, and ataxia may be symptoms of the tumor or the result of surgery or radiation therapy. Patients may experience hemiparesis or aphasia following surgery. If the tumor continues to grow despite treatment, the patient experiences further decline in function. Gradually the patient becomes more lethargic and unre-

sponsive. Once the patient becomes comatose, death occurs within a matter of days, particularly if artificial nutrition and hydration are not administered.

Nursing Process: The Patient with a Brain Tumor

Assessment

Perform routine neurological assessments to determine level of functioning and presence of neurological deficits such as vision changes, movement problems, altered thought processes, or changes in level of consciousness. A pain assessment is done using the WHAT'S UP? format presented in Chapter 1. Asking the patient open-ended questions about how he or she is coping with the diagnosis may help open up communication about fears and grieving.

Nursing Diagnosis, Planning, and Implementation

The patient who is not anticipating surgery or curative treatment is assisted to function as effectively as possible for as long as possible. Nursing diagnoses are based on actual problems the patient is experiencing. Possible diagnoses and interventions are below.

DISTURBED THOUGHT PROCESSES RELATED TO INVOLVEMENT OF BRAIN TISSUE. If the patient is disoriented, implement routine precautions to keep the patient safe. Reorient the patient as needed. The use of calendars, clocks, and familiar furnishings may help reorient the patient. A sudden worsening in thought processes should be reported to the RN or physician immediately. The cause may be reversible.

SELF-CARE DEFICIT RELATED TO IMPAIRED MOBILITY AND THOUGHT PROCESSES. The patient may be unable to care for himself or herself because of altered thought processes or mobility problems. Provide assistance as needed, while encouraging the patient to maintain as much independence as possible. If the patient becomes totally dependent, a long-term care facility may become necessary.

PAIN RELATED TO CEREBRAL EDEMA. If the patient experiences headaches or other discomforts, pain medication is provided. Nonnarcotic medications are preferred because they do not alter the level of consciousness. If these are not effective, codeine preparations, which have a minimal effect on LOC, may be prescribed.

SENSORY-PERCEPTUAL DISTURBANCE RELATED TO CRANIAL NERVE INVOLVEMENT. Alterations in sensations can take on a variety of forms, including changes in vision, hearing, and paresthesia. See Chapters 48 and 49 for interventions for patients with sensory deficits. Care must be taken to protect the patient's skin if tactile sensation is reduced. Assist the patient out of bed and into a different environment to help prevent sensory deprivation. Remember to provide sensory stimulation such as conversation, radio, and television if tolerated and enjoyed by the patient.

RISK FOR INJURY RELATED TO SEIZURES OR SENSORY DEFICITS. In addition to routine safety precautions, the patient is protected from injury that may occur as a result of seizures. Seizure precautions are listed in Table 46–3.

ANTICIPATORY GRIEVING RELATED TO POTENTIAL LOSS OF FUNCTION AND DEATH. Both the family and patient may be grieving loss of function, as well as a terminal prognosis. Patients and their significant others require emotional support to face the challenges presented by the diagnosis of brain tumor. They must make decisions regarding treatment at the same time that they may be facing a deterioration in function. How aggressively to pursue treatment and when to change the focus from treatment to palliation are questions that confront these individuals. Patients should be encouraged to organize their personal affairs and make their decisions known while they are still able. Referral to a support group, social worker, or pastoral care person may be beneficial.

Evaluation

An effective plan will result in a patient who is safe and comfortable. The patient and significant others will be able to express feelings and have the support necessary to plan and carry out necessary care.

► INTRACRANIAL SURGERY

The primary purpose of intracranial surgery is to remove a mass lesion. These types of lesions include hematomas, tumors, arteriovenous malformations, and, occasionally, contused brain tissue. Other indications for surgery include elevation of a depressed skull fracture, removal of a foreign body, débridement of a wound, or resection of a seizure focus. *Craniotomy* refers to any surgical opening in the skull. A burr hole is an opening into the cranium made with a drill. *Craniectomy* is the term used to describe removal of part of the cranial bone. *Cranioplasty* refers to repair of bone or use of a prosthesis to replace bone following surgery.

The goal of intracranial tumor surgery for a tumor is gross total resection of the tumor. This involves removal of all visible tumor, called debulking. Even with the use of an operative microscope, there may be viable tumor cells left behind. It is these cells that give rise to recurrence. If all the tumor cannot be removed, the surgeon debulks as much as possible. By debulking the tumor, the surgeon reduces the amount of neoplasm, thereby giving radiation therapy or chemotherapy less of a burden to combat. In some cases it is not feasible to attempt more than a biopsy of the tumor. Location of the tumor or the patient's age or medical condition may not allow the patient to tolerate a full craniotomy. The biopsy may be done under local or general anesthesia, depending on the patient's condition. The goal of a biopsy is to obtain tissue that allows pathological diagnosis of the tumor. The diagnosis then guides any further treatment.

Intracranial surgery is usually performed under general anesthesia. Occasionally a procedure requires that the patient be awake and cooperative.

Preoperative Care

Preoperative care of the patient undergoing intracranial surgery is similar to that of patients having other surgeries. (See Chapter 11.) The patient undergoes a laboratory workup and anesthesia evaluation. If the patient has cognitive impairments, it is important that a significant other be available to provide information. A thorough baseline neurological assessment should be documented.

Patient education is important preoperatively. The extent of education depends on the patient's ability to absorb new information. This is influenced by the disease process, cognitive functioning, anxiety, and educational level. Significant others are involved as needed. Information about the disease process and surgery are provided by the surgeon. You can play an important role in reinforcing and clarifying the information presented.

Anxiety is also a significant concern before surgery. The patient is anticipating serious surgery, as well as an unknown outcome. Allow time for the patient and significant others to express their fears and ask questions. Honest and accurate information should be provided.

Significant others should be prepared for how the patient will look after surgery. A preoperative visit to the intensive care unit may help prevent some anxiety postoperatively. Significant others should be accompanied on this visit by a knowledgeable nurse who can explain what they are seeing.

Surgery may last 2 hours for a biopsy to 12 hours or longer for more intricate procedures. Patients and significant others should be prepared for the idea that some or all of the patient's hair will be shaved off. Some people prefer to have all their hair shaved rather than just part. The patient should be prepared to see his or her face swollen after surgery, particularly around the eyes. The periorbital region may be bruised. Many patients wish to wear a scarf or scrub cap after the dressing is removed.

Postoperative Care

Assessment

After intracranial surgery, plan to assist the RN with frequent neurological assessments in addition to routine postoperative monitoring. Patients should have their neurological status assessed every hour for the first 24 hours or as ordered by the physician. Any deterioration in status should be immediately reported to the physician. Many patients undergo a CT scan within the first 24 hours following surgery to assess cerebral edema.

Nursing Diagnosis, Planning, and Implementation

The primary goal following intracranial surgery is prevention of complications. Once the patient is stabilized, goals can change to longer-term outcomes such as acceptance of changes in body image and understanding of self-care following discharge. If the patient has severe deficits following surgery, rehabilitation or long-term care may become necessary. A consultation with a social worker can help with

planning for this transition. Priority nursing diagnoses include the following.

RISK FOR INEFFECTIVE CEREBRAL TISSUE PERFUSION RELATED TO EDEMA OF THE OPERATIVE SITE. Patients who have undergone intracranial surgery are placed in an intensive care unit postoperatively. They are typically positioned with the head of the bed at 30 degrees or higher, unless ordered otherwise, to promote venous drainage and minimize increases in intracranial pressure. The exception to this is patients who have had a chronic subdural hematoma removed, who must remain flat. Patients may turn from side to side or lie on their back. The patient should be encouraged not to lie on the operative side. Seizure precautions are instituted because the patient is at risk for seizures.

The patient may have an intracranial monitor in place following surgery to monitor intracranial pressure. Some patients may also have central venous pressure catheters or pulmonary artery catheters. Urinary catheters are used during the immediate postoperative period to accurately monitor fluid balance.

Dressings should be monitored for drainage. Drainage that is blood tinged in the center with a yellowish ring around it may be CSF leakage. A suspected CSF leak should be reported to the RN or physician immediately.

PAIN RELATED TO SURGICAL PROCEDURE. Intramuscular codeine and oral acetaminophen with codeine (Tylenol with Codeine Number 3) are the pain medications of choice for patients after intracranial surgery. These medications provide pain relief without causing sedation, which can interfere with the neurological assessment. Opioids are not used because they depress respirations and can mask signs of increasing intracranial pressure. Most patients complain of a headache postoperatively, but not severe pain.

RISK FOR INFECTION RELATED TO SURGICAL PROCEDURE. As with any surgery, a break in the integrity of the skin (and in this case skull) creates a risk for entry of pathogenic organisms. Infection following craniotomy can be deadly. All care of the incision, dressing, and monitoring equipment sites should be done using strict aseptic technique. Any signs of infection should be reported immediately.

IMPAIRED PHYSICAL MOBILITY RELATED TO MOTOR DEFICITS. Some patients have residual effects from the tumor or other pathological condition or from the surgery. These can range from weakness and paresthesias to paralysis. To prevent contractures and skin breakdown, the patient should be turned every 1 to 2 hours after surgery and avoid lying on the operative site unless specifically permitted by the surgeon. Careful positioning in correct body alignment also helps prevent contractures or other injuries. High-top tennis shoes, trochanter rolls, and slings can be used to keep the body in alignment. Range-of-motion exercises and physical therapy are initiated when permitted by the surgeon. An occupational therapist may also be able to assist the patient in learning to perform ADLs with a new disability.

BODY IMAGE DISTURBANCE RELATED TO CHANGES IN APPEARANCE OR FUNCTION. The patient will have a shaved or partially shaved head after surgery. In addition, depending on the outcome of surgery, residual motor or sensory deficits may be present. Allow the patient to express his or her feelings if desired. Portray an accepting attitude. A turban, scarf, or hat may help conceal a shaved head.

DEFICIENT KNOWLEDGE RELATED TO CHANGE IN TREATMENT REGIMEN FOLLOWING SURGERY. If the patient will be discharged home, discuss any activity restrictions, particularly driving. Evaluate the patient's understanding of the medication regimen and wound care. Have the patient and significant others verbalize the signs of infection or other possible complications to report.

Evaluation

Interventions have been effective if infection and other complications have been prevented and the patient states that pain is controlled. The patient might be able to look in the mirror and begin to show evidence of acceptance of changes in body image, though this may not happen until after discharge from the hospital. The patient and significant others should be able to describe appropriate follow-up care.

 **CRITICAL THINKING**

Mr. Esposito
Mr. Esposito is a 24-year-old white male who was involved in a motor vehicle accident. His blood alcohol level was 0.24. Mr. Esposito has no preexisting medical problems. Emergency medical services personnel report that Mr. Esposito was unconscious on their arrival at the scene and then became alert and combative. His CT scan shows a left-sided epidural hematoma. Mr. Esposito is admitted to your unit for observation.

1. What symptoms would you expect to see if Mr. Esposito's hematoma increases in size?
2. What emergency preparations should you have ready?
3. What psychosocial assessments should you perform?

Answers at end of chapter.

► SPINAL DISORDERS

Herniated Disks

Herniated intravertebral disks are a common health problem. They are characterized by pain and paresthesias that follow a radicular (nerve path) pattern. It is not uncommon for patients to have more than one herniated disk or to have herniated disks in different areas of the spine.

Pathophysiology

When the disk between two vertebrae herniates, it moves out of its normal anatomic position. In most cases the annulus fibrosus, the tough outer ring of the disk, tears. This allows escape of the nucleus pulposus, the soft inner portion of the disk. Displacement of the disk compresses

one or more nerve roots, causing the characteristic symptoms (Fig. 46–14).

Etiology

In some cases a specific event can be correlated with a herniated disk. The patient may describe a fall, lifting a heavy object, or a motor vehicle crash. In other instances the patient cannot identify a triggering incident.

Signs and Symptoms

Cervical disk herniation causes pain and muscle spasm in the neck. The patient may exhibit decreased range of motion secondary to pain. Hand and arm pain is unilateral (one sided) and follows the distribution of the spinal nerve root. Patients often complain of numbness or tingling in the extremity. Asymmetric weakness and atrophy of specific muscle groups may be detected. If weakness involves the entire extremity, it is unlikely that disk herniation is the etiology. The severity of the pain or paresthesia does not correlate directly with the severity of the nerve compression. However, weakness and atrophy are indicators of significant nerve compression.

Thoracic herniated disks are not common. This portion of the spine is the least mobile, therefore less stress is exerted on the disk. Patients with herniated thoracic disks may complain of pain in the back. It is uncommon to detect muscular weakness.

A herniated lumbar disk is typically characterized by low back pain, pain radiating down one leg, paresthesias, and weakness. The patient may limp on the affected leg or may have difficulty walking on his or her heels or toes. Muscle spasm is often present. Pain and muscle spasm may limit the patient's range of motion. Depending on the disk affected, the knee or ankle deep tendon reflex may be decreased or absent. A severely herniated L5–S1 disk may affect bowel or bladder continence. This is an emergency situation and should be reported immediately.

Figure 46-14 A herniated disk places pressure on a spinal nerve root.

The WHAT'S UP? mnemonic can be used to assess symptoms of herniated disks at any level:

W—Where is the pain? Does it radiate into an extremity? In what distribution?

H—How does it feel? Sharp, stabbing, burning?

A—Do certain positions or activities alleviate or aggravate the pain? Holding the affected arm above the head may alleviate cervical pain. Sitting places pressure on disks and aggravates lumbar pain. Lying down may relieve it.

T—Is there a correlation between time and pain? Some patients have more pain at the end of the day. Is the pain constant or intermittent?

S—Ask the patient to rate the severity of the pain on a scale of 0 to 10. Which is the most painful, the spine or the extremity?

U—Ask the patient to identify associated symptoms such as numbness, tingling, or weakness.

P—What is the patient's perception of the pain? Is it interfering with work or other aspects of the patient's life?

Diagnostic Tests

An MRI will detect herniation of a disk and compression or abnormality of the spinal cord. If the patient has previously had surgery in the area of the suspected herniation, the MRI is done with and without contrast to differentiate between scar tissue and herniated disk.

If the patient cannot tolerate MRI or if the MRI does not provide enough information, a myelogram is done. Refer to Chapter 45 for a description of both tests.

Treatment

Most clinicians and patients prefer to try conservative medical therapy before performing surgery for a herniated disk.

MEDICAL MANAGEMENT

Rest. In the past, bedrest was advised as part of conservative management. The current recommendation is 1 or 2 days of bedrest, followed by a careful, gradual increase in activity.

Physical Therapy. Physical therapy can be very useful for some patients. A gradually progressive course of exercise strengthens the muscles. This is particularly important in the lumbar spine, where the muscles help stabilize the spine. Techniques such as ultrasound, heat, ice, and deep massage can decrease muscle spasm and allow for increased range of motion. Instructions in proper body mechanics and strategies for avoiding reinjury are an important component of physical therapy.

A transcutaneous electrical nerve stimulator (commonly called a TENS unit) is a noninvasive pain-relief technique. Small electrodes are placed on the skin around the area of the pain. The device then transmits a low-voltage electrical current through the skin. The patient feels a tingling or buzzing sensation, which may block the pain impulses. A physical therapist or pain specialist teaches the patient where to place the electrodes and how to operate the unit. The patient decides when to use it and at what settings. This allows the patient to actively par-

ticipate in his or her care and have some control over the pain level.

Traction. Cervical traction is a noninvasive technique sometimes used by physical therapists for patients with herniated cervical disks. The patient's head is placed in a halterlike device. A series of ropes and pulleys connect the halter to a weight. This gently pulls the head away from the shoulders. The rationale is that this traction slightly separates the vertebral bodies and may allow the disk to return to its proper position. If it is effective in relieving the patient's pain, cervical traction may be done at home on an as-needed basis. Traction is discontinued immediately if it increases the patient's pain. Lumbar traction is not particularly effective because the lumbar paraspinal muscles are very large and strong. The amount of traction needed to overcome the muscular resistance can cause injury.

Medication. Muscle relaxants are often prescribed for patients who are experiencing spasm. These medications decrease pain by decreasing the spasm, helping the patient increase range of motion and activity. Muscle spasm is actually a protective mechanism. Muscles tighten and become painful, causing the patient to limit movement. This lessens the chance that the disk will be further injured. However, chronic spasm can cause tearing and scarring of the muscles. It is hard to predict which muscle relaxant will be most effective for a given patient. Patients should be warned that drowsiness is a common side effect of many muscle relaxants. They should be cautioned against driving or operating machinery until they determine how well they tolerate the medication. Diazepam is an effective muscle relaxant; however, it has a strong potential for addiction. Therefore it is usually used only if muscle spasm cannot be adequately treated with other medications.

Inflammation of the nerve root is caused by compression and irritation from the herniated disk. NSAIDs can be effective in reducing this inflammation, but there is no way of predicting response to a given drug. It may be necessary for the patient to try several nonsteroidal drugs before an effective one is found. Because several of these drugs are now available without prescription, the patient should be cautioned not to use a nonprescription NSAID at the same time as a prescription NSAID. Patients should be instructed to report any stomach upset to the clinician, because NSAIDs have the potential to cause gastric bleeding. Occasionally, oral steroids are used on a short-term basis for patients with severe inflammation that does not respond to other treatments. A rapidly tapering dose of steroid over 1 week is often prescribed. Steroids may also cause gastric upset, in addition to elevated serum glucose levels. Instruct patients with diabetes to monitor glucose levels closely and consult a physician if the levels are outside their normal parameters.

Epidural injections are an option for patients who are unable or do not wish to have surgery. A mixture of medications, typically a steroid, long-acting anesthetic, and long-acting pain reliever, is injected into the epidural space. The anesthetic provides immediate relief while the steroid

reduces swelling for a longer-lasting effect. If relief is obtained, the injection can be repeated every 3 to 4 months.

The use of pain medication is a subject of concern in the treatment of patients with herniated disks. Opioids may be appropriate for short-term use. This includes patients who are trying conservative therapy or those who are not able to have surgery immediately. If surgery is not an option or is not successful, the condition may be a chronic source of pain. In that circumstance, the physician is unlikely to prescribe ongoing opioids. The patient, on the other hand, may wish to continue using opioids because they provide substantial pain relief. The physician and patient must discuss the potential complications of long-term opioid use, such as constipation, tolerance, and dependence. Patients taking opioids should not consume alcohol.

SURGICAL MANAGEMENT. Several types of surgery can be done. A **laminectomy** removes one of the laminae, the flat pieces of bone on each side of a vertebra. This may be done to relieve pressure or to gain access for removal of a herniated disk. A **discectomy** removes the entire disk. A **spinal fusion** uses a bone graft to fuse two vertebrae together if the area is unstable. Surgery may be done through a microscope for less scarring and better recovery. Most patients are discharged within 24 hours of surgery. This is in contrast to several weeks in the hospital on bedrest, which was necessary in the recent past.

A discectomy is generally done for a herniated cervical disk. This can be accomplished via an anterior or posterior approach. Most surgeons use the anterior approach for cervical herniations, because the muscles in the front of the neck are much smaller and more moveable than those in the back of the neck. Therefore there is less pain and muscle spasm following surgery. It is also safer than the posterior approach, which involves more maneuvering around the spinal cord.

Most surgeons replace the disk with bone or another material. This prevents collapse of the disk space and creates a spinal fusion. If bone is used, it may be harvested from the patient's iliac crest or donated from a cadaver. Mobility of the spine is lost in the area of a fusion. Spinal fusions may also be done to correct instability of the spine from other causes, such as scoliosis or degenerative disorders.

A posterior approach is used for a herniated lumbar disk. Typically the vertical incision is 1 to 2 inches long. It is necessary to pull some of the muscle away from the bone, which accounts for some of the postoperative pain that patients experience. A laminectomy is done, and the herniated portion of the disk is resected. The remainder of the disk continues to provide a cushion between the intravertebral bodies. The surgeon removes any free fragments and any disk material that appears unstable.

Percutaneous discectomy involves insertion of a large needle into the disk under local anesthesia to aspirate herniated disk material. This technique is not used for severely

laminectomy: lamin—posterior portion of the vertebra + ectomy—surgical removal of

herniated disks. Laser disk surgery may be used to disintegrate the herniated tissue. Laparoscopic techniques may also be used.

Complications after Surgery

HEMORRHAGE. As with any surgery, intraoperative hemorrhage is possible. It is not common in disk surgery. If a postoperative hemorrhage occurs in a patient who has had an anterior cervical discectomy, the airway may become occluded. The patient is monitored for bleeding from the incision and respiratory distress.

NERVE ROOT DAMAGE. If the nerve root is severed during surgery, the patient has loss of motor and sensory function in that distribution. This may result in decreased use of the extremity. If the nerve root is damaged or excessive scarring occurs, the patient may experience pain, weakness, or paresthesias. In some cases, physical therapy and NSAIDs may be effective in improving function and lessening pain.

REHERNIATION. Lumbar disks may reherniate. This can occur anywhere from 1 week to several years after the initial surgery. If the reherniation occurs within a few weeks to months after the first surgery, the patient usually undergoes another microdiscectomy. Reherniation of the cervical disk does not occur because the entire disk is removed.

HERNIATION OF ANOTHER DISK. Fusion of the cervical spine results in loss of movement at that motion segment. This can place increased stress on the disks above and below the fusion. This may increase the risk of another herniated disk, especially if the patient already has degeneration of other disks. The patient should be instructed to maintain an exercise program and to frequently move the spine through range-of-motion exercises.

Spinal Stenosis

Spinal stenosis is a condition in which the spinal canal compresses the spinal cord (Fig. 46-15). Arthritis is a major cause of spinal stenosis. The facet joints of the spine become inflamed and enlarged, narrowing the diameter of the spinal canal and compressing the spinal cord. Patients may complain of pain and weakness. Compression of the cervical portion of the spinal cord may result in hyperreflexia and weakness of the legs and arms.

A laminectomy may be done to relieve pressure on the spinal cord. The size of the incision depends on the number of vertebrae involved. Patients are typically in the hospital for 4 or 5 days. These patients are often elderly and may have concurrent illnesses. They may require inpatient rehabilitation before returning to their homes.

Nursing Process: The Patient Having Spinal Surgery

Preoperative Care

Routine preoperative care is appropriate for the patient undergoing spinal surgery. In addition to routine teaching, the patient is instructed in how to logroll following surgery.

Figure 46-15 Stenosis of the cervical spine (*left*). Compare with normal spinal column (*right*).

This procedure involves keeping the body in alignment and rolling as a unit, without twisting the spine, to prevent injury to the operative site.

Postoperative Care

ASSESSMENT. In addition to routine postoperative assessment, the extremities are monitored for changes in circulation, movement, and sensation. Circulation is checked by the color, warmth, and presence of pulses in the extremity. Movement is assessed by asking the patient to move the extremity. Sensation is assessed by gently touching the patient's extremity and asking if feeling is present. Any changes are reported immediately to the physician because this may indicate nerve or circulatory damage. Pain is assessed. The pain that necessitated surgery should be relieved, but the patient may still have muscle and incisional pain. The patient should be reassured that it will gradually subside. The surgical dressing and drain if present are monitored for CSF drainage or bleeding. If bone was taken from a separate donor site, this site must also be monitored. Intake and output are measured to ensure that the patient is able to void. The physician is notified if the patient has difficulty voiding.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Goals of nursing are to keep the patient safe and free from injury or complications and free from pain. Gradual return to normal physical activity is expected. Possible postoperative diagnoses include the following.

Pain Related to Surgical Procedure. If a local anesthetic was injected into the surgical site during surgery, the patient

may not have pain immediately postoperatively. Muscle relaxants, analgesics, and NSAIDs are given as ordered. The patient is positioned in bed in correct body alignment and may have orders to be kept flat for 6 to 8 hours. A pillow between the legs when lying on the side promotes alignment and comfort.

Risk for Impaired Physical Mobility Related to Neuromuscular Impairment. The patient is assisted to logroll to get out of bed and ambulate on the first postoperative day. If spinal fusion has been done, the fused area of the spine will be immobile. The patient with a cervical laminectomy may have a soft cervical collar for neck support.

Risk for Impaired Urinary Elimination Related to Effects of Surgery. Patients may have difficulty voiding following lumbar surgery because of anesthesia, immobility, or occasionally because of nerve damage related to surgery. Getting up to go to the bathroom (or standing for men) and running water should promote bladder emptying. If difficulty urinating occurs, the physician should be contacted for an order for intermittent catheterization until the problem resolves.

EVALUATION. The patient is expected to be free of complications and pain, be able to urinate, be able to move all extremities, and return gradually to preillness activity.

► SPINAL CORD INJURIES

Injuries to the spinal cord affect people of all ages but take their greatest toll on young people. These injuries are characterized by decrease or loss of sensory and motor function below the level of the injury.

Pathophysiology

The spinal cord is made up of nerve fibers that allow communication between the brain and the rest of the body. Damage to the spinal cord results in interference with this communication process. Damage may be caused by bruising, tearing, cutting, edema, or bleeding into the cord. The damage may be caused by external forces or by fragments of fractured bone.

Causes and Types

The causes of spinal cord injury are similar to those of traumatic brain injury. It is not uncommon for a patient to have both a spinal cord injury and traumatic brain injury. Motor vehicle crashes, falls, and sports-related injuries are common causes. Diving into shallow water is often the cause of cervical cord injury. Assaults may cause cord injury if a knife or bullet penetrates the spinal cord.

Spinal cord injuries may be classified by location or by degree of damage to the cord. A complete spinal cord injury means that there is no motor or sensory function below the level of the injury. An incomplete lesion means that there is some function remaining. This does not necessarily mean that the remaining function will be useful to the patient. Some patients find that having areas where sensation is intact may be more painful than useful.

The cervical and lumbar portions of the spine are injured more often than the thoracic or sacral segments. This is because the cervical and lumbar areas are the most mobile portions of the spine.

Signs and Symptoms

Cervical Injuries

Cervical cord injuries can affect all four extremities, causing paralysis and paresthesias, impaired respiration, and loss of bowel and bladder control. Paralysis of all four extremities is called **quadriplegia**; weakness of all extremities is called **quadriparesis**. If the injury is at C3 or above, the injury is usually fatal because muscles used for breathing are paralyzed. An injury at the fourth or fifth cervical vertebrae affects breathing and may necessitate some type of ventilatory support. These patients typically need long-term assistance with activities of daily living (Fig. 46-16).

Thoracic and Lumbar Injuries

Thoracic and lumbar injuries affect the legs, bowel, and bladder. Paralysis of the legs is called **paraplegia**; weakness of the legs is called **paraparesis**. Sacral injuries affect bowel and bladder continence and may affect foot function. Individuals with thoracic, lumbar, and sacral injuries can usually learn to perform activities of daily living independently.

Spinal Shock

Spinal cord injury has a profound effect on the autonomic nervous system. Immediately following injury the cord below the injury stops functioning completely. This causes a disruption of the sympathetic nervous system, resulting in vasodilation, hypotension, and bradycardia (neurogenic shock or spinal shock). Dilation of the blood vessels allows more blood flow just beneath the skin. This blood cools and is circulated throughout the body, causing hypothermia. The patient is unable to maintain control of body temperature. Keep the patient covered as much as possible but avoid overheating. In addition, all reflexes below the level of the injury are lost, and retention of urine and feces occurs. Spinal shock can last from a week to many weeks in some patients.

Complications

Infection

Impaired respiratory effort, decreased cough, mechanical ventilation, and immobility all predispose the cervical cord-injured patient to pneumonia. Catheterization, whether indwelling or intermittent, places patients at risk for urinary tract infection.

quadriplegia: quad—four + plegia—paralysis

quadriparesis: quad—four + paresis—partial paralysis

paraplegia: para—beside + plegia—paralysis

paraparesis: para—beside + paresis—partial paralysis

Figure 46-16 Spinal cord injury—quadriplegia versus paraplegia. (Modified from Scanlon, VC, and Sanders, T: Workbook for Essentials of Anatomy and Physiology, ed 2. FA Davis, Philadelphia, 1995, p 167, with permission.)

Deep Vein Thrombosis

Lack of movement in the legs inhibits normal blood circulation. Compression stockings, sequential compression devices, and subcutaneous heparin may be used separately or together to reduce the risk of deep vein thrombosis.

Orthostatic Hypotension

Most spinal cord-injured patients no longer have muscular function in their legs to promote venous return to the heart. They also have impaired vasoconstriction. This leads to pooling of the blood in the legs when the patient moves

from a supine to a sitting position. If the movement is sudden, the patient may faint. Gradual elevation of the head, use of elastic stockings, and a reclining wheelchair help lessen this response.

Skin Breakdown

Patients or their caregivers must be diligent about relieving pressure on the skin by position changes and cushioning of bony prominences. Development of pressure ulcers can lead to infection and loss of skin, muscle, or bone. Treatment of pressure ulcers is time consuming and expensive and may interfere with work or school.

Renal Complications

Urinary tract infections are an ongoing concern to spinal cord–injured patients. Both urinary reflux and untreated urinary tract infections can cause permanent damage to the kidneys.

Depression and Substance Abuse

Patients with spinal cord injury have a higher than average incidence of depression and substance abuse. Both these factors can interfere with the patient's ability to care for himself or herself. Individual or family counseling may be helpful. Some rehabilitation centers have support groups for spinal cord–injured patients.

Autonomic Dysreflexia

This life-threatening complication occurs in patients with injuries above the T6 level. The spinal cord injury impairs the normal equilibrium between the sympathetic and parasympathetic autonomic nervous system. Some type of noxious stimuli below the spinal cord injury causes activation of the sympathetic system. This response continues unchecked because the parasympathetic responses cannot descend past the spinal cord injury.

The most common cause of autonomic **dysreflexia** is bladder distention. Other causes include bowel impaction, urinary tract infection, ingrown toenails, pressure ulcers, pain, and labor. Stimulation of the sympathetic nervous system results in cool, pale skin; gooseflesh; and vasoconstriction below the level of the injury. Blood pressure may rise as high as 300 mm Hg systolic. The parasympathetic response results in vasodilation, causing flushing and diaphoresis above the lesion, and bradycardia as low as 30 beats per minute. The patient complains of a pounding headache and nasal congestion secondary to the dilated blood vessels.

Diagnostic Tests

Plain radiographs are done to identify fractures or displacement of vertebrae. A CT scan is also useful for identifying fractures. MRI may demonstrate lesions within the cord.

Treatment

Patients with spinal cord injuries typically are brought to the emergency department. They should be kept immobilized until they are assessed by the physician. If injury to the spinal cord is detected, the patient needs to remain immobilized.

Emergency Medical Management

Emergency management involves careful monitoring of vital signs and airway and keeping the patient immobilized. Intubation and mechanical ventilation may be necessary. Intravenous normal saline may be used for fluid replacement. The physician does not rely on fluid administration alone to correct hypotension. It is possible to administer enough fluid to cause pulmonary edema and not correct the hypotension. Vasoactive drugs may be required. Various medications to reduce the extent of injury, including intravenous methylprednisolone (a steroid), are currently being researched.

RESPIRATORY MANAGEMENT. Patients with injuries above C4–5 have some degree of respiratory impairment. The patient may require a tracheostomy and continuous mechanical ventilation or require a ventilator only at night or when fatigued. Some patients are able to breathe by using a phrenic nerve stimulator. This device, similar to a pacemaker, artificially stimulates the phrenic nerve, causing the diaphragm to move. These patients use a mechanical ventilator at night. This lessens the stress on the phrenic nerve and removes the risk of the system failing while the patient is asleep.

Patients may be breathing independently when they first arrive in the emergency department and then experience respiratory compromise as the spinal cord becomes edematous. Edema can compress the spinal cord above the lesion, leading to symptoms at a higher level. This deterioration is usually temporary. Fatigue of the accessory muscles may also cause respiratory compromise. The intercostal muscles are not normally of major importance in respiration. However, if the diaphragm is paralyzed, the intercostal muscles become very important. As these muscles fatigue, the patient's breathing becomes shallow and rapid. Elective intubation and mechanical ventilation protect the patient from expending huge amounts of energy trying to breathe. Feeling their breathing becoming more labored is terrifying to these patients, and they need to be reassured that it is probably a temporary setback. As the edema recedes and the accessory muscles become stronger, the patient is weaned from the ventilator.

GASTROINTESTINAL MANAGEMENT. Absence of bowel sounds is a common finding on examination. Oral or enteral feedings are not started until bowel function resumes. The metabolic needs of the patients are influenced by the work of breathing and the extent of other injuries. If positioning or paralytic ileus precludes oral or enteral feedings, hyperalimentation is begun.

GENITOURINARY MANAGEMENT. An indwelling urinary catheter is placed to prevent bladder distention and protect skin integrity until spinal shock resolves. Once it is determined what degree of hand function the patient will have, a bladder management program is devised.

dysreflexia: dys—abnormal + reflexia—reflex activity

IMMOBILIZATION. The cervical spine may be immobilized with skeletal traction such as Crutchfield or Gardner-Wells tongs (Fig. 46–17). Some patients have a halo brace, a device that attaches to the skull with four small pins. The skull ring attaches to a rigid plastic vest by four poles (Fig. 46–18). This device keeps the head and neck immobile while fusion and healing take place. The advantage over traction is that the patient is not confined to bed.

Surgical Management

The goal of surgery following spinal cord injury is to stabilize the bony elements of the spine and relieve pressure on the spinal cord. Surgery may or may not improve functional outcome.

Stabilization of the spine allows for earlier mobilization of the patient. This decreases the risk of complications from immobility and quickens the transition to rehabilitation. Patients who have been in cervical traction before surgery may be placed in a halo brace postoperatively.

Unstable thoracic and lumbar fractures may also be treated with surgical implantation of rods to stabilize the spine. It is more difficult to stabilize these areas in the post-operative recovery period. Patients may wear a supportive corset, a rigid brace, or occasionally a body cast to supplement the support provided by the internal fixation devices (Box 46–8). For more information, visit the Spinal Cord Injury Information Network at <http://spinalcord.uab.edu>.

Figure 46-18 Halo brace.

BOX 46-8 Spinal Cord Injury Summary

Symptoms

- Flaccid paralysis and paresthesia (dependent on level of the lesion)
- Loss of reflex activity below the level of the lesion
- Spinal shock initially (bradycardia, hypotension)
- Risk for autonomic dysreflexia (injuries above sixth thoracic vertebra)

Diagnostic Tests

- Radiograph
- CT scan
- MRI

Therapeutic Management

- Immobilization
- Maintenance of airway and respiratory status
- Bowel and bladder training
- Nutrition/diet
- Activity/rehabilitation
- Prevention of dysreflexia
- Prevention of skin breakdown
- Sexual counseling
- Education

Nursing Process

Assessment

Patients with spinal cord injury need ongoing evaluation of all body systems. Frequent neurological and respiratory assessments are done. Early assessment of the patient's support system can help with discharge and rehabilitation planning.

Nursing Diagnosis, Planning, and Implementation

Initial goals for the patient include maintenance of safety and prevention of complications. Long-term goals include rehabilitation and maximizing remaining function.

IMPAIRED PHYSICAL MOBILITY RELATED TO INJURY.

Range-of-motion exercises help prevent contractures. Regular turning and repositioning help prevent respiratory and other complications. Some patients are placed on special beds (such as the Roto-Rest bed) that move the patient frequently without the need for turning. Splints may be used to maintain functional positioning of extremities. This may include the use of high-top tennis shoes to prevent foot-drop. If the patient is ambulatory, he or she should not walk alone initially. Special care should be provided when ambulating the patient with a halo brace. The halo brace alters the patient's center of gravity and requires an adjustment of the patient's sense of balance. Falling while in the halo brace can cause further injury to the spinal cord.

IMPAIRED URINARY ELIMINATION RELATED TO NERVE DAMAGE.

Male patients may use an external, condom type of catheter if the bladder empties reflexively when full. If the bladder does not empty reflexively or if the patient does not wish to wear a leg bag to collect urine, the physician may order intermittent catheterization. Clean technique is used to intermittently insert a catheter and empty the bladder. (See Chapter 34.) Male patients with good hand function can be taught to catheterize themselves. Patients with poor hand function may need a caregiver to perform intermittent catheterization or use an indwelling catheter.

Female patients with good hand function may still find self-catheterization difficult because of positioning problems. They may choose to use indwelling catheters. External urine collection devices for female patients are available but may be cumbersome.

Reliance on incontinence pads is discouraged for all patients because of the threat to skin integrity. The importance of adequate fluid intake must be stressed to patients. Some individuals limit fluid intake in an effort to lessen the chances of incontinence. This predisposes the patient to constipation, urinary tract infection, and renal calculi.

CONSTIPATION RELATED TO IMMOBILITY AND NERVE DAMAGE.

Once oral feedings are begun, a bowel management program should be instituted. The patient has decreased or absent sphincter tone. This, combined with an inability to detect the need to defecate, puts the patient at risk for incontinence. Slowed bowel motility, as well as generalized immobility, contributes to constipation. A high-

fiber diet with adequate fluid intake is important. Use of a suppository on a scheduled daily or every-other-day basis enables most patients to maintain bowel continence.

SELF-CARE DEFICIT RELATED TO PARALYSIS. Explaining the rationale for nursing activities prepares the patient and significant others to assume responsibility for care. Encourage the patient and significant others to participate in hands-on care as much as possible. If the patient will not be able to perform self-care, assist him or her to learn to direct care. Physical and occupational therapists can help the patient adapt to a wheelchair or other mobility aids. Most patients spend some time in a rehabilitation facility to learn to function independently. Some patients may require long-term care.

RISK FOR INEFFECTIVE COPING RELATED TO LIFE CRISIS.

The psychosocial impact of a spinal cord injury is devastating. Patients may be afraid of dying yet express the feeling that they would be better off dead than being paralyzed. These types of statements are difficult for significant others to cope with. Encourage the patient to focus on reasons for living (e.g., seeing children or grandchildren grow up or having a loving partner). Consult a social worker or pastoral care worker who is familiar with spinal cord-injured patients. Support groups may also be helpful.

RISK FOR AUTONOMIC DYSREFLEXIA RELATED TO STIMULI BELOW THE LEVEL OF INJURY.

If you suspect autonomic dysreflexia, immediately take the patient's blood pressure and continue to monitor it every 5 minutes. Remember that patients with spinal cord injury are typically hypotensive, so a finding of even mild hypertension may represent a dramatic increase from their baseline blood pressure.

Uncontrolled blood pressure may cause seizures, intracerebral hemorrhage, or death. The goal of treatment is to identify the cause and relieve it without increasing the sympathetic nervous system response. Place the patient in a Fowler's position to utilize the effect of orthostasis to control blood pressure. Evaluate the indwelling catheter for patency. If it is not patent or a catheter is not in place, obtain an order to insert one immediately. Monitor blood pressure during catheterization.

A rectal examination is performed to determine if an impaction is present. Apply anesthetic ointment to the rectum before disimpaction, because further rectal stimulation may exacerbate symptoms. Simultaneously monitor blood pressure and stop disimpaction if the blood pressure increases.

If bowel or bladder distention is not present, examine the patient for other causative mechanisms. If a cause cannot be identified, or removal of the cause does not relieve hypertension, notify the physician immediately; an antihypertensive agent may be ordered. If hypertension is treated with medication, remember that the blood pressure may decrease rapidly once the cause of the autonomic dysreflexia is corrected. Continue to carefully monitor blood pressure.

Once the acute episode is past, work with significant others to devise a plan to prevent reoccurrence. The patient

should be taught how to direct caregivers in treating autonomic dysreflexia.

INEFFECTIVE AIRWAY CLEARANCE RELATED TO INEFFECTIVE COUGH AND DECREASED MUSCLE CONTROL. Patients with cervical injuries have difficulty clearing secretions. They no longer have adequate muscle strength to cough effectively. Initially, suctioning is required to keep the airway clear. Once the patient is stable, an assisted cough may be used to clear secretions. This involves the nurse or other caregiver gently pushing upward and inward on the patient's chest while the patient coughs as strongly as possible. It is similar to the Heimlich maneuver but not as forceful. Humidified air and oral or enteral fluids help keep secretions thin and mobile.

RISK FOR IMPAIRED SKIN INTEGRITY RELATED TO IMMOBILITY AND POSSIBLE PARESTHESIAS. Extreme care must be taken to protect the skin of the injured patient, beginning with the initial emergency treatment. In the emergency department be sure to remove anything between the patient and the backboard. Patients have developed pressure ulcers from lying on keys or other objects in their pockets. If on a Roto-Rest bed, make sure the patient is not sliding as the bed turns. This could cause shearing of the skin. When permitted by the physician, turn the patient frequently and assess bony prominences for redness. Ensure that the patient's extremities do not get caught in side rails or wheelchair spokes. If a patient is in traction or a halo brace, assess pin sites frequently. Keep the sites clean and dry and report any sign of infection.

RISK FOR SEXUAL DYSFUNCTION RELATED TO AUTONOMIC NERVOUS SYSTEM DYSFUNCTION. Male patients with paraplegia usually have difficulty achieving and maintaining an erection. Male patients with quadriplegia may develop an erection during any penile stimulation. This includes catheterization and can be embarrassing to the patient. If this occurs, discontinue the procedure and continue at a later time if possible. It should be treated with a matter-of-fact attitude. Males with spinal cord injuries do not ejaculate in the normal manner. Consultation with a fertility specialist or urologist may provide some help for conception if desired.

Spinal cord injury does not impair female fertility. Patients who wish to become pregnant should seek an obstetrician familiar with spinal cord injuries. See Table 46-7 for contraception for females with spinal cord injuries.

RISK FOR INEFFECTIVE ROLE PERFORMANCE RELATED TO EFFECTS OF INJURY. Interpersonal relationships are significantly stressed by spinal cord injury. Both short-term and long-term relationships may become stronger or disintegrate. Patients and significant others should be encouraged to draw support from all available sources. Friends, family, and members of the patient's religious affiliation can provide emotional and physical help.

Loss of income may be temporary or permanent. Financial concerns add to the burden of spinal cord injury. Not all insurance policies cover the extensive inpatient rehabilita-

TABLE 46-7 BIRTH CONTROL ISSUES FOR PATIENTS WITH SPINAL CORD INJURY

Method	Comments
Oral contraceptives	Contraindicated because of the risk of deep vein thrombosis
Diaphragm	May be difficult for a patient with poor hand function to insert
Intrauterine device	Patient may not feel IUD move out of position; patient may not feel perforation of uterus
Norplant	No contraindications
Condom	No contraindications

tion needed by spinal cord-injured patients. Uninsured patients may have a difficult time finding a rehabilitation program that will accept them. Adaptive equipment is expensive and may not be covered by insurance. A social worker can help the patient gain access to appropriate assistance.

Patient Education

Education of the spinal cord-injured patient is an ongoing process. It begins with a basic explanation of the anatomy and physiology of the spine. Treatment of spinal cord injury and prognosis are early learning needs.

As the patient's condition stabilizes, teaching focuses on caring for the patient. This can seem overwhelming to the patient and caregiver. Break tasks down into simple steps. Focus on one body system at a time. For example, do not try to teach suctioning and bowel care at the same time. Begin with the basics; extensive teaching will be done in the rehabilitation setting.

Be aware that performing tasks such as catheterization or bowel care may interfere with feelings of intimacy between partners. Encourage partners to verbalize these feelings and make alternative arrangements for care if possible. Some patients with the financial resources to do so may choose to hire an attendant rather than rely on significant others for personal care.

Both patients and caregivers should be involved in determining contingency plans. These include what to do in the event of a power failure, fire, or illness of the caregiver.

Spinal cord-injured patients experience the same basic health care needs as noninjured individuals. Encourage the patient to establish a relationship with a primary practitioner who is familiar with spinal cord injury. This facilitates the patient's adaptation to changes in his or her condition. Female patients may find that they do not fit in the wheelchair as pregnancy advances. A patient who requires cardiac bypass may be unable to transfer or propel the wheelchair because use of the arms is impaired by the sternal incision. These and many other situations require creativity and flexibility on the part of the patient, caregiver, and health professional.

Evaluation

Avoidance of preventable complications is one sign of a successful care plan. The patient should have regular bowel

and bladder function. Mobility is maximized based on the patient's rehabilitation potential. The patient and significant others should verbalize basic understanding of spinal cord injury and self-care.

▶ DEGENERATIVE NEUROMUSCULAR DISORDERS

Degenerative nervous system disorders involve the extrapyramidal tracts and basal ganglia in the brain. The extrapyramidal tracts are the efferent pathways outside the pyramidal system that connect the cerebral cortex with the spinal nerve pathways. Because these are motor pathways, movement rather than sensation is affected. The resulting symptoms can include rigidity, tremor, and abnormal movements.

Parkinson's Disease

Parkinson's disease is a chronic degenerative movement disorder that arises in the basal ganglia in the cerebrum. It usually begins in the fourth or fifth decade of life, with symptoms becoming progressively worse as the patient ages. The disease is characterized by tremors, changes in posture and gait, rigidity, and slowness of movements. Approximately 1 million people in the United States are currently living with Parkinson's disease. It occurs most often in people older than age 50.

Pathophysiology

The substantia nigra is a group of cells located within the basal ganglia, which is situated deep within the brain. These cells are responsible for the production of dopamine, an inhibitory neurotransmitter. Dopamine facilitates the transmission of impulses from one neuron to another. Parkinson's disease is caused by widespread destruction of the cells of the substantia nigra, resulting in decreased dopamine production. Loss of dopamine function results in impairment of semiautomatic movements. Dopamine also plays a part in the fight-or-flight mechanism by activating epinephrine and norepinephrine.

Acetylcholine, an excitatory neurotransmitter, is secreted normally in individuals with Parkinson's disease. The normal counterbalance of acetylcholine and dopamine is interrupted in these patients, causing a relative excess of acetylcholine, which results in the tremor, muscle rigidity, and **akinesia** (loss of muscle movement) characteristic of Parkinson's disease.

Etiology

The etiology of Parkinson's disease is unknown. It was first described in 1817 by London surgeon James Parkinson. Although scientists now know that the symptoms are caused by death of dopamine-producing cells in the substantia nigra, they do not know what causes the cells to die. Parkinson-like symptoms, referred to as parkinsonism, may be associated with use of certain drugs, such as phenothiazines.

Parkinsonism was also linked to an outbreak of encephalitis in the 1920s.

Signs and Symptoms

The onset of symptoms in patients with Parkinson's disease is usually gradual and subtle. A substantial percentage of the dopamine-producing cells are nonfunctional before the patient becomes symptomatic. Symptoms may be mistakenly attributed to aging or fatigue. In retrospect, patients and their significant others often identify a long period in which symptoms were present but not identified as symptoms of Parkinson's disease.

The primary symptoms of Parkinson's disease are muscular rigidity, **bradykinesia** (slow movement) or akinesia, changes in posture, and tremors. The brain is no longer able to direct the muscles to perform in the usual manner. This lack of communication between the brain and the muscles can have a profound impact on the patient's ability to ambulate safely, perform ADLs and job functions, or enjoy leisure activities. The symptoms may also have a significant negative impact on the patient's self-esteem.

The patient may have difficulty in initiating movement; this may be particularly apparent when the patient attempts to start walking, rise from a sitting position, or begin dressing. Because considerable effort is required to move the rigid muscles, the patient performs voluntary movements very slowly.

The extensor muscles are more affected by Parkinson's disease than the flexor muscles. This impaired function of the extensor muscles results in the stooped posture typical of patients with Parkinson's disease (Fig. 46-19). Flexion of the hips, knees, and neck shifts the center of gravity forward. The gait is characterized by shuffling, short steps. This

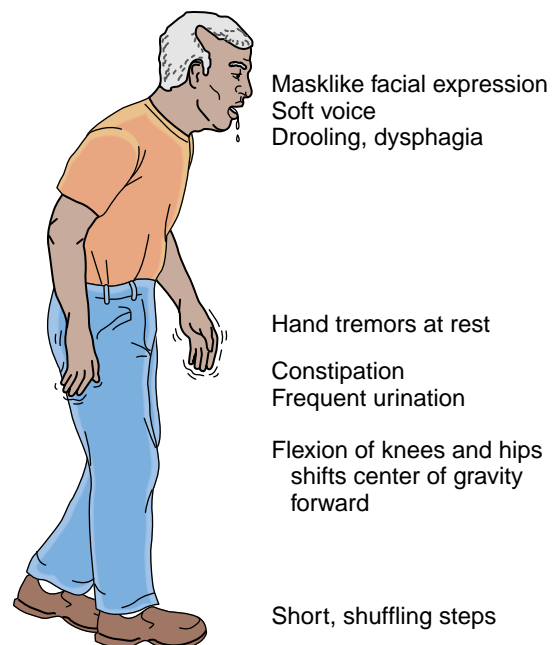

Figure 46-19 Manifestations of Parkinson's disease.

akinesia: a—not + kinesia—movement

bradykinesia: brady—slow + kinesia—movement

shuffling gait may increase in speed once the patient finally gets walking, and the patient may have difficulty stopping. The patient maintains a broad base when making turns to try to compensate for imbalance. These changes place patients at high risk for falls. Slowness of movement and stiff muscles make it much harder for patients to catch themselves if they start to fall or to relax the muscles to minimize injury.

Tremors typically begin in the hand and then progress to the **ipsilateral** foot. In most patients the tremor then moves to the **contralateral** side. Many patients identify one side of the body as being more affected by the tremor than the other. Tremor of the hand has been described as a pill-rolling tremor; the thumb typically moves back and forth across the fingers and looks like the patient is rolling a pill. Tremors typically lessen or disappear during movement and are more noticeable when the extremity is at rest or when trying to hold an object still (this is called a resting tremor). The tremors disappear when the patient is asleep. The inability to hold an object still can make simple acts such as drinking a glass of water or reading a book nearly impossible. The signs and symptoms of Parkinson's disease tend to increase in severity when the patient becomes fatigued.

Another type of tremor, a benign familial (or essential) tremor, may sometimes be mistaken for Parkinson's disease. Treatment is different for each. See Table 46–8 for differentiation of these tremors. The secondary symptoms of Parkinson's disease include generalized weakness, muscle fatigue and cramping, and difficulty with fine motor activities. This fine motor dysfunction may make it difficult for the patient to button a shirt or tie shoes. Handwriting typically deteriorates as the disease progresses. A soft, monotone voice and masklike facial expression may make the patient appear to be lacking in emotional responses. It may be necessary to ask patients about their emotional status and help them develop ways of expressing their emotions. The normal blink response is diminished, so the patient and significant others must be educated about eye care to prevent corneal abrasions.

TABLE 46–8 SYMPTOMS OF PARKINSON'S DISEASE VERSUS ESSENTIAL TREMOR

Disease	Parkinson's Tremor	Benign Familial Tremor
Resting tremor	Yes	No
Intention tremor (with movement)	No	Yes
Pill-rolling tremor	Yes	No
Head/voice tremor	No	Yes
Relieved with beta-blocking medication (propranolol)	No	Yes
Relieved with anti-Parkinson's medications	Yes	No

ipsilateral: ipsi—same + lateral—side
contralateral: contra—opposite + lateral—side

Dysfunction of the autonomic system may be manifested by diaphoresis, constipation, orthostatic hypotension, drooling, dysphagia, seborrhea, and frequent urination. Patients who experience seborrhea and diaphoresis need frequent attention to personal hygiene. Drooling and dysphagia may make the patient reluctant to appear in public. Slowness in initiating walking, balance problems, and frequent urination place the patient at risk for urinary incontinence, which may also increase the patient's reluctance to leave home.

Late in the disease, mental function may become slowed and the patient may become demented. This is compounded by the side effects of many anti-Parkinson's drugs. Death is usually from complications of immobility.

Complications

The most typical acute complications of Parkinson's disease are related to the patient's difficulties with mobility and balance. These patients are very prone to falls, which may result in injuries ranging from bruises or fractures to head or spinal cord injuries. Constipation is common because of decreased activity, diminished ability to take in food and fluids, and side effects of anticholinergic medications. Patients are encouraged to increase the fiber and roughage in their diet. If constipation is not alleviated by dietary modifications, the patient may need to use stool softeners. The patient should be counseled not to rely on laxatives or enemas.

Muscular rigidity and bradykinesia contribute to joint immobility, which decreases patients' ability to ambulate and care for themselves. Position changes may be painful for patients. A turning sheet and adequate personnel are necessary when turning a patient in bed to prevent stress on the joints. Tremors interfere with ADLs, consume immense amounts of energy, and may prevent the patient from working or performing leisure activities. Swallowing may become so impaired that enteral (tube) feeding is required. Depression is a common complication at any stage of Parkinson's disease and may compromise communication, ability to learn, and performance of ADLs. Patients may require counseling or antidepressants.

Diagnostic Tests

No specific tests are used to diagnose Parkinson's disease. The diagnosis is based on the history given by the patient and a thorough physical examination.

Medical Treatment

There is no cure for Parkinson's disease. Treatment is aimed at controlling symptoms and maximizing the patient's functional level. Drugs used to control symptoms are listed in Table 46–9.

Many patients with Parkinson's disease experience fluctuations in motor function related to their drug therapy. This is referred to as the on-off phenomenon. Patients may experience a decreased response to levodopa, or off period, particularly as the dose is wearing off. As the disease progresses, patients may notice that the off periods become less

TABLE 46-9 MEDICATIONS USED TO TREAT PARKINSON'S DISEASE

Class	Medication	Action	Side Effects/Comments
Anticholinergic	Trihexyphenidyl (Artane)	Blocks the action of acetylcholine to control tremor and salivation.	Urine retention, dry mouth, constipation, blurring of memory, dizziness, confusion
Dopamine agonists	Amantadine (Symmetrel)	Facilitates production and secretion of dopamine.	Leg edema, hypotension, dizziness, confusion
	Levodopa (L-Dopa)	Levodopa is converted into dopamine in the brain by the amino acid decarboxylase. Reduces tremor, rigidity, and bradykinesia.	May cause nausea, vomiting, dyskinesias Breakdown products of protein metabolism compete with levodopa for transport from intestine to brain Take 15–30 minutes before meals and minimize protein intake during active times
	Levodopa/carbidopa combination (Sinemet)	Carbidopa is a peripheral decarboxylase inhibitor that prevents peripheral breakdown of levodopa so more is available in the CNS.	
	Pramipexole (Mirapex)	Improves motor function; may protect dopamine neurons.	Nausea, dizziness, weakness; may cause sudden excessive sleepiness
Monamine oxidase B inhibitor	Selegiline (Eldepryl)	Blocks the metabolism of central dopamine, increasing dopamine in CNS.	Nausea, dizziness, confusion; may have potential to slow progression of Parkinson's disease
COMT inhibitor	Entacapone (Comtan)	Blocks the enzyme COMT to prevent breakdown of levodopa, prolonging levodopa action. For use with Sinemet.	Dyskinesias, orthostatic hypotension, hallucinations, nausea, yellow-orange urine

predictable and occur more rapidly. The patient may have a delayed or absent response to the next dose of levodopa, resulting in the patient being stuck in the off stage and being significantly disabled for that period. Fluctuations in motor function may be accompanied by other symptoms such as pain, diaphoresis, anxiety attacks, hallucinations, or mood swings. These symptoms significantly increase the disability associated with the episodes.

Patients who are taking maximum doses of medication for Parkinson's symptoms may benefit from a "drug holiday." During a drug holiday, patients are taken off all drugs for a time, then restarted on lower doses. Hospitalization may be necessary during this time to maintain patient safety.

Surgical Treatment

Pallidotomy is an option for patients whose rigidity, tremor, and bradykinesia are uncontrollable by medical management. During this stereotactic procedure, a destructive lesion is placed in the basal ganglia. The surgery is only performed on one side at a time. The patient remains awake during the surgery to make sure that the lesion is being placed in the appropriate location. These patients need a great deal of education and support before and during the surgery. Some centers are experimenting with implanting fetal tissue or adrenal gland tissue in the brain to produce dopamine. For more information, visit the National Parkinson Foundation at www.parkinson.org.

Nursing Process: The Patient with Parkinson's Disease

ASSESSMENT. Assess the patient for symptoms of Parkinson's disease and their effect on level of functioning. Observe ability to move, walk, and perform ADLs. Determine risk for injury related to immobility or falls. Assess nutritional status and condition of skin. Identify presence of confusion and side effects of medications. Psychosocial assessment includes the patient's and caregiver's response to the disease, coping strategies, and support systems.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. The patient with Parkinson's disease is at risk for many problems. Typical diagnoses include the following.

Impaired Physical Mobility Related to Muscle Stiffness and Tremor. Patients often plan their daily activities based on anticipated response to their medications. This allows them to be as active as possible within the restrictions of the medication schedule. Encourage patients to determine their own best schedule for activities that require mobility. For patients in skilled nursing facilities, plan leisure activities around the patient's most active times.

Physical and occupational therapy can help maintain mobility, provide assistive devices, and provide diversional activities. Provide assistance with range-of-motion exercises. Teach patients who have difficulty initiating walking to pick up their foot as though attempting to step over

something to take the first step. It may also help to take several steps in place before starting to walk.

Self-Care Deficit Related to Reduced Mobility. The most common setting for treatment of the patient with Parkinson's disease is the home. Encourage the patient to participate in ADLs as much as possible. The occupational therapist can assist with devices and strategies for maintaining independence. Patients have usually developed their own coping strategies, such as wearing clothing without buttons or shoes with adherent fasteners. As self-care abilities further decline, caregivers provide more assistance with ADLs.

As the patient ages, so do the significant others who are providing care. The point may be reached at which the caregiver is no longer able to meet the increasing needs of the patient. The decision to place the patient in a skilled nursing facility is extremely difficult and emotional. Every effort should be made to retain as much of the patient's usual routine as possible during hospitalization or admission to a skilled nursing facility.

Imbalanced Nutrition Related to Dysphagia and Reduced Mobility. Assist patients to open packages and prepare meals, so they can feed themselves if at all possible. If the patient has a severe tremor, a spoon may be safer than a fork for self-feeding. Finger foods may also be helpful. A cup with a lid and spout can help minimize spilling. Patients in the advanced stages of Parkinson's disease are at high risk for aspiration because they have difficulty swallowing. Adding thickening agents to liquids and assisting the patient to a chair or high Fowler's position for meals may help prevent aspiration. Meals that are high in fiber help prevent constipation. Small, frequent meals may be less overwhelming to the patient who must eat slowly.

Disturbed Thought Processes Related to Effects of Disease and Medication. Memory impairment is one of the most distressing symptoms that patients with Parkinson's disease experience. Many patients state that memory impairment and loss of social outlets are more troublesome than the physical impairments. Assist the patient to devise coping methods, such as written daily schedules, calendars, and reminders to take medications. If the patient becomes confused, frequent reorientation may be helpful.

Caregiver Role Strain Related to Demands of Caring for Patient. The significant others and caregivers of the patient with Parkinson's disease should be included in the plan of care. Encourage caregivers to utilize all community, personal, and governmental support systems available. Caregivers may need to be reminded that if they neglect their own health, both physical and mental, it will have a negative impact on the patient as well. Some caregivers may only need an hour or two away on an occasional basis. Others may require a more extended break. Options for relief from caregiving range from having a friend or neighbor visit to employing a home health aide or utilizing adult day care on a part-time or full-time basis. Some skilled care facilities offer respite care, in which the patient is admitted for a short time. This may be a viable option for caregivers

who must be hospitalized for their own health care. A social worker may be able to assist with identification of resources.

Risk for Injury Related to Reduced Mobility and Balance. The patient is at risk for injury from falls related to problems with mobility. If the patient is in the hospital or extended care facility, keep the call light within reach at all times. The bed should be kept in the low position, with side rails raised. Restraints should be avoided, but alarm systems are available that alert the staff that the patient is getting up. The environment should be kept free from clutter, throw rugs, or other items that may cause a patient to trip. Remind the patient to request assistance with ambulation. Walkers and other assistive devices may be helpful.

CRITICAL THINKING

Ms. Simpson
Ms. Simpson is a 47-year-old Caucasian female. She has had Parkinson's disease for the last 5 years, and the symptoms are becoming progressively worse. She is now admitted for a urinary tract infection.

1. What problems do you foresee when caring for Ms. Simpson?
2. What safety measures should you implement?

Answers at end of chapter.

Huntington's Disease

Huntington's disease is a progressive, hereditary, degenerative, incurable neurological disorder. It was first described in 1872 by George Huntington, a general practitioner from New York. The uncontrolled movements associated with Huntington's disease caused some sufferers in the seventeenth century to be accused of and executed for witchcraft. Many of the cases around the world can be traced back to specific individuals.

Pathophysiology and Etiology

Huntington's disease is inherited in the autosomal dominant manner, meaning that each offspring of an affected parent has a 50-percent chance of inheriting the disorder. It is uncertain what caused the mutation of the gene responsible for Huntington's disease. Structurally the disease is characterized by degeneration of the corpus striatum, caudate nucleus, and other deep nuclei of the brain and portions of the cerebral cortex.

Signs and Symptoms

Signs and symptoms develop slowly and become progressively more apparent. Cognitive signs may be noticed before movement problems. Patients who are not aware of their hereditary risk for Huntington's disease may be incorrectly diagnosed as being mentally ill or alcoholic.

The patient may display personality changes and inappropriate behavior. The patient may be euphoric or irritable and may rapidly alternate between moods. Paranoia is common, and behavior may become violent as **dementia** (men-

tal impairment) worsens. The patient eventually becomes so demented that he or she is incontinent and totally dependent on others for care. These symptoms are difficult for caregivers, whether family members or professionals, to cope with. They are particularly devastating for offspring, who may or may not know whether they have inherited the disease.

Physical symptoms also develop slowly. Huntington's disease is characterized by involuntary, irregular, jerky, dancelike (choreiform) movements. Initially these symptoms may take the form of mild fidgeting and facial grimacing. In the early stages of the disease the patient may try to cover the movements by incorporating them into a voluntary movement such as crossing the arms or scratching. The involuntary movements usually start in the arms, face, and neck and progressively involve the remainder of the body. Patients display hesitant speech, eye blinking, irregular trunk movements, abnormal tilt of the head, and constant motion (Fig. 46–20). The gait is wide, and the patient may appear to be dancing. Emotional upset, stress, or trying to perform a voluntary task can significantly increase the severity and rate of the abnormal movements. The movements typically diminish or disappear during sleep. Dysphagia may significantly impair the patient's nutritional status.

Depression and suicide are common in the earlier stages of the disease. As the disease progresses, the patient becomes more and more dependent. Aspiration resulting in respiratory failure is the primary cause of death. Life span following diagnosis is about 10 to 20 years.

Diagnostic Tests

Huntington's disease has typically been diagnosed based on the clinical examination and a family history of the disease. MRI or CT may be helpful. Genetic testing is available for prenatal use and to determine if an individual has Huntington's disease before he or she becomes symptomatic. This is a significant breakthrough because Huntington's disease does not become symptomatic until patients are in their

thirties or forties, when they may already have children who may be affected.

Medical Treatment

Because there is no cure, treatment of Huntington's disease focuses on minimizing symptoms and preventing complications. Antipsychotic, antidepressant, and antichorea drugs may be used to treat both the involuntary movements and behavioral outbursts. Some medical centers are transplanting fetal nerve tissue in patients with Huntington's disease. For more information, visit the Huntington's Disease Society of America at www.kumc.edu/hospital/huntingtons.

Nursing Management

Patients with Huntington's disease are typically cared for on an outpatient basis. When a patient with Huntington's disease is admitted to an inpatient facility, it is important to obtain as much information as possible about that person's response to medication, daily routine, and emotional and cognitive functioning from the caregivers. For example, knowing that a certain patient is intensely afraid of bathtubs but willingly takes showers can prevent unnecessary struggles and outbursts. Providing some objects from home may make the new environment seem less threatening. The caregivers may relate that the patient has better cognitive functioning at a particular time of day. As the dementia progresses, the patient responds less to attempts at reasoning. Giving directions in a calm but firm tone may help the patient cooperate with activities. The environment should be modified to keep the patient safe. Keep in mind that forceful, involuntary movements of the patient's extremities can happen at any time. These movements should never be misinterpreted as an attempt to harm caregivers.

Difficulty swallowing typically begins toward the middle of the disease course. Patients exhibit trouble swallowing liquids in particular. At this stage it may still be possible to teach the patient to hold the chin down to the chest while swallowing, which lessens the chance of aspiration. Patients

Figure 46-20 A 47-year old patient with Huntington's disease. Note constant fidgety movement. (From Spillane, JD: *An Atlas of Clinical Neurology*. Oxford University Press, New York, 1968, p 219, by permission.)

should sit straight upright while eating. Thickening agents may be added to thin liquids to help prevent aspiration. Adaptive devices may prolong the patient's ability to eat independently. Soft foods that are easily manipulated in the mouth are most suitable. These patients may have difficulty taking in adequate calories to maintain a normal body weight, even if a caregiver assists with feeding them. One of the many ethical issues faced by these patients and their significant others is whether artificial feeding should be used, and if so, for how long. Patients and their significant others should be encouraged to discuss end-of-life decisions early in the course of the disease.

Alzheimer's Disease

Alzheimer's disease (also called dementia of the Alzheimer's type, or DAT) is the most common of several types of dementia. Dementia is "a loss of intellectual function (thinking, remembering, and reasoning) so severe that it interferes with an individual's daily functioning and eventually results in death."¹

Alois Alzheimer, a German neurologist, first described the disease in 1907. He described pathological changes, now referred to as neurofibrillary tangles and neuritic plaques, that he discovered while performing an autopsy. Alzheimer's disease is a progressively degenerative disease that is inevitably fatal. The incidence of Alzheimer's disease is more common in women than men and doubles for every 5 years the person lives beyond age 65.

Etiology and Pathophysiology

Many etiologies have been theorized for Alzheimer's disease, including a genetic cause. Chromosome 21 is the location for the gene sequence that is associated with Alzheimer's disease. Chromosome 21 is also the location of the genetic abnormality responsible for Down syndrome. Patients older than age 40 who have Down syndrome usually develop Alzheimer's disease. The exact correlation between the two disorders is still being studied.

Although the exact cause of Alzheimer's disease is unknown, the structural changes associated with it have been well documented. An abnormality exists within the protein of the cell membrane of a neuron. As the axon terminals and dendrite branches disintegrate, they collect in neuritic plaques. Within the normal brain is a precise arrangement of filaments and tubules, responsible for cell integrity. Individuals with Alzheimer's disease develop neurofibrillary tangles instead of the normal orderly arrangement. Instead of remaining a small area of abnormality, these neuritic plaques and neurofibrillary tangles spread via axons to other areas of the brain.

Advancement of neurofibrillary tangles and neuritic plaques typically affect the hippocampus first, resulting in short-term memory dysfunction. As the tangles and plaques spread to the temporal lobe, the memory impairment becomes more severe. It may be at this point that the patient accesses the health care system. Personality changes and incontinence are inevitable results of Alzheimer's disease.

These symptoms can be attributed to the spread of plaques and tangles to the frontal lobes of the brain.

It is believed that the younger the patient is at the time of onset, the faster the neurofibrillary tangles and neuritic plaques spread. Therefore these patients tend to deteriorate faster, require complete care earlier, and have a shorter life span.

One area of the brain that is left relatively untouched by tangles and plaques is the subcortical area. This structure is responsible for our subconscious urge to survive. The needs for basic requirements such as shelter, food and water, security, and reproduction are controlled by the subcortical area, as are emotional responses to situations. The patient with Alzheimer's disease may experience hunger but no longer know how to meet that basic need. Left to their own devices, these individuals would starve.

Signs and Symptoms

The signs and symptoms of Alzheimer's disease are typically broken down into three stages. The early stage lasts from 2 to 4 years and is characterized by increasing forgetfulness. At this stage the patient may attempt to cope by using lists and reminders. Interest in day-to-day activities, acquaintances, and surroundings tends to diminish. The patient is reluctant to take on tasks because of uncertainty in how to perform them. If the patient is still working, his or her performance deteriorates and may result in being terminated from the job.

The middle stage is the longest in duration, lasting 2 to 12 years. Progressive memory loss is demonstrated by difficulty doing simple calculations or answering questions. Patients may become irritable, particularly when asked to perform a task that they know they should be able to perform but cannot. It may help the patient to break down the task into manageable steps. Depression is common. Aphasia and the resulting inability to make themselves understood may exacerbate patients' irritability. It is during the middle stage, as cognitive function significantly deteriorates, that the patient becomes more physically active. The normal sleep-wake cycle is disrupted, and the patient tends to wander aimlessly, particularly at night. The patient may become lost in familiar surroundings, which compounds the anxiety that typically develops during this stage. Hallucinations and seizures may occur. Management of day-to-day activities such as feeding a pet or paying bills becomes overwhelming. Personal hygiene deteriorates, as does appropriate social behavior. Patients may make up stories to cover for deficits, saying that possessions they misplaced were stolen. Some patients hoard food or money.

The third stage of Alzheimer's disease is characterized by progression to complete dependency. The patient loses the ability to converse or control bowel or bladder function. Constant supervision is required, if the patient is still mobile, to protect from wandering and avoid injury. Emotional control and ability to recognize significant others are lost. This lack of recognition is particularly devastating for family members. Eventually the patient is unable to move independently, swallow, or express needs. Death occurs from complications of immobility.

The duration of the final stage of Alzheimer's disease, characterized by complete dependence, depends in part on the physical stamina and general health of the individual. The healthier the patient, the longer the body will continue to function. Another factor is the decisions that have been made regarding artificial feeding and respiratory support. Few significant others or health care practitioners advocate intubation and mechanical ventilation for patients with Alzheimer's disease. The issue of enteral feedings, however, is an emotional one with few easy answers. The use of enteral feedings can prolong the patient's life, despite the absence of cognitive functioning. As with patients suffering from Huntington's disease, every effort should be made to determine the patient's wishes before cognitive impairment makes that impossible. See Table 46–10 for a comparison of the symptoms of Parkinson's, Huntington's, and Alzheimer's diseases.

Diagnostic Tests

The only absolute method of confirming a diagnosis of Alzheimer's is by pathological examination at autopsy. In actuality, the disease is diagnosed on the basis of clinical examination, history, and elimination of other possible causes of the symptoms. MRI may reveal the presence of the classic neurofibrillary tangles and neuritic plaques. Positron emission tomography (PET) and single photon emission computed tomography (SPECT) scans show areas of neuronal inactivity. Newer tests are being evaluated that hold promise for better diagnosis.

Medical Treatment

There is no known cure for Alzheimer's disease. Treatment has traditionally focused on minimizing the effects of the disease and maintaining independence as long as possible. Tacrine (Cognex) was the first drug released expressly for the treatment of Alzheimer's disease. Tacrine is thought to inhibit the breakdown of the neurotransmitter acetylcholine. Increased levels of acetylcholine in the brain allow better functioning of the remaining neurons. Tacrine appears most effective for those patients who exhibit mild to moderate symptoms of Alzheimer's disease. A minimum of 19 weeks may be required to notice any effects of the drug. Use of tacrine diminishes the amount of medical care and social service interventions required and delays admission to skilled nursing facilities. This delay in institutionaliza-

tion can result in significant positive impact on quality of life, as well as thousands of dollars in savings. Newer drugs such as donepezil (Aricept) also inhibit the breakdown of acetylcholine in the brain but have fewer side effects than tacrine.

Antidepressants, antipsychotics, and antianxiety drugs may be used as a last resort to control symptoms of depression and behavioral disturbances, but they do not treat the dementia. Patients should be carefully monitored for drug interactions and side effects. For more information, visit the Alzheimer's Association at www.alz.org.

Nursing Process: The Patient with Dementia

ASSESSMENT. Assess mental status, including memory, orientation, and judgment. (See Chapter 45.) Assess patients' functional level to determine the level of self-care they are able to engage in. The abilities of the family or caregiver to provide the care needed are also assessed, so that appropriate referrals can be made. Availability and use of resources are determined. Nutritional status and usual food preferences are assessed to aid in planning for adequate nutritional intake.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION.

Patients with dementia are at risk for numerous problems. Goals include helping patients maintain the ability to care for themselves for as long as possible. Maintenance of safety and nutrition are priorities (Box 46–9). Incontinence should be minimized and skin protected. Goals should include not only the patient but the caregiver as well. If the caregiver does not have adequate support, the burden of caring for the patient may become overwhelming.

Risk for Injury. Many individuals who have a loved one with dementia wish to keep that individual at home as long as possible. Caregivers need a great deal of education and support. Although every effort should be made to retain the patient's dignity, devices designed to protect small children may be effectively used in the home. (See Home Health Hints.) Baby gates at stairways and baby latches on doors and outlets provide relatively unobtrusive protection. Because they may misinterpret the environment, patients may find mirrors frightening. Forgetfulness and impaired judgment make safety a major concern for Alzheimer's patients who live at home. Patients may strongly resist efforts to keep them from cooking or driving. It may be necessary to

TABLE 46–10 SYMPTOMS OF PARKINSON'S DISEASE, HUNTINGTON'S DISEASE, AND ALZHEIMER'S DISEASE

	Parkinson's Disease	Huntington's Disease	Alzheimer's Disease
Tremors	Present	Absent	Absent
Bradykinesia/akinesia	Present	Absent	Absent
Muscle rigidity	Present	Absent	Absent

Cognitive dysfunction	Late	Present	Early
Inability to perform ADLs	Progressive	Progressive	Progressive
Involuntary movements	Absent	Present	Absent
Depression	Present	Present	Present

BOX 46-9 Managing Mealtimes for Patients with Dementia

Dining rooms should be quiet and have adequate lighting. Occupying the same chair for every meal lends familiarity. Serving one course at a time and providing necessary but not extraneous flatware, large handled if necessary, limits distractions. Dishes with high sides enable the patient to scoop the food onto a spoon or fork. Finger foods that the patient can manage may increase intake with minimal staff assistance.

Patients with dementia must be reminded of the steps involved in self-feeding: putting the food on the spoon, directing it to the mouth, swallowing. Use verbal cues or guide the patient's hand to start the necessary movement. Despite the surroundings, common courtesies model social expectations. Introducing the patient to the other persons at the table, providing a cup rather than a carton for milk, and offering foods separately rather than mixing them all together maintain a person's dignity.^{1,2}

Quiet music with a slow tempo—at or below the human heart rate—has been used to dampen environmental noises that might otherwise startle patients. Fewer incidents of agitated behaviors occurred during the weeks that music was played compared with weeks without music.³ Because staff members listened along with the patients, perhaps some of the effect was obtained by relaxing them also.

1. Kayser-Jones, J, and Schell, E: The mealtime experience of a cognitively impaired elder: ineffective and effective strategies. *J Gerontol Nurs* 23:33, 1997.

2. Tully, MW, et al: The eating behavior scale: a simple method of assessing functional ability in patients with Alzheimer's disease. *J Gerontol Nurs* 23:9, 1997.

3. Denney, A: Quiet music: an intervention for mealtime agitation? *J Gerontol Nurs* 23:16, 1997.

remove car keys from the patient's access. If patients live alone, they may resist changes in living arrangements.

The patient with dementia is typically admitted to a skilled nursing facility when the significant other can no longer handle care at home. Patients may wander, making them prone to injury. Doors of units should be equipped with alarms indicating when they have been opened. A medical alert bracelet can be worn to identify patients in case they wander and become lost. Special Alzheimer's units are available at many long-term care facilities.

Imbalanced Nutrition. Maintaining adequate nutrition intake for a patient with limited attention span is a nursing challenge. Because these patients have difficulty making choices, one food at a time should be offered. Frequent high-calorie meals and snacks that can be eaten with the fingers may help increase intake.

Disturbed Thought Processes. To facilitate communication, gently touch patients to get their attention before speaking. Gestures, simple phrases, and a calm quiet setting may also help. Patients must be allowed adequate time for

**HOME HEALTH HINTS**

To assess a patient's neurological status at home:

- Note whether the patient's clothes are matched and properly fastened. Is the patient clean and well groomed?
- Observe the patient during bathing, grooming, or dressing to assess motor function and coordination.
- Assess energy level by noting if the patient makes frequent requests to sit or lie down.
- Observe the patient's gait for steadiness.

To help the patient perform ADLs easier at home:

- Ask permission to move furniture and small rugs in order to provide a clear path for ambulation.
- Position frequently used items such as a comb, glass of water, eyeglasses, books, tissues, and phone where they are easily accessible.
- Recommend shoes with Velcro closures.
- Use chairs with armrests—the patient can use the armrests to push against to stand.
- Keep the patient cleaner at meals with a clip-on bib such as those used at the dentist's office. Attach clips from suspenders to a piece of elastic and place around the back of the patient's neck. Attach a clean napkin or washcloth for each meal.

To help the patient with Alzheimer's disease who has perceptual deficits:

- Have things used together the same color (e.g., toothbrush and toothpaste).
- Contrast colors in the environment to help patients function independently—slipper color should be different than the floor, a dark-colored placemat can be used under light dishes, and the first and last steps of a stairway can be painted a contrasting color.
- Use a bath or shower seat, handheld shower head, and soothing music to help the patient feel safe and oriented to the task while bathing.
- Cover doorknobs with a piece of cloth to keep the patient from wandering away.

the information to be processed before a response is expected.

Difficult behavior may be caused by inability to express needs or fears. The patient may feel the urge to urinate but can no longer communicate this need or accomplish the process independently. Because understanding the environment is difficult, help the patient to maintain a predictable routine. Scheduled voiding may minimize incontinence. Patients feel safer and may cope better in a stable environment.

Patients often rummage through drawers, closets, or boxes. Unfortunately, these patients do not recognize the difference between their own possessions and those of others, which becomes more problematic if they are in a nursing facility. They may not know what they are looking for, but they do feel that they need to find something. Giving the patient a box of safe, familiar items, such as empty thread spools, may occupy the patient repeatedly.

Incontinence. Regular toileting for both bowel and bladder can help prevent episodes of incontinence. As incontinence becomes more frequent, adult briefs should be used.

An indwelling catheter should be avoided because of the risk for injury and infection. Briefs should be changed regularly to prevent skin breakdown.

Caregiver Role Strain. Dementia often takes at least as much of a toll on caregivers as it does on the sufferer. Fear of the diagnosis may keep people from seeking medical care. Some patients consider suicide because they fear losing their dignity and becoming a burden to their significant others. As the disease progresses, the patient gradually loses awareness of the neurological deterioration. Occasional lucid moments can be very difficult for patient and caregiver as they realize what has been lost.

Caregivers should be encouraged to share their perspectives and coping strategies with others in similar situations.

Support, both informal and formal, is vital to caregiver coping. Caregivers of patients with Alzheimer's disease have unique concerns and needs. You can help caregivers find Alzheimer's support groups and resources.

EVALUATION. If the plan of care is successful, the patient with dementia will remain safe and without injury in an environment that is as comfortable and nonrestrictive as possible. If nutrition is adequate, the patient's weight will remain stable. The patient's needs will be anticipated so that communication frustrations will be kept to a minimum. Incontinence will be managed without skin breakdown. Patients and caregivers should be able to identify resources and obtain relief from caregiver activities when needed.

REVIEW QUESTIONS

- Which of the following problems predisposed Jennie to develop meningitis?
 - A muscle injury in her back
 - A migraine headache
 - A sore throat for 3 days
 - Vision changes
- Mr. Delmar has receptive aphasia. This means that he has difficulty with which of the following?
 - Swallowing
 - Speaking
 - Hearing
 - Understanding language
- David complains of seeing flashing lights. You know he has a history of seizures. Which of the following actions do you take first?
 - Help him lie down in a safe place.
 - Record the events of the seizure.
 - Take him to the emergency department.
 - Assess his eyes.
- Teresa is admitted following a traumatic brain injury. Which of the following actions do you take to help prevent increased ICP?
 - Cluster care so she can have long periods of rest.
 - Keep the head of her bed elevated at 30 degrees.
 - Suction frequently to keep her airway clear.
 - Do not give her anything by mouth.
- Intracranial hemorrhage can be caused by which of the following?
 - Hypertension
 - Trauma
 - Ruptured aneurysm
 - All of the above
- Jason is admitted following a T4 spinal injury. When taking his morning vital signs, you note that he appears restless and his blood pressure is elevated. Which of the following actions is appropriate?
 - Recheck his blood pressure in an hour.
 - No action is necessary.
 - Check for a full bladder.
 - Encourage him to express his anxiety.
- The symptoms of Parkinson's disease are caused by depletion of which neurotransmitter?
 - Dopamine
 - Acetylcholine
 - Serotonin
 - Norepinephrine
- The symptoms of Alzheimer's disease are associated with depletion of which neurotransmitter?
 - Dopamine
 - Acetylcholine
 - Serotonin
 - Norepinephrine

- Alzheimer's Association: Fact Sheet. <http://www.alz.org/dinfo/factsheet/ADFS.html>, 1998.

Answers to CRITICAL THINKING

Mr. Chung

1. Likely tests include CT scan and lumbar puncture.
2. You should use short, simple sentences, because he may be very anxious or disoriented. Involve his family. Further education can be provided when he is feeling better.
3. Because meningococcal meningitis is contagious, he should be placed in isolation. Gloves, gowns, and masks should be used. Explain the need for these practices to Mr. Chung and his visitors.
4. Comfort measures include tepid baths; a quiet, dark environment; and minimal stimulation. Administer acetaminophen and analgesics as ordered.
5. The health service at his college should be notified of his diagnosis. Close contacts may require prophylactic treatment. If Mr. Chung lives at home rather than at college, his family should be advised to see their family practitioner and begin prophylactic treatment.

Mrs. Washington

1. Uncontrolled hypertension might have precipitated Mrs. Washington's CVA.
2. Her left extremities are affected.
3. Mrs. Washington is disoriented. Her room should be as close to the nurse's station as possible. Reorient her to her surroundings and condition frequently. Keep side rails up when Mrs. Washington is alone.
Mrs. Washington is also hemiparetic. Obtain a commode because Mrs. Washington will probably not be able to walk to the bathroom. Place the call light and telephone on her right side. Assist Mrs. Washington with positioning to prevent injury to hemiparetic limbs.

4. You should teach Mrs. Washington and her daughter about the relationship of uncontrolled hypertension to intracranial hemorrhage; options for inpatient, outpatient, and in-home therapy; and memory strategies to prevent missed medication doses (e.g., weekly pill box, keeping medications with breakfast food or an alarm clock or watch).

Mr. Esposito

1. You might expect to see impaired speech, right-sided weakness, and a rapid decrease in consciousness if Mr. Esposito's hematoma is enlarged.
2. Intubation equipment, mannitol, and intravenous access should be ready. He should be given nothing by mouth (NPO) and the results of laboratory tests should be ready in the event of emergency surgery. The location of Mr. Esposito's next of kin must be known.
3. Who are Mr. Esposito's support people? Was this drinking episode an isolated incident or a chronic problem that should be addressed?

Ms. Simpson

1. Urinary tract infection is often accompanied by urinary urgency. Ms. Simpson may have difficulty getting to the bathroom quickly and safely.
2. Keep a bedside commode nearby if the bathroom is not close. Assist Ms. Simpson to the bathroom or commode at regular intervals to prevent urgency. Remind her to ask for help if she needs to get up. Make sure that her call light is within reach.

QUESTIONS TO GUIDE YOUR READING

1. What disorders are caused by disruption of the peripheral nervous system?
2. What are the pathophysiology, major signs and symptoms, and complications of selected peripheral nervous system disorders?
3. What are the medical and surgical treatments of selected peripheral nervous system disorders?
4. What are the steps in the nursing process for the patient with a peripheral nervous system disorder?

► PERIPHERAL NERVOUS SYSTEM DISORDERS

The peripheral nervous system (PNS) consists of all nervous system structures outside the central nervous system (CNS). A variety of disorders affect the PNS. Some of these disorders become chronic and cause **degeneration** of body systems. Some other disorders are of a temporary nature. Two common types of PNS disorders are discussed in this chapter. Neuromuscular disorders compose one group. The second group includes cranial nerve disorders. Both types of disorders present a challenge to the nurse caring for the patient and family.

Neuromuscular Disorders

This group of neurological conditions is chronic and degenerative in nature. Neuromuscular disorders involve a disruption of the transmission of impulses between neurons and the muscles that they stimulate (Fig. 47–1). This breakdown in transmission results in muscle weakness. If the muscles of the respiratory system are affected, deadly complications can develop, including pneumonia and respiratory failure. Common neuromuscular disorders include multiple **sclerosis** (MS), myasthenia gravis (MG), amyotrophic lateral sclerosis (ALS), and Guillain-Barré syndrome

Figure 47-1 The myelin sheath breaks down in multiple sclerosis, interrupting transmission of nerve impulses. (A) Normal myelin sheath. (B) Myelin beginning to break down. (C) Total myelin disruption. (Modified from Scanlon, VC, and Sanders, T: Workbook for Essentials of Anatomy and Physiology, ed 2. FA Davis, Philadelphia, 1995, p 109, with permission.)

(GBS). An additional neuropathic disorder is discussed in Cultural Consideration Box 47-1.

Multiple Sclerosis

ETIOLOGY. Multiple sclerosis is a chronic progressive degenerative disease that affects the myelin sheath on the neurons in the central nervous system. It results from an autoimmune process and may be affected by viral infections, heredity, and other factors. However, the cause of MS is not known. This disease affects 36 to 80 per 100,000 persons in the United States. Onset of the disease usually occurs between ages 15 and 50. Women are affected more than men.

PATHOPHYSIOLOGY. Myelin is responsible for the smooth transmission of nerve impulses. Muscles contract when nerve impulses stimulate the muscle tissue. If the myelin

sheath is damaged, nerve impulses cannot be transmitted to the muscle and contraction of the muscle does not occur. In multiple sclerosis, the myelin sheath begins to break down (degenerate) as a result of the activation of the body's immune system. The nerve becomes inflamed and edematous. Nerve impulses to the muscles slow down. As the disease progresses, sclerosis from scar tissue damages the nerve. Nerve impulses become completely blocked, causing permanent loss of muscle function in that area of the body.

SIGNS AND SYMPTOMS. The patient with MS presents with muscle weakness, tingling sensations, and numbness. These symptoms may begin slowly over weeks to months or start suddenly and dramatically. MS affects many systems of the body. Box 47-2 lists problems experienced by patients with MS. A variety of factors can trigger the onset or aggravate the condition. These factors include extreme heat and cold, fatigue, infection, and physical and emotional stress. Periods of **exacerbation** and remission of symptoms lead patients with MS to be uncertain about when the disease will flare up and what system of the body will be affected. Intense fatigue is a common complaint among patients. Therefore immobility can become a problem. Accidents and falls are common because of muscular weakness of the trunk and extremities. Pneumonia can occur from immobility and from weakness of the diaphragm and intercostal muscles. Death, usually resulting from respiratory infection, typically occurs 20 to 35 years after diagnosis.

DIAGNOSTIC TESTS. Diagnosis is based on the history and signs and symptoms experienced by the patient. MS cannot be diagnosed by a specific test. Analysis of cerebrospinal fluid

BOX 47-1 CULTURAL CONSIDERATION

Navajo neuropathy is unique to the Navajo Indian population. Characteristics include poor weight gain, short stature, sexual infantilism, serious systemic infections, and liver derangement. Manifestations include weakness, hypotonia, areflexia, loss of sensation in the extremities, corneal ulcerations, acral mutilation, and painless fractures.¹ Nerve biopsies show a nearly complete absence of myelinated fibers, which is different from other neuropathies, which present as a gradual demyelination process. Individuals who survive have many complications and are generally ventilator dependent. None have been known to survive past the age of 24.

1. Singleton, R, et al: Neuropathy in Navajo children: clinical and epidemiologic features. *Neurology* 40(2):363, 1990.

BOX 47-2 Problems Associated with Multiple Sclerosis

Weakness/paralysis of limbs, trunk or head	Impaired hearing
Diplopia (double vision)	Nystagmus
Slurred speech	Ataxia
Spasticity of muscles	Dysarthria
Numbness and tingling	Dysphagia
Patchy blindness (scotomas)	Constipation
Blurred vision	Spastic (uninhibited) bladder
Vertigo	Flaccid (hypotonic) bladder
Tinnitus	Sexual dysfunction
	Anger, depression, euphoria

(CSF) may show an increase in oligoclonal immunoglobulin G (IgG). Magnetic resonance imaging (MRI) may be helpful in diagnosis because sclerotic plaques can be detected.

MEDICAL TREATMENT. MS has no cure. Interferon therapy may reduce exacerbations and delay disability. Other treatment is supportive and symptomatic. Steroids are given to de-

crease inflammation and edema at the neuron, which may relieve some symptoms. Immunosuppressant drugs such as azathioprine (Imuran) and cyclophosphamide (Cytoxan) may be given to depress the immune system. Anticonvulsants such as phenytoin (Dilantin) and carbamazepine (Tegretol) help relieve neuropathic pain. Valium (Diazepam), baclofen (Lioresal), and physical therapy assist in controlling muscle spasms. Bladder problems are treated with several different medications such as bethanechol (Urecholine), neostigmine (Prostigmin), propantheline (Pro-Banthine), and oxybutynin (Ditropan). Rehabilitation after an acute episode includes physical, speech, and occupational therapies. Rehabilitation therapy assists the patient and family in adapting the home environment. Instruction in the use of assistive devices (e.g., braces, canes, wheelchairs, splints) by physical and occupational therapists allows the patient increased mobility and independence. Patients who develop speech difficulties benefit from speech therapy.

NURSING CARE. See Nursing Care Plan Box 47-3 for Care of the Patient with a Progressive Neuromuscular Disorder.

BOX 47-3**NURSING CARE PLAN FOR THE PATIENT WITH A PROGRESSIVE NEUROMUSCULAR DISORDER****Impaired Physical Mobility Related to Muscle Weakness****PATIENT OUTCOMES**

Patient will identify measures to help maintain mobility. Patient will perform exercises that help maintain current mobility. Patient will maintain optimum activity level.

EVALUATION OF OUTCOMES

Can patient identify measures that will help maintain mobility? Does patient perform exercises that help maintain mobility? Is optimum activity level maintained?

INTERVENTIONS

Determine current level of mobility.
Identify factors that affect ability to be mobile and active.
Encourage patient to perform self-care to maximum ability.
Consult physical therapist (PT) or occupational therapist (OT) to provide assistive devices for walking (canes, braces, walker, wheelchair) and other activities.
Reposition frequently when patient is immobile.
Provide active/passive range-of-motion (ROM) exercises on a regular basis.
Plan activities with a balance of frequent rest periods.
Administer medications as ordered.

RATIONALE

Provides information to formulate plan of care.
Provides opportunity to seek answers for problems.
Promotes sense of control and independence for patient.
Assistive devices decrease fatigue, promote independence, comfort, and safety.
Prevents skin breakdown and stasis of pulmonary secretions.
Prevents contractures and disuse atrophy.
Rest decreases fatigue.
Medications may slow progress of disease and reduce symptoms.

EVALUATION OF INTERVENTIONS

What is patient's present level of mobility?
Is patient able to identify factors that help or hinder mobility?
Does patient perform self-care activities? Is assistance required?
Does patient use assistive devices safely during activities? Do they help keep patient active?
Is patient free from complications of immobility?
Does patient have any contractures or atrophy?
Is fatigue controlled?
Are symptoms controlled?

Ineffective airway clearance related to muscle weakness, impaired cough and gag reflex**PATIENT OUTCOMES**

Patient will maintain a patent airway. Patient will be free of signs and symptoms of respiratory distress.

EVALUATION OF OUTCOMES

Is patient's airway patent? Is patient free of signs and symptoms of respiratory distress?

BOX 47-3 NURSING CARE PLAN FOR THE PATIENT WITH A PROGRESSIVE NEUROMUSCULAR DISORDER—CONT'D

INTERVENTIONS

Monitor respiratory rate and depth, oxygen saturation, and arterial blood gases (as ordered).
Encourage patient to cough and deep breathe every 2 hours.
Observe patient for breathlessness while speaking.
Elevate head of bed.

Evaluate cough, swallow, and gag reflexes frequently. Notify physician if absent.
Suction secretions as needed, noting color and amount of secretions.

RATIONALE

Increasing respiratory distress indicates progressing muscle weakness that may require mechanical ventilation or end-of-life decisions.
Effective coughing helps keep airway clear.

Inability to speak without breathlessness indicates declining respiratory function.
Fowler's position improves lung expansion, decreases work of breathing, improves cough efforts, and decreases risk for aspiration.
Frequent evaluation of reflexes is needed to prevent aspiration, respiratory infections, and respiratory failure.
Muscle weakness may result in inability to clear airway.

EVALUATION OF INTERVENTIONS

Is patient's respiratory rate stable or is intervention indicated?

Does patient have the strength to cough effectively?
Is patient able to finish sentences without needing to take a breath?
Does elevation of head of bed help relieve dyspnea and prevent aspiration?

Is patient able to cough effectively? Is gag reflex intact?

Does patient require suctioning to clear airway? What color are secretions?

▶ Risk for imbalanced nutrition related to weakness or incoordination of muscles of chewing and swallowing.

PATIENT OUTCOMES

Patient will maintain body weight within normal limits for height and frame.

EVALUATION OF OUTCOMES

Is patient's weight stable and within normal limits (WNL)?

INTERVENTIONS

Evaluate cough, swallow, and gag reflexes frequently. Notify physician if absent.
Offer soft, easy to chew and swallow foods.
Institute swallowing precautions as needed. (See Nutrition Notes Box 46-5.)
Request speech therapy and dietitian consultations as indicated.

RATIONALE

If patient is unable to swallow, a feeding tube may be indicated, depending on patient's wishes.
Soft foods require less effort to chew and are less fatiguing.
Swallowing precautions help prevent aspiration and allow patient to maintain oral intake as long as possible.
Speech therapist can help evaluate swallowing and make recommendations. Dietitian can provide appropriate foods.

EVALUATION OF INTERVENTIONS

Does patient eat and drink without aspirating?

Is patient able to chew and swallow without excessive fatigue?
Do precautions prevent aspiration?

Are consults indicated? Are recommendations implemented?

▶ Impaired verbal communication related to impaired respiratory and muscle function.

PATIENT OUTCOMES

Patient will be able to communicate needs.

EVALUATION OF OUTCOMES

Does patient indicate that needs are met with a minimum of frustration?

INTERVENTIONS

Assess ability to speak and communicate.
Request referral to speech therapist for assistance if indicated.
Assess for nonverbal signs of pain or distress, such as restlessness, agitation, grimacing.
Use picture board or paper and pencil. Ask questions that require yes or no answer.
Use unhurried, calm, and caring approach while providing care.
Explain all procedures.

RATIONALE

Assessment is essential to planning appropriate communication interventions.
Speech therapist can recommend appropriate alternative communication techniques.
Patient may not be able to tell you if he or she is in pain or distress.
These do not require the patient to speak to communicate.
This will help decrease anxiety and provide emotional support to patient and family.
Patient can still hear and needs to know what is happening.

EVALUATION OF INTERVENTIONS

Can patient speak or communicate needs?

Is speech therapy referral indicated? Is referral completed?
Are signs of pain or distress present? Are they attended to?

Do alternative methods help patient communicate needs?

Do patient and family appear anxious? Does calm approach help?
Does patient indicate understanding?

In addition to routine care, instruct the patient to avoid factors that can exacerbate symptoms. This includes avoiding stressful situations as much as possible, as well as avoiding infection and illness. Any infection, especially respiratory, should be reported immediately to a physician. Two sources of information on MS are the National Multiple Sclerosis Society at www.nmss.org and the Multiple Sclerosis Foundation at www.msfacts.org.

LEARNING TIPS

Myelin facilitates impulse transmission to the muscle. If myelin is interrupted, the impulse cannot get to the muscle efficiently.

Myasthenia Gravis

ETIOLOGY. *Myasthenia gravis* (MG) means “grave muscle weakness” or weakness of the voluntary or striated muscles of the body. Myasthenia gravis is an autoimmune process. No specific cause has been found for MG. However, current thought is that a virus may initiate the disease. Prevention of MG is not possible at this time. Incidence of the disease is estimated from 43 to 84 persons per million. Peak age of onset in women is 20 to 30 years. MG occurs slightly more often in women than men.

PATHOPHYSIOLOGY. MG is a disease of the neuromuscular junction (Fig. 47–2). At the neuromuscular junction, the neuron releases the chemical neurotransmitter acetylcholine (ACh), which crosses the synaptic cleft. Receptors on the muscle tissue take up ACh, and contraction of the muscle results. In MG the body’s immune system is activated, producing antibodies that attack and destroy ACh receptors at the neuromuscular junction. ACh cannot stimulate muscle contraction because the number of ACh receptors has been reduced, resulting in loss of voluntary muscle strength.

SIGNS AND SYMPTOMS. MG results in progressive extreme muscle weakness. Muscles are strongest in the morning, when the person is rested. Activity causes the muscles to fatigue easily, but rest allows the muscles to regain strength. Activities affected by MG include eye and eyelid movements, chewing, swallowing, speaking, and breathing, as well as skeletal muscle function. Patients often present with drooping of eyelids (**ptosis**). Facial expressions are masklike. After long conversations, the voice fades. Falls occur because of weakness of the arm and leg muscles. Patients with MG experience periods of exacerbation and remission of symptoms, as do patients with multiple sclerosis. Exacerbations can be caused by emotional or physical stress, such as pregnancy, menses, illness, trauma, extremes in temperature, electrolyte imbalance, surgery, and drugs that block actions at the neuromuscular junction.

COMPLICATIONS. Major complications associated with MG result from weakness of muscles that assist with swallowing and breathing. Aspiration, respiratory infections, and respiratory failure are the leading causes of death. Sudden onset of muscle weakness in patients with MG resulting from not enough medication is called a myasthenic crisis. Overmedication with **anticholinesterase** drugs causes a cholinergic crisis (Table 47–1). Both crises require immediate medical attention.

LEARNING TIPS

Symptoms of cholinergic crisis can be remembered with the acronym SLUDGE: salivation, lacrimation, urination, diarrhea, gastrointestinal cramping, and emesis. A severe crisis has been described as “liquid pouring out of every body orifice.”

anticholinesterase: anti—against + cholinesterase—chemical that breaks down acetylcholine

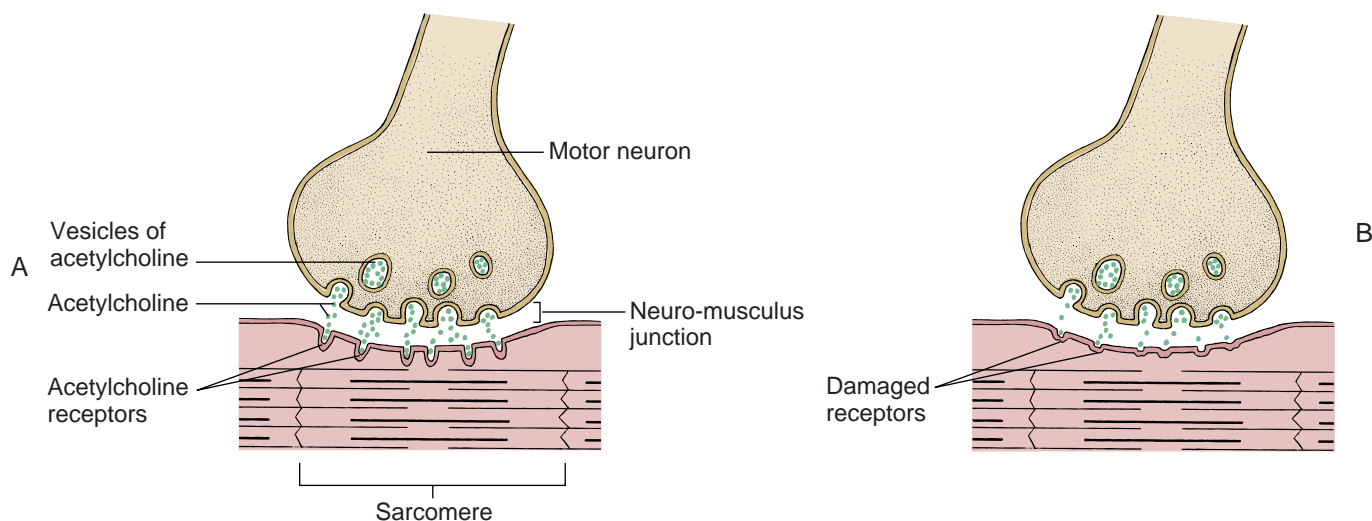

Figure 47-2 Myasthenia gravis. (A) Normal neuromuscular junction. (B) Note damaged acetylcholine receptor sites in myasthenia gravis. (Modified from Scanlon, VC, and Sanders, T: *Workbook for Essentials of Anatomy and Physiology*, ed 2. FA Davis, Philadelphia, 1995, p 97, with permission.)

TABLE 47-1 COMPARISON OF MYASTHENIC CRISIS AND CHOLINERGIC CRISIS

Myasthenic Crisis	Cholinergic Crisis
<i>Cause</i>	<i>Cause</i>
Too little medication	Too much medication
<i>Signs and Symptoms</i>	<i>Signs and Symptoms</i>
Ptosis	Increasing muscle weakness
Difficulty swallowing	Dyspnea
Difficulty speaking	Salivation
Dyspnea	Nausea or vomiting
Weakness	Abdominal cramping
	Sweating
	Increased bronchial secretions
	Miosis (contraction of pupils)

DIAGNOSTIC TESTS. Diagnosis of myasthenia gravis is based on history of symptoms and physical examination of the patient. A simple test involves the patient looking upward for 2 to 3 minutes. Increased droop of the eyelids (ptosis) occurs if MG is present. After a brief rest, the eyelids can be opened without difficulty. Another test involves an intravenous injection of edrophonium (Tensilon, an anticholinesterase drug). If muscle strength improves dramatically (e.g., the patient can suddenly open the eyes wide), MG is diagnosed. However, improvement is only temporary. An increased number of anti-ACh receptor antibodies in the blood are present in 90 percent of patients with MG. Electromyography (EMG) may be done to rule out other conditions.

MEDICAL TREATMENT. As with multiple sclerosis, no cure has been found for MG. Treatment options include the use of drugs and **plasmapheresis** (Table 47-2). Removal of the thymus gland (thymectomy) can decrease production of

plasmapheresis: plasma—liquid of blood + pheresis—removal

ACh receptor antibodies and decrease symptoms in most patients. Medications used to treat MG include the anticholinesterase drugs neostigmine (Prostigmin) and pyridostigmine (Mestinon). These drugs improve symptoms of MG by destroying the acetylcholinesterase that breaks down ACh. Remember that ACh causes muscles to contract. If ACh is allowed more time to attach to muscle tissue receptors, the muscle contracts and strength is increased. Steroids such as prednisone and immunosuppressants are used to suppress the body's immune response. Plasmapheresis (similar to dialysis) can be used to remove antibodies from the patient's blood.

NURSING CARE. See Nursing Care Plan 47-3 for Care of the Patient with a Progressive Neuromuscular Disorder. In addition, anticholinesterase drugs should be scheduled so that peak action occurs at times when increased muscle strength is needed for activities such as meals and physical therapy. Be aware of symptoms and treatment of myasthenic and cholinergic crises, so you can determine what immediate actions need to be taken.

Patient Education. Instruct the patient that nutritious, well-balanced meals provide caloric intake to maintain strength and resistance to infections. Teach the patient to schedule activities such as grocery shopping or errands at times when medication is at peak action, so that muscle strength is increased. Teach methods to conserve energy, such as sitting down to do grooming and housekeeping activities whenever possible. Teach the importance of avoidance of persons with infections and exposure to cold to minimize risk for respiratory infections, which can exacerbate symptoms and increase risk for ineffective airway clearance. Teach signs and symptoms of crisis conditions because both crises constitute medical emergencies and require immediate medical attention. (See Table 47-1.) Provide information about support groups that can provide encouragement and assistance to patients and their families. Visit the Myasthenia Gravis Foundation of America at www.myasthenia.org.

TABLE 47-2 PLASMAPHERESIS

Plasmapheresis, also known as plasma exchange therapy, is a procedure that removes the plasma component from whole blood. The goal of this therapy is to remove inflammatory agents through exchanging plasma to suppress the immune response and inflammation.

Preprocedure Nursing Care

Teach patient about the procedure and what to expect, including what the machine looks like (similar, but smaller than a dialysis machine), the need for arterial and venous access sites, and the length of the procedure (2 to 5 hours).

The physician may order medications held until after the procedure. Assess baseline vital signs and weight.

Assess complete blood cell count (CBC), platelet count, and clotting studies.

Check blood type and crossmatch for replacement blood products.

Postprocedure Nursing Care

Observe the patient for signs of dehydration (hypovolemia), such as dizziness and hypotension.

Apply pressure dressings to access sites.

Monitor patient for infection and bruits at the intravenous port site.

Monitor electrolytes and signs of electrolyte loss. Report imbalances, and administer replacement electrolytes as ordered.

Reevaluate preprocedure laboratory data, such as CBC, platelet count, and clotting times.

LEARNING TIPS

Rest promotes an increase in ACh, which results in an increase in muscle strength.

CRITICAL THINKING

Jamie

Jamie is referred to a neurologist with complaints of muscle weakness.

1. What history can help differentiate between MS and MG?
2. What assessment can be done to differentiate between MS and MG?

Answers at end of chapter.

Amyotrophic Lateral Sclerosis

PATHOPHYSIOLOGY AND ETIOLOGY. Amyotrophic lateral sclerosis (ALS; also called Lou Gehrig's disease) is a progressive, degenerative condition that affects motor neurons. Within the brain and spinal cord, motor neurons begin to degenerate and form scar tissue. Transmission of nerve impulses is blocked. Without stimulation, **atrophy** of muscle tissue occurs. Muscle strength and coordination decrease. As the disease progresses, more muscle groups, including muscles controlling breathing and swallowing, become involved. However, the ability to think and reason is not affected. A specific cause has not been discovered, though ALS may have a genetic predisposition in some cases.

ALS can occur at any age, but usually does not appear until adulthood. The incidence in the United States is 1.5 per 100,000. The usual age of onset is between 40 and 70. ALS is more prevalent in men than women.

SIGNS AND SYMPTOMS. Symptoms are vague early in the course of ALS. Primary symptoms include progressive muscle weakness and decreased coordination of arms, legs, and trunk. Atrophy of muscles and twitching (**fasciculations**) also occur. Muscle spasms can cause pain. Difficulty with chewing and swallowing place the patient at a risk for choking and aspiration as the disease progresses. Inappropriate emotional outbursts of laughing and crying may occur. Speech becomes increasingly difficult. Bladder and bowel functions remain intact, yet problems such as constipation, urinary urgency, hesitancy, or frequency may occur. Late in the disease, communication becomes limited to moving and blinking of eyes in response to questions. Pulmonary function becomes severely compromised to the point of requiring mechanical assistance (ventilator). Other complications that may occur include extreme malnutrition, falls, pulmonary emboli, and congestive heart failure. ALS eventually leads to death from respiratory complications (atelec-

tasis, respiratory failure, and pneumonia). Death usually occurs 3 to 5 years after diagnosis.

DIAGNOSTIC TESTS. Diagnosis is made from clinical symptoms. Other tests may be done to rule out other conditions (CSF analysis, electroencephalogram [EEG], nerve biopsy, EMG). Blood enzymes may be increased as a result of muscle atrophy.

MEDICAL TREATMENT. Goals of treatment are aimed at improving function as long as possible and emotionally supporting the patient and family through the process. Baclofen and diazepam may be given to relieve muscle spasticity. Quinine is used for muscle cramps. Nonpharmacological measures such as physical therapy, massage, position changes, and diversional activities may be instituted for pain control. Tube feedings via a surgically placed gastrostomy tube help provide adequate nutrition. Prevention of infections, such as pneumonia and urinary tract infection (UTI), is vital. Meticulous skin care minimizes the incidence of pressure ulcers. Rehabilitation therapy, including physical, occupational, and speech therapy, allows the patient to maximize function and control. Therapy also decreases the occurrence of complications such as aspiration, falls, and contractures. Support groups and counseling provide emotional support for the patient and family.

