# TABLE OF CONTENTS

Foreword.....	xi
Preface.....	xiii
Acknowledgments.....	xv
Editors.....	xvii

## SECTION 1: AMINO ACIDS, PEPTIDES, AND PROTEINS

Properties of Amino Acids.....	3
Data on the Naturally Occurring Amino Acids.....	7
Structures and Symbols for Synthetic Amino Acids Incorporated into Synthetic Polypeptides.....	43
Unnatural Amino Acids for Incorporation into Proteins.....	53
Properties of the $\alpha$ -Keto Acid Analogs of Amino Acids.....	55
$\alpha,\beta$ -Unsaturated Amino Acids.....	57
Amino Acid Antagonists.....	59
Coefficients of Solubility Equations of Certain Amino Acids in Water.....	65
Heat Capacities, Absolute Entropies, and Entropies of Formation of Amino Acids and Related Compounds.....	67
Heat of Combustion, Enthalpy and Free Energy of Formation of Amino Acids and Related Compounds.....	69
Solubilities of Amino Acids in Water at Various Temperatures.....	71
Heats of Solution of Amino Acids in Aqueous Solution at 25°C.....	75
Free Energies of Solution and Standard Free Energy of Formation of Amino Acids in Aqueous Solution at 25°C.....	77
Far Ultraviolet Absorption Spectra of Amino Acids.....	79
UV Absorption Characteristics of <i>N</i> -Acetyl Methyl Esters of the Aromatic Amino Acids, Cystine and of <i>N</i> -Acetylcysteine.....	81
Numerical Values of the Absorbances of the Aromatic Amino Acids in Acid, Neutral and Alkaline Solutions.....	83
Luminescence of the Aromatic Amino Acids.....	89
Luminescence of Derivatives of the Aromatic Amino Acids.....	91
Luminescence of Proteins Lacking Tryptophan.....	93
Luminescence of Proteins Containing Tryptophan.....	95
Hydrophobicities of Amino Acids and Proteins.....	99
Chemical Specificity of Reagents for Protein Modification.....	115
Reagents for the Chemical Modification of Proteins.....	117
Protein pK Values.....	137
Protease Inhibitors and Protease Inhibitor Cocktails.....	141
Assay of Solution Protein Concentration.....	155
Spectrophotometric Determination of Protein Concentration in the Short-Wavelength Ultraviolet.....	161

## SECTION 2: LIPIDS

A Comprehensive Classification System for Lipids.....	165
Properties of Fatty Acids and Their Methyl Esters.....	189
Densities, Specific Volumes, and Temperature Coefficients of Fatty Acids from C <sub>8</sub> to C <sub>12</sub> .....	191
Composition and Properties of Common Oils and Fats.....	193
Androgens.....	199
Bile Acids.....	201
Corticoids.....	203
Estrogens.....	205
Progestogens.....	207
Sterols.....	209
Prostaglandins and Related Fatty-Acid Derived Materials.....	221

## SECTION 3: VITAMINS AND COENZYMES

Properties of Vitamins.....	225
Biological Characteristics of Vitamins.....	237
Properties for Ascorbic Acid and Ascorbate-2-Sulfate.....	241
Vitamins.....	243
Vitamin Names Discarded.....	251

## SECTION 4: NUCLEIC ACIDS

UV Spectral Characteristics and Acidic Dissociation Constants of 280 Alkyl Bases, Nucleosides, and Nucleotides.....	255
Ultraviolet Absorbance of Oligonucleotides Containing 2'- <i>O</i> -Methylpentose Residues.....	263

Spectrophotometric Constants of Ribonucleotides.....	265
Purines, Pyrimidines, Nucleosides, and Nucleotides: Physical Constants and Spectral Properties .....	269
Chemical Modification of Nucleic Acids.....	359
Transfection Technologies.....	373

## SECTION 5: CARBOHYDRATES

Introduction to Carbohydrates.....	383
Natural Alditols, Inositols, Inososes, and Amino Alditols and Inosamines .....	407
Natural Acids of Carbohydrate Derivation.....	417
Natural Aldoses.....	431
Natural Ketoses .....	457
Carbohydrate Phosphate Esters.....	473
The Naturally Occurring Amino Sugars.....	491
Oligosaccharides (Including Disaccharides).....	499
Mucopolysaccharides (Glycosaminoglycans).....	533

## SECTION 6: PHYSICAL AND CHEMICAL DATA

Recommendations for Nomenclature and Tables in Biochemical Thermodynamics .....	537
Standard Transformed Gibbs Energies of Formation for Biochemical Reactants .....	551
Enthalpy, Entropy, and Free Energy Values for Biochemical Redox Reactions.....	555
Oxidation-Reduction Potentials, Absorbance Bands and Molar Absorbance of Compounds Used in Biochemical Studies.....	557
Calorimetric $\Delta H$ Values Accompanying Conformational Changes of Macromolecules in Solution.....	565
Free Energies of Hydrolysis and Decarboxylation.....	579
Deci-Normal Solutions of Oxidation and Reduction Reagents.....	585
Guidelines for Potentiometric Measurements in Suspensions Part A. The Suspension Effect.....	587
Ionization Constants of Acids and Bases .....	595
Guidelines for NMR Measurements for Determination of High and Low $pK_a$ Values .....	637
Measurement and Interpretation of Electrokinetic Phenomena .....	645
Measurement of pH Definition, Standards, and Procedures.....	675
General Comments on Buffers.....	693
List of Buffers.....	695
Brønsted Acidities.....	707
Measurement of pH.....	709
Buffer Solutions.....	715
Amine Buffers Useful for Biological Research .....	719
Preparation of Buffers for Use in Enzyme Studies .....	721
Buffer for Acrylamide Gels (Single-Gel Systems).....	725
Buffer for Acrylamide Gels with More Than One Layer .....	726
Starch Gels.....	729
Indicators for Volumetric Work and pH Determinations .....	731
Acid and Base Indicators.....	735
Specific Gravity of Liquids.....	739
Viscosity and Density Tables.....	743
A Listing of Log P Values, Water Solubility, and Molecular Weight for Some Selected Chemicals.....	747
Chemicals Commonly Used in Biochemistry and Molecular Biology and Their Properties .....	751
Common Detergents Used in Biochemical Research .....	811
Some Properties of Detergents and Surfactants Used in Biochemistry and Molecular Biology .....	813
Some Biological Stains and Dyes.....	819
Mordant Dyes .....	843
Metal Chelating Agents .....	847
Water .....	855
Stability of Solutions for GLP and cGMP Use.....	857
General Information on Spectroscopy.....	859
Microplates.....	861
Plastics .....	863
Chemical and Physical Properties of Various Commercial Plastics.....	869
Generic Source-Based Nomenclature for Polymers.....	871
Definitions of Terms Relating to Reactions of Polymers and to Functional Polymeric Materials .....	877
Definitions of Terms Related to Polymer Blends, Composites, and Multiphase Polymeric Materials.....	887
Organic Name Reactions Useful in Biochemistry and Molecular Biology.....	899
Enzymes in Synthetic Organic Chemistry .....	927

**Table of Contents**

**Appendix B: Glossary of Terms Useful in Biochemistry ..... 959**  
**Index..... 1075**

## FOREWORD

For almost a century, CRC Press has been a leader in providing concise compilations of scientific data for researchers, teachers, and students. The *CRC Handbook of Chemistry and Physics*, which first appeared in 1913 and is now in its 90th edition, is the basic source of physical science data that most chemists, physicists, and engineers turn to. Other widely used handbooks from CRC Press cover materials science, engineering, and mathematics. Many specialized handbooks have also appeared under the CRC imprint, ranging from semiconductors to lipids.

The 1968 publication of the *CRC Handbook of Biochemistry*, edited by Herbert A. Sober, marked a milestone in bioscience data. Appearing just 15 years after Watson and Crick elucidated the structure of DNA, the subtitle of this work, *Selected Data for Molecular Biology*, was a recognition that molecular biology

was the new frontier of the biosciences. This was followed by the multivolume *Handbook of Biochemistry and Molecular Biology*, edited by Gerald D. Fasman, and its single volume abridged version *Practical Handbook of Biochemistry and Molecular Biology*, which appeared in 1989. The intervening 20 years has seen an explosion of data in this field and an exponential growth in the translation of recent discoveries into new technology. This new *Handbook of Biochemistry*, edited by Roger Lundblad and Fiona M. Macdonald, is thus a welcome addition to the list of handbooks available through CRC Press. I am sure it will find heavy use in both basic research and biotechnology.

**David R. Lide**

*Editor-in-Chief, CRC Handbook of Chemistry and Physics*

## PREFACE

This is the fourth edition of the *Handbook of Biochemistry and Molecular Biology*. The first edition was published as a single volume in 1968 under the guidance of Herbert Sober. The second edition appeared in 1970 and the third, with Gerald Fasman as editor, appeared in eight volumes published in 1975–6. This increase in size reflected the rapid advances in knowledge in the then relatively new field of molecular biology.

It is intended that current *Handbook of Biochemistry and Molecular Biology* be a companion volume to the *CRC Handbook of Chemistry and Physics*—a single volume ready-reference work that will find a home on the bookshelves of biochemists and molecular biologists everywhere.

This fourth edition contains materials from the previous editions as well as extensive new material. Staying within the confines of a single volume has meant difficult decisions on which tables to include, and the editors welcome feedback from readers. The advent of electronic media allows for more frequent updating and it is hoped that any infelicities in our selection may be

readily rectified. Additionally, suggestions on new topics for this Handbook and notification of errors are always appreciated. Address all comments to Editor, *Handbook of Biochemistry and Molecular Biology*, Taylor & Francis Group, 6000 Broken Sound Parkway NW, Suite 300, Boca Raton, FL 33487.

Much of the current content is derived from the research of the giants of biochemistry and molecular biology in the three decades following World War II. While it seems the vogue to develop new names and descriptions for old, established concepts, biochemistry and molecular biology continue to be the mainstays of current biomedical research.

## ACKNOWLEDGMENTS

This work would not have been possible without the outstanding support of Jill Jurgensen and Glen Butler of Taylor & Francis. The support of Professor Edward A. Dennis is acknowledged. The help of various research librarians at the University of North Carolina at Chapel Hill is also

acknowledged. Professors Charles Craik of the University of California at San Francisco and Bryce Plapp of the University of Iowa provided advice on selection of materials to be included. However, the editors take all responsibility for the selection of content.

## EDITORS

### **Roger L. Lundblad, PhD**

Roger L. Lundblad is a native of San Francisco, California. He received his undergraduate education at Pacific Lutheran University and his PhD degree in biochemistry at the University of Washington. After postdoctoral work in the laboratories of Stanford Moore and William Stein at the Rockefeller University, he joined the faculty of the University of North Carolina at Chapel Hill. He joined the Hyland Division of Baxter Healthcare in 1990. Currently Dr. Lundblad is an independent consultant and writer in biotechnology in Chapel Hill, North Carolina. He is an adjunct professor of Pathology at the University of North Carolina at Chapel Hill and editor-in-chief of the Internet Journal of Genomics and Proteomics.

### **Fiona M. Macdonald, PhD, F.R.S.C.**

Fiona M. Macdonald received her BSc in chemistry from Durham University, UK. She obtained her PhD in inorganic biochemistry at Birkbeck College, University of London, studying under Peter Sadler. Having spent most of her career in scientific publishing, she is now at Taylor & Francis and is involved in developing chemical information products.

Assay of Solution Protein Concentration .....	155
Spectrophotometric Determination of Protein Concentration in the Short-Wavelength Ultraviolet .....	161

## PROPERTIES OF AMINO ACIDS

This table gives selected properties of some important amino acids and closely related compounds. The first part of the table lists the 20 "standard" amino acids that are the basic constituents of proteins. The second part includes other amino acids and related compounds of biochemical importance. Within each part of the table the compounds are listed by name in alphabetical order. Structures are given in the following table.

Symbol : Three-letter symbol for the standard amino acids

$M_r$  : Molecular weight

$t_m$  : Melting point

$pK_a$ ,  $pK_b$ ,  $pK_c$ ,  $pK_d$  : Negative of the logarithm of the acid dissociation constants for the COOH and NH<sub>2</sub> groups (and, in some cases, other groups) in the molecule (at 25°C)

pI: pH at the isoelectric point

S: Solubility in water in units of grams of compound per kilogram of water; a temperature of 25°C is understood unless otherwise stated in a superscript. When quantitative data are not available, the notations s.l.s. (for slightly soluble), s. (for soluble), and v.s. (for very soluble) are used.

$V_2^0$ : Partial molar volume in aqueous solution at infinite dilution (at 25°C)

Data on the enthalpy of formation of many of these compounds are included in the table "Heat of Combustion, Enthalpy and Free

Energy of Formation of Amino Acids and Related Compounds" on p. 69 of this Handbook. Absorption spectra and optical rotation data can be found in Reference 3. Partial molar volume is taken from Reference 5; other thermodynamic properties, including solubility as a function of temperature, are given in References 3 and 5. Most of the pK values come from References 1, 6, and 7.

## STRUCTURES OF COMMON AMINO ACIDS (Continued)

# DATA ON THE NATURALLY OCCURRING AMINO ACIDS

Elizabeth Dodd Mooz

The amino acids included in these tables are those for which reliable evidence exists for their occurrence in nature. These tables are intended as a guide to the primary literature in which the isolation and characterization of the amino acids are reported. Originally, it was planned to include more factual data on the chemical and physical properties of these compounds; however, the many different conditions employed by various authors in measuring these properties (i.e., chromatography and spectral data) made them difficult to arrange into useful tables. The rotation values are as given in the references cited; unfortunately, in some cases there is no information given on temperature, solvent, or concentration.

The investigator employing the data in these tables is urged to refer to the original articles in order to evaluate for himself the reliability of the information reported. These references are intended to be informative to the reader rather than to give credit to individual scientists who published the original reports. Thus not all published material is cited.

The compounds listed in Sections A to N are known to be of the L configuration. Section O contains some of the D amino acids which occur naturally. This last section is not intended to be complete since most properties of the D amino acids correspond to those of their L enantiomorphs. Therefore, emphasis was placed on including those D amino acids whose L isomers have not been found in nature. The reader will find additional information on the D amino acids in the review by Corrigan<sup>263</sup> and in the book by Meister.<sup>1</sup>

Compilation of data for these tables was completed in December 1974. Appreciation is expressed to Doctors L. Fowden, John F. Thompson, Peter Müller, and M. Bodanszky who were helpful in supplying recent references and to Dr. David Pruess who made review material available to me prior to its publication. A special word of thanks to Dr. Alton Meister who made available reprints of journal articles which I was not able to obtain.

<sup>a</sup> Melting point or decomposition point in degrees, C.

<sup>b</sup> c, grams/100 mL of solution at 20 to 25°C unless specified; wavelength as subscript in millimicrons; temperature as superscript. References are 1, 3, and 290 unless indicated.

<sup>c</sup> The isolated amino acid appears to be a racemic DL mixture.

<sup>d</sup> The naturally occurring isomer is the *erythro*-L-form 290.

<sup>e</sup> Thermodynamic values.

<sup>f</sup> As hydrochloride of amino acid.

<sup>g</sup> For cycloalliin sulfoxide.

# STRUCTURES AND SYMBOLS FOR SYNTHETIC AMINO ACIDS INCORPORATED INTO SYNTHETIC POLYPEPTIDES

M. C. Khosla and W. E. Cohn

The amino acids included in this list are those that have been incorporated into biologically active peptides, e.g., angiotensin II,<sup>a</sup> to study structure-activity relationships. Most of these amino acids are synthetic and are either available commercially or have been synthesized by various investigators as structural variants of naturally occurring amino acids. However, a few of these are also naturally occurring.<sup>b</sup> The selection here is of those most widely used and whose representation by symbols in peptide sequences has caused problems for authors and editors. The symbols listed are those considered most in keeping with the system originated by the IUPAC-IUB Commission on Biochemical Nomenclature<sup>c,d</sup>

and have been chosen with an eye to internal consistency, ability to evoke the proper name, and suitability for use in sequences. Only one new one has been invented:  $\blacktriangle$  for -yn- (triple bond), by analogy with  $\Delta$  for -en- (double bond).

The list may also be useful in selecting suitable isosteres of natural amino acids. The bibliography may be helpful in synthesis, resolution, or studies of the effects of these substances on the biological activity of various peptides.

The following trivial names are listed under other names (given by the number of the entry): *N*-amidinoglycine (67), 6-aminocaproic acid (18), 2-aminoethanesulfonic acid (112),  $\beta,\beta$ -bis(trifluoromethyl)alanine (70), carbamoylglycine (73), 2-(2-carboxyhydrazino)propane (83), cycloleucine (15), diethylalanine (17), dihydrophenylalanine (46), dopa (57), glycoamine (67), isolysine (52),  $\beta$ -lysine (52), mercaptovaline (60),  $\alpha$ -methylalanine (21), penicillamine (60), 5-pyrrolidone-2-carboxylic acid (109), surinamine (94), tetrahydrophenylalanine (47), trimethylammoniocaproic acid (116).

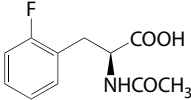

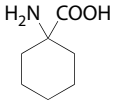

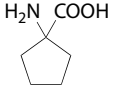

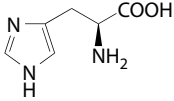

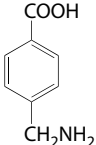

<sup>a</sup> For a review of structure-activity relationships and a listing of various analogs in which a number of these amino acids have been incorporated in angiotensin molecule, see Khosla, Smeby, and Bumpus.<sup>26</sup>

## STRUCTURE AND SYMBOLS FOR SYNTHETIC AMINO ACIDS INCORPORATED INTO SYNTHETIC POLYPEPTIDES (Continued)

No.	Structure	Name/Reference	Symbol
1	$\text{H}_2\text{C}=\text{C}(\text{NHCOCH}_3)\text{COOH}$	2-Acetamidoacrylic acid	AcAcr
2		<i>N</i> <sup>α</sup> -Acetyl-2-fluorophenylalanine	AcPhe(2F)
3	$\text{H}_2\text{N}(\text{CH}_2)_4\text{CH}(\text{NHCOCH}_3)\text{CONHCH}_3$	<i>N</i> <sup>α</sup> -Acetyllysine- <i>N</i> -methylamide	Ac-Lys-NHMe
4	$\text{H}_2\text{NCH}_2\text{CH}_2\text{COOH}$	$\beta$ -Alanine <sup>b</sup>	$\beta\text{Ala}^c$
5	$\text{CH}_3\text{CH}_2\text{CH}(\text{CH}_3)\text{CH}(\text{NH}_2)\text{COOH}$	Alloisoleucine <sup>b</sup>	alle <sup>c</sup>
6	$\text{HOOC}(\text{CH}_2)_2\text{CH}(\text{NH}_2)\text{COOH}$	2-Aminoadipic acid	Aad <sup>c</sup>
7	$\text{HOOCCH}_2\text{CH}_2\text{CH}(\text{NH}_2)\text{CH}_2\text{COOH}$	3-Aminoadipic acid	$\beta\text{Aad}^c$
8	$\text{H}_2\text{NCH}_2\text{CH}(\text{CH}_2\text{C}_6\text{H}_5)\text{COOH}$	3-Amino-2-benzylpropionic acid	$\beta\text{Apr}(\alpha\text{Bzl})$
9	$\text{H}_2\text{NCH}(\text{CH}_2\text{C}_6\text{H}_5)\text{CH}_2\text{COOH}$	3-Amino-3-benzylpropionic acid	$\beta\text{Apr}(\beta\text{Bzl})$
10	$\text{CH}_3\text{CH}_2\text{CH}(\text{NH}_2)\text{COOH}$	2-Aminobutyric acid	Abu <sup>c</sup>
11	$\text{CH}_3\text{CH}(\text{NH}_2)\text{CH}_2\text{COOH}$	3-Aminobutyric acid	$\beta\text{Abu}^c$
12	$\text{H}_2\text{N}(\text{CH}_2)_3\text{COOH}$	4-Aminobutyric acid	$\gamma\text{Abu}$
13	$\text{CH}_3\text{CH}=\text{C}(\text{NH}_2)\text{COOH}$	2-Aminocrotonic acid	ACrt
14		1-Aminocyclohexane-1-carboxylic acid (cyclonorleucine)	cHxA( $\alpha\text{Cx}$ ); cNle <sup>b</sup>
15		1-Aminocyclopentane-1-carboxylic acid (cycloleucine)	cPeA( $\alpha\text{Cx}$ ); cLeu <sup>c</sup>
16	$(\text{CH}_3)_2\text{NCH}_2\text{C}\equiv\text{CCH}_2\text{CH}(\text{NH}_2)\text{COOH}$	2-Amino-6-dimethylamino-4-hexynoic acid (1)	$\alpha\epsilon\text{A}_2\text{hx}(\blacktriangle, \text{N}^e\text{Me}_2)$
17	$\text{CH}_3\text{CH}_2\text{CH}(\text{CH}_2\text{CH}_3)\text{CH}(\text{NH}_2)\text{COOH}$	2-Amino-3-ethylvaleric acid (diethylalanine)	Ala( $\beta\text{Et}_2$ )
18	$\text{H}_2\text{N}(\text{CH}_2)_5\text{COOH}$	6-Aminohexanoic acid (6-aminocaproic acid)	$\epsilon\text{Ahx}^c$
19	$(\text{CH}_3)_2\text{CHCH}_2\text{CH}(\text{NH}_2)\text{CH}(\text{OH})\text{CH}_2\text{COOH}$	4-Amino-3-hydroxy-6-methylheptanoic acid (2,3)	$\gamma\text{Ahp}(\beta\text{OH}, \epsilon\text{Me})$
20		2-Amino-3-(2-imidazolyl)propionic acid	Apr( $\beta\text{Im-2}$ )
21	$(\text{CH}_3)_2\text{C}(\text{NH}_2)\text{COOH}$	2-Aminoisobutyric acid ( $\alpha$ -methylalanine)	Ala( $\alpha\text{Me}$ )
22	$\text{H}_2\text{NCH}_2\text{SO}_3\text{H}$	Aminomethanesulfonic acid	Ams
23		4-Aminomethylbenzoic acid	Bz(4Ame); Bz(4CH <sub>2</sub> NH <sub>2</sub> )

STRUCTURE AND SYMBOLS FOR SYNTHETIC AMINO ACIDS INCORPORATED INTO SYNTHETIC POLYPEPTIDES (Continued)

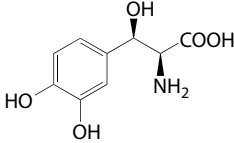

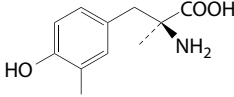

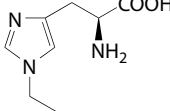

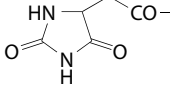

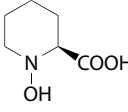

No.	Structure	Name/Reference	Symbol
24	$\text{CH}_3\text{CH}_2\text{CH}(\text{CH}_3)\text{CH}_2\text{CH}(\text{NH}_2)\text{COOH}$	2-Amino-4-methyl-hexanoic acid (4)	Ahx( $\gamma\text{Me}$ )
25	$\text{CH}_3\text{CH}=\text{C}(\text{CH}_3)\text{CH}_2\text{CH}(\text{NH}_2)\text{COOH}$	2-Amino-4-methyl-4-hexenoic acid (4)	Ahx( $\Delta^4$ , $\gamma\text{Me}$ )
26	$\text{CH}_2=\text{C}(\text{CH}_3)\text{CH}_2\text{CH}_2\text{CH}(\text{NH}_2)\text{COOH}$	2-Amino-5-methyl-5-hexenoic acid (4)	Ahx( $\Delta^5$ , $\delta\text{Me}$ )
27	$\text{H}_2\text{N}(\text{CH}_2)_7\text{COOH}$	8-Amino-octanoic acid	$\omega\text{Aoc}$
28		(4-Amino)phenylalanine (5)	Phe(4NH <sub>2</sub> )
29		3-Amino-4-phenylbutyric acid	$\beta\text{Abu}(\gamma\text{Ph})$
30	$\text{HOOCCH}(\text{NH}_2)(\text{CH}_2)_4\text{COOH}$	2-Aminopimelic acid	$\alpha\text{Apm}$
31		2-Amino-3-(2-pyridyl)propionic acid	Apr( $\beta\text{Prd-2}$ )
32		2-Amino-3-(2-pyrimidyl)propionic acid	Apr( $\beta\text{Pyr-2}$ ) <sup>c,d</sup>
33	$(\text{CH}_3)_3\text{N}^+(\text{CH}_2)_4\text{CH}(\text{NH}_2)\text{COOH}$	2-Amino-6-(trimethylammonio)hexanoic acid	$\alpha,\epsilon\text{A}_2\text{hx}(\text{N}^+\text{Me}_3)$
34		3-Aminotyrosine	Tyr(3NH <sub>2</sub> )
35	$\text{HOOCCH}_2\text{CH}(\text{NH}_2)\text{CONHCH}_3$	Aspartic $\alpha$ -methylamide	Asp-NHMe
36	$\text{CH}_3\text{NHCOCH}_2\text{CH}(\text{NH}_2)\text{COOH}$	Aspartic $\beta$ -methylamide	Asn(Me); Asp(NHMe)
37		Azetidine-2-carboxylic acid	Azt
38		Aziridinecarboxylic acid	Azr
39		Aziridinonecarboxylic acid (6)	Azro
40	$(\text{PhCH}_2)_2\text{C}(\text{NH}_2)\text{COOH}$	( $\alpha$ -Benzyl)phenylalanine (7)	Phe( $\alpha\text{Bzl}$ )
41		3-Benzyltyrosine (8)	Tyr(3Bzl)

## STRUCTURE AND SYMBOLS FOR SYNTHETIC AMINO ACIDS INCORPORATED INTO SYNTHETIC POLYPEPTIDES (Continued)

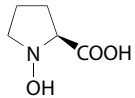

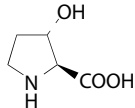

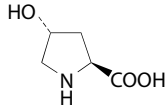

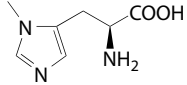

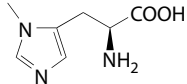

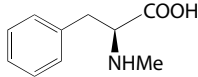

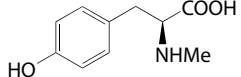

No.	Structure	Name/Reference	Symbol
42		(4-Chloro)phenylalanine (5)	Phe(4Cl)

## UNNATURAL AMINO ACIDS FOR INCORPORATION INTO PROTEINS

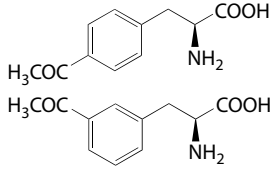

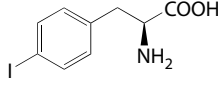

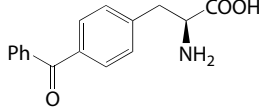

Amino acids can be divided into two groups. Proteinogenic amino acids are defined as amino acids which can be incorporated into proteins.<sup>1-4</sup> Proteogenic amino acids are differentiated from amino acids which are subject to post translational modification<sup>5,6</sup> such as the  $\gamma$ -carboxylation of glutamic acid. Non proteinogenic (non protein) amino acids<sup>7</sup> such as cyclopentenylglycine<sup>8</sup> and L-*p*-hydroxyphenylglycine<sup>9</sup> are involved in metabolism and in peptide antibiotics. There has been considerable interest in the development of unnatural amino acids. While the broad definition of an unnatural amino acid is any synthetic organic carboxylic acid which contains an amino or imino function, the definition for this section is that an unnatural amino acid must be capable of incorporation into a protein in a specific manner using a biological system.<sup>10-17</sup>

<sup>a</sup> h = water; e = ethyl acetate; l = ligroin; hc = hydrochloric acid; ac = glacial acetic acid; a = ethanol.

<sup>b</sup> Mole  $\times 10^{-8}$  of DPNH oxidized per mg of enzyme per minute at 26° (9, 10).

<sup>c</sup>  $\mu$ L. CO<sub>2</sub> per hour (10).

<sup>d</sup>  $\alpha$ -Amino- $\delta$ -hydroxy-*n*-valeric acid.

<sup>e</sup> Originally designated *d* (11). Originally designated *l* (11).

<sup>f</sup> Additional data have been published on the reduction of  $\alpha$ -keto acids by lactic dehydrogenase (12).

<sup>h</sup> This keto acid has been reported to be decarboxylated by yeast preparations; the reaction is much more rapid at pH 6.3 than at 5 (13).

## $\alpha,\beta$ -UNSATURATED AMINO ACIDS

$\alpha,\beta$ -Unsaturated amino acids with free  $\alpha$ -amino groups are not stable; *N*-acylated  $\alpha,\beta$ -unsaturated amino acids are stable compounds. The  $\alpha,\beta$ -unsaturated amino acids listed in this table are present in natural products in which they are stabilized by

peptide bond formation. The addition of mercaptans to  $\alpha,\beta$ -unsaturated amino acids and the reversible conversion to keto acids and amides are of biological significance.<sup>1,2,11</sup>

No.	Amino Acid/Synonym	Source	Structure	Formula (Mol Wt)	References	
					Chemistry	Spectral Data
1	<b>Dehydroalanine</b>	Nisin Subtilin	$H_2C=C(NH_2)COOH$	$C_3H_5NO_2$ 87.08	1, 2 2	1, 2 2
2	<b><math>\beta</math>-Methyldehydroalanine</b>	Nisin, Subtilin Stendomycin	$H_3CCH=C(NH_2)COOH$	$C_4H_7NO_2$ 101.10	1, 2 3	1, 2 3
3	<b>Dehydroserine</b>	Viomycin Capreomycin	$HOHC=C(NH_2)COOH$	$C_3H_5NO_3$ 103.08	4 4	4 4
4	<b>Dehydroleucine</b>	Albonoursin	$(H_3C)_2CHCH=C(NH_2)COOH$	$C_6H_{11}NO_2$ 129.16	5	
5	<b>Dehydrophenylalanine</b>	Albonoursin	$PhCH=C(NH_2)COOH$	$C_9H_9NO_2$ 163.17	5	
6	<b>Dehydrotryptophan</b>	Telomycin		$C_{11}H_{10}N_2O_2$ 202.21	6	6
7	<b>Dehydroarginine</b>	Viomycin Capreomycin	$H_2NC(=NH)NHCH_2CH_2CH=C(NH_2)COOH$	$C_6H_{12}N_4O_2$ 172.19	4	4
8	<b>Dehydroproline</b>	Ostreogrycin A		$C_5H_7NO_2$ 113.11	7	7
9	<b>Dehydrovaline</b>	Penicillin	$(H_3C)_2C=C(NH_2)COOH$	$C_5H_9NO_2$ 115.13	8	
10	<b>Dehydrocysteine</b>	Micrococцин Thiostrepton	$HSCH=C(NH_2)COOH$	$C_3H_5NO_2S$	9, 10	10

## AMINO ACID ANTAGONISTS

Amino Acid	Analog	System	Reference	
<b><math>\alpha</math>-Alanine</b>	$\alpha$ -Aminoethanesulfonic acid	Bacteria	1	
	Glycine	Mouse tumor	2	
	$\alpha$ -Aminoisobutyric acid	Bacteria	3	
	Serine	Bacteria	4	
<b>D-Alanine</b>	D-Cycloserine	Bacteria	3	
	O-Carbamyl-D-serine	Bacterial cell wall	5–10	
	D- $\alpha$ -Aminobutyric acid	Bacterial cell wall	11	
<b><math>\beta</math>-Alanine</b>	$\beta$ -Aminobutyric acid	Bacterial cell wall	12	
	Propionic acid	Yeast	13	
	Asparagine	Bacteria	14	
	D-Serine	Yeast	15	
<b>Arginine</b>	Canavanine	Bacteria	16	
		Yeast, <i>Neurospora</i> , bacteria	17, 18-22	
		Carcinoma	23	
		Animals	24, 25	
		Plants	26, 27	
		Tissue culture	28, 29	
		Arginase	30	
		Ornithine	Arginase	31
		Homoarginine	Bacteria	22, 32
		Cysteic acid	Bacteria	1, 33, 34
<b>Aspartic acid</b>		Bacteria	35	
	$\beta$ -Hydroxyaspartic acid	Bacteria	34, 36, 37	
	Diaminosuccinic acid	Bacteria	36	
	Aspartophenone	Bacteria, yeast	4	
	$\alpha$ -Aminolevulinic acid	Bacteria, yeast	4	
	$\alpha$ -Methylaspartic acid	Bacteria	38	
	$\beta$ -Aspartic acid hydrazide	Bacteria	38	
	S-Methylcysteine sulfoxide	Bacteria	39	
	$\beta$ -Methylaspartic acid	Bacteria	40	
	Hadacidin	Purine biosynthesis	41	
	2-Amino-2-carboxyethanesulfonamide	<i>Neurospora</i>	42	
	<b>Asparagine</b>	Allylglycine	Bacteria, yeast	43
<b>Cysteine</b>				
<b><math>\alpha,\epsilon</math>-Diaminopimelic acid</b>	$\alpha,\alpha$ -Diaminosuberic acid	Bacteria	44	
	$\alpha,\alpha$ -Diaminosebacic acid	Bacteria	44	
	$\beta$ -Hydroxy- $\alpha,\epsilon$ -diaminopimelic acid	<i>Escherichia coli</i>	45	
	$\gamma$ -Methyl- $\alpha,\epsilon$ -diaminopimelic acid	<i>E. coli</i>	46	
	Cystine	<i>E. coli</i>	47	
<b>Glutamic acid</b>	Methionine sulfoxide	Bacteria	48, 49	
		Glutamine synthesis	50	
	$\gamma$ -Glutamylethylamide	Bacteria	51	
	$\beta$ -Hydroxyglutamic acid	Bacteria	52, 53	
	Methionine sulfoximine	Bacteria	54, 55	
	$\alpha$ -Methylglutamic acid	Enzymes	56, 57	
	$\gamma$ -Phosphonoglutamic acid	Glutamine synthesis	58	
	P-Ethyl- $\gamma$ -phosphonoglutamic acid	Glutamine synthesis	58	
	$\gamma$ -Fluoroglutamic acid <sup>a</sup>	Glutamine synthesis	59	
		Bacteria	60	
<b>Glutamine</b>	S-Carbamylcysteine	Ascites cells	61	
		Bacteria	62	
	O-Carbamylserine	Bacteria	63	
	O-Carbazylserine	Bacteria	63	
	3-Amino-3-carboxypropanesulfonamide	<i>E. coli</i>	64	
	N-Benzylglutamine	<i>Streptococcus lactis</i>	65	
	Azaserine	Enzymes	66	
	6-Diazo-5-oxonorleucine	Enzymes	66	
	$\gamma$ -Glutamylhydrazide	<i>S. faecalis</i>	67	
		Bacteriophage	68	
<b>Glycine</b>		Vaccinia virus	69	
		Bacteria	1	
		<i>E. coli</i>	4	

## AMINO ACID ANTAGONISTS (Continued)

Amino Acid	Analog	System	Reference
<b>Histidine</b>	D-Histidine	Histidase	70
	Imidazole		70
	2-Thiazolealanine	<i>E. coli</i>	71
	1,2,4-Triazolealanine	<i>E. coli</i>	71, 72
<b>Isoleucine</b>	Leucine	Salmonella	73
		Bacteria	74
		Rats	75
	Methylglycine	Bacteria, yeast	4, 43
	$\omega$ -Dehydroisoleucine	Bacteria	76
	3-Cyclopentene-1-glycine	Bacteria	77
	Cyclopentene glycine	Bacteria	78
	2-Cyclopentene-1-glycine	Bacteria	79
	O-Methylthreonine	Tumor cells	80
	$\beta$ -Hydroxyleucine	Bacteria	37
<b>Leucine</b>	D-Leucine	Bacteria	81
	$\alpha$ -Aminoisoamylsulfonic acid	Bacteria	1, 33
		Mouse tumor	2
	Norvaline	Bacteria	4
	Norleucine	Bacteria	1, 4, 82
	Methylglycine	Yeast, bacteria	4
	$\alpha$ -Amino- $\beta$ -chlorobutyric acid	Yeast, bacteria	4
	Valine	Bacteria	83
	$\delta$ -Chloroleucine	<i>Neurospora</i>	84
	Isoleucine	Bacteria	85
	$\beta$ -Hydroxynorleucine	Bacteria	86
	$\beta$ -Hydroxyleucine	Bacteria	86
	Cyclopentene alanine	Bacteria	87
	3-Cyclopentene-1-alanine	Bacteria	88
	2-Amino-4-methylhexenoic acid	Bacteria	89
	5,5,5'-Trifluoroleucine	<i>E. coli</i>	90
	4-Azaleucine	<i>E. coli</i>	91
	$\alpha$ -Amino- $\epsilon$ -hydroxycaproic acid	Rat	92
	Arginine	<i>Neurospora</i>	93
	2,6-Diaminoheptanoic acid	Bacteria	94
Oxalysine	Bacteria	95	
3-Aminomethylcyclohexane glycine	Bacteria	96	
3-Aminocyclohexane alanine	Bacteria	97	
<i>trans</i> -4-Dehydrolysine	Bacteria	98	
<i>S</i> -( $\beta$ -Aminoethyl)cysteine	Bacteria	99	
<b>Methionine</b>	4-Azalsysine	Bacteria	
	2-Amino-5-heptenoic acid (crotylalanine)	<i>E. coli</i>	100
	2-Amino-4-hexenoic acid (crotylglycine)	<i>E. coli</i>	101
	Methoxinine	Bacteria	102
		Vaccinia virus	69
		Rats	103
	Norleucine	Bacteria	82, 104, 105
		Animal tissues	106
		Casein	107
	Ethionine	Bacteria, animals	28, 102, 105, 108–120
		Amylase	121, 122
		Yeast	123
		Tumors	124
		Pancreatic proteins	125
	Methionine sulfoximine	Bacteria	126
Threonine	<i>Neurospora</i>	127	
Selenomethionine	<i>Chlorella</i>	128	
	<i>E. coli</i> , yeast	129–132	
<b>Ornithine</b>	$\alpha$ -Amino- $\delta$ -hydroxyvaleric acid	Bacteria	21
	Canaline	Bacteria	21
<b>Phenylalanine</b>	$\alpha$ -Amino- $\beta$ -phenylethanesulfonic acid	Mouse tumor	2
	Tyrosine	Bacteria	133
	$\beta$ -Phenylserine	Bacteria	134–136
	Cyclohexylalanine	Rats	137
	<i>o</i> -Aminophenylalanine	<i>E. coli</i>	138
	<i>p</i> -Aminophenylalanine	Bacteria	139, 140

<sup>a</sup> Solubility equations:

- a.  $\log S = a_1 + b_1 t + c_1 t^2$  (grams per 1,000 gms water)
- b.  $\log m = a_2 + b_1 t + c_1 t^2$  (moles per 1,000 gms water)
- c.  $\ln m = a_3 + b_3 T + c_3 T^2$
- d.  $\ln N_2 = a_4 + b_4 T + c_4 T^2$

<sup>b</sup> The five sets of values which are given under L-valine refer to the various crystal forms.

<sup>c</sup> The first set of values refer to 273.1 K to 303.1 K and the second set to 298.1 K to 323.5 K absolute.

<sup>d</sup> Values are not strictly accurate due to contamination of the leucine with a small amount of methionine.

# HEAT CAPACITIES, ABSOLUTE ENTROPIES, AND ENTROPIES OF FORMATION OF AMINO ACIDS AND RELATED COMPOUNDS

John O. Hutchens

Heat capacity ( $C_p^\circ$ ), absolute entropy ( $S^\circ$ ), and the entropy change for formation from the elements ( $\Delta S_f^\circ$ ) are given for a temperature of 298.15 K. The units are cal deg<sup>-1</sup> mole<sup>-1</sup> for all entries except for proteins where they are cal deg<sup>-1</sup> g<sup>-1</sup>. 1 cal = 4.1840 absolute joules and 0°C = 273.15 K. International Atomic Weights of 1959 are employed. In calculating  $\Delta S_f^\circ$  the entropies of the elements used are (in cal deg<sup>-1</sup> mole<sup>-1</sup>) C (graphite), 1.3609; H<sub>2</sub> (gas), 31.211; O<sub>2</sub> (gas), 49.003; N<sub>2</sub> (gas), 45.767; Cl<sub>2</sub> (gas), 53.31; and S (rhombic), 7.62.<sup>1</sup>  $S^\circ$  for D<sub>2</sub> (gas) is 34.620 cal deg<sup>-1</sup> mole<sup>-1</sup>.<sup>2</sup>

The references cited give heat capacities at other temperatures, and, in most cases, the additional thermodynamic functions ( $H^\circ - H_0^\circ$ ),  $(H^\circ - H_0^\circ)/T$  and  $-(F^\circ - H_0^\circ)/T$ . None of the stated values is more accurate than  $\pm 0.2\%$ . Values obtained by extrapolating below 90 K are uncertain by  $\pm 1-2$  cal deg<sup>-1</sup> mole<sup>-1</sup>. Entries are listed in alphabetical order under (1) amino acids, (2) peptides, (3) proteins, and (4) miscellaneous related substances.

# HEAT OF COMBUSTION, ENTHALPY AND FREE ENERGY OF FORMATION OF AMINO ACIDS AND RELATED COMPOUNDS

John O. Hutchens

Heat of combustion ( $\Delta H_c^\circ$ ) is given as the enthalpy change for the reaction of burning the compound at constant pressure to produce  $\text{CO}_2$  (gas),  $\text{H}_2\text{O}$  (liquid),  $\text{N}_2$  (gas), and S (rhombic). The enthalpy of formation ( $\Delta H_f^\circ$ ) is given for formation of the compound from C (graphite),  $\text{H}_2$  (gas),  $\text{O}_2$  (gas),  $\text{N}_2$  (gas), and S (rhombic). In calculating  $\Delta H_f^\circ$ , the enthalpies of formation of  $\text{CO}_2$  (gas,  $p = 0$ ) = 94.0518 Kcal mole<sup>-1</sup> and of  $\text{H}_2\text{O}$  (liquid) = 68.3174 Kcal mole<sup>-1</sup> were employed.<sup>1</sup> Most of the heats of combustion were originally reported as the enthalpy change for the combustion reaction with all gases at  $p = 1$  atmosphere. No correction has been made for further expansion of the gases. However, all heats of combustion have been corrected so that International Atomic Weights of 1959 apply. The listings are for a temperature of 298.15°K. 0°C = 273.15°K and 1 cal = 4.1840 absolute joules. The units for all entries are kcal mole<sup>-1</sup>.

In calculating  $\Delta G_f^\circ$  the free energy change for formation of the compound from C (graphite),  $\text{H}_2$  (gas,  $f = 1$ );  $\text{O}_2$  (gas,  $f = 1$ ),  $\text{N}_2$  (gas,  $f = 1$ ), and S (rhombic) the entropies of formation ( $\Delta S_f^\circ$ ) of amino

acids and peptides listed in table on page 65 were employed.  $\Delta G_f^\circ = \Delta H_f^\circ - T\Delta S_f^\circ$ . Where available  $\Delta S_f^\circ$  for the L-isomer of an amino acid was used in calculating  $\Delta G_f^\circ$  for D- and DL-form on the assumption that this entropy value was more reliable. Available entropy data on D- and DL-forms depend on extrapolation of heat capacity data below 90°K while those for the L-amino acids in most cases do not.

The table is intended to be comprehensive rather than selective. All heats of combustion which have come to the compiler's attention have been included regardless of degree of reliability. Where more than one heat of combustion has been reported for a compound,  $\Delta H_f^\circ$  and  $\Delta G_f^\circ$  have been calculated only from the apparently more reliable data. Where no reasonable choice could be made between apparently equally reliable recent heats of combustion (since 1930)  $\Delta H_f^\circ$  and  $\Delta G_f^\circ$  have been calculated from both.

Compounds are listed alphabetically under (1) Amino Acids, (2) Peptides, and (3) Miscellaneous related compounds.

# SOLUBILITIES OF AMINO ACIDS IN WATER AT VARIOUS TEMPERATURES

**John O. Hutchens**

The table gives the solubilities of the amino acids in grams per kilogram of water at various temperatures. None of the experimental observations were made at temperatures above 70°C. In most cases the experimental values were obtained both from a colder originally unsaturated solution and a warmer originally saturated

solution. Even where four significant figures are given, many of the values probably are not reliable to better than 1 to 2% as judged by agreement between investigators. Lack of a value at a given temperature indicates that, in the opinion of the compiler, extrapolation of the curve from lower temperatures could not be justified.

## SOLUBILITIES OF AMINO ACIDS IN WATER AT VARIOUS TEMPERATURES 0°–100° C (g/kg)

# HEATS OF SOLUTION OF AMINO ACIDS IN AQUEOUS SOLUTION AT 25° C

John O. Hutchens

Enthalpy changes are given for: (1) Solution of the solid crystalline amino acid into the infinitely dilute solution ( $\bar{H}_2^\circ - H_2^\circ$ ), (2) solution of the solid crystalline substance into saturated solution ( $\bar{H}_2^\circ(\text{sat}) - H_2^\circ$ ), and (3) dilution of the saturated solution to infinite dilution ( $\bar{H}_2^\circ - H_2^\circ(\text{sat})$ ). All entries are Kcal mole<sup>-1</sup> and are for 25° C. Columns headed "cal" indicate direct calorimetric measurement. Columns headed "soly" indicate that the value was calculated from solubility and activity data. Generally speaking the two methods agree within the limits of error of either method.

The data suffer from multiple defects. The purity of many of the amino acids used in older work<sup>1</sup> is subject to question. Calculations from solubility data are handicapped by poor knowledge of activity coefficients, particularly for sparingly soluble amino acids. Some amino acids form hydrates, and it is not always clear that the solubility data are for the crystalline anhydrous form or that equilibrium has been reached as regards either crystalline form or solubility.

## FREE ENERGIES OF SOLUTION AND STANDARD FREE ENERGY OF FORMATION OF AMINO ACIDS IN AQUEOUS SOLUTION AT 25° C

The table lists the molality (m, moles per kg of H<sub>2</sub>O) of the saturated solution at 25°C (298.15 K); the appropriate molal activity coefficient ( $\gamma_m$  or  $\gamma_m^\pm$ ); the free energy change for transporting one mole of the solute from the saturated solution to a hypothetical

aqueous solution at an activity of 1 molal ( $\Delta G_{\text{soln}}$ ); and the free energy change for formation of the substance in hypothetical 1 molal solution from the elements ( $\Delta G_f^\circ$ ). The units of  $\Delta G_{\text{soln}}$  and  $\Delta G_f^\circ$  are kcal mole<sup>-1</sup>.

## FAR ULTRAVIOLET ABSORPTION SPECTRA OF AMINO ACIDS

The absorption of a chromophoric amino acid in this spectral region is due to the combined absorptions of the side chain chromophore and of the carboxylate group. Because the carboxylate group is consumed in polymerizing amino acids to polypeptides, an amino acid residue absorbs less intensely than a free amino acid. The magnitude of this difference

can be estimated from the spectra of the nonchromophoric amino acids – leucine, proline, alanine, serine, and threonine – whose total absorption is due only to the carboxylate group. The variations between the absorptions of these amino acids reflect the variability of carboxylate absorption in slightly different environments.

Far ultraviolet spectra of amino acids. All amino acids were in aqueous solution at pH 5, except cystine (pH 3). The dibasic amino acids were measured as hydrochlorides and the absorbance corrected by subtracting the absorbance contribution of chloride ion. Taken from Wetlaufer, *Adv. Protein Chem.*, 17, 320 (1962). With the permission of Academic Press and R. Sussman-McDiarmid and W. Gratzer.

<sup>a</sup> The excitation wavelength in nanometers. When not listed it is either not cited in the original reference or else encompasses a range of wavelengths.

<sup>b</sup> The wavelength, in nanometers, of maximum fluorescence intensity.

<sup>c</sup> The absolute quantum yield.

<sup>d</sup> The excited lifetime, in nanoseconds.

# HYDROPHOBICITIES OF AMINO ACIDS AND PROTEINS

C. C. Bigelow and M. Channon

**TABLE 1: Hydrophobicities of Amino Acids**

The hydrophobicity of an amino acid side chain is derived from the measurement of the solubility of the amino acid in water and an organic solvent.<sup>1,2</sup> The data are converted into the molar free energy of transfer for the amino acid from an aqueous solution to a solution in the organic solvent at the same mole fraction at the limit of infinite dilution:

$$\Delta F_t = RT \ln \frac{N_w \gamma_w}{N_{org} \gamma_{org}}$$

The hydrophobicity of the side chain,  $H\Phi$ , is then determined by subtracting  $\Delta F_t$  for glycine. The thermodynamic interpretation of the hydrophobicity has been discussed by Noaki and Tanford.<sup>2</sup>

Amino Acid	HΦ (cal/mol)	Amino Acid	HΦ (cal/mol)
Trp	3,400	Cys/2	1,000
Ile	2,950	Arg	750
Pro	2,600	His	500
Phe	2,500	Ala	500
Tyr	2,300	Thr	400
Leu	1,800	Gly	(0)
Val	1,500	Asp	0 <sup>a</sup>
Lys	1,500	Glu	0 <sup>a</sup>
Met	1,300	Ser	-300

Compiled by C. C. Bigelow and M. Channon.

<sup>a</sup> Assumed values.