NURSING CARE. See Nursing Care Plan 47-1 for Care of the Patient with a Progressive Neuromuscular Disorder.

Patient Education. Reinforce information given by the physician to the patient and family about ALS and its prognosis. Referral to support groups can provide emotional support as the patient and family deal with the reality of eventual death. Rehabilitation using assistive devices and exercises helps prevent complications. Teaching family members how to perform physical therapy and other health care activities allows the patient to spend as much time as possible at home. Teach the patient to avoid exposure to persons with infections, because an infection can be deadly to the patient with a debilitating disease.

LEARNING TIPS

A person with ALS has an intact mind—it is the body that is deteriorating.

CRITICAL THINKING

Mr. Miller

Mr. Miller has been having difficulty swallowing. He is diagnosed with ALS.

1. What are the priority nursing diagnoses for him?
2. How can the patient and his family be supported in coping with this disease?

Answers at end of chapter.

atrophy: a—without + trophy—nourishment

Guillain-Barré Syndrome

ETIOLOGY. Guillain-Barré syndrome (GBS) is also called acute inflammatory **polyneuropathy**. This term is more descriptive of the actual disease process. GBS is an inflammatory disorder characterized by abrupt onset of symmetrical paresis (weakness) that progresses to paralysis. It is believed to be caused by an autoimmune response to some type of viral infection or vaccination, though the exact cause is not known. Usually the viral illness occurs within 2 weeks of the onset of symptoms. Incidence is 1 to 2 cases per 100,000 people, with men and women being equally affected. Average age at onset is 30 to 50.

GBS has worldwide distribution, is not seasonal, and affects individuals of all races and ages. Higher rates, however, have been found in people 45 years and older. The incidence of the disease is 50 to 60 percent higher in Caucasians than in African-Americans.

PATHOPHYSIOLOGY. The myelin sheath of the spinal and cranial nerves is destroyed by a diffuse inflammatory reaction. The peripheral nerves are infiltrated by lymphocytes, which leads to edema and inflammation. Segmental **demyelination** causes axonal atrophy, resulting in slowed or blocked nerve conduction. Typically the demyelination begins in the most distal nerves and ascends in a symmetrical fashion. **Remyelination**, which is a much slower process, occurs in a descending pattern and is accompanied by a resolution of symptoms.

There are four recognized variants of GBS. The most common form is ascending Guillain-Barré. It is characterized by progressive weakness and numbness that begins in the legs and ascends up the body. The numbness tends to be mild, but the muscle weakness usually progresses to paralysis. The paralysis may ascend all the way to the cranial nerves or stop anywhere between the legs and head. Deep tendon reflexes are either depressed or absent. In approximately 50 percent of patients with ascending Guillain-Barré, respiratory function becomes compromised.

Descending Guillain-Barré is less common. It affects the cranial nerves that originate in the brainstem first. These patients present with difficulty swallowing and speaking. The weakness progresses downward toward the legs. Respiratory compromise is rapid. Numbness is more problematic in the hands than in the feet, and the reflexes are diminished or absent.

Miller Fisher syndrome, a variant of GBS, is rare. Typically there is no respiratory compromise or sensory loss. The classic symptoms are profound ataxia, absence of reflexes, and paralysis of the extraocular muscles. Some people believe that the fourth form, pure motor Guillain-Barré, is actually a milder version of ascending Guillain-Barré. The symptoms are the same, except for the lack of numbness or paresthesias.

SIGNS AND SYMPTOMS. GBS is divided into three stages. The first stage starts with the onset of symptoms and lasts until the progression of symptoms stops. This stage can last from 24 hours to 3 weeks and is characterized by abrupt and

rapid onset of muscle weakness and paralysis, with little or no muscle atrophy. Many patients give a history of a recent viral illness or vaccination, supporting the theory that the cause is autoimmune in nature. The degree of respiratory involvement correlates to the type of GBS and the level of paralysis. Patients with ascending Guillain-Barré may gradually notice a reduced ability to take deep breaths or carry on conversations and may feel short of breath. These patients are terrified that they will not be able to breathe. Patients with descending Guillain-Barré may require intubation on an emergent basis.

The autonomic nervous system is often affected by GBS. Patients may experience labile blood pressure, cardiac dysrhythmias, urinary retention, paralytic ileus, or syndrome of inappropriate antidiuretic hormone (SIADH). Patient complaints of discomfort range from annoying numbness and cramping to severe pain. The discomfort is exacerbated by the patient's inability to move voluntarily.

The second stage is the plateau stage, when symptoms are most severe but progression has stopped. It may last from 2 to 14 days. Patients may become discouraged if no improvement is evident.

Axonal regeneration and remyelination occur during the recovery phase. This stage lasts from 6 to 24 months. Symptoms slowly improve. Most patients with GBS recover completely within a few months to a year. A few patients experience chronic disability.

COMPLICATIONS. Complications that can occur include respiratory failure, infection, and depression. Fatigue and paralysis of the respiratory muscles lead to insufficient respiratory effort. Some patients with impending respiratory failure attempt to convince the staff that they are not in distress and do not need to be intubated. Discussion of the possible need for intubation early in the patient's illness is important. Constant monitoring of respiratory parameters and continuous pulse oximetry provide information indicating the need for immediate intervention.

Patients with GBS are prone to pneumonia and UTIs. Maintaining infection control practices and maximizing the patient's nutritional status help decrease the likelihood of infections occurring. Immobility leads to such problems as skin breakdown, pulmonary embolus, deep vein thrombosis, and muscle atrophy. Patients with Guillain-Barré have little time to adjust to their illness and deterioration. They fear that they will not recover function. Calm, supportive reassurance is important.

DIAGNOSTIC TESTS. A lumbar puncture is performed to obtain CSF. The CSF analysis shows a normal cell count with an elevated protein level. Electromyogram and nerve conduction velocity tests are done to evaluate nerve function.

MEDICAL TREATMENT. During the first stage, patients are partially or completely dependent for all needs. They are often frightened and anxious. In an effort to reduce inflammation, steroids are often administered. Plasmapheresis is used to remove the patient's plasma and replace it with al-

bumin. This procedure is thought to lessen the body's immune response. To be most effective, plasmapheresis should begin 7 to 14 days from the onset of symptoms.

During the plateau phase, patients may become discouraged because they are not getting any better. Emotional support is important during this phase.

Axonal regeneration and remyelination occur during the recovery phase. Intensive rehabilitation helps the patient regain function during this phase.

NURSING CARE. See Nursing Care Plan 47-3 for Care of the Patient with a Progressive Neuromuscular Disorder. The goal of therapy is to support body systems until the patient recovers. Serial assessments of vital capacity and ABGs reveal deterioration in respiratory function. Monitor gag, corneal, and swallowing reflexes, so protective interventions can be implemented if necessary. Manage pain with administration of narcotics and nonpharmacological methods such as position changes, massage, and diversional activities. Nutritional needs may be met via tube feedings or parenteral nutrition if the patient is unable to swallow. Communication boards provide a means for the patient to indicate needs to staff. Because recovery can be prolonged, diversional activities such as visits from family and friends, listening to music or relaxation tapes, and watching television or videos can help alleviate boredom, loneliness, and depression. As the patient begins to regain function, encourage participation in therapy and point out any returning function to the patient and family.

Patient Education. All procedures should be explained to the patient and family. The patient and family need to understand the reasons for continuous respiratory monitoring. Patients may deny any respiratory difficulty because of a fear of intubation and mechanical ventilation. Informing the patient about the possibility of respiratory support and the measures taken to alleviate discomfort help decrease anxiety and encourage patient cooperation. Information about the disease, treatments, and recovery should be given, because recovery may take months or years. Educating family members about how to perform specific patient care activities encourages participation and prepare the patient and family for discharge.

Cranial Nerve Disorders

Cranial nerves are the peripheral nerves of the brain. There are 12 pairs of cranial nerves. Areas that the cranial nerves innervate include the head, neck, and special sensory structures. Cranial nerve problems are classified as peripheral **neuropathies**. Disorders may affect the sensory, motor, or both branches of a single nerve. Causes of cranial nerve disorders include tumors, infections, inflammation, trauma, and unknown causes. Two common cranial nerve problems are trigeminal **neuralgia** (tic douloureux) and Bell's palsy.

Trigeminal Neuralgia

PATHOPHYSIOLOGY AND ETIOLOGY. Trigeminal neuralgia involves the fifth cranial (trigeminal) nerve. This cranial nerve has three branches that include both sensory and motor functions. The branches innervate areas of the face, including the forehead, nose, cheek, and jaw. Trigeminal neuralgia affects only the sensory portion of the nerve. Irritation or chronic compression of the nerve is suspected to initiate onset of symptoms. The incident rate per year is 4.3 per 100,000 persons. This condition is seen more often in women and usually begins around age 50 to 60.

SIGNS AND SYMPTOMS. Intense recurring episodes of pain, described as sudden, jabbing, burning, or knifelike, characterize this condition. Episodes of pain begin and end suddenly, lasting a few seconds to minutes. Attacks can occur in clusters up to hundreds of times daily. However, some patients experience only a few attacks per year. Pain is felt in the skin on one side of the face. Slight touching, cold breezes, talking, or chewing can trigger attacks of pain. The areas of the face where pain is triggered are referred to as trigger zones. Areas affected include the lips, upper or lower gums, cheeks, forehead, or side of nose (Fig. 47-3). Sleep provides a period of relief from the pain. Therefore persons with trigeminal neuralgia may sleep most of the time to avoid painful attacks. They may also refrain from activities such as talking, face washing, teeth brushing, shaving, and eating to prevent pain. Frequent blinking and tearing of the eye on the affected side also occurs.

DIAGNOSTIC TESTS. History of symptoms and direct observation of an attack confirm diagnosis. Radiological studies, including computed tomography (CT) scan and MRI, may be used to rule out other causes of the pain.

MEDICAL TREATMENT. Initial management includes the use of the anticonvulsants phenytoin and carbamazepine to reduce transmission of nerve impulses. Most persons experience relief with medications. These drugs cause bone marrow suppression, so routine complete blood counts are necessary. However, medications do not offer a permanent

Figure 47-3 Areas innervated by the three main branches of the trigeminal nerve (cranial nerve V) are affected in trigeminal neuralgia.

neuropathies: neuro—nerve + pathies—disease

neuralgia: neur—nerve + algia—pain

solution because they lose their effectiveness after a period. Another treatment option is nerve blocks using local anesthetics. This option offers 8 to 16 months of relief. If medications and nerve blocks do not provide relief, surgical options are available. Surgery is done to identify and remove the cause of irritation and inflammation of the nerve. Radiofrequency ablation is used to destroy some of the nerve branches, resulting in anesthesia of the area.

NURSING PROCESS

Assessment. Assess attacks using the WHAT'S UP? format, being sure to include factors that trigger pain. Assess the effect of the pain on the patient's life, including nutritional status, general and oral hygiene, behavior, and emotional state.

Nursing Diagnosis. The priority diagnosis is pain related to inflammation or compression of the trigeminal nerve. Other important diagnoses include imbalanced nutrition: less than body requirements, and anxiety.

Planning and Implementation. Administer analgesics as needed for pain. Alternative pain relief measures such as biofeedback and use of diversional activities may be used in addition to drugs or if drugs do not work. Evaluation of effectiveness of pain relief measures is important. The patient's environment needs to be monitored and kept free of potential triggers. The room should be free of drafts and kept at an even, moderate temperature. Care must be taken to avoid touching the patient's face. Hygiene measures should include the use of lukewarm water, soft cloths, and solutions not requiring rinsing when cleansing the face. A soft-bristled toothbrush or a warm mouthwash can provide adequate oral hygiene. The patient must be given control over when and how care is provided. Hygiene may be avoided when an attack occurs. Small, frequent meals that are high in protein and calories and easy to chew help meet nutritional needs.

Patient Education. Instruct the patient to chew on the unaffected side and to avoid very hot or very cold foods and drinks. The importance of meticulous oral hygiene should be emphasized. Electric razors may be more comfortable for men who shave. If corneal sensation is lost, goggles and sunglasses should be used as needed to protect the affected eye. An eye patch may be needed at night to prevent injury during sleep. Protecting the face from cold or windy weather helps prevent attacks.

Evaluation. The patient will express adequate pain relief with a decrease in or absence of attacks. Caloric intake will be adequate to meet nutritional needs. The patient will verbalize understanding of the use of measures to prevent recurrent attacks.

Bell's Palsy

PATHOPHYSIOLOGY AND ETIOLOGY. In Bell's palsy, cranial nerve VII (facial) becomes inflamed and edematous or compression of the blood vessel feeding the nerve occurs causing interruption of nerve impulses. Loss of motor con-

trol occurs on one side of the face. Contracture of facial muscles may occur if recovery is slow. The etiology is unknown; it may be the result of an inflammatory process. The incidence is 23 cases per 100,000, with men and women affected equally. Although the incidence may be slightly higher among diabetics, the condition occurs in all ages and at all times of the year.

SIGNS AND SYMPTOMS. Onset of symptoms occurs over a 2- to 5-day period. Pain behind the ear may precede the onset of facial paralysis. The patient may be unable to close the eyelid, wrinkle the forehead, smile, raise the eyebrow, or close the lips effectively. The mouth is pulled toward the unaffected side (Fig. 47-4). Drooling of saliva occurs, and the affected eye has constant tearing. Sense of taste is lost over the anterior two-thirds of the tongue. Speech difficulties are present.

DIAGNOSTIC TESTS. History of the onset of symptoms is used to diagnose Bell's palsy. Observation of the patient confirms the diagnosis. An EMG may be done. The possibility of a stroke is ruled out.

MEDICAL TREATMENT. Prevention of complications is the goal of treatment, because 80 percent of patients should have complete recovery of function within weeks to months. However, recovery may take up to a year. Prednisone may be given over 7 to 10 days to decrease edema. Analgesics are given for pain control. Moist heat with gentle massage to the face and ear also eases pain. Use of a facial sling aids in eating and supports facial muscles.

NURSING PROCESS

Assessment. Assess facial muscles for signs of weakness. Evaluate for other signs and symptoms of Bell's palsy and carefully document findings.

Nursing Diagnosis. Priority diagnoses include pain related to inflammation of cranial nerve VII (facial), imbalanced nutrition: less than body requirements related to inability to chew, risk for trauma to eye related to inability to blink, and body image disturbance.

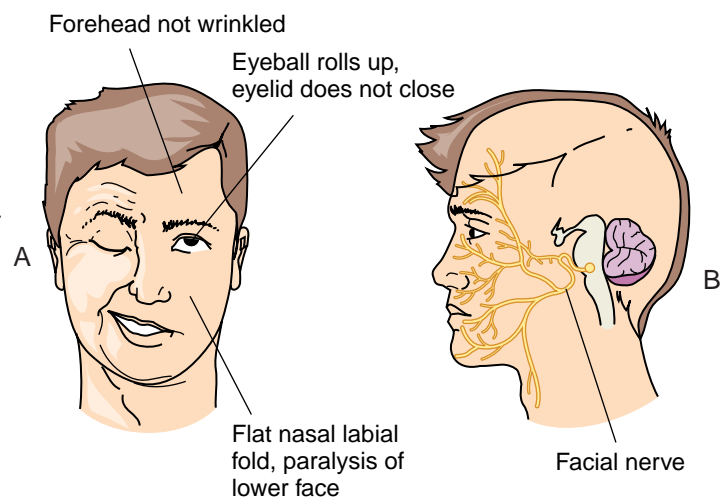

Figure 47-4 Bell's palsy. (A) Note weakness of affected side of face. (B) Distribution of facial nerve.

Planning and Implementation. Administration of analgesics, moist heat, and massage can help relieve pain. Eye drops or eye ointment as ordered by the physician and a patch are used to protect the eye. Facial exercises several times a day prevent muscle atrophy. Use of a facial sling aids in eating meals and prevents atrophy. A nutritious, well-balanced diet in a consistency the patient can tolerate is important to maintain nutritional status.

Patient Education. Instruct the patient to chew on the unaffected side. Emphasize meticulous oral and eye care. Have the patient demonstrate facial exercises and the use of a facial sling before discharge. Support from family and friends should be encouraged (Home Health Hints).

Evaluation. The patient will express adequate pain control. Caloric intake will meet nutritional needs as evidenced by maintenance of weight and normal laboratory values. The affected eye will remain free of injury.

HOME HEALTH HINTS

- If the patient has difficulty speaking (dysarthria), try using magnetic alphabet letters. Ask questions that require a yes or no answer. The patient can respond with the letter *y* or *n*.
- Bedside commode lids can be kept up with patches of Velcro attached to the seat and the frame.

LEARNING TIPS

Trigeminal neuralgia (cranial nerve V) is a sensory disorder; Bell's palsy (cranial nerve VII) is a motor disorder.

Answers to CRITICAL THINKING

Jamie

1. Muscle weakness caused by myasthenia gravis improves with rest.
2. Have Jamie look up for 2 to 3 minutes. If ptosis occurs, let the patient close her eyes for several minutes. If she can open her eyelids and look up, myasthenia gravis is confirmed.

Mr. Miller

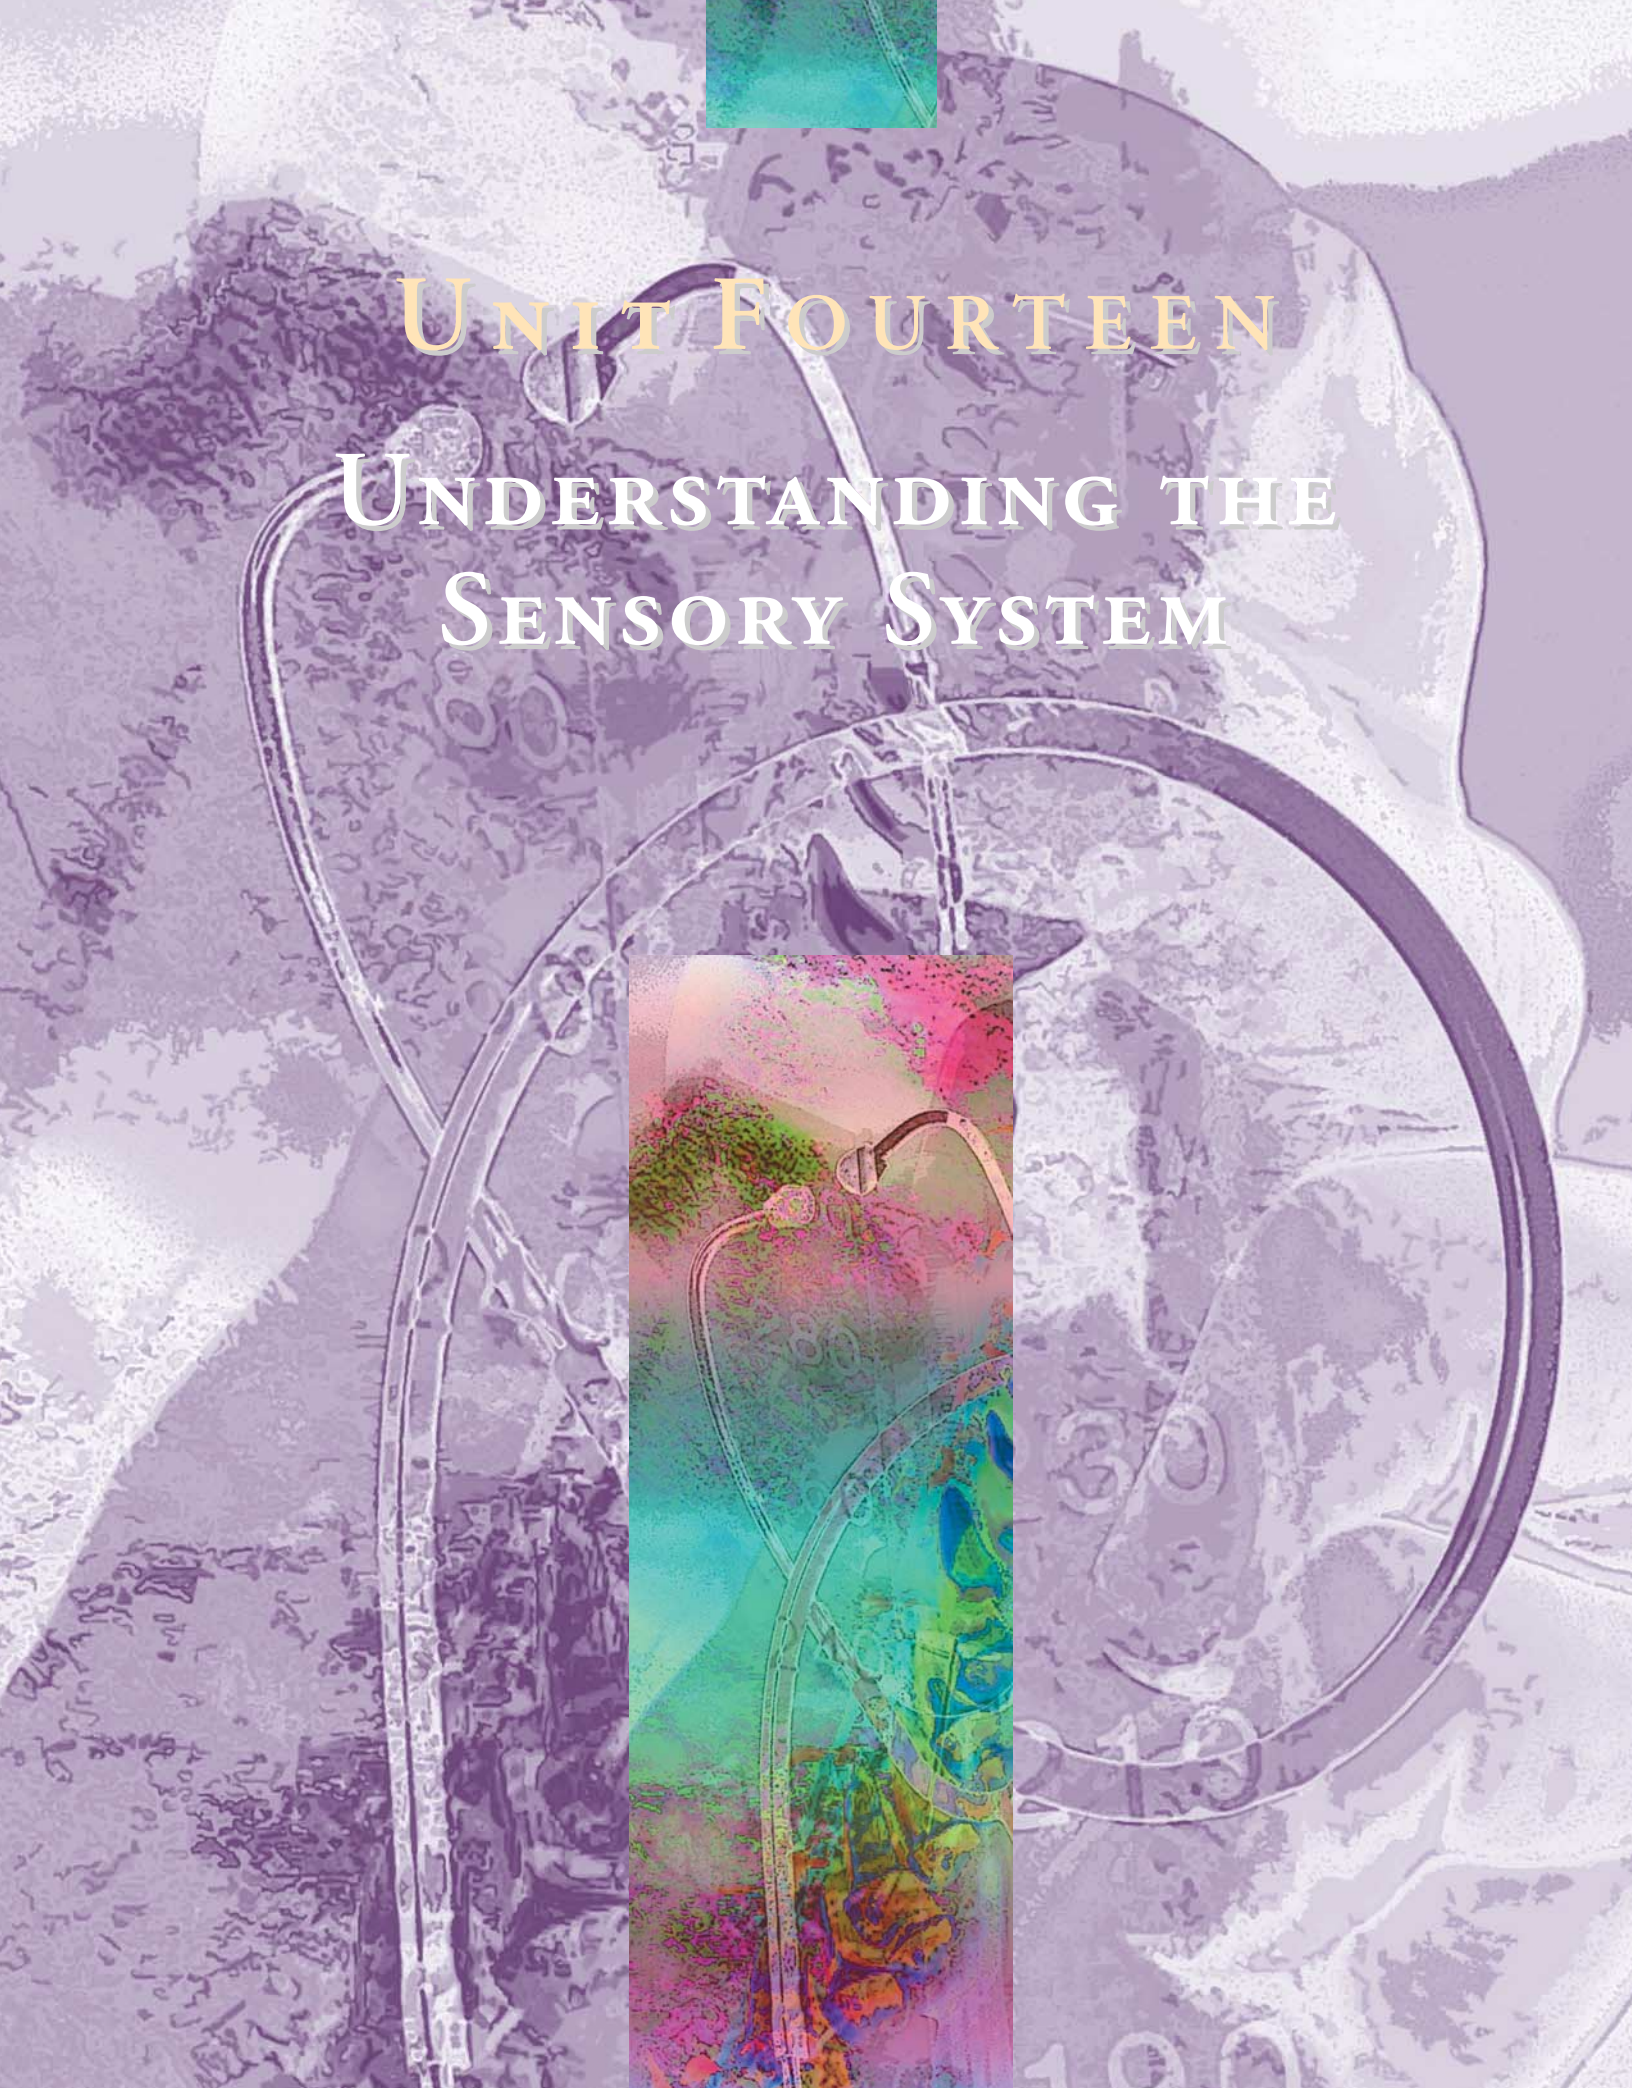

1. Nursing diagnoses include ineffective airway clearance related to muscle weakness and risk for aspiration related to muscle weakness. If a patient's respiratory system is compromised by a disease, nursing care should be focused on maintaining pulmonary function to preserve life.
2. Compassionate care for the patient and providing information about the disease and its prognosis to the patient and family establish an honest and supportive environment. Support groups provide resources and emotional support.

REVIEW QUESTIONS

1. Tegretol may be given to a patient with MS for what purpose?
 - a. Decrease inflammation
 - b. Depress the immune system
 - c. Help relieve pain
 - d. Control bladder spasms
2. What medication is used to help diagnose myasthenia gravis?
 - a. Prostigmin
 - b. Tensilon
 - c. Acetylcholine
 - d. Prednisone
3. Karesa comes to the clinic complaining of a burning pain on her right cheek. Which of the following findings further supports a diagnosis of trigeminal neuralgia?
 - a. Tearing of the eye
 - b. Inability to close the affected eye
 - c. Asymmetry of facial expressions
 - d. Lack of a pupillary response
4. Which of the following systems should take priority when doing a nursing assessment for a patient with ALS?
 - a. Skin assessment
 - b. Bowel function assessment
 - c. Bladder function assessment
 - d. Respiratory assessment
5. In caring for a patient admitted with a diagnosis of Guillain-Barré syndrome, the nurse should continuously monitor the patient for which of the following?
 - a. Increasing pain
 - b. Urinary retention
 - c. Respiratory distress
 - d. Blurred vision
6. Bell's palsy is a disorder of which cranial nerve?
 - a. Third
 - b. Fifth
 - c. Seventh
 - d. Ninth

QUESTIONS TO GUIDE YOUR READING

1. What is the normal anatomy of the sensory systems?
2. What is the normal function of the sensory system?
3. What data should you collect when caring for a patient with a disorder of the sensory system?
4. What are the diagnostic tests commonly performed to diagnose disorders of the sensory system?
5. What nursing care should you provide for patients undergoing each of the diagnostic tests?
6. What are the common therapeutic measures used for patients with disorders of the sensory system?

Our eyes and ears provide us with a great deal of sensory information. It is difficult to imagine what it would be like not to see or hear the world around us. Nurses have an important role in assessing vision and hearing. Patients depend on health care personnel to assist them in maintaining these primary senses. To learn more about ways to promote vision and hearing health, visit <http://web.health.gov/healthypeople>.

► VISION

Normal Anatomy and Physiology of the Eye

The eye contains the receptors for vision and a refracting system that focuses light rays on these receptors in the retina.

External Structures

The eyelids are the protective covers for the front of the eyeball; on the border of each lid are eyelashes that help keep dust out of the eyes. The eyelids are lined with a thin transparent membrane called the conjunctiva, which is also folded over the white of the eye.

Associated with each eyeball is a lacrimal gland located within the bony socket at the upper, outer corner of the eye-

ball. Small ducts take tears to the front of the eyeball, and blinking helps spread the tears over the surface. Tears contain lysozyme, an enzyme that inhibits the growth of most bacteria on the surface of the eye. The lacrimal canals at the medial corner of each eye collect tears, which then drain into the lacrimal sac to the nasolacrimal duct to the nasal cavities.

Structure of the Eyeball

Most of the eyeball is within the orbit, the bony socket that provides protection from trauma. The six extrinsic muscles that move the eyeball are attached to the orbit and to the outer surface of the eyeball. There are four rectus muscles that move the eyeball side to side or up and down and two oblique muscles that rotate the eye. The cranial nerves that innervate these muscles are the oculomotor, trochlear, and abducens (third, fourth, and sixth cranial).

The wall of the eyeball has three layers: the outer sclera, the middle choroid (uvea), and the inner retina. The sclera is made of fibrous connective tissue that is visible as the white of the eye. The most anterior portion is the transparent cornea (Fig. 48-1), which has no capillaries and is the first part of the eye that refracts light rays.

Figure 48-1 Internal anatomy of the eye. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 192, with permission.)

The choroid layer contains blood vessels and a dark-blue pigment that prevents glare within the eyeball by absorbing light. The anterior of the choroid is modified into the ciliary body and the iris. The ciliary body (or muscle) is a circular muscle that surrounds the edge of the lens and is connected to the lens by suspensory ligaments. The lens is made of a transparent, elastic protein and, like the cornea, has no capillaries. The shape of the lens is changed by the ciliary muscle, which permits the focusing of light from objects at varying distances.

In front of the lens is the circular iris, which is made of two sets of smooth muscle fibers that change the diameter of the pupil, the central opening. Contraction of the radial fibers is a sympathetic response and dilates the pupil. Contraction of the circular fibers is a parasympathetic response (mediated by the oculomotor nerves) and constricts the pupil. Pupillary constriction is a reflex that protects the retina from intense light or that permits more acute near vision.

The retina lines the posterior two-thirds of the eyeball and contains the rods and cones, the receptors for vision. Rods detect only the presence of light, whereas cones detect the different wavelengths of light as colors. The fovea centralis is a small depression in the macula lutea of the retina, directly behind the center of the lens, and contains only cones. It is therefore the area of most acute color vision. Rods are proportionally more abundant toward the periphery of the retina, and for this reason night vision is best at the sides of the visual field.

Neurons called ganglion neurons transmit the impulses generated by the rods and cones. These neurons all converge at the optic disc and pass through the wall of the eyeball as the optic nerve. The optic disc may also be called the blind spot because no rods or cones are present.

Cavities of the Eyeball

There are two cavities within the eye, posterior and anterior. The larger posterior cavity is between the lens and retina and contains vitreous humor. This semisolid substance helps keep the retina in place.

The anterior cavity is between the cornea and the front of the lens and contains aqueous humor, the tissue fluid of the eyeball that nourishes the lens and cornea. Aqueous humor is formed by capillaries in the ciliary body, flows anteriorly through the pupil, and is reabsorbed by the canal of Schlemm (scleral venous sinus) at the junction of the iris and the cornea. The rate of reabsorption normally equals the rate of production.

Physiology of Vision

Vision involves the focusing of light rays on the retina and the transmission of the subsequent nerve impulses to the visual areas of the cerebral cortex.

The refractive structures of the eye are, in order, the cornea, aqueous humor, lens, and vitreous humor. The lens is the only adjustable part of this focusing system. When the eye is focused on a distant object, the ciliary muscle is relaxed and the lens is elongated and thin. When the eye is focused on a near object, the ciliary muscle contracts and

forms a smaller circle and the elastic lens recoils and bulges in the middle and has greater refractive power.

When light rays strike the retina, they stimulate chemical reactions in the rods and cones. Receptors contain a light-absorbing molecule called retinal (a derivative of vitamin A) bonded to a protein called an opsin. In the rods, light stimulates the breakdown of rhodopsin into scotopsin and retinal; this generates a nerve impulse for transmission. The cones also contain retinal, and similar reactions take place. The opsins of the cones are specialized to respond to a portion of the visible light spectrum; there are red-absorbing, blue-absorbing, and green-absorbing cones. The chemical reactions within the cones also generate electrical nerve impulses.

The impulses from the rods and cones are transmitted to the ganglion neurons, which converge at the optic disc and become the optic nerve. The optic nerves from both eyes converge at the optic chiasma, just in front of the pituitary gland. Here, the medial fibers of each optic nerve cross to the other side. This crossing permits each visual area to receive impulses from both eyes, which is important for binocular vision.

The visual areas are in the occipital lobes of the cerebral cortex. It is here that the upside-down retinal images are righted and the slightly different pictures from the two eyes are integrated into one image; this is binocular vision, which also provides depth perception.

Aging and the Eye

The most common changes in the aging eye are those in the lens. Over a long period the lens may become partially or totally opaque. The lens also loses its elasticity with age; most people become farsighted as they get older and by age 40 begin to need correction with glasses. Peripheral vision losses may occur. Depth perception decreases and glare is more difficult to adjust to, which can affect safety. Color vision fades with poorer discrimination of blue, green, and violet colors. Red, yellow, and orange colors are seen best.

Nursing Assessment of the Eye and Visual Status

As with most examinations, nursing assessment of the eye begins with the collection of subjective data, then moves to observation and testing, and finally a more invasive physical examination is performed. Licensed practical nurses/licensed vocational nurses (LPN/LVNs) generally do not conduct invasive examinations on the eye, but rather assist the advanced practitioner in conducting this portion of data collection.

Subjective Data

The nurse interviews patients and collects data about family history that may affect vision, particularly glaucoma, diabetes, blindness, and cataracts. Because many eye disorders are genetically transmitted, this information alerts the nurse to possible alterations in eye health. Patients should be asked about their general health and the presence of

diseases such as diabetes and hypertension. The nurse determines the types of medication the patient is taking to assess for any ocular (eye) effects. Last, the nurse asks the patient about any changes in visual acuity or symptoms of abnormality (Table 48–1).

Objective Data

VISUAL ACUITY. Objective data collection begins by assessing the patient's visual acuity. Visual acuity is measured in a variety of ways but usually starts with the use of the **Snellen's chart**, E chart, or handheld visual acuity chart (Rosenbaum card) to test near and far vision. Snellen's chart is imprinted with alphabetical letters graduating in size from the smallest on the bottom to the largest on the top (Fig. 48–2). The examiner measures 20 feet and marks the distance on the floor. The examiner then asks the patient to cover one eye with a 3 × 5 card or eye cover and then read out loud an indicated line of letters. The lowest line on the chart that the patient is able to read accurately is used to indicate visual acuity for that eye. Normal vision is 20/20, which means the patient can read at 20 feet what the normal eye can read at 20 feet. Visual impairment occurs at 20/70 and legal blindness at 20/200 or more with correction. An example of findings is the patient who identifies all the letters correctly on the line marked 30; this patient has a visual acuity of 20/30. This means that the patient can see at 20 feet what the average individual can see at 30 feet. The examination is conducted on both eyes separately, then together, and documented as follows: "oculus dexter (OD) 20/30, oculus sinister (OS) 20/20, oculus uterque (OU) 20/20." In addition to identifying the eye tested, the examiner conducts the examination with and without the patient's corrective lenses, if applicable. When corrective lenses are used, documentation reflects this as

"OD 20/100 without correction, OD 20/20 with correction." The E chart is used for patients who are illiterate. The patient is asked to indicate the direction of the E-shaped figure. The handheld visual acuity chart is used to indicate visual acuity by having the patient hold the card approximately 14 inches from the eyes. The test is conducted and documented in the same way as the Snellen's and E chart examinations. For resources on helping those with blindness, visit the American Foundation for the Blind at www.afb.org or the National Federation of the Blind at www.nfb.org.

Visual Fields by Confrontation. The examiner also tests peripheral vision, which is the ability of the eye to see objects peripherally while the eye is fixed or kept in one position. This is also known as testing visual fields by confrontation. To do this, the examiner compares his or her own ability to see peripheral objects with that of the patient. This test should be done with an examiner who has normal peripheral vision. The examiner stands 2 feet in front of the patient and instructs the patient to cover one eye. The examiner covers his or her own corresponding eye (e.g., if the patient's right eye is covered, the examiner's left eye is covered). The examiner uses the arm opposite the covered eye, extends it to the space midway between the patient and the examiner, and brings it toward the eye from three directions: superior, inferior, and temporal (middle). The examiner wiggles the finger while moving the arm. The examiner asks the patient to look straight ahead and indicate at what point he or she is able to see the examiner's finger. One eye is tested and then the other. The patient has full visual fields if the point at which the patient sees the finger matches that of the examiner. The examiner documents the results as "visual fields equal to examiner," "full

TABLE 48-1 SUBJECTIVE NURSING ASSESSMENT DATA QUESTIONS

Obtain information about the family history.	Do you have any family members with a history of diabetes? Hypertension? Cataracts? Glaucoma? Blindness? Diabetes mellitus? Do any family members wear glasses or contact lenses? Is their vision corrected with the lens?
Find out about the patient's general health.	How would you describe your general health? What health problems do you currently have? How are they treated? What health problems have you had in the past? Have you ever had trauma to your eyes? What medications do you take? How often do you have eye examinations? When was the last time you had an eye examination?
Obtain information about visual acuity.	Do you wear glasses or contact lenses? Have you had any changes in vision such as difficulty seeing distances, difficulty seeing close up, difficulty seeing at night? Do you see things double? Do you have clouded vision? Do you see halos around lights? Does it look like you are looking through a veil or web? Is there sensitivity to light? Is there pain? Itching? Tearing? Burning? Do you have headaches? If so, what are the precipitating events?

Figure 48-2 Using Snellen's chart to assess visual acuity.

visual fields,” or, if abnormal, “visual fields unequal to examiner in. . .” (identify position, e.g., left superior).

MUSCLE BALANCE AND EYE MOVEMENT. The examiner tests extraocular muscle balance and cranial nerve function by instructing the patient to look straight ahead and follow the examiner's finger movement without moving his or her head. As with the confrontation test, the patient and examiner face each other either standing or sitting. The examiner moves his or her finger in the six cardinal fields of gaze, coming back to the point of origin between each field of gaze (Fig. 48-3). If the patient's eyes are able to follow the examiner's finger in all fields of gaze without nystagmus, the patient is assessed to have adequate extraocular muscle strength and innervation. Nystagmus is an involuntary, cyclical, rapid movement of the eyes in response to vertical, horizontal, or rotary movement.

The corneal light reflex test is used to assess muscle balance. This test is conducted by shining a penlight toward the cornea while the patient is staring at an object straight ahead. The light reflection should be at exactly the same place on both pupils. If the eyes lack symmetry, muscle weakness could be present.

The cover test is used in conjunction with an abnormal corneal light reflex test to evaluate muscle balance. The patient is asked to look straight ahead at a far object. The examiner covers one of the patient's eyes with a 3×5 card. The uncovered eye should have a steady gaze; if it moves, there may be muscle weakness. Next, the cover is quickly removed and the action of this eye is observed. If this eye moves to fixate on the light instead of staring straight ahead, it indicates a drifting of the eye when it was covered, which is a sign of muscle weakness. This deviation of the eye away from the visual axis is known as **tropia**. Deviation

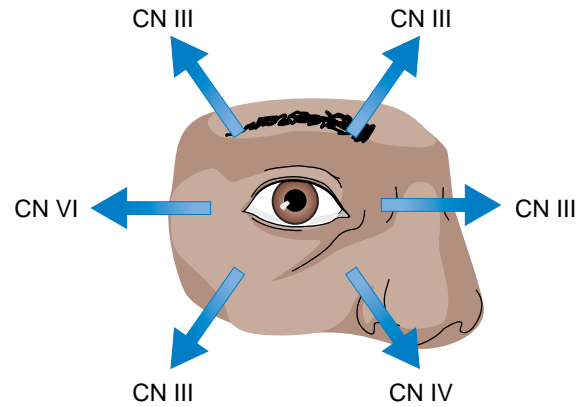

Figure 48-3 Six cardinal fields of gaze.

of the eye toward the nose is known as **esotropia**, movement laterally is known as **exotropia**, and downward deviation is **hypotropia**.

PUPILLARY REFLEXES. The pupils are observed. They should be round, symmetrical, and reactive to light. To test pupillary response to light, both consensual and direct examinations should be completed. A slightly darkened room works best. The patient is asked to look straight ahead, and the size of the pupil is noted. A penlight is shone toward the pupil from a lateral position, and the movement of the pupil is observed. The pupil should quickly constrict. The size of the pupil is noted when it constricts. This is known as direct response.

To conduct a consensual pupil examination, observe the eye just tested for reaction while shining the penlight into the other eye. The observed pupil should constrict. This is known as **consensual response**. Repeat the procedure for the opposite eye.

The examiner now proceeds to test for **accommodation**. Accommodation is the ability of the pupil to respond to near and far distances. The patient is told to focus on an object far away. The size and shape of the pupils are observed. The examiner continues to observe the pupils as the patient focuses on a near object (the examiner's penlight or finger) held approximately 5 inches from the patient's face. Normally the patient's eyes turn inward and the pupils constrict. These responses, convergence and constriction, are called accommodation (Gerontological Issues Box 48-1). Examiners use the acronym PERRLA to indicate pupils equal, round, reactive to light, accommodation. If accommodation is not tested along with the other tests, the examiner may use the acronym PERRL.

INSPECTION AND PALPATION OF EXTERNAL STRUCTURES. The extraocular structures are inspected beginning with the eyebrows. The presence of eyebrows, symmetry, hair texture, size, and extension of the brow are noted. The examiner inspects and palpates the orbital area for edema,

esotropia: eso—inward + tropia—movement of the eye
exotropia: exo—out + tropia—movement of the eye

BOX 48-1 GERONTOLOGICAL ISSUES**Age-related Changes in Vision and Hearing****Vision**

Elderly people commonly have the following changes in their vision:

- Presbyopia, an inability to focus up close because of decreased elasticity in the ocular lens
- Narrowing of the visual field and more difficulty with peripheral vision
- Decreased pupil size and responsiveness to light
- Difficulty with vision in dim areas or at night (requires more light to see adequately)
- Increased opacity of the lens, which causes sensitivity to glare, blurred vision, and interference with night vision
- Yellowing of the lens, which makes the person less able to differentiate low-tone colors of blues, greens, and violets (yellow, orange, and red hues are more clearly visible)
- Distorted depth perception and difficulty correctly judging the height of curbs and steps
- Decreased lacrimal secretions

Because visual accommodation is decreased with aging, elderly people have an increased risk of falling. An older person has difficulty making a visual adjustment when moving from a well-lit room into the evening darkness, for example, or when stepping out of a dark area into the sunlight.

The increased time needed to accommodate to near and far and dark and light is often the reason that older adults do not drive at night. Usually they complain that the light from oncoming traffic blinds them or that their eyes do not focus properly.

Hearing

Elderly people commonly have presbycusis (progressive hearing loss caused by loss of hair cells and decreased blood supply) and a decreased ability to hear high-frequency sounds. Deafness or decreased hearing acuity is one of the main reasons that older adults withdraw from social activities. The loss of high-pitched hearing causes the older adult to hear distracting background noises more clearly than conversation.

Older adults who are deaf may require adaptive equipment in their home for safety. The use of a hearing aid can increase hearing for elderly people who do not have nerve damage deafness. The use of flashing lights instead of buzzers or alarms increases the safety of an older adult who is not able to hear a smoke detector or fire alarm.

lesions, puffiness, and tenderness. Then the eyelids are inspected for symmetry, presence of eyelashes, eyelash position, tremors, flakiness, redness, and swelling. The patient is asked to open and close the eyelids. When open, the eyelid should cover the iris margin but not the pupil. The distance between the upper and lower eyelid, known as the palpebral fissure, is inspected; it should be equal in both eyes. If the palpebral fissure is nonsymmetrical, observe for ptosis, a drooping of the eyelid, which is commonly seen in stroke patients. Next the medial canthus of the lower lid is gently palpated and observed for exudate. The eyelids are palpated for nodules while the eye is palpated for firmness over the closed eyelid.

The lower eyelid is pulled down, and the patient is asked to look upward. The conjunctiva and sclera are inspected for color, discharge, and pterygium (thickening of the con-

junctiva). To inspect the upper eyelid, the upper lid is everted over a cotton-tipped applicator. The patient blinks to return the eyelid to its resting position when the inspection is complete.

The external eyes are inspected for color and symmetry of the irises, clarity of the cornea, and depth and clarity of the anterior chamber. Shining a light obliquely across the cornea assesses the clearness of the cornea. The cornea should be transparent without cloudiness. In individuals older than 40 years of age, there may be bilateral opaque whitening of the outer rim of the cornea known as **arcus senilis**. It is caused from lipid deposits and is considered normal. It does not affect vision. The anterior chamber (the area between the cornea and the iris) of the eye is inspected using oblique light. The anterior chamber should be clear when the light shines on it.

INTERNAL EYE EXAMINATION. Examination of the internal eye is done by the advanced practitioner. The LPN/LVN may be required to explain the procedure to the patient and to assist the practitioner in the examination. To perform the internal eye examination, specialized equipment must be used. It is useful, but not always necessary, to have the pupil dilated for the internal eye examination. Having a dark room allows the pupil to dilate, as does the application of anticholinergic mydriatic eye drops.

The instrument used to examine the internal eye is called an **ophthalmoscope**. The ophthalmoscope magnifies the structures of the eye, so the examiner can visualize the retina, optic nerve, blood vessels, and macula. The device is handheld and has a light source that is directed into the patient's internal eye. The patient should be instructed to hold the head still with the eyes focused on a distant object. The patient should be notified that the bright light might be uncomfortable. The **ophthalmologist** may examine the eye using a stationary device called a slit-lamp microscope rather than the handheld ophthalmoscope. The patient is seated and rests the chin on a support. This examination allows the examiner to visualize the internal eye by use of a microscope and light source directed into the eye.

Intraocular Pressure. Estimation of intraocular pressure is measured by using one of several types of tonometer. Generally the procedure is performed with the patient lying down, and anesthetic drops may be instilled. One type of tonometer testing uses a puff of air to make an indentation in the cornea to measure intraocular pressure. Readings above the normal range may indicate glaucoma.

Diagnostic Tests

CULTURE. If there is exudate from any portion of the eye or surrounding structure, a culture may be ordered. Results of the culture determine if antiinfective treatment is necessary.

FLUORESCEIN ANGIOGRAPHY. Fluorescein angiography is a procedure used to monitor, diagnose, and treat eye diseases. The patient is assessed for dye allergies before the procedure. Then the pupil is dilated and fluorescein dye is injected into the patient's venous system. The dye travels to

the retinal arteriovenous circulation, and the eye is examined via a slit-lamp microscope. The blood vessels in the eye are extremely visible with the addition of the dye.

ELECTRORETINOGRAPHY. Electoretinography is useful in diagnosing diseases of the rods and cones of the eye. The procedure evaluates differences in the electrical potential between the cornea and retina in response to light wavelengths and intensity. The test is conducted by placing contact lenses with electrodes directly on the eye.

ULTRASONOGRAPHY. Ultrasound is useful as an examination tool when the internal eye cannot be visualized directly because of obstructions such as corneal opacities or bloody vitreous. The eye is anesthetized with instillation of anesthetic drops, and a transducer probe is placed on the eye to perform the ultrasound. Patients should be instructed to keep the eye and head still during the procedure.

RADIOLOGICAL TESTS. Several radiological examinations are used to assess eye health. X-ray films are used to view bone structure and tumors. Computed tomography (CT) and magnetic resonance imaging (MRI) are used to visualize ocular structures and abnormalities of the eye and surrounding tissues.

Therapeutic Measures

Nurses have an important role in educating individuals, families, and the community about the care of healthy eyes. Nurses often have the opportunity to screen and educate people about the prevention of disease and impairment. To learn more about ways to promote vision and hearing health, visit www.lighthouse.org.

Regular Eye Examinations

Regular eye examinations should be encouraged. Individuals who are not known to have visual deficits and do not have diseases associated with visual loss such as diabetes should have their eyes examined at regular intervals throughout their life. Screening tests are usually done during an annual physical examination to detect gross visual deficits. Patients who wear corrective lenses or have disease processes that place them at risk for visual loss should have their eyes examined by an eye care provider at least yearly.

Eye care providers include the ophthalmologist and **optometrist**. An ophthalmologist is a physician who specializes in the comprehensive care of the eyes and visual system, including diagnosing and treating eye diseases. An optometrist is a health care provider who specializes in visual examinations, diagnosis, and treatment of visual problems, such as prescribing lenses. The optometrist is not a physician but is identified as a doctor of optometry. An **optician** is a person trained to grind and fit lenses according to prescriptions written by the ophthalmologist or optometrist.

Eye Hygiene

Individuals should be careful to keep debris out of their eyes to prevent scratching of the eye's delicate surfaces. When a foreign object gets into the eye, such as dirt or an eyelash,

the individual should be taught not to rub the eye but to allow tears to wash out the object. This can be done by pulling the eyelid down over the eye for a brief time. When wiping the eyes, the nurse should wipe from the inner canthus to the outer canthus.

Nutrition for Eye Health

Adequate nutrition is important not only for the whole body but the eye as well (Nutrition Notes Box 48–2). Eye disorders related to inadequate vitamin intake include corneal damage and night blindness from lack of vitamin A and optic neuritis as a result of vitamin B deficiency.

BOX 48-2 Nutrition Notes

Interpreting the Role of Antioxidants in Eye Disease

In developing countries, vitamin A deficiency is a leading cause of blindness. In developed countries, antioxidants have been investigated in relation to macular degeneration and cataracts, two conditions that also lead to blindness. The strongest evidence links consumption of fruits and vegetables to a reduced risk of macular degeneration, cataract, and other diseases. The role of specific nutrients in the fruits and vegetables is less clear. Therefore eating fruits and vegetables (five servings a day, according to the Food Guide Pyramid) is recommended. If a person chooses to take supplements, a multivitamin and multimineral product at no more than recommended daily levels is advocated rather than separate preparations of individual nutrients.

Eye Safety and Prevention

Many people in the United States suffer eye injuries each year. Common household activities are responsible for the majority of injuries. Activities such as microwave cooking, lawn care, and shooting rubber bands and BB guns all contribute to eye injury. Many of these injuries could be prevented with education and implementation of safety measures (Table 48–2).

Eye Irrigation

It is sometimes necessary to irrigate foreign bodies or chemical substances out of the eye. The nurse prepares the patient by explaining the procedure. Usually an isotonic solution is used to irrigate the eye. Refer to Box 48–3 and Figure 48–4.

Medication Administration

A variety of drugs are available for eye application. Most of the drugs are applied as drops, ointments, or irrigations. The nurse must know the usual dosage and strength, desired action, side effects, and contraindications of the medication being administered to prevent harm to the patient. Systemic adverse reactions can occur and medical diseases can be exacerbated from the administration of eye medications. The elderly are especially susceptible to this because they have more chronic diseases, as well as long-term use of oph-

TABLE 48-2 EYE SAFETY AND INJURY PREVENTION

To Protect From: Foreign objects	Use These Eye Safety Measures: Wear safety goggles. Avoid mowing over rocks or sticks.
Chemical splashes	Always wear safety goggles when using lawn edging yard devices. Use splash shields when working with chemicals such as cleaning solution or body fluids. Close eyes to avoid getting hair spray in them.
Contact lens abrasions/infections	Follow manufacturer's or eye care professional's directions for length of use and cleaning procedures. Do not overwear lenses.
Ultraviolet light (UV)	Wear UV-protected sunglasses when outdoors. Instruct patients to wear sunglasses with side shields after administration of mydriatics. Wear hats to shield sun.
Visual deficits in adult with corrective lenses	Update prescription of glasses yearly. Glasses should fit properly, be clean, and be free of scratches.
Eye strain from computer usage	The position of the bottom of the monitor should be 20 degrees below the line of sight and should be positioned 13 to 18 inches from the eyes. The light in the room should prevent glare. Increase the font size on the screen if letters appear too small. If dry eyes are a problem while using a computer, adjust the monitor to a lower level so the eyes do not have to open as wide, which increases evaporation.
Eye injury from sports	Wear protective eyewear with polycarbonate lenses. Wear facemasks or helmets while participating in any high-contact or high-impact sports.

BOX 48-3 Eye Irrigation

1. Explain the procedure to the patient.
2. Wash hands.
3. Gather equipment. For low-volume irrigation, a prefilled squeezable bottle is used. For large-volume irrigation, an intravenous (IV) bag of isotonic solution such as normal saline or lactated Ringer's is used. Attach IV tubing to the bag and flush the line.
4. Apply anesthetic drops, if ordered.
5. Place a basin by the side of the patient's head and pad the area with towels to absorb irrigant.
6. Apply gloves.
7. The eye may be irrigated by holding the distal end of the IV tubing at the inner canthus of the eye, or a Morgan lens may be attached. (See Fig. 48-4.) The lens is placed directly on the anesthetized eye, and the tubing is connected to the IV bag tubing. Proceed with irrigation using a slow, steady stream of irrigant. Generally, use of the lens is more comfortable for patients because the eyelids do not need to be held open.
8. Assess patient's tolerance to the procedure.
9. Remove Morgan lens.
10. Remove gloves. Wash hands.
11. Document assessment, type and amount of irrigant, and patient's tolerance to the procedure.

thalmic agents. These agents can interact with other medications the patient is taking. The nurse needs to observe patients for possible reactions.

Chapter 49 discusses specific ophthalmic medications and their uses. Boxes 48-4 and 48-5 identify the steps in the application of eyedrops and eye ointments, respectively. Whenever eye medications, especially eye drops, are administered, the punctum (tear duct) of the eye should have pressure applied to it by either the nurse wearing gloves or the patient if able for at least 1 minute. This reduces sys-

Figure 48-4 (A) Morgan lens. (B) Irrigation of eye.

temic absorption of the medication via the punctum. Some eye medications can have serious cardiac or respiratory effects, and patients have had life-threatening reactions to them. The nurse should educate the patient on the proper instillation of eye medications to reduce these reactions.

LEARNING TIPS

Elderly patients, when instilling their own eye drops, may not feel the drops go in. Teaching patients to refrigerate the drops, if not contraindicated, for 15 to 30 minutes before instillation helps them feel if the drops go into the eye or on the face.

BOX 48-4 Administration of Eye Drops

1. Explain procedure to the patient.
2. Check medication for dosage, strength, side effects, contraindications, and expiration date.
3. Wash hands and apply gloves.
4. Instruct patient to tilt head backward and look up toward the ceiling.
5. Gently pull the lower lid down and out. This forms a pocket to catch the eye drop.
6. Approach the patient's eye from the side and instill the prescribed amount of medication into the pocket. Be careful to avoid touching the patient's eye or surrounding structure with the tip of the dropper. It is helpful for the nurse, and the patient who is self-administering eye drops, to use the forehead as a stabilizing area for the hand administering the drop.
7. Release the lower eyelid.
8. Gently apply pressure with a tissue to the punctum (over the tear duct) for at least 1 minute to prevent the medication from being systemically absorbed. The nurse or patient can do this.
9. Wipe any excess medication off of the eyelids or cheek.
10. Remove gloves. Wash hands.
11. Document medication administration and the patient's tolerance to the procedure.

BOX 48-5 Administration of Eye Ointments

1. Explain procedure to the patient.
2. Check medication for dosage, strength, side effects, contraindications, and expiration date.
3. Wash hands and apply gloves.
4. Instruct patient to tilt head backward and look up toward the ceiling.
5. Gently pull the lower lid down. This forms a pocket into which the ointment is placed.
6. Express the ointment directly into the exposed palpebral conjunctiva in the direction of inner to outer canthus. Be careful to avoid touching the patient's eye or surrounding structure with the tip of the ointment tube.
7. Release the lower eyelid over the ointment.
8. Instruct the patient to gently close the eyes.
9. Remove gloves. Wash hands.
10. Instruct the patient that vision may be blurred while the ointment is in the eye.
11. Document medication administration and the patient's tolerance to procedure.

EYE PATCHING. After treating an injured or infected eye, the physician may order the eye to be patched. The nurse applies ointment or drops if ordered, requests that the patient keep the eyelid shut, and then places a disposable, cotton gauze eye patch over the depression of the eye socket. If the patient has a deep eye socket, the nurse may need to place two pads over the socket to assist the eyelids in remaining closed. The purpose of eye patching is to protect the eye from further damage by keeping the lids closed. Sometimes an additional metal shield is placed over the soft pads to protect the eye from external injury. The patch is

taped in place and the patient instructed to rest the eyes. The nurse should suggest quiet activities to the patient such as listening to music or an audiotaped book or sleeping. Watching television or reading is not recommended because the patched eye follows the movement of the unpatched eye.

► HEARING**Normal Anatomy and Physiology of the Ear**

The ear consists of three areas: the outer ear, the middle ear, and the inner ear (Fig. 48-5). The inner ear contains the receptors for the senses of hearing and equilibrium.

Outer Ear

The outer ear consists of the auricle (or pinna) and the ear canal. The auricle is made of cartilage covered with skin. The ear canal is a tunnel into the temporal bone that curves slightly forward and downward. The canal is lined with skin that contains ceruminous glands. Cerumen, or earwax, is the secretion that keeps the eardrum pliable and, because it is sticky, traps dust.

Middle Ear

The middle ear is an air-filled cavity in the temporal bone. The eardrum (or tympanic membrane) is stretched across the end of the ear canal and vibrates when sound waves strike it. These vibrations are transmitted to the three auditory bones—the malleus, incus, and stapes. The stapes then transmits vibrations to the fluid-filled inner ear at the oval window.

The eustachian tube (or auditory tube) extends from the middle ear to the nasopharynx and permits air to enter or leave the middle ear cavity. The air pressure in the middle ear must be the same as the external atmospheric pressure for the eardrum to vibrate properly. Swallowing or yawning opens the eustachian tubes and permits equalization of these pressures.

Inner Ear

The inner ear is a cavity in the temporal bone called the bony labyrinth, lined with membrane called the membranous labyrinth. The fluid between bone and membrane is called perilymph, and that within the membrane is called endolymph. These membranous structures are the cochlea, concerned with hearing, and the utricle, saccule, and semi-circular canals, all concerned with equilibrium.

The cochlea is shaped like a snail shell and partitioned internally into three fluid-filled canals. The medial canal is the cochlear duct, which contains the receptors for hearing in the organ of Corti (spiral organ). The receptors are called hair cells (their projections are stereocilia), which contain endings of the cochlear branch of the eighth cranial nerve. A membrane called the tectorial membrane hangs over the hair cells.

The process of hearing involves the transmission of vibrations and the generation of nerve impulses. When sound waves enter the ear canal, vibrations are transmitted by the

Figure 48-5 The ear in frontal section through the right temporal bone. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 198, with permission.)

following structures: eardrum, malleus, incus, stapes, oval window of the inner ear, perilymph and endolymph within the cochlea, and hair cells of the organ of Corti. When the hair cells bend, they generate impulses that are carried by the eighth cranial nerve to the brain. The auditory areas, for both hearing and interpretation, are in the temporal lobes of the cerebral cortex.

The utricle and saccule are membranous sacs between the cochlea and semicircular canals. Each contains a patch of hair cells embedded in a gelatinous structure that contains otoliths, small crystals of calcium carbonate. The hair cells bend in response to the pull of gravity on the otoliths as the position of the head changes. The impulses generated are carried by the vestibular branch of the eighth cranial nerve to the cerebellum, midbrain, and temporal lobes of the cerebrum. The cerebellum and midbrain use this information to maintain equilibrium at a subconscious level; the cerebrum provides a conscious awareness of the position of the head.

The three semicircular canals are fluid-filled membranous ovals oriented in three planes. At the base of each is an enlarged portion called the ampulla, which contains hair cells (the crista) that are affected by movement. As the body moves forward, for example, the hair cells at first bend backward. The bending of the hair cells generates impulses carried by the vestibular branch of the eighth cranial nerve to the cerebellum, midbrain, and temporal lobes of the cerebrum. These impulses are interpreted as starting or stopping, turning, or changing speeds, and this information is used to maintain equilibrium while a person is moving.

Aging and the Ear

In the ear, cumulative damage to the hair cells in the organ of Corti usually becomes apparent sometime after the age of 60. Hair cells that have been damaged by a lifetime of noise cannot be replaced. Sounds in high-pitched ranges are usually those lost first (presbycusis), whereas hearing may still

be adequate for lower-pitched ranges. The high-pitched sounds *f*, *s*, *k*, and *sh* are usually lost first. It becomes more difficult to filter out background noises, so noisy environments make it difficult to hear conversations.

LEARNING TIPS

Presbycusis is the loss of hearing high-pitched sounds (pitch = cycles per second; loudness = decibels). Because the ability to hear pitch is lost rather than loudness, it is not helpful to talk louder to a patient with this type of hearing loss. In fact, talking louder can make it more difficult to discriminate sounds. It is important to know the type of hearing loss a patient has.

Nursing Assessment of the Ear and Hearing Status

A nursing assessment of the ear includes obtaining the patient's health history and performing a physical examination. A complete nursing assessment is conducted on admission. Provide privacy and make the patient as comfortable as possible before beginning the nursing assessment. A quiet environment is helpful for an accurate assessment of hearing. During the initial assessment, observe the patient's behavior and note any information the patient shares.

Subjective Data

To understand the patient's ear disorder, perform a focused health history. Use knowledge of pathophysiology to guide questions in an appropriate and complete manner. Assessment of symptoms includes asking the WHAT'S UP? questions: where it is, how it feels, aggravating and alleviating factors, timing, severity, useful data for associated symptoms, and perception of the problem by the patient.

HEALTH HISTORY. Obtaining the patient's self-appraisal of his or her hearing or related symptoms is completed during the health history. You should also gather information about medications, surgeries, treatments, allergies, and habits. The health history helps in formulating the nursing care plan.

Symptoms and complaints related to the ear include decreased or loss of hearing, **otorrhea** (discharge), **otalgia** (ear pain), itching, fullness, tinnitus (ringing, buzzing, or roaring in the ears), or vertigo (dizziness). If any of these symptoms or complaints is positive, explore the symptoms in more detail using the WHAT'S UP? format. Record all the information accurately and completely.

Other information about the patient's medical history, including previous ear problems and use of **hearing aids** or assistive hearing devices, is obtained. You should also ask about any surgeries, allergies, recent upper respiratory infections, history of infections, injury to the ear, hospitaliza-

tions, swimming habits, exposure to pressure changes (flying or diving), medical diseases, and exposure to any loud noises. Positive findings should be assessed using the WHAT'S UP? format and results recorded.

Information about current and past medications should be obtained. Many medications are potentially toxic to the ear and can cause hearing loss or decreased hearing. Pay particular attention to any exposure to medications that are potentially **ototoxic**, such as certain antibiotics or diuretics. (See Chapter 49.)

Family history related to ear disorders includes any hearing problems or hearing loss and family members with Ménière's disease. Significant findings are recorded, including the relationship of the family member with the problem to the patient.

Information about the patient's care of the ears is also gathered. It is important to assess what preventive measures the patient practices and what the patient's learning needs are concerning care and protection of the ears. Determine how the patient cleans the ears, any exposure to loud noises during recreational activities or during work activities, any changes in ability to hear, and any exposure to ototoxic medications. You should determine if the patient has had a hearing evaluation and if there is a history of ear problems. Instruct the patient in ways to care for the ears and maintain ear health (Table 48-3).

Objective Data

Physical assessment of the ear begins by observing the behaviors of the patient. Note how the patient communicates. Observe how the patient talks, noting any slurred speech or words. Certain behaviors can be early indicators of hearing loss, as listed in Box 48-6. Examination of the ear includes inspection, palpation, testing auditory acuity, and, for the advanced practitioner, otoscopic examination.

INSPECTION AND PALPATION OF THE EXTERNAL EAR.

Inspection of the external ear begins with examining the auricle. A penlight or otoscope may be used to improve visualization of the external ear. The external ear should be inspected for size, symmetry, configuration, and angle of attachment. Note any obvious deformities or scars. The skin should be smooth and without breaks, particularly behind the ear in the crevice. The color should be uniform, without signs of inflammation. To inspect the external ear canal, tip the adult patient's head to the side and uses a penlight or otoscope to inspect the canal. Note any drainage or cerumen (wax), including the color, odor, and clarity of the drainage. The skin should be smooth and without inflammation, edema, or breaks. There should be no lesions, foreign bodies, erythema, or edema observed within the external ear canal. Inspection of the external ear canal should be completed before obtaining an infrared ear temperature, because the presence of cerumen can alter the accuracy of the reading.

otorrhea: oto—related to the ear + rreha—to flow
otalgia: ot—related to the ear + algia—signifying pain

ototoxic: oto—related to the ear + toxic—poison

TABLE 48-3 PREVENTION OF EAR PROBLEMS

Activity	Patient Education	Rationale
Care of external ear	Wash external ear with soap and water only. Do not routinely remove wax from the ear canal.	Keeps external ear clean. The ear is generally self-cleaning. Wax is normally removed during showering. Wax serves as a protective mechanism to lubricate and trap foreign material.
Preventing ear trauma	Avoid inserting any objects or solutions into the ear. Avoid swimming in polluted areas. Avoid flying when the ear or upper respiratory system is congested.	Prevents traumatizing the ear and tympanic membrane or exposing the ear to infection. Prevents barotrauma due to pressure changes.
Preventing damage from noise pollution	Avoid exposure to excessive occupational noise levels. Avoid other causes of excessive noise such as use of firearms and high-intensity music. Use protective earplugs or earmuffs if exposure to noise cannot be avoided.	Normal speech is 60 decibels; heavy traffic is 70 decibels. Above 80 decibels is uncomfortable. If there is ringing in the ear, damage may be occurring. Occupational noise is the primary cause of hearing loss. Hearing loss can occur due to exposure to loud noises. Protects ears from hearing loss by decreasing exposure to loud noises.
Early detection of hearing loss	Instruct adults to have hearing checked every 2 to 3 years. Monitor for side effects of ototoxic drugs. Instruct patient to report any dizziness, decreased hearing acuity, or tinnitus when taking ototoxic medications. Caution elderly patients who use aspirin that it is ototoxic. Instruct patient to report to physician any prolonged symptoms of ear pain, swelling, drainage, or plugged feeling. Instruct patient to blow nose with both nostrils open during upper respiratory infections (colds).	Degenerative changes occur in the ear with aging. Prevents side effects of medications from causing hearing loss. Elderly patients may have hearing loss and not be able to hear the tinnitus. Many medical problems can be prevented with prompt treatment. Prevents infected secretions from moving up the eustachian tubes into the middle ear.

BOX 48-6 Behaviors Indicating Hearing Loss

Adults with hearing loss may display any or all of the following behaviors:

- Turns up the volume on the television or radio
- Frequently asks, "What did you say?"
- Leans forward or turns head to one side during conversations to hear better
- Cups hand around ear during conversation
- Complains of people talking softly or mumbling
- Speaks in an unusually quiet or loud voice
- Answers questions inappropriately or not at all
- Has difficulty hearing high-frequency consonants
- Avoids group activities
- Shows loss of sense of humor
- Face looks strained or serious during conversations
- Appears to ignore people or aloof, does not participate
- Is irritable or sensitive in interpersonal relations
- Complains of ringing, buzzing, or roaring noise in the ears

Next the auricles are palpated and any topoi, lesions, or masses are noted. Topoi are deposits of uric acid crystals that appear as small, hard nodules in the helix (external ear margin); they may also occur in gout. The auricle should be nontender when it is palpated; tenderness can indicate an external ear infection. A downward protrusion of the helix, called Darwin's tubercle, is a normal finding. The mastoid

process should be smooth and hard when palpated. The mastoid process can be of different sizes but should not be tender or swollen.

AUDITORY ACUITY TESTING. Auditory function can be grossly evaluated using three different assessment tests. The whisper voice test is one test to check hearing function in each ear. The patient occludes one ear with a finger, and the nurse stands 1 to 2 feet away on the opposite side. The nurse whispers two-syllable words toward the unoccluded ear. The patient restates the whispered words. The nurse should be by the patient's side to prevent the patient from lip reading. The nurse's voice can be increased from a soft, medium, or loud whisper to a soft, medium, or loud voice. The process is repeated on the other ear. The patient is asked if hearing is better in one ear than in the other ear. The patient should be able to hear a soft whisper equally well in both ears. Findings of one ear hearing better than the other or inability to hear a soft whisper can be indicative of hearing impairment. Results of the test are documented.

A second acuity test is the **Rinne test**. This test is performed with a tuning fork and is useful for differentiating between conductive and sensorineural hearing loss. To perform the test, strike the tuning fork and place it on the patient's mastoid process (Fig. 48-6). Verify that the patient is able to hear the tuning fork and then instruct the patient to say immediately when the sound is no longer heard. When

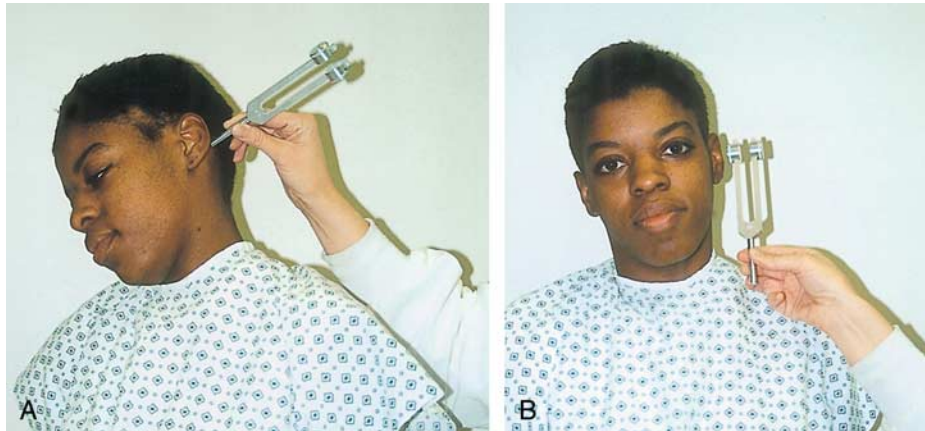

Figure 48-6 Rinne test. (A) Bone conduction. (B) Air conduction.

the patient indicates that the sound is not heard, place the vibrating tuning fork 2 inches in front of the ear. (See Fig. 48-6.) Ask the patient if he or she hears the tuning fork and then to indicate when the sound is no longer heard. Normally, air conduction (AC) is heard twice as long as bone conduction (BC). The patient reports this by hearing the tuning fork when placed in front of the ear (AC) after no longer hearing the tuning fork placed on the mastoid process (BC). Normal results are recorded as “AC > BC” (air conduction is greater than bone conduction). The test is repeated on the other ear and findings recorded. Abnormal findings can indicate conduction or sensorineural problems. See Table 48-4 for a summary of possible findings.

The **Weber test** is a third test to assess hearing acuity. The Weber test is also performed using a tuning fork. Place the vibrating tuning fork on the center of the patient’s forehead or head (Fig. 48-7). Verify that the patient can hear the tuning fork. Then, with a positive answer, asks the patient if he or she hears the sound better in the left ear, better in the right ear, or the same in both ears. It is important to give the patient three choices from which to choose. Normally the patient hears the sound the same in both ears. Table 48-4 identifies abnormal findings.

BALANCE TESTING. When the patient complains of dizziness, nystagmus, or problems with equilibrium, simple tests can be performed to assess vestibular function. The first test is simply to observe the patient’s gait by having the patient walk away from the examiner and then walk back to the examiner. Note the patient’s balance, posture, and movement of arms and legs. The patient should be able to walk with an upright position with no difficulties in balance or movement.

Romberg’s test, or falling test, is another simple test to assess vestibular function. Instruct the patient to stand with feet together, first with eyes open and then with eyes closed. Normally the patient has no difficulty maintaining a standing position with only minimal swaying. If the patient has difficulty maintaining balance or loses balance (a positive Romberg’s test), it can indicate an inner ear problem. If a

Figure 48-7 Weber test.

TABLE 48-4 AUDITORY ACUITY TUNING FORK TESTS

Test	Expected Results	Conductive Hearing Loss	Sensorineural Hearing Loss
Rinne Test	Air conduction heard longer than bone conduction	Bone conduction heard longer than air conduction in affected ear	Air conduction heard longer than bone conduction in affected ear (may be less than 2:1 ratio).
Weber Test	Tone heard in center of the head; no lateralization	Sound heard louder in affected ear	Sound heard louder in better ear

fall appears likely, be prepared to support the patient to prevent injury.

OTOSCOPIC EXAMINATION. An otoscope is an instrument consisting of a handle, a light source, a magnifying lens, and an optional speculum for inserting in the ear. Some otoscopes have a pneumatic device for injecting air into the canal to test the eardrum's mobility and integrity. The otoscope is used to visualize the external ear, ear canal, and tympanic membrane. Otoscopic examination is completed to identify specific disorders or infections, remove wax, or remove foreign bodies. Examination of the ear canal should be completed during insertion and removal of the speculum. The ear canal should be smooth and empty. There should be no redness, scaliness, swelling, drainage, nodules, foreign objects, or excessive wax. The internal otoscopic examination is conducted to examine the eardrum and is done by the experienced practitioner. The eardrum should appear slightly conical, shiny, and smooth and be a pearly gray color.

Diagnostic Tests

AUDIOMETRIC TESTING. Audiometric testing is used as a screening tool to determine the type and degree of hearing loss. An audiologist conducts the hearing tests in a soundproof booth. The audiometer produces a stimulus that consists of a musical tone, pure tone, or speech. To test air conduction, the patient is placed in the booth, wears earphones, and signals the audiologist when and if the tone is heard. Each ear is tested separately as the patient is exposed to sounds of varying frequency or pitch (hertz) and intensity (decibels). By varying the levels of the sound, a hearing level is established (Table 48–5). The use of earphones measures air conduction, level of speech hearing, and understanding of speech. During bone conduction testing, a vibrator is placed on the mastoid process and the earphones are removed. Testing proceeds as with air conduction.

A patient with normal hearing should have the same air conduction as bone conduction hearing levels. Alterations in testing air and bone conduction hearing can provide information about the location and type of hearing loss.

TABLE 48–5 COMMON NOISE LEVELS

Human hearing threshold	0–25 dB
Quiet room	30–40 dB
Conversational speech	60 dB
Heavy traffic	70 dB
Telephone	70 dB
Alarm clock	80 dB
Vacuum cleaner	80 dB
Unsafe noise levels begin	90 dB
Circular saw	100 dB
Rock music	120 dB
Jet planes	120–130 dB
Pain threshold	130 dB
Firearms	140 dB

TYMPANOMETRY. Tympanometry is a test used to measure compliance of the tympanic membrane and differentiate problems in the middle ear. Varying amounts of pressure are applied to the tympanic membrane, and the results create a distinctive response recorded on a graph called a tympanogram. The test is useful in determining the amount of negative pressure within the middle ear. The patient is informed that the tympanometry may cause transient vertigo. The patient should report any nausea or dizziness experienced during the test.

CALORIC TEST. The caloric test is used to test the function of the eighth cranial nerve and to assess vestibular reflexes of the inner ear that control balance. The test is performed first on one ear and then the other. Warm (44.5° C or 112° F) or cold (30° C or 86° F) water is instilled into the ear canal. This stimulates the endolymph of the semicircular canals, which stimulates movement of the head. Nystagmus is a normal response. The patient may also experience dizziness. No nystagmus is seen if the patient has a disease of the labyrinth such as Ménière's disease. The test is contraindicated if the patient has a perforated tympanic membrane. Otoscopic examination should be completed before this test to assess for excessive cerumen or perforated tympanic membrane.

ELECTRONYSTAGMOGRAM. The electronystagmogram is used to diagnose the causes of unilateral hearing loss of unknown origin, vertigo, or ringing in the ears. It is similar to the caloric test. The test is usually completed in a darkened room. Five electrodes are taped to the patient's clean face at certain positions around the eye. The electrodes measure nystagmus in response to vestibular stimulation. Measurements are taken at rest, looking at different objects, with eyes open and closed, in different positions, with water of different temperatures, and with air. Usually tranquilizers, alcohol, stimulants, and antivertigo agents are held for 1 to 5 days before the test. The patient should also avoid tobacco and caffeine on the day of the test. The test is contraindicated in patients who have pacemakers. The patient may experience nausea, vertigo, or weakness following the test.

COMPUTED TOMOGRAPHY. A CT scan produces radiographs similar to those used in conventional radiography. A special scanner system produces cross-sectional images of anatomic structures without superimposing tissues on each other. CT is useful for visualizing the temporal and mastoid bones, the middle and inner ears, and the eustachian tube. The patient should remove hairpins and jewelry from the area of visualization.

MAGNETIC RESONANCE IMAGING. MRI produces cross-sectional images of the human anatomy through exposure to magnetic energy sources without using radiation. It is useful in differentiating between healthy and diseased tissue. The MRI allows the membranous organs, nerve, and blood vessels of the temporal bone to be examined. The test is contraindicated in patients with implanted heart valves, surgical and aneurysm clips, and internal orthopedic screws

and rods. The patient should remove dental bridges and appliances, credit cards, keys, hairclips, shoes, belts, jewelry or clothing with metal fasteners, wigs, and hairpieces before entering the magnetic resonance room.

LABORATORY TESTS

Culture. Culture of drainage from the ear canal or surgical incision is important in diagnosis and treatment of acute infections. Identifying the organism responsible for the infection allows the appropriate antibiotic to be used. Often with chronic infections, the culture is less helpful because gram-negative bacilli cover up the original pathogen. Drainage from the external ear is collected using a sterile cotton-tipped or polyester-tipped swab. Samples should be taken to the laboratory immediately.

Pathological Examination. Pathological examination of tissue obtained during surgery is completed to rule out a malignancy and identify any unusual problems. A cholesteatoma (cyst of epithelial cells and cholesterol found in the middle ear) is usually documented by a pathological examination.

CRITICAL THINKING

Mr. Frank

Mr. Frank's wife expressed concern about his changing behavior during the last 6 months. She reports that Mr. Frank no longer enjoys talking to neighbors or visiting with friends in their church group, is irritable, has lost his sense of humor, and does not always answer her questions appropriately.

1. What do you suspect is wrong with Mr. Frank?
2. What examination techniques or tests might you use to assess Mr. Frank's signs and symptoms?
3. What are the expected findings?

Answers at end of chapter.

Therapeutic Measures

Medications

The medications most often used to treat ear disorders include anti-infectives, anti-inflammatories, antihistamines, decongestants, cerumenolytics, and diuretics. Anti-infectives can be administered systemically or as a topical solution. Ear medications are generally in a liquid form for ease in administration as drops. Box 48-7 and Figure 48-8 guide the nurse in administering ear drops. Anti-inflammatories, antihistamines, and decongestants are used with acute infections to reduce nasal and middle ear congestion. Cerumenolytics are used to soften cerumen and remove it from the ear canal. Diuretics are used with some inner ear disorders to reduce pressure caused by fluids.

Ear Health Maintenance

Routine cleaning and care of the ears should be taught to all patients. Patient education should include prevention of trauma, prevention of hearing loss, and early detection of

BOX 48-7 Administration of Ear Drops

1. Wash hands
2. Ensure medication is at room temperature.
3. Position patient sitting up with head tilted toward unaffected side or side lying on unaffected side.
4. Pull auricle down and back on children and pull auricle up and back for adults.
5. Instill prescribed number of drops, being careful not to touch the tip of the dropper to prevent contamination.
6. Have patient remain in position for 2 to 3 minutes.
7. A small cotton plug may be inserted to prevent medication from running out of ear.
8. Wash hands.

Figure 48-8 Ear drop administration.

hearing loss. All patients can benefit from this type of education, as found in Table 48-3.

Assistive Devices

Hearing aids are instruments that amplify sounds. (See Chapter 49.) Certain hearing aids may be designed to amplify sounds and attenuate certain portions of the sound signal. A microphone receives the sounds and converts them to electrical signals. These signals are amplified, and a receiver then converts the signal to sound. A small battery serves as the energy source. Digital hearing aids contain computers that provide clearer and crisper sound that is tailored to the person's hearing loss. Digital hearing aids are more expensive than analog hearing aids. There are four types of commonly used hearing aids:

1. The in-the-ear aid fits into the ear. It is small and unobtrusive to the wearer and others.
2. The behind-the-ear, or postauricular, aid is the most common type. This fits behind the ear and is comfortable to wear.
3. The all-in-one eyeglass aid combines eyeglasses with a hearing aid and is the least commonly used type.
4. The body-worn aid has a fitted ear mold inserted into the external ear and is connected to a receiver. The receiver is

wired to a transmitter, which is worn around the neck. The wearer is not able to hide the receiver and wires.

To care for a hearing aid, ensure that it is turned off and the battery is removed when it is not in use. This reduces battery expense for the patient, who may be on a fixed income. When turning the hearing aid on, the volume should be turned up just until it squeals and then turned down until the patient indicates it is at the appropriate level for hearing. At least weekly, clean the hearing aid by washing the ear mold portion with either a dry cloth or a damp, soapy cloth and then rinsing with a damp cloth. A brush may come with the hearing aid for cleaning, or a cotton-tipped swab can be used to clean the small tip that fits into the ear.

Another type of hearing aid is the implantable middle ear hearing device, called the Vibrant Soundbridge, for those with a sensorineural hearing loss. It provides sound perception by enhancing the normal middle ear hearing function. An audio processor picks up environmental sound and transmits it to the receiver implanted under the skin. The sound is then sent to a tiny floating transducer that directly vibrates the ossicles, which sends the message to the cochlea, as in normal hearing. The hair cells in the cochlea stimulate the auditory nerve, and the brain interprets the message as sound. For more information or to see the Vibrant Soundbridge, visit www.symphonix.com.

A person who is profoundly deaf and has lost all hearing may use a **cochlear implant**. All cochlear implants feature a microelectronic processor for converting the sound into electrical signals, a transmission system to relay signals to the implanted parts, and a long, slender electrode placed in

the cochlea to deliver the electrical stimuli directly to the fiber of the auditory nerve. The electrode is surgically placed. Patients commonly have difficulty understanding and learning speech, even with the cochlear implant.

Diet

The patient with an ear problem usually does not have any diet modifications. However, the patient with Ménière's disease may benefit from a lower-sodium diet to prevent retention of fluid. Increased fluid may contribute to Ménière's disease symptoms.

Hearing Ear Dogs

Hearing ear dogs are now available to assist those with hearing problems. The dogs are trained to respond to sounds that the person who is hard of hearing cannot hear. Examples include a crying baby, oven timer, and smoke alarm. These dogs provide a valuable service that enriches the lives of those with hearing problems.

Answers to CRITICAL THINKING

Mr. Frank

1. He is exhibiting behaviors of hearing loss.
2. Ear inspection, a whisper voice test, a Rinne test, and a Weber test might be performed.
3. For inspection of ear, cerumen impaction may be found. For a whisper voice test, the whisper is not heard in affected ear. For a Rinne test, bone conduction is heard longer than air conduction in affected ear. For a Weber test, sound is heard louder in affected ear.

REVIEW QUESTIONS

1. Which of the following methods can be used to assess visual fields?
 - a. Inspection with an ophthalmoscope
 - b. Fluorescein angiography
 - c. Testing vision with Snellen's chart
 - d. Comparing the patient's visual fields with your own
2. Which of the following should the nurse do to reduce systemic absorption of eye drops?
 - a. Instruct the patient to keep eyes closed for 30 seconds after administration
 - b. Apply pressure to punctum of the eye for 1 minute after application
 - c. Keep eye drops in the refrigerator before applying
 - d. Have the patient look up for 1 minute after application
3. Which of the following patient behaviors is indicative of hearing loss?
 - a. Turns volume low on the television
 - b. Is irritable or sensitive in interpersonal relations
 - c. Answers questions appropriately
 - d. Complains of people talking too loudly
4. Which of the following is the most important nursing intervention during Romberg's test?
 - a. Ensure patient safety
 - b. Whisper softly into each ear
 - c. Ensure a quiet environment
 - d. Remove all cerumen from ear canal
5. Which of the following patient statements indicates that the patient understands ear care teaching?
 - a. "I should insert a cotton swab into my ear canal for cleaning."
 - b. "I should not get my external ear wet during bathing."
 - c. "Ear wax should be routinely removed."
 - d. "Aspirin can be toxic to the ears."

QUESTIONS TO GUIDE YOUR READING

1. How would you explain the pathophysiology of each of the disorders of the sensory system?
2. How would you define blindness and the refractive errors of vision?
3. What are the etiologies, signs, and symptoms of sensory disorders?
4. What care would you provide for patients undergoing tests for sensory disorders?
5. What is the medical treatment for each sensory disorder?
6. What medications are contraindicated for patients with acute angle-closure glaucoma?
7. What are three ototoxic drugs?
8. What data should you collect when caring for patients with disorders of the sensory system?
9. What nursing care will you provide for patients with disorders of the eye or ear?
10. What nursing care interventions would you use for the patient with a hearing impairment?
11. How will you know if your nursing interventions have been effective?

Early detection and treatment of sensory injuries or diseases can reduce their impact. Any disturbance in vision or hearing disrupts a person's role performance, safety, and activities of daily living (ADLs). Treatment for sensory disturbances, such as glasses for refractive errors or hearing aids, can interfere with an individual's self-concept and body image. Nurses play an important role in recognizing symptoms of visual and hearing disorders and in assisting the individual to follow treatment, prevent recurrence, and learn new adaptive skills.

► VISION

Infections and Inflammation

Infections and inflammation of the eye and surrounding structures can be bacterial or viral in origin. The eye may become aggravated by allergens, chemical substances, or mechanical irritation, leading to infection by microorganisms. Mechanical irritation may be caused by sunburn or bacterial infection. Inflammation results from allergies to environmental substances or by irritation of chemical irritants found in perfumes, makeup, sprays, or plants. Viral agents that cause infection include herpes simplex virus, cytomegalovirus, and human adenovirus. Bacterial agents that infect the eye include *Staphylococcus* and *Streptococcus*. The most common type of acute infection is **conjunctivitis** (Cultural Consideration Box 49-1).

BOX 49-1 CULTURAL CONSIDERATION

Vision

Onchocerciasis, commonly called river blindness, is a filarial (worm) infection in which larvae infect almost all ocular tissues. Blindness typically follows infestation of the choroids, retina, and optic nerve. The disease is spread by blood-sucking insects such as flies, gnats, or mosquitoes that ingest the larvae from blood and then inject another host. This infection affects more than 18 million people and is predominant in Africa, South America, and Central America. All of the 18 million infected, 1 to 2 million are either blind or visually impaired. The use of the medication ivermectin has revolutionized the treatment of this disease. Ivermectin is administered annually to the infected individual for 10 years or longer.

Trachoma, a form of conjunctivitis, is a common, chronic disease that affects approximately 600 million people worldwide. It is primarily seen among low-income persons in the Mediterranean, Africa, Brazil, and the Far East. Trachoma is caused by a viral strain of *Chlamydia trachomatis* that is highly contagious. Following the acute conjunctivitis phase, the eyelids shrink as a result of scarring. The shrinking tends to pull the eyelashes inward (entropion), which may scratch the cornea. In addition, granulations form on the inner eyelids. This painful condition may eventually lead to corneal ulceration and blindness. Trachoma is medically treated with topical and oral erythromycin or tetracycline.

Conjunctivitis

Conjunctivitis is inflammation of the conjunctiva caused by either a virus or bacteria. Viral conjunctivitis occurs more commonly than bacterial conjunctivitis and is highly contagious. The virus is usually transmitted via contaminated eye secretions on the hand that then touches or rubs an eye, which infects the eye. The virus is hardy and may live on dry surfaces for 2 weeks or more. Viral conjunctivitis lasts 2 to 4 weeks. Bacterial conjunctivitis (commonly called pink-eye) usually is due to staphylococcal or streptococcal bacteria and is also highly contagious. Conjunctivitis can also be caused from the organisms *Haemophilus influenzae*, *Chlamydia trachomatis*, and *Neisseria gonorrhoeae*. Conjunctivitis is commonly transmitted among children and then among family members. Interestingly, conjunctivitis may also be caused from the use of nonprescription decongestant eye drops containing vasoconstrictors. When the eye drop is discontinued, a pharmacologically induced rebound phenomenon may occur. The eye vessels dilate and may become ischemic. This condition eventually subsides.

The symptoms of conjunctivitis include conjunctival redness and crusting exudate on the lids and corners of the eyes. Individuals may complain that their eyes itch and are painful. The eyes may tear excessively in response to the irritation.

Viral conjunctivitis is treated by supportive measures, which seek to keep the patient comfortable until the infection resolves on its own. Treatment includes eyewashes or eye irrigations, which cleanse the conjunctiva and relieve the inflammation and pain. Bacterial conjunctivitis is treated with antibiotic eye drops or ointments (Table 49-1). Eye drops are generally preferred by adults because they do not impair vision. Ointments are commonly used when the eye is resting (at night) or with children, who may squeeze their eyes shut and cry when ocular medications are applied, thus expelling the medication. With either type of conjunctivitis, handwashing is the best means of preventing the spread of the disease.

Blepharitis

Blepharitis, an inflammation of the eyelid margins, is a chronic inflammatory process. There are two types: seborrheic blepharitis and ulcerative blepharitis. Cause may include staphylococcal infection, seborrhea (dandruff), rosacea (a chronic disease of the skin usually affecting middle-aged and older adults), dry eye, or abnormalities of the meibomian glands and their lipid secretions. Seborrheic blepharitis is characterized by reddened eyelids with scales and flaking at base of the lashes. Ulcerative blepharitis produces crusts at eyelashes, reddened eyes, and inflamed corneas. Eyelids chronically infected with *Staphylococcus* may become thickened and eyelashes may be lost.

Treatment requires a commitment to long-term daily cleansing with cotton-tipped swabs dipped in diluted baby shampoo or sterile eyelid cleanser solutions to prevent infection. If infection occurs, antistaphylococcal antibiotic ointment (bacitracin, erythromycin) is applied to the lid

TABLE 49-1 OPTHALMIC MEDICATIONS

Drug Type	Uses	Nursing Considerations
<i>Diagnostic Aids</i> Fluorescein sodium	Staining of eye. Lesions of foreign objects pick up bright yellow-orange stain so abnormality can be detected.	Stain needs to be irrigated out of eye when examination is complete. Stain is colorfast, so caution should be used when irrigating.
Topical anesthetics	Provides local anesthesia to area, making examination painless. Also used to reduce pain of injury.	Corneal anesthesia is achieved within 1 minute and lasts about 15 minutes. The eye must be protected because the blink reflex is temporarily lost. The lid should be kept closed to keep eye moist when examination and treatment are completed.
<i>Anti-infectives</i> Antibiotics	Combats eye infections of bacterial origin.	Patients must be asked about previous allergic reaction to any ophthalmic or systemic medications.
Antivirals	Combats eye infections of viral origin.	To minimize systemic absorption of anti-infectives, apply pressure on tear duct up to 5 minutes after medication is applied.
Antifungals	Combats eye infections of fungal origin.	
<i>Anti-inflammatories</i> Steroidal	Used to reduce inflammation of the conjunctiva, cornea, or eyelids due to infection, edema, allergic reaction, or burns.	To minimize systemic absorption of anti-inflammatories, apply pressure on tear duct up to 5 minutes after medication is applied.
Nonsteroidal		Long-term use of corticosteroids can contribute to cataract formation.
<i>Lubricants</i>	Used to moisten the eyes in healthy and ill persons. Lubricants maintain the moisture on the eyeball, which contributes to maintenance of the epithelial surface.	Lubricants come in liquid and ointment forms. For patients who have ointments placed in the eye during surgery to prevent eye dryness, patient teaching should be done, informing patients that vision will be distorted in the presence of ophthalmic ointments.
<i>Miotics</i>	Used to lower the intraocular pressure by stimulating papillary and ciliary sphincter muscles. This assists in improving blood flow to the retina and flow of aqueous humor.	There are two types of miotics, which work differently to reduce ocular pressure—cholinergics and cholinesterase inhibitors. Miotic side effects include headache, eye pain, and brow pain. Systemic absorption can cause nausea, vomiting, diarrhea, respiratory attacks in patients with asthma, and respiratory difficulty. Pilocarpine, a miotic, causes miosis (contraction of the pupil). Expect to see a smaller than normal pupil with little if any reaction to light.
<i>Carbonic Anhydrase Inhibitors</i>	Used to decrease aqueous humor formation and decrease intraocular pressure. Used primarily for treatment of glaucoma when other miotics have not been successful.	Side effects include lethargy, anorexia, depression, nausea, and vomiting. Do not administer to persons allergic to sulfonamides. Carbonic anhydrase inhibitors may also cause photosensitivity. Use of the medication may cause dry eyes and dry oral membranes. Encourage patient to maintain eye and oral hygiene.
<i>Osmotics</i>	Used to reduce intraocular pressure in emergency situations such as acute open-angle glaucoma or used preoperatively and postoperatively to decrease vitreous humor volume, thereby reducing intraocular pressure.	Disorientation, especially in elderly, may be caused by change in electrolytes secondary to use of osmotics. Monitor for headache, nausea, vomiting, and confusion.
<i>Anticholinergic Mydriatics</i>	Used to dilate the pupils for examination or surgical procedures.	If pupils are dilated, they can no longer protect the eye from bright light. Instruct patient to wear dark glasses until the effects of the drug have worn off.
<i>Cycloplegics</i>	Used to paralyze the muscles of accommodation for examination or surgical procedures.	Contraindicated in patients with glaucoma because of increase in intraocular pressure with use. Side effects include tachycardia, dry mouth, and symptoms of atropine toxicity.

margins one to four times a day after the eyelids have been cleansed. Warm compresses may also be used.

Hordeolum and Chalazion

Another type of eyelid infection is a **hordeolum**. An external hordeolum (sty) is a small staphylococcal abscess in the

sebaceous gland at the base of the eyelash (either Zeis' glands or the glands of Moll). Use of cosmetics on the eyes may contribute to hordeolum formation. Styes are small, raised, reddened areas. A second type of abscess, **chalazion** (internal hordeolum), may form in the connective tissue of the eyelids, specifically in the meibomian glands. A cha-

lazion is larger than an external hordeolum. Styes do not cause discomfort; however, a chalazion often puts pressure on the cornea, causing more discomfort.

Hordeolum usually form and heal spontaneously within a few days and require no treatment. Chalazions may require surgical incision and drainage (I & D) if they do not drain spontaneously. If either type of abscess persists, administration of oral antibiotics may be prescribed along with application of warm compresses to aid healing.

Keratitis

PATHOPHYSIOLOGY AND ETIOLOGY. Keratitis is inflammation of the cornea and may be acute or chronic and superficial or deep. The depth of keratitis is determined by the layers of the cornea that may be affected. Keratitis may be associated with bacterial conjunctivitis, a viral infection such as herpes simplex, a corneal ulcer, or diseases such as tuberculosis and syphilis. Children may develop keratitis from vitamin A deficiency, allergic reactions, or viral diseases such as mumps or measles. Herpes simplex keratitis is the most common corneal infection in developed countries, with bacterial and fungal infections more prevalent throughout the rest of the world. People who wear contact lenses or have dry eyes, practice poor contact lens hygiene, have decreased corneal sensation, or are immunosuppressed are at increased risk of keratitis. Overnight wearing of soft contact lenses increase the risk even more. *Pseudomonas aeruginosa* is the pathogen most commonly associated with infection following overnight wear of soft contact lenses. If this infection occurs, the patient may be advised to dispose of the contaminated lenses and be treated with antibiotics.

SIGNS AND SYMPTOMS. The cornea has many pain receptors, so any inflammation of the cornea is painful. This pain increases with movement of the lid over the cornea. Other symptoms of keratitis include decreased vision, **photophobia** (sensitivity to light), tearing, and blepharospasm (spasm of the eyelids). The conjunctiva often appears reddened. In advanced cases the cornea may appear opaque (cloudy).

photophobia: photo—light + phobia—fear of

DIAGNOSTIC TESTS. Assessment of keratitis or corneal ulcer is made by use of a slit lamp or a handheld light. The cornea is examined by shining the light source obliquely (diagonally) across the cornea to show opacity in the cornea. Fluorescein stain may also be used to outline the area of involvement. When the stained area is viewed with a blue light, the disruption in the corneal surface shows up clear. If the patient is having pain from blepharospasm (contraction of the orbicularis oculi muscle), the examiner may instill a topical ophthalmic anesthetic such as proparacaine.

MEDICAL TREATMENT. Medical treatment may include topical antibiotics, antiviral medications for herpes simplex, cycloplegic agents (to keep iris and ciliary body at rest), and warm compresses. If the cornea is severely damaged, corneal transplant may be required. The eye may be patched to decrease the amount of eyelid movement over the cornea during healing.

COMPLICATIONS. Corneal infections are usually serious and are often sight threatening. The corneal tissue may become thin and susceptible to perforation. Untreated, keratitis can cause permanent scarring of the cornea, resulting in permanent loss of vision

Nursing Process: The Patient with Inflammation and Infection of the Eye

ASSESSMENT. Assessment of symptoms for any eye problem includes gathering subjective and objective data (Table 49–2). Objective assessment data includes the condition of the conjunctiva, eyelids and eyelashes; presence of exudate, tearing, any visible abscess on palpebral border, or a palpable abscess in eyelid; opacity of the cornea; and visual acuity testing comparing unaffected and affected eyes.

NURSING DIAGNOSIS. The major nursing diagnoses for inflammation and infection of the eye include but are not limited to the following:

- Acute pain related to inflammation or infection of the eye or surrounding tissues
- Disturbed sensory perception: visual related to altered sensory reception

TABLE 49-2 SUBJECTIVE ASSESSMENT OF EYE INFLAMMATION AND INFECTION CONDITIONS

W	Where is it? What part of the eye is affected? Eyelid, conjunctiva, cornea?
H	How does it feel? Pressure? Itchy? Painful? No pain? Irritated? Spasm?
A	Aggravating and alleviating factors. Is it worse when rubbing eyes or blinking? Is there photosensitivity?
T	Timing. Was there exposure to a pathogen? Previous infection or irritation? How long have symptoms persisted?
S	Severity. Is there visual impairment? Does pain affect ADLs?
U	Useful data for associated symptoms. Is patient infected with lice? Immunosuppression? Do other members of the family or peer group have symptoms? Are decongestant eye drops used? Is there exudate? Are the eyelids stuck together on awakening? Does patient wear contact lenses, soft contact lenses overnight, disposable contact lenses? Does patient have dry eyes? Is patient infected with tuberculosis, syphilis, HIV? What is typical eye hygiene?
P	Perception by the patient of the problem. What does patient think is wrong?

HIV = human immunodeficiency virus.

- Risk for injury related to visual impairment
- Risk for infection related to poor eye hygiene, use of contact lenses
- Deficient knowledge related to eye disease process, prevention, and treatment from lack of previous experience

PLANNING. The patient and family are included in the planning phase to help patients return to their preillness state and prevent further eye disorders. Patient goals may include the following:

- Indicates pain is decreased or absent as evidenced by a lower rating on a pain scale
- Vision returns to preillness state
- Injury does not occur as a result of impairment
- Does not develop eye infection
- Explains disease process, prevention, and treatment measures
- Demonstrates treatment regimen correctly, such as administration of eye drops

NURSING INTERVENTIONS. Nursing care focuses on relieving the patient's pain, promoting safety, maintaining eye function, educating the patient about the disorder, applying medication if ordered, performing eye hygiene, and providing preventive eye care.

Assess the patient for pain. Use of dark glasses, rubbing the eye, squinting, and avoiding light may be indicators of pain that should be assessed. Eye pain is generally treated with topical anesthetic drops or ointments, antibiotics, and antiinflammatory agents. Warm or cool packs may also assist in soothing the eye. Patching of the affected eye also helps reduce pain by decreasing the movement of the eye across the eyelid. For severe pain, analgesics may also be prescribed. Other methods of pain reduction, such as guided imagery, relaxation techniques, music, or distraction, are explored.

Visual impairment of any type raises safety concerns for the patient. Safety is promoted by assessing and planning for visual impairments that may be present. Inflamed eyes often do not focus well and may have exudate, tearing, or ointment present, which interfere with vision. Patients with one eye patched should be advised that depth perception is altered and they should not drive. They must be taught to be cautious and careful when ambulating and reaching for things.

Interventions to maintain eye function must be implemented. If the patient is to rest the eye, reading and television should be discouraged because they require use of the eyes. Quiet activity, which can be carried out with the eyes closed, is best. Listening to music, radio, or a recorded book may provide distraction and rest for the eye. Contact lenses should be avoided when the eye or surrounding structure is inflamed. When the eye has healed and infection is gone, contact wear usually can be resumed. Contact lenses must be sterilized before use to prevent reinfection of the eye. Soft contact lenses that cannot be sterilized need to be discarded.

Patients require education in prevention, care of the affected eye, medication administration, safety issues, and

outcomes. Patients should demonstrate the administration of ointments or drops after teaching has occurred. The patient and family are taught how to prevent spreading the infection if it is contagious. The patient is also taught good eye hygiene to prevent further complications.

EVALUATION. The goals for the patient are met if the following occur:

- Pain is reduced to an acceptable rating
- Vision improves or returns to preillness level
- Injury does not occur as a result of visual impairment
- Infection does not occur as a result of poor eye hygiene or contact lens wear
- Patient explains disease process, prevention, or treatment regimen accurately
- Prescribed treatment is stated or demonstrated correctly (e.g., administering eye drops or ointments)

Refractive Errors

Pathophysiology and Etiology

Refraction refers to the bending of light rays as they enter the eye. Emmetropia, or normal vision, means that light rays are bent to focus images precisely on the macula of the retina. *Ametropia* is a term used to describe any refractive error. When an image is not clearly focused on the retina, refractive error is present. Refractive errors account for the largest number of impairments in vision. Ametropia occurs when parallel light rays entering the eye are not refracted to focus on the retina. There are four common ametropic disorders: **myopia**, **hyperopia**, **astigmatism**, and **presbyopia**.

HYPEROPIA. Hyperopia, also known as farsightedness, is caused by light rays focusing behind the retina (Fig. 49-1). People who are hyperopic see images that are far away more clearly than images that are close. Physiologically the globe or eyeball is too short from the front to the back, causing the light rays to focus beyond the retina. Hyperopia is corrected with convex lenses.

MYOPIA. Myopia, commonly referred to as nearsightedness, is caused by light rays focusing in front of the retina. The eyeball is elongated and thus the light rays do not reach the retina. Persons with myopia hold things close to their eyes to see them better. Distance vision is blurred. Myopia is corrected with concave lenses. (See Fig. 49-1.)

ASTIGMATISM. Astigmatism results from unequal curvatures in the shape of the cornea. When parallel light rays enter the eye, the irregular cornea causes the light rays to be refracted to focus on two different points. This can result in either myopic or hyperopic astigmatism. The person with astigmatism has blurred vision with distortion. The corneal irregularities can be caused by injury, inflammation, corneal surgery, or an inherited autosomal dominant trait.

PRESBYOPIA. Presbyopia is a condition in which the crystalline lenses lose their elasticity, resulting in a decrease in

presbyopia: presby—old age + opia—concerning vision

Figure 49-1 Refractive disorders. (A) Hyperopia (farsighted). The eyeball is too short, causing the image to focus beyond the retina. (B) Corrected hyperopia. (C) Myopia (nearsighted). A long eyeball causes the image to focus in front of the retina. (D) Corrected myopia.

ability to focus on close objects. The loss of elasticity causes light rays to focus beyond the retina, resulting in hyperopia. This condition usually is associated with aging and generally occurs after age 40. If an individual has preexisting hyperopia, the onset of presbyopia may occur earlier than 40 years. Likewise, if an individual has myopia, presbyopia may correct the myopia by projecting the light rays directly on the retina. Because accommodation for close vision is accomplished by lens contraction, people with presbyopia exhibit the inability to see objects at close range. They often compensate for blurred close vision by holding objects to be viewed farther away. Complaints of eyestrain and mild frontal headache are common. These symptoms are relieved with eye rest and corrective lenses.

LEARNING TIPS

To remember the type of vision a person has, use this saying: *You are what you say*. For example, if you say you are farsighted, this means that you have clear vision of far away images but difficulty seeing images that are nearer. If you say you are nearsighted, this means that you have clear vision of near images but difficulty seeing images that are farther away.

Signs and Symptoms

Individuals with refractive errors often complain of difficulty reading or seeing objects. Often the eyestrain that occurs as one attempts to improve visual acuity causes headache. Myopic individuals may hold reading materials close to the eyes. Hyperopic individuals hold reading materials farther away from their eyes.

Diagnostic Tests

A refractive error may be roughly estimated by use of Snellen's chart or by determining the individual's vision at different distances and comparing it with that of the examiner. To obtain a more definitive refractive error measurement, a retinoscopic examination is necessary. Before this examination, a cycloplegic drug is often instilled. (See Table 49-1.) A cycloplegic drug dilates the pupil and temporarily paralyzes the ciliary muscle, thus preventing accommodation. During the examination, an ophthalmologist or optometrist examines the internal and external eye and uses trial lenses via a retinoscope to assess the type of lens best suited to correct the refractive error. If convex-shaped trial lenses correct the focusing power of the eyes, the patient is determined to be hyperopic. If concave-shaped trial lenses correct the focusing power, the patient is said to be myopic. The amount of focusing power needed in the trial lens to correct the visual defect indicates the degree of refractive error. Left and right eyes of the same person may not have the same degree of refractive error. If a cycloplegic agent has been used, patients need to be told that blurred vision will be present and sunglasses need to be worn until the agent wears off. In addition, the patient should be instructed that driving and reading are not possible until the effect of the cycloplegic drug is gone.

Medical and Surgical Treatment

Refractive errors are commonly treated with corrective lenses, either eyeglasses or contact lenses. The lenses bend the parallel light rays so that they converge on the macula portion of the retina. Incisional radial keratotomy and photorefractive keratectomy (PRK) are surgical procedures used to correct refractive error. With incisional radial kerato-

tomy, surgical incisions are made on the cornea to reshape it. PRK utilizes laser technology to accomplish the same goal of reshaping the cornea (Box 49–2). The cornea is made flatter for individuals with myopia and more cone shaped for those with hyperopia.

Complications

Complications of corrective lens use are primarily related to safety. Eyeglasses can be broken. Eyeglass lenses can be made with special polymers that do not break as easily as traditional glass. It is a myth that if corrective lenses are not worn, vision becomes worse. Complications of contact lens use include corneal abrasions, infections, and keratitis. Incisional radial keratotomy and PRK both have surgical risks and may not always be successful.

Blindness

Blindness is described in many terms that are often reflective of the degree of visual impairment an individual has. Generally, blindness is the complete or almost complete absence of the sense of sight. Terms such as *profound blindness*, *partially sighted*, and *blind* may all have different meanings. Some people consider the terms *blind* and *partially sighted* to be negative and prefer the term *visually impaired* to describe their condition. For information or resources, visit the following sites:

- American Foundation for the Blind at <http://afb.org>
- Canadian National Institute for the Blind at www.cnib.ca
- National Federation of the Blind at www.nfb.org
- Prevent Blindness America at www.prevent-blindness.org

Pathophysiology and Etiology

Few people are born blind. Blindness is caused by a variety of factors, including trauma, complications from various diseases such as hypertension and diabetes, conditions such as **cataracts** and **glaucoma**, and, in children, malnutrition, infectious diseases, and parasitic infestations. Blindness is produced when there is an obstacle to the rays of light on their way to the optic nerve or by disease of the optic nerve or tract of the part of the brain connected with vision. Blindness may be permanent or transient or complete or partial or may occur only in darkness (night blindness). There are blind people in every age group, but about half the blind people in the United States are older adults.

BOX 49–2 Laser Treatment

Laser is an acronym for light amplification by stimulated emission of radiation. Lasers are devices that amplify light and produce synchronized light waves. Lasers are based on the principle that atoms, molecules, and ions can be excited by absorption of thermal, electrical, or light energy. After this energy is absorbed, the atoms, molecules, or ions give off a beam of synchronized light waves. By using this extremely intense, highly directional, pure-colored light, lasers can be used for a variety of purposes, such as making incisions, removing tissue, or stopping bleeding.

Signs and Symptoms

Aside from a general loss of vision, patients may describe their visual image as blurred, distorted, or absent in specific areas of the visual field. Objects may appear dark or absent around the peripheral field in glaucoma or retinitis pigmentosa. Retinitis pigmentosa causes this visual disturbance because the pigmented layer of the retina has degenerated. The center of the visual field may appear dark for individuals with diabetic **retinopathy** or **macular** degeneration. Half the visual field may be impaired in patients with hemianopia. This results from a defect in the optic pathways in the brain and is often seen with stroke. Patients may report that the visual field appears blurry or hazy in corneal visual problems, cataracts, diabetic retinopathy, or refractive errors (Fig. 49–2).

Diagnostic Tests

Diagnostic tests are usually done to determine the exact cause of the blindness and may include a visual field examination, tonometry, and slit-lamp microscope examination. Retinal angiography is used to follow blood flow through the retinal vessels and to detect vascular changes. Ultrasonography may be used to visualize changes in the posterior eye that cannot be directly examined because of other pathological conditions, such as a cloudy cornea, a bloody vitreous, or an opaque lens.

Medical Treatment

Medical treatment for blindness centers on treating the underlying condition and preventing further impairment. Depending on the cause of the blindness, treatment may include medication prescription, surgical intervention, corrective eyewear prescription, and referral to supportive services.

Nursing Process: The Patient with Visual Impairment

ASSESSMENT. Collection of subjective data for assessment of visual impairment can be made using the WHAT'S UP? format (Table 49–3). Collection of objective data includes observations of the patient. Is there squinting? Rubbing of eyes? Is the patient using compensatory measures—magnifying glass, sitting close to television, using large-print reading materials, avoiding reading, using eyeglasses? Psychosocial data are important because a blind person may be withdrawn or socially isolated, have low self-esteem or poor coping mechanisms, or have poor interpersonal skills as a result of the visual impairment.

NURSING DIAGNOSIS. The major nursing diagnoses for visual impairment include but are not limited to the following:

- Disturbed sensory perception: visual related to altered sensory reception

retinopathy: retino—having to do with the retina + pathy—illness, disease, or suffering

Figure 49-2 Visual field abnormalities. (A) Normal vision. (B) Diabetic retopathy. (C) Cataracts. (D) Macular degeneration. (E) Advanced glaucoma.

TABLE 49-3 SUBJECTIVE ASSESSMENT OF VISUAL IMPAIRMENTS

W	Where is it? What part of the visual field is affected? If there is vision, what are the characteristics of what can be seen? Blurry? Hazy? Dark? Halos around lights?
H	How does it feel? Is there associated pain with the visual impairment? Headaches? How does it make the patient feel? Fearful? Anxious? Depressed? Helpless? Hopeless? Accepting?
A	Aggravating and alleviating factors. Is it worse when reading? Is it worse when watching TV? Does it affect the patient only at night? Is vision better at distances or close up?
T	Timing. When did the symptoms start? Do they come and go? Is the impairment progressively getting worse? Was onset sudden?
S	Severity. Does the impairment affect the patient's ADLs? If so, how severely? Does the patient need assistance to cook, dress, bathe, read mail, pay bills, access health care, obtain transportation, maintain household, shop?
U	Useful data for associated symptoms. Does the patient have diabetes, hypertension, a family history of retinitis pigmentosa, a history of eye infection, or eye trauma? Has the patient recently traveled out of the country?
P	Perception of the problem by the patient. What does the patient think is wrong? How severe does the patient perceive the impairment to be?

- Self-care deficit (specify area) related to visual impairment
- Risk for injury related to visual impairment
- Risk for impaired home maintenance related to lack of assistance, lack of rehabilitation, or other factors
- Interrupted family processes related to change in role secondary to visual impairment
- Ineffective role performance related to visual impairment, lack of rehabilitation
- Deficient knowledge related to disease process, prevention, and treatment due to lack of prior exposure
- Deficient diversional activity related to transition from sighted to visually impaired
- Fear related to blindness
- Anxiety related to sensory perception changes (visual)

See also Nursing Care Plan Box 49-3 for the Patient with Visual Loss.

PLANNING. A patient's level of independence must be included in the planning phase. If patients have minimal visual impairment or have attended rehabilitation, they may be able to function independently. If a patient has recently become visually impaired, he or she may be completely dependent until learning alternative ways of coping with this impairment. Planning focuses on meeting self-care needs, keeping the patient safe from injury, supporting the grieving process, and helping the patient acquire knowledge of agencies, services, and devices that allow maintenance of independence. Families must be included in the planning phase because they need to understand and be supportive of the self-image and role performance changes that may occur. Patient goals include the following:

- Maintains ability to complete activities of daily living with minimal assistance

BOX 49-3 NURSING CARE PLAN FOR THE PATIENT WITH VISUAL LOSS**Disturbed sensory perception: visual related to altered sensory reception****PATIENT OUTCOMES**

Patient will attain optimum level of sensory stimulation. Patient will become aware of visual impairment and ways to compensate. Patient will demonstrate ability to perform activities of daily living, with assistance if necessary.

EVALUATION OF OUTCOMES

Patient perceives maximum visual sensory input. Patient is able to compensate for sensory impairment by using other senses and resources. Patient is able to perform activities of daily living as independently as possible.

INTERVENTIONS

Assess visual acuity using a standard Snellen's vision chart. If the individual is unable to read letters, use directional arrows or pictures.

Assess visual fields using the cover test or confrontation test.

Structure environment to compensate for visual loss by adding color and contrast (e.g., chairs and carpeting should be in contrasting colors, bright tape or paint on stairs, medicine bottles color coded with colored dot stickers).

Structure environment to compensate for visual loss by use of large-print directional signs and arrows, well-lit areas, nonglare surfaces, consistent placement of objects, traffic areas free of clutter. Provide for optimum care of assistive appliances such as eyeglasses, including maintenance of proper prescription, fit, and cleaning. Introduce other assistive devices such as handheld magnifying glasses, tableside magnifiers, television magnifiers, large-print items, and phone dial covers with large numbers, talking watches, alarm clocks, and calculators.

Allow patient to verbalize feelings and grieving about visual loss.

Identify coping strategies that have been successful for patient in the past.

Refer to specialized clinician such as ophthalmologist or occupational therapist or to specialized resources such as American Federation for the Blind or Prevent Blindness America.

RATIONALE

Determines patient's ability to see.

Identifies deficits in visual fields.

Makes the environment easier to visualize and interpret and assists in depth perception and identifying medications.

Large directional signs assist the individual in maintaining orientation. Shiny floors or areas with bright window glass can impair vision.

Traffic areas free of clutter assist in preventing injury.

Improperly fitting or dirty eyeglasses may impair vision even further.

Older adults should have their eyeglass prescription checked yearly.

Patients may not be aware of assistive devices, which may help them adapt to visual loss and continue previous activities such as watching TV or reading letters and magazines. Allows people to rely on hearing rather than vision.

Losing a primary sense such as vision can be devastating for patients. Opportunity to ventilate feelings assists in processing the loss.

By identifying successful coping strategies, the nurse assists patient in dealing with stress or visual loss. A positive approach for nurses to use focuses on individual's capabilities rather than deficits.

Specialized clinicians can provide detailed examination and treatment for the disorder.

Specialized resource groups have networks in place to assist individuals in coping with loss and assisting with maximizing abilities.

EVALUATION

Does patient have 20/20 vision? Is there an impairment? If so, how severe is it?

Are visual fields of patient equal to examiner's? Is there a deficit? Is it bilateral or unilateral?

Does the environment have clearly delineated walkways, sitting areas, and doorways?

Are areas with changes in elevation clearly identified using contrasting tape or paint?

Is there a way for patient to safely self-administer medications?

Can the visually impaired individual identify locations such as bathroom, dining room, and office areas? Is the individual able to ambulate freely without safety hazards?

Do eyeglasses fit properly? Are lenses clean? Is prescription current?

Is patient aware of assistive devices that allow participation in previously enjoyed activities such as TV or reading? Is the visually impaired patient able to pay bills? Read mail? Communicate on telephone?

Is patient able to verbalize feelings about visual impairment and its loss?

Is patient able to identify successful coping strategies and use them to deal with the stress of visual impairment?

Does patient know who to call for detailed examination and treatment of problems? Does patient know that there are specialized clinicians and resource groups to help with the visual impairment? Does patient know how to access these specialists?

- Remains free of injury
- Demonstrates ability to access agencies and services for visually impaired
- Maintains healthy relationships among family members
- Maintains positive self-esteem
- Verbalizes understanding of disease process, prevention, and treatment
- Participates in diversional activities
- Verbalizes lessened fear or anxiety about perceptual changes

NURSING INTERVENTIONS. Nursing care begins by understanding how to interact with the visually impaired patient (Box 49-4). Patient teaching is included in the plan of care. The goal of the teaching is to promote independence and safety for the patient while in the hospital and in the home.

Organizations exist whose mission is to enhance the independence of visually impaired persons. Referring patients to these resources enhances their ability to maintain independence. Visit the following organizations:

- American Academy of Ophthalmology at www.eyenet.org
- Americans with Disabilities Act Document Center at www.janweb.icdi.wvu.edu/kinder
- Guide Dogs for the Blind at www.guidedogs.com
- National Association for Visually Handicapped at www.navh.org
- National Eye Institute at www.nei.nih.gov
- National Eye Care Project (for qualified seniors) at www.aas.org

BOX 49-4 Interacting with the Visually Impaired Patient

- People entering a room and at each contact with the patient should identify themselves.
- Post a sign on the door or over the bed that identifies the patient's visual status so that others can interact appropriately.
- Remember that the individual is not having hearing problems, so use a normal tone of voice and do not yell.
- Ask visually impaired patients what their needs are; do not assume they need help with everything.
- Do not hesitate to use the words *blind* and *see*.
- Talk directly to the impaired patient, not through a companion.
- At mealtime, explain the location of items on the tray by comparing their position to the numbers on a clock (e.g., milk is at 2 o'clock, peas are at 7 o'clock).
- Explain any activity going on in the room or within the patient's auditory range.
- Explain procedures before beginning them. Speak to the patient before touching.
- When walking, allow the patient to grasp an assistant's arm and walk a half step behind. Be aware of obstacles on either side when walking.
- When seating a patient, place the patient's hand on the arm of the chair.
- Tell the patient when leaving the room or area so the patient does not continue conversation in an empty room, which may cause embarrassment.
- When orienting the patient to the hospital room, explain the location of items the patient may need, such as the water pitcher, call light, bed controls, urinal, tissues. Attempt to keep these items in the same place at all times.
- If the patient has a Seeing Eye dog, do not play with the dog, pet it, or feed it without consulting the patient—the dog is working! Make sure the patient's dog is near the bed, on a mat provided especially for the dog, preferably on the side of the bed that is less likely to be used by staff. Instruct staff and visitors about the Seeing Eye dog.

- Talking books: National Library Service for the Blind and Visually Handicapped at <http://lcweb.loc.gov/nls/nls.html>

EVALUATION. Evaluation of the nursing care plan is based on patient attainment of goals. The goals for the visually impaired patient are met if the following occur:

- Demonstrates ability to complete activities of daily living with increasing independence
- Remains free of injury
- Demonstrates ability to assess agencies and services for visually impaired
- Maintains healthy relationships among family members
- Maintains positive self-esteem
- Verbalizes understanding of disease process, prevention, and treatment
- Participates in diversional activities
- Verbalizes lessened fear or anxiety about perceptual changes

Diabetic Retinopathy *Pathophysiology and Etiology*

Retinopathy is a disorder in which there are vascular changes in the retinal blood vessels. The most common incidence of retinopathy is found in persons with diabetes. It is estimated that half of the people with diabetes in the United States have at least early signs of retinopathy. The pathological changes that occur with diabetic retinopathy are related to excess glucose, changes in the retinal capillary walls, formation of microaneurysms, and constriction of retinal blood vessels. Three stages of diabetic retinopathy have been identified: background retinopathy, preproliferative retinopathy, and proliferative retinopathy.

Background retinopathy is the earliest stage, in which microaneurysms form on the retinal capillary walls. These microaneurysms may leak blood into the central retina or macula. If the leakage causes edema, the patient may notice a decrease in color discrimination and visual acuity.

The second stage, preproliferative retinopathy, is characterized by swollen and irregularly dilated veins, which results in sluggish or blocked blood flow. Patients generally are not aware of this stage because there are no symptoms.

Proliferative retinopathy, the third stage, is characterized by the formation of new blood vessels growing into the retinal and optic disc area as an attempt to increase the blood supply to the retina. The newly formed blood vessels are fragile and often leak blood into the vitreous and retina. In addition to leaking, the newer vessels may grow into the vitreous, which causes a traction effect, pulling the vitreous away from the retina and subsequently pulling the retina away from the choroid. This condition is called retinal detachment (discussed later).

Signs and Symptoms

Individuals may experience a reduction in central visual acuity or color vision as a result of macular edema. (See Fig. 49-2.) Many patients with diabetic retinopathy do not have any symptoms until the proliferative stage, at which point

vision is lost. Visual loss at the last stage usually cannot be restored.

Diagnostic Tests

Diabetic retinopathy, as well as the other retinopathies, can be diagnosed only on examination of the internal eye. The examination is conducted with an ophthalmoscope following dilation of the pupil using a cycloplegic agent. The examination may be enhanced by use of retinoangiography. In the initial stages, vessels may appear swollen and tortuous (twisted).

Medical Treatment

Treatment of diabetic retinopathy focuses on stopping the leakage of blood and fluid into the vitreous and retina. The leaking microaneurysms are sealed by use of laser photocoagulation. (See Box 49–2.) If blood has already leaked into the vitreous, a vitrectomy is performed. During a vitrectomy, the vitreous humor is drained out of the eye chamber and replaced with saline or silicon oil. The replacement fluid is necessary to support the structures of the eyeball until healing can occur. Further treatment may be needed if the patient has sustained retinal detachment.

Complications

Early treatment for diabetic retinopathy is highly successful in preventing further visual loss; however, visual loss cannot be reversed. For this reason it is very important for patients with diabetes to have a comprehensive eye examination through dilated pupils at least once each year or as directed by their physician. Careful control of diabetes during the first 5 years following diagnosis reduces the occurrence and delays the onset of diabetic retinopathy.

Nursing Process: The Patient with Retinopathy

ASSESSMENT. Nursing assessment for diabetic retinopathy focuses on risk factors associated with the incidence of the disease. The patient may not have any symptoms. If patients with diabetes do have changes in perceptions of visual acuity or color discrimination, they should immediately contact their physician.

NURSING DIAGNOSIS. Nursing diagnoses for diabetic retinopathy include but are not limited to the following:

- Risk for (or actual) impaired home maintenance
- Risk for (or actual) ineffective therapeutic regimen management
- Disturbed sensory perception: visual related to altered sensory reception and transmission

PLANNING. The planning phase of the nursing process focuses on prevention of visual loss by early detection and treatment. If the patient has entered phase three and is already visually impaired, the nursing care plan for the visually impaired patient is used. Additionally, planning includes a method for monitoring blood glucose and for drawing up and administering the correct amount of insulin

for the visually impaired patient with diabetes. Specialty devices are available that can be preset to draw up amounts of insulin for the visually impaired patient with diabetes. Family members may have to assist the patient.

NURSING INTERVENTIONS. Nursing interventions for diabetic retinopathy focus on preventive eye care. Patients are taught the importance of yearly comprehensive eye examinations. Assisting patients to keep their diabetes under control also helps reduce the onset of this condition. If the patient with diabetes has experienced visual loss, nursing interventions focus on assisting the individual with home and health maintenance.

EVALUATION. Patient goals are met if the patient is able to do the following:

- Manage home maintenance
- Manage therapeutic regimen
- Prevent further visual impairment via preventive care (e.g., manage blood sugars within normal limits)

Retinal Detachment Pathophysiology and Etiology

Retinal detachment is a separation of the retina from the choroid layer of the eye that allows fluid to enter the space between the layers. There are three types of retinal detachment:

1. Rhegmatogenous retinal detachment is caused by a hole or tear in the retina that allows fluid to flow between the two layers. The tears are related to degenerative changes in the retina or vitreous. This type of retinal detachment can also be precipitated by moderate trauma, such as stooping or lifting weights, or by direct trauma to the eye. The incidence of rhegmatogenous detachment increases with age.
2. Nonrhegmatogenous tractional detachment occurs when fibrous tissue in the vitreous humor attaches to the sensory retina and, as it contracts, pulls the retina away from its normal position. It occurs in patients with sickle cell disease or diabetes mellitus.
3. Exudative detachment occurs when fluid or exudate accumulates in the subretinal space and separates the layers. Exudative detachment occurs most often in conditions such as advanced hypertension, pre-eclampsia, or eclampsia and from intraocular tumors.

Signs and Symptoms

Patients experiencing a retinal detachment report a sudden change in vision. Initially, as the retina is pulled, “flashing lights” are reported, and then “floaters” are seen. The flashing lights are caused by vitreous traction on the retina, and the floaters are caused by the hemorrhage of vitreous fluid or blood. When the retina detaches, the patient describes it as “looking through a veil” or “cobwebs” and finally “like a curtain being lowered over the field of vision,” with darkness resulting. There is no pain because the retina does not contain sensory nerves. On visual examination the patient

generally has a loss of peripheral vision when the visual fields are tested and a loss of acuity in the affected eye.

Diagnostic Tests

Indirect ophthalmoscopy is used by the physician to examine the interior of the eye. This examination allows the examiner to visualize the retina, which may be pale, opaque, and in folds with retinal detachment. The examiner is able to diagnose the type of detachment based on this examination. If there are lesions in the eye, the slit-lamp examination allows the examiner to magnify the lesions.

Medical Treatment

Prompt medical treatment must be sought to prevent loss of vision. One of several procedures may be performed to reattach the retina to prevent blindness.

- Laser reattachment involves focusing a laser beam on the detached area of the retina and causing a controlled burn, which reattaches the layers together by forming an adhesion. (See Box 49–2.) This procedure is used when only a small area of the retina is involved.
- Cryosurgery involves the placement of a supercooled probe on the sclera. The probe causes injury to the tissue, forming an adhesion, a principle similar to the laser procedure.
- Electrodiathermy, the least used procedure, involves placement of an electrode needle into the sclera to allow fluid that has accumulated to drain. The retina later adheres to the choroid layer.
- Scleral buckling is a surgical procedure that involves placing a silicon implant in conjunction with a beltlike device around the sclera to bring the choroid in contact with the retina. Cryosurgery or laser is used before the buckling procedure to seal the tear and form a scar that helps adhere the retina and choroid layers together.
- Pneumatic retinopexy is a procedure that can be conducted in the physician's office and is time consuming for the patient. This procedure involves injecting air or gas into the chamber to hold the retina in place. The patient must be extremely compliant with the treatment regimen, reclining for about 16 hours before the procedure to allow the retina to fall back toward the choroid. Because air rises, the patient must maintain a position that keeps the air bubble against the detached area for up to 8 hours a day for 3 weeks.

Complications

With any of the retinal reattachment procedures there is risk of increased intraocular pressure (IOP) and recurrent detachment. The patient is also at risk for future breaks in the retina.

Nursing Process: The Patient with Retinal Detachment

Nursing process for patients with retinal detachment can be found in the section on nursing process for patients undergoing eye surgery. Assessment data specific to retinal detachment follows.

ASSESSMENT. Subjective data collected includes patient observation of the loss of peripheral vision, any change in visual acuity, and the presence of floaters, flashing lights, cobwebs, or veil-like visual impairments. There should be an absence of pain. Objective data collected includes the patient's visual acuity, visual fields, ability to perform ADLs, and level of anxiety.

CRITICAL THINKING

Mr. Samuel
Mr. Samuel, age 65, is working in the yard when a branch strikes his right eye. He sees flashes of light and then a short time later a dark shadow out of the right eye.

1. What should Mr. Samuel do?
2. After having a scleral buckling procedure, Mr. Samuel reports nausea. What action should you take?

Answers at end of chapter.

Glaucoma

Glaucoma is a group of diseases characterized by abnormal pressure within the eyeball. This pressure causes damage to the cells of the optic nerve, the structure responsible for transmitting visual information from the eye to the brain. The damage is silent, progressive, and irreversible until the end stages, when loss of peripheral vision occurs, followed by reductions in central vision and eventually blindness. (See Fig. 49–2.) Once glaucoma occurs, the patient will always have it and must follow treatment to maintain stable intraocular eye pressures.

Pathophysiology

The most common form of glaucoma, called primary, consists of two types: primary open-angle glaucoma (POAG) and acute angle-closure glaucoma (AACG). Secondary glaucoma may be caused by infections, tumors, or injuries. A third form, congenital glaucoma, primarily is due to developmental abnormalities.

AACG occurs in people who have an anatomically narrowed angle at the junction where the iris meets the cornea. When nearby eye structures such as the iris protrude into the anterior chamber, the angle is occluded, which blocks the flow of aqueous fluid. This is considered a medical emergency and results in partial or total blindness if not treated. POAG occurs when the drainage system of the eye, the trabecular meshwork and Schlemm's canal, degenerate and subsequently block the flow of aqueous humor.

Etiology and Prevention

The incidence of AACG is highest among Asians, women older than age 45, and nearsighted individuals; the incidence of POAG increases in those older than 40 years of age (older than age 50 for European-Americans, older than age 35 for African-Americans), in persons with diabetes, and in those with a family history of glaucoma and is four to five times more prevalent in African-Americans than Euro-

pean-Americans. Those in high-risk groups should have yearly eye examinations for glaucoma detection.

Signs and Symptoms

An ophthalmic emergency, AACG typically has a unilateral, rapid onset. The patient may complain of severe pain over the affected eye, blurred vision, rainbows around lights, eye redness, a steamy-appearing cornea, photophobia, and tearing. Nausea and vomiting may occur from the increased IOP.

POAG develops bilaterally. The onset is usually gradual and painless, so the patient may not experience noticeable symptoms or after time may experience mild aching in the eyes, headache, halos around lights, or frequent visual changes that are not corrected with eyeglasses.

Diagnostic Tests

Traditionally, tonometry is utilized to detect increased IOP (normal IOP: 12 to 20 mm Hg). Applanation tonometry uses a tiny instrument to apply pressure to the anesthetized cornea. Noncontact tonometry is performed with a tonometer mounted on a slit-lamp microscope using a warm puff of air that flattens an anesthetized area of the cornea to obtain a pressure reading. In contact tonometry the instrument is placed directly on the anesthetized cornea to measure eye pressure. Tonometry is not adequate to detect glaucoma alone, so three other methods are used. The optic nerve is examined with an ophthalmoscope through dilated pupils, visual field examination looks for loss of peripheral vision, and the angle where the iris meets the cornea is checked. In AACG, IOP may exceed 50 mm Hg. A new glaucoma screening device, the GDx Access, uses infrared laser technology to measure the thickness of the retinal nerve fiber layers to identify damage to the fibers. The advantages of this diagnostic tool are that it catches glaucoma earlier than other tests, which allows greater vision to be saved with treatment, and it is painless.

Medical Treatment

The first-line treatment for glaucoma focuses on opening the aqueous flow by administering cholinergic agents (**miotics**) such as carbachol (Isopto) or pilocarpine (Pilocar) to constrict the pupil. When the pupil is constricted, the iris pulls away from the drainage canal so that the aqueous fluid can flow freely. A second type of medication may be given to slow the production of aqueous fluid. These included carbonic anhydrase inhibitors such as acetazolamide (Diamox), adrenergic agonists such as dipivefrin (Propine), or beta blockers such as timolol (Timoptic). Slowing the aqueous fluid production helps decrease IOP. Additionally, the physician may order steroid eye drops to reduce inflammation. The patient experiencing an acute attack of AACG is given these medications and mannitol, a hyperosmolar agent, to rapidly reduce IOP, as well as analgesics and ordered to stay maintain complete bedrest.

Patients with glaucoma are required to administer life-long eye-drop medications twice or more daily. In the absence of symptoms, compliance is often an issue. Other fac-

tors that contribute to noncompliance include age of the patient, inability to afford the medication, and lack of understanding of the disease process. Patients need to carry medical alert identification indicating they have glaucoma and what their medications are. This can help prevent administration of contraindicated medications in emergency situations.

Certain medications, regardless of their route, are contraindicated in AACG and can result in blindness if given to a patient with AACG. These medications include any anticholinergics such as atropine and antihistamines such as diphenhydramine (Benadryl) or hydroxyzine (Vistaril) because they are mydriatics. Before a medication is given, it should be determined that it is not contraindicated in glaucoma to prevent blindness from occurring.

LEARNING TIPS

- Mydriatic medications are contraindicated in acute angle-closure glaucoma because they can cause an acute episode of increased IOP by dilating the pupil and pushing the iris back, blocking the outflow of aqueous humor.
- Miotic medications constrict the pupil and so may be given to patients with acute angle-closure glaucoma.
- To remember what miotic medications and mydriatic medications do, so that the appropriate medication is given and contraindicated ones are never given, remember the following:

D = dilate = mydriatic = do not give
No **D** = constricts = miotic = okay to give

Surgical Management

When medication is no longer able to control the aqueous humor flow, surgical intervention may become necessary. Surgery focuses on creating an area for the aqueous humor to flow freely, thus preventing increased IOP. For AACG, laser peripheral iridotomy or surgical iridectomy is performed. Laser iridotomy is a noninvasive procedure utilizing a laser to remove a portion of the iris, thus allowing aqueous fluid to flow through the area. Prophylactic iridotomy may be performed on the other eye to prevent AACG. POAG is treated with argon laser trabeculoplasty (noninvasive laser beam creates openings in trabecular meshwork), trabeculectomy (part of iris and trabecular meshwork removed), or cyclocryotherapy (cryoprobe destroys part of ciliary body) (Fig. 49–3).

Nursing Process: The Patient with Glaucoma

ASSESSMENT. The patient should be assessed for loss of both central and peripheral vision, discomfort, understanding of disease and compliance with treatment regimen, and ability to conduct activities of daily living.

NURSING DIAGNOSIS. Nursing diagnoses may include the following:

- Pain related to increased intraocular pressure
- Disturbed sensory perception: visual related to altered sensory reception

Figure 49-3 Flow of aqueous humor after trabeculoplasty (arrows).

- Self-care deficit related to decreased vision
- Anxiety related to partial or total visual loss
- Risk for injury related to decreased vision
- Impaired home maintenance related to decreased vision
- Deficient knowledge related to medical regimen, disease process due to no prior experience

PLANNING. Planning for nursing interventions needs to take into account the patient's level of understanding of disease process and medical regimen and ability to comply with the time-consuming medication regimen. The goal of nursing care for the glaucoma patient is to prevent further visual loss and to promote comfort if the patient is experiencing pain as in acute glaucoma. The patient who needs surgical intervention has additional goals (see Nursing Process: The Patient Having Eye Surgery).

NURSING INTERVENTIONS. The patient is taught how to administer medications and performs a return demonstration to ensure that eye drops are administered properly. If the patient has trouble with a steady hand when administering eye drops, teach the patient to rest his or her hand on the forehead to steady the hand. If the patient is unable to see the label on the eye drop bottle, consider large-print labels or audiotaped directions. For patients with multiple medications, consider using large, multicolored dot stickers placed on medication bottle with a corresponding direction card with a matching colored dot.

Patients are taught the need for having regular eye examinations through dilated pupils. Family members should also be advised that they are at increased risk of developing glaucoma and should have regular eye examinations.

Analgesics are given as needed for acute glaucoma. The patient is also assisted with self-care as needed. Patients are allowed to verbalize their concerns about losing their sight. Other interventions that may be implemented if the patient is experiencing severe visual loss or having surgery are in the nursing process sections for impaired vision and the patient having eye surgery, respectively.

EVALUATION. Patient goals are met if the patient does the following:

- Maintains an acceptable level of comfort
- Has no further loss of vision
- Is able to care for self with assistance if needed
- Expresses concerns and anxieties
- Does not suffer injury as a result of the visual impairment
- Is able to manage home maintenance with assistance if needed
- Demonstrates correct instillation of eye medications
- Is able to verbalize understanding of condition and treatment

Cataracts

Pathophysiology and Etiology

A cataract is an opacity in the lens of the eye that may cause a loss of visual acuity. (See Fig. 49-2.) Vision is diminished because the light rays are unable to get to the retina through the clouded lens.

Factors that contribute to cataract development may include age, ultraviolet radiation (sunlight), diabetes, smoking, steroids, nutritional deficiencies, alcohol consumption, intraocular infections, trauma, and congenital defects.

Signs and Symptoms

Cataracts are painless. Symptoms of cataract formation may include halos around lights, difficulty reading fine print or seeing in bright light, increased sensitivity to glare such as when driving at night, double or hazy vision, and decreased color vision.

Diagnostic Tests

Cataract formation is diagnosed through an eye examination. Visual acuity is tested for near and far vision. The direct ophthalmoscope and slit-lamp microscope are used to examine the lens and other internal structures.

Surgical Treatment

The only treatment for cataract formation is surgical removal of the cloudy lens. With the no-stitch cataract operation, there are no postoperative activity restrictions and vision is fine in about 2 days. After the lens is removed, there are several treatment options to correct the visual deficit that occurs when the eye is aphakic (absence of lens) and cannot accommodate or refract light properly. One treatment option is to provide the patient with eyeglasses or contact lenses that help correct the visual deficit. Another option is to replace the lens with a synthetic intraocular lens. For more information, visit the American Society of Cataract and Refractive Surgery at www.ascrs.org.

Complications

Complications of cataract surgery are rare but include inflammation, increased IOP, macular edema, retinal detachment, vitreous loss, hyphema, endophthalmitis, and expulsive hemorrhage.

Nursing Process: The Patient with Cataracts

Preoperative and postoperative nursing care is the primary nursing responsibility for the patient with cataracts. The pa-

tient is assessed for visual deficits to assist care planning, as well as knowledge needs about the disease process, surgical intervention, postoperative care, and medical regimen. The majority of patients undergoing cataract surgery have same-day surgery and then go home. The home situation, the ability of the patient or family member to follow the medical regimen, and transportation to and from the hospital for the patient are evaluated.

Nursing Process: The Patient Having Eye Surgery

Assessment

Subjective assessment data for patients having eye surgery can be collected using the WHAT'S UP? format (Table 49-4). Objective data may include visual acuity and peripheral field measurements. Visual acuity should be tested with and without corrective lenses. Eye tearing, redness, or swelling is noted.

Nursing Diagnosis

Nursing diagnoses for the patient undergoing eye surgery may include but are not limited to the following:

- Disturbed sensory perception: visual related to altered sensory reception
- Deficient knowledge related to preoperative and postoperative eye care
- Risk for infection related to surgical procedure
- Risk for injury related to altered visual acuity
- Anxiety related to visual alteration
- Fear related to surgery

Planning

The patient goals are to remain free of injury, to prevent further visual impairment by rapid diagnosis and treatment, and to have minimal anxiety surrounding the visual alteration, treatment, and recovery.

Nursing Interventions

A key nursing intervention involves patient teaching about the disease process, surgical intervention, preoperative and postoperative activity restrictions, use of dark glasses to decrease the discomfort of photophobia, use of correct technique for administration of eye medications, reporting for medical follow-up as instructed, and protecting the eye from

further injury. In some types of cataract surgery, patients may be advised to avoid activities that might increase intraocular pressure, such as vomiting, coughing, sneezing, straining, or bending over. They should not drive a car. They are told to return to the hospital if they experience sudden, worsening pain, increase in watery or bloody discharge, or sudden loss of vision, because these are signs of hemorrhage.

Anxiety is reduced by allowing patients the opportunity to discuss their feelings about the visual loss, by answering questions honestly, and by explaining any restrictions in activity. To help prevent injury, patients should be aware that their depth perception may be affected, which can result in falls. Patient should walk carefully and use clearly marked stairs. To prevent spills and slippery floors, beverages can be poured ahead of the surgery and stored in the refrigerator in single-serving glasses.

Evaluation

The patient goals have been met if the following occur:

- The patient is able to regain visual loss as a result of corrective treatment
- Injury is prevented
- Anxiety is lessened

Macular Degeneration

Pathophysiology and Etiology

Age-related macular degeneration (ARMD) is the leading cause of visual impairment in U.S. residents older than age 50. It involves a deterioration in the macula, the area on the retina where light rays converge for the sharp, central vision needed for reading and seeing small objects. The macula is also responsible for color vision (Fig. 49-4). There are two types of ARMD: dry (atrophic) and wet (exudative). In the dry form, photoreceptors in the macula fail to function and are not replaced because of advancing age. This accounts for 70 to 90 percent of the cases. In the wet form, retinal tissue degenerates, allowing vitreous fluid or blood into the subretinal space. New blood vessels are formed and compromise the macular tissue, causing subretinal edema. Eventually, fibrous scar tissue is formed, severely limiting central vision.

People at risk of developing macular degeneration include those older than age 60, those with a family history of macular degeneration, persons with diabetes, people who

W	Where is the visual disturbance? Is it centrally located? Peripherally? Throughout the entire visual field? Unilateral? Bilateral?
H	How does it feel? Painful? Is there an absence of pain?
A	Aggravating or alleviating factors. Is it worse in bright light or at night? Better when resting eyes or with head of bed elevated?
T	Timing. Was there a sudden onset? Gradual onset?
S	Severity. Does it affect ADLs? Does it affect close-up work?
U	Useful data for associated symptoms. Does the patient suffer from hypertension? Diabetes? Has there been trauma? Vascular disease? What is the level of anxiety? Is the patient older than age 50?
P	Perception of the problem by the patient. Will the visual disturbance impair ability to carry out ADLs? Ability to comply with medical regimen? Ability to manage home maintenance?

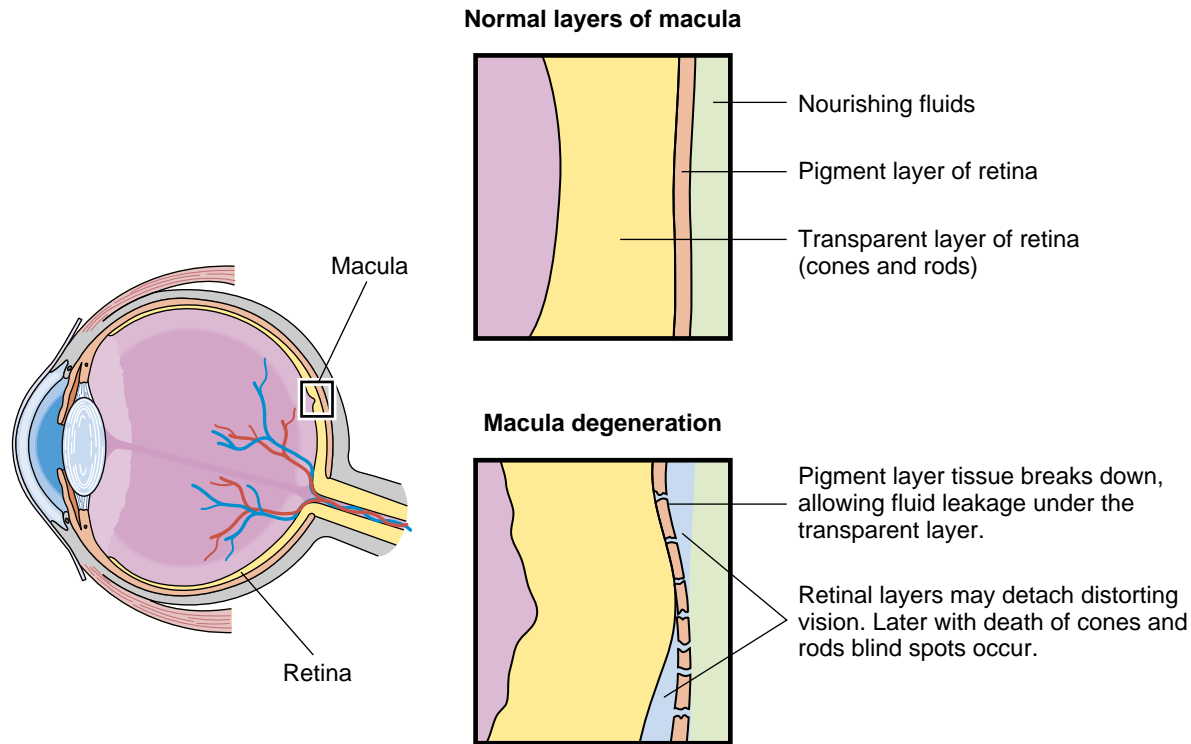

Figure 49-4 Macular degeneration. The macula is a small area of the retina responsible for central and color vision.

smoke, those frequently exposed to ultraviolet light, and Caucasian people.

Signs and Symptoms

Macular degeneration of the dry type is characterized by slow, progressive loss of central and near vision. (See Fig. 49-2.) Although individuals usually have the condition in both eyes, each eye may be affected in different degrees. Macular degeneration of the wet type has the same loss of central and near vision, but the onset is sudden. The loss can occur in one or both eyes. This visual loss is described as blurred vision, distortion of straight lines, and a dark or empty spot in the central area of vision. For some patients there may be a decreased ability to distinguish colors.

Diagnostic Tests

Examination of the patient begins with visual acuity for near and far vision and an examination of the internal eye structures with an ophthalmoscope. The examiner uses an Amsler grid (Fig. 49-5) to detect central vision distortion and a color vision test to evaluate color differences. Patients are given an Amsler grid to take home and look at on a regular basis to monitor their vision changes. If any of the grid lines look crooked or disappear, the patient should contact the physician. Intravenous fluorescein (dye) angiography to look at the retina may also be utilized to evaluate blood vessel leakage or abnormalities in the eye.

Medical Treatment

Unfortunately, there is no treatment for the dry type of ARMD. Most patients with the dry type do not lose pe-

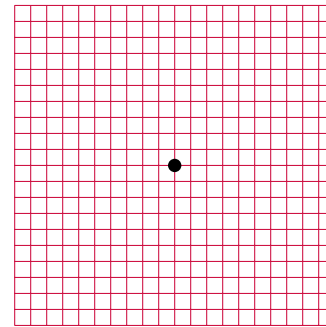

Figure 49-5 Amsler grid is used to identify central vision blind spots or distortions.

ripheral vision or become totally blind, but most are classified as legally blind (less than 20/200 vision with correction). Special low-vision lenses can enhance remaining vision. If the wet type of ARMD is diagnosed early, argon laser photocoagulation can seal the leaking blood vessels, slowing the rate of vision loss. If the patient receives argon laser photocoagulation, there is a small, permanent blind spot at the point of laser contact with the macula. With either type of ARMD, patients have significant visual loss and need to adapt their patterns of daily living.

Research is exploring cell transplant in an attempt to provide a cure in the future. Studies are focusing on transplanting retinal pigmented epithelial cells that grow and function normally.

Nursing Process

See the nursing process section for the visually impaired.

Trauma

Emergencies and trauma of the eye must be assessed immediately so that proper treatment can be initiated. Injuries to the eye include foreign bodies, burns, abrasions, lacerations, and penetrating wounds. Treatment for chemical burns and sudden, painless loss of vision should be initiated within minutes to preserve vision.

Pathophysiology and Etiology

Foreign bodies are the most common cause of corneal injury. Dust particles or propellants may lodge in the conjunctiva or cornea. Patients naturally rub their eyes to dislodge the object, which further irritates the cornea. Burns may occur from chemical, ultraviolet, and direct heat sources. Depending on the agent causing the burn, it may be superficial or deep. Abrasions and lacerations usually occur as a result of something dragging across the eye, such as a fingernail or clothing.

Penetrating wounds are the most serious eye injury. Eye structures may be damaged permanently with complete blindness resulting. A penetrating wound also puts the patient at great risk of infection.

Signs and Symptoms

Foreign bodies produce pain when the eyeball or eyelid moves, causing the foreign body to drag over the opposing surface. Usually the eye tears excessively in an attempt to irrigate the noxious substance out of the eye.

Injuries that irritate or penetrate layers of the cornea range from mild to severe pain. With corneal abrasions, the pain sensation may be delayed for several hours. Other symptoms that may be seen with abrasions, lacerations, and foreign bodies include conjunctival redness, photosensitivity, decreased visual acuity, erythema, and pruritus.

Acute pain and burning are characteristic symptoms of a burn to the eye. Chemical burns must be treated immediately with an eyewash or irrigation to remove the caustic substance from the eye.

Penetrating wounds may result in a variety of symptoms depending on the area of the eye involved and the extent of the damage. If the nerve has been damaged, the patient may have no pain.

Diagnostic Tests

With any eye trauma or injury, visual acuity must be tested. It is important to establish baseline acuity to evaluate effectiveness of treatment, although many patients resist acuity testing because of the discomfort. Testing includes examination by slit-lamp microscope and direct ophthalmoscope. Fluorescein staining is used to evaluate abrasions.

Medical Treatment

Foreign bodies are treated with a normal saline flush to irrigate the object out of the eye or to a point where it can be

removed with a swab. Topical antibiotic ointment is prescribed to prevent infection.

Most chemical burns are treated with a 15- to 20-minute irrigation of either tap water at the work site or sterile solution in the health care facility. Topical antibiotic ointments are usually prescribed. Burns from heat or ultraviolet (UV) radiation are not irrigated.

Abrasions and lacerations are generally treated with anti-infective ointments or drops after cleansing the eye with a normal saline solution.

An eye specialist treats penetrating wounds. At initial injury, both eyes should be covered to prevent ocular movement. If there is a protruding object, it should be stabilized but not removed until the physician can assess the patient. The nature and extent of the penetrating wound determine treatment.

Complications

If the eye cannot be saved via medical treatment, it may be necessary to surgically remove the eye. This procedure is called **enucleation** (entire eyeball removal).

Nursing Process: The Patient with Eye Trauma

ASSESSMENT AND INTERVENTION

Foreign bodies. The eye is inspected for foreign bodies, which may be visible on the eyeball. The lids should be everted to examine the surface. Then the eye is irrigated.

Burns. Assessment of the type of burn is done because treatment options vary. Immediate irrigation of the eyes is performed once it has been established that a chemical burn has taken place. Medication and eye patching are done as indicated.

Abrasions and Lacerations. The eye is assessed for visible lacerations and then cleansed with medication and patching of the eye as indicated.

Penetrating Wounds. The patient is kept calm and relaxed to minimize eye movement and increased IOP. If a protruding object is present, the object is stabilized with tape or other supports.

NURSING DIAGNOSIS. Nursing diagnoses for the patient with eye trauma include the following:

- Acute pain related to inflammatory process and injury
- Disturbed sensory perception related to trauma or disease of the eye
- Risk for infection
- Anxiety related to visual-sensory deficit
- Deficient knowledge related to medical regimen due to lack of prior experience

PLANNING. Planning for the eye trauma patient must take into account the ability of the patient to carry out the medical regimen, to verbalize concerns about the visual alteration, and to verbalize comfort levels.

enucleation: e—removed from + nuclear—center

EVALUATION. Patient goals have been met if the following occur:

- Pain level is within an acceptable range for the patient
- Vision is retained
- Patient remains free of infection
- Patient is able to verbalize a reduction in anxiety
- Patient is able to verbalize care of the eye

▶ HEARING

Hearing Loss

Hearing loss is the most common disability in the United States and can be acquired or congenital. Hearing impairment ranges from difficulty understanding words or hearing certain sounds to total deafness. Hearing impairment can affect communication, social activities, and work activities. Hearing impairment can diminish the individual's quality of life. Nurses have a responsibility to communicate with the hearing impaired and provide necessary information regarding health care. For more information on hearing impairment, visit the following sites:

- American Academy of Ear, Nose and Throat at <http://entnet.org>
- Canadian Hard of Hearing Association at www.cyberus.ca/~chhanational/english.html
- National Information Center on Deafness at www.galludet.edu/~nicd
- National Institute on Deafness and Other Communication Disorders at www.nidcd.nih.gov
- National Organization for the Deaf at www.nad.org

Conductive Hearing Loss

Conductive hearing loss is any interference with the conduction of sound impulses through the external auditory canal, the eardrum, or the middle ear. The inner ear is not involved in a pure conductive hearing loss. Conductive hearing loss can be caused by anything that interferes with the ability of the sound wave to reach the inner ear. Conductive hearing loss is a mechanical problem. Causes of conductive hearing loss include cerumen, foreign bodies, infection, perforation of the tympanic membrane, trauma, fluid in the middle ear, cysts, tumor, and **otosclerosis**. Many causes of conductive hearing loss, such as infection, foreign bodies, and impacted cerumen, can be corrected. Hearing devices may improve hearing for conditions that cannot be corrected, such as scarred tympanic membrane or otosclerosis. Hearing devices are most effective with conductive hearing loss when no inner ear and nerve damage are present.

Sensorineural Hearing Loss

Sensory hearing loss originates in the cochlea and involves the hair cells and nerve endings. Neural hearing loss originates in the nerve or brainstem. **Sensorineural** hearing loss results from disease or trauma to the sensory or neural components of the inner ear. Some of the causes of nerve deaf-

ness are complications of infections (such as measles, mumps, and meningitis), ototoxic drugs (Table 49–5), trauma, noise, neuromas, arteriosclerosis, and the aging process.

Presbycusis is hearing loss caused by the aging process that results from degeneration of the organ of Corti. This degenerative process usually begins in the fifth decade of life. The individual develops an inability to decipher high-frequency sounds (consonants *s, z, t, f, g*). This interferes with the individual's ability to understand what has been said, especially in noisy environments. The aging individual commonly has more difficulty understanding higher-pitched female voices than lower-pitched male voices.

Other Types of Hearing Loss

Mixed hearing loss occurs when an individual has both conductive and sensorineural hearing loss. This can be caused by a combination of any of the disorders previously mentioned. Central hearing loss occurs when the central nervous system cannot interpret normal auditory signals. This condition occurs with such disorders as cerebrovascular accidents and tumors. Functional hearing loss is a hearing loss for which no organic cause or lesion can be found. It is also called psychogenic hearing loss and is precipitated by emotional stress.

Medical and Surgical Management

Medical management consists of improving the patient's hearing. The majority of persons with ear disorders have some degree of hearing loss. With any permanent hearing loss, the use of a hearing aid should always be considered. A hearing aid is designed to amplify sound or attenuate certain portions of the sound signal and amplify other sounds. Various types of hearing aids are available (Fig. 49–6). The in-the-ear aid is a small device that fits in the ear canal. The in-the-ear aid is unobtrusive and may be preferred by the individual. The behind-the-ear aid is worn postauricular. The all-in-one eyeglass aid is attached to glasses and is positioned behind the ear. An older model is the body-worn hearing aid worn around the neck or connected to clothing.

Indomethacin	Methotrexate
Quinidine	

otosclerosis: oto—ear + sclerosis—hardening

Figure 49-6 Hearing aids. (A) Behind-the-ear hearing aid. (B) In-the-ear hearing aid.

Surgical intervention may be available for patients whose hearing is not improved with hearing aids. Implantable middle ear hearing aids can improve sound perception for patients with moderate-to-severe sensorineural hearing loss. Cochlear implants are surgically placed electrical devices that receive sound and transmit the resulting electrical signal to electrodes implanted in the cochlea of the ear. The signal stimulates the cochlea, allowing the patient to hear. The cochlear implants are able to restore up to half of the patient's hearing.

Nursing Management

Nursing management includes identifying those patients at risk for hearing impairment. Patients with renal or hepatic disease, using two or more ototoxic drugs, or previously having used ototoxic drugs are at risk for developing hearing impairment. Monitor for signs of vertigo, horizontal nystagmus, nausea, vomiting, and spinning or rocking sensation while sitting still.

Nursing management for the patient with hearing impairment focuses on enhancing communication and quality of life (Nursing Care Plan Box 49-5 for the Patient with Hearing Loss). Social isolation may be more pronounced for the hearing impaired than it is for the visually impaired. Families should be included in discussions about therapeutic hearing devices and their care, enhancing communication, and limiting isolation.

Nursing Process: The Patient Who Is Hearing Impaired

ASSESSMENT. To collect assessment data for the hearing impaired patient, ask family members, as well as the patient, questions related to the patient's hearing status. Assessment of symptoms for the patient with hearing impairment includes gathering subjective data using the WHAT'S UP? format (Table 49-6).

Objective data focus on obtaining a gross screening of hearing function. Assessment should start with engaging in

TABLE 49-6 SUBJECTIVE ASSESSMENT OF HEARING IMPAIRMENT

W	Where is it? Are both ears affected? Is one side worse than the other?
H	How does it feel? Are certain words unclear, or entire conversations? Are high-frequency sounds (consonants s, t, z, f, g, and female voices) unclear or difficult to understand? Is there any pain associated with the hearing loss? Any tinnitus or vertigo?
A	Aggravating and alleviating factors. Is hearing worse in large groups or when there is a lot of background noise? Is hearing improved in a quiet environment or when speaking only to an individual? Is it easier to understand someone when seeing the person's lips move? Does the patient own or use any assistive hearing devices? Are they effective? What type is used?
T	Timing. When did the hearing loss start? Was it gradual or sudden? Is the hearing loss associated with any illness or traumatic event? Is it associated with any recent flying? Any history of ototoxic drug use?
S	Severity. Does it cause communication impairment? How much? Does it affect ADLs? Does it affect or limit usual social activities? Have family or friends commented on decreased hearing? Does patient avoid communication or social activities because of difficulty hearing? Is patient having difficulties hearing telephone voices, radio, television, or movies?
U	Useful data for associated symptoms. Is there any fever, nausea, vomiting, or dizziness? Is there any history of occupational or environmental exposure to loud noises? What are the usual ear self-care habits? Any history of impacted cerumen? Has patient ever had cerumen removed from ears?
P	Perception of problem by the patient. What does the patient feel is wrong? Does the patient think that he or she has a hearing problem? How does the patient feel about hearing assistive devices? How does the patient perceive the hearing loss, and how is it influencing the patient's life?

BOX 49-5 NURSING CARE PLAN FOR THE PATIENT WITH HEARING LOSS

Disturbed sensory perception: hearing related to altered sensory reception and transmission

PATIENT OUTCOMES

Patient will attain optimum level of sensory stimulation. Patient will become aware of auditory impairment and ways to compensate. Patient will demonstrate ability to perform activities of daily living, with assistance if necessary.

EVALUATION OF OUTCOMES

Patient perceives maximum auditory sensory input. Patient is able to compensate for sensory impairment by using other senses and resources. Patient is able to perform activities of daily living as independently as possible.

INTERVENTIONS

Begin assessment of hearing by inspecting ear canals for mechanical obstruction. If cerumen is found, the use of a softening product is recommended to assist in wax removal. If canal is clear, continue assessment of hearing by use of a tuning fork, loud ticking clock, or verbal cues to determine auditory ability at various distances.

Enhance hearing by giving auditory cues in quiet surroundings.

Enhance understanding of auditory cues by getting patient's attention before speaking, speak slowly with careful enunciation of words, add hand gestures, speak face to face with impaired person, and adjust pitch downward without increasing volume.

Structure environment to compensate for hearing loss by adding visual indicators to telephone ringer, doorbell, smoke detectors, and other emergency sounds.

Provide for optimum care of assistive appliances such as hearing aids by making sure that cerumen has been cleaned from the device, that batteries are charged, and that appliance is placed correctly in ear.

Introduce other assistive devices such as hearing amplifiers, telephone amplifiers, telephones with extra-loud bells, written communication, and sign language.

Allow patient to verbalize feelings and grieving about hearing loss.

Identify coping strategies that have been successful for patient in the past.

Refer to specialized clinician such as audiologist or occupational therapist or to specialized resources such as National Association of the Deaf or American Speech, Language and Hearing Association.

RATIONALE

Hearing loss may occur due to the buildup of cerumen in the auditory canal. Determination of hearing ability assists nurse in developing interventions appropriate to the hearing level of patient.

Background noise such as television, radio, or large numbers of people make hearing more difficult.

Hearing is enhanced when additional cues assist the impaired individual in understanding the message. Use of hand gestures to point, lip-reading, facial expression, and lower pitch all assist communication.

Assists in communication.

Appliances that are not functioning properly will not assist patient in hearing.

Patients may not be aware of assistive devices, which may help them adapt to hearing loss and continue previous activities such as talking on telephone or listening to television.

Losing a primary sense such as hearing can be devastating for patients. Opportunity to ventilate feelings assists in processing the loss.

By identifying successful coping strategies, the nurse assists patient in dealing with stress of hearing loss. A positive approach for nurses to use focuses on the individual's capabilities rather than deficits.

Specialized clinicians can provide detailed examination and treatment for the disorder. Specialized resource groups have networks in place to assist individuals in coping with the loss and assisting them with maximizing abilities.

EVALUATION

Is ear canal free of mechanical obstruction?

Is patient able to hear verbal input? If not, how severe is the impairment?

Are auditory cues being delivered in an environment free of extraneous background noises? Are auditory cues being understood by patient?

Are instructions given in step-by-step format with written cues?

Is patient able to receive input in ways other than auditory?

Is patient's hearing aid in place correctly? Is there cerumen blocking sound conduction? Do batteries work?

Is patient aware of assistive devices that will allow him or her to continue to verbally communicate with others? Is patient able to use the devices to compensate for auditory impairment?

Is patient able to verbalize feelings about the auditory impairment and its loss?

Is patient able to identify successful coping strategies and use them to deal with stress of hearing impairment?

Does patient know who to call for detailed examination and treatment of problems? Does patient know that there are specialized clinicians and resource groups to help with hearing impairment? Does patient know how to access these specialists?

normal conversation with the patient. Observe the patient for any difficulty understanding conversation or interview questions. Clarity of the patient's speech is also determined during the interview. Physical assessment includes the whisper voice, Rinne, and Weber tests. Test results provide an estimate of conductive or sensorineural hearing loss. The patient should be assessed for the underlying cause of the problem to determine if it is an external, middle, or inner ear problem. Examination of the external ear may reveal an external ear problem. The experienced practitioner may examine the ear canal for impacted cerumen or a tympanic membrane problem. Any assistive hearing devices should be noted and inspected for proper functioning. The results of the examination are documented and communicated with other health team members.

NURSING DIAGNOSIS. The major nursing diagnoses for the patient with hearing impairment may include but are not limited to the following:

- Disturbed sensory perception: auditory related to noise exposure, age, trauma, or ear disorder
- Impaired verbal communication related to impaired hearing
- Impaired social interaction related to impaired hearing and decreased communication skills
- Disturbed body image related to impaired hearing and use of assistive hearing devices
- Ineffective coping related to difficult communication
- Deficient knowledge related to care of hearing aid due to lack of prior experience

PLANNING. Planning focuses on helping the patient optimize hearing, promoting communication, and promoting adjustment to impaired hearing. The patient's goals include the following:

- Establish effective method of communication
- Maintain usual social activities
- Verbalize acceptance of altered appearance when using assistive device
- Develop coping responses to the emotional reaction of the hearing impairment
- Demonstrate care of hearing aid

NURSING INTERVENTIONS. Nursing interventions focus on establishing and maintaining effective communication. Communicating with the hearing impaired requires sensitivity to the patient's needs. Reducing or eliminating background noise provides a quiet environment. Allow extra time for patient interactions and maintain eye contact. The patient should be faced while speaking, because many hearing-impaired individuals supplement hearing with lip reading. Speak at a normal rate and volume, avoiding overarticulating or shouting and keeping hands away from the mouth when talking. If the patient hears better out of one ear, speak toward that ear. A paper and pencil should be available so the patient may write responses or questions. Using gestures enhances communication. The patient is in-

formed of topics to be discussed and when a change of topic occurs. Monitor the patient's understanding by having the patient repeat important information. During communications, avoid the appearance of frustration. Box 49-6 has additional information on communicating with the hearing impaired.

The patient is encouraged to maintain usual social activities. Assess the patient's normal activities and assist with participation in the activities by arranging transportation, scheduling activities, and involving other persons.

The patient's feelings are discussed regarding the use of assistive devices. If the patient has a hearing aid or is getting one for the first time, ensure that the patient is able to operate and care for it (Box 49-7). Check to see that hearing aid batteries are working and the volume is set at a minimal level to reduce humming. Ways to minimize the appearance of the assistive device are explored. Women may use a different hairstyle to cover the device. Stress the positive results of using the assistive device.

The patient is asked to identify prior coping methods and discuss strategies to improve hearing. Help the patient identify additional coping strategies to deal with decreased hearing.

BOX 49-6 Communicating with the Hearing Impaired

1. Get the person's attention before beginning to speak.
2. Face and stand close to the person being spoken to and maintain eye contact.
3. Avoid standing in the glare of bright sunlight or other bright lights.
4. Speak clearly, at a normal rate and volume. Do not shout or overarticulate.
5. Inform the listener of topics to be discussed and when a change of topic occurs. Stick to a topic for a while and avoid quick shifts.
6. Use short sentences and assess for understanding. If the listener does not understand after the message is repeated, rephrase the message. If the listener has difficulty with high-pitched sounds, lower the voice pitch.
7. Allow extra time for the listener to respond and do not rush the listener.
8. Ensure an optimum environment by reducing background noises by turning off television and radio, closing the door, or moving to a quieter area.
9. Encourage nonverbal communication such as touch or gestures as appropriate.
10. If the listener uses a hearing device, ensure that it is operational and in place before beginning to communicate. Give the person time to adjust the hearing device before speaking.
11. Do not smile, chew gum, or cover the mouth when talking.
12. Use active listening with attentive body posture, pleasant facial expressions, and a calm, unhurried manner.
13. Do not avoid conversation with a person who has hearing loss.
14. Use written communication if unable to communicate verbally.

BOX 49-7 Care of Hearing Aids

1. Insert hearing aid over a soft surface such as a pillow to prevent damage if the hearing aid is dropped during insertion.
2. Remove hearing aid before showering or bathing. Do not immerse in water.
3. Turn the hearing aid off when not in use to conserve battery.
4. Do not expose the hearing aid to extreme heat or cold.
5. Clean the hearing aid daily with a dry, soft cloth. Clean ear mold with small brush or toothpick to keep free of ear-wax.
6. Turn off the hearing aid and turn the volume down before inserting. Turn hearing aid on and increase volume once it is inserted.
7. Minimize whistling noise by ensuring that the volume is not too high, the aid fits securely, and the aid is free from ear-wax.
8. Check battery or lower the volume if sound is not clear or is intermittent. Buzzing noise may indicate that the battery door is not completely closed.
9. Do not expose the hearing aid to medicinal or hair sprays. Apply sprays before inserting hearing aid.

EVALUATION. The patient's goals are met if the following occur:

- Patient communicates effectively
- Patient engages in usual social activities
- Patient verbalizes acceptance of assistive hearing device
- Patient copes with emotional reaction of hearing impairment
- Patient demonstrates care of hearing aid

External Ear

Infections

PATHOPHYSIOLOGY AND ETIOLOGY. Infections are the most common disorder of the external ear, with **external otitis** being the most common infection. Exposure to moisture, contamination, or local trauma provides an ideal environment for pathological growth in the external ear, which results in external otitis. It may be caused by bacterial or fungal pathogens. Staphylococci are the most common causative organisms, but other gram-negative or gram-positive bacteria can cause problems. *Pneumocystis* infections have been seen in patients who have human immunodeficiency virus (HIV). A diffuse bacterial external otitis that occurs when water is left in the ear after swimming is known as swimmer's ear. External otitis occurs more often in the summer months than in the winter months. However, swimmer's ear can be seen year round in patients who swim indoors.

A localized infection called ear canal **furuncle** or abscess results when a hair follicle becomes infected. A **carbuncle** forms when several hair follicles are involved forming the abscess. Most furuncles and carbuncles erupt and drain spontaneously. Otomycosis is an infection caused by fungal growth and is typically seen after topical corticosteroid or antibiotic use. Otomycosis occurs more often in hot weather. An infection of the auricle is called perichondritis, which can result in necrosis of cartilage.

SIGNS AND SYMPTOMS. The most common sign of infection of the external ear is pain. An early indication of infection is pain with gentle pulling on the pinna. The patient may also experience pain when moving the jaw or when the otoscope is inserted into the ear canal. Pruritus (itching) is also a common symptom and can be an early sign of infection. Signs of inflammation are present on the external ear. The ear canal may become swollen or occluded, and as a result hearing may be diminished. Redness, swelling, and drainage can be observed during otoscopic examination. If drainage is present, it usually starts out clear and becomes purulent as the disease progresses. The patient may also be febrile.

DIAGNOSTIC TESTS. Laboratory tests such as a complete blood cell count (CBC) and cultures of discharge may be completed to diagnose infections. The white blood cell (WBC) count may be elevated. Culture and sensitivity tests isolate the specific infective organism, as well as antibiotics to treat the infection. Rinne and Weber tests can indicate conductive hearing impairment.

Impacted Cerumen

PATHOPHYSIOLOGY AND ETIOLOGY. Normally the ear is self-cleaning. However, cerumen may become impacted, blocking the ear canal. People with large amounts of hair in the ear canal or who work in dusty or dirty areas are prone to cerumen impaction. Improper cleaning can also result in cerumen impaction. The older adult is at risk to develop impacted cerumen. This occurs because the amount of cerumen secreted is decreased and because of increased amounts of keratin. These two factors cause the cerumen to be drier, harder, and more easily impacted. Patients with hearing aids tend to have problems with impacted cerumen. Patients with bony growths secondary to osteophyte or osteoma are at risk for cerumen impaction.

SIGNS AND SYMPTOMS. The patient may experience hearing loss, a feeling of fullness, or blocked ear if cerumen has become impacted. Otoscopic examination reveals cerumen blocking the ear canal.

DIAGNOSTIC STUDIES. Audiometric testing reveals conductive hearing loss in the affected ear. Hearing acuity can be decreased by 45 decibels because of an impacted cerumen. Whisper voice, Rinne, and Weber tests also indicate conductive hearing loss. (See Chapter 48.)

Masses

PATHOPHYSIOLOGY AND ETIOLOGY. Benign masses of the external ear are usually cysts resulting from sebaceous glands. Other benign masses are lipomas, warts, keloids, and infectious polyps. Infectious polyps usually arise from the middle ear and enter the external ear through a hole in the tympanic membrane. Actinic keratosis is a precancerous lesion that can be found on the auricle and may be seen in the elderly. Malignant tumors such as basal cell carcinoma on the pinna and squamous cell in the ear canal may develop. These tumors can spread to surrounding tissue and bones if not treated.

SIGNS AND SYMPTOMS. Changes in the appearance of the skin can occur with benign or malignant masses. Usually impaired conductive or sensorineural hearing occurs with masses. Pain is another symptom and is usually described as deep pain radiating inward on the affected side. Ear drainage may be present. As the condition progresses, facial paralysis occurs. Visualization of the mass may be observed during otoscopic examination.

DIAGNOSTIC STUDIES. A biopsy may be obtained to determine if the mass is benign or malignant. Imaging studies are also used to diagnose tumors. Audiometric studies reveal any hearing impairment.

Trauma

PATHOPHYSIOLOGY AND ETIOLOGY. Injuries to the external ear are commonly caused by a blow to the head, automobile accidents, burns, foreign bodies lodged in the ear canal, and cold temperatures. Foreign bodies in the ear canal are common among children, with small toys being the most common object. Cotton ball pieces and insects are the most common foreign bodies found in adults.

SIGNS AND SYMPTOMS. Lacerations, contusions, hematomas, abrasions, erythema, and blistering are signs seen with thermal or physical trauma. Repeated trauma to the ear can cause hypertrophy, also known as cauliflower ear. This is common among boxers. Conductive hearing loss can occur if the ear canal is partially or totally blocked. Patients who have contusions or hematomas commonly complain of numbness, pain, and paresthesia of the auricle. The patient may or may not have symptoms associated with foreign bodies. These symptoms include decreased hearing, itching, pain, and infection. Examination of the ear canal with a penlight usually reveals the foreign body. Care should be taken during otoscopic examination not to push the foreign body further into the ear canal.

DIAGNOSTIC STUDIES. Imaging studies may be needed to determine the extent of the trauma. Audiometric, whisper voice, Rinne, and Weber testing may demonstrate conductive hearing loss.

Complications of External Ear Disorders

Complications can result from delayed treatment, no treatment, or spreading of the external ear disorder. If not treated, infections can spread, causing cellulitis, abscesses, middle ear infection, and septicemia. Metastasis can occur if malignant tumors are not treated. Infection, trauma, and malignant tumors may cause temporary or permanent hearing loss, disfigurement, discoloration, and scarring. Prompt identification and treatment of external ear disorders can prevent many complications.

Medical and Surgical Management of External Ear Disorders

External ear infections are treated with topical antibiotics in the form of drops or ointment. Systemic antibiotics are used for severe infections that are localized or have spread

to surrounding tissues. Topical or systemic steroids may be used to treat inflammation. The ear is thoroughly cleaned before starting any topical treatment. If the external ear canal has drainage or is swollen shut, a wick may be inserted. The wick serves to aid in removing drainage or to aid in administering medication into the ear canal. Cerumen may be removed with installations, a blunt ear curette, or a wire ear curette. Installation is not used with history of perforated tympanic membrane (eardrum). External ear disorders are usually painful, and analgesics are used to control pain.

Débridement, surgical repair, or application of a protective covering may be done when trauma occurs to the external ear. Surgical management consists of incision and drainage of abscesses. Excision of cysts or cutaneous carcinomas may also be required.

Nursing Process: The Patient with External Ear Disorders

ASSESSMENT. Subjective data are obtained in a patient history. Data include any reports of pain, fullness, previous cerumen impaction, itching, or hearing loss, as well as onset, duration, and severity of symptoms. Additional data include patient's occupation, previous ear problems, use of a hearing aid, and typical ear hygiene. Inspection and palpation are primarily used to obtain objective data. Observe for redness, swelling, drainage, furuncles, carbuncles, lesions, abrasions, lacerations, growths, cerumen, scaliness, or crusting. The patient may report pain when the ear is palpated. Basic hearing acuity tests are conducted to evaluate hearing loss. (See Chapter 48.)

NURSING DIAGNOSIS. The major nursing diagnoses for external ear disorders may include but are not limited to the following:

- Acute pain related to inflammation or trauma
- Disturbed sensory perception: auditory related to altered sensory reception
- Risk for injury related to self-cleaning of external ear
- Deficient knowledge related to lack of information on preventive ear care

PLANNING. Planning focuses on helping the patient return to his or her preillness state and preventing any further ear disorders. The patient's goals are as follows:

- Indicates pain is decreased or absent as evidenced by a lower rating on a pain scale
- Hearing returns to preillness state
- Explains or demonstrates prescribed treatment
- Explains or demonstrates procedures to maintain wellness of the external ear

NURSING INTERVENTIONS. Nursing care focuses on relieving the patient's pain, promoting hearing, maintaining ear function, and educating the patient about the disease and preventive ear care. The patient should be assessed for nonverbal signs of ear pain. External ear pain is relieved by pharmacological and nonpharmacological interventions.

Identify with the patient an optimum analgesic schedule to promote comfort. Nonpharmacological methods such as relaxation, massage, music, guided imagery, or distraction techniques can also be used to relieve pain. Heat may be applied to the area to promote comfort. Liquid or soft foods may be offered if the patient experiences pain when chewing.

Interventions to restore hearing and relieve blockage of the ear canal are important. Topical antibiotics and anti-inflammatory medications should be administered using aseptic technique.

BOX 49-8 Removing Cerumen

Instillations and irrigations should not be used on any person with a history of perforated tympanic membrane. Commercial ceruminolytics or common products such as baby oil, mineral oil, and virgin olive oil can be used to soften impacted cerumen and aid in the removal of the impacted wax. The patient should instill several drops of the solution at bedtime and then place a cotton plug in the ear to hold the solution in place. Excess oil and drainage are removed in the morning. Earwax is usually softened for 3 to 4 days before an irrigation is attempted. Patients prone to cerumen buildup should be taught how to safely remove earwax. A few drops of half-strength peroxide may be instilled into the ear canal during the day and three drops of glycerin instilled at bedtime. This can be repeated each week to minimize wax buildup.

The ear can be irrigated with an ear irrigation syringe or a Water Pik. The irrigation solution, usually water, should be warmed to body temperature. The patient is draped with a protective plastic drape, and a basin is placed below the ear to catch the irrigating solution. The patient sits with the ear toward the nurse and the head tilted toward the opposite ear. (See Fig. 49-12.) The external ear is pulled upward and backward for the adult. A low-pressure stream of water is directed toward the top of the ear canal. Care is taken not to obstruct the canal with the syringe so that the irrigation solution can backflow out of the canal. Ensure that only the tip of the syringe is in the ear canal to prevent perforation of the eardrum.

If the patient has a wick inserted into the ear canal, monitor for drainage. Experienced practitioners or physicians remove cerumen (Box 49-8; Fig. 49-7).

Instruct the patient how to complete the prescribed treatment and maintain ear health (Box 49-9). Patient teaching includes how to administer ear drops or ointments. The patient should keep the ear clean and dry. During an infection, cotton with petroleum jelly or earplugs should be used to avoid getting water in the ears.

EVALUATION. The goals for the patient are met if the following occur:

- Indicates pain is decreased or absent as evidenced by a lower rating on a pain scale
- Hearing improves or returns to preillness level
- States or demonstrates prescribed treatment (e.g., administering ear drops or ointments)
- Explains or demonstrates measures to maintain wellness of the external ear

BOX 49-9 Ear Care

1. Cleanse the external ear with a wet washcloth. Gently cleanse the helix.
2. Never insert anything into the ear canal, including hairpins, cotton-tipped applicators, matchsticks, safety pins, toothpicks, paper clips, and fingers.
3. An individual with a history of ear infections, perforated tympanic membrane, or swimmer's ear should prevent moisture from entering the ear canal. Avoid swimming in contaminated water. Moisture or water in the ear canal can be prevented by using special earplugs or by using a piece of cotton rolled into a cylinder and covered with petroleum jelly.
4. Avoid home remedies for ear care without consulting a physician.
5. An individual with an upper respiratory infection should gently blow the nose with both nares open to prevent infection being forced up the eustachian tubes.

Figure 49-7 Ear irrigation. (A) Child. (B) Adult.

Middle Ear, Tympanic Membrane, and Mastoid Disorders

Infections

PATHOPHYSIOLOGY AND ETIOLOGY. Otitis media is the most common disease of the middle ear. *Otitis media* is a general term for inflammation of the middle ear, mastoid, and eustachian tube. Inflammation of the nasopharynx causes most cases of otitis media. As inflammation occurs the nasopharynx mucosa becomes edematous and discharge is produced. When fluid, pus, or air builds up in the middle ear, the eustachian tube becomes blocked, and this impairs middle ear ventilation.

There are several types of otitis media in which inflammation can occur alone, with infective drainage, or with noninfective drainage. The first type of otitis media is otitis media without effusion. This is an inflammation of the middle ear mucosa without drainage. The second type of otitis media occurs when there is a bacterial infection of the middle ear mucosa. This is called acute otitis media, suppurative otitis media, or purulent otitis media. The infected fluid becomes trapped in the middle ear. If the infection continues longer than 3 months, chronic otitis media results. The third type of otitis media is otitis media with effusion. Other names include serous otitis media, nonsuppurative otitis media, and glue ear. With this type of otitis media, noninfective fluid accumulates within the middle ear.

SIGNS AND SYMPTOMS. Acute otitis media commonly follows an upper respiratory infection. A fever, earache, and feeling of fullness in the affected ear are common symptoms. As purulent drainage forms, there is pain and conductive hearing loss. Nausea and vomiting may also be present. Purulent drainage may be evident in the external ear canal if the tympanic membrane ruptures. Mastoid tenderness indicates that the infection may have spread to the mastoid area. Otoloscopic examination reveals a reddened, bulging tympanic membrane.

Symptoms of otitis media with effusion may go undetected in adults because there are no signs of infection. The patient may complain of fullness, bubbling, or crackling in the ear. The patient may have a slight conductive hearing loss or allergies or be a mouth breather. Otoloscopic examination can reveal a bulging tympanic membrane with a fluid level, but the eardrum is not reddened.

DIAGNOSTIC STUDIES. Laboratory studies may indicate an elevated WBC count. Ear cultures may be obtained on any drainage to identify the specific infective organism. Conductive hearing loss is usually present on audiometric studies and Rinne, Weber, and whisper voice tests. Imaging studies may be done to diagnose infection.

COMPLICATIONS. A perforation may occur with an acute or chronic infection. Buildup of fluid and pressure in the middle ear can cause a spontaneous perforation of the tympanic membrane. The patient usually experiences pain before the rupture and relief of pain after the rupture. The fluid in the middle ear moves through the perforation into

the ear canal, relieving the pressure and pain. A tympanic membrane perforation causes hearing loss. The location and size of the perforation determine the extent of hearing loss. Damage to the ossicles can also occur with perforation.

Repeated infections in the middle ear or mastoid can cause a cholesteatoma, which is an epithelial cystlike sac that fills with debris such as degenerated skin and sebaceous material. The cholesteatoma starts in the external ear canal and spreads to the middle ear through a perforation in the tympanic membrane. Damage occurs in the middle ear structures as a result of pressure necrosis. The cholesteatoma causes conductive hearing loss. As the disease progresses, facial paralysis and vertigo may occur.

Tympanosclerosis is another complication of repeated middle ear infections. Tympanosclerosis consists of deposits of collagen and calcium on the tympanic membrane. The condition can slowly progress over time to the area around the middle ear ossicles. These deposits appear as chalky white plaques on the tympanic membrane and contribute to conductive hearing loss.

Mastoiditis can occur if acute otitis media is not treated. The infection spreads to the mastoid area, causing pain. Since the use of antibiotics, acute mastoiditis is relatively uncommon. Chronic mastoiditis is still seen with repeated middle ear infections.

MEDICAL AND SURGICAL TREATMENT. Medical treatment consists of treating the infections with antibiotics. Amoxicillin, penicillin V, erythromycin, cefaclor, and cotrimoxazole are commonly used. Analgesics such as aspirin, acetaminophen, or codeine or ear drops control the pain.

Surgical intervention includes several techniques. Paracentesis may be performed with a needle and syringe. The tympanic membrane is punctured with the needle, and the fluid is drained from the middle ear. A **myringotomy** may also be performed. During this procedure, an incision is made on the tympanic membrane and fluid is allowed to drain out or is suctioned out of the middle ear. An other technique is laser-assisted myringotomy, which vaporizes the tympanic membrane. Various types of transtympanic tubes may be inserted to keep the incision open. The transtympanic tube keeps the incision in the tympanic membrane open, equalizes pressure, and prevents further fluid formation and buildup. The transtympanic tubes are left in place until the infection is cured. Most tubes spontaneously extrude in 3 to 12 months and rarely have to be removed.

Reconstructive repair of a perforated tympanic membrane is called a **myringoplasty**. One technique involves placing Gelfoam over the perforation. A graft from the temporal muscle behind the ear or tissue from the external ear is then placed over the perforation and Gelfoam. The Gelfoam is absorbed, and the graft repairs the perforation.

A mastoidectomy involves incision, drainage, and surgical removal of the mastoid process if the infection has spread to the mastoid area.

myringoplasty: myringo—tympanic membrane + plasty—surgical repair

Otosclerosis

PATHOPHYSIOLOGY AND ETIOLOGY. Otosclerosis, or hardening of the ear, results from the formation of new bone along the stapes. With the new bone growth, the stapes becomes immobile and causes conductive hearing loss. The formation of the new bone growth begins in adolescence or early adulthood and progresses slowly. Hearing loss is most apparent after the fourth decade. Otosclerosis is more common in women than in men. The disease usually affects both ears. Although the exact cause of otosclerosis is not known, most patients have a family history of the disease. It is therefore thought to be a hereditary disease.

SIGNS AND SYMPTOMS. The primary symptom of otosclerosis is progressive hearing loss. The patient usually experiences bilateral conductive hearing loss, particularly with soft, low tones. Usually medical assistance is sought when the hearing loss interferes with the patient's ability to hear conversations. The patient may also experience tinnitus. Otoloscopic examination reveals a pinkish-orange tympanic membrane because of vascular and bony changes in the middle ear.

DIAGNOSTIC STUDIES. Audiometric testing indicates the type and extent of the hearing loss. Imaging studies indicate the location and the extent of the excessive bone growth. Whisper voice test and normal conversation show decreased hearing. The patient hears best with bone conduction in the Rinne test, whereas lateralization to the most affected ear occurs with the Weber test.

MEDICAL AND SURGICAL MANAGEMENT. There is no cure for otosclerosis, but hearing aids may be used to improve hearing for the patient. The hearing aid is most effective for conductive hearing loss when there is no sensorineural involvement.

Although total restoration of hearing is not possible, reconstruction of necrotic ossicles is done to restore some of the patient's hearing. Various methods are used to reposition and replace some or all of the ossicles. Unfortunately, the surgeries are not always successful over the long term. Ossiculoplasty is the reconstruction of the ossicles. Prostheses made of plastic, ceramic, or human bone are used to replace the necrotic ossicles. Total or partial ossicular replacement prosthesis may be used. The **stapedectomy** is the treatment of choice for otosclerosis. Either part or all of the stapes is removed and replaced with a prosthesis. The prosthesis is placed between the incus and the oval window. Advances in surgical treatment include the use of lasers for improved visualization, less trauma, and greater precision during surgery. The goal is to restore vibration from the tympanic membrane to the oval window and allow sound transmission. Many patients experience improved hearing immediately, others not until swelling subsides. Complications of ossiculoplasty and stapedectomy include extrusion of the prosthesis, infection, hearing loss, dizziness, and facial

nerve damage. Some patients may have the surgery repeated if complications develop.

Nursing Management

The operative ear is placed upward when lying in bed. An earplug may be used to help keep the area aseptic; the proximity of the brain makes this necessary to prevent brain infection. Activity orders may vary. The patient may be dizzy and experience nausea. Antiemetics should be given promptly to prevent vomiting. The patient's safety should be ensured if dizziness occurs. To prevent dislodgment or damage to the prosthesis, patient are instructed not to cough, sneeze, blow their nose, vomit, fly in an airplane, lift heavy objects, or shower. If the patient develops a cold, the physician should be contacted.

CRITICAL THINKING

Mrs. Smith
Mrs. Smith is an 83-year-old woman who is scheduled to be discharged from the hospital following a stapedectomy. She lives alone at home and is able to care for herself.

1. How would you communicate with Mrs. Smith to ensure that she understands the discharge instructions?
2. What teaching methods would you use to enhance communication?
3. What ear care instructions would you give her?

Answers at end of chapter.

Trauma

ETIOLOGY AND PHYSIOLOGY. Trauma such as a blasting force, a blunt injury to the side of the head, or sudden changes in atmospheric pressure can cause the tympanic membrane to perforate and middle ear ossicles to fracture. Blast injuries cause injury from the direct pressure on the ear. Blunt injury to the head can cause temporal skull fractures and trauma to both the middle and inner ear. Barotrauma caused by sudden changes in atmospheric pressure in the ears can occur during scuba diving and airplane take-offs and landings. Pressure changes can occur during normal atmospheric conditions such as nose blowing, heavy lifting, and sneezing. During these rapid changes of pressure, the eustachian tube does not ventilate because of occlusion or dysfunction and a negative pressure develops in the middle ear. The resulting pressure can cause the tympanic membrane to rupture or cause damage to the middle and inner ear.

SIGNS AND SYMPTOMS. Pain and hearing loss are the most common symptoms associated with trauma. Other signs and symptoms of barotrauma include fullness of the ears, vertigo, nausea, disorientation, edema of the affected area, and hemorrhage in the external or middle ear. In severe cases of barotrauma when scuba diving, these symptoms can cause drowning or cerebral air embolism from an overly rapid ascent. Otoloscopic examination may reveal a retracted, reddened, and edematous tympanic membrane.

stapedectomy: stape(s)—stirrup + ectomy—excision of

DIAGNOSTIC STUDIES. Audiometric studies are completed to determine the hearing loss. Imaging studies may be done to determine the extent of middle and inner ear damage. Conductive or sensorineural hearing loss may be evident, depending on the extent and location of the damage.

Nursing Process: The Patient with Middle Ear, Tympanic Membrane, and Mastoid Disorders

ASSESSMENT. Assessment of symptoms includes asking the patient for subjective data using the WHAT’S UP? format (Table 49–7). The external ear should be inspected and palpated to obtain objective data. Pain with palpation is indicative of external ear problems, not middle ear problems. Pain over the mastoid area can indicate a mastoid problem. The middle ear and mastoid cavity cannot be visualized directly. The tympanic membrane is the only middle ear structure that can be directly visualized by the experienced practitioner with an otoscope. Objective assessment should also include vital signs, noting any elevation in temperature. Hearing acuity should be screened by the experienced practitioner using the whisper voice, Rinne, and Weber tests. Any drainage from the ear should be noted and described.

NURSING DIAGNOSIS. Nursing diagnoses for middle ear disorders may include but are not limited to the following:

- Risk for infection related to broken skin, pressure necrosis, chronic disease, or surgical procedure
- Disturbed sensory perception: auditory related to altered sensory reception
- Acute pain related to fluid accumulation, inflammation, or infection
- Fear related to hearing loss and lack of information
- Deficient knowledge related to lack of exposure to information due to no prior experience

PLANNING. The patient and family are included in planning care. Planning focuses on improving hearing, controlling infection, and improving the quality of life. The patient’s goals include but are not limited to the following:

- Exhibits no signs of infection (no drainage from ear, no tenderness over mastoid, negative culture, afebrile)

- Hearing improves or stabilizes
- Indicates pain is decreased or absent as evidenced by a lower rating on a pain scale
- States methods for preventing problems in the middle ear, tympanic membrane, and mastoid process
- States rationale and desired outcome of any impending surgery

NURSING INTERVENTIONS. The family should be included in teaching sessions. The patient is instructed about medications. The patient is instructed to complete all therapy as directed by the physician. Ensure that the patient knows how to administer ear drops and ear ointment. Care of the ears to prevent infection is discussed. The patient is also taught to avoid getting water in the ears.

If medical or surgical management is necessary to improve the patient’s hearing, the patient is instructed on this treatment. Methods to improve communication with the hearing impaired are used. (See Nursing Care Plan Box 49–3.)

Monitor pain using a pain scale, and provide measures to promote comfort. Nonpharmacological measures for pain reduction may include heat, distraction, and relaxation techniques. If analgesics are used, the optimum schedule for pain control is identified.

The patient is instructed on methods to maintain ear health and prevent ear damage from trauma, noise exposure, and environmental or occupational conditions. To equalize ear pressure, the patient should yawn or perform the jaw-thrust maneuver (opening mouth wide and moving jaw). Preventing the spread of upper respiratory infections up the eustachian tube is accomplished by telling the patient not to blow the nose by pinching off a nares. If the patient’s pain worsens, hearing decreases, or drainage from ear is present, the patient should seek further medical attention. Prior to surgical procedures, the patient’s knowledge is assessed and instructions are given as needed (Table 49–8).

EVALUATION. The goals for the patient are met if the following occur:

- Does not have ear drainage or pain over mastoid; has negative culture and remains afebrile
- Responds appropriately to auditory cues indicating improvement of hearing

TABLE 49–7 SUBJECTIVE ASSESSMENT OF MIDDLE EAR, TYMPANIC MEMBRANE, AND MASTOID DISORDERS

W	Where is it? Are both ears affected? Is it deep within the head?
H	How does it feel? Is there pressure? Fullness? Is it painful—sharp, dull, continuous, intermittent, throbbing, localized? No pain?
A	Aggravating and alleviating factors. Is it worse with change of position? Worse with movement? Is there relief after drainage? Relief with change of position? Relief with heat or analgesics?
T	Timing. When did it start? Has there been any recent upper respiratory infection, airline travel, scuba diving, trauma, or weight lifting? Was it a gradual or sudden onset? How long have symptoms persisted? Has there been a change in symptoms?
S	Severity. Does it cause hearing impairment? How much? Does it affect ADLs?
U	Useful data for associated symptoms. Is there any fever, drainage from the ear canal, nausea, vomiting, dizziness? Is there a family history of otosclerosis? Any previous ear problems or ear surgeries? Any occupational or recreational risk factors, such as scuba diving, weight lifting, or frequent airline travel?
P	Perception by the patient of the problem. What does the patient think is wrong? Has problem occurred before? If so, how was it the same and what was different?

TABLE 49-8 PREOPERATIVE AND POSTOPERATIVE NURSING INTERVENTIONS FOR THE PATIENT HAVING EAR SURGERY**Preoperative Care**

Nursing care for the patient undergoing ear surgery begins as soon as the decision to have surgery is made. The nurse collects data, determines if the patient understands the events, assesses the patient's mental readiness, and obtains baseline physiological data.

1. Assess understanding of the surgery and explain whether local or general anesthesia will be used.
2. Help alleviate the patient's fear by encouraging the patient to ask questions. Ensure that all questions are answered before the surgery.
3. Explain the type of pain, any packing or dressings that may be in place postoperatively, and any other postoperative restrictions that may be needed.
4. Establish baseline vital signs and document findings.
5. Ensure that the operative permit is signed.
6. Determine current medications the patient is taking and document in the patient's record.
7. Assess if the patient understands that surgery does not always correct impaired hearing.
8. Leave any hearing devices in place as long as possible before the surgery.

Postoperative Care

Postoperatively the nurse is responsible for assessing the patient's physiological status. The nurse is also responsible for ensuring that the patient and family members understand discharge instructions.

1. Some degree of pain may be expected, even with minor procedures. Explain how and when to take pain medication when the patient is discharged.
2. Monitor postoperative vital signs and return to presurgical baseline.
3. Tell patients that if an occlusive dressing is in place, hearing may be decreased until the dressing is removed.
4. Instruct patients with tubes to avoid getting water in the ear. A shower cap or earplugs may be used.
5. Instruct the patient to seek medical attention if excessive bleeding or drainage occurs. If a cotton plug is to be left in place, instruct the patient to change it daily.
6. Teach the patient, unless contraindicated, to blow the nose very gently one side at a time for the first week after surgery. Instruct the patient to sneeze or cough with the mouth open for 1 week after surgery.
7. Avoid airplane flights for 1 week after surgery. For sensations of ear pressure, hold nose, close mouth, and swallow to equalize pressure.
8. The patient should avoid strenuous work for several weeks. The patient may return to work in a few days, depending on the type of surgery and the type of work the patient does.
9. Tell the patient to take prescribed medication and antibiotics as ordered.
10. Have the patient arrange for follow-up appointment by calling physician's office.

- States that no pain is present or pain is decreased
- Verbalizes care of ears, methods to prevent further infection; describes signs requiring medical attention
- Verbalizes rationale and outcome for any upcoming surgery

Inner Ear**Labyrinthitis**

PATHOPHYSIOLOGY AND ETIOLOGY. Labyrinthitis is an inflammation or infection of the inner ear and can be caused by either viral or bacterial pathogens. The bacteria or virus enters the inner ear from the middle ear, meninges, or bloodstream. Serous labyrinthitis is a type of acute labyrinthitis that sometimes follows drug intoxication or overindulgence in alcohol. It can also be caused by an allergy. Diffuse suppurative labyrinthitis occurs when acute or chronic otitis media spreads into the inner ear or after middle ear or mastoid surgery. Destruction of soft tissue structures from the infection can cause permanent hearing loss.

SIGNS AND SYMPTOMS. Vertigo, tinnitus, and sensorineural hearing loss are the most common symptoms. Vertigo, or dizziness, occurs when the vestibular structures are involved. Tinnitus, or ringing in the ear, occurs when the infection is located in the cochlea. Sensorineural hearing loss can be caused by infections in the cochlea or vestibular structures. Nystagmus on the affected side may occur. Other signs and symptoms include pain, fever, ataxia, nausea, vomiting, and beginning nerve deafness.

DIAGNOSTIC TESTS. Laboratory tests such as a CBC may be completed to diagnose infection. Thorough hearing evaluation by an audiologist may reveal mild to complete hearing loss. Rinne and Weber tests can indicate conductive or sensorineural hearing loss.

MEDICAL MANAGEMENT. Antibiotics are used to treat bacterial inner ear infections. Viral infections usually run their course in about 1 week. Mild sedation may help the patient relax. Although there is no specific medicine to relieve dizziness, antihistamines can be used if they prove helpful on an individual basis. Patients may be placed on bedrest.

NURSING MANAGEMENT. Nursing management includes helping the patient manage symptoms, self-care, and educating the patient about safety issues while on bedrest and sedatives. The patient should avoid turning the head quickly to help alleviate the vertigo. The patient is assisted to cope with anxiety that may be present because of the frustration surrounding hearing loss or loss of work.

Neoplastic Disorders

PATHOPHYSIOLOGY AND ETIOLOGY. Inner ear tumors can be benign or malignant. Acoustic neuroma, a tumor of the eighth cranial nerve, is the most common benign tumor. It is slow growing, occurs at any age, and usually occurs unilaterally. As it spreads, it compresses the nerve and adjacent structures. Malignant tumors arising from the inner ear

are rare. Squamous and basal carcinomas arise from the epidermal lining of the inner ear.

SIGNS AND SYMPTOMS. Early symptoms of an acoustic neuroma include progressive unilateral sensorineural hearing loss of high-pitched sounds, unilateral tinnitus, and intermittent vertigo. Headache, pain, and balance disorders may also be present. Symptoms progress as the tumor spreads to other structures. Most malignant tumors grow quickly. The symptoms vary depending on the area of the ear that is involved.

DIAGNOSTIC TESTS. Neurological, audiometric, and vestibular testing are used to diagnose the neuroma. Auditory brainstem evoked response (ABR) and electronystagmography (ENG) are completed. Examination of the cerebrospinal fluid shows increased protein. Computed tomography (CT) and magnetic resonance imaging (MRI) are used to determine size and location of the tumor.

MEDICAL AND SURGICAL TREATMENT. The preferred method of treatment involves surgical removal of the tumor. The labyrinth is destroyed, with a resulting permanent hearing loss. Steroids and radiation may be used to decrease the size of the tumor or for inoperable tumors.

NURSING MANAGEMENT. Nursing management focuses on preparing the patient for surgery and adjusting to the diagnosis and the resulting hearing loss.

Ménière's Disease

PATHOPHYSIOLOGY AND ETIOLOGY. Ménière's disease is a balance disorder. Its cause is unknown. With the disease, there is a dilation of the membranous labyrinth resulting from a disturbance in the fluid physiology of the endolymphatic system. The exact etiology is unknown but is thought to stem from hypersecretion, hypoabsorption, deficit membrane permeability, allergy, virus, hormonal imbalance, or mental stress. The disease usually develops between 40 and 60 years of age. The symptoms range from vague to severe and debilitating.

SIGNS AND SYMPTOMS. A triad of symptoms of vertigo, hearing loss, and tinnitus characterizes Ménière's disease. Recurring episodic bouts of the incapacitating triad of symptoms and nausea and vomiting occur with Ménière's disease. The attacks may occur suddenly, or the patient may experience warning signs such as headache or fullness in the ears. During an acute episode, the patient experiences vertigo that lasts 2 to 4 hours. The vertigo is usually accompanied by nausea and vomiting, followed by dizziness and unsteadiness. The patient is uncoordinated and has gait changes when walking. Hearing loss is often described as a fluctuating fullness in the ears. Tinnitus is present. Irritability, depression, and withdrawal are common behavioral changes. The vital signs usually remain normal. It takes several weeks for symptoms to resolve, and hearing loss in the affected ear remains. The patient then enters a stage of remission until the next attack. The acute episodes occur two to three times per year. Eventually the patient

has complete remission with some degree of permanent hearing loss.

DIAGNOSTIC TESTS. Diagnostic tests include audiometric studies, neurological testing, and radiographs of the internal ear. Audiometric studies identify the type and magnitude of the hearing loss. Neurological testing and radiographic studies are done to rule out other pathological conditions. A caloric stimulation test may demonstrate a difference in eye movement.

MEDICAL AND SURGICAL TREATMENT. Medical treatment consists of symptomatic treatment for acute attacks and prophylactic treatment between attacks. Tranquilizers and vagal blockers may be needed during acute attacks. Salt-restricted diet, diuretics, antihistamines, and vasodilators are used during prophylactic treatment. The patient should avoid alcohol, caffeine, and tobacco use. The patient may be placed on bedrest during acute attacks. Most patients respond to medical protocol but continue to have acute attacks. Some patients who do not respond to treatment may be placed on low doses of methotrexate. The goals of medical treatment are to preserve hearing and reduce symptoms.

Surgical treatment is used only when medical management has failed. When involvement is unilateral, a labyrinthectomy is performed. This causes complete loss of hearing in that ear. Another surgical intervention establishes a shunt from the inner ear to the subarachnoid space. This procedure helps drain the fluid and prevent future hearing loss. Another surgical treatment is intratympanic gentamycin injection, which is usually done in the physician's office.

NURSING MANAGEMENT. Nursing management focuses on managing the patient's symptoms and providing safety during the acute attacks. Administer medication, monitor fluid and nutritional status, and ensure safety. Because of the unpredictability of Ménière's disease, the nursing care focuses on emotional support for the patient during periods of remission. Provide emotional support and resources to help the patient cope with the unpredictable nature of the disease and the physical impairments associated with the disease.

Nursing Process: The Patient with Inner Ear Disorders

ASSESSMENT. Assessment of symptoms for the patient with inner ear disorders includes asking the patient for subjective data using the WHAT'S UP? format (Table 49-9). Objective data include assessment of gross hearing. The whisper voice, Rinne, and Weber tests and a physical examination can be performed. The patient should be assessed for any nutritional deficiencies, including dehydration, weight loss, or weight gain. Any musculoskeletal abnormalities such as unsteady gait are also noted. The patient's vital signs are taken to determine if symptoms are associated with an infection. Laboratory data and diagnostic data are examined for abnormal findings.

TABLE 49-9 SUBJECTIVE ASSESSMENT OF INNER EAR DISORDERS

W	Where is it? Are both ears affected?
H	How does it feel? Is there pressure? Fullness? Vertigo? Tinnitus? Is it painful—sharp, dull continuous, intermittent, throbbing, localized? No pain?
A	Aggravating and alleviating factors. Is it worse with change of position? Worse with movement? Is there relief with medications? Is the patient taking current medications? Are there any allergies?
T	Timing. When did it start? Was it a gradual or sudden onset? How long have symptoms persisted? Do symptoms progress in a set timing pattern? Do symptoms occur together or separately? Has there been a change in symptoms?
S	Severity. Does it cause hearing impairment? How much? Does it affect ADLs, nutritional intake, work, or leisure?
U	Useful data for associated symptoms. Any fever, nausea, vomiting, or dizziness? Any previous ear problems or ear surgeries? Headache?
P	Perception by the patient of the problem. What does the patient think is wrong? Has patient had this problem before? If so, what was the same and what was different?

NURSING DIAGNOSIS. The major nursing diagnoses for internal ear disorders may include but are not limited to the following:

- Anxiety related to unpredictability of sudden and severe acute attacks
- Fear related to potential permanent hearing loss
- Ineffective role performance related to impaired equilibrium
- Impaired social interaction related to communication barriers
- Grieving related to hearing loss
- Risk for injury related to impaired equilibrium
- Deficient fluid volume related to nausea and vomiting
- Nutrition: less than body requirements related to nausea and vomiting
- Deficient knowledge related to lack of information of diagnosis and treatment due to no prior experience

PLANNING. Planning focuses on helping the patient maintain a normal lifestyle, remain free of injuries, cope with the illness or hearing loss, and maintain adequate nutrition and hydration. The patient's goals are as follows:

- Signs of anxiety are decreased
- Is not injured from falling
- Identify ways of increasing meaningful relationships and diversional activities
- Experiences adequate nutrition and hydration

NURSING INTERVENTIONS. Nursing care focuses on relieving anxiety, protecting the patient from injuries, maintaining and developing relationships, and providing adequate nutrition. Encourage the patient to explore concerns about hearing loss and the unpredictability of acute attacks. The patient's understanding about the disorder should be explored and additional information provided as needed. A medication regimen to help control symptoms should be explained. Explain methods to minimize symptoms during acute episodes, such as decreasing movement.

Nursing measures to prevent injury include assessing the patient for any pattern of dizziness and environmental haz-

ards. Instruct the patient to seek assistance before ambulating. Antivertiginous drugs are administered, and the patient is taught the medication regimen. Environmental hazards such as throw rugs, electrical cords in walkways, and poor lighting should be removed by the family.

Assist the patient in maintaining relationships and activities that were present before the disorder. Provide information about disease processes to ensure that the patient is informed about the disease. Diversional activities are planned.

EVALUATION. The goals for the patient are met if the following occur:

- Signs of anxiety are decreased
- Patient remains free from injury
- Patient verbalizes satisfaction with relationships
- Patient maintains weight within normal range

Answers to CRITICAL THINKING

Mr. Samuel

1. Mr. Samuel should seek assistance, patch both eyes, and have someone take him to receive medical treatment immediately.
2. Ensure that an antiemetic is ordered postoperatively on the patient's return to the unit. When Mr. Samuel reports nausea, the antiemetic should be given promptly.

Mrs. Smith

1. Gain her attention, face and stand in her visual field, avoid glare, speak clearly, inform her of topics to be discussed, assess for understanding, allow extra time, reduce background noises, use nonverbal communication, and do not cover your mouth when talking.
2. Use active listening. Use written communication to enhance spoken words. Use demonstration and return demonstration. Allow questions. Do not hurry. Provide information in short segments. Reassess understanding at each session.
3. Place the operative ear upward when lying in bed. Use ear plug as ordered. Do not cough, sneeze, blow nose, vomit, fly in an airplane, lift heavy objects, or shower. If a cold develops, call the physician. If dizzy, be careful when up.

REVIEW QUESTIONS

1. A patient comes to the physician's office for an eye examination. The patient has a family history of macular degeneration. Which of the following symptoms is expected with macular degeneration?
 - a. Loss of peripheral vision
 - b. Sudden darkness
 - c. Dull ache in the eyes
 - d. Loss of central vision
2. A nurse is working on a postoperative unit for eye surgery. In planning interventions for an eye surgery patient, the nurse understands that which of the following patients needs specific positioning orders postoperatively to prevent complications?
 - a. 4-year-old child after removal of congenital cataract
 - b. 30-year-old woman after scleral buckling
 - c. 52-year-old man after trabeculectomy
 - d. 82-year-old man after corneal transplant
3. A nurse is caring for a patient who has a history of acute angle-closure glaucoma and is scheduled for surgery. Which of the following medication orders should the nurse clarify to prevent serious eye complications?
 - a. morphine
 - b. cefazolin (Kefzol)
 - c. atropine
 - d. ranitidine (Zantac)
4. A patient comes to the health clinic for a suspected ear infection. Which of the following assessment findings does the nurse expect with an external ear infection?
 - a. Pain
 - b. Fullness in ears
 - c. Fever
 - d. Dizziness
5. The nurse is contributing to the plan of care for a patient with Ménière's disease. Which one of the following is the primary goal for a patient with Ménière's disease that the nurse should recommend be included in the plan of care?
 - a. Prevent dehydration
 - b. Decrease pain
 - c. Prevent injury
 - d. Preserve hearing

UNIT FIFTEEN
UNDERSTANDING THE
INTEGUMENTARY SYSTEM

50

INTEGUMENTARY FUNCTION, ASSESSMENT, AND THERAPEUTIC MEASURES

Rita Bolek Trofino and Valerie C. Scanlon

KEY TERMS

alopecia (AL-oh-**PEE**-she-ah)
ecchymosis (eck-uh-**MOH**-sis)
erythema (ER-i-**THEE**-mah)
petechiae (pe-**TEE**-kee-eye)
turgor (**TER**-ger)

QUESTIONS TO GUIDE YOUR READING

1. What is the normal anatomy of the integumentary system?
2. What is the normal function of the integumentary system?
3. What are the effects of aging on the integumentary system?
4. What data should you collect when caring for a patient with a disorder of the integumentary system?
5. What laboratory and diagnostic tests are commonly performed to diagnosis integumentary disorders?
6. What common therapeutic measures are used for patients with integumentary disorders?
7. What nursing care should you provide for patients with disorders of the integumentary system?

► REVIEW OF NORMAL ANATOMY AND PHYSIOLOGY

The skin, its accessory structures, and the subcutaneous tissue make up the integumentary system, the covering of the body that separates the living internal environment from the external environment. The skin itself is considered an organ and consists of two layers, the outer epidermis and the inner dermis (Fig. 50–1).

Epidermis

The epidermis is made of stratified squamous epithelial tissue and is avascular, meaning that it has no capillaries within it. Its nourishment comes from the dermis beneath it. The epidermis is thickest on the palms of the hands and soles of the feet. The innermost layer of the epidermis is called the stratum germinativum, and it is here that mitosis takes place to produce new epidermal cells. The rate of mitosis is fairly constant, but it may be increased by chronic pressure on the skin (as in callus formation). The new cells produce the protein keratin. As they are pushed to the sur-

face of the skin, they die and become the stratum corneum, the outermost of the epidermal layers.

The stratum corneum is many layers of dead cells; all that remains is their keratin. An unbroken stratum corneum is an effective barrier against pathogens and most chemicals, although even microscopic breaks are sufficient to permit their entry. Keratin is relatively waterproof, so it prevents the loss of water—that is, dehydration—and also prevents the entry of excess water by way of the body surface. As dead cells are worn off the surface of the skin (which also contributes to the removal of pathogens), they are continuously replaced by cells from within. Loss of large portions of the stratum corneum, as with extensive third-degree burns, greatly increases the risk for infection and dehydration.

Melanocytes are cells in the lower epidermis that produce the protein melanin; the amount of melanin is a genetic characteristic and gives color to skin and hair. When the skin is exposed to ultraviolet (UV) rays (part of sunlight), production of melanin increases and it is incorporated into the epidermal cells before they die, making the cells darker. Melanin is a pigment barrier to prevent further

Figure 50-1 Structure of the skin and subcutaneous tissue. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed 3. FA Davis, Philadelphia, 1999, p 85, with permission.)

exposure of living skin (the stratum germinativum within) to ultraviolet rays. Ultraviolet rays are considered mutagenic—that is, capable of damaging the DNA within cells and causing mutations that may result in malignant cells.

Also in the epidermis (and dermis) are Langerhans cells, a type of macrophage that presents foreign antigens to helper T cells. This is the first step in the destruction of pathogens that have penetrated the epidermis.

Dermis

The dermis is made of fibrous connective tissue; the cells present are called fibroblasts. Fibroblasts produce the protein fibers collagen and elastin. Collagen fibers are very strong and form the bulk of the dermis; elastin fibers are capable of recoil and make the dermis somewhat stretchable. Within the dermis are the hair and nail follicles, glands, nerve endings, and blood vessels. The capillaries in the papillary layer of the dermis are important to nourish the stratum germinativum, which has no capillaries of its own.

Hair

Hair develops in epidermal structures called follicles. At the base of a follicle is the hair root, a group of cells that undergoes mitosis to produce the hair shaft. The cells quickly

die after producing keratin and incorporating melanin. Human hair with significant functions includes the eyelashes and eyebrows, which keep dust and sweat out of the eyes, and nostril hair, which filters air entering the nasal cavities. Hair on the head provides thermal insulation (sparse body hair does not).

Nails

Nail follicles are found at the ends of the fingers and toes, and growth of nails is similar to growth of hair. Mitosis in the nail root is a continuous process to produce new cells, which contain keratin. As these cells die, they form the visible nail. Nails protect the ends of the digits from mechanical injury and are useful for picking up small objects.

Receptors

The sensory receptors in the dermis are those for the cutaneous senses. Free nerve endings are the receptors for heat, cold, and pain; encapsulated nerve endings are specific for touch, and pressure. The sensitivity of an area of skin is determined by the number of receptors present.

Sebaceous Glands

The ducts of sebaceous glands open into hair follicles or directly to the skin surface. Their secretion is sebum, a

lipid substance that inhibits the growth of some bacteria and prevents drying of skin and hair. Skin that is dry tends to crack or fissure more easily, and even these small breaks in the epidermis are potential portals of entry for pathogens.

Sudoriferous (Sweat) Glands

Sudoriferous glands are also known as sweat glands. There are two kinds of sudoriferous glands: apocrine and eccrine. Apocrine glands are really modified scent glands and are most numerous in the axillae and genital area; they are activated by stress and emotions.

Eccrine glands are found throughout the dermis but are most numerous on the face, palms, and soles. They are activated by high temperatures or by exercise and secrete sweat onto the skin surface. The sweat is evaporated by excess body heat, which is a very effective cooling mechanism, although it does have the potential to lead to dehydration if water is not replaced by drinking.

Modified sweat glands called ceruminous glands are found in the dermis of the ear canals. Their secretion is called cerumen or ear wax. Cerumen prevents drying of the outer surface of the eardrum. Excess cerumen, however, may become impacted against the eardrum, prevent it from vibrating properly, and diminish the acuity of hearing.