2. Nozaki and Tanford, *J. Biol. Chem.*, 246, 2211 (1971),

**TABLE 2: Average Hydrophobicities of Selected Proteins**

The values in the table have been calculated for proteins from amino acid compositions in the literature. Proteins have been included only if the content of all the amino acids is known. The selection has been guided by a desire to include proteins of different properties (globular and fibrous, aggregating and

monomeric) as well as members of some families of related proteins.

$$H\Phi_{ave} = \frac{\sum_i n_i H\Phi_i}{\sum_i n_i}$$

where

$n_i$  = the number of residues of the  $i$ th amino acid;  
 $H\Phi_i$  = its hydrophobicity from Table 1.<sup>475, 476</sup>

Protein	Average Hydrophobicity	Reference
1 Acetoacetic acid decarboxylase ( <i>Clostridium acetobutylicum</i> )	1,140	1

59	Aldolase, fructose-1,6-diphosphate ( <i>Gallus domesticus</i> , liver)	970	46
60	Aldolase, fructose diphosphate ( <i>Micrococcus aerogenes</i> )	940	47
61	Aldolase, fructose-1,6-diphosphate (ox)	970	48
62	Aldolase, fructose-1,6-diphosphate (porcine)	960	48
63	Aldolase, fructose-1,6-diphosphate (rabbit liver)	960	49
64	Aldolase, fructose-1,6-diphosphate (rabbit, muscle)	960	48
65	Aldolase, fructose-1,6-diphosphate (sturgeon)	990	48
66	Aldolase, fructose-1,6-diphosphate ( <i>Trematomus borchgrevinki</i> )	980	43
67	Aldolase, fructose-1,6-diphosphate (yeast)	990	50
68	Aldolase, 2-keto-3-deoxy-6-phosphogluconate ( <i>Pseudomonas putida</i> )	1,090	51
69	Alkaline phosphatase ( <i>Bacillus licheniformis</i> MC 14)	940	52
70	Alkaline phosphatase ( <i>Escherichia coli</i> )	810	53

TABLE 2: Average Hydrophobicities of Selected Proteins (Continued)

	Protein	Average Hydrophobicity	Reference
71	Alkaline proteinase-B ( <i>Streptomyces rectus proteolyticus</i> )	820	54
72	$\omega$ -Amidase (rat liver)	980	55
73	Amino acid decarboxylase, aromatic (porcine kidney)	1,050	56
74	D-Amino acid oxidase (porcine kidney)	1,050	57
75	Aminopeptidase ( <i>Aeromonas proteolytica</i> )	860	58
76	Aminotripeptidase, TP-2 (porcine kidney)	1,090	59
77	Amylase ( <i>Bacillus macerans</i> )	910	60
78	Amylase (rat pancreas)	970	61
79	Amylase PI (rabbit pancreas)	940	62
80	Amylase PII (rabbit pancreas)	950	62
81	Amylase PIII (rabbit pancreas)	930	62
82	Amylase (rabbit parotid)	940	62
83	$\alpha$ -Amylase ( <i>Aspergillus aryzae</i> )	990	63
84	$\alpha$ -Amylase ( <i>Bacillus stearothermophilus</i> )	970	64
85	$\alpha$ -Amylase ( <i>Bacillus subtilis</i> )	970	65
86	$\alpha$ -Amylase (porcine pancreas)	1,040	66
87	$\alpha$ -Amylase (human saliva)	940	67
88	$\alpha$ -Amylase-I (porcine pancreas)	960	68
89	$\alpha$ -Amylase-II (porcine pancreas)	970	68
90	Anthranilate synthetase, component I ( <i>Pseudomonas putida</i> )	1,020	69
91	Anthranilate synthetase, component II ( <i>Pseudomonas putida</i> )	950	69
92	Apo-high density lipoprotein (bovine plasma)	960	70
93	Apolipoprotein – alanine-I (human plasma)	830	71
94	Apolipoprotein – alanine-II (human plasma)	830	71
95	Apolipoprotein – glutamine-I (human plasma)	870	72
96	Apolipoprotein – glutamine-I (porcine plasma)	890	72
97	Apolipoprotein – glutamine-II (human plasma)	970	73
98	Apolipoprotein-valine (human plasma)	920	74
99	Apovitellin-I ( <i>Dromaeus novaehollandiae</i> )	1,210	75
100	$\alpha$ -L-Arabinofuranosidase ( <i>Aspergillus niger</i> K1)	900	76
101	L-Arabinose-binding protein ( <i>Escherichia coli</i> B/r)	1,020	77
102	L-Arabinose isomerase ( <i>Escherichia coli</i> )	990	78
103	Arginine decarboxylase ( <i>Escherichia coli</i> )	980	79
104	Arginine kinase ( <i>Callinectes sapidus</i> )	940	80
105	Arginine kinase ( <i>Homarus americanus</i> )	980	81
106	Arginine kinase, negative ( <i>Limulus polyphemus</i> )	950	80
107	Arginine kinase, neutral ( <i>Limulus polyphemus</i> )	970	80
108	Arginine kinase ( <i>Pagurus bernhardus</i> )	970	80
109	Asparaginase ( <i>Escherichia coli</i> B)	870	82
110	Asparaginase (guinea pig)	970	83
111	L-Asparaginase ( <i>Proteus vulgaris</i> )	950	84
112	Aspartate aminotransferase (ox heart)	980	85
113	Aspartate aminotransferase (rat brain, cytoplasm)	1,050	86
114	Aspartate aminotransferase (rat brain, mitochondria, fraction II)	990	86
115	Aspartate aminotransferase (rat brain, mitochondria, fraction III)	990	86
116	Aspartate- $\beta$ -decarboxylase ( <i>Alcaligenes faecalis</i> )	1,010	87
117	Aspartate- $\beta$ -decarboxylase ( <i>Pseudomonas dacunhae</i> )	1,020	88
118	Aspartate transcarbamylase, catalytic chain ( <i>Escherichia coli</i> )	990	89
119	Aspartate transcarbamylase, regulatory chain ( <i>Escherichia coli</i> )	980	89
120	Aspartokinase, lysine sensitive ( <i>Escherichia coli</i> K-12, HfrH)	940	90
121	Aspergillopeptidase B ( <i>Aspergillus oryzae</i> )	810	91
122	Avidin (chicken egg)	930	92
123	Azurin ( <i>Pseudomonas fluorescens</i> )	880	93
124	Azurin ( <i>Pseudomonas polymyxa</i> )	970	94
125	Biotin carboxyl carrier protein ( <i>Escherichia coli</i> )	1,300	95
126	Blastokinin (rabbit)	1,030	96
127	Bradykininogen (bovine)	980	97
128	$\alpha$ -Bungarotoxin ( <i>Bungarus multicinctus</i> )	1,040	98
129	C <sub>1</sub> -inactivator (human plasma)	1,020	99

TABLE 2: Average Hydrophobicities of Selected Proteins (Continued)

	Protein	Average Hydrophobicity	Reference
130	Calcitonin (bovine)	1,080	100
131	Calcitonin (human)	1,100	101
132	Calcitonin (porcine)	1,100	102
133	Calcitonin (salmon)	860	103
134	Calcium-binding protein (bovine adrenal medulla)	780	104
135	Calcium-binding protein (chick duodenal mucosa)	930	105
136	Calcium-binding protein-B (parvalbumin) ( <i>Cyprinus carpio</i> muscle)	890	106
137	Calcium-binding protein (porcine brain)	740	107
138	Carbamyl phosphate synthetase ( <i>Escherichia coli</i> B)	960	108
139	Carbonic anhydrase (bovine)	1,000	109
140	Carbonic anhydrase ( <i>Gallus domesticus</i> )	1,000	110
141	Carbonic anhydrase (parsley)	1,100	111
142	Carbonic anhydrase (sheep)	990	112
143	Carbonic anhydrase B (bovine)	950	113
144	Carbonic anhydrase B (equine)	940	114
145	Carbonic anhydrase B ( <i>Macaca mulata</i> )	960	115
146	Carbonic anhydrase B (porcine)	1,000	116
147	Carbonic anhydrase C (equine)	960	114
148	Carbonic anhydrase C (porcine)	1,010	117
149	$\beta$ -Carboxy-cis,cis-muconate lactonizing enzyme ( <i>Pseudomonas putida</i> )	940	118
150	$\gamma$ -Carboxymuconolactone decarboxylase ( <i>Pseudomonas putida</i> )	1,170	119
151	Carboxypeptidase A (bovine pancreas)	1,010	120
152	Carboxypeptidase A ( <i>Penaeus setiferus</i> )	910	121
153	Carboxypeptidase B ( <i>Penaeus setiferus</i> )	940	121
154	Carboxypeptidase B ( <i>Protopterus aethiopicus</i> )	1,010	122
155	Procarboxypeptidase B ( <i>Protopterus aethiopicus</i> )	990	122
156	Carboxypeptidase B (dogfish pancreas)	1,070	123
157	Carboxypeptidase Y (yeast)	1,050	124
158	Carboxytransphosphorylase (propionic acid bacteria)	950	125
159	Catalase (bovine liver)	1,110	126
160	Colchicine-binding protein (sea urchin)	930	127
161	Colchicine-binding protein (porcine brain)	930	128
162	Chorionic gonadotropin- $\alpha$ (human)	960	126
163	Chorionic gonadotropin- $\beta$ (human)	1,120	130
164	Chorismate mutase-prephenate dehydratase ( <i>Escherichia coli</i> K-12)	990	131
165	Chymoelastase, lysine free ( <i>Streptomyces griseus</i> K-1)	720	132
166	Chymoelastase, guanidine stable ( <i>Streptomyces griseus</i> K-1)	760	132
167	Chymotrypsin anionic (fin whale)	1,060	133
168	Chymotrypsin II (human)	940	134
169	Chymotrypsinogen A (dogfish)	1,010	135
170	Chymotrypsinogen B (bovine pancreas)	950	136
171	Chymotrypsinogen B (porcine pancreas)	1,010	137
172	Chymotrypsinogen C (porcine pancreas)	970	137
173	Cocoonase ( <i>Antheraea pernyi</i> )	840	138
174	Cocoonase ( <i>Antheraea polyphemus</i> )	860	138
175	Prococoonase ( <i>Antheraea polyphemus</i> )	840	138
176	Colicin I <sub>a</sub> -CA53 ( <i>Escherichia coli</i> )	880	139
177	Colicin I <sub>b</sub> -P9 ( <i>Escherichia coli</i> )	940	139
178	Collagen (chicken tendon)	880	140
179	Collagen, $\alpha$ -fraction (calf skin)	880	141
180	Collagen, spongin B (sponge)	760	142
181	Collagen (sturgeon swim bladder)	770	143
182	Collagenase ( <i>Uca pugilator</i> )	920	144
183	Conalbumin (chicken)	980	145
184	Corrinoid protein ( <i>Clostridium thermoaceticum</i> )	890	146
185	Creatine kinase ( <i>Cyprinus carpio</i> L.)	960	147
186	Creatine kinase (human)	970	148
187	Crotonase ( <i>Clostridium acetobutylicum</i> )	970	149

TABLE 2: Average Hydrophobicities of Selected Proteins (Continued)

	Protein	Average Hydrophobicity	Reference
188	Crotoxin ( <i>Crotalus terrificus terrificus</i> )	970	150
189	Cystathionase (rat liver)	980	151
190	Cytochrome b <sub>5</sub> (bovine liver)	1,000	152
191	Cytochrome b <sub>5</sub> (equine liver)	970	152
192	Cytochrome b <sub>5</sub> (porcine liver)	900	152
193	Cytochrome c (horse heart)	1,050	153
194	Cytochrome c (chicken)	1,050	154
195	Cytochrome c (cow, pig, sheep)	1,020	154
196	Cytochrome c (dog)	1,070	154
197	Cytochrome c (kangaroo)	1,130	154
198	Cytochrome c (king penguin)	1,060	154
199	Cytochrome c ( <i>Macaca mulata</i> )	1,060	154
200	Cytochrome c (moth)	1,060	154
201	Cytochrome c (pigeon)	1,070	154
202	Cytochrome c (rabbit)	1,070	154
203	Cytochrome c (rattlesnake)	1,050	154
204	Cytochrome c ( <i>Saccharomyces</i> )	1,040	154
205	Cytochrome c (tuna)	1,050	154
206	Cytochrome c (turkey)	1,050	154
207	Cytochrome CA ( <i>Humicola lanuginosa</i> )	910	155
208	Cytochrome C <sub>3</sub> ( <i>Desulfovibrio desulfuricans</i> )	920	156
209	Cytochrome C <sub>3</sub> ( <i>Desulfovibrio gigas</i> )	870	157
210	Cytochrome C <sub>3</sub> ( <i>Desulfovibrio salexigens</i> )	840	157
211	Cytochrome C <sub>3</sub> ( <i>Desulfovibrio vulgaris</i> )	840	158
212	Cytochrome 553 ( <i>Monochysis lutheri</i> )	730	159
213	Daunorubicin reductase (rat liver)	1,100	160
214	3-Deoxy-D-arabinoheptulose 7-phosphate synthetase-chorismate mutase ( <i>Bacillus subtilis</i> )	1,000	161
215	Deoxycytidylate deaminase (T <sub>2</sub> r <sup>+</sup> bacteriophage)	970	162
216	Deoxyribonuclease (bovine pancreas)	930	163
217	Deoxyribonuclease A (bovine pancreas)	970	164
218	Deoxyribonuclease B (bovine pancreas)	980	164
219	Deoxyribonuclease C (bovine pancreas)	980	164
220	Deoxyribonuclease II (porcine spleen)	1,050	165
221	Deoxyribonucleic acid ligase ( <i>Escherichia coli</i> )	970	166
222	Deoxyribonucleotidase inhibitor II (calf spleen)	1,010	167
223	$\alpha$ -Dialkylamino transamidase ( <i>Pseudomonas cepacia</i> )	930	168
224	Dihydrofolate reductase (T <sub>4</sub> bacteriophage)	1,030	169
225	Dihydrofolate reductase ( <i>Escherichia coli</i> MB 1428)	1,030	170
226	Dihydrofolate reductase ( <i>Lactobacillus casei</i> )	1,010	171
227	Dihydrofolate reductase ( <i>Streptococcus faecium</i> )	1,060	172
228	3,4-Dihydroxyphenylacetate-2,3-oxygenase ( <i>Pseudomonas ovalis</i> )	980	173
229	Dopamine- $\beta$ -hydroxylase (bovine adrenal)	950	174
230	Elastin (bone aorta)	940	175
231	Elastin (bovine ear cartilage)	990	175
232	Elastin (bovine ligamentum nuchae)	980	175
233	Encephalitogenic A-1 protein (bovine brain)	850	176
234	Encephalitogenic A-1 protein (human brain)	820	176
235	Endopolygalacturonase ( <i>Verticillium albo-atrum</i> )	850	177
236	Enolase (monkey muscle)	970	178
237	Enolase ( <i>Onkorhynchus keta</i> )	980	179
238	Enolase ( <i>Onkorhynchus kisutch</i> )		
239	Enolase (rabbit muscle)	990	180
240	Enolase ( <i>Thermus</i> X-1)	900	181
241	Enolase ( <i>Thermus aquaticus</i> YT-1)	770	182
242	Enolase (yeast)	890	183
243	Enterotoxin C ( <i>Staphylococcus</i> 137)	990	184
244	Enterotoxin E ( <i>Staphylococcus aureus</i> FRI-326)	940	185
245	Enterotoxin A ( <i>Staphylococcus aureus</i> 13N-2909)	980	186

TABLE 2: Average Hydrophobicities of Selected Proteins (Continued)

	Protein	Average Hydrophobicity	Reference
246	Erythrocuprein (human)	740	187
247	Esterase (pig liver)	1,100	188
248	Estradiol dehydrogenase (human placenta)	940	189
249	Factor III lac ( <i>Staphylococcus aureus</i> )	850	190
250	Factor VIII (bovine plasma)	1,030	191
251	Factor VIII (human plasma)	990	192
252	Ferredoxin ( <i>Chlorobium thiosulfatophilum</i> )	910	193
253	Ferredoxin ( <i>Clostridium pasteurianum</i> )	920	194
254	Ferredoxin ( <i>Chromatium</i> )	870	195
255	Ferredoxin ( <i>Cyperus rotundus</i> )	900	196
256	Ferredoxin ( <i>Desulfovibrio gigas</i> )	930	196
257	Ferredoxin ( <i>Spinacea</i> )	850	197
258	Ferredoxin ( <i>Scenedesmus</i> )	800	198
259	Ferredoxin I ( <i>Azotobacter vinelandii</i> )	1,050	199
260	Ferredoxin I ( <i>Bacillus polymxa</i> )	920	200
261	Ferredoxin II ( <i>Bacillus polymxa</i> )	920	200
262	Ferritin (horse spleen)	900	201
263	Ferritin (tadpole red blood cell)	850	202
264	Fibrinogen B (lobster)	990	203
265	Fibroin ( <i>Bombyx mori</i> )	330	204
266	Fibroin ( <i>Tussah</i> )	430	204
267	Ficin II ( <i>Ficus glabrata</i> )	930	205
268	Ficin III ( <i>Ficus glabrata</i> )	960	205
269	Flagellin ( <i>Proteus vulgaris</i> )	730	206
270	Flagellin ( <i>Salmonella</i> SJ 25)	680	207
271	Flagellin ( <i>Salmonella typhimurium</i> )	700	208
272	Flavodoxin ( <i>Clostridium</i> MP)	1,010	209
273	Flavodoxin ( <i>Clostridium pasteurianum</i> )	820	210
274	Flavodoxin ( <i>Desulfovibrio gigas</i> )	890	211
275	Flavodoxin ( <i>Desulfovibrio vulgaris</i> )	870	212
276	Flavodoxin ( <i>Peptostreptococcus elsdenii</i> )	870	213
277	Follicle stimulating hormone (ovine)	900	214
278	<i>N</i> -formimino-L-glutamate iminohydrolase ( <i>Pseudomonas</i> ATCC 11299b)	930	215
279	Fructose-1,6-diphosphatase (porcine kidney)	1,010	216
280	$\beta$ -Galactosidase ( <i>Escherichia coli</i> )	970	217
281	Gastricin (human)	920	218
282	Gastricin (porcine)	1,100	219
283	Gliadin SP 2-2 (Cappelle 1966 flour)	1,300	220
284	Gliadin SP 2-1 (wheat, Wichita 1963)	1,250	220
285	Gliadin SP 2-2 (wheat, Wichita 1963)	1,180	220
286	Gliadin SP 2-3 (wheat, Wichita 1963)	1,180	220
287	Globulin, 0.6 S $\gamma_2$ (human plasma)	1,090	221
288	Glucagon (bovine)	810	222
289	Glutamate decarboxylase ( <i>Escherichia coli</i> )	1,080	223
290	Glutamate dehydrogenase (bovine liver)	1,000	224
291	Glutamate dehydrogenase ( <i>Neurospora crassa</i> )	880	225
292	Glutaminase-asparaginase ( <i>Achromobacteraceae</i> )	960	226
293	Glutamine synthetase (rate liver)	1,010	227
294	$\gamma$ -Glutamyl cyclotransferase (porcine liver)	960	228
295	Glyceraldehyde-3-phosphate dehydrogenase ( <i>Bacillus stearothermophilus</i> )	940	229
296	Glyceraldehyde-3-phosphate dehydrogenase (bovine liver)	980	230
297	Glycerol-3-phosphate dehydrogenase (rabbit muscle)	1,040	231
298	Glycocyanine kinase ( <i>Nephtys coeca</i> )	990	232
299	Glycogen phosphorylase (Baker's yeast)	1,050	233
300	Glycogen phosphorylase ( <i>Carcharhinus falciformis</i> )	1,080	234
301	Glycogen phosphorylase (human)	1,060	235
302	Glycogen phosphorylase (rabbit liver)	1,060	236
303	Glycogen phosphorylase (rat)	1,070	237
304	Glycogen synthetase (porcine kidney)	870	238

TABLE 2: Average Hydrophobicities of Selected Proteins (Continued)

Protein	Average Hydrophobicity	Reference	
305	$\gamma$ -Glycoprotein (human plasma)	1,070	239
306	Growth hormone (human)	950	240
307	Haptoglobin, $\alpha_2$ -chain (human plasma)	960	241
308	Haptoglobin, $\alpha_{15}$ -chain (human plasma)	990	241
309	Haptoglobin, $\beta$ -chain (human plasma)	1,020	242
310	Hemagglutinin ( <i>Lens esculenta</i> Muench)	1,000	243
311	Hemagglutinin I ( <i>Pisum sativum</i> L. var. <i>pyram</i> )	990	244
312	Hemagglutinin II ( <i>Pisum sativum</i> L. var. <i>pyram</i> )	930	244
313	Hemagglutinin ( <i>Robina pseudoaccacia</i> )	990	245
314	Hemagglutinin II (snail)	1,070	246
315	Hemagglutinin (soy)	990	247
316	Hemagglutinin ( <i>Ulex europeus</i> )	950	248
317	Hemerythrin ( <i>Golfingia gouldii</i> )	1,170	249
318	Hemocyanin ( <i>Cancer magister</i> )	1,000	250
319	Hemocyanin ( <i>Crustaceae C. sapidus</i> )	980	251
320	Hemocyanin ( <i>Crustaceae E. spinifrons</i> )	980	251
321	Hemocyanin ( <i>Crustaceae H. vulgaris</i> )	980	251
322	Hemocyanin ( <i>Crustaceae P. vulgaris</i> )	980	251
323	Hemocyanin ( <i>Mollusca E. moschata</i> )	1,050	251
324	Hemocyanin ( <i>Mollusca M. brandaris</i> )	1,000	251
325	Hemocyanin ( <i>Mollusca M. tranculus</i> )	1,010	251
326	Hemocyanin ( <i>Mollusca O. macropus</i> )	1,050	251
327	Hemocyanin ( <i>Mollusca O. vulgaris</i> )	1,080	251
328	Hemocyanin ( <i>Xiphosura L. polyphemus</i> )	980	251
329	Hemoglobin ( <i>Ascaris</i> body wall)	980	252
330	Hemoglobin ( <i>Entosphenus japonicus</i> )	1,010	253
331	Hemoglobin ( <i>Glycera dibranchiata</i> )	870	254
332	Hemoglobin, $\alpha$ -chain ( <i>Catostomus clarkii</i> )	1,100	255
333	Hemoglobin, $\alpha$ -chain (human)	960	256
334	Hemoglobin, $\gamma$ -chain (bovine)	960	256
335	Hemoglobin, $\gamma$ -chain (human)	960	256
336	Hemoglobin, F-1 ( <i>Eptatretus burgeri</i> )	1,170	258
337	Hemoglobin, F-2 ( <i>Eptatretus burgeri</i> )	1,160	258
338	Hemoglobin, F-3 ( <i>Eptatretus burgeri</i> )	1,140	258
339	Hemoglobin, F-4 ( <i>Eptatretus burgeri</i> )	1,040	258
340	Hemopexin (human)	1,020	259
341	Hemopexin (rabbit)	1,010	259
342	High potential iron sulfur protein ( <i>Chromatium vinosum</i> D)	880	260
343	High potential iron sulfur protein ( <i>Thiocapsa pfennigii</i> )	930	261
344	Histidine: ammonia lyase ( <i>Pseudomonas</i> ATCC 11299b)	890	262
345	Histidine-binding protein ( <i>Salmonella typhimurium</i> )	970	263
346	Histidine decarboxylase ( <i>Lactobacillus</i> 30a)	980	264
347	L-Histidinol phosphate aminotransferase ( <i>Salmonella typhimurium</i> )	970	265
348	Histidyl-tRNA synthetase ( <i>Salmonella typhimurium</i> )	940	266
349	Histone III (Calf thymus)	990	267
350	Histone III ( <i>Letiobus bubalus</i> )	980	268
351	Histone III (pea)	980	269
352	Histone III (rainbow trout)	950	270
353	Hyaluronidase (bovine testicular)	1,030	271
354	Hydrogenase ( <i>Clostridium pasteurianum</i> W5)	1,160	272
355	3-Hydroxyacyl coenzyme A dehydrogenase (porcine heart muscle)	960	273
356	$\beta$ -Hydroxybutyrate dehydrogenase (bovine heart mitochondria)	930	274
357	$\alpha^1$ -Hydroxysteroid dehydrogenase ( <i>Pseudomonas testosteroni</i> )	900	275
358	17- $\beta$ -Hydroxysteroid dehydrogenase (human placenta)	910	276
359	Immunoglobulin, Eu heavy chain (human plasma)	980	277
360	Immunoglobulin, Eu light chain (human plasma)	860	277
361	Immunoglobulin, New $\lambda$ -chain (human plasma)	870	278
365	Inorganic pyrophosphatase (yeast)	1,130	279
363	Insulin (bovine)	1,020	280

TABLE 2: Average Hydrophobicities of Selected Proteins (Continued)

	Protein	Average Hydrophobicity	Reference
364	Insulin (cod)	1,110	281
365	Invertase ( <i>Saccharomyces</i> FH4C)	990	282
366	Isoamylase I (porcine pancreas)	960	283
367	Isoamylase II (porcine pancreas)	970	283
368	Isocitrate dehydrogenase ( <i>Azotobacter vinelandii</i> ATCC 9104)	980	284
369	Isocitrate dehydrogenase (porcine liver)	990	285
370	Isomerase I (rabbit)	1,080	286
371	Isomerase II (rabbit)	1,100	286
372	Keratinase ( <i>Trichophyton mentagrophytes</i> )	880	287
373	$\Delta^5$ -3-Ketosteroid isomerase ( <i>Pseudomonas testosteronii</i> )	910	288
374	$\alpha$ -Lactalbumin (bovine milk)	1,050	289
375	Lactoferrin (bovine)	920	290
376	$\beta$ -Lactoglobulin (caprid)	1,040	291
377	$\beta$ -Lactoglobulin A (bovine)	1,070	291
378	$\beta$ -Lactoglobulin A (ovine)	1,050	291
379	$\beta$ -Lactoglobulin A (bovine)	1,060	291
380	$\beta$ -Lactoglobulin A (ovine)	1,050	291
381	$\beta$ -Lactoglobulin C (bovine)	1,070	292
382	Lactoperoxidase (bovine milk)	1,080	292
383	Lectin, $\alpha$ -D-galactosyl-binding ( <i>Bandeiraea simplicifolia</i> )	980	293
384	Leghemoglobin I (soybean root nodule)	1,010	294
385	Leghemoglobin II (soybean root nodule)	1,010	294
386	Leucine aminopeptidase (bovine lens)	1,010	295
387	Lipase (rat pancreas)	980	61
388	$\beta$ -Lipolytic hormone (porcine pituitary)	950	296
389	$\gamma$ -Lipolytic hormone (sheep)	780	297
390	$\alpha$ -Lipovitellin (chicken egg yolk)	980	298
391	Luciferase ( <i>Renilla reniformis</i> )	940	299
392	Luciferase- $\alpha$ (MAV)	880	300
393	Luciferase- $\beta$ (MAV)	960	300
394	Luciferase- $\alpha$ ( <i>Photobacterium fischeri</i> )	960	300
395	Luciferase- $\beta$ ( <i>Photobacterium fischeri</i> )	990	300
396	Luteinizing hormone- $\alpha$ chain (equine)	1,070	301
397	Luteinizing hormone- $\beta$ chain (equine)	1,120	301
398	Lysine decarboxylase ( <i>Escherichia coli</i> )	1,080	302
399	L-Lysine monooxygenase ( <i>Pseudomonas fluorescens</i> )	1,040	303
400	Lysostaphin ( <i>Staphylococcus aureus</i> )	950	304
401	Lysozyme ( <i>Chalaropsis</i> )	960	305
402	Lysozyme, chick type (black swan)	970	306
403	Lysozyme, goose type (black swan)	930	306
404	Lysozyme (chicken)	890	307
405	Lysozyme (papaya)	1,080	308
406	Lysozyme (turkey)	910	309
407	Lysyl: tRNA ligase ( <i>Escherichia coli</i> )	990	310
408	Lysyl: tRNA ligase (yeast)	1,040	310
409	$\alpha$ -Lytic protease ( <i>Sorangium</i> sp.)	780	311
410	$\beta$ -Lytic protease ( <i>Sorangium</i> sp.)	820	311
411	Melate dehydrogenase ( <i>Bacillus subtilis</i> )	970	312
412	Malate-lactate transhydrogenase ( <i>Micrococcus lactilyticus</i> )	960	313
413	Malate-vitamin K reductase ( <i>Mycobacterium phlei</i> )	890	314
414	L-Malic enzyme ( <i>Escherichia coli</i> )	1,020	315
415	$\beta$ -Melanocyte stimulating hormone (bovine)	1,180	316
416	Melilotate hydroxylase ( <i>Pseudomonas</i> sp.)	970	317
417	Methionyl-tRNA synthetase ( <i>Escherichia coli</i> )	1,040	318
418	$\beta$ -Methyl aspartase ( <i>Clostridium tetanomorphum</i> )	980	319
419	$\beta$ -Methylcrotonylcoenzyme A carboxylase ( <i>Achromobacter</i> )	890	320
420	Methylmalonatesemialdehydedehydrogenase ( <i>Pseudomonas aeruginosa</i> )	1,030	321
421	Molybdenum-iron protein (soybean root nodule bacteroid)	1,010	322
422	Monellin ( <i>Dioscoreophyllum cumminsii</i> )	1,140	323

TABLE 2: Average Hydrophobicities of Selected Proteins (Continued)

Protein	Average Hydrophobicity	Reference	
423	Motilin (porcine intestinal mucosa)	1,020	324
424	cis,cis-Muconate lactonizing enzyme ( <i>Pseudomonas putida</i> )	990	325
425	Muconolactone isomerase ( <i>Pseudomonas putida</i> )	1,070	325
426	Mutarotase (bovine kidney cortex)	850	326
427	Myoglobin (human)	1,000	327
428	Myoglobin (whale)	1,040	328
429	Myoglobin ( <i>Zalophus californianus</i> )	1,030	329
430	Myohemery thrin ( <i>Dendrostamum pyroides</i> )	1,090	330
431	Myosin (bovine heart)	880	331
432	Myosin (cod)	860	332
433	myosin (rabbit)	890	333
434	myosin (tuna)	880	333
435	Neocarzinostatin ( <i>Streptomyces carzinostaticus</i> F-41)	750	334
436	Neurophysin I (bovine pituitary)	850	335
437	Neurophysin II (bovine pituitary)	830	335
438	Neurophysin III (bovine pituitary)	820	336
439	Neurotoxin I ( <i>Androctonus australis</i> )	1,070	337
440	Neurotoxin II ( <i>Androctonus australis</i> )	990	337
441	Neurotoxin III ( <i>Androctonus australis</i> )	1,120	337
442	Neurotoxin I ( <i>Leiurus quinquestriatus quinquestriatus</i> )	1,040	337
443	Neurotoxin II ( <i>Leiurus quinquestriatus quinquestriatus</i> )	970	337
444	Neurotoxin III ( <i>Leiurus quinquestriatus quinquestriatus</i> )	1,030	337
445	Neurotoxin IV ( <i>Leiurus quinquestriatus quinquestriatus</i> )	1,050	337
446	Neurotoxin V ( <i>Leiurus quinquestriatus quinquestriatus</i> )	1,020	337
447	Nuclease ( <i>Micrococcus sodonecis</i> ATCC 11880)	880	338
448	Nuclease ( <i>Staphylococcus</i> )	980	339
449	Nucleoside diphosphokinase (Brewer's yeast)	1,030	340
450	Nucleoside phosphotransferase-A-chain (carrot)	920	341
451	Nucleoside phosphotransferase-B-chain (carrot)	860	341
452	5'-Nucleotidase ( <i>Escherichia coli</i> )	930	342
453	Ornithine transcarbamylase (bovine liver)	1,040	343
454	Ornithine transcarbamylase ( <i>Streptococcus faecalis</i> )	990	343
455	Ovalbumin (chicken egg)	980	145
456	Ovomacroglobulin (chicken egg)	1,040	344
457	Ovomucin (chicken egg)	990	345
458	Ovomucoid (chicken egg)	830	145
459	Ovotransferrin (chicken egg)	960	346
460	2-Oxoglutarate dehydrogenase (porcine heart)	1,010	347
461	Oxytocin (mammalian)	1,290	348
462	Papain (papaya)	1,030	349
463	Parathyroid hormone (bovine)	900	350
464	Parvalbumin (rabbit skeletal muscle)	920	351
465	Penicillocarboxypeptidase-S ( <i>Penicillium janthinellum</i> )	980	352
466	Pepsin (bovine)	940	353
467	Pepsin (human)	930	218
468	Pepsin I ( <i>Rhizopus chinensis</i> )	910	354
469	Pepsin II ( <i>Rhizopus chinensis</i> )	910	354
470	Pepsin A (bovine)	960	355
471	Pepsinogen A ( <i>Mustelus canis</i> )	920	356
472	Pepsinogen A (porcine)	970	357
473	Pepsinogen C (porcine)	1,020	358
474	Phenylalanine ammonia lyase ( <i>Solanum tuberosum</i> )	1,030	359
475	Phenylalanine ammonia lyase ( <i>Zea mays</i> L.)	940	359
476	Phenylalanine hydroxylase (rat liver)	930	360
477	Phosphatidyl serine decarboxylase ( <i>Escherichia coli</i> )	1,050	361
478	Phosphoenol pyruvate carboxykinase (yeast)	1,030	362
479	Phosphofructokinase (chicken liver)	940	363
480	Phosphoglucomutase (rabbit muscle)	1,020	364
481	Phosphoglucose isomerase (human)	1,020	365

TABLE 2: Average Hydrophobicities of Selected Proteins (Continued)

	Protein	Average Hydrophobicity	Reference
482	Phosphoglucose isomerase (rabbit muscle)	1,010	366
483	Phosphoglycerate kinase (human erythrocyte)	980	367
484	Phospholipase A ( <i>Bitis gabonica</i> venom)	910	368
485	Phospholipase A <sub>1</sub> ( <i>Crotalus adamanteus</i> )	1,030	369
486	Phospholipase A <sub>2</sub> ( <i>Crotalus atrox</i> )	920	370
487	Phospholipase A ( <i>Laticuda semifasciata</i> )	950	371
488	Phosphorylase (frog skeletal muscle)	1,070	372
489	Phycocyanin ( <i>P. calothricoides</i> )	910	93
490	Phycocyanin ( <i>S. lividicus</i> )	1,040	93
491	Phycoerythrin ( <i>P. tenera</i> )	830	373
492	Phytochrome (oat)	1,010	374
493	Plastocyanin (parsley)	880	375
494	Prealbumin (human serum)	990	376
495	Prealbumin, Pt 1-1 (monkey)	990	377
496	Prealbumin, Pt 2-2 (monkey)	1,010	377
497	Procarboxypeptidase A (bovine)	1,010	378
498	Procarboxypeptidase A ( <i>Squalus acanthias</i> )	1,010	379
499	Progesterone-binding protein (guinea pig plasma)	1,040	380
500	Prohistidine decarboxylase ( <i>Lactobacillus</i> 30a)	990	381
501	Prolactin (ovine pituitary)	950	382
502	Protease ( <i>Bacillus thermoprotolyticus</i> )	940	383
503	Protease ( <i>Mucor miehei</i> CBS 370.65)	940	384
504	Protease ( <i>Staphylococcus aureus</i> V8)	900	385
505	Protease – A <sub>1</sub> ( <i>Streptomyces griseus</i> )	700	386
506	Protease-acid ( <i>Rhizopus chinensis</i> )	950	387
507	Protein kinase modulator (lobster tail muscle)	720	388
508	Prothrombin (bovine)	960	389
509	Protyrosinase ( <i>Rana pipiens pipiens</i> )	1,100	390
510	Putidaredoxin ( <i>Pseudomonas putida</i> )	910	391
511	Putrescine oxidase ( <i>Micrococcus rubens</i> )	860	392
512	Pyruvate kinase (bovine skeletal muscle)	1,010	393
513	Quinonoid dihydropterin reductase (sheep liver)	890	394
514	Retinol-binding protein (human)	960	395
515	Retinol-binding protein (monkey)	960	396
516	Rhodopsin (bovine)	1,120	397
517	Riboflavin-binding protein (chicken)	910	398
518	Ribonuclease ( <i>Aspergillus fumigatus</i> )	830	399
519	Ribonuclease ( <i>Bacillus subtilis</i> )	1,000	400
520	Ribonuclease (bovine pancreas)	780	401
521	Rubonuclease (ovine pancreas)	750	402
522	Ribonuclease Ch. ( <i>Chalaropsis</i> sp.)	940	403
523	Ribonuclease N ( <i>Neurospora crassa</i> )	890	404
524	Ribonuclease R <sub>1</sub> ( <i>Rhizopus oligosporus</i> )	970	405
525	Ribonuclease R <sub>2</sub> ( <i>Rhizopus oligosporus</i> )	960	405
526	Ribonuclease T <sub>1</sub> ( <i>Aspergillus oryzae</i> )	740	406
527	Ribonuclease U <sub>1</sub> ( <i>Ustilago sphaerogena</i> )	760	407
528	Ribonucleotide reductase ( <i>Lactobacillus leichmanii</i> )	960	408
529	Ribulose diphosphate carboxylase ( <i>Hydrogenomonas eutropha</i> )	980	409
530	Ribulose diphosphate carboxylase ( <i>Hydrogenomonas facilis</i> )	980	409
531	Ribulose diphosphate carboxylase ( <i>Rhodospirillum rubrum</i> )	940	410
532	Rubredoxin ( <i>Clostridium pasteurianum</i> )	990	411
533	Rubredoxin ( <i>Micrococcus aerogenes</i> )	1,120	412
534	Rubredoxin ( <i>Pseudomonas oleovorans</i> )	960	413
535	D-Serine dehydratase ( <i>Escherichia coli</i> )	920	414
536	Streptokinase (human plasma)	980	415
537	Subtilisin BPN ( <i>Bacillus subtilis</i> )	810	416
538	Succinyl coenzyme A synthetase ( <i>Escherichia coli</i> )	970	417
539	Sucrose synthetase ( <i>Phaseolus aureus</i> )	1,040	418
540	Superoxide dismutase ( <i>Neurospora crassa</i> )	760	419

TABLE 2: Average Hydrophobicities of Selected Proteins (Continued)

	Protein	Average Hydrophobicity	Reference
541	Thermolysin ( <i>Bacillus thermoproteolyticus</i> )	890	420
542	Thioredoxin (T-4 bacteriophage)	1,150	421
543	Thioredoxin II (yeast)	960	422
544	Thrombin (bovine)	1,040	423
545	Thymidylate synthetase (T-2 bacteriophage)	1,140	424
546	Thyroglobulin (calf)	950	425
547	Thyroglobulin (human)	950	425
548	Thyroglobulin (porcine)	950	425
549	Thyroglobulin (rabbit)	920	425
550	Thyroglobulin (sheep)	950	425
551	Thyroid stimulating hormone – $\alpha$ -chain (human)	1,010	426
552	Thyroid stimulating hormone – $\beta$ -chain (human)	1,170	426
553	Toxin FVII ( <i>Dendroaspis angusticeps</i> )	890	427
554	Toxin $\alpha$ ( <i>Dendroaspis polylepsis</i> )	940	428
555	Toxin $\gamma$ ( <i>Dendroaspis polylepsis</i> )	1,000	428
556	Toxin 4 ( <i>Enhydryna schistosa</i> )	760	429
557	Toxin 5 ( <i>Enhydryna schistosa</i> )	710	429
558	Toxin ( <i>Laticauda colubrina</i> )	790	430
559	Toxin ( <i>Laticauda laticauda</i> )	790	430
560	Toxin a ( <i>Laticauda semifasciata</i> )	880	431
561	Toxin b ( <i>Laticauda semifasciata</i> )	930	431
562	Toxin ( <i>Naja haje haje</i> )	830	432
563	Toxin b ( <i>Naja melanoleuca</i> )	1,090	433
564	Toxin d ( <i>Naja melanoleuca</i> )	830	433
565	Toxin ( <i>Naja naja atra</i> )	680	434
566	Toxin ( <i>Naja nigricollis</i> )	930	435
567	$\alpha$ -Toxin A ( <i>Staphylococcus aureus</i> Woods 46)	890	436
568	$\alpha$ -Toxin B ( <i>Staphylococcus aureus</i> Woods 46)	890	436
569	Transaminase B ( <i>Salmonella typhimurium</i> )	980	437
570	Transcortin (guinea pig)	960	438
571	Transcortin (human)	970	438
572	Transcortin (rabbit)	960	440
573	Transcortin (rat)	1,030	440
574	Transferrin (bovine)	930	441
575	Transferrin (equine)	970	441
576	Transferrin (human)	930	442
577	Transferrin (porcine serum)	970	441
578	Transferrin (rabbit serum)	970	441
579	Triose phosphate dehydrogenase ( <i>Bombus nevadensis</i> )	1,040	443
580	Triose phosphate dehydrogenase (honey bee)	1,020	443
581	Triose phosphate dehydrogenase (lobster)	980	443
582	Triose phosphate dehydrogenase (porcine)	990	443
583	Triose phosphate isomerase-I (human erythrocyte)	920	444
584	Triose phosphate isomerase-III (human erythrocyte)	940	444
585	Triose phosphate isomerase (rabbit muscle)	930	445
586	Triose phosphate isomerase (yeast)	970	446
587	Troponin-C (rabbit muscle)	780	447
588	Troponin-T (rabbit muscle)	1,040	447
589	Trypsin ( <i>Evasterias trochelli</i> )	1,000	448
590	Trypsin (lungfish)	920	449
591	Trypsin (human)	870	450
592	Trypsin, anionic (human)	930	451
593	Trypsin (porcine)	970	452
594	Trypsin (sheep)	850	453
595	Trypsin (shrimp)	840	454
596	Trypsin ( <i>Streptomyces griseus</i> )	820	455
597	Trypsin inhibitor ( <i>Ascaris lumbricoides suis</i> )	970	456
598	Trypsin inhibitor (bovine pancreas)	1,150	457
599	Trypsin inhibitor (porcine pancreas)	900	458

TABLE 2: Average Hydrophobicities of Selected Proteins (Continued)

	Protein	Average Hydrophobicity	Reference
600	Trypsin inhibitor (bovine pancreas)	1,070	459
601	Trypsin inhibitor I ( <i>Phaseolus vulgaris</i> )	800	460
602	Trypsin inhibitor II ( <i>Phaseolus vulgaris</i> )	780	460
603	Trypsinogen (bovine)	910	461
604	Trypsinogen (dogfish)	950	462
605	Trypsinogen (lungfish)	930	449
606	Trypsinogen, anionic (porcine)	980	463
607	Trypsinogen (sheep)	900	464
608	Tryptophan synthetase A ( <i>Escherichia coli</i> )	1,060	465
609	Tryptophan synthetase – $\alpha$ -chain ( <i>Aerobacter aerogenes</i> )	1,060	466
610	Tryptophan synthetase – $\alpha$ -chain ( <i>Bacillus subtilis</i> )	1,020	467
611	Tryptophan synthetase – $\alpha$ -chain ( <i>Salmonella typhimurium</i> )	980	466
612	Tryptophan synthetase – $\beta$ -chain ( <i>Bacillus subtilis</i> )	940	468
613	Tryptophanase ( <i>Bacillus alvei</i> )	980	469
614	Tryptophanase ( <i>Escherichia coli</i> B/1t7-A)	1,030	470
615	Tyrosyl-tRNA synthetase ( <i>Bacillus stearo thermophilus</i> )	1,060	471
616	Urease (jackbean meal)	990	472
617	Urokinase S-1 (human urine)	1,030	473
618	Urokinase S-2 (human urine)	990	473
619	Valine:tRNA ligase (yeast)	1,080	310
620	Vasopressin, lysine (mammalian)	1,210	474

## CHEMICAL SPECIFICITY OF REAGENTS FOR PROTEIN MODIFICATION<sup>a</sup>

Amino Acid	Reagent	Other Residues Modified
$\alpha$ -amino groups ( <i>N</i> -terminal amino acids) <sup>b</sup>	Glyoxal	Slower reaction at lysine
$\alpha$ -amino groups ( <i>N</i> -terminal amino acids)	Cyanate	Slower reaction at lysine
Arginine	Diones and glyoxals including 2,3-butanedione and phenylglyoxal; products usually not stable in the absence of borate buffers	Possible reaction with lysine
Asparagine	Mild acid with deamidation and potential cyclization with formation of $\beta$ -aspartic acid	Glutamine, minor oxidation at cysteine, cystine; possible peptide bond cleavage which is sequence-dependent
Aspartic Acid	Carbodiimides	Minor reaction at hydroxyl functions; modification of C-terminal carboxyl group
Aspartic Acid	Woodward's reagent K	Minor reaction at hydroxyl functions; modification of C-terminal carboxyl group
Cysteine	Haloalkyl reagents such as bromoacetamide, bromoethylamine	Histidine, amino groups, carboxyl groups. Unless residue at active site, reaction is very slow compared to cysteine. Reaction does occur with thiourea
Cysteine	Alkylmethanesulfonates (modification reversible)	No other reactions demonstrated
Cysteine	Cyanylation (cleavage can be achieved after cyanylation)	Lysine although specificity can be obtained with reagents other than cyanate such as 1-cyano-4-dimethylamino-pyridinium tetrafluoroborate
Cysteine	Maleimides such as <i>N</i> -ethylmaleimide	No other reactions demonstrated
Cysteine	Sodium tetrathionate (reversible)	No other reactions demonstrated
Cystine	Reducing agents such mercaptoethanol, dithiothreitol, phosphines	No other reactions demonstrated
Cystine	Performic acid oxidation for cleavage to cysteic acid	Methionine, histidine, tyrosine, tryptophan
Cystine	Sodium sulfite (oxidative sulfitolysis)	Cysteine
Glutamine	Mild acid	Deamidation; rate slower than asparagine
Glutamic Acid	Carbodiimides	Possible reaction at hydroxyl groups; modification of C-terminal
Histidine	Diethylpyrocarbonate	Tyrosine, possible amino groups
Histidine	Haloalkyl reactions such as iodoacetic acid	Cysteine will predominate unless histidine is active site residue
Histidine	Photooxidation	Cysteine, methionine, tyrosine, tryptophan
Lysine	Methyl acetamidate; methyl picolinimidate	Amino-terminal
Lysine	Cyanate	Cysteine, amino-terminal
Lysine	Trinitrobenzene sulfonic acid	Cysteine
Lysine	<i>N</i> -Hydroxysuccinimide	Amino-terminal
Lysine	Reducing sugars, glyoxal, methyl glyoxal, aldehyde	Arginine, histidine
Methionine	Oxidation with performic acid	Cysteine, cystine, histidine, tryptophan, tyrosine
Methionine	Alkylation with $\alpha$ -haloketoalkyl acids/amide such as iodoacetate at pH 3.0	No other reactions demonstrated
Methionine	Cyanogen bromide with peptide bond cleavage. The <i>S</i> -methyl group is lost in the reaction as methyl thiocyanate	Oxidation at cysteine possible
Tryptophan	<i>N</i> -Bromosuccinimide	Cysteine, methionine
Tryptophan	BPNS-skatole	Possible
Tryptophan	2-Hydroxy-5-nitrobenzyl bromide	Cysteine possible
Tryptophan	<i>N</i> -Bromosuccinimide	Cysteine and cystine possible
Tryptophan	Nitrophenyl sulfonyl chlorides	Cysteine and cystine possible
Tyrosine	<i>N</i> -Acetylimidazole; reversible at alkaline pH or in the presence of hydroxylamine	Lysine, amino groups which not reversible
Tyrosine	Tetranitromethane (converted by amine by reduction)	Sulfhydryl, also cross-linking at tyrosine residues

<sup>a</sup> Specificity of reaction is rarely absolute

<sup>b</sup> The pK<sub>a</sub> of amino-terminal amino groups is lower than that of most lysine residues and specificity of modification can be enhanced by performing modification reactions pH below 7.

## REAGENTS FOR THE CHEMICAL MODIFICATION OF PROTEINS

Chemical structures for these reagents may be found on p. 126.

	Reagent	Specificity/Conditions <sup>a</sup>	M.W.	References
1	Acetic anhydride	Lysine, $\alpha$ -amino groups, tyrosine hydroxyl; preferred reaction is at lysine; pH 8 or greater; reaction can be "driven" $\alpha$ -amino groups at pH less than 6.5. Avoid nucleophilic buffers such as Tris; hydrolysis of the reagent is an issue above pH 9.5. Acetic anhydride has been used for trace labeling in the study of protein conformation and more recently the deuterated derivative has been used in proteomics for differential isotope tagging	102.1	1-5
2	<i>N</i> -Acetylimidazole (1-acetylimidazole)	Tyrosine hydroxyl groups, lysine $\epsilon$ -amino groups, transient reaction at histidine; neutral pH	110.1	6-10
3	BNPS-skatole [3-bromo-3-methyl-2-(2-nitrophenylmercapto)-3 <i>H</i> -indole; 2-(2'-nitrophenylsulfenyl)-3-methyl-3-bromindolenine	Tryptophan; 50-70% acetic acid; associated with peptide bond cleavage	363.3	11-15
4	Bromoacetamide (2-bromoacetamide)	Cysteine; reaction with active site histidine residues; also reaction with lysine, methionine and possibly carboxylic acids. Reaction at pH 5-9 but reaction with methionine at pH 3.0. Reaction rate below pH 7.5 is usually slow as the modification of cysteine requires thiolate anion (pK <sub>a</sub> <sup>2</sup> for cysteine is 8.7. Reaction is slower than iodoacetamide. A neutral reagent <sup>b</sup>	138	16-20
5	Bromoacetic acid (2-bromoacetic acid)	Reaction parameters similar to bromoacetamide except bromoacetic acid is a charged reagent at pH greater than 4 (pK <sub>a</sub> is 2.7 at 25°C). Amide and acid derivatives can show different reaction patterns <sup>c</sup>	139	21-25
6	Bromoethylamine	Modification of sulfhydryl groups; conversion of cysteine to lysine analogue ( <i>S</i> -2-aminoethylcysteine); reaction with cysteine at alkaline pH (see bromoacetamide). Reaction is reasonably specific for cysteine with possible modification at the amino-terminal $\alpha$ -amino group and histidine	204.9 as HBr salt	26-30
7	<i>N</i> -Bromosuccinimide	Modification of tryptophan with some oxidative side reactions; pH 4-6	178	31-35
8	2,3-Butanedione (diacetyl)	Modification of arginine residues; reversible reaction with the product stabilized by the presence of borate; reaction at alkaline pH	86.1	36-40
9	Citraconic anhydride	Reversible modification of lysine residues; modification at pH above 8.0 and reversed below pH 6.0	112.1	41-45
10	Cyanate <sup>d</sup>	Carbamylation of $\alpha$ -amino groups in proteins at alkaline pH with some preference toward the modification of <i>N</i> -terminal $\alpha$ -amino groups. Reaction also occurs at cysteine residues using 2-nitro-5-thiocyanatobenzoic acid <sup>d</sup>	N/A	46-50
11	1,2-Cyclohexanedione	Modification of arginine in the presence of borate. At pH 7-9, the reaction is reversible; above pH 9, the reaction is irreversible with the formation of several products	112.1	51-55
12	DCC (1,3-dicyclohexylcarbodiimide)	Modification of carboxyl groups in proteins (activated carboxyl group which is then modified with a nucleophile such as glycine methyl ester; solubility issues have made EDC a more attractive reagent); also used for synthesis of phosphate ester bonds and peptide bonds; pH less than 5, modification requires protonated carboxyl group. The reagent has been used at more alkaline pH values. The modification of tyrosine and cysteine has been reported. DCC is an inhibitor of the proton-translocating ATPase in mitochondria and has been extensively used to characterize that activity	206.3	56-60
14	Diethylpyrocarbonate	Modification of histidine residues in proteins with transient modification of tyrosine; possible reaction at amino groups. Disubstitution of histidine results in ring-opening	162.1	61-65

## REAGENTS FOR THE CHEMICAL MODIFICATION OF PROTEINS (Continued)

	Reagent	Specificity/Conditions <sup>a</sup>	M.W.	References
15	EDC [1-ethyl-3-(3-dimethylaminopropyl)-carbodiimide]; <i>N</i> -(3-dimethylaminopropyl)- <i>N'</i> -ethylcarbodiimide	Modification of carboxyl groups in proteins frequently with <i>N</i> -hydroxysuccinimide. Used for zero-length cross-linking in proteins and for the coupling of proteins to matrices and for the preparation of protein conjugates	155.2	66-70
16	Ellman's reagent (5,5'-dithiobisnitrobenzoic acid)	Modification and measurement of cysteine (sulfhydryl) groups in proteins	396.4	71-75
17	<i>N</i> -Ethylmaleimide	Modification of sulfhydryl groups via Michael addition to the maleimide ring. There are some proteins which are distinguished by their modification with <i>N</i> -ethylmaleimide including <i>N</i> -ethylmaleimide-sensitive fusion protein (NSF) and soluble <i>N</i> -ethylmaleimide-sensitive factor attachment protein receptors (SNARES)	125.1	76-80
18	Ethyleneimine (aziridine)	Early as modification reagent for cysteine but largely supplanted by bromoethylamine. Aziridine (ethyleneimine) serves a functional base for reagents used for the modification of cysteine in proteins	43.1	81-85
19	Formaldehyde <sup>e,f</sup> (reductive methylation)	Formation of a Schiff base with a primary amine (e.g., $\epsilon$ -amino group of lysine) which is reduced with sodium borohydride or more often with sodium cyanoborohydride which results in the formation, the in the case of lysine, of $\epsilon$ -methyllysine and $\epsilon$ -dimethyllysine. The modification is performed at alkaline pH; in a related reaction, the formylation of tryptophan occurs with formic acid under acidic conditions (HCOOH/HCl) which is reduced by base <sup>g</sup>	30.0	86-90
20	Gold	Reaction with cysteine. This process is used to bind proteins to solid matrices. The reaction of gold with proteins provides some of the basis for the use of gold and gold compounds in the treatment of arthritis	N/A	91-95
21	2-Hydroxy-5-nitrobenzyl bromide (Koshland's reagent)	Modification of tryptophan by alkylation of the indole ring. Reaction at acid pH (pH 2-6). Disubstitution can occur. This was one of the first "reporter groups" <sup>h</sup>	232.0	96-100
22	<i>N</i> -Hydroxysuccinimide	Functional group for modification of amino groups in proteins, frequently with carbodiimide for carboxyl modification and coupling in proteins	115.1	101-105
23	2-Iminothiolane (Traut's reagent)	Placement of a sulfhydryl groups by the modification of amino groups in proteins and other amino-containing materials	137.6 as the HCl	105-110
24	Iodoacetamide	Reaction is faster than with bromo or chloro derivatives. Reaction characteristics similar to bromoacetamide; as bromoacetamide, iodoacetamide is neutral	185	111-115
25	Iodoacetic acid	See bromoacetic acid for reaction conditions. As with bromoacetic acid, reagent is charged at pH greater than 5 (pKa is 3.12 at 25°C)	186	116-120
26	2-Mercaptoethanol ( $\beta$ -mercaptoethanol; 2-thioethanol)	Used to maintain proteins in reduced states, previously used for the reduction of disulfide bonds but largely replaced by TCEP (see below)	78.1	121-125
27	Mercuric chloride (HgCl <sub>2</sub> )	Reaction with organic sulfhydryl groups such as cysteine. The chemistry of this reaction is poorly understood <sup>i</sup> . Mercuric chloride is used for the inhibition of membrane enzymes and is described as a specific inhibitor of aquaporin <sup>j</sup>	271.5	126-130
28	Methyl acetimidate	Modification of amino groups. Imido esters are the functional groups for a number of cross-linking agents such as dimethylsuberimidate <sup>k</sup> . One of the more interesting imido esters is methyl picolinimidate <sup>l</sup> . Reaction at pH 8-10	109.6 as HCl	131-135
29	Methyl methane-thiosulfonate	Methyl methanethiosulfonate is one of a group of alkyl methanethiosulfonate derivatives which reversibly modify cysteine residues in proteins <sup>m</sup> . Reaction occurs at slightly alkaline pH (pH 7.8)	126.2	136-140
30	Ninhydrin (1 <i>H</i> -indene-1,2,3-trione monohydrate; 2,2-dihydroxy-1,3-indanedione)	Determination of amino groups; provides the basis for detection in amino acid analysis; modification of arginine residues <sup>n</sup> . Ninhydrin is also used for the detection of cyanide	178.1	141-145

## REAGENTS FOR THE CHEMICAL MODIFICATION OF PROTEINS (Continued)

	Reagent	Specificity/Conditions <sup>a</sup>	M.W.	References
31	2-Nitrophenylsulfenyl chloride ( <i>o</i> -nitrophenylsulfenyl chloride)	Modification of tryptophan residues in proteins; reaction occurs at acid pH; modified tryptophan can be converted to the 2-thioltryptophan derivatives. This modification has been used to purify tryptophan peptides from protein hydrolyzates. An analogue, 2-(trifluoromethyl)benzenesulfenyl chloride has been developed for use in mass spectrometry <sup>o</sup>	189.6	146-150
32	Performic acid (peroxyformic acid)	Cleavage of disulfide bonds; oxidation of cysteine and methionine in proteins with side reactions at tryptophan with other minor modifications <sup>p</sup>	62	151-155
33	Phenylglyoxal	Modification of arginine residues in proteins; reaction accelerated in the presence of bicarbonate buffers; reaction at alkaline pH. <i>p</i> -Hydroxyphenylglyoxal and <i>p</i> -nitrophenylglyoxal are useful derivatives <sup>q</sup>	134.1 as hydrate	156-160
34	Sodium cyanoborohydride	Reducing agent for Schiff bases in proteins; reduces ketones, aldehydes, hydrazones, and enamines but does not reduce lactones, amides, or disulfide bonds. Used to "stabilize" Schiff base linkages between amine "probes" and aldehyde-based matrices	62.8	161-165
35	Sodium sulfite	Oxidative sulfitolysis to cleave disulfide bonds; conversion of cysteine to <i>S</i> -sulfocysteine	126	166-170
36	Sodium tetrathionate (Na <sub>2</sub> S <sub>4</sub> O <sub>6</sub> )	Modification of cysteine to <i>S</i> -sulfoderivatives; a reversible modification. Also a mild oxidizing agent which can, via the <i>S</i> -sulfoderivative, drive the formation of disulfide bonds thus serving a protein cross-linking reagent <sup>r</sup>	306.3	171-175
37	TCEP (tris[2-(carboxyethyl)] phosphine)	Reduction of disulfide bonds in proteins; reagent of choice. The reagent is readily soluble in water and reduces disulfide bonds at low pH (3.0)	286.7 at HCl	176-180
38	Tetranitromethane (TNM)	Nitration of tyrosine residues in proteins with nitration and possible cross-linking; also reacts with sulfhydryl groups; possible reaction with indole ring of tryptophan. Reaction at alkaline pH; does introduce a "reporter group" in proteins. The nitrotyrosine function can be reduced to aminotyrosine with sodium dithionite (sodium hydrosulfite). The modification with peroxytrinitrite is a similar reaction <sup>s</sup>	196	181-185
39	TNBS (trinitrobenzenesulfonic acid)	Modification of amino groups in proteins; used for the determination of amino groups. Reaction at alkaline pH; also reacts with sulfhydryl groups	293.2	186-190
40	Vinyl pyridine	Modification of sulfhydryl groups with majority of use in protein structure analysis; both the 2-vinylpyridine and the 4-vinylpyridine are used	105.1	191-195
41	Woodward's reagent K ( <i>N</i> -ethyl-5-phenylisoxazolium-3-sulfonate)	Reagent used for the modification of carboxyl groups in proteins. Reaction at acidic pH	253.3	196-200

<sup>a</sup> Absolute specificity of modification cannot be guaranteed. Conditions are most common with the caveat that specific buffer effects are observed (see Buffers)

<sup>b</sup> Chaiken, I.M. and Smith, E.L., Reaction of chloroacetamide with the sulfhydryl group of papain, *J.Biol.Chem.* 244, 5087-5094, 1969; Chaiken, I.M. and Smith, E.L., Reaction of the sulfhydryl group of papain with chloroacetic acid, *J.Biol.Chem.* 244, 5095-5099, 1969

<sup>c</sup> Gerwin, B.I., Properties of the single sulfhydryl group of streptococcal proteinase. A comparison of the rates of alkylation by chloroacetic acid and chloroacetamide, *J.Biol.Chem.* 242, 451-456, 1967

<sup>d</sup> Early concern regarding the reaction of cyanate with protein was directed at urea. This was followed with work using potassium cyanate. More recent work has used 2-nitro-5-thiocyanatobenzoic acid for the modification of cysteine residues in proteins (Degani, Y. and Patchornik, A., Cyanylation of sulfhydryl groups by 2-nitro-5-thiocyanatobenzoic acid. High-yield modification and cleavage of peptides at cysteine residues, *Biochemistry* 13, 1-11, 1974; Price, N.C., Alternative products in the reaction of 2-nitro-5-thiocyanatobenzoic acid with thiol groups, *Biochem.J.* 159, 177-180, 1976; Wu, J. and Watson, J.T., Optimization of the cleavage reaction for cyanylated cysteinyl proteins for efficient and simplified mass mapping, *Anal.Biochem.* 258, 268-276, 1998)

<sup>e</sup> Other aldehydes such 4-hydroxy-2-nonenal, glyceraldehydes, reducing sugars such as glucose, also react in a similar manner. The reaction with reducing sugars and 4-hydroxy-2-nonenal is more complex; the reaction with glucose and reducing sugars is part of the Maillard reaction.