Blood Vessels

The blood vessels in the dermis serve the usual function of tissue nourishment, but the arterioles are also involved in the maintenance of body temperature. Blood carries the heat produced by active organs and distributes it throughout the body. In a warm environment, dilation of blood vessels in the dermis increases blood flow and loss of heat to air or clothing (if cooler than the body). Constriction of blood vessels in a cold environment decreases blood flow to the skin and conserves body heat.

Stressful situations also bring about vasoconstriction in the dermis, which allows blood to circulate to more vital organs, such as the heart, liver, brain, or muscles.

Other functions of the skin are the formation of vitamin D from cholesterol when the skin is exposed to the UV rays of the sun and the excretion of small amounts of urea and sodium chloride in sweat.

Subcutaneous Tissue

The subcutaneous tissue, between the dermis and the muscles, is made of areolar connective tissue and adipose tissue. Although an unbroken stratum corneum is an excellent barrier to pathogens, even small breaks provide portals of entry. In the subcutaneous tissue are numerous white blood cells that destroy any pathogens that have entered by way of broken skin. Subcutaneous adipose tissue cushions some bones and provides some insulation from cold, but its most important function is energy storage. Excess nutrients are changed to fat and stored as potential energy for times when food intake may decrease.

Aging and the Integumentary System

The effects of age on the integumentary system are often quite visible. Cell division in the epidermis slows, fibroblasts in the dermis die and are not replaced, and both skin layers become thinner and more fragile. Both the collagen and elastin fibers in the dermis deteriorate, causing wrinkles. Sebaceous glands and sweat glands decrease their activity. The skin becomes dry, and temperature regulation in hot weather becomes more difficult. There is often less fat in the subcutaneous layer, which may make an elderly person more sensitive to cold temperatures. Hair follicles become inactive, and the hair thins. Melanocytes die, and the hair that remains becomes gray.

► NURSING ASSESSMENT

Health History

Skin problems are a fairly common complaint for the patient entering the health system. Many factors can influence the integumentary system. A skin problem may be the only complaint the patient has, or it may be a manifestation of an underlying systemic condition or psychological stress. Most important, the skin visibly communicates the patient's health. Therefore the questions that are posed to the patient are important in determining if the skin problem is a disease entity of its own or a sign of a more systemic disorder. Table 50–1 provides examples of general questions that can be asked of the patient to elicit information.

If further assessment of a particular problem area is necessary, the WHAT'S UP? line of questioning may be used. For example, if the patient has a rash, you can respond with the following questions:

Where is it? Is that the only area where you have a rash?

How does it feel? Does it itch? Burn?

Aggravating and alleviating factors. Does scratching aggravate it? Does anything else aggravate it, such as soaps and detergents? What relieves it? How have you treated it in the past?

Timing. How long have you had this problem? Does it recur?

Severity. How bad is the discomfort on a scale of 0 to 10, with 0 being comfortable and 10 being unable to touch the area?

Useful other data. Do you have other symptoms besides the rash, such as itching, discharge, tingling, or loss of sensation?

Patient's perception. What do you think is causing your rash?

Physical Assessment

Assessment of the skin involves not only the entire skin area, but also the hair, nails, scalp, and mucous membranes. The main techniques utilized in physical assessment of the skin are inspection and palpation. Ensure that the patient is disrobed but adequately draped in a well-lighted and warm environment. A handheld magnifying glass or penlight may be utilized to see small details and further illuminate the area.

Normally the skin is intact, with no abrasions, and is smooth, dry, well hydrated, and warm. Skin **turgor** is firm and

TABLE 50-1 QUESTIONS ASKED DURING NURSING ASSESSMENT OF THE INTEGUMENTARY SYSTEM

Question	Rationale
Do you (or does anyone in your family) have a history of dryness, rashes, itching, skin diseases, psoriasis, eczema, dermatitis, asthma, hay fever, hives, or allergies?	These conditions may be hereditary.
Have you noticed any changes in your skin, such as a sore that does not heal, rashes, lumps, or a change in an existing mole?	A sore that does not heal, a lump, or change in a mole may indicate cancer. Slow healing may also occur with vascular disease or diabetes mellitus. Rashes are associated with a variety of conditions.
Have you had any recent trauma to your skin?	A break in skin integrity can lead to infection.
Do you have a tendency to sunburn easily? Do you use sunblock?	Repeat sunburns are a risk factor for skin cancer.
Do you go to tanning salons or utilize sun lamps or tanning pills?	These are risk factors for skin cancer.
How often do you bathe or shower? What kind of soap do you use?	Some soaps may cause allergic reactions.
Do you wear a wig or hairpiece?	Adequate assessment of the scalp requires permission for removal of a wig or hairpiece.
Have you noticed a change in the growth or loss of your hair?	Hair loss can result from systemic illness or treatment or sometimes from infections or hair care products.
Have you experienced recent trauma or changes in your nails?	Nail changes may be caused by circulatory problems.
Do you wear artificial nails?	Artificial nails may mask changes.
Do you or any members of your immediate family or your coworkers have recent skin complaints?	Some skin disorders are contagious.
What medications do you take every day (prescription or nonprescription)? What is the dosage and frequency?	The patient may be taking medication for a skin disorder. Many medications cause skin reactions, from hives and photosensitivity to serious inflammatory conditions.
What medications did you take most recently? When did you take your last dose?	This might help pinpoint the cause of a new reaction.
What is your occupation?	Occupational exposures can lead to skin problems.
What recreational activities do you participate in?	Skin disorders can be caused by gym equipment that was not cleaned properly. Poison ivy may result from jogging in wooded areas.
Have you traveled recently?	This could help to pinpoint causes of suspicious skin changes.
Is there anything in your current environment, at home or work, that may be causing any skin problems (e.g., animals, plants, chemicals, infections, new carpeting, or new soaps or detergents)?	Various environmental factors can be causes of contact dermatitis; release of some chemicals can cause skin disorders.
Is there anything that touches your skin that causes a rash?	This may help pinpoint causes of contact dermatitis.

elastic. The skin surface is flexible and soft. Skin color ranges from light to ruddy pink or olive in white-skinned patients and light brown to deep brown in dark-skinned patients.

You need to be aware of normal developmental changes when performing an assessment. The skin of the neonate is very thin and friable (easily broken). During adolescence, the skin becomes thicker, with active sebaceous, eccrine, and apocrine glands. Body hair also changes during adolescence as a result of hormonal influences. In older patients the skin loses some of its elasticity and moisture. There is decreased activity of sebaceous and sweat glands. The older patient's skin is thinner, more fragile, and more wrinkled.

Inspection

Inspect each area of the skin, including nails, hair, scalp, and mucous membranes, for color, moisture, lesions, edema, intactness, vascular markings, turgor, and cleanliness. This examination should be done in an orderly sequence, such as hair, scalp, nails, buccal mucosa, and then the general skin surface from head to toe (Gerontological Issues Box 50-1).

COLOR. Skin color can be influenced by many factors, including the temperature of the patient, oxygenation, blood

flow, exposure to UV rays, and positioning. Because skin color can differ genetically from very light to very dark, skin assessment can be difficult for the novice practitioner.

Commonly noted alterations can include pallor, **erythema** (redness), jaundice, cyanosis, and brown color. Pallor is a paleness or decrease in color and can be caused by vasoconstriction, decreased blood flow, or decreased hemoglobin levels from anemia. Pallor is best assessed on the face, conjunctivae, nailbeds, and lips. Erythema, or red discoloration, may indicate circulatory changes and can be caused by vasodilation or increased blood flow to the skin from fever or inflammation. Erythema is best assessed on the face or area of trauma.

Jaundice, a yellow-orange discoloration, may occur as a result of liver disease. The best place to inspect for jaundice is in the sclera of the eye. Cyanosis, or bluish discoloration, may indicate a cardiac, pulmonary, or perfusion problem. The best places to inspect for cyanosis are the lips, nailbeds, conjunctivae, and palms. People of Mediterranean descent normally have a bluish tone to their lips; this is not cyanosis.

A brown color may be caused by increased melanin production and can indicate chronic exposure to sunlight or pregnancy. This is best assessed on the face, areola, nipples,

BOX 50-1 GERONTOLOGICAL ISSUES

In acute care settings, priorities are determined by medical diagnoses and often center around cardiovascular, respiratory, nutrition, comfort, or other immediate concerns. The feet may be forgotten in the rush to care for the patient and plan a timely discharge.

Feet are also viewed by some as dirty; washing the feet may be seen as a lowly job. It may be assumed that people take care of their own feet. However, many older people are unable to bend down or bring the feet up high enough to see or care for them.

For these reasons it is especially important for the nurse to assess and care for the feet, both in institutional settings and at home. General guidelines for assessment include the following:

- Inspect feet for redness or pressure ulcers over bony prominences
- Inspect feet for dryness or cracking
- Inspect between toes for cracking, wounds, or excess moisture
- Inspect and palpate for callouses
- Palpate dorsalis pedis and posterior tibial pulses for circulatory status
- Assess patient's sensation using a wisp of cotton or light touch

Hints to promote healthy feet:

- Soak the patient's feet briefly in warm water and wash using a gentle soap. Test the water to be sure it is not too warm, especially for the patient with reduced sensation.
- Thoroughly dry the feet, including between the toes. Water left to evaporate can cause drying and cracking.
- Use a pumice stone to help remove dry dead skin over heels or calluses. Work gently, rubbing the stone in one direction only and removing only a small amount of dead skin at any one time.
- Use a cream or lotion that does not contain alcohol to moisturize the feet. Apply it with a gentle massage while moving the patient's feet through range-of-motion exercises. To prevent falls, never apply lotion before the patient steps into the tub or shower.
- Use gauze or a commercially made pad to decrease pressure and friction in areas between toes that cross or other areas where breakdown is likely.
- Encourage the patient to wear cotton socks and shoes or slippers to avoid injury to the feet and prevent falls.

and areas exposed to the sun. A brownish color may also be the result of chronic peripheral vascular disease, especially noted on the lower extremities.

LESIONS. A lesion is any change or injury to tissue. Assessment of skin lesions helps determine the cause of a skin disorder. Lesions are described as primary or secondary. Primary lesions are the initial reaction to a disease process. Secondary lesions are the changes that take place in the primary lesion because of trauma, scratching, infection, or various stages of a disease. Lesions are further described according to type and appearance (Fig. 50-2).

When assessing and documenting skin lesions, note the color or colors of the lesion, the size (usually in centimeters), location, distribution, and configuration. *Configuration* refers to the pattern of the lesions, shown in Figure 50-3. Also note any exudate, including amount, color, and odor, and any accompanying symptoms. Gently stretching the skin over the rash area makes it stand out more for further assessment.

In general, healthy patients with naturally dark skin have a reddish undertone, with pinkish buccal mucosa, tongue, nails, and lips. If a dark-skinned patient is pale, the mucous membranes has an ash-gray color, lips and nailbeds appear paler than usual, and the skin appears yellow-brown to ash gray. Erythema presents as a purplish-gray color. Cyanosis presents as a gray cast to the skin. The nailbeds, palms, and soles may have a bluish cast. Jaundice can be noted in the oral mucosa, particularly the hard palate and the sclera closest to the cornea.

MOISTURE/DRYNESS. The assessment of moisture provides clues to the patient's level of hydration. Observe the skin for dryness, moisture, scales, and flakes. Moisture may be found in skin fold areas. The skin should normally be smooth and dry. Flaking and scaling of the skin indicate dry skin.

EDEMA. Edema occurs because of a buildup of fluid in the tissues. Edema can cause the skin to become stretched, dry, and shiny. The location, distribution, and color of edematous areas are determined and documented. If edema is unilateral, compare it with the opposite side of the body. Edematous extremities can be measured to track improvement or worsening of the condition. Dependent edema is edema that occurs in the part of the body that is at the lowest point, typically noted in the feet and ankles or in the sacrum if the patient is lying down.

VASCULAR MARKINGS. Vascular markings may be classified as normal and abnormal. Two common abnormal vascular changes are **petechiae** and **ecchymosis**. Petechiae are small purplish hemorrhagic spots, smaller than 0.5 mm in diameter. In the darker-skinned patient, petechiae are usually not visible on the skin but can be visualized in the conjunctivae and oral mucosa. Ecchymosis is a bruise in which the color changes from blue-black to greenish-brown or yellow over time.

GENERAL INTEGRITY AND CLEANLINESS. Assess the integrity of the skin. Elderly patients have thin, fragile skin that may have breaks or tears. Be sure to check between toes and skin folds and under a pendulous abdomen or breasts. Check over bony prominences for signs of pressure. Note general cleanliness and odors.

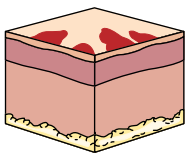

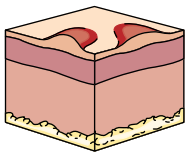

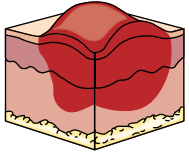

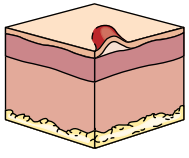

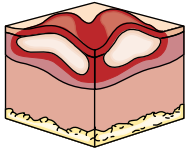

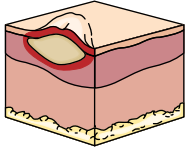

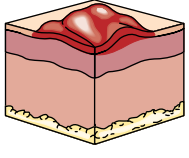

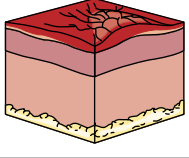

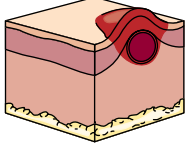

Palpation

Palpation is utilized in conjunction with inspection. Use the dorsum (back) of the hand to palpate temperature, because this part of the hand is most sensitive to changes in temperature. Use the fingertips to gently palpate over the skin to

ecchymosis: ec—out + cchymos—juice + is—condition

PRIMARY LESIONS

SECONDARY LESIONS

<p>Macule: Flat, nonpalpable change in skin color, with different sizes, shapes, color; usually smaller than 1 cm. (e.g. rubella, scarlet fever freckles)</p>	
<p>Papule: Palpable solid raised lesion that is less than 1 cm. in diameter due to superficial thickening in the epidermis. (e.g. ringworm, rosea, wart, mole)</p>	
<p>Nodule: Solid elevated lesion that is larger and deeper than a papule (e.g. fibroma, intradermal nevi)</p>	
<p>Vesicle: A small, blister-like raised area of the skin that contains serous fluid, up to 1 cm. in diameter (e.g. poison ivy, shingles, chicken pox)</p>	
<p>Bulla: A fluid-filled vesicle or blister larger than 1 cm. (e.g. burns, contact dermatitis)</p>	
<p>Pustule: Small elevation of skin or vesicle or bulla that contains lymph or pus (e.g. impetigo, scabies, acne)</p>	
<p>Wheal: Round, transient elevation of the skin caused by dermal edema and surrounding capillary dilatation; white in center and red in periphery. (e.g. hives, insect bites)</p>	
<p>Plaque: A patch or solid, raised lesion on the skin or mucous membrane that is greater than 1 cm. in diameter (e.g. psoriasis)</p>	
<p>Cyst: A closed sac or pouch which consists of semisolid, solid, or liquid material (e.g. sebaceous cyst)</p>	

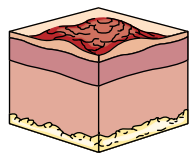

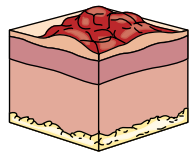

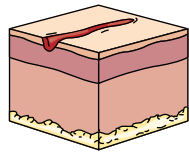

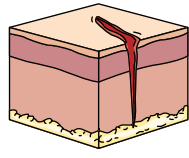

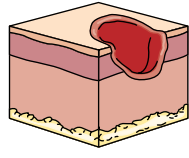

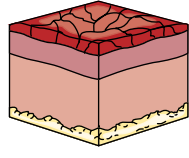

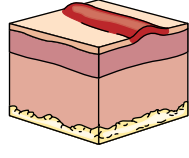

<p>Scales: Dry exfoliation of dead epidermis that may develop as a result of inflammatory changes (e.g. very dry skin, cradle cap, psoriasis)</p>	
<p>Crusts: A scab formed by dry serum, pus, or blood (e.g. infected dermatitis, impetigo)</p>	
<p>Excoriations: Traumatized abrasions of the epidermis or linear scratch marks (e.g. scabies, dermatitis, burns)</p>	
<p>Fissure: A slit or cracklike sore that extends into dermis usually due to continuous inflammation and drying (e.g. athlete's foot, anal fissure)</p>	
<p>Ulcer: An open sore or lesion that extends to the dermis (e.g. pressure sores)</p>	
<p>Lichenification: Thickening and hardening of skin from continued irritation such as intense scratching looks like surface of mass.</p>	
<p>Scar: A mark left in the skin due to fibrotic changes following healing of a wound or sore or surgical incision.</p>	

Figure 50-2 Description of skin lesions.

Figure 50-3 To assess configuration, observe the relationship of the lesions to each other. Then characterize the configuration by one of the patterns illustrated in the chart.

determine size, contour (flat, raised, depressed), and consistency (soft or indurated) of lesions. If the lesion is moist or draining, wear gloves to protect against the spread of infectious organisms. Note the degree of pain or discomfort associated with light palpation of lesions.

Assess turgor and texture of the skin. Skin turgor is a measure of the amount of skin elasticity. To assess for turgor, the skin on the back of the forearm or over the sternum is pinched between the thumb and forefinger and then released. Normally the skin lifts easily and then quickly returns to its normal state. Poor skin turgor is indicated by

“tenting” of the skin, with more gradual return to its normal state. Poor skin turgor may indicate dehydration. Normal aging of skin produces some loss of skin elasticity; the preferred place to check skin turgor in the elderly is over the sternum.

If edema is suspected, palpate those areas to assess for tenderness, mobility, and consistency. When pressure from your fingers leaves an indentation, this is called pitting edema. Pitting edema is classified by its depth. Press the edematous area (against bone, if possible) with your thumb for 5 seconds and then release. One way to measure edema is to measure depth of the pitting in millimeters. For example:

1+ edema = 1 mm depth, or trace edema
 2+ edema = 2 mm depth of indentation, or a small amount
 3+ = moderate edema
 4+ = a large amount of edema

Hair distribution over the entire body is palpated. Assess for hair color, quantity, thickness, and texture. Note any areas of **alopecia** (hair loss). Determine any recent changes in color and growth pattern. Note cleanliness, itching, redness, scaling, flakes, and tenderness. If lesions or lice are suspected, utilize disposable gloves to avoid spread of infection.

Terminal hair is the hair on the scalp, eyebrows, axillae, and pubic areas and on the face and chest of males. Vellus hairs are the soft, tiny hairs covering the body. Normally body hair has uniform distribution. Male and female pubic hair distribution may be noted. Scalp hair can normally be thick, thin, coarse, smooth, shiny, curly, or straight. Describe scalp hair distribution and cleanliness.

Nails can reflect the patient’s general health. Assess fingers and nails for color, shape, texture, thickness, and abnormalities. Normally for all patients the nail appears pink, smooth, hard, and slightly convex (160-degree angle), with a firm base. The nails of elderly patients may have a yellowish-gray color, thickening, and ridges. Brown or black pigmentation between the nail and nail base is normal in dark-skinned patients. Abnormal findings include clubbing, which may indicate hypoxia, and spoon nails (concave nails, also called koilonychia), which may be associated with anemia. (See Chapter 26.) Thick nails may indicate fungal infection. Palpate for nail consistency and observe for redness, swelling, or tenderness around the nail area. See Table 50–2 for other nail abnormalities.

TABLE 50-2 ABNORMALITIES OF THE NAILS

Nail Abnormality	Description	Causes
Beau’s lines	Transverse depressions in the nails	Systemic illnesses or nail injury
Splinter hemorrhages	Red or brown streaks in the nailbed	Minor trauma, subacute bacterial endocarditis, or trichinosis
Paronychia	Inflammation of the skin at the base of the nail	Local infection or trauma

Describe any abnormal skin conditions in detail. Include findings such as color of lesion, pain, swelling, redness, location, size, drainage (including amount, color, and odor), and eruption patterns.

► DIAGNOSTIC TESTS

Laboratory Tests

Cultures

Skin cultures are done to determine the presence of fungi, bacteria, and viruses. When a fungal infection is suspected, gently scrape scales from the lesion into a Petri dish or other indicated container. The specimen is then treated with a 10-percent potassium hydroxide (KOH) solution to make fungi more prominent. The specimen can remain at room temperature until sent to the laboratory.

LEARNING TIPS

When scraping scales, position the patient so that the skin lesion is vertical. Place the slide against the skin below the lesion. Be sure to wash your hands before and after, and wear gloves when collecting specimens.

If a viral culture is ordered, the fluid is expressed (gently squeezed) from an intact vesicle, collected with a sterile cotton swab, and placed in a special viral culture tube. If the lesion has crusts, they are removed or punctured before swabbing. The viral culture tube must be kept in ice and sent to the laboratory as soon as possible.

Wound cultures may also be collected with a sterile swab or wound culture kit. See Box 50–2 for specific instructions.

Skin Biopsy

A skin biopsy is indicated for deeper infections, to establish an accurate diagnosis, or for the evaluation of current treatment. A biopsy is an excision of a small piece of tissue for microscopic assessment. Three common types of skin biopsies are punch, shave, and incisional.

A punch biopsy uses a small round cutting instrument, called a punch, to cut a cylinder-shaped plug of tissue for a full-thickness specimen. An incisional biopsy is performed with a scalpel to make a deep incision and almost always requires a suture closure. A shave biopsy removes just the area that has risen above the rest of the skin.

BOX 50-2 Steps in Culturing a Wound

1. Use sterile saline to remove excess drainage and debris from the wound. Purulent material may have different bacteria than those actually causing the infection.
2. Using a sterile calcium aginate swab in a rotating motion, swab wound and wound edges 10 times in a diagonal pattern across the entire surface of the wound.
3. Do not swab over eschar.

For all biopsies, explain the procedure, assist in preparing a sterile field, calm and comfort the patient during the procedure, and assist in dressing the site following the procedure. The most uncomfortable part of the procedure is usually the injection of the local anesthetic agent. Explaining the procedure and providing appropriate calming techniques can make the procedure less traumatic to the patient.

Other Diagnostic Tests

Wood's Light Examination

Wood's light examination is the use of ultraviolet rays to detect fluorescent materials in the skin and hair present in certain diseases such as tinea capitis (ringworm). This examination is performed with a handheld black light in a darkened room.

Skin Testing

Patch and scratch tests are performed when allergic contact dermatitis is suspected. These are usually done by a dermatologist on uninvolved skin, such as the upper back or arms. Any hair in the area must first be shaved.

For the scratch test, the skin is superficially scratched or pricked with an allergen for an immediate reaction. If a reaction such as a wheal occurs, the test is positive for that allergen. Resuscitation equipment should be in the immediate vicinity in the event of a severe allergic (anaphylactic) reaction.

With the patch test, a delayed hypersensitivity reaction develops in 48 to 96 hours. The allergens are applied under occlusive tape patches. For this test, the skin should be free of oils. Cleanse the skin first with alcohol to promote patch adhesion. The test site must remain dry and free from moisture. The patch is removed in 2 days. Any reaction is noted, with a final reading in 2 to 5 days.

► THERAPEUTIC MEASURES

Open Wet Dressings

Wet compresses may be ordered for acute, weeping, crusted, inflammatory, or ulcerative lesions. The purpose of these dressings is to decrease inflammation, cleanse and dry the wound, and continue drainage of infected areas. They may be ordered either sterile or clean, depending on the risk for infection. The solutions commonly consist of room temperature to cool tap water or normal saline, aluminum acetate solution (Burrow's solution), or magnesium sulfate. The dressing is saturated with the solution before it is applied. Wet dressings are usually applied every 3 to 4 hours for 15 to 30 minutes.

LEARNING TIPS

To prevent chilling, no more than one-third of the body should be treated at one time. Keep the patient warm during this treatment.

Wet dressings should not be prescribed for more than 72 hours, because the skin may become too dry or macerated. If cool compresses are used, they should be reapplied every 5 to 10 minutes, because they become too warm from body heat. If warm compresses are utilized, monitor the skin closely to prevent burns.

Balneotherapy

Balneotherapy (therapeutic bath) is useful in applying medications to large areas of the skin, as well as for débridement, or removing old crusts; for removing old medications; and to relieve itching and inflammation. The temperature of the water should be kept at a comfortable level, avoiding hot baths. The bath should last for 15 to 30 minutes, while maintaining its warmth. Fill the tub half full. Keep the room warm to minimize changes in temperature. Advise the patient to wear loose clothing after the bath.

LEARNING TIPS

A bath mat should be used for treatment baths because some may make the tub slippery.

Water and saline are utilized for weeping, oozing, and erythematous lesions. Colloidal baths (such as oatmeal or Aveeno) are utilized for widely distributed skin lesions, for drying, and for relief of itching. Medicated tar baths, such as Almar-Tar or Bainetar, are used for chronic eczema problems and psoriasis. Any loose skin crusts can be removed after the bath. The room should be well ventilated, because tars are volatile.

To increase hydration after the bath, a lubricating agent is applied to damp skin, if emollient action is prescribed. Bath oils, such as Alpha-Keri, Avenol, and Lubath, are used for lubrication and itching.

Topical Medications

Many types of topical medications are used to treat skin conditions. These include lotions, ointments and creams, powders, gels, pastes, and intralesional therapy. Systemic medications may also be given for more serious conditions.

Lotions tend to cool the skin through water evaporation. They may also have a protective effect and may be antipruritic (treat itching). Lotions are usually applied with cotton gauze, gloves, or a soft brush.

Ointments and creams have a varied base (greasy, non-greasy, or penetrating), depending on the drug applied. These medications can protect the skin, provide lubrication, and prevent water loss. They are used for localized or chronic skin conditions. Ointments and creams can cause some reduction in blood flow to the skin. They are applied with a gloved hand or wooden tongue depressor.

Powders usually have a zinc oxide, talc, or cornstarch base. They act as a hygroscopic agent, to absorb moisture and reduce friction. Powders are usually applied with a shaker top. Powders are avoided around patients with respiratory disease or tracheostomies.

LEARNING TIPS

Avoid applying too much powder in skin fold areas. Dermatitis can occur with too much powder in these areas. Products with a cornstarch base can provide a good medium for growth of microorganisms.

Gels, or semisolid emulsions, become liquid with topical application. They are usually greaseless and do not stain. Many topical steroids are prescribed in this manner.

Pastes are semisolid substances comprised of ointments and powders. They are used for inflammatory disorders. Mineral oil can facilitate removal of these agents.

Topical corticosteroids are used to reduce or relieve pain and itching by decreasing inflammation. Steroids should be used sparingly and according to package directions. Overuse of topical steroids can cause thinning of the skin. Caution is needed when used on the face to prevent glaucoma, cataracts, and perioral dermatitis.

Intralesional therapy has an anti-inflammatory action. This procedure utilizes a tuberculin syringe, most often of a sterile suspension of a corticosteroid, injected just below the lesion. Local atrophy may occur if the injection is made into subcutaneous tissue. Common conditions that are treated with this therapy include psoriasis and keloids.

CRITICAL THINKING

Mr. Evans

Mr. Evans comes to the doctor's office with atrophic skin (thin, shiny, pink, with visible vessels) at the area of psoriasis where he is applying his corticosteroid ointment. He states that he has been generously applying a thick layer four times a day.

1. What might be the cause of this condition?
2. What should you include when you document his skin condition?

Answer at end of chapter.

Dressings

Dressings may be used to enhance absorption of topical medications, promote retention of moisture, prevent evaporation of medication, and reduce pain and itching. Occlusive dressings (for sealing the wound) are commonly used for skin disorders. An airtight plastic film is applied directly over the topical agent. Corticosteroids are also available as a special plastic surgical tape and can be cut to size. See Nursing Care Plan Box 50–3 for care of the patient with an occlusive dressing. Proper application of a plastic wrap dressing includes washing the area, lightly patting dry, applying the medication to moist skin, covering the medicated area with plastic wrap, and covering with a dressing to seal the edges. Wet dressings and ointments should only be applied to affected areas, not to healthy intact skin, because this can cause maceration of good skin. Plastic wrap dressings should be used for no more than 10 to 12 hours a day.

BOX 50-3 NURSING CARE PLAN FOR THE PATIENT WITH AN OCCLUSIVE DRESSING**▶ Impaired skin integrity related to open lesions****PATIENT OUTCOME**

Improved skin integrity as evidenced by reduction in size of lesion.

EVALUATION OF OUTCOME

Is there a decrease in wound size?

INTERVENTIONS

Assess areas of lesions for changes three times a day or as ordered.
Assess lesions for presence or absence of dead tissue and exudates.
Cleanse wound as prescribed (see text for specific bathing instructions). Lightly pat dry.
Apply prescribed topical agent (see text for specifics) to moist skin. Apply sparingly or as directed.
Apply plastic film, cut to size.
Cover with an appropriate dressing to seal edges.
Remove dressing for 12 out of 24 hours.

RATIONALE

Areas of redness, swelling, pain, and drainage may indicate infection.
Indicates areas of healing and infection.

Helps provide a healthy granulation area for healing.

Various agents have specific properties (control bacterial growth, prevent itching, have a protective effect, provide lubrication, relieve pain, or decrease inflammation).
Enhances absorption of medication and helps retain moisture.

Continued use may cause skin atrophy, folliculitis, erythema, and systemic absorption of medication.

EVALUATION

Are lesions free of redness, swelling, pain, and drainage?
Are lesions free of exudates and dead tissue?

Is wound clean and free of debris, crusts, and exudate?

Does area exhibit signs of healing (e.g., decrease in size and numbers of lesions, free from infection, less itching)?

Is the topical agent adherent to the skin?

Are there signs of healthy granulation tissue?
Is skin pink? Are there less open areas?
Is dressing removed for at least 12 hours?

▶ Body image disturbance related to presence of lesion or wound**PATIENT OUTCOMES**

Patient verbalizes acceptance of condition. Patient is willing to participate in care of lesion or wound.

EVALUATION OF OUTCOMES

Does patient verbalize acceptance of condition? Does patient participate in care of lesions?

INTERVENTIONS

Assess patient's feelings regarding condition.

Care for patient with an accepting attitude.
Allow opportunities for patient to verbalize concerns about condition.
Provide referrals to support groups and counselors as appropriate.

Assist patient in concealing lesion or wound in a safe and appropriate manner.

RATIONALE

Provides a baseline for care. If patient denies condition, he or she may not comply with care.
Patient will be aware of nuances in nurse's behavior.
Verbalizations allow patient to begin to accept and problem solve.

Patient may benefit from talking to others with similar condition or to another professional for objective evaluation.
Long sleeves and long pants may help conceal lesions, protect lesions, and prevent further skin damage.

EVALUATION

Does patient state willingness to follow care instructions?

Does patient allow nurse to partake in care of lesion or wound?
Does patient verbalize feelings appropriately?

Is patient receptive to appropriate referrals?

Is patient accepting of appearance of lesions?
Are lesions or wounds visible?

▶ Bathing/hygiene self-care deficit, related to presence of lesions or wound and discomfort**PATIENT OUTCOMES**

Patient verbalizes importance of good hygiene. Patient is willing to participate in bathing/hygiene.

EVALUATION OF OUTCOMES

Does patient verbalize importance of good hygiene? Is patient clean?

INTERVENTIONS

Assess patient's level of hygiene.

Instruct patient in appropriate bathing/hygiene:

RATIONALE

Provides a baseline for care.

Patient needs to be able to properly cleanse lesions to prevent infection. Avoidance of fric-

EVALUATION

Is patient's level of hygiene at an acceptable level?
Is patient able to verbalize understanding, as well as demonstrate good bathing techniques?

BOX 50-3 NURSING CARE PLAN FOR THE PATIENT WITH AN OCCLUSIVE DRESSING—CONT'D

- Avoid strong detergents and soaps; utilize gentle emollient soaps or prescribed soaps
 - Gently stroke areas of lesions
 - Pat dry; no friction
 - Maintain a little moisture on skin
 - Maintain comfortable environmental temperature
 - Have temperature of bath at a comfortable level to patient, but not too hot
- tion and strong soaps prevents further trauma to skin. Patient will not shiver in comfortable temperatures.
- Are lesions free of infection?

LEARNING TIPS

Continued use of occlusive dressings may cause skin atrophy, folliculitis, maceration, erythema, and systemic absorption of the medication. To prevent some of these complications, the dressing is removed for 12 out of every 24 hours.

Other dressings commonly used with topical treatments for skin conditions include gauze or cotton cloth held in place with small, stretchable tubular material (e.g., Surgitube, Tube gauze) for fingers, toes, and extremities; disposable polyethylene gloves sealed at the wrist; cotton socks or plastic bags for the feet; cotton cloth held in place with tubular material for the extremities; disposable diapers or cotton diapers for the groin and perineal areas; cotton cloth held in place with dress shields for the axillae; cotton or light flannel pajamas for the trunk; a shower cap for the scalp; and a face mask made from gauze and stretchable dressings with holes cut out for eyes, nose, mouth, and ears. The patient's primary care provider should specify the type of dressing and particular materials needed for this dressing.

Other Dressings

A variety of other types of dressing materials are available for wound and skin care. Transparent dressings (e.g., Op-Site, Tegaderm) can be used over skin tears or intravenous

insertion sites. Hydrocolloid dressings can help protect areas exposed to pressure and treat pressure ulcers in early stages. Gels, pastes, and granules can be used to fill in deep wounds to promote granulation and aid healing. See Chapter 51 for additional dressings used specifically for pressure ulcers.

▶ WOUND HEALING

Wounds can heal by first intention, second intention, and third intention. The edges of the wound are approximated with staples or sutures with first-intention healing. This usually results in minimal scarring. With healing by second intention, the wound is usually left open and allowed to heal by granulation. Scarring is usually extensive with prolonged healing. With healing by third intention, an infected wound is left open until there is no evidence of infection and the wound is then surgically closed. Additional information about wound healing is found in Chapter 11.

Answers to CRITICAL THINKING**Mr. Evans**

1. He may be sensitive or allergic to the medication. Most likely, he is applying too much too often. This ointment is applied as a thin layer, and usually only twice daily.
2. Note the size (usually in centimeters), location, color, distribution, and configuration. Describe exactly what you see, avoiding judgments about what you think it is.

REVIEW QUESTIONS

- Which of the following is the protein in epidermal cells that makes the skin relatively waterproof?
 - Collagen
 - Keratin
 - Melanin
 - Elastin
- Which of the following skin lesions is typically seen in chickenpox?
 - Macule
 - Papule
 - Vesicle
 - Wheal
- Why should wet dressings be applied only to one-third of the body at one time?
 - So the rest of the body can be observed for reaction to the dressing
 - To prevent chilling the patient
 - To prevent absorption of too much water, causing fluid overload
 - To enable the patient to be more mobile
- Which of the following terms describes a small, flat, red lesion?
 - Macule
 - Papule
 - Bulla
 - Crust
- Where can pallor best be assessed in a dark-skinned individual?
 - Upper back
 - Ear lobes
 - Antecubital fossa
 - Mucous membranes
- What equipment is most important to have readily available when a patient is undergoing testing for allergies?
 - Resuscitation equipment
 - Flashlight
 - Measuring device
 - Alcohol and cotton swabs

QUESTIONS TO GUIDE YOUR READING

1. How would you explain the pathophysiology of each of the skin disorders listed in this chapter?
2. What are the etiologies, signs, and symptoms of each of the skin disorders listed in this chapter?
3. What is the current medical treatment for each of the skin disorders listed?
4. What data should you collect when caring for patients with disorders of the integumentary system?
5. What nursing care will you provide for patients with each of the covered skin disorders?
6. How will you know if your nursing interventions have been effective?

Skin disorders cover a wide array of diseases and conditions. Disorders can be generalized or localized, acute, chronic, or traumatic. This chapter discusses common skin disorders encountered by nurses. An excellent resource on skin disorders, with pictures, is at www.nsc.gov.sg/commskin/skin.html. The American Academy of Dermatology can be accessed at www.aad.org.

► PRESSURE ULCERS *Pathophysiology and Etiology*

Pressure ulcers are often referred to by patients with old terms such as bedsores, decubitus ulcers, or pressure sores. Essentially a pressure ulcer is a sore caused by prolonged pressure against the skin. This may occur from spending a

prolonged period in one position, causing the weight of the body to compress the capillaries against a bed or chair, especially over bony prominences. Pressure ulcers are the result of tissue anoxia and begin to develop within 20 to 40 minutes of unrelieved pressure on the skin. Other causes include pressure from a tight splint or cast, traction, or other device. Those at risk are immobile patients, those with decreased circulation, and those with impaired sensory perception or neurological function.

Mechanical forces (pressure, friction, and shear) lead to the formation of pressure ulcers. The pressure level that closes capillaries in healthy people is 25 to 32 mm Hg. When pressure applied to the skin is greater than the pressure in the capillary bed, it can impair cellular metabolism. It decreases the blood supply to the tissues and eventually causes tissue ischemia. This reduction in blood flow causes **blanching** of the skin. The longer the pressure occurs, the greater the risk of skin breakdown and the development of a pressure ulcer.

Friction is the rubbing of the skin surface with an external mechanical force. Also referred to as “sheet burns,” this can happen when the patient is dragged or pulled across bed linens instead of being lifted.

Shearing occurs when the patient slides down in bed when the head of the bed is raised, or when being pulled or repositioned without being lifted off the sheets. With shearing, the skin and subcutaneous tissue remain stationary and the fat, muscle, and bone shift in the direction of body movement. As a result, there is damage deep within the tissues.

Any patient experiencing prolonged pressure is at risk for a pressure ulcer. Elderly patients have increased risk because of normal aging changes of the skin. Because thin patients have little padding when pressure is present, they have the greatest pressure applied to their capillaries. Obesity also is a contributing factor, because adipose tissue is poorly vascularized and is therefore more likely to develop ischemic changes. Impaired peripheral circulation also makes the skin more susceptible to ischemic damage.

Prevention

There are many interventions for the prevention of pressure ulcers. Assess and document the condition of the skin daily, so all are aware of developing problems. Gently cleanse the skin daily with tepid water and mild soap to prevent drying. To reduce friction, pat the skin dry rather than rubbing it dry. After bathing, daily lifelong lubrication of the skin with moisturizers is important to prevent dryness. Thoroughly dry skin-to-skin surfaces, such as under the breasts, skin folds (especially in the groin and abdominal folds), and between the toes, to prevent prolonged exposure to moisture. If incontinence is a problem, clean the skin promptly with tepid water and mild soap, pat dry, and apply a moisture barrier to prevent breakdown. Bony prominences or reddened skin areas should never be massaged; research has shown that blood vessels are damaged by massage when ischemia is present or when they lie over a bone.

Pressure on the skin should be avoided. Teach patients to shift their weight every 15 minutes if possible when lying or

sitting. When the patient is immobile, the highest level of mobility should be maintained; frequent active or passive range-of-motion exercises should be performed, as well as turning according to a written repositioning schedule. If patients are on bedrest, turn and reposition them at least every 2 hours, but preferably more often because ischemia development begins after 20 to 40 minutes of pressure. When positioning patients on their side, place them at a 30-degree angle or less and not directly on their trochanter, because this area is especially sensitive to pressure and can quickly break down. If patients are placed on the trochanter, they usually become restless and squirm around to get off the trochanter. If the patient is seated in a chair, repositioning every hour is important. A mobility program specific to the patient must be developed.

The patient’s heels should not rest on the bed surface. They should be elevated off the bed with pillows placed lengthwise under the calf or with heel elevators. Take care so pressure is not applied on the calf from the pillows. Be sure to also protect the patient’s elbows, sacrum, scapula, ears, and occipital area from pressure.

Donut-shaped cushions should never be used. They create a circle of pressure that cuts off the circulation to the surrounding tissue, promoting ischemia rather than preventing it. Pad skin contact surfaces, especially bony prominences, so they do not press against each other. (For example, place a small pillow between the knees when the patient is in a side-lying position.) Provide an appropriate pressure-relieving or pressure-reducing mattress and chair cushion for immobile patients. To avoid friction, use a sheet to lift and move patients; provide a trapeze to assist patients to move themselves. Prevent malnutrition and dehydration by ensuring an adequate intake of protein, calories, and fluid; provide 2500 mL of fluid each day if not contraindicated by other medical problems. See Gerontological Issues Box 51–1 for additional preventive measures.

Signs and Symptoms

The most common sites for pressure ulcers are the sacrum, heels, elbows, lateral malleoli, greater trochanters, and ischial tuberosities. Most patients experience pain at the ulcer site. A report of pain requires continual assessment, documentation, and treatment.

LEARNING TIPS

Pressure ulcers may be described according to a three-color system.

- *Black* wounds indicate necrosis.
- *Yellow* wounds have exudate and are infected.
- *Red* wounds are pink or red and are in the healing stage.

A wound may contain a mixture of black, yellow, and red colors. Necrotic wounds are the worst, because they have dead tissue. Beefy red wounds are desired because they are healing wounds. It is important to consider treating the worst color present first or healing will be delayed. For ex-

BOX 51-1 GERONTOLOGICAL ISSUES**Interventions to Prevent Skin Breakdown**

- Avoid the use of soap and water on dry skin areas. Use a moisture barrier cream or ointment on dry skin areas *before* bathing to protect the skin from the drying effects of water.
- Clean and dry areas between toes.
- Use perineal cleansing products to cleanse urine and feces residue from the perineum and anal areas. These products are specially designed to break down and facilitate the complete removal of urine and feces without irritating the skin.
- Use moisturizing creams that have no alcohol or perfume, which can irritate the skin.
- Avoid areas of skin pressure, especially over bony areas, by assisting the older adult to change positions on a regular schedule.
- Assess skin for areas of redness. If redness (stage I breakdown) occurs, the positioning schedule should be more frequent.
- Keep fingernails short.
- Use pillows and pads to help maintain alignment with position changes. Use specialized mattresses and chair cushions designed to decrease pressure.
- Encourage the older adult to be out of bed and active throughout the day. Remember to assess skin and reposition frequently even when out of bed, because areas of pressure occur whether the patient is in or out of bed.
- Provide a high-protein, vitamin-rich diet.

ample, if a wound is both yellow and black, the dead tissue must be removed first before the infection can be effectively treated. This color system is a helpful system for patients and families to use to describe wounds to the home care nurse, because colors are easily recognized and understood by most people.

Complications

Wound infection is a common complication. New ulcers can also appear, and the present ulcer can progress to a deeper wound. Wounds that do not heal or take a prolonged time to heal also occur and may cause pain.

Diagnostic Tests

All pressure ulcers are considered to be colonized with bacteria. This means that bacteria are present, but the wound is not necessarily infected. In most cases, adequate cleansing and debridement can prevent bacterial colonization from advancing to clinical infection. Swab cultures and culture and sensitivity tests may be done to identify the causative organism in suspected infection sites. (See Chapter 50 for instructions for obtaining a culture.) Results need to be interpreted to distinguish between true wound infection and bacterial colonization. If the wound is healing by second intention, it becomes colonized by bacterial flora on the skin and from the environment. If, however, the wound is extensive, bacterial growth may exceed the local tissue defenses and a true wound infection results.

If the wound does not demonstrate any healing or if an ischemic ulcer is suspected, noninvasive and invasive arterial blood supply studies are recommended. Also, quantita-

tive wound biopsies may be performed for large, extensive wounds.

Medical Treatment

Treatment varies according to the size, depth, and stage of the pressure ulcer, as well as special needs of the patient and health care provider preference. All pressure must be removed from the affected area for healing to occur. Cleanliness must be maintained. Basic treatment includes debridement, cleansing, and dressing of the wound to provide a moist and healing environment.

LEARNING TIPS

The epidermis skates on moisture, so the wound must be kept moist to heal.

DEBRIDEMENT. Debridement is the removal of dead or nonviable tissue from a wound. It may be done surgically or nonsurgically. Nonsurgical debridement methods include mechanical, enzymatic, and autolytic. Surgical debridement is used only if the patient has sepsis or **cellulitis** or to remove extensive **eschar**. Eschar is a black, hard scab or dry crust that forms from necrotic tissue. It may hide the true depth of the wound and must be removed for the wound to heal.

Scissors and forceps can be used for mechanical debridement to selectively debride nonviable tissue. Dextranomer beads, another method of mechanical debridement, may also be sprinkled over the wound to absorb exudate and all other products of tissue breakdown, as well as surface bacteria. Whirlpool baths and wet-to-dry saline gauze dressings may also be used for mechanical debridement. The wet gauze is placed directly on the wound (avoiding surrounding healthy tissue) and allowed to dry completely. The drying process causes the gauze to adhere to the wound; when it is pulled off, tissue is pulled off with it. This results in nonselective debridement, because viable tissue may also be removed in this process. These methods are painful, so the patient should be premedicated for pain and assessed frequently.

Enzymatic debridement involves the application of a topical debriding agent. These agents vary as to application methods, so careful reading of instructions is necessary. Most of these debriding agents are proteolytic enzymes that selectively digest necrotic tissue.

Autolytic debridement is the use of a synthetic dressing or moisture-retentive dressing over the ulcer. The eschar is then self-digested via the action of the enzymes that are present in the fluid environment of the wound. This method is not used for infected wounds.

cellulitis: cellu—cell + itis—inflammation

eschar: eschara—scab

Surgical debridement is the removal of devitalized tissue, or thick, adherent eschar, utilizing a scalpel, scissors, or other sharp instrument. Depending on the amount of debridement to be done, this may be performed in the operating room, the treatment room, or the patient's room. Following surgical debridement, grafting may be required to close the wound. This becomes necessary if it is a full-thickness ulcer, if there is loss of joint function, or for cosmetic purposes. The patient is assessed continually for pain during the procedure, especially if there is a donor site for grafting.

WOUND CLEANSING. The ulcer should be thoroughly cleansed via whirlpool, handheld shower head, or irrigating system with a pressure between 4 and 15 pounds per square inch (psi), such as a 30-mL syringe with an 18-gauge needle. Pressure less than 4 psi does not adequately cleanse the wound, and greater than 15 psi may damage tissue. If an irrigating system is used, 250 mL of normal saline (or sometimes tap water for home wound care) should be used to thoroughly cleanse the wound. If the wound is red, gentle irrigation with a needleless 30- to 60-mL syringe should be used to prevent trauma and bleeding. When bleeding occurs, wound healing has been impaired. However, if the wound has been diagnosed as being infected, pressure flushing with a 30- to 60-mL syringe and an 18-gauge needle is needed to help remove bacteria.

LEARNING TIPS

Dilution is the solution to wound pollution!

Once the wound is cleansed and debrided, apply a dressing. The wound heals more rapidly in a moist environment, with minimal bacterial colonization and a healing temperature. This takes 12 hours to occur after the wound is covered with an occlusive dressing. If a dressing is frequently removed, the wound may not reach its healing temperature and healing may be impaired. When possible, the dressing should be left in place for extended periods. Infected wounds are not covered with occlusive dressings; draining wounds may require frequent dressing changes.

WOUND DRESSINGS. Dressings vary according to size, location, depth, stage of ulcer, and preference of the ordering practitioner. Commonly used dressing materials include hydrogel dressings, polyurethane films, hydrocolloid wafers, biologic dressings, alginates, and cotton gauze. These materials promote an optimum healing environment. Hypoallergenic tape should be used to secure dressings if tape is necessary. Protective paste may be applied to protect nonaffected tissue from topical agents. In all cases, pressure should be kept off the wound. No treatment will be effective if pressure continues to damage the tissue.

Nursing Process

ASSESSMENT. Provide an ongoing assessment of the status of the pressure ulcer, as well as underlying causes and impediments to healing. Monitor for risk factors such as prolonged immobility, incontinence, and inadequate hydration and nutrition.

Use transparency film or a disposable ruler to measure the diameter of the ulcer in centimeters. Depth can be measured with a cotton-tipped applicator. Also, gently probe a cotton-tipped applicator under the skin edges to detect tunneling and measure lateral tissue destruction.

There are several different staging systems for pressure sores based on the depth of tissue destroyed. In general, the staging systems are categorized from I to IV. See Figure 51-1 for photos of ulcers at each stage.

- Stage I: The skin is still intact, but the area is red and does not blanch. There may also be warmth, hardness, and discoloration of the skin. Be aware that even though the skin is intact, there may be deeper tissue damage that is difficult to observe.
- Stage II: There is a break in the skin, with partial-thickness skin loss of epidermis, dermis, or both. The ulcer may appear as an abrasion, a shallow crater, or a blister.
- Stage III: There is full-thickness skin loss, which extends to the subcutaneous tissue, but not fascia. There may be undermining of adjacent tissue. The ulcer looks like a deep crater and may have eschar.
- Stage IV: There is full-thickness skin loss with damage to the muscle, bone, or support structures such as tendons. There may be undermining and sinus tracts (tunneling).

Assess wound exudate. Two common types of wound exudate are serosanguineous and **purulent**. Serosanguineous exudate is fluid consisting of serum and blood. It is blood-tinged, amber-colored fluid. Purulent fluid is a fluid that contains pus. It can vary in color and have different odors, which are suggestive of different wound colonizations. Creamy yellow pus may indicate *Staphylococcus*. Beige pus that has a fishy odor may suggest *Proteus*. Green-blue pus with a fruity odor may indicate *Pseudomonas*. Brown pus with a fecal odor may suggest *Bacteroides*.

Gently palpate the wound with a gloved hand to assess the texture of granulations. If the granulations are healthy, they have a slightly spongy texture.

Document all findings carefully in the medical record, so all health team members can monitor progress of healing. Many institutions have specific forms for drawing pictures of the locations and sizes of wounds. There may be a special instant camera to document progress. Follow policy at the institution where you work.

purulent: purulentus—pus

LEARNING TIPS

Many institutions now have nurses who have been specially trained in wound care. Consult one of these nurses for expert wound assessment and treatment recommendations.

NURSING DIAGNOSIS. Possible nursing diagnoses include impaired skin integrity related to immobility or pressure on skin surface; risk for infection related to open wound; pain related to ulcer and treatments; and ineffective coping related to chronic condition of ulcer.

NURSING CARE. See Nursing Care Plan Box 51–2 for the Patient with a Pressure Ulcer.

BOX 51-2 NURSING CARE PLAN FOR THE PATIENT WITH A PRESSURE ULCER

▶ Impaired skin integrity related to pressure on skin surface

PATIENT OUTCOMES

Skin integrity is improved as evidenced by decrease in wound size, no further development of other pressure ulcers.

EVALUATION OF OUTCOMES

Is there a decrease in wound size? Are there any new pressure ulcers?

INTERVENTIONS

Assess status of pressure ulcer according to stage, color, exudates, texture, size, and depth.
Assess cause of pressure (e.g., immobility, friction, shearing).
Cleanse wound gently with warm water; rinse; pat dry gently with gauze.
Debride wound as prescribed (method depends on patient's condition and goals of care).
Dress wound appropriately for prescribed topical agent.
Position patient off the ulcer.
If a leg ulcer, provide for frequent rest periods with leg elevation; if immobile, reposition every 2 hours.

RATIONALE

Provides baseline data on which care is based.
Allows for correction and also prevents further trauma.
Reduces number of bacteria. Drying prevents maceration of skin. Gentle handling prevents further trauma.
Debridement removes drainage and wound debris. Permits granulation of tissue.
Protects underlying wound and helps promote healing.
Prevents further pressure and trauma on ulcer.
Prevents further tissue breakdown.

EVALUATION

What stage is ulcer? Are there any other outstanding characteristics?
What is the cause of this ulcer?
Is wound clean and dry?
Does wound look clean and free of debris?
Is dressing applied appropriately?
Is patient positioned off the ulcer?
Is leg elevated?
Is patient repositioned every 2 hours?

BOX 51-2 NURSING CARE PLAN FOR THE PATIENT WITH A PRESSURE ULCER—CONT'D**Risk for infection related to open wound****PATIENT OUTCOMES**

Patient will not experience further wound infection or systemic sepsis. (Total elimination of bacteria is impossible due to nature of the condition.)

EVALUATION OF OUTCOMES

Is patient free from signs and symptoms of further infection? Is patient free from systemic infection?

INTERVENTIONS	RATIONALE	EVALUATION
Assess ulcer at every dressing change or at least every 24 hours. Note color and appearance of skin; diameter and depth of ulcer; areas of tenderness, swelling, redness, and heat; and drainage.	Allows for early recognition of infection and response to treatment.	Are signs of infection present?
Monitor temperature at least every 12 hours.	Elevated body temperature is one sign of infection.	Is patient afebrile?
Provide meticulous wound care (see under Impaired Skin Integrity).	Helps decrease the level of contamination. Prevents further infection.	Is wound showing signs of healing?
Use thorough handwashing techniques. Use sterile technique for dressing changes.	Prevents cross-contamination.	Does nurse take proper wound precautions?

Pain related to ulcer and treatments**PATIENT OUTCOMES**

Patient will be as comfortable and as pain free as possible as evidenced by statement of increased comfort, statement of decreased pain, and ability to sleep at night.

EVALUATION OF OUTCOMES

Does patient express comfort? Does patient express a decrease in pain? Is patient able to sleep?

INTERVENTIONS	RATIONALE	EVALUATION
Assess level of pain through verbalizations, facial expressions, and positioning of body.	Monitors level of pain and response to therapy.	At what level is pain? Is it better or worse with treatment?
Offer analgesics as prescribed.	Analgesics help relieve pain.	Do analgesics relieve pain?
Decrease anxiety with relaxation techniques (e.g., distraction, music).	Relaxation can lessen pain intensity.	Is patient less anxious? Does patient verbalize less pain?
Maintain a comfortable environment: cover; provide for privacy; position in good alignment and comfortably; and maintain a comfortable room temperature.	Relaxes patient and lessens intensity of discomfort.	Does patient express an increase in comfort?

INFLAMMATORY SKIN DISORDERS**Dermatitis****Pathophysiology and Etiology**

Dermatitis is the inflammation of the skin and is characterized by itching, redness, and skin lesions, with varying borders and distribution patterns. Dermatitis can be caused by exposure to allergens or irritants, by heredity, or by emotional stress. Many times the cause is not known; in this

case the terms *eczema* or *nonspecific eczematous dermatitis* may be used. The terms *eczema* and *dermatitis* are sometimes used interchangeably. There are three common types of dermatitis: contact dermatitis, atopic dermatitis, and seborrheic dermatitis. All types tend to be chronic and respond well to treatment, but are prone to recur. See Table 51-1 for common types of dermatitis.

Prevention

The patient should prevent irritation to the skin by avoiding irritants, allergens, excessive heat, and dryness and by controlling perspiration. Baths should be short, and water should be tepid. Deodorant soaps should be avoided; mild

dermatitis: derma—skin + itis—inflammation

TABLE 51-1 COMMON TYPES OF DERMATITIS

Type	Description
Contact	Acute or chronic condition; caused by contact with irritant or allergen
Irritant contact	Caused by direct contact with an irritating substance, such as soap, detergent, strong medication, astringent, cosmetic, or industrial chemical
Allergic contact	From contact with an allergen, such as perfume, tanning lotion, medication, hair dye, poison ivy, poison oak; contact results in cell-mediated immune response
Atopic	Chronic inherited condition; may be associated with respiratory allergies or asthma; can vary between bright red maculas, papules, oozing, lichenified , and hyperpigmented
Seborrheic	Chronic, inflammatory disease usually accompanied by scaling, itching, and inflammation; seborrhea is excessive production of sebaceous secretions; found in areas with abundant sebaceous glands (scalp, face, axilla, genitocrural areas) and where there are folds of skin; can appear as dry, moist, or greasy scales, yellow or pink-yellow crusts, redness, and dry flakiness; can be associated with emotional stress; may be genetic predisposition

Contact dermatitis caused by nail polish

Contact dermatitis caused by topical anesthetic.

Seborrheic dermatitis.

superfatted soaps are recommended instead. Dry skin is lubricated with creams, oils, or ointments as appropriate. Itching and scratching are prevented as much as possible.

Signs and Symptoms

Itching and rashes or lesions are the main clinical manifestations of dermatitis. The lesions vary depending on the type and location of dermatitis. Rashes and lesions can be dry, flaky scales; yellow crusts; red; fissures; macules; papules; and vesicles. (These are described in Chapter 50, Fig. 50-2). Scratching can make any of these lesions worse.

LEARNING TIPS

Itching and scratching can occur during sleep, causing the rash to worsen. Place mitts on baby's hands or have the adult or older child wear cotton gloves at night.

Complications

The lesion or rash worsens with continued irritation, exposure to offending agents, or scratching. Infections of the skin are common and may be due to the many open areas and breaks in the skin, as well as the patient's reluctance to properly wash the affected area because of pain from the lesions. Some infections can also become systemic.

Diagnostic Tests

Diagnosis is usually based on history, symptoms, and clinical findings. If infection is suspected, cultures of the lesions may be ordered to identify the infecting agent.

Medical Treatment

Treatment varies according to symptoms. Basic treatment objectives are to control itching; alleviate discomfort and pain; decrease inflammation; control or prevent crust formation and oozing; prevent infection; prevent further damage to the skin; and heal the skin as much as possible.

Itching and discomfort can be somewhat relieved by antihistamines, analgesics, and antipruritic medications as ordered. Colloidal oatmeal preparations added to baths can also help relieve some of the **pruritus**.

Steroids may be used to suppress inflammation. They may be administered as a topical, intralesional, or systemic agent. The specific type and vehicle used depends on the type of lesion, the body area involved, and the extent of the lesion. Topical administration is preferred if possible, because systemic steroids can cause systemic side effects, including adrenal suppression.

pruritus: prur—itch + itis—condition

Tub baths and wet dressings help control oozing and prevent further crust formation. These interventions serve to loosen exudates, scales, and other wound debris, providing a clean area for topical application of medication. Skin is protected by lightly patting dry, avoiding friction, avoiding hot water, and using a sunscreen agent when outdoors.

Nursing Process

ASSESSMENT. You can use the WHAT'S UP? format to assess the rash, as described in Chapter 50.

Also refer to Chapter 50, Table 50–1 for specific questions to ask. Observe the rash or lesions for character, distribution, description, skin tenderness, signs of scratching, and other associated problems. (See Fig. 50–2.)

NURSING DIAGNOSIS. Possible nursing diagnoses include impaired skin integrity related to rash, lesions, and scratching; disturbed body image related to visible rash or lesions; and deficient knowledge related to disease and treatment.

PLANNING. The goals of treatment are to keep the skin intact or improve integrity, prevent infection, and maintain comfort. The patient will have improved body image as evidenced by a statement of acceptance of the condition and ability to socialize with others. The patient will verbalize understanding of the condition and demonstrate ability to perform self-care measures.

IMPLEMENTATION

Impaired Skin Integrity. Cleanse the area as ordered by the physician, taking care not to further irritate the skin. Cool moist compresses, dressings, or tepid tub baths may be ordered to help relieve inflammation and itching, debride lesions, and soften crusts and scales. Pat the skin dry rather than rubbing to prevent further trauma.

Apply topical agents as ordered to help suppress inflammation. Administration at bedtime helps promote comfortable sleep. Many antihistamines also have a sedative effect. If lesions are generalized, protein can be lost through oozing of serum. Patients are encouraged to eat a high-protein diet to promote healing and replace lost protein.

Gloves or mitts, especially at night, help prevent scratching. The patient is also encouraged to keep fingernails short to prevent scratching. Application of slight pressure with a clean cloth may help relieve itching. Relaxation exercises or referral to a support group may help the patient cope with distressing symptoms.

Disturbed Body Image. Allow patients to verbalize concerns if they wish. Refer to a support group, if available, to get help from others in similar circumstances. Display an accepting attitude while caring for skin lesions. The patient will be quick to pick up your reaction to the lesions, especially if it is negative. Encourage the patient to participate in skin care to allow more control over the situation. Long sleeves or other appropriate covering may make the lesions less noticeable and the patient more comfortable.

Deficient Knowledge. Instruct the patient in application of topical agents and dressings. Overuse of medications can

further traumatize skin, so application of a very thin layer is advised. Instruct the patient in how to recognize changes, improvement, or flare-ups of the disorder and what symptoms to report to the health care provider. Because most skin conditions are cared for at home, it is important for the patient to have the skills needed to monitor the condition and carry out treatment appropriately. Advise the patient to avoid overexposure to sun to prevent skin damage. Sunscreen agents should be used when outdoors. A humidifier in the home helps maintain hydration of skin and control itching during dry weather, especially in winter. It is important for the patient to know if the condition is chronic and how to prevent flare-ups if possible.

LEARNING TIPS

When applying topical medications, *more is not better!*

EVALUATION. If medical and nursing care have been effective, the lesions will be controlled or in remission, the patient will state that itching and other discomforts are controlled, the patient will be able to socialize without undue difficulty, and the patient will be able to describe and demonstrate self-care measures.

Psoriasis

PATHOPHYSIOLOGY AND ETIOLOGY. Psoriasis is a chronic inflammatory skin disorder in which the epidermal cells proliferate abnormally fast. Usually, epidermal cells take about 27 days to shed. With psoriasis, the cells shed every 4 to 5 days. The abnormal keratin forms loosely adherent scales with dermal inflammation.

Psoriasis is characterized by exacerbations and remissions. The cause is not known; however, often there may be a family history. The onset can be at any age, with 27 years the average age. The condition can be severe if the onset is in childhood. Many factors can influence the suppression and outbreak of lesions, but this varies from individual to individual. Sun and humidity may suppress lesions. Aggravating factors include streptococcal pharyngitis, emotional upset, stress, hormonal changes, cold weather, skin trauma, and certain drugs (e.g., antimalarials, lithium, beta blockers).

PREVENTION. Because the exact etiology is not known, measures to prevent exacerbation of symptoms are specific to the patient's circumstances. General preventive measures include avoidance of upper respiratory infections, especially streptococcal infections; avoidance of or coping with emotional stress; avoidance of skin trauma, including sunburns; and avoidance of medications that may precipitate a flare-up.

SIGNS AND SYMPTOMS. Signs and symptoms vary according to the patient and the particular type of psoriasis. Lesions are red papules that join to form plaques with distinct borders (Fig. 51–2). Silvery scales develop on un-

psoriasis: psor—itch + iasis—inflammation

Figure 51-2 Psoriasis. Note bright red scaly plaque with silvery scale. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA Davis, Philadelphia, 1997, p 258, with permission.)

treated lesions. Areas most often affected are the elbows and knees, scalp, umbilicus, and genitals. Other signs and symptoms include nail involvement, intergluteal pinking, itching, and dry or brittle hair.

COMPLICATIONS. Because of the nature of the disease, with its lesions and itching, secondary infections can occur. Psoriatic arthritis may develop after the psoriasis has developed, with nail changes and destructive arthritis of large joints, the spine, and interphalangeal joints. If the psoriasis becomes severe and widespread, fever, chills, increased cardiac output, and benign lymphadenopathy can result.

DIAGNOSTIC TESTS. Testing depends on the severity of the psoriasis. Normally this disease is diagnosed by physical assessment alone. Diagnostic tests may be performed to rule out concurrent disease or secondary infections.

MEDICAL TREATMENT. Treatment varies according to the type and extent of the disease, as well as physical preference. Psoriasis is a chronic disease with remissions and exacerbations. Basic treatment objectives are to decrease the rapid epidermal proliferation, inflammation, and itching and scaling. Usually the patient is instructed to bathe daily in a tub bath, using a soft brush to assist in the removal of scales.

Topical therapy includes steroids, salicylic acid, keratolytics, coal tar, anthralin, ultraviolet (UV) light, and, in severe cases, antimetabolite chemotherapy agents. Topical corticosteroids may be used for their anti-inflammatory effect. Occlusive dressings are commonly used to enhance penetration of medications. (See Chapter 50.) Keratolytic ointments or gels enhance the effects of salicylic acid to loosen or remove scales.

Tar preparations are usually prescribed along with the corticosteroids for conditions that warrant it. The tar acts as

an antimitotic, slowing the epidermal cell division. Occlusive dressings are not used with tars. Anthralin is a substance extracted from coal tar. It also suppresses mitotic activity. The anthralin may be mixed with salicylic acid in a stiff paste. The patient must be closely observed, because the anthralin is a strong irritant and can cause chemical burns. It is usually applied for no longer than 2 hours. Both coal tar and anthralin are commonly used in combination with UV light and are usually administered in inpatient settings or specialized outpatient clinics.

Ultraviolet light may be designated as UVB, shorter wavelength, or UVA, longer wavelengths. UVA is from an artificial source, such as special mercury vapor lamps or special cabinets. The amount of exposure depends on the patient's condition, pigmentation, and susceptibility to burning. The patient must wear eye guards during treatments. Oral psoralen tablets (a photosensitizing agent) followed by exposure to UVA is called PUVA therapy. PUVA therapy temporarily inhibits DNA synthesis, which is antimitotic. Because psoralen is a photosensitizing agent, the patient must not only wear dark glasses during the treatment period, but also for the entire day after treatments. The long-term safety of PUVA therapy is still unknown. Possible side effects include increased skin carcinomas, premature skin aging, and actinic keratosis (pre-malignant lesions of the skin). The patient should be observed closely for redness, tenderness, edema, and eye changes. Therefore initial and follow-up eye examinations, skin biopsies, urinalysis, and blood tests may be ordered.

Antimetabolites are reserved for the most severe cases, as a last resort. Methotrexate is the most common agent given. Because of its hepatotoxicity, it is contraindicated in patients with liver disease, alcoholism, renal disease, and bone marrow suppression. Before therapy, a liver biopsy and routine laboratory tests are completed.

CRITICAL THINKING

Mrs. Long
Mrs. Long arrives at the health clinic to complain that the prescribed shampoo she is using for her scalp is not working. She states that she washes her hair thoroughly with the medicated shampoo and immediately rinses completely. She wants to know why her scalp shows no signs of improvement. What should you tell her?
Answers at end of chapter.

Nursing Care

Nursing care for the patient with psoriasis is the same as nursing care for the patient with dermatitis. The only addition is to encourage frequent periods of rest to enhance the antimitotic effects of the therapeutic agents.

► INFECTIOUS SKIN DISORDERS

A variety of infections can affect the skin. The most common disorders are discussed in this section. See Table 51-2 for a summary of additional skin infections.

TABLE 51-2 INFECTIOUS SKIN DISORDERS

Type	Description	Complications	Treatment/Nursing Care
Impetigo contagiosa	<p>Common contagious, infectious, inflammatory skin disorders usually caused by streptococcus or <i>Staphylococcus aureus</i>; sources of infection include swimming pools, pets, dirty fingernails, beauty and barber shops, and contaminated clothing, towels, sheets; may occur secondary to scrapes, cuts, insect bites, burns, dermatitis, poison ivy.</p> <p>Primary skin infection can appear on exposed areas of the body (extremities, hands, face, neck) or skin-fold areas (axillae).</p> <p>Rash appears as oozing, thin-roofed vesicle that rapidly grows and develops a honey-colored crust; crusts are easily removed, and new crusts appear; lesions heal in 1 to 2 weeks if allowed to dry.</p>	<p>Glomerulonephritis resulting from a particular strain of streptococcus infection.</p> <p>Lesions may spread from one skin area to another.</p> <p>Lesions may persist if not permitted to dry.</p> <p>Secondary pyoderma, or acute inflammatory purulent dermatitis, may occur if lesions are unresponsive to treatment.</p>	<p>Systemic antibiotics are administered as prescribed.</p> <p>Topical antibiotics are used after crust removal.</p> <p>Gentle washing with a mild soap, or soaking with warm, moist compresses, aids in crust removal, removes debris, and provides a clean bed for topical therapy.</p> <p>Appropriate antipyretic are prescribed as necessary.</p> <p>Keep fingernails short and clean.</p> <p>Glove or mitt hands as necessary to prevent scratching.</p> <p>Patient must remain home until all lesions are healed.</p> <p>Teach proper disposal or washing of any material that comes in contact with lesions.</p> <p>Appropriate hygienic practices must be adhered to in preventing skin-to-skin or person-to-person spread.</p> <p>Observe client for 6 to 7 weeks for signs/symptoms of glomerulonephritis.</p>

Impetigo on the face.

Herpes Simplex

Pathophysiology and Etiology

Herpes simplex virus (HSV) is a common viral infection that tends to recur repeatedly. There are two types: type I virus (HSV-I), which occurs above the waist and causes the fever blister or cold sore (Fig. 51-3); and type II virus (HSV-II), which occurs below the waist and causes genital herpes.

The primary infection occurs through direct contact, respiratory droplet, or fluid exposure from another infected person. Following this, the virus lies dormant in nerve ganglia near the spinal column, where the immune system cannot destroy it. The patient is asymptomatic at this time.

Recurrence of the infection can happen spontaneously or be triggered by fever, sunburn, stress, illness, menses, fatigue, or injury. The secondary lesion may appear isolated or as groups of small vesicles or pustules on an erythematous base. Crusts eventually form, and the lesions heal in about 1 week. The lesions are contagious for 2 to 4 days before dry crusts form.

Figure 51-3 Herpes simplex. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA Davis, Philadelphia, 1997, p 306, with permission.)

Prevention

Avoidance of contact with a known infected lesion during the blistering phase can prevent the primary lesions. Patients should also be taught to avoid sharing contaminated items such as toothbrushes, lipsticks, and drinking glasses. This disease can recur spontaneously. Avoidance of certain stressors, such as sunburn, injury, and fatigue, may delay a recurrence. The use of sunscreens, especially on the lips, may be helpful.

TABLE 51-2 INFECTIOUS SKIN DISORDERS — CONT'D

Type	Description	Complications	Treatment/Nursing Care
Furuncles and carbuncles	<p>A furuncle is a small, tender boil that occurs deep in one or more hair follicles and spreads to surrounding dermis; may be single or multiple; usually caused by <i>Staphylococcus</i>; usually occurs on body areas prone to excessive perspiration, friction, and irritation (e.g., buttocks, axillae); can recur; the boil eventually comes to a soft yellow, black, or white head; there is localized pain, tenderness, and surrounding cellulitis; lymphadenopathy may be present.</p> <p>A carbuncle is an extension of a furuncle; an abscess of skin and subcutaneous tissue; deeper than furuncle; caused by <i>Staphylococcus</i>; usually appears where skin is thick, fibrous, and inelastic (e.g., back of neck, upper back, and buttocks); associated symptoms may include fevers, pain, leukocytosis, prostration.</p> <p>Both tend to occur in debilitated clients, and more often in diabetics.</p>	<p>Furuncles may progress to carbuncles.</p> <p>Carbuncles may progress to infection of bloodstream.</p> <p>Further spread of infection can occur to self and others.</p> <p>Occasionally, scarring may occur.</p>	<p>Prevent trauma; avoid squeezing or irritation.</p> <p>Cleanse surrounding skin with antibacterial soap, followed by application of antibacterial ointment.</p> <p>Surgical incision and drainage may be performed.</p> <p>Cover draining lesion with dressing.</p> <p>Follow standard precautions. Double bag all soiled dressings and dispose of properly.</p> <p>Systemic antibiotic therapy (based on sensitivity studies) is instituted for carbuncles or spreading furuncles.</p> <p>Analgesia and antipyretics are ordered as necessary.</p> <p>Bed rest is advised with carbuncles or furuncles on perineal or anal regions.</p> <p>Cover mattress and pillows with plastic and wipe daily with a disinfectant.</p> <p>Wash all linens, towels, and clothing after each use.</p> <p>Properly discard razor blades after each use.</p> <p>Strict hand washing is maintained to prevent cross-contamination.</p>

Signs and Symptoms

Some patients may have a prodromal phase of burning or tingling at the site for a few hours before eruption. The area becomes erythematous and swollen. Vesicles and pustules erupt in 1 to 2 days. There may also be redness with no blistering. Lesions can burn, itch, and be painful. The attacks vary in frequency but diminish with age. The patient is contagious until scabs are formed.

Complications

If herpes simplex is present in the vagina at childbirth, the newborn may be infected (meningoencephalitis or a pan-visceral infection may occur). If the person touches the affected area and then rubs the eyes, the eyes can become severely infected.

Diagnostic Tests

Cultures of the lesions provide a definitive diagnosis. Most lesions are diagnosed on the basis of history, signs, and symptoms.

Medical Treatment

There is no complete cure. Recurrences will happen. Topical acyclovir (Zovirax) ointment is the drug of choice for primary lesions, to suppress the multiplication of vesicles. It does not benefit secondary lesions. Oral acyclovir may be recommended for severe or frequent attacks (six or more attacks per year) or for patients who are immunosuppressed. Various lotions, creams, and ointments may be prescribed to accelerate drying and healing of lesions (e.g., camphor, phenol, alcohol). Antibiotics may be indicated for secondary infections.

Nursing Care

Educating the patient about the disease and recurrences is very important. Instruct the patient about when the infection is contagious and how to prevent spreading the virus from one part of the body to another or to other individuals.

Herpes Zoster (Shingles)

Pathophysiology and Etiology

Herpes zoster, or shingles, is an acute inflammatory and infectious disorder that produces a painful vesicular eruption on bright red edematous plaques along the distribution of nerves from one or more posterior ganglia. This eruption follows the course of the cutaneous sensory nerve and is almost always unilateral (one sided) (Fig. 51-4).

Herpes zoster is caused by the varicella zoster virus. This virus appears identical to the one that causes chickenpox. It is thought that herpes zoster is a reactivation of this latent varicella virus. The incubation period is 7 to 21 days. The vesicles appear in 3 to 4 days. Eruption usually occurs posteriorly and progresses anteriorly and peripherally along the dermatome. The total duration of the disease can vary from 10 days to 5 weeks.

This disease occurs most commonly in the elderly or in those who have a diminished resistance, such as the patient with acquired immunodeficiency syndrome (AIDS), the patient on immunosuppressant agents, or the patient with a malignancy or injury to the spine or a cranial nerve.

Prevention

Avoidance of the person with this disease during the contagious phase (a few days before eruption until vesicles dry or scab) is the best prevention.

Signs and Symptoms

In addition to the vesicles and plaques, there may be irritation, itching, fever, malaise, and, depending on the location of lesions, visceral involvement. Lesions may be very painful; the likelihood of pain increases with age.

Complications

Postherpetic neuralgia, persistent dermatomal pain, and hyperesthesia are common in the elderly and can last for weeks to months after the lesions have healed. The incidence and severity of these complications increases with age.

Ophthalmic herpes zoster affects the fifth cranial nerve and can be a serious complication. Consultation with an ophthalmologist is imperative because this complication can affect eyesight. Other complications can occur with facial and acoustic nerve involvement, including hearing loss, tinnitus, facial paralysis, and vertigo. Full-thickness skin necrosis and scarring can occur if lesions do not heal properly; systemic infection can occur from scratching, causing the virus to enter the bloodstream.

Diagnostic Tests

Diagnosis is usually confirmed by the clinical picture of the patient and associated signs and symptoms. Cultures may be ordered if secondary bacterial infections are suspected.

Medical Treatment

Treatment is aimed at controlling the outbreak, reducing pain and discomfort, and preventing complications. Acyclovir, either intravenous (IV), oral, or topical, may be prescribed in the early stages of the initial infection, for a severe outbreak, and if the patient is immunosuppressed or debilitated. Acyclovir does not cure, but it may help control the initial outbreak. Analgesics are prescribed for pain and discomfort. Cor-

Figure 51-4 Herpes zoster (shingles). (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA Davis, Philadelphia, 1997, p 307, with permission.)

ticosteroids may be administered to prevent postherpetic neuralgia and reduce pain but are not used for ocular involvement. Topical steroids should not be applied if a secondary infection is present, because they suppress the immune system. Antihistamines are administered to control itching. Antibiotics are prescribed for secondary bacterial infections.

Nursing Care

Appropriate precautions during the contagious stage are necessary to prevent spread. Cool compresses two or three times a day help cleanse and dry lesions, as well as lessen itching. Hyperesthesia may be somewhat relieved with stockings, wraps, or a tight T-shirt that provides continuous firm pressure. Any appropriate measures to increase comfort should be initiated.

Fungal Infections

Pathophysiology and Etiology

Dermatophytosis, or a fungal infection of the skin, occurs when there is an impairment of the skin integrity in a warm, moist environment. This infection occurs through direct contact with infected humans, animals, or objects. *Tinea* is the term used to describe fungal skin infections; the name used after tinea indicates the body area affected. For example, tinea capitis is a fungal infection of the scalp. Common fungal infections and treatments are described in Table 51-3.

dermatophytosis: derma—skin + phyton—plant + osis—condition

TABLE 51-3 FUNGAL INFECTIONS

Type	Description	Treatment/Nursing Care
Tinea pedis (athlete's foot)	<p>Common fungal infection, most frequently seen in those with warm, moist, sweaty feet; occlusive shoes; or friction/trauma to the feet. Three types: chronic plantar scaling, acute vesicular, and interdigital.</p> <p>Chronic plantar scaling will have slight redness and mild to severe scaling; fold lines on sole appear to have white powder because of scaling; may be toenail involvement; itching is usually not present.</p> <p>Acute vesicular appears as a sudden eruption of small, painful, itchy vesicles; may also accompany chronic plantar scaling.</p> <p>Interdigital is more common; there is erosion, scaling, and fissuring in toe webs; area is painful, burning, and itchy, and there is usually an offensive odor.</p>	<p>Chronic plantar scaling may be treated with kerolytics and topical antifungal agents; these agents help in relieving symptoms and improve appearance; they are not curative.</p> <p>Acute vesicular is treated with soaks or baths two or three times a day for 2 to 3 days to dry up blisters; astringent paint is applied to debrided areas; topical corticosteroids help relieve itching.</p> <p>Interdigital may be treated with combined antifungal and antibacterial therapies or antifungals alone; soak feet twice daily and dry well.</p> <p>Teach patient prevention measures: keep feet dry; dry carefully between toes; apply foot powder to absorb perspiration; wear cotton socks to absorb perspiration; if weather permits, use perforated shoes or sandals; avoid plastic or rubber-soled shoes; wear water shoes in public showers and near swimming pools.</p> <p>Apply topical agents properly: apply antifungals thinly; treat for time specified, even after apparent clearing.</p>
Tinea capitis (ringworm of scalp)	<p>Contagious; commonly causes hair loss in children.</p> <p>Appears as scattered round, red, scaly patches; small papules or pustules may be evident at edges of patches; hair is brittle at site, breaks off, and temporary areas of baldness result; may be mild itching; kerion inflammation may occur after weeks.</p>	<p>Teach prevention measures: never share combs, brushes, pillowcases, or headgear.</p> <p>Systemic antifungals are prescribed because of high relapse rate with topical agents; review side effects with client.</p> <p>Oral corticosteroids are indicated for kerion inflammation to help prevent alopecia; review side effects with client.</p> <p>Instruct family on contagious aspect of disease; assess other family members and pets for organism.</p>

Tinea capitis.

TABLE 51-3 FUNGAL INFECTIONS — CONT'D

Type	Description	Treatment/Nursing Care
Tinea corporis (tinea circinata; ringworm of body)	Erythematous macule that progresses to rings of vesicles or scale with a clear center that appears alone or in clusters; usually occurs on exposed areas of body; can be moderately to intensely itchy. Infected pet is common source of infection.	Teach prevention measures: keep skin areas, especially folds, dry; use clean towel and washcloth daily; wear cotton clothing, especially on hot, humid days. Topical antifungals are prescribed for small, localized lesions. Oral antifungals are indicated for severe, widespread, resistant, or follicular cases. Topical corticosteroids are prescribed for itching.
Tinea cruris (jock itch)	Ringworm of groin that may extend to inner thighs and buttocks area; may occur with tinea pedis; often in obese people who are athletic. Lesion first appears as a small red scaly patch and then progresses to a sharply demarcated plaque with elevated scaly or vesicular borders; itching can range from absent to severe.	Teach patient prevention measures: avoid heat, moisture, and friction. Topical antifungals are prescribed; apply in a thin layer to rash and a few centimeters beyond border. Oral antifungals may be indicated for widespread cases or those resistant to topical therapy. Topical corticosteroids may be prescribed for itching.
		
Tinea cruris. The inner thigh is the typical location for tinea cruris, or “jock itch.” The border is pronounced and scaly.		
Tinea unguium	Ringworm of the nails; also referred to as onychomycosis . Chronic fungal infection of nails, usually the toenails; a lifelong disease. There is yellow thickening of nail plate; it is friable and lusterless; eventually crumbly debris accumulates under free edge of the nail and causes nail plate to become separated; over time, the nail may become thickened, painful, and destroyed.	Systemic antifungals are rarely given for toenail involvement, but may be prescribed for fingernail involvement (review side effects). Topical antifungals are usually ineffective. Nail may have to be surgically removed (nail avulsion). Explain high relapse rate to patient. Keep nails neatly trimmed and buffed flat; gently scrape out any nail debris.
		
Onychomycosis (tinea unguium).		

Cellulitis

Pathophysiology and Etiology

Cellulitis is the inflammation of skin cells or cellular or connective tissue resulting from a generalized infection, usually with *Staphylococcus* or *Streptococcus* spp. It can occur as a result of skin trauma or a secondary bacterial infection of an open wound, such as a pressure sore, or it may be unrelated to skin trauma. It most often occurs in the extremities, usually the lower legs.

Prevention

Good hygiene and prevention of cross-contamination are important. If there is an open wound, preventing infection and promoting healing are critical.

Signs and Symptoms

The initial sign of cellulitis is a localized area of inflammation that may become more generalized if not treated properly. Common clinical manifestations include warmth, redness, localized edema, pain, tenderness, fever, and lymphadenopathy. It may be seen in any areas of an open wound, with skin trauma, and in the lower legs. The infection can worsen rapidly if not treated properly.

Diagnostic Tests

Culture and sensitivity testing of any pustules or drainage is necessary to identify the infecting organism. Blood cultures may also be indicated to rule out bacteremia.

Medical Treatment

Topical and systemic antibiotics are prescribed according to culture and sensitivity test results. Debridement of nonviable tissue is necessary when there is an open wound. Systemic antibiotics are indicated if fever and lymphadenopathy are present.

Nursing Care

Assess for a history of recent skin trauma. The affected extremity can be measured to determine degree of edema and to monitor for improvement. Temperature and other signs of worsening or systemic infection are monitored for and reported. The affected extremity should be elevated to decrease edema. Analgesics and application of warm compresses as ordered may increase comfort. Antibiotics are administered as ordered. Use of standard precautions, including frequent, thorough handwashing, is a must to prevent spread of infection. The patient should be taught infection control measures, especially if home dressing changes are ordered.

Acne Vulgaris

Pathophysiology and Etiology

Acne vulgaris is a common skin disorder of the sebaceous glands and their hair follicles that usually occurs on the face, chest, upper back, and shoulders. The etiology is multifocal. The most common cause is hormonal changes.

The sebaceous glands are under endocrine control, especially the androgens. Stimulation of androgens (e.g., during adolescence or the menstrual cycle) in turn stimulates the sebaceous glands to increase sebum production. This, along with gradual obstruction of the pilosebaceous ducts with accumulated debris, ruptures the sebaceous glands, which causes an inflammatory reaction that may lead to papules, pustules, nodules, and cysts. Acne occurs when the ducts through which this sebum flows become plugged.

Other factors that influence occurrence and severity of acne include a hereditary tendency, stress, and external irritants such as strong soaps or cosmetics. It is not related to diet, chocolate, sexual activity, or uncleanliness.

Prevention

Acne vulgaris occurs regardless of interventions; however, certain interventions can lessen the severity or prevent complications. Avoidance of “picking” pimples prevents further inflammation and scarring. The patient should avoid excessive washing, irritants, and abrasives.

Signs and Symptoms

The initial lesions are comedones. Closed comedones, or whiteheads, are small white papules with tiny follicular openings. These may eventually become open **comedo**, or blackheads. The color is not caused by dirt but to lipids and melanin pigment. Scarring occurs as a result of significant skin inflammation; picking can worsen inflammation and lead to further scarring. The resulting inflammation can lead to papules, pustules, nodules (Fig. 51–5), cysts, or abscesses.

Medical Treatment

Medical treatment prevents new lesions and helps control current lesions. Effective topical agents include benzoyl peroxide (Desquam-X; Benzagel), an antibacterial that may help prevent pore plugging; antibiotics (erythromycin,

Figure 51-5 Acne vulgaris. (From Goldsmith, LA, Lazarus, and GS, Tharp, MD: *Adult and Pediatric Dermatology*. FA Davis, Philadelphia, 1997, p 351, with permission.)

tetracycline) to kill bacteria in follicles; and vitamin A acid (Retin-A, tretinoin) to loosen pore plugs and prevent occurrence of new comedones. Topical agents may be used alone or in combination. It may take 3 to 6 weeks before improvement is seen.

Systemic antibiotics (long term, low dose) and isotretinoin (Retin-A) are usually reserved for severe cases; the patient must be closely monitored for side effects. Estrogen therapy (oral contraceptives) may also be prescribed for young women; however, the risks often outweigh the benefits. Women should be aware that some antibiotics reduce the effectiveness of oral contraceptives. Systemic corticosteroids may occasionally be prescribed for severe nodular acne, but they are associated with severe side effects.

Other medical treatments include comedo extraction, intralesional injections of corticosteroids, cryosurgery (freezing with liquid nitrogen), mild peeling (UV light, carbon dioxide, liquid nitrogen, mild acid), dermabrasion (deep chemical peel), excision of scars, and injection of fibrin or collagen below the scars. These treatments depend on the severity, age, condition, and physician and patient preference.

Nursing Care

Review all medication instructions with the patient. Antibiotics should be used as directed to avoid development of antibiotic-resistant strains of bacteria. Encourage the patient to gently wash the face twice daily, especially before topical medication application, using a mild soap. All topical agents should be applied with clean hands to acne-prone areas, not just where the acne is. These agents must be applied to dry skin. Medications should not be applied near eyes, nasolabial folds, and corners of the mouth because of the potential for irritation.

LEARNING TIPS

Topical benzoyl peroxide may bleach colored fabrics. Have the patient wear a white cotton T-shirt under clothing if benzoyl peroxide is used on the back, and use an old or white pillowcase at night.

If the patient is ordered a combination of topical agents, unless contraindicated, the tretinoin is used at night and the others in the morning or afternoon. Tretinoin could be neutralized if mixed directly with other agents. The patient must be careful with sun or sunlamp exposure while using tretinoin. Also, remind the patient that it may be necessary to continue treatment even when the skin clears.

Above all, try to dispel misconceptions regarding the cause of the acne and give appropriate health education. Advise the patient to keep hands away from the face and especially not to touch or squeeze pimples. Keep hair clean and off the face. Avoid cosmetics, lotions, and shaving creams on the face.

▶ PARASITIC SKIN DISORDERS

Pediculosis

Pathophysiology and Etiology

Pediculosis is an infestation by lice. There are three basic types: pediculosis capitis (head lice), pediculosis corporis (body lice), and pediculosis pubis (pubic or crab lice). Generally the lice bite the skin and feed on human blood, leaving their eggs and excrement, which can cause intense itching. The lice are oval and are approximately 2 mm in length.

In pediculosis capitis the female louse lays eggs (nits) close to the scalp, where the nits become firmly attached to hair shaft. The most common areas of infestation are the back of the scalp and behind the ears. The nits are about 1 to 3 mm in length and appear silvery white and glistening. Transmission is by direct contact or contact with infested objects, such as combs, brushes, wigs, hats, and bedding. It is most common in children and people with long hair.

Pediculosis corporis is caused by body lice that lay eggs in the seams of clothing and then pierce the skin. Areas of the skin usually involved are the neck, trunk, and thighs.

Pediculosis pubis is caused by crab lice. It is generally localized in the genital region, but it can also be seen on hairs of the chest, axillae, eyelashes, and beard. The lice are about 2 mm in length and appear crablike. It is chiefly transmitted through sexual contact or to a lesser degree by infested bed linen.

Prevention

Obvious prevention is avoidance of contact with an infested person or object. Brushes, combs, hats, and other personal items should not be shared. Good personal hygiene and routine clothes washing are other preventive measures; however, even someone with meticulous hygiene can develop this infection if there is contact with the organism.

Signs and Symptoms

Pediculosis capitis can result in no itching or intense itching and scratching, especially at the back of the head. Nits may be noticeably attached to hair. A papular rash may be seen.

Pediculosis corporis may appear as minute hemorrhagic points. Excoriations may be noted on the back, shoulders, abdomen, and extremities. It may also cause intense itching.

Pediculosis pubis results in mild to severe itching, especially at night. Black or reddish-brown dots (lice excreta) may be noted at the base of hairs or in underclothing. Gray-blue macules may also be noted on the trunk, thighs, and axillae; this is the result of the insects' saliva mixing with bilirubin.

Complications

Secondary bacterial infections can occur with pediculosis capitis, resulting in impetigo, furuncles, pustules, crusts, and matted hair. Secondary lesions that can occur with pediculosis corporis include parallel linear scratches, hyperemia, eczema, and hyperpigmentation. Most important, body lice

pediculosis: pedicul(us)—louse + osis—condition

may be vectors for rickettsiae disease. Complications with pediculosis pubis include dermatitis and the coexistence of other sexually transmitted diseases.

Diagnostic Tests

Diagnosis is through history and physical assessment. The patient may also be tested for sexually transmitted diseases if pediculosis pubis is present.

Medical Treatment

Medical treatment is aimed at killing the parasites and mechanically removing nits. Pediculicides containing pyrethrum or permethrin are the most commonly recommended compounds. These agents should kill the lice and nits, although some lice develop pesticide resistance, making mechanical removal necessary. Permethrin (Nix) remains active for about a week, killing the adult lice immediately and the nits when they hatch days later. Pyrethrins (RID, A-200 Pyrinate) must be reapplied in 1 week to kill newly hatched lice.

Complications are treated, as appropriate, with antipruritics, topical corticosteroids, and systemic antibiotics. Physostigmine ophthalmic ointment is applied to affected eyebrows and eyelashes. Other medications should not be applied to eyebrows or eyelashes.

Nursing Care

Reassure the patient and family that head lice can happen to anyone, and this is not a sign of uncleanliness. These infections are treated on an outpatient basis, so patient education is important. Package instructions should be followed for correct usage of all medications.

Instruct the patient to bathe with soap and water and to disinfect combs and brushes in hot, medicated soapy water. A fine-toothed comb dipped in vinegar can be used to re-

move nits from hairy areas. Nits can be removed from eyebrows and eyelashes with a cotton-tipped applicator after treatment. Clothing, linens, and towels should be laundered in hot water and detergent; unwashable clothing should be dry-cleaned or sealed in a plastic bag for 10 days. Treatment should be started immediately to prevent rapid spread. Family members and close contacts (sexual contact with pediculosis pubis) should be examined for infestation and should put on clean clothing.

Shampoos and lotions kill nits, but they do not remove them. To loosen nits from the scalp, the hair may be soaked in a solution of equal parts vinegar and water and a shower cap worn for 15 minutes. The hair is then combed with a fine-toothed comb and thoroughly rinsed or shampooed to mechanically remove the nits. Children may return to school after adequate medical treatment, even if dead nits are still present.

LEARNING TIPS

It is not possible to dry-clean or wash all infected items, such as mattresses and upholstered furniture. Adult lice can live away from humans for only 3 to 4 days. Therefore simply vacuum the upholstered furniture. The lice die in 3 to 4 days without human contact.

Scabies

Pathophysiology and Etiology

Scabies is a contagious skin disease caused by the mite *Sarcoptes scabiei*. It results from intimate or prolonged skin contact or prolonged contact with infected clothing, bedding, or animals (e.g., dogs, cats, other small animals). The parasite burrows into the superficial layer of the skin (Fig. 51-6). These burrows appear as short, wavy, brownish-black

Figure 51-6 Scabies. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*, FA Davis, Philadelphia, 1997, p 295, with permission.)

lines. The patient is asymptomatic while the organism multiplies, but it is most contagious at this time. Symptoms do not occur for almost 4 weeks from time of contact.

Prevention

All persons (and animals) in intimate contact with an infected patient should be treated at the same time to eliminate the mites. The mites survive less than 24 hours without human contact. Therefore bed linen, clothes, and towels should be washed, but furnishings need not be cleaned. Clean clothing and linens should be applied.

Signs and Symptoms

The major complaints are itching and rash. Itching can be intense, especially at night. The itching occurs 1 month after infestation and may persist for days to weeks after treatment. The rash may appear as small, scattered erythematous papules, concentrated in finger webs, axillae, wrist folds, umbilicus, groin, and genitals. Male patients may exhibit excoriated papules on the penis and groin area.

Complications

Hypersensitivity reactions to the mite can result in crusted lesions, vesicles, pustules, excoriations, and bacterial superinfections.

Diagnostic Tests

Diagnosis is confirmed by a superficial shaving of a lesion and microscopic evaluation for adult mite, eggs, or feces.

Medical Treatment

Topical scabicides are used for chemical disinfection. Usually the cream or lotion is applied in a thin layer to the entire body from neck to feet (including genitals, umbilicus, and skin-fold areas), is left on overnight (8 to 12 hours), and is washed off in the morning; however, package instructions should be referred to for each medication. One or two applications is usually curative, depending on the agent prescribed. Antipruritics and corticosteroids may be prescribed for itching.

Nursing Care

A warm soapy bath or shower removes scales and skin debris. Advise the patient to apply the topical medication as ordered; not to repeatedly use scabicides, because it can increase itching and cause further skin irritation; to follow medication directions; to treat family members and close contacts simultaneously to eliminate mites; to wear clean clothing; and to use clean linens. Remind the patient that itching may continue for up to 2 weeks after treatment, until the allergic reaction subsides. (Dead mites remain in the epidermis until exfoliated.)

► PEMPHIGUS

Pathophysiology and Etiology

Pemphigus is an acute or chronic serious skin disease characterized by the appearance of bullae (large fluid-filled blisters) of various sizes on otherwise normal skin and mucous membranes. The etiology is unknown, but it is probably due to an autoimmune disorder. It usually occurs in patients from middle to older age.

Successive crops of bullae suddenly appear on skin or mucous membranes. The bullae are fragile and flaccid. They enlarge, rupture, and form painful, raw, eroded, partial-thickness wounds that bleed, ooze, and form crusts. Pemphigus usually originates in the oral mucosa and then spreads to the trunk. Large areas of the body become involved.

Signs and Symptoms

Besides the appearance of the blisters, the patient experiences pain, burning, and itching. The lesions have a foul smell. Involvement of the oral mucosa can interfere with chewing, swallowing, and talking. The patient is in constant misery.

Complications

The major complication is a bacterial secondary infection. There is a high morbidity and mortality rate associated with this disease.

Diagnostic Tests

A positive Nikolsky's sign is a characteristic finding. This occurs when there is sloughing or blistering of normal skin when minimal pressure is applied. A biopsy of a blister reveals acantholysis, or separation of epidermal cells from one another.

Medical Treatment

Treatment is aimed at controlling the disease, healing the skin, and preventing complications. Corticosteroids in large doses and cytotoxic agents are prescribed to control the disease and bring about remission. Medicated mouthwashes may be prescribed for mouth lesions. Analgesics and antipruritics are prescribed according to the patient's specific signs and symptoms. Because of fluid, blood, and protein losses through the partial-thickness injury, a high-protein, high-calorie diet is recommended along with appropriate fluid replacement therapy.

Nursing Care

The patient is educated on the effects and side effects of medications. Fluid balance is monitored with regular intake and output, body weight, and blood pressure measurement.

LEARNING TIPS

Animals infected with scabies should be treated by a veterinarian.

pemphigus: pemphix—blister

The patient is encouraged to maintain adequate fluid intake. Administer tepid wet dressings or baths to lessen secondary infection, cleanse the area, decrease odor, and increase the comfort level of the patient. Potassium permanganate baths may decrease infection and clean and deodorize the area. Always thoroughly dissolve potassium permanganate crystals in a small container before adding to tub water. Undissolved crystals may further damage and burn the skin. Dry the patient thoroughly after the bath. Do not use tape on the patient because this may cause further blistering. Talcum powder may be indicated to keep the skin from sticking to linens and bedclothes. Maintain meticulous oral hygiene. Offer cool drinks often to lessen discomfort. Provide appropriate psychosocial support necessary because of the length of illness, the chronic nature of the condition, and the physical appearance of lesions.

► BURNS

Many people are hospitalized each year for burns. Burns affect not only the skin but every major body system. Smoke inhalation and wound infections complicate care of the patient who has been burned.

Pathophysiology and Signs and Symptoms

Burns are wounds caused by an energy transfer from a heat source to the body, heating the tissue enough to cause damage. Locally, the heat denatures cellular protein and interrupts the blood supply. The three zones of tissue damage are described in Figure 51-7.

Figure 51-7 Three zones of tissue damage. (Modified from Ruppert, SD, Kernick, JG, and Dolan, JT: *Dolan's Critical Care Nursing*. FA Davis, Philadelphia, 1996, p 942, with permission.)

The amount of skin damage is related to (1) the temperature of the burning agent; (2) the burning agent itself; (3) the duration of exposure; (4) the conductivity of tissue; and (5) the thickness of the involved dermal structures. Alterations in normal skin functioning resulting from a major burn injury include loss of protective functions, impaired temperature regulation, increased risk for infection, changes in sensory function, loss of fluids, impaired skin regeneration, and impaired secretory and excretory functions.

SYSTEMIC RESPONSES. The alterations in the functional capacity of the skin affect virtually all major body systems. Following a major burn, increased capillary permeability leads to the leakage of plasma and proteins into the tissue, resulting in the formation of edema and loss of intravascular volume. There is also an evaporative water loss through burn tissue that can be 4 to 15 times normal. The increase in metabolism leads to further water loss through the respiratory system.

Cardiac function is affected. There is an initial decrease in cardiac output, which is further compromised by the circulating plasma volume loss. Severe hematological changes resulting from tissue damage and vascular changes occur in patients with major burns. Plasma moves into the interstitial space because of increased capillary permeability. In the first 48 hours after a burn, fluid shifts lead to hypovolemia and, if untreated, hypovolemic shock. Loss of intravascular fluid causes an increase in hematocrit, and there is red blood cell destruction. The intense heat decreases platelet function and half-life. Leukocyte and platelet aggregation may progress to thrombosis.

Metabolic demands are very high in patients with burns. A high metabolic rate proportional to the severity of the burn is usually maintained until wound closure. This hypermetabolism is further compromised by associated injuries, surgical interventions, and the stress response. Severe catabolism also begins early and is associated with a negative nitrogen balance, weight loss, and decreased wound healing. Elevated catecholamine levels are triggered by the stress response. This, along with elevated glucagon levels, can stimulate hyperglycemia.

Gastrointestinal problems that can develop with a major burn include gastric dilation, Curling's ulcer, paralytic ileus, and superior mesenteric artery syndrome. Most of these problems occur in response to fluid shifting, dehydration, opioid analgesics, immobility, depressed gastric motility, and the stress response.

Acute renal insufficiency can occur as a result of hypovolemia and decreased cardiac output. Fluid loss and inadequate fluid replacement can lead to decreased renal plasma flow and glomerular filtration rate. With an electrical burn injury, renal damage can occur from direct electrical current or the formation of myoglobin casts (because of the muscle destruction), which can cause acute tubular necrosis.

Pulmonary effects are mostly related to smoke inhalation. However, hyperventilation is usually proportional to the severity of the burn. There is increased oxygen consumption

resulting from the hypermetabolic state, fear, anxiety, and pain.

Immunologically, with the skin destroyed, the body loses its first line of defense against infection. Major burns also cause a depression of the immunoglobulins IgA, IgG, and IgM.

CLASSIFICATION OF BURN INJURIES. The severity of a burn injury is influenced by the depth of destruction, percentage of injury, cause of the burn, age of the patient, concomitant injuries, medical history (e.g., heart disease, diabetes), and location of the burn wound. Table 51-4 describes classification of burn depth (Figs. 51-8, 51-9, and 51-10).

The size of the burn wound is determined by an estimation of the extent of the burn injury. A common method is the rule of nines. This method divides the body into segments whose areas are either 9 percent or multiples of 9 percent of the total body surface, with the perineum counted as 1 percent. This formula is easy, but it is not accurate in assessing children. A more accurate method uses a table with a relative anatomic scale or diagram that estimates total burned area by ages and by smaller anatomic areas of the body. Figure 51-11 provides an example of each method.

Etiology

Burn injuries have many causes. The most common causes include flame, contact, chemical, electrical, and radiation (Table 51-5).

Complications

A major complication that can occur with a flame burn in an enclosed space is inhalation injury. Infection is another common complication with a major burn. The incidence of infection increases with the size of the burn wound, because the first line of defense against microorganisms is the skin.

Neurovascular compromise can also occur with a major burn. Eschar formation creates pressure and contributes to decreasing blood flow to areas distal to the burned area. Other systemic complications are reviewed under Systemic Responses earlier in this chapter.

Diagnostic Tests

Burns are diagnosed through clinical manifestations. Various diagnostic tests are performed for systemic reactions, infection, and other complications. Common tests include complete blood cell count (CBC) and differential, blood urea nitrogen (BUN), serum glucose and electrolytes, arte-

TABLE 51-4 CLASSIFICATION OF BURN DEPTH

Classification	Formerly	Areas Involved	Appearance	Sensitivity	Healing Time
Partial-thickness (superficial)	1°–2°	Epidermis Papillae of dermis	Bright red to pink. Blanches to touch. Serum-filled blisters. Glistening, moist.	Sensitive to air, temperature, and touch.	7–10 days
Partial-thickness (deep)	2°	Epidermis, ½ to ⅔ of dermis Appendage usually present	Blisters may be present. Pink to light red to white. Soft and pliable. Blanching present.	Pressure may be painful from exposed nerve endings.	14–21 days. May need grafting to decrease scarring.
Full-thickness	3°–4°	Epidermis Dermis Tissue Muscle Bone	Snowy white, gray, or brown. Texture is firm and leathery. Inelastic.	No pain as nerve endings are destroyed, unless surrounded by areas of partial-thickness burns.	Needs grafting to complete healing.

rial blood gases, blood protein and albumin, urine cultures, urinalysis, clotting studies, cervical spine series, electrocardiogram, wound cultures, and, if there is a suspected inhalation injury, arterial blood gasses, bronchoscopy, and carboxyhemoglobin levels.

Medical Treatment

Medical treatment varies according to the severity of the burn and the stage the patient is in. The treatment of the patient is managed over three overlapping stages (Table 51-6).

EMERGENT STAGE. At the time of injury, the burning process must be stopped. The clothes are removed, and the wound is cooled with tepid water and covered with clean sheets to decrease shivering and contamination. The burn wound itself takes a lower priority to the ABCs (airway, breathing, circulation) of trauma resuscitation. The patient should be stabilized in terms of fractures, hemorrhage, spine immobilization, and other injuries. Inhalation injury is suspected if the patient sustained a burn from a fire in an enclosed space or was exposed to smoldering materials, if the face and neck were burned, if there are vocal changes, and

Figure 51-11 Estimation of extent of burn injury. (From Venes, D (ed): Taber's Cyclopedic Medical Dictionary, ed 19. FA Davis, Philadelphia, 2001. Beth Anne Willert, M.S., Dictionary Illustrator.)

if the patient is coughing up carbon particles. Intravenous fluids are given to prevent and treat hypovolemic shock. The patient is treated for pain with appropriate IV opioid analgesics. Patient-controlled analgesia (PCA) is very effective.

An accurate history of the injury is obtained to determine severity, probable complications, and any associated trauma. The patient's medical history is also obtained. Admission to the facility and burn care treatment are explained to the patient and family.

ACUTE STAGE. If the patient is in a facility with a special burn unit, multidisciplinary care from a burn team is pro-

TABLE 51-5 COMMON CAUSES OF BURNS

<i>Flame</i>	House fire is a common cause. Usually associated with an inhalation injury. Flash injury occurs from a sudden ignition or explosion.
<i>Contact</i>	Hot tar, hot metals, hot grease produce a full-thickness injury on contact.
<i>Scald</i>	A burn from hot liquid. Common in children less than 5 years and adults older than 65 years. With an immersion scald, there are usually no splash marks; usually involves lower regions of body.
<i>Chemical</i>	Usually occurs in an industrial setting. Extent and depth of injury are directly proportional to concentration and quantity of agent, duration of contact, and chemical activity and penetrability of agent.
<i>Electrical</i>	One of the most serious types of burn injury; can be full thickness with possible loss of limbs, as well as cause internal injuries. Entry wound is usually ischemic, charred, and depressed. Exit wound may have an explosive appearance. Extent of injury depends on voltage, resistance of body, type of current, amperage, pathway of current, and duration of contact. Bones offer greatest resistance to the current; can have much damage. Tissue fluid, blood, and nerves offer least resistance; therefore the current travels this path.
<i>Radiation</i>	Can occur in an industrial setting, due to treatment of diseases, or from ultraviolet light (sun or tanning salons). Severity depends on type of radiation, duration of exposure, depth of penetration, distance from source, and absorbed dose.

TABLE 51-6 STAGES OF BURN CARE

Stage	Duration
I (emergent)	From onset of injury to completion of fluid resuscitation
II (acute)	From start of diuresis to near completion of wound closure
III (rehabilitation)	From wound closure to return of optimal level of physical and psychosocial function

Source: Trofino, RB: Nursing management of the patient with burns. In Ruppert, SD, Kernick, JG, and Dolan, JT (eds): Dolan's Critical Care Nursing. FA Davis, Philadelphia, 1996, p 948.

vided during the acute stage. Management goals include wound closure with no infection; minimum scarring; maximum function; maintenance of comfort as much as possible; adequate nutritional support; and maintenance of fluid, electrolyte, and acid-base balance. The patient continues to be medicated for pain as needed, especially before painful treatments. Nutritional support is maintained via a small Silastic nasogastric feeding tube.

The wound is cleansed and debrided daily to promote healing, prevent infection, and provide a clean bed for grafting. Wound cleansing is achieved by tubing with a Hubbard tank, showering using a shower trolley or shower chair, and bedside care.

Debridement, or the removal of nonviable tissue (eschar), can be mechanical, chemical, surgical, or a combination of these methods. Mechanical debridement can involve the use of scissors and forceps to manually excise loose nonviable tissue or the use of wet-to-moist or wet-to-dry fine mesh gauze. Chemical debridement involves the use of a proteolytic enzymatic debriding agent that digests necrotic tissue. Surgical debridement is the excision of full-thickness and deep partial-thickness burns. This method is followed by an application of a skin graft.

If the patient has a circumferential burn (one that surrounds an extremity or area), there is an increase in tissue pressure secondary to tissue edema. The burn then acts like a tourniquet, impeding arterial and venous flow. Common sites for these burns are the extremities, trunk, and chest. If this occurs on the chest and trunk, respiratory insufficiency can occur as a result of restricted chest expansion. An **escharotomy** is immediately necessary to relieve this pressure. An escharotomy is a linear excision through the eschar to the superficial fat that allows for expansion of the skin and return of blood flow (Fig. 51-12).

Once the area is cleaned, the burn dressing and topical treatment are prescribed. The type of dressing and topical agent chosen are dependent on the area involved, extent and depth of injury, and physician preference. Several common topical agents are listed in Table 51-7.

Figure 51-12 Escharotomy. (From Trofino, RB: Nursing Care of the Burn-Injured Patient. FA Davis, Philadelphia, 1991, plate 16, with permission.)

Dressings may be open, closed, biologic, synthetic, or a combination. The open method is the use of a topical agent without any dressing. The closed method involves the use of an occlusive dressing over the wound. General principles for dressings include the following:

1. Limit the bulk of the dressing to facilitate range of motion.
2. Never wrap skin-to-skin surfaces (e.g., wrap fingers or toes separately; place a donut gauze dressing around the ear).
3. Base dressings on the size of wounds, absorption, protection, and type of debridement.
4. Wrap extremities distal to proximal to promote venous return.
5. Elevate affected extremities.

Biologic dressing refers to tissue from living or deceased humans (cadaver skin) or deceased animals (e.g., pigskin). These dressings may be used as donor site dressings, to manage a partial-thickness burn, and to cover the clean, excised wound before autografting. Biologic dressings assist with wound healing and stimulate **epithelialization**.

Synthetic dressings are used in the management of partial-thickness burns and donor sites. These dressings are more readily available, less costly, and easier to store than biologic dressings. They are made from a variety of materials and come in many different sizes and shapes. Most of these dressings contain no antimicrobial agents.

Biologic and synthetic dressings are used as temporary wound coverings over clean partial- and full-thickness injuries. These skin substitutes help maintain the wound surface until healing occurs, a donor site becomes available, or the wound is ready for autografting.

Skin Grafts. An autograft is a skin graft from the patient's unburned skin to be placed on the clean excised burn. The two common types of autografts are the split-thickness skin graft (STSG), which includes the epidermis and part of the dermis, and the full-thickness skin graft (FTSG), which includes the epidermis and entire dermal layer.

An STSG (0.006 to 0.016 inch) may be applied as a sheet graft or a meshed graft. A sheet graft is used for cos-

escharotomy: eschara—scab + otomy—incision

epithelialization: epi—over + thele—nipple + ization—condition

TABLE 51-7 COMMON TOPICAL ANTIBIOTIC AGENTS

Agent	Dressings	Advantages	Disadvantages
Silver sulfadiazine 1% cream	Buttered on. With light dressings once or twice a day.	Broad spectrum. Low toxicity. Painless, easy to apply and remove. Can be used with or without dressings.	Intermediate penetration of eschar; leukopenia.
Mafenide acetate (Sulfamylon)	Buttered on. Open exposure method. Applied 3–4 times daily.	Broad spectrum. Rapid, deep penetration of eschar. Rapid excretion.	Pain on application. Pulmonary toxicity. Metabolic acidosis. Inhibits wound healing. Hypersensitivity.
Silver nitrate solution 0.5%	Wet dressings. Change bid. Resoak every 2 hours.	Broad spectrum. Nonallergenic. Low toxicity. Inexpensive. Does not interfere with healing.	Poor penetration of eschar. Ineffective on established wound infections. Can cause an electrolyte imbalance. Discoloration of wound and environment makes assessment difficult.
Bacitracin	Buttered on. Reapply every 4–6 hours.	No pain. Clear, odorless. Useful for face burns. Softens eschar.	Poor penetration of eschar. Not effective in reducing sepsis in large burns. Occasional allergic sensitivity.
Gentamicin	Apply gently 3–4 times daily.	Broad spectrum. May be covered or left open to air.	Ototoxic. Nephrotoxic. Pain on application.
Nitrofurazone	Apply thin layer directly to wounds or impregnate into gauze. Change dressings twice daily.	Bactericidal. Broad spectrum.	Painful application. May lead to overgrowth of fungus and <i>Pseudomonas</i> .

Source: Modified from Trofino, RB: Nursing management of the patient with burns. In Ruppert, SD, Kernick, JG, and Dolan, JT (eds): Dolan's Critical Care Nursing. FA Davis, Philadelphia, 1996, p 951.

metic effect, such as for a face, neck, upper chest, breast, or hand burn. It is placed on the area as a full sheet. A meshed graft is passed through a mesher that produces tiny splits in the skin, similar to a fishnet, with openings in the shape of diamonds (Fig. 51-13), to permit the skin to expand 1.5 to 9 times its original size. The meshing allows for coverage of a large burn area with a small piece of skin by stretching it and securing it with sutures or staples. A mesh graft is especially useful when there are extensive burns resulting in few available donor sites. Graft “take,” or vascularization, is complete in about 3 to 5 days.

Full-thickness skin grafts (0.035 to 0.040 inch) can be sheet grafts or pedicle flaps. FTSGs are used over areas of muscle mass, soft tissue loss, hands, feet, and eyelids. They are not used for extensive wounds, because the donor sites usually require an STSG for closure, or closure from the wound edges. A pedicle graft or flap includes the skin flap and subcutaneous tissue that is attached by its pedicle to a blood supply (artery and vein); it is then attached to the area in need of grafting. Once the distal part of the graft takes, it remains in place and the flap is divided, with the remainder returning to the original site. Pedicle flaps are not as popular as free skin flaps, because they require more than one surgery and take longer for the graft site and donor site to heal. Table 51-8 provides a comparison of split-thickness and full-thickness grafts.

Donor sites are considered a partial-thickness wound. Donor sites usually heal in 10 to 14 days, but this is dependent on thickness and method of grafting and the general health of the patient. Treatment for the donor site varies with the individual patient, the area of the body, and physician preference. Considerations for care include promoting comfort and preventing trauma and infection. An

Figure 51-13 Meshed graft. (From Trofino, RB: Nursing Care of the Burn-Injured Patient. FA Davis, Philadelphia, 1991, plate 17, with permission.)

outer dressing, used to apply pressure for hemostasis, remains in place for 1 to 2 days. For dry exposure healing, a bed cradle may be used to promote circulation and avoid pressure on the site. A heat lamp (60 to 100 watts) may be employed to assist in drying, but it must be kept at least 2 feet away from the site. Loose, separating gauze is trimmed to avoid accidental trauma. The donor site is very painful. Appropriate pain medications are provided, along with nonpharmacological measures (e.g., back rub, distraction).

With any type of graft, the patient must keep the graft site immobilized until the graft takes, to prevent movement or slippage of the grafted skin. Dressings may be bulky to assist in immobilization. These dressings must not be disturbed. The involved area requires frequent circulatory checks (color, warmth, sensation, pulses, and capillary refill). Any involved extremities must be elevated to maintain circulation. Table 51-9 describes factors affecting graft viability. A

TABLE 51-8 COMPARISON OF SPLIT-THICKNESS AND FULL-THICKNESS SKIN GRAFTS

	Split-Thickness	Full-Thickness
Layers	Epidermis Partial layer of dermis	Epidermis Entire dermal layer
Advantages	Donor site may be reused Healing of donor site is more rapid, results in good “take”	Allows more elasticity over joints Can reconstruct cosmetic defects Soft, pliable Gives full appearance Provides good color-match Less hyperpigmentation May allow hair growth
Disadvantages	Prone to chronic breakdown Likely to hypertrophy More likely to contract	Donor site takes longer to heal Requires split-thickness graft to heal or closure from wound edges

Source: Konop, D: General local treatment. In Trofino, RB (ed): Nursing Care of the Burn-Injured Patient. FA Davis, Philadelphia, 1991, p 61.

TABLE 51-9 FACTORS AFFECTING GRAFT VIABILITY

Factors Inhibiting Graft “Take”	Factors Promoting Graft “Take”
Infection	Adequate hemostasis
Necrotic skin (tissue)	Anatomic location of graft
Anatomic location of graft	Smooth contour
Perineum	Nonjoints
Axilla	Graft secured well
Buttocks	Immobilization of graft area
Poor-quality donor skin	Good nutritional status
Poor nutritional status	
Bleeding	
Mechanical trauma	
Shock	

Source: Konop, D: General local treatment. In Trofino, RB (ed): Nursing Care of the Burn-Injured Patient. FA Davis, Philadelphia, 1991, p 62.

Figure 51-14 Burn deformity: contracture. (From Trofino, RB: Nursing Care of the Burn-Injured Patient. FA Davis, Philadelphia, 1991, plate 36, with permission.)

graft has been successful if there is good adherence of the graft to the wound with no evidence of necrosis or infection.

REHABILITATION PHASE. The therapy started during the acute phase continues in the rehabilitation phase. There is wound closure, and the goal is to return the patient to an optimum level of physical and psychosocial function. This may take months to years to accomplish. Reconstructive surgery can be ongoing for many years.

Two things to keep in mind when caring for the patient with a major burn are that (1) the most comfortable position (flexion) is the position of contracture, and (2) the burn wound will shorten until it meets an opposing force. To avoid contractures (Fig. 51-14), a specific exercise program is begun 24 to 48 hours after injury, along with the use of splinting devices to maintain proper positioning and stretching. Hypertrophic scarring, or a proliferation of scar tissue, can be minimized or prevented through the use of a pressure garment (Fig. 51-15).

The burn affects the patient’s psychosocial status in many ways. The magnitude of these effects are related to the age of the patient, location of the burn (e.g., face, hands), recovery from injury, cause of the injury (especially

Figure 51-15 Full-body pressure garment (From Trofino, RB: Nursing Care of the Burn-Injured Patient. FA Davis, Philadelphia, 1991, plate 39, with permission.)

if related to negligence or a deliberate act), and ability to continue at preburn level of normal daily activities, disruption of role, family involvement, and general health and coping ability. Treatment involves the patient and significant others. Support groups, counselors, and psychiatrists should be utilized appropriately.

Nursing Process

ASSESSMENT. A major burn is painful and frightening to the patient and frightening to the family. Elicit information from the patient, family, and rescuers. If the injury occurred in an enclosed space with flames or smoldering materials, inhalation injury is suspected. If an electrical injury, ask about voltage, duration of contact, host susceptibility (wet or dry skin), entry and exit sites, and associated falls. With chemical burns, determine type of agent and duration of exposure.

General information to assess in all burns (in addition to normally assessed data, such as medical history, known allergies, and current medications) include extent, depth, type and location of the burn; duration of contact with the

burning agent; amount and location of pain; and associated injuries. Determine the immediate first aid treatment provided at the scene. Elicit psychosocial information: other people injured; additional losses (home, pets); whether the patient was at fault; and how this injury affects the patient's role function.

NURSING DIAGNOSIS. Priority nursing diagnoses for a patient with a major burn include impaired skin integrity; impaired gas exchange; deficient fluid volume; pain; ineffective peripheral tissue perfusion; and risk for sepsis. These are covered in Nursing Care Plan Box 51–3. Additional possible diagnoses are imbalanced nutrition, activity intolerance, self-care deficit, disturbed body image, and ineffective coping.

BOX 51-3 NURSING CARE PLAN FOR THE PATIENT WITH A BURN INJURY

Impaired skin integrity related to thermal injury

PATIENT OUTCOMES

Skin integrity is improved as evidenced by healing of burned areas with no infection present, healing of burning process.

EVALUATION OF OUTCOMES

Is burned area healed? Is it free from infection? Did burning process stop?

INTERVENTIONS	RATIONALE	EVALUATION
Assess burning process. If heat is felt on wound, cool with tepid tap water or sterile water.	Depth of injury increases with length of exposure to burning agent.	Is heat felt over wounds?
Assist registered nurse (RN) or physician to assess the burn area for extent (percentage) and depth (partial thickness, full thickness) of injury.	Provides basis for triage of care. Important also for calculating resuscitation fluid therapy.	What is the estimation of percentage of burn injury? What is depth of injury?
Remove clothing and jewelry.	These items can retain heat and thermal agent, therefore increasing depth of injury. Jewelry can be constrictive when edema develops.	Are clothing and jewelry removed?
Do not apply ice.	Ice causes vasoconstriction, further increasing wound damage. Ice also causes a decrease in core body temperature, which may promote shock.	Is water tepid? Has use of ice been avoided?
Cover patient with clean sheet or blanket.	Prevents excessive heat loss. Decreases pain from air exposure. Protects patient from environmental contamination.	Is patient covered?
Obtain history of burning agent.	Provides information related to depth, duration of contact, and resistance of tissues. If fire scenario, provides clues to possible inhalation injury.	What caused this thermal injury? How long was patient in contact with agent?
Initiate immediate copious tepid water lavage for 20 minutes for all chemical burns, along with simultaneous removal of contaminated clothing. (Do not neutralize chemical, because this takes too much time and resulting reaction may generate heat and cause further skin injury.)	Dilution and removal of chemical agent halts burning process. Lavage dissipates heat. Gloves and gauze are necessary to protect health care workers from injury.	Has lavage been initiated? Were there any injuries to health care workers?
Brush off dry chemicals before lavage. Use heavy rubber gloves or thick gauze for removal of clothing.		
Cleanse wound via tubbing or showers.	Promotes healing and helps decrease infection.	Is burn wound clean and free of wound debris?

BOX 51-3 NURSING CARE PLAN FOR THE PATIENT WITH A BURN INJURY—CONT'D

Assist RN or physician with debriding wound via surgical, chemical, or mechanical means. Apply topical agent as prescribed.

Apply dressing as prescribed. Use common practices:

1. Do not wrap skin surface to skin surface (e.g., wrap fingers and toes separately; donut bandage around ears).
2. Limit bulk of dressings.
3. Wrap extremities distal to proximal.

Promotes healing and healthy granulation bed. Most agents prevent infection and promote healing.

Dressing types vary and are influenced by area, extent, and depth of injury, as well as by topical agent used. Dressing protects burn area and promotes healing.

Wrapping separately prevents webbing and contractures.

Mobility is enhanced with less bulky dressing.

Circulation is increased when extremities are wrapped distal to proximal.

Is there any eschar? Is wound free of wound debris?

Is agent applied as directed?

Is dressing applied appropriately?

 **Impaired gas exchange related to upper airway edema, carbon monoxide poisoning, edema of alveolar capillary membranes**

PATIENT OUTCOMES

Gas exchange will be improved as evidenced by patent airway, CO level less than 10 percent, clear lung sounds, PaO₂ 80–100 mm Hg, PaCO₂ 35–45 mm Hg, responsive and aware.

EVALUATION OF OUTCOMES

Are blood levels improved: CO, PaO₂, PaCO₂? Do the lungs sound clear on auscultation? Is patient aware of surroundings? Are there no signs of respiratory distress (e.g., retractions, nasal flaring, use of accessory muscles)?

INTERVENTIONS

Assess respiratory status: auscultate breath sounds every 15 minutes or as necessary; note any adventitious breath sounds; observe for chest excursion: monitor ability to cough.

Monitor arterial blood gases and CO level.

Monitor for nasal flaring, retractions, wheezing, and stridor.

Administer humidified 100-percent oxygen by tight-fitting face mask for the breathing patient.

Elevate head of bed (if no cervical spine injuries or no history of multiple trauma).

Provide appropriate pulmonary care: turn, cough, deep breathe every 2–4 hours. Incentive spirometer every 2–4 hours, suction frequently as needed.

Obtain sputum cultures. Note amount, color, and consistency of pulmonary secretions.

Administer bronchodilators and antibiotics as prescribed.

RATIONALE

Detects changes in pulmonary function to alter therapy.

Assesses level of oxygenation. Helps guide oxygen therapy.

Stridor may signal upper airway involvement; nasal flaring, retractions, and wheezing may indicate lower airway involvement.

Provides oxygen for adequate gas exchange.

Decreases swelling of face and neck.

Mobilizes secretions and promotes lung expansion.

Carbonaceous sputum is diagnostic for smoke inhalation injury. Infection changes color, amount, and consistency of sputum. Assists in selection of appropriate antibiotic.

Bronchodilators decrease bronchospasms and edema; antibiotics fight infection.

EVALUATION

What is patient's respiratory status? Are any adventitious lung sounds noted?

What are the patient's blood gas levels? Are they abnormal?

Does patient exhibit nasal flaring, retractions, wheezing, and stridor?

Is oxygen administered appropriately? Are blood gases improving?

Is head of bed elevated? Is there any change in facial or neck swelling?

Is patient on scheduled activities for vigorous pulmonary care?

Is patient coughing up any sputum? Has character of sputum been documented?

Are medications given appropriately?

 **Deficient fluid volume related to evaporative losses from wound, capillary leak, and decreased fluid intake**

PATIENT OUTCOMES

Patient will maintain adequate circulating volume as evidenced by urine output of 50 mL/h (in the adult), blood pressure within normal limits, heart rate at about 100 beats per minute (adult), and stabilized body weight.

EVALUATION OF OUTCOMES

Is urine output maintained at least at 50 mL/h? Are the blood pressure and heart rate within normal limits? Is patient's weight stable?

BOX 51-3 NURSING CARE PLAN FOR THE PATIENT WITH A BURN INJURY—CONT'D

INTERVENTIONS	RATIONALE	EVALUATION
<p>Obtain admission weight and monitor weight daily. Record intake and output (I & O) hourly. Assess for signs and symptoms of hypovolemia (hypotension, tachycardia, tachypnea, extreme thirst, restlessness, disorientation). Monitor electrolytes, CBC.</p>	<p>Helps measure fluid loss or gain. Serves as guide for fluid loss and replacement. Fluid volume loss is multifocal (e.g., through increased capillary permeability, insensible loss).</p>	<p>Is patient's weight documented? Is it stable? What is patient's I & O? Does patient exhibit any signs or symptoms of hypovolemia?</p>
<p>Administer IV fluids as ordered. Insert large-bore catheter. Insert indwelling urinary catheter.</p>	<p>Serves as guide for electrolyte replacement and blood product replacement. Fluid replacement begins immediately. Large vessels are needed for rapid delivery of fluids. Fluid replacement is titrated based on urine output.</p>	<p>What are patient's lab values? Are they within normal limits? Is patient's fluid replacement adequate? Is catheter patent? Is catheter patent?</p>
<p>Monitor urine for amount, specific gravity, and hemochromogens.</p>	<p>Specific gravity can predict volume replacement; hemochromogens can cause renal-tubular damage.</p>	<p>What are patient's urine values?</p>
<p>Administer osmotic diuretics as ordered; monitor response to therapy. Assess gastrointestinal function for absence of bowel sounds. Maintain nasogastric tube.</p>	<p>Decreased urinary output can be caused by decreased renal flow (due to myoglobin in urine). Splanchnic constriction due to hypovolemia can cause a paralytic ileus.</p>	<p>What is urinary output? Has it changed due to therapy? Are patient's bowel sounds normal? Is nasogastric tube patent?</p>

 **Pain related to burns or graft donor sites**

PATIENT OUTCOMES

Patient will experience pain control as evidenced by verbalizations of pain tolerance, nonverbal cues: less thrashing; better rest or sleep; body positioning.

EVALUATION OF OUTCOMES

Does patient verbalize better pain control? How many hours of rest/sleep does patient have in 24 hours? Does patient state she or he feels rested?

INTERVENTIONS	RATIONALE	EVALUATION
<p>Assess level of pain: nature, location, intensity, and duration at various times (during procedures, at rest). Rate pain on visual analog scale.</p>	<p>Provides baseline to monitor response to therapy.</p>	<p>Is patient's individual response to pain documented?</p>
<p>Observe for varied responses to pain: increase in blood pressure, pulse, respiration; increased restlessness and irritability; increased muscle tension; facial grimaces; guarding.</p>	<p>Responses to pain are variable. These parameters change in response to pain.</p>	<p>What are patient's responses to pain? Do responses change with treatment?</p>
<p>Acknowledge presence of pain. Explain causes of pain. Administer narcotics IV. Utilize PCA as appropriate.</p>	<p>Encourages understanding. IV administration is necessary due to edema and poor tissue perfusion. Narcotics are necessary for severe burn pain. PCA allows patient more control.</p>	<p>Is patient more trusting of the treatments? Is patient being medicated for pain appropriately?</p>
<p>Offer diversional activities (e.g., music, TV, books, games, relaxation techniques). Properly position patient. Elevate burned extremities. Maintain comfortable environment (e.g., bed cradle; comfortable environmental temperature, 86–91.4° F; quiet environment).</p>	<p>Helps patient focus on something other than pain. Increases comfort. Elevation decreases edema and pain. Pressure from bed linens may cause discomfort; with loss of integument, body cannot self-regulate temperature.</p>	<p>Does patient utilize diversional activities? Do they help? Is patient positioned as comfortably as possible? Are extremities elevated? Does patient verbalize comfort of environment?</p>

BOX 51-3 NURSING CARE PLAN FOR THE PATIENT WITH A BURN INJURY—CONT'D**▶ Ineffective peripheral tissue perfusion related to circumferential burns, blood loss, decreased cardiac output****PATIENT OUTCOMES**

Patient will maintain adequate tissue perfusion as evidenced by presence of peripheral pulses; minimal edema; adequate circulation, sensation, and motion; and warm extremities.

EVALUATION OF OUTCOMES

Are peripheral pulses present? Are extremities warm, with adequate sensation, motion, and circulation? Is edema decreased?

INTERVENTIONS

Elevate burned extremity above level of the heart.

Assess pulses on burned extremities every 15 minutes.

Use Doppler as necessary. Assess capillary refill, sensation, color, swelling, and motion.

Assess for numbness, tingling, and increased pain in burned extremity. Measure circumference of burned extremities.

Apply burn dressing loosely.

Assist with muscle compartment pressures.

Assist with escharotomy as necessary.

RATIONALE

Enhances venous return and decreases edema formation.

Assesses need for escharotomy.

Assesses peripheral perfusion.

Can be indicative of increased pressure from edema.

Monitors edema formation.

Prevents constriction and allows for expansion as edema forms.

Helps determine need for escharotomy (if pressure greater than 25 mm Hg).

If indicated, removal of eschar allows for edema expansion and permits peripheral perfusion.

EVALUATION

Are all burned extremities elevated above heart level? Is edema decreasing?

Are pulses present and documented?

Is the extremity warm, with adequate color, sensation, motion, and capillary refill?

Does patient complain of numbness, tingling, or pain?

Is there change in measurements of circumference?

Is dressing too tight?

What is patient's pressure?

Does patient require an escharotomy?

Is edema relieved?

▶ Risk for sepsis related to wound infection**PATIENT OUTCOMES**

Patient will not develop a wound infection.

EVALUATION OF OUTCOMES

Is there healthy granulation tissue on unhealed areas with less than 10^5 colonies of bacteria (wound culture)? Are donor sites free of infection? Have skin grafts taken? Is there absence of clinical manifestation of infection (temperature 98.6°F ; normal WBC count)?

INTERVENTIONS

Use sterile technique with wound care.

Maintain protective isolation with good handwashing technique.

Administer immunosupportive medications as prescribed: tetanus and gamma globulin.

Perform wound care as prescribed, which may include the following: inspect and debride wounds daily; culture wound three times a week or at sign of infection; shave hair at least 1 inch around burn areas (excluding eyebrows); inspect invasive line sites for inflammation (especially if line is through a burn area).

Continually assess for signs and symptoms of sepsis: temperature elevation; change in sensorium; changes in vital signs and bowel sounds; decreased output; positive blood/wound cultures.

Administer systemic antibiotics and topical agents as prescribed.

RATIONALE

The unhealed burn wound is a culture medium for bacterial growth.

Prevents spread of bacteria from patient to patient or nurse to patient.

Immunoglobulins are depressed at time of severe burn injury.

Provides quick identification of bacterial wound invasion and decreases incidence of infection. Presence of hair increases medium for bacterial growth.

The burn patient may experience several septic episodes until wound is healed.

Useful in eliminating or controlling infection. Systemic antibiotics are prescribed based on results of wound cultures.

EVALUATION

Is sterile technique used for all wound care?

Do all persons in contact with patient maintain proper precautions?

Does patient require these medications?

What does wound look like? Is it debrided? What are culture results? Is there any hair near burn or line sites?

Does patient exhibit any signs or symptoms of sepsis?

Does patient require systemic antibiotics? Are they working? Are topical agents applied appropriately? Is wound healing?

PLANNING, IMPLEMENTATION, AND EVALUATION. See Nursing Care Plan 51–3 for the Patient with a Burn Injury. For more information on burns, go to the American Burn Association Website at www.ameriburn.org.

► SKIN LESIONS

Skin lesions can be either benign (noncancerous) or malignant. Benign lesions are described in Table 51–10. Malignant lesions are discussed in the next section. See also Cultural Consideration Box 51–4.

Malignant Skin Lesions

Pathophysiology and Etiology

The most common skin malignancies include basal cell carcinoma, squamous cell carcinoma, and malignant melanoma. The major cause of skin malignancies is overexposure to ultraviolet rays, most commonly sunlight. Other factors include being fair skinned and blue eyed; genetic tendencies; history of x-ray therapy; exposure to certain chemical agents (e.g., arsenic, paraffin, coal tar); burn scars; chronic osteomyelitis; and immunosuppressive therapy.

BOX 51-4 CULTURAL CONSIDERATION

Some African-American men have facial hair that is kinky, curls back on itself, and penetrates the skin, which can result in pustules and small keloids. Many use depilatories or electric razors to prevent nicking the skin, which can also cause keloids.

Darker-skinned people have an increased incidence of birthmarks and mongolian spots compared with lighter-skinned people. Mongolian spots disappear over time. The nurse must be cautious to not mistake these spots for bruising indicating injury or abuse.

Darker-skinned people have a tendency toward an overgrowth of connective tissue components concerned with the protection against infection and repair after injury. Keloid formation is one example of this tendency toward overgrowth of connective tissue. Lymphoma and systemic lupus erythematosus may occur due to this overgrowth of connective tissue.

For people with light skin, such as Germans, Polish, and Irish, prolonged exposure to the sun may increase the incidence of skin cancer. The nurse needs to teach patients to protect themselves from sun exposure to reduce their risk of skin cancer. Nevi (freckles and skin discolorations) occur more often in lighter-skinned individuals. They are most common in European-Americans, followed by Asians, and then darker-skinned African-Americans.

TABLE 51-10 BENIGN SKIN LESIONS

Type	Description	Treatment
Cyst	<p>A saclike growth with a definite wall that may contain liquid, semifluid, or solid material.</p> <p>An epidermal cyst is a saclike growth of the upper portion of a hair follicle. It is due to blockage of the pilosebaceous follicle. It is a soft hemispherical module, usually with an overlying comedo, that is usually seen on the face, neck, or upper trunk. It is usually asymptomatic.</p> <p>A pilar cyst, or sebaceous cyst, is a saclike growth of the middle portion of the hair follicle that contains hair and cuticle-like material. It is a hard, hemispherical nodule without a surmounted pore that is usually seen on the scalp.</p>	If bothersome, it may be surgically excised. If excision is done, the entire cyst wall is removed to prevent recurrence.

Epidermoid cyst.

TABLE 51-10 BENIGN SKIN LESIONS — CONT'D

Type	Description	Treatment
Seborrheic keratosis	A benign skin lesion that is pigmented light tan to dark brown patches. The plaques or papules have a “stuck on” appearance caused by the proliferation of epidermal cells and keratin piled on the skin surface. Cause is unknown, but it tends to occur in middle-aged to older patients, most commonly on the trunk, scalp, face, and extremities.	Treatment is cosmetic only, or if lesion becomes irritated from friction. Liquid nitrogen cryotherapy or light curettage is performed if necessary for removal.
Keloid	A benign growth of fibrous tissue (scar formation) at the site of trauma or surgical incision; occurs in various sizes. Growth of tissue is out of proportion to what is needed for normal healing. The benign wartlike lesion or nodule extends beyond the original injury and occurs mainly in middle-aged and elderly clients and darker-skinned patients.	Treatment varies, is not always successful, and is difficult; a larger scar may ensue. Treatments include surgical excision, intralesional steroid therapy, low-dose radiation, and pressure garments worn over the area, or a combination of these therapies.
Pigmented nevi	A benign, flesh-colored to dark brown macule or papule located randomly over the entire skin surface of the body. Can be inherited or acquired and occurs mostly in light-skinned patients. Usually begin to appear between 1 to 4 years of age, increasing in number into adulthood. Some contain a few hairs. There are many variations. Rate of transformation to a malignant melanoma is higher in congenital moles and larger lesions. Clinical signs to observe for in differentiating between a mole and a melanoma include change in color or size; inflammation of surrounding skin; irregular borders; spreading borders; variegated colors, especially a bluish pigmentation; bleeding; and oozing, crusting, and itching. Usually nevi larger than 1 cm should be carefully examined.	Treatment is indicated for any of the previously listed indications of melanoma; unsightly nevi (cosmetic); repeated irritation (rubbing from belt, bra); trauma; large moles; and client conviction of a change in the mole. Surgical removal can include excision (preferred) or surgical shave. All excised moles should be examined histologically.

Seborrheic keratosis.

Dermal mole.

TABLE 51-10 BENIGN SKIN LESIONS — CONT'D

Type	Description	Treatment
Warts	<p>Small, common, benign growths of the skin resulting from the hypertrophy of the papillae and epidermis. Caused by a virus.</p> <p>Common warts, often seen on hands and fingers, appear as raised, flesh-colored papules that have a rough surface. These warts may crack, fissure, bleed, and be painful to lateral pinching and direct, firm pressure.</p> <p>Plantar warts occur on the sole of the foot. They may appear granular, pitted, or protuberant, with a callous of surrounding normal skin.</p> <p>Incubation period can be several weeks to months. Virus is spread by direct contact into areas of broken skin or to other nails by nail cuticle biting.</p>	<p>If no pain or discomfort, no treatment may be indicated.</p> <p>Patient should be cautioned not to spread lesions by picking or biting them.</p> <p>Treatment is indicated for symptomatic warts and for cosmetic purposes. General treatments include kerolytic agents (e.g., salicylic acid plasters) to soften and reduce keratin; cryotherapy (liquid nitrogen); and light electrodesiccation and curettage (requires local anesthesia).</p> <p>Treatment of choice is usually cryotherapy, because local anesthesia is not necessary and it leaves little scarring.</p>
		
	Warts.	
Hemangiomas (angiomas)	<p>Benign vascular tumors of dilated blood vessels that can have varied clinical manifestations.</p> <p>Nevus flammeus involves mature capillaries on the face and neck. It is a congenital neoplasm that appears as a pink-red to bluish-purple macular patch. Port-wine stains or port-wine angiomas appear as violet-red macular patches, usually singular lesions, growing proportionately as the child grows. These lesions can persist indefinitely.</p> <p>Cherry hemangiomas are commonly seen in the elderly patient. They appear as small round papules that can vary in color from red to purple.</p>	<p>Nevus flammeus is usually treated for cosmetic reasons. Port-wine stains, if large enough, may require surgical excision with skin grafting. Laser therapy may also be used.</p> <p>Noninvasive treatment is the use of cosmetics to camouflage the affected area.</p> <p>Treatment for cherry hemangiomas is usually not prescribed, except for cosmetic purposes.</p>

Basal cell carcinoma (Fig. 51-16) arises from the basal cell layer of the epidermis. It is the most common type of skin cancer. This tumor is mainly seen on sun-exposed areas of the body. The lesion appears as a small pearly or translucent papule with a rolled, waxy edge; depressed center; telangiectasia (lesion formed by dilation of vessels); crusting; and ulceration. Metastasis is rare, though it may be locally invasive.

Squamous cell carcinoma arises from the epidermis. This tumor can occur on sun-exposed areas of the skin and mucous membranes and is mainly seen on the lower lip, neck,

tongue, head, and dorsa of the hands. It can occur on normal skin or a preexisting lesion (actinic keratosis). The lesion appears as a single, crusted, scaled, eroded papule, nodule, or plaque (Fig. 51-17). A neglected lesion appears more rough, scaly, and darker colored. The lesion is fragile and prone to oozing and bleeding. This is a truly invasive carcinoma. Metastasis is related to histological type, depth of invasion, and size of the lesion.

Malignant melanoma (Fig. 51-18), as the name implies, is a malignant growth of pigment cells (melanocytes). It is highly metastatic, with a higher mortality rate than basal or

Figure 51-16 Basal cell carcinoma. Note pearly, flesh-colored papule with depressed center and rolled edge. (From Goldsmith, LA, Lazarus, and GS, Tharp, MD: Adult and Pediatric Dermatology. FA Davis, Philadelphia, 1997, p 158, with permission.)

Figure 51-17 Squamous cell carcinoma. Surface is fragile and bleeds easily. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: Adult and Pediatric Dermatology, FA Davis, Philadelphia. 1997, p 237, with permission.)

Figure 51-18 Malignant melanoma. (From Goldsmith, LA, Lazarus, GS, Tharp, MD: Adult and Pediatric Dermatology. FA Davis, Philadelphia, 1997, p 137, with permission.)

squamous cell carcinoma. This tumor can occur anywhere on the body, and about half arise from pre-existing nevi or moles. There are three general types: lentigo maligna, superficial spreading, and nodular.

Lentigo maligna melanoma (Fig. 51-19) appears as a slow-growing dark macule on exposed skin surfaces (especially the face) of elderly patients. The lesion has irregular borders and brown, tan, and black coloring. Prognosis is good if treated in the early stage.

Superficial spreading melanoma is the most common melanoma. It can occur anywhere on the body and is usually seen in middle-aged persons. The lesion appears as a slightly elevated plaque with an irregular border. The coloring of the lesion varies in combinations of black, brown, and pink. The fragile surface may bleed or ooze. Eventually the plaque develops into a nodule. The cure rate is excellent when it is in the plaque phase; prognosis is poor with the nodular phase.

Nodular melanoma occurs suddenly as a spherical papule or nodule on the skin or in a mole. Coloration in blue-black, blue-gray, or reddish-blue color that may have a rim of inflammation. The lesion is fragile and bleeds easily. Metastasis occurs rapidly. This type of melanoma has the least favorable prognosis. Early diagnosis and treatment is imperative.

Prevention

Most types of skin cancer can be prevented by limiting or avoiding direct exposure to ultraviolet rays (sun, tanning booths). If exposure to the sun is necessary, exposure should be avoided during its highest intensity (10 A.M. to 2 P.M.). The patient should use a protective sunscreen with sun protection factor (SPF) of 15 or more. The patient should also wear sun-protective clothing, such as hats and long sleeves. The patient should seek medical advice if there is a change in color, size, shape, sensation, or character of a lesion or mole.

Diagnostic Tests

A preliminary diagnosis can be based on the appearance of the lesion. A definitive diagnosis is made by biopsy. Other tests are performed based on the results of the pathological examination.

Medical Treatment

Medical treatment depends on the type, thickness, and location of the lesion; the stage of the disease; and the age and general health of the patient. Generally lesions are surgically excised with a 1- to 2-cm margin. Regional node dissection varies; it may be advised if the nodes in the area drain to one group. Grafting may be necessary for closure or repair. Chemotherapy may be used for metastasis. Radiation therapy may be used as adjunct treatment, or may be recommended for patients with a deeply invasive tumor or those who are poor surgical risks. Other therapies that also may be used include cryosurgery and curettage and electrodesiccation.

Nursing Care

Perform a complete skin assessment. Lesions are palpated to determine texture, size, and firmness. All lesions should be described as to size, location, color, surface characteristics, pain, discomfort, itching, and bleeding. Note when the patient first discovered the lesion.

Nursing care of the patient with cancer is documented in Chapter 10. Specific nursing care related to cryosurgery includes preparing the patient for the procedure. Minor discomfort can be expected with little or no local anesthesia. Expect swelling, local tenderness, and hemorrhagic blister formation 1 to 2 days after the procedure. After the procedure, the area is cleansed as ordered and prescribed ointments are applied.

Specific nursing care for curettage and electrodesiccation include preparing the patient for the procedure. After local

Figure 51-19 Lentigo maligna. (From Goldsmith, LA, Lazarus, and GS, Tharp, MD: *Adult and Pediatric Dermatology*. FA Davis, Philadelphia, 1997, p 55, with permission.)

anesthesia, a dermal curette is used to scrape away the lesion, followed by electrodesiccation of the remaining wound; the wound heals by secondary intention, usually with minimal scarring. After the procedure the wound is cleansed and dressed as prescribed.

► DERMATOLOGIC SURGERY

Plastic or reconstructive surgery is performed to correct certain defects, scars, and malformations, as well as to restore function or prevent further loss of function. This type of surgery is usually an elective procedure; it may be prescribed by the physician or it may be the wish of the patient in hopes of improving his or her body image. Common types of plastic surgical procedures are listed in Table 51–11.

Answers to CRITICAL THINKING

Mrs. Long

You should ask Mrs. Long if she read the package instructions. She would find that for medicated scalp shampoos to work properly, they must remain on the scalp for several minutes. Package instruction should be carefully checked for each product, because they vary from product to product.

HOME HEALTH HINTS

- A wound-measuring device that will not be misplaced is your hand. Measure your hand, such as the nailbed of the particular finger or a joint of a finger. Use these as a guide to determine wound measurements.
- Sanitary pads make great cushions for bony prominences. You can also place them in a cotton sock for better molding purposes.
- A handheld shower head is useful in debriding some leg ulcers. Do not use it if it is too painful.
- To relieve itchy skin (pruritus), oatmeal baths are sometimes prescribed. An inexpensive way to do this is to place a half cup of quick-cooking oatmeal in a cotton sock. Put it under the faucet as you fill the tub and ring out the sock.
- Instruct patients to prevent red, dried, cracked skin on hands by doing the following: wear gloves outside in the cold or windy weather to prevent chapping; avoid overheating the house; use a humidifier to keep the air moist; apply hand lotion two or three times a day and after each hand washing; use soaps with added oil and avoid those with deodorants; use sunscreen with an SPF factor of at least 15; and stop smoking (smoking reduces blood flow to the skin).

TABLE 51-11 COMMON PLASTIC SURGICAL PROCEDURES

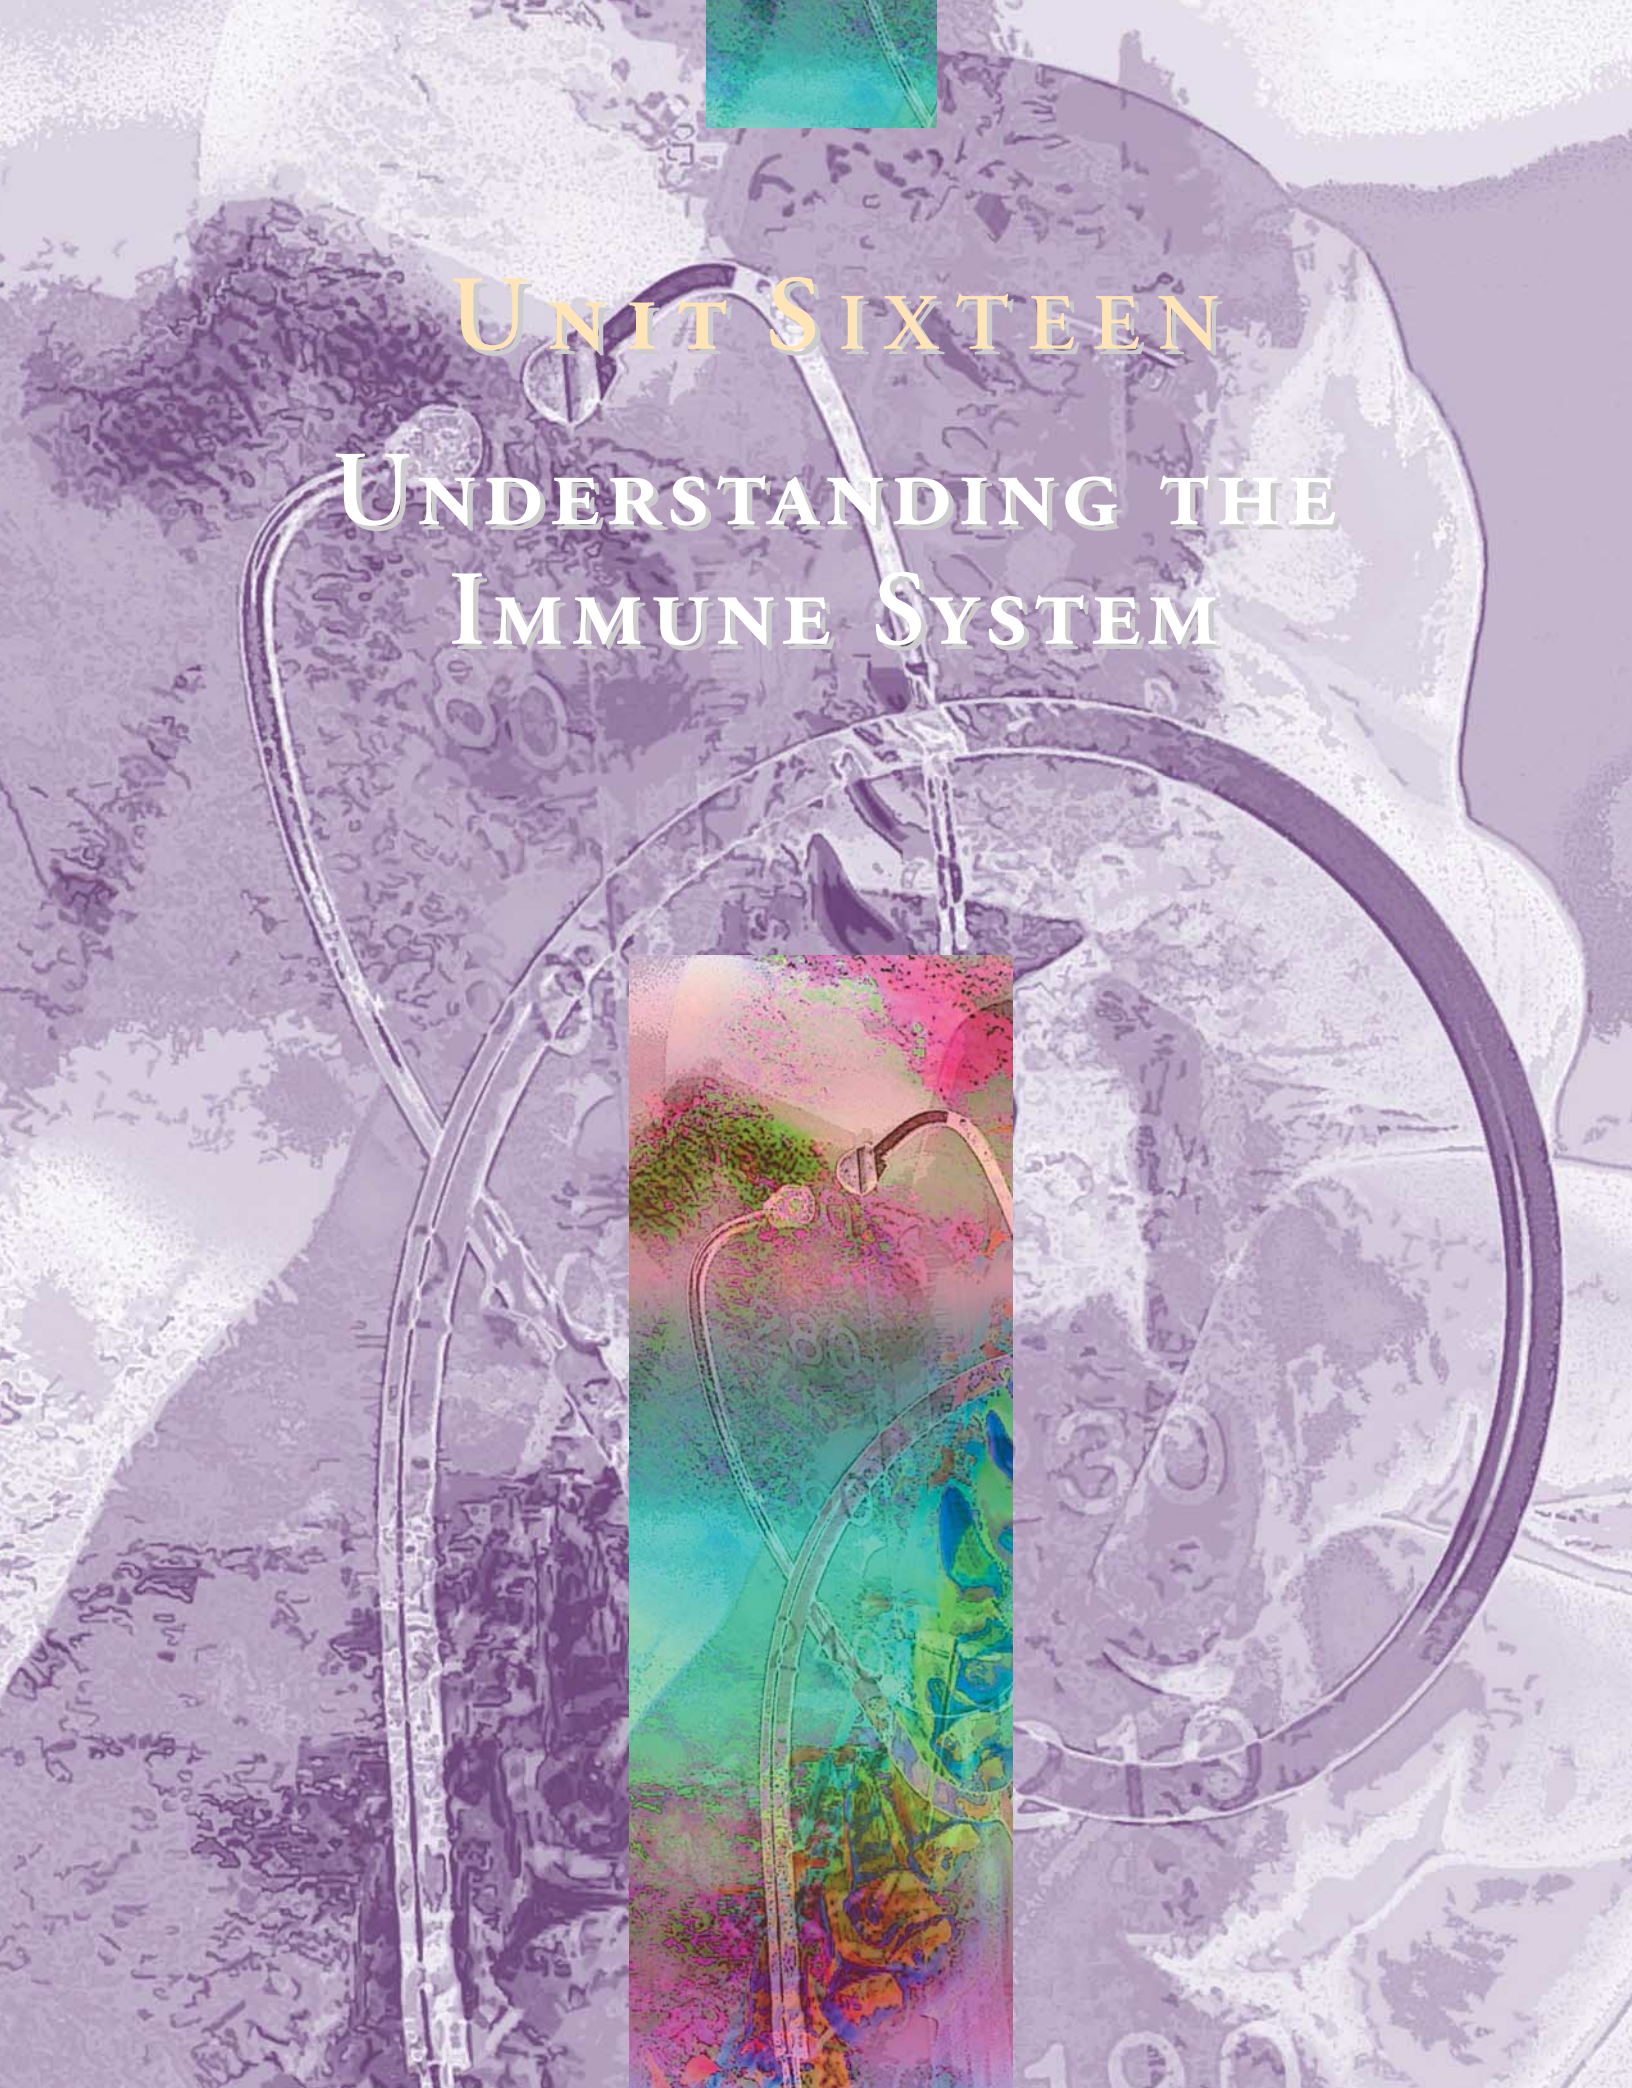

Operation	Description	Purpose	Possible Complications	Postoperative Nursing Treatment Considerations
Rhinoplasty (nose)	Removal of excessive nasal cartilage, tissue, or bone; reshaping of nose.	Correct congenital or acquired septal defects; improve cosmetic shape of nose.	Hemorrhage, hematoma; temporary ecchymosis and edema; infection, septal perforation.	Monitor dressing and packings for bright-red bleeding; monitor vital signs and level of consciousness; maintain semi-Fowler's position to minimize edema.
Blepharoplasty (eyelid)	Incisions on upper and lower lids with excision of fat and skin and primary closure.	Removal of bags under eyes and wrinkles and bulges.	Corneal injury; hematoma; ectropion; rarely visual loss and wound infection.	Eye dressings; antibiotic ointment around eyes and lids; discoloration and swelling usually subsides in about 10 days; maintain semi-Fowler's position to minimize edema.
Rhytidoplasty (facelift)	Incision anterior to ear with removal of excessive skin and tissue; the subcutaneous tissue and fascia are folded and stretched.	Removal of excessive wrinkling or sagging skin.	Hemorrhage; hematoma, ecchymosis, and edema (temporary); wound infection, facial nerve damage.	Surgical improvement lasts from 5–10 years; antibiotic ointment to suture line; maintain semi-Fowler's position to minimize edema.
Otoplasty (ear)	Incision of ear for correction of defect.	Correct congenital defects; correct deformities; improve cosmetic shape of ear.	Hemorrhage; hematoma; edema; wound infection.	Ear dressing for about 1 week; protect ear at times of sleep for about 3 weeks.
Breast augmentation	Skin incision to insert breast implant.	Improve cosmetic shape and size of breasts.	Hemorrhage; hematoma, wound infection.	Dressing to site; antibiotic ointment to suture line. Drains may be in place—note color and amount of drainage.
Breast reduction	Skin incision to excise excess breast tissue and skin.	Improve cosmetic shape and size of breasts; comfort measure.	Hemorrhage; hematoma, wound infection; wound dehiscence; necrosis of areola and nipple area.	Dressing to site; antibiotic ointment to suture line. Drains may be in place—note color and amount of drainage.

REVIEW QUESTIONS

- Which of the following mechanical forces can lead to formation of a skin ulcer?
 - Pressure
 - Friction
 - Shear
 - All of the above
- Which of the following actions by the nurse is appropriate when caring for the patient with dermatitis?
 - Bathe in hot oatmeal baths.
 - Dry vigorously to prevent moisture buildup.
 - Apply gloves to hands at night.
 - Apply a thick layer of the prescribed topical agent.
- Psoriasis is an inflammatory skin disorder that is characterized by which underlying condition?
 - Epidermal proliferation
 - Excessive subcutaneous fat
 - Herpes infection
 - Excessive melanin production
- Which of the following is appropriate instruction for the parent of a child with impetigo contagiosa, to help prevent spread of infection? Send back to school:
 - One week after treatment is started
 - After the lesions scab
 - When all lesions are healed
 - After spread of lesions has stopped
- Which of the following is appropriate patient education about treating scabies?
 - Dry-clean all linens, towels, clothes.
 - Throw away infested mattresses.
 - Wash linens, towels, clothes.
 - Remove infested pets.
- Jan Smith, 42 years old, is admitted to the emergency department with flame burns to her entire chest, back, and upper extremities. Using the rule of nines, you estimate the percentage of burns to be which of the following:
 - 36 percent
 - 45 percent
 - 54 percent
 - 64 percent
- Which of the following actions is appropriate initial treatment of a chemical burn?
 - Neutralize the chemical.
 - Lavage with water.
 - Apply the prescribed topical agent.
 - Wrap the patient in sterile sheets.
- Which of the following is the most common cause of malignant skin lesions?
 - Overexposure to ultraviolet rays
 - Genetic predisposition
 - Fair skin, blue eyes, red hair
 - Numerous moles on body

QUESTIONS TO GUIDE YOUR READING

1. What is the normal function of the immune system?
2. What is the function of antigens, lymphocytes, T cells, and B cells?
3. How do antibodies function in an immune response?
4. What occurs in a cell-mediated immune response?
5. What occurs in a humoral immune response?
6. What occurs in an antibody response?
7. How does aging affect the immune system?
8. What data is collected when caring for a patient with a disorder of the immune system?
9. What nursing care is provided for patients undergoing diagnostic tests for the immune system?
10. What are common therapeutic measures used for a patient with disorders of the immune system?

► NORMAL IMMUNE ANATOMY AND PHYSIOLOGY

Immunity is defined as the ability to destroy pathogens or other foreign material and to prevent further cases of certain infectious diseases. Immunity is most often thought of in terms of the body's response to microorganisms such as bacteria, viruses, and fungi, all of which are foreign to the body. However, immunity also involves processes directed toward other cells or substances that are identified by the body, correctly or incorrectly, as foreign. Malignant cells are also foreign in that they have mutated from the normal state and are usually destroyed by the immune system before they become cancer. Transplanted organs unfortunately are also perceived as foreign; rejection of a transplanted organ is an immune response. Occasionally the immune system mistakenly reacts to part of the body itself (autoimmune disease).

The immune system consists of lymphoid organs, **lymphocytes** and other white blood cells, and the many chemicals produced that are involved in activation of our own cells for the destruction of foreign **antigens** (Fig. 52–1). The lymphatic system consists of lymphatic vessels that help return tissue fluid to the circulatory system; lymph nodes and nodules, which are masses of lymphatic tissue that differ in size and location; the spleen, which phagocytizes pathogens and produces **white blood cells** and antibodies; and the thymus, which functions primarily in childhood and shrinks before adulthood. Lymph nodes are grouped along lymph vessels to destroy foreign material. Three major groups are the cervical, axillary, and inguinal nodes. Lymph nodules

lymphocyte: lympho—lymph + kytos—cell
antigen: anti—against + gennan—to produce

Figure 52-1 Immune system organs, lymph vessels, and major lymph nodes.

are smaller than nodes and are found under the surface of mucous membranes (e.g., tonsils).

Antigens

Antigens are chemical markers that identify cells or molecules. Examples of molecular antigens include bacterial toxins, plant pollens or proteins that trigger allergies, and the protein products of viral activity within cells. Human cells (except red blood cells [RBCs]) have their own self-antigens,

thousands of markers that identify the cell as belonging in the body. These are the major histocompatibility complex (MHC) antigens, also called human leukocyte antigens (HLAs), which are genetically determined. The MHC antigens of identical twins are identical. These MHC antigens serve as a comparison for cells of the immune system; the antigens of foreign cells do not “match” MHC antigens and may therefore be recognized as foreign and destroyed in one of several ways.

Lymphocytes

There are three types of lymphocytes: natural killer (NK) cells, T cells, and B cells, each with very different functions.

Natural Killer Cells

Natural killer cells are found in the blood, bone marrow, lymph nodes, and spleen and are able to destroy many kinds of pathogens and tumor cells. How NK cells recognize foreign antigens is not known with certainty, but they may respond to the absence of MHC antigens on foreign cells. It is believed that NK cells destroy foreign cells by rupturing their membranes or by some other form of direct contact. The action of NK cells is considered a nonspecific resistance mechanism because it is effective against a variety of foreign antigens.

T Cells and B Cells

The lymphocytes called T cells and B cells are involved in specific immune responses; that is, each cell is genetically programmed to respond to one kind of foreign antigen. It is estimated that the human immune system can respond to hundreds of millions of different foreign antigens.

In the fetus, both T cells and B cells develop in the bone marrow. T cells then migrate to the thymus, where the thymic hormones bring about their maturation. From the thymus, T cells migrate to the lymph nodes and nodules and to the spleen. B cells mature in the bone marrow and migrate directly to lymphatic tissue. When activated during an immune response, some B cells become plasma cells that produce antibodies to a specific foreign antigen. Meanwhile, other B cells become memory cells and remember the specific antigen for future encounters. Upon subsequent exposures to the antigen, the specific memory cells turn on the immune response immediately, creating a quick response and usually a stronger response.

Antibodies

Antibodies are also called immunoglobulins (Ig) or gamma globulins and are proteins produced by plasma cells in response to foreign antigens. Antibodies do not themselves destroy foreign antigens, but rather become attached to such antigens to “label” them for destruction. Each **antibody** is specific for only one antigen, and the B cells (those

that become plasma cells) of an individual are capable of producing millions of different antibodies. There are five classes of human antibodies, designated by letter names: IgG, IgM, IgA, IgE, and IgD. Their functions are summarized in Table 52–1.

Mechanisms of Immunity

The two mechanisms of immunity are **cell-mediated immunity**, which involves T cells, and **humoral immunity**, which involves both T cells and B cells. Although the mechanisms are different, invasion by a pathogen often triggers both.

The first step in the destruction of a foreign antigen is the recognition of it as foreign. B cells in lymphatic tissue are able to recognize the foreign antigens for which they are genetically programmed and become activated B cells. Their activation is greatly enhanced if the foreign antigen is presented to them by antigen-processing cells called dendritic cells. A specific type of T cell called helper T cells (CD4) also recognize the foreign antigen and provide a further stimulation to B cells, causing them to divide (proliferate) and become more specialized (differentiate). Helper T cells are assisted in their recognition of foreign antigens by macrophages or other antigen-processing cells, which present the foreign antigen, as well as their own MHC antigens to the T cell, providing a comparison. The macrophages also provide chemical stimulation to the T cells, which then begin to divide and become more specialized.

Cell-Mediated Immunity

This mechanism of immunity does not involve the production of antibodies, but it is effective against intracellular pathogens (such as viruses), fungi, malignant cells, and grafts of foreign tissue. The first step is the recognition of the foreign antigen by helper T cells, assisted by macrophages. The activated T cells divide many times and become specialized in one of several ways. Cytotoxic, or killer, T cells (CD8) are able to lyse cells such as cancer cells or those infected by viruses or other intracellular parasites. They also release chemicals that activate phagocytes such as macrophages and **neutrophils**.

neutrophil: neutro—neuter + philein—to love

TABLE 52-1 CLASSES OF ANTIBODIES

Name	Location	Function
IgG	Blood, extracellular fluid	Crosses the placenta to provide passive immunity for newborns Provides long-term immunity following a vaccine or illness recovery
IgA	External secretions: tears, saliva, etc.	Provides passive immunity for breast-fed infants Found in secretions of all mucous membranes
IgM	Blood	Produced first by the maturing immune system of the infant
IgD	B cells	Produced first during an infection (IgG production follows)
IgE	Mast cells or basophils	Are antigen-specific receptors on B lymphocytes Important in allergic reactions; mast cells release histamine

Source: From Scanlon, V, and Sanders, T: Understanding Human Structure and Function. FA Davis, Philadelphia, 1999, p 311.)

Memory T cells remember the specific foreign antigen and quickly activate an immune response should the antigen reappear. Suppressor T cells are believed to inhibit the proliferation of both T cells and B cells, which limits the immune response to just what is needed and no more.

Humoral Immunity

Humoral immunity is also called antibody-mediated immunity and does indeed involve antibody production. Again the first step is the recognition of the antigen as foreign, this time by B cells. The helper T cells that recognize the antigen further stimulate the B cells to proliferate and differentiate. Some B cells become plasma cells that produce antibodies specific for this particular antigen. Other B cells become memory B cells that will remember this antigen and initiate a rapid response should it return.

Although B cells are stationary, the antibodies produced by plasma cells circulate throughout the body. The antibodies bond to the antigen, forming an antigen-antibody complex. This is termed opsonization, which means that the antigen is now “labeled” for phagocytosis by macrophages or neutrophils. The antigen-antibody complex also stimulates the process of complement fixation.

Complement is a group of about 20 plasma proteins that circulate in the blood until activated by an antigen-antibody complex. The activation of complement may result in the formation of an enzyme complex that lyses the cell and brings about its death. Other complement proteins bind to foreign antigens and serve as further labels to attract macrophages.

▶ **ANTIBODY RESPONSES**

The first exposure to a foreign antigen stimulates antibody production, but the antibodies are produced so slowly and in such small amounts that this production may be too late to prevent the disease. However, with time, the person has antibodies and memory cells that are specific for that pathogen. On a second exposure to the antigen, the memory cells initiate rapid production of large amounts of antibody, often enough to prevent a second case of the illness

(Fig. 52–2). This is the basis for the protection given by vaccines. A vaccine contains an antigen that is not pathogenic (e.g., bacterial capsules, in the case of the pneumococcal vaccine). The vaccine stimulates the formation of antibodies and memory cells.

Antibodies may also neutralize viruses; that is, they attach to a virus and render it unable to enter a cell. Outside living cells, viruses cannot reproduce, and those coated with antibodies are phagocytized by macrophages. Another aspect of our defenses against viruses is interferon, a chemical produced by cells infected with viruses. Although it does not help the infected cell, interferon protects surrounding cells by enabling them to resist viral reproduction by limiting or slowing growth of the virus.

Antibodies are also involved in allergic responses, in which the immune system responds to foreign but harmless antigens (an allergen), such as plant pollen. IgE antibodies bond to mast cells, which break down and release histamine and other chemicals that contribute to inflammation. **Anaphylactic shock** is this very same allergic reaction, only massive in nature. It is characterized by loss of plasma from capillaries (an effect of histamine) and a sudden drop in intravascular blood volume and blood pressure.

▶ **TYPES OF IMMUNITY**

Two categories of immunity are **passive immunity** and **active immunity**. In passive immunity, antibodies are not produced by the individual but are obtained from another source. One form of naturally acquired passive immunity includes placental transmission of antibodies from mother to fetus and transmission of antibodies in breast milk. Artificially acquired passive immunity involves injection of preformed antibodies; this may help prevent disease after exposure to a pathogen such as the hepatitis A virus. Passive immunity is always temporary, in that antibodies from another source eventually break down.

anaphylactic: ana—up + phylaxis—protection

Figure 52-2 Antibody responses to a first and then subsequent exposure to a pathogen. (From Scanlon, V, and Sanders, T: Understanding Human Structure and Function. FA Davis, Philadelphia, 1999, p 317.)

Active immunity means that the individual produces his or her own antibodies. An example of naturally acquired active immunity occurs when a person recovers from a disease and then has antibodies and memory cells specific for that pathogen. Artificially acquired active immunity occurs as the result of a vaccine that stimulates production of antibodies and memory cells. The duration of active immunity depends on the particular disease or vaccine; some confer lifelong immunity, but others do not.

▶ AGING AND THE IMMUNE SYSTEM

The efficiency of the immune system decreases with age. As such, elderly people are more susceptible to infections, especially secondary infections such as the development of pneumonia following the flu (Gerontological Issues Box 52-1). Autoimmune disorders are also more common among older people; the immune system mistakenly perceives the body's own tissues as foreign and initiates their destruction. The incidence of cancer is also higher; malignant cells that might once have been quickly destroyed by the immune system remain alive and proliferate.

BOX 52-1 GERONTOLOGICAL ISSUES

Significant changes occur in the immune system of the older adult. These changes are known as immune senescence, which refers to a decline in immune system function. Some specific changes include the following:

- Thymus gland decreases in size, increases production of immature T cells, and has a subsequent decline in response to antigens.
- Antibody response to pneumococcus, influenza, and tetanus decreases, creating need for vaccine.

Immunizations to support the immune responses of older adults include the following:

- Diphtheria tetanus booster every 10 years
- Pneumovax once in a lifetime (reimmunization or boosters not necessary)
- Influenza vaccine yearly (before influenza season)
- Hepatitis B vaccine if medium to high risk for exposure to hepatitis B.

▶ IMMUNE SYSTEM ASSESSMENT

Nursing Assessment

A thorough assessment of the immunologically compromised patient is the first step in the nursing process. It gives substance to the nursing care plan, which guides nursing practice. Because disorders of the immune system can affect every system in the body, it is vitally important that a thorough head-to-toe assessment and history is performed.

Subjective Data

DEMOGRAPHIC DATA. The patient's age, gender, race, and ethnic background data are important because some disease processes tend to be associated with a particular gender, race, or age group. For instance, systemic lupus erythematosus

(SLE), an autoimmune disorder, tends to affect women eight times more than men. Inquiring about the patient's place of birth may give insight to ethnic ties that are not initially evident in the interview. Also, where the patient lives and has lived may shed light on the patient's current problem.

HISTORY. Inquiry into medication, food, and environmental allergies such as dust, pollen, and insects should include the patient's allergies, as well as those of family members. There may be a familial tendency to react to substances, so a previous exposure and sensitization to a substance may not be necessary before a severe reaction occurs. Many times if there is a family history of a severe reaction (anaphylaxis) to penicillin, a physician does not order penicillin for the patient. Some reactions can be fatal within minutes without immediate medical treatment.

As with allergies, inquiring about past and present medical conditions or disease processes should also include a family history, as well as the patient's history. Many atopic (allergic) disorders such as allergic rhinitis and asthma or autoimmune disorders such as SLE and ankylosing spondylitis are thought to be either familial or have a genetic predisposition in certain races or cultures (Cultural Consideration Box 52-2).

BOX 52-2 CULTURAL CONSIDERATION

The Navajo people have a high incidence of severe combined immunodeficiency syndrome (SCIDS), and immunodeficiency syndrome unrelated to acquired immunodeficiency syndrome (AIDS). SCIDS results in a failure of the antibody response and cell-mediated immunity. Infants who survive initially are sent to tertiary care facilities. They must receive gamma globulin on a regular basis until a bone marrow transplant can be performed. Thus far, studies indicate that SCIDS is unique to this Navajo population.

The patient's previous surgeries may play an important role in the patient's current condition or give clues about prior health. If the patient has had his or her thymus gland removed (thymectomy), T-cell production may be altered, which affects the cell-mediated immune response. If the patient has had his or her spleen removed (splenectomy), lymphocyte and plasma cell production may be altered, which affects humoral immune response.

Further questioning about previous blood transfusions, radiation exposure (therapeutic or accidental), and current medications (prescription and over-the-counter drugs) provides data that may be associated with the current problem. For example, corticosteroids and immunosuppressants alter the immune response. Other medications, such as some anti-infectives or antineoplastics, depress the bone marrow, resulting in decreased production of the cells made in the bone marrow. Bone marrow depression of white blood cells can alter cell-mediated and humoral immune responses.

A patient's lifestyle may influence immune system function and should be assessed. Exposures to caustic chemicals

or fumes at work may lead to systemic or topical immune reactions or bone marrow depression. Anaphylactic reactions can be caused by exposure to latex, which is found in gloves and other medical products that health care workers and their patients touch. Be aware of this potentially life-threatening reaction and know the agency's latex allergy protocol. These patients should wear a medical alert bracelet and carry an anaphylactic epinephrine kit. It is also important to know if the patient uses illicit drugs or has multiple sexual partners or partners of the same gender. These behaviors place the patient at risk for contracting the human immunodeficiency virus (HIV). Knowing the patient's diet habits and supplemental vitamins gives insight into the potential reserve of the immune system for fighting infection.

The patient's life stressors, coping behaviors, and support systems should be explored. Stress (environmental, physical, and psychological) can depress the immune system's function. Coping behaviors are essential in keeping stress within manageable limits to maintain an optimum-functioning immune system. Support systems play an important role in coping with stress and should be encouraged and nurtured by nurses.

Current Problem

Use the WHAT'S UP? format to collect data about the current immune system problem. For immune disorders, the patient is asked the following questions:

- Where is it? What part of the body is affected?
- How does it feel? Painful? Itching?
- Aggravating and alleviating factors?
- Timing. Was there exposure to a pathogen? Did you have a previous infection? Does it occur only in certain settings? Did you have chemotherapy or radiation therapy? How long have symptoms persisted?
- Severity. Does it affect activities of daily living (ADLs)? Work? Roles?
- Useful data for associated symptoms. Immunosuppression? Family history? Allergies?
- Perception of the patient of the problem. What do you think is wrong?

When investigating the patient's current problem, the following are examples of common signs and symptoms that may be found with immune disorders: fever, fatigue, joint pain, swollen glands, weight loss, and skin rash.

CRITICAL THINKING

Laura

Laura is scheduled for a lymph node biopsy and is seen in preadmission testing before surgery. As the licensed practical nurse/licensed vocational nurse (LPN/LVN) prepares to draw blood specimens, he learns that Laura is allergic to latex.

1. Why is this patient information important?
2. What should the LPN/LVN do next?
3. What precautions should the LPN/LVN use to draw the blood specimen?

Answers at end of chapter.

LEARNING TIPS

A normally functioning immune system is required to trigger an inflammatory response that produces the signs of inflammation or infection: fever, redness, pain, swelling, and warmth. If the immune system is suppressed or functioning abnormally, this normal inflammatory response may not occur. Thus the patient may exhibit only a low-grade fever with none of the other signs of inflammation or infection (redness, pain, swelling, and warmth).

Recognize patients with suppressed immune systems, so that low-grade fevers are reported to the physician for prompt treatment. This may be the only sign of a life-threatening infection that develops because of the suppressed immune system.

Objective Data

PHYSICAL ASSESSMENT. The physical assessment begins by observing the patient's general appearance, color, posture, gait, and facial expressions. While talking with the patient, alertness and orientation to person, place, and time are assessed. Patients with various immune disorders, such as SLE or acquired immunodeficiency syndrome (AIDS), may exhibit mentation changes, especially if they develop central nervous system complications in advanced stages.

The patient's skin, bone joints, and nailbeds should be carefully examined. Any cyanosis or erythema (redness) is noted. Rashes should be examined for size, shape, location, texture, drainage, and pruritus (itching). Painless, small purple lesions are Kaposi's sarcoma (Fig. 52-3). This sarcoma is often associated with AIDS. Bone joints, especially of the hands, should be inspected for swollen, painful nodules that are associated with rheumatoid arthritis. Any swelling, tenderness, or limited range of motion is noted. Nails are assessed; if they separate from the nailbed, it is called onycholysis and can be associated with thyroiditis.

Vision and hearing changes can be associated with an immunologic disorder. Eye movements are assessed by testing the six cardinal positions of gaze for muscle weakness. (See Chapter 48.) The conjunctiva should be deep pink and moist. If the patient is anemic, the conjunctiva is pale. Edema around the eyes (periorbital edema) may indicate hypothyroidism or renal disease. Darkened areas under the eyes (shiners) are common in patients experiencing allergic rhinitis.

Adventitious lung sounds, such as wheezing, may indicate asthma or an allergic response. Crackles are often associated with an upper respiratory infection. Crackles heard with a dry cough and labored tachypnea are a sign of *Pneumocystis carinii* pneumonia, a common opportunistic lung infection of patients with AIDS. A pleural or pericardial friction rub may be a sign of rheumatoid arthritis or SLE.

Lymph nodes should be inspected and then gently palpated. (See Fig. 52-1.) Normally, lymph nodes are not palpable in the adult (usually they can be palpated in young children). If on palpation a lymph node is enlarged, the following characteristics need to be noted: location, size, shape, tenderness, temperature, consistency, mobility, symmetry, pulsation, and if red streaks, redness, or edema is

present. Generally when lymph nodes are tender and enlarged, inflammation is present. Lymph nodes that are nontender, hard, fixed, and enlarged are often associated with cancer.

If enlarged, the spleen may be palpable (by advanced practitioner) in the left upper quadrant of the abdomen with disorders in which there is an overproduction or excessive destruction of red blood cells.

Gastrointestinal signs and symptoms such as nausea, vomiting, and diarrhea should be noted because they may have an immunologic basis. The renal system may also show impairment because of an immunologic disorder, exhibited through a change in urinary output, flank pain, edema, weight gain, or elevated renal function studies.

A general neurological assessment of muscle strength and coordination, changes, or abnormalities is noted. Changes may be an indication of an immunologically based disorder such as multiple sclerosis or myasthenia gravis.

Diagnostic Tests

Blood Tests

Initially, screening tests are performed. Table 52–2 describes the most common screening blood tests for patients with allergic, autoimmune, or immune disorders. If the screening tests detect an abnormality, further specific tests may be ordered to precisely identify the disorders. Table 52–3 examines the more common of these specific immune tests.

Radiographic Tests

A chest x-ray examination, magnetic resonance imaging (MRI) or computed tomography (CT) scan may also be performed to identify size and density of structures, as well as new abnormal growths.

Biopsies

Biopsies of organs or structures possibly affected by an immune disorder aid in confirming a diagnosis, determining a prognosis, or evaluating a treatment. Biopsies may include lymph node biopsies, organ biopsies, or bone marrow aspirations. These procedures require a consent to be signed by the patient. Biopsies may be performed as inpatient, outpatient, or physician's office procedures. The specific biopsy being performed determines any required patient preparation or postprocedure care.

Skin Tests

When the immune system is intact, skin tests can be used to test for infectious diseases such as *Candida*, tetanus, or tuberculosis (purified protein derivative [PPD] test) or to identify the allergen responsible for symptoms of allergic rhinitis or drug and food allergies. Patients may also have skin testing performed to determine the specific allergen they are sensitive to. This information allows the patient to either avoid the allergen or have immunotherapy (allergy shots) to desensitize the immune system to the specific offending allergen.

Gene Testing

Mapping of the human genome has made current and future gene testing and manipulation possible. Scientists are now able to test for numerous diseases, predisposition to diseases, and enzyme deficiencies that can alter the immune response. These tests are possible but are still new and expensive.

► THERAPEUTIC MEASURES

Allergies

A medical alert bracelet or some sort of readily available identification of an allergy should be worn by the patient. It is important to always be aware of patient allergies. Allergies should be noted before giving any medications or foods. All allergies, including those to food, must be taken seriously.

Food allergies create serious management problems and have caused numerous deaths from anaphylactic shock (Nutrition Notes Box 52-3). The offending allergen may be present in extremely tiny amounts. Sometimes a food product is contaminated by a previous batch of food made with the same equipment. Occasionally the allergen may enter the body not by ingestion but by inhalation or contact with skin or mucous membranes.

If an antigen is environmental, such as bee or wasp stings, carrying an epinephrine pen may be vital because the allergic person may not be near medical treatment when it is needed. Epinephrine is the drug of choice for an

TABLE 52-2 COMMON BLOOD SCREENING TESTS FOR ALLERGIC, IMMUNE, AND AUTOIMMUNE DISORDERS

Test	Explanation of Normal Values	Explanation of Abnormal Values
Red blood cell count	Number of red blood cells per mm of blood	Decreased in anemias, multiple myeloma; may be low in rheumatoid arthritis
Total white blood cell count (WBC)	Number of white blood cells per millimeter of blood	Increases in acute infection, inflammation, and leukemias Decreased in chronic infections, cancer, bone marrow failure and immunosuppression (AIDS), chronic cortisol therapy, antibiotic therapy, chemotherapy, myelosuppression
WBC differential	Percentage of type of white blood cells in 1 mm of blood	
Neutrophils		Increased in acute bacterial infections Decreased in acute viral infections, chemotherapy, radiation therapy, aplastic anemia, and neoplastic invasion of bone marrow
Lymphocytes		Increased in leukemias, pertussis, tuberculosis, and viral infections Decreased in acute bacterial infections, AIDS
Eosinophils		Increased in allergic reactions and parasitic infestations Decreased in corticosteroid therapy, bone marrow failure, and immunosuppression
Basophils		Increased in allergic reactions Decreased in bone marrow failure and immunosuppression
Serum IgG levels	Amount of IgG in milligrams per deciliter of blood and percentage of IgG of total immunoglobulins Normal: 70–75%	Increased in infection, AIDS, and autoimmune disorders Decreased in lymphocytic leukemia and agammaglobulinemia
Serum IgA levels	Amount of IgA in milligrams per deciliter of blood and percentage of IgA of total immunoglobulins Normal: 10–15%	Increased in chronic infections, autoimmune disorders Decreased in immunosuppression, lymphocytic leukemias, and agammaglobulinemia
Serum IgM levels	Amount of IgM in milligrams per deciliter of blood and percentage of IgM of total immunoglobulins Normal: 10%	Increased in autoimmune disorders, systemic lupus erythematosus Decreased in immunosuppression and chronic lymphocytic leukemia
Serum IgE levels	Amount of IgE in milligrams per deciliter of blood and percentage of IgE of total immunoglobulins Normal: 0.002%	Increased in asthma and allergic conditions Decreased in immunosuppression
Complement assay	Measures the amount of each of the components in the complement system	Increased in thyroiditis, rheumatoid arthritis, ulcerative colitis Decreased in systemic lupus erythematosus, acute poststreptococcal glomerulonephritis, acute serum sickness, multiple myeloma, and hereditary angioedema
Sedimentation rate	Measures the red blood cell descent (in millimeters) in test tube after being in normal saline for 1 hour	Increased in inflammatory, infectious, necrotic, and cancerous conditions due to the increased protein content in plasma
C-reactive protein test	An abnormal protein found in plasma during acute inflammatory processes; more sensitive than sedimentation rate	Increased in rheumatoid arthritis, cancer, systemic lupus erythematosus Suppressed by aspirin and steroids

anaphylactic reaction. Time plays a crucial role when this type of reaction occurs. The patient must seek immediate medical care and begin treatment by administering epinephrine until help is available.

An anaphylaxis kit is often prescribed for patients with allergies to food or insect stings. The kit contains injectable epinephrine, oral chewable antihistamine tablets, a tourniquet, and instructions for use. The patient must carry the kit at all times when insect stings are possible. The patient must be taught how to use the kit and give the subcutaneous epinephrine injection. The tourniquet, applied to the extremity that was stung, slows blood flow carrying the allergen to reduce its spread in the body. The tourniquet is released every 15 minutes to allow some blood flow in the extremity.

Immunotherapy

To help desensitize a patient with anaphylactic reactions to allergens or with chronic allergic symptoms, immunotherapy involves injecting small amounts of an extract of the allergen. Over time the strength of the allergen injected is increased, until the desired hyposensitivity is reached. The subcutaneous injections are given once or twice a week initially, then every few weeks indefinitely for years. It is important that the patient does not miss a dose. If this happens, the allergen strength may need to be reduced. This therapy is helpful for insect sting allergies.

When administering the injection, it is important to understand that an anaphylactic reaction can occur. A physi-

TABLE 52-3 COMMON TESTS PERFORMED FOR ALLERGIC, IMMUNE, AND AUTOIMMUNE DISORDERS

Test	Explanation of Test	Explanation of Abnormal Values
Rheumatoid factor (RF)	An abnormal protein found in serum when IgM reacts with an abnormal IgG; found in 80% of patients with rheumatoid arthritis, as well as other autoimmune disorders	Increased in rheumatoid arthritis, SLE, leukemia, tuberculosis, older age, scleroderma, infectious mononucleosis
Antinuclear antibodies (ANA)	Measures antibodies that attack the cell's nuclei	Most commonly present in SLE, leukemia, scleroderma, rheumatoid arthritis, and myasthenia gravis; many medications influence these levels
Lupus erythematosus test (LE Prep)	Nonspecific test for lupus	Increased in SLE, rheumatoid arthritis, scleroderma; many medications influence levels
Western blot	ANA is a more sensitive test for lupus	Positive when antibodies for HIV are present
Murex SUDS	Tests for antibodies to HIV; technical and labor-intensive test, therefore not used as a screening test; used as a confirmation test; positives are difficult to determine	Positive when antibodies for HIV are present
Enzyme-linked immunosorbent assay (ELISA)	Tests for antibodies to HIV-1; manual, qualitative test; visually read in 10 minutes; used as a screening test	Positive when antibodies for HIV are present, as well as numerous other viruses
p24 Antigen	Tests for antibodies to HIV; inexpensive and easily performed, therefore a good screening test for HIV; high incidence of false-positive results due to the test's nonspecificity	Positive when p24 antigen produced by HIV is present
Polymerase chain reaction	Tests for the formation of the p24 antigen, which occurs before the production of antibodies, therefore testing can occur during the window between infection and seroconversion (antibody production); p24 antigen is present for only a short time and is replaced with the antibodies	Positive when HIV is present
CD4+ T cells	Detects nonreplicating viral genomes; requires only 1–2 mL of blood; costly and time consuming, therefore not a screening test	Increased in allergy-proven patients Decreased in cancer, AIDS, and immunosuppression
CD8+ T cells	Measures the actual number and percentage of CD4+ T cells in a specimen	Increased in viral infections Decreased in SLE
	Measures the actual number and percentage of CD8+ T cells in a specimen	

cian and emergency equipment should be readily available. The patient should be observed following the injection for about 20 to 30 minutes to detect a reaction. The patient should be taught that a reaction could occur up to 24 hours after the injection and how to respond.

Medications

Medications are one of the primary treatment options for immune disorders. General categories of these medications include epinephrine, corticosteroids, antihistamines, histamine (H₂) blockers, decongestants, mast-cell stabilizing drugs, antivirals, antibiotics, immunosuppressants, interferon, leukotriene antagonists, and hormone therapy. (See Chapter 53.)

Surgical Management

In some cases, splenectomy is necessary to control symptoms of an immunologic disorder.

New Therapies

Monoclonal antibodies can be produced against a variety of antigens. A monoclonal antibody is made by cloning one

specific antibody and then growing unlimited amounts of it in tissue cultures. Many uses are being found for these antibodies, such as in dealing with transplant rejections. Further study will lead to expanded knowledge on these antibodies.

Recombinant DNA technology combines genes from one organism with genes from another. This therapy is used for replacing an abnormal or missing gene to produce a normal gene. The normal gene can then be injected into the patient in an attempt to cure the disorder as the patient's body reproduces the normal genes. T lymphocytedirected gene transfer for severe combined immune deficiency has been performed successfully. Along these same lines is the research regarding injection of the precursors to all cells, the stem cell, into abnormal areas to produce normal cells. Studies continue in this area for possible uses of gene therapy, and since the completion of the mapping portion of the Human Genome Project, new discoveries in this area occur daily. For additional up-to-date information on these topics, visit the National Institutes of Health at www.nhgri.nih.gov or www.ncbi.nlm.nih.gov.

BOX 52-3

Nutrition Notes

Respecting Food Allergies

Allergy to food can be fatal. An analysis of 13 anaphylactic reactions to food identifies points along the critical path that had the potential to alter the outcome. Of 13 cases identified, 6 were fatal. In all cases the patient was known to have asthma and to be allergic to some food. None of the patients were aware that the allergen was present in the foods consumed. The items were candy, cookies, and pastry. Symptoms began soon after ingestion but in some cases abated before becoming severe. Of particular significance is the fact that fewer than half the children had self-injectable epinephrine prescribed and only one of the six children used a dose. The average delay between ingestion of the allergenic food and receipt of a dose of epinephrine was two and one-half times as long in the fatal cases as in the nonfatal cases. Also, more of the fatal cases occurred in public places rather than a private home. These and other similarities and differences are tabulated below, followed by recommendations for the management of potential for anaphylaxis.

Situational Factor	Fatal Cases	Near-Fatal Cases
Age of patient (average and range)	11.5 years 2–16 years	12.4 years 9–17 years
Gender	1 male 5 females	2 males 5 females
Known to have asthma	6	7
Cause of anaphylactic reaction	Peanuts 3 Cashews 2 Eggs 1	Filberts 2 Milk 2 Peanuts 1 Brazil nuts 1 Walnuts 1
Average number of foods identified as allergenic for each patient	1.7	2
Onset of symptoms	3–30 minutes	1–5 minutes
Location	School 4 Fair 1 Home 1	Home 2 Relative's home 2 Friend's home 2 Vacation home 1
Parent present at site	3	4
Had a prescription for self-injectable epinephrine	3	3
Used the self-injectable dose	0	1
Number of minutes after ingestion that any epinephrine was given (average and range)	93.3 15–180	36.4 10–130

Several recommendations came from this study:

- Epinephrine should be prescribed, kept available, and used for patients with IgE-mediated food allergies.
- Children and adolescents who have an allergic reaction to food should be observed for 3 to 4 hours after the reaction at a center capable of dealing with anaphylaxis.
- Parents of such children should be taught to ensure a rapid response by schools and other institutions.

Summarized from Sampson AA, Mendelson I, Rosen JP: Fatal and near-fatal anaphylactic reactions to food in children and adolescents. *New England Journal of Medicine* 327:380, 1992.

Answers to CRITICAL THINKING

Laura

1. The patient can have an anaphylactic reaction if exposed to latex, which may result in death for some patients.
2. The LPN/LVN should follow the agency's latex allergy protocol, enter this information into the patient's medical record, notify surgery scheduling so latex precaution protocols can be planned for surgery, and have the patient's physician informed.
3. Follow the agency's protocol, the nurse should wear nonlatex gloves and use nonlatex equipment to draw the specimens.

REVIEW QUESTIONS

1. The nurse who is teaching a patient about vaccines would be correct in teaching that a vaccine provides which of the following types of immunity?
 - a. Naturally acquired passive immunity
 - b. Artificially acquired passive immunity
 - c. Naturally acquired active immunity
 - d. Artificially acquired active immunity
2. The nurse is assisting with data collection. Which one of the following past surgeries may be useful in assessing potential immune system dysfunction?
 - a. Splenectomy
 - b. Thyroidectomy
 - c. Pneumonectomy
 - d. Parathyroidectomy
3. The nurse is assisting with data collection and the patient reports tenderness in the cervical lymph nodes. The nurse recognizes that lymph nodes that are enlarged and tender usually indicate which of the following problems?
 - a. Cancer
 - b. Degeneration
 - c. Inflammation
 - d. Arthritis
4. The nurse is caring for a patient with suspected HIV. The nurse anticipates that which of the following is a confirmation test that will be ordered to test for HIV antibodies?
 - a. Murex SUDS
 - b. Enzyme-linked immunosorbent assay
 - c. Western blot
 - d. p24 antigen testing
5. The nurse is giving immunizations. Which of the following vaccines are recommended annually for the elderly patient?
 - a. Influenza
 - b. Pneumovax
 - c. Diphtheria tetanus
 - d. Polio

53

NURSING CARE OF PATIENTS WITH IMMUNE DISORDERS

Sharon M. Nowak

KEY TERMS

anaphylaxis (an-uh-fi-**LAK**-sis)
 angioedema (AN-gee-o-eh-**DEE**-ma)
 ankylosing spondylitis (ANG-ki-**LOH**-sing

 histamine (**HISS**-ta-mean)
 urticaria (UR-ti-**KAIR**-ee-ah)

QUESTIONS TO GUIDE YOUR READING

1. How would you explain the immunologic mechanism for the four types of hypersensitivities?
2. How would you explain the pathophysiology of disorders of the immune system?
3. What are the etiologies, signs, and symptoms of immune system disorders?
4. What care would you provide for patients undergoing tests for immune system disorders?
5. What is the current medical treatment for immune system disorders?
6. What data are collected when caring for patients with disorders of the immune system?
7. What factors alter or influence the self-recognition portion of the immune system?
8. What nursing care will you provide for patients with disorders of the immune system?
9. How will you know if your nursing interventions have been effective?

Disorders of the immune system can be divided into three categories. The first category is hypersensitivity reactions, which include conditions such as **anaphylaxis**, hemolytic transfusion reactions, measles, and transplant rejections. Autoimmune disorders (e.g., rheumatoid arthritis, ulcerative colitis, and multiple sclerosis) are the second category. The third category includes the immune deficiencies, such as hypogammaglobulinemia and acquired immunodeficiency syndrome (AIDS). (See Chapter 54.)

► HYPERSENSITIVITY REACTIONS

The immune system is an adaptive, protective system of the body. However, there are times when this system causes injury to the body because of its exaggerated response. One of these occasions is when a hypersensitivity reaction occurs.

In the past these reactions were classified as either immediate or delayed hypersensitivity. Gell and Coombs have

developed a more precise classification system, which is used today. This four-division system (Types I, II, III, and IV) classifies hypersensitivity reactions according to the way the tissue is injured.

Type I

A type I reaction, an anaphylactic reaction, is an immediately occurring reaction when exposure to a specific antigen occurs. The reaction can be mild to severe and life threatening. The patient must have had previous exposure (sensitization) to the antigen. During this exposure, immunoglobulin E (IgE) antibodies are made and attach to mast cells throughout the body. When a subsequent exposure occurs, the antigen causes IgE to trigger mast cells to release their contents. One of the substances released is **histamine**, which causes vasodilation, changes in vascular permeability, an increase in mucus production, and contraction of various smooth muscles.

If the second antigen exposure is localized, the reaction is small and remains local. However, if the exposure is

anaphylaxis: ana—up + phylaxis—protection

systemic, the reaction is massive and widespread. Respiratory allergies, such as allergic rhinitis and allergic asthma, with associated disorders of atopic dermatitis, tend to be reactions of a larger scale. Anaphylaxis, **urticaria**, and **angioedema** are the severest forms of type I reactions.

A type I reaction occurs when the patient has a positive reaction to a scratch test. A scratch test is done to identify specific allergens to which a patient is reactive. Tiny amounts of a variety of common allergens are scratched onto the skin, which is then observed for indications of a reaction: redness, edema, and pruritus. If these indicators occur, it is considered to be a local reaction.

Allergic Rhinitis

Allergic rhinitis is the most common form of allergy. When symptoms occur throughout the year, it is called perennial allergic rhinitis. If the symptoms occur seasonally, it is called hay fever. The causative antigens are environmental and airborne.

PATHOPHYSIOLOGY. Allergic rhinitis is the result of an antigen-antibody reaction. Ciliary action decreases and mucous secretions increase. Vasodilation and local tissue edema occur.

SIGNS AND SYMPTOMS. Signs and symptoms vary in intensity and include sneezing, nasal itching, profuse watery rhinorrhea (runny nose), and itchy red eyes. The nasal mucosa is pale, cyanotic, and edematous. Frequently there are dark circles under the eyes, called allergic shiners, caused by venous congestion in the maxillary sinuses.

COMPLICATIONS. Allergic rhinitis is minor and self-limiting for most patients. Repeated occurrences of allergic rhinitis can lead to infection of the sinuses (sinusitis), nasal polyps, asthma, or chronic bronchitis.

DIAGNOSTIC TESTS. Diagnosis is generally made from a detailed history and visual inspection of the nasal passages. Sometimes, skin testing is performed to identify the specific offending allergens to allow avoidance of the allergen. However, skin testing is expensive, does not always identify the allergen, and has limited usefulness for allergens that cannot be easily avoided once identified.

MEDICAL TREATMENT. Initial treatment involves eliminating the offending environmental stimuli. Antihistamines and nasal decongestants may be prescribed for symptomatic relief. If the symptoms are severe, corticosteroids via inhalation or nasal spray may also be given. Immunotherapy, referred to as allergy shots, is reserved for patients with severe or debilitating symptoms. Immunotherapy involves receiving weekly subcutaneous injections of tiny amounts of the offending antigen. Once a tolerance to a particular dose is reached, the amount of antigen is slightly increased. This therapy continues until the patient no longer exhibits symptoms when exposed to the environmental antigen.

NURSING MANAGEMENT. Education of the patient and significant other is an important nursing function. Monitoring the patient's symptoms and compliance with the treatment plan is also a nursing responsibility. Skin testing and immunotherapy injections, given in the allergist's office, maybe performed. Being alert to signs of anaphylaxis during these procedures is essential.

Education. The teaching plan focuses on the patient avoiding allergens and following the therapeutic regimen. Exploring creative ways to prevent allergen exposure is helpful. Allergen avoidance might involve wearing a mask when mowing the lawn or working outdoors or having heating ducts cleaned or heating registers covered with filters. Frequent home vacuuming and dusting is recommended. Ensuring that patients understand prescribed medications and their correct usage is important.

Atopic Dermatitis

PATHOPHYSIOLOGY. Atopic dermatitis, often called eczema, is an inflammatory skin response. The skin lesions are not typical for a type I hypersensitivity reaction, and there usually is not a specific antigen identified as the cause. However, it is believed that the pathophysiology of atopic dermatitis is a type I hypersensitivity reaction, mediated by IgE antibodies, because it is commonly found in patients with allergic rhinitis or allergic asthma.

SIGNS AND SYMPTOMS. Initially there is pruritus, edema, and extremely dry skin, which is followed by eruptions of tiny vesicles (blisters); these eventually break open, crust over, and scale off. There is decreased sweating in these areas with the skin eventually thickening in the areas of dermatitis.

COMPLICATIONS. With open skin lesions, there is always a risk for infection. Staphylococci are found on the dermal layer of the skin, so these bacteria tend to be the most common source of secondary infections of the affected area of skin.

DIAGNOSTIC TESTS. There are no tests to confirm this diagnosis. A detailed history and physical examination are used to diagnose it. Of course, if there is an infection, culture and sensitivity tests may be ordered to determine the infecting organism and appropriate treatment.

MEDICAL TREATMENT. Treatment is focuses on symptoms. Oil-in-water lubricants such as Alpha-Keri oil tend to be the most effective for dryness. Topical corticosteroids may be ordered for their anti-inflammatory properties. If skin lesions become infected, topical or systemic antibiotics are prescribed.

NURSING MANAGEMENT. Assess and document the lesions for signs of infection: redness, warmth, swelling, and purulent drainage. Administer medications and lubricants as ordered.

Education. Instruct the patient on the signs and symptoms of infection. Assessment of the patient's knowledge about

prescribed medications and over-the-counter preparations is needed for teaching and reinforcement of knowledge. Teach the patient that humidification during the winter months is a necessity, cotton clothing may minimize irritation, and cool soaks decrease pruritus.

Anaphylaxis

PATHOPHYSIOLOGY. Anaphylaxis is a severe systemic type I hypersensitivity reaction. IgE antibodies produced from previous antigen sensitization are attached to mast cells throughout the body. In this reaction the antigen is introduced at a systemic level, which causes widespread release of histamine and other chemical mediators contained within the mast cells.

ETIOLOGY. There are numerous causes of anaphylaxis. See Table 53–1 for potential causes.

SIGNS AND SYMPTOMS. Anaphylaxis produces sudden and life threatening signs and symptoms. Generalized smooth muscle spasms occur, causing bronchial narrowing and creating stridor, wheezing, dyspnea, and laryngeal edema, which can lead to respiratory arrest. Cramping, diarrhea, nausea, and vomiting also result from these spasms. Capillary permeability increases, allowing fluid to shift from the vessels to the interstitium. This causes hypotension, tachycardia, and an increase in respiratory symptoms. The blood volume within the vessels decreases while the blood vessels dilate, resulting in a further decrease in circulating blood volume. The dilation also causes diffuse erythema (redness) and warmth of the skin. Neurological changes include apprehension, drowsiness, profound restlessness, headache, and possible seizures.

TABLE 53–1 SUBSTANCES THAT COMMONLY TRIGGER ANAPHYLACTIC REACTIONS

<i>Antibiotics</i>	<i>Foods</i>
Penicillins	Beans
Sulfonamides	Chocolate
Tetracyclines	Eggs
Cephalosporins	Fruits (e.g., strawberries)
Amphotericin B	Grains (e.g., wheat)
Aminoglycosides	Nuts
<i>Medical Products</i>	Shellfish
Latex rubber	<i>Pollens</i>
<i>Diagnostic Agents</i>	Grass
Contrast dyes	Ragweed
<i>Anesthetics/Antiarrhythmics</i>	<i>Proteins</i>
Lidocaine	Horse serum
Procaine	Rabbit serum
<i>Other Medications</i>	<i>Venoms</i>
Barbiturates	Bees, wasps, hornets
Phenytoin (Dilantin)	Fire ants
Protamine	Snakes
Salicylates	<i>Hormones</i>
Diazepam (Valium)	Insulin
<i>Food Additives</i>	Vasopressin
Bisulfites	Estradiol
Monosodium glutamate (MSG)	Adrenocorticotrophic hormone

COMPLICATIONS. The most profound complications of an anaphylactic reaction are respiratory and cardiac arrest. Immediate treatment is necessary to prevent death.

DIAGNOSTIC TESTS. There is no time for tests to be performed during an anaphylactic reaction other than those needed to guide symptom treatment, such as arterial blood gases or electrocardiogram (ECG) monitoring. Anaphylaxis is diagnosed based on physical assessment and history from the patient or significant other. After the patient's recovery, allergen testing may be considered for future prevention.

MEDICAL TREATMENT. Intravenous access is a priority for administration of intravenous epinephrine and vasopressor drugs (dopamine) to increase blood pressure. Oxygen therapy is started. If respiratory symptoms are severe, a tracheostomy or endotracheal intubation may be necessary, with mechanical ventilation. Antihistamines and corticosteroids may also be given orally, by injection, or intravenously.

NURSING MANAGEMENT. Early recognition of anaphylaxis is important. Staying with the patient while calling for immediate help minimizes the patient's anxiety and allows close monitoring of vital signs and symptoms. Maintaining a patent airway is vital. Anticipation and preparation of emergency medication and equipment facilitates rapid treatment.

Education. The patient who is prone to anaphylactic reactions should be educated on the importance of avoiding the offending antigen and wearing medical alert identification. If the antigen is environmental, such as an insect sting or food, obtaining a prescription and providing instruction on the use of an anaphylaxis kit or an epinephrine pen is crucial. (See Chapter 52).

Urticaria

PATHOPHYSIOLOGY. Urticaria (hives) is a type I hypersensitivity reaction. The antigen-stimulated reaction of IgE antibodies causing the release of mast cell contents, especially histamine, triggers urticaria.

ETIOLOGY. There are numerous causes of urticaria. In addition to medications and foods, cold, local heat, pressure, and stress can also cause urticaria. Many patients with underlying chronic conditions, such as systemic lupus erythematosus, lymphoma, hyperthyroidism, or cancer, are susceptible to urticaria.

SIGNS AND SYMPTOMS. The lesions of urticaria are raised, pruritic, nontender, and erythematous wheals on the skin. They tend to be concentrated on the trunk and proximal extremities.

DIAGNOSTIC TESTS. Diagnosis is made on the basis of physical examination and patient history.

MEDICAL TREATMENT. Treatment depends on the degree of symptoms. In the most severe cases, epinephrine may be given to quickly resolve the urticaria. Corticosteroids may be prescribed orally, topically, or intravenously. Antihista-

mines and histamine (H₂) blockers, such as cimetidine and ranitidine, may aid in resolution by blocking the release of histamine.

NURSING MANAGEMENT. Nursing management includes monitoring the patient's symptoms, administering prescribed medications, and evaluating the patient's response to medications. In severe cases, maintaining a patent airway is a priority. Cool soaks and diversionary activities may help with pruritus.

Education. Instruct the patient on the use and side effects of prescribed medications. Be creative in investigating with the patient ways to avoid the causative agent of the urticaria. Some patients benefit from instruction on stress management and relaxation techniques.

Angioedema

PATHOPHYSIOLOGY AND ETIOLOGY. Angioedema is a form of urticaria. The pathophysiology and etiology of angioedema are the same as for urticaria. However, angioedema affects submucosal and subcutaneous tissue rather than the skin.

SIGNS AND SYMPTOMS. Angioedema is painless and minimally pruritic, with dermal erythematous and subcutaneous eruptions. There is also skin and mucous membrane edema. The eruptions may last longer than with urticaria.

DIAGNOSTIC TESTS. A comprehensive history and physical examination confirm the diagnosis. Skin testing may be performed to determine the specific antigen.

MEDICAL TREATMENT. The most basic treatment involves avoidance of the antigen. Symptomatic relief may be obtained through the use of antihistamines and corticosteroids. For long-term treatment, immunotherapy for allergen desensitization may be indicated.

NURSING MANAGEMENT. Assessment of the patient's symptoms is needed, as well as the administration and then evaluation of the patient's response to medications. If the reaction is severe, maintenance of a patent airway is a priority.

Education. Assessing the patient's baseline knowledge of the condition and medications is necessary. Further education may be indicated. The patient and nurse may need to find creative ways for the patient to either avoid or minimize future exposure to the causative antigen.

Type II

A type II hypersensitivity reaction involves the destruction of a cell or substance that has an antigen attached to its cell membrane, which is sensed by either immunoglobulin G (IgG) or immunoglobulin M (IgM) as being a foreign antigen. When an antigen marker is sensed as foreign, an antibody attaches to the antigen on the cell membrane, causing lysis of the cell or accelerated phagocytosis (engulfing and ingestion). When a cell is foreign, such as a bacterium, this process is beneficial. However, sometimes anti-

gens on a red blood cell (RBC) can be sensed as foreign for the different blood types, which results in the RBC being destroyed.

Hemolytic Transfusion Reaction

PATHOPHYSIOLOGY. A hemolytic transfusion reaction is a type II hypersensitivity reaction in which RBCs with antigens foreign to the individual are rapidly lysed. The rapid RBC lysis results in a massive amount of cellular debris that occludes the blood vessels throughout the body. This leads to ischemia and necrosis of tissue and organs and can be life threatening.

ETIOLOGY. Occasionally, antibodies form after a bacterial or viral infection. However, prior sensitization is usually from a previous blood transfusion or past pregnancy. If maternal and fetal blood Rh factors (RBC surface antigens) are different, the mother becomes sensitized by the fetal Rh type, which can affect future fetuses. For example, a Rh_o(D)-negative pregnant woman becomes sensitized by a Rh_o(D)-positive fetus. As a result, the blood cells of future Rh_o(D)-positive fetuses can be destroyed by maternal antibodies crossing the placenta.

SIGNS AND SYMPTOMS. With a hemolytic transfusion reaction, there is usually a rather sudden onset of low back or chest pain, hypotension, fever rising more than 1.8° F (1° C), chills, tachycardia, tachypnea, wheezing, dyspnea, urticaria, and anxiety. The patient may also complain of a headache and nausea.

COMPLICATIONS. Patients who survive severe reactions are at risk for developing shock and acute renal failure because of the massive occlusion of blood vessels.

DIAGNOSTIC TESTS. The direct Coombs' test confirms this diagnosis. In the laboratory a small amount of the patient's RBCs are washed to remove any unattached antibodies. Antihuman globulin is added to see if agglutination (clumping) of the RBCs results. If agglutination occurs, an immune reaction such as a hemolytic transfusion reaction is taking place.

MEDICAL TREATMENT. To prevent production of anti-Rho(D) antibodies, a Rho(D) immune globulin (RhoGAM) injection is given to Rho(D)-negative patients accidentally given Rho(D)-positive blood or exposed to Rho(D)-positive fetal blood by delivery, miscarriage, abortion, amniocentesis or intra-abdominal trauma. When antibodies do not form, then a hemolytic reaction can be prevented occur.

If a hemolytic reaction does occur, the medical treatment depends on the severity of the reaction and what tissue and organs are specifically affected by the reaction. Antihistamines, corticosteroids, or even epinephrine may be given. Diuretics may be given to assist the kidneys with excretion if they become occluded with cellular debris.

NURSING MANAGEMENT. Prevention of hemolytic reactions is crucial. Following strict institutional guidelines for blood transfusion administration helps ensure the patient's safety. After blood is released from the hospital blood bank,

two nurses, designated per institutional policy, double-check specified data. At the bedside, transfusion guidelines include double-checking the patient's name and identification number on the chart, unit of blood, and patient's identification bracelet, as well as checking the patient's blood type in the chart, on the unit of blood, and paperwork with the unit of blood.

Agency policy is followed for taking vital signs during a blood transfusion. Usually, baseline vital signs are taken before the beginning of the blood transfusion, then every 15 minutes for 30 minutes, then every half hour or hourly, and again when the transfusion is completed. It takes only a small amount of blood to trigger a hemolytic transfusion reaction, so it is critical to stay with the patient at the bedside during the first 15 minutes of any blood transfusion. This enables detection of a blood transfusion reaction early for quick action to minimize cell destruction and complications, including death.

LEARNING TIPS

Every unit of blood, even of the same blood type, is unique and can trigger a blood transfusion reaction. Careful monitoring with every transfusion is necessary.

If symptoms of a reaction are noted, the blood is immediately stopped and agency policy for a suspected transfusion reaction is followed. A normal saline infusion is started to keep the vein patent. The physician and blood bank are immediately notified. A nurse remains with the patient for reassurance and monitoring of symptoms and vital signs. If a blood incompatibility is suspected, the unused blood and blood tubing is returned to the blood bank for testing. A series of blood and urine specimens are collected and sent to the laboratory for analysis. The physician's orders are followed to treat the patient's symptoms.

Education. Autologous (self) blood donation, as ordered by the physician, may be an option for patients having elective surgery, to avoid a transfusion reaction. Once patients have had a hemolytic transfusion reaction, it is important to inform them and their significant others of the reaction. Patients should inform their health care providers of this reaction, so that specific blood tests are performed for less common antibodies if the patient is ever typed for a blood transfusion again.

Type III

A type III hypersensitivity reaction involves immune complexes formed by antigens and antibodies, usually of the IgG type. The patient is sensitized with an initial exposure to the antigen, and on a subsequent exposure the reaction occurs. The reaction is localized and evolves over several hours, with symptoms ranging from a red, edematous skin

lesion to hemorrhage and necrosis. The process involves the formation of antigen-antibody complexes within the blood vessels, as the antigen is absorbed through the vessel wall. Neutrophils are attracted to the area and release enzymes that ultimately lead to blood vessel damage.

Serum Sickness

PATHOPHYSIOLOGY. Serum sickness is a type III hypersensitivity immune reaction in which antigen-antibody complexes are formed and cause symptoms of inflammation.

ETIOLOGY. In the past, serum sickness occurred after inoculation of equine (horse) antiserum for diseases such as tetanus and diphtheria. With the refinement of these vaccines, serum sickness does not usually occur from them. Today serum sickness is seen occasionally after administration of penicillin and sulfonamide.

SIGNS AND SYMPTOMS. The signs and symptoms usually occur 7 to 10 days after the exposure. The most predominant manifestation is severe urticaria and angioedema. The patient may experience a fever, malaise, muscle soreness, arthralgia, splenomegaly, and occasionally nausea, vomiting, and diarrhea. Lymphadenopathy may occur, especially at the lymph nodes closest to the antigen entry site.

COMPLICATIONS. Serum sickness is usually a brief and self-limiting condition, although at times it can become chronic. Systemic complications may arise, such as renal failure.

DIAGNOSTIC TESTS. With serum sickness there is often a slight elevation in the white blood cell count and the sedimentation rate, and a complement assay decreases.

MEDICAL TREATMENT. Antipyretics may be given for the fever and analgesics for the arthralgia. Antihistamines and epinephrine may be prescribed for the urticaria and angioedema. If the symptoms continue to persist, corticosteroids may be ordered.

NURSING MANAGEMENT. Nursing care focuses on assessing symptoms, evaluating the effectiveness of prescribed medications, and educating the patient regarding the therapeutic regimen and measures to prevent further exposure to the antigen. Identification of the causative agent may be done through the history-taking process.

Education. Knowledge of the disease and offending agent is important for the patient to prevent a recurrence of the condition.

Type IV

A type IV hypersensitivity reaction, also called a delayed reaction, occurs when a sensitized T lymphocyte comes in contact with the particular antigen to which it is sensitized. The resulting necrosis is caused by the actions of the macrophages and the various T lymphocytes involved in the cell-mediated immune response.

Contact Dermatitis

PATHOPHYSIOLOGY. When a substance or chemical comes in contact with the skin, it is absorbed into the skin and binds with special skin proteins called haptens. With the first contact, there is no reaction or symptoms, but within 7 to 10 days T memory cells are formed. Therefore on subsequent exposures the T memory cells quickly become activated T cells, which secrete the chemicals that cause symptoms.

ETIOLOGY. Poison ivy and poison oak are the most common irritants causing this reaction. Latex rubber has also been found to be a cause for contact dermatitis and can trigger type I anaphylactic reactions.

Latex Allergy. Latex allergy is a serious problem for health care workers. Anaphylactic reactions to latex can be fatal. Exposure to latex for health care workers has increased dramatically since the implementation of universal precautions and the use of latex gloves began in 1987. Many times latex gloves are worn unnecessarily, which increases exposure to the latex protein. For patients who are allergic to latex, special protocols are followed using latex-free equipment. For information about latex allergy, visit the American Academy of Allergy, Asthma, and Immunology at www.aaaai.org. Also visit the U.S. Food and Drug Administration at www.fda.gov.

SIGNS AND SYMPTOMS. Within a number of hours from the exposure, the area of contact becomes reddened and pruritic, with fragile vesicles. Secondary infections may develop. (See earlier discussion of atopic dermatitis.)

DIAGNOSTIC TESTS. Diagnosis is usually made by assessment of the skin and lesions, as well as a detailed patient history.