<sup>f</sup> Formaldehyde (paraformaldehyde) is used for tissue fixation and the chemistry is complex with the formation of protein cross-links. Antigen retrieval techniques have been developed for immunohistochemistry (Chu, W.S., Furusato, B., Wong, K., et al., Ultrasound-accelerated formalin fixation of tissue improves morphology, antigen and mRNA preservation, *Mod.Pathol.* 18, 850-863, 2005; Namimatsu, S., Ghazizadeh, M., and Sugisaki, Y., Reversing the effects of formalin fixation with citraconic anhydride and heat: a universal antigen retrieval method, *J.Histochem.Cytochem.* 53, 3-11, 2005; Shi, S.R., Liu, C., Balgley, B.M., et al., Protein extraction from formalin-fixed, paraffin-embedded tissue sections: quality evaluation by mass spectrometry, *J.Histochem.Cytochem.* 54, 739-743, 2006; Sompuram, S.R., Vani, K., Hafer, L.J., and Bogen, S.A., Antibodies immunoreactive with formalin-fixed tissue antigens recognize linear protein epitopes, *Am.J.Clin.Pathol.* 125, 82-90, 2006; Yamashita, S., Heat-induced antigen retrieval: mechanisms and application to histochemistry, *Prog.Histochem.Cytochem.* 41, 141-200, 2007)

## REAGENTS FOR THE CHEMICAL MODIFICATION OF PROTEINS (Continued)

- <sup>1</sup> Mercuric sulfide is the principle ore of mercury and exists in two forms;  $\alpha$ HgS (red hexagonal) which is known as cinnabar and  $\beta$ HgS (black amorphous) which is known as metacinnabar. The solubility product of mercuric sulfide is approximately  $10^{-52}$ . Mercury salts can exist as mercurous [mercury(I)] and mercuric [mercury(II)]. Mercurous exists as a polyanion  $\text{Hg}_2^{2+}$  which can under disproportionation to form Hg and  $\text{Hg}^{2+}$ . Mercuric ion can form tight complexes with free sulfhydryl group and disulfide bonds. The chemistry and structure of these derivatives are still poorly understood. The possibility of a Hg crosslink between sulfhydryl groups is a possibility. The term mercaptan is derived from the phrase "mercury capture." See *The Chemistry of Mercury*, ed. C.A. McAuliffe, MacMillan Press, Ltd., London, UK, 1977; Roberts, H.L., Some general aspects of mercury chemistry, *Adv.Inorg.Chem.Radiochem.* 11, 309-339, 1968; Grant, G.J., Mercury: Inorganic and Coordination Chemistry, in *Encyclopedia of Inorganic Chemistry*, ed. # PROTEIN pK VALUES

Lynne H. Botelho and Frank R. N. Gurd

The general techniques for determining individual pK values in proteins usually depend on NMR,<sup>1,2</sup> absorption,<sup>3</sup> or kinetic<sup>4</sup> procedures. Effects of neighboring groups may be evident in chemical shift influences<sup>5-7</sup> or in electrostatic influences on the hydrogen ion equilibria proper.<sup>8</sup>

## PROTEASE INHIBITORS AND PROTEASE INHIBITOR COCKTAILS

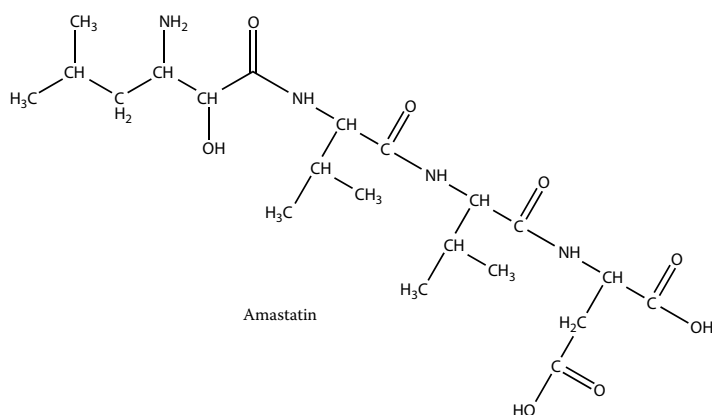

While protease inhibitor cocktails have been in use for some time,<sup>1</sup> there are few rigorous studies examining their effect on proteolysis and very few concerned with proteolytic degradation during the processing of material for analysis or during purification.<sup>2</sup> It is usually assumed that proteolysis can be a problem and protease inhibitors or protease inhibitor cocktails are usually included as part of a protocol without the provision of justification. There are several excellent review articles in this area. Salveson and Nagase<sup>3</sup> discuss the inhibition of proteolytic enzymes in great detail including much practical information that should be considered in experimental design. The discussion of the relationship between inhibitor concentration, inhibitor/enzyme binding constants (association constants, binding constants,  $t_{1/2}$ , inhibition constants, etc.), and enzyme inhibition is of particular importance. For example, with a reversible enzyme inhibitor (such as benzamide), if the  $K_i$  value is 100 nM, a 100  $\mu$ M concentration of inhibitor would be required to decrease protease activity by 99.9%. Salveson and Nagase<sup>3</sup> also note the well-known differences in the reaction rates of inhibitors such as DFP and PMSF with the active site of serine proteases. DFP is much faster than PMSF with trypsin but equivalent rates are seen with chymotrypsin. PMSF is included in commercial protease inhibitor cocktails because of its lack of toxicity compared to DFP; 3,4-dichloroisocoumarin (3,4-DCI), as described by Powers and colleagues,<sup>4</sup> is faster than either DFP or PMSF. Also enzyme inhibition occurs in the presence of substrate (proteins), which will influence the effectiveness of both irreversible and reversible enzyme inhibitors. In addition, some protease inhibitor cocktails include both PMSF and benzamide. Benzamide is a competitive inhibitor of trypticlike serine proteases and slows the rate of inactivation of such enzymes by reagents such as PMSF.<sup>5</sup> The investigator is also advised to consider the modification of proteins and other biological compounds by protease inhibitors in reactions not

associated with proteases such as the modification of tyrosine by DFP or PMSF.<sup>6</sup> In addition, some of the protease inhibitors such as DFP and PMSF are subject to hydrolysis under conditions ( $\text{pH} \geq 7.0$ ) used for modification. For those unfamiliar with the history of DFP, DFP is a potent neurotoxin (inhibitor of acetyl cholinesterase) and should be treated with considerable care; a prudent investigator has a DFP repair kit in close proximity (weak base and pralidoxime-2-chloride [2-PAM]). Given these various issues, it is critical to validate that, in fact, the sample is being protected against proteolysis.

### Characteristics of Selected Protease Inhibitors, Which Can be Used in Protease Inhibitor Cocktails<sup>a</sup>

Common Name	Other Nomenclature	M.W.	Primary Design
<p><b>Amastatin</b></p>  <p>Amastatin</p>	<i>N</i> -[(2 <i>S</i> ,3 <i>R</i> )-3-amino-2-hydroxy-5-methylhexanoyl]-L-valyl-L-valyl-L-aspartic acid	529.0	Inhibitor of some aminopeptidases.

## Characteristics of Selected Protease Inhibitors, Which Can be Used in Protease Inhibitor Cocktails (Continued)

Common Name	Other Nomenclature	M.W.	Primary Design
<p>Amastatin is a complex peptidlike inhibitor of aminopeptidases obtained from <i>Actinocyetes</i> culture. Amastatin is a competitive inhibitor of aminopeptidase A, aminopeptidase M, and other aminopeptidases. Amastatin has been used for the affinity purification of aminopeptidases. Amastatin has been shown to inhibit amino acid isomerases. Amastatin is structurally related to bestatin and has been described as an immunomodulatory factor. See Aoyagi, T., Tobe, H., Kojima, F. et al., Amastatin, an inhibitor of aminopeptidase A, produced by actinomycetes, <i>J. Antibiot.</i> 31, 636–638, 1978; Tobe, H., Kojima, F., Aoyagi, T., and Umezawa, H., Purification by affinity chromatography using amastatin and properties of the aminopeptidase A from pig kidney, <i>Biochim. Biophys. Acta</i> 613, 459–468, 1980; Rich, D.H., Moon, B.J., and Harbeson, S., Inhibition of aminopeptidases by amastatin and bestatin derivatives. <b>Aprotinin</b>		6512	Protein protease inhibitor.
<p>Basic pancreatic trypsin inhibitor; Kunitz pancreatic trypsin inhibitor; Trasylol®. This protein inhibits some but not all trypticlike serine proteinases and is included in some protease inhibitor cocktails. See Hulsemann, A.R., Jongejan, R.C., Rolien Raatgeep, H. et al., Epithelium removal and peptidase inhibition enhance relaxation of human airways to vasoactive intestinal peptide, <i>Am. Rev. Respir. Dis.</i> 147, 1483–1486, 1993; Cornelius, R.M. and Brash, J.L., Adsorption from plasma and buffer of single- and two-chain high molecular weight kininogen to glass and sulfonated polyurethane surfaces, <i>Biomaterials</i> 20, 341–350, 1999; Lafleur, M.A., Handsley, M.M., Knauper, V. et al., Endothelial tubulogenesis with fibrin gels specifically requires the activity of membrane-type-matrix metalloproteinases (MT-MMPs), <i>J. Cell Sci.</i> 115, 3427–3438, 2002; Shah, R.B., Palamakula, A., and Khan, M.A., Cytotoxicity evaluation of enzyme inhibitors and absorption enhancers in Caco-2 cells for oral delivery of salmon calcitonin, <i>J. Pharm. Sci.</i> 93, 1070–1082; Spens, E. and Häggerström, L., Protease activity in protein-free (NS) myeloma cell cultures, <i>In Vitro Cell Dev. Biol.</i> 41, 330–336, 2005. As it is a potent inhibitor of plasmin, aprotinin is frequently included in fibrin gel-based cultures to preserve the fibrin gel structure. See Ye, Q., Zund, G., Benedikt, P. et al., Fibrin gel as a three-dimensional matrix in cardiovascular tissue engineering, <i>Eur. J. Cardiothorac. Surg.</i> 17, 587–591, 2000; Krasna, M., Planinsek, F., Knezevic, M. et al., Evaluation of a fibrin-based skin substitute prepared in a defined keratinocyte medium, <i>Int. J. Pharm.</i> 291, 31–37, 2005; Sun, X.T., Ding, Y.T., Yan, X.G. et al., Antiangiogenic synergistic effect of basic fibroblast growth factor and vascular endothelial growth factor in an <i>in vitro</i> quantitative microcarrier-based three-dimensional fibrin angiogenesis system, <i>World J. Gastroenterol.</i> 10, 2524–2528, 2004; Gille, J., Meisner, U., Ehlers, E.M. et al., Migration pattern, morphology and viability of cells suspended in or sealed with fibrin glue: a histomorphology study, <i>Tissue Cell</i> 37, 339–348, 2005; Yao, L., Swartz, D.D., Gugino, S.F. et al., Fibrin-based tissue-engineered blood vessels: differential effects of biomaterial and culture parameters on mechanical strength and vascular reactivity, <i>Tissue Eng.</i> 11, 991–1003, 2005. Aprotinin is used therapeutically in the inhibition of plasmin activity both as a freestanding product and as a component of fibrin sealant products.</p>			
<b>Benzamidine HCl</b>		156.61	Inhibitor of trypticlike serine proteases.
			
Benzamidine			
<p>An aromatic amidine derivative (Markwardt, F., Landmann, H., and Walsmann, P., Comparative studies on the inhibition of trypsin, plasmin, and thrombin by derivatives of benzylamine and benzamidine, <i>Eur. J. Biochem.</i> 6, 502–506, 1968; Guvench, O., Price, D.J., and Brooks, C.L., III, Receptor rigidity and ligand mobility in trypsin-ligand complexes, <i>Proteins</i> 58, 407–417, 2005), which is used as a competitive inhibitor of trypticlike serine proteases. It is not a particularly tight-binding inhibitor and is usually used at millimolar concentrations. Ensinnck, J.W., Shepard, C., Dudl, R.J., and Williams, R.H., Use of benzamidine as a proteolytic inhibitor in the radioimmunoassay of glucagon in plasma, <i>J. Clin. Endocrinol. Metab.</i> 35, 463–467, 1972; Bode, W. and Schwager, P., The refined crystal structure of bovine beta-trypsin at 1.8 Å resolution. II. **Bestatin**

<i>N</i> -[(2 <i>S</i> ,3 <i>R</i> )-3-amino-2-hydroxy- <i>L</i> -oxo-4-phenylbutyl]- <i>L</i> -leucine	344.8	Aminopeptidase inhibitor; also described as a metalloproteinase inhibitor.
---	-------	--

Bestatin is an inhibitor of some aminopeptidases and it was isolated from *Actinomyces* culture. Bestatin was subsequently shown to have immunomodulatory activity and induces apoptosis in tumor cells. Bestatin is included in some proteaseinhibitor cocktails and has been demonstrated to inhibit intracellular protein degradation. See Umezawa, H., Aoyagi, T., Suda, H. et al., Bestatin, an inhibitor of aminopeptidase B, produced by actinomycetes, *J. Antibiot.* 29, 97–99, 1976; Suda, H., Takita, T., Aoyagi, T., and Umezawa, H., The structure of bestatin, *J. **Cystatins**

Protein Inhibitors of Cysteine Proteases	Inhibitors of cysteine proteinases.
--	-------------------------------------

Cystatin refers to a diverse family of protein cysteine protease inhibitors. There are three general types of cystatins: Type 1 (stefens), which are primarily found in the cytoplasm but can appear in extracellular fluids; Type 2, which are secreted and found in most extracellular fluids; and Type 3, which are multidomain protease inhibitors containing carbohydrates and that include the kininogens. Cystatin 3 is used to measure renal function in clinical chemistry. See Barrett, A.J., The cystatins: a diverse superfamily of cysteine peptidase inhibitors, *Biomed. Biochim. Acta* 45, 1363–1374, 1986; Katunuma, N., Mechanisms and regulation of lysosomal proteolysis, *Revis. Biol. Cellular* 20, 35–61, 1989; Gauthier, F., Lalmanach, G., Moeau, T. et al., Cystatin mimicry by synthetic peptides, *Biol. Chem. Hoppe Seyler* 373, 465–470, 1992; Bobek, L.A. and Levine, M.J., Cystatins — inhibitors of cysteine proteinases, *Crit. Rev. Oral Biol. Med.* 3, 307–332, 1992; Calkins, C.C., and Sloane, B.F., Mammalian cysteine protease inhibitors: biochemical properties and possible roles in tumor progression, *Biol. Chem. ## Diisopropyl Phosphorofluoridate

DFP; Diisopropyl Fluorophosphate

184

Reaction at active site serine.

## Characteristics of Selected Protease Inhibitors, Which Can be Used in Protease Inhibitor Cocktails (Continued)

Common Name	Other Nomenclature	M.W.	Primary Design
<p>DFP was developed during World War II as a neurotoxin. DFP reacts with the active serine of serine proteases and was used to define the presence of this amino acid at the active sites of trypsin and chymotrypsin. DFP has been replaced by PMSF as a general reagent for inhibition of proteases although it is still used on occasion because of the ease of identification of the phosphoserine derivative. See Jansen, E.F., Jang, R., and Balls, A.K., The inhibition of purified, human plasma cholinesterase with diisopropylfluorophosphate, <i>J. Biol. Chem.</i> 196, 247–253, 1952; Gladner, J.A. and Neurath, H.A., C-terminal groups in chymotrypsinogen and DFP-<math>\alpha</math>-chymotrypsin in relation to the activation process, <i>Biochim. Biophys. Acta</i> 9, 335–336, 1952; Schaffer, N.K., May, S.C., Jr., and Summerson, W.H., Serine phosphoric acid from diisopropylphosphoryl chymotrypsin, <i>J. Biol. Chem.</i> 202, 67–76, 1953; Oosterbaan, R.A., Kunst, P., and Cohen, J.A., The nature of the reaction between diisopropylfluorophosphate and chymotrypsin, <i>Biochim. Biophys. Acta</i> 16, 299–300, 1955; Wahlby, S., Studies on <i>Streptomyces griseus</i> protease. I. Separation of DFP-reacting enzymes and purification of one of the enzymes, <i>Biochim. Biophys. Acta</i> 151, 394–401, 1968; Hoskin, R.J. and Long, R.J., Purification of a DFP-hydrolyzing enzyme from squid head ganglion, <i>Arch. Biochem. Biophys.</i> 150, 548–555, 1972; Craik, C.S., Rocznik, S., Largman, C., and Rutter, W.J., The catalytic role of the active aspartic acid in serine proteases, <i>Science</i> 237, 909–913, 1987; D'Souza, C.A., Wood, D.D., She, Y.M., and Moscarello, M.A., Autocatalytic cleavage of myelin basic protein: an alternative to molecular mimicry, <i>Biochemistry</i> 44, 12905–12913, 2005. DFP is a potent neurotoxin and attention should be given to antidotes to organophosphates (Tuovinen, K., Kaliste-Korhonen, E., Raushel, F.M., and Hanninen, O., Phosphotriesterase, pralidoxime-2-chloride (2-PAM), and eptastigmine treatments and their combinations in DFP intoxication, <i>Toxicol. Appl. Pharmacol.</i> 141, 555–560, 1996; Auta, J., Costa, E., Davis, J., and Guidotti, A., Imidazenil: a potent and safe protective agent against diisopropyl fluorophosphate toxicity, <i>Neuropharmacology</i> 46, 397–403, 2004; Tuovinen, K., Organophosphate-induced convulsions and prevention of neuropathological damages, <i>Toxicology</i> 196, 31–39, 2004).</p>			
E-64		L- <i>trans</i> -epoxysuccinyl-leucylamide-(4-guanido)butane or N-[N-(L- <i>trans</i> -carboxyoxiran-2-carbonyl)-L-leucyl]-agmatine	357.4 Inhibitor of sulfhydryl proteases.
E-64 from <i>Aspergillus japonicus</i>			
<p>E-64 is a reasonably specific inhibitor of sulfhydryl proteases and it functions by forming a thioether linkage with the active site cysteine. E-64 is frequently referred to as an inhibitor of lysosomal proteases and antigen processing. See Hashida, S., Towatari, T., Kominami, E., and Katunuma, N., Inhibition by E-64 derivatives of rat liver cathepsins B and cathepsin L <i>in vitro</i> and <i>in vivo</i>, <i>J. Biochem.</i> 88, 1805–1811, 1980; Grinde, B., Selective inhibition of lysosomal protein degradation by the thiol proteinase inhibitors E-64, Ep-459, and Ep-457 in isolated rat hepatocytes, <i>Biochim. <b>Iodoacetamide</b>		185	Primary reaction with sulfhydryl groups and slower reaction with other protein nucleophiles.
----------------------	--	-----	--

Iodoacetamide

Iodoacetic acid

Iodoacetic acid and iodoacetamide can both be used to modify nucleophiles in proteins. The chloro- and bromo-derivatives can be used as well but the rate of modification is slower. The haloacetyl function can also be used as the reactive function for more complex derivatives. Iodoacetamide is neutral compared to iodoacetic acid and is less influenced by the local environment of the reactive nucleophile. See Janatova, J., Lorenz, P.E., and Schechter, A.N., Third component of human complement: appearance of a sulfhydryl group following chemical or enzymatic inactivation, *Biochemistry* 19, 4471–4478, 1980; Haas, A.L., Murphey, K.E., and Bright, P.M., The inactivation of ubiquitin accounts for the inability to demonstrate ATP, ubiquitin-dependent proteolysis in liver extracts, *J. Biol. Chem.* 260, 4694–4703, 1985; Molla, A., Yamamoto, T., and Maeda, H., Characterization of 73 kDa thiol protease from *Serratia marcescens* and its effect on plasma proteins, *J. The haloalkyl derivatives do react with thiourea and are perhaps less reliable than maleimides.

Characteristics of Selected Protease Inhibitors, Which Can be Used in Protease Inhibitor Cocktails (Continued)

Common Name	Other Nomenclature	M.W.	Primary Design
LBTI	Lima Bean Trypsin Inhibitor	6500	Protein protease inhibitor.

Lima bean trypsin inhibitor is a protein/peptide with unusual stability. It is stable to heat (90°C for 15 minutes at pH 7 with no loss of activity) and acid (the original purification uses extraction with ethanol and dilute sulfuric acid). This is a reflection of the high content of cystine resulting in a “tight” structure. As a Bowman–Birk inhibitor, LBTI has seven disulfide bonds (Weder, J.K.P. and Hinkers, S.C., Complete amino acid sequence of the Lentil trypsin-chymotrypsin inhibitor LCI-1.7 and a discussion of atypical binding sites of Bowman–Birk inhibitors, *J. Agric. Food Chem.* 52, 4219–4226, 2004). LBTI also inhibits both trypsin and chymotrypsin (Krahn, J. and Stevens, F.C., Lima bean trypsin inhibitor. Limited proteolysis by trypsin and chymotrypsin, *Biochemistry* 27, 1330–1335, 1970) as well as various other serine proteases. For additional information, see Fraenkel-Conrat, H., Bean, R.C., Duca, E.D., and Olcott, H.S., Isolation and characterization of a trypsin inhibitor from lima beans, *Arch. Biochem. Leupeptin

(ac/pr-LeuLeuArginal)

Transition-state inhibitor of proteinase.

## Characteristics of Selected Protease Inhibitors, Which Can be Used in Protease Inhibitor Cocktails (Continued)

Common Name	Other Nomenclature	M.W.	Primary Design
-------------	--------------------	------	----------------

A tripeptide aldehyde (ac/pr-LeuLeuArginal) proteinase inhibitor isolated from *Actinomycetes*. It is a relatively common component of protease inhibitor cocktails used to preserve proteins during storage and purification. See Alpi, A. and Beevers, H., Proteinases and enzyme stability in crude extracts of castor bean endosperm, *Plant Physiol.* 67, 499–502, 1981; Ratajzak, T., Luc, T., Samec, A.M., and Hahnel, R., The influence of leupeptin, molybdate, and calcium ions on estrogen receptor stability, *FEBS Lett.* 136, 115–118, 1981; Takei, Y., Marzi, I., Kauffman, F.C. et al., Increase in survival time of liver transplants by protease inhibitors and a calcium channel blocker, nisoldipine, *Transplantation* 50, 14–20, 1990; Satoh, M., Hosoi, S., Miyaji, M. et al., Stable production of recombinant pro-urokinase by human lymphoblastoid Namalwa KJM-1 cells: host-cell dependency of the expressed-protein stability, *Cytotechnology* 13, 79–88, 1993; Hutchesson, A.C., Hughes, C.V., Bowden, S.J., and Ratcliffe, W.A., *In vitro* stability of endogenous parathyroid hormone-related protein in blood and plasma, *Ann. **(p-Amidinophenyl) Methanesulfonyl Fluoride**

aPMSF

163

Reaction at active site serine.

(p-amidinophenyl) methanesulfonyl fluoride

(p-Amidinophenyl) methanesulfonyl fluoride was developed by Bing and coworkers (Laura, R., Robison, D.J., and Bing, D.H., [p-Amidinophenyl] methanesulfonyl fluoride, an irreversible inhibitor of serine proteases, *Biochemistry* 19, 4859–4864, 1980) to improve the specificity of PMSF for trypticlike enzymes. aPMSF readily reacts with trypsin but is only poorly reactive with chymotrypsin. See Katz, I.R., Thorbecke, G.J., Bell, M.K. et al., Protease-induced immunoregulatory activity of platelet factor 4, *Proc. Natl. Acad. Sci. USA* 83, 3491–3495, 1986; Unson, C.G. and Merrifield, R.B., Identification of an essential serine residue in glucagon: implications for an active site triad, *Proc. Natl. Acad. Sci. USA* 91, 454–458, 1994; Nikai, T., Komori, Y., Kato, S., and Sugihara, H., Biochemical properties of kinin-releasing enzyme from *Trimeresurus okinavensis(himehabu)* venom, *J. Nat. Toxins* 7, 23–35, 1998; Ishidoh, K., Takeda-Ezaki, M., Watanabe, S. et al., Analysis of where and which types of proteinases participate in lysosomal proteinase processing using balifomycin A1 and *Helicobacter pylori* Vac A toxin, *J. Biochem.* 125, 770–779, 1999; Komori, Y., Tatematsu, R., Tanida, S., and Nikai, T., Thrombin-like enzyme, flavovilase, with kinin-releasing activity from *Trimeresurus flavoviridis(habu)* venom, *J. Nat. Toxins* 10, 239–248, 2001; Luo, L.Y., Shan, S.J., Elliott, M.B. et al., Purification and characterization of human kallikrein 11, a candidate prostate and ovarian cancer biomarker, from seminal plasma, *Clin. Cancer Res.* 12, 742–750, 2006. Reaction at a residue other than a serine has not been demonstrated although it is not unlikely that, as with DFP and PMSE, reaction could occur at a serine residue.

**p-(Aminoethyl) Benzene Sulfonyl Fluoride**

AEBSF;

165

Reaction at active site serine.

4-(2-aminoethyl)benzenesulfonyl fluoride

4-(2-aminoethyl)-  
benzenesulfonyl  
fluoride (Pefabloc™  
SC)

This reagent was developed to improve the reactivity of PMSF. It was originally considered to be somewhat more effective than PMSF; however, AEBSF has been shown to be somewhat promiscuous in its reaction pattern and care is suggested in its use during sample preparation. See Su, B., Bochan, M.R., Hanna, W.L. et al., Human granzyme B is essential for DNA fragmentation of susceptible target cells, *Eur. J. Immunol.* 24, 2073–2080, 1994; Helser, A., Ulrichs, K., and Muller-Ruchholtz, W., Isolation of porcine pancreatic islets: low trypsin activity during the isolation procedure guarantees reproducible high islet yields, *J. Agents Chemother.</i> 50, 2316–2322, 2006.			
<b>Phenylmethylsulfonyl Fluoride</b>	PMSF	174	Reaction at active site serine.

Phenylmethylsulfonyl fluoride (PMSF)

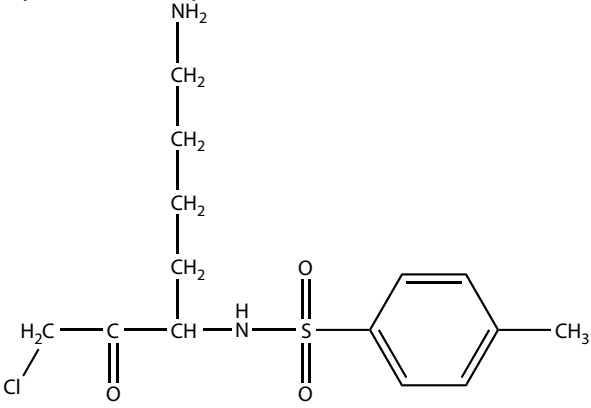

Phenylmethylsulfonyl fluoride was developed by David Fahrney and Allen Gold and inhibits serine proteases such as trypsin and chymotrypsin in a manner similar to DFP. The rate of modification of trypsin and chymotrypsin with PMSF is similar to that observed with DFP; however, the reaction with acetylcholinesterase with PMSF is much less than that of DFP ( $>6.1 \times 10^{-2} \text{ M}^{-1}\text{min}^{-1}$  vs.  $1.3 \times 10^4 \text{ M}^{-1}\text{min}^{-1}$ ) (Fahrney, D.E. and Gold, A.M., Sulfonyl fluorides as inhibitors of esterases. I. Rates of reaction with acetylcholinesterase,  $\alpha$ -chymotrypsin, and trypsin, *J. Amer. Chem. Soc.* 85, 997–1000, 1963). For other applications see Lundblad, R.L., A rapid method for the purification of bovine thrombin and the inhibition of the purified enzyme with phenylmethylsulfonyl fluoride, *Biochemistry* 10, 2501–2506, 1971; Pringle, J.R., Methods for avoiding proteolytic artefacts in studies of enzymes and other proteins from yeasts, *Methods Cell Biol.* 12, 149–184, 1975; Bendtzen, K., Human leukocyte migration inhibitory factor (LIF). I. Effect of synthetic and naturally occurring esterase and protease inhibitors, *Scand. J. Immunol.* 6, 125–131, 1977; Carter, D.B., Efrid, P.H., and Chae, C.B., Chromatin-bound proteases and their inhibitors, *Methods Cell Biol.* 19, 175–190, 1978; Hubbard, J.R. and Kalimi, M., Influence of proteinase inhibitors on glucocorticoid receptor properties: recent progress and future perspectives, *Mol. Cell. Biochem.* 66, 101–109, 1985; Kato, T., Sakamoto, E., Kutsana, H. et al., Proteolytic conversion of STAT3 $\alpha$  to STAT3 $\gamma$  in human neutrophils: role of granule-derived serine proteases, *J. Biol. Chem.* 279, 31076–31080, 2004; Cho, I.H., Choi, E.S., Lim, H.G., and Lee, H.H., Purification and characterization of six fibrinolytic serine proteases from earthworm *Lumbricus rubellus*, *J. Biochem. Mol. Biol.* 37, 199–205, 2004; Khosravi, J., Diamandi, A., Bodani, U. et al., Pitfalls of immunoassay and sample for IGF-1: comparison of different assay methodologies using fresh and stored serum samples, *Clin. Biochem.* 38, 659–666, 2005; Shao, B., Belaouaj, A., Velinde, C.L. et al., Methionine sulfoxide and proteolytic cleavage contribute to the inactivation of cathepsin G by hypochlorous acid: an oxidative mechanism for regulation of serine proteinases by myeloperoxidase, *J. Biol. Chem.* 260, 29311–29321, 2005; Pagano, M.R., Paredi, M.E., and Crupkin, M., Cytoskeletal ultrastructural and lipid composition of 1-Z-1 fraction in muscle from pre- and post-spawned female hake (*Merluccius hubbsi*), *Comp. Biochem. Physiol. B Biochem. Mol. Biol.* 141, 13–21, 2005. Although PMSF is reasonably specific for reaction with the serine residue at the active site of serine proteinases, as with DFP, reaction at tyrosine has been reported (De Vendittis, E., Ursby, T., Rullo, R. et al., Phenylmethanesulfonyl fluoride inactivates an archaeal superoxide dismutase by chemical modification of a specific tyrosine residue. Cloning, sequencing, and expression of the gene coding for *Sulfolobus solfataricus* dismutase, *Eur. J. Biochem.* 268, 1794–1801, 2001). PMSF does have solubility issues and usually ethanol or another suitable water-miscible organic solvent is used to introduce this reagent. On occasion, the volume of ethanol required influences the reaction (see Bramley, T.A., Menzies, G.S., and McPhie, C.A., Effects of alcohol on the human placental GnRH receptor system, *Mol. Hum. Reprod.* 5, 777–783, 1999).

<b>SBTI</b>	Soybean Trypsin Inhibitor	21,500	Protein protease inhibitor.
-------------	---------------------------	--------	-----------------------------

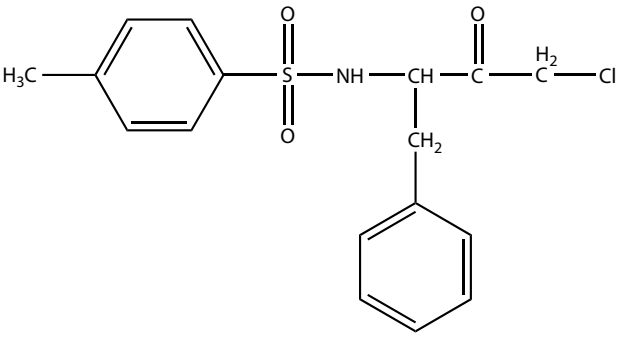

Soybean trypsin inhibitor (SBTI, STI) usually refers to the inhibitor first isolated by Kunitz (Kunitz, M., Crystalline soybean trypsin inhibitor, *J. Gen. Physiol.* 29, 149–154, 1946; Kunitz, M., Crystalline soybean trypsin inhibitor. II. General properties, *J. Gen. Physiol.* 30, 291–310, 1947). This material is described as the Kunitz inhibitor and is reasonably specific for trypticlike enzymes. There are other protease inhibitors derived from soybeans; the Bowman–Birk inhibitor (Birk, Y., The Bowman–Birk inhibitor. Trypsin and chymotrypsin-inhibitor from soybeans, *Int. J. Pept. Protein Res.* 25, 113–131, 1985; Birk, Y., Protein proteinase inhibitors in legume seeds — overview, *Arch. Latinoam. Nutr.* 44 (4 Suppl. 1), 26S–30S, 1996) is the best known and, unlike the Kunitz inhibitor, inhibits both trypsin and chymotrypsin; the Bowman–Birk inhibitor is also a double-headed inhibitor having two reactive sites (see Frattali, V. and Steiner, R.F., Soybean inhibitors. I. Separation and some properties of three inhibitors from commercial crude soybean trypsin inhibitor, *Biochemistry* 7, 521–530, 1968; Frattali, V. and Steiner, R.F., Interaction of trypsin and chymotrypsin with a soybean proteinase inhibitor, *Biochem. Biophys. Res. Commun.* 34, 480–487, 1969; Krogdahl, A. and Holm, H., Inhibition of human and rat pancreatic proteinases by crude and purified soybean trypsin inhibitor, *J. Nutr.* 109, 551–558, 1979). Soybean trypsin inhibitor (Kunitz) is used as a model protein (Liu, C.L., Kamei, D.T., King, J.A. et al., Separation of proteins and viruses using two-phase aqueous micellar systems, *J. Chromatog. B* 711, 127–138, 1998; Higgs, R.E., Knierman, M.D., Gelfanova, Y. et al., Comprehensive label-free method for the relative quantification of proteins from biological samples, *J. Proteome Res.* 4, 1442–1450, 2005). The broad specificity of the Kunitz inhibitor for trypticlike serine proteases provides the basis for its use in the demonstration of protease processing steps (Hansen, K.K., Sherman, P.M., Cellars, L. et al., A major role for proteolytic and proteinase-activated receptor-3 in the pathogenesis of infectious colitis, *Proc. Natl. Acad. Sci. USA* 102, 8363–8368, 2005).

## Characteristics of Selected Protease Inhibitors, Which Can be Used in Protease Inhibitor Cocktails (Continued)

Common Name	Other Nomenclature	M.W.	Primary Design
<p><b>Tosyl-lysine Chloromethyl Ketone</b></p>  <p>Tosyl-lysine chloromethyl ketone</p>	TLCK; 1-chloro-3-tosylamido-7-amino-2-heptanone	369.2 (HCl)	Reaction at active site histidine residues of trypsinlike serine proteases.

Tosyl-lysine chloromethyl ketone (TLCK) was developed by Elliott Shaw and colleagues (Shaw, E., Mares-Guia, M., and Cohen, W., Evidence of an active center histidine in trypsin through use of a specific reagent, 1-chloro-3-tosylamido-7-amido-2-heptanone, the chloromethyl ketone derived from *N*- $\alpha$  tosyl-L-lysine, *Biochemistry* 4, 2219–2224, 1965). As with TPCK, reaction is not absolutely specific for trypticlike serine proteases (Earp, H.S., Austin, K.S., Gillespie, G.Y. et al., Characterization of distinct tyrosine-specific protein kinases in B and T lymphocytes, *J. Biol. Chem.* 260, 4351–4356, 1985; Needham, L. and Houslay, M.D., Tosyl-lysyl chloromethylketone detects conformational changes in the catalytic unit of adenylate cyclase induced by receptor and G-protein stimulation, *Biochem. Biophys. Res. Commun.* 156, 855–859, 1988). Reaction of this chloroalkyl compound with sulfhydryl groups would be expected and it is possible that other protein nucleophilic centers would react, although this has not been unequivocally demonstrated. Attempts to synthesize the direct arginine analogue were unsuccessful; it was possible to make more complex arginine derivatives such as Ala-Phe-Arg-CMK, which was more effective with human plasma Kallikrein than the corresponding lysine derivatives ( $K_i = 0.078 \mu\text{M}$  vs.  $M$  vs.  $4.9 \mu\text{M}$ ) (Kettner, C. and Shaw, E., Synthesis of peptides of arginine chloromethyl ketone. Selective inactivation of human plasma kallikrein, *Biochemistry* 17, 4778–4784, 1978).

<p><b>Tosyl-phenylalanine Chloromethyl Ketone</b></p>  <p>Tosyl phenylalanine chloromethylketone</p>	TPCK; L-1-tosylamido-2-phenylethyl chloromethyl ketone)	351.9	Reaction at active site histidine residues of chymotrypsinlike serine proteases.
---	---	-------	--

Tosyl-phenylalanine chloromethyl ketone (TPCK) was developed by Guenther Schoellmann and Elliott Shaw (Schoellmann, G. and Shaw, E., Direct evidence for the presence of histidine in the active center of chymotrypsin, *Biochemistry* 2, 252–255, 1963). TPCK was developed as an affinity label (Plapp, B.V., Application of affinity labeling for studying structure and function of enzymes, *Methods Enzymol.* 87, 469–499, 1982) where binding to chymotrypsin is driven by the phenyl function with subsequent alkylation of the active site histidine. The chloroalkyl function was selected to reduce reactivity with other protein nucleophiles such as cysteine. TPCK does undergo a slow rate of hydrolysis to form the corresponding alcohol. TPCK inactivates proteases with chymotrypsinlike specificity. The rate of inactivation is relatively slow but is irreversible; reaction rates can be enhanced by a more elaborate peptide chloromethyl ketone structure. In the case of cucumisin, a plant serine proteinase, TPCK did not result in inactivation while inactivation was achieved with *Z*-Ala-Ala-Pro-Phe-chloromethyl ketone (Yonezawa, H., Uchikoba, T., and Kaneda, M., Identification of the reactive histidine of cucumisin, a plant serine protease: modification with peptidyl chloromethyl ketone derivative of peptide substrate, *J. Biochem.* 118, 917–920, 1995). There is, however, significant reaction of TPCK with other proteins at residues other than histidine (see Rychlik, I., Jonak, J., and Sdelacek, J., Inhibition of the EF-Tu factor by L-1-tosylamido-2-phenylethyl chloromethyl ketone, *Acta Biol. Med. Ger.* 33, 867–876, 1974); TPCK has been described as an inhibitor of cysteine proteinases (Bennett, M.J., Van Leeuwen, E.M., and Kears, K.P., Calnexin association is not sufficient to protect T cell receptor proteins from rapid degradation in CD4<sup>+</sup>CD8<sup>+</sup> thymocytes, *J. Biol. Chem.* 273, 23674–23680, 1998). TPCK has been suggested to react with a lysine residue in aminoacylase (Frey, J., Kordel, W., and Schneider, F., The reaction of aminoacylase with chloromethylketone analogs of amino acids, *Z. Naturforsch.* 32, 769–776, 1966). Other reactions continue to be described (McCray, J.W. and Weil, R., Inactivation of interferons: halomethyl ketone derivatives of phenylalanine as affinity labels, *Proc. Natl. Acad. Sci. USA* 79, 4829–4833, 1982; Conseiller, E.C. and Lederer, F., Inhibition of NADPH oxidase by aminoacyl chloromethane protease inhibitors in phorbol-ester-stimulated human neutrophils: A reinvestigation. Are proteases really involved? *Eur. J. Biochem.* 183, 107–114, 1989; Borukhov, S.I. and Strongin, A.Y.,

## Characteristics of Selected Protease Inhibitors, Which Can be Used in Protease Inhibitor Cocktails (Continued)

Common Name	Other Nomenclature	M.W.	Primary Design
Chemical modification of the recombinant human $\alpha$ -interferons and $\beta$ -interferons, <i>Biochem. Biophys. Res. Commun.</i> 167, 74–80, 1990; Gillibert, M., Dehry, Z., Terrier, M. et al., Another biological effect of tosylphenylalanylchloromethane (TPCK): it prevents p47(phox) phosphorylation and translocation upon neutrophil stimulation, <i>Biochem. J.</i> 386, 549–556, 2005).			
<b>Peptide Halomethyl Ketones:</b> While TPCK and TLCK represented a major advance in modifying active site residues in serine proteases, slow and relatively nonspecific reaction was a problem. The development of tripeptide halomethyl ketones provided a major advance in the value of such derivatives as presented in some specific examples below. However, even with these derivatives, reactions occur with “unexpected” enzymes. More general information can be obtained from the following references: Poulos, T.L., Alden, R.A., Freer, S.T. et al., Polypeptide halomethyl ketones bind to serine proteases as analogs of the tetrahedral intermediate. X-ray crystallographic comparison of lysine- and phenylalanine-polypeptide chloromethyl ketone-inhibited subtilisin, <i>J. Biol. Chem.</i> 251, 1097–1103, 1976; Powers, J.C., Reaction of serine proteases with halomethyl ketones, <i>Methods Enzymol.</i> 46, 197–208, 1977; Navarro, J., Abdel Ghany, M., and Racker, E., Inhibition of tyrosine protein kinases by halomethyl ketones, <i>Biochemistry</i> 21, 6138–6144, 1982; Conde, S., Perez, D.L., Martinez, A. et al., Thienyl and phenyl $\alpha$ -halomethyl ketones: new inhibitors of glycogen synthase kinase (GSK-3 $\beta$ ) from a library of compound searching, <i>J. Med. Chem.</i> 46, 4631–4633, 2003.			
<b>Peptide Fluoromethyl Ketones:</b> Fluoroalkyl derivatives of the peptide chloromethyl ketones have been prepared in an attempt to improve specificity by reducing nonspecific alkylation at cysteine residues (Rasnick, D., Synthesis of peptide fluoromethyl ketones and the inhibition of human cathepsin B, <i>Anal. Biochem.</i> 149, 461–465, 1985). Nonspecific reaction with sulfhydryl groups such as those in glutathione was reduced; there was still reaction with active site cysteine although at a slower rate than with the chloroalkyl derivative (16,200 M <sup>-1</sup> s <sup>-1</sup> vs. 45,300 M <sup>-1</sup> s <sup>-1</sup> ; t <sub>1/2</sub> 21.9 min. vs. 5.1 min.). Reaction also occurred with serine proteases (Shaw, E., Angliker, H., Rauber, P. et al., Peptidyl fluoromethyl ketones as thiol protease inhibitors, <i>Biomed. Biochim. Acta</i> 45, 1397–1403, 1986) where the modification occurred at a histidine residue (Imperiali, B. and Abeles, R.H., Inhibition of serine proteases by peptide fluoromethyl ketones, <i>Biochemistry</i> 25, 3760–3767, 1986). The trifluoromethyl derivative was also an inhibitor but formed a hemiacetal derivative. The peptide fluoromethyl ketone, z-VAD-FMK, has proved to be a useful inhibitor of caspases			
D-Phe-Pro-Arg-chloromethyl Ketone	PPACK		Reaction at active site histidine residues of trypsinlike serine proteases.

D-Phe-Pro-Arg-chloromethyl ketone was one of the first complex peptide halomethyl ketones synthesized. These derivatives have the advantage of increased reaction rate and specificity (see Williams, E.B. and Mann, K.G., Peptide chloromethyl ketones as labeling reagents, *Methods Enzymol.* 222, 503–513, 1993; Otake, S., Kam, C.M., and Powers, J.C., Inhibition of thrombin by arginine-containing peptide chloromethyl ketones and bis chloromethyl ketone-albumin conjugates, *J. Enzyme Inhib.* 9, 17–27, 1995; Lundblad, R.L., Bergstrom, J., De Vreker, R. et al., Measurement of active coagulation factors in Autoplex®-T with colorimetric active site-specific assay technology, *Thromb. Haemostas.* 80, 811–815, 1998). With chymotrypsin, CHO-PheCH<sub>2</sub>Cl,  $k_{\text{obs.}}/[I] = 0.55 \text{ M}^{-1}\text{s}^{-1}$  and Boc-Ala-Gly-Phe-CH<sub>2</sub>Cl,  $k_{\text{obs.}}/[I] = 3.34 \text{ M}^{-1}\text{s}^{-1}$  (Kurachi, K., Powers, J.C., and Wilcox, P.E., Kinetics of the reaction of chymotrypsin A  $\alpha$  with peptide chloromethyl ketones in relation to subsite specificity, *Biochemistry* 12, 771–777, 1973. See also Ketter, C. and Shaw, E., The selective affinity labeling of factor Xa by peptides of arginine chloromethyl ketone, *Thromb. Res.* 22, 645–652, 1981; Shaw, E., Synthetic inactivators of kallikrein, *Adv. Exp. Med. Biol.* 156, 339–345, 1983; McMurray, J.S. and Dyckes, D.F., Evidence for hemiketals as intermediates in the inactivation of serine proteinases with halomethyl ketones, *Biochemistry* 25, 2298–2301, 1986). There is a similar peptide chloromethyl ketone, PPACK II (D-Phe-Phe-Arg-CMK), which has been used to stabilize B-type natriuretic peptide (BNP) in plasma samples (Belenky, A., Smith, A., Zhang, B. et al., The effect of class-specific protease inhibitors on the stabilization of B-type natriuretic peptide in human plasma, *Clin. Chim. Acta* 340, 163–172, 2004).

## z-VAD-FMK

z-VADFMK

Benzyloxycarbonyl-Val-Ala-Asp(OMe) fluoromethyl ketone

Inhibitor of caspases.

Benzyloxycarbonyl-Val-Ala-Asp(OMe) fluoromethyl ketone (z-VAD-FMK) is a peptide halomethyl ketone used for the inhibition of caspases and related enzymes. Because z-VAD-FMK is neutral, it passes the cell membrane and can inhibit intracellular proteolysis and is useful in understanding the role of caspases and related enzymes in cellular function. See Zhu, H., Fearnhead, H.O., and Cohen, G.M., An ICE-like protease is a common mediator of apoptosis induced by diverse stimuli in human monocytes THP.1 cells, *FEBS Lett.* 374, 303–308, 1995; Mirzoeva, O.K., Yaqoob, P., Knox, K.A., and Calder, P.C., Inhibition of ICE-family cysteine proteases rescues murine lymphocytes from lipoxigenase inhibitor-induced apoptosis, *FEBS Lett.* 396, 266–270, 1996; Slee, E.A., Zhu, H., Chow, S.C. et al., Benzyloxycarbonyl-Val-Ala-Asp(OMe) fluoromethylketone (z-VAD-FMK) inhibits apoptosis by blocking the processing of CPP32, *Biochem. ## ASSAY OF SOLUTION PROTEIN CONCENTRATION

The determination of protein concentration is a somewhat overlooked procedure that is critical for the determination of the specific biological/therapeutic activity of most biopharmaceuticals, the "standardization" or normalization of samples for proteomic analysis and the comparison of cell homogenates. As such, it is unfortunate that most investigators do not recognize the limitations of the various procedures. The reader is recommended to some recent reviews of protein assay methods<sup>1-3</sup>. The purpose of this short section is to describe some commonly used techniques for the determination of protein concentration. Care must be taken with the use of these techniques several of the more frequently used techniques depend on protein quality as well as quantity. Thus the technique which is facile might not be accurate. It is noted that accuracy is an attribute in assay validation while facile is not. There are two issues which are common to any of the below assays. The first is the standard and the second is the solvent. The standard should be representative of the sample; albumin might not be the best choice. The concentration of the standard protein cannot be verified by preparation but must be verified by analysis. In other words, accurate dispensing of the standard protein and subsequent dissolution to a given volume does not ensure an accurate standard. The final concentration of a standard solution must be verified by analysis. For well-characterized proteins it is possible to employ ultraviolet spectroscopy using the known extinction coefficient for the standard protein. Thus the A280 of a 1 mg/mL of bovine serum albumin is 0.66 in a cuvette of 1 cm pathlength [126]. It is important to correct for any light scattering due to aggregated material, dust, etc., by recording the baseline over the range 400 to 310 nm where the protein does not absorb. While this procedure may seem somewhat tedious, it is necessary. It is possible to prepare a standard solution which can be used for a substantial period of time. The standard solution is best stored frozen in small aliquots, each of which is used once to calibrate the assay. The precise storage conditions used would require validation.