MEDICAL TREATMENT. Treatment consists of controlling symptoms. Oral or topical antihistamines and topical drying agents may be used. Topical corticosteroids may be used, and if the symptoms are severe, systemic corticosteroids may be prescribed.

NURSING MANAGEMENT. To aid in the relief of symptoms, tepid baking soda baths or colloidal oatmeal baths (e.g., Aveeno) may help dry the vesicle and minimize the pruritus (Nursing Care Plan Box 53-1). Administer and evaluate the effectiveness of medications.

Education. The patient is instructed to wash with a brown soap (e.g., Fels-Naphtha) or, if unavailable, any soap when contact with the offending agent is suspected. The best advice is to avoid contact with the agent. The patient should also be instructed not to scratch the skin to prevent the spread of the dermatitis, as well as infection development.

Transplant Rejection

ETIOLOGY AND PATHOPHYSIOLOGY. Any form of transplanted living tissue is sensed as foreign material by the immune system. Lymphocytes become sensitized during an in-

duction phase immediately after the tissue is transplanted. The sensitized lymphocytes invade the transplanted tissue and destroy it via the release of chemicals and macrophage activity.

SIGNS AND SYMPTOMS. Various signs and symptoms occur depending on the transplanted tissue or organ that is involved and the severity of the reaction. Signs and symptoms reflect failure of the organ or tissue, such as renal failure for a rejected kidney.

COMPLICATIONS. A total failure and loss of the transplanted tissue or organ can occur, or the tissue or organ can be damaged from immunologic reactions and not function at full capacity. The greatest cause of death following a transplant is from infection. Immunosuppression therapy, which is necessary to prevent tissue rejection following the transplant, is a major contributory factor for severe infection development. Because the immune system is suppressed, it is unable to effectively fight infections.

DIAGNOSTIC TESTS. Biopsy, scans, blood tests, arteriogram, and ultrasound are some tests that may be performed to aid in diagnosing a transplant rejection.

MEDICAL TREATMENT. Depending on the type of transplant, the body's immunologic system is prepared before surgery with medications, transfusions, or radiation to minimize the risk of rejection.

NURSING MANAGEMENT. Nursing care depends greatly on the type of transplant performed. Initially the patient is in an intensive care unit under close observation and support. Observing for signs of rejection is a priority throughout the patient's hospitalization. Another consideration for nursing care is the psychological support of the patient and family. Many patients wait on a transplant list a long time before a donor match is found. Once a matching donor is found there is usually great elation. Yet if a donor's death made the transplant possible, the patient and family may be simultaneously feeling a profound sadness for the donor's family. Patients need time to verbalize feelings and understand that these feelings are normal and diminish with time. Also the fear of transplant rejection is always present and must be discussed.

Education. Rejection can take place weeks, months, or years following a transplant (with decreasing risk). The patient and family need to be educated about specific signs and symptoms of rejection. Also, because infection is a major complication resulting from long-term immunosuppressive medications, the patient and family need to know signs and symptoms of infection and when to notify the physician of problems. Steroid use may mask the symptoms of infection, so small indicators such as a low-grade fever should be promptly reported. Education regarding prescribed medications is a must, because long-term success of a transplant is dependent on compliance with immunosuppressive medication therapy. Avoidance of people with colds or infections is also important to reduce the patient's infection risk.

BOX 53-1 NURSING CARE PLAN FOR THE PATIENT WITH CONTACT DERMATITIS

Risk for impaired skin integrity related to effects of allergic reaction

PATIENT OUTCOMES

Patient's skin will remain intact.

EVALUATION OF OUTCOME

Is patient's skin intact? If not intact, is skin healing? Does patient express a plan for preventing impaired skin integrity?

INTERVENTIONS

Assess and document skin and lesions.
 Teach patient to keep fingernails short and clean.
 Teach patient to apply clean, white cotton clothing over affected area (soaks, gloves/mittens, undershirt), especially at bedtime.
 Teach patient to use gentle rubbing or pressure instead of scratching.

RATIONALE

Assessment provides a basis for intervention planning and evaluation of healing.
 Short, clean nails cause less damage or infection if scratching occurs.
 Cotton allows air movement. White cloth is less irritating than those with dyes. Scratching is decreased during sleep with the use of gloves/mittens or covering affected area.
 Use of gentle rubbing or pressure instead of scratching cause less skin trauma.

EVALUATION

Are lesions present? Are lesions healing?
 Does skin remain intact in spite of scratching?
 Are symptoms of skin irritation reduced?
 Does skin remain intact in spite of itchy sensation?

Ineffective health maintenance related to lack of knowledge of methods to decrease inflammation and pruritus and reduce episodes of inflammation.

PATIENT OUTCOMES

Patient or caregiver will follow the mutually agreed upon plan of care.

EVALUATION OF OUTCOME

Can patient express knowledge of etiology, signs and symptoms, and treatment plan? Does patient discuss any emotional, social, financial, or material blocks to attaining treatment goals?

INTERVENTIONS

Assess patient's knowledge of disease and causes.
 Assess patient's values and beliefs regarding plan of care.
 Assess barrier's to patient's ability to carry out plan of care and plan interventions to decrease barriers.
 Teach patient to wear medical alert identification for allergen.
 Discuss methods of avoiding allergen with patient.

RATIONALE

Assessment provides a basis for the teaching plan.
 Patients are more compliant if their belief system fits into plan of care.
 Barriers can prevent patient from carrying out plan of care.
 With allergen identification, prompt medical care can be given in case patient is unable to give information.
 Understanding prevention methods can help prevent allergen exposure.

EVALUATION

Does patient state baseline knowledge?
 Does patient's belief system work with plan of care?
 Are barrier's identified? Are solutions to barriers planned?
 Does patient agree to use allergen identification?
 Can patient state methods can help prevent allergen exposure?

AUTOIMMUNE DISORDERS

In autoimmune disorders the immune system no longer recognizes the body's normal cells as self and not foreign. Instead the antigens on these normal body cells are recognized as foreign material, and an immune response to destroy them is launched.

A number of factors either cause or influence this breakdown of self-recognition, including viral infections, drugs, and cross-reactive antibodies. Some microbes stimulate the production of antibodies but are so closely related to normal cell antigens that the antibodies also attack some normal cells. Hormones have also been found to influence this breakdown of self-recognition.

Table 53-2 lists additional autoimmune disorders and the chapters in which they are discussed.

TABLE 53-2 AUTOIMMUNE DISORDERS	
<i>Idiopathic thrombocytopenic purpura</i>	Refer to Chapter 24.
<i>Multiple sclerosis</i>	Refer to Chapter 47.
<i>Myasthenia gravis</i>	Refer to Chapter 47.
<i>Rheumatoid arthritis</i>	Refer to Chapter 44.
<i>Systemic lupus erythematosus</i>	Refer to Chapter 44.
<i>Ulcerative colitis</i>	Refer to Chapter 31.

Pernicious Anemia

PATHOPHYSIOLOGY. Antibodies against the gastric parietal cells and intrinsic factor lead to destruction of these cells and decrease secretion and function of intrinsic factor.

Because intrinsic factor is needed for vitamin B₁₂ to be absorbed in the small bowel, a vitamin B₁₂ deficiency ensues and production of RBCs is decreased.

ETIOLOGY. There tends to be a familial tendency toward pernicious anemia in relation to immune causes. Non-immune-related causes of pernicious anemia include any type of gastric or small bowel resections coupled with no or inadequate vitamin B₁₂ or intrinsic factor replacement.

SIGNS AND SYMPTOMS. The patient experiences increasing weakness, loss of appetite, glossitis, and pallor. Irritability, confusion, and numbness or tingling in the extremities (peripheral neuropathy) occur because the nervous system is affected.

COMPLICATIONS. Patients with pernicious anemia have a greater risk of developing gastric carcinoma.

DIAGNOSTIC TESTS. On microscopic examination of the patient's RBCs, macrocytic (enlarged cells) anemia is diagnosed. Macrocytic anemia and low vitamin B₁₂ levels are indicators of pernicious anemia and folic acid deficiency. To further determine if the diagnosis is pernicious anemia or folic acid deficiency, the Schilling test can be performed. For the Schilling test, radioactive vitamin B₁₂ is administered to the patient. The patient's urine is then collected for 24 hours (48 hours for patients with renal disease), and the amount of radioactive vitamin B₁₂ excreted in the urine is measured. If intrinsic factor is decreased, gastric absorption of vitamin B₁₂ is also decreased, so that more vitamin B₁₂ is excreted in the urine. Gastric secretion analysis is done to measure levels of hydrochloric acid (HCl) because low or absent HCl may be indicative of pernicious anemia.

MEDICAL TREATMENT. Treatment with corticosteroids may rectify the problem if it is immunologically based. Otherwise, weekly and then monthly intramuscular injections of vitamin B₁₂ must be given for life to prevent pernicious anemia.

NURSING MANAGEMENT. Vitamin B₁₂ is administered as ordered. Care related to fatigue and safety are important. Ambulation, frequent rest periods, and providing assistance with activities of daily living (ADLs) as indicated by the patient's activity tolerance are helpful for the patient with anemia.

Education. The patient and family need education regarding medication therapy. If vitamin B₁₂ injections are prescribed, they must understand that this is a lifelong need to prevent the return of symptoms. Patients should not miss injections, periodic B₁₂ level testing, or follow-up appointments.

Idiopathic Autoimmune Hemolytic Anemia

PATHOPHYSIOLOGY. Autoantibodies, for no known reason, are produced that attach to RBCs and cause them to either lyse or agglutinate (clump). When lysis occurs, fragments of the destroyed RBCs circulate in the blood. If

agglutination occurs, occlusions in the small blood vessels result from the clumping and then tissue ischemia follows.

SIGNS AND SYMPTOMS. Clinical manifestations vary from mild fatigue and pallor to severe hypotension, dyspnea, palpitations, and jaundice.

DIAGNOSTIC TESTS. The RBC count, hemoglobin (Hgb), and hematocrit (Hct) are low, and microscopic examination reveals fragmented RBCs. Lactate dehydrogenase (LDH) is elevated because of RBC destruction and tissue ischemia.

MEDICAL TREATMENT. Supportive measures such as supplemental oxygen may be initiated. Folic acid may be prescribed to increase production of RBCs. The use of immunosuppressive medications and corticosteroids may be useful in obtaining remission. In more severe cases, blood transfusions and erythrocytapheresis (a process whereby abnormal RBCs are removed and replaced with normal RBCs) may be instituted. A splenectomy may be performed in an attempt to stop the destruction of RBCs for severe cases.

NURSING MANAGEMENT. The patient's signs and symptoms should be monitored and reported as necessary. Frequent rest periods should be planned into the patient's daily routine to prevent fatigue. Blood products are administered as ordered to replace RBCs. The patient and family are instructed on the medical regimen, and their understanding is verified.

Hashimoto's Thyroiditis

PATHOPHYSIOLOGY. Autoantibodies for thyroid-stimulating hormone (TSH) form in Hashimoto's thyroiditis. However, instead of inactivating TSH, the autoantibodies bind with the hormone receptors on the thyroid gland and stimulate the thyroid gland to secrete thyroid hormones. The thyroid gland enlarges as a result of this overstimulation (hyperthyroidism). It becomes infiltrated with lymphocytes and phagocytes, causing inflammation and further enlargement. Then different autoantibodies appear that destroy thyroid cells, which slows secretion activity, causing hypothyroidism.

ETIOLOGY. The exact cause is unknown, although it occurs in females eight times more often than in males. It is also more common in people 30 to 50 years old and patients with Down syndrome and Turner's syndrome.

SIGNS AND SYMPTOMS. Initially the manifestations are those of hyperthyroidism, such as restlessness, tremors, chest pain, increased appetite, diarrhea, moist skin, heat intolerance, and weight loss. These manifestations may go unrecognized and progress quickly into hypothyroidism. At this point, an enlarged thyroid gland (goiter) may be seen. Clinical manifestations may include fatigue, bradycardia, hypotension, dyspnea, anorexia, constipation, dry skin, weight gain, sensitivity to cold, facial puffiness, and a slowing of mental processes.

DIAGNOSTIC TESTS. Immunofluorescent assay, a test that detects antigens on cells using an antibody with a fluorescent tag, detects antithyroid antibodies. Serum thyroid-stimulating hormone levels are elevated, while triiodothyronine (T₃) and thyroxine (T₄) levels are low. A thyroid scan is also done.

MEDICAL TREATMENT. Thyroid hormone replacement therapy of thyroxine is the primary means of treatment. Lifelong thyroid hormone therapy is needed.

NURSING MANAGEMENT. If the patient has a goiter, a soft diet may be necessary for comfort. Frequent rest periods may be necessary, as well as slowly increasing patient activity. Antiembolic stockings may help prevent venous stasis during the low-energy, decreased-activity phase. Daily weights and monitoring intake and output when cardiac status is compromised are important to detect abnormalities such as fluid retention. Because weight gain and facial puffiness alter patients' self-image, they need an opportunity to verbalize their feelings to help them adjust to this disease process.

Education. Patients taking thyroid hormone replacement therapy should avoid foods high in iodine. The diet should also consist of large amounts of fiber to combat constipation. During the hyperthyroidism phase, a diet high in protein and carbohydrates encourages weight gain. Education regarding prescribed medications is also needed.

Ankylosing Spondylitis

PATHOPHYSIOLOGY. Ankylosing spondylitis, also called rheumatoid spondylitis, is a chronic progressive inflammatory disease of the sacroiliac, costovertebral, and large peripheral joints. The inflammatory process begins in the lower region of the back and progresses upward. A specific histocompatibility antigen (antigen that identifies self), human leukocyte antigen (HLA) B27, is formed that stimulates an immune response.

ETIOLOGY. There is strong evidence of a familial tendency, but no other specific causes are known. Ankylosing spondylitis tends to afflict men more than women.

SIGNS AND SYMPTOMS. There is an insidious onset of lower back stiffness and pain, which is worse in the morning. As the disease progresses, the pain worsens and there are spasms of the back muscles. The normal curvature of the lower back (lordosis) flattens, and the curvature of the upper back increases (kyphosis). Patients may also experience fatigue, anorexia, and weight loss.

COMPLICATIONS. Because of thoracic structural changes, carditis, pericarditis, and pulmonary fibrosis may develop occasionally.

DIAGNOSTIC TESTS. A culmination of findings, such as a positive family history, radiographs of the joints, a positive

ankylosing spondylitis: ankyle—stiff joint + osing—condition + spondyl—vertebrae + itis—inflammation

HLA-B27 blood test, and negative Rh, confirms a diagnosis of ankylosing spondylitis. There are no specific immunologic tests to diagnose ankylosing spondylitis.

MEDICAL TREATMENT. Because there is no cure for ankylosing spondylitis, treatment consists of measures to minimize the symptoms. Analgesics for pain relief, anti-inflammatory agents to decrease joint inflammation, and physical therapy to maintain muscle strength and joint range of motion are used. Surgery can be done to replace fused joints. For kyphosis, cervical or lumbar osteotomy can be performed.

NURSING MANAGEMENT. Nursing care focuses on patient education and administration and evaluation of prescribed medications.

Education. The patient and family need information about the disease process. Proper posture and range-of-motion exercises are taught and reinforced by nursing staff. The patient should also be instructed not to stay in any one position for any length of time. The patient should sleep on a mattress that is firm without a pillow to help reduce pain and stiffness.

CRITICAL THINKING

Mr. Beck

Mr. Beck, a 55-year-old truck driver who was recently diagnosed with ankylosing spondylitis, verbalizes concern about how this diagnosis will affect his ability to work.

- How would you answer his questions?
 - "What is happening to me?"
 - "Will I have to quit my job driving an interstate truck?"
 - "Am I eventually going to be in really bad pain?"
 - "Am I eventually going to be dependent on someone?"
- Mr. Beck plans to continue driving his truck and therefore has a need upon discharge for specific interventions that will help him maintain his independence. Why are each of the following instructions given to Mr. Beck upon discharge?
 - Perform range-of-motion exercises daily.
 - Do not stay in one position too long. You may need to stop and walk around often.
 - Sleep on a firm mattress without a pillow.
 - Maintain good posture, even when driving the truck.

Answers at end of chapter.

IMMUNE DEFICIENCIES

Immune deficiencies occur when one or more components of the immune system are either completely absent or deficient in quantities sufficient to elicit or sustain an adequate immune response to combat an infectious agent.

Hypogammaglobulinemia

PATHOPHYSIOLOGY AND ETIOLOGY. This condition is either a hereditary congenital disorder or acquired after childhood from unknown causes. It is characterized by the absence or deficiency of one or more of the five classes of immunoglobulins (IgG, IgM, IgA, IgD, and IgE) from defective B-cell function. The lack of normal function of

these antibodies makes the patient prone to infections. The congenital form of this disorder affects males. Patients usually have a normal life span.

SIGNS AND SYMPTOMS. The infant is usually asymptomatic until 6 months of age, when the maternal immunoglobulins are gone. At this time the infant begins having many recurrent infections, especially from *Staphylococcus* and *Streptococcus* organisms.

DIAGNOSIS. Until the infant is 9 months old, diagnosis is extremely difficult. At 9 months of age, immunoelectrophoresis, which measures the level of each immunoglobulin, can be performed.

MEDICAL TREATMENT. Treatment is aimed at minimizing infections while increasing the immune system through injections of immunoglobulin. These injections mainly contain IgG, so fresh frozen plasma is given to replace IgM. IgA cannot be replaced, increasing the risk for frequent pulmonary infections.

NURSING MANAGEMENT. The infant is monitored for infections. The family is educated on signs and symptoms of a variety of infections and the importance in seeking medical help immediately. The infant should not be around crowds. Good nutrition, hydration, and hygiene are important in preventing infections. Any break in the skin must be cleansed immediately and monitored for infection development. Genetic counseling may be recommended for parents.

Answers to CRITICAL THINKING

Mr. Beck

1. a. "Human leukocyte antigen B27 is formed, stimulating a chronic immune (inflammatory) response specifically in the sacroiliac, costovertebral, and large peripheral joints. This leads to thickening of the joints, joint pain, and stiffness."
 - b. "No, you shouldn't have to quite your job, but you may need to alter the way you go about driving your truck."
 - c. "No, you may not eventually be in severe pain, with use of medications and exercise."
 - d. "No, this disease may not affect your independence, with proper treatment and rehabilitation."
2. a. "Range-of-motion exercises will help maintain joint mobility and a full range of motion and prevent contractures from forming."
 - b. "Again, this frequent movement prevents stiffness and joint pain and contractures of joints."
 - c. "Sleeping on a firm mattress without a pillow keeps the spine in correct alignment, which in turn helps prevent progressive changes in spine alignment (kyphosis, scoliosis), which affect various major body systems (respiratory, etc)."
 - d. "Again, good posture will aid in preventing bone deformities."

REVIEW QUESTIONS

1. The nurse is contributing to the plan of care for a patient with allergic rhinitis. Which of the following interventions should the nurse anticipate will be included in the treatment plan?
 - a. Epinephrine
 - b. Gold salts
 - c. Anticholinergic medication
 - d. Avoiding environmental stimuli
2. A patient who has an allergy to penicillin is receiving preoperative medications, which include ranitidine (Zantac), metoclopramide (Reglan), and cefazolin (Ancef) intravenously. Fifteen minutes after the cefazolin is started, the patient reports an uneasy feeling, as well as feeling very warm. The nurse would appropriately recognize that the patient is experiencing which of the following?
 - a. Urticaria
 - b. Anaphylaxis
 - c. Angioedema
 - d. Contact dermatitis
3. The nurse is contributing to the plan of care for a patient with ankylosing spondylitis. Which of the following interventions would be appropriate for the nurse to suggest?
 - a. Avoid massage.
 - b. Use interferon injections.
 - c. Avoid one position for prolonged periods.
 - d. Use topical steroids.
4. The nurse is contributing to the plan of care for a patient with an immune system deficiency. Which of the following complications should the nurse consider is most likely to occur when recommending prevention interventions?
 - a. Overwhelming infection
 - b. Fatal allergic reaction
 - c. Asphyxiation
 - d. Delayed anaphylactic reaction
5. A patient is admitted with an autoimmune disease and asks the nurse what *autoimmune* means. Which of the following would be the appropriate response by the nurse?
 - a. "Immune cells produce too many antibodies."
 - b. "Immune cells grow and multiply too rapidly."
 - c. "Immune cells are not produced in sufficient amounts."
 - d. "Immune cells are unable to distinguish between 'self' and 'not self.'"

NURSING CARE OF PATIENTS WITH HIV DISEASE AND AIDS

George Byron Smith

KEY TERMS

acquired immunodeficiency syndrome (uh-**KWHY**-erd im-YOO-noh-de-**FISH**-en-see **SIN**-drohm)

cytomegalovirus (sigh-**TOW**-meg-ul-low-vigh-rus)

human immunodeficiency virus (**HYOO**-man im-YOO-noh-dee-**FISH**-en-see **VIGH**-rus)

Kaposi's sarcoma (Ka-**POE**-sees sar-**CO**-mah)

Pneumocystis carinii pneumonia (new-moh-**SIS**-tis ca-**RIN**-ee-eye new-**MOH**-nee-ah)

QUESTIONS TO GUIDE YOUR READING

1. What is human immunodeficiency virus (HIV) and how is it transmitted?
2. What is the definition of acquired immunodeficiency syndrome (AIDS)?
3. What would you include in a teaching plan to prevent HIV infection?
4. What are prevention measures to decrease infection and opportunistic diseases for patients with HIV?
5. What would you include in a teaching plan for a patient with HIV receiving highly active antiretroviral therapy?
6. What nursing care will you provide for patients with HIV/AIDS related to infection prevention and maintaining nutritional status?
7. What teaching will you reinforce for the patient with HIV/AIDS to prevent infection and maintain health?

Acquired immunodeficiency syndrome (AIDS) is the final phase of a chronic, progressive immune function disorder. AIDS is caused by the **human immunodeficiency virus** (HIV). Not all HIV-infected people have AIDS. The Centers for Disease Control and Prevention (CDC) defines the diagnosis of AIDS as being when an HIV-infected person has the following:

- Less than 200 CD4+ T lymphocytes cells per microliter
or
- CD4+ T lymphocyte percentage of total lymphocytes under 14
and
- Opportunistic clinical disease (Box 54-1)

LEARNING TIPS

HIV disease is no longer characterized as a life-ending illness. With highly active antiretroviral therapy (HAART), HIV disease is a chronic, progressive immune disorder.

There is no cure for AIDS, which develops after a long period of HIV infection and may eventually be fatal.

AIDS, more than any other chronic disease in recent history, is a multidimensional disease that challenges nurses to call into play their physical, emotional, social, and spiritual care skills. As you care for patients who are HIV positive or

BOX 54-1 CDC Conditions in the AIDS Surveillance Case Definition

CD4+ T-lymphocyte count below 200/ μ L, or a CD4+ T-lymphocyte percentage under 14 of total lymphocytes, or the presence of one of the following specified clinical conditions:

- Bacterial infection, multiple or recurrent
- Candidiasis of bronchi, trachea, or lung
- Candidiasis, esophageal
- Cervical cancer, invasive
- Coccidioidomycosis, disseminated or extrapulmonary
- Cryptococcosis, extrapulmonary
- Cytomegalovirus (CMV) disease (not including liver, spleen, or nodes)
- CMV retinitis and loss of vision
- Encephalopathy
- Herpes simplex, chronic ulcers; or bronchitis, pneumonitis, or esophagitis
- Histoplasmosis, disseminated or extrapulmonary
- Isosporiasis, chronic intestinal
- Kaposi's sarcoma
- Lymphoid interstitial pneumonia or pulmonary lymphoid hyperplasia
- Lymphoma, Burkitt's
- Lymphoma of the brain, primary
- *Mycobacterium avium intracellulare* complex or *Mycobacterium kansasii*, disseminated or extrapulmonary
- *Pneumocystis carinii* pneumonia
- Pneumonia, recurrent
- Progressive multifocal leukoencephalopathy
- *Salmonella* septicemia, recurrent
- Toxoplasmosis of brain
- Wasting syndrome

Modified from Centers for Disease Control and Prevention: Revised classification system of HIV infection and expanded surveillance case definition for AIDS among adolescents and adults, MMWR 41(RR17):2, 1992.

have AIDS, it is important for you to understand current information. Being informed helps you to provide caring, competent, nonjudgmental care without fear. Knowledge and treatment related to HIV and AIDS rapidly changes with new discoveries. Current information and guidelines can be found at HIV/AIDS Treatment Information Service, www.hivatis.org or 1-800-HIV-0440 (1-800-448-0440). For other resources, see Table 54-1.

► INCIDENCE

The HIV and AIDS epidemic was first reported by the CDC in June 1981 (Table 54-2). A rapid increase in AIDS was seen through the 1980s, followed by a decrease in the later 1990s. As we move into the third decade of the epidemic, an estimated 40,000 new cases of HIV infection continue to be reported each year in the United States. Increases in HIV infection are occurring the fastest in women and men who have sex with men, especially in racial and ethnic minority groups. In the United States from 1981 through 2000, 774,467 persons developed AIDS; of these, 448,060 died. The number of persons living today with AIDS is at its highest level because of treatment with Highly Active Antiretroviral Therapy (HAART), which was introduced in 1996. Although any age group can be affected by HIV and AIDS, 85 percent of those diagnosed with AIDS have been 20 to 49 years old. Given the long latency period between infection with HIV and an AIDS-defining illness, most people diagnosed with HIV disease younger than the age of 30 years were probably infected as adolescents. The age group older than 50 is seeing an increase in HIV infection. Of those with AIDS, male-to-male sex has caused the greatest exposure, followed by the use of injected drugs and by heterosexual contact. However, since 1996 heterosexual contact has resulted in more AIDS cases than male-to-male sex

TABLE 54-2 DATA FOR U.S. ADULTS/ADOLESCENTS WITH AIDS, 1981–2000

Data Category	Trends for Totals from 1981–1987 vs. Totals for 1996–2000	Total Cases
<i>Gender</i>		
Male	Declined from 92% to 77.4%	640,022
Female	Increased from 8% to 22.6%	134,441
<i>Years of Age</i>		
≤12	Declined from 1.5% to 0.7%	8,908
13–19	Increased from 0.4% to 0.7%	4,061
20–29	Declined from 20.9% to 13.7%	128,727
30–39	Declined from 46.2% to 43.1%	345,824
40–49	Increased from 20.8% to 29.5%	202,901
50–59	Increased from 7.3% to 9.1%	61,311
>59	Increased from 2.8% to 3.2%	22,734
<i>Ethnicity/Race</i>		
White	Declined from 59.7% to 34%	778,220
Black	Declined from 25.5% to 44.9%	292,522
Hispanic	Increased from 14% to 19.7%	141,694
Asian/Pacific Islander	Increased from 0.6% to 0.8%	5,728
American Indian/Alaskan Native	Increased from 0.1% to 0.4%	2,337
Deceased	Declined from 95.5% to 22.6%	448,060

or injection drug use. Current statistics can be found at www.cdc.gov.

▶ PATHOPHYSIOLOGY

Infection with the HIV virus causes destruction of immune cells. There are two identified subtypes of the HIV virus: HIV-1 and HIV-2. Both of these subtypes can cause AIDS. HIV-1 is found in Asia, Europe, and the Western Hemisphere. HIV-2 is found in West Africa. Without a normally functioning immune system, infections and cancers may take over. AIDS is the result of this immunodeficiency.

HIV is a retrovirus (which only has ribonucleic acid [RNA] for genetic material). After the HIV viral particle is taken into a human cell, its covering is destroyed to expose its viral RNA. The retrovirus then uses an enzyme called reverse transcriptase to force the human cell to produce a new piece of deoxyribonucleic acid (DNA) from the viral RNA. The new DNA is integrated into the person's cellular DNA. As a result, the human cell creates more viral particles, which spread through the lymphoid system (Fig. 54–1).

HIV is attracted to immune cells with a surface-attaching site referred to as a CD4 receptor. Cells with CD4 receptors include lymphocytes (called CD4+ T lymphocytes, T4 lymphocytes, or helper T lymphocytes) and macrophages (in which HIV hides). The CD4+ T lymphocytes are the primary targets for HIV infection. Because CD4+ T lymphocytes orchestrate all immune functions, HIV's attack of these cells results in progressive impairment of the body's immune response. The CD4+ T lymphocytes do not function normally and are too busy replicating more HIV to perform their own immune function.

After exposure to HIV, the person infected with HIV may develop a mononucleosis-like syndrome (called an acute retroviral syndrome) (Fig. 54–2). The mononucleosis-like symptoms (e.g., fever, rash, joint pain, lymphadenopathy, or malaise) are mild and are usually not attributed to an

HIV infection. After the person has been infected with HIV, other immune system components form antibodies to fight the HIV. Detection of these antibodies via laboratory testing in most cases shows that the person was exposed to HIV. HIV antibodies typically become present within 3 weeks to 3 months. When antibodies are present, the person is said to be HIV positive.

LEARNING TIPS

Being HIV positive means that the person has been infected with the HIV virus. It does not mean that the person has AIDS.

Progression

The initial infection is followed by a relatively symptom-free period called the clinical latency stage. The virus remains in the lymph nodes, liver, and spleen and reproduces. A decrease in CD4+ T lymphocytes continues. This period, from infection to the beginning of the symptomatic stage, varies for each person and averages 8 to 12 years. During this stage, the person is considered to be HIV-infected.

During the early symptomatic stage of HIV disease, symptoms of the weakening immune system are seen. When the immune system is severely weakened, opportunistic infections and cancers occur. At this point, the person is diagnosed with AIDS.

LEARNING TIPS

Opportunistic diseases are referred to as opportunistic because a normal immune system would prevent them from occurring. With an impaired immune system, invading organisms have the "opportunity" to survive.

Figure 54-1 (A) Normal immune system. (B) HIV contains several proteins: gp 120 protein around it and viral RNA and p24 protein inside. The gp 120 proteins attach to CD4+ receptors of T lymphocytes; HIV enters the cell and makes viral DNA; the enslaved host cell produces new viruses that bud, which destroys the host cell’s membrane, causing cellular death and allowing the virus to leave to attack other CD4+ T-lymphocyte cells.

Figure 54-2 Typical phases of HIV infection, AIDS development, and CD4+ T-lymphocyte counts. Length of latency period varies but is usually many years. As CD4+ T-lymphocyte counts drop symptoms, AIDS and then death result.

► PREVENTION

Prevention and education are the best ways to manage the HIV/AIDS epidemic. Education regarding the disease and its transmission should begin with the older school-age child and include the general population, as well as older adults (Gerontological Issues Box 54–2).

BOX 54-2 GERONTOLOGICAL ISSUES

Nearly 10 percent of diagnosed AIDS cases occur in people age 50 and older. Numbers will continue to rise as the older population increases, yet little attention has been given to this age group. Lack of attention to this group's needs may be due an ageist view of the elderly and sexual activity.

It is important to understand that HIV infection can occur at any age. Older adults should be asked about their sexual and drug use history and be given preventive education and information about products that reduce transmission of HIV and sexually transmitted diseases. At-risk people older than age 50 are less likely than younger at-risk adults to use condoms during sex or to be tested for HIV. In this age group, condoms are often thought of as a birth control measure.

HIV/AIDS is thought of as being a disease of young, sexually active people. Older people remain sexually active, and previously monogamous people find themselves dating again because they are divorced or widowed and engaging in sexual activity, often without using condoms. Older people are also contracting the virus through homosexual contact.

A decline in the older adult's immune system increases the risk for infection with HIV. Because older adults are not usually taught HIV prevention, the rise in HIV infection among the elderly is expected to continue. With AIDS death rates dropping as a result of more effective treatments, the number of older adults living with HIV will increase.

Symptoms of HIV in older adults may be confused with commonly perceived problems of aging, such as fatigue, decreased endurance, and altered cognitive status. The effect of HIV on the brain is often misdiagnosed as Alzheimer's disease. The misdiagnosis keeps the person from obtaining treatment for HIV/AIDS.

Mode of Transmission

HIV is a fragile virus that is transmitted from human to human only through infected blood, semen, vaginal secretions, or breast milk. HIV is not spread casually. Kissing, hugging, shaking hands, or sharing eating utensils, towels, or bathroom fixtures with an HIV-positive person does not transmit HIV. There is also no evidence that HIV can be transmitted through insect bites or tears, nasal secretions, saliva, sweat, sputum, emesis, urine, or feces unless blood is present. Even then the transmission risk is considered very low. Blood transfusions before 1985 may have been a source for HIV transmission. However, since 1985, donated blood has been tested for HIV.

HIV needs a portal of entry into the body, such as a tear in a mucous membrane or nonintact skin, or access to the bloodstream or lymphatic tissue. Routes of transmission for HIV are as follows:

- Sexual—anal, vaginal, or oral sexual contact of mucous membranes to infected body fluids

- Parenteral—injection by needles contaminated with infected blood; sharing needles; transfusions of contaminated blood products
- Perinatal—infected mother to fetus/infant during pregnancy, childbirth, or breast-feeding

LEARNING TIPS

An HIV-infected person can transmit HIV to others within a few days after initial infection and then throughout all stages of the disease. This is thought to be true even when HAART treatment has driven the viral load below detectable levels.

Counseling

Early knowledge of HIV status aids in reducing the spread of HIV infection. The CDC has recommended guidelines for counseling and testing people at risk for HIV. Counseling should be done by trained workers to help the patient make an informed decision about testing. Education is also provided that fits the patient's personal risk situation. Posttest counseling is provided to help the patient understand the test results, how to inform sexual partners and drug needle sharers, risk factor reduction, and care options if needed.

Sexual Transmission

HIV is transmitted more easily to women than men. This is due to the vagina having a greater amount of mucous membrane than the penis, as well as the increased amount of virus found in semen as compared with vaginal secretions. Sexual acts that are the riskiest for transmission of HIV are those that promote contact between infected body fluids and mucous membranes or nonintact skin. These risky acts include oral sex or anal sex. Anal sex is the riskiest type of sexual act, for either gender, because it often results in tearing of the mucous membrane that is then exposed to infected semen.

Safer Sex Practices

Abstaining from sexual intercourse is the only safe way to prevent sexual exposure to HIV. A mutually monogamous sexual relationship is considered safe if the partners are not or will not become infected with HIV. Alternative methods of sexual activities can be used that prevent exposure to blood and secretions, such as massage or masturbation. The benefits of limiting sexual partners should be explained. For vaginal or anal intercourse, the use of male or female condoms and safer sex techniques should be discussed (Box 54–3). Latex gloves protect hands during genital or anal contact. Dental dams (latex sheets) should be used as a barrier between the mouth and genitals or anus.

Parenteral Transmission

The best way to prevent parenteral transmission of HIV is to avoid injection drug use. Drug injection equipment

BOX 54-3 Patient Education: Condom Use to Prevent HIV Transmission

Condoms should be:

- New for each intercourse act.
- Latex (or polyurethane if allergic to latex), because other materials have large pores that allow HIV to pass.
- Nondamaged, current (not past expiration date).
- Applied before partner is touched. (Tip of condom is held while unrolled over erect penis, allowing room at tip for semen collection.)
- Used with adequate amounts of only water-soluble lubricants. (Petroleum or oil-based lubricants such as petroleum jelly, cooking oil, shortening, or lotions can damage latex condoms.)
- Replaced if broken. (If ejaculation occurs before replacement, immediate use of a spermicide may give some protection.)
- Withdrawn from partner by holding condom against base of erect penis to avoid semen leakage.

should not be shared. If a person who uses injected drugs is unable or unwilling to stop sharing needles, he or she should be carefully taught how to clean the needle and syringe: The needle and syringe are filled and flushed with water. The syringe is then filled with bleach and shaken for 1 minute. The bleach is flushed through the needle and syringe and then they are rinsed with water. Additionally, sexual activity should not occur when judgment is impaired from drug use, because protective measures may not be used.

Autologous (one's own) blood transfusion, when possible, is the safest type of transfusion to prevent HIV infection. Screening of blood for HIV antibodies is done on all donated blood in the United States. There is a very small

chance of HIV transmission from blood that is infected but has not yet had time to develop antibodies.

Perinatal Transmission

The U.S. Public Health Service guidelines for HIV screening of pregnant women recommend that voluntary HIV pretest counseling and testing are offered during prenatal care for all pregnant women.¹ Pregnant women who are HIV positive can reduce the risk of perinatal HIV transmission to 2 percent by taking zidovudine (or other antiretroviral therapy) during pregnancy, labor, and delivery. At the time of delivery, pregnant women who have not been tested for HIV or received prophylactic treatment should be offered testing for HIV. After delivery, the infant is given zidovudine for 6 weeks.

Health Care Workers and HIV Prevention

Needle-stick injury is a source of HIV transmission to health care workers. The Needlestick Safety and Prevention Act is designed to aid health care workers in preventing needle-stick injuries. Careful use of needles—including not recapping needles, use of needless systems, and needle safety devices—can reduce needle-stick injury. To prevent HIV after a needle stick or other forms of exposure to patient body fluids, the CDC has developed postexposure prophylaxis guidelines (Table 54-3).²

Standard Precautions

All those at risk of contacting blood and body fluids and substances must follow CDC standard precautions to reduce their risk of HIV exposure. (See Chapter 7.) Health care workers should always use these precautions for all patients to protect themselves and other patients. Additionally, to protect patients, HIV-infected health care workers with open lesions or weeping dermatitis should avoid direct patient care.

TABLE 54-3 OCCUPATIONAL HIV EXPOSURE: POSTEXPOSURE PROPHYLAXIS

Consider occupational exposure an urgent medical condition.	
<i>Immediate care</i>	Wash exposure site with soap and water. For mucous membrane exposure, flush with water.
<i>Consider exposure risk</i>	What is the type of fluid person was exposed to? What is the type of exposure?
<i>Test exposure source</i>	Assess risk of infection and test known sources for HIV antibody
<i>Postexposure prophylaxis</i>	Start treatment within hours of exposure for 4 weeks. Consider pregnancy test if of childbearing age. Basic prophylaxis regimen or alternate basic prophylaxis regimen available: zidovudine (Retrovir, ZDV, AZT) 300 bid or 200 tid and lamivudine (Epivir, 3TC) 150 mg bid; or as combination tablet of both drugs: Combivir one tablet bid. Expanded prophylaxis regimen (basic prophylaxis regimen and one of the following): indinavir (Crixivan, IDV) 800 mg q8h; nelfinavir (Viracept, NFV) 750 mg tid or 1250 mg bid; efavirenz (Sustiva, EFV) 600 mg qh; or abacavir (Ziagen, ABC) 300 mg bid. Trizivir, a combination of ZDV, 3TC, and ABC, may be used.
<i>Follow-up testing and counseling</i>	HIV-antibody testing at baseline, 6 weeks, 3 months, and 6 months after exposure or if a retroviral syndrome type illness occurs. During postexposure care, exposed person should use precautions to prevent secondary transmission of HIV, including abstaining from sex or using condoms; no donation of blood, plasma, organs, or semen; if breast-feeding, consider stopping.

Source: CDC: Basic and Expanded HIV Postexposure Prophylaxis Regimens. MMWR 50(RR11):47, 2001.

► SIGNS AND SYMPTOMS

Initially after HIV infection, the patient may have no symptoms or may have mononucleosis-like symptoms, such as extreme fatigue, headache, fever, lymphadenopathy (enlarged lymph nodes in two different sites other than inguinal nodes), diarrhea, or a sore throat. These symptoms generally develop 6 to 12 weeks after HIV exposure and may last a few days to weeks.

Each patient's response to HIV is unique. After an extended asymptomatic phase, HIV infection progresses to a symptomatic stage when the virus has greatly impaired the immune system. The patient may exhibit shortness of breath, fever, weight loss, fatigue, night sweats, persistent diarrhea, oral or vaginal candidiasis ulcers, dry skin, skin lesions, peripheral neuropathy, shingles (varicella zoster virus reactivation), seizures, or dementia. In the final stage of HIV infection, AIDS is diagnosed as opportunistic infections and diseases, with their specific signs and symptoms, occur. (See Box 54–1.)

► COMPLICATIONS

Many complications are seen with HIV/AIDS that vary from patient to patient. Some of the common complications are discussed next.

AIDS Wasting Syndrome

AIDS wasting syndrome occurs in most patients with AIDS. The syndrome is defined by the occurrence of the following:

- Involuntary baseline body weight loss of more than 10 percent
- Chronic weakness or fever for more than 30 days or chronic diarrhea of two loose stools daily for more than 30 days

Several factors contribute to this syndrome: decreased appetite, oral lesions, altered metabolism, malabsorption, gastrointestinal (GI) infections, diarrhea, medication side effects, and cognitive impairment. The progressive weight loss impairs function of all body systems from malnourishment. Careful intervention, planning, and education of the patient when HIV is first diagnosed can help maintain body weight.

LEARNING TIPS

AIDS wasting syndrome is challenging. Do not give up! Be creative in developing interventions to help increase the patient's appetite.

Opportunistic Infection and Cancer

Opportunistic infections are a primary complication of HIV/AIDS because the person with HIV/AIDS has a very impaired immune system. Other types of infections that occur even with a healthy immune system are seen as well, such as tuberculosis. Opportunistic infections are not spread

to those with healthy immune systems, but other types of infections can be. Cancer incidence also rises when the immune system is impaired.

Candida Albicans

Candida albicans is a fungus normally found in the GI tract that does not infect a person with a healthy immune system. In AIDS, overgrowth of this fungus occurs from the impaired immune system. Candidiasis of the mouth or esophagus occurs often with AIDS. Signs and symptoms of candidiasis include mouth or esophageal pain, dysphagia, and yellow-white plaques that look like cottage cheese in the mouth and throat. Nutrition can be affected by oral or esophageal candidiasis. Vaginal candidiasis can also occur in women with AIDS. Severe itching and a white discharge occur.

Cytomegalovirus

Cytomegalovirus (CMV) is a common viral infection that can affect many areas of the body. The eye is a common site (cytomegalovirus retinitis). Vision impairment ranges from little impairment to total blindness. A variety of symptoms are seen when other areas are involved, such as fever, fatigue, diarrhea, GI upset, and hepatitis, to name a few.

Pneumocystis carinii pneumonia

***Pneumocystis carinii pneumonia* (PCP)** is caused by a fungus (formerly thought to be a protozoa) that produces shortness of breath, fever, nonproductive cough, and fatigue. PCP is the most common opportunistic infection in HIV/AIDS. To prevent PCP, oral trimethoprim-sulfamethoxazole (Septra) is given prophylactically. Pentamidine isethionate (Pentam) inhalation therapy is also used to prevent PCP when CD4+ T-lymphocyte counts fall below 200/ μ L. PCP may be treated with oxygen, oral or intravenous trimethoprim-sulfamethoxazole, or parenteral pentamidine isethionate. Steroids may also be given to reduce lung inflammation.

Tuberculosis

Tuberculosis may occur in up to 10 percent of those with AIDS. Symptoms include dyspnea, cough, chest pain, fever, night sweats, and weight loss. A positive purified protein derivative (PPD) skin test should be performed at least annually in patients with HIV infection. Induration of 5 mm or more is defined as a positive result in patients with HIV infection. (See Chapter 28).

LEARNING TIPS

When assessing the results of a PPD test, only the raised area (if present) is measured and recorded (in millimeters).

Viral Infections

Herpes simplex virus infections are found in the oral, genital, or rectal area of those with AIDS. Symptoms include blisterlike lesions that rupture and leave ulcerations, fever, pain, or bleeding. Varicella zoster virus infection is usually

the result of the virus being present from a prior episode of the chickenpox. The virus remains present in the nerve ganglia. With depressed immune function, the virus can cause shingles.

Kaposi's Sarcoma

Kaposi's sarcoma (KS) is the most common cancer associated with AIDS. Painless, small purple-blue lesions on the skin occur. (See Fig. 52–3.) The lesions may scale, ulcerate, and bleed. KS may occur anywhere on the body in patients with HIV. Treatment includes bleomycin, cryotherapy, or radiation.

AIDS Dementia Complex

HIV infection of the brain or other parts of the central nervous system results in AIDS dementia complex (ADC). Symptoms range from mild to severe and may include memory impairment, personality changes, hallucinations, leg weakness, loss of balance, and slower responses. ADC is a common complication of HIV/AIDS. With ADC, safety is an important consideration for the patient and caregiver.

▶ DIAGNOSIS

Finger-stick blood, oral fluid, and urine and serum specimens are used for HIV testing. Rapid HIV testing provides results the same day. Home sample collection devices can be purchased; the sample is sent in for HIV testing, with the person calling for results, counseling, and referral if needed.

HIV Antibody Tests

After HIV infection, antibodies may not be formed for 3 weeks to 3 months or longer in some cases. The typical HIV antibody testing pattern is as follows:

- Enzyme-linked immunosorbent assay (ELISA) test is done to detect antibodies in the patient's blood to HIV antigen on test plates.
- If positive, the ELISA test is repeated, because false positives may occur (0.1 percent).
- If the ELISA test is again positive, the Western blot test is done to detect the presence of antibodies to four major HIV antigens. The test is positive if two antibodies are present.
- If all test results are positive, the patient is HIV-antibody positive.
- Other tests can be used, especially if initial test results are not conclusive.

Complete Blood Cell Count/ Lymphocyte Count

Because patients with HIV are susceptible to leukopenia, lymphopenia, anemia, and thrombocytopenia related to HIV infection and as a complication of antiretroviral therapy, a complete blood cell count (CBC) including a lymphocyte count should be obtained. The CBC should be repeated at 3- to 4-month intervals or more often if the patient's clinical course is unstable.

CD4+/CD8+ T-Lymphocyte Count

The count of CD4+ and CD8+ (cytotoxic cells) T lymphocytes is essential for evaluating the status of the immune system. In healthy adults, CD4+ levels average 500 to 1600 cells per mm³. In HIV/AIDS, CD4+ cell levels drop but CD8+ cell levels do not. A low ratio of CD4+ cells to CD8+ cells is seen as HIV/AIDS progresses. It is recommended that CD4+/CD8+ T-lymphocyte counts be performed at 4-month intervals for most patients.

Viral Load Testing

Viral load testing measures the amount of HIV RNA in plasma and is extremely important for determining prognosis and monitoring the response to antiretroviral therapy. Combination antiretroviral regimens usually produce a 50-percent decrease in total-body HIV levels within just a few days. Viral loads should be performed 1 month after initiation of new treatments and at 4-month intervals thereafter.

General Tests

Standard serological testing for syphilis is recommended annually in patients who are sexually active. Hepatitis serology and liver chemistry panels are indicated in the early evaluation of most patients because of the high incidence of concurrent hepatitis for HIV-positive patients.

▶ MEDICAL TREATMENT

Because there is no cure for HIV/AIDS, the goal of therapy is to prevent or delay development of opportunistic diseases. Treatment with antiretroviral drugs is recommended when the CD4+ T-lymphocyte cell count falls below 350 cells per milliliter (Table 54–4). To increase life expectancy and treatment cost effectiveness, it may be recommended that patients be prophylactically treated for opportunistic infections, especially hepatitis A and hepatitis B virus, herpes simplex virus, and *Pneumocystis carinii* pneumonia (Table 54–5). Other opportunistic infections are treated with appropriate medications.

Antiretroviral drugs that inhibit reproduction of the virus (but do not kill it) are used to treat HIV infection. These antiretroviral agents have been developed to act predominantly on processes specific to the virus particle to keep the integrity of the host cell. Several potential strategies specifically aimed at interruption of the viral life cycle have been defined, including the following:

- Preventing the virus from attaching to the CD4+ receptor of the T4 lymphocyte
- Interfering with “uncoating” of the virus within the cell, the first essential step in allowing the virus to integrate into the cell's DNA
- Inhibiting reverse transcriptase (RT), a viral enzyme specific to retroviruses, which enables the virus to make a DNA copy from single-stranded viral RNA prior to integration into cellular DNA
- Blocking viral regulatory and transactivating proteins, which are involved in the transcription and translation

TABLE 54-4 MEDICATIONS FOR HIV INFECTION

Drug	Adult Dose	Nursing Considerations
Non-Nucleoside Analog Reverse Transcriptase Inhibitors		
delavirdine (Rescriptor)	PO: 400 mg tid	Monitor WBC count, liver tests, especially with history of hepatitis B or C. Do not give within 1 hour of antacids or didanosine (ddl, Videx).
efavirenz (Sustiva)	PO: 600 mg qd	Monitor for rash (especially during first month); may be severe and life threatening. Teach patient to report rash. Stevens-Johnson syndrome (systemic erythema with rash) may occur. Nausea common. Avoid giving with high-fat meal.
nevirapine (Viramune)	PO: 200 mg qd for 2 weeks, then 200 mg bid	Monitor for rash (especially 1st month); may be life threatening and require stopping drug immediately. Teach patient to report rash immediately. Stevens-Johnson syndrome may occur. Monitor liver tests. For contraception, advise a nonhormonal contraceptive during therapy.
Nucleoside Analog Reverse Transcriptase Inhibitors		
abacavir (Ziagen)	PO: 300 mg q12h	Flulike symptoms indicate need to discontinue drug or life-threatening condition may develop.
didanosine (ddl, Videx)	PO: 125–300 mg q12h	Do not give with food. Monitor CBC for bone marrow suppression.
lamivudine (Epivir, 3TC+)	PO: 150 mg q8h	Monitor for peripheral neuropathy—extremity numbness, tingling, burning, pain—and report. Advise patient to avoid fatty foods.
stavudine (d4T, Zerit)	PO: 40 mg q12h	Monitor for peripheral neuropathy—extremity numbness, tingling, burning, pain—report.
zalcitabine (ddC, HIVID)	PO: 0.75 mg q8h	Monitor liver function tests and for lactic acidosis, which can be fatal. Monitor for peripheral neuropathy—extremity numbness, tingling, burning, and pain—and report, so drug may be promptly stopped to prevent irreversible severe pain. Monitor for pancreatitis, which can be fatal: nausea; vomiting; abdominal pain; rising levels of serum amylase, lipase, triglycerides; decreasing calcium.
zidovudine (Retrovir)	PO: 100 mg q4h or 200 mg tid or 300 mg q12h	Monitor liver function tests and for lactic acidosis, which can be fatal. Monitor for dizziness, seizures. Reduces bone marrow function and is toxic to liver and kidneys.
Nucleotide Analog Reverse Transcriptase Inhibitors		
tenofovir disoproxil fumarate (Viread)	PO: 300 mg qd	Monitor for hepatomegaly with steatosis for lactic acidosis, which can be fatal, especially in women. Use cautiously with history of liver disease, obesity, prolonged nucleoside use. Nausea, vomiting, diarrhea common. Take with food. Take 2 hours before or 1 hour after didanosine (ddl, Videx).
Protease Inhibitors		
amprenavir (Agenerase)	PO: 1200 mg q12h	Assess for sulfonamide allergy. Monitor for rash, may be life threatening and require stopping of drug. Teach patient to report rash. Monitor blood glucose. Avoid vitamin E. For contraception, advise a nonhormonal contraceptive during therapy.
indinavir (Crixivan)	PO: 800 mg q8h	Avoid giving with high-fat, high-protein meals. Do not give within 1 hour of didanosine (ddl, Videx). May cause hyperglycemia. Increase fluids because kidney stones may develop.
lopinavir (Kaletra, ABT-378/r)	PO: 400 mg q12h	Assess for sulfonamide allergy. Give with food. Give with 100 mg ritonavir.
nelfinavir (Viracept)	PO: 750 mg q8h or 1250 mg bid	Monitor for seizures. May cause hyperglycemia. Give with food. Diarrhea may occur.
ritonavir (Norvir)	PO: 300 mg bid once, then 400 mg bid 3 days, then 500 mg bid once, then 600 mg bid	For contraception, advise a nonhormonal contraceptive during therapy. Do not confuse with zidovudine (Retrovir). Monitor for seizures, hyperglycemia. Nausea, vomiting, diarrhea common. For contraception, advise a nonhormonal contraceptive during therapy.

WBC = white blood cells.

TABLE 54-4 MEDICATIONS FOR HIV INFECTION — CONT'D

saquinavir (Fortovase, Invirase)	PO: 600 mg q8h	Must be taken within 2 hours of meal for increased blood concentration. Monitor for seizures, hyperglycemia, Stevens-Johnson syndrome. Nausea, vomiting, diarrhea common. Advise sunscreen because photosensitivity occurs.
Ribonucleotide Reductase Inhibitors		
hydroxyurea (Hydrea)	PO: 500–1000 mg daily	Monitor CBC for bone marrow suppression.

TABLE 54-5 TREATMENT FOR AIDS-RELATED CONDITIONS

Opportunistic Infection/Complication	Treatment
Candidiasis	ketoconazole (Nizoral); fluconazole (Diflucan); amphotericin B (Fungizone)
Cytomegalovirus retinitis	ganciclovir (Cytovene)
Hepatitis B virus	hepatitis B virus vaccine when HIV infection diagnosed
Herpes simplex, herpes zoster, varicella zoster	acyclovir (Zovirax) therapy
Influenza	annual influenza vaccine
Pneumococcal pneumonia	pneumococcal vaccine when HIV infection diagnosed
<i>Pneumocystis carinii</i> pneumonia	trimethoprim-sulfamethoxazole (Bactrim, Septra); pentamidine isethionate
Tuberculosis	PPD testing; drug therapy per CDC guidelines: pyrazinamide, isoniazid (Laniazid, Isotamine), ethambutol (Myambutol)
HIV wasting	<p>Patient education:</p> <ul style="list-style-type: none"> Eat three high-calorie and high-protein meals with snacks daily. Drink liquids before meals. Eat low-residue diet for diarrhea control. Control odors. Develop easy meal plan: favorite foods, meal programs, frozen dinners, cold food to control nausea. Use antiemetics. Rest, listen to music. Numb painful oral sores with ice, Popsicles, or topical analgesic; avoid spicy foods. Use artificial saliva for dry mouth. Use nutritional supplements. Use food stamps or free meal programs as needed. Exercise to increase muscle mass. Take medications prescribed to treat HIV wasting.

of viral RNA proteins from proviral DNA as the virus goes from the quiet, integrated state to active replication

- Inhibiting protease, a viral enzyme responsible for the adherence of viral proteins both before proviral integration and as the viral particles recombine into functional proteins needed for viral maturation
- Preventing viral assembly and budding out of the cell

For more information, visit the Medscape quick reference guide to antiretrovirals at www.medscape.com.

Highly Active Antiretroviral Therapy

Early, aggressive treatment with multiple-drug therapy, aimed at reducing the viral load to an undetectable amount, is the most effective line of treatment for HIV. “Cocktails” of multiple antiretroviral drugs (i.e., HAART) have reduced virus loads in the bloodstream and increased CD4+ T-lymphocyte counts, resulting in prolonged survival. HAART, in use since 1996, has made monotherapy (using one drug) an outdated concept, except for some cases involving pregnant women. Several combination drug regimens can be used. A current common cocktail consists of

two nucleoside analog and a nonnucleoside analog. The use of HAART is important to help reduce drug resistance, which is a common cause of treatment failure.

Many HIV drugs have side effects. If they occur, the drug regimen may be changed or interventions may be used to help control side effects. The patient should be taught to always report side effects, especially rashes (such as with trimethoprim-sulfamethoxazole) and abdominal pain (such as with zidovudine [AZT]); they could be serious.

Nucleoside Analog Reverse Transcriptase Inhibitors

Nucleoside analog reverse transcriptase inhibitors (NARTI) inhibit production of reverse transcriptase and viral replication.

Non-Nucleoside Reverse Transcriptase Inhibitors

Non-nucleoside reverse transcriptase inhibitors (NNRTI) have a high affinity for the active site of HIV reverse transcriptase and block it. These agents are best employed

in combination regimens for patients who have not received prior antiretroviral therapy.

Protease Inhibitors

Protease inhibitors (PI) bind to the active site of the HIV protease enzyme whose function is to cut reproduced HIV strands. Thus PIs interrupt the formation of mature viral particles and reduce viral replication by as much as 99 percent. PIs have rapid resistance development. However, in combination with nucleoside analogs, they can be used as part of a cocktail.

Nucleotide Reverse Transcriptase Inhibitors

Tenofovir disoproxil fumarate (Viread) is the newest drug approved for HIV combination treatment in patients on prior antiretroviral therapy. Tenofovir is a nucleotide reverse transcriptase inhibitor that also blocks reverse transcriptase. The benefit of tenofovir is its longer action, so it can be taken once a day as a 300-mg dose. Tenofovir should be taken at the same time each day with a full meal.

LEARNING TIPS

Key points to remember:

- HIV and AIDS are disease labels, not people labels.
- Each person reacts to an HIV or AIDS diagnosis differently.
- It is not HIV that ultimately causes death, it is compromised immunity and the invasion of an opportunistic infection or disease that the patient's body is unable to successfully fight off, even with medical intervention.
- With today's current successful antiretroviral treatments, HIV has changed from being a life-ending infection to more of a chronic disease requiring constant management.

NURSING MANAGEMENT

Assessment

Ongoing assessment is important for the patient with HIV/AIDS to detect problems early. Health history information is obtained (Box 54–4). Determining patient understanding of HIV/AIDS information is useful for planning and teaching. A physical assessment provides data on the effects of HIV/AIDS. Signs and symptoms of opportunistic diseases are noted.

Nursing Diagnosis

Nursing care is individualized to the patient's presenting symptoms. Primary nursing diagnoses for HIV/AIDS include but are not limited to the following:

- Risk for infection related to decreased immune function
- Acute or chronic pain related to neuropathy, cancer, infection, or dyspnea

BOX 54-4 Assessment: Health History Information for HIV/AIDS

Demographic data: Gender, age, marital status, occupation, residence
 Date of diagnosis of HIV/AIDS
 Current health status and concerns
 Allergies
 Medications
 Height/weight: weight loss
 Blood transfusions/treatment for hemophilia
 Infections/cancers (see Box 54–1)
 Sexually transmitted diseases
 Safer sex practices
 Injection drug use

- Fatigue related to HIV infection
- Imbalanced nutrition: less than body requirements related to anorexia, nausea and vomiting, increased caloric need, diarrhea, dysphagia, painful oral lesions
- Impaired oral mucous membranes related to decreased immune function
- Diarrhea related to infection, medications
- Impaired skin integrity related to infection, cancer, immobility, incontinence
- Social isolation related to fear, infection control, transmission of virus
- Risk for situational low self-esteem related to decreased self-esteem and body image changes
- Deficient knowledge related to lack of prior experience with HIV/AIDS and treatment

Additional diagnoses may include the following:

- Anticipatory grieving related to loss of function or death
- Disturbed thought processes related to AIDS dementia
- Disabled family coping related to chronic, progressive disease
- Ineffective coping related to chronic progressive disease
- Ineffective sexuality pattern related to disease transmission
- Risk for injury related to weakness, fatigue, sedation, neurological impairment

See Nursing Care Plan Box 54–5.

Implementation

HIV/AIDS affects every system of the body and every aspect of a person's life. Nurses have the opportunity to positively influence the patient's experience with HIV/AIDS with a nonjudgmental approach, empathy, and psychological support.

Risk for Infection

To reduce infection risk the patient should be taught to avoid large crowds; wash hands frequently, especially before eating; bathe daily; avoid sharing personal grooming items (e.g., toothbrush, toothpaste, deodorant); cleanse

BOX 54-5

NURSING CARE PLAN FOR THE PATIENT WITH ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS)*

Risk for infection, nosocomial related to weakened immune system, skin breakdown, intravenous therapy, and possible invasive procedures

PATIENT OUTCOMES

Patient will remain free of nosocomial infections. Patient will describe measures to maintain skin integrity and avoid infections.

EVALUATION OF OUTCOMES

Is patient free of nosocomial infections? Can patient explain and demonstrate skin maintenance techniques?

INTERVENTIONS

Assess patient's risk factors, such as skin condition, laboratory results, portals of entry for infections, and presence of any infections.

Caregivers should use standard precautions and strict aseptic technique for *all* patients and procedures.

Instruct visitors about techniques to avoid transmission of infection, such as handwashing and not visiting when they have an infection. The nurse with an infection, especially respiratory infection, should not care for patient with AIDS.

Promote skin integrity by frequent turning, optimum mobilization, protective mattress and chair pads, application of emollient to dry areas, and prompt treatment of any injuries.

Teach strategies for skin care and avoidance of infection to patient.

RATIONALE

Status of these assessment factors determines plan for care.

Transmission of microorganisms can occur in both directions.

The immune system is damaged by HIV. Ability to combat infections is severely compromised. A minor infection for most people may kill a person who has AIDS.

Skin is the body's first line of defense.

Self-care offers a measure of control in frequently uncontrollable situation.

EVALUATION

Does patient have intact skin or nonreddened, nonpurulent sites of interrupted integrity?

Do all caregivers use standard precautions?

Do those with infections avoid contact with patient until their infection is resolved? Do laboratory tests indicate that patient is so immunocompromised that reverse isolation may be necessary?

Does patient's skin remain intact and infection free?

Does patient satisfactorily explain or demonstrate good skin care and knowledge of how to avoid infection?

Risk for injury related to impaired mobility, weakness, fatigue, possible electrolyte imbalances, neurological impairment, and sedative effects of pain medications

PATIENT OUTCOMES

Care and mobility needs will be met without injury.

EVALUATION OF OUTCOMES

Does patient remain free from injury?

INTERVENTIONS

Assess patient's abilities and disabilities.

Look for potential hazards in environment (hospital or home) and eliminate as many hazards as possible.

Instruct patient about how to avoid hazards (if cognitively and physically able to comply).

Encourage self-care as much as is feasible without tiring patient.

Assist with care activities as needed.

RATIONALE

Particular disabilities may increase danger to patient.

Awareness of hazards is necessary to decrease occurrence of accidents and injuries.

Patients can help avoidance of injury if they understand hazards.

Self-care promotes feelings of self-efficacy and can combat depression.

Varying levels of assistance with care are necessary due to the debilitating nature of disease.

EVALUATION

Does patient have deficits?

Are there any hazards in the environment presently?

Is patient effectively avoiding hazards, or is patient a danger to self?

Does patient evidence satisfaction with self-care efforts?

Are patient's care and mobility needs being met satisfactorily without injury?

*Written by Linda Hopper Cook.

BOX 54-5**NURSING CARE PLAN FOR THE PATIENT WITH ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS)—CONT'D**

Institute safety measures as required, such as close observation, frequent reorientation, two staff members for ambulation, use of side rails, bed motion alarm, or room near nurse's station.

Protection of patient against inadvertent removal of tubes or equipment, falls, and other injuries may require extraordinary measures due to neurological damage.

Are safety measures effective for patient? Does patient respond negatively to the protective measures? Can these be modified to be less offensive?

▶ Ineffective individual coping related to terminal disease and progressive debility

PATIENT OUTCOME

Patient will show use of effective coping skills.

EVALUATION OF OUTCOME

Does patient show use of effective coping skills?

INTERVENTIONS

Establish and maintain open and trusting therapeutic relationship. Allow grieving to take place (keeping a journal has been effective for some patients who have AIDS).

Encourage patient to express feelings and concerns. Contact counselor, chaplain, or AIDS support worker if patient so desires.

Provide patient with desired information or refer to others who can supply information.

Ask if patient would like information about support group and arrange such.

RATIONALE

Effective communication is based on trust—assurance of confidentiality is essential.

AIDS brings about losses of health, strength, employment, and in many cases friends and threatens one's sense of security and reasonableness of life. Healthy grieving is a natural coping response.

Talking about feelings and concerns helps defuse anger, clarify needs, and relieve tension.

Knowledge dispels unreasonable fears and helps patient prepare adequately to cope with stressors.

Social support can help patient cope.

EVALUATION

Does patient talk about concerns with nurse?

Is grief being expressed? Is finishing things that matter to him or her?

How are family members, friends, and support persons interacting with patient? How is patient responding to family members, friends, and support persons?

Does patient evidence enough understanding of disease to be able to cope effectively?

Does patient show satisfaction with coping resources?

toothbrush; and wash all dishes between uses (Table 54-6). In addition, the patient is taught signs of infection to report to health care provider (Box 54-6). Treatment of opportunistic infections is most effective when begun early.

Impaired Gas Exchange

If a patient develops a condition that interferes with respiration, the goal is to maintain oxygenation within normal limits and reduce dyspnea. PCP is a common respiratory infection with HIV infection. (See Table 54-5.) Monitoring the patient's vital signs, including respiratory rate, depth, and rhythm and oxygen saturation, is important. Medications and oxygen therapy are given as ordered. Positioning the patient for comfort is often done by raising the head of the bed. Assisting with activities helps reduce fatigue.

Pain

Pain may occur from a variety of causes. Treatment is focused on the cause to achieve pain control and relief. Medications may be given as ordered. Complementary therapy may be used by patients. (See Chapter 4.) Measures such as heat or cold, massage, and frequent position changes may be helpful.

BOX 54-6 Patient Teaching: Signs and Symptoms of Opportunistic Infections to Report

Instruct patient to monitor temperature daily and to report the following symptoms to a health care provider immediately:

- New fever higher than 100° F (38.5° C) or a change in fever pattern if low-grade fevers are commonly present
- Cough, shortness of breath, fever, or chest tightness, which may be signs of early pneumonia
- Signs of central nervous system infection, such as severe headache; stiff neck; visual changes; problems with balance, walking, or speech; weakness of an arm or leg; and changes in moods or memory
- Foul-smelling drainage or pus
- Cloudy or foul-smelling urine
- Signs of dehydration, such as a dry mouth, dark concentrated urine, or dizziness when standing
- Diarrhea lasting longer than 48 hours; more than six stools a day; watery, mucous, or bloody stools
- Rashes (possible side effect of medication)
- Sore mouth or tongue, difficulty swallowing, white patches on tongue or back of mouth
- Worsening fatigue

TABLE 54-6 PATIENT TEACHING: PREVENTING OPPORTUNISTIC INFECTIONS

Precaution Category	Reducing Exposure Risk	To Protect From
<i>Environmental/Occupational</i>	<p>Consider risk for exposure to infectious agents from the following: health care settings, correctional facilities, homeless shelters.</p> <p>Child care settings: Wash hands after diaper changing/body fluid contact.</p> <p>Animal contact: Exposure possible from veterinary work, pet stores, farms.</p> <p>Gardening/soil contact: Avoid gardening/houseplant care/bird-roosting site soil, cleaning chicken coops. Wash hands after soil contact.</p>	<p>Tuberculosis</p> <p>CMV, cryptosporidiosis, hepatitis A, giardiasis</p> <p>Cryptosporidiosis, toxoplasmosis salmonellosis, campylobacteriosis</p> <p>Cryptosporidiosis, toxoplasmosis, histoplasmosis, coccidioidomycosis</p>
<i>Food/water</i>	<p>General measures for home or restaurants include the following: Food handlers should practice good handwashing and hygiene. Discard food past expiration date, dented or swollen cans. Maintain adequate refrigeration and cooking temperatures. Control insects and rodents to prevent food contamination.</p> <p>Foods to avoid:</p> <ul style="list-style-type: none"> Raw/undercooked eggs and foods with raw eggs, such as hollandaise sauce, Caesar dressing, mayonnaise, uncooked batters, ice cream, egnog. Raw/undercooked poultry, meat, seafood. Unpasteurized milk/dairy products and fruit juice, raw seed sprouts. Soft cheeses, which may harbor bacteria: feta, Brie, Camembert, blue veined, queso fresco. Wash produce and avoid unwashed produce on salad bars. Avoid cross-contamination of foods with uncooked meat. Cook meat until internal temperature is 180° F for poultry, 165° F for red meats, with no trace of pink. <p>Foods to avoid or cook until steaming hot: leftovers, ready-to-eat, delicatessen foods, refrigerated pates, and meat spreads.</p> <p>Water safety:</p> <ul style="list-style-type: none"> Avoid public drinking fountains. Avoid drinking or swallowing water directly from lakes or rivers. Use safe water supply or boil water 1 minute when unsure. Use safe, solid-block activated carbon home water filter (absolute 1-μm filter; reverse osmosis; certified for cyst removal); have someone change filter or wear gloves when doing so, because organisms collect on outside of filter. Avoid beverages made from tap water in public places. Drink bottled water purified from reverse osmosis, filtration through absolute 1-μm filter, or distillation (only safe methods). For information, contact www.bottledwater.org. Bottled or canned carbonated soft drinks, commercially packaged nonrefrigerated beverages, pasteurized beverages, and beers are safe. 	<p>Foodborne and waterborne infections caused by bacterial, viral, protozoal, or parasitic pathogens</p> <p>Cryptosporidiosis, giardiasis</p>
<i>Sexual</i>	<p>Always use latex condom for every sex act.</p> <p>Avoid oral-anal contact or use dental dams; use latex gloves for hand-anal contact; wash hands and genitals with warm soapy water after contact.</p> <p>Get hepatitis A vaccine.</p> <p>Get hepatitis B vaccine</p>	<p>STDs, herpes simplex virus, cytomegalovirus, human papillomavirus, resistant HIV strain</p> <p>Intestinal infections: amebiasis, hepatitis A, cryptosporidiosis, shigellosis, campylobacteriosis, giardiasis.</p> <p>Hepatitis B</p>
<i>Injection drug use</i>	<p>Get hepatitis A and B vaccines.</p> <p>Stop using injection drugs and enter substance abuse treatment.</p> <p>If unable to stop, never reuse or share syringes, needles, water, or drug preparation equipment.</p> <p>If shared, use bleach and water to clean equipment.</p> <p>Use sterile syringes from pharmacies or community syringe exchange programs and dispose of safely.</p> <p>Use clean water and equipment and new alcohol swab.</p>	<p>Hepatitis B</p> <p>Hepatitis A, hepatitis B, hepatitis C, resistant HIV strain</p>

TABLE 54-6 PATIENT TEACHING: PREVENTING OPPORTUNISTIC INFECTIONS — CONT'D

Precaution Category	Reducing Exposure Risk	To Protect From
<i>Pet-related</i> Counsel on pet contact risks but recognize emotional benefits of pets.	Avoid pet feces/diarrhea; seek veterinary treatment for pet's illness. For new pet, avoid those younger than 6 months old (and cats younger than 1 year old); obtain pets from known sanitary source; avoid strays; wash hands after handling pets. Avoid exotic pets. Cat ownership increases risk from litter box cleaning, scratches, bites, licking, fleas. Unhealthy birds may transmit infectious organisms.	<i>Cryptosporidium</i> , <i>Salmonella</i> , <i>Campylobacter</i> spp. infection Toxoplasmosis, <i>Bartonella</i> spp. infection, salmonellosis, campylobacteriosis <i>Cryptococcus neoformans</i> , <i>Mycobacterium avium</i> , <i>Histoplasma capsulatum</i> infection Salmonellosis
<i>Travel</i>	Wear gloves for cleaning aquariums. Consult health care providers on travel to developing countries. Traveler's diarrhea prophylaxis is not recommended. Carry supply of antimicrobial agent to take for diarrhea. Consider prophylaxis for other types of exposures. Avoid raw fruits, vegetables, raw/ undercooked seafood or meat, tap water, ice from tap water, unpasteurized milk/dairy products, items from street vendors. Safe items include steaming-hot foods, self-peeled fruits, bottled (especially carbonated) beverages, hot coffee/tea, beer, wine, and water boiled 1 minute. Avoid soil/sand contact by wearing shoes, using beach towels.	<i>Mycobacterium marinum</i> infection Opportunistic pathogens, foodborne and waterborne infections

Source: Data from U.S. Department of Health and Human Services: 2001 USPHS/IDSA Guidelines for the Prevention of Opportunistic Infections in Persons Infected with Human Immunodeficiency Virus. <http://hivatis.org>, November 28, 2001.
STD = sexually transmitted disease.

Fatigue

Many patients with HIV experience fatigue. Other causes of fatigue include infections, medications, anemia, dehydration, depression, and poor nutrition. The patient can help manage fatigue by alternating periods of activity and rest. Tasks that use more energy should be planned at times when the patient is most energetic.

Imbalanced Nutrition: Less than Body Requirements

Maintaining general health and nutrition is important for a healthy immune system. For patients with HIV, maintaining health is vital. Patients with AIDS often have difficulty maintaining adequate nutrition and preventing weight loss. Many factors interfere with nutrition in HIV/AIDS (e.g., anorexia, oral lesions, nausea and vomiting, diarrhea, or wasting syndrome). The cause needs to be identified for appropriate intervention planning.

The patient's baseline weight is obtained. Then ongoing monitoring of the patient's weight, calorie intake, and intake and output is done. A dietitian is consulted to help plan nutritious and affordable meals. The patient should be on a low-microbial (reduces infection), high-calorie, high-protein diet. Small, frequent meals may be helpful. Vitamins, nutritional supplements, tube feedings, or parenteral nutrition (partial parenteral nutrition [PPN] or total parenteral nutrition [TPN]) may be needed to maintain adequate nutrition. Antiemetics are used to control nausea and

vomiting. Creative interventions and resources may be needed to ensure the patient receives adequate nutrition. (See Table 54-5.)

Along with adequate nutrition, exercise helps maintain muscle mass, promotes relaxation, aids sleep, and gives an individual a sense of control and well-being. An effective exercise program includes exercises that increase strength, flexibility, and endurance. Becoming physically fit is a lifestyle change that requires dedication.

Impaired Oral Mucous Membranes

Oral or esophageal candidiasis is common. The painful lesions interfere with swallowing and nutrition. In patients with AIDS who smoke there is an increased incidence of oral thrush (candidiasis). Therefore patients should be encouraged to quit smoking. Antifungal medication is given, such as ketoconazole (Nizoral) or fluconazole (Diflucan). Mouth care is very important. A soft toothbrush promotes comfort. Viscous lidocaine can be given to decrease pain during eating.

Diarrhea

Diarrhea often occurs in patient with AIDS. For diarrhea caused by opportunistic causes (except *Salmonella*), an antimotility agent (diphenoxylate/atropine [Lomotil]) may be prescribed. Consulting the dietitian may be helpful in making diet changes that reduce diarrhea (e.g., low-residue diet, no dairy products, no spicy foods, no caffeine or alcohol). Sitz baths may be soothing. Thorough cleansing of the rec-

tal area after each stool is a must. Ointments may be applied to protect and soothe the anal area from excoriation.

Impaired Skin Integrity

Skin infections or malignancies can occur. Medications can cause skin infections that can be life threatening and must be reported immediately. Kaposi's sarcoma is the most common skin condition (discussed earlier). To help maintain a positive body image, patients can cover the lesions by using hats, clothing, or makeup (with closed lesions).

Social Isolation

Many patients with HIV/AIDS face discrimination, rejection, and isolation. The Americans with Disabilities Act (ADA) makes discrimination toward patients with AIDS illegal. Relatives, friends, and others sometimes avoid or refuse to have anything to do with the person with HIV (Ethical Consideration Box 54–7). Misunderstanding and fear lead to misuse of infection control procedures and increase a patient's isolation. Being knowledgeable about the transmission of HIV allows interaction with the patient to reduce feelings of isolation. Providing patient education to reduce fear of HIV transmission also decreases isolation.

BOX 54-7 ETHICAL CONSIDERATION

Caring for a Patient with AIDS

Edward, 28, is hospitalized in a large research hospital in California. He is in the terminal stages of AIDS, with widespread metastatic cancer and lung infections. He wants to see his parents before he dies. However, when he left his middle-class home on a ranch in Oklahoma in the middle of the Bible Belt to attend college, his parents had no knowledge of his homosexuality. They have not seen him since that time and still have no knowledge that he is homosexual.

Edward does not want his parents to know about his homosexuality or that he has AIDS. He feels that their rigid religious beliefs may make them disown him and cause a scene in the hospital. Before they come to visit him at the hospital, he asks the licensed practical nurse/licensed vocational nurse (LPN/LVN) who is assigned to care for him to answer any of his parents' questions about his illness by telling them he has leukemia, pneumonia, or another rare disease that they would know nothing about. After the third day of visiting their severely ill son, Edward's parents directly ask the LPN/LVN, "Does our son have AIDS?"

How should the LPN/LVN respond? To whom does the LPN/LVN owe the greatest obligation, the patient or his family? What principles are in conflict? What virtues play a role in this situation? Use the decision-making model and determine several possible solutions for this situation.

Risk for Situational Low Self-esteem

Changes in self-esteem and self-concept occur from several of the effects of HIV infection. Patients often experience changes in their relationships with others and in day-to-day activities such as work. Dramatic changes in appearance may occur that alter body image and reduce self-esteem.

Nurses can assist patients in maintaining self-esteem and self-concept by ensuring a climate of acceptance and promoting a trusting relationship. Patients should be encouraged to express feelings if ready and to identify positive aspects of self. Emotional and spiritual support of the patient can help improve self-esteem.

Stress impacts health. Having others to talk with and provide support is essential to stress management. Identifying and maintaining social networks is important. Patients should be taught a variety of relaxation strategies and techniques to reduce stress. Relaxation strategies can range from working on a favorite hobby to talking with friends. Relaxation techniques include progressive muscle relaxation and imagery to aid in relaxation. Stress management techniques are most effective when used every day, not just during times of stress.

Deficient Knowledge

Extensive teaching is needed for patients to understand this chronic, life-threatening disease that alters everything in their lives. (See also the Prevention section.) Adherence to treatment and medication regimens is necessary to prevent infection and prolong the time before AIDS occurs.

MEDICATIONS. It is vital that medication doses are not missed; this must be stressed during patient teaching. Tell the patient to take medications exactly as instructed. If a dose is missed, it should be taken as soon as possible unless it is very close to the time of the next dose. Doses should not be doubled. Missing doses of medication could cause therapy failure because viral loads can increase. Tell the patient to consult the physician with any questions or side effects promptly. Many of these medications can cause severe reactions.

FOOD AND WATER SAFETY. Food and water safety is vital to an immunocompromised patient. Bacterial, viral, protozoal, or parasitic pathogens can cause foodborne and waterborne infections. The patient must be taught methods to prevent foodborne and waterborne infections for all phases of handling. (See Table 54–6.) Kitchen counters and food preparation appliances (e.g., cutting boards, can openers) should be disinfected with a bleach solution. Freezing does not kill bacteria in foods. Foods should not be thawed at room temperature. Dating and using the oldest foods first is helpful. If symptoms of foodborne or waterborne infection develop (e.g., diarrhea, nausea, vomiting, abdominal cramps, headache, fever), teach patient to report them immediately.

RESOURCES. Financial resources may need to be addressed so that food and medications can be obtained. Treatment can be expensive, and the patient be unable to work. However, with the new combination antiretroviral therapies, individuals are now able to continue working longer. Referrals to financial resources and support groups can be helpful.

Community and Home Health Care

During the course of HIV infection, the patient will be primarily at home. Hospitalization may be needed intermittently for acute illness. As the disease progresses, the patient

may require more care from caregivers and home health nurses. The home health nurse provides physical care, establishes a therapeutic relationship with patients with AIDS and their significant others, and coordinates care with other health care team members (Home Health Hints). Caregivers should be assessed for caregiver role strain. Support services should be identified, such as community AIDS organizations, Meals on Wheels, respite care services, community mental health, and Internet support groups. Respite care provides the caregiver time away from the caregiver role to reduce stress. When a patient is terminal, comfort care and emotional support for the family are essential. Hospice care may be used at this time.

Evaluation

Patient goals are met if the patient remains free from infection and maintains desired quality of life and activities as long as possible. As the disease progresses, goals are met if the patient's needs are met and the patient's dignity is maintained.

CRITICAL THINKING

Zoe Sampson

Zoe, 22, is diagnosed as HIV positive. She is tearful and asks many questions.

- How would you answer her questions?
 - "Am I going to die?"
 - "How is AIDS diagnosed?"
 - "Can my boyfriend get it?"
- What food and water safety methods would you teach her?
- Years later Zoe loses weight and becomes malnourished. What interventions can you use to promote adequate nutrition?

Answers at end of chapter.

HOME HEALTH HINTS

- When providing patient care, wash hands frequently, follow standard precautions, and use plastic bags to contain soiled items or clothing.
- Teach patients with AIDS and their families how to properly clean and disinfect the home to prevent infections. The recommended disinfectant is a diluted bleach mixture that contains 1 part household bleach to 10 parts water.
- Wearing gloves, clean body fluid spills with soap and water.
- Flush body fluids, solid waste, and contaminated solutions down toilet.
- Use disinfectant to (a) disinfect spill areas; (b) clean toilet seats and bathroom fixtures; (c) clean inside the refrigerator to avoid mold growth.
- Rinse clothing and then wash separately from other clothes with 1 cup of bleach if soiled with blood, urine, feces, or semen.
- Patients with AIDS do not require separate sets of dishes or silverware. Dishes and silverware are washed in hot, soapy water and rinsed thoroughly or placed in dishwasher.
- Dispose of sharps (e.g., needles, razors) in a rigid labeled container (such as a tin can with a sealable lid). Add 1:10 bleach solution to disinfect. Tape the lid. Place in a bag and dispose of in the trash.
- Contaminated articles are disposed of by bagging in plastic and placing in the trash.
- Teach the family of a patient with AIDS which signs and symptoms to report to the physician or nurse immediately: fever; increased dyspnea; pain; change in sputum production; upper respiratory tract infection; pneumonia; respiratory distress syndrome; diarrhea five times a day or more for 5 days; uncontrolled weight loss greater than 10 pounds in the last month; persistent headaches; falling; seizures; mental status changes, including memory loss and personality changes; rashes and skin changes; difficulty swallowing; and problems with urination.

REVIEW QUESTIONS

- The nurse is caring for a patient who is newly diagnosed with HIV infection. The patient asks what his future health status will be. The best response for the nurse to give is based on the understanding that HIV disease and AIDS are now characterized as which of the following?
 - An acute disease
 - A life-ending disease
 - A chronically managed disease
 - A disease with remissions and exacerbations
- The nurse would evaluate the patient as understanding modes of HIV transmission if the patient stated that the modes of HIV transmission include which of the following?
 - Saliva, tears, fecal-oral contamination
 - Close physical contact involving skin surfaces, mosquito bites
 - Sharing towels, sharing eating utensils, skin contact
 - Unprotected sex with HIV infected partner, contact with infected blood/products
- The nurse would recognize the patient needs further reinforcement of knowledge if the patient stated that one of the goals of highly active antiretroviral therapy is which of the following?
 - Reduce the viral load
 - Improve survival rates
 - Decrease CD4+ T lymphocytes
 - Delay the progression of HIV disease

4. The nurse would recognize that the patient is having a reaction to zidovudine (AZT) if which of the following occurred?
 - a. Rash
 - b. Edema
 - c. Abdominal pain
 - d. Blurred vision
5. The nurse is to give lamivudine (3TC) 150 mg PO now and has available a 10 mg/mL solution. How many milliliters should the nurse give?
 - a. 0.5 mL
 - b. 1 mL
 - c. 10 mL
 - d. 15 mL

Answers to CRITICAL THINKING

Zoe Sampson

1.
 - a. There currently is no cure for HIV/AIDS; however, medications are available that slow the disease's progression and make HIV a manageable chronic illness. Research continues on finding improved treatments and a cure.
 - b. AIDS is diagnosed when CD4+ T-lymphocyte counts are below 200 cells per microliter or CD4+ T-lymphocyte percentage is under 14 of total lymphocytes and an opportunistic clinical disease, as defined by the CDC, is present in an HIV-infected person.
 - c. Yes, your boyfriend could become infected through exposure to your blood or vaginal secretions. You need to learn about preventive measures and discuss them with him.
2. Food handlers must maintain good handwashing and hygiene practices. Discard food past the expiration date and dented or swollen cans. Ensure adequate refrigeration and cooking. Control insects and rodents to prevent food contamination. Avoid public drinking fountains. Drink purified bottled water. Use a safe water supply or boil water 1 minute when unsure. Avoid unpasteurized milk, other dairy products, and fruit juice and raw seed sprouts. Avoid raw and undercooked eggs, meats, and seafood.
3. Eat three high-calorie, high-protein meals and snacks daily. Drink liquids before meals. Eat a low-residue diet for diarrhea control. Develop easy meal plan use antiemetics. Numb painful oral sores. Avoid spicy foods. Refer for food stamps/free meal programs if necessary. Engage in regular exercise.

 tolerance (**TALL**-ler-ens)
 withdrawal (with-**DRAW**-ul)

► NORMAL FUNCTION

The study of **mental illness** is fairly new to the health care field. There are differing opinions within the mental health community as to what **mental health** and mental illness are. Mental health has been defined in many ways. These definitions include the ability to do the following:

- Be flexible
- Be successful
- Form close relationships
- Make appropriate judgments
- Solve problems
- Cope with daily **stress**
- Have a positive sense of self

Mental illness is defined as experiencing the following:

- Impaired ability to think
- Impaired ability to feel
- Impaired ability to make sound judgments
- Difficulty or inability to cope with reality
- Difficulty or inability to form strong personal relationships.

It is important to remember that mental health and mental illness exist on a continuum. It is natural for emotions to ebb and flow from day to day in response to the degree of stress that is experienced. People who remain mentally healthy are able to keep their stress in perspective. Others are not able to do so, and over time they may develop physical or emotional illnesses as a result of the constant stress in their life.

Visualize the seesaw that children play on. Mental health and mental illness are like a seesaw. When children of approximately equal weight get on each end of the seesaw, they can balance each other and keep the seesaw even. Mentally healthy people keep themselves in a state of emotional balance. Sometimes one child weighs just a little more than the other, and the seesaw tips just a little to one side. Mentally healthy people can cope with this fluctuation. Sometimes another child gets on or one child greatly outweighs the other, and the seesaw gets out of balance completely; one end goes way up while the other goes way down, and it stays there until someone alters the balance. Ultimately it must be the patient who finds his or her own balance. When people's moods are way down or way up, they are not in emotional homeostasis.

The discussion surrounding the etiology (causes) of mental illness continues to revolve around the "nature versus nurture" or "organic versus inorganic or functional" arguments. The connections between physical and emotional health are so closely intertwined that it is sometimes hard to decide if emotional causes trigger physical responses or vice versa. Nurses must have a basic understanding of both the nature and nurture schools of thought on the causes of alterations in mental health.

Explanations of mental illness include concepts from the psychoanalytic (or psychological) theory and the psychobiologic (or biologic) theory. When pertinent, other theories

(e.g., behavioral, environmental) are also presented. Most mental illnesses have no absolute cause. Some etiologic theories have stronger positive correlations to illnesses than others. When it is appropriate, this chapter gives the most current or most widely accepted view of an etiology.

Many professionals in the field of psychology believe that social and cultural environments have a great influence on the way people develop and process life experiences. Some psychoanalysts believe that some cultural traditions and beliefs cause disturbances in personal relationships, which can lead to forms of emotional disturbances. It is part of the nurse's role to take time to learn about the traits that are common among people and those traits that are different. It is important to have an understanding of people's customs and beliefs to avoid unrealistic expectations of patients. See Cultural Consideration Box 55–1 for more detailed information about culture and mental health issues.

Spirituality and religion are extremely important to some patients and unimportant to others. A person's success in recuperating from physical or emotional illness may be deeply tied to his or her spirituality. It is necessary to be comfortable talking to the patient about spiritual needs while being careful not to impose personal values on the patient. If you are not comfortable in these situations, you should offer to call the chaplain in the facility or the spiritual leader of the patient's choice. It is important to keep the lines of communication open. People learn by sharing with each other. It is much better to ask a person about something than to make an assumption about it. For more information about mental health and illness, visit the National Institute of Mental Health at www.nimh.nih.gov or the American Psychiatric Association at www.psych.org. For a list of other Websites, visit <http://mentalhealth.about.com>.

► NURSING ASSESSMENT

During the data collection/assessment part of the nursing process, the mental status examination is performed. This is a series of questions and activities that evaluate eight areas: appearance and behavior, level of awareness and reality **orientation**, thinking/content of thought, memory, speech and ability to communicate, mood and **affect**, judgment, and perception. There are a number of different tools of varying names, lengths, and formats used to assess the patient's mental capabilities. See Table 55–1 for a sample mental status examination.

After data have been collected, the licensed practical nurse/licensed vocational nurse (LPN/LVN) collaborates with the registered nurse (RN) to develop nursing diagnoses. Box 55–2 lists nursing diagnoses commonly used when caring for patients experiencing mental health problems.

► DIAGNOSTIC TESTS

The diagnostic tool that is used most widely by psychiatrists and psychologists is the *Diagnostic and Statistical Manual of Mental Disorders IV*, or DSM-IV. The DSM-IV uses a system for grouping illnesses into categories of clinical disorders. This is a complex diagnostic tool. Although the LPN is not responsible to complete the assessment, he or she may contribute valuable information.

BOX 55-1 CULTURAL CONSIDERATION

Among many Haitians, some African-Americans, and some other groups, conjure (practicing magic) and root doctors are believed to know more about mental illness than Western-educated physicians. Some depressive and obsessive behaviors are viewed as culture-bound syndromes. These behaviors are expected of some Haitians, and those affected fulfill some expected roles in the society. Some of these illnesses are viewed as having no cure. Thus the nurse may need to include folk healers when working with African-Americans and patients of Haitian descent.

Smoking, alcoholism, and deaths from suicide or violence are prevalent problems in the American culture. Violent deaths account for high mortality rates among adolescents and young adults of African-American, Cuban, Mexican-American, and Puerto Rican origin. Programs targeting these populations should be personalized to include adolescents and their families. Given their strong family values, an important approach is to begin early in church groups or family settings.

Hispanics require lower doses of antidepressants and experience greater side effects than Caucasians. Thus careful observations need to be undertaken when observing for side effects of medications in patients of Mexican heritage.

One of the few drugs found to have a higher rate of side effects in individuals of Ashkenazi ancestry is clozapine, used to treat schizophrenia. Twenty percent of Jewish patients taking this drug developed agranulocytosis compared with about 1 percent of non-Jewish patients. Thus the nurse may need to suggest testing for agranulocytosis when Jewish patients are prescribed clozapine.

Asian patients require lower dosages and have side effects at lower dosages than Caucasians for a variety of psychoactive drugs (e.g., lithium, haloperidol) even when matched with body weight. Asians commonly believe that Western drugs are too strong for them and take less than prescribed. Most Asians are more sensitive to alcohol, resulting in facial flushing, palpitations, and tachycardia.

Many Vietnamese people believe that mental illness results from offending a deity and that such a condition brings disgrace to the family and must be concealed. A shaman may be enlisted to help. Additional therapy is sought only with the greatest discretion and often after a dangerous delay. Unmistakable emotional disturbance is usually attributed to possession by malicious spirits, the bad luck of familial inheritance, or, for Buddhists, bad karma accumulated by misdeeds in past lives. Additionally, the term *psychiatrist* has no direct translation in Vietnamese and may be interpreted to mean nerve physician or specialist who treats crazy people. The nervous system sometimes is seen as the source of mental problems, neurosis being thought of as “weakness of the nerves” and psychosis as “turmoil of the nerves.”

Poles and other groups from Eastern Europe usually look for a physical basis of disease before considering a mental disorder. If mental health problems exist, home visits are preferred to clinic visits and talk therapies without suitable psychosocial strategies are not maintained unless interventions are action oriented. In addition, Poles look to other family members and the community to assess appropriateness of treatments. Polish-Americans often seek self-help groups such as Alcoholics Anonymous before seeing a health care provider. A family physician is preferred over a specialist.

Mental illness among the Navajo is perceived as resulting from placing a curse on an individual. In these instances a healer who deals with dreams or a crystal gazer is consulted. Individuals may wear turquoise to ward off evil; however, an individual who wears too

much turquoise is sometimes thought to be an evil person and someone to avoid. In some tribes, mental illness may mean that the affected person has special powers. Additionally, many Native Americans metabolize alcohol at a faster rate than European-Americans, resulting in them having a lowered tolerance for alcohol.

Mental illness in the Korean culture is viewed as a stigma. *Hwabyung*, a traditional Korean illness, occurs from the suppression of sadness, depression, worry, anger, fright, and fear. These emotions are commonly related to conflicts with close relatives or significant others. Symptoms include physical complaints such as headaches, poor appetite, insomnia, and lack of energy. Most people accept the symptoms as inevitable, although currently programs are underway to change the stigma.

Newer immigrants from Ireland have a higher incidence of mental illness than the rest of the population. Undocumented Irish immigrants in the United States report more stressors and mental health problems than their legal counterparts. Because many Irish people have difficulty expressing emotions, health care providers may need to encourage Irish-Americans to express their concerns.

Mental illness is strongly stigmatized among Iranians and is thought to be genetic. Should a family member have mental illness, it is likely to be called a “neurological disorder” so as not to stigmatize the family, which may result in daughters having a lesser chance of marrying. Psychotherapeutic help may be avoided because of stigma or because it is perceived as irrelevant. People prefer a medicine that might cure them. There is a tendency to pay more attention to somatic symptoms when under emotional stress; Iranians consider psychopharmacology most effective, and have a high rate of compliance.

Because of the stigma attached to seeking professional psychiatric help, many Hindus do not access the health care system. Instead, family and friends seem to be the best help, and a general belief is that time is the best healer. Physical and mental illnesses are considered God’s will, or karma, and are associated with a fatalistic attitude.

Among Greeks, mental illness is accompanied by social stigma for the afflicted individual, as well as the relatives. The shame originates in the notion that mental illness is hereditary, and afflicted individuals are viewed as having lifelong conditions that pollute the bloodline.

Because of social stigma attached to mental illness and retardation, Arabs may keep their family from public view. However, when Arab patients suffer from mental distress, they seek medical care. They are likely to have complaints such as abdominal pain, lassitude, anorexia, or shortness of breath. Arabs have an increased tendency to experience elevated blood levels and adverse effects when customary dosages of antidepressants are prescribed. Patients often expect and insist on somatic treatment, at least vitamins and tonics.

African-Americans may be at a greater risk for being misdiagnosed with a psychiatric disorder than Caucasians. African-Americans with psychiatric disorders are more likely to have hallucinations, delusions, somatization, and hostility, even when controlled for socioeconomic class. Maintaining direct eye contact with some African-Americans may be misinterpreted as aggressive behavior. Thus nurses must take these nonverbal behaviors into consideration when working with the patient with an emotional or mental concern. Additionally, African-Americans are more susceptible to tricyclic antidepressants and thus experience more toxic side effects.¹

TABLE 55-1 SAMPLE MENTAL STATUS EXAMINATION

Area of Assessment	Type of Assessment	Normal Parameters	Alterations from Normal
<i>Appearance and behavior</i>	Objective and subjective observations about dress, hygiene, posture, and appearance and about the patient's actions and reactions to health care personnel.	Clean, combed hair. Clothing intact and appropriate to weather or situation. Teeth/dentures in good repair. Posture erect. Cooperates with health care personnel.	Displays either unusual apathy or concern about appearance. Displays uncooperative, hostile, or suspicious behaviors toward health care personnel.
<i>Level of awareness and orientation</i>	Subjective and objective assessment of the patient's degree of alertness (wakefulness) and the degree of the patient's knowledge of self.	Awareness is measured on a continuum that ranges from unconsciousness to mania. "Normal alertness" is the desired behavior. Facilities may provide a standard guideline for helping with this assessment, but subjective observations can be documented as well if the patient is not able to stay awake for even short intervals or if the patient is overly active and has difficulty staying in one place.	Outcome is not considered within accepted normal limits if the patient is difficult to arouse and keep awake or if the patient has difficulty feeling calm. Abnormal results of orientation are the patient's inability to correctly answer questions pertaining to the self or to commonly known social information, such as who is the president.
<i>Thinking/content of thought</i>	Subjective assessment of what the patient is thinking and the process the patient uses in his or her thinking.	Formal testing may be done by the psychologist or psychiatrist to determine the patient's general thought content and pattern. Nurses may contribute to the assessment of thought by documenting statements the patient makes regarding daily care and routines.	Behaviors including flight of ideas, loose associations, phobias, delusions, and obsessions may become apparent.
<i>Memory</i>	Subjective assessment of the mind's ability to recall recent and remote (long-term) information.	Recent memory: Recall of events that are immediately past or within 2 weeks before the assessment, such as a recent news event. One measurement technique is to verbally list five items. After 1 minute, patient can recall four or five of those items. Continue with assessment, and at 5 minutes patient should be able to recall three or four of the items. Remote memory: Recall of events of the past beyond 2 weeks before assessment. Patients may be asked where they were born, where they went to grade school, etc.	Inability to accurately perform recent or remote (long-term) recall exercises within parameters. May indicate symptom of delirium or dementia.
<i>Speech and ability to communicate</i>	Objective and subjective assessment of aspects of how patient uses verbal and nonverbal communication.	Patient can coherently produce words appropriate to age, education, and life experience. Rate of speech reflects other psychomotor activity (e.g., faster if the patient is agitated). Volume is not too soft or too loud. Stuttering, repetition of words, and words that the patient makes up (neologisms) are also assessed.	Limited speech production. Rate of speech is inconsistent with other psychomotor activity. Volume is not appropriate to situation (speaks in very loud volume even when asked to speak more quietly). Presence of stuttering, word repetition, or neologisms may indicate physical or psychological illness.
<i>Mood and affect</i>	Subjective and objective assessment of the patient's stated feelings and emotions. Affect measures the outward expression of those feelings.	Mood is the stated emotional condition of the patient and should fluctuate to reflect situations as they occur. Facial expression, body language (affect) should match (be congruent with) the stated mood. Affect should change to fluctuate with the changes in mood.	Mood and affect do not match (e.g., facial expression does not appear sad while the patient is expressing sad feelings).

TABLE 55-1 SAMPLE MENTAL STATUS EXAMINATION — CONT'D

Area of Assessment	Type of Assessment	Normal Parameters	Alterations from Normal
Judgment	Subjective assessment of a patient's ability to make appropriate decisions about his or her situation or to understand concepts.	Give the patient a proverb or situation to solve, such as "You can't teach an old dog new tricks." The patient should be able to give some sort of acceptable interpretation, such as "Old habits are hard to break" or "It is hard to learn something new." Another example is to ask the patient what he or she would do if a small child was lost in the store. An appropriate response might be "Call the manager" or "Try to calm the child."	Patient cannot interpret the sayings in some acceptable manner. Patient cannot complete problem-solving questions appropriately. The patient might answer very literally, "Dogs can't learn anything when they get old" or might say, "I would go through the child's pockets looking for phone numbers."
Perception	Assesses the way a person experiences reality. Assessment is based on the patient's statements about his or her environment and the behaviors expressed in association with those statements. Nurses and health team members must document this often subjective information in very objective terms.	All five senses are monitored for interaction with the patient's reality. The patient's insight into his or her condition is also assessed.	Presence of hallucinations and illusions (schizophrenia). Individuals who are not within normal boundaries of judgment or insight will not be able to state understanding of the origin of the illness and the behaviors that are associated with it.

BOX 55-2 Nursing Diagnoses Commonly Used for Patients with Mental Health Problems

- Disturbed thought processes
- Ineffective role performance
- Anxiety (mild to panic)
- Disturbed body image
- Dysfunctional grieving
- Impaired social interaction
- Ineffective coping
- Disturbed personal identity
- Powerlessness
- Risk for violence (toward self or others)
- Self-care deficit
- Low self-esteem (chronic or situational)
- Disturbed sensory-perception
- Sexual dysfunction
- Disturbed sleep pattern
- Social isolation

Physicians also use other diagnostic criteria to diagnose mental illness. It is important to rule out physical illness as a cause of symptoms. The physician may choose to refer the patient to a psychiatrist or psychologist for further testing and diagnosis.

There are also batteries of psychological tests that can be administered and interpreted by psychiatrists or psychologists. Age, hand tremors, vision, language barriers, educational background, and the interpretation of the psychiatrist or psychologist are some factors that can influence the results of these tests.

Tests that may be performed to either confirm or rule out a diagnosis of a mental illness include the following:

- Laboratory tests (e.g., to rule out electrolyte imbalances, dehydration, drug toxicity)
- Computed tomography (CT) scans (to rule out tumors, lesions, or other physical problems)
- Positron emission tomography (PET) scans (to identify how the parts of the brain are functioning by showing chemical activity or metabolism)

▶ COPING AND DEFENSE MECHANISMS

"Oh, just learn to cope with it." "Get a grip." "Don't make a mountain out of a molehill." These are pieces of advice that people may have heard or given at some point. But what do they mean? What is **cop**ing? Coping is the way one adapts psychologically, physically, and behaviorally to a **stressor**. Individuals have different methods of coping or dealing with their stressors. Culture, religion, individual belief systems, experience, and personal choice influence an individual's responses to stress. It is not the value of a be-

CRITICAL THINKING

Joe

Joe is noted wailing loudly and continuously after the death of his wife. It is disturbing the other patients on the wing, and one of the nurses comments, "He is a real nut case. Get him out of here." What is an appropriate response to this nurse and patient? How would you document his behavior?

Answers at end of chapter.

havior that we assess as nurses; it is the desired outcome that is important. What is an effective coping skill? Is it healthy? Does it work? How do we as nurses observe and measure it?

Effective coping skills offer healthy choices for dealing with stressors. Hospitalization is stressful for patients and families. Many things are unknown and unfamiliar. The patient may not understand the illness or the implications of the treatment plan. It is common for patients to use mechanisms to help them cope during hospitalization. The process of effective coping is sometimes called **adaptation**. Allowing the patient to practice new coping techniques will give him or her confidence and will decrease the stress that can accompany change.

Often the dividing line between effective and ineffective coping is the frequency of its use. For instance, a little worry or **anxiety** can be positive. Generally, when there is a little tension, people are more alert and ready to respond. The fight-or-flight mechanism can actually help one adapt to a new situation. However, too much worry begins to cloud the consciousness and interfere with the ability to make appropriate choices and to recall the new adaptive tools one has learned. One of the most helpful roles you can perform is to listen to the patient's thoughts and feelings about the stressor and then provide information that will reinforce the patient's positive feelings.

Sometimes coping is ineffective. When conscious techniques are not successful, humans often unconsciously fall into habits that give the illusion of coping. These habits are called defense mechanisms (or coping or mental mechanisms). Defense mechanisms are mental pressure valves. The purpose of defense mechanisms is to reduce or eliminate anxiety. They give the impression that they are helping alleviate the stress level. When used in very small doses, defense mechanisms can be helpful. When they are overused, they can become ineffective and unhealthy. People are not born with these behaviors; they are learned as responses to stress. Many times they develop by the age of 10 years old. They appear to be conscious, but they are, for the most part, unconscious mechanisms. Some commonly used defense mechanisms are listed in Table 55–2.

CRITICAL THINKING

Mrs. Beison

Mrs. Beison, a 44-year-old mother of three teenagers, is diagnosed with breast cancer. She is refusing treatment because she does not believe she has cancer. She says if anything is really wrong, her vitamins will take care of it.

What coping mechanism is Mrs. Beison using? Is it effective or ineffective? Why? How can you help?

Answers at end of chapter.

THERAPEUTIC MEASURES

People who experience alterations in their mental health have special treatment needs. When emotional health is threatened, many other daily activities can be altered as well. **Cognitive** ability (the ability to think rationally and to

process those thoughts) can be impaired. Emotional responses can be decreased or even absent in some conditions. This can be extremely frightening and can lead to a worsening of the mental disorder or even the development of another disorder. This section will provide an overview of selected therapies.

Milieu

One area over which you can have some control is the therapeutic environment. In the mental health setting, this therapeutic environment is called the **milieu** or therapeutic milieu. It is believed that environment has an effect on behavior.

A therapeutic milieu is an environment that provides safety and help during the patient's stay. Furnishings may be arranged to look like a home. Patients may help govern the running of the unit, with regular meetings to set rules and assign tasks. Patients may help with dishes or other small jobs. Structured activities are provided to assist the patient to learn coping and social skills. Some things you can do include keeping the area calm and quiet; arranging for roommate changes if needed; and assisting with the running of the unit. As the patient progresses, the milieu is changed to allow the patient to take on more responsibility.

Psychopharmacology

Psychopharmacology is the use of medications to treat psychological disorders. Since the introduction of the phenothiazine class of drugs in the 1950s, the number of medications available for treating mental health disorders has increased greatly. The reason for using medications is twofold: First, the medications control symptoms, helping the patient feel more comfortable emotionally. Second, the patient is generally more receptive and able to focus on other types of therapy if medications are effective. Classifications of psychoactive drugs are provided in Table 55–3. See Chapter 4 for some commonly used herbal therapies. See also Nutrition Notes Box 55–3 for the impact of nutrition on the effects of some drugs.

Psychotherapies

Psychotherapy is the term used to describe the form of treatment chosen by the psychologist or psychiatrist. The goals of psychotherapy include the following:

- Decrease the patient's emotional discomfort
- Increase the patient's social functioning
- Increase the ability of the patient to behave or perform in a manner appropriate to the situation

Several specific types of therapy that are typically used are described next.

psychopharmacology: psycho—soul or mind + pharmaco—drug or medicine + ology—study of

TABLE 55-2 DEFENSE MECHANISMS

Mechanism	Description	Examples
<i>Denial</i>	Usually the first defense learned and used. Unconscious refusal to see reality. Is not conscious lying.	The alcoholic states, "I can quit any time I want to."
<i>Repression (stuffing)</i>	An unconscious "burying" or "forgetting" mechanism. Excludes or withholds from our consciousness events or situations that are unbearable.	A step deeper than "denial." A patient may "forget" about an appointment he or she does not want to keep.
<i>Rationalizing</i>	Using a logical-sounding excuse to cover up true thoughts and feelings. Is the most frequently used defense mechanism.	1. "I did not make a medication error; I followed the doctor's order." 2. "I failed the test because the teacher wrote bad questions."
<i>Compensation</i>	Making up for something we perceive as an inadequacy by developing some other desirable trait.	1. The small boy who wants to be a basketball center instead becomes an honor roll student. 2. The physically unattractive person who wants to model instead becomes a famous designer.
<i>Reaction formation (overcompensation)</i>	Similar to compensation, except the person usually develops the exact opposite trait.	1. The small boy who wants to be a basketball center becomes a political voice to decrease the emphasis of sports in the elementary grades. 2. The physically unattractive person who wants to be a model speaks out for eliminating beauty pageants.
<i>Regression</i>	Emotionally returning to an earlier time in life when patient experienced far less stress. Commonly seen in patients while hospitalized. NOTE: Everyone will not go back to the same developmental age. This is highly individualized.	1. Children who are toilet trained beginning to wet themselves. 2. Adults who may start crying and have a "temper tantrum."
<i>Projection (scapegoating)</i>	Blaming others. A mental or verbal "finger-pointing" at another for patient's own problem. Memory tool: Think of a projector at the movie theater. It "points" the images of the film onto the screen just as a person using this defense mechanism "points" blame on another person or situation.	1. "I didn't get the promotion because you don't like me." 2. "I'm overweight because you make me nervous."
<i>Displacement (transference)</i>	The "kick-the-dog syndrome." Transferring anger and hostility to another person or object that is perceived to be less powerful than yourself.	Parent loses job without notice; goes home and verbally abuses spouse, who unjustly punishes child, who slaps the dog.
<i>Restitution (undoing)</i>	Make amends for a behavior one thinks is unacceptable. Makes an attempt at reducing guilt.	1. Giving a treat to a child who is being punished for a wrongdoing. 2. The person who sees someone lose a wallet with a large amount of cash does not return the wallet, but puts extra in the collection plate at the next church service.
<i>Conversion reaction</i>	Anxiety is channeled into physical symptoms. NOTE: Often the symptoms disappear soon after the threat is over.	Nausea develops the night before a major exam, causing the person to miss the exam. Nausea may disappear soon after the scheduled test is finished.
<i>Avoidance</i>	Unconsciously staying away from events or situations that might open feelings of aggression or anxiety.	"I can't go to the class reunion tonight. I'm just so tired, I have to sleep."