Solvent can have an effect on the analytical response and should be selected for (1) lack of an effect on the signal and (2) the ability to be used for both standard and samples. The reader is directed to the List of Buffers (p. 695) for a discussion of the effect of various buffers on protein analysis.

### Biuret assay

The biuret assay measures the formation of a purple complex between copper salts and two or more peptide bonds under alkaline conditions. The assay was developed by Gornall and coworkers<sup>4</sup> and modified to a microplate format by Jenzano and coworkers<sup>5</sup>. The biuret assay is not available in kit form and the preparation of the reagents requires some skill. The biuret assay also lacks the sensitivity of many of the other assays. The biuret assay is accurate as it is insensitive to protein quality<sup>2,3</sup>.

Selected references on the use of this method with various proteins are provided in Table 1.

### Bicinchoninic acid (BCA) protein assay

This assay was developed by Smith and coworkers<sup>6</sup>. A modification for microplate use was developed by Jenzano and coworkers<sup>5</sup>. This procedure is a modification of the Lowry et al.<sup>7</sup> reaction, but it is significantly easier and somewhat more sensitive<sup>6</sup>. The reaction is based on the formation of a complex of BCA with cuprous ion (Brenner, A.J. and Harris, E.D., A quantitative test for copper using

bicinchoninic acid, *Anal.Biochem.* 226, 80-84, 1995). The BCA reaction has the advantage of being able to measure protein bound to surfaces. This reaction is quite sensitive but it does reflect qualitative differences in proteins. As a reflection of the dependence on protein quality,<sup>2</sup> it is critical to select a standard that is qualitatively similar, if not identical, with the samples. This is obviously difficult when the assay is used with heterogeneous mixtures such as saliva or serum. Selected references to the use of this method are given in Table 2. Information on the use of the Lowry assay is presented in Table 3.

### Dye-binding assay for protein using Coomassie Brilliant Blue G-250 (Bradford assay)

The dye-binding assay for proteins using Coomassie Brilliant Blue G-250 is likely the most sensitive and most extensively used protein assay at this time. It is also extremely easy to perform. The technique, as noted below, is extremely dependent on the quality of the protein. The procedure was developed by Bradford<sup>8</sup>. A modification for microplate technology is given by Jenzano and coworkers<sup>5</sup>. As noted above, this assay technique is likely the most sensitive and facile of the currently available procedures. Rigorous application of the dye-binding assay to the quantitative determination of a broad spectrum of proteins is difficult because of the marked influence of protein quality on the reaction. This is reflected by various studies attempting to modify the assay system to eliminate dependence on the quality of the protein.<sup>9-14</sup>. Examples of the application of the Coomassie Blue dye-binding assay are presented in Table 4.

### Kjeldahl assay

The Kjeldahl assay was developed in 1883<sup>15</sup> and is based on the determination of ammonia after hydrolysis of the sample in sulfuric acid. Most recent references to the use of this method relate to its use in food and environmental sciences<sup>16-20</sup>. It is our view that the Kjeldahl method remains a "gold" standard for protein assays<sup>21</sup> but we also appreciate the issues of technical complexity and lack of sensitivity which make routine use difficult for biopharmaceuticals. In addition, problems can arise in the analysis of proteins which contain impurities which themselves contain significant quantities of nitrogen, or in the analysis of proteins of unusual amino acid composition where the usual conversion factors may not apply. There are numerous commercial sources for support of the Kjeldahl assay<sup>22-27</sup>. Zellmer et al.,<sup>28</sup> have recently described an assay system which appears to have the accuracy of the Kjeldahl method with greatly improved sensitivity. Recent applications of the Kjeldahl assay are presented in Table 5.

### Total amino acid analysis

Current technology for total amino acid analysis certainly has the various analytical attributes (sensitivity, accuracy, ruggedness) and is sufficiently rapid for use in the analysis of protein concentration<sup>29-34</sup> and has been suggested as a reference procedure for the determination of total protein concentration<sup>35,36</sup>. With a characterized biopharmaceutical such as a growth factor, the concentration of the protein can be

determined by measuring the amounts of specific stable and abundant amino acids such as alanine and lysine with reference to an added internal standard such as norleucine<sup>37</sup>. Application of amino acid analysis for total protein concentration are presented in Table 6.

### Amido schwarz

The above approaches are certainly worth considering. However, it is somewhat remarkable that more attention has not been given to the amido black (Amidoschwarz 10B) assay developed by Schaeffner and Weissman<sup>38</sup>. This assay is based on the quantitative precipitation of protein from solution with trichloroacetic acid, the capture of the precipitated material by filtration followed by quantitative measurement of captured protein with amido schwarz dye (amido black is the preferred term). This study has been cited 2356 times (ISI) since its publication in 1973. The original assay used the addition of an equal amount of 60% trichloroacetic acid to a final concentration of 10%. The precipitate is captured by filtration and stained with amido black dye in methanol/glacial acetic acid/H<sub>2</sub>O. The protein is visualized as a blue spot on an almost colorless background. The spot is excised from the filter, eluted with 25 mM NaOH-0.05 mM EDTA in 50% aqueous ethanol. The absorbance of the eluate at 630 nm is determined and concentration is determined by comparison with the results obtained with a standard protein. This assay has been used for the determination of protein concentration in grape juices and wines<sup>39</sup>, low concentration of protein in phospholipids<sup>40</sup>, and the *Escherichia coli* multidrug transporter EmrE<sup>41</sup> in the presence of detergents. Of direct relevance to proteomic analyses are the studies of Eliane<sup>42</sup> and coworkers on the determination of protein concentration of a *Medicago truncatula* root microsomal fraction with the amido black assay in a solution composed of 7.0 M urea-2.0 M thiourea-4% CHAPS (w/v)-0.1% (w/v) Triton X-100-2 mM tributylphosphine-2% ampholines. The reader is also commended to the study by Tate and coworkers<sup>41</sup> who validated the amido black assay with quantitative amino acid analysis which has been suggested as a method of choice for accurate determination of protein concentration<sup>34,35</sup>. A list of some other applications of amido black for protein assay is given in Table 7.

There has been limited application of fluorescent dyes for the determination of protein concentration (Table 8).

Determination of protein concentration in human milk	13
Determination of protein in human lens	14
Protein assay in cell-based toxicity studies	15

**TABLE 4: Coomassie Blue Dye-Binding Assay (Bradford Assay)**

Application	Reference
Measured soy protein extraction from various sources including soybean meal, soyprotein concentrate, and textured soy flake	16
Measured protein in aqueous phase from oil-water distribution. The amount of protein measured with Coomassie blue dye correlated ( $r^2 = 0.91$ ) with protein concentration determined by tryptophan emission spectra (fourth derivative)	17
Measured glomalin extraction from soil	18
Automation of Coomassie dye-binding assay	19
Resonance light scattering with Bordeaux red correlates with Coomassie method for the determination of protein concentration in human serum, saliva, and urine.	20
Measured protein concentration in phenol extracts of plant tissues after precipitation with ammonium acetate in methanol	21
Measured total protein concentration in rat tissue (pancreas, parotid gland, submandibular gland, lacrimal gland) extracts	22
Measure protein release from alginate-dextran microspheres	23
Protein release from <i>Candida albicans</i> secondary to microwave irradiation	24

**TABLE 5: Kjeldahl Assay for Protein Concentration**

Application	Reference
Measurement of protein concentration in therapeutic protein concentrate. Kjeldahl used as the "gold standard." The biuret assay gave comparable values while dye-binding was lower. Specific activity differed with the protein concentration	25
Measurement of crude microbial protein derived from carbohydrate fermentation	26
Measurement of polylysine coating on alginate beads	27
Measurement of IgG concentration in the presence of nonionic surfactants and glycine	28
Manure protein concentration	29
Whey protein concentration	30

**TABLE 6: Amino Acid Analysis for Protein Concentration**

Application	Reference
Use of amino acid analysis as a primary method for the determination of the concentration of poly ADP-ribose polymerase 1 (PARP-1)	31
Determination of the concentration of NADH:ubiquinone oxidoreductase and establishment of coenzyme (FMN) and iron-sulfur cluster stoichiometry	32
Determination of the concentration of immobilized protein	33
Determination of IgG protein concentration	34
Protein concentration of troponin in standard reference preparations	35

TABLE 7: Amido Black (Schwarz) Method for Protein Assay

Application	Reference
Measurement of protein concentration by binding to a nitrocellulose membrane by filtration followed by staining with amido black. Protein concentration determined by densitometry	36
Measurement of protein in antibody-polysaccharide complexes	37
Measurement of anchorage-dependent cells	38
Measurement of cell viability in an immortalized keratinocyte cell line	39
Determination of protein concentration after transfer to nitrocellulose from SDS-PAGE gel	40

# SPECTROPHOTOMETRIC DETERMINATION OF PROTEIN CONCENTRATION IN THE SHORT-WAVELENGTH ULTRAVIOLET

W. B. Gratzner

Whereas the extinction coefficients of proteins in the aromatic absorption band at 280 nm vary widely, the spectrum at shorter wavelengths is dominated by the absorption of the peptide bond and, therefore, has only a secondary dependence on amino acid composition and conformation. Measurements in this region can therefore serve for approximate concentration determinations of any protein. The following relations are available:

1. Scopes, *Anal. Biochem.*, 59, 277 (1974):

- a.  $E(1 \text{ mg/mL}; 1 \text{ cm})$  at 205 nm = 31 with a stated error of 5%.
- b. This can be improved by applying a correction for the relatively strongly absorbing aromatic residues, by measuring the absorbance also at 280 nm. Two forms of this correction are

$$E(1 \text{ mg/ml}; 1 \text{ cm}) \text{ at } 205 \text{ nm} = 27.0 + 120 \times (A^{280}/A^{205})$$

or

$$E(1 \text{ mg/ml}; 1 \text{ cm}) \text{ at } 205 \text{ nm} = \frac{27.0}{1 - 3.85(A^{280}/A^{205})}$$

where the bracket term is the ratio of the absorbances measured at 280 and 205 nm; stated error, 2%.

2. Tombs, Soutar, and Maclagan, *Biochem. J.*, 73, 167 (1959):

$$E(1 \text{ mg/mL}; 1 \text{ cm}) \text{ at } 210 \text{ nm} = 20.5$$

3. Waddell, *J. Lab. Clin. Med.*, 48, 311 (1956): To avoid wavelength-setting error on steeply sloping curves, measurements are made at two wavelengths 10 nm apart and the absorbance difference is used to give the concentration:

$$C(\text{mg/ml}) = 0.144(A^{215} - A^{225})$$

where  $A^{215}$  and  $A^{225}$  are the absorbances read in 1 cm at 215 and 225 nm.

Note that the longer the wavelength, the lower the sensitivity of the spectrophotometric method, but the hazard of interference from ultraviolet absorbing contaminants is less.

**Abstract** Lipids are produced, transported, and recognized by the concerted actions of numerous enzymes, binding proteins, and receptors. A comprehensive analysis of lipid molecules, “lipidomics,” in the context of genomics and proteomics is crucial to understanding cellular physiology and pathology; consequently, lipid biology has become a major research target of the postgenomic revolution and systems biology. To facilitate international communication about lipids, a comprehensive classification of lipids with a common platform that is compatible with informatics requirements has been developed to deal with the massive amounts of data that will be generated by our lipid community. As an initial step in this development, we divide lipids into eight categories (fatty acyls, glycerolipids, glycerophospholipids, sphingolipids, sterol lipids, prenol lipids, saccharolipids, and polyketides) containing distinct classes and subclasses of molecules, devise a common manner of representing the chemical structures of individual lipids and their derivatives, and provide a 12 digit identifier for each unique lipid molecule. The lipid classification scheme is chemically based and driven by the distinct hydrophobic and hydrophilic elements that compose the lipid.<sup>1</sup> This structured vocabulary will facilitate the systematization of lipid biology and enable the cataloging of lipids and their properties in a way that is compatible with other macromolecular databases.—Fahy, E., S. Subramaniam, H. A. Brown, C. K. Glass, A. H. Merrill, Jr., R. C. Murphy, C. R. H. Raetz, D. W. Russell, Y. Seyama, W. Shaw, T. Shimizu, F. Spener, G. van Meer,

M. S. VanNieuwenhze, S. H. White, J. L. Witztum, and E. A. Dennis. **A comprehensive classification system for lipids.** *J. Lipid Res.* 2005. 46: 839–861.

**Supplementary key words** lipidomics • informatics • nomenclature • chemical representation • fatty acyls • glycerolipids • glycerophospholipids • sphingolipids • sterol lipids • prenol lipids • saccharolipids • polyketides

The goal of collecting data on lipids using a “systems biology” approach to lipidomics requires the development of a comprehensive classification, nomenclature, and chemical representation system to accommodate the myriad lipids that exist in nature. Lipids have been loosely defined as biological substances that are generally hydrophobic in nature and in many cases soluble in organic solvents (1). These chemical properties cover a broad range of molecules, such as fatty acids, phospholipids, sterols, sphingolipids, terpenes, and others (2). The LIPID MAPS (LIPID Metabolites And Pathways Strategy; <http://www.lipidmaps.org>), Lipid Library (<http://lipidlibrary.co.uk>), Lipid Bank (<http://lipid-bank.jp>), LIPIDAT (<http://www.lipidat.chemistry.ohiostate.edu>), and Cyberlipids (<http://www.cyberlipid.org>) websites provide useful online resources for an overview of these molecules and their structures. More accurate definitions are possible when lipids are considered from a structural and biosynthetic perspective, and many different classification schemes have been used over the years. However, for the purpose of comprehensive classification, we define lipids as hydrophobic or amphipathic small molecules that may originate entirely or in part by carbanion-based condensations of thioesters (fatty acids, polyketides, etc.) and/or by

TABLE 1: Lipid Categories and Examples

Category	Abbreviation	Example
Fatty acyls	FA	dodecanoic acid
Glycerolipids	GL	1-hexadecanoyl-2-(9 Z-octadecenoyl)- <i>sn</i> -glycerol
Glycerophospholipids	GP	1-hexadecanoyl-2-(9 Z-octadecenoyl)- <i>sn</i> -glycero-3-phosphocholine
Sphingolipids	SP	<i>N</i> -(tetradecanoyl)-sphing-4-enine
Sterol lipids	ST	cholest-5-en-3 $\beta$ -ol
Prenol lipids	PR	2 <i>E</i> ,6 <i>E</i> -farnesol
Saccharolipids	SL	UDP-3- <i>O</i> -(3 <i>R</i> -hydroxy-tetradecanoyl)- $\alpha$ D- <i>N</i> -acetylglucosamine
Polyketides	PK	aflatoxin B <sub>1</sub>

carbocation-based condensations of isoprene units (prenols, sterols, etc.). Additionally, lipids have been broadly subdivided into “simple” and “complex” groups, with simple lipids being those yielding at most two types of products on hydrolysis (e.g., fatty acids, sterols, and acylglycerols) and complex lipids (e.g., glycerophospholipids and glycosphingolipids) yielding three or more products on hydrolysis. The classification scheme presented here organizes lipids into well-defined categories that cover eukaryotic and prokaryotic sources and that is equally applicable to archaea and synthetic (man-made) lipids.

Lipids may be categorized based on their chemically functional backbone as polyketides, acylglycerols, sphingolipids, prenols, or saccharolipids. However, for historical and bioinformatics advantages, we chose to separate fatty acyls from other polyketides, the glycerophospholipids from the other glycerolipids, and sterol lipids from other prenols, resulting in a total of eight primary categories. An important aspect of this scheme is that it allows for subdivision of the main categories into classes and subclasses to handle the existing and emerging arrays of lipid structures. Although any classification scheme is in part subjective as a result of the structural and biosynthetic complexity of lipids, it is an essential prerequisite for the organization of lipid research and the development of systematic methods of data management. The classification scheme presented here is chemically based and driven by the distinct hydrophobic and hydrophilic elements that constitute the lipid. Biosynthetically related compounds that are not technically lipids because of their water solubility are included for completeness in this classification scheme.

The proposed lipid categories listed in **Table 1** have names that are, for the most part, well accepted in the literature. The fatty acyls (FA) are a diverse group of molecules synthesized by chain elongation of an acetyl-CoA primer with malonyl-CoA (or methylmalonyl-CoA) groups that may contain a cyclic functionality and/or are substituted with heteroatoms. Structures with a glycerol group are represented by two distinct categories: the glycerolipids (GL), which include acylglycerols but also encompass alkyl and 1 *Z*-alkenyl variants, and the glycerophospholipids (GP), which are defined by the presence of a phosphate (or phosphonate) group esterified to one of the glycerol hydroxyl groups. The sterol lipids (ST) and prenyl lipids (PR) share a common biosynthetic pathway via the polymerization of dimethylallyl pyrophosphate/isopentenyl pyrophosphate but have obvious differences in terms of their eventual structure and function. Another well-defined category is the sphingolipids (SP), which contain a long-chain base as their core structure. This classification does not have a glycolipids category per se but rather places

glycosylated lipids in appropriate categories based on the identity of their core lipids. It also was necessary to define a category with the term “saccharolipids” (SL) to account for lipids in which fatty acyl groups are linked directly to a sugar backbone. This SL group is distinct from the term “glycolipid” that was defined by the International Union of Pure and Applied Chemists (IUPAC) as a lipid in which the fatty acyl portion of the molecule is present in a glycosidic linkage. The final category is the polyketides (PK), which are a diverse group of metabolites from plant and microbial sources. Protein modification by lipids (e.g., fatty acyl, prenyl, cholesterol) occurs in nature; however, these proteins are not included in this database but are listed in protein databases such as GenBank (<http://www.ncbi.nlm.nih.gov>) and SwissProt (<http://www.ebi.ac.uk/swissprot/>).

## Lipid nomenclature

A naming scheme must unambiguously define a lipid structure in a manner that is amenable to chemists, biologists, and biomedical researchers. The issue of lipid nomenclature was last addressed in detail by the International Union of Pure and Applied Chemists and the International Union of Biochemistry and Molecular Biology (IUPAC-IUBMB) Commission on Biochemical Nomenclature in 1976, which subsequently published its recommendations (3). Since then, a number of additional documents relating to the naming of glycolipids (4), prenols (5), and steroids (6) have been released by this commission and placed on the IUPAC website (<http://www.chem.qmul.ac.uk/iupac/>). A large number of novel lipid classes have been discovered during the last three decades that have not yet been systematically named. The present classification includes these new lipids and incorporates a consistent nomenclature.

In conjunction with our proposed classification scheme, we provide examples of systematic (or semisystematic) names for the various classes and subclasses of lipids. The nomenclature proposal follows existing IUPAC-IUBMB rules closely and should not be viewed as a competing format. The main differences involve *a*) clarification of the use of core structures to simplify systematic naming of some of the more complex lipids, and *b*) provision of systematic names for recently discovered lipid classes.

Key features of our lipid nomenclature scheme are as follows:

- The use of the stereospecific numbering (*sn*) method to describe glycerolipids and glycerophospholipids (3). The glycerol group is typically acylated or alkylated at the *sn*-1

and/or *sn*-2 position, with the exception of some lipids that contain more than one glycerol group and archaeobacterial lipids in which *sn*-2 and/or *sn*-3 modification occurs.

- b) Definition of sphinganine and sphing-4-enine as core structures for the sphingolipid category, where the *D-erythro* or *2S,3R* configuration and *4E* geometry (in the case of sphing-4-enine) are implied. In molecules containing stereochemistries other than the *2S,3R* configuration, the full systematic names are to be used instead (e.g., *2R*-amino-1,3*R*-octadecanediol).
- c) The use of core names such as cholestane, androstane, and estrane for sterols.
- d) Adherence to the names for fatty acids and acyl chains (formyl, acetyl, propionyl, butyryl, etc.) defined in Appendices A and B of the IUPAC-IUBMB recommendations (3).
- e) The adoption of a condensed text nomenclature for the glycan portions of lipids, where sugar residues are represented by standard IUPAC abbreviations and where the anomeric carbon locants and stereochemistry are included but the parentheses are omitted. This system has also been proposed by the Consortium for Functional Glycomics (<http://web.mit.edu/glycomics/consortium/main.shtml>).
- f) The use of *E/Z* designations (as opposed to *trans/cis*) to define double bond geometry.
- g) The use of *R/S* designations (as opposed to  $\alpha/\beta$  or *D/L*) to define stereochemistries. The exceptions are those describing substituents on glycerol (*sn*) and sterol core structures and anomeric carbons on sugar residues. In these latter special cases, the  $\alpha/\beta$  format is firmly established.
- h) The common term “lyso,” denoting the position lacking a *radyl* group in glycerolipids and glycerophospholipids, will not be used in systematic names but will be included as a synonym.
- i) The proposal for a single nomenclature scheme to cover the prostaglandins, isoprostanes, neuroprostanes, and related compounds, where the carbons participating in the cyclopentane ring closure are defined and where a consistent chain-numbering scheme is used.
- j) The “*d*” and “*t*” designations used in shorthand notation of sphingolipids refer to 1,3-dihydroxy and 1,3,4-trihydroxy long-chain bases, respectively.

### Lipid structure representation

In addition to having rules for lipid classification and nomenclature, it is important to establish clear guidelines for drawing lipid structures. Large and complex lipids are difficult to draw, which leads to the use of shorthand and unique formats that often generate more confusion than clarity among lipidologists. We propose a more consistent format for representing lipid structures in which, in the simplest case of the fatty acid derivatives, the acid group (or equivalent) is drawn on the right and the hydrophobic hydrocarbon chain is on the left (**Figure 1**). Notable exceptions are found in the eicosanoid class, in which the hydrocarbon chain wraps around in a counterclockwise direction to produce a more condensed structure. Similarly, with regard to the glycerolipids and glycerophospholipids, the *radyl* chains are drawn with the hydrocarbon chains to the left and the glycerol group depicted

horizontally with stereochemistry at the *sn* carbons defined (if known). The general term “*radyl*” is used to denote either acyl, alkyl, or 1-alkenyl substituents (<http://www.chem.qmul.ac.uk/iupac/lipid/lip1n2.html>), allowing for coverage of alkyl and 1 *Z*-alkenylglycerols. The sphingolipids, although they do not contain a glycerol group, have a similar structural relationship to the glycerophospholipids in many cases and may be drawn with the C1 hydroxyl group of the long-chain base to the right and the alkyl portion to the left. This methodology places the head groups of both sphingolipids and glycerophospholipids on the right side. Although the structures of sterols do not conform to these general rules of representation, the sterol esters may conveniently be drawn with the acyl group oriented according to these guidelines. In addition, the linear prenyls or isoprenoids are drawn in a manner analogous to the fatty acids, with the terminal functional group on the right side. Inevitably, a number of structurally complex lipids, such as acylaminosugar glycans, polycyclic isoprenoids, and polyketides, do not lend themselves to these simplified drawing rules. Nevertheless, we believe that the adoption of the guidelines proposed here will unify chemical representation and make it more comprehensible.

### Databasing lipids, annotation, and function

A number of repositories, such as GenBank, SwissProt, and ENSEMBL (<http://www.ensembl.org>), support nucleic acid and protein databases; however, there are only a few specialized databases [e.g., LIPIDAT (7) and Lipid Bank (8)] that provide a catalog, annotation, and functional classification of lipids. Given the importance of these molecules in cellular function and pathology, there is an imminent need for the creation of a well-organized database of lipids. The first step toward this goal is the establishment of an ontology of lipids that is extensible, flexible, and scalable. Before establishing an ontology, a structured vocabulary is needed, and the IUPAC nomenclature of the 1970s was an initial step in this direction.

The ontology of lipids must contain definitions, meanings, and interrelationships of all objects stored in the database. This ontology is then transformed into a well-defined schema that forms the foundation for a relational database of lipids. The LIPID MAPS project is building a robust database of lipids based on the proposed ontology.

Our database will provide structural and functional annotations and have links to relevant protein and gene data. In addition, a universal data format (XML) will be provided to facilitate exportation of the data into other repositories. This database will enable the storage of curated information on lipids in a web-accessible format and will provide a community standard for lipids.

An important database field will be the LIPID ID, a unique 12 character identifier based on the classification scheme described here. The format of the LIPID ID, outlined in **Table 2**, provides a systematic means of assigning unique IDs to lipid molecules and allows for the addition of large numbers of new categories, classes, and subclasses in the future, because a maximum of 100 classes/subclasses (00 to 99) may be specified. The last four characters of the ID constitute a unique identifier within a particular subclass and are randomly assigned. By initially using numeric characters, this allows 9,999 unique IDs per subclass, but with the additional use of 26 uppercase alphabetic characters, a total of 1.68 million possible combinations can be generated, providing ample scalability within each subclass. In cases in which lipid structures are obtained from

**FIGURE 1** Representative structures for each lipid category.

**TABLE 2: Format of 12 Character LIPID ID**

Characters	Description	Example
1–2	Fixed database designation	LM
3–4	Two letter category code	FA
5–6	Two digit class code	03
7–8	Two digit subclass code	02
9–12	Unique four character identifier within subclass	7312

other sources such as LipidBank or LIPIDAT, the corresponding IDs for those databases will be included to enable cross-referencing. The first two characters of the ID contain the database identifier (e.g., LM for LIPID MAPS), although other databases may choose to use their own two character identifier (at present, LB for Lipid Bank and LD for LIPIDAT) and assign the last four or more characters uniquely while retaining characters 3 to 8, which pertain to classification. The corresponding IDs of the other databases will always be included to enable cross-referencing. Further details regarding the numbering

TABLE 3: Shorthand Notation for Selected Lipid Categories

Category	Abbreviation	Class or Subclass	Example <sup>a</sup>
GP	GPCho	Glycerophosphocholines	GPCho (16:0/9Z,12Z-18:2)
GP	GPnCho	Glycerophosphocholines	
GP	GPETn	Glycerophosphoethanolamines	
GP	GPnEtn	Glycerophosphoethanolamines	
GP	GPSer	Glycerophosphoserines	
GP	GPGro	Glycerophosphoglycerols	
GP	GPGroP	Glycerophosphoglycerophosphates	
GP	GPIns	Glycerophosphoinositols	
GP	GPInsP	Glycerophosphoinositol monophosphates	
GP	GPInsP <sub>2</sub>	Glycerophosphoinositol bis-phosphates	
GP	GPInsP <sub>3</sub>	Glycerophosphoinositol tris-phosphates	
GP	GPA	Glycerophosphates	
GP	GPP	Glyceropyrophosphates	
GP	CL	Glycerophosphoglycerophosphoglycerols	
GP	CDP-DG	CDP-glycerols	
GP	[glycan] GP	Glycerophosphoglucose lipids	
GP	[glycan] GPIns	Glycerophosphoinositolglycans	EtN-P-6Man $\alpha$ 1-2Man $\alpha$ 1-6 Man $\alpha$ 1-4GlcNa1-6GPIns (14:0/14:0)
SP	Cer	Ceramides	Cer (d18:1/9E-16:1)
SP	SM	Phosphosphingolipids	SM (d18:1/24:0)
SP	[glycan]Cer	Glycosphingolipids	NeuAc $\alpha$ 2-3Gal $\beta$ 1-4Glc $\beta$ -Cer (d18:1/16:0)
GL	MG	Monoradyl glycerols	MG (16:0/0:0/0:0)
GL	DG	Diradyl glycerols	DG (18:0/16:0/0:0)
GL	TG	Triradyl glycerols	TG (12:0/14:0/18:0)

<sup>a</sup> Shorthand notation for radyl substituents in categories GP and GL are presented in the order of *sn*-1 to *sn*-3. Shorthand notation for category SP is presented in the order of long-chain base and *N*-acyl substituent. Numbers separated by colons refer to carbon chain length and number of double bonds, respectively.

system will be decided by the International Lipids Classification and Nomenclature Committee (see below). In addition to the LIPID ID, each lipid in the database will be searchable by classification (category, class, subclass), systematic name, synonym(s), molecular formula, molecular weight, and many other parameters that are part of its ontology. An important feature will be the databasing of molecular structures, allowing the user to perform web-based substructure searches and structure retrieval across the database. This aim will be accomplished with a chemistry cartridge software component that will enable structures in formats such as MDL molfile and Chemdraw CDX to be imported directly into Oracle database tables.

Furthermore, many lipids, in particular the glycerolipids, glycerophospholipids, and sphingolipids, may be conveniently described in terms of a shorthand name in which abbreviations are used to define backbones, head groups, and sugar units and the radyl substituents are defined by a descriptor indicating carbon chain length and number of double bonds. These shorthand names lend themselves to fast, efficient text-based searches and are used widely in lipid research as compact alternatives to systematic names. The glycerophospholipids in the LIPIDAT database, for example, may be conveniently searched with a shorthand notation that has been extended to handle side chains with acyl, ether, branched-chain, and other functional groups (7). We propose the use of a shorthand notation for selected lipid categories (Table 3) that incorporates a condensed text nomenclature for glycan substituents. The abbreviations for the sugar units follow the current IUPAC-IUBMB recommendations (4).

## Lipid classes and subclasses

### Fatty acyls [FA]

The fatty acyl structure represents the major lipid building block of complex lipids and therefore is one of the most

fundamental categories of biological lipids. The fatty acyl group in the fatty acids and conjugates class (Table 4) is characterized by a repeating series of methylene groups that impart hydrophobic character to this category of lipids. The first subclass includes the straight-chain saturated fatty acids containing a terminal carboxylic acid. It could also be considered the most reduced end product of the polyketide pathway. Variants of this structure have one or more methyl substituents and encompass quite complex branched-chain fatty acids, such as the mycolic acids. The longest chain in branched-chain fatty acids defines the chain length of these compounds. A considerable number of variations on this basic structure occur in all kingdoms of life (9–12), including fatty acids with one or more double bonds and even acetylenic (triple) bonds. Heteroatoms of oxygen, halogen, nitrogen, and sulfur are also linked to the carbon chains in specific subclasses. Cyclic fatty acids containing three to six carbon atoms as well as heterocyclic rings containing oxygen or nitrogen are found in nature. The cyclopentenyl fatty acids are an example of this latter subclass. The thia fatty acid subclass contains sulfur atom(s) in the fatty acid structure and is exemplified by lipoic acid and biotin. Thiols and thioethers are in this class, but the thioesters are placed in the ester class because of the involvement of these and similar esters in fatty acid metabolism and synthesis.

Separate classes for more complex fatty acids with multiple functional groups (but nonbranched) are designated by the total number of carbon atoms found in the critical biosynthetic precursor. These include octadecanoids and lipids in the jasmonic acid pathway of plant hormone biosynthesis, even though jasmonic acids have lost some of their carbon atoms from the biochemical precursor, 12-oxophytodienoic acid (13). Eicosanoids derived from arachidonic acid include prostaglandins, leukotrienes, and other structural derivatives (14). The docosanoids contain 22 carbon atoms and derive from a common precursor, docosahexaenoic acid (15). Many members of these separate subclasses of more complex fatty acids have distinct biological activities.

TABLE 4: Fatty acyls [FA] Classes and Subclasses

Fatty acids and conjugates [FA01]
Straight-chain fatty acids [FA0101]
Methyl branched fatty acids [FA0102]
Unsaturated fatty acids [FA0103]
Hydroperoxy fatty acids [FA0104]
Hydroxy fatty acids [FA0105]

Docosanoids [FA04]
Fatty alcohols [FA05]
Fatty aldehydes [FA06]
Fatty esters [FA07]
Wax monoesters [FA0701]
Wax diesters [FA0702]
Cyano esters [FA0703]
Lactones [FA0704]
Fatty acyl-CoAs [FA0705]
Fatty acyl-acyl carrier proteins (ACPs) [FA0706]
Fatty acyl carnitines [FA0707]
Fatty acyl adenylates [FA0708]
Fatty amides [FA08]
Primary amides [FA0801]
<i>N</i> -Acyl amides [FA0802]
Fatty acyl homoserine lactones [FA0803]
<i>N</i> -Acyl ethanolamides (endocannabinoids) [FA0804]
Fatty nitriles [FA09]
Fatty ethers [FA10]
Hydrocarbons [FA11]
Oxygenated hydrocarbons [FA12]
Other [FA00]

Other major lipid classes in the fatty acyl category include fatty acid esters such as wax monoesters and diesters and the lactones. The fatty ester class also has subclasses that include important biochemical intermediates such as fatty acyl thioester-CoA derivatives, fatty acyl thioester-acyl carrier protein (ACP) derivatives, fatty acyl carnitines (esters of carnitine), and fatty adenylates, which are mixed anhydrides. The fatty alcohols and fatty aldehydes are typified by terminal hydroxy and oxo groups, respectively. The fatty amides are also *N*-fatty acylated amines and unsubstituted

amides, and many simple amides have interesting biological activities in various organisms. Fatty acyl homoserine lactones are fatty amides involved in bacterial quorum sensing (16).

Hydrocarbons are included as a class of fatty acid derivatives because they correspond to six electron reduction products of fatty acids that may have been generated by loss of the carboxylic acid from a fatty acid or fatty acyl moiety during the process of diagenesis in geological samples. Long-chain ethers also have been observed in nature. Chemical structures of the fatty acyls are shown in **Figure 2**.

### Glycerolipids [GL]

The glycerolipids essentially encompass all glycerol-containing lipids. We have purposely made glycerophospholipids a separate category because of their abundance and importance as membrane constituents, metabolic fuels, and signaling molecules. The glycerolipid category (**Table 5**) is dominated by the mono-, di- and tri-substituted glycerols, the most well-known being the fatty acid esters of glycerol (acylglycerols) (17, 18). Additional subclasses are represented by the glycerolglycans, which are characterized by the presence of one or more sugar residues attached to glycerol via a glycosidic linkage (19). Examples of structures in this category are shown in **Figure 3**. Macrocyclic ether lipids also occur as glycerolipids in the membranes of archaeobacteria (20).

### Glycerophospholipids [GP]

The glycerophospholipids are ubiquitous in nature and are key components of the lipid bilayer of cells. Phospholipids may be subdivided into distinct classes (**Table 6**) based on the nature of the polar “head group” at the *sn*-3 position of the glycerol backbone in eukaryotes and eu-bacteria or the *sn*-1 position in the case of archaeobacteria (21). In the case of the glycerophosphoglycerols and glycerophosphoglycerophosphates, a second glycerol unit constitutes part of the head group, whereas for the glycerophosphoglycerophosphoglycerols (cardiolipins), a third glycerol unit is typically acylated at the *sn*-1' and *sn*-2' positions to create a pseudosymmetrical molecule. Each head group class is further differentiated on the basis of the *sn*-1 and *sn*-2 substituents on

the glycerol backbone. Although the glycerol backbone is symmetrical, the second carbon becomes a chiral center when the *sn*-1 and *sn*-3 carbons have different substituents. A large number of trivial names are associated with phospholipids. In the systematic nomenclature, mono/di-radylglycerophospholipids with different acyl or alkyl substituents are designated by similar conventions for naming of classes (see below) and are grouped according to the common polar moieties (i.e., head groups).

Typically, one or both of these hydroxyl groups are acylated with long-chain fatty acids, but there are also alkyl-linked and 1 *Z*-alkenyl-linked (plasmalogen) glycerophospholipids, as well as dialkylether variants in prokaryotes. The main biosynthetic pathways for the formation of GPCho and GPEtn (see Table 3 for shorthand notation) were elucidated through the efforts of Kennedy and co-workers (22) in the 1950s and 1960s, and more detailed interconversion pathways to form additional classes of phospholipids were described more recently. In addition to serving as a primary component of cellular membranes and binding sites for intracellular and intercellular proteins, some glycerophospholipids in eukaryotic cells are either precursors of, or are themselves, membrane-derived second messengers. A separate class, called oxidized glycerophospholipids, is composed of molecules in which one or more of the side chains have been oxidized. Several overviews are available on the classification, nomenclature, metabolism, and profiling of glycerophospholipids (18, 23–26). Structures from this category are shown in Figure 4.

### Sphingolipids [SP]

Sphingolipids are a complex family of compounds that share a common structural feature, a sphingoid base backbone that is synthesized *de novo* from serine and a long-chain fatty acyl-CoA, then converted into ceramides, phosphosphingolipids, glycosphingolipids, and other species, including protein adducts (27, 28). A number of organisms also produce sphingoid base analogs that have many of the same features as sphingolipids (such as long-chain alkyl and vicinal amino and hydroxyl groups) but differ in other features. These have been included in this category because some are known to function as inhibitors or antagonists of sphingolipids, and in some organisms, these types of compounds may serve as surrogates for sphingolipids.

Sphingolipids can be divided into several major classes (Table 7): the sphingoid bases and their simple derivatives (such as the 1-phosphate), the sphingoid bases with an amide-linked fatty acid (e.g., ceramides), and more complex sphingolipids with head groups that are attached via phosphodiester linkages (the phosphosphingolipids), via glycosidic bonds (the simple and complex glycosphingolipids such as cerebroside and gangliosides), and other groups (such as phosphono- and arseno-sphingolipids). The IUPAC has recommended a systematic nomenclature for sphingolipids (3).

The major sphingoid base of mammals is commonly referred to as “sphingosine,” because that name was affixed by the first scientist to isolate this compound (29). Sphingosine is (2*S*,3*R*,4*E*)-2-aminooctadec-4-ene-1,3-diol (it is also called *D*-erythro-sphingosine and sphing-4-enine). This is only one of many sphingoid bases found in nature, which vary in alkyl chain length and branching, the number and positions of double bonds, the presence of additional hydroxyl groups, and other features. The structural variation has functional significance; for example, sphingoid bases in the dermis have additional hydroxyls at position 4 (phytoceramides) and/or 6 that can interact with neighboring molecules, thereby strengthening the permeability barrier of skin.

Sphingoid bases are found in a variety of derivatives, including the 1-phosphates, lyso-sphingolipids (such as sphingosine 1-phosphocholine as well as sphingosine 1-glycosides), and *N*-methyl derivatives (*N*-methyl, *N,N*-dimethyl, and *N,N,N*-trimethyl). In addition, a large number of organisms, such as fungi and sponges, produce compounds with structural similarity to sphingoid bases, some of which (such as myriocin and the fumonisins) are potent inhibitors of enzymes of sphingolipid metabolism.

Ceramides (*N*-acyl-sphingoid bases) are a major subclass of sphingoid base derivatives with an amide-linked fatty acid. The fatty acids are typically saturated or monounsaturated with chain lengths from 14 to 26 carbon atoms; the presence of a hydroxyl group on carbon 2 is fairly common. Ceramides sometimes have specialized fatty acids, as illustrated by the skin ceramide in Figure 5i, which has a 30 carbon fatty acid with a hydroxyl group on the terminal ( $\omega$ ) carbon. Ceramides are generally precursors of more complex sphingolipids. The major phosphosphingolipids of mammals are sphingomyelins (ceramide phosphocholines), whereas insects contain mainly ceramide phosphoethanolamines and fungi have phytoceramide phosphoinositols and mannose-containing head groups.

Glycosphingolipids (4) are classified on the basis of carbohydrate composition: 1) neutral glycosphingolipids contain one or more uncharged sugars such as glucose (Glu), galactose (Gal), *N*-acetylglucosamine (GlcNAc), *N*-acetylgalactosamine (GalNAc), and fucose (Fuc), which are grouped into families based on the nature of the glyco-substituents as shown in the listing; 2) acidic glycosphingolipids contain ionized functional groups (phosphate or sulfate) attached to neutral sugars or charged sugar residues such as sialic acid (*N*-acetyl or *N*-glycoloyl neuraminic acid). The latter are called gangliosides, and the number of sialic acid residues is usually denoted with a subscript letter (i.e., mono-, di- or tri-) plus a number reflecting the subspecies within that category; 3) basic glycosphingolipids; 4) amphoteric glycosphingolipids. For a few glycosphingolipids, historically assigned names as antigens and blood group structures are still in common use (e.g., Lewis x and sialyl Lewis x). Some aquatic organisms contain sphingolipids in which the phosphate is replaced by a phosphono or arsenate group. The other category includes sphingolipids that are covalently attached to proteins; for example,  $\omega$ -hydroxyceramides and  $\omega$ -glucosylceramides are attached to surface proteins of skin, and inositol-phosphoceramide are used as membrane anchors for some fungal proteins in a manner analogous to the glycosylphosphatidylinositol anchors that are attached to proteins in other eukaryotes. Some examples of sphingolipid structures are shown in Figure 5.

### Sterol lipids [ST]

The sterol category is subdivided primarily on the basis of biological function. The sterols, of which cholesterol and its derivatives are the most widely studied in mammalian systems, constitute an important component of membrane lipids, along with the glycerophospholipids and sphingomyelins (30). There are many examples of unique sterols from plant, fungal, and marine sources that are designated as distinct subclasses in this schema (Table 8). The steroids, which also contain the same fused four ring core structure, have different biological roles as hormones and signaling molecules (31). These are subdivided on the basis of the number of carbons in the core skeleton. The  $C_{18}$  steroids include the estrogen family, whereas the  $C_{19}$  steroids comprise the androgens such as testosterone and androsterone.

FIGURE 4 Representative structures for glycerophospholipids.

The  $C_{21}$  subclass, containing a two carbon side chain at the  $C_{17}$  position, includes the progestogens as well as the glucocorticoids and mineralocorticoids. The secosteroids, comprising various forms of vitamin D, are characterized by cleavage of the B ring of the core structure, hence the “seco” prefix (32). Additional classes within the sterols category are the bile acids (33), which in mammals are primarily derivatives of cholan-24-oic acid synthesized from cholesterol in the liver and their conjugates (sulfuric acid, taurine, glycine, glucuronic acid, and others). Sterol lipid structures are shown in **Figure 6**.

### Prenol lipids [PR]

Prenols are synthesized from the five carbon precursors isopentenyl diphosphate and dimethylallyl diphosphate that are produced mainly via the mevalonic acid pathway (34). In some bacteria (e.g., *Escherichia coli*) and plants, isoprenoid precursors are made by the methylerythritol phosphate pathway (35). Because the simple isoprenoids (linear alcohols, diphosphates, etc.) are formed by the successive addition of  $C_5$  units, it is convenient to classify them in this manner (**Table 9**), with a polyterpene subclass for those structures containing more than 40

carbons (i.e., >8 isoprenoid units) (36). Note that vitamin A and its derivatives and phytanic acid and its oxidation product pristanic acid are grouped under  $C_{20}$  isoprenoids. Carotenoids are important simple isoprenoids that function as antioxidants and as precursors of vitamin A (37). Another biologically important class of molecules is exemplified by the quinones and hydroquinones, which contain an isoprenoid tail attached to a quinonoid core of nonisoprenoid origin. Vitamins E and K (38, 39) as well as the ubiquinones (40) are examples of this class.

Polyprenols and their phosphorylated derivatives play important roles in the transport of oligosaccharides across membranes. Polyprenol phosphate sugars and polyprenol diphosphate sugars function in extracytoplasmic glycosylation reactions (41), in extracellular polysaccharide biosynthesis [for instance, peptidoglycan polymerization in bacteria (42)], and in eukaryotic protein *N*-glycosylation (43, 44). The biosynthesis and function of polyprenol phosphate sugars differ significantly from those of the polyprenol diphosphate sugars; therefore, we have placed them in separate subclasses. Bacteria synthesize polyprenols (called bactoprenols) in which the terminal isoprenoid unit attached to oxygen remains unsaturated, whereas in animal polyprenols (dolichols) the terminal isoprenoid is reduced. Bacterial polyprenols are typically 10 to 12 units long (40), whereas dolichols

usually consist of 18 to 22 isoprene units. In the phytopenols of plants, the three distal units are reduced. Several examples of prenil lipid structures are shown in **Figure 7**.

### Saccharolipids [SL]

We have avoided the term “glycolipid” in the classification scheme to maintain a focus on lipid structures. In fact, all eight lipid categories in the present scheme include important glycan derivatives, making the term glycolipid incompatible with the overall goal of lipid categorization. We have, in addition, coined the term “saccharolipids” to describe compounds in which fatty acids are linked directly to a sugar backbone, forming structures that are compatible with membrane bilayers. In the saccharolipids (**Table 10**), a sugar substitutes for the glycerol backbone that is present in glycerolipids and glycerophospholipids. Saccharolipids can occur as glycan or as phosphorylated derivatives. The most familiar saccharolipids are the acylated glucosamine precursors of the lipid A component of the lipopolysaccharides in Gram-negative bacteria (41). Typical lipid A molecules are disaccharides of glucosamine, which are derivatized with as many as seven fatty acyl chains (41, 45). Note that in naming these compounds, the total number of fatty acyl groups are counted regardless of the nature of the linkage (i.e., amide or ester). The minimal lipopolysaccharide required for growth in *E. coli* is a hexa-acylated lipid A that is glycosylated with two 3-deoxy-D-mannooctulosonic acid residues (see below). In some bacteria, the glucosamine backbone of lipid A is replaced by 2,3-diamino-2,3-dideoxyglucose (46); therefore, the class has been designated “Acylaminosugars.” Included also in this class are the Nod factors of nitrogen-fixing bacteria (47), such as *Sinorhizobium meliloti*. The Nod factors are oligosaccharides of glucosamine that are usually derivatized with a single fatty acyl chain. Additional saccharolipids include fatty acylated derivatives of glucose, which are best exemplified by the acylated trehalose units of certain mycobacterial lipids (11). Acylated forms of glucose and sucrose also have been reported in plants (48). Some saccharolipid structures are shown in **Figure 8**.

### Polyketides [PK]

Polyketides are synthesized by classic enzymes as well as iterative and multimodular enzymes with semiautonomous active sites that share mechanistic features with the fatty acid synthases, including the involvement of specialized acyl carrier proteins (49, 50); however, polyketide synthases generate a much greater diversity of natural product structures, many of which have the character of lipids. The class I polyketide synthases form constrained macrocyclic lactones, typically ranging in size from 14 to 40 atoms, whereas class II and III polyketide synthases generate complex aromatic ring systems (**Table 11**). Polyketide backbones are often further modified by glycosylation, methylation, hydroxylation, oxidation, and/or other processes. Some polyketides are linked with nonribosomally synthesized peptides to form hybrid scaffolds. Examples of the three polyketide classes are shown in **Figure 9**. Many commonly used antimicrobial, antiparasitic, and anticancer agents are polyketides or polyketide derivatives. Important examples of these drugs include erythromycins, tetracyclines, nystatins, avermectins, and antitumor epothilones. Other polyketides are potent toxins. The possibility of recombining and reengineering the enzymatic modules that assemble polyketides has recently stimulated the search for novel “unnatural” natural products, especially in the antibiotic arena (51, 52).

We consider this minimal classification of polyketides as the first step in a more elaborate scheme. It will be important ultimately to include as many polyketide structures as possible in a

lipid database that can be searched for substructure and chemical similarity.

## Discussion

The goals of the LIPID MAPS initiative are to characterize known lipids and identify new ones, to quantitate temporal and spatial changes in lipids that occur with cellular metabolism, and to develop bioinformatics approaches that establish dynamic lipid networks; the goals of Lipid Bank (Japan) are to annotate and curate lipid structures and the literature associated with them; and the goals of the European Lipidomics Initiative are to coordinate and organize scientific interactions and workshops associated with lipid research. To coordinate the independent efforts from three continents and to facilitate collaborative work, a comprehensive classification of lipids with a common platform that is compatible with informatics requirements must be developed to deal with the massive amounts of data that will be generated by the lipid community. The proposed classification, nomenclature, and chemical representation system was initially designed to accommodate the massive data that will result from the LIPID MAPS effort, but it has been expanded to accommodate as many lipids as possible. We also have attempted to make the system compatible with existing lipid databases and the lipids currently annotated in them. It is designed to be expandable should new categories, classes, or subclasses be required in the future, and updates will be maintained on the LIPID MAPS website. The development of this system has been enriched by interaction with lipidologists across the world in the hopes that this system will be internationally accepted and used.<sup>11†</sup>

The authors appreciate the agreement of the International Lipids Classification and Nomenclature Committee to advise on future issues involving the maintenance of these recommendations. This committee currently includes Edward A. Dennis (chair), Christian Raetz and Robert Murphy representing LIPID MAPS, Friedrich Spener representing the International Conference on the Biosciences of Lipids, Gerrit van Meer representing the European Lipidomics Initiative, and Yousuke Seyama and Takao Shimizu representing the LipidBank of the Japanese Conference on the Biochemistry of Lipids. The authors are most

appreciative of informative discussions and encouragement of this effort with Professor Richard Cammack, King's College, London, who is the Chairman of the Nomenclature Committee of IUBMB and the IUPAC/IUBMB Joint Commission on Biochemical Nomenclature. The authors thank the Consortium for Functional Glycomics (headed by Ram Sasisekharan at the Massachusetts Institute of Technology) for providing us with their text nomenclature for glycosylated structures. We are grateful to Dr. Jean Chin, Program Director at the National Institutes of General Medical Sciences, for her valuable input to this effort. This work was supported by the LIPID MAPS Large-Scale Collaborative Grant GM-069338 from the National Institutes of Health.

## PROPERTIES OF FATTY ACIDS AND THEIR METHYL ESTERS

This table gives the names and selected properties of some important fatty acids and their methyl esters. It includes most of the acids that are significant constituents of naturally occurring oils and fats. Compounds are listed first by number of carbon atoms and, secondly, by the degree of unsaturation. Both the systematic name and the common or trivial name are given, as well as the Chemical Abstracts Service Registry Number and the shorthand acid code that is frequently used. The first number in this code gives the number of carbon atoms; the number following the colon is the number of unsaturated centers (mainly double bonds). The location and orientation of the unsaturated centers follow. The symbols used are: *c* = *cis*; *t* = *trans*; *a* = acetylenic center; *e* = ethylenic center at end of chain; *ep* = *epoxy*. Thus 9*c*,11*t* indicates a double bond with *cis* orientation at the No. 9 carbon and another with *trans* orientation at the No. 11 carbon. More details on the codes can be found in Reference 1.

The table gives the molecular weight and melting point of the acid and the melting and boiling points of the methyl ester of the acid when available. A superscript on the boiling point indicates the pressure in mmHg (torr); if there is no superscript, the value refers to one atmosphere (760 mmHg). The references cover many

other fatty acids beyond those listed here and give additional properties.

We are indebted to Frank D. Gunstone for advice on the content of the table.

## COMPOSITION AND PROPERTIES OF COMMON OILS AND FATS

This table lists some of the most common naturally occurring oils and fats. The list is separated into those of plant origin, fish and other marine life origin, and land animal origin. The oils and fats consist mainly of esters of glycerol (i.e., triglycerides) with fatty acids of 10 to 22 carbon atoms. The four fatty acids with the highest concentration are given for each oil; concentrations are given in weight percent. Because there is often a wide variation in composition depending on the source of the oil sample, a range (or sometimes an average) is generally given. More complete data on composition, including minor fatty acids, sterols, and tocopherols, can be found in the references.

The acids are labeled by the codes described in the previous table, "Properties of Fatty Acids and Their Methyl Esters," which gives the systematic and common names of the acids. Thus 18:2 9c,12c indicates a C<sub>18</sub> acid with two double bonds in the 9 and 12 positions, both with a *cis* configuration (*cis,cis*-9,12-octadecadienoic acid, or linoleic acid).

The density and refractive index of the oils are typical values; superscripts indicate the temperature in °C.

Notes:

- The composition figure given for oleic acid (18:1 9c) often includes low levels of other 18:1 isomers.

- In some oils where a concentration is given for 18:2 9c,12c (linoleic acid), other isomers of 18:2 may be included.
- Likewise, where a concentration is given for 18:3 9c,12c,15c ( $\alpha$ -linolenic acid), other isomers of 18:3 may be included.
- The acid 20:5 6c,9c,12c,15c,17c, which is prevalent in many fish oils, is often abbreviated as 20:5  $\omega$ -3 or 20:5 n-3.

The assistance of Frank D. Gunstone in preparing this table is gratefully acknowledged.

<sup>a</sup> Jojoba oil consists primarily of wax esters of the acids listed here and long-chain alcohols.

<sup>b</sup> Kapok oil also contains up to 15% cyclopropene acids.

<sup>c</sup> Stillingia oil also contains 5–10% *trans, cis*-2,4-decadienoic acid (stillingic acid, 10:2 2t,4c).

<sup>d</sup> Capelin oil also contains about 10% 16:1.