Psychoanalysis

Psychoanalysis is the form of therapy that was developed from the theory of Sigmund Freud. In psychoanalysis the focus is on the cause of the problem, which is believed to be buried somewhere in the patient's unconscious. The therapist uses questioning and memory probing techniques to investigate the patient's past in an effort to determine where the problem began.

psychoanalysis: psycho—soul or mind + analysis—dissolving

Behavior Management

Behavior management (also called behavior modification) is a treatment method that is a result of the studies of behavioral theorists such as Skinner and Pavlov. It is a common treatment modality used in long-term care facilities and facilities that treat patients with alterations in mental health.

According to behavior management theory, behavior can be changed by either positive or negative reinforcement. Positive reinforcement is the act of rewarding the patient with something pleasant when the desired behavior

TABLE 55-3 MEDICATIONS USED FOR ALTERATIONS IN MENTAL HEALTH

Classification and Common Trade Names	Uses	Side Effects	Nursing Considerations	Patient Teaching
Antipsychotics chlorpromazine (Thorazine), haloperidol (Haldol), trifluoperazine (Stelazine), fluphenazine (Prolixin), clozapine (Clozaril), risperidone (Risperdal)	Treatment of schizophrenia and other psychotic behavior that is violent or potentially violent	Blood dyscrasias, photosensitivity Darkening of the skin Extrapyramidal side effects (EPSEs): parkinsonism, akathisia, dystonia, tardive dyskinesia	Observe for any signs of EPSEs. Monitor blood work for any kind of abnormality. Discontinue slowly. Antacids decrease absorption of antipsychotics.	These are very strong medications. Wear a large-rimmed hat, cover all exposed skin, and use a sunscreen when in the sun, especially if using chlorpromazine. Avoid alcohol, sleeping pills, and other medications. Do not alter dose before discussing it with the doctor. Take medication 1–2 hours before going to bed. Take antacids 1–2 hours after oral doses of antipsychotics.
Antianxiety Drugs alprazolam (Xanax), buspirone (BuSpar), diazepam (Valium), lorazepam (Ativan)	Decrease the effects of stress or mild depression without causing sedation	Can cause physical and psychological dependence, drowsiness, lethargy, fainting, transient hypotension, nausea, and vomiting; if discontinued abruptly, severe side effects, including nausea, hypotension, and fatal grand mal seizures	Administer intramuscular (IM) dosages deeply, slowly, and into large muscle masses. Z-track method of IM administration is preferred.	Teach the patient and family that it is not safe to drive or use alcohol while using this classification of medication.
Antidepressants amitriptyline (Elavil), perphenazine/amitriptyline (Triavil), imipramine (Tofranil), nortriptyline (Pamelor), paroxetine (Paxil), fluoxetine (Prozac), sertraline (Zoloft), amoxapine (Asendin), maprotiline (Ludiomil), tranylcypromine (Parnate), phenelzine (Nardil), isocarboxazid (Marplan)	Treatment of depression	Dependence, sedation, dry mouth, agitation, hypotension, vertigo, blood dyscrasias	Encourage patients to continue taking the medication during this time, because they may not feel any change in their mood for up to 3 weeks after starting medication.	Reinforce the teaching that these medications may take 2–3 weeks to reach a therapeutic level and provide the desired effect for the patient. See Nutrition 1 Notes Box 55–2.
Stimulants phenylpropanolamine (Acutrim, Dexatrim), dextroamphetamine (Dexedrine), methylphenidate (Ritalin)	Promotes alertness, diminishes appetite, combats narcolepsy, local anesthesia	Rapid or irregular heart rates, hypertension, hyperactivity, hand tremor, rapid speech, confusion, depression, seizures, suicidal thoughts, psychological dependence	Physical or psychological dependence, especially with long-term use. Patients with diabetes should be informed that amphetamines can cause changes in their insulin requirements. Can also cause changes in judgment; people should use extreme caution when driving or operating equipment, and should avoid these activities if possible.	Patients with diabetes should monitor insulin carefully and inform the doctor of any changes. Use extreme caution when driving or operating equipment, and avoid these activities if possible. Do not stop medication without consulting doctor. Use plain water to rinse mouth or use hard, sugarless candy to relieve dry mouth.
Antiparkinsonism Agents benzotropine (Cogentin), trihexyphenidyl (Artane), biperiden (Akineton)	Decrease the effects of drug-induced and non-drug-induced symptoms of parkinsonism	Blurred vision, dry mouth, dizziness, drowsiness, confusion, tachycardia, urinary retention, constipation, changes in blood pressure, and melanoma	They should be avoided in children under 12 years old. Monitor blood pressure carefully (at least every 4 hours when beginning the course of treatment).	Use hard, sugarless candy to combat the effects of dry mouth. Increase dietary roughage to maintain bowel functioning. May cause drowsiness, so should not drive or operate equipment until the response to medication is established.

BOX 55-3

Nutrition Notes

Anticipating Food-Drug Interactions in Patients with Mental Health Disorders

Monoamine Oxidase Inhibitors. Some antidepressant drugs (e.g., phenelzine, tranylcypromine) are monoamine oxidase inhibitors (MAO inhibitors). These drugs counteract depression by preventing the breakdown of dopamine and tyramine, an intermediate product in the conversion of tyrosine to epinephrine. The increased concentration of these chemicals in the central nervous system elevates the patient's mood.

When a patient taking an MAO inhibitor consumes foods high in tyramine, the drug prevents the normal breakdown of tyramine, leading to excessive epinephrine. Hypertension results, sometimes severe enough to cause intracranial hemorrhage. Some other drugs (e.g., furazolidone, isoniazid, procarbazine, selegiline) produce similar reactions with tyramine-containing foods.

All food groups except breads and cereals have some items with sufficient tyramine to be create problems for patients taking MAO inhibitors. Examples of common foods to be avoided are bananas, aged cheese, yogurt, bologna, salami, pepperoni, summer sausage, chocolate, beer, and wine.

Lithium Carbonate. Lithium carbonate, used to treat bipolar disorder, is absorbed, distributed, and excreted alongside sodium. Fluctuations in sodium intake affect the metabolism of lithium. Thus decreased sodium intake with decreased fluid intake may lead to retention of lithium and overmedication. Increased sodium intake from food or medications and increased fluid intake may hasten excretion of lithium, resulting in worsening signs and symptoms of mania.

has been performed. For instance, if Mrs. Powell has the habit of using foul language in an attempt to have a need met, the desired behavior change might be to come to a staff member and ask quietly for what she needs. Mrs. Powell loves to be outside but is not allowed out except at supervised times. A suitable positive reinforcement for her might be to allow 15 more minutes outdoors when she remembers to come ask for her needs quietly.

Negative reinforcement is the act of responding to the undesired behavior by taking away a privilege or adding a responsibility. Negative reinforcement can be misinterpreted as punishment. Parents who “ground” their children for unacceptable behavior are using negative reinforcement; requiring the child to perform extra household tasks for a stated period is reinforcing the fact that the behavior has consequences. The child may not repeat the undesired behavior after negative reinforcement has been used. It is necessary to be very careful when performing behavior management with patients to avoid an infraction of the Patient's Bill of Rights. A signed consent from the patient is advised when using this form of therapy.

The patient must understand the consequences of the behavior to be changed and the purpose for the type of consequence that is chosen. If the person is not capable of understanding the situation or is not able to remember the consequences because of some other problem, behavior management could be considered a questionable alternative to other kinds of treatment.

Cognitive Therapies

RATIONAL-EMOTIVE THERAPY. Dr. Albert Ellis and other cognitive therapists believe that people teach themselves to be ill because of the way they think about their situations. Cognitive (or cognitive/behavioral) therapy stresses ways of rethinking situations. The therapist confronts the patient with certain behaviors and then works out ways of thinking about them differently.

Feeling sad about an unpleasant experience (such as the death of a loved one) is acceptable and normal, but long-term depression about the death is an extreme emotion and therefore considered to be unhealthy. In this situation the patient might be helped to see the death as a sad loss, but extreme, long-term depression would be viewed as an inappropriate response.

Cognitive therapies are gaining in popularity because they are usually significantly more short term than psychoanalysis and therefore less costly to the patient. It is commonly performed in groups. The patients are given “homework” that is specific to their needs. Patients practice their assignments between sessions.

Person-Centered/Humanistic Therapy

Abraham Maslow and Carl Rogers are two theorists who are often credited with the concept of person-centered or humanistic therapy. In this form of treatment, caregivers focus on the whole person and work in the “present.” It is not important in humanistic treatment to understand the cause of the problem or what happened in the person's past; what is important is the here and now. With this therapy the patient learns to see himself or herself as a person who has value and who is respected by others.

Nursing is very strongly centered in person-centered principles. Three qualities are essential for caregivers: empathy, which is the ability to identify with the patient's feelings without actually experiencing them with the patient; unconditional positive regard (respect); and genuineness or honesty. Although you may not be an active participant in the actual therapy sessions with patients, it is important to maintain these three qualities in all therapeutic relationships.

Counseling

Counseling is the provision of help or guidance by a health care professional. The area of counseling is licensed and regulated differently not only state by state but sometimes municipality by municipality. Nurses prepared at an LPN/LVN level or at an RN level can, in some areas and with special advanced education, practice some forms of counseling.

You may be asked or expected to accompany patients to counseling sessions or even to facilitate a group discussion. Remember that these are confidential sessions, even if they are group oriented. Patients are there to work; others are there by invitation for special reasons.

Group Therapy

Groups are formed for many reasons; they can be ongoing or short term, depending on the needs of the patients or the

type of disorder. For example, Alcoholics Anonymous (AA) and similar 12-step self-help groups are well-established, ongoing groups formed around treatment of a specific problem. Family counseling sessions may occur with individual therapists with a specialty in the problem area for that family. Marriage counseling may be done in a group with other couples. Many times, peer counselors are used.

Therapists and counselors are tools, or facilitators, in the therapeutic process. They do not heal the patient; the patient heals himself or herself. Patients must take the suggestions given by the therapist, try them, and see what works for them. You can help by reinforcing the good work patients do in learning to stay mentally healthy and develop more effective life skills.

Electroconvulsive Therapy

Electroconvulsive therapy (ECT), sometimes called electroshock therapy (EST), is another form of treatment that is used in special situations. Some experts believe ECT works because it breaks up thought patterns in the brain, helping people to forget painful past experiences. Others believe it stimulates increases in the neurotransmitters serotonin, neorpinephrine, and dopamine. ECT is very frightening to some people. Many changes have been made in this form of therapy since the 1940s to make it safer for the patient.

ECT often takes place in the recovery room of an operating suite, where there is ready access to emergency equipment. Written consent is required. Patients are given a short-acting anesthetic before the treatment and a smooth muscle relaxant to minimize injury. Patients are secured with restraints during the treatment, so movement is minimal. Carefully monitor blood pressure and pulse before and after the treatment. During treatment, an electric stimulus is delivered to the brain via electrodes. The amount of electrical energy used is individualized to the patient. A treatment usually lasts only a few seconds, and if you are slow to look, you might miss seeing any kind of seizure activity (convulsion). Often, because of the medications given, only a toe or a finger twitches slightly.

Side effects of ECT can be unpleasant. The patient may feel confused and forgetful immediately after the treatment. This can be from a combination of the ECT itself and the medication that was used before the treatment. If there has been a strong seizure, the patient may have some muscle soreness.

Electroconvulsive therapy is not used indiscriminately. It is used when other therapies have not been helpful, and it is usually reserved for severe or long-term depression and certain types of schizophrenia (Patient Perspective Box 55-4).

The nurse's responsibilities include careful monitoring of vital signs and accurate documentation relating to the patient's subjective and objective responses to the treatment. The patient should receive nothing by mouth (NPO) for at least 4 hours before a treatment. Remind the patient to empty his or her bladder and to remove dentures, contact lenses, hair pins, and so on. Because of the possibility of

BOX 55-4 Patient Perspective

My mom is now 83 and has had a total of 35 electroconvulsive therapy (ECT) treatments in her lifetime. If you met her, you'd never know; you'd find her delightful. She's a sweet little plump German lady with a big heart. I am a nurse, and when I tell fellow nurses about my mom, they often ask me why I didn't get her on antidepressants. I want to scream, "How dumb do you think I am?!" Of course Mom is on antidepressants. But at intervals they don't work and she sinks into severe depression. My choice then is to help her have ECT or let her stay depressed and miserable and put her in a nursing home. And she would soon die, because when she is depressed she refuses to move, doesn't sleep, and is horribly miserable.

The first time my mom was scheduled for ECT, one of the nurses in our local community hospital told her to refuse it, that no one should have to go through that. It was a cruel thing to do. My mom doesn't do well in counseling—she doesn't believe in it. In her mind you don't talk about your "dirty linen." My mom was in an abusive relationship with my father for 47 years, and she hid all the problems away and doesn't talk about them to this day. I'm so grateful to have my mom doing okay and grateful that ECT treatments exist. With ECT my mother is doing well and enjoying life. Without treatment she would be gone. Please understand that there are times when ECT treatments are the best thing for severely depressed people, when other treatments have been ineffective.

confusion and forgetfulness, it is common to restrict activity for 24 hours after a treatment. Stay with the patient until he or she is oriented and able to care for himself or herself. Ensuring that the person is kept safe after therapy is a major concern.

Relaxation Therapy

A variety of relaxation techniques can be taught to help patients manage their responses to stress. Relaxation exercises such as deep, rhythmic breathing can increase oxygenation and provide distraction from stressors. Breathing exercises may be coupled with progressive muscle relaxation exercises. For this technique, patients are taught to start at the head and neck and systematically tense and then relax muscle groups as they progress toward the lower extremities. Soft music may enhance the patient's ability to fully relax.

Imagery is the use of the imagination to promote relaxation. For this technique, the patient is taught to imagine a pleasurable experience from his or her past, such as lying on a beach or soaking in a warm bath. Use of all senses is encouraged—for a beach image, the patient might see the beach, feel the warm sun, smell the salt air, and hear the waves crashing against the shore. The patient might also be taught to visualize being successful in a problem situation.

Biofeedback uses computerized or other instruments to provide feedback about the patient's degree of relaxation. Heart rate, skin temperature, and muscle tension might be measured; the patient is taught by a specialist to control these variables with a variety of relaxation techniques.

Relaxation techniques may be used individually, but they are often used in combination with each other or with other therapies for maximum effect.

► MENTAL HEALTH DISORDERS

Anxiety Disorders

Stress is everywhere in our society. Stress produces anxiety. Most often, stress is associated with negative situations, but the good things that happen to us, such as weddings and job promotions, also produce stress. The stress from positive experiences is called **eustress**. Eustress can produce just as much anxiety as the negative stressors. A stressor is any person or situation that produces an anxiety response. Stress and stressors are different for each person; therefore it is important to ask patients what their personal stress producers are.

Anxiety is the uncomfortable feeling of dread that occurs in response to extreme or prolonged periods of stress. It is commonly ranked as mild, moderate, severe, or panic. It is believed that a mild amount of anxiety is a normal part of being human and that mild anxiety is necessary to change and develop new ways of coping with stress.

Anxiety may also be influenced by one's culture. It may be acceptable for some people to acknowledge and discuss stress, but others may believe that one does not discuss personal problems with others. This cultural behavior can be a challenge for the nurse during an assessment.

Anxiety is usually referred to as either free-floating anxiety or signal anxiety. Free-floating anxiety is described as a general feeling of impending doom. The person cannot pinpoint the cause but might say something like "I just know something bad is going to happen if I go on vacation." Sig-

nal anxiety, on the other hand, is an uncomfortable response to a known stressor ("Finals are only a week away and I've got that nausea again.") Both types of anxiety are involved in the various anxiety disorders.

Etiologic Theories

Psychoanalytical theory says that anxiety is a conflict between the id (the "all for me" part of the personality) and the superego (the conscience), which was repressed in early development but emerges again in adulthood.

Biologic theory looks at this situation differently. Biologic theories consider the sympathoadrenal (fight-or-flight) responses to stress and observe that the blood vessels constrict because epinephrine and norepinephrine have been released, causing blood pressure to rise. If the body adapts to the stress, hormone levels adjust to compensate for the epinephrine-norepinephrine release and body functions return to homeostasis. If the body does not adapt to the stress, the immune system is challenged, lymph nodes swell, and risk for physical illness increases.

The LPN/LVN usually observes mental illness in conjunction with medical-surgical illness. It is important to recognize the relationship between physical and emotional responses to stress. Some examples of medical conditions and the effects of the body's adaptation response to stress are shown in Table 55-4.

Differential Diagnosis

Because there are so many symptoms associated with anxiety disorders, it is important for people to have a complete physical examination before diagnosing an anxiety disorder. More than one condition may occur at the same time.

eustress: eu—normal or good + stress

TABLE 55-4 ADAPTATION RESPONSES TO STRESS

Stress-related Medical Condition	Body's Adaptation to the Stress	Outcome of Stress on the Body
Lowered immunity	Interferes with effectiveness of the body's antibodies; possibly related to interactions among the hypothalamus, pituitary gland, adrenal glands, and immune system	Increased susceptibility to colds and other viruses and illnesses
Burnout	Associated with stress-related depression	Emotional detachment
Migraine, cluster, and tension headaches	Tightening skeletal muscles, dilating of cranial arteries	Nausea, vomiting, tight feeling in or around head and shoulders, tinnitus, inability to tolerate light, weakness of a limb
Stress (peptic) ulcers	Stress contributes to the formation of ulcers by stimulating the vagus nerve and ultimately leading to hypersecretion of hydrochloric acid	Nausea, vomiting, gastrointestinal bleeding, perforation of intestinal walls
Hypertension	Role of stress not positively known; thought to contribute to hypertension by negatively interacting with the kidneys, autonomic nervous system, and endocrine system	Resistance to blood flow through the cardiovascular system, causing pressure on the arteries; can lead to stroke, heart attack, and kidney failure
Coronary artery disease	Stressor increases the amount of epinephrine and norepinephrine	Coronary vessels dilate, pulse and respirations increase
Cancer	Stress lowers immune response	Lowered immunity may allow for overcolonization of opportunistic cancer cells
Asthma	Autonomic nervous system stimulates mucus, increases blood flow, and constricts bronchial tubes; may be associated with other stress-related conditions such as allergy and viral infection	Wheezing, coughing, dyspnea, apprehension; may lead to respiratory infections, respiratory failure, or pneumothorax

Types of Anxiety Disorders

PHOBIA. Phobia is the most common of the anxiety disorders. Phobia is defined as an irrational fear of a specific object or situation. The person is very aware of the fear and even the fact that it is irrational, but the person is unable to gain control over the stressor and the fear continues.

The psychoanalytical view implies that it really is not the object that is the source of the fear, but rather the fear is a result of a defense mechanism called **displacement**. For example, the person with a phobia of snakes may have seen a frightening movie in which someone died from a snakebite. The stated object of the phobia would be interpreted as a symbol for the underlying cause of the fear.

PANIC DISORDER. Panic is a state of extreme fear that cannot be controlled. It is also referred to as panic attack, and lay people may not consider it to be a serious disorder.

Panic episodes present quickly. Patients must exhibit several episodes within a specified time frame to be given the diagnosis of panic disorder. Some of the symptoms associated with panic disorder include the following:

- Fear (usually of dying, losing control of self, or “going crazy”)
- Dissociation (feeling that it is happening to someone else or not happening at all)
- Nausea
- Diaphoresis
- Chest pain
- Increased pulse
- Shaking

GENERALIZED ANXIETY DISORDER. In generalized anxiety disorder (GAD) the anxiety itself (also referred to as excessive worry or severe stress) is the expressed symptom. Symptoms that may be present in GAD include the following:

- Restlessness or feeling “on edge”
- Shaking
- Palpitations
- Dry mouth
- Nausea, vomiting
- Easy frightening
- Hot flashes
- Chills
- Polyuria
- Difficulty swallowing

OBSSIVE-COMPULSIVE DISORDER. Obsessive-compulsive disorder (OCD) is a different type of anxiety disorder. It consists of two parts: **obsession** (repetitive thought, urge, or emotion) and **compulsion** (repetitive act that may appear purposeful). An example of obsessive-compulsive disorder is the need to check that the doors are locked numerous times before one is able to sleep or leave the house. In reality, this need to repetitively check the locks may prevent the person from sleeping or leaving at all. Behaviors become very ritualistic. The person with OCD is unable to stop the thought or the action. Performing the thought or the action is the mechanism that reduces the anxiety.

POSTTRAUMATIC STRESS DISORDER. Posttraumatic stress disorder (PTSD) develops in response to some unexpected emotional or physical trauma that could not be controlled. People who have fought in wars, who have been raped, or who have survived violent storms or violent acts (such as the Oklahoma Federal Building bombing in 1995) are examples of those who are susceptible to suffering from this disorder.

A condition that is associated with PTSD is survivor guilt. This is the feeling of guilt expressed by those who survived. A survivor of an airline crash may say, “Why me? Why did I make it? I should have died too!”

Symptoms may appear immediately or may be repressed until years later. Symptoms include the following:

- Flashbacks in which the person may relive and act out the traumatic event
- Social withdrawal
- Feelings of low self-esteem
- Changes in relationships with significant others
- Difficulty forming new relationships
- Irritability and outbursts of anger seemingly for no obvious reason
- Depression
- Chemical dependency

Medical Treatment for Patients with Anxiety Disorders

Treatment is individualized for the patient and may include one or more of the following: psychopharmacology, individual psychotherapy, group therapy, systematic desensitization, hypnosis, imagery, relaxation exercises, and biofeedback.

Psychopharmacology usually involves the antianxiety classification of medications. The benzodiazepines, such as diazepam (Valium) and alprazolam (Xanax), are commonly used and are effective in most cases. Use of antianxiety drugs is short term whenever possible because of the strong potential for chemical dependency. Individuals who have anxiety disorders and who are chemically dependent on other substances are managed with other medications that have calming qualities but do not have the same high potential for **addiction** as the antianxiety drugs. Hydroxyzine hydrochloride (Atarax), clonidine (Catapres), and sertraline (Zoloft) are common alternatives in this situation.²

In systematic desensitization, the patient is gradually exposed to the object that causes the anxiety. Hypnosis places the patient in a subconscious state, then helps the patient recall events that may be producing anxiety so they can be dealt with. Other therapies were discussed earlier.

Nursing Interventions for Patients with Anxiety Disorders

1. Maintain a calm milieu.
2. Maintain open communication. Encourage the patient to verbalize thoughts and feelings. Honesty in dealing with patients helps them learn to trust others and enhances their self-esteem. Observe nonverbal communication.

3. Observe for signs of suicidal thoughts.
4. Report and document any changes in behavior. Any change can be significant to that patient's care. Positive or negative alterations in the way a patient responds to the nursing staff, to the treatment plan, or to other people and situations should be reported.
5. Encourage activities. Activities that are enjoyable and nonstressful provide diversion and give staff an opportunity to provide positive feedback about the progress the patient is making. The patient should not be put in a competitive situation.

CRITICAL THINKING

Tommy
Tommy has come to your clinic with numerous cracks on his hands. They are bleeding and very sore. Tommy tells you that he has to wash his hands all the time. His mother says he washes for 2 to 3 hours at a time and he will not stop when she tells him to. The doctor has diagnosed Tommy with obsessive-compulsive disorder and has explained the illness to Tommy and his mother. When the doctor leaves the room, Tommy's mother begins to cry. "What did he just say? What am I supposed to do? What did I do wrong that Tommy got this illness?" How do you respond?

Answers at end of chapter.

Mood Disorders

Mood disorders (also called affective disorders) are disorders in which the major symptom is extreme changes in mood (emotions) and affect (the outward expression of the mood). Sadness becomes depression when it lasts a very long time (generally 2 years or more) or when it begins to interfere with normal day-to-day functioning. People of all age groups and all ethnic and socioeconomic groups can develop mood disorders.

Etiologic Theories

Psychoanalytical theory indicates that people who have suffered loss in their lives are at risk for developing depression. Depression is also associated with unresolved anger and has been explained as "anger turned inward." In other words, people who cannot or do not deal appropriately with situations that anger them tend to repress the anger (turn it inside) and become depressed.

Cognitive theorists believe that the way people perceive events and situations may lead to depression. Instead of thinking about failing an exam as being unfortunate and disappointing, some people with tendencies toward depression may exaggerate the emotion and turn the situation into something much deeper, such as thoughts of "I'm stupid" or "I'll never get anywhere."

Biologic theories offer genetic links and neurochemical interactions as two etiologies. Serotonin and norepinephrine have an effect on mood; if these neurochemicals are el-

evated, mood is elevated, and if they are low, mood is low. Biologic theorists also believe that there is a connection between these neurochemicals and female hormones.

Differential Diagnosis

Symptoms of depression may occur as a result of other disorders, such as schizophrenia or drug side effects or overuse. Symptoms can mimic heart failure, nutritional deficiencies, fluid and electrolyte imbalances, infections, or diabetes.

Types of Mood Disorders

MAJOR (UNIPOLAR) DEPRESSION. People who develop major depression exhibit a vast array of symptoms. Some behavioral and physical symptoms of major depression include the following:

- Sad mood
- Loss of pleasure in things that are usually pleasurable
- **Hallucinations or delusions** (possible but uncommon)
- Weight loss or gain resulting from changes in appetite
- Sleep pattern disturbances
- Increased fatigue
- Increased agitation
- Increase or decrease in normal activity
- Lowered pleasure for life, including sexual activity
- Social withdrawal
- Decreased ability to think, remember, or concentrate
- Suicidal thoughts.

BIPOLAR DEPRESSION. Approximately 2 million people in the United States suffer from **bipolar** depression. Bipolar depression (also called manic-depressive illness or bipolar disorder) is a type of depression with both **mania** (extreme elation or agitation) and extreme depression. The mania is part of the depression. Think of a color you like. Now think of all the shades of that color from the very palest shade to the brightest shade (like the color cards that you can get in paint stores). Both extremes of color are very different, but both are still part of the same color. This is one way to remember that mania and depression are opposite poles of the same illness. It takes only one episode of mania to be diagnosed with bipolar disorder, but it is more common to see the patient alternating, or cycling, from one "pole" to the other. Individuals can cycle slowly (over weeks or months or even years), or they can be "rapid cyclers" who can change moods several times in an hour.

Common signs of depression were covered in the preceding section. Common signs of mania include the following:

- Excessive high (euphoric) moods
- Sustained period of behavior that is different from usual
- Increased energy, activity, restlessness, racing thoughts, and rapid talking
- Decreased need for sleep
- Unrealistic beliefs in one's abilities and powers
- Extreme irritability and distractibility
- Uncharacteristically poor judgment
- Increased sexual drive

- Abuse of drugs, particularly cocaine, alcohol, and sleeping medications
- Obnoxious, provocative, or intrusive behavior
- Denial that anything is wrong.

Medical Treatment for Patients with Mood Disorders

With treatment, it is estimated that approximately 80 percent of people with serious depression can be helped in a matter of a few weeks. Some common medical treatments for depression include the following:

- Lithium
- Antidepressants
- Psychotherapy
- Electroconvulsive therapy.

Lithium is the drug of choice in most instances for the treatment of bipolar depression. Antidepressants such as amitriptyline (Elavil), fluoxetine hydrochloride (Prozac), and trazodone hydrochloride (Desyrel) and antianxiety drugs such as lorazepam (Ativan) may also be used.

Psychotherapy for the patient and family may be helpful in understanding the illness and learning problem solving and other new adaptive coping behaviors. For young children, play therapy is the most common and effective form of therapy. Electroconvulsive therapy is an option when other therapy is not effective.

Nursing Interventions for Patients with Mood Disorders

- Be patient! The patient moves and thinks more slowly when depressed.
- Monitor lithium levels. Normal range of lithium is 1.0 to 1.5 mEq/L when receiving loading doses and 0.6 to 1.2 mEq/L when on maintenance doses.
- Be honest in communicating thoughts and feelings with the patient.
- Be consistent in communication and in all areas of implementation of the care plan.
- Provide appropriate activities. Activity needs to be planned carefully and should be age appropriate. Activity that includes small groups can be helpful for building esteem. Activities that can be done alone are helpful when it is necessary to decrease stimulation.
- Maintain nutrition. Physical health is important for mental health. The dietitian may be consulted for assistance.
- Use therapeutic communication and active listening. This is not a time for false reassurance. Do not use phrases such as “Cheer up!” or “It could be worse!” Making an observation such as “I like the way you look in that blue outfit. Is it new?” may go further in helping the person improve self-esteem than “Cheer up!” (See Gerontological Issues Box 55-5 for interventions for older adults who are suicidal.)
- Ensure that a referral to a community support agency is made for long-term follow-up.

BOX 55-5 GERONTOLOGICAL ISSUES

Suicide and the Older Adult

Older adults are not immune to suicidal thoughts. White males over the age of 75 have an especially high suicide rate.

Comments by any older adult referring to hopelessness or desire to die must be explored to assess suicide risk. The following comments could be a reflection of suicide potential in an older adult who is depressed:

- “Living is harder than dying could ever be.”
- “I am a used-up old man who is a burden for everyone.”
- “I am useless. I can’t do anything anymore.”
- “I don’t know why God won’t take me.”

To adequately assess suicide potential, the nurse must ask questions that establish whether the older adult has done the following:

- Thought about ending his or her life
- Attempted to end his or her life in the past
- Developed a plan to end his or her life
- Set the plan into action (i.e., bought a gun, has a full bottle of pills in the bed stand)

Any older adult who has a plan to end his or her life and has the ability or resources to do so must be immediately referred for psychological evaluation. Never leave a person with suicidal thoughts alone.

Crisis Intervention for an Older Adult Who Is Suicidal

- Remove any items that the older adult could use to inflict an injury or end his or her life, such as razors, jewelry with pins or sharp points, and mirrors.
- Make arrangements for direct supervision and observation that are reliable, considering personnel and family resources. Often, hospital admission is the most appropriate intervention for a person at a very high risk for suicide.
- Help the older adult talk about the crisis or life event that has devastated his or her desire to live. For example, encourage reminiscence about the patient’s spouse, or allow the older person to express the frustration of being unable to physically meet the daily demands of life.
- Develop a “do no harm” or suicide contract with the older adult. Outline a short-term, structured plan to keep the older adult safe. Focus on decreasing social isolation by requiring personal social contacts (e.g., stay at daughter’s home for a weekend; go to the senior center for lunch; call a specific person who is willing and wants to listen to feelings and concerns; exercise; take a walk outside; volunteer services at a nursing home, hospital, or school).

Older adults often need assistance to develop or enhance skills required to cope with life events. Self-care and personal independence in care choices need to be encouraged. Developing an understanding and a manner of avoiding personal thinking patterns and behaviors that increase depression are important skills to learn as part of managing depression.

CRITICAL THINKING

Mr. Zenz

Mr. Zenz is the manager of a busy office/clinic. His usual behavior is rather sullen and comes across as “quiet” or “sad” to various members of the staff. He is a man in his 40s, married, with three children ages 4, 5, and 7. He speaks of them proudly but always comments that they “take after their mother.” His management style in the office is to let people do their jobs; he rarely interferes, although his door is always open and staff members are told they are welcome any time. Recently, however, staff members are noticing a change in Mr. Zenz. He moves quickly, speaks quickly, and has set grandiose goals for the staff. He says he has not slept in several days and he feels terrific. He has changed his wardrobe and has begun pointing out specific performance issues to staff. He jokes with staff. Staff is made aware that he has “bipolar disorder” and has quit taking his medications. His wife has asked for the staff’s help. Remember: He is your boss. How do you respond to Mrs. Zenz? How do you approach him?

Answers at end of chapter.

Somatoform/Psychosomatic Disorders

The **somatoform** (or **psychosomatic**) disorders are conditions in which physical symptoms occur with no known organic cause. It is believed that the physical symptoms are connected to a psychological conflict. Because the patient is not able to control the symptoms, they are considered to be caused by some unconscious mechanism.

Etiologic Theories

Psychoanalytical theorists believe that the somatoform disorders are rooted in unconscious mechanisms that develop to deny, repress, and displace anxiety. Biologically there is research into the possibility of a genetic predisposition to somatic difficulties.

Types of Somatoform Disorders

There are five separate illnesses within the category of somatoform disorders and two additional illnesses that are closely related. These include **conversion disorder**, hypochondriasis, dysmorphophobia/body dysmorphic disorder, somatization disorder, and somatoform pain disorder. Discussion of all these disorders is beyond the scope of this book. This chapter gives a brief explanation of conversion disorder.

CONVERSION DISORDER. Conversion disorder is an illness that emerges from overuse of the conversion reaction defense mechanism. (See Table 55–2.) In conversion disorder there is a loss or decrease in physical functioning that seems to have a neurological connection. Paralysis and blindness are two common examples of this disorder. Age of onset is usually adolescence and young adulthood, but it can occur later in life as well.

The symptoms, although not caused by organic disease, are very real to the patient. It should not be conveyed to the

patient that you think the person is “faking” the illness; this is not true. Patients are truly experiencing the symptoms.

The belief about this disorder is that the symptom is allowing the person to avoid some situation that is unacceptable to him or her. The symptom helps the patient relieve the anxiety. This is called primary gain. Secondary gain results from the extra benefits one may acquire as a result of staying ill, such as extra emotional support, sympathy, love, or financial benefits.

Medical Treatment for Patients with Somatoform Disorders

Because of the physical symptoms, hospitalized patients are usually admitted to a medical unit rather than a psychiatric unit. Treatment is individualized for the patient. Hypnosis and relaxation techniques are used with many patients. Methods of stress management are taught. Behavior management may be effective for some patients. Patients may resist accepting the fact that their problem is psychological or emotional in nature and may feel insulted and become resistant to treatment.

Medications are used sparingly. When they are ordered for a patient, the classifications of choice are usually antidepressants, antianxiety agents, or both.

Nursing Management for Patients with Somatoform Disorders

Nursing management for somatoform disorders includes the following:

- Skillful communication. Honesty and gaining trust encourage the patient to verbalize thoughts and feelings about the physical and emotional aspects of this disorder. An example of a way to be honest about the situation would be to reinforce what the physician has said to the patient, such as, “Ms. Parks, your doctor can find no physical or life-threatening conditions at this time. We will continue to observe and examine you. We will make every attempt to help you improve.” Sometimes the practitioner helps the patient find a healthy behavior to substitute for the symptom.
- Therapy. Keeping the patient focused on other topics may help in the recovery.
- Support. When caring for the patient with a somatoform disorder, you must pay attention to the person but must not reinforce the symptom. A thorough head-to-toe assessment should always be done. The patient will see your concern for his or her health, but you will not be focusing on the area of dysfunction or reinforcing the problem. All findings should be documented objectively.

Schizophrenia

Schizophrenia is becoming more widely viewed as a group of illnesses rather than a single condition. It most often strikes adolescents and young adults. The National Institute of Mental Health estimates that nearly 3 million persons in the United States will develop schizophrenia during the course of their lives.

The term *schizophrenia* (which means “split mind”) was first used by a Swiss psychiatrist, Eugene Bleuler.³ Schizophrenia is a serious psychiatric disorder. People who have schizophrenia have a split between their thoughts and their feelings and between their reality and society’s reality. The person may have splits concerning gender identity. People who have schizophrenia may not be able to differentiate between what is “theirs” and what is “everybody else’s” in relation to social functioning. Poor self-esteem may be an issue. People with schizophrenia are generally highly intelligent and seem very distractible. It is difficult for them to focus on one topic for any length of time. Schizophrenia is not the same thing as multiple personality disorder.

Schizophrenia has an insidious onset. This means that it develops over time, and symptoms may go unnoticed for a time prior to diagnosis. The early symptoms of quietness and withdrawal in an adolescent person may be shrugged off as normal adolescent behavior. It may be a school nurse or counselor who begins to notice these changes. Grades may begin to suffer. The adolescent may have a change in personality or a change in the way he or she relates to other people. It is easy to misinterpret these new behaviors as part of the adolescent experience.

Eugene Bleuler used a system of four As to define schizophrenia. The four As are associative disturbance, affect, autism, and ambivalence, discussed next.

Associative Disturbance

A patient with associative disturbance (also referred to as associative looseness) typically exhibits three main behaviors: (1) making up words (neologisms); (2) rambling from topic to topic; and (3) using revolving words and syllables that may be associated with a specific word but that are out of context with the conversation. Making up words that rhyme with other words is another behavior that is sometimes observed.

Affect

Affect, as discussed earlier, is the outward expression of emotion. People with schizophrenia generally have what is called a “flat” or “blunted” affect. This means that they rarely show signs of any emotion.

In schizophrenia there may also be inappropriate or incongruent affect. This means the outward expression of the mood does not match the stated feeling (e.g., patients laughing when they say they feel sad or depressed). Exaggerations of affect may also be present in some patients.

Autism

Autism associated with schizophrenia is an emotional detachment. People who display autistic behavior are preoccupied with the self and show little concern for any reality outside their own world.

Ambivalence

Ambivalence means to have opposite feelings about a person or situation at the same time. An example of this is the love/hate relationships sometimes seen in jobs or marriages.

(Caution: Not all people who have love/hate relationships are schizophrenic.)

In addition to the four As, patients with schizophrenia display other common symptoms, such as delusions, hallucinations, and **illusions**. Delusions are fixed, false beliefs that cannot be changed by logic or factual proof. Typically patients exhibit delusions of grandeur, persecutory delusions, or guilt. Hallucinations are false sensory perceptions. They can affect any of the five senses; auditory and visual are most common. Illusions are mistaken perceptions of reality.

Hallucinations and illusions are easily confused. Anyone who has ever watched a magician or seen certain pictures in cloud formations has witnessed an illusion. In illusion, something is there; it is just perceived incorrectly. The card did not magically appear; it was set up to appear when the magician wanted it to. In hallucination there is nothing to misinterpret. The person who sees a lamb in a certain cloud formation is experiencing an illusion; the person who sees a lamb in the sky when there are no clouds is experiencing a hallucination.

Etiologic Theories

There are psychoanalytical and biologic theories of the causes of schizophrenia. The symptoms of schizophrenia are highly debated on both sides of the nature-versus-nurture theories.

The psychoanalytical, or nurture, theories revert to the anal stage of Freudian theory. The inability to meet the challenge of oral gratification leaves people in the adolescent and young adult years unable to handle their developing sexuality, according to Freud. Lack of nurturing mother-child relationships can also lead to personalities that are cool or aloof (or indifferent) in their relationships. Freud would also attribute the disruption of effective communication to failure to attain oral gratification.

The role of genetics in schizophrenia have been examined in twins studies, family studies, and adoption studies for more than 75 years. Studies of identical twins (the psychobiologic, or nature, theory) show that if one twin has schizophrenia, the other has about a 50-percent chance of developing it also. In fraternal twins that percentage drops to about 10 percent. It is believed that the more genes twins or family members have in common, the greater the probability of the second twin developing schizophrenia. Other studies have examined the relationship of dopamine and schizophrenia. Patients with schizophrenia generally have elevated amounts of dopamine or a brain that overreacts to the amount of dopamine that is present.

Types of Schizophrenia

There are several categories of schizophrenia. This chapter discusses only the most common: paranoid schizophrenia. Paranoid schizophrenia is defined as schizophrenia in which the person exhibits unusual suspiciousness and fear. People who have paranoid schizophrenia may also be hostile and aggressive in their behavior.

Patients with paranoid schizophrenia tend to have delusions of persecution or grandeur. In persecutory delusions,

patients state that they feel tormented and followed by people. Patients often integrate people around them into their delusions. These people could be staff, relatives, or the announcer on the radio or television. In delusions of grandeur, patients may state that they are God or the President of the United States.

Hallucinations often accompany delusions. The hallucinations can affect any of the five senses but are most commonly auditory or visual. Patients with paranoid schizophrenia speak about “the voices.” These voices are frightening and derogatory to the patient and are responsible for many of the actions performed by people with paranoid schizophrenia. Patients experience increased fear, anxiety, and suicidal ideation as a result of the voices. You may see or hear patients arguing with what at first appears to be themselves. Actually the patient is arguing with the voices. Describing the voices is difficult, but imagine that you are in a room with six televisions on different stations at the same time. This example comes close to what some patients have described as the voices.

Medical Treatment for Patients with Schizophrenia

Medications, ECT, and psychotherapy are indicated for patients with schizophrenia. Among the classifications of medications that may be prescribed for certain patients are the antipsychotics, which block dopamine action in the brain. Unfortunately, decreased dopamine action creates extrapyramidal (parkinsonian) side effects. Anticholinergic medications such as benztropine (Cogentin) or trihexyphenidyl (Artane) are used to combat the extrapyramidal side effects of the antipsychotics by helping return balance between dopamine, acetylcholine, and other neurotransmitters. Newer antipsychotic medications such as clozapine (Clozaril) and risperidone (Risperdal), with fewer side effects, have been developed specifically for use in schizophrenia.

Psychotherapy may include individual, group, and family therapy. Electroconvulsive therapy is used in some severe cases or in cases that are difficult to treat; ECT is usually not used until other methods of therapy have been exhausted.

Nursing Interventions for Patients with Schizophrenia

- Develop trust. It is crucial for a trusting relationship to exist between the nurse and the patient. Promises must be kept. Be honest and consistent in all areas of the patient’s treatment plan. Allow the patient to vent thoughts and feelings when appropriate to the time and place. Whenever possible, the same nurse should be assigned to the same patients to ensure the best possible continuity of care.
- Never whisper or laugh when the patient cannot hear the whole conversation. Face the patient when having a conversation, even a personal conversation. Turning away may be interpreted as rejection.

- Avoid placing the patient in situations of competition or embarrassment.
- Never reinforce hallucinations, delusions, or illusions. It is necessary to keep the patient in reality as you know it. Some examples of responses to patients who are hallucinating are listed in Table 55–5.
- Provide a therapeutic milieu. Structure the treatment setting in a way that promotes healthy behaviors and minimizes anxiety. Providing written instructions and information boards can help promote reality and self-responsible behavior.
- Keep communication simple. Be brief and clear with all directions. State what is acceptable; give the rationale and consequences at the same time. Stating information in positive rather than negative terms is also helpful; for example, “Eat your food calmly” rather than “Do not throw your food!”

CRITICAL THINKING

Anne

While preparing to invite Anne, a patient receiving chemotherapy on your oncology unit, to the movie in the day room, you observe her standing in the corner of her room trembling. You ask her what’s wrong and she responds that she’s talking to the woman in the wall. Your first instinct is to giggle, but you ask her, “What woman?” She tells you that you wouldn’t understand and says, “You helped put her there and you told me that it is my job to be sure the woman can’t get out.” You report this to the charge nurse, who calls the doctor. Tests are run, and it is determined that Anne is not experiencing side effects from the chemotherapy. Further workup delivers the diagnosis of paranoid-type schizophrenia for Anne. What responses are appropriate for the situation above? What special needs might Anne now experience relating to her chemotherapy, if any? How will you get Anne to the movie or to participate in other care activities?

Answers at end of chapter.

Substance Abuse Disorders

Alcoholism and chemical dependency are serious conditions. People start using alcohol and drugs for many reasons, but often it is to feel accepted by a peer group or to feel comfortable in a social situation. People mistake the temporary high as a stimulant. In reality, alcohol is a depressant. You must understand that any chemical can be potentially dangerous.

Physical **dependence** on a substance, **tolerance** (the ability to endure the effects of a drug or the need for increasing amounts of the drug to produce the high), and **withdrawal** (unpleasant physical, psychological, or cognitive effects that result from decreasing or stopping the use of the chemical after regular use) are characteristics of addiction. The general definitions of substance abuse and substance dependence apply to any substance. Substance dependence is a condition in which a person has had several (usually three) of the following symptoms for 1 month or longer:

TABLE 55-5 SUGGESTED INTERVENTIONS FOR PATIENTS WITH SCHIZOPHRENIA WHO ARE HALLUCINATING

Suggested Action	Rationale
1. “Mr. R., I don’t see any snakes. It is time for lunch. I will walk to the dining room with you.”	1. Lets the patient know you heard him, but brings him immediately into the reality of time of day and need to go to the dining room.
2. “I see a crack in the wall, Mr. R. It is harmless; you are safe. Susan is here to take you down to occupational therapy now.”	2. This is in response to a probable illusion. It lets the patient know that you see something. It validates his fear, but it tells him what you see and then moves him into the here and now.
3. “I know that your thoughts seem very real to you, Ms. C., but they do not seem logical to me. I would like for you to come to your room and get dressed now, please.”	3. Again, you are validating the patient’s concern without exploring and focusing on the delusion.
4. “Ms. C, it appears to me that you are listening to someone. Are you hearing voices other than mine?”	4. This is a method of validating your impression of what you see. This is as far as you will go into exploring what she may be hearing.
5. “Thank you, Ms. C. I want to help you focus away from the other voices. I am real; they are not. Please come with me to the reading room.”	5. Responds to her in the present and reinforces her response to you. Attempts to redirect her thinking.

- The patient needs more of the substance and at more frequent intervals to achieve the “high,” or the desired effect of the substance.
- The patient spends much time obtaining the substance.
- The patient gives up important social or professional functions to use the substance.
- The patient has tried at least once to quit but still obsesses about the substance.
- Misuse or withdrawal symptoms interfere with job, family, or social activities.
- The patient uses the substance regardless of the problems it causes.
- Tolerance increases greatly (by approximately 50 percent).
- The patient uses the substance to avoid withdrawal symptoms.

Substance abuse is defined differently than dependence and is often diagnosed by a rating system similar to the following:

- Mild—The person meets three of the above criteria, but social functioning is only minimally affected.
- Moderate—Symptoms are somewhere between mild and severe.
- Severe—The patient meets more than three of the above criteria, and social obligations are impaired.
- Partial remission—No substance use for more than 6 months; some symptoms have occurred.
- Full remission—No substance use for more than 6 months; no symptoms have occurred.

Not all patients who have a substance abuse disorder go through all stages, and not everyone goes through them in the same order.

Nurses need to be informed about chemical dependency for several reasons. First, many medical-surgical patients are chemically dependent. This affects their healing and the effect of their medications. Second, as part of the human ex-

perience, your chance of being in a close personal relationship with a person who is chemically dependent is great. Third, and perhaps most importantly, you are part of a profession whose members are statistically high users and abusers of drugs and alcohol (Ethical Considerations Box 55-6). Studies indicate that 10 to 20 percent of nurses in the United States will be chemically impaired at some point in their lifetime.⁴

Substance abuse is not a one-person illness; it affects personal and professional relationships with people who are associated with the user. The term **dysfunctional** is often used to refer to the relationships within an alcoholic family or work environment. Dishonesty and inability to discuss the situation are strong components of the disease. Many times, people who live or work in the dysfunctional group begin to cover up for the user’s behaviors and lack of responsibility. Family members or significant others often take sides, begin to be dishonest with each other, and erode the bond within that group. Eventually this leads to a condition called **codependence**, which can be as serious as the use and abuse of the substance. In codependence the significant others in the family group begin to lose their own sense of identity and purpose and exist solely for the abuser. Their actions take away the opportunity for the user to take responsibility for his or her own actions. This is called enabling.

Etiologic Theories

Why do some people become addicted or dependent and others do not? Can it be the chemical, or is it the person? Some theorists believe in the existence of an addictive personality, which may begin to explain addictions to food, sex, and gambling, as well as alcohol, chemicals, and other dependencies.

dysfunctional: dys—bad or difficult + functional—performance

BOX 55-6 ETHICAL CONSIDERATION

Ellen and Julie are LPNs who work on a busy medical unit in a large hospital. They were close friends in nursing school and have been working the night shift together for 3 years. Recently Ellen went through a difficult and painful divorce, and Julie has noticed that Ellen's personality has changed. Ellen, usually serious and almost compulsive in the completion of her work, has taken on a vary lackadaisical attitude, laughs or giggles at inappropriate times, and often calls in sick. She also displays hostility toward the hospital administration and seems very irritated when corrected. Julie has observed Ellen taking increasingly large doses of "nerve medication" and fears her friend is becoming a drug abuser.

One evening, Ellen arrives at work with glassy eyes and slurred speech. She asks Julie to watch her patients for her while she takes a little nap to "sleep it off." Julie asks Ellen if she is becoming a drug abuser, and after some initial denial, Ellen admits that she has been taking increasingly large doses of medication to continue functioning from day to day. Ellen pleads with Julie not to tell the head nurse or anyone else about the drug problem. Because of their friendship, Julie consents to cover for Ellen this night.

The next night, Ellen again comes to work with obvious signs of drug intoxication. She again asks Julie to cover for her, swearing that this would be the absolute last time it would happen. Ellen falls asleep while listening to the taped report for the change of shifts. What should Julie do?

The substance-abusing nurse is one of the most common situations nurses may encounter during their careers. It is estimated that about 40,000 nurses who work in the United States are alcoholics, and drug addiction among nurses is reported to be 30 to 100 times greater than among the general population. Nurses have easy access to drugs because they are usually responsible for obtaining and maintaining the supply of controlled drugs in a hospital. Other factors that contribute to the

increased drug abuse among nurses include job stress, short staffing, double shifts, unrealistic expectations, frustration and anxiety, personal problems, and lack of autonomy in practice.

Professional and emotional conflicts are felt by the drug-abusing nurse's colleagues, who must use their professional training as promoters of health to try to understand a nurse's abuse of drugs. Underlying the ethical dilemma is the right of the patient to safe and competent treatment versus the nurse's right to self-determination. However, the nurse does not have a totally unrestricted right to self-determination. This right has limits when it comes to endangering others, especially the patients assigned to this nurse for their care and safety. Although the National Association for Practical Nurse Education and Services (NAPNES) Code does not directly address any obligation to protect the public from practitioners who are unsafe, various elements that are related include faithfulness and responsibility with a general admonition to protect patients.

In this particular situation Julie does have an obligation to do something about Ellen's drug problem. Covering for Ellen will not solve the problem. The first thing to do is to get a second opinion about Ellen's drug problem and then to confront her. She can also file a report through the institution's chain of command to the unit manager and head nurse and finally the director of nursing. If the institution hierarchy does not take any action, the nurse should submit the report to the state board of nursing. This report should be well documented and signed, and it should include a request for confidentiality if the nurse submitting the report does not want to be known. To allow Ellen to practice while under the influence of drugs puts Julie in a very serious legal position. If Ellen were to do something wrong and harm a patient and Julie knew that Ellen was under the influence of drugs, Julie could be held liable under the law, depending on the state in which she is practicing.

Psychoanalytical theories state that people who develop addictions to alcohol or other substances are people who failed to successfully pass through the "oral" stage of development.

Biologic theories include numerous studies that imply that there is some sort of genetic metabolic disorder. Many of these studies were done on twins born to an alcoholic parent or parents and who were separated from the parents at birth or shortly after birth. The number of twins who were born of alcoholic parents but raised by nonalcoholic adoptive or foster parents and yet developed alcoholism was consistently elevated.

Cognitive-behavioral theorists suggest the way in which a person perceives being high may influence the act of becoming high. It can be a very innocent beginning: Obtaining relief from the medications given by the doctor can, according to cognitive theory, leave people perceiving that the use of these drugs is a miracle cure. It becomes appealing to want that kind of relief again, and very soon a pattern is formed and other substances may be involved.

Differential Diagnosis

Commonly the alcoholic patient is admitted to the medical unit with primary medical diagnoses including dehydration, hyperemesis, or respiratory infections. Nursing assessment, laboratory test results, patient need for frequent pain medication, or symptoms of withdrawal may lead you or the physician to pursue the possibility of chemical dependency.

Types

ALCOHOL ABUSE AND DEPENDENCE. Use and abuse of alcohol is present in all walks of life, in all economic levels, and in both genders. Sometimes a very fine line exists between a person who is a social drinker and a person who has an abuse condition. One factor used to make that differentiation is the degree of need or compulsion to drink. There is a high incidence of alcohol use and abuse among the elderly, teenagers, and even younger children. Alcoholism either directly or indirectly decreases a person's life expectancy by an average of 10 to 12 years.

Denial is a common defense mechanism used by people who are substance abusers. The alcohol-dependent person often uses statements such as “I can quit anytime I want to” or “I just need a little bump to loosen me up.”

Typical symptoms of alcohol dependence include the following:

- Impaired social function and relationships
- Inability to cut down or stop using; daily use is common
- Binges usually lasting 2 days or more
- Blackouts (amnesia while intoxicated)
- Vomiting
- Dehydration
- Disorientation
- Increased vulnerability to infections, accidents, and other injuries

Sometimes patients who are actively using drugs or alcohol when admitted to an inpatient setting, or who are cut off from their alcohol abruptly, experience a condition called **delirium tremens** (DTs). In DTs, hyperexcitability in the sensory activity of the individual can cause visual hallucinations, tremors, and possibly tonic-clonic seizures. Elevated blood pressure and pulse and cardiac dysrhythmias may also occur. This condition occurs within hours or days after the patient has stopped drinking and can last a week or more; hospitalization is necessary.

Treatments for Alcohol Abuse and Dependence. Perhaps the single most effective treatment for alcoholism is involvement in Alcoholics Anonymous (AA). Treatment for and recovery from alcohol dependency and abuse is a slow process. With very few exceptions, an alcoholic who is recovering cannot ever have another drink, or he or she will risk the chance of returning to previous abusive patterns.

Rationale-emotive therapy (RET) is used as an adjunct therapy for control of substance abuse. RET advocates believe that with homework and practice, a person can learn to think differently about the event that led to the drinking. When the person changes the belief system about the activating event and the drinking, the consequences of drinking will be less powerful. AA and RET are group activities.

Psychoanalysis may also be used. Psychoanalysis provides one-on-one therapy. Because addiction affects an entire family, family therapy is important in reinstating honesty in communications.

Medications are used cautiously because of risk for abuse. It is not always wise to substitute another chemical for alcohol. If, however, the anxiety level prohibits participation in therapy, or if a depressive disorder accompanies the abuse, medications may be prescribed. Antidepressant or anti-anxiety drugs are most often prescribed. Disulfiram (Antabuse) is a medication that is sometimes prescribed as a deterrent to using alcohol. Disulfiram should never be administered without full informed consent of the patient. If the patient taking disulfiram ingests alcohol, a severe reaction causes chest pain, nausea, vomiting, confusion, and other symptoms. Persons taking disulfiram can also be ad-

versely affected if they use products that contain alcohol, such as cologne, mouthwash, aftershave, or cough syrup. The effects of disulfiram last 2 to 3 weeks after the last dose.

Research is being conducted on other medications to assist in treating alcohol addictions. One such drug showing promise is acamprasate, which works on neurotransmitters to alter functions of other brain chemicals. Use of benzodiazepines (Valium, Ativan) can help prevent symptoms of DTs during acute withdrawal.

Milieu can be varied as well. Therapy may range from in-house hospitalizations of 2 weeks or more to independent attempts to help oneself by attending AA. It is not uncommon for patients to seek treatment more than once. This is not to be interpreted as a weakness in the individual or the treatment program. It is only a sign that the person is learning more about the disorder and the need to help himself or herself. People with all kinds of chronic disease experience relapse at times (Home Health Hints).

HOME HEALTH HINTS

- Listen to what your patient says and how he or she says it. Listen to what is said by other persons in the home who are familiar with the patient.
- Look for signs of any chemical use, misuse, or abuse by the patient or any caregiver. Count pills and take note of alcohol containers in refrigerators, on counters, or in trash cans.
- Be observant of the health status of the patient's caregivers, with particular attention to signs of exhaustion, depression, or anger. Discuss this with your supervisor.
- Familiarize yourself with the mental health services and professionals in your community. Learn about criteria for admission, cost, and modalities of treatment.

Nursing Care for Patients with Alcohol Abuse and Dependence

- Be honest. Effective therapeutic communication is essential. You need to be in touch with your own thoughts and feelings about addictions.
- Provide group support. Many chemical dependency units provide group support meetings. Twelve-step programs are a popular form of group support.
- Be aware of the use of defense mechanisms. The patient should be confronted immediately if rationalization or denial behaviors are noted.
- Use positive reinforcement. Positive reinforcement for successes is important when helping a person with an addiction. Every step is a big one in this field; every step taken is a new one.
- Provide a safe environment. Patients who are chemically addicted may become suicidal or display other bizarre behavior, especially during DTs. A patient under the influence of alcohol or another chemical may have poor impulse control or judgment. Maintaining a safe milieu and calm demeanor will help the patient through this difficult time. Also, the fact that a patient is hospitalized does not

guarantee that he or she does not have access to the chemical or even use it in your presence. Unfortunately family members or friends sometimes smuggle drugs or alcohol in to the patient. You must be constantly alert. Suspicions should be expressed honestly and nonjudgmentally to the patient. All findings and behaviors that may be potential safety issues for the patient are reported and documented.

- Practice “tough love.” This concept encourages patients to be responsible for their own healing. “Doing for” patients may be tempting, but it is not in the patient’s best interest most of the time. Praising (validating) the patient’s attempts at self-responsible behavior and using therapeutic communication skills to constructively confront behaviors that are inconsistent with the plan of care are two examples of effective nursing interventions.

DRUG ABUSE AND DEPENDENCE. Many substances can be addictive to humans. Caffeine and nicotine are two that are very readily available. Coffee, tea, soda, and cigarettes are everywhere in our society and yet are very addicting. Many experts believe that the single most difficult addiction to overcome is the addiction to nicotine. Illegal substances such as marijuana, cocaine, crack, and PCP and prescription medications for pain and mental health treatment are also among potentially addictive substances.

It is becoming popular among the youth in the United States to use inhalants such as lighter fluid, paint, paint thinners, and gasoline to get high. The term for this is *huffing*. These are highly toxic, potentially lethal, and usually available in the house or garage.

Signs and Symptoms of Drug Abuse and Dependence.

The signs and symptoms of drug abuse and dependence can be very similar to those of people who are alcohol abusers. Additional signs of drug abuse include the following:

- Red, watery eyes
- Runny nose
- Hostile behavior
- **Paranoia**
- Needle tracks on arms or legs

Treatments for Patients with Drug Abuse and Dependence

- Narcotics Anonymous
- Group therapy

- Psychotherapy
- Methadone programs

Methadone acts as a sort of “stepdown” for people addicted to certain drugs. Methadone can be legally prescribed and dispensed. It, too, is potentially addicting, and its critics believe it is only a substitute for heroin. It is typically given once a day. Psychotherapy is also provided for patients in methadone programs.

Nursing Interventions for Patients with Drug Abuse and Dependence.

Nursing care for people who are drug dependent is essentially the same as for those who are alcohol dependent. It is important to remember that nurses and doctors cannot “fix” the patient who is chemically dependent. The desire to be chemically free must come from the individual who is addicted.

Caring for patients with mental health disorders is challenging and rewarding. You will learn that there are very few absolutes in the area of mental health nursing. There are many guidelines about the illnesses, but caring for the patients who have the illnesses is as individualized as the patients themselves. It is also important to remember to care for the whole person. The mind and body work together, so be sure to take care of the physical, emotional, cognitive, and behavioral parts of patients.

CRITICAL THINKING

Maria
 You are one of the team of school nurses in your local high school. You notice that Maria, a 17-year-old student, is behaving oddly. She has always been rather loud and even has been referred to as “obnoxious” by several of her peers. Lately you have observed her sitting alone, as if waiting for someone, but when you approach her, she barely greets you and then moves away. What are your concerns about Maria? What are some of the possibilities that might be affecting her? How will you approach her more effectively the next time you see her?

Answers at end of chapter.

REVIEW QUESTIONS

- When assessing mental health, which patient behavior would cause the nurse to be concerned or ask further questions?
 - Patient is always happy and smiling.
 - Patient can verbalize emotions.
 - Patient is able to cope with bad news.
 - Patient maintains some close, personal relationships.
- A person who always sounds like he or she is making excuses is displaying which defense mechanism?
 - Denial
 - Fantasy
 - Rationalization
 - Transference
- Which of the following is one of the major skills a chemically dependent person and family can learn during treatment?
 - Honest communication
 - Codependency
 - Denial
 - Scapegoating
- Which of the following best defines a therapeutic environment (milieu)?
 - Able to provide for all the patient's needs
 - Locked and supervised
 - Structured to decrease stress and encourage learning new behavior
 - Designed to be homelike for persons who are hospitalized for life
- Which of the following does not state a goal of psychotherapy?
 - Decrease emotional pain/discomfort.
 - Increase social functioning.
 - Increase ability to behave appropriately.
 - Allow patient to avoid/deny uncomfortable situations.
- Psychopharmacology is used for which of the following purposes?
 - As a cure for mental illness and substance abuse
 - Only when necessary to control violent behavior
 - To alter the pain receptors in the brain
 - To decrease symptoms and facilitate other therapies
- If an extrapyramidal side effect such as tardive dyskinesia occurs, which of the following is the treatment of choice?
 - Administer anticholinergic drugs as ordered.
 - Discontinue the drugs per order.
 - Increase the dose per order.
 - Administer antianxiety drugs per order.
- A patient who is a veteran of the Gulf War has difficulty driving through a parking ramp because "there are people hiding behind the pillars! They have guns! Be careful!" This person is most likely experiencing which of the following?
 - Auditory hallucinations
 - Flashbacks
 - Delusions of grandeur
 - Free-floating anxiety

Answers to CRITICAL THINKING

Joe

Different people cope in different ways. This may be a healthy way to cope in this gentleman's culture. Gently guide the grieving husband to a room where he can express his emotions without disturbing others. Ask if he would like you to contact someone to come in to support him. Document objectively: "Patient's husband weeping loudly; guided to consultation room for privacy."

Mrs. Beison

Mrs. Beison is using denial to cope with her cancer diagnosis. Although at times denial can be an effective coping mechanism, if Mrs. Beison continues to deny her disease and refuse treatment, her life will be in danger. The nurse can help Mrs. Beison verbalize her fears about cancer and cancer treatment and can provide accurate information to help her make wise choices. If necessary, a psychiatric evaluation can be requested.

Tommy

You can reassure Tommy's mother that his OCD is not her fault. Tommy can learn to control his illness with medications and therapy. The family must be part of the therapy, for both Tommy's sake and the family's sake. Positive communication between Tommy and his family is encouraged. Tommy's mother can also be encouraged to attend a support group herself.

Mr. Zenz

It is important to be supportive of Mrs. Zenz while maintaining Mr. Zenz's confidentiality and privacy. Encouraging Mrs. Zenz to talk to Mr. Zenz's physician is acceptable. Showing empathy with statements such as, "It must be confusing and difficult to watch your husband change moods so quickly" are good tools to use. It may be a

bit more challenging to approach him as your boss. You may certainly ask if you can speak frankly and share specific observations. You may share your concern, such as "Mr. Zenz, you are a wonderful boss, but I am frightened when you become loud and boisterous." This may help him to reflect. Chances are, however, that if he is in manic stage, he will not hear your concern. It may require delicate talking to the next in the corporate chain of command. This is a tough one. Good luck!

Anne

Appropriate communication skills are to be positive, reassuring and not reinforcing of the hallucinations. "I don't see or hear a woman, Anne. It is time for the movie. I'd like you to come with me for a while at least" is an example of an appropriate verbal interaction. Reinforcing expectations is also appropriate. "Anne, part of your care plan includes attending one major activity per day. This is the last opportunity for you to meet your care plan objective for today" is also acceptable. At all times, nurses need to be aware of drug interactions. Anne will most likely be medicated for her schizophrenia and those medications may interact unfavorably with her chemotherapy. Good nursing data collection skills are essential.

Maria

A number of options may explain Maria's behavior, including depression, drug use, schizophrenia, anorexia, or bulimia. Next time you see Maria you might try constructively confronting her behavior by saying something like "Maria, you used to be much more outgoing. We always were friendly and now you leave when I'm near. That change in you concerns me. I'm here if you want to talk." Or, "Maria, I see your behavior is changing. You are loud one moment and very quiet the next. That is unusual for you. What is happening?"

 Trauma, risk for
 Unilateral Neglect
 Urinary Elimination, impaired
 Urinary Incontinence, functional
 Urinary Incontinence, reflex
 Urinary Incontinence, stress
 Urinary Incontinence, total
 Urinary Incontinence, urge
 Urinary Incontinence, risk for urge
 Urinary Retention [acute/chronic]
 Ventilation, impaired spontaneous
 Ventilatory Weaning Response, dysfunctional
 Violence, [actual]/risk for other-directed
 Violence, [actual]/risk for self-directed
 Walking, impaired
 Wandering

Appendix B

NORMAL REFERENCE LABORATORY VALUES

BLOOD, PLASMA, OR SERUM VALUES		
Determination	Reference Range	
	Conventional	SI
Aldolase	1.3–8.2 U/L	22–137 nmol · sec ⁻¹ /L
Ammonia	12–55 μmol/L	12–55 μmol/L
Amylase	4–25 units/mL	4–25 arb. unit
Ascorbic acid	0.4–1.5 mg/100 mL	23–85 μmol/L
Bilirubin	Direct: up to 0.4 mg/100 mL Total: up to 1.0 mg/100 mL	Up to 7 μmol/L Up to 17 μmol/L
Blood volume	8.5–9.0% of body weight in kg	80–85 mL/kg
Calcium	8.5–10.5 mg/100 mL (slightly higher in children)	2.1–2.6 mmol/L
Carbamazepine	4.0–12.0 mg/mL	17–51 μmol/L
Carbon dioxide content	24–30 mEq/L	24–30 mmol/L
Chloride	100–106 mEq/L	100–106 mmol/L
CK isoenzymes	5% MB or less	
Creatine kinase (CK)	Female: 10–79 U/L Male: 17–148 U/L	167–1317 nmol · sec ⁻¹ /L 283–2467 nmol · sec ⁻¹ /L
Creatinine	0.6–1.5 mg/100 mL	53–133 μmol/L
Ethanol	0 mg/100 mL	0 mmol/L
Glucose	Fasting: 70–110 mg/100 mL	3.9–5.6 mmol/L
Iron	50–150 mg/100 mL (higher in males)	9.0–26.9 μmol/L
Iron-binding capacity	250–410 μg/100 mL	44.8–73.4 μmol/L
Lactic dehydrogenase	45–90 U/L	750–1500 nmol · sec ⁻¹ /L
Lipase	2 units/mL or less	Up to 2 arb. unit
Lipids		
Cholesterol	120–220 mg/100 mL	3.10–5.69 mmol/L
Very low density lipoprotein	13–32 mg/dL	
Low density lipoprotein	38–40 mg/dL	
High density lipoprotein	20–48 mg/dL	
Triglycerides	40–150 mg/100 mL	0.4–1.5 g/L
Lithium	0.5–1.5 mEq/L	0.5–1.5 mmol/L
Magnesium	1.5–2.0 mEq/L	0.8–1.3 mmol/L
Osmolality	280–296 mOsm/kg water	280–296 mmol/kg
Oxygen saturation (arterial)	96–100%	0.96–1.00
PCO ₂	35–45 mm Hg	4.7–6.0 kPa
pH	7.35–7.45	Same
PO ₂	75–100 mm Hg (dependent on age) while breathing room air Above 500 mm Hg while on 100% O ₂	10.0–13.3 kPa
Phenobarbital	15–50 μg/mL	65–215 μmol/L
Phenytoin (Dilantin)	5–20 μg/mL	20–80 μmol/L
Phosphatase (acid)	Male—Total: 0.13–0.63 sigma U/mL Female—Total: 0.01–0.56 sigma U/mL Prostatic: 0–0.5 Fishman–Lerner U/100 mL	36–175 nmol · sec ⁻¹ /L 2.8–156 nmol · sec ⁻¹ /L

BLOOD, PLASMA, OR SERUM VALUES — CONT'D

Determination	Reference Range	
	Conventional	SI
Phosphatase (alkaline)	13–39 U/L, infants and adolescents up to 104 U/L	217–650 nmol · sec ⁻¹ /L, up to 1.26 μmol · sec ⁻¹ /L
Phosphorus (inorganic)	3.0–4.5 mg/100 mL (infants in first year up to 6.0 mg/100 mL)	1.0–1.5 mmol/L
Potassium	3.5–5.0 mEq/L	3.5–5.0 mmol/L
Protein: Total	6.0–8.4 g/100 mL	60–84 g/L
Albumin	3.5–5.0 g/100 mL	35–50 g/L
Globulin	2.3–3.5 g/100 mL	23–35 g/L
Salicylate:	0	
Therapeutic	20–25 mg/100 mL	1.4–1.8 mmol/L
	25–30 mg/100 mL to age 10 yr 3 hr post dose	1.8–2.2 mmol/L
Sodium	135–145 mEq/L	135–145 mmol/L
Transaminase, aspartate aminotransferase	7–27 U/L	117–450 nmol · sec ⁻¹ /L
Transaminase, alanine aminotransferase	1–21 U/L	17–350 nmol · sec ⁻¹ /L
Urea nitrogen (BUN)	8–25 mg/100 mL	2.9–8.9 mmol/L
Uric acid	3.0–7.0 mg/100 mL	0.18–0.42 mmol/L

URINE VALUES

Determination	Reference Range			
	Conventional		SI	
Acetone plus acetoacetate (quantitative)	0		0 mg/L	
Amylase	24–76 units/mL		24–76 arb. unit	
Calcium	300 mg/day or less		7.5 mmol/day or less	
Catecholamines	Epinephrine: under 20 mg/day Norepinephrine: under 100 μg/day		<109 nmol/day <590 nmol/day	
Creatine	Under 100 mg/day or less than 6% of creatine. In pregnancy: up to 12%. In children younger than 1 yr: may equal creatinine. In older children: up to 30% of creatinine.		<0.75 mmol/day	
Creatinine	15–25 mg/kg of body weight/day		0.13–0.22 mmol · kg ⁻¹ /day	
Cystine or cysteine	0		0	
Hemoglobin and myoglobin	0			
pH	5–7		5–7	
Phosphorus (inorganic)	Varies with intake; average, 1 g/day		32 mmol/day	
Protein:				
Quantitative	<150 mg/24 hr		<0.15 g/day	
Steroids:				
17-Ketosteroids (per day)	Age	Male	Female	
	10	1–4 mg	1–4 mg	3–14 μmol 3–14 μmol
	20	6–21	4–16	21–73 14–56
	30	8–26	4–14	28–90 14–49
	50	5–18	3–9	17–62 10–31
	70	2–10	1–7	7–35 3–24
17-Hydroxysteroids	3–8 mg/day (women lower than men)		8–22 μmol/day as tetrahydrocortisol	
Sugar:				
Quantitative glucose	0		0 mmol/L	
Urobilinogen	Up to 1.0 Ehrlich U		To 1.0 arb. unit	

HEMATOLOGIC VALUES

Determination	Reference Range	
	Conventional	SI
Coagulation screening tests:		
Bleeding time (Simplate)	3–9.5 min	180–570 sec
Prothrombin time	Less than 2-sec deviation from control	Less than 2-sec deviation from control
Partial thromboplastin time (activated)	25–38 sec	25–38 sec
Whole-blood clot lysis	No clot lysis in 24 hr	0/day
“Complete” blood count:		
Hematocrit	Male: 45–52% Female: 37–48%	Male: 0.45–0.52 Female: 0.37–0.48
Hemoglobin	Male: 13–18 g/100 mL Female: 12–16 g/100 mL	Male: 8.1–11.2 mmol/L Female: 7.4–9.9 mmol/L
Leukocyte count	4300–10,800/mm ³	4.3–10.8 × 10 ⁹ /L
Erythrocyte count	4.2–5.9 million/mm ³	4.2–5.9 × 10 ¹² /L
Mean corpuscular volume (MCV)	86–98 μm ³ /cell	86–98 fl
Mean corpuscular hemoglobin (MCH)	27–32 pg/RBC	1.7–2.0 pg/cell
Mean corpuscular hemoglobin concentration (MCHC)	32–36%	0.32–0.36
Platelet count	150,000–350,000/mm ³	150–350 × 10 ⁹ /L

MISCELLANEOUS VALUES

Determination	Reference Range	
	Conventional	SI
Carcinoembryonic antigen (CEA)	0–2.5 ng/mL	0–2.5 μg/L
Digoxin	1.2 ± 0.4 ng/mL 1.5 ± 0.4 ng/mL	1.54 ± 0.5 nmol/L 1.92 ± 0.5 nmol/L
Gastric analysis	Basal: Females: 2.0 ± 1.8 mEq/hr Males: 3.0 ± 2.0 mEq/hr Maximal (after histalog or gastrin): Females: 16 ± 5 mEq/hr Males: 23 ± 5 mEq/hr	0.6 ± 0.5 μmol/sec 0.8 ± 0.6 μmol/sec 4.4 ± 1.4 μmol/sec 6.4 ± 1.4 μmol/sec
Gastrin-I	0–200 pg/mL	0–95 pmol/L
Immunologic tests:		
Alpha-fetoprotein	Undetectable in normal adults	
Alpha-1-antitrypsin	85–213 mg/100 mL	0.85–2.13 g/L
Rheumatoid factor	<60 IU/mL	
Antinuclear antibodies	Negative at a 1:8 dilution of serum	

Reference range values may differ from one institution to another. These data from Scully, Robert E (ed.): Case Records of the Massachusetts General Hospital, New England Journal of Medicine 314:39–49, 1986.

Appendix D

MEDICAL ABBREVIATIONS

ABG	arterial blood gas	gr	grain
a.c.	before a meal	Gtt, gtt	drops
AD	advance directive	GYN	gynecology
ad lib.	freely; as desired	h, hr	hour
ALT	alanine aminotransferase	hgb	hemoglobin
AM	morning	hor. som., h.s.	bedtime
A-P	anterior-posterior	IM	intramuscular
AST	aspartate aminotransferase	IUD	intrauterine device
AV	atrioventricular	IV	intravenous
b.i.d.	twice a day	IVP	intravenous pyelogram
BM	bowel movement	J	joule
BP	blood pressure	kg	kilogram
BUN	blood urea nitrogen	KUB	kidney, ureter, and bladder
\bar{c}	with	L	liter
cap.	a capsule	lb	pound
CBC	complete blood count	lmp	last menstrual period
cc	cubic centimeter	mEq	milliequivalent
cm	centimeter	mg	milligram
CNS	central nervous system	ml	milliliter
CSF	cerebrospinal fluid	mm	millimeter
CV	cardiovascular	MRI	magnetic resonance imaging
D and C	dilatation and curettage	MS	mitral stenosis; multiple sclerosis
dc	discontinue	mEq	microequivalent
DNR	do not resuscitate	mg	microgram
DOA	dead on arrival	n.p.o.	nothing by mouth
dr.	dram	NSAID	nonsteroidal anti-inflammatory drug
Dx	diagnosis	NSR	normal sinus rhythm
ECF	extracellular fluid	OB	obstetrics
ECG	electrocardiogram	OC	oral contraceptive
ECT	electroconvulsive therapy	OD	right eye
EEG	electroencephalogram	OS	left eye
EMG	electromyogram	OU	both eyes
EMS	emergency medical service	oz	ounce
ENT	ear, nose, and throat	\bar{p}	after
EOM	extraocular muscles	p.c.	after meals
ER	Emergency Room	PCO ₂	carbon dioxide pressure
ESR	erythrocyte sedimentation rate	PERRLA	pupils equal, regular, react to light and accommodation
F	Fahrenheit	pH	hydrogen ion concentration
g, gm	gram	PM	afternoon/evening
GERD	gastroesophageal reflux disease	PMI	point of maximal impulse
GI	gastrointestinal		

post.	posterior
p.r.	through the rectum
p.r.n.	as needed
qh	every hour
q2h	every 2 hours
q3h	every 3 hours
q.i.d.	four times a day
q.s.	as much as is needed
RBC	red blood cell; red blood count
̄	without
SA	sinoatrial
SC, sc, s.c.	subcutaneous(ly)
SOB	shortness of breath
s.o.s.	if necessary
s.q.	subcutaneous(ly)
stat.	immediately

STD	sexually transmitted disease
T	temperature
tab.	medicated tablet
temp.	temperature
t.i.d.	three times a day
top.	topically
URI	upper respiratory infection
USP	United States Pharmacopeia
UTI	urinary tract infection
WBC	white blood cell; white blood count
WF/BF	white female/black female
WM/BM	white male/black male
wt.	weight

Appendix E

PREFIXES, SUFFIXES, AND COMBINING FORMS

- a-, an-.** Without; away from; not.
ab-, abs-. From; away from; absent.
abdomin-, abdomino-. Abdomen.
-ad. Toward; in the direction of.
aden-, adeno-. Gland.
adip-, adipo-. Fat.
-aemia. Blood.
aer-, aero-. Air.
-algesia, -algia. Suffering; pain.
andro-. Man; male; masculine.
angi-, angio-. Blood or lymph vessels.
aniso-. Unequal; asymmetrical; dissimilar.
ankyl-, ankylo-. Crooked; bent; fusion or growing together of parts.
ante-. Before.
antero-. Anterior; front; before.
ant-, anti-. Against.
arteri-, arterio-. Artery.
arthr-, arthro-. Joint.
-ase. Enzyme.
-asis, esis, -iasis, -isis, -sis. Condition; pathological state.
aut-, auto-. Self.
axo-. Axis; axon.
bacteri-, bacterio-. Bacteria; bacterium.
bi-, bis-. Two; double; twice.
bili-. Bile.
bio-. Life.
blast-, -blast. Germ; bud; embryonic state of development.
blephar-, blepharo-. Eyelid.
brady-. Slow.
bronch-, bronchi-, broncho-. Airway.
cardi-, cardio-. Heart.
cat-, cata-, cath-, kat-, kata-. Down; downward; destructive; against; according to.
cent-. Hundred.
cephal-, cephalo-. Head.
cervic-, cervico-. Head; the neck of an organ.
chrom-, chromo-. Color.
-cide. Causing death.
contra-. Against; opposite.
crani-, cranio-. Skull; cranium.
cry-, cryo-. Cold.
cyan-, cyano-. Blue.
cyst-, cysto-, -cyst. Cyst; urinary bladder.
cyt-, cyto-, -cyte. Cell.
derm-, derma-, dermat-, dermo-. Skin.
di-. Double; twice; two; apart from.
dors-, dorsi-, dorso-. Back.
-dynia. Pain.
dys-. Difficult; bad; painful.
ec-, ecto-. Out; on the outside.
-ectomy. Excision.
ef-, es-, ex-, exo-. Out.
electr-, electro-. Electricity.
-emesis. Vomiting.
-emia. Blood.
en-. In; into.
end-, endo-. Within.
ent-, ento-. Within; inside.
enter-, entero-. Intestine.
ep-, epi-. Upon; over; at; in addition to; after.
erythr-, erythro-. Red.
eury-. Broad.
ex-. Out; away from; completely.
exo-. Out; outside of; without.
extra-. Outside of; in addition; beyond.
-facient. Causing; making happen.
-ferous. Producing.
ferri-, ferro-. Iron.
fluo-. Flow.
fore-. Before; in front of.
-form. Form.
-fuge. To expel; to drive away; fleeing.
gaster-, gastero-, gastr-, gastro-. Stomach.
gen-. Producing; forming.
-gen, -gene, -genesis, -genetic, -genic. Producing; forming.

- glosso-. Tongue.
gluc-, gluco-, glyc-, glyco-. Sugar; glycerol or similar substance.
gyn-, gyne-, gynec-, gyno-. Woman; female.
hem-, hema-, hemato-, hemo-. Blood.
hemi-. Half.
hepat-, hepato-. Liver.
heter-, hetero-. Other; different.
histo-. Tissue.
homo-. Same; likeness.
hydra-, hydro, hydr-. Water.
hyp-, hyph-, hypo-. Less than; below; under.
hyper-. Above; excessive; beyond.
hyster-, hystero-. Uterus.
-ia. Condition, esp. an abnormal state.
-iasis. SEE: -asis.
-iatric. Medicine; medical profession; physicians.
in-. In; inside; within; intensive action; negative.
infra-. Below; under; beneath; inferior to; after.
inter-. Between; in the midst.
intra-, intro-. Within; in; into.
ipsi-. Same.
irid-, irido-. Iris.
-ism. Condition; theory.
iso-. Equal.
-itis. Inflammation of.
kera-, kerato-. Horny substance; cornea.
kolp-, kolpo, colp-, colpo-. Vagina.
kypho-. Humped.
leuk-, leuko-. White; colorless; rel. to a leukocyte.
lip-, lipo-. Fat.
-lite, -lith, lith-, litho-. Stone; calculus.
-logia, -logy. Science of; study of.
lumbo-. Loins.
-lysis. 1. Setting free; disintegration. 2. In medicine, reduction of; relief from.
macr-, macro-. Large; long.
mal-. Ill; bad; poor.
med-, medi-, medio-. Middle.
mega-, megal-, megal-. Large; of great size.
-megalia, -megaly. Enlargement of a body part.
melan-, melano-. Black.
mening-, meningo-. Meninges.
-meter. Measure.
metr-, metra-, metro-. Uterus.
micr-, micro-. Small.
mon-, mono-. Single; one.
muc-, muc-, muco-, myxa-, myxo-. Mucus.
multi-. Many; much.
musculo-, my-, myo-. Muscle.
my-, myo-. SEE *musculo-*.
myel-, myelo-. Spinal cord; bone marrow.
naso-. Nose.
necr-, necro-. Death; necrosis.
neo-. New; recent.
neph-, nephra-, nephro-. Kidney.
neur-, neuri-, neuro-. Nerve; nervous system.
non-. No.
normo-. Normal; usual.
oculo-. Eye.
-ode, -oid. Form; shape; resemblance.
-odynia, odyno-. Pain.
olig-, oligo-. Few; small.
-ology. Science of; study of.
-oma. Tumor.
onco-. Tumor; swelling; mass.
oo-, ovi-, ovo-. Egg; ovum.
oophor-, oophoro-, oophoron-. Ovary.
ophthalm-, ophthalm-. Eye.
-opia. Vision.
optico-, opto-. Eye; vision.
orchi-, orchid-, orchido-. Testicle.
orth-, ortho-. Straight; correct; normal; in proper order.
os-. Mouth; bone.
-osis. Condition; status, process; abnormal increase.
oste-, osteo-. Bone.
ot-, oto-. Ear.
-otomy. Cutting.
-ous. 1. Possessing; full of; 2. Pertaining to.
pan-. All; entire.
para-, -para. 1. Prefix: near; alongside of; departure from normal. 2. Suffix: Bearing offspring.
path-, patho-, -path, -pathic, -pathy. Disease; suffering.
ped-, pedi-, pedo-. Foot.
-penia. Decrease from normal; deficiency.
peri-. Around; about.
perineo-. Perineum.
phaco-. Lens of the eye.
phag-, phago-. Eating; ingestion; devouring.
-phil, -philia, -philic. Love for; tendency toward; craving for.
phlebo-. Vein.
-phobia. Abnormal fear or aversion.
photo-. Light.
phren-, phreno-, -phrenia. Mind; diaphragm.
-phyllaxis. Protection.
-plasia. Growth; cellular proliferation.
plasm-, -plasm. 1. Prefix: Living substance or tissue. 2. Suffix: To mold.
-plastic. Molded; indicates restoration of lost or badly formed features.
-plegia. Paralysis; stroke.
pneo-. Breath; breathing.
pneum-, pneuma-, pneumato-. Air; gas; respiration.
-poesis, -poietic. Production; formation.
poly-. Much; many.
post-. After.
pre-. Before; in front of.
presby-. Old age.
pro-. Before; in behalf of.
proct-, procto-. Anus; rectum.
pseud-, pseudo-. False.
psych-, psycho-. Mind; mental processes.
pulmo-. Lung.
py-, pyo-. Pus.
pyro-. Heat; fire.
ren-, reno-. Kidneys.

retro-. Backward; back; behind.
rheo-, **-(r)rhea**. Current; stream; to flow; to discharge.
rhino-. Nose.
-(r)rhage, **-(r)rhagia**. Rupture; profuse fluid discharge.
-(r)rhaphy. A suturing or stitching.
salping-, **salpingo-**. Auditory tube; fallopian tube.
sclero-. Hard; relating to the sclera.
-scopy. Examination.
semi-. Half.
sero-. Serum.
somat-, **somato-**. Body.
sperma-, **spermat-**, **spermato-**. Sperm; spermatozoa.
steno-. Narrow; short.
-stomosis, **-stomy**. SEE: *-ostomosis*.
sub-. Under; beneath; in small quantity; less than normal.
super-. Above; beyond; superior.
supra-. Above; beyond; on top.
tachy-. Swift; rapid.
tel-, **tele-**. 1. End. 2. Distant; far.
tendo-, **teno-**. Tendon.
thorac-, **thoraci-**, **thoraco-**. Chest; chest wall.

thrombo-. Blood clot; thrombus.
thyro-. Thyroid gland; oblong; shield.
-tomy. Cutting operation; excision.
top-, **topo-**. Place; locale.
tox-, **toxi-**, **toxico-**, **tox-**, **-toxic**. Toxin; poison; toxic.
tracheo-. Trachea; windpipe.
trans-. Across; over; beyond; through.
-tropin. Stimulation of a target organ by a substance, esp. a hormone.
tympano-. Eardrum; tympanum.
ultra-. Beyond; excess.
-uria. Urine.
uter-, **utero-**. Uterus.
vaso-. Vessel (e.g., blood vessel).
veno-. Vein.
ventro-, **ventr-**, **ventri-**. Abdomen; anterior surface of the body.
vertebro-. Vertebra; vertebrae.
vesico-. Bladder; vesicle.1

Glossary

- Ablation:** (un-BLAY-shun) Removal of part, pathway, or function by surgery, chemical electrocautery, or radio frequency. (Ch. 20)
- Abrasion:** (a-BRAY-zhun) A scraping away of skin or mucus membrane as a result of injury or by mechanical means. (Ch. 12)
- Abuse:** (uh-BYOOS) Misuse; excessive or improper use. May refer to substances or individuals. (Ch. 55)
- Acidosis:** (ass-i-DOH-sis) An actual or relative increase in the acidity of blood caused by an accumulation of acid or a loss of base. (Ch. 5, 8)
- Accommodation:** (uh-KOM-uh-DAY-shun) A reflex action of the eye for focusing. (Ch. 48)
- Acquired immunodeficiency syndrome (AIDS):** (uh-KWHY-erd IM-yoo-noh-de-FISH-en-see SIN-drohm) Suppression or deficiency of the cellular immune response, acquired by exposure to human immunodeficiency virus (HIV). (Ch. 54)
- Active immunity:** (AK-tiv im-YOO-ni-tee) Acquired immunity attributable to the presence of antibodies or of immune lymphoid cells formed in response to antigenic stimulus. (Ch. 52)
- Activities of daily living (ADLs):** (ack-TIV-i-tees of DAY-lee LIV-ing) Those activities and behaviors that are performed in the care and maintenance of self (e.g., bathing, dressing, eating). (Ch. 14)
- Acupuncture:** (ak-yoo-PUNGK-chur) Technique using needles inserted at specific points to create anesthesia or treat certain conditions. (Ch. 4)
- Acute coronary syndromes:** (a-cute KOR-un-na-ree sin-DROMES) Group of conditions, including unstable angina, non-Q wave myocardial infarction, and ST segment elevation myocardial infarction, caused by a lack of oxygen to the heart muscle. (Ch. 18)
- Acute pulmonary hypertension:** (ah-KEWT PULL-muh-NAIR-ee HIGH-per-TEN-shun) Sudden obstruction of the pulmonary artery causes excessive buildup of pressure in the pulmonary arteries. (Ch. 8)
- Adaptation:** (ad-dap-TAY-shun) Adjustment to changes in internal or external conditions or circumstances; coping. (Ch. 55)
- Addiction:** (uh-DIK-shun) Psychological dependence characterized by drug seeking and craving for an opioid or other substance for effects other than the intended purpose of the substance. (Ch. 9, 55)
- Adjunct:** (ADD-junkt) An addition to the principal procedure or course of therapy. (Ch. 11)
- Adjuvant:** (ad-JOO-vant) Something that assists something else, such as a second form of treatment added to treat a disease. (Ch. 9, 28)
- Administrative laws:** (ad-MIN-i-STRAY-tiv LAWZ) Establishes the licensing authority of the state to create, license, and regulate the practice of nursing. (Ch. 2)
- Adnexa:** (ad-NECK-sah) Appendages or accessory organs. (Ch. 39)
- Adventitious:** (ad-ven-TI-shus) Abnormal or extra; often refers to extra breath sounds, such as wheezes or crackles. (Ch. 26)
- Aerobic:** (air-O-bick) Living only in the presence of oxygen. (Ch. 7)
- Afterload:** (AFF-ter-lohd) The forces impeding the blood flow out of the heart (vascular pressure, aortic compliance, blood mass, and viscosity). (Ch. 21)
- Affect:** (AF-feckt) Emotional tone. (Ch. 36, 55)
- Agensis:** (ay-JEN-uh-sis) Failure of an organ or part to develop or grow. (Ch. 40)
- Agonist:** (AG-un-ist) A type of opioid that binds to opioid receptors in the central nervous system to relieve pain. (Ch. 9)
- Akinesia:** (a-ki-NEE-zee-ah) Absence or loss of the power of voluntary movement. (Ch. 46)
- Alkalosis:** (al-ka-LOH-sis) An actual or relative decrease in the acidity of blood caused by loss of acid or accumulation of base. (Ch. 5)

- Allopathic:** (AL-oh-PATH-ik) Method of treating disease with remedies that produce effects different from those caused by the disease. (Ch. 4)
- Alopecia:** (AL-oh-PEE-she-ah) The loss of hair from the body and the scalp. (Ch. 10, 50)
- Amenorrhea:** (ay-MEN-uh-REE-ah) The absence or suppression of menstruation. Amenorrhea is normal before puberty, after menopause, and during pregnancy and lactation. (Ch. 37, 40)
- Amputation:** (am-pew-TAY-shun) The removal of a limb or other appendage or outgrowth of the body. (Ch. 12)
- Anaerobic:** (AN-air-ROH-bik) Able to live without oxygen. (Ch. 7, 8)
- Analgesic:** (AN-uhl-JEE-zik) A drug that relieves pain. (Ch. 9)
- Anaphylactic shock:** (AN-uh-fi-LAK-tik) Systemic reaction that produces life-threatening changes in the circulation and bronchioles. (Ch. 12, 52)
- Anaphylaxis:** (AN-uh-fi-LAK-sis) A sudden severe allergic reaction. (Ch. 8, 53)
- Anastomose:** (uh-NAS-tuh-MOS) To surgically connect two parts. (Ch. 22)
- Anemia:** (uh-NEE-mee-yah) A condition in which there is reduced delivery of oxygen to the tissues as a result of reduced numbers of red cells or hemoglobin. (Ch. 10, 24)
- Anergy:** (AN-er-jee) Diminished ability of the immune system to react to an antigen. (Ch. 28)
- Anesthesia:** (AN-es-THEE-zee-uh) Lack of feeling or sensation; artificially induced loss of ability to feel pain. (Ch. 11)
- Anesthesiologist:** (an-es-THEE-zee-uhl-la-just) A physician who specializes in anesthesiology. (Ch. 11)
- Aneurysm:** (AN-yur-izm) A sac formed by the localized dilation of the wall of an artery, a vein, or the heart. (Ch. 18)
- Angina pectoris:** (an-JIGH-nah PEK-tuh-riss) Severe pain and pressure in the chest caused by insufficient supply of blood and oxygenation to the heart. (Ch. 18)
- Angioedema:** (AN-gee-o-eh-DEE-ma) A localized edematous reaction of the deep dermis or subcutaneous or submucosal tissues appearing as giant wheals. (Ch. 53)
- Anion:** (AN-eye-on) Electrolyte that carries a negative electrical charge. (Ch. 5)
- Anisocoria:** (an-i-soh-KOH-ree-ah) Inequality in size of the pupils of the eyes. (Ch. 45)
- Ankylosing spondylitis:** (ANG-ki-LOH-sing SPON-da-LIGHT-is) Inflammatory disease of the spine causing stiffness and pain. (Ch. 53)
- Annuloplasty:** (AN-yoo-loh-PLAS-tee) Repair of a cardiac valve. (Ch. 19, 22)
- Anorexia:** (AN-oh-REK-see-ah) Absence or loss of appetite for food. Seen in depression, with illness, and as a side effect of some medications. (Ch. 10, 30)
- Anorexia nervosa:** (AN-oh-REK-see-ah ner-VOH-sah) Refusal to maintain body weight over a minimal normal weight for age and height. (Ch. 30)
- Antagonist:** (an-TAG-on-ist) Medication used to counteract the effects of an opioid (e.g., naloxone). (Ch. 9)
- Anteflexion:** (AN-tee-FLECK-shun) The abnormal bending forward of part of an organ. (Ch. 40)
- Anteversio:** (AN-tee-VER-zhun) A tipping forward of an organ as a whole, without bending. (Ch. 40)
- Antibodies:** (AN-ti-baw-dees) An immunoglobulin molecule having a specific amino acid sequence that gives each antibody the ability to adhere to and interact only with the antigen that induced the synthesis. (Ch. 7, 52)
- Anticholinesterase:** (AN-ti-KOH-lin-ESS-ter-ays) A substance that breaks down acetylcholinesterase. (Ch. 47)
- Antidiuretic:** (AN-ti-DYE-yoo-RET-ik) Lessening urine excretion. (Ch. 5)
- Antigen:** (AN-tih-jen) A protein marker on the surface of cells that identifies the type of cell. (Ch. 7, 52)
- Antitussive:** (an-tee-TUSS-iv) An agent that prevents or relieves cough. (Ch. 28)
- Anuria:** (an-YOO-ree-ah) Complete suppression of urine formation by the kidney. (Ch. 35)
- Anxiety:** (ang-ZIGH-uh-tee) The uncomfortable feeling of apprehension or dread that occurs in response to a known or unknown threat. (Ch. 55)
- Aphasia:** (ah-FAY-zee-ah) Defect or loss of the power of expression by speech, writing, or signs, or of comprehension of spoken or written language, caused by disease or injury of the brain centers, such as stroke syndrome. (Ch. 45)
- Aphthous stomatitis:** (AF-thus STO-h-mah-TIGH-tis) Small, white, painful ulcers (also known as canker sores) that appear on the inner cheeks, lips, gums, tongue, palate, and pharynx. They tend to recur. (Ch. 30)
- Apnea:** (ap-NEE-ah) Temporary absence of breathing. (Ch. 26)
- Appendicitis:** (uh-PEN-di-SIGH-tis) Inflammation of the vermiform appendix. (Ch. 31)
- Arcus senilis:** (AR-kus se-NILL-us) A benign white or gray opaque ring in the corneal margin of the eye. (Ch. 48)
- Arrhythmia:** (uh-RITH-mee-yah) Irregular rhythm, especially heartbeat. (Ch. 14)
- Arthritis:** (are-THRYE-tis) Inflammation of a joint. (Ch. 44)
- Arthrocentesis:** (ar-THROW-sen-tee-sis) Puncture of a joint space with a needle to remove fluid accumulated in the joint. (Ch. 43, 44)
- Arteriosclerosis:** (ar-TIR-ee-oh-skle-ROH-sis) Term applied to a number of pathological conditions in which there is gradual thickening, hardening, and loss of elasticity of the walls of the arteries. (Ch. 15, 18)
- Arthroplasty:** (AR-throw-PLAS-te) Repair of a joint. Also called joint replacement. (Ch. 44)
- Arthroscopy:** (are-THROSS-scop-ee) Examination of the interior of a joint with an arthroscope. (Ch. 43)
- Articular:** (ar-TIK-yoo-lar) Pertaining to a joint. (Ch. 43)
- Ascites:** (a-SIGH-teez) Abnormal accumulation of fluid in the peritoneal cavity. (Ch. 33)
- Asepsis:** (ah-SEP-sis) A condition free from germs, infection, and any form of life. (Ch. 7)
- Aseptic:** (ah-SEP-tik) Free of pathogenic organisms; asepsis. (Ch. 11)
- Asphyxia:** (as-FIX-ee-a) A condition in which there is a deficiency of oxygen in the blood and an increase in carbon dioxide in the blood and tissues. (Ch. 12)

- Aspiration:** (ASS-pi-**RAY**-shun) Accidental drawing in of foreign substances into the throat or lungs during inspiration. (Ch. 14)
- Assessment:** (ah-**SESS**-ment) An appraisal or evaluation of a client's condition. (Ch. 1)
- Asterixis:** (AS-ter-**ICK**-sis) Hand flapping tremor and involuntary movements of tongue and feet; may be present in hepatic encephalopathy. (Ch. 35)
- Astigmatism:** (uh-**STIG**-mah-**TIZM**) An error of refraction in which a ray of light is not sharply focused on the retina but is spread over a more or less diffuse area. (Ch. 49)
- Ataxia:** (ah-**TAK**-see-ah) Failure of muscular coordination; irregularity of muscular action. (Ch. 46)
- Atelectasis:** (AT-e-**LEK**-tah-sis) Collapsed or airless condition of the lung or portion of lung, caused by obstruction or hypoventilation. (Ch. 11, 22, 28)
- Atheroma:** (ATH-er-**OMA**) Fatty deterioration or thickening of the walls of the larger arteries occurring in atherosclerosis. (Ch. 18)
- Atherosclerosis:** (ATH-er-oh-skle-**ROH**-sis) A form of arteriosclerosis characterized by accumulation of plaque, blood, and blood products lining the wall of the artery, causing partial or complete blockage of an artery. (Ch. 15, 18)
- Atrial depolarization:** (AY-tree-uhl DE-poh-lahr-i-**ZAY**-shun) Electrical activation of the atria. (Ch. 20)
- Atrial systole:** (AY-tree-uhl **SIS**-tuh-lee) The contraction of the atria. (Ch. 20)
- Atrioventricular node:** (AY-tree-oh-ven-**TRICK**-yoo-lar **NOHD**) Located in lower right atrium; receives an impulse from the sinoatrial (SA) node and relays it to the ventricles. (Ch. 20)
- Atrophy:** (AT-ruh-fee) Without nourishment; wasting. (Ch. 47)
- Atypical:** (ay-**TIP**-i-kuhl) Deviating from normal. (Ch. 28)
- Augmentation:** (AWG-men-**TAY**-shun) The act or process of increasing in size, quantity, degree or severity. (Ch. 40)
- Auscultation:** (AWS-kul-**TAY**-shun) Process of listening for sounds within the body, usually sounds of thoracic or abdominal viscera, to detect an abnormality. (Ch. 1)
- Autoimmune:** (AW-toh-im-**YOON**) A condition in which the body does not recognize itself and the immune system attacks normal cells. (Ch. 37)
- Avascular necrosis:** (a-**VAS**-cue-lur ne-**CROW**-sis) Disruption of blood supply causing tissue death. (Ch. 12, 44)
- Ayurvedic:** (AY-**YUR**-**VAY**-dik) An ancient Hindu system of medicine that improves health by harmonizing mind and body. (Ch. 4)
- Azotemia:** (AY-zoh-**TEE**-me-ah) An increase in nitrogenous bodies in the blood, especially urea, as measured by the serum blood urea nitrogen (BUN) level. (Ch. 35)
- Bacteria:** (back-**TEER**-e-ah) One-celled organism that can reproduce but needs a host for food and supportive environment. Bacteria can be harmless, normal flora, or disease-producing pathogens. (Ch. 7)
- Balanitis:** (BAL-uh-**NIGH**-tis) Inflammation of the skin covering the glans penis. (Ch. 40)
- Bariatric:** (BAR-ry-**AT**-rick) Branch of medicine that deals with the prevention, control, and treatment of obesity. (Ch. 30)
- Basal cell secretion test:** (**BAY**-zuhl **SELL** see-**KREE**-shun **TEST**) Part of a gastric analysis; measures the amount of gastric acid produced in 1 hour. (Ch. 29)
- Behavior management:** (be-**HAYV**-yer **MAN**-ij-ment) Treatment method that uses positive and negative reinforcement to alter behavior. (Ch. 55)
- Belief:** (bee-**LEEF**) Something accepted as true. Does not have to be proven. (Ch. 3)
- Benevolence:** (buh-**NEF**-i-sens) To provide good care; to do good for clients. One of the oldest requirements for health care providers. (Ch. 2)
- Benign:** (bee-**NINE**) Not progressive; for example, a tumor that is not cancerous. (Ch. 10)
- Beta-hemolytic streptococci:** (**BAY**-tuh-**HEE**-moh-**LIT**-ick **STREP**-toh-**KOCK**-sigh) Gram-positive bacteria that, when grown on blood-agar plates, completely hemolyze the blood and produce a clear zone around the bacteria colony. Group A beta-hemolytic streptococci cause disease in humans. (Ch. 17)
- Bigeminy:** (bye-**JEM**-i-nee) Occurring every second beat, as in bigeminal premature ventricular contractions. (Ch. 20)
- Bilateral salpingo-oophorectomy:** (by-**LAT**-er-uhl sal-**PINJ**-oh-ah-fuh-**RECK**-tuh-mee) Surgical removal of both fallopian tubes and ovaries. (Ch. 40)
- Bimanual:** (by-**MAN**-yoo-uhl) With both hands. (Ch. 39)
- Biofeedback:** (**BYE**-oh-**FEED**-bak) A form of therapy that uses provision of visual or auditory evidence to a person of the status of an autonomic body function such as heart rate, blood pressure, or respiratory rate. (Ch. 55)
- Biopsy:** (**BY**-ahp-see) A sample of tissue removed for examination. (Ch. 10)
- Bipolar:** (bye-**POH**-ler) Having two poles or pertaining to both poles. Bipolar disorder is characterized by episodes of manic and depressive behavior. (Ch. 55)
- Blanch:** (**BLANCH**) To lose color. (Ch. 51)
- Bleb:** (**BLEB**) An irregularly shaped elevation of the skin, such as a blister. May also occur in lung tissue. (Ch. 28)
- Blepharitis:** (**BLEF**-uh-**RIGH**-tis) Inflammation of the glands and lash follicles along the margin of the eyelids. (Ch. 49)
- Blindness:** (**BLYND**-ness) Lack or loss of ability to see. (Ch. 49)
- Bolus:** (**BOH**-lus) A dose of intravenous medication injected all at once. (Ch. 6)
- Bone:** (**BOWN**) The hard, rigid form of connective tissue constituting most of the skeleton of vertebrates, composed chiefly of calcium salts. (Ch. 43)
- Bowel sounds:** (**BOW**'L **SOWNDS**) Gurgling and clicking sounds heard over the abdomen caused by air and fluid movement from peristaltic action. Normal bowel sounds occur every 5 to 15 seconds at a rate of 5 to 35 sounds per minute. Absent—no bowel sounds heard after 5 minutes of listening in each quadrant. Hyperactivebowel sounds that are rapid, high-pitched, and loud. Hypoactivebowel sounds that occur at a rate of one every minute or longer. (Ch. 29)

- Bradycardia:** (BRAY-dee-KAR-dee-yah) A slow heartbeat characterized by a pulse rate below 60 beats per minute. (Ch. 15, 20)
- Bradykinesia:** (BRAY-dee-kin-EE-zee-ah) Abnormal slowness of movement; sluggishness. (Ch. 46)
- Breakthrough:** (BRAYK-throo) Pain that occurs during use of long-acting analgesic therapy. (Ch. 9)
- Bronchiectasis:** (BRONG-key-EK-tah-sis) Chronic dilation of a bronchus or bronchi, usually associated with secondary infection and excessive sputum production. (Ch. 28)
- Bronchitis:** (brong-KIGH-tis) Inflammation of the mucous membrane of the bronchial airways; may be viral or bacterial. (Ch. 28)
- Bronchodilator:** (BRONG-koh-DYE-lay-ter) A drug that expands the bronchial tubes by relaxing bronchial smooth muscle. (Ch. 28)
- Bronchospasm:** (BRONG-koh-spazm) Spasm of the bronchial smooth muscle resulting in narrowing of the airways; associated with asthma and bronchitis. (Ch. 8, 28)
- Bruit:** (BROUT) A humming heard when auscultating a blood vessel that is caused by turbulent blood flow through the vessel. (Ch. 15)
- Bulimia nervosa:** (buh-LEE-mee-ah ner-VOH-sah) Recurrent episodes of binge eating and self-induced vomiting. (Ch. 30)
- Bulla:** (BUHL-ah) A large blister or skin lesion filled with fluid. May also occur in lung tissue. (Ch. 28)
- Bundle of His:** (BUN-duhl of HISS) A bundle of fibers of the impulse-conducting system of the heart. Originates in the atrioventricular (AV) node. (Ch. 20)
- Bursae:** (BURR-sah) A small fluid-filled sac or saclike cavity situated in tissues such as joints where friction would otherwise occur. (Ch. 43)
- Calculi:** (KAL-kyoo-lye) An abnormal concentration, usually composed of mineral salts, occurring within the body, chiefly in the hollow organs or their passages. Called also stones, as in kidney stones and gallstones. (Ch. 35)
- Cancer:** (KAN-sir) A general name for over 100 diseases in which abnormal cells grow out of control; a malignant tumor. (Ch. 10)
- Cannula:** (KAN-yoo-lah) A flexible tube that can be inserted into the body guided by a stiff, pointed rod. For example, an intravenous cannula is guided by a metal needle. (Ch. 6)
- Capillary permeability:** (KAP-i-lar-ee PER-me-a-BILL-i-tee) The ability of substances to diffuse through capillary walls into tissue spaces. (Ch. 12)
- Capillary refill:** (KAP-i-lar-ee RE-fill) The amount of time required for color to return to the nailbed after having been compressed; normally 3 seconds or less. Indicator of peripheral circulation. (Ch. 12)
- Caput medusae:** (KAP-ut mi-DOO-see) Dilated veins around the umbilicus, associated with cirrhosis of the liver. (Ch. 32)
- Carbuncle:** (KAR-bung-kull) A necrotizing infection of skin and subcutaneous tissue composed of a cluster of boils. (Ch. 49)
- Carcinoembryonic antigens (CEA):** (KAR-sin-oh-EM-bree-ah-nik AN-ti-jens) A class of antigens normally present in fetal cells; CEA level is elevated in many cancers and is measured to guide cancer treatment. (Ch. 29)
- Carcinogen:** (kar-SIN-oh-jen) Specific agents known to promote the cancer process. (Ch. 10)
- Cardiac output:** (KAR-dee-yak OWT-put) A measure of the pumping ability of the heart; amount of blood pumped by the heart per minute. (Ch. 8, 16)
- Cardiac tamponade:** (KAR-dee-yak TAM-pon-AID) The life-threatening compression of the heart by the fluid accumulating in the pericardial sac surrounding the heart. (Ch. 17)
- Cardiogenic shock:** (KAR-dee-o-JEN-ick SHOCK) Occurs when the heart muscle is unhealthy and contractility is impaired. (Ch. 8, 12)
- Cardiomegaly:** (KAR-dee-oh-MEG-ah-lee) Enlargement of the heart. (Ch. 17)
- Cardiomyopathy:** (KAR-dee-oh-my-AH-pah-thee) A group of diseases that affect the myocardium's (heart muscle's) structure or function. (Ch. 17)
- Cardioplegia:** (KAR-dee-oh-PLÉE-jee-ah) Arrest of myocardial contraction, as by use of chemical compounds or cold temperatures in cardiac surgery. (Ch. 22)
- Cardioversion:** (KAR-do-oh-VER-zhun) An elective procedure in which a synchronized shock is delivered to attempt to restore the heart to a normal sinus rhythm. (Ch. 20)
- Cataract:** (KAT-uh-rakt) Opacity of the lens of the eye. (Ch. 13, 49)
- Cation:** (KAT-eye-on) Electrolytes that carry a positive electrical charge. (Ch. 5)
- Ceiling effect:** (SEE-ling e-FEKT) The dose of medication at which the maximum therapeutic effect is achieved. Increasing the dose beyond the therapeutic dose will not result in increased relief and may result in undesirable side effects. (Ch. 9)
- Cell-mediated immunity:** (SELL ME-dee-ay-ted im-YOO-ni-tee) Production of lymphocytes by thymus in response to antigen exposure. (Ch. 52)
- Cellulitis:** (sell-yoo-LYE-tis) Inflammation of cellular or connective tissue. (Ch. 51)
- Cerebrovascular:** (SER-ee-broh-VAS-kyoo-lur) Pertaining to the blood vessels of the cerebrum or brain. (Ch. 45)
- Chalazion:** (kah-LAY-zee-on) A small eyelid mass resulting from chronic inflammation of a meibomian gland. (Ch. 49)
- Chancre:** (SHANK-er) A hard, syphilitic primary ulcer, the first sign of syphilis, appearing approximately 2 to 3 weeks after infection. (Ch. 42)
- Chemotherapy:** (KEE-moh-THER-uh-pee) The treatment of disease with medication; often refers to cancer therapy. (Ch. 10)
- Chiropractic:** (ky-RUH-prak-tik) Treatment modality that uses manual adjustment of the vertebral column and extremities to remove interference with nerve function. (Ch. 4)
- Cholecystitis:** (KOH-lee-sis-TIGH-tis) Inflammation of the gallbladder. (Ch. 33)