## PROSTAGLANDINS AND RELATED FATTY-ACID-DERIVED MATERIALS

- Eicosanoid** The term eicosanoid is derived from “icos” referring to 20. The term eicosanoid refers to a diverse group of long-chain derivatives of eicosanoic acid which is more commonly referred to as arachidic acid. Arachidic acid is a saturated C<sub>20</sub> fatty acid. Eicosanoid is used to include leukotriene, prostaglandins, lipoxins, and other derivatives of arachidonic acid. See Famaey, J.P., Phospholipases, eicosanoid production and inflammation, *Clin. Rheumatol.* 1, 84-94, 1982; Weber, P.C., Membrane phospholipid modification by dietary n-3 fatty acids: effects on eicosanoid formation and cell function, *Prog. Clin. Biol. Res.* 282, 263-294, 1988; Decker, K., Signal paths and regulation of superoxide, eicosanoid and cytokine formation in macrophages of rat liver, *Adv. Exp. Med. Biol.* 283, 507-520, 1991; Granström, E. and Kindahl, H., A critical approach to eicosanoid assay, *Adv. Prostaglandin Thromboxane Leukot. Res.* 21A, 295-302, 1991; Clissold, D. and Thickitt, C., Recent eicosanoid chemistry, *Nat. Prod. Rep.* 11, 621-637, 1994; Breyer, R.M., Kennedy, C.R., Zhang, Y., and Breyer, M.D., Structure-function analyses of eicosanoid receptors. Physiologic and therapeutic implications, *Ann. N. Y. Acad. Sci.* 905, 221-231, 2000; Leslie, C.C., Regulation of arachidonic acid availability for eicosanoid production, *Biochem. Cell. Biol.* 82, 1-17, 2004; and Serhan, C.N., Novel eicosanoid and docosanoic mediators: resolvins, docosatrienes, and neuroprotectins, *Curr. Opin. Clin. Nutr. Metab. Care* 8, 115-121, 2005.
- Leukotriene** A group of biologically active lipids containing three conjugated double bonds derived from arachidonic acid. These materials were first obtained from leukocytes. Certain leukotrienes (C<sub>4</sub>, D<sub>4</sub>, and LTE<sub>4</sub>) have been designated as cysteinyl leukotrienes (Evans, J.F., The cysteinyl leukotriene receptors, *Prostaglandins Leukot. Essent. Fatty Acids* 69, 117-122, 2003). See also Samuelsson, B., Borgeat, P., Hammarström, S., and Murphy, R.C., Introduction of a nomenclature: leukotrienes, *Prostaglandins* 17, 785-787, 1979; Borgeat, P. and Samuelsson, B., Transformation of arachidonic acid by rabbit polymorphonuclear leukocytes. Formation of a novel dihydroxyeicosatetraenoic acid, *J. Biol. Chem.* 254, 2643-2646, 1979; Lam, B.K. and Austen, K.F., Leukotriene C<sub>4</sub> synthase: a pivotal enzyme in cellular biosynthesis of the cysteinyl leukotrienes, *Prostaglandins Other Lipid Mediat.* 68-69, 511-520, 2002; Capra, V., Molecular and functional aspects of human cysteinyl leukotriene receptors, *Pharmacol. Res.* 50, 1-11, 2004; Norel, X. and Brink, C., The quest for new cysteinyl-leukotriene and lipoxin receptors: recent clues, *Pharmacol. Ther.* 103, 81-94, 2004; Currie, G.P. and McLaughlin, K., The expanding role of leukotriene receptor antagonists in chronic asthma, *Ann. Allergy Asthma Immunol.* 97, 731-741, 2006; and Zaitsu, M., Imbalance between leukotriene synthesis and catabolism contributes to the pathogenesis of allergic diseases, *Med. Chem.* 3, 365-368, 2007
- Lipoxin** A family of trihydroxyeicosatetraenoic acids derived from arachidonic acid which are mediators of inflammation and infection. The lipoxin receptor (ALX) is also considered a chemoattractant receptor. See Ramstedt, U., Ng, J., Wigzell, H., *et al.*, Action of novel eicosanoids lipoxin A and B on human natural killer cell cytotoxicity: effects on intracellular cAMP and target cell binding, *J. Immunol.* 135, 3434-3438, 1985; Hansson, A., Serhan, C.N., Haeggström, J., *et al.*, Activation of protein kinase C by lipoxin A and other eicosanoids. - Prostaglandins** A group of unsaturated, oxygenated long-chain fatty acids having diverse biological function. The material was first isolated by von Euler from the prostate gland (von Euler, U.S., On the specific vaso-dilating and plain muscle stimulating substance from accessory genital glands in man and certain animals (prostagland and vesio glandin), *J. Physiol.* 88, 213-234, 1936). See also Morrow, J.D., Chen, Y., Brame, C.J., *et al.*, The isoprostanes: unique prostaglandin-like products of free radical-initiated lipid peroxidation, *Drug Metab. Rev.* 31, 117-139, 1999; Hylton, C. and Robin, A.L., Update on prostaglandin analogs, *Curr. Opin. Ophthalmol.* 14, 65-69, 2003; Serhan, C.N. and Levy, B., Success of prostaglandin E<sub>2</sub> in structure-function is a challenge for structure-based therapeutics, *Proc. Nat. Acad. Sci. USA* 100, 8609-8611, 2003; Simmons, D.L., Botting, R.M., and Hla, T., Cyclooxygenase isozymes: The biology of prostaglandin synthesis and inhibition, *Pharmacol. Rev.* 56, 387-437, 2004; Samuelsson, B., Morgenstern, R., and Jakobsson, P.J., Membrane prostaglandin E synthase-1: a novel therapeutic target, *Pharmacol. Rev.* 59, 207-224, 2007.

Properties of Vitamins.....	225
Biological Characteristics of Vitamins.....	237
Properties for Ascorbic Acid and Ascorbate-2-Sulfate.....	241
Vitamins.....	243
Vitamin Names Discarded.....	251

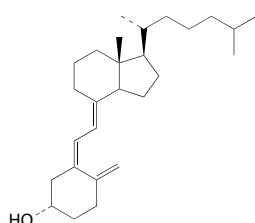

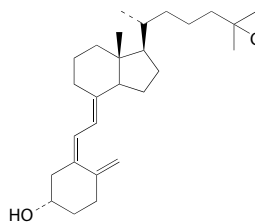

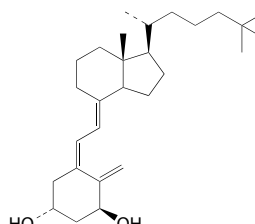

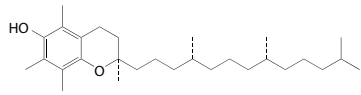

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<b>VITAMIN A</b>				
<b>Retinol</b> Vitamin A alcohol Vitamin A <sub>1</sub> Axerophthol Anti-infective vitamin Antixerophthalmia factor Lard factor Biosterol Oleovitamin A 3,7-Dimethyl-9-(2,6,6-trimethyl-1-cyclohexen-1-yl)-2,4,6,8-nonatetraen-1-ol 2,6,6-Trimethyl-1-8'-hydroxy-3',7' dimethylnona-1',3',5',7'-tetraenyl cyclohex-1-ene	 $C_{20}H_{30}O$ mol wt 286.44	Pale yellow prism crystals; mp 62 to 64°C (all <i>trans</i> ); $\lambda_{max} = 325$ nm (ethanol); $E_{1cm}^{1\%} = 1,835$ ; optically inactive; 1 mg = 3,333 IU or USP units	Sol in most organic solvents; sol in fats and oils; insol in water and glycerol	Unstable to oxygen, air, and UV light; esters relatively more stable
<b>Dehydroretinol</b> Retinol <sub>2</sub> Vitamin A <sub>2</sub> 3-Dehydroretinol	 $C_{20}H_{28}O$ mol wt 284.42	Yellow crystals or oil; mp 17 to 19°C (all <i>trans</i> ); $\lambda_{max} = 288, 352$ nm (ethanol); $E_{1cm}^{1\%} = 820, 1,450$ ; optically inactive; 1 mg = 1,333 IU or USP units	Sol in most organic solvents; sol in fats and oils; insol in water and glycerol	Unstable to oxygen
<b>Retinaldehyde<sup>a,b</sup></b> Retinal <sup>a</sup> Vitamin A aldehyde Retinene Axerophthal	 $C_{20}H_{28}O$ mol wt 284.42	Orange crystals; mp 61 to 64°C (all <i>trans</i> ); $\lambda_{max} = 373$ nm (cyclohexane); $E_{1cm}^{1\%} = 1,548$ ; all <i>trans</i> retinal has about 90% of the biopotency of all <i>trans</i> vitamin A acetate	Sol in most organic solvents; sol in fats and oils; practically insol in water	Unstable to oxygen
<b>Retinoic acid</b> Vitamin A acid Tretinoin 3,7-Dimethyl-9-(2,6,6-trimethyl-1-cyclohexen-1-yl)-2,4,6,8-nonatetraenoic acid	 $C_{20}H_{28}O_2$ mol wt 300.44	Crystals; mp 180 to 182°C (all <i>trans</i> ); $\lambda_{max} = 350$ nm (ethanol); $E_{1cm}^{1\%} = 1,510$ ; fully active for growth but not for visual function or reproduction	Sol in most organic solvents and oils	Unstable and subject to oxidation but more stable than alcohol or esters

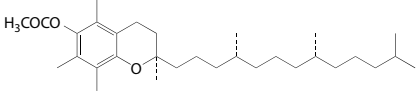

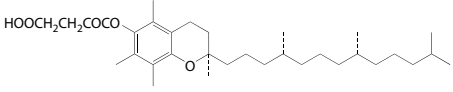

## PROPERTIES OF VITAMINS (Continued)

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<b>VITAMIN A (Continued)</b>				
<b>Retinyl acetate</b> Vitamin A acetate	 $C_{22}H_{32}O_2$ mol wt 328.5	Yellow prismatic crystals; mp 57 to 60°C (all <i>trans</i> ); $\lambda_{max} = 326$ nm (ethanol) $E_{1\%}^{1\text{cm}} = 1,550$ ; 1 mg = 2,907 IU or USP units	Like retinol; insol in water	Unstable but more stable than alcohol; can be stabilized
<b>Retinyl palmitate</b> Vitamin A palmitate	 $C_{36}H_{60}O_2$ mol wt 524.8	Yellow amorphous or crystalline; mp 27 to 29°C (all <i>trans</i> ) $\lambda_{max} = 325$ to 328 nm (ethanol); $E_{1\%}^{1\text{cm}} = 940$ to 975; 1 mg = 1,820 IU or USP units	Like retinol; insol in water	Unstable but more stable than alcohol or acetate; can be stabilized
<b>PROVITAMIN A CAROTENOIDS</b>				
<b><math>\beta</math>-Carotene</b>	 $C_{40}H_{56}$ mol wt 536.89	Deep purple prisms or red leaflet crystals; mp 180 to 182°C (all <i>trans</i> ); $\lambda_{max} = 273, 453, 481$ (petroleum ether); $E_{1\%}^{1\text{cm}} = 383, 2,592, 2,268$ ; optically inactive; 1 mg = 1,667 to 333 IU (depending on species fed)	Slightly sol in most organic solvents; very slightly sol in alcohol and oils; insol in glycerol and water	Unstable to oxygen; oxidizes to colorless products; can be used, however, as food color
<b><math>\beta</math>-Apo-8'-carotenal</b>	 $C_{30}H_{40}O$ mol wt 416.65	Dark violet crystals; mp 136 to 140°C (all <i>trans</i> ); $\lambda_{max} = 461$ and 488 nm (cyclohexane); $E_{1\%}^{1\text{cm}} = 2,640$ at 461; 1 mg = 1,220 IU (rat)	Sol in most organic solvents; slightly sol in alcohol; insol in glycerol and water	Unstable to oxygen; can be used, however, as food color
<b>VITAMIN D</b>				
<b>Ergocalciferol</b> Vitamin D <sub>2</sub> Activated ergosterol Calciferol Oleovitamin D <sub>2</sub> Viosterol 9,10-Secoergosta-5,7,10(19),-22-tetraen-3-ol Irradiated ergosta-5,7,22-trien-3 $\beta$ -ol	 $C_{28}H_{44}O$ mol wt 396.66	White prism crystals; mp 115 to 118°C; $\lambda_{max} = 264$ nm (hexane); $E_{1\%}^{1\text{cm}} = 459$ ; $[\alpha]_D^{25} = +103$ to 106 (alcohol); 1 mg = 40,000 IU or USP units	Sol in most organic solvents; slightly sol in oils; insol in water	Crystals relatively unstable to air, accelerated by unsaturated fat and trace mineral contact; can be stabilized

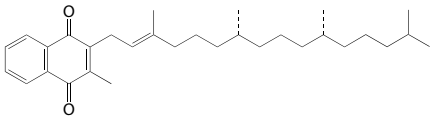

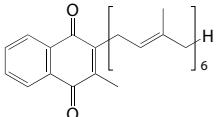

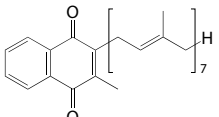

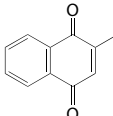

## PROPERTIES OF VITAMINS (Continued)

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<b>VITAMIN D (Continued)</b>				
<b>Cholecalciferol</b> Vitamin D <sub>3</sub> Activated 7-dehydrocholesterol Oleovitamin D <sub>3</sub> 22,23-Dihydro-24-demethylcalciferol Activated 5,7-cholestadien-3β-ol	 <chem>CC(C)CCCC[C@H]1CC[C@@H]2[C@@]1(CC[C@H]3[C@H]2CC=C4[C@@]3(CC[C@@H](C4)O)C)C</chem> C <sub>27</sub> H <sub>44</sub> O mol wt 384.65	White, fine needle crystals; mp 84 to 88°C; λ <sub>max</sub> = 264 nm (hexane); E <sub>1cm</sub> <sup>1%</sup> = 450 490; [α] <sub>D</sub> <sup>25</sup> = +105 to 112° (alcohol); 1 mg = 40,000 IU or USP units; E <sub>mol</sub> = 18,300 (ethanol)	Like D <sub>2</sub>	Similar to D <sub>2</sub>
<b>25-Hydroxycholecalciferol</b>	 <chem>CC(C)(O)CCCC[C@H]1CC[C@@H]2[C@@]1(CC[C@H]3[C@H]2CC=C4[C@@]3(CC[C@@H](C4)O)C)C</chem> C <sub>27</sub> H <sub>44</sub> O <sub>2</sub> mol wt 416.65	Colorless, fine, needlelike crystals; mp 97 to 108°C; [α] <sub>D</sub> <sup>25</sup> = +78 (dioxane); λ <sub>max</sub> = 264 nm E <sub>1 mol</sub> = 17,400 (ethanol)	Similar to D <sub>3</sub>	Similar to D <sub>3</sub>
<b>1α,25-Dihydroxycholecalciferol</b>	 <chem>CC(C)(O)CCCC[C@H]1CC[C@@H]2[C@@]1(CC[C@H]3[C@H]2CC=C4[C@@]3(CC[C@@H](C4)O)C)C</chem> C <sub>27</sub> H <sub>44</sub> O <sub>2</sub> mol wt 400.65	Colorless, fine, needlelike crystals; mp 113 to 114°C; [α] <sub>D</sub> <sup>25</sup> = +48 (ethanol); λ <sub>max</sub> = 264 nm; E <sub>1 mol</sub> = 14,270 (ethanol)	Sol in esters, ethers, and alcohols	Similar to D <sub>3</sub>
<b>VITAMIN E</b>				
<b>d-α-Tocopherol</b> 2D,4'D,8'D-α-Tocopherol 2R,4'R,8'R-α-Tocopherol Antisterility factor 5,7,8-Trimethyltolcol 2,5,7,8-Tetramethyl-2-(4',8',12'-trimethyltridecyl)-6-chromanol Abbreviation: α-T	 <chem>CC(C)CCCC(C)CCCC(C)CCCC(C)CCCC(C)C1=CC(=C(C)C(C)C1)O</chem> C <sub>29</sub> H <sub>50</sub> O <sub>2</sub> mol wt 430.69	Pale yellow viscous oil; mp 2.5 to 3.5°C; bp 200 to 220°C; (0.1 mm); λ <sub>max</sub> = 292 (ethanol); E <sub>1cm</sub> <sup>1%</sup> = 74 to 76; [α] <sub>D</sub> <sup>25</sup> = 0.32° (ethanol), K <sub>3</sub> Fe (CN) <sub>6</sub> oxidation product: [α] <sub>D</sub> <sup>25</sup> = + 26° (isooctane); 1 mg = 1.49 IU	Very sol in oils, fats, and many organic solvents; insol in water	Free tocopherol very unstable to air, iron salts, and bleaching agents; can be stabilized; esters quite stable

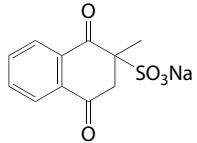

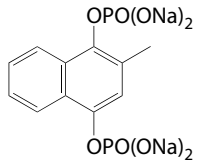

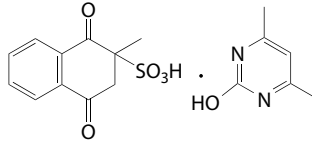

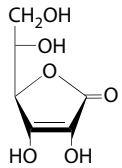

## PROPERTIES OF VITAMINS (Continued)

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<i>VITAMINE (Continued)</i>				
<b><i>dl</i>-<math>\alpha</math>-Tocopherol</b> 2DL,4'DL,8'DL- $\alpha$ -Tocopherol 2RS,4'RS,8'RS- $\alpha$ -Tocopherol <i>all-rac</i> - $\alpha$ -Tocopherol		Pale yellow viscous oil; $\lambda_{\max} = 292$ (ethanol); $E_{1\text{cm}}^{1\%} = 72$ to 76; 1 mg = 1.10 IU	Very sol in oils, fats, and many organic solvents; insol in water	Free tocopherol very unstable to air, iron salts, and bleaching agents; can be stabilized; esters quite stable
<b><i>d</i>-<math>\alpha</math>-Tocopheryl acetate</b> <i>d</i> , $\alpha$ -Tocopheryl acetate <i>d</i> , $\alpha$ -Tocopherol acetate 2,5,7,8-Tetramethyl-2- (4'8',12'-trimethyltridecyl) 6-chromanol acetate 2D,4'D,8'D- $\alpha$ -tocopheryl acetate 2R,4'R,8'R- $\alpha$ -tocopheryl acetate	 $C_{31}H_{52}O_3$ mol wt 472.73	Pale yellow crystals; mp 28°C; $\lambda_{\max} =$ 284 nm (ethanol); $E_{1\text{cm}}^{1\%} = 43.6$ ; $[\alpha]_D^{25} =$ + 3.2° (ethanol); 1 mg = 1.36 IU	Like $\alpha$ -tocopherol	Relatively stable
<b><i>dl</i>-<math>\alpha</math>-Tocopheryl acetate</b> 2DL,4'DL,8'DL- $\alpha$ -tocopheryl acetate 2RS,4'RS,8'RS- $\alpha$ -tocopheryl acetate <i>all-rac</i> - $\alpha$ -Tocopheryl acetate		Yellow viscous oil; bp 184°C (0.01 mm), 194°C (0.025 mm), 224°C (0.3 mm); $\lambda_{\max} = 284$ nm (ethanol); $E_{1\text{cm}}^{1\%} =$ 43.6; 1 mg = 1.00 IU		
<b><i>d</i>-<math>\alpha</math>-Tocopheryl acid succinate</b> 2D,4'D,8'D-s,q 2D,4'D,8'- $\alpha$ -Tocopheryl acid succinate 2R,4'R,8'R- $\alpha$ -Tocopheryl acid succinate		White crystals; mp 73 to 78°C; $\lambda_{\max} = 286$ nm (ethanol); $E_{1\text{cm}}^{1\%} = 38.5$ ; 1 mg = 1.21 IU	Less sol than acetate	Relatively stable
<b><i>dl</i>-<math>\alpha</math>-Tocopheryl acid succinate</b> 2DL,4'DL,8'DL- $\alpha$ -Tocopheryl acid succinate 2RS,4'RS,8'RS- $\alpha$ -Tocopheryl acid succinate <i>all-rac</i> - $\alpha$ -Tocopheryl acid succinate	 $C_{33}H_{54}O_5$ mol wt 530.80	White crystals; $\lambda_{\max} = 284$ nm; $E_{1\text{cm}}^{1\%} = 38.5$ ; 1 mg = 0.89 IU	Less sol than acetate	Relatively stable

## PROPERTIES OF VITAMINS (Continued)

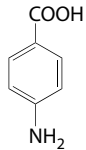

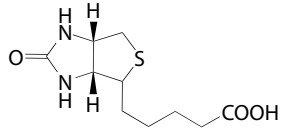

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<b>VITAMIN K</b>				
<b>Phtylmenaquinone</b> Vitamin K <sub>1</sub> Antihemorrhagic vitamin Phylloquinone Phytylmenadione Phytonadione Coagulation vitamin Prothrombin factor 2-Methyl-3-phytyl-1,4-naphthoquinone Abbreviation: K <sup>a</sup> or PMQ <sup>b</sup>	 $C_{31}H_{46}O_2$ mol wt 450.71	Yellow viscous oil; mp $-20^{\circ}C$ ; $\lambda_{max}=243, 248, 261, 269,$ $325\text{ nm (isooctane)}$ ; $E_{1\text{ cm}}^{1\%}=425, 428,$ $424,424, 350$ ; $[\alpha]_D^{20}=-0.4^{\circ}$ (benzene)	Sol in many organic solvents; insol in water	Fairly stable to heat decomposed by sunlight and alkali; can be stabilized
<b>Prenylmenaquinone-6</b> Vitamin K <sub>2</sub> K <sub>2</sub> (30) Farnoquinone Menaquinone-6 2-Methyl-2-difarnesyl-1,4-naphthoquinone Abbreviation: MQ-6	 $n=6\ C_{41}H_{56}O_2$ mol wt 580.89	Yellow crystals; mp $53.5\text{ to }54.5^{\circ}C$ ; $\lambda_{max}=243, 248, 261,$ $270, 325\text{ nm (petroleum ether)}$ ; $E_{1\text{ cm}}^{1\%}=304, 320, 290, 292, 53$	Slightly less sol than K <sub>1</sub>	Similar to K <sub>1</sub>
<b>Prenylmenaquinone-7</b> K <sub>2</sub> (35) Menaquinone-7 2-Methyl-3-all <i>trans</i> -farnesylgeranylgeranyl- 1,4-naphthoquinone Abbreviation: MQ-7	 $n=7\ C_{46}H_{64}O_2$ mol wt 649.02	Yellow crystals; mp $57^{\circ}C$ ; $\lambda_{max}=243,$ $248, 261, 270, 325\text{ nm (petroleum}$ <i>ether)</i> ; $E_{1\text{ cm}}^{1\%}=278, 295, 266, 267, 48$	–	Similar to K <sub>1</sub>
<b>Menaquinone</b> Vitamin K <sub>3</sub> Menadione Menaphthone 2-Methyl-1,4-naphthoquinone Abbreviation: MK	 $C_{11}H_8O_2$ mol wt 172.19	Bright yellow crystals; mp $105\text{ to}$ $107^{\circ}C$ ; $\lambda_{max}=244, 253, 264, 325, 328$ $\text{nm (hexane)}$ ; $E_{1\text{ cm}}^{1\%}=1,150$ (at 244 nm)	Sol in many organic solvents; insol in water; water sol forms are available	Fairly stable in air; decomposed by sun light

## PROPERTIES OF VITAMINS (Continued)

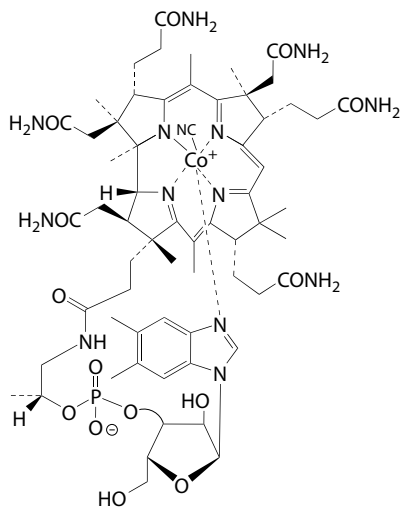

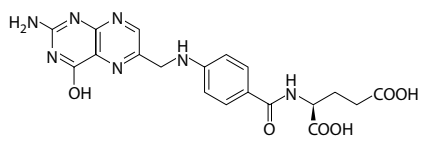

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<i>VITAMIN K WATER SOLUBLE COMPOUNDS</i>				
<b>Menadione sodium bisulfite</b> 2-Methyl-1,4-naphthoquinone sodium bisulfite Abbreviation: MSB	  C <sub>11</sub> H <sub>8</sub> O <sub>2</sub> NaHSO <sub>3</sub> ·3H <sub>2</sub> O mol wt 330.29	White hygroscopic crystals; λ <sub>max</sub> <sup>1%</sup> =229, 267 nm (aqueous solution); E <sub>1cm</sub> <sup>1%</sup> = 868, 290	50, water; sol in alcohol; almost insol in benzene and water	–
<b>Menadiol diphosphate (tetrasodium salt)</b> 2-Methyl-1,4-naphthalenediol diphosphoric acid ester tetrasodium salt	  C <sub>11</sub> H <sub>8</sub> Na <sub>4</sub> O <sub>8</sub> P <sub>2</sub> mol wt 422.09 (anhydrous) 530.18 (hexahydrate)	Hexahydrate, white to pinkish crystals; hygroscopic	Very sol in water; insol in ether and acetane	–
<b>Menadione dimethyl-pyrimidinol bisulphate</b> Abbreviation: MPB	  C <sub>17</sub> H <sub>18</sub> O <sub>6</sub> N <sub>2</sub> S mol wt 378.41	White crystals; mp 215 to 217°C λ <sub>max</sub> <sup>1%</sup> =229, 267, 297 nm (water); E <sub>1cm</sub> <sup>1%</sup> = 810, 285, 234	1, water	–
<i>VITAMIN C</i>				
<b>Ascorbic acid</b> L-Ascorbic acid Vitamin C Antiscorbutic factor Cevitamic acid Hexuronic acid Antiskorbutin L-Threo-3-ketohexonic acid-eno-lactone L-Threo-2,3,4,5,6-pentahydroxy-2-hexene-γ-lactone L-3-Ketothreo-hexuronic acid lactone	  C <sub>6</sub> H <sub>8</sub> O <sub>6</sub> mol wt 176.13	Colorless or white crystals; mp 190 to 192°C; (decomposes); λ <sub>max</sub> <sup>1%</sup> =245 nm (aqueous solution); E <sub>1cm</sub> <sup>1%</sup> = 560; [α] <sub>D</sub> <sup>25</sup> = +20.5 to 21.5° (aqueous solution); 1 mg = 20 IU or USP units; characteristic acid taste	33, water; 3.5, alcohol; 1, glycerol; insol in oils and most organic solvents	Stable to air when dry; oxidizes in solution; catalyzed by metals, copper and iron, and by alkali

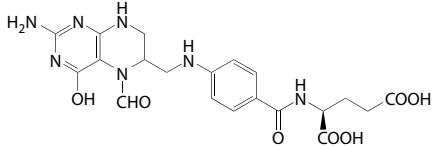

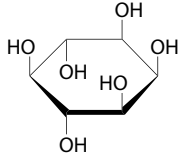

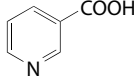

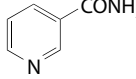

## PROPERTIES OF VITAMINS (Continued)

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<b>PABA</b>				
<b>p-Aminobenzoic acid</b> PABA 4-Aminobenzoic acid Achromotrichia factor Antigray hair factor	 $C_7H_7NO_2$ mol wt 137.13	Monoclinic prisms; mp 187°C; $\lambda_{max}$ =266 nm (water); $E_{1cm}^{1\%}$ -1,070; optically inactive	0.5, water; very sol in alcohol, ether and glacial acetic acid; slightly sol in benzene	Stable in dry form; unstable in presence of ferric salts and oxidizing agents
<b>BIOTIN</b>				
<b>d-Biotin</b> Vitamin H Coenzyme R Factor X Bios 11 or 11 B Egg white injury preventative or factor $\beta$ -Hexahydro-2-oxo-1 H-thiene [3,4]-Imidazole-4-valeric acid 3,4-(2'-Ketoimidazolido)-2-( $\omega$ - carboxybutyl)-thiophane	 $C_{10}H_{16}N_2O_3S$ mol wt 244.31	Colorless needle crystals; mp 230 to 233°C (decomposes); $[\alpha]_D^{21}$ = +91° (0.1 N NaOH)	0.020, water; 0.080 alcohol; more sol in hot water or dilute alkali	Stable, dry, in air and heat; stable in acid solution; less stable in alkali solution
<b>CHOLINE</b>				
<b>Choline</b> Bilineurine, amantine, gossypine, vidine ( $\beta$ -Hydroxyethyl) trimethylammonium hydroxide	$(H_3C)_3N(OH)CH_2CH_2OH$  $C_5H_{15}NO_2$ mol wt 121.18	Viscous hygroscopic liquid or colorless crystals; optically inactive	Very sol in water and alcohol; insol in ether	Stable in aqueous solution; decomposed by hot alkali
<b>Chloride salt</b> Choline chloride ( $\beta$ -Hydroxyethyl) trimethylammonium chloride (2-Hydroxyethyl) trimethylammonium chloride	$[(H_3C)_3NCH_2CH_2OH]Cl^-$  $C_5H_{14}ClNO$ mol wt 139.63	Deliquescent hygroscopic white crystals; optically inactive	Like choline	Similar to choline

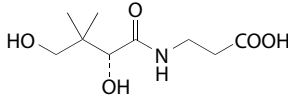

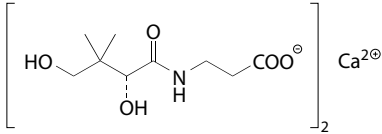

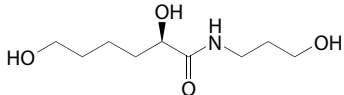

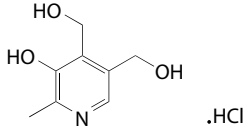

## PROPERTIES OF VITAMINS (Continued)

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<b>VITAMIN B<sub>12</sub></b>				
<b>Cyanobalamin</b> Vitamin B <sub>12</sub> Antipernicious anemia factor <i>Lactobacillus lactis</i> -Dorner factor Animal protein factor Extrinsic factor Zoopherin 5,6-Dimethylbenzimidazolyl cyanocobamide	 <p><math>C_{63}H_{88}N_{14}O_{14}PCo</math> mol wt 1,355.42</p>	Dark red crystals; mp > 212°C (decomposes); $\lambda_{max}=278, 361, 550$ nm (aqueous solution); $E_{1cm}^{1\%}=115,204, 63$ ; $[\alpha]_{D}^{25}=-59\pm 9^{\circ}$ (aqueous solution)	1.25, water; sol in alcohol, insol in chloroform, acetone, and ether	Most stable in aqueous solution at pH 4.5 to 5; decomposes slowly in weak acid or alkali; decomposition accelerated by oxidizing and reducing agents, ferrous salts, etc.
<b>FOLIC ACID<sup>a</sup> OR FOLACIN<sup>b</sup></b>				
<b>Pteroylglutamic acid</b> Folic acid+ Folacin Vitamin M <i>Lactobacillus casei</i> factor Vitamin Bc, B <sub>10</sub> or B <sub>11</sub> Norite eluate factor Factor U or R Abbreviation: PGA+ or PteGlu <sup>a</sup> <i>N</i> -[4-([2-Amino-4-hydroxy-6-pteridyl)methyl]amino)-benzoyl] glutamic acid	 <p><math>C_{19}H_{19}N_7O_6</math> mol wt 441.40</p>	Yellowish-orange crystals; mp > 250°C (decomposes); $\lambda_{max}=256, 283, 265$ nm (alkaline solution); $E_{1cm}^{1\%}=603, 600, 215$	Sol in acetic acid, alkaline solution; very sol in acetone; insol in chloroform, ether and benzene	Relatively stable dry; unstable in acid medium; decomposed by sunlight and heat

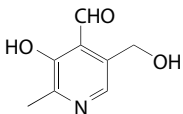

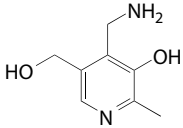

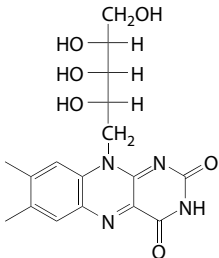

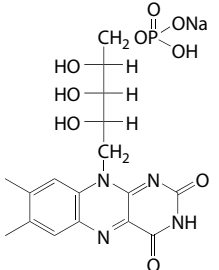

## PROPERTIES OF VITAMINS (Continued)

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<b>FOLIC ACID<sup>a</sup> OR FOLACIN<sup>b</sup> (Continued)</b>				
<b>5-Formyltetrahydrofolic acid</b> Folinic acid [N-[p-[(2-Amino-5-formyl-5,6,7,8-tetrahydro-4-hydroxy-6-pteridiny)methyl] amino] benzoyl]glutamic acid  Citrovorum factor Leucovorin Abbreviation: N <sup>5</sup> -formyl THFA or N <sup>5</sup> -F-PGAH <sub>4</sub> or 5-HCO-H <sub>4</sub> PteGlu	 $C_{20}H_{23}N_7O_7$ mol wt 473.44	Colorless crystals; mp 240 to 250°C (decomposes); $\lambda_{max}$ =282 nm (alkaline solution); = +14.26°	Very slightly sol in water	More stable at neutral or mild alkaline pH
<b>INOSITOL</b>				
<b>Myo-inositol</b> Inositol meso-Inositol <i>i</i> -Inositol Bios 1 Inosite Mouse antialopecia factor Rat antispectacle eye factor Hexahydroxycyclohexane Cyclohexanehexol, cyclohexitol	 $C_6H_{12}O_6$ mol wt 180.16	White crystals; mp 225 to 227°C (anhydrous); mp 218°C (dihydrate); optically inactive; sweet taste	15, water; insol in absolute alcohol and ether	Relatively stable
<b>NIACIN</b>				
<b>Nicotinic acid</b> Niacin Antiblacktongue factor Pellegra preventive (PP) factor Vitamin PP Pyridine-3-carboxylic acid Pyridine- $\beta$ -carboxylic acid	 $C_6H_5NO_2$ mol wt 123.11	Colorless or white needles; mp 235 to 237°C; $\lambda_{max}$ =261 nm (0.1 N HCl), 263 nm (pH 11); $E_{1cm}^{1\%}$ =435, 260; optically inactive	1.6, water; 0.73 alcohol; insol in ether	Stable to air, light, and PH
<b>Nicotinamide</b> Niacinamide Nicotinic acid amide Vitamin PP Vitamin B <sub>3</sub> 3-Pyridinecarboxylic acid amide	 $C_6H_6N_2O$ mol wt 122.13	Colorless or white needles; mp129 to 131°C; $\lambda_{max}$ =261 nm (0.1 N HCl), 262 nm (pH 11); $E_{1cm}^{1\%}$ =432, 250; optically inactive	100, water; 66.6, alcohol; 10 glycerol; slightly sol in ether	Stable in air and heat, light, and pH (may hydrolyze to nicotinic acid)

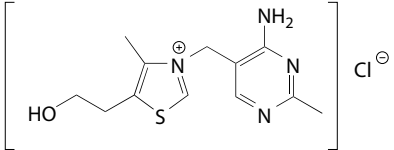

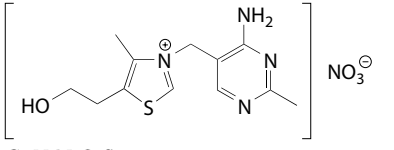

## PROPERTIES OF VITAMINS (Continued)

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<b>PANTOTHENIC ACID</b>				
<b>Pantothenic acid, D-(+)</b> Chick antidermatitis factor Liver filtrate factor Antidermatosis vitamin Vitamin B <sub>5</sub> , D-(+)-N-(2,4-Dihydroxy-3,3-dimethylbutyryl)-β-alanine Pantoyl-β-alanine	 $C_9H_{17}NO_5$ mol wt 219.23	Colorless, hygroscopic, viscous oil; $[\alpha]_D^{25} = +37.5^\circ$ (aqueous solution); only d-form is biologically active	Freely sol in water and acetic acid; moderately sol in alcohol; insol in benzene and chloroform	Stable at near neutral pH (5 to 7); unstable in acid or alkali; labile to prolonged heat
<b>Calcium salt</b> Calcium pantothenate	 $C_{18}H_{32}CaN_2O_{10}$ mol wt 476.55	Colorless or white needles; mp 195 to 196°C (decomposes); $[\alpha]_D^{25} = +28.2^\circ$ (aqueous solution); 1 g=70,000 to 75,000 chick units	35, water; very sol in glycerol and glacial acetic acid; slightly sol in ether, insol in benzene and chloroform	-
<b>Pantothenyl alcohol</b> Panthenol Provitamin for pantothenic acid N-(2,4-Dihydroxy-3,3-dimethylbutyryl)-β-aminopropanol Pantoyl-β-aminopropanol	 $C_9H_{19}NO_4$ mol wt 205.39	Viscous liquid (d); white crystals (dl); mp 64.5 to 67.5°C (dl); $[\alpha]_D^{20} = +29.7^\circ$ (in water) (d)	Very sol in water and glycerol	More stable in solution than pantothenic acid or salts
<b>VITAMIN B<sub>6</sub></b>				
<b>Pyridoxine · HCl</b> Pyridoxol hydrochloride Adermine hydrochloride Antiacrodynia factor Yeast eluate factor 5-Hydroxy-6-methyl-3,4-pyridinedimethanol hydrochloride 2-Methyl-3-hydroxy-4,5-bis(hydroxymethyl)pyridine hydrochloride	 $C_8H_{11}NO_3 \cdot HCl$ mol wt 205.64	Platelets or rods, white crystals; mp 206°C (decomposes); $\lambda_{max} = 291$ nm (0.17 N HCl); $E_{1cm}^{1\%} = 422$ ; optically inactive	22, water; 1.1, ethanol; slightly sol in acetone; insol in ether	Stable, dry to air, light, and heat; sol in acid solution

## PROPERTIES OF VITAMINS (Continued)

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<b>VITAMIN B<sub>6</sub> (Continued)</b>				
<b>Pyridoxal</b> 3-Hydroxy-5-(hydroxymethyl)- 2-methylisonicotinaldehyde	  C <sub>8</sub> H <sub>9</sub> NO <sub>3</sub> mol wt 167.16	-	-	-
<b>Pyridoxal · HCl</b>	C <sub>8</sub> H <sub>9</sub> NO <sub>3</sub> HCl mol wt 203.62	Colorless rhombic crystals; mp 165°C (decomposes); λ <sub>max</sub> =292.5 nm; E <sub>mol</sub> =7,600	-	-
<b>Pyridoxamine</b> Dihydrochloride 2-Methyl-3-hydroxy-4- aminomethyl-5- hydroxymethylpyridine dihydrochloride	  C <sub>8</sub> H <sub>12</sub> N <sub>2</sub> O <sub>2</sub> mol wt 168.19  C <sub>8</sub> H <sub>12</sub> N <sub>2</sub> O <sub>2</sub> ·2HCl mol wt 241.12	Colorless crystals; mp 193 to 193.5°C  Colorless platelets; mp 226 to 227°C (decomposes); λ <sub>max</sub> =287.5 nm (at pH 1.94); E <sub>mol</sub> =9,100	-	-
<b>VITAMIN B<sub>2</sub></b>				
<b>Riboflavin</b> Riboflavine Vitamin B <sub>2</sub> Vitamin G Lactoflavin Ovoflavin Hepatoflavin Lyochrome 7,8-Dimethyl-10-(D-ribo- 2,3,4,5-tetrahydroxypentyl) isoalloxazine 7,8-Dimethyl-10- ribitylisoalloxazine	  C <sub>17</sub> H <sub>20</sub> N <sub>4</sub> O <sub>6</sub> mol wt 376.37	Yellow to orange-yellow; polymorphic crystals; mp 280 to 290°C (decomposes); λ <sub>max</sub> =223, 266, 271, 444 nm(0.1HCl); E <sub>1cm</sub> <sup>1%</sup> = 800, 870, 288, 310; [α] <sub>D</sub> <sup>25</sup> = -112 to 122° (dilute alcoholic NaOH); strong green fluorescence when irradiated by UV light	0.013, water; 0.040, alcohol; insol in ether, acetone, chloroform, and benzene; riboflavin phosphate, sodium salt quite water soluble	Unstable in alkali solution especially in light; stable in acid solution dark; reversibly reduced by sodium hydrosulfite and other reducing agents to dehydroriboflavin (leucoflavin); relatively stable in dry form
<b>Vitamin B<sub>2</sub> phosphate sodium</b> Riboflavin 5'-phosphate sodium Flavin mononucleotide Riboflavin 5'-phosphate ester monosodium salt	  C <sub>17</sub> H <sub>20</sub> N <sub>4</sub> O <sub>9</sub> PNa · 2H <sub>2</sub> O mol wt 514.37	Orange-yellow crystals; [α] <sub>D</sub> <sup>20</sup> = +38 to 42° (20% HCl)	4 to 11, water (depending on pH)	Similar to riboflavin

## PROPERTIES of VITAMINS(Continued)

Compound	Formula	Properties	Solubility (g/100 ml)	Stability
<b>VITAMIN B<sub>1</sub></b>				
<b>Thiamine · HCl</b> Thiamine chloride hydrochloride Vitamin B <sub>1</sub> hydrochloride Aneurine (hydrochloride) Oryzamin Antiberiberi vitamin 3-(4-Amino-2-methylpyrimidyl-5-methyl-4-methyl-5-(β-hydroxyethyl)thiazolium chloride hydrochloride	 $C_{12}H_{17}ClN_4OS$ HCl mol wt 337.28	White monoclinic crystals; mp 246 to 250°C (decomposes); $\lambda_{max}$ = 246 nm (0.1 N HCl); $E_{1cm}^{1\%}$ = 410; optically inactive; 1 mg=333 IU	100, water; 1, alcohol; insol in organic solvents	Stable when dry, stable in acid, unstable at alkaline pH, to prolonged heating, presence of bisulfite or thiaminase; very hygroscopic
<b>Thiamine mononitrate</b> Aneurine mononitrate Vitamin B <sub>1</sub> mononitrate	 $C_{12}H_{17}N_5O_4S$ mol wt 327.36	White crystals; mp 196 to 200°C (decomposes); less hydroscopic than chloride hydrochloride; 1 mg=343 IU	2.7, water; insol in organic solvents	More stable than chloride salt in dry products; not hygroscopic

Compiled by J. C. Bauernfeind and E. De Ritter.

<sup>a</sup>Approved by IUPAC-IUB.

<sup>b</sup>Approved by IUNS.

Compound	Function	Deficiency Symptoms	Hyper-Use Symptoms	Coenzyme and Enzyme Involved	Remarks
Vitamin A	Primary role in vision as 11-cis retinal; synthesis of mucopolysaccharides; maintenance of mucous membranes and skin; bone development and growth; maintenance of cerebrospinal fluid pressure; production of corticosterone	Retarded growth, xerophthalmia, nyctalopia, hemeralopia, ataxia, tissue keratinization, cornification, desquamation, emaciation, lachrymation, impaired reproduction or hatchability (eggs), increased susceptibility to infection, optic nerve degeneration, odontoblast atrophy	Weight loss, bone abnormalities, inflammations, exfoliated epithelium, liver enlargement, pain, loss of hair, facial pigmentation	None identified	Other carotenes, $\alpha$ -, $\beta$ -, $\gamma$ -, and $\beta$ -zeacarotene, cryptoxanthin, echinenone, certain apocarotenals, cis isomers of retinol, and dehydroretinol have fractional vitamin A activity, differing for various animal species; retinoic acid may be metabolically active form for certain functions
Vitamin D	Absorption and transport of calcium and phosphorus; synthesis of calcium protein carrier; interrelationship with parathyroid hormone; maintains alkaline phosphatase levels at bone site	Rickets, enlarged joints, softened bones, stilted gait, arched back, thin-shelled eggs, disturbed reproduction and hatchability, osteomalacia, faulty calcification of teeth, tetany, convulsions, raised plasma phosphatase, parturient paresis (dairy cattle)	Abnormal calcium deposition in bones and tissues, brittle or deformed bones, vomiting, abdominal discomfort, renal damage, weight loss	None identified	D <sub>3</sub> is the most effective form for the avian species; for man D <sub>2</sub> and D <sub>3</sub> are fully active; 1 $\alpha$ ,25 dihydroxycholecalciferol is the active metabolic form of D <sub>3</sub> and is considered by some, a hormone
Vitamin E	Biological antioxidant, interrelated with Se; metabolism of nucleic and sulfur amino acids; ubiquinone synthesis; detoxicant and oxidation-reduction action; stabilizes biological membranes against oxidative attack	Muscular dystrophy, encephalomalacia, hepatic necrosis, erythrocyte hemolysis, hock disorders, steatitis, reduced reproduction and hatchability, exudative diathesis, liver dystrophy, anemia, degeneration of testicular germinal epithelium, creatinuria	None identified; relatively nontoxic	None identified	Other tococls ( $\beta$ -, $\gamma$ -, $\delta$ -tocopherol) and trienols ( $\alpha$ -, $\beta$ -, $\gamma$ -, $\delta$ -tocotrienol) exist differing in ring substituents and in the side chain and having fractional vitamin activity; presence of unsaturated fat in the diet increases dietary vitamin E requirements
Vitamin K	Hepatic synthesis of prothrombin; synthesis of thromboplastin; needed in RNA formation and electron transport	Hemorrhage, impaired coagulation (low prothrombin levels), increased blood clotting time	Vomiting, albuminuria, porphyrinuria, polycythemia, splenomegaly, kidney and liver damage	None identified	K <sub>1</sub> is plant form of the vitamin; K <sub>2</sub> the microbiologically synthesized form; K <sub>1</sub> and K <sub>2</sub> are metabolically active forms; they also occur with longer or shorter side chain (isoprene) units; coumarin compounds and excess sulfa drugs are dietary stress agents for vitamin K
Ascorbic acid	Required for collagen formation; protects enzymes, hydrogen carriers, and adrenal steroids; functions in incorporation of iron into liver ferritin, folic acid into folinic acid; prevents scurvy, increases phagocytic activity	Scurvy, fragile capillaries, bleeding gums, loose teeth, anemia, follicular keratosis, sore muscles, weak bones, decreased egg shell strength, poor wound healing	None identified; relatively nontoxic	None identified	Dietary essential for man, monkey, guinea pig, fish, Indian pipitrel, Indian fruit bat, and flying fox, most other species synthesize it; glucoascorbic acid is an antagonist

## BIOLOGICAL CHARACTERISTICS OF VITAMINS (Continued)

Compound	Function	Deficiency Symptoms	Hyper-Use Symptoms	Coenzyme and Enzyme Involved	Remarks
<i>p</i> -Aminobenzoic acid	Function or need not well understood or accepted; a microbial factor involved in melanin formation and pigmentation; inhibits oxidation of adrenaline; influences activity of tyrosinase; involved in microbial synthesis of folic acid	Nutritional achromotrichia (animals), retarded growth (chicks), disturbed lactation (mice)	Rash, nausea, fever, acidosis, vomiting, pruritis	None identified	Sulfa drugs, carbarzones, and others are antagonists; PAB and sulfa drugs have a common point of attack on certain enzyme systems; PAB has some chemotherapeutic uses
Biotin	As an enzyme component activating carbon dioxide and its transfer in amino acid, carbohydrate, and lipid metabolism; deamination of certain amino acids; synthesis of long-chain fatty acids; potassium metabolism; interrelationship with pyridoxine, cyanocobalamin, pantothenic acid, folic acid, and ascorbic acid	Dermatosis, perosis, scaly skin, loss of hair, spectacle alopecia, cracked foot pads or hoofs, impaired reproduction, retarded growth, anorexia, lassitude, sleeplessness, muscle pain, electrocardial changes	None identified	Carboxybiotin, carboxylases, transcarboxylases, carbamyl phosphate synthetase	Biocytin, a biotin bound form. is(+)-epsilon- <i>N</i> -biotinyl-L-lysine; mild oxidation converts biotin to sulfoxide, strong oxidation to the sulfone; biotin inactivated by avidin; antagonists are $\alpha$ -dehydrobiotin, biotin sulfone, avidin, and others
Choline	Source of methyl group, a methyl donor; for acetylcholine and phospholipid formation; essential for liver functioning	Fatty liver, hemorrhagic degeneration of kidneys, cirrhosis of liver, involution of thymus, enlarged spleen, retarded growth, impaired production (eggs) lactation and reproduction, perosis, muscle weakness or paralysis	Diarrhea and edema, erythrocyte formation inhibition	None identified	Choline occurs widespread in nature and is synthesized within the body to a limited extent; triethylcholine and others are choline antimetabolites
Cyanocobalamin	Cofactor for methyl malonyl CoA isomerase; involved in isomerizations; dehydrogenations, methylations; interrelated in choline, folic acid, ascorbic acid, pantothenic acid, biotin, and <i>S</i> -amino acid metabolism; synthesis of nucleoproteins	Retarded growth, perosis, poor feathering, megaloblastic anemia, anorexia, degenerative changes in spinal cord, posterior incoordination, impaired hatchability	Polycythemia	Cyanocobalamin coenzyme	Other B <sub>12</sub> molecule variations exist wherein cyanide is replaced by chlorine, bromine, hydroxylcyanate, nitrite thiocyanate, etc; 5,6-dichlorobenzimidazole is an antimetabolite

## BIOLOGICAL CHARACTERISTICS OF VITAMINS (Continued)

Compound	Function	Deficiency Symptoms	Hyper-Use Symptoms	Coenzyme and Enzyme Involved	Remarks
Folic acid	Concerned with single carbon metabolism; for methyl, hydroxyl, and formyl transfers; for purine synthesis and normal histidine metabolism; interconversion of serine and glycine; a growth and hematopoietic factor; interrelationship with cyanocobalamin, ascorbic acid, iron, etc.	Retarded growth, sprue, diarrhea, macrocytic anemia, cervical paralysis, reduction and abnormalities in white cells, dermatitis, impaired reproduction and lactation, perosis, poor feathering and lowered hatchability (poultry)	Obstruction of renal tubules	Tetrahydrofolic acid enzyme	The compound is a chelate, binding Co; certain molecular modifications of folic and tetrahydrofolic acid yield antagonists such as aminopterin, tetrahydroaminopterin, and others; the active forms of folic acid may have additional group such as formyl or methyl on the nitrogen in the molecule; thus, $N^5$ -formyltetrahydrofolic acid is folinic acid and $N^5$ -methyltetrahydrofolic acid is the form in blood
Inositol	Function or need not well understood or accepted; believed to be a lipotropic factor; a supply of methyl group functioning with cyanocobalamin; needed for acetyl choline production, functions in some microbial metabolic role	Fatty liver, hair loss, impaired reproduction and lactation, reduced growth (animal)	None identified; relatively nontoxic	None identified	Hexachlorocyclohexane (lindane) is an antimetabolite; while inositol can exist in eight cis-trans isomeric forms, only the optically inactive, <i>i</i> - or <i>meso</i> -inositol, is active; it occurs in animal tissues in free and phosphate ester form; inositol concentration is high in heart muscle, brain, and skeletal muscle
Nicotinic acid	Involved in enzyme mechanisms in carbohydrate, fat, and protein metabolism; functions as hydrogen transfer agent; interrelated with pyridoxine and tryptophan metabolism	Retarded growth, poor feathering or hair coat, black tongue (dog), pellagra, necrotic enteritis, impaired reproduction and hatchability, bowed legs (ducks and turkeys), enlarged hocks, perosis, stomatitis, diarrhea, headache, depression, paralysis, dermatitis	Vasodilation, flushing, tingling, pruritis, hyperhidrosis, nausea, abdominal cramps	NAD (DPN) NADP (TPN) dehydrogenases, coenzymes such as lactate dehydrogenase	In addition to vitamin need, niacin has pharmacological activity as a vasodilator; possessed to a markedly less degree by the amide; 3-acetylpyridine-6-aminonicotinamide and pyridine-3-sulfonic acid or amide are antagonists
Pantothenic acid	A component of coenzyme A; functions in acetylation (or 2 carbon) reactions in amino acid, carbohydrate, and fat metabolism; involved in biosynthesis of acetyl choline, steroids, triglycerides, phospholipids, and ascorbic acid; interrelationship with cyanocobalamin, folic acid, and biotin mechanisms	Retarded growth, dermatitis, anorexia, weakness, spastic abnormalities or gait, scours, achromotrichia (animals), adrenal hemorrhagic necrosis, burning sensation in hands and feet, impaired reproduction and hatchability	None identified; relatively nontoxic	Coenzyme A, acetylases	d-Form is the one in nature; the dl- and d-forms are also manufactured as calcium salts; $\omega$ -methyl pantothenic acid and other compounds are antagonists

## BIOLOGICAL CHARACTERISTICS OF VITAMINS (Continued)

Compound	Function	Deficiency Symptoms	Hyper-Use Symptoms	Coenzyme and Enzyme Involved	Remarks
Pyridoxine	Functions in amino acid metabolism, decarboxylation, transamination, and desulfhydration; oxidation of amines and amino acid transport; phosphorylase activity of muscle; conversion of tryptophan to nicotinic acid and amino acids to biogenic amines	Retarded growth, hyperexcitability, myelin degeneration, convulsions, heart changes, spastic gait, nervousness, anorexia, insomnia, acrodynia, microcytic anemia, impaired production (eggs), reproduction and hatchability, tryptophan metabolites in urine	Convulsions and abnormal encephalograms	Pyridoxal phosphate, pyridoxamine phosphate, transaminases, amino acid decarboxylases	The term vitamin B <sub>6</sub> refers to the 3 compounds, pyridoxine (ol), pyridoxal, and pyridoxamine, the latter 2 being important metabolic forms; isonicotinic acid hydrazide, toxopyrimidine, deoxypyridoxine, and 1-amino-D-proline are antagonists; high tryptophan and/or methionine diets increase need for pyridoxine
Riboflavin	Functions as coenzyme; needed in cellular respiration, hydrogen and electron transfer; growth and tissue maintenance; role in visual mechanism	Retarded growth, ocular and orogenital disturbances, greasy scaling of nasolabial folds, cheeks, and chin, angular stomatitis, myelin degeneration, poor feathering or hair growth, impaired reproduction and hatchability, muscle weakness, curled toe paralysis, scours	Itching, paresthesia, anuria	Flavin mono- and dinucleotide, amino acid oxidase, cytochrome <i>c</i> reductase, succinic dehydrogenase, xanthine oxidase, others	Irradiation of alkaline solution produces lumiflavin of acid solution, lumichrome; riboflavin in solution is one of the most photosensitive compounds of the vitamin class; 5-deoxyriboflavin and several other compounds act as antimetabolites
Thiamine	Functions as a coenzyme; activation and transfer of active acetaldehyde, glycoaldehyde, and succinic semialdehyde; functions in carbohydrate metabolism	Polyneuritis, beriberi, convulsions, muscle paralysis, anorexia, bradycardia, heart dilation, myocardial lesions, retarded growth, edema, pyruvic acid accumulation in blood and tissues	Analgesic effect on peripheral nerves, vascular hypertension	Coccarboxylase, transketolase, carboxylases	Like most water-soluble vitamins, there is no significant tissue storage; amprolium, pyriethamine, oxythiamine, and others are antimetabolites; the two important forms in production are the hydrochloride and the mononitrate

## PROPERTIES FOR ASCORBIC ACID AND ASCORBATE-2-SULFATE

### Compound

#### Ascorbic acid

Vitamin C  
L-Ascorbic acid  
L-Threoscorbic acid  
L-Xyloascorbic acid (obsolete)  
Cevamic acid (obsolete)  
Hexuronic acid (obsolete)  
L-Threo-2,3,4,5,6-pentahydroxy-2-hexene- $\gamma$ -lactone (also available as sodium ascorbate)

$C_6H_8O_6$  MW = 176.13

### Properties

Colorless or white crystals; mp 191°, decomposes  
 $\lambda_m$  (pH 5.2–10), 263.5 nm;  $\epsilon_{263}$   $1.47 \times 10^4$   
 $\lambda_m$  (acid soln), 243.5 nm;  $\epsilon_{244}$  9,600  
 $\lambda_m$  (isobestic), 252.8 nm  
Characteristic acid taste

### Solubility

33, water; 3.5, alcohol; 1, glycerol; sol, acetonitrile, dimethyl sulfoxide, dimethyl formamide, methanol, formic acid, acetic acid, etc., insol oils, and most organic solvents

### Stability

Solid is stable in air in pure or tablet form unless hot and/or humid. Oxidizes autocatalytically in aqueous solution: Dilute (<0.1 mg/ml), very rapidly; concentrated (>1 mg/ml) moderate rate. Stable in solution if all  $O_2$  excluded. Oxidation catalyzed by metals, especially  $Cu^{++}$  or  $Fe^{++}$ . Stabilized by acid solutions, especially metaphosphoric acid or trichloroacetic acid. Alkaline solutions unstable. Oxidation intermediates: Monodehydroascorbic acid (a free radical); dehydroascorbic acid; L-2,3-diketogulonate; plus many other products.