- Cholelithiasis:** (koh-LED-oh-koh-li-THIGH-ah-sis) Gallstones in the common bile duct. (Ch. 33)
- Cholelithiasis:** (koh-LED-oh-KOS-koh-pee) An endoscopic test of the gallbladder and common bile duct. (Ch. 33)
- Cholelithiasis:** (KOH-lee-li-THIGH-ah-sis) Gallstones in the gallbladder. (Ch. 33)
- Chorea:** (kaw-REE-ah) A nervous condition marked by involuntary muscular twitching of the limbs or facial muscles. (Ch. 17)
- Chronic illness:** (KRAH-nick ILL-ness) An illness that is long-lasting or recurring, which usually interferes with a person's ability to perform activities of daily living. Medical care and hospitalization are often required on an ongoing basis. (Ch. 13)
- Circumcise:** (SIR-kuhm-size) Surgical removal of the foreskin covering the head of the penis. (Ch. 39)
- Cirrhosis:** (si-ROH-sis) Chronic disease of the liver, associated with fat infiltration and development of fibrotic tissue. (Ch. 33)
- Civil law:** (SIV-il LAW) Provides the rules by which individuals seek to protect their personal and property rights. (Ch. 2)
- Claudication:** (KLAW-di-KAY-shun) Severe pain in the calf muscle from inadequate blood supply. (Ch. 15)
- Clubbing:** (KLUB-ing) A condition in which the ends of the fingers and toes appear bulbous and shiny, most often the result of lung disease. (Ch. 15)
- Cochlear implant:** (KOK-lee-er IM-plant) A device consisting of a microphone, signal processor, external transmitter, and implanted receiver to aid hearing. (Ch. 48, 49)
- Code of ethics:** (KOHD of ETH-icks) A traditional compilation of ideal behaviors of a professional group. (Ch. 2)
- Codependence:** (KO-de-PEN-dense) A situation in which the significant others in a family group begin to lose their own sense of identity and purpose and exist solely for the abuser. (Ch. 55)
- Cognitive:** (KAHG-ni-tiv). The ability to think rationally and to process thoughts. (Ch. 55)
- Colectomy:** (koh-LEK-tuh-me) Excision of the colon or a portion of it. (Ch. 31)
- Colic:** (KAH-lick) Spasm of a hollow organ or duct, causing pain. (Ch. 33)
- Colitis:** (koh-LYE-tis) Inflammation of the colon. (Ch. 31)
- Collateral circulation:** (koh-LA-ter-al SIR-kew-LAY-shun) Small branches off of larger blood vessels that will increase in size and capacity next to a main blood vessel that is obstructed. (Ch. 18)
- Colonization:** (COLLIN-i-ZAY-shun) The presence of pathogenic microbes in the body, without development of a symptomatic infection. (Ch. 7)
- Colonoscopy:** (KOH-lun-AHS-kuh-pee) Examination of the upper portion of the rectum with a colonoscope. (Ch. 29)
- Colostomy:** (koh-LAH-stuh-me) An artificial opening (stoma) created in the large intestine and brought to the surface of the abdomen for evacuating the bowels. (Ch. 31)
- Colporrhaphy:** (kohl-POOR-ah-fee) Surgical repair of the vagina. (Ch. 40)
- Colposcopy:** (kul-POS-koh-pee) Examination of the vulva, vagina, and cervix by means of a magnifying lens and a bright light. (Ch. 39)
- Comedone:** (KOH-me-doh) Skin lesion that occurs in acne vulgaris (closed form: whitehead; open form: blackhead). (Ch. 51)
- Commissurotomy:** (KOM-i-shur-AHT-oh-mee) Surgical incision of any commissure as in cardiac valves to increase the size of the orifice. (Ch. 19, 22)
- Compliance:** (kom-PLIGH-ens) The ability to alter size or shape in response to an outside force; the ability of the lungs to distend. (Ch. 28)
- Compulsion:** (kum-PUHL-shun) A recurrent, unwanted, and distressing urge to perform an act. (Ch. 55)
- Conductive hearing loss:** (kon-DUK-tiv HEER-ing LOSS) Impaired transmission of sound waves through the external ear canal to the bones of the middle ear. (Ch. 49)
- Condylomata acuminata:** (KON-di-LOH-ma-tah ah-KY-OOM-in-AH-tah) Warts in the genital region caused by the human papillomavirus (HPV); a contagious sexually transmitted disease. (Ch. 41)
- Condylomatous:** (KON-di-LOH-ma-tus) Pertaining to a condyloma. (Ch. 41)
- Confidentiality:** (KON-fi-den-she-AL-i-tee) Maintaining privacy of client information. Client and client's care can be discussed only in the professional setting. (Ch. 2)
- Congestive heart failure:** (kon-JESS-tive HART FAIL-yur) Results from inability of heart to pump sufficient amounts of blood because of impaired pumping function and sodium and water retention. Congestion refers to the buildup of fluid that ranges from mild to life-threatening (pulmonary edema). With right-sided heart failure, the fluid buildup is seen systemically (lower legs/feet, sacral area in bedridden persons, jugular veins, liver, spleen). With left-sided heart failure, the fluid buildup occurs in the lungs and if severe, immediate treatment is required or death can occur.
- Conization:** (KOH-ni-ZAY-shun) The removal of a cone of tissue, as in partial excision of the cervix uteri. (Ch. 39)
- Conjunctivitis:** (kon-JUNK-ti-VIGH-tis) Inflammation of the conjunctiva of the eye. (Ch. 42, 49)
- Consensual response:** (kon-SEN-shoo-uhl ree-SPONS) Reaction of both pupils when one eye is exposed to greater intensity of light than the other. (Ch. 48)
- Constipation:** (KON-sti-PAY-shun) A condition of sluggish or difficult bowel action/evacuation. (Ch. 14, 31)
- Contraceptive:** (KON-truh-SEP-tiv) Any process, device, or method that prevents conception. (Ch. 40)
- Contracture:** (kon-TRACK-chur) Abnormal accumulation of fibrosis connective tissue in skin, muscle or joint capsule that prevents normal mobility at that site. (Ch. 14, 46)
- Contralateral:** (KON-truh-LAT-er-uhl) Originating in or affecting the opposite side of the body. (Ch. 46)
- Conversion disorder:** (kon-VER-zhun dis-OR-der) An illness that emerges from overuse of the conversion reaction

- defense mechanism, in which there is impaired physical functioning that appears to be neurological, but no organic disease can be identified. (Ch. 55)
- Coping:** (KOH-ping) The process of contending with the stresses of daily life in an effort to overcome or work through them. (Ch. 55)
- Coronary artery disease:** (KOR-uh-na-ree AR-tuh-ree di-ZEEZ) Narrowing of the coronary arteries sufficient to prevent adequate blood supply to the myocardium. (Ch. 18)
- Cor pulmonale:** (KOR PUL-mahNAH-lee) Hypertrophy or failure of the right ventricle from disorders of the chest wall, lungs, and pulmonary vessels. As with increased pulmonary pressure caused by chronic obstructive pulmonary disease (COPD). (Ch. 21)
- Craniectomy:** (KRAY-nee-EK-tuh-me) Excision of a segment of the skull. (Ch. 46)
- Cranioplasty:** (KRAY-nee-oh-plas-tee) Any plastic repair operation on the skull. (Ch. 46)
- Craniotomy:** (KRAY-nee-AHT-oh-mee) Any incision through the cranium. (Ch. 46)
- Crepitation:** (crep-i-TAY-shun) A dry, crackling sound or sensation, such as that produced by the grating of the ends of a fractured bone. (Ch. 43)
- Crepitus:** (KREP-i-tuss) Crepitation. (Ch. 26)
- Criminal law:** (KRIM-i-nuhl LAW) Regulates behaviors for citizens within a country. (Ch. 2)
- Critical thinking:** (KRIT-i-kuhl THING-king) Use of knowledge and skills to make the best decisions possible in client care situations. (Ch. 1)
- Cryotherapy:** (KRY-oh-THER-uh-pee) The therapeutic use of cold. (Ch. 40)
- Cryptorchidism:** (kript-OR-ki-dizm) A birth condition in which one or both of the testicles have not descended into the scrotum. (Ch. 41)
- Culdocentesis:** (KUL-doh-sen-TEE-sis) The procedure for obtaining material from the posterior vaginal cul-de-sac by aspiration or surgical incision through the vaginal wall, performed for therapeutic or diagnostic reasons. (Ch. 40)
- Culdoscopy:** (kul-DOS-koh-pee) Direct visual examination of the female viscera through an endoscope introduced into the pelvic cavity through the posterior vaginal fornix. (Ch. 39)
- Culdotomy:** (KUL-DOT-uh-mee) Incision or needle puncture of the cul-de-sac of Douglas through the vagina. (Ch. 40)
- Cultural awareness:** (KUL-chur-uhl a-WARE-ness) Being aware of history and ancestry and having an appreciation of and attention to the crafts, arts, music, foods, and clothing of various cultures. (Ch. 3)
- Cultural competence:** (KUL-chur-uhl KOM-pe-tens) Having an awareness of one's own culture and not letting it have an undue influence over another person's culture. Having the knowledge and skills about a culture that are required to provide care. (Ch. 3)
- Cultural diversity:** (KUL-chur-uhl di-VER-si-tee) Representing two or more cultures; the differences among cultures. For example, the United States includes people from many different countries. (Ch. 3)
- Cultural sensitivity:** (KUL-chur-uhl SEN-si-TIV-i-tee) Being aware of and sensitive to cultural differences. Avoiding behavior or language that may be offensive to another person's cultural beliefs. (Ch. 3)
- Culture:** (KUL-chur) The socially transmitted behavior patterns, beliefs, values, customs, arts, and all other characteristics of people that guide their worldview. (Ch. 3)
- Curet:** (kyoo-RET) A loop, ring, or spoon-shaped instrument, attached to a handle and having sharp or blunt edges; used to scrape tissue from a surface. (Ch. 39)
- Custom:** (KUS-tum) A custom is the usual way of acting in a given circumstance or something that an individual or group does out of habit. For example, many people have turkey on Thanksgiving. (Ch. 3)
- Cyanosis:** (SIGH-uh-NOH-sis) Slightly bluish, grayish, or dark purple discoloration of the skin caused by the presence of abnormal amounts of reduced hemoglobin in the blood. (Ch. 8, 21, 26)
- Cystic:** (SIS-tik) Pertaining to cysts or the urinary bladder. (Ch. 39)
- Cystitis:** (sis-TIGH-tis) Inflammation of the urinary bladder. (Ch. 35)
- Cystocele:** (SIS-toh-seel) A bladder hernia that protrudes into the vagina. (Ch. 40)
- Cytomegalovirus:** (sigh-TOW-meg-ul-low-vigh-rus) Species-specific herpesvirus; usually harmless to those with functional immune systems. May cause fatal pneumonia in those who are immunocompromised. Affects retina and may cause blindness in those with acquired immunodeficiency syndrome. (Ch. 54)
- Cystoscopy:** (sis-TAHS-koh-pee) A diagnostic procedure using an instrument (cystoscope) via the urethra to view the bladder. (Ch. 34)
- Cytotoxic:** (SIGH-toh-TOCK-sick) Destructive to cells. (Ch. 10, 42)
- Data:** (DAY-tuh) A group of facts or statistics. (Ch. 1)
- Data, objective:** SEE objective data. (Ch. 1)
- Data, subjective:** SEE subjective data. (Ch. 1)
- Debridement:** (day-breed-MAHNT) The removal of foreign material and contaminated and devitalized tissues from or adjacent to a traumatic or infected area until surrounding healthy tissue is exposed. (Ch. 11)
- Decerebrate:** (dee-SER-e-brayt) Posture of an individual with absence of cerebral function. (Ch. 45)
- Decorticate:** (dee-KOR-ti-kayt) Posture of an individual with a lesion at or above the upper brain stem. (Ch. 45)
- Defibrillation:** (dee-FIB-ri-lay-shun) Use of an electrical device that applies countershock to the heart through electrodes placed on the chest wall to stop fibrillation of the heart. (Ch. 20)
- Degeneration:** (de-jen-er-AY-shun) Deterioration. (Ch. 47)
- Dehiscence:** (dee-HISS-ents) A splitting open (i.e., rupture) of an incision. (Ch. 11)
- Dehydration:** (DEE-high-DRAY-shun) A condition resulting from excessive loss of body fluid that occurs when fluid output exceeds intake. (Ch. 5)

- Delirium tremens:** (dee-LIR-ee-uhm TREE-menz) An acute alcohol withdrawal syndrome marked by acute, transient disturbance of consciousness. (Ch. 55)
- Delusions:** (dee-LOO-zhuns) False beliefs that are firmly maintained in spite of incontrovertible proof to the contrary. (Ch. 55)
- Dementia:** (dee-MEN-cha) A broad term that refers to cognitive deficit, including memory impairment. (Ch. 14, 46)
- Demyelination:** (dee-MY-uh-lin-AY-shun) Loss of myelin from neurons. (Ch. 47)
- Deontology:** (DA-on-TOL-o-gee) The study of moral obligations and commitments, including medical ethics. (Ch. 2)
- Dependence:** (di-PEN-dens) A state of reliance on something. Psychological craving for a drug that may or may not be accompanied by a physiological need. (Ch. 55)
- Depression:** (dee-PRESS-shun) A mental disorder marked by altered mood with loss of interest. (Ch. 14)
- Dermatitis:** (DER-mah-TIGH-tis) Inflammation of the skin. (Ch. 51)
- Dermatophytosis:** (DER-mah-toh-fye-TOH-sis) A fungal infection of the skin. (Ch. 51)
- Dermoid:** (DER-moyd) Resembling the skin. (Ch. 40)
- Developmental stage:** (DEE-vell-up-MEN-tal STAYJ) An age-defined period with specific psychological tasks that need to be accomplished to maintain ego as proposed by Erik Erikson, a psychoanalyst. (Ch. 13)
- Diabetes mellitus:** (DYE-ah-BEE-tis mel-LYE-tus) A chronic disease characterized by impaired production or use of insulin and high blood glucose levels. (Ch. 38)
- Diarrhea:** (DYE-uh-REE-ah) Passage of fluid or unformed stools. (Ch. 31)
- Diastolic blood pressure:** (dye-ah-STAH-lik BLUHD PRE-shure) The amount of pressure exerted on the wall of the arteries when the ventricles are at rest. The bottom number in a blood pressure reading. (Ch. 16)
- Diffusion:** (di-FEW-zhun) The tendency of molecules of a substance (gaseous, liquid, or solid) to move from a region of high concentration to one of lower concentration. (Ch. 5)
- Dilation and curettage:** (DIL-AY-shun and kyoor-e-TAHZH) A surgical procedure that expands the cervical canal of the uterus (dilation) so that the surface lining of the uterine wall can be scraped (curettage). (Ch. 40)
- Displacement:** (dis-PLAYSS-ment) Transference of emotion from the original idea with which it was associated to a different idea, allowing the client to avoid acknowledging the original source. (Ch. 55)
- Disseminated intravascular coagulation:** (dis-SEM-i-NAY-ted IN-trah-VAS-kyoo-lar koh-AG-yoo-LAY-shun) A pathological form of coagulation that is diffuse (widespread) rather than localized, as would be the case in normal coagulation. Clotting factors are consumed to such an extent that generalized bleeding may occur. (Ch. 24)
- Distributive shock:** (dis-TRIB-yoo-tiv) Excessive dilation of the venules and arterioles, leading to decreased distribution of blood, resulting in shock. (Ch. 8, 12)
- Distributive justice:** (dis-TRIB-yoo-tiv JUS-tiss) The right of individuals to be treated equally regardless of race, sex, marital status, sexual preference, medical diagnosis, social standing, economic level, or religious belief. (Ch. 2)
- Diverticulitis:** (DYE-ver-tik-yoo-LYE-tis) Inflammation of a diverticulum (a sac or pouch in the walls of a canal or organ, usually the colon), especially inflammation involving diverticula of the colon. (Ch. 31)
- Diverticulosis:** (DYE-ver-tik-yoo-LOH-sis) The presence of diverticula in the absence of inflammation. (Ch. 31)
- Dormant:** (DOOR-mant) Condition of greatly reduced metabolic activity permitting long-term survival and possible reactivation of bacterial endospores, protozoan cysts, larval stages of worm parasites, and viruses. (Ch. 7)
- Dressler's syndrome:** (DRESS-lers SIN-drohm) Postmyocardial infarction syndrome; pericarditis. (Ch. 17)
- Dysarthria:** (dis-AR-three-ah) Imperfect articulation of speech caused by disturbances of muscular control resulting from central or peripheral nervous system damage. (Ch. 45)
- Dysfunctional:** (dis-FUNCK-shun-uhl) Family or work environment that does not function effectively, sometimes because of other problems of members. (Ch. 55)
- Dysmenorrhea:** (DIS-men-oh-REE-ah) Pain in association with menstruation. (Ch. 40)
- Dyspareunia:** (DIS-puh-ROO-nee-ah) Occurrence of pain in the labia, vagina, or pelvis during or after sexual intercourse. (Ch. 40)
- Dysphagia:** (dis-FAYJ-ee-ah) Inability to swallow or difficulty swallowing. (Ch. 27, 37, 45)
- Dysplasia:** (dis-PLAY-zee-ah) Abnormal development of tissue. (Ch. 40)
- Dyspnea:** (DISP-nee-ah) Subjective sense of labored breathing that occurs because of insufficient oxygenation. (Ch. 26)
- Dysreflexia:** (DIS-re-FLEK-see-ah) State in which an individual with a spinal cord injury at or above T7 experiences an uninhibited sympathetic response to a noxious stimulus. (Ch. 46)
- Dysrhythmia:** (dis-RITH-mee-yah) Abnormal, disordered, or disturbed cardiac rhythm. (Ch. 5, 8, 15, 20)
- Dysuria:** (dis-YOO-ree-ah) Difficult or painful urination. (Ch. 34, 35)
- Echymoses:** (ECK-uh-MOH-sis) A bruise of varying size, the color of which may be blue-black, changing to greenish yellow or yellow with time. (Ch. 23, 50)
- Ectasia:** (ek-TAY-zee-ah) Replacement of normal tissue with fibrous tissue. (Ch. 40)
- Ectopic:** (eck-TOP-ick) Ectopic hormones are secreted from sites other than the gland where they would normally be found. (Ch. 28, 37, 39)
- Edema:** (uh-DEE-muh) Collection of excess fluid in body tissues. (Ch. 5, 14, 21)
- Ejaculation:** (ee-JAK-yoo-LAY-shun) The release of semen from the male urethra. (Ch. 39)
- Electrocautery:** (ee-LECK-troh-CAW-tur-ee) Cauterization using platinum wires heated to red or white heat by an electric current, either direct or alternating. (Ch. 42)
- Electrocardiogram:** (ee-LECK-troh-KAR-dee-oh-GRAM) A recording of the electrical activity of the heart. (Ch. 20)
- Electrocoagulated:** (ee-LECK-troh-coh-AG-yoo-LAY-ted) Coagulation of tissue by means of a high-frequency electric current. (Ch. 42)

- Electroconvulsive therapy (ECT):** (ee-LEK-troh-kun-VUL-siv THER-uh-pee) A type of somatic therapy in which an electric current is used to produce convulsions to treat such conditions as depression. (Ch. 55)
- Electroencephalogram:** (ee-LEK-troh-en-SEFF-uh-loh-gram) A record produced by electroencephalography; tracing of the electrical impulses of the brain. (Ch. 45)
- Electrolyte:** (ee-LEK-troh-lite) A substance that when dissolved in water can conduct electricity. (Ch. 5)
- Electroretinography:** (ee-LEK-troh-RET-in-AHG-ruh-fee) Measurement of the electrical response of the retina to light stimulation. (Ch. 48)
- Emboli:** (EM-boh-li) Solid, liquid, or gaseous masses of undissolved matter traveling with the fluid current in a blood or lymphatic vessel. (Ch. 17)
- Embolism:** (EM-buh-lizm) Foreign substance or blood clot that travels through the circulatory system until it obstructs a vessel. (Ch. 18, 28)
- Empathy:** (EM-puh-thee) Objective awareness of and insight into the feelings, emotions, and behavior of another person. (Ch. 2)
- Emphysema:** (EM-fi-SEE-mah) Distention of interstitial tissue by gas or air; chronic pulmonary disease marked by terminal bronchiole and alveolar destruction and air trapping. (Ch. 28)
- Empyema:** (EM-pigh-EE-mah) Pus in a body cavity, especially the pleural space. (Ch. 28)
- Encephalitis:** (EN-seff-uh-LYE-tis) Inflammation of the brain. (Ch. 46)
- Encephalopathy:** (en-SEFF-uh-LAHP-ah-thee) Dysfunction of the brain. (Ch. 22, 33, 46)
- Endarterectomy:** (end-AR-tur-ECK-tuh-mee) Excision of thickened atheromatous areas of the innermost coat of an artery. (Ch. 22, 46)
- Endogenous:** (en-DAH-jen-us) Produced or originating from within a cell or organism. (Ch. 38, 40)
- Endometritis:** (EN-doh-me-TRY-tis) Inflammation of the endometrium of the uterus. (Ch. 42)
- Endorphins:** (en-DOR-fins) Naturally occurring opioids in the body, many times more potent than analgesic medications. (Ch. 9)
- Endoscope:** (EN-doh-skohp) A device consisting of a tube and optical system for observing the inside of a hollow organ or cavity. Can be flexible or rigid. (Ch. 29)
- Enkephalins:** (en-KEF-e-lins) One type of endorphin. (Ch. 9)
- Enteritis:** (en-ter-EYE-tis) Inflammation of the intestines, particularly of the mucosa and submucosa of the small intestine. (Ch. 31, 42)
- Enucleation:** (ee-NEW-klee-AY-shun) Removal of an organ or other mass intact from its supporting tissues, as of the eyeball from the orbit. (Ch. 49)
- Epidemiological:** (EP-i-DEE-me-ah-LAHJ-i-kuhl) The study of the distribution and determinants of health-related states and events in populations and the application of this study to the control of health problems. (Ch. 42)
- Epididymitis:** (EP-i-DID-i-MY-tis) Inflammation or infection of the epididymis. (Ch. 41)
- Epidural:** (EP-i-DUHR-uhl) Situated on or outside the dura mater. (Ch. 46)
- Epinephrine:** (EP-i-NEFF-rin) A hormone secreted by the adrenal medulla in response to stimulation of the sympathetic nervous system. (Ch. 8)
- Epistaxis:** (EP-iss-TAX-iss) Nosebleed. (Ch. 27)
- Epithelialization:** (ep-i-THEE-lee-al-eye-ZAY-shun) The growth of skin over a wound. (Ch. 51)
- Equianalgesic:** (EE-kwee-AN-uhl-JEE-zik) Drugs having equal pain killing effect. The same degree of pain relief may require different doses when different medications are given or medications are given by different routes. (Ch. 9)
- Erectile dysfunction:** (e-RECK-tile dis-FUNCK-shun) Inability to have an erection sufficient for sexual intercourse. (Ch. 41)
- Erection:** (e-REK-shun) Enlargement and hardening of the penis caused by engorgement of blood. (Ch. 39)
- Erythema:** (ER-i-THEE-mah) Diffuse redness over the skin. (Ch. 50)
- Eschar:** (ESS-kar) Hard scab or dry crust that results from necrotic tissue. (Ch. 51)
- Escharotomy:** (ess-kar-AHT-oh-mee) Removal of a slough or scab formed on the skin and underlying tissue of severely burned skin. (Ch. 51)
- Esophagogastroduodenoscopy:** (e-SOFF-ah-go-GAS-troh-doo-AH-den-AHS-kuh-pee) An endoscopic procedure that allows the physician view the esophagus, stomach, and duodenum. (Ch. 32)
- Esophagoscopy:** (ee-soff-ah-GAHS-kuh-pee) Examination of the esophagus using an endoscope. (Ch. 29)
- Esotropia:** (ESS-oh-TROH-pee-ah) Strabismus in which there is deviation of the visual axis of one eye toward that of the other eye, resulting in diplopia. Also called cross-eyed. (Ch. 48)
- Essential hypertension:** (e-SEN-shul HIGH-per-TEN-shun) Chronic elevation of blood pressure resulting from an unknown cause. (Ch. 16)
- Ethical:** (ETH-i-kuhl) Describes behavior guided by a system of moral principles or standards. (Ch. 2)
- Ethnic:** (ETH-nick) Pertaining to a religious, racial, national, or cultural group. For example, individuals may identify with the Jewish, Catholic, or Islamic religions. (Ch. 3)
- Ethnocentrism:** (ETH-noh-SEN-trizm) The tendency to think that one's own ways of thinking, believing, and acting are the only right ways. People who are different are seen as strange or bizarre. An example is one who believes that his or her religious beliefs are the only right beliefs and other religions are wrong. (Ch. 3)
- Eustress:** (YOO-stress) Stress from positive experiences. (Ch. 55)
- Euthyroid:** (yoo-THY-royd) Normal thyroid function. (Ch. 37)
- Evaluation:** (e-VAL-yoo-AY-shun) The judgment of anything. (Ch. 1)
- Evisceration:** (E-VIS-sir-a-shun) Extrusion of viscera outside the body, especially through a surgical excision. (Ch. 11)
- Exacerbation:** (egg-sass-sir-BAY-shun) Aggravation of symptoms. (Ch. 47)
- Exophthalmos:** (ECKS-off-THAL-mus) Abnormal protrusion of the eyeball. (Ch. 36, 37)

- Exotropia:** (EKS-oh-TROH-pee-ah) Abnormal turning outward of one or both eyes; divergent strabismus. (Ch. 48)
- Expectorant:** (ek-SPEK-tuh-rant) Agent that promotes removal of pulmonary secretions. (Ch. 28)
- Expectorate:** (eck-SPECK-tuh-RAYT) The act or process of coughing up materials from the air passageways leading to the lungs. (Ch. 14)
- External otitis:** (eks-TER-nuhl oh-TIGH-tis) Inflammation of the external ear. (Ch. 49)
- Extracardiac:** (EX-trah-KAR-dee-ack) Outside the heart. (Ch. 8)
- Extracellular:** (EX-trah-SELL-yoo-ler) Outside the cell. (Ch. 5)
- Extracorporeal shock wave lithotripsy (ESWL):** (ECKS-trah-koar-POR-ee-uhl SHAHK WAYV LITH-oh-TRIP-see) Noninvasive treatment using shock waves to break up gallstones or kidney stones. (Ch. 33, 35)
- Extravasation:** (eks-TRA-vah-ZAY-shun) The escape of fluids into surrounding tissue. (Ch. 6)
- Extrinsic factors:** (eks-TRIN-sik FAK-ters) External variables. (Ch. 14)
- Exudate:** (EKS-yoo-dayt) Accumulated fluid in a cavity; ooze of pus or serum; often the result of inflammation. (Ch. 27, 28)
- Fasciculation:** (fah-SIK-yoo-LAY-shun) Twitching. (Ch. 47)
- Fasciotomy:** (fash-e-OTT-oh-me) Incision of fascia. (Ch. 44)
- Feminist:** (FEM-un-nist) A person who advocates for women the same rights as men. (Ch. 2)
- Fetor hepaticus:** (FEE-tor he-PAT-i-kus) Foul breath associated with liver disease. (Ch. 33)
- Fibrocystic:** (FIGH-broh-SIS-tik) Consisting of fibrocysts, which are fibrous tumors that have undergone cystic degeneration or accumulated fluid. (Ch. 40)
- Fidelity:** (fi-DEL-i-tee) The obligation to be faithful to commitments made to self and others. (Ch. 2)
- Filtration:** (fill-TRAY-shun) The process of removing particles from a solution by allowing the liquid portion to pass through a membrane or other partial barrier. (Ch. 5)
- Fissure:** (FISH-er) A narrow slit or cleft, especially one of the deeper or more constant furrows separating the gyri of the brain. (Ch. 31)
- Fistula:** (FIST-yoo-lah) Any abnormal, tubelike passage within body tissue, usually between two internal organs, or leading from an internal organ to the body surface. (Ch. 31)
- Flaccid:** (FLA-sid) Weak, lax, soft muscles. (Ch. 46)
- Flail chest:** (FLAY-ul chesst) Condition of the chest wall caused by two or more fractures on each affected rib resulting in a segment of rib that is not attached on either end; the flail portion moves paradoxically in with inspiration and out with expiration. (Ch. 12)
- Flora:** (FLOOR-a) Microbial life adapted for living in a specific environment such as the intestines, skin, or urinary tract. (Ch. 7)
- Fluoroscope:** (FLAW-or-oh-skohp) A device consisting of a fluorescent screen suitably mounted, either separately or in conjunction with an x-ray tube, by means of which the shadows of objects interposed between the tube and the screen are made visible. (Ch. 29)
- Fluoroscopy:** (fluh-RAHS-kuh-pee) The use of a fluoroscope for medical diagnosis or for testing various materials by roentgen rays. (Ch. 20)
- Full-thickness burn:** (FUL-THICK-ness BERN) Burn in which all of the epithelializing elements and those lining the sweat glands, hair follicles, and sebaceous glands are destroyed. (Ch. 12, 51)
- Fungi:** (FUNG-guy) A general term for a group of eukaryotic organisms (e.g., mushrooms, yeasts, molds). (Ch. 7)
- Furuncle:** (FYOOR-ung-kull) An acute circumscribed inflammation of the subcutaneous layers of the skin or of a gland or hair follicle. (Ch. 49)
- Gastrectomy:** (gas-TREK-tuh-mee) Any surgery that involves partial or total removal of the stomach. (Ch. 30)
- Gastric acid stimulation test:** (GAS-trik ASS-id STIM-yoo-LAY-shun TEST) A test that measures the amount of gastric acid for 1 hour after subcutaneous injection of a drug that stimulates gastric acid secretion. (Ch. 29)
- Gastric analysis:** (GAS-trik ah-NAL-i-sis) A test performed to measure secretions of hydrochloric acid and pepsin in the stomach. (Ch. 29)
- Gastric lavage:** (GAS-trik la-VAHJ) Washing out of the stomach; used to empty the stomach when the contents are irritating. (Ch. 12)
- Gastritis:** (gas-TRY-tis) Acute—The inflammation of the stomach mucosa; also known as heartburn or indigestion. Chronic—Gastritis that is recurrent; classified as type A (asymptomatic) or type B (symptomatic). (Ch. 30)
- Gastroduodenostomy:** (GAS-troh-DOO-oh-den-AHS-toh-mee) Excision of the pylorus of the stomach with anastomosis of the upper portion of the stomach to the duodenum. (Ch. 30)
- Gastroepiploic:** (GAS-troh-EP-i-PLOH-ick) Pertaining to the stomach and greater omentum. (Ch. 22)
- Gastrojejunostomy:** (GAS-troh-JAY-joo-NAHS-toh-mee) Subtotal excision of the stomach with closure of the proximal end of the duodenum and side-to-side anastomosis of the jejunum to the remaining portion of the stomach. (Ch. 30)
- Gastroparesis:** (GAS-troh-puh-REE-sis) Paralysis of the stomach, resulting in poor emptying. (Ch. 38)
- Gastroplasty:** (GAS-troh-PLAS-tee) Plastic surgery of the stomach. Used to decrease the size of the stomach to treat morbid obesity. (Ch. 30)
- Gastrosocopy:** (gas-TRAHS-kuh-pee) Examination of the stomach and abdominal cavity by use of a gastroscope. (Ch. 29)
- Gastrostomy:** (gas-TRAHS-toh-mee) Surgical creation of a gastric fistula through the abdominal wall. (Ch. 29)
- Gavage:** (gah-VAZH) Feeding with a stomach tube or with a tube passed through the nares, pharynx, and esophagus into the stomach. The food is in liquid or semiliquid form at room temperature. (Ch. 29)

- Generalization:** (JEN-er-al-i-ZAY-shun) An assumption about a group or an individual item or person that leads to seeking additional information to determine if the generalization fits the individual. Whereas generalizations are true for the group, they may not be true for the individual. (Ch. 3)
- Glaucoma:** (glaw-KOH-mah) A group of eye diseases characterized by increased intraocular pressure. (Ch. 14, 49)
- Glomerulonephritis:** (gloh-MER-yoo-loh-ne-FRY-tis) A form of nephritis in which the lesions involve primarily the glomeruli. (Ch. 35)
- Glossitis:** (glah-SIGH-tis) An inflammation of the tongue. (Ch. 24)
- Glycosuria:** (GLY-kos-YOO-ree-ah) Abnormal amount of glucose in the urine, often associated with diabetes mellitus. (Ch. 38)
- Goitrogens:** (GOY-troh-jenz) Foods or medications that cause a goiter. (Ch. 37)
- Gummas:** (GUM-ahs) A soft granulomatous tumor of the tissues characteristic of the tertiary stage of syphilis. (Ch. 42)
- Gynecomastia:** (JIN-e-koh-MASS-tee-ah) Excessive breast tissue on a male. (Ch. 39)
- Hallucinations:** (huh-LOO-si-NAY-shuns) False perceptions having no relation to reality and not accounted for by any exterior stimuli. (Ch. 55)
- Health:** (HELLTH) A condition in which all functions of the body and mind are normally active. (Ch. 13)
- Hearing aid:** (HEER-ing AYD) An instrument to amplify sounds for those with hearing loss. (Ch. 48)
- Heatstroke:** (HEET-strohk) An acute and dangerous reaction to heat exposure, characterized by high body temperature, usually higher than 105° F (40.5° C). (Ch. 12)
- Helicobacter pylori:** (HEH-lick-co-back-tur PIE-lori) Bacterium that causes some peptic ulcers. (Ch. 30)
- Hemarthrosis:** (HEEM-ar-THROH-sis) Bleeding into a joint. (Ch. 24, 43)
- Hematochezia:** (HEM-uh-toh-KEE-zee-uh) Blood in the feces. (Ch. 31)
- Hematoma:** (HEE-muh-TOH-mah) A localized collection of extravasated blood, usually clotted, in an organ, space, or tissue. (Ch. 11)
- Hematuria:** (HEM-uh-TYOOR-ee-ah) Blood in the urine. (Ch. 34)
- Hemiparesis:** (hem-ee-puh-REE-sis) Weakness affecting one side of the body. (Ch. 45, 46)
- Hemipelvectomy:** (hem-ee-pell-VEC-toe-me) The surgical removal of half of the pelvis and the leg. (Ch. 44)
- Hemiplegia:** (hem-ee-PLÉE-jee-ah) Paralysis of only one side of the body. (Ch. 46)
- Hemodialysis:** (HEE-moh-dye-AL-i-sis) A method for replacing the function of the kidneys by circulating blood through tubes made of semipermeable membranes. (Ch. 35)
- Hemolysis:** (he-MAHL-e-sis) The destruction of the membrane of red blood cells with the liberation of hemoglobin, which diffuses into the surrounding fluid. (Ch. 22, 24)
- Hemophilia:** (HEE-moh-FILL-ee-ah) A hereditary blood disease marked by greatly prolonged coagulation time, with consequent failure of the blood to clot and abnormal bleeding. (Ch. 24)
- Hemoptysis:** (hee-MOP-ti-sis) Coughing up of blood from respiratory tract. (Ch. 28)
- Hemorrhoids:** (HEM-uh-royds) A mass of dilated, tortuous veins in the anorectum involving the venous plexuses of that area. (Ch. 31)
- Hemothorax:** (HEE-moh-THAW-raks) Blood in the pleural space; may be associated with trauma, tuberculosis, or pneumonia. (Ch. 28)
- Hepatomegaly:** (HEP-uh-toh-MEG-ah-lee) Enlargement of the liver. (Ch. 21)
- Hepatitis:** (HEP-uh-TIGH-tis) Inflammation of the liver, most often viral. (Ch. 33)
- Hepatorenal syndrome:** (hep-PAT-oh-REE-nuhl SINDroh) A deadly kidney failure that sometimes accompanies liver disease. (Ch. 33)
- Hepatosplenomegaly:** (he-PA-toh-SPLE-noh-MEG-ah-lee) Enlargement of the liver and spleen. (Ch. 42)
- Hernia:** (HER-nee-uh) The protrusion or projection of an organ or a part of an organ through the wall of the cavity that normally contains it. (Ch. 31)
- Herpettic:** (her-PET-ick) Pertaining to herpes. (Ch. 42)
- Hiatal hernia:** (high-AY-tuhl HER-nee-ah) A condition in which part of the stomach protrudes through and above the diaphragm. (Ch. 30)
- High-density lipoprotein (HDL):** (HIGH DEN-si-tee LIP-oh-PROH-teen) Plasma lipids bound to albumin consisting of lipoproteins. It has been found that those with high levels of HDL have less chance of having coronary artery disease. (Ch. 18)
- Histamine:** (HISS-ta-mean) A substance produced in the body that increases gastric secretion, increases capillary permeability, contracts the bronchial smooth muscle. Plays a role in allergic reaction. (Ch. 53)
- Homans' sign:** (HOH-manz SIGHN) An assessment for venous thrombosis in which calf pain with dorsiflexion occurs if thrombosis is present. (Ch. 15)
- Homeopathy:** (HO-mee-AH-pa-thee) System of medicine based on the theory that "like cures like," and uses tiny doses of a substance that create the symptoms of disease. (Ch. 4)
- Homeostasis:** (HOH-mee-oh-STAY-sis) Maintaining a constant balance, especially whenever a change occurs. (Ch. 14)
- Hopelessness:** (HOHP-less-ness) Subjective state in which a person sees limited or unavailable alternatives; lacking energy. (Ch. 13)
- Hordeolum:** (hor-DEE-oh-lum) Sty. (Ch. 49)
- Host:** (HOE-st) The organism from which a parasite obtains its nourishment. (Ch. 7)
- Human immunodeficiency virus (HIV):** (HYOO-man im-YOO-noh-dee-FISH-en-see VIGH-rus) A retrovirus that causes acquired immunodeficiency syndrome (AIDS). (Ch. 54)

- Humoral:** (HYOO-mohr-uhl) Pertaining to body fluids or substances contained in them. (Ch. 52)
- Hydrocele:** (HIGH-droh-seel) A collection of fluid in the scrotal sack. (Ch. 39, 41)
- Hydrocephalus:** (HIGH-droh-SEF-uh-luhs) A condition caused by enlargement of the cranium caused by abnormal accumulation of cerebrospinal fluid within the cerebral ventricular system. (Ch. 46)
- Hydronephrosis:** (HIGH-droh-ne-FROH-sis) Abnormal dilation of kidneys caused by obstruction of urine flow. (Ch. 35, 41)
- Hydrostatic:** (HIGH-droh-STAT-ik) Pertaining to the pressure of liquids in equilibrium and to the pressure exerted by liquids. (Ch. 5)
- Hypercalcemia:** (HIGH-per-kal-SEE-mee-ah) An excessive amount of calcium in the blood. (Ch. 5)
- Hyperglycemia:** (HIGH-per-gligh-SEE-mee-ah) Excess glucose in the blood. (Ch. 38)
- Hyperkalemia:** (HIGH-per-kuh-LEE-mee-ah) An excessive amount of potassium in the blood. (Ch. 5, 20)
- Hyperlipidemia:** (HIGH-per-LIP-i-DEE-mee-ah) Excessive quantity of fat in the blood. (Ch. 18)
- Hypermagnesemia:** (HIGH-per-MAG-nuh-ZEE-mee-ah) Excess magnesium in the blood. (Ch. 5)
- Hypernatremia:** (HIGH-per-nuh-TREE-mee-ah) Excess sodium in the blood. (Ch. 5)
- Hyperopia:** (HIGH-per-OH-pee-ah) Farsightedness. (Ch. 49)
- Hyperplasia:** (HIGH-per-PLAY-zee-ah) Excessive increase in the number of normal cells. (Ch. 37, 41)
- Hypertension:** (HIGH-per-TEN-shun) Abnormally elevated blood pressure. (Ch. 16)
- Hypertensive crisis:** (HIGH-per-TEN-siv CRY-sis) Arbitrarily defined as severe elevation in diastolic blood pressure above 120 to 130 mm Hg. (Ch. 16)
- Hypertonic:** (HIGH-per-TAHN-ik) Exerts greater osmotic pressure than blood. (Ch. 5, 6)
- Hypertrophy:** (high-PER-truh-fee) An increase in the size of an organ or structure, or of the body, owing to growth rather than tumor formation. (Ch. 16, 40)
- Hyperuricemia:** (HIGH-per-yoor-a-SEE-me-ah) An excess of uric acid or urates in the blood. (Ch. 44)
- Hyperventilation:** (HIGH-per-VEN-ti-LAY-shun) Increased ventilation that results in a lowered carbon dioxide (CO₂) level (hypocapnia). (Ch. 5)
- Hypervolemia:** (HIGH-per-voh-LEE-mee-ah) An abnormal increase in the volume of circulating blood. (Ch. 5)
- Hypocalcemia:** (HIGH-poh-kal-SEE-mee-ah) Reduced amount of calcium in the blood. (Ch. 5)
- Hypoglycemia:** (HIGH-poh-gligh-SEE-mee-ah) Below-normal amount of glucose in the blood. (Ch. 38)
- Hypokalemia:** (HIGH-poh-kuh-LEE-mee-ah) Reduced amount of potassium in the blood. (Ch. 5)
- Hypomagnesemia:** (HIGH-poh-MAG-nuh-ZEE-mee-ah) Reduced amount of magnesium in the blood. (Ch. 5, 20)
- Hyponatremia:** (HIGH-poh-nuh-TREE-mee-ah) Reduced amount of sodium in the blood. (Ch. 5)
- Hypophysectomy:** (HIGH-pah-fi-SECK-tuh-mee) Surgical removal of the pituitary gland. (Ch. 37)
- Hypoplasia:** (HIGH-poh-PLAY-zee-ah) Underdevelopment of a tissue organ or body. (Ch. 40)
- Hypoproteinemia:** (HIGH-poh-pro-teen-EE-mee-ah) A decrease in the amount of protein in the blood. (Ch. 12)
- Hypospadias:** (HIGH-poh-SPAY-dee-ahz) A congenital male defect in which the opening of the urethra is on the underside of the penis, instead of the tip. (Ch. 39)
- Hypostatic:** (HIGH-poh-STA-tik) Hypostatic pneumonia occurs from congestion in the lungs associated with lack of activity. (Ch. 28)
- Hypotension:** (HIGH-poh-TEN-shun) Abnormally low blood pressure below 90 mm Hg systolic. (Ch. 8)
- Hypothermia:** (HIGH-poh-THER-mee-ah) Body temperature below 95° F (35° C). (Ch. 11, 22)
- Hypotonic:** (HIGH-poh-TAHN-ik) Pertaining to defective muscular tone or tension; having a lower concentration of solute than intracellular or extracellular fluid. (Ch. 5, 6)
- Hypovolemia:** (HIGH-poh-voh-LEE-mee-ah) The most common form of dehydration resulting from the loss of fluid from the body; results in decreased blood volume. (Ch. 5)
- Hypovolemic:** (HIGH-poh-voh-LEEM-ick) Low volume of blood in the circulatory system. (Ch. 8, 37)
- Hypovolemic shock:** (HIGH-poh-voh-LEEM-ick SHAHK) Shock that occurs when blood or plasma is lost in such quantities that the remaining blood cannot fill the circulatory system despite constriction of the blood vessels. (Ch. 12)
- Hypoxemia:** (HIGH-pock-SEE-mee-ah) Deficient oxygenation of the blood. (Ch. 22)
- Hypoxia:** (high-POCK-see-ah) Diminished availability of oxygen to the body tissues. (Ch. 22)
- Hysterectomy:** (HISS-tuh-RECK-tuh-mee) Surgical removal of the uterus through the abdominal wall or vagina. (Ch. 40)
- Hysterosalpingogram:** (HIS-tur-oh-SAL-pinj-oh-gram) Radiograph of the uterus and fallopian tubes. (Ch. 39)
- Hysteroscopy:** (HIS-tur-AHS-koh-pee) Endoscopic direct visual examination of the canal of the uterine cervix and the cavity of the uterus. (Ch. 39)
- Hysterotomy:** (HISS-tuh-RAH-tuh-mee) Incision of the uterus. (Ch. 40)
- Icterus:** (ICK-ter-us) Yellowing of the skin and the sclera of the eye. (Ch. 32)
- Idiopathic thrombocytopenic purpura:** (ID-ee-oh-PATH-ik THROM-boh-SIGH-toh-PEE-nik PUR-pew-rah) The total number of circulating platelets is greatly diminished, even though platelet production in the bone marrow is normal, resulting in slowed blood clotting. (Ch. 24)
- Ileostomy:** (ILL-ee-AH-stuh-me) An artificial opening (stoma) created in the small intestine (ileum) and brought to the surface of the abdomen for the purpose of evacuating feces. (Ch. 31)
- Illness:** (ILL-ness) The state of being sick. (Ch. 13)
- Illusions:** (i-LOO-zhuns) Mistaken perceptions of reality. (Ch. 55)

- Imagery:** (IM-ij-ree) The use of the imagination to promote relaxation. (Ch. 55)
- Immunocompromised:** (IM-yoo-noh-KAHM-prah-mized) Having an immune system that is not capable of reacting to a pathogen or tissue damage. (Ch. 28)
- Impaction:** (im-PAK-shun) An immovable accumulation of feces in the bowels. (Ch. 29, 31)
- Imperforate:** (im-PER-foh-rate) Without an opening. (Ch. 40)
- Induction:** (in-DUCK-shun) The process or act of causing to occur, as in anesthesia induction. (Ch. 11)
- Induration:** (IN-dyoo-RAY-shun) Area of hardened tissue. (Ch. 28)
- Infective endocarditis:** (in-FECK-tive EN-doh-kar-DYE-tis) Inflammation of the heart lining caused by microorganisms. (Ch. 17)
- In situ:** (in-SIT-yoo) Localized, not invading surrounding tissue. (Ch. 10)
- Inspection:** (in-SPEK-shun) Use of observation skills to systematically gather data that can be seen. (Ch. 1)
- Insufficiency:** (IN-suh-FISH-en-see) The condition of being inadequate for a given purpose, such as heart valves that do not close properly. (Ch. 19)
- Insufflation:** (in-suff-LAY-shun) Used to inflate the abdomen during laparoscopic or endoscopic procedures to enhance visualization of structures. (Ch. 39, 40)
- Intermittent claudication:** (IN-ter-MIT-ent KLAU-di-KAY-shun) A symptom associated with arterial occlusive disease. It refers to pain in the calf of a lower extremity, usually brought on by activity or exercise, and ceases with rest. (Ch. 18)
- International normalized ratio:** (IN-ter-NASH-uh-nul NOR-muh-lized RAY-she-oh) The World Health Organization's standardization for reporting the prothrombin time assay test when the thromboplastin reagent developed by the first International Reference Preparation is used. The reagent was developed to prevent variability in prothrombin time testing results and provide uniformity in monitoring therapeutic levels for coagulation during oral anticoagulation therapy. (Ch. 17)
- Interstitial:** (IN-ter-STISH-uhl) Fluid between tissues. (Ch. 5)
- Intervention:** (in-ter-VEN-shun) One or more actions taken in order to modify an effect. (Ch. 1)
- Intracellular:** (IN-trah-SELL-yoo-ler) Fluids located within the blood cell. (Ch. 5)
- Intracranial:** (IN-trah-KRAY-nee-uhl) Within the cranium or skull. (Ch. 5)
- Intraoperative:** (IN-trah-AHP-er-uh-tiv) Occurring during a surgical procedure. (Ch. 11)
- Intravascular:** (IN-trah-VAS-kyoo-lar) Fluids located within the blood vessels. (Ch. 5)
- Intravenous:** (IN-trah-VEE-nus) Within or into a vein. (Ch. 6)
- Intrinsic factors:** (in-TRIN-sik FAK-ters) Internal variables. (Ch. 14)
- Intussusception:** (IN-tuh-suh-SEP-shun) The slipping of one part of an intestine into another adjacent to it. (Ch. 31)
- In vitro fertilization:** (in VEE-troh FER-ti-li-ZAY-shun) Fertilization in a test tube. (Ch. 40)
- Ipsilateral:** (IP-si-LAT-er-uhl) On the same side; affecting the same side of the body. (Ch. 46)
- Ischemia:** (iss-KEY-me-ah) Condition of inadequate blood supply. (Ch. 8, 15)
- Isoelectric line:** (EYE-so-e-LEK-trick LINE) The period when the electrical tracing is at zero and is neither positive nor negative. (Ch. 20)
- Isolated systolic hypertension:** (EYE-suh-lay-ted sis-TAH-lik high-per-TEN-shun) The systolic pressure is 160 mm Hg or more, but the diastolic pressure is lower than 95 mm Hg. (Ch. 16)
- Isotonic:** (EYE-so-TAHN-ik) A fluid that has the same osmolarity as the blood. (Ch. 5, 6)
- Jaundice:** (JAWN-diss) Yellowing of the skin and the sclera of the eye. (Ch. 32)
- Joint:** (JOYNT) An articulation. The point of juncture between two bones. (Ch. 43)
- Kaposi's sarcoma:** (ka-POE-sees sar-CO-mah) A vascular malignancy that is often first apparent in the skin or mucous membranes but may involve the viscera. (Ch. 54)
- Ketoacidosis:** (KEE-toh-ass-i-DOH-sis) A condition in which fat breakdown produces ketones, which cause an acidic state in the body; may be associated with weight loss or diabetes mellitus. (Ch. 38)
- Kussmaul's:** (KOOS-mahlz) Term describing deep respirations of an individual with ketoacidosis. (Ch. 38)
- Laceration:** (la-sir-A-shun) A wound or irregular tear of the flesh. (Ch. 12)
- Lactic acid:** (LAK-tik ASS-id) By-product of anaerobic metabolism. (Ch. 8)
- Laminectomy:** (LAM-i-NEK-toh-mee) The excision of a vertebral posterior arch, usually to remove a lesion or herniated disk. (Ch. 46)
- Laparoscopy:** (LAP-uh-roh-SKOP-ee) Exploration of the abdomen with an endoscope. (Ch. 33)
- Laparotomy:** (LAP-uh-RAH-tuh-mee) The surgical opening of the abdomen; an abdominal operation. (Ch. 40)
- Laryngeal edema:** (lah-RIN-jee-uhl uh-DEE-muh) Sudden swelling of the larynx occurring with severe allergic reactions. (Ch. 8)
- Laryngectomy:** (lar-in-JEK-tah-mee) Surgical removal of the larynx. (Ch. 27)
- Laryngitis:** (lare-in-JIGH-tiss) Inflammation of the larynx. (Ch. 27)
- Laser ablation:** (LAY-zer uh-BLAY-shun) Therapeutic destruction of a growth or part of a growth by laser treatment. (Ch. 40)
- Lavage:** (lah-VAZH) Washing out of a cavity. (Ch. 29)
- Law:** (LAW) The further formalization of moral considerations. (Ch. 2)
- Leiomyoma:** (LYE-oh-my-OH-ma) A myoma consisting principally of smooth muscle tissue. (Ch. 40)

- Leukemia:** (loo-KEE-mee-ah) A malignancy of the blood-forming cells in the bone marrow. (Ch. 24)
- Leukocytosis:** (LOO-koh-sigh-TOH-sis) An increase in the number of leukocytes in the blood, generally caused by presence of infection and usually transient. (Ch. 22)
- Leukopenia:** (LOO-koh-PEE-nee-yah) Abnormal decrease of white blood cells, usually below 5000/mm³. (Ch. 10)
- Liability:** (LYE-uh-BIL-i-tee) The level of responsibility that society places on individuals for their actions. (Ch. 1)
- Libido:** (li-BEE-doh) Sexual drive, conscious or unconscious. (Ch. 39)
- Lichenified:** (lye-KEN-i-fyed) Thickened or hardened from continued irritation. (Ch. 51)
- Limitation of liability:** (lim-i-TAY-shun OF LYE-uh-BIL-i-tee) Steps that health care professionals can take to limit their liability. (Ch. 2)
- Lobectomy:** (loh-BEK-tuh-mee) Surgical removal of a lobe of any organ or gland. (Ch. 28)
- Lower gastrointestinal series (lower GI):** (LOH-er GAS-troh-in-TES-ti-nuhl SEER-ees) The use of barium sulfate as an enema to facilitate x-ray and fluoroscopic examination of the colon. (Ch. 29)
- Lymphadenopathy:** (lim-FAD-e-NAH-puh-thee) Any disorder of the lymph nodes. (Ch. 42)
- Lymphangitis:** (lim-FAN-je-EYE-tis) Inflammation of lymphatic channels or vessels. (Ch. 18)
- Lymphedema:** (LIMPF-uh-DEE-mah) An abnormal accumulation of tissue fluid (potential lymph) in the interstitial space. (Ch. 23)
- Lymphocytes:** (LIM-foh-sites) Cells present in the blood and lymphatic tissue that provide the main means of immunity for the body; white blood cells. (Ch. 52)
- Lymphoma:** (lim-FOH-mah) A usually malignant lymphoid neoplasm. (Ch. 25)
- Macular degeneration:** (MACK-you-lar dee-JEN-uh-RAY-shun) Age-related breakdown of the macular area of the retina of the eye. (Ch. 14, 49)
- Malignant:** (muh-LIG-nunt) Growing, resisting treatment; used to describe a tumor of cancerous cells. (Ch. 10)
- Malpractice:** (mal-PRAK-tiss) A breach of duty arising out of the relationship that exists between the client and the health care worker. (Ch. 2)
- Mammography:** (mah-MOG-rah-fee) Use of radiography of the breast to diagnose breast cancer. (Ch. 39)
- Mammoplasty:** (MAM-oh-PLAS-tee) Plastic surgery of the breast. (Ch. 40)
- Mania:** (MAY-nee-ah) Mental disorder characterized by excessive excitement. (Ch. 55)
- Marsupialization:** (mar-SOO-pee-al-i-ZAY-shun) Process of raising the borders of an evacuated tumor sac to the edges of the abdominal wound and stitching them there to form a pouch. (Ch. 40)
- Mastalgia:** (mass-TAL-jee-ah) Pain in the breast. (Ch. 40)
- Mastectomy:** (mass-TECK-tuh-mee) Excision of the breast. (Ch. 40)
- Mastitis:** (mass-TIGH-tis) Inflammation of the breast. (Ch. 40)
- Mastopexy:** (MAS-toh-PEKS-ee) Correction of a pendulous breast by surgical fixation and plastic surgery. (Ch. 40)
- Mediastinum:** (ME-dee-ah-STYE-num) A septum or cavity between two principal portions of an organ. (Ch. 22)
- Megacolon:** (MEG-ah-KOH-lun) Extremely dilated colon. (Ch. 31)
- Melena:** (muh-LEE-nah) Black, tarry feces caused by action of intestinal secretions on free blood. (Ch. 31)
- Menarche:** (me-NAR-kee) The initial menstrual period, normally occurring between the ninth and seventeenth year. (Ch. 39)
- Meniere's disease:** (MAY-nee-AIRZ di-ZEEZ) A recurrent and usually progressive group of symptoms including progressive deafness, ringing in the ears, dizziness, and a sensation of fullness or pressure in the ears. (Ch. 49)
- Meningitis:** (men-in-JIGH-tis) Inflammation of the membranes of the spinal cord and brain. (Ch. 46)
- Menopause:** (MEN-oh-pawz) The period that marks the permanent cessation of menstrual activity, usually occurring between the ages of 35 and 58. (Ch. 39)
- Mental health:** (MEN-tuhl HELLTH) State of being adjusted to life; able to be flexible, successful, maintain close relationships, solve problems, make appropriate judgments, and cope with daily stresses. (Ch. 55)
- Mental illness:** (MEN-tuhl ILL-ness) Any illness that affects the mind or behavior. (Ch. 55)
- Metastasis:** (muh-TASS-tuh-sis) Movement of bacteria or body cells (especially cancer cells) from one part of the body to another. (Ch. 10)
- Milieu:** (me-LYU) Environment. (Ch. 55)
- Miotic:** (my-AH-tik) An agent that causes the pupil to contract. (Ch. 49)
- Morality:** (muh-RAL-i-tee) A social barometer that dictates what is good or bad in a society. (Ch. 2)
- Morbidity:** (more-BID-it-ee) State of being diseased. (Ch. 7)
- Mortality:** (more-TAL-it-ee) Condition of being mortal; number of deaths in a population. (Ch. 7)
- Mucolytic:** (MYOO-koh-LIT-ik) Agent that liquefies sputum. (Ch. 28)
- Mucopurulent cervicitis:** (MYOO-koh-PYOOR-uh-lent SIR-vi-SIGH-tis) Inflammation of the cervix producing mucus and purulent discharge. (Ch. 42)
- Mucositis:** (MYOO-koh-SIGH-tis) Inflammation of a mucous membrane. (Ch. 10)
- Multifocal:** (MUHL-tee-FOH-kuhl) Many foci (areas) or sites. (Ch. 20)
- Murmur:** (MUR-mur) An abnormal sound heard on auscultation of the heart and adjacent large blood vessels. (Ch. 15, 19)
- Muscle:** (MUSS-uhl) A bundle of long slender cells or fibers that have the power to contract and hence to produce movement. (Ch. 43)
- Myalgia:** (my-AL-jee-ah) Muscle pain or tenderness. (Ch. 27)
- Myectomy:** (my-ECK-tuh-mee) Surgical removal of a hypertrophied muscle. (Ch. 17)

- Myelogram:** (MY-e-loh-gram) The film produced by radiography of the spinal cord after injection of a contrast medium into the subarachnoid space. (Ch. 45)
- Myocardial infarction:** (MY-oh-KAR-dee-yuhl in-FARK-shun) Death of cells of an area of the heart muscle, myocardium, as a result of oxygen deprivation, which in turn is caused by obstruction of the blood supply. Commonly referred to as a heart attack. (Ch. 18)
- Myocarditis:** (MY-oh-kar-DYE-tis) The inflammatory process that causes nodules to form in the myocardial tissue; the nodules become scar tissue over time. Inflammation of the heart muscle. (Ch. 8, 17)
- Myocardium:** (MY-oh-KAR-dee-um) Heart muscle. (Ch. 8)
- Myomectomy:** (my-oh-MECK-tuh-mee) Removal of a portion of muscle or muscular tissue. (Ch. 40)
- Myopia:** (my-OH-pee-ah) The error of refraction in which rays of light entering the eye parallel to the optic axis are brought to a focus in front of the retina; nearsightedness. (Ch. 49)
- Myringoplasty:** (mir-IN-goh-PLASS-tee) Surgical reconstruction of the tympanic membrane. (Ch. 49)
- Myringotomy:** (MIR-in-GOT-uh-mee) Incision of the tympanic membrane, usually performed to relieve pressure and allow for drainage of either serous or purulent fluid in the middle ear behind the tympanic membrane. (Ch. 49)
- Myxedema:** (MICK-suh-DEE-mah) Condition resulting from hypofunction of the thyroid gland. (Ch. 37)
- Nasoseptoplasty:** (NAY-zoh-SEP-toh-plass-tee) Surgical correction of the nasal septum. (Ch. 27)
- Naturopathy:** (NAY-chur-AH-pa-thee) System of medicine that uses natural therapies such as nutrition, herbs, hydrotherapy, counseling, physical medicine, and homeopathy to treat disease, promote healing, and prevent illness. (Ch. 4)
- Negligence:** (NEG-li-jense) An unintentional tort. (Ch. 2)
- Neoplasm:** (NEE-oh-PLAZ-uhm) New abnormal tissue growth, as in a tumor. (Ch. 10)
- Nephrectomy:** (ne-FREK-tuh-mee) Surgical removal of a kidney. (Ch. 35)
- Nephrogenic:** (NEFF-roh-JEN-ick) Caused by the kidneys. (Ch. 37)
- Nephrolithotomy:** (NEFF-roh-li-THOT-uh-mee) Incision of a kidney for removal of kidney stones. (Ch. 35)
- Nephropathy:** (ne-FROP-uh-thee) Any disease of the kidney. (Ch. 35, 38)
- Nephrosclerosis:** (NEFF-roh-skle-ROH-sis) Hardening of the kidney associated with hypertension and disease of the renal arterioles. (Ch. 35)
- Nephrostomy:** (ne-FRAHS-toh-mee) Creation of a permanent opening into the renal pelvis. (Ch. 35)
- Nephrotoxin:** (NEFF-roh-TOCK-sin) A toxin having a specific destructive effect on kidney tissue. (Ch. 22, 35)
- Neuralgia:** (new-RAL-jee-ah) Nerve pain. (Ch. 47)
- Neurogenic:** (NEW-roh-JEN-ik) Originating in the nervous system. (Ch. 8)
- Neuropathic pain:** (NEW-roh-PATH-ik PAYN) Pain resulting from peripheral nerve injury. (Ch. 9)
- Neuropathy:** (new-RAH-puh-thee) A general term denoting functional disturbances and pathologic changes in the peripheral nervous system. (Ch. 38, 47)
- Neutrophils:** (NEW-troh-fils) Granular leukocytes (white blood cells) having a nucleus with three to five lobes connected by threads of chromatin and cytoplasm containing very fine granules. (Ch. 52)
- Nociceptive:** (NOH-see-SEP-tiv) Pain sensitive. (Ch. 9)
- Nocturia:** (nock-TYOO-ree-ah) Excessive urination at night. (Ch. 14, 37, 38)
- Nodal or junctional rhythm:** (NOHD-uhl or JUNGK-shun-uhl RITH-uhm) A cardiac rhythm with its origin at the atrioventricular (AV) node. (Ch. 20)
- Nonmaleficence:** (NON-muh-LEF-i-sens) The requirement that health care providers do no harm to their clients, either intentionally or unintentionally. (Ch. 2)
- Norepinephrine:** (NOR-ep-i-NEFF-rin) A hormone produced by the adrenal medulla, similar in chemical and pharmacological properties to epinephrine, but chiefly a vasoconstrictor with little effect on cardiac output. (Ch. 8)
- Normotensive:** (nor-moh-TEN-siv) Normal blood pressure. (Ch. 16)
- Nosocomial infection:** (no-zoh-KOH-mee-uhl in-FECK-shun) Infection acquired in a health care agency. (Ch. 7)
- Nuchal rigidity:** (NEW-kuhl re-JID-i-tee) Rigidity of the nape, or back, of the neck. (Ch. 46)
- Nursing diagnosis:** (NER-sing DYE-ag-NOH-sis) A standardized label placed on a client's problem to make it understandable to all nurses. (Ch. 1)
- Nursing process:** (NER-sing PRAH-sess) An orderly, logical approach to administering nursing care so that the client's needs for such care are met comprehensively and effectively. (Ch. 1)
- Nystagmus:** (nis-TAG-muss) Involuntary, rapid, rhythmic eye movement. (Ch. 45, 48)
- Obesity:** (oh-BEE-si-tee) Abnormal amount of fat on the body from 20% to 30% over average weight for age, sex, and height. (Ch. 30)
- Objective data:** (ob-JEK-tiv DAY-tuh) Factual data obtained through physical assessment and diagnostic tests; objective data are observable or knowable through the five senses. (Ch. 1)
- Obsession:** (ub-SESH-un) Repetitive thought, urge, or emotion. (Ch. 55)
- Obstipation:** (OB-sti-PAY-shun) Intractable constipation. (Ch. 31)
- Obstructive shock:** (ub-STRUCK-tive SHAHK) Shock caused by indirect pump failure. (Ch. 12)
- Occult blood test:** (ah-KULT BLUHD TEST) A chemical test or microscopic examination for blood, especially in feces, that is not apparent on visual inspection. (Ch. 29)
- Oliguria:** (AWH-li-GYOO-ree-ah) Diminished urination. (Ch. 8, 35)
- Oncology:** (on-CAW-luh-jee) The study of cancer and cancer treatment. (Ch. 10)
- Oncovirus:** (ON-koh-VIGH-russ) Viruses linked to cancer in humans. (Ch. 10)

- Onychomycosis:** (ON-i-koh-my-KOH-sis) Disease of the nails caused by fungus. (Ch. 51)
- Ophthalmia neonatorum:** (ahf-THAL-mee-ah NEE-oh-nuh-TOR-uhm) Conjunctivitis in the newborn resulting from exposure to infectious or chemical agents. (Ch. 42)
- Ophthalmologist:** (AHF-thal-MAH-luh-jist) A physician who specializes in the treatment of disorders of the eye. (Ch. 48)
- Ophthalmoscope:** (ahf-THAL-muh-skohp) An instrument used for examining the interior of the eye, especially the retina. (Ch. 48)
- Opioid:** (OHP-ee-OYD) A narcotic drug with morphine-like effects. True opioids are derived from opium. (Ch. 9)
- Optician:** (ahp-TISH-uhn) One who specializes in filling prescriptions for corrective lenses for eyeglasses and contact lenses. (Ch. 48)
- Optimum level of functioning:** (OP-teh-mum LEV-uhl of FUNK-shun-ing) Highest level of client activity considering the client's condition. (Ch. 14)
- Optometrist:** (ahp-TOM-uh-trist) A doctor of optometry who diagnoses and treats conditions and diseases of the eye per state laws. (Ch. 48)
- Orchiectomy:** (or-ki-EK-toh-mee) Removal of one or both testicles; a treatment for prostate cancer. (Ch. 41)
- Orchitis:** (or-KIGH-tis) Inflammation of a testis. (Ch. 41)
- Orgasm:** (OR-gazm) Pleasurable physical release sensation related to physical, sexual, and psychological stimulation. (Ch. 39, 41)
- Orientation:** (OR-ee-en-TAY-shun) The ability to comprehend and to adjust oneself in an environment with regard to time, location, and identity of persons. (Ch. 55)
- Orthopnea:** (or-THOP-knee-a) Labored breathing that occurs when lying flat; relieved when sitting up; associated with left ventricular heart failure. (Ch. 21)
- Osmolality:** (ahs-moh-LAL-i-tee) Osmotic concentration; ionic concentration of the dissolved substances per unit of solvent. (Ch. 37)
- Osmosis:** (ahs-MOH-sis) The passage of solvent through a semipermeable membrane that separates solutions of different concentrations. (Ch. 5)
- Osteomyelitis:** (AHS-tee-oh-my-LIGHT-tis) Inflammation of bone, especially the marrow, caused by a pathogenic organism. (Ch. 44)
- Osteopathy:** (AHS-tee-ah-PATH-ee) System of medicine emphasizing the inter-relationship of the body's nerves, muscles, bones, and organs; involves treating the whole person, and stresses the importance of diet, exercise, and fitness, with a focus on prevention. (Ch. 4)
- Osteoporosis:** (AHS-tee-oh-por-OH-sis) A condition in which there is a reduction in the mass of bone per unit volume. (Ch. 5, 14)
- Osteosarcoma:** (AHS-tee-oh-sar-KOH-mah) A malignant sarcoma of a bone. (Ch. 44)
- Otalgia:** (oh-TAL-jee-ah) Pain in the ear. (Ch. 48)
- Otorrhea:** (OH-toh-REE-ah) Inflammation of the ear with purulent discharge. (Ch. 48)
- Otosclerosis:** (OH-toh-skle-ROH-sis) A condition characterized by chronic, progressive deafness, especially for low tones. (Ch. 49)
- Ototoxic:** (OH-toh-TOK-sik) Having a detrimental effect on the eighth cranial nerve or the organs of hearing. (Ch. 48)
- Pain:** (PAYN) An unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage. Is whatever the client says it is whenever the client says it occurs. (Ch. 9)
- Palliation:** (pal-ee-AY-shun) The relief of symptoms without cure. (Ch. 10)
- Palpation:** (pal-PAY-shun) Use of the fingers or hands to feel something. (Ch. 1)
- Pancreatectomy:** (PAN-kree-uh-TECK-tuh-mee) Removal of all or part of the pancreas. (Ch. 33)
- Pancreatitis:** (PAN-kree-uh-TIGH-tis) Inflammation of the pancreas. (Ch. 22)
- Pancytopenia:** (PAN-sigh-toh-PEE-nee-ah) Abnormal depression of all the cellular elements of the blood. (Ch. 24)
- Panhysterectomy:** (PAN-hiss-tuh-RECK-tuh-mee) Excision of the entire uterus, including the cervix uteri. (Ch. 40)
- Panmyelosis:** (PAN-my-e-LOH-sis) Increased level of all bone marrow components, red blood cells, white blood cells, and platelets. (Ch. 24)
- Paradoxical respirations:** (PAR-uh-DOK-si-kuhl RES-pi-RAY-shuns) Chest movement on respiration that is opposite to that expected. (Ch. 28)
- Paranoia:** (PAR-uh-NOY-uh) Behavior that is marked by delusions of persecution or delusional jealousy. (Ch. 55)
- Paraparesis:** (PAR-ah-pah-REE-sis) Partial paralysis of the lower extremities. (Ch. 46)
- Paraphimosis:** (PAR-uh-figh-MOH-sis) Uncircumcised foreskin that has swollen and stuck behind the head of the penis. (Ch. 41)
- Paraplegia:** (PAR-ah-PLÉE-jah) Paralysis of the lower body, including both legs, resulting from a spinal cord lesion. (Ch. 46)
- Paresis:** (puh-REE-sis) Weakness; incomplete paralysis. (Ch. 45)
- Paresthesia:** (PAR-es-THEE-zee-ah) A heightened sensation, such as burning, prickling, or tingling. (Ch. 22, 45, 46)
- Paroxysmal nocturnal dyspnea:** (PEAR-ox-IS-mall knock-TURN-al DISP-knee-a) Sudden attacks of shortness of breath that usually occur during sleep. Person wakes gasping for breath and sits up to relieve symptoms; associated with left ventricular heart failure. (Ch. 21)
- Partial-thickness burn:** (PAR-shul THICK-ness BERN) Burn in which the epithelializing elements remain intact. (Ch. 12)
- Passive immunity:** (PASS-iv im-YOO-ni-tee) Reinforcement of the immune system with immune serum for such conditions as tetanus, diphtheria, and venomous snake bite. (Ch. 7, 52)
- Paternalism:** (puh-TER-nuhl-izm) A unilateral and sometimes unreasonable decision by health care providers that implies they know what is best, regardless of the client's wishes. (Ch. 2)
- Pathogen:** (PATH-o-jen) A microorganism or substance capable of producing a disease. (Ch. 7)

- Pathological fracture:** (PATH-uh-LAH-jik-uhl FRAHK-chur) Fracture resulting from weakening of the bone structure by pathological processes such as neoplasia or osteomalacia. (Ch. 24, 25)
- Patient-controlled analgesia (PCA):** (PAY-shent kon-TROHLD an-uhl-JEE-zee-ah) An apparatus that delivers an intravenous analgesic to relieve pain, which is controlled by the client. (Ch. 9)
- Pedicle:** (PED-i-kuhl) The stem that attaches a new growth. (Ch. 40)
- Pediculosis:** (pe-DIK-yoo-LOH-sis) Infestation with lice. (Ch. 51)
- Pemphigus:** (PEM-fi-gus) Acute or chronic serious skin disease characterized by the appearance of bullae (blisters) of various sizes on normal skin and mucous membranes. (Ch. 51)
- Peptic ulcer disease:** (PEP-tick UL-sir di-ZEEZ) A condition in which the lining of the esophagus, stomach, or duodenum is eroded. (Ch. 30)
- Perception:** (per-SEP-shun) A unique impression of events by an individual. These impressions are strongly influenced by personality, cultural orientation, attitudes, and life experiences. (Ch. 14)
- Percussion:** (per-KUSH-un) A tapping technique used by physicians and advanced practice nurses to determine the consistency of underlying tissues. (Ch. 1)
- Percutaneous:** (PER-kyoo-TAY-nee-us) Through the skin; may refer to an injection, a medication application, or a biopsy. (Ch. 34)
- Perfusion:** (per-FEW-zhun) Supplying an organ or tissue with blood. (Ch. 8)
- Pericardial effusion:** (PER-ee-KAR-dee-uhl ee-FYOO-zhun) A buildup of fluid in the pericardial space. (Ch. 17)
- Pericardial friction rub:** (PER-ee-KAR-dee-uhl FRICK-shun RUB) Friction sound heard over the fourth left intercostal space near the sternum; a classic sign of pericarditis. (Ch. 15, 17)
- Pericardial tamponade:** (PER-ee-KAR-dee-uhl TAM-pon-AID) Compression of the heart by an abnormal filling of the pericardial sac with blood. (Ch. 8, 17)
- Pericardiectomy:** (PER-ee-kar-dee-ECK-tuh-mee) Excision of part or all of the pericardium. (Ch. 17)
- Pericardiocentesis:** (PER-ee-KAR-dee-oh-sen-TEE-sis) Surgical perforation of the pericardium. (Ch. 17, 22)
- Pericardiotomy:** (PER-ee-KAR-dee-AH-tah-mee) Incision of the pericardium. (Ch. 22)
- Pericarditis:** (PER-ee-kar-DYE-tis) Inflammation of the pericardium. (Ch. 17, 22)
- Perimenopausal:** (PER-ee-MEN-oh-PAWS-uhl) The phase before the onset of menopause, during which the cycle of a woman with regular menses changes, perhaps abruptly, to a pattern of irregular cycles and increased periods of amenorrhea. (Ch. 40)
- Perinatal:** (PAIR-ee-NAY-tuhl) Concerning the period beginning after the 28th week of pregnancy and ending 28 days after birth. (Ch. 42)
- Perioperative:** (PER-ee-AHP-er-uh-tiv) Occurring in the period immediately before, during, and after surgery. (Ch. 11)
- Peripheral arterial disease:** (puh-RIFF-uh-ruhl ar-TIR-ee-uhl di-ZEEZ) Disease of the peripheral arteries that interferes with adequate flow of blood. (Ch. 18)
- Peripheral parenteral nutrition:** (puh-RIFF-uh-ruhl par-EN-te-ruhl new-TRISH-un) Nutrition by intravenous injection. (Ch. 29)
- Peripheral vascular resistance:** (puh-RIFF-uh-ruhl VAS-kyoo-lar ree-ZIS-tense) Opposition to blood flow through the vessels. (Ch. 16, 21)
- Peristalsis:** (paris-TALL-sis) Progressive, wave-like movement that occurs involuntarily in hollow tubes of the body such as the alimentary (digestive) canal; causes contents of tube to be moved onward. (Ch. 29)
- Peristomal:** (PER-i-STOH-muhl) Area around a stoma. (Ch. 31)
- Peritoneal dialysis:** (PER-i-toh-NEE-uhl dye-AL-i-sis) The employment of the peritoneum surrounding the abdominal cavity as a dialyzing membrane for the purpose of removing waste products or toxins accumulated as a result of renal failure. (Ch. 35)
- Peritonitis:** (per-i-toh-NIGH-tis) Inflammation of the peritoneum. (Ch. 31)
- Petechiae:** (pe-TEE-kee-ee, puh-TEE-kee-eye) Small, purplish, hemorrhagic spots on the skin that appear in certain illnesses and bleeding disorders. (Ch. 17, 23, 50)
- Phagocytosis:** (fay-go-sigh-TOH-sis) Ingestion and digestion of bacteria and particles by phagocytes, cells that have the ability to ingest and destroy particulate substances such as bacteria, protozoa, and cell debris. (Ch. 7)
- Pharyngitis:** (fair-in-JIGH-tiss) Inflammation of the mucous membranes and lymph tissues of the pharynx, usually caused by infection. (Ch. 27)
- Pheochromocytoma:** (FEE-oh-KROH-moh-sigh-TOH-mah) Rare tumor of the adrenal system that secretes catecholamines. (Ch. 37)
- Phimosis:** (figh-MOH-sis) Uncircumcised foreskin that cannot be moved down from the head of the penis. (Ch. 41)
- Phlebitis:** (fla-BYE-tis) Inflammation of a vein; may be due to irritating IV fluids or thrombosis. (Ch. 6)
- Phlebotomy:** (fle-BAH-tuh-mee) Entry into a vein for the removal or withdrawal of blood. (Ch. 24)
- Phobia:** (FOH-bee-ah) A persistent, irrational, intense fear of a specific object, activity, or situation. (Ch. 55)
- Photophobia:** (FOH-toh-FOH-bee-ah) Abnormal visual intolerance to light. (Ch. 46, 49)
- Physical dependence:** (FIZ-ik-uhl dee-PEN-dens) A pharmacologic phenomenon characterized by signs and symptoms of withdrawal when medication is withdrawn. (Ch. 9)
- Plaque:** (PLAK) A deposit of fatty material on the lining of an artery. (Ch. 16, 18)
- Plasmapheresis:** (PLAS-mah-fer-EE-sis) Removal of blood to separate cells from plasma. (Ch. 47)
- Pleurodesis:** (PLOO-roh-DEE-sis) Creation of adhesions between the parietal and visceral pleura to treat recurrent pneumothorax. (Ch. 28)

- Pneumocystis carinii pneumonia:** (new-mo-SIS-tis ca-RIN-ee-eye new-MOH-nee-ya) An acute pneumonia caused by *Pneumocystis carinii*, a fungus. It occurs in immunodeficient adults and is a defining opportunistic infection of AIDS. (Ch. 54)
- Pneumonectomy:** (NEW-moh-NEK-tuh-mee) Surgical removal of all or part of a lung. (Ch. 28)
- Pneumothorax:** (NEW-moh-THAW-raks) Air in the pleural space. (Ch. 28)
- Poikilothermy:** (POY-ki-loh-THER-mee) The absence of sufficient arterial blood flow, causing the extremity to become the temperature of the environment. (Ch. 15)
- Point of maximal impulse:** (POYNT of MAKS-i-muhl IM-puls) The area of the chest where the greatest force can be felt with the palm of the hand when the heart contracts or beats. Usually at the fourth to fifth intercostal space in the midclavicular line. (Ch. 15)
- Polycythemia:** (PAH-lee-sigh-THÉE-mee-ah) Excessive red cells in the blood. (Ch. 18, 24, 28)
- Polydipsia:** (PAH-lee-DIP-see-ah) Excessive thirst. (Ch. 37, 38)
- Polymyositis:** (PAH-lee-my-oh-SIGH-tis) A rare, inflammatory disease of the skeletal muscle tissue characterized by symmetric weakness of proximal muscles of the limbs, neck, and pharynx. (Ch. 44)
- Polyneuropathy:** (PAH-lee-new-RAH-puh-thee) A disease involving multiple nerves. (Ch. 47)
- Polyphagia:** (PAH-lee-FAY-jee-ah) Excessive eating. (Ch. 38)
- Polyuria:** (PAH-lee-YOOR-ee-ah) Excessive urination. (Ch. 35, 37)
- Portal hypertension:** (POR-tuhl HIGH-per-TEN-shun) Persistent blood pressure elevation in the portal circulation of the abdomen. (Ch. 33)
- Postcoital:** (post-KOH-i-tal) Following sexual intercourse. (Ch. 40)
- Postictal:** (pohst-IK-tuhl) Occurring after a sudden attack, such as an epileptic seizure. (Ch. 46)
- Postoperative:** (post-AHP-er-uh-tiv) Following a surgical operation. (Ch. 11)
- Powerlessness:** (POW-er-less-nes) Perceived lack of control over a situation. (Ch. 13)
- Preload:** (PREE-lohd) End-diastolic stretch of cardiac muscle fibers; equals end-diastolic volume. (Ch. 15, 21)
- Preoperative:** (pre-AHP-er-uh-tiv) Preceding an operation. (Ch. 11)
- Presbycusis:** (PRESS-bee-KYOO-sis) Progressive, bilaterally symmetrical perceptive hearing loss occurring with age; usually occurs after age 50 and is caused by structural changes in the organs of hearing. (Ch. 49)
- Presbyopia:** (PREZ-bee-OH-pee-ah) Diminution of accommodation of the lens of the eye occurring normally with aging, and usually resulting in hyperopia, or farsightedness. (Ch. 49)
- Pressure ulcer:** (PRESS-sure ULL-sir) An open sore or lesion of the skin that develops because of prolonged pressure against an area. (Ch. 14)
- Priapism:** (PRY-uh-pizm) Erection that lasts too long. (Ch. 41)
- Primary hypertension:** (PRY-mare-ee HIGH-per-TEN-shun) Abnormally elevated blood pressure of unknown cause. Also called essential hypertension. (Ch. 16)
- Proctitis:** (prock-TIGH-tis) Inflammation of the rectum and anus. (Ch. 42)
- Proctosigmoidoscopy:** (PROK-toh-SIG-moy-DAHS-kuh-pee) Visual examination of the rectum and sigmoid colon by use of a sigmoidoscope. (Ch. 29)
- Prodrome:** (PROH-droh-m) A symptom indicating the onset of a disease. (Ch. 46)
- Prostaglandins:** (PRAHS-tah-GLAND-ins) Chemical neurotransmitters usually associated with pain at the site of an injury, periphery. (Ch. 9)
- Prostatectomy:** (PRAHS-tuh-TEK-tuh-mee) Removal of the prostate gland. (Ch. 41)
- Prostatitis:** (PRAHS-tuh-TIGH-tis) Inflammation or infection of the prostate gland. (Ch. 41)
- Protozoa:** (pro-tow-ZOH-ah) Single-celled parasitic organisms that can move and live mainly in the soil. (Ch. 7)
- Pruritis:** (proo-RYE-tis) Severe itching. (Ch. 51)
- Pseudoaddiction:** (soo-doh-ad-DICK-shun) Syndrome in which behaviors similar to addiction appear as a result of inadequate pain control and clients fear not receiving adequate pain medications. (Ch. 9)
- Psoriasis:** (suh-RYE-ah-sis) Chronic inflammatory skin disorder in which epidermal cells proliferate abnormally fast. (Ch. 51)
- Psychoanalysis:** (SIGH-koh-uh-NAL-i-sis) Form of therapy based on the theories of Sigmund Freud, regarding the dynamics of the unconscious. (Ch. 55)
- Psychogenic:** (SIGH-koh-JEN-ick) Of mental origin. (Ch. 37)
- Psychological dependence:** (SY-ko-LAW-ick-al dee-PEN-dens) Obsession of obtaining drugs for use other than medicinal; addiction. (Ch. 9)
- Psychopharmacology:** (SIGH-koh-FAR-meh-KAHL-uh-jee) The study of the action of drugs on psychological functions and mental states. (Ch. 55)
- Psychosomatic:** (SIGH-koh-soh-MAT-ik) Having bodily symptoms of psychological, emotional, or mental origin; illness traceable to an emotional cause. (Ch. 55)
- Psychotherapy:** (SICH-koh-THER-uh-pee) A method of treating disease (especially mental illness) by mental rather than pharmacological means. (Ch. 55)
- Ptoxis:** (TOH-sis) Drooping of eyelid. (Ch. 47, 48)
- Puerperal:** (pyoo-ER-per-uhl) Concerning the puerperium, or period of 42 days after childbirth. (Ch. 42)
- Pulmonary edema:** (PULL-muh-NAIR-ee uh-DEE-muh) Acute heart failure in which there is severe fluid congestion in the alveoli of the lungs; life-threatening. (Ch. 21)
- Pulse deficit:** (PULS DEF-i-sit) A condition in which the number of pulse beats counted at the radial artery is less than those counted in the same period of time at the apical heart rate. (Ch. 15)
- Purpura:** (PUR-pur-uh) Hemorrhage into the skin, mucous membranes, internal organs, and other tissues. (Ch. 23)

- Purulent:** (PURE-u-lent) Fluid that contains pus. (Ch. 11, 51)
- Pyelogram:** (PIE-loh-GRAM) A diagnostic procedure involving x-ray of the kidneys; may be done after injection of a dye into the bloodstream or directly into the kidneys. (Ch. 34)
- Pyelonephritis:** (PYE-e-loh-ne-FRY-tis) Inflammation of the kidney and renal pelvis. (Ch. 35)
- Pyoderma:** (PYE-oh-DER-mah) Any acute, inflammatory, purulent bacterial dermatitis. (Ch. 51)
- Quadripareisis:** (kwod-ri-par-E-sis) Weakness involving all four limbs caused by spinal cord injury. (Ch. 46)
- Quadriplegia:** (KWA-dri-PLÉE-jah) Paralysis of all four limbs caused by spinal cord injury. (Ch. 46)
- Radiation therapy:** (RAY-dee-AY-shun THER-uh-pee) Cancer treatment with ionizing radiation. (Ch. 10)
- Range of motion (ROM):** (RANJE of MOH-shun) The range of movement of a body joint. (Ch. 14)
- Raynaud's disease:** (ra-NOHZ di-ZEEZ) A primary or idiopathic vasospastic disorder characterized by bilateral and symmetrical pallor and cyanosis of the fingers. (Ch. 18)
- Reality orientation:** (ree-AL-i-tee OR-ee-en-TAY-shun) A process to orient a person to facts such as names, dates, and time, through the use of verbal and nonverbal repeating messages. (Ch. 14)
- Rectocele:** (RECK-toh-seel) Protrusion or herniation of the posterior vaginal wall with the anterior wall of the rectum through the vagina. (Ch. 40)
- Regurgitation:** (ree-GUR-ji-TAY-shun) A backward flowing, as in the backflow of blood through a defective heart valve. (Ch. 19)
- Remyelination:** (ree-MY-uh-lin-AY-shun) Replacement of myelin or neurons. (Ch. 47)
- Replantation:** (re-plan-TAY-shun) The replacement of an organ or other structure, such as a digit, limb, or tooth, to the site from which it was previously lost or removed. (Ch. 44)
- Reservoir:** (REZ-er-VWAR) A person, animal, arthropod, plant, soil, or substance in which an infectious agent normally lives and multiplies, on which it depends for survival. (Ch. 7)
- Respiratory excursion:** (RES-pi-rah-TOR-ee eks-KUR-zhun) Downward movement of diaphragm with inspiration. (Ch. 26)
- Respite care:** (RES-pit CARE) Short-term, intermittent care for the chronically ill; provides rest for the family members or caregivers from the stress of sustained caregiving. (Ch. 13)
- Respondent superior:** (ress-POND-ee-et sue-PEER-ee-or) An institution that employs a worker may be liable for the acts or omissions of its employees. (Ch. 2)
- Retinopathy:** (RET-i-NAH-puh-thee) Disease of the retina of the eye. (Ch. 38, 49)
- Retroflexion:** (RET-roh-FLECK-shun) A bending or flexing backward. (Ch. 40)
- Retrograde:** (RET-roh-grayd) Moving backward; degenerating from a better to a worse state. (Ch. 40, 41)
- Retrograde cholangiopancreatography:** (RET-roh-grayd koh-LAN-jee-oh-PAN-kree-ah-TOG-rah-fee) An endoscopic procedure that permits the physician to visualize the liver, gallbladder, and pancreas using an endoscope, dye, and x-ray examinations. (Ch. 32)
- Retroversion:** (RET-roh-VER-zhun) A turning, or a state of being turned back; the tipping of an entire organ. (Ch. 40)
- Rheumatic carditis:** (roo-MAT-ick kar-DYE-tis) Serious complication of rheumatic fever in which all layers of the heart become inflamed. (Ch. 17)
- Rheumatic fever:** (roo-MAT-ick FEE-ver) A hypersensitivity reaction to antigens of group A beta-hemolytic streptococci. (Ch. 17)
- Rhinitis:** (rye-NIGH-tis) Inflammation of the nasal mucosa, usually associated with congestion, itching, sneezing, and nasal discharge. (Ch. 27)
- Rhinoplasty:** (RYE-noh-plass-tee) Plastic surgery of the nose. (Ch. 27)
- Rickettsia:** (ra-KET-see-ah) A genus of bacteria of the tribe Rickettsiae that multiply only in host cells. (Ch. 7)
- Rinne test:** (RIN-nee TEST) A test of hearing made with tuning forks. (Ch. 48)
- Romberg's test:** (RAHM-bergs TEST) A test to determine if a person has the ability to maintain body balance when the eyes are shut and the feet are close together. (Ch. 48)
- Roux-en-Y:** (roo-ehn-Y) Gastric bypass surgery. A small stomach pouch the size of a thumb is created with staples, then a Y-shaped section of the small intestine is attached to the pouch to allow food to bypass the lower stomach and duodenum. (Ch. 30)
- Rule of nines:** (ROOL of NINES) A formula for estimating percentage of body surface areas, particularly helpful in judging the portion of skin that has been burned. (Ch. 12)
- Sacral radiculopathy:** (SAY-krul ra-DICK-yoo-LAH-puh-thee) Pathology of sacral nerve roots. (Ch. 42)
- Salpingitis:** (SAL-pin-JIGH-tis) Inflammation of a fallopian tube. (Ch. 42)
- Salpingoscopy:** (SAL-ping-AHS-koh-pee) Endoscopic visualization of the fallopian tubes. (Ch. 39)
- Scleroderma:** (SKLER-ah-DER-ma) A chronic manifestation of progressive systemic sclerosis in which the skin is taut, firm, and edematous, limiting movement. (Ch. 44)
- Sclerosis:** (skle-ROH-sis) A hardening or induration of an organ or tissue, especially from excessive growth of fibrous tissue. (Ch. 47)
- Seborrhea:** (SEB-oh-REE-ah) Disease of the sebaceous glands marked by increase in the amount and often alteration of the quality of sebaceous secretions. (Ch. 51)
- Secondary hypertension:** (SEK-un-DAR-ee HIGH-per-TEN-shun) High blood pressure that is a symptom of a specific cause, such as a kidney abnormality. (Ch. 16)
- Semipermeable:** (SEM-ee-PER-mee-uh-buhl) Partly permeable; said of a membrane that will allow fluids but not the dissolved substance to pass through it. (Ch. 5)

- Sensorineural:** (SEN-suh-ree-NEW-ruhl) Hearing loss caused by impairment of a sensory nerve. (Ch. 49)
- Sensory deprivation:** (SEN-suh-ree DEP-ri-VAY-shun) No or minimal stimulation of the senses that creates the potential for maladaptive coping. (Ch. 14)
- Sensory overload:** (SEN-suh-ree OH-ver-lohd) Excessive stimulation of the senses that creates the potential for maladaptive coping. (Ch. 14)
- Sepsis:** (SEP-sis) Systematic infection caused by microorganisms in the bloodstream. (Ch. 7, 8)
- Serologic:** (SEAR-uh-LAJ-ick) Study of substances present in blood serum. (Ch. 42)
- Serosanguineous:** (SEER-oh-SANG-gwin-ee-us) Fluid consisting of serum and blood. (Ch. 11)
- Serotonin:** (SER-ah-TOH-nin) A chemical neurotransmitter important in sleep-wake cycles. Reduced serotonin levels are associated with depression. (Ch. 9)
- Shock:** (SHAHK) A clinical syndrome in which the peripheral blood flow is inadequate to return sufficient blood to the heart for normal function, particularly transport of oxygen to all organs and tissues. (Ch. 12)
- Sinusitis:** (SINE-u-SIGH-tiss) Inflammation of the sinuses; may be due to viral or bacterial infection, or to allergies. (Ch. 27)
- Sinoatrial node:** (SIGH-noh-AY-tree-al NOHD) Node at the junction of the superior vena cava and right atrium, regarded as the starting point of the heartbeat. (Ch. 20)
- Snellen's chart:** (SNEL-ens CHART) A chart imprinted with lines of black letters graduating in size from smallest on the bottom to largest on top; used for testing visual acuity. (Ch. 48)
- Somatoform:** (soh-MAT-uh-form) Denoting psychogenic symptoms resembling those of physical disease; psychosomatic. (Ch. 55)
- Spider angioma:** (SPY-der an-jee-OH-mah) Thin reddish-purple vein lines close to the skin surface. (Ch. 32)
- Spirituality:** (SPIHR-it-u-AL-it-tee) Sense of connectedness with all of life and the universe. (Ch. 13)
- Splenectomy:** (sple-NEK-tuh-mee) Excision of the spleen. (Ch. 25)
- Splenomegaly:** (SPLEE-noh-MEG-ah-lee) Enlargement of the spleen. (Ch. 21, 25)
- Standard of best interest:** (STAND-erd OF BEST IN-ter-est) A type of decision made about clients' health care when they are unable to make an informed decision about their own care. (Ch. 2)
- Standard precautions:** (STAN-derd pre-KAW-shuns) Guidelines recommended by the Centers for Disease Control and Prevention to reduce the risk of the spread of infection. (Ch. 7)
- Stapedectomy:** (stuh-puh-DEK-tuh-mee) Excision of the stapes in order to improve hearing, especially in cases of otosclerosis. (Ch. 49)
- Staphylococcus:** (STAFF-il-oh-KOCK-uss) A genus of gram-positive bacteria; they are constantly present on the skin and in the upper respiratory tract and are the most common cause of localized suppurating infections. (Ch. 7)
- Status asthmaticus:** (STAT-us az-MAT-i-kus) Prolonged period of unrelieved asthma symptoms. (Ch. 28)
- Steatorrhea:** (STEE-ah-toh-REE-ah) Fat in the stools; may be associated with pancreatic disease. (Ch. 29, 30, 31, 33)
- Stenosis:** (ste-NOH-sis) The constriction or narrowing of a passage or orifice, such as a cardiac valve. (Ch. 19)
- Stent:** (STENT) Any mold or device used to hold tissue in place or to provide a support, graft, or anastomosis while healing is taking place. (Ch. 35)
- Stereotype:** (STER-ee-oh-TIGHP) An opinion or belief about an individual or group that may not be true. (Ch. 3)
- Sternotomy:** (stir-NAH-tuh-mee) The operation of cutting through the sternum. (Ch. 22)
- Stoma:** (STOH-mah) A mouth, small opening, or pore. (Ch. 31)
- Stomatitis:** (STOH-mah-TIGH-tis) Inflammation of the mouth. (Ch. 10, 30)
- Stress:** (STRESS) The physical (gravity, mechanical, pathogenic, injury) and psychological (fear, anxiety, crisis, joy) forces that are experienced by individuals. (Ch. 55)
- Stressor:** (STRESS-er) Any person or situation that produces an anxiety response. (Ch. 55)
- Striae:** (STRIGH-ee) A line or band of elevated or depressed tissue; may differ in color or texture from surrounding tissue. (Ch. 32)
- Subarachnoid:** (SUB-uh-RAK-noyd) Below or under the arachnoid membrane and the pia mater of the covering of the brain and spinal cord. (Ch. 45)
- Subdural:** (sub-DUHR-uhl) Beneath the dura mater. (Ch. 46)
- Subjective data:** (sub-JEK-tiv DAY-tuh) Information that is provided verbally by the client. (Ch. 1)
- Suffering:** (SUFF-er-ing) A state of severe distress associated with events that threaten the intactness of the person. Emotional pain associated with real or potential tissue damage. (Ch. 9)
- Summons:** (SUM-muns) A notice of suit. (Ch. 2)
- Suprapubic:** (SOO-pruh-PEW-bik) Bone of the groin (or region) located above the pubic arch. (Ch. 41)
- Surgeon:** (SURGE-on) A medical practitioner who specializes in surgery. (Ch. 11)
- Synovitis:** (sin-oh-VIGH-tis) Inflammation of the synovial membrane that may be the result of an aseptic wound, a subcutaneous injury, irritation, or exposure to cold and dampness. (Ch. 43, 44)
- Systolic blood pressure:** (sis-TAL-ik BLUHD PRESS-ur) Maximal pressure exerted on the arteries during contraction of the left ventricle of the heart. The top number of a blood pressure reading. (Ch. 16)
- Tachycardia:** (TAK-ee-KAR-dee-yah) An abnormal rapidity of heart action, usually defined as a heart rate greater than 100 beats per minute in adults. (Ch. 8)
- Tachydysrhythmia:** (TACK-ee-dis-RITH-mee-yah) An abnormal heart rhythm with rate greater than 100 beats per minute in an adult. (Ch. 22)
- Tachypnea:** (TAK-ip-NEE-ah) Abnormally rapid respiratory rate. (Ch. 8, 28)

- Tamponade:** (TAM-pon-AYD) Compression of a part. (Ch. 41)
- Tension pneumothorax:** (TEN-shun NEW-moh-THOR-raks) Abnormal accumulation of air with buildup of pressure in the pleural space. (Ch. 8)
- Teratoma:** (ter-uh-TOH-muh) A congenital tumor containing one or more of the three primary embryonic germ layers. (Ch. 40)
- Terminal illness:** (TERM-in-al ILL-ness) An illness that will probably cause death in 6 months or less. (Ch. 13)
- Tetanus:** (TET-nus) A highly fatal disease caused by the bacillus *Clostridium tetani* and characterized by muscle spasm and convulsions. (Ch. 12)
- Tetany:** (TET-uh-nee) Muscle spasms, numbness, and tingling caused by changes in pH and low serum calcium. (Ch. 37)
- Thoracentesis:** (THOR-uh-sen-TEE-sis) Insertion of a large-bore needle into the pleural space to remove fluid. (Ch. 26)
- Thoracotomy:** (THAW-rah-KAH-tah-mee) Surgical incision into the chest wall. (Ch. 28)
- Thrill:** (THRILL) Abnormal vessel that has a bulging or narrowed wall; a vibration is felt. (Ch. 15)
- Thrombi:** (THROM-bye) Blood clots. (Ch. 8)
- Thrombocytopenia:** (THROM-boh-SIGH-toh-PEE-nee-uh) Abnormal decrease in the number of blood platelets. (Ch. 10, 23, 24)
- Thrombolytic:** (throm-bo-LIT-ik) Agent that dissolves or splits up a thrombus, an aggregation of blood factors. (Ch. 46)
- Thrombophlebitis:** (THROM-boh-fle-BYE-tis) The formation of a clot and inflammation within a vein. (Ch. 17)
- Thrombosis:** (throm-BOH-sis) Formation, development, or presence of a thrombus, an aggregation of blood factors. (Ch. 18)
- Tidaling:** (TIGH-dah-ling) Rise and fall; may refer to water in water-seal chamber of a chest drainage system. (Ch. 26)
- Titration:** (tigh-TRAY-shun) Adjustment of medication up or down to meet client needs. (Ch. 9)
- Tolerance:** (TALL-er-ens) The response of the body to medication that requires increased medication administration to achieve the same effect. Often refers to opioids. (Ch. 9, 55)
- Torts:** (TORTS) Lawsuits involving civil wrongs. (Ch. 2)
- Toxemia:** (tock-SEE-me-ah) Spread of poisonous products of bacteria throughout the body. (Ch. 8)
- Tracheostomy:** (TRAY-key-AHS-tuh-me) A surgical opening in the neck into the trachea to provide an airway when the trachea is obstructed. (Ch. 26)
- Tracheotomy:** (TRAY-key-AH-tuh-me) An opening in the neck into the trachea. (Ch. 26)
- Traditions:** (tra-DISH-uns) Practices and customs handed down through the generations, often by word of mouth. (Ch. 3)
- Transcellular:** (trans-SELL-yoo-lar) Across cell membranes. (Ch. 5)
- Transdermal:** (trans-DER-mal) Entering through the dermis, or skin, as in administration of a drug applied to the skin in ointment or patch form. (Ch. 9)
- Transillumination:** (TRANS-i-loo-mi-NAY-shun) The passage of strong light through a body structure to permit inspection of an observer on the opposite side. (Ch. 39)
- Transjugular intrahepatic portosystemic shunt (TIPS):** (TRANZ-jug-yoo-lar intra-hep-PAT-ik POR-toh-sis-TEM-ik SHUNT) Shunt that sidetracks venous blood around the liver to the vena cava for treatment of ascites. (Ch. 33)
- Transmyocardial** (TRANS-my-o-KAR-dee-yah) Across all layers of the heart. (Ch. 22)
- Trauma:** (TRAW-mah) Physical injury caused by an external force. (Ch. 8)
- Trendelenburg:** (tren-DELL-en-berg) A position in which the client's head is low and the body and legs are on an elevated and inclined plane. (Ch. 8)
- Triage:** (TREE-ahj) To sort. (Ch. 12)
- Trigeminy:** (try-JEM-i-nee) Occurring every third beat, as in trigeminal premature ventricular contractions. (Ch. 20)
- Tropia:** (TROH-pee-ah) A manifest deviation of an eye from the normal position when both eyes are open and uncovered. (Ch. 48)
- T-tube:** (TEE-toob) A T-shaped tube in the bile duct that allows drainage of bile following gallbladder surgery. (Ch. 33)
- Tumor:** (TOO-mur) An abnormal growth of cells or tissues; tumors may be benign or malignant. (Ch. 10)
- Turbid:** (TER-bid) Cloudy. (Ch. 46)
- Turgor:** (TER-ger) The resistance of the skin to being grasped between the fingers. Dehydration causes poor skin turgor. (Ch. 50)
- Unifocal:** (YOO-ni-FOH-kuhl) Coming or originating from one site or focus. (Ch. 20)
- Upper gastrointestinal series (upper GI, UGI):** (UH-per GAS-troh-in-TES-ti-nuhl SEER-ees) X-ray and fluoroscopic examinations of the stomach and duodenum after the ingestion of a contrast medium. (Ch. 29)
- Uremia:** (yoo-REE-mee-ah) An excess in the blood of urea, creatinine, and other nitrogenous end products of protein and amino acid metabolism. (Ch. 34, 35)
- Urethritis:** (YOO-ree-THRIGH-tis) Inflammation of the urethra. (Ch. 35, 42)
- Urethroplasty:** (yoo-REE-throh-PLAS-tee) Plastic repair of the urethra. (Ch. 35)
- Urinary incontinence:** (YOOR-i-NAR-ee in-KON-tinents) Inability to control urine excretion creating accidental urinary leakage. (Ch. 14, 34, 35)
- Urodynamic:** (YOO-roh-dye-NAM-ik) The study of the holding or storage of urine in the bladder, the facility with which it empties, and the rate of movement of urine out of the bladder during urination. (Ch. 41)
- Urosepsis:** (YOO-roh-SEP-sis) Septicemia resulting from urinary tract infection. (Ch. 35, 41)
- Urticaria:** (UR-ti-CARE-ee-ah) Hives signifying an allergic reaction. (Ch. 8, 53)
- Utilitarian:** (yoo-TILL-I-TAR-I-en) Consequences or outcomes of a dilemma are the most important element. (Ch. 2)

- Vaginosis:** (VAJ-i-NOH-sis) Inflammation of the vagina caused by *Gardnerella vaginalis*. (Ch. 40)
- Values:** (VAL-use) Ideals or concepts that give meaning to an individual's life. (Ch. 2, 3)
- Valvotomy:** (val-VAH-tuh-mee) Cutting through a valve. (Ch. 22)
- Valvuloplasty:** (VAL-vyoo-loh-PLAS-tee) Plastic or restorative surgery on a valve, especially a cardiac valve. (Ch. 19)
- Varices:** (VAR-i-seez) Dilated veins. (Ch. 33)
- Varicocele:** (VAR-i-koh-seel) Varicose veins of the scrotum; can lead to infertility. (Ch. 39, 41)
- Varicose veins:** (VAR-i-kohs VAINS) Swollen, distended, and knotted veins, usually in the subcutaneous tissue of the leg. (Ch. 18)
- Vasculitis:** (VAS-kue-LIGH-tis) Inflammation of a vessel. (Ch. 44)
- Vasectomy:** (va-SEK-tuh-mee) Surgically cutting and sealing the vas deferens to prevent sperm from getting outside the body. Used as a birth control method for men. (Ch. 41)
- Vector:** (VECK-tur) Living organism that transmits disease. (Ch. 7)
- Venous stasis ulcers:** (VEE-nus STAY-sis UL-sers) Poorly healing ulcers that result from inadequate venous drainage. (Ch. 18)
- Ventricular diastole:** (ven-TRICK-yoo-lar dye-AS-tuh-lee) The period of relaxation of the two ventricles. (Ch. 20)
- Ventricular escape rhythm:** (ven-TRICK-yoo-lar es-KAYP RITH-uhm) The naturally occurring rhythm of the ventricles when the rest of the cardiac conduction system fails. (Ch. 20)
- Ventricular repolarization:** (ven-TRICK-yoo-lar RE-pol-lahr-i-ZAY-shun) Reestablishment of the polarized state of the muscle after contraction. (Ch. 20)
- Ventricular systole:** (ven-TRICK-yoo-lar SIS-tuh-lee) The contraction of the two ventricles. (Ch. 20)
- Ventricular tachycardia:** (ven-TRICK-yoo-lar TACK-ee-KAR-dee-yah) A series of at least three beats arising from a ventricular focus at a rate greater than 100 beats per minute. (Ch. 20)
- Verrucous:** (ve-ROO-kus) Wartlike, with raised portions. (Ch. 42)
- Vertebrae:** (VER-te-bray) Any of the 33 bony segments of the spinal column: 7 cervical, 12 thoracic, 5 lumbar, 5 sacral, and 4 coccygeal vertebrae. (Ch. 43)
- Vesicant:** (VESS-i-kant) Agent that causes blistering of tissue. (Ch. 10)
- Vesicular:** (ve-SICK-yoo-ler) Pertaining to vesicles or small blisters. (Ch. 42)
- Virulence:** (VEER-you-lence) The power of an organism to cause disease. (Ch. 7)
- Virus:** (VIGH-rus) The smallest organism identified by use of electron microscopy; intracellular parasites that may cause disease. (Ch. 7)
- Viscosity:** (vis-KAH-si-tee) Thickness, as of the blood. (Ch. 16)
- Volvulus:** (VOL-view-lus) A twisting of the bowel on itself, causing obstruction. (Ch. 31)
- Vulvovaginitis:** (VUL-voh-VAJ-I-NIGH-tis) Inflammation of the vulva and vagina. (Ch. 42)
- Weber test:** (VAY-ber TEST) A test for unilateral deafness. (Ch. 48)
- Welfare rights:** (WELL-fare RIGHTS) Also called legal rights; rights that are based on a legal entitlement to some good or benefit. (Ch. 2)
- White blood cells:** (WIGHT BLUHD SELLS) Leukocytes; the body's primary defense against infection. (Ch. 52)
- Withdrawal:** (with-DRAW-ul) Symptoms caused by cessation of administration of a drug, especially a narcotic or alcohol, to which the individual has become either physiologically or psychologically addicted. (Ch. 55)
- Worldview:** (WERLD-vyoo) The way individuals look on the world to form values and beliefs about life and the world around them. (Ch. 3)
- Xerostomia:** (ZEE-roh-STOH-mee-ah) Dry mouth caused by reduction in secretions. (Ch. 10)

Index

Page numbers in italics indicate figures. Page numbers followed by t indicate tables; b, boxes.

A

- Abdomen, 479–480
 - flat plate of the abdomen, 481, 580
 - hernias, 517–518
 - preoperative phase of surgery assessments, 151
 - trauma, 182
- Ablation, 316, 322–323
- Abortion, 705–706
 - chemical agents, 706–707