### Compound

#### Ascorbate-2-sulfate

(Dipotassium salt)  
Vitamin  $C_2$   
L-Ascorbic acid 2-sulfate  
Potassium 2-O-sulfonato-L-ascorbate

$C_6H_6O_9SK_2$  MW = 332.37

### Properties

Colorless or white crystals, pKa, (sulfate group) ~2, pKa<sub>2</sub> (3-OH) ~3.  $\lambda_m$ (pH 4–10), 254 nm;  $\epsilon_{254}$  17,700.  $\lambda_m$  (pH 2), 231 nm;  $\epsilon_{231}$  11,000.

### Solubility

Very sol, water; slightly sol, dimethyl formamide, dimethyl sulfoxide, acetonitrile; insoluble most organic solvents. Barium salt slightly sol in water.

### Stability

Stable in dry solid form; moist solid subject to autocatalytic acid hydrolysis; stable in solution pH 5–9; hydrolyzes in solution < pH 5, rapidly below pH 3; not subject to air oxidation.

Compiled by Bert M. Tolbert.

## BIOLOGICAL CHARACTERISTICS FOR ASCORBIC ACID

### Compound

L-Ascorbic acid

### Function

Prevents scurvy; required for normal collagen formation; involved in transferrin system; required for normal neurological function; a water soluble antioxidant and free radical scavenger; probably the functional cofactor for several hydroxylases; fundamental biochemical role(s) not known in animals nor in plants

### Deficiency symptoms

Scurvy: Follicular hyperkeratosis, petechiae, ecchymosis, subconjunctival hemorrhage, joint effusions, dyspnea on exertion, swollen gums, neuropathy, edema, psychological impairment; terminal stage, heart blockage

### Hyper-use symptoms

None substantiated; relatively nontoxic in oral form, probably due to limited gut transport and efficient urinary clearance

### Coenzyme and enzymes involved

No proven coenzyme role; Cofactor roles implicated in prolyl hydroxylase, lysyl hydroxylase, p-hydroxyphenylpyruvate hydroxylase, homogentisic acid oxidase, dopamine- $\beta$ -hydroxylase and others

Subject to active transport through illium (in man), across blood-brain barrier and into the eye

### Remarks

Probably present in all animals and plants; essential in the diet of man, monkey, baboon (probably all primates), guinea pig, trout, salmon, carp, catfish, several birds (especially insect or fruit eater, as swallows and redwing bulbul), Indian fruit bat, some insects; ascorbate-2-sulfate can substitute for ascorbate in trout and salmon but not in guinea pig; D-erythroascorbic acid (isoascorbic acid, erythorbic acid) is a common food additive, but has little nutritional value.

## VITAMERS

A vitamer is one of several chemical compounds, most often of closely related structure, which can fulfill the function of a given vitamin. One of the more prominent examples is Vitamin B<sub>6</sub> where the vitamers include pyridoxal, pyridoxine, 4-pyridoxic acid, and pyridoxal 5'-phosphate. Other examples include Vitamin B<sub>2</sub> (flavin Vitamers), folic acid, vitamin K, biotin, Vitamin A, Vitamin D and vitamin E. Vitamers are not pseudovitamins. There are also phytonutrients which have been considered to have vitamin-like status. For example, the bioflavonoids are plant derivatives with antioxidant and anti-inflammatory properties; derived from citrus fruit rinds, berries, grains, and wines. Some are considered to have anticancer activity. Bioflavonoids/flavonoids are considered to be polyphenols (Albert, A., Manach, C., Morand, C., Rémésy, C., and Jiménez, L., Dietary polyphenols and the prevention of diseases, *Crit.Rev.Food Sci.Nutr.* 45, 287-306, 2005).

**Vitamin A:**  $\beta$ -Carotene and retinaldehyde and other retinol derivatives can be considered vitamers of vitamin A. Retinoic acid, although derived from  $\beta$ -Carotene via retinaldehyde or by the oxidation of retinol, is suggested to have a totally different function in growth and development unrelated to vision<sup>1-6</sup>. In addition, there is considerable interest in the use of vitamin A in cosmeceuticals/skin therapy<sup>7-9</sup>.

**Vitamin D:** Vitamin D<sub>2</sub> and D<sub>3</sub> are derived from 7-dehydrocholesterol. Early work identified ergocalciferol (vitamin D<sub>2</sub>) as an

active component obtained from the irradiation of ergosterol. Later work established vitamin D<sub>3</sub> (cholecalciferol) as the major active component. Either must be converted to the 1 $\alpha$ -hydroxyderivative (e.g. 1 $\alpha$ ,25-dihydroxyvitamin D<sub>3</sub> (1 $\alpha$ ,25-dihydroxyvitamin D)<sup>10-13</sup>.

**Vitamin E:** There are a number of vitamin E (tocopherols/tocotrienols) vitamers<sup>14-22</sup> as well as the water-soluble derivative, Trolox<sup>23-31</sup> which is used as a standard for antioxidant measurements.

**Vitamin K:** Several vitamers<sup>32-41</sup> which have different activities in the support of  $\gamma$ -carboxylation reactions.

**Thiamin (Vitamin B<sub>1</sub>):** Thiamine and several phosphate esters comprise the vitamers of thiamine<sup>42-44</sup> as well as some analogues<sup>45-47</sup>.

**Niacin (Vitamin B<sub>3</sub>):** Niacin is also referred to as nicotinic acid. Nicotinic acid and nicotinamide have equivalent activity and are incorporated into a coenzyme, nicotinamide adenine dinucleotide (NAD) and nicotinamide adenine dinucleotide phosphate (NADP). Nicotinic acid and nicotinamide are the major niacin vitamers<sup>48-54</sup>.

**Pyridoxine (Vitamin B<sub>6</sub>):** Multiple vitamers including pyridoxine, pyridoxal, pyridoxamine and the corresponding phosphates and precursors<sup>55-61</sup>.

**Biotin (Vitamin B<sub>7</sub>; also Vitamin H):** Biotin and precursors and precursors including 7-oxo-8-aminopelargonic acid<sup>62-68</sup>

**Folic Acid (Vitamin B<sub>9</sub>):** Several vitamers<sup>69-74</sup> which are derivatives of the parent pteroyl glutamate.

## VITAMIN NAMES DISCARDED

- Vitamins B<sub>6</sub>, B<sub>10</sub>, B<sub>11</sub>, and B<sub>x</sub> (these mostly have been used to refer to folic acid or folic acid precursors such *p*-aminobenzoic acid although it would appear that these terms were also used to refer to mixtures of vitamins).
  - Vitamin M is a term that has recently been used to describe delta(Δ)-1-tetrahydrocannabinol. Earlier the term vitamin M was used to describe a mixture of B-complex vitamins
  - Vitamin B<sub>4</sub> (mostly used to describe adenine but occasionally for choline) Lecoq, R., The role of adenine (vitamin B4 in the metabolism of organic compounds and its repercussions on acid-base equilibrium, *J.Physiol.* 46, 406-410, 1954; Whelan, W.J., Vitamin B4, *IUBMB Life* 57, 125. 2005; Hartmann, J. and Getoff, N., Radiation-induced effect of adenine (vitamin B4) on mitomycin C activity. *In vitro* experiments, *Anticancer Res.* 26, 3005-3010, 2006
  - Vitamin L (anthranilic acid; *o*-aminobenzoic acid)
  - Vitamin Bc – folate although earlier used to describe the B complex vitamins
  - Vitamin B<sub>10</sub> –folate, precursors of folate such as *p*-aminobenzoic acid; R factor; also used to refer to vitamin A/retinoic acid; Wang, Y. and Okabe, N., Crystal structures and spectroscopic properties of Zinc(II) ternary complexes of Vitamin L, H' and their isomer *m*-aminobenzoic acid with bipyridine, *Chem.Pharm.Bull.* 53, 645-652, 2005
  - Vitamin B<sub>11</sub> – folic acid: Getoff, N., Transient absorption spectra and kinetics of folic acid (vitamin B11) and some kinetic data of folinic acid and methotrexate, *Oncol.Res.* 15, 295-300, 2005
- Pseudovitamins (also described as “fake” vitamins; Young, V.R. and Newberne, P.M., Vitamins and cancer prevention: Issues and dilemmas, *Cancer* 47, 1226-1240, 1981)
- Vitamin B<sub>17</sub> (Laetrile®; amygdalin; 1-mandelonitrile-β-glucuronic acid)  
Vitamin B<sub>15</sub> (pangamic acid; not a chemically defined entity)  
Vitamin B<sub>13</sub> (Orotic acid)  
H<sub>3</sub> (Gerovital)  
U (methionine sulfonium salts)

# UV SPECTRAL CHARACTERISTICS AND ACIDIC DISSOCIATION CONSTANTS OF 280 ALKYL BASES, NUCLEOSIDES, AND NUCLEOTIDES

## B. Singer

The  $\lambda_{\max}$  (nm), in those cases where more than one value has been reported, are either the most frequent value or an average of several values, the range being  $\pm 1$  to 2 nm for the  $\lambda_{\max}$ . Since the  $\lambda_{\min}$  is more sensitive than the  $\lambda_{\max}$  to impurities in the sample, the values of  $\lambda_{\min}$  in the table are generally the lowest reported. Values in parentheses are shoulders or inflexions. The cationic and anionic forms are either so stated by the authors or are arbitrarily taken at pH 1 and pH 13. Individual values are given for  $pK_a$  except when there are more than two values. In that case, a range is given.

Complete spectra representing a range of derivatives are shown in the figures, and reference to these is made in the table with an asterisk and number preceding the name of the compound.

All spectra were obtained in the author's laboratory from samples isolated from paper chromatograms. It is recognized that pH 1 or pH 13 is not ideal for obtaining the cationic or anionic forms when these pHs are close to a  $pK$ . Nevertheless, these conditions are useful for purposes of identification since the spectra are reproducible.

Additional data not quoted here are available in many of the references. These data include spectral characteristics in other solvents than  $H_2O$  and at other pH values, extinction coefficients,  $R_f$  values in various paper chromatographic systems, column chromatographic systems, methods of synthesis or preparation of alkyl derivatives, mass spectra, and NMR, optical rotatory dispersion and infrared spectra.

<sup>a</sup> Much of the data and some of the spectra were published in a review by B. Singer in *Prog. Nucleic Acids Res. Mol. Biol.*, 15, 219–284, 330–332 (1975).

<sup>b</sup> N<sup>2</sup>-Alkyl guanines and guanosines do not exhibit sharp maxima or minima, particularly in basic solution, as shown in the spectra published by Hall,<sup>4</sup> Smith and Dunn,<sup>34</sup> and Singer and Fraenkel-Conrat.<sup>39</sup> Therefore, some of the data are given as a range of values.

<sup>c</sup> All 7-alkyl purine nucleosides and nucleotides and 7,9-dialkyl purines are unstable in alkali and the imidazole ring opens at varying rates. For this reason spectral data obtained in alkaline solution do not represent the original compound and thus such data are omitted. The opening of the imidazole ring in alkali can be used as a means of identifying this class of alkyl compounds. Ring opening can lead to a number of derivatives.<sup>39</sup>

<sup>d</sup> Basic values are those of the dianion (pH 14).

<sup>e</sup> Alkylation of ribose does not cause any change in spectrum.

<sup>f</sup> Alkylated nucleoside diphosphates have the same spectral characteristics as alkylated nucleotides and the data are not separated. Alkylation of the phosphate group does not cause any change in spectrum.

Compiled by A. R. Trim.

<sup>a</sup> The pentose is presumed to be 2'-O-methylribose since the dinucleotides were obtained from yeast ribonucleic acid. Evidence for the chemical constitution of the modified pentose is given in Howlett et al.<sup>1</sup> and Trim and Parker.<sup>2</sup>

<sup>b</sup> Absorbance ratios were calculated from optical densities at 240, 250, 270, 280, and 290 nm relative to that at 260 nm.

Values for trinucleotides are from Trim and Parker.<sup>3</sup> Data on dinucleotides are from Trim and Parker, *Biochem. J.*, 116, 589 (1970). With permission. Copyright by the Biochemical Society.

Contributed by Jane N. Toal.

<sup>a</sup> Absorbance ratios were calculated from optical densities at 240, 250, 270, 280, and 290 m $\mu$  relative to that at 260 m $\mu$ . Ratios not calculated where optical density was less than 0.1.

<sup>b</sup> Slack = the absolute sum of the catalog mismatch at every wavelength.

<sup>c</sup> cat. = catalog.

From data in Toal, Rushizky, Pratt, and Sober, *Anal. Biochem.*, 23, 60 (1968). With permission of the copyright owners, Academic Press, New York.

Contributed by Jane N. Toal.

<sup>d</sup> Hyperchromicity ratios were calculated as the optical density of a hydrolyzed compound divided by the optical density of the corresponding intact compound at the same wavelength. Ratios are calculated where optical density was less than 0.1From data in Toal, Rushizky, Pratt, and Sober, *Anal. Biochem.*, 23, 60 (1968). With permission of the copyright owners, Academic Press, New York.

From data of Hoffman, J. L., and Bock, R. M., Mononucleoside 5'-phosphates obtained from P-L Biochemicals, Milwaukee, Wisconsin, were used. The spectra were determined using a Cary 15 spectrometer. These tables originally appeared in Sober, H., *Handbook of Biochemistry and selected data for Molecular Biology*, 2nd ed., Chemical Rubber Co., Cleveland, 1970.

# PURINES, PYRIMIDINES, NUCLEOSIDES, AND NUCLEOTIDES: PHYSICAL CONSTANTS AND SPECTRAL PROPERTIES

David B. Dunn and Ross H. Hall

Data are included for most modified components of nucleic acids, for some naturally occurring purine and pyrimidine compounds, and for some related synthetic compounds. An index to the 246 compounds is provided (arranged as free bases, nucleosides, and nucleotides).

It is recommended that, where possible, compounds be referred to by the trivial names given in bold type. (Some of these, such as "wye", "wyosine" and "zeatosine", are new proposals made by W. E. Cohn and D. B. Dunn.) Systematic and other trivial names are given, particularly where these already occur in the literature. Compounds are arranged as: purines and pyrimidines, ribonucleosides (including arabinonucleosides), deoxyribonucleosides, ribonucleotides and deoxyribonucleotides. The principal compounds are arranged alphabetically, with derivatives grouped

after each, the position of the latter depending first on the locant of the substituent and second on its initial letter. Compounds with a modified, or more than one substituent group, follow the simpler compounds.

The symbols are in accord with the examples and principles set out by the IUPAC-IUB Commission on Biochemical Nomenclature. A summary of these rules is found elsewhere in the Handbook. The "3-letter" symbols are proposed for use in tables, figures, equations involving the monomeric units themselves, the "1-letter" symbols for sequences. For deoxyribonucleosides in sequences, d may precede the sequence and thus be eliminated from each residue. Symbols that have been proposed or used, but are not now recommended are marked by an asterisk. The following symbols for substituents are used:

Substituent	Structure	Symbols	
		3-Letter	1-Letter
acetyl-	CH <sub>3</sub> CO-	Ac	ac
(-)amino-, imino-	NH <sub>2</sub> -, -NH-, NH=	NH <sub>2</sub> ,NH	n
-α-aminobutyric acid (3-carboxy-3-aminopropyl-)	HOOC-C(NH <sub>2</sub> )-(CH <sub>2</sub> ) <sub>2</sub> -	(NH <sub>2</sub> Bto) (NH <sub>2</sub> CxPr)	nbt
arabinosyl-		Ara	a
		a	
butyl-	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>3</sub> -	Bu	b
-butyramide (3-carbamoylpropyl-)	NH <sub>2</sub> CO(CH <sub>2</sub> ) <sub>3</sub> -	Btn NcPr	
-butyric acid (3-carboxypropyl-)	HOOC(CH <sub>2</sub> ) <sub>3</sub> -	Bto CxPr	bt
dihydro		H <sub>2</sub>	h
carbamoyl-	NH <sub>2</sub> CO-	Nc	nc
carbamoylmethyl- (-acetamide)	NH <sub>2</sub> COCH <sub>2</sub> -	Ncm NcMe	ncm
-carbonyl-	-CO-	CO	c
carboxy- (-oxycarbonyl-)	HOOC-, -OOC-	Cx	c
carboxymethyl- (-acetic acid)	HOOC-CH <sub>2</sub> -	Cm	cm
		CxMe	
<i>cis</i>		<i>cis</i>	
formamido-	HCONH-	Fn	fn
glycino-	HOOC-CH <sub>2</sub> NH-	Gly	g
hydroperoxy-	HOO-	O <sub>2</sub>	o <sub>2</sub>
methoxy-	CH <sub>3</sub> O-	MeO	mo
-oxy-	-O-	O	o
pentyl-	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>4</sub> -	Pe	
putrescino- (aminobutylamino-)	NH <sub>2</sub> (CH <sub>2</sub> ) <sub>4</sub> NH-	Put (NH <sub>2</sub> BuNH)	nbn
propyl-	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>2</sub> -	Pr	
ribosyl-		Rib	r
(-)thio (mercapto-)	-S-, S=	S	s
threonino-	CH <sub>3</sub> -CHOH-C(COOH)NH-	Thr	t
threoninocarbonyl-	CH <sub>3</sub> -CHOH-C(COOH)NH-CO-	(ThrCO)	tc
<i>trans</i>		<i>tr</i>	
hydroxy-	HO-	HO	o
hydroxymethyl- (-methanol)	HOCH <sub>2</sub> -	HOMe Hm	om hm*
isopropeno-methyl-		im*	
<i>iso</i>		<i>iso</i>	
isopentenyl- (3-methyl-2-butenyl-)	(CH <sub>3</sub> ) <sub>2</sub> C=CHCH <sub>2</sub> -	iPe Pe <sup>i</sup>	i
methoxycarbonylmethyl- (-acetic acid methyl ester)	CH <sub>3</sub> O-CO-CH <sub>2</sub> -	MeCm	mcm
3-methoxycarbonyl-3- methoxyformamidopropyl-	CH <sub>3</sub> O-CO-C(NHCOOCH <sub>3</sub> )-(CH <sub>2</sub> ) <sub>2</sub> -	Y (MeO) <sub>2</sub> FnBto	y m <sub>2</sub> fnbt
methyl-	CH <sub>3</sub> -	Me	m

Data were taken where possible on chemically synthesized material.

The first reference cited in the origin and synthesis column gives the origin of the compound used to obtain the principal spectral data. C = chemical synthesis; E = prepared enzymically; R = isolated from RNA; D = isolated from DNA; N = isolated from natural product other than nucleic acids.

The melting points were taken from the first reference to chemical synthesis except where otherwise indicated by footnote (*a*); dec. signifies decomposition.

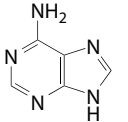

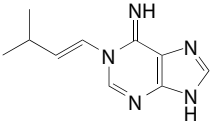

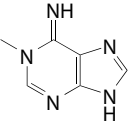

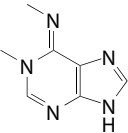

For  $[\alpha]_D^t$  the temperature is given as a superscript and the concentration and solvent used in obtaining the value in parenthesis; H<sub>2</sub>O = in water; EtOH = in ethanol; MeOH = in methanol; Me<sub>2</sub>SO = in dimethylsulfoxide.

pK values were taken from the first reference quoted except where values differed by only 0.2 pH units when a mean value was used. References that give values deviating from those quoted by more than  $\pm 0.1$  pH units are marked with an asterisk (\*). The pK values involved are similarly marked. The pK values for nucleotides are only those for the nucleoside moiety, not phosphate ionizations. Where pK values were determined from electrophoretic mobilities (footnote *p*) values were obtained from mobilities relative to the parent compounds and pK values of these given by Jordan (1955) in *The Nucleic Acids*, Chargaff and Davidson, Eds., Academic Press, New York I, p 447.

Where possible, all spectral values are given at pH values away from pK values; exceptions to this are indicated by a footnote. Data obtained at a pH value where the compound was unstable were obtained soon after subjecting the material to this pH and differ from those of the decomposition products. The reference giving the maximum amount of spectral data is cited first; other references giving additional data are marked by footnotes. (These, *c* to *e*, indicate that some but not necessarily all the data mentioned come from this reference.) The ratio columns give ratio of absorption at the wavelength given to that at 260 nm. In the pH column of spectral data. H<sub>2</sub>O=in water; EtOH=in ethanol; MeOH=in methanol. References that give spectral data differing from the values quoted are marked with an asterisk as are also the values involved. For this, deviations were marked only where they were more than  $\pm 1$  nm for  $\lambda_{\max}$  or  $\lambda_{\min}$ ,  $\pm 5$  per cent for  $\epsilon_{\max}$ , and  $\pm 10$  per cent for spectral ratios. (The latter applies to all instances where spectral ratios are quoted in the additional reference but not necessarily to all references giving spectra.)

<sup>a</sup> Melting point from this reference.

<sup>b</sup> Full spectrum given.

<sup>c</sup>  $\lambda_{\max}$  and/or  $\lambda_{\min}$  from this reference.

<sup>d</sup>  $\epsilon_{\max}$  from this reference.

<sup>e</sup> Spectral ratios from this reference.

<sup>f</sup> pK of 2-methyl-6-methylaminoadenine. Compare the similar pK of adenine and N<sup>6</sup>-methyladenine.<sup>15</sup>

<sup>g</sup> Spectral data taken on material synthesized this way then further purified by paper chromatography.

<sup>h</sup> In 50% dimethylformamide (HCONMe<sub>2</sub>).

<sup>i</sup> In 50% dimethylsulfoxide/ethanol (Me<sub>2</sub>SO/EtOH).

<sup>j</sup> For an explanation of this nomenclature and abbreviations, see General Remarks on Wyosine in Natural Occurrence of Modified Nucleosides.

<sup>k</sup> pK of 6-amino-5-formamidoisocytosine.

<sup>l</sup> pK of nucleotide.

<sup>m</sup>  $\lambda_{\max}$  and  $\epsilon_{\max}$  due to adenosine.

<sup>n</sup>  $\epsilon$  calculated from spectral data using  $\epsilon_{\max}$  acid of nucleoside.

<sup>o</sup> Decomposes at this pH.

<sup>p</sup> Determined from electrophoretic mobility.

<sup>q</sup> Values very dependent on pH (near pK).

<sup>r</sup> Basic ionization at all pH values.

<sup>s</sup> Spectral data in water and pH 11 indicate decomposition.

<sup>t</sup> Alkaline degradation product of 7-methylguanosine or nucleotide.

<sup>v</sup> Spectra in acid and neutral similar.

<sup>w</sup>  $\epsilon$  estimated from conversion to N<sup>6</sup>-methyladenosine 3' (2')- or 5'-phosphate using  $\epsilon$  of  $15.2 \times 10^3$  in alkali, for the N<sup>6</sup>-isomers.

<sup>x</sup> Based on  $\epsilon$  of 7-methylguanosine 3' (2')-phosphate assuming quantitative conversion in alkali. For a possible error in this value see General Remarks on 7-Methylguanosine in Natural Occurrence of Modified Nucleosides.

<sup>y</sup> Cyclohexylamine salt.

<sup>z</sup> Data on mixed 2' and 3' phosphates.

The authors are indebted to a number of authors who supplied unpublished data, provided original spectra for calculations of the values or gave advice on the selection of the most reliable data. They also wish particularly to thank Mr. I. H. Flack, Mr. R. Thedford and Miss L. Csonka for their assistance in the preparation of the table.

## CHEMICAL MODIFICATION OF NUCLEIC ACIDS

The chemical modification of nucleic acids is not as complex as that of proteins since there are fewer monomer units and, for all practical purposes, only nitrogen as a nucleophilic reactive group; the nitrogen is reactive as a primary and secondary amine. Reaction at the primary amine groups

of, for example, adenine, is referred to an exocyclic modification whereas reaction at the imine nitrogens of pyrimidines and purine rings is referred to as an endocyclic modification. There are also ring-opening reactions and cross-linking reactions.

**TABLE 1: Chemical Modification of Nucleic Acids**

Reagent	Base Modified	Product	Reference
Aldehydes <sup>a</sup>	Most data on pyrimidines with less on purines	Various adducts	1-10
Alkylation	Purine and pyrimidines	Various product resulting from environmental agents such as ethylene oxides and nitrogen mustards	11-20
Diethylpyrocarbonate	Purine and pyrimidines	Carboxethylation of the N-7 site on the purine ring followed by ring opening; pyrimidines react at primary amino groups to yield carboethoxy derivatives <sup>b</sup>	21-28
Dimethyl Sulfate (Methylation)	Purines and Pyrimidines	N <sup>7</sup> -Methylguanidine with minor reaction at the N <sup>1</sup> and N <sup>3</sup> -positions; reaction also occurs at N <sup>3</sup> in adenine and at N <sup>3</sup> -position in cytidine; reactivity is controlled by polynucleotide structure <sup>c,d</sup>	29-41
Hydrazine	Pyrimidines	Ring cleavage yielding pyrazole derivatives <sup>e</sup> and the ribosyl backbone ; reaction used sequence analysis and footprinting	42-47
Hydroxylamine	Purines and pyrimidines	Hydroxamate formation at "exocyclic" nitrogen; conversion of guanine to isoxazolone.	48-55
Nitrous Acid (HNO <sub>2</sub> )	Purines and pyrimidines	Deamination; crosslinking at guanine, cytosine bases	56-64
Potassium Permanganate	Purines and Pyrimidines	Oxidation at double bonds; preferential reaction with thymidine	65-75
Sodium Bisulfate	Cytosine	Uracil (5-methylcytosine is converted to thymine) <sup>f</sup>	76-84

<sup>a</sup> e.g. formaldehyde, acetaldehyde, acrolein, crotonaldehyde; 4-hydroxy-2-nonenal (4-HNE)

<sup>b</sup> Diethylpyrocarbonate modification is used for DNA footprinting (Fox, K.R., Webster, R., Phelps, R.J., *et al.*, Sequence selective binding of bis-daunorubicin WP631 to DNA, *Eur.J.Biochem.* 271, 3556-3566, 2004)

<sup>c</sup> The N<sup>7</sup>-position of guanine is always reactive for methylation (the N<sup>7</sup>-position of guanine is the most reactive site in nucleic acids); methylation of guanine also occurs at the N<sup>1</sup>-position of guanine at high concentrations of methylating agents. Methylation of the N<sup>3</sup>-position of cytidine occurs in single-stranded DNA but is blocked in double-stranded DNA. Methylation (alkylation) also occurs at the N<sup>1</sup> and N<sup>3</sup> position of adenine but methylation is restricted in at the N<sup>1</sup> position in double-stranded DNA. *In vivo* methylation of DNA occurs at cytidine residues largely in CpG islands (Ehrlich, M. and Wang, R.Y., 5-Methylcytosine in eukaryotic DNA, *Science* 212, 1350-1357, 1981; Lewis, J. and Bird, A., DNA methylation and chromatin structure, *FEBS Lett.* 285, 155-159, 1991; Cheng, X., Structure and function of DNA methyltransferases, *Annu.Rev.Biophys.Biomol.Struct.* 24, 293-318, 1995; Scheule, R.K., The role of CpG motifs in immunostimulation and gene therapy, *Adv Drug Deliv.Rev.* 44, 119-134, 2000).

<sup>d</sup> Base treatment of N<sup>7</sup>-methylguanine results in opening of the imidazolium ring while N<sup>3</sup>-methylcytidine undergoes base-catalyzed deamination to give N<sup>3</sup>-methyluridine. Methylation of cytidine blocks conversion to thymidine by sodium bisulfite

<sup>e</sup> 4-methyl-5-pyrazolone with thymidylic acid; 3(5)-aminopyrazole with deoxycytidine

<sup>f</sup> Conversion to uracil does not occur with 5-methylcytosine; 5-methylcytosine is converted to thymine. The rate of reaction of 5-methylcytosine with sodium bisulfite is much slower than reaction of cytosine.

There are modifications of ribose moiety in ribonucleotides such as periodate oxidation which was used in early structural analysis. Oxidation of the ribose ring has also been used to couple RNA to protein amino groups and to amino-containing matrices for affinity chromatography.

**TABLE 2: Reaction of Periodate with Nucleic Acids**

Reaction	Conditions	Reference
Coupling of periodate-oxidized RNA to hydrazide-agarose	140 $\mu$ L 0.2 M NaIO <sub>4</sub> added to 500 – 3000 $\mu$ g RNA in a volume of 1 mL 0.1 M sodium acetate, pH 5.0 for one hour at 23°C in the dark; reaction terminated with 80 $\mu$ L ethylene glycol; after removal of reactants, the modified RNA was coupled to hydrazide matrix in the same solvent	1
Coupling of double-stranded RNA to agarose	12 $\mu$ L 0.1 M NaIO <sub>4</sub> (sodium meta-periodate) / 10 A <sub>260</sub> units of RNA (40 A <sub>260</sub> units/mL) in 0.1 M sodium acetate, pH 5.0, and incubated for 1 hr at 23°C. The reaction is terminated by precipitation of the RNA with ethanol. Coupling to agarose was accomplished in 0.1 M sodium acetate, pH 5.0	2

# TRANSFECTION TECHNOLOGIES

- 1 Overview of Transfection Technologies
- 2 Calcium Phosphate Transfection in Eukaryotic Cell Culture
- 3 DEAE-Dextran and Transfection in Eukaryotic Cell Culture
- 4 Electroporation for the Transfection of Eukaryotic Cells
- 5 Lipofection for Transfection of Eukaryotic Cells in Culture
- 6 Polyethyleneimine and Transfection in Eukaryotic Cell Culture

## 1 Overview of transfection technologies

Transfection refers to the process by which foreign DNA (transgene) is incorporated into and expressed by a eukaryotic cell<sup>1</sup>. Stable transfection describes the incorporation of the transgene into the host cellular genome such that it is transferred with other host genetic material to daughter cells. In general, transfected cells must be “selected” from transiently transfected cells to obtain a stable transfected type. Selection is accomplished by inclusion of a “selectable” trait such as drug resistance such as the inclusion of dihydrofolate reductase (DHFR) gene to provide for growth in the presence of methotrexate when a DHFR-deficient cell is used as substrate<sup>2-6</sup>. The work of Robert Schimke and colleagues on the development of this system was one the critical factors in the development of the current biotechnology industry. In transient transfection, the transgene persists for several days with a peak period of expression after the first day. Transformation is the term used to describe the incorporation of naked DNA into prokaryocytes while conjugation refers to bacterial-bacterial exchange of DNA and transduction refers to the phage-mediated transfer of DNA. The use of naked DNA is usually ineffective with eukaryotic cells and a carrier or process is required<sup>7</sup>. Electroporation appears to be the most popular method with cationic lipids used to a less extent. Calcium phosphate and polyethyleneimine are some less frequently used. DEAE-dextran is used the least. Other technologies such as the gene gun (biolistic labeling)<sup>8-11</sup> are also being developed.

## 2 Calcium phosphate transfection in eukaryotic cell culture

Calcium phosphate is used to transfect mammalian cells. It was first used by Graham and Van Der Eb in 1973<sup>1</sup> and despite considerable use over the past three decades, this technique is still poorly understood<sup>2,3</sup>. It seems likely the use of calcium phosphate evolved from the earlier use of calcium for in bacterial transformation<sup>4-9</sup>. Graham and Van der Eb<sup>1</sup> separated the calcium phosphate-mediated transfection into three steps:

- (1) Calcium phosphate + DNA → DNA-CaPO<sub>4</sub>
- (2) DNA-CaPO<sub>4</sub> + Cells → DNA transport into Cell (DNA-Cells)
- (3) DNA-Cells → Cell Growth

Each of these steps has been subsequently demonstrated to be critical and has critical process attributes and critical process parameters (See [Table 1](#)). Other observations which are important to calcium phosphate-mediated transfection include:

- Inclusion of a “carrier” DNA appears to enhance the efficiency of transfection<sup>10-12</sup>.
- pH is critical with a very narrow pH optima between 7.0-7.2<sup>1,3,13</sup>. Tris buffer was used in the first study on calcium phosphate transfection<sup>1</sup> but was replaced by HEPES<sup>1,14</sup> to provide stronger buffering in the critical pH range. HEPES is a problematic buffer<sup>15</sup> and it is of interest that one of the basic studies on the use of calcium phosphate<sup>13</sup> used BES instead of HEPES.

TABLE 1: Critical Process Attributes and Critical Process Parameters for Calcium Phosphate Transfection

Calcium phosphate + DNA → DNA-CaPO <sub>4</sub>	<ol style="list-style-type: none"> <li>1. Source of Calcium ions<sup>3ab, 16, 17</sup>(See note 1)</li> <li>2. DNA – Calcium -phosphate(order of mixing)<sup>17</sup></li> <li>3. Source of orthophosphate<sup>17</sup>(See note 1)</li> <li>4. pH of mixing and choice of buffer<sup>1,2,3,13</sup></li> <li>5. Method of mixing<sup>16,17,20</sup></li> <li>6. Temperature of mixing<sup>1,2,13,18</sup></li> <li>7. DNA concentration<sup>1,3,13,14,17,18</sup></li> <li>8. Mixing container<sup>17</sup></li> </ol>
DNA-CaPO <sub>4</sub> + Cells → DNA transport into Cell (DNA-Cells)	<ol style="list-style-type: none"> <li>1. Cells growth status (S Stage)<sup>1,20</sup></li> <li>2. Time of “storage” of DNA-CaPO<sub>4</sub> before addition to cells<sup>1,3,13,18,19,20</sup></li> <li>3. Presence or absence of media during addition of DNA-CaPO<sub>4</sub><sup>2</sup></li> <li>4. Presence or absence of serum during addition of DNA-CaPO<sub>4</sub><sup>2</sup> (See Note 2)</li> <li>5. Time of contact with cells<sup>1,3ab,17,20</sup></li> <li>6. Volume of transfectant solution added to medium<sup>21</sup></li> <li>7. Use of EDTA wash to remove reagents (See Note 3)</li> </ol>
DNA-Cells → Cell Growth	<ol style="list-style-type: none"> <li>1. Growth time</li> <li>2. Growth temperature</li> </ol>

*Note 1:* Most investigators use a sterile source of calcium ions and phosphate solutions. Also, filtration immediately prior to mixing is a frequently cited practice.

*Note 2:* Fetal Calf Serum (FCS, 10% final concentration in medium, usually Dulbecco's minimal essential medium; DMEM) is usually included in the medium for culturing the cells. Protein has an effect on the organization of calcium phosphate crystals. An additional complication is provided by CO<sub>2</sub> which, as HCO<sub>3</sub><sup>1-</sup>/CO<sub>3</sub><sup>2-</sup> will incorporate into calcium phosphate crystals<sup>16</sup>. The cell cultures are usually maintained under CO<sub>2</sub> and CO<sub>2</sub> levels have been shown to be critical during the incubation of DNA with cells<sup>3,13</sup>.

*Note 3:* Calcium phosphate is toxic to some cells. Individual protocols differ on the washing procedure for the cells following the calcium phosphate step.

### 3 DEAE-Dextran and transfection in eukaryotic cell culture

The ability of DEAE-Dextran to promote nucleic acid uptake into eukaryotic cells was first noted by Vaheri and Pagano<sup>1-2</sup>. Dimethylsulfoxide (DMSO) was also observed to enhance

nucleic acid uptake<sup>3,4</sup>. DMSO was subsequently demonstrated to enhance calcium phosphate transfection<sup>5</sup>. DMSO "osmotic shock" was later shown to markedly enhance DEAE-dextran transfection efficiency<sup>6-8</sup>. DEAE-dextran is used less than polyethyleneimine. It would appear that DEAE-dextran is used more with Cos cells or BHK cells than with CHO cells. It is also noted that polyamines such as DEAE-dextran have been demonstrated to enhance nucleic acid transfer in *Escherichia coli* spheroplast<sup>9</sup>.

Several transfection technologies were evaluated using a CMV-LacZ plasmid containing a bacterial  $\beta$ -galactosidase as a reporter gene. DEAE-dextran(with DMSO osmotic shock) was slightly more effective than a variety of cationic lipids.

## 4 Electroporation for the transfection of eukaryotic cells

Electroporation is a process for transfection where cells are suspended at relatively high density ( $10^6$ - $10^7$  mL) and subjected to a short (milliseconds to microseconds) electric pulses<sup>1-8</sup>. While electroporation tends to be challenging to cells with cell losses up to 50%, it does see extensive use in commercial biotechnology where it is viewed as a robust process. Iontophoresis is an alternative drug delivery related to electroporation when a low-level electrical current is used to administer ionic drug to the skin<sup>9-12</sup>. Electroporation has been reported to promote protein uptake by cells<sup>13-14</sup>

Maxwell, I.H. and Maxwell, F., Electroporation of mammalian cells with a firefly luciferase expression plasmid: kinetics of transient expression differ markedly among cells types, *DNA* 7, 557-5562, 1988

Transfection by electroporation was examined in a several mammalian cell types. In some cell lines, expression of the transgene was maximal at 12 hours followed by a rapid decline. It was concluded that the time course of transgene expression following electroporation must be determined for each cell line.

Andreason, G.L. and Evans, G.A., Optimization of electroporation for transfection of mammalian cell lines, *Anal.Biochem.* 180, 269-275, 1989

Evaluated transfection technologies (electroporation, calcium phosphate, and DEAE-dextran) in several rodent cells lines including PC12 and B50 (rat neuroblastoma) with firefly luciferase as the reporter gene. The relative effective of a specific transfection technology varied with the cell line. It was observed that electroporation was more effective at 23°C than at 4°C.

Gauss, G.H. and Lieber, M.R., DEAE-dextran enhances electroporation of mammalian cells, *Nucleic Acids Res.* 20, 6739-6740, 1992

The presence of DEAE-dextran increase transfection efficiency with electroporation.

Rols, M.P., Delteil, C, Serin, G., and Teissie, J., Temperature effects on electroporation of mammalian cells, *Nucleic Acids Res.* 22, 540, 1994

Experiments with CHO cells in 10 mm phosphate, pH 7.2, containing 250 mM sucrose and 1 mM MgCl<sub>2</sub> showed that there are different temperature optima for the steps in the transfection process. Incubation at 4°C prior to electroporation yielded the best results while incubation at 37°C after electroporation increased transfection efficiency.

Teifel, M., Heine, L.T., Milbredt, S., and Friedl, P., Optimization of transfection of human endothelial cells, *Endothelium* 5, 21-35, 1997

Electroporation is suggested to more useful than lipofection, DEAE-dextran, or calcium phosphate for the transfection of endothelial cells.

Nickoloff, J.A. and Reynolds, J.A., Electroporation-mediated gene transfer efficiency is reduced by linear plasmid carrier DNAs, *Anal.Biochem.* 205, 237-243, 1992

Linear DNA inhibited transfection by electroporation in CHO cells while circular plasmids enhanced transfection efficiency with electroporation.

Melkonyan, H., Sorg, C. and Klempt, M., Electroporation efficiency in mammalian cells is increased by dimethyl sulfoxide (DMSO), *Nucleic Acids Res.* 24, 4356-4367, 1996

DMSO improved transfection efficiency by electroporation in four cells lines (HL60, TR146, Cos-7, and L132). DMSO was present during electric pulse and in the following incubation.

Yang, T.A., Heiser, W.C., and Sedivy, J.M., Efficient *in situ* electroporation of mammalian cells grown on microporous membranes, *Nucleic Acids Res.* 23, 2803-2810, 1995

Electroporation with cells grown on microporous membranes such as polyethylene terephthalate or polyester.

## 5 Lipofection for transfection of eukaryotic cells in culture

Cationic or neutral lipids can be used to prepare liposomes to condense nucleic acids for transfer into cells<sup>1-9</sup>. These supramolecular structures are known as lipoplexes. Lipoplexes are sometimes referred to as polyplexes but it would seem that the term polyplex is used more often to describe polyamine complexes with DNA such as PEI-DNA or DNA-DEAE-dextran complexes. The cationic lipids include *N*-[1-(2,3-dioleoyl)propyl]-*N,N,N*-trimethylammonium chloride (DOTAP) and *N*-[1-(2,3-dioleoyloxy)propyl]-*N,N,N*-trimethylammonium chloride (DOTMA)<sup>10,11</sup>. The inclusion of neutral lipids such as cholesterol or 1,2-dioleoyl-*sn*-glycero-3-phosphoethanolamine (DOPE) has been shown to enhance transfection<sup>12-14</sup>. It is thought that cationic lipids bind to the DNA condensing into a liposomal structure which can then fuse with the cell wall and undergo membrane fusion/endocytosis forming an intracellular endocytotic vesicle which is destabilized in the cytoplasm with the release of DNA. The DNA then enters the nucleus as postulated for the other polyplexes where the transgene may or may not be expressed in, most likely, a transient manner.

## 6 Polyethyleneimine and transfection in eukaryotic cell culture

Polyethyleneimine (PEI) is one of several vehicles used for non-viral transfection of cells and results in transient rather than stable transfection. PEI appears to be used more frequently than DEAE-dextran. Polyamines such as PEI function in transfection by condensing of DNA with the formation of a polyplex (the term polyplex refers to the DNA/carrier condensate). Branched forms and linear forms of PEI are used. The polyplex binds to the cell membrane, passes into the cell via endocytosis, is released from the endosome and passes into the nucleus<sup>1-12</sup>. Early studies by Pollard and coworkers<sup>1</sup> showed the polycation was not only required for effective endocytosis of DNA, polycation also stimulated nuclear uptake of the DNA<sup>1</sup>. These early studies have been extended by a number of workers including Breung and coworkers<sup>2</sup>. There have been a number studies on the endocytotic process but the mechanism remains elusive<sup>8,12</sup>. Recent studies<sup>13</sup> have suggested that process efficiency is limited by passage of DNA into the nucleus and expression of all inserted DNA. PEI is also useful for transferring RNAi derivatives to the cytoplasm<sup>14-18</sup>. There is one report on the use of PEI as a transmembrane carrier for fluorescently labeled proteins<sup>19</sup>.

Vancha, A.R., Govindaraju, S., Parsa, K.V., *et al.*, Use of polyethyleneimine polymer in cell culture as attachment factor and lipofection enhancer, *BMC Biotechnol.* 4, 23, 2004

PEI as attachment factor for weakly anchoring cell lines. PEI also appears to enhance lipofection efficiency. Experimental results with PC-12 and HEK-293 cells.

Schlatter, S., Stansfield, S.H., Dinnis, D.M., *et al.*, On the optimal ratio of heavy to light chain genes for efficient recombinant antibody production by CHO cells, *Biotechnol.Prog.* 21, 122-133, 2005

PEI transfection in CHO cells. It was determined that a low heavy chain/light chain ratio was optimal for transient expression

Mennesson, E., Erbacher, P., Piller, V., *et al.*, Transfection efficiency and uptake process of polyplexes in human lung endothelial cells: a comparative study non-polarized and polarized cells, *J.Gene Med.* 7, 729-738, 2005

Compared transfection efficiency of PEI polyplexes with histidylated polylysine (polylysine where approximately 50% of the  $\epsilon$ -amino groups are substituted with a histidyl-residue-see Midoux, P. and Monsigny, M., Efficient gene transfer by histidylated polylysine/pDNA complexes, *Bioconjug. Chem.* 10, 406-411, 1999) with human lung microvascular endothelial cells in monolayer culture. Transfection was more effective with PEI polyplexes as judged with YOYO-labelled plasmids and luciferase activity.

Bengali, Z., Pannier, A.K., Segura, T., *et al.*, Gene delivery through cell culture substrate adsorbed DNA complexes, *Biotechnol.Bioeng.* 90, 290-302, 2005

Transfection efficiency increased when serum-coated tissue culture plate used. The polyplex complexes were immobilized on the serum-coated plate prior to the transfection step. Transfection efficiency was measured by luciferase(transgene) expression NIH/3T3 cells.

Breunig, M., Lungwitz, U., Liebl, R., *et al.*, Gen delivery with low molecular weight linear polyethyleneimines, *J.Gene Med.* 7, 1287-1298, 2005

Low molecular weight PEI polymers (5-9 kDa) may be better than higher molecular weight materials as a result of higher transfection efficiency and lower cytotoxicity. Transfection was measure by green fluorescent protein expression in either CHO cells or HeLa cells.

Banerjee, P., Weissleder, R. and Bogdanov, A., Jr., Linear polyethyleneimine grafted to a hyperbranched poly(ethylene glycol)-like core: a copolymer for gene delivery, *Bioconjug.Chem.* 17, 125-131, 2006

The block copolymer of branched PEI and hyperbranched PEG provided DNA condensates with longer life stability and much higher transfection efficiency that a block copolymer of branched PEI and PEG.

Arnold, A.S., Laporte, V., Dumont, S., *et al.*, Comparing reagents for efficient transfection of human primary myoblasts: FuGENE 6, Effectene and ExGen 500, *Fundam.Clin.Pharmacol.* 20, 81-89, 2006

Fugene 6 (a cationic lipid), Effectene (a cationic lipid), and ExGen500 (a linear PEI polymer) were compared with respect to their transfection efficiency in primary myoblast cells. Transfection was measured by cell viability (mitochondrial dehydrogenase activity). Fugene 6 was the most effective but was more dependent on the presence of serum than ExGen.

Braga, D., Laize, V, Tiago, D.M., and Cancela, M.L., Enhanced DNA transfer into fish bone cells using polyethyleneimine, *Mol.Biotechnol.* 34, 51-54, 2006

Transfection efficiency measured with green fluorescent protein and luciferase.

Galbraith, D.J., Tait, A.S., Racher, A.J., *et al.*, Control of culture environment for improved polyethyleneimine-mediated transient production of recombinant monoclonal antibodies by CHO cells, *Biotechnol.Prod.* 22, 753-762, 2006

Used a branched 25 kDa PEI with suspension-adapted CHO cells. The production of recombinant MABs was followed by ELISA and with alkaline phosphatase reporter gene in static culture and green fluorescent protein in shake cultures. The addition of growth factors to media improved production.

Breunig, M., Langwitz, U., Liebl, R., *et al.*, Mechanistic insights into linear polyethyleneimine-mediated gene transfer, *Biochim.Biophys.Acta* 1770, 196-205, 2007

Linear PEI (6.6 kDa) demonstrated high transfection efficiency (44%) with relatively low cytotoxicity. CHO cells were used in adherent culture. A plasmid with green fluorescent protein transgene was used as the reported gene.

# INTRODUCTION TO CARBOHYDRATES

## Nomenclature for carbohydrates

The reader is directed to recommendations from the International Union of Pure and Applied Chemistry (IUPAC) (1,2). The IUPAC recommendations are contained in the excellent work on carbohydrate structure by Collins (3). There are also excellent discussions of nomenclature in several reference texts (4,5). The reader is also directed to several recent articles concerning specific nomenclature issues (6-17). There are also IUPAC guidelines for glycolipids (18) as well as a separate article on the nomenclature of inositol derivatives (19).

The following are some simple definitions which might be useful. The reader is directed to the formal IUPAC documents for detail.

- **Aldaric acids** are aldoses where the aldehyde and terminal primary alcohol function are replaced by carboxylic acid residues.
- **Alditols** are polyhydric alcohols where the aldehyde function in an aldose or the ketone function in a ketose has been replaced by a hydroxyl function.
- **Aldonic acids** are monosaccharides which contain an aldehyde and a carboxylic acid function.
- **Aldoses** are monosaccharides with a terminal aldehyde function.
- **Aldosuloses** are monosaccharides which contain an aldehyde and a ketone function.
- An **Amino sugar** is a monosaccharide where a hydroxyl group has been replaced by an amino group such as with glucosamine.
- **Carbohydrates** includes monosaccharides, disaccharides, oligosaccharides, and oligosaccharides or glycans. The term **sugar** is usually confined to carbohydrates with lower molecular weights such as monosaccharides and disaccharides.
- **Deoxy** is a term describing a monosaccharide where an hydroxyl group has been replaced by a hydrogen.
- **Dialdoses** are dialdehyde monosaccharides.
- **Disaccharide** refers to a compound composed of two monosaccharide units connected by a glycosidic bond.
- **Furanose** (from furan) designates a five-membered ring.
- The term **glycan** is used to describe a oligosaccharide covalently bound to a protein. The **N-linked glycans** are frequently branched and are described a monoantennary, biantennary, triantennary, etc.
- A **glycerolipid** is a glycolipid with one or more glycerol groups.
- **Glycidiuloses** are diketo monosaccharides (5-keto-fructose).
- A **glycolipid** is a compound composed of one or more monosaccharide units bound by a glycosidic linkage to a hydrophobic group such as sphingoid or ceramide.
- A **glycoside (glycosidic) bond** joins monosaccharide units into disaccharides and oligosaccharide/polysaccharides. The glycoside bond joins the hydroxyl group on the anomeric carbon of a monosaccharide with any hydroxyl group on another monosaccharide through an acetal linkage.
- A **glycoside** is an acetal derivative of the cyclic form of a sugar where the hydrogen in the hemiacetal is replaced by an alkyl, aryl, or similar group.
- **Glycosonic acids (ketoaldonic acids)** are monosaccharides which contain a ketone function and a carboxylic acid function.
- A **glycosphingolipid** is a lipid containing at least one monosaccharide residue and either a sphingoid or ceramide.
- **Monosaccharide** denotes a single or monomer unit without glycosidic connection to another monosaccharide. The suffix **-ose** is used to designate a carbohydrate (**aldose**) such a glucose, pentose, hexose, galactose, etc. The suffix **-ulose** is used to designate a ketose, which is a carbohydrate containing a ketone function.
- The term **oligosaccharide** describes a compound composed of 10-20 monosaccharide units connected by glycosidic bonds. The length quoted here is arbitrary. Oligosaccharide is used to describe a oligomer of defined length rather than one, such as with starch or glycogen, of undefined length.
- The term **polysaccharide** is usually used to describe a large amorphous polymer consisting of monosaccharide units connected by glycosidic bonds.
- **Pyranose** (from pyran) designates a six-membered ring
- A **reducing sugar** contains an aldehyde or ketone function which reacts with alkaline ferricyanide or alkaline cupric tartrate (Fehling's solution).
- **Trisaccharide** describes a compound composed of three monosaccharides connected by glycosidic bonds.

### SOME TRIVIAL NAMES FOR MONOSACCHARIDES<sup>a</sup>

Allose (All)	<i>allo</i> -hexose	Mannosamine (ManN)	2-amino-2-deoxy-mannose
Altrose (Alt)	<i>altro</i> -hexose	Mannose (Man)	<i>manno</i> -hexose
Erythrose	<i>erythro</i> -tetrose	Psicose (Psi)	<i>ribo</i> -hex-2-ulose
Erythrulose	<i>glycero</i> -tetrulose	Quinovose (Qui)	6-deoxyglucose
Fructose (Fru)	<i>arabino</i> -hex-2-ulose	Rhamnosamine (RhaN)	2-amino-2,6-dideoxymannose
Galactosamine (GalN)	2-amino-2-deoxygalactose	Rhamnose (Rha)	6-deoxymannose
Galactose (Gal)	<i>galacto</i> -hexose	Ribose (Rib)	<i>ribo</i> -pentose
Glucose (Glu)	<i>gluco</i> -hexose	Ribulose (Rul)	<i>erythro</i> -pent-2-ulose
Glyceraldehyde	2,3-dihydroxy-propanal	Sorbose (Sor)	<i>xylo</i> -hex-2-ulose
Glycerol (Gro)	1,2,3-propanetriol	Tagatose (Tag)	<i>lyxo</i> -hex-2-ulose
Gulose (Gul)	<i>gulo</i> -hexose	Talose (Tal)	<i>talo</i> -hexose
Idose (Ido)	<i>ido</i> -hexose	Tartaric acid	Erythraric/Threarc Acid
Lyxose (Lyx)	<i>lyxo</i> -hexose	Xylose (Xyl)	<i>xylo</i> -pentose

<sup>a</sup> Adapted from McNaught, A.D., Nomenclature of carbohydrates, *IUPAC Pure & Applied Chemistry* 68, 1919-2008, 1996

## Selected references for disaccharides

Structures for these carbohydrates are available on p.390.

### Glycosides

- The term glycoside refers to a compound composed of a carbohydrate and a non-carbohydrate moiety. The non-carbohydrate moiety is referred to as the aglycone. There are O-glycosides and C-glycosides. The carbohydrate portions generally contain between one and three monosaccharide units connected by a glycosidic bond.

- O-Glycosides are composed of saccharides where the hydroxyl group of a hemiacetal is replaced by an alkoxy or aryloxy group. A thioglycoside is a glycoside where the hydroxyl group of a hemiacetal is replaced by an alkylthio or arylthio group. The replacement of the hydroxyl group of a hemiacetal with an alkylamine or arylamine function is called a glycosylamine. Replacement of the hydroxyl group with an alkyl or aryl group results in a C-glycoside. A C-glycoside is also referred to as an anhydroalditol. A C-glycoside is not cleaved by hydrolysis. The carbohydrate portion may be a five-membered ring (furanoside), a six-membered ring (pyranoside), or rarely a seven-membered ring (septanoside).

Aldaric acids are a group of carbohydrate dicarboxylic acids characterized by the general formula  $\text{HOOC}-(\text{CHOH})^n-\text{COOH}$

**Aldonic Acids**

Glycollic acid  
(hydroxyacetic acid)  
MW 76.05

Glyceric acid  
2,3-Dihydroxypropanoic acid  
MS 106.08

D-Lactic acid  
(2R)-Hydroxypropanoic acid

L-Lactic acid  
(2S)-Hydroxypropanoic acid

Lactic acid  
MW 90.08

Gluconic acid  
MW 196.16

Galactonic acid  
MW 196.16

Mannonic acid  
MW 196.16

Aldonic acids are carboxylic acids formed by the oxidation of aldehyde functions

**Allose and Altrose**

Allose  
MW 181.16

Altrose  
MW 189.16

## Arabinose and Derivatives

Arabinose (alpha-D-pyranose form)

Arabinose  
MW 150.13Arabinic acid  
(Arabinonic acid)  
MW 166.13

D-Arabitol

MW 152.15

L-Arabitol

## Butanetetrol

*(R\*,S\*)*-1,2,3,4-Butanetetrol  
Erythritol  
MW 122.12*(R\*,R\*)*-1,2,3,4-Butanetetrol  
Threitol  
MW 122.12

## Conduritol

Conduritol A  
(5-cyclohexene-1,2,3,4-tetrol)  
MW 146.4Conduritol B  
MW 146.14

Conduritol B epoxide

**Dialdoses**

**Fructose**

## Galactose and Galactose Derivatives

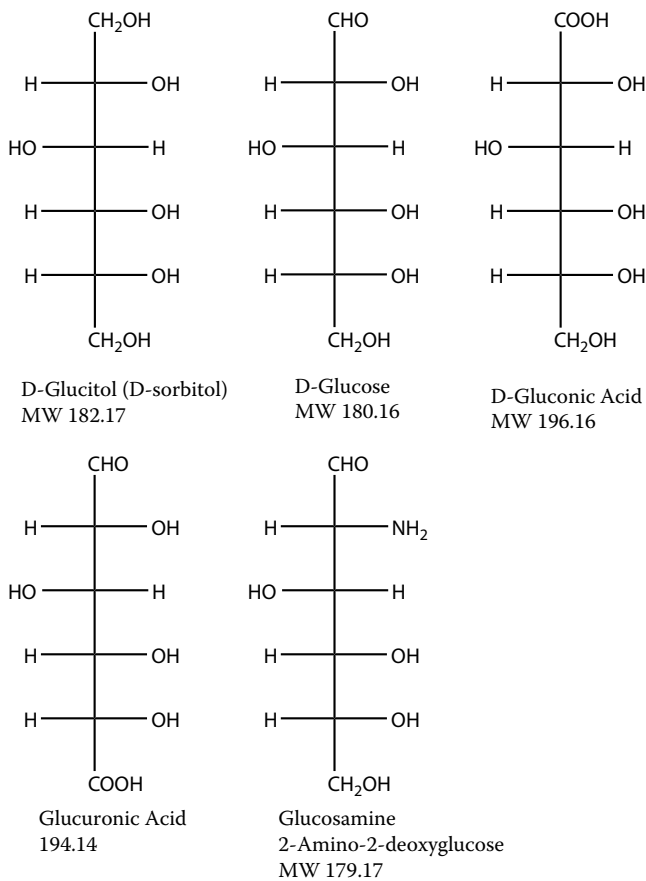

Glucitol (sorbitol)

Different Presentations of Glucose

Glucose and Glucose Derivatives

Glucose Oxidation

## Glucuronic Acid

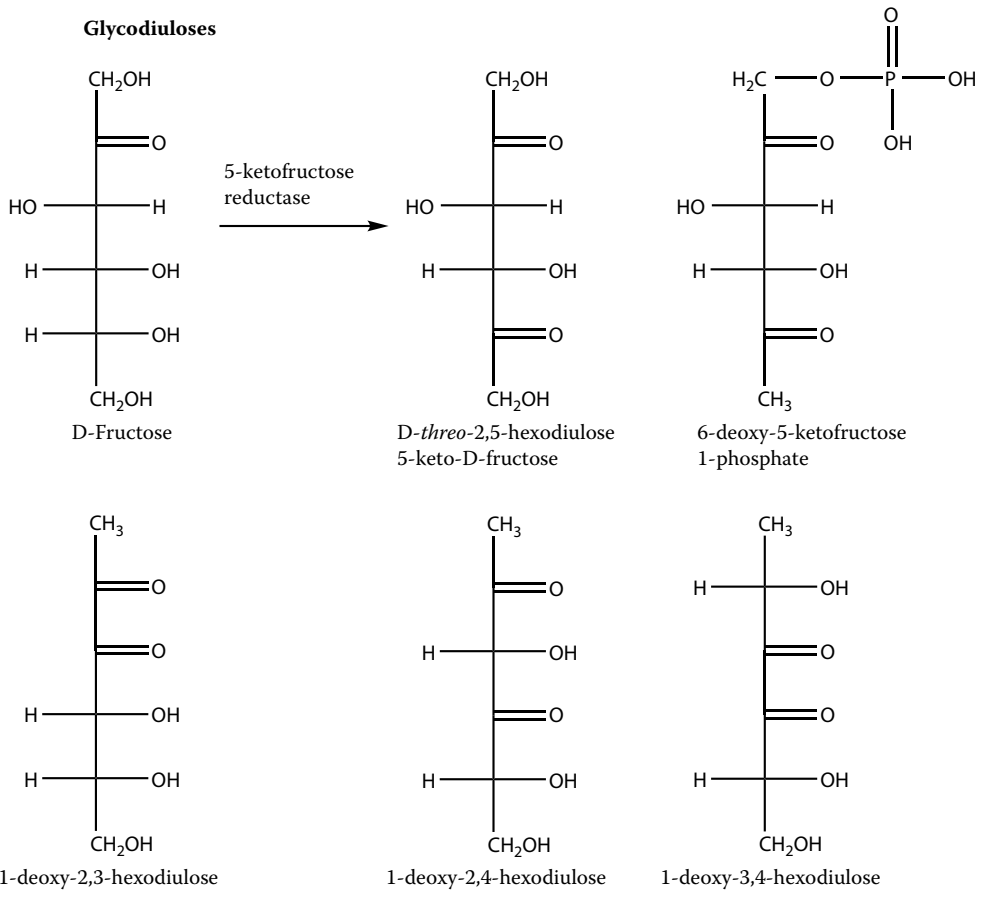

Uridine diphosphate glucuronosyltransferase

glucuronidation

Glycidiuloses

**Glycosulose**

Glycosuloses are obtained by the oxidation of a secondary hydroxyl groups in an aldose yielding a ketone

Glycosonic Acids (ketoaldonic acids) are obtained by the oxidation of secondary hydroxyl group in an aldonic acid yielding a ketone

## Heptose Derivatives

*D-glycero-D-galacto*-heptitol  
 Perseitol  
 MW 212.20

*D-glycero-D-manno*-heptitol  
 Volemitol  
 MW 212.20

*altro*-3-Heptulose  
 Coriose  
 MW 210.18

*D-glycero-D-manno*-heptose

*D-glycero-D-manno*-heptose

*D-altro*-2-heptulose  
 Sedoheptulose

## Heptoses and heptonic acids

*D-glycero-D-galacto-heptose*  
MW 210.18  
alpha-D-pyranose form

*D-glycero-D-gulo-heptose*  
MW 210.18  
alpha-D-pyranose form

*D-glycero-D-gulo-heptonic acid*  
MW 220.18

## Lactone Formation

Shikimic acid  
3,4,5-Trihydroxy-1-cyclohexene-1-carboxylic acid (3*R*,4*S*,5*R*)  
MW 174.15

Validatol  
4-Hydroxymethyl-1,2,3-hexanetriol, (1*S*,2*R*,3*R*,4*S*)  
MW 162.19

**Cellulose; Lactose: Maltose**

Cellulose; MW 342.30  
4-*O*-beta-D-glucopyranosyl-D-glucose

Lactose; MW 342,3  
4-*O*-beta-D-galactopyranosyl-D-glucose

Maltose, MW 342.30  
4-*O*-alpha-D-glucopyranosyl-D-glucose

**Melibiose Trehalose Isomaltose**

Melibiose MW 342.30  
6-O-alpha-D-galactopyranosyl-D-glucose

Trehalose MW 342.30  
alpha-D-glucopyranosyl-alpha-D-glucopyranoside

Isomaltose MW 342.30  
Brachiose  
6-O-alpha-D-glucopyranosyl-D-glucose

**Sucrose Trehalulose Isomaltulose**

Sucrose MW 342.30  
alpha-D-glucopyranosyl-beta-D-fructofuranoside

Trehalulose  
alpha-D-glucopyranosyl-1-1-D-fructofuranose

Isomaltulose' Palatinose  
alpha-D-glucopyranosyl-1,6-D-fructofuranose

Compiled by George G. Maher.

<sup>a</sup> In order of increasing carbon chain length in the parent compounds grouped in the classes – alditols, inositols, inososes, amino alditols, and inosamines.<sup>b</sup> [ $\alpha$ ]<sub>D</sub> for 1–5 g solute, c, per 100 ml aqueous solution at 20–25°C unless otherwise given.<sup>c</sup> References for melting point and specific rotation data. Letter indicates the reference also has chromatographic data according to: c = column, e = electrophoresis, g = gas, p = paper, and t = thin-layer.<sup>d</sup> R value times 100, given relative to that of the compound indicated by abbreviation: f = solvent front, gal = galactose, glc = glucose, glcl = glucitol, glcn = glucosamine, myol = *myo*-inositol, perl = perseitol, pinl = pinitol, rib = ribose, sorl = sorbitol, suc = sucrose, xyll = xylitol, (as the pentaacetate or the pentamethyl ether, as pertains), and aral = arabinitol (as the pentaacetate). Under gas chromatography (Column GLC or G) numbers without code indication signify retention time in minutes. The conditions of the chromatography are correlated with the reference given in parentheses and are found in Table 5.<sup>e</sup> Said to exist as a phosphate ester also.<sup>10</sup><sup>f</sup> Data given are for the enantiomorphous isomer.<sup>g</sup> The author names as 3-dehydroquinic acid, but it is actually 5-dehydroquinic.<sup>h</sup> The early given name, *l*-quercitol, of this compound does not make it the enantiomorph of *d*-quercitol; other isomeric relations are involved.<sup>i</sup> This compound is isomeric with the previous one in regard to the *N*-methyl group position.

Compiled by George G. Maher.

<sup>a</sup> In order of increasing carbon chain length in the parent compounds grouped in the classes-aldonic, uronic, aldaric, and amino sugar acids.<sup>b</sup> [ $\alpha$ ]<sub>D</sub> for 1–5 g solute, *c*, per 100 ml aqueous solution at 20–25°C, unless otherwise given.<sup>c</sup> References for melting point and specific rotation data. Letter indicates the reference also has chromatographic data according to: c = column, e = electrophoresis, g = gas, p = paper, and t = thin-layer.<sup>d</sup> R value times 100, given relative to that of the compound indicated by abbreviation: f = solvent front, ala = alanine, ara = arabinose, asa = ascorbic acid, Cl = chloride ion, eic = eicosane, galn = galactono-1,4-lactone, galU = galacturonic acid, glc = glucose, glcN = glucosamine, glcU = glucuronic acid, gNac = *N*-acetyl-glucosamine, gNUA = glucosaminuronic acid, kdH = 3-deoxy-*erythro*-hexulosonic acid, kdo = 3-deoxy-*manno*-octulosonic acid, kgu = 2-keto-gulonic acid, mal = malonic acid, manU = mannuronic acid, myo = *myo*-inositol, myot = *myo*-inositol trimethylsilyl ether, MU = methylene standard hydrocarbon units, nana = *N*-acetyl-neuraminic acid, pa = picric acid, rha = rhamnose, tmg = 2,3,4,6-tetra-*O*-methyl glucose, and xyl = xylitol pentamethylether. Under gas chromatography (column Glc or G) numbers without code indications signify retention time in minutes. The conditions of the chromatography are correlated with the reference given in parentheses and are found in Table E.<sup>e</sup> Value is in cm/h.<sup>f</sup> Equilibrates with the lactone.<sup>g</sup> Data given are for the enantiomorphous isomer.<sup>h</sup> The analytical elemental analysis indicates the compound is an anhydride.<sup>i</sup> The enol form is L-ascorbic acid.<sup>j</sup> Reference 99 terms this compound 2-deoxy-5-keto-*D*-gluconic acid; neither name nor structure seem definite.<sup>k</sup> Value is in cm/9 h.<sup>l</sup> Value is in cm/24 h.<sup>m</sup> Value is in cm/1.5 h.<sup>n</sup> Some workers relate the formula C<sub>12</sub>H<sub>21</sub>NO<sub>10</sub> whose elemental analysis is little different from that of C<sub>11</sub>H<sub>19</sub>NO<sub>9</sub>.

Compiled by George C. Maher.

<sup>a</sup> In alphabetical order of parent sugar names within groups of increasing carbon chain length in the parent compounds.<sup>b</sup> [ $\alpha$ ]<sub>D</sub> for 1, 5 g solute, *c*, per 100 ml aqueous solution at 20, 25°C, unless otherwise given.<sup>c</sup> References for melting point and specific rotation data. Letter indicates that the reference also has chromatographic data as follows: c = column, e = electrophoresis, g = gas, p = paper, and t = thin layer.<sup>d</sup> R value times 100, given relative to that of the compound indicated by abbreviation: f = solvent front, aco = acovenose, amgl = tetraacetyl dimethyl glucitol, aral = arabinitol pentaacetate, cym = cymarose, cymo = cymaronolactone, dang = methyl 4,6-di-*O*-acetyl-2,3-di-*O*-methyl- $\alpha$ -D-glucopyranoside, digx = digitoxose, dmxyl = 2,3-di-*O*-methyl-xylitol triacetate, drho = 2-deoxy-rhamnonolactone, erya = erythritol tetraacetate, fuc = fucose, gal = galactose, gals = galactose 6-sulfate, glc = glucose, glca = glucitol hexaacetate, glcl = glucitol, glcs = glucitol trimethylsilyl ether, glct = glucose trimethylsilyl ether, hep = *D*-glycero-*D*-manno-heptonolactone, manl = mannitol hexaacetate, mant = mannose trimethylsilyl ether, mfuc = methyl  $\alpha$ -fucopyranoside, mmt = methyl  $\alpha$ -mannopyranose trimethylsilyl ether, ole = oleandrose, rha = rhamnose, rib = ribose, sor = sorbitol, temg = 2,3,4,6-tetra-*O*-methyl-glucose, atemg = methyl 2,3,4,5-tetra-*O*-methyl- $\alpha$ -glucoside,  $\beta$ temg = methyl 2,3,4,5-tetra-*O*-methyl- $\beta$ -glucoside, temga = 2,3,4,6-tetra-*O*-methyl-glucitol diacetate, temgt = 2,3,4,6-tetra-*O*-methyl-galactose trimethylsilyl ether,  $\beta$ tma = methyl 2,3,4-tri-*O*-methyl- $\beta$ -D-arabinoside, trma = 2,3,4-tri-*O*-methyl-L-arabinose, trmal = 2,3,4-tri-*O*-methyl-L-arabinitol, xyl = xylose, and xyll = xylitol pentaacetate. Under gas chromatography (column GLC or G), numbers without code indication signify retention time in min. The conditions of the chromatography are correlated with the reference given in parentheses and are found in Table E.<sup>e</sup> As the methyl furanoside.<sup>f</sup> Data are for the enantiomeric isomer.<sup>g</sup> By inference from the enantiomeric isomer.<sup>h</sup> Value is in cm/3.75 hr.<sup>i</sup> Not, however, anomeric with aldgaroside A. Reference 88 assigns a 4-deoxy- $\beta$ -D-ribo-hexopyranose or 4-deoxy-D-allose structure.<sup>j</sup> Value is in cm/5 hr.

## TABLE C: NATURAL ALDOSES (Continued)

<sup>k</sup> As the methyl pyranoside.

<sup>l</sup> The reference is not clear as to D or L configuration.

<sup>m</sup> Reference 202 structures this as a glycoside, not an ester; but it may be an ester in view of the recent comparative isolates of Reference 58 under D-ribose, C-hydroxymethyl-.

<sup>n</sup> The inference is that olivomycolic *iso*-butyrate exists in the parent antibiotic.

<sup>o</sup> Value is in cm/17 hr.

<sup>p</sup> Value is in cm/23 hr.

<sup>q</sup> Reference 95 has the definitive names for tyvelose and abequose reversed from those of References 265 and 300.

<sup>r</sup> Although rhodiose is the L-isomer, it is not clear whether the sugar form in ydiginic acid is D or L.

<sup>s</sup> Early work had supported an L-*xylo*-configuration,<sup>333</sup> but additional study has established the L-*ribo*-320, 322

<sup>t</sup> A recent publication gives the reverse sign to the glycoside's optical rotation.

<sup>u</sup> A more recent publication has tentatively assigned the L-rhamnose configuration to the natural compound and called it nogalose.<sup>349</sup>

<sup>v</sup> Though never proved, some evidence exists for this sugar, or for L-altrose, in the polysaccharide varianose.

<sup>w</sup> As data here are meager, see those for the enantiomorphous isomer.

<sup>x</sup> Column was at 210° instead of 140°.

<sup>y</sup> Value is for the D-*glycero*-L-*hexo*- isomer.

<sup>z</sup> These may well be D-*glycero*-D-*manno*-, D-*glycero*-L-*manno*-, and L-*glycero*-D-*manno*- for References 404, 405, and 406, respectively; Reference 407 remains uncertain.

## Compiled by George G. Maher.

<sup>a</sup> In alphabetical order by parent sugar names within groups of increasing carbon chain length in the parent compounds.

<sup>b</sup> [ $\alpha$ ]<sub>D</sub> for 1–5 g solute, c, per 100 ml aqueous solution at 20–25°C, unless otherwise given.

<sup>c</sup> References for m.p. and specific rotation data. Letter indicates that the reference also has chromatographic data as follows: c = column, e = electrophoresis, g = gas, p = paper, and t = thin-layer.

<sup>d</sup> R value times 100, given relative to that of the compound indicated by abbreviation: f = solvent front, for = formaldehyde 2,4-dinitrophenylhydrazone, fru = fructose, glc = glucose, glcl = glucitol, glct = glucose trimethylsilyl ether, manh = manno-heptulose, rha = rhamnose, rib = ribose, sed = sedoheptulose, sor = sorbitol, van = vanillin, xyl = xylose. Under gas chromatography (column GLC or G), numbers without code indication signify retention time in minutes. The conditions of the chromatography are correlated with the reference given in parentheses and are found in Table E.

<sup>e</sup> A possible finding of glyoxal as a component in ethanol distillery streams exists, retention time of 29.9 min, but the identification needs other evidence.<sup>3</sup>

<sup>f</sup> There is no clear evidence that the configuration is D- or L.

<sup>g</sup> Value is in cm<sup>3</sup>/hr.

<sup>h</sup> Data are for the enantiomorphous isomer.

<sup>i</sup> The 1/2H<sub>2</sub>O and 2H<sub>2</sub>O forms also exist.

<sup>j</sup> From cured tobacco and animal products fructose and amino acid combinations, which are probably rearranged glycoside compounds and hence not included here, have been isolated; see References 71 and 72.

<sup>k</sup> This is an early structural name. The modern, preferred one is 3-hydroxy-2-furyl methyl ketone.<sup>98</sup> While perhaps not carbohydrates in a strict sense, this group of pyranose compounds is included because of their intimate relationship.

<sup>l</sup> A hemihydrate of lower melting point forms from the anhydrous anhydro sugar upon aging.

**Table E: CHROMATOGRAPHIC CONDITIONS FOR CHROMATOGRAPHY DATA IN TABLES A–D**

Reference <sup>a</sup> (A)	Conditions <sup>b</sup> (B)
	<b>FOR TABLE A</b>
(2)	Whatman <sup>®</sup> No. 4 paper, pH 9.6 Na <sub>2</sub> HAsO <sub>3</sub> (as 19.8 g As <sub>2</sub> O <sub>3</sub> /1 and NaOH added), 90-min runs at 20–25 V/cm, 20–25° using 18–20° cooling water.
(3)	Polypak 1 (120–200 mesh), 0.5 or 1 m by 6 mm O.D. glass column, N <sub>2</sub> gas at 32.5 ml/min, 250° isothermic or programmed 150–250° at 4°/min.
(4)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (9:2:2 v/v), front moves 30 cm in 3–4 h, descending.
(5)	Silica Gel H, 0.25 mm thick, 30 min 110° activation, EtOH-32% NH <sub>3</sub> -H <sub>2</sub> O (21:2:3.5).
(6)	Chromosorb <sup>®</sup> W (80–100 mesh) with 10% Carbowax <sup>®</sup> 20 M terminated with terephthalic acid, 4 ft by 0.25 in. O.D. copper column, He gas at 85 ml/min, 190°.
(7)	Gas-Chrom <sup>®</sup> Q with 3% QF-1 (w/w), 180 cm by 0.45 cm O.D. coiled hardened aluminum column, N <sub>2</sub> gas at 60 ml/min, 110°.
(8)	Chromosorb W (60–80 mesh) with 20% diethylene glycol succinate, 6 ft by 0.25 in. O.D. aluminum column, He gas at 55 ml/min, programmed 70–220° at 15°/min.
(11)	Silanized Celite <sup>®</sup> (60–80 mesh) with 15% LAC-2R-446 diethylene glycol adipate cross-linked with pentaerythritol, 20 ft by 0.37 in. O.D. copper column, H <sub>2</sub> gas at 300 ml/min, 175°.
(12)	Whatman No. 3 paper, water-saturated, EtAc descending.
(14)	Diatoport <sup>®</sup> S (60–80 mesh) with 20% SF96, 8 ft by 0.25 in. O.D. coiled copper column, He gas at 88 ml/min, 130° for 6 min and programmed to 220° at 3°/min.
(20)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (12:5:4), descending.
(21)	Chromosorb W coated by hexamethyldisilazane (60–80 mesh) with 10% LAC-1R-296 diethylene glycol adipate, 1.84 m by 0.32 cm I.D. glass column, N <sub>2</sub> gas at 30–50 ml/min, programmed 170–220° at 0.8°/min.
(26)	Silica Gel G (240–270 μm), 2 mm thick, dried at room temperature and 55–60° relative humidity 1–3 days, MeC(O)Et-HAc-H <sub>2</sub> O (60:20:20).
(31)	Magnesium silicate, air-dried plates with no chamber saturation, PrOH-H <sub>2</sub> O (5:5 v/v).
(32)	Diatoport S (80–100 mesh) with 10% SF-96, 8 ft by 0.25 in. O.D. copper column, He gas, 190°.
(35g)	Silanized Diatomate C (85–100 mesh) with 3.5% SE 52, 5 ft glass column, gas (not specified) flow rate at 45 ml/min.
(35t)	Merck <sup>®</sup> Silica Gel F 254, C <sub>6</sub> H <sub>6</sub> .
(38)	Celite AW (80–100 mesh) with 10% butanediol succinate polyester, 6 ft by 0.25 in. O.D. glass column, He gas at 28 ml/min, programmed 125–215° at 4°/min.
(44)	Whatman No. 1 paper, AmOH-Pyr-H <sub>2</sub> O (4:3:2 v/v).
(50a)	Silica Gel G, dried overnight at 135°, upper phase of C <sub>6</sub> H <sub>6</sub> -EtOH-H <sub>2</sub> O-0.8 sp gr NH <sub>4</sub> OH (200:47:15:1 v/v).
(50b)	Same as (50a) but solvent is BuOH-HAc-EtOEt-H <sub>2</sub> O (9:6:3:1 v/v).
(55a)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (40:11:19), descending.
(55b)	Whatman No. 1 paper, EtAc-HAc-HC(O)OH-H <sub>2</sub> O (18:3:1:4), descending.
(57p)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (10:4:3 v/v), descending.
(57g)	Chromosorb W (80–100 mesh) with 10% neopentylglycol sebacate polyester, 120 cm by 0.5 cm I.D. glass column, Ar gas at 150 ml/min, 205°.
(60)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (4:1:1), descending (?).
(66)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(70)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(72)	Whatman No. 1 paper, MeC(O)Me-H <sub>2</sub> O (95:5 v/v), descending.
(74)	Paper not described, BuOH-MeC(O)Me-H <sub>2</sub> O (4:1:5).
(79)	Anakrom <sup>®</sup> ABS (100–110 mesh) with 5% QF-1, 5 ft by 0.13 in. O.D. column (material of construction not given), N <sub>2</sub> gas at 20 ml/min, 150°.
(80)	Whatman No. 3 paper, 0.05 M Na <sub>2</sub> B <sub>4</sub> O <sub>7</sub> , 15 h run at 10 V/cm, room temperature.
(81)	Whatman No. 1 paper, MeC(O)Me-BuOH-H <sub>2</sub> O (3:1:1), ascending.
(82)	Whatman No. 1 paper, 0.15 M Na <sub>2</sub> B <sub>4</sub> O <sub>7</sub> , 10 V/cm, room temperature.
(84)	Gas-Chrom Q (100–120 mesh) with 3% silicone polymer JXR, 1.8 m by 4 mm O.D. coiled glass column, N <sub>2</sub> gas at 60 ml/min, 140° for 2 min and programmed to 210° at 3°/min.
(87a)	pH 10 Borate buffer solvent, only detail given.
(87b)	Whatman No. 1 paper, MeC(O)Me-aq 10% HAc (4:1).
(87c)	Whatman No. 1 paper impregnated with DMSO; <i>iso</i> -propylether solvent.
(89)	Breite, Macherey, Nagel, and Company No. MN847 paper, BuOH-Pyr-H <sub>2</sub> O (10:3:3 v/v).
(93)	Embacel kieselguhr (60–100 mesh) with 1.5% polyester resin LAQ 1-R-296, 115 cm by 4.5 mm I.D. glass column, N <sub>2</sub> gas at 30 ml/min, 215°.
(94)	Whatman No. 3 MM paper, aq Na <sub>2</sub> MoO <sub>4</sub> · 2H <sub>2</sub> O (25 g/1,200 ml) made to pH 5 with H <sub>2</sub> SO <sub>4</sub> , 2-h run at 30–60 V/cm, cooled.
(103)	Whatman No. 1 paper, EtAc-HAc-HC(O)OH-H <sub>2</sub> O (18:3:1:4), descending.
(109)	Whatman No. 1 paper, <i>sec</i> -BuOH-HAc-H <sub>2</sub> O (14:1:5).
(113)	Anachrom ABS with 10% XE-60, 24 in. by 0.19 in. O.D. stainless steel column, He gas at 70 ml/min, 170°.
(128)	Acid-alkali-washed Celite with 1.5% LAC 1-R-296 polyester, N <sub>2</sub> gas at 30–40 ml/min, 210°.

Table E: CHROMATOGRAPHIC CONDITIONS FOR CHROMATOGRAPHY DATA IN TABLES A–D (Continued)

Reference <sup>a</sup> (A)	Conditions <sup>b</sup> (B)
<i>FOR TABLE A (Continued)</i>	
(132)	Whatman No. 1 paper, MeC(O)Me-H <sub>2</sub> O (9:1 v/v), descending.
(134)	Whatman No. 3 MM paper, EtAc-HAc-H <sub>2</sub> O (3:1:3), descending.
(145)	Toyo No. 50 paper, BuOH-HAc-H <sub>2</sub> O (4:2:1 v/v).
(149)	Whatman No. 1 paper, Pyr-EtAc-HAc-H <sub>2</sub> O (5:5:1:3), descending (?).
<i>FOR TABLE B</i>	
(2)	Whatman No. 3 MM paper, ca. 0.1 M (NH <sub>4</sub> ) <sub>2</sub> CO <sub>3</sub> (7.9 g/l) at pH 8.9, 25-min run at 80 V/cm, 8°.
(3)	Chromosorb W(HP) (80–100 mesh) with 3% OV-1, 1.9 m by 4 mm I.D. glass column, He gas at 80 ml/min, programmed 70–325° at 10°/min.
(4)	Cellulose MN300HR, 350 μm thick, dried 24 h at room temperature, <i>iso</i> -PrOH-EtAc-H <sub>2</sub> O (23.5:65:11.5).
(8)	Whatman No. 1 paper, PrOH-conc NH <sub>3</sub> (7:3 v/v), descending.
(10)	Chromosorb G-AW-DMCS (60–80 mesh) with 3% polypenyl ether-5 ring, 4.5 m by 0.13 in. O.D. A1S1 321 stainless steel coiled column, Ar gas at 20 ml/min, 200°.
(11)	Gas-Chrom Q with 3% QF-1 (w/w), 180 cm, by 0.45 cm O.D. coiled hardened aluminum column, N <sub>2</sub> gas at 60 ml/min, 110°.
(14)	Whatman No. 1 paper, 0.05 M acetate buffer at pH 4, 1-h run at 35 V/cm.
(15)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(16)	Avirin <sup>®</sup> microcrystalline cellulose, dried 30–60 min at 80°, EtAc-HAc-HC(O)OH-H <sub>2</sub> O (18:3:1:4).
(23)	Silica Gel G (240–270 μm), 2 mm thick, dried at room temperature and 55–60° relative humidity 1–3 days MeC(O)Et-HAc-H <sub>2</sub> O (60:20:20).
(28)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3), ascending.
(29)	Paper not described, PrOH-HC(O)OH-H <sub>2</sub> O (6:3:1) for the acid, BuOH saturated with aq 3% conc NH <sub>3</sub> for the hydrazone.
(32)	Silica Gel G, dried overnight at 135°, BuOH-HAc-H <sub>2</sub> O (2:1:1 v/v).
(41)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (3:1:3), upper phase (?).
(44)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(57)	Gas-Chrom Q (100–200 mesh) with 3% silicone polymer JXR, 1.8 m by 4 mm O.D. coiled glass column, N <sub>2</sub> gas at 60 ml/min, 140° for 2 min and programmed at 210° at 3°/min.
(61)	Whatman No. 1 paper, acid-washed, PrOH-HC(O)OH-H <sub>2</sub> O (6:3:1), descending.
(62)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (3:1:3), upper phase (?).
(70)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (4:1:1), descending (?).
(71)	Whatman No. 1 paper, Pyr-EtAc-HAc-H <sub>2</sub> O (5:5:1:3), descending (?).
(73)	Kieselgur G, phosphate-impregnated, air-dried overnight, BuOH-MeC(O)Me-phosphate buffer (40:50:10).
(80)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (4:1:5), descending.
(81)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (4.4:1.6:4.0), descending.
(83)	Whatman No. 1 paper, water-saturated isobutyric acid, descending.
(88)	Paper not described, 0.1 M formate buffer at pH 3, 45-min run at 50 V/cm.
(89a)	Whatman P20 phosphocellulose paper, PrOH-EtAc-25% NH <sub>3</sub> -H <sub>2</sub> O (5:1:1:3), descending.
(89b)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (80:34:12), descending.
(91)	Chromosorb G (HP) (80–100 mesh) with 1% OV-17, 3 m by 3 mm I.D. stainless steel column, He gas at 35 ml/min, 130–190°.
(96)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (5:2:3 v/v), descending.
(97)	Silica Gel Supelcosil 12B, 0.5 mm thick, CHCl <sub>3</sub> -MeOH-HAc-H <sub>2</sub> O (65:50:2:12 v/v).
(98)	Whatman No. 3HR paper, EtAc-HAc-H <sub>2</sub> O (3:1:3), descending.

(110)	Toyo-Roshi No. 52 paper, BuOH-HAc-H <sub>2</sub> O (4:1:5 v/v), descending.
(112)	Whatman No. 1 paper, acid-washed, <i>tert</i> -AmOH-98% HC(O)OH-H <sub>2</sub> O (3:3:1), descending.
(113)	Schleicher & Schull No. 2043 paper, washed 2 days with developing solvent, BuOH-HAc-H <sub>2</sub> O (4:1:1 v/v).
(116)	Whatman No. 1 paper, BuOH-Pyr-0.1 N HCl (5:3:2), descending.
(117)	Pyr-HAc-H <sub>2</sub> O (100:40:860 v/v, pH 5.3), only details given.
(118)	Whatman Chromedia SG-41, 0.20 mm thick, MeOH-CHCl <sub>3</sub> (2:98), ascending.
(119)	Whatman No. 3 paper, EDTA-washed, EtOH-HAc-H <sub>2</sub> O (70:1:29), ascending.
(125)	Silica Gel G, CHCl <sub>3</sub> -MeC(O)Me (4:1).
(138a)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (4:1:5), descending.
(138b)	Whatman No. 1 paper, Pyr-EtAc-HAc-H <sub>2</sub> O (5:5:1:3), descending (?).
(141a)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (100:21:50), ascending.
(141b)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (40:11:6), descending.
(141c)	Whatman No. 1 paper, Pyr-EtAc-HAc-H <sub>2</sub> O (5:5:1:3), descending (?).
(144)	Schleicher & Schull No. 2043b paper, 0.01 M borax sol 0.007 M with CaCl <sub>2</sub> pH 9.2, 0.5 mA/cm.
(145)	Cellulose Pulver MN300HR, 0.5 mm thick, <i>iso</i> -PrOH-Pyr-HAc-H <sub>2</sub> O (8:8:1:4).
(148)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (50:12:25), descending.
(149)	Whatman No. 1 paper, EtAc-HAc-HC(O)OH-H <sub>2</sub> O (18:3:1:4), descending.
(152)	Whatman No. 1 paper, 0.1 M cadmium acetate, 90-min run at 20 V/cm.
(153)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (40:11:6), descending.
(154)	Siliconized Gas-Chrom P (100–140 mesh) with 1% SE-30, column not detailed, N <sub>2</sub> gas at 30 cc/min, 140°.

Table E: CHROMATOGRAPHIC CONDITIONS FOR CHROMATOGRAPHY DATA IN TABLES A–D (Continued)

Reference <sup>a</sup> (A)	Conditions <sup>b</sup> (B)
<i>FOR TABLE B (Continued)</i>	
(156)	Chromosorb W (80–100 mesh) with 14% ethylene glycol succinate polyester, 3 ft column, He gas at 23 psi, 155°.
(166a)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (4:1:1), descending (?).
(166b)	Silica Gel (Merck), BuOH-HAc-H <sub>2</sub> O (4:1:1), thickness not given.
(170)	Whatman No. 1 paper, EtOH-0.88d. NH <sub>3</sub> -H <sub>2</sub> O (80:5:15), descending.
(171)	0.2 M NH <sub>4</sub> Ac buffer, pH 5.8, only detail given.
(173)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (4:1:5), descending.
(177)	Chromedia <sup>®</sup> CC 41 binder free cellulose, 0.01 M NH <sub>3</sub> and 0.0033 M HAc, pH 10.2, 16-min run at 4.5 kV.
(178)	Whatman No. 1 paper, <i>sec</i> -BuOH-90% HC(O)OH-H <sub>2</sub> O (15:3:2), ascending.
(179)	Silica Gel G (Merck), BuOH-HAc-H <sub>2</sub> O (3:1:1).
(185)	Paper not described, DMF- <i>iso</i> -PrOH-MeC(O)Et-H <sub>2</sub> O (10:25:45:20).
(188)	Whatman No. 1 paper, 0.05 M acetate pH 4.5 buffer, 90-min run at 20 V/cm.
(189)	Paper not described, BuOH-HAc-H <sub>2</sub> O (7:7:2.3).
(191)	Whatman No. 1 paper, BuAc-HAc-EtOH-H <sub>2</sub> O (3:2:1:1).
(192a)	Whatman No. 3 MM paper, aq Na <sub>2</sub> MoO <sub>4</sub> · 2H <sub>2</sub> O (25 g/1,200 ml) made to pH 5 with H <sub>2</sub> SO <sub>4</sub> , 2 h-run at 30–60 V/cm, cooled.
(192b)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(192c)	Glass beads (120–140 mesh) with 0.05% OV-11, 150 cm by 0.3 cm I.D. stainless steel column, gas not described, programmed from 80° at 10°/min.
(193a)	Toyo No. 51A paper with the buffer of (192a) above.
(193b)	Toyo No. 51A paper, EtAc-Pyr-HAc-H <sub>2</sub> O (5:5:1:3 v/v), descending.
(194)	Whatman No. 1 paper, phenol-aq NH <sub>3</sub> , only detail given.
(205)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(206a)	Gas-Chrom A (60–80 mesh) with 3% OV-17, 300 cm by 0.3 cm I.D. stainless steel column, gas not described, programmed from 120° at 5°/min.
(206b)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (6:1:1 v/v), descending.
(208a)	Cellulose MN 300, 0.25 mm thick, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(208b)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (50:12:25), descending.
(209a)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (5:2:2 v/v), descending.
(209b)	Cellulose Sigmacell, BuOH-HAc-H <sub>2</sub> O (5:1:2 v/v), thickness not given.
(209c)	Gas-Chrom A (60–80 mesh) with 3% OV-17, 300 cm by 0.3 cm I.D. stainless steel column, gas not described, programmed from 120° at 5°/min.
(210a)	Whatman No. 3 MM paper, water-washed, BuOH-Pyr-HAc-H <sub>2</sub> O (40:5:1:95:4), pH 5.8, 75-min run at 35 V/cm.
(210b)	Whatman No. 1 paper, 0.2 M pyridine acetate buffer pH 6.5, time not given, 57 V/cm.
(212)	Schleicher & Schüll No. 2043b paper, BuOH-HAc-H <sub>2</sub> O (4:1:5).
(214)	KSK Silica Gel (150–200 mesh), PrOH-H <sub>2</sub> O (7:3), thickness not given.
(216)	Varaport 30 with 5% OV-210, 2 m by 2 mm I.D. Pyrex <sup>®</sup> U glass column, N <sub>2</sub> gas at 7.5 ml/min, programmed from 90° at 1°/min.
(217)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(218)	Schleicher & Schüll No. 2043b paper, BuOH-PrOH-0.1 N HCl (1:2:1).
(219)	Silica Gel F <sub>245</sub> (Merck) impregnated with 0.2 M NaH <sub>2</sub> PO <sub>4</sub> , thickness not given, BuOH-EtOH-H <sub>2</sub> O (2:1:1).
(221)	Whatman No. 3 MM paper, BuOH-HAc-H <sub>2</sub> O (4:1:5).
(222)	Whatman No. 17 paper, EtOH-H <sub>2</sub> O (70:30 v/v).
(223)	Whatman No. 3 MM paper, BuOH-PrOH-0.1 N HCl (1:2:1 v/v).
<i>FOR TABLE C</i>	
(2)	Chromosorb W (60–80 mesh) with 10% Carbowax 20M, 12 ft by 0.125 in. I.D. column, N <sub>2</sub> gas at 40 ml/min, programmed 65–210° at 8°/min.
(3)	Silica Gel G (Merck 7731) with 0.3 parts Carbowax 4000 and 0.0035 parts Tinopol WG (w/w), 0.3 mm thick, dried 30 min at 80°, benzene-heptane (65:35 v/v).
(5)	Whatman No. 3 MM paper, aq Na <sub>2</sub> MoO <sub>4</sub> · 2H <sub>2</sub> O (25 g/1,200 ml) made to pH 5 with H <sub>2</sub> SO <sub>4</sub> , 2-h run at 30–60 V/cm, cooled.
(6)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) organic phase.
(7)	Kieselgel G (Merck), BuOH-HAc-H <sub>2</sub> O (4:1:5).
(9)	Acid-washed and silanized Chromosorb W (80–100 mesh) with 3% SE-52, 6 ft by 0.25 in. O.D. coiled stainless steel column, unspecified gas at 75 ml/min, 140°.
(14a)	Chromosorb W (80–100 mesh) with 10% Carbowax 6000, 120 cm by 0.5 cm I.D. glass column, no gas or temperature data.
(14b)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (10:3:3 v/v), descending.
(14c)	Silica Gel G, dried 10 h at 110°, solvent as in (14b).
(17)	Silica Gel G (240–270 μm), 2 mm thick, dried at room temperature and 55–60° relative humidity 1–3 days, MeC(O)Et-HAc-H <sub>2</sub> O (60:20:20).
(19a)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(19b)	Neosorb NC with 15% butanediol succinate polyester, 100 cm by 0.4 cm I.D. stainless steel column, He gas at 40 ml/min, 200°.
(19c)	Whatman No. 1 paper, 0.1 M borate buffer at pH 9.6, 400 V, 3.5 h.
(19d)	Whatman No. 1 paper, MeC(O)Et-H <sub>2</sub> O azeotrope.
(23a)	Silica Gel G, 0.25 mm thick, MeC(O)Et-H <sub>2</sub> O azeotrope (85:7 v/v).
(23b)	Chromosorb W (100–120 mesh) with 15% LAC-4R-886, 120 cm by 0.5 cm ID. glass column, unspecified gas at 20 ml/min, 200°.

Table E: CHROMATOGRAPHIC CONDITIONS FOR CHROMATOGRAPHY DATA IN TABLES A–D (Continued)

Reference <sup>a</sup> (A)	Conditions <sup>b</sup> (B)
<i>FOR TABLE C (Continued)</i>	
(28)	Whatman No. 4 paper, pH 9.6 Na <sub>2</sub> HAsO <sub>3</sub> (as 19.8 g As <sub>2</sub> O <sub>3</sub> /l and NaOH added), 90-min runs at 20–25 V/cm, 20–25° using 18–20° cooling water.
(29)	Whatman No. 1 paper (?), BuOH-HAc-H <sub>2</sub> O (4:1:5), descending.
(30a)	Avirin microcrystalline cellulose, dried 30–60 min at 80°, BuOH-HAc-H <sub>2</sub> O (3:1:1).
(30b)	Avirin microcrystalline cellulose, dried 30–60 min at 80°, MeC(O)Et-water azeotrope.
(30c)	Avirin microcrystalline cellulose, dried 30–60 min at 80°, Pyr-EtAc-HAc-H <sub>2</sub> O (5:5:1:3).
(34)	Chromosorb W (60–80 mesh) with 20% diethylene glycol succinate, 6 ft by 0.25 in. O.D. aluminum column, He gas at 55 ml/min programmed 70–220° at 15°/min.
(35a)	Whatman 3 MM paper, 0.05 M Pyr-HAc buffer, pH 6.
(35b)	Whatman 3 MM paper, EtAc-Pyr-H <sub>2</sub> O (10:4:3 v/v).
(37)	“Kieselgel nach Stahl” (Merck), with 0.1 M sodium bisulfite, 0.25 mm thick, dried 1 h at 110–120°, EtAc-HAc-MeOH-H <sub>2</sub> O (6:1.5:1.5:1).
(38)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(40)	Silica Gel G (Merck), 0.25 mm thick, dried 0.5 h at 100°, EtOEt-toluene (2:1 v/v).
(47)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (52.5:32:15.5), descending.
(49)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (9:2:2 v/v), front moves 30 cm in 3–4 h, descending.
(50)	Kieselgel G (Merck) with 0.15 M phosphate buffer, pH 8, 0.25 mm thick, dried overnight, phenol-H <sub>2</sub> O (75:25 w/v), ascending.
(52)	Chromosorb W coated by hexamethyldisilazane (60–80 mesh) with 10% LAC-IR-296 diethylene glycol adipate, 1.84 m by 0.32 cm I.D. glass column, N <sub>2</sub> gas at 30–50 ml/min, programmed 170–220° at 0.8°/min.
(56)	Whatman No. 1 paper, water-saturated BuOH.
(57)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(58)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(59a)	Kieselgel G (Merck), 0.25 mm thick, dried 2 h at 120°, activated 15 min at 120°, benzene.
(59b)	Acid-washed, silicized Gas-Chrom P (100–140 mesh) with 1% SE-30, 6 ft by 4 mm glass U column treated with hexamethyldisilazane, N <sub>2</sub> gas at 40–60 ml/min, 150°.
(60a)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (3:1:1 v/v), descending.
(60b)	Silica Gel G, 0.5 mm thick, CHCl <sub>3</sub> -MeOH-H <sub>2</sub> O (65:25:4 v/v).
(60c)	Unspecified support with 3% SE-30 (methyl silicone), 5 ft by 0.125 in. unspecified column, He gas at 25 ml/min, 150°.
(67)	Chromosorb W (80–100 mesh) with 14% ethylene glycol succinate polyester, 3 ft column, He gas at 23 psi, 155°.
(68)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(69)	Silica Gel G, dried overnight at 135°, upper phase of C <sub>6</sub> H <sub>6</sub> -EtOH-H <sub>2</sub> O-0.8 sp gr NH <sub>4</sub> OH (200:47:15:1 v/v).
(72)	Acid-washed Chromosorb W (80–100 mesh) with 20% butanediol succinate, 1.5 m by 0.375 cm unspecified column, He gas at 120 ml/min, 145°.
(74)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(76a)	Acid-washed Chromosorb W (100–120 mesh) with 2% octylphenoxypoly (oxyethylene) ethanol, 115 cm by 3.8 mm unspecified U column purged 1 d at 180°, He gas at 50 ml/min, 165°.
(76b)	Support of (76a) with 5% LAC-4R-886 polyester wax, purged 1 d at 200°, He gas at 100 ml/min, 190°.
(77)	Whatman No. 1 paper, borate buffer, pH 10, 400 V.
(80)	Acid-washed Celite (80–100 mesh) with 15% butanediol succinate, 120 cm by 0.5 cm unspecified column, unspecified gas at 80–100 ml/min, 175°.
(82a)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(82b)	Whatman No. 3 paper, borate buffer, pH 10.4, 26.3 V/cm, 4.25-h run.
(82c)	ECNSS-M liquid phase in a glass column at 155–165° only data given.
(85a)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(85b)	Substrate not given, BuOH-Pyr-H <sub>2</sub> O (6:4:3 v/v).
(85c)	Glass column at 155–165° only detail, see <i>Angew. Chem.</i> , 82, 643 (1970).
(86)	Embacel AW (60–70 mesh) with 5% XE-60, 6 ft by 0.25 in. O.D. unspecified column, N <sub>2</sub> gas at 39 ml/min, programmed 100–220° at 10°/min.
(91a)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (3.6:1:1.15), descending.
(91b)	Unspecified support with 3% ECNSS-M (ethylene glycol succinate combined with cyanoethylsilicone), 10 ft by 0.25 in. unspecified column, N <sub>2</sub> gas at 60 ml/min, 175°.
(94a)	Whatman No. 3 paper, borate buffer, pH 10.4, 30 V/cm, 5-h run.
(94b)	Whatman No. 1 paper, toluol-BuOH (1:2)/H <sub>2</sub> O.
(95)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(96a)	Whatman No. 3 paper, borate buffer, pH 10.4, 26.3 V/cm, 4.25-h run.
(96b)	Kieselgel G (Merck), activated 1 h at 120°, EtAc- <i>iso</i> -PrOH-MeOH (70:15:15).
(96c)	Whatman No. 1 paper, toluol-BuOH (1:2)/H <sub>2</sub> O.
(98)	Gas-Chrom Q (100–120 mesh) with 3% ECNSSM, 1.3 m by 3 mm I.D. glass U column, gas and temperature.
(102)	Kieselgel G (Merck), activated 1 h at 120°, EtAc- <i>iso</i> -PrOH-MeOH (70:15:15).
(113)	Kieselgel G (Merck), activated 1 h at 120°, EtAc- <i>iso</i> -PrOH-MeOH (70:15:15).
(124)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (40:11:19).
(127)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (10:4:3 v/v), descending.
(130)	TIC grade silica gel (Fluka DO) with 0.03 M H <sub>3</sub> BO <sub>3</sub> , 0.3 mm thick, dried at room temperature 24 h, activated 1 h at 110°, BuOH-HAc-H <sub>2</sub> O (4:1:5).

Table E: CHROMATOGRAPHIC CONDITIONS FOR CHROMATOGRAPHY DATA IN TABLES A–D (Continued)

Reference <sup>a</sup> (A)	Conditions <sup>b</sup> (B)
<i>FOR TABLE C (Continued)</i>	
(131)	Chromosorb W (60–80 mesh) with 2% EGSS-X, 2.74 mm by 3.16 mm I.D. glass column, N <sub>2</sub> gas at 40 ml/min, 199°.
(135)	Whatman No. 1 paper, BuOH-H <sub>2</sub> O (1:1?), descending.
(136)	Whatman No. 1 paper, MeC(O)Et-H <sub>2</sub> O (4:1).
(140a)	Silica Gel, C <sub>6</sub> H <sub>6</sub> -MeC(O)Me (1:1).
(140b)	Silica Gel, C <sub>6</sub> H <sub>6</sub> -MeC(O)Me (5:1).
(140c)	Shimadzu Gaschromatograph apparatus, NGS, 136°, only details given.
(144)	Chromosorb W (60–80 mesh) with 3% OV-101, 1.8 m by 6.25 mm O.D. glass column, He gas at 60 ml/min, 140°.
(145a)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (3:1:3), upper phase (?).
(145b)	Diatoport W (60–80 mesh) with 10% SE-30, 6 ft by 0.25 in. column, He gas at 46 ml/min, 190°.
(149)	Chromosorb W (HMDS) with 5% Ucon LB 550X, 2 m by 3 mm stainless steel column, undescribed gas and temperature.
(150)	Whatman No. 3 paper, BuOH-HAc-H <sub>2</sub> O (10:1:3), descending.
(153a)	Whatman 3 MM paper, 0.05 M Pyr-HAc buffer, pH 6, 40 V/cm.
(153b)	Whatman No. 54 paper, EtAc-HAc-H <sub>2</sub> O (6:3:2).
(155a)	Whatman 3 MM paper, 0.1 M borate buffer, pH 10, 40 V/cm., 1-h run.
(155b)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (5:1:4), descending.
(159a)	Silica Gel (KSK), CHCl <sub>3</sub> -MeC(O)Me (6:4).
(159b)	Silica Gel (KSK), water-saturated cyclohexanol.
(159c)	Volodarskii M paper, 0.2 M borate buffer, pH 9.2, 8.5 V/cm, 5-h run.
(160)	Volodarskii C paper, EtAc-HAc-HC(O)OH-MeC(O)Et-H <sub>2</sub> O (17:3:1:15:5), descending.
(164)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(167)	Celite AW (80–100 mesh) with 10% butanediol succinate polyester, 6 ft by 0.25 in. O.D. glass column, He gas at 28 ml/min, programmed 125–215° at 4°/min.
(169)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(175a)	Toyo No. 51 paper, 0.1 M HAc-Pyr buffer, pH 6.5, 3000 V, 30-min run.
(175b)	Toyo No. 51 paper, BuOH-HAc-H <sub>2</sub> O (50:12:25) descending.
(180a)	Toyo-Roshi No. 51A paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3), descending.
(180b)	Gas-Chrom P with 2% XF-1105, 1.8 m by 4 mm I.D. glass column, N <sub>2</sub> gas at 70 ml/min 140°.
(184)	Chromosorb W (60–80 mesh) 15% LAC-4R-886, 120 cm by 0.5 cm I.D. glass column, unspecified gas at 190 ml/min and 190°.
(188a)	Ederol 208 paper impregnated with 40% dimethylformamide in acetone, cyclohexane-benzene-dimethyl-formamide (7:2:1 v/v).
(188b)	Kieselgel G (Merck), 0.25 mm thick, cyclohexane-diisopropyl ether-Pyr (4:4:2 v/v).
(189)	Chromosorb W (100–125 mesh) with 10% diethylene glycol succinate, column not given, N <sub>2</sub> gas at 45 ml/min, 175°.
(192)	Chromosorb W (60–80 mesh) with 1.5% SE-30, 1.5 m by 3 mm I.D. stainless steel column, N <sub>2</sub> gas at undisclosed flow, 170°.
(197)	Whatman No. 1 paper, water-saturated BuOH.
(203a)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (3.6:1:1.15), descending, (?).
(203b)	Kieselgel G (Merck), C <sub>6</sub> H <sub>6</sub> -MeC(O)Me (2:1).
(205)	BuOH-HAc-H <sub>2</sub> O only detail given.
(210a)	Chromosorb W (80–100 mesh) with 10% Carbowax 6000, 6 ft by 0.25 in. unspecified column, N <sub>2</sub> gas at 120 ml/min, 145°.
(210b)	Silica Gel G (nach Stahl), EtAc-EtOH-H <sub>2</sub> O (15:2:1 v/v).
(217)	Whatman No. 4 paper, phenol-H <sub>2</sub> O, 20°.
(219a)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (10:3:3 v/v), descending.
(219b)	Aeropak 30 with 10% Carbowax, 5 ft by 0.125 in. stainless steel column, N <sub>2</sub> gas at 15–20 ml/min, 170°.
(219c)	Silica Gel H, EtAc-HAc-HC(O)OH-H <sub>2</sub> O (18:3:1:4 v/v), ascending.
(219d)	Whatman No. 1 paper, borate buffer, pH 10, 1,250 V, 2-h run.
(223)	Whatman No. 3 paper, borate buffer, pH 10, 1,500 V.
(238a)	Gas-Chrom Q (100–200 mesh) with 3% ECNSSM, 1.3 m by 3 mm I.D. glass U column, gas and temperature not given.
(238b)	Whatman No. 1 paper, Pyr-EtAc-H <sub>2</sub> O (2:5:5: v/v), upper layer, descending.
(241)	Whatman No. 4 paper, 0.05 M sodium tetraborate, 90-min runs at 20–25 V/cm, 20–25° using 18–20° cooled water.
(243)	Acid-washed Celite (80–100 mesh) with 10% <i>m</i> -bis( <i>m</i> -phenoxyphenoxy) benzene, 120 cm by 0.5 cm unspecified column, unspecified gas at 80–100 ml/min, 175°.
(244a)	Silica Gel G (Merck), MeC(O)Et saturated with H <sub>2</sub> O.
(244b)	Silica Gel G (Merck), EtAc-toluene (2:1).
(244c)	Chromosorb W with SE-30, 150 cm by 0.3 cm stainless steel column, N <sub>2</sub> gas at 70 ml/min, programmed 110–170° at 4°/min.
(245)	Whatman No. 1 paper, PrOH-HAc-H <sub>2</sub> O (6:1:2 v/v), descending.
(246)	Silica Gel G, PrOH-EtAc-H <sub>2</sub> O (3:2:1 v/v).
(252)	Kieselgel G (Merck), activated at 140°, EtOEt-cyclohexane (5:1).
(253a)	Cellulose MN 300, 0.25 mm thick, BuOH-Pyr-H <sub>2</sub> O (6:4:3), (?).
(253b)	Chromosorb G (80–100 mesh) with 3% ECNSS-M, 200 cm by 0.318 cm column, only details given.
(255)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(258a)	Whatman No. 2 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(258b)	Silica gel as aqueous silicic acid (activity grade IV); <150 mesh, 0.5 mm thick, C <sub>6</sub> H <sub>6</sub> -MeC(O)Me(1:1).
(258c)	Neutral alumina (Al <sub>2</sub> O <sub>3</sub> , activity grade V), 0.5 mm thick, C <sub>6</sub> H <sub>6</sub> -MeC(O)Me (1:1).
(259a)	Kieselgel F254 Fertigplatten (Merck), activated at 140°; EtAc.
(259b)	EtAc-MeOH (8:2), only detail.

(262)	Schliecher and Schüll No. 2043b paper, EtAc-Pyr-H <sub>2</sub> O (2:1:2).
(263a)	Whatman No. 1 paper, toluene-BuOH (9:1), 6-h run.
(263b)	Kieselgel G (Merck), EtAc-MeOH (9:1), 45-min run.
(263c)	Whatman No. 1, paper toluene-BuOH-Pyr-H <sub>2</sub> O, 18-h run.
(265)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(266)	Silica Gel G, EtAc-MeOH (19:1) or (9:1).
(268)	Whatman No. 2 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(269)	Whatman No. 1 paper, water-saturated BuOH, ascending.
(273)	Borate buffer in the method of Foster, <i>Chem. Ind.</i> , 828, 1050 (1952).
(276a)	Spinco No. 300–846 or Schleicher and Schüll No. 2043 A gl paper, 0.083 M borax at pH 9.2, 380 V, 2 h and 10 min run.
(276b)	Paper not given, MeOH saturated with heptane.
(277)	Silica Gel G, 0.25 mm thick, activated at 120°, CH <sub>2</sub> Cl <sub>2</sub> -EtOEt (1:1).
(278)	Silica Gel G, EtAc-petroleum ether (3:2 v/v).
(279)	Whatman No. 2 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(280a)	Neutral alumina (Al <sub>2</sub> O <sub>3</sub> , activity grade V), 0.5 mm thick, C <sub>6</sub> H <sub>6</sub> -MeC(O)Me (3:1).
(280b)	Silica Gel as aqueous silica acid (activity grade IV); <150 mesh, 0.5 mm thick, CHCl <sub>3</sub> -MeC(O)Me (1:2).
(280c)	Neutral alumina (AlCO <sub>3</sub> , activity grade V); 0.5 mm thick, C <sub>6</sub> H <sub>6</sub> -MeC(O)Me (2:1).
(280d)	Silica Gel as aqueous silica acid (activity grade IV); <150 mesh, 0.5 mm thick, EtAc-heptane (3:1).
(280e)	Silica Gel as aqueous silicic acid (activity grade IV); <150 mesh, 0.5 mm thick, C <sub>6</sub> H <sub>6</sub> -MeC(O)Me (1:1).
(281a)	Silica Gel (Merck), EtAc.
(281b)	Silica Gel (Merck), EtAc-CHCl <sub>3</sub> (1:1 v/v).
(289)	Whatman No. 1 paper, water-saturated BuOH, 17 h.
(290)	Whatman No. 1 paper, toluene-BuOH (4:1)/H <sub>2</sub> O, 18-h run.
(292)	Kieselgur G, EtAc-65% <i>iso</i> -PrOH (65:35 v/v).
(294)	Chromosorb W (80–100 mesh) with 3% SE-52 silicone gum, 6 ft by 0.125 in. O.D. stainless steel column, unspecified gas, programmed from 120° at 2°/min.
(299)	Whatman No. 3 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(300)	Whatman No. 3 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(301)	Kieselgel F254 Fertigplatten (Merck), activated at 140°; EtAc, (?).
(302)	<i>tert</i> -BuOH-HAc-H <sub>2</sub> O (2:2:1), only detail given.
(303)	Silica Gel (Merck), EtAc.
(304)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(305a)	Lenigrad factory N <sub>2</sub> "M" paper, BuOH-HAc-H <sub>2</sub> O (4:1:1), ascending.
(305b)	Alumina with Brockmann activity of II-III, C <sub>6</sub> H <sub>6</sub> -MeOH (9:1).
(306)	Silica Gel G, CHCl <sub>3</sub> -MeC(O)Me (1:7).
(307a)	Silica Gel G, CHCl <sub>3</sub> -MeC(O)Me (1:7).
(307b)	Whatman No. 1 paper, BuOH-HAc-H <sub>2</sub> O (4:1:1), descending (?).
(310)	Whatman No. 1 paper, BuOH-MeC(O)Et (1:1)/borate buffer 50%, descending.
(312)	Whatman No. 3 MM paper, aq Na <sub>2</sub> MoO <sub>4</sub> · 2H <sub>2</sub> O (25 g/1,200 ml) made to pH 5 with H <sub>2</sub> SO <sub>4</sub> , 2-h run at 30–60 V/cm, cooled.
(315)	Toluene-MeC(O)Et (1:1)/H <sub>2</sub> O, descending, 23-h run.
(317a)	Schleicher and Schüll No. 2043b paper, BuOH-borate buffer.
(317b)	Silica thin-layer foil (Merck, Kieselgel-Fertigfolien), CH <sub>2</sub> Cl <sub>2</sub> -MeOH (100:5 v/v).
(317c)	Silica thin-layer foil (Merck, Kieselgel-Fertigfolien), CH <sub>2</sub> Cl <sub>2</sub> -MeOH (100:3 v/v).
(320a)	Paper not given, 0.1 M sodium borate buffer, pH 10, 1,600 V, 0°.
(320b)	Paper not given, BuOH-H <sub>2</sub> O, [see <i>J. Chromatogr.</i> , 3, 63 (1960)].
(329)	Whatman No. 1 paper, solvent as in (315) above.
(333)	Silica Gel as aqueous silicic acid (activity grade IV); <150 mesh, 0.5 mm thick, C <sub>6</sub> H <sub>6</sub> -MeC(O)Me (1:1).
(334a)	Toyo No. 51A paper, toluene-BuOH-H <sub>2</sub> O (1:1:2), descending.
(334b)	Toyo No. 51A paper, EtAc-HAc-H <sub>2</sub> O (3:1:3), descending.
(334c)	Toyo No. 51A paper, 0.1 M sodium borate pH 9.5, 30 V/cm, 70-min run.
(337)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:1).
(338)	Schleicher and Schüll No. 589 green paper, <i>teri</i> -AmOH-PrOH-H <sub>2</sub> O (3:1:1), descending.
(341)	Whatman No. 1 paper, MeC(O)Et saturated with H <sub>2</sub> O, descending.
(342)	Whatman No. 1 paper, MeC(O)Et-H <sub>2</sub> O (10:1 v/v).
(345)	Silica Gel, C <sub>6</sub> H <sub>6</sub> -EtAc (7:1).
(347)	Whatman No. 1 paper, MeC(O)Et saturated with H <sub>2</sub> O, descending.
(350a)	Whatman No. 3 MM paper, 0.05 M sodium tetraborate, 25 V/cm, 2–3-h run.
(350b)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(350c)	Chromosorb W (80–100 mesh) with 10% neopentylglycol sebacate polyester, 120 cm by 0.5 cm I.D. glass column, Ar gas at 150 ml/min, 205°.
(352)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(354a)	0.05 M Sodium tetraborate, only detail given.
(354b)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.

Table E: CHROMATOGRAPHIC CONDITIONS FOR CHROMATOGRAPHY DATA IN TABLES A–D (Continued)

Reference <sup>a</sup> (A)	Conditions <sup>b</sup> (B)
<i>FOR TABLE C (Continued)</i>	
(356)	Cellulose Sigmacell, BuOH-HAc-H <sub>2</sub> O (5:1:2 v/v), thickness not given.
(357a)	Whatman No. 1 paper, Pyr-EtAc-H <sub>2</sub> O (2:5:5 v/v), upper layer, descending.
(357b)	Chromosorb W (80–100 mesh) with 10% neopentylglycol sebacate polyester, 120 cm by 0.5 cm I.D. glass column, Ar gas at 150 ml/min, 205°.
(357c)	0.05 M Sodium tetraborate, only detail given.
(360a)	Whatman No. 1 paper, EtAc-PrOH-H <sub>2</sub> O (5:3:2).
(360b)	Whatman No. 4 paper, pH 9.6 Na <sub>2</sub> HAsO <sub>3</sub> (as 19.8 g As <sub>2</sub> O <sub>3</sub> /l and NaOH added), 90-min runs at 20–25 V/cm, 20–25° using 18–20° cooling water.
(373)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O-NH <sub>3</sub> (40:10:49:1).
(375a)	Borate buffer in the method of Foster, <i>Chem. Ind.</i> , 828, 1050 (1952).
(375b)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(379)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O-NH <sub>3</sub> (40:10:49:1).
(382)	Whatman No. 1 paper, AmOH-Pyr-H <sub>2</sub> O (4:3:2 v/v).
(383)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (3:1:3), upper phase (?).
(391)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (2:1:2) water-poor phase, descending.
(393)	Whatman No. 1 paper, BuOH-Pyr-H <sub>2</sub> O (6:4:3).
(395)	Whatman No. 1 paper, EtAc-HAc-HC(O)OH-H <sub>2</sub> O (18:3:1:4), descending.
(397)	Whatman No. 3 MM paper, 0.1 M sodium tetraborate, 25 V/cm, 2–3-h run.
(398a)	Whatman No. 1 paper, MeC(O)Me-H <sub>2</sub> O (95:5 v/v), descending.
(398b)	Chromosorb W (80–100 mesh) with 10% neopentylglycol sebacate polyester, 120 cm by 0.5 cm I.D. glass column, Ar gas at 150 ml/min, 204° for acetates and 165° for ethers.
(401a)	Acid-washed Chromosorb W (100–200 mesh) with 10% LAC-4R-886 polyester wax, 5 ft by 0.125 in. coiled metal column, N <sub>2</sub> gas at 75 ml/min, 190°.
(401b)	Acid-washed, siliconized Gas-Chrom P (100–400 mesh) with 15% SE-30, same column as (401a), N <sub>2</sub> gas at 60 ml/min, 180°.
(402a)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (9:2:2 v/v), front moves 30 cm in 3–4 h, descending.
(402b)	ECNSS-M, only data given; glass column at 155–165° assumed.
(406a)	Whatman No. 1 paper, MeC(O)Me-H <sub>2</sub> O (95:5 v/v), descending.
(406b)	Whatman No. 1 paper, <i>iso</i> -BuOH-Pyr-H <sub>2</sub> O (10:3:3 v/v).
(410)	Kieselgel G (Merck), C <sub>6</sub> H <sub>6</sub> -MeC(O)Me (2:1).
<i>FOR TABLE D</i>	
(2)	Kieselgel G (Merck), BuOH-HAc-H <sub>2</sub> O (4:1:5).
(3)	Gas-Chrom Z (60–80 mesh) with 20% Carbowax 20M, 7 ft by 0.25 in. O.D. stainless steel U column, He gas at 80 ml/min, 90°.
(4)	Toyo No. 51 paper, <i>n</i> -PrOH-EtAc-H <sub>2</sub> O (7:1:2), ascending.
(5)	Chromosorb G-AW-DMCS (60–80 mesh) with 3% polyphenyl ether-5 ring, 4.5 m by 0.13 in. O.D. A1S1 321 stainless steel coiled column, Ar gas at 20 ml/min, 200°.
(6)	Chromosorb W (60–80 mesh) with 10% Carbowax 20M, 12 ft by 0.125 in. I.D. column, N <sub>2</sub> gas at 40 ml/min, programmed 65–210° at 8°/min.
(7)	Whatman No. 3 MM paper, <i>n</i> -BuOH-0.5 M NH <sub>3</sub> in H <sub>2</sub> O (1:1 v/v), descending.
(8)	Whatman No. 4 paper dipped in 25% solution of DMF in EtOH, dried 10–15 min, cyclohexane.
(9)	Whatman No. 1 paper, <i>iso</i> -BuC(O)Me-HC(O)OH-H <sub>2</sub> O (1,000:4:96 v/v), descending.
(10)	Whatman No. 4 paper, pH 9.6 Na <sub>2</sub> HAsO <sub>3</sub> (as 19.8 g As <sub>2</sub> O <sub>3</sub> /l and NaOH added), 90-min runs at 20–25 V/cm, 20–25° using 18–20° cooling water.
(13)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (12:5:4), descending.
(14)	Silica Gel G (Merck 7731) with 0.3 parts Carbowax 4000 and 0.0035 parts Tinopol WG (w/w), 0.3 mm thick, dried 30 min at 80°, benzene-heptane (65:35 v/v).
(17)	Silica Gel G (Merck), after Stahl, 0.5 mm thick, toluene-EtAc (2:1 v/v).
(19a)	Whatman No. 3 paper, bisulphite buffer, pH 4.7, 12–18 V/cm, 50°.
(19b)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (4:1:5 v/v) upper phase, descending.
(19c)	3% ECNSS containing column, 150°, only details given.
(20a)	Whatman No. 3 paper, bisulphite buffer, pH 4.7, 12–18 V/cm, 50°, (see also Reference 21).
(20b)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (3:1:3), upper phase (?).
(26)	Toyo-Roshi No. 50 paper, <i>iso</i> -PrOH-H <sub>2</sub> O (6:1), ascending.
(28)	Acid-washed and silanized Chromosorb W (80–100 mesh) with 3% SE-52, 6 ft by 0.25 in. O.D. coiled stainless steel column, unspecified gas at 75 ml/min, 140°.
(30)	Whatman No. 4 paper, water-saturated phenol, descending.
(31)	Paper not given, 0.05 M borate buffer, pH 10, 500 V, 3-h run.
(34)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (40:11:19).
(36)	Microcrystalline cellulose (Avirin), BuOH-EtOH-H <sub>2</sub> O (40:11:19 v/v), ascending.
(38)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (5:2:2 v/v), descending.
(43)	Whatman No. 3 MM paper, aq Na <sub>2</sub> MoO <sub>4</sub> · 2H <sub>2</sub> O (25 g/1,200 ml) made to pH5 with H <sub>2</sub> SO <sub>4</sub> , 2-h run at 30–60 V/cm, cooled.
(44)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (9:2:2 v/v), front moves 30 cm in 3–4 h, descending.
(45)	Paper not given, phenol-H <sub>2</sub> O (4:1).

(64)	"Kieselgel nach Stahl" (Merck), with 0.1 M sodium bisulfite, 0.25 mm thick, dried 1 h at 110–120°. EtAc-HAc-MeOH-H <sub>2</sub> O (6:1.5:1.5:1).
(66)	Silica Gel G, dried overnight at 135°, upper phase of C <sub>6</sub> H <sub>6</sub> -EtOH-H <sub>2</sub> O-0.8 sp gr NH <sub>4</sub> OH (200:47:15:1 v/v).
(67)	Silica Gel G (Merck), 0.25 mm thick, dried 0.5 h at 100°, EtOEt-toluene (2:1 v/v).
(74)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (40:11:19).
(79)	3–10% XE-60 on silanized glass capillary, 28 m by 0.17 mm I.D., N <sub>2</sub> gas flow not given, 130–170°.
(81)	Whatman No. 1 paper, MeC(O)Et-EtC(O)OH-H <sub>2</sub> O (75:25:30 v/v), ascending.
(84)	Whatman No. 1 paper, BuOH-EtOH-H <sub>2</sub> O (40:11:19).
(91)	Toyo-Roshi No. 50 paper, PrOH-H <sub>2</sub> O (4:1 v/v).
(92a)	Gas-Chrom P (60–80 mesh) with 20% Carbowax 20M, 9 ft by 0.25 in O.D. stainless steel column, He gas at 1 80 ml/min, 80°, programmed irregularly at 215° in 76 min.
(92b)	Bio Sil A, dried overnight at 135°, upper phase of C <sub>6</sub> H <sub>6</sub> -EtOH-H <sub>2</sub> O-0.8 sp gr NH <sub>4</sub> OH (200:47:15:1 v/v).
(100)	Diatoport A (80–100 mesh) with 10% UCW 98, 6 ft by 0.125 in. O.D. stainless steel column, He gas at 120 ml/min, 130°.
(101)	Whatman No. 1 paper, EtAc-HAc-HC(O)OH-H <sub>2</sub> O (18:3:1:4), descending.
(103)	Whatman No. 1 paper, phenol-H <sub>2</sub> O (80:10 w/v).
(106)	Chromosorb W with 1.5% SE-30, 225 cm by 4 mm stainless steel column.
(110)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (8:2:1 v/v), descending.
(113)	Whatman No. 1 paper, EtAc-HAc-H <sub>2</sub> O (9:2:2 v/v), front moves 30 cm in 3–4 h, descending.
(116)	Whatman No. 3 MM paper, aq Na <sub>2</sub> MoO <sub>4</sub> · 2H <sub>2</sub> O (25g/1,200 ml) made to pH5 with H <sub>2</sub> SO <sub>4</sub> , 2-h run at 30–60 V/cm, cooled.
(117)	Whatman No. 1 paper, EtAc-Pyr-H <sub>2</sub> O (8:2:1 v/v), descending.
(118)	Whatman No. 1 paper, water saturated phenol, pH 5.5, descending.
(125)	Gas-Chrom A with 3% SE-52, 183 cm by 0.6 cm column, N <sub>2</sub> gas at 100 ml/min, programmed 75–280 at 11°/min.

Compiled by George G. Maher.

<sup>a</sup> The reference number correlates with the same reference number in the respective preceding tables.

<sup>b</sup> Abbreviations used in developing solvent compositions: Ac = CH<sub>3</sub> C(O)O, Am = *n*-amyl, Bu = *n*-butyl, DMF = dimethylformamide, DMSO = dimethylsulfoxide, Et = ethyl, Me = methyl, Pr = *n*-propyl, Pyr = pyridine. For trade names of support and liquid phase materials, one is referred to an adequate chemical supply house catalog of chromatographic materials, or to *Handbook of Chromatography*, Vol. 2, Zweig, G. and Sherma, J., Eds., CRC Press, Cleveland, Ohio, 1972, 255.

## CARBOHYDRATE PHOSPHATE ESTERS

The next two tables are taken directly from 3rd Edition of *The Handbook of Biochemistry and Molecular Biology* which was edited by late Gerald Fasman. This material appeared in the original edition of *The Handbook of Biochemistry and Molecular Biology* which was edited by Herbert Sober. These tables have been retained in the current edition without modification to ensure the retention of data. It is the intent of the editor to ensure that this material is revised for subsequent editions.

<sup>a</sup> In order of increasing carbon chain-length in the parent compounds, grouped in the classes: alditols, acids, aldoses, ketoses, and disaccharides. The term phosphate ester denotes a carbohydrate dihydrogen phosphate wherein the two acidic groups of the acid ester are combined with suitable cations.

<sup>b</sup> For the ester group that is farthest in the carbon chain structure from the asymmetric center which determines the D or L configuration of the parent compound.

<sup>c</sup> FA = free acid, Ag = silver salt, Ba = barium salt, K = potassium salt, Na = sodium salt, B = brucine salt, cha = cyclohexylammonium salt, d = di, tr = tri, and t = tetra.

<sup>d</sup>  $[\alpha]_D$  at the sodium D line, 5876 Å, unless indicated otherwise in parentheses.

<sup>e</sup> In grams per 100 ml of solution at 20–25°C. Other temperatures are in parentheses. Unless otherwise indicated, the concentration is 1–5 g in water.

<sup>f</sup> Calculated by the contributors from the data of the reference cited, using  $k = 0.30/\text{time in min}$  for 50% hydrolysis of the ester linkage.

<sup>g</sup> For the pyrophosphate group.

<sup>h</sup> For the second ester group.

<sup>i</sup> Both ester linkages hydrolyze equally.

<sup>j</sup> D-Mannonic acid 6-phosphate and 2-deoxy-D-*arabino*-hexose 6-phosphate have been reported as skin metabolites in unnatural environments (see Reference 123).

Compiled by Donald L. MacDonald, with acknowledgments to George C. Maher and the late Melville L. Wolfrom, compilers of the corresponding tables in earlier editions.

<sup>a</sup> Compounds are grouped in order of increasing chain length. Within each group, they are arranged in the order alcohols, aldoses, ketoses, and acids.

<sup>b</sup> For the ester group at the lowest numbered carbon atom. The  $k$  values are in  $\text{min}^{-1}$  (natural logarithms).

<sup>c</sup> FA = free acid, Ag = silver salt, B = brucine salt, Ba = barium salt, cha = cyclohexylammonium salt, K = potassium salt, Na = sodium salt, d = di, tr = tri, t = tetra.

<sup>d</sup>  $[\alpha]$ , at the sodium D line, 5890 Å, unless otherwise indicated in parenthesis.

<sup>e</sup> Concentrations are 1–5 g/100 ml of solution at 20–25°; solvents other than water are indicated, and other temperatures are given in parentheses.

<sup>f</sup> Calculated by the contributor from the data of the reference cited;  $k = 0.69/\text{time in minutes}$  for 50% hydrolysis of the ester linkage.

<sup>g</sup> For the pyrophosphate group.

<sup>h</sup> For the second ester group.

<sup>i</sup> Both ester groups hydrolyze with equal ease.

## THE NATURALLY OCCURRING AMINO SUGARS (Continued)

<sup>a</sup> MP, melting point;  $[\alpha]_D$  – Rotation solvent; water, unless otherwise indicated in which case W-E = water:ethanol (1:1); W-HCl = water-HCl; E = ethanol; M = methanol. The abbreviations ( $\alpha$ ) or ( $\beta$ ) indicate the anomer, FB = free base; HCl indicates the hydrochloride; Ac the acetate.

<sup>b</sup> Solvent system:

- |                  |   |    |   |
|------------------|---|----|---|
| A.               | n-butanol-pyridine-water (6:4:3)  | J. | isobutyric acid- <i>N</i> ammonia (10:0:6)            |
| A <sup>Δ</sup> . | solvent system A on paper treated with 0.1 M BaCl <sub>2</sub> or BaAc <sub>2</sub> | K. | pyridine-ethyl acetate-water (10:3.0:1.5 upper layer) |
| B.               | n-butanol glacial acetic acid-water (5:1:2)   | L. | n-butanol-ethanol-water (13:8:4)                      |
| C.               | phenol-water (70:30)  | M. | n-butanol-acetic acid-water (3:1:1)                   |
| D.               | phenol-water (80:20), ammonia atmosphere  | N. | n-butanol-ethanol-water (4:1:1)                       |
| E.               | ethylacetate-pyridine-water-acetic acid (5:5:3:1)                                   | O. | n-butanol-pyridine-0.1 <i>N</i> HCl (5:3:2)           |
| F.               | pyridine-ethyl acetate-water (10:36:11.5)   | P. | n-butanol-acetic acid-water (25:6:25)                 |
| G.               | phenol-water (80:20)  | Q. | ethylacetate-pyridine-water (2:1:2)                   |
| H.               | n-butanol-acetic acid-water (5:1.2:2.5)   | R. | n-butanol-ethanol-water (5:1:4)                       |
| I.               | ethylacetate-pyridine-n-butanol-butyric acid water (10:10:5:1:5)                    | S. | n-propanol-1 per cent ammonia (7:3)                   |

<sup>c</sup> System I: Dowex 50 H<sup>+</sup> column 1 × 50 cm packed according to Gardell and eluted with 0.33 *N* HCl.<sup>44</sup>

System II: Technicon amino acid analyzer modified by Brendel et al.<sup>4</sup> and eluted with 0.133 *M* pyridine-acetic acid (0.82 *M*) buffer pH 3.85.

<sup>d</sup> Denotes the reference describing the characterization of the compound in question.

<sup>e</sup> Denotes chromatographic identification.

<sup>f</sup> Indicates that the recorded physical properties are for the synthetic compound.

<sup>g</sup> Brendel et al. system using 3.1 *M* pyridine-acetic buffer at pH 4.5.<sup>4</sup>

<sup>h</sup> Not all of the *N*-acetamido compounds have necessarily been found in nature, but are listed here for convenience.

<sup>i</sup> *N*-acetylmannosamine and *N*-acetylgalactosamine have an R<sub>N</sub>-acetylglucosamine of 0.4–0.5 when run on Borate-treated paper with solvent A.

<sup>j</sup> The *c*-2 carbon configuration is in doubt.

## OLIGOSACCHARIDES (INCLUDING DISACCHARIDES)

The next two tables are taken directly from 3<sup>rd</sup> Edition of *The Handbook of Biochemistry and Molecular Biology* which was edited by the late Gerald Fasman. This material appeared in the original edition of *The Handbook of Biochemistry and Molecular*

*Biology* which was edited by Herbert Sober. These tables have been retained in the current edition without modification to assure the retention of data. It is the intent of the Editor to assure that this material is revised for subsequent editions.

Substance <sup>a</sup> (Synonym) (A)	Derivative (B)	Chemical Formula (C)	Melting Point °C (D)	Specific Rotation <sup>b</sup> [α] <sub>D</sub> (E)	Reference (F)
<b>DISACCHARIDES</b>					
O-6-Deoxy-3-O-methyl-β-D-Allp-(1 → 4)-D-digitoxose (Drebyssobiose)		C <sub>13</sub> H <sub>24</sub> O <sub>8</sub>	108–110	+25.8	324
	Drebyssobionic acid lactone	C <sub>13</sub> H <sub>22</sub> O <sub>8</sub>	125–131	+29.6 (c 0.7, CHCl <sub>3</sub> )	324
O-(4-O-Benzoyl)-D-apiosyl-(1 → 2)-D-glucopyranosyl benzoate		C <sub>25</sub> H <sub>26</sub> O <sub>12</sub>	148–150	–106 (CH <sub>3</sub> OH)	1, 2
	Pentaacetate	C <sub>35</sub> H <sub>36</sub> O <sub>17</sub>	203–204	–35 (CHCl <sub>3</sub> )	1
O-D-Fruf-(2 → 2)-D-Fruf-anhydride (Alliuminoside)		C <sub>12</sub> H <sub>20</sub> O <sub>10</sub>	92–93	–23.8	3
	Hexaacetate	C <sub>24</sub> H <sub>32</sub> O <sub>16</sub>	98–99	–29.3	3

Compiled by George G. Maher.

<sup>a</sup> In alphabetical order by the sequence (starting at the nonreducing end) of the component monosaccharide glycosyl units constituting the oligosaccharide arranged within the groups—disaccharides, trisaccharides, etc. The oligosaccharides entered are only those which have been as a naturally existing entity or have been found to derive from the known reaction of a known natural enzyme on a known natural carbohydrate substrate under conditions not foreign to natural biological systems.

<sup>b</sup> [α]<sub>D</sub> for 1–5 g solute, c per 100 ml aqueous solution at 20–25°C unless otherwise given.

<sup>c</sup> Crystallizes in one of two forms, depending on solvent used.

Compiled by Akira Kobata.

<sup>a</sup> In the order of pentose, hexose, methylpentose, hexosamine, hexuronic acid, and sialic acid at the nonreducing end of the oligosaccharide, arranged within the groups-disaccharides, trisaccharides, etc. Oligosaccharides which have other component than sugar are entered at the end of each group.

<sup>b</sup> [α]<sub>D</sub> for 1–5 g solute, c, per 100 ml aqueous solution at 20–25°C unless otherwise noted.

## MUCOPOLYSACCHARIDES (GLYCOSAMINOGLYCANS)

Name <sup>a</sup>	Repeating Unit <sup>b</sup>	$[\alpha]_D$ , Degrees <sup>c</sup>	Infrared, $\text{Cm}^{-1}$ , <sup>d</sup>	Intrinsic Viscosity (21)	Molecular Weight	Occurrence
Chitin	(1 → 4)-O-2-Acetamido-2-deoxy-β-D-glucopyranose (1)	-14 to +56 <sup>i</sup> (1)	884–890 (1)	—	—	Skeletal substance of arthropods, molluscs, and annelids, cell wall of many fungi, green algae
Chondroitin	(1 → 4)-O-β-D-Glucopyranosyluronic acid-(1 → 3)-2-acetamido-2-deoxy-β-D-galactopyranose (2, 3)	-21 (3)	—	—	—	Bovine cornea
Chondroitin 4-sulfate (Chondroitin sulfate A)	(1 → 4)-O-β-D-glucopyranosyluronic acid-(1 → 3)-2-acetamido-2-deoxy-4-O-sulfo-β-D-galactopyranose (4)	-26 to -30 (4)	724, 851, 930 (17, 18)	0.2–1.0	5×10 <sup>4</sup> (22)	Bone cornea, cartilage, notochord, skin
Chondroitin 6-sulfate (Chondroitin sulfate C)	(1 → 4)-O-Glucopyranosyluronic acid-(1 → 3)-2-acetamido-2-deoxy-6-O-sulfo-β-D-galactopyranose (5)	-12 to -22 (5)	775, 820, 1,000 (17,18)	0.2–1.3	5×10 <sup>3</sup> –50×10 <sup>3</sup> (21)	Cartilage, aorta, skin, umbilical cord
Dermatan sulfate (Chondroitin sulfate B, β-heparin)	(1 → 4)-O-α-L-Idopyranosyluronic acid-(1 → 3)-2-acetamido-2-deoxy-4-O-sulfo-β-D-galactopyranose (6) <sup>e</sup>	-55 to -63 (13)	724, 851, 930 (18)	0.5–1.0	1.5×10 <sup>4</sup> –4×10 <sup>4</sup> (21)	Aorta, skin, umbilical cord, tendon
Heparan sulfate (Heparitin sulfate)	Glucopyranosyluronic acid-(1 → 4)-2-amino-2-deoxy-O-sulfo-D-glucopyranose (7) <sup>f</sup>	+39 to +69 (14)	920, 1,050 (19)	—	—	Aorta, lung
Heparin	(1 → 4)-O-α-D-Glucopyranosyluronic acid-(1 → 4)-2-sulfoamino-2-deoxy-6-O-sulfo-α-D-glucopyranose and (1 → 4)-O-α-L-idopyranosyluronic acid-2-sulfate-(1 → 4)-2-sulfoamino-2-deoxy-6-O-sulfo-α-D-glucopyranose (8, 9) <sup>g</sup>	+48 (15)	890, 940 (14)	0.1–0.2	8×10 <sup>3</sup> –20×10 <sup>3</sup> (23)	Liver, lung, skin, mast cells
Hyaluronic acid	(1 → 4)-O-β-D-Glucopyranosyluronic acid-(1 → 3)-2-acetamido-2-deoxy-β-D-glucopyranose (10)	-68 (16)	900, 950 (16)	2.0–48	2×10 <sup>5</sup> –10×10 <sup>5</sup> (24)	Synovial fluid, vitreous humor, umbilical cord, skin
Keratan sulfate (Keratosulfate)	(1 → 3)-O-β-D-Galactopyranose-(1 → 4)-2-acetamido-2-deoxy-6-O-sulfo-β-D-glucopyranose (7, 11) <sup>h</sup>	+4.5	775, 820, 998 (20)	0.2–0.5	8×10 <sup>3</sup> –12×10 <sup>3</sup> (21)	Aorta, cornea, cartilage, nucleus pulposus

Compiled by I. Danishefsky.

<sup>a</sup> Certain mucopolysaccharides have been given different names by various investigators. In such cases, alternative names are given in parentheses.

<sup>b</sup> The repeating unit, which is indicated, is the one that is most prevalent. In many mucopolysaccharides there may be some variations in parts of the chain (microheterogeneity), especially with regard to sulfation. The units involved in the linkage to the proteins are not given here.

<sup>c</sup> Many of the values for specific rotation and intrinsic viscosity are given as ranges because these depend on the method of isolation and the original tissue source. In these cases, the references cited are review articles which include the original research papers.

<sup>d</sup> Fingerprint region.

<sup>e</sup> Also contains small but significant amounts of glucuronic acid.<sup>25,26</sup>

<sup>f</sup> Some amino groups are acetylated and others are sulfated. There are also variations in the position of O-sulfate. Part of the uronic acid is iduronic acid.

<sup>g</sup> There are O-sulfates in about one third of the uronic acid residues. Although both iduronate and glucuronate are present their relative proportion is not completely defined.<sup>27</sup>

<sup>h</sup> Some of the galactose is sulfated on position-6.

<sup>i</sup> In HCl; change in rotation occurs as a result of hydrolysis.

# IUBMB-IUPAC JOINT COMMISSION ON BIOCHEMICAL NOMENCLATURE (JCBN) RECOMMENDATIONS FOR NOMENCLATURE AND TABLES IN BIOCHEMICAL THERMODYNAMICS

(IUPAC Recommendations 1994)

<http://www.chem.qmul.ac.uk/iubmb/thermod/>

**Robert A. Alberty**

Department of Chemistry, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

\*Membership of the Panel on Biochemical Thermodynamics during the preparation of this report (1991–1993) was as follows:

*Convener:* R. A. Alberty (USA); A. Cornish-Bowden (France); Q. H. Gibson (USA); R. N. Goldberg (USA); G. G. Hammes (USA); W. Jencks (USA); K. F. Tipton (Ireland); R. Veech (USA); H. V. Westerhoff (Netherlands); E. C. Webb (Australia).

†Membership of the IUBMB–IUPAC Joint Commission on Biochemical Nomenclature (JCBN):

*Chairman:* J. F. G. Vliegthart (Netherlands); *Secretary:* A. J. Barrett (UK); A. Chester (Sweden); D. Coucouvanis (USA); C Liébecq (Belgium); K. Tipton (Ireland); P. Venetianer (Hungary); *Associate Members:* H. B. F. Dixon (UK); J. C. Rigg (Netherlands).

Chemical equations are written in terms of specific ionic and elemental species and balance elements and charge, whereas biochemical equations are written in terms of reactants that often consist of species in equilibrium with each other and do not balance elements that are assumed fixed, such as hydrogen at constant pH. Both kinds of reaction equations are needed in biochemistry. When the pH and the free concentrations of certain metal ions are specified, the apparent equilibrium constant  $K'$  for a biochemical reaction is written in terms of sums of species and can be used to calculate a standard transformed Gibbs energy of reaction  $\Delta_r G'^{\circ}$ . Transformed thermodynamic properties can be calculated directly from conventional thermodynamic properties of species. Calorimetry or the dependence of  $K'$  on temperature can be used to obtain the standard transformed enthalpy of reaction  $\Delta_r H'^{\circ}$ . Standard transformed Gibbs energies of formation  $\Delta_f G'^{\circ}(i)$  and standard transformed enthalpies of formation  $\Delta_f H'^{\circ}(i)$  for reactants (sums of species) can be calculated at various  $T$ , pH, pMg, and ionic strength ( $I$ ) if sufficient information about the chemical reactions involved is available. These quantities can also be calculated from measurement of  $K'$  for a number of reactions under the desired conditions. Tables can be used to calculate  $\Delta_r G'^{\circ}$  and  $\Delta_r H'^{\circ}$  for many more reactions.

## 1. Preamble

In 1976 an Interunion Commission on Biothermodynamics (IUPAC, IUB, IUPAB) published *Recommendations for Measurement and Presentation of Biochemical Equilibrium*

Reproduced from:  
*Pure & Appl. Chem.*, Vol. 66, No.8, pp. 1641–1666, 1994.  
© 1994 IUPAC

*Data* (ref. 1). This report recommended symbols, units, and terminology for biochemical equilibrium data and standard conditions for equilibrium measurements. These recommendations have served biochemistry well, but subsequent developments indicate that new recommendations and an expanded nomenclature are needed. In 1985 the Interunion Commission on Biothermodynamics published *Recommendations for the Presentation of Thermodynamic and Related Data in Biology* (1985) (ref. 2).

Before discussing the new recommendations, some of the basic recommendations of 1976 are reviewed and the recommended changes in these basic matters are given.

## 2. Basic 1976 recommendations on symbols and nomenclature

In the 1976 *Recommendations* (ref. 1), the overall reaction for the hydrolysis of ATP to ADP was written as

and the expressions for the apparent equilibrium constant  $K'$  and the apparent standard Gibbs energy change  $\Delta G^{\circ'}$  were written as\*

$$K' = \frac{[\text{total ADP}][\text{total P}_i]}{[\text{total ATP}]} \quad (2)$$

$$\Delta G^{\circ'} = -RT \ln \frac{[\text{total ADP}][\text{total P}_i]}{[\text{total ATP}]} \quad (3)$$

where these are equilibrium concentrations, recommended to be molar concentrations. The 1976 *Recommendations* further recommended that information about the experimental conditions could be indicated by writing  $K'_c(\text{pH} = x, \text{etc.})$  and  $\Delta G_c^{\circ'}(\text{pH} = x, \text{etc.})$ , where the subscript  $c$  indicates that molar concentrations are used. The 1976 *Recommendations* pointed out that the hydrolysis of ATP can also be formulated in terms of particular species of reactants and products. For example, at high pH and in the absence of magnesium ion

leads to the equilibrium constant expression

$$K_{\text{ATP}^{4-}} = \frac{[\text{ADP}^{3-}][\text{P}_i^{2-}][\text{H}^+]}{[\text{ATP}^{4-}]} \quad (5)$$

where the equilibrium constant  $K_{\text{ATP}^{4-}}$  is independent of pH. The 1976 *Recommendations* went on to show how  $K'$  is related to  $K_{\text{ATP}^{4-}}$ .

## 3. Corresponding new recommendations

The new recommendation is that reaction 1 be should be written as

where ATP refers to an equilibrium mixture of  $\text{ATP}^{4-}$ ,  $\text{HATP}^{3-}$ ,  $\text{H}_2\text{ATP}^{2-}$ ,  $\text{MgATP}^{2-}$ ,  $\text{MgHATP}^-$ , and  $\text{Mg}_2\text{ATP}$  at the specified pH and pMg. This is referred to as a *biochemical equation* to emphasize that it describes the reaction that occurs at specified pH and pMg. The apparent equilibrium constant  $K'$  is made up of the equilibrium concentrations of the reactants relative to the standard state concentration  $c^\circ$ , which is 1 M; note that M is an abbreviation for mol L<sup>-1</sup>.

\* Note Abbreviations used in this document are: AMP, adenosine 5'-monophosphate; ADP, adenosine 5'-diphosphate; ATP, adenosine 5'-triphosphate; Glc, glucose; Glc-6-P, glucose 6-phosphate; P<sub>i</sub>, orthophosphate. The designator (aq) is understood as being appended to all species that exist in aqueous solution.

$$K' = \frac{([\text{ADP}/c^\circ][\text{P}_i/c^\circ])}{([\text{ATP}/c^\circ]} = \frac{[\text{ADP}][\text{P}_i]}{[\text{ATP}]c^\circ} \quad (7)$$

The term  $c^\circ$  arises in the derivation of this equilibrium constant expression from the fundamental equation of thermodynamics and makes the equilibrium constant dimensionless. The logarithm of  $K'$  can only be taken if it is dimensionless (ref. 3). The standard state concentration used is an absolutely essential piece of information for the interpretation of the numerical value of an equilibrium constant. The apparent equilibrium constant  $K'$  is a function of  $T$ ,  $P$ , pH, pMg, and  $I$  (ionic strength). Various metal ions may be involved, but  $\text{Mg}^{2+}$  is used as an example. As described below,

$$\Delta_r G^{\circ'} = -RT \ln K' \quad (8)$$

where  $\Delta_r G^{\circ'}$  is the standard transformed Gibbs energy of reaction. The important point is that when the pH, and sometimes the free concentrations of certain metal ions, are specified, the criterion of equilibrium is the transformed Gibbs energy  $G'$  (ref. 4, 5). The reason for this name is discussed later in the section on transformed thermodynamic properties. Since the apparent equilibrium constant  $K'$  yields the standard value (the change from the initial state with the separated reactants at  $c^\circ$  to the final state with separated products at  $c^\circ$ ) of the change in the transformed Gibbs energy  $G'$ , the superscript  $\circ$  comes after the prime in  $\Delta_r G^{\circ'}$ . The subscript r (recommended in ref. 3) refers to a reaction and is not necessary, but it is useful in distinguishing the standard transformed Gibbs energy of reaction from the standard transformed Gibbs energy of formation  $\Delta_f G^{\circ'}(i)$  of reactant  $i$ , which is discussed below.

The hydrolysis of ATP can also be described by means of a *chemical equation* such as

A *chemical equation* balances atoms and charge, but a *biochemical equation* does not balance H if the pH is specified or Mg if pMg is specified, and therefore does not balance charge. Equation 9 differs from equation 4 in one way that is significant but not of major importance. Writing  $\text{HPO}_4^{2-}$ , rather than  $\text{P}_i^{2-}$  is a move in the direction of showing that atoms and charge balance in equation 9. Strictly speaking  $\text{ATP}^{4-}$  ought to be written  $\text{C}_{10}\text{H}_{12}\text{O}_{13}\text{N}_5\text{P}_3^{4-}$ . That is not necessary or advocated here, but we will see later that the atomic composition of a biochemical species is used in calculating standard transformed thermodynamic properties. Chemical equation 9 leads to the following equilibrium constant expression

$$K = \frac{[\text{ADP}^{3-}][\text{HPO}_4^{2-}][\text{H}^4]}{[\text{ATP}^{4-}](c^\circ)^2} \quad (10)$$

where  $c^\circ = 1$  M. The equilibrium constant  $K$  is a function of  $T$ ,  $P$ , and  $I$ . This equilibrium constant expression does not completely describe the equilibrium that is reached except at high pH and in the absence of  $\text{Mg}^{2+}$ . Chemical equations like equation 4 are useful in analyzing biochemical reactions and are often referred to as reference equations; thus, the corresponding equilibrium constants may be represented by  $K_{\text{ref}}$ . The effect of  $\text{Mg}^{2+}$  is discussed here, but this should be taken as only an example because the effects of other metal ions can be handled in the same manner.

## 4. Additional new recommendations

### 4.1 Recommendations concerning chemical reactions

The thermodynamics of reactions of species in aqueous solution is discussed in every textbook on physical chemistry, but this section is included to contrast the nomenclature with that of the next section and to respond to the special needs of biochemistry. As mentioned in section 3, equilibrium constants of chemical reactions that are used in biochemistry are taken to be functions of  $T$ ,  $P$ , and  $I$ . Therefore, the standard thermodynamic properties are also functions of  $T$ ,  $P$ , and  $I$ . The standard Gibbs energy of reaction  $\Delta_r G^\circ$  for reaction 9 is calculated using

$$\Delta_r G^\circ = -RT \ln K \quad (11)$$

and there are corresponding values of  $\Delta_r H^\circ$  and  $\Delta_r S^\circ$  that are related by

$$\Delta_r G^\circ = \Delta_r H^\circ - T\Delta_r S^\circ \quad (12)$$

The standard enthalpy of reaction is given by

$$\Delta_r H^\circ = RT^2 \left[ \frac{\partial \ln K}{\partial T} \right]_{P,I} \quad (13)$$

If  $\Delta_r H^\circ$  is independent of temperature in the range considered, it can be calculated using

$$\Delta_r H^\circ = [RT_1 T_2 / (T_2 - T_1)] \ln (K_2 / K_1) \quad (14)$$

If the standard molar heat capacity change  $\Delta_r C_p^\circ$  is not equal to zero and is independent of temperature, the standard molar enthalpy of reaction varies with temperature according to

$$\Delta_r H^\circ(T) = \Delta_r H^\circ(T^*) + \Delta_r C_p^\circ(T - T^*) \quad (15)$$

The reference temperature  $T^*$  is usually taken as 298.15 K. In this case,  $\Delta_r G^\circ$  and  $K$  vary with temperature according to (ref. 6)

$$\begin{aligned} \Delta_r G^\circ(T) &= -RT \ln K(T) \\ &= \Delta_r H^\circ(T^*) + \Delta_r C_p^\circ(T - T^*) + T \{ \Delta_r G^\circ(T^*) \\ &\quad - \Delta_r H^\circ(T^*) / T^* - T \Delta_r C_p^\circ \ln (T / T^*) \} \end{aligned} \quad (16)$$

Additional terms containing  $(\partial \Delta_r C_p^\circ / \partial T)_P$  and higher order derivatives may be needed for extremely accurate data or for a very wide temperature range.

Equations 13 and 14 are exact only when the equilibrium constants are based on a molality standard state. If the equilibrium constants were determined with a standard state based on molarity, these equilibrium constants should be converted to a molality basis prior to using equation 13. For dilute aqueous solutions,  $m_i = c_i / \rho$  where  $m_i$  and  $c_i$  are, respectively, the molality and the molarity of substance  $i$  and  $\rho$  is the mass density of water in kg L<sup>-1</sup>. If this conversion is not made, there is an error of  $RT^2(\partial \ln \rho / \partial T)_{P,I}$  for each unsymmetrical term in the equilibrium constant. This quantity is equal to 0.187 kJ mol<sup>-1</sup> for dilute aqueous solutions at 298.15 K. Similar statements pertain to equations 27 and 28, which are given later in this document.

Since the standard thermodynamic properties  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  apply to the change from the initial state with the separated reactants at  $c^\circ$  to the final state with separated products at  $c^\circ$ , it is of interest to calculate the changes in the thermodynamic

properties under conditions where the reactants and products have specified concentrations other than  $c^\circ$ . The change in Gibbs energy  $\Delta_r G$  in an isothermal reaction in which the reactants and products are not all in their standard states, that is, not all at 1 M, is given by

$$\Delta_r G = \Delta_r G^\circ + RT \ln Q \quad (17)$$

where  $Q$  is the reaction quotient of specified concentrations of species. The reaction quotient has the same form as the equilibrium constant expression, but the concentrations are arbitrary, rather than being equilibrium concentrations. Ideal solutions are assumed. The change in Gibbs energy  $\Delta_r G$  in an isothermal reaction is related to the change in enthalpy  $\Delta_r H$  and change in entropy  $\Delta_r S$  by

$$\Delta_r G = \Delta_r H - T\Delta_r S \quad (18)$$

The corresponding changes in entropy and enthalpy are given by

$$\Delta_r S = \Delta_r S^\circ - R \ln Q \quad (19)$$

$$\Delta_r H = \Delta_r H^\circ \quad (20)$$

The standard reaction entropy can be calculated from the standard molar entropies of the reacting species:  $\Delta_r S^\circ = \sum v_i^\circ(i)$ , where  $v_i$  is the stoichiometric number (positive for products and negative for reactants) of species  $i$ .

The electromotive force  $E$  of an electrochemical cell is proportional to the  $\Delta_r G$  for the cell reaction.

$$\Delta_r G = -|v_e|FE \quad (21)$$

where  $|v_e|$  is the number of electrons transferred in the cell reaction and  $F$  is the Faraday constant (96 485.31 C mol<sup>-1</sup>). Substituting equation 17 yields

$$E = E^\circ - \frac{RT}{|v_e|F} \ln Q \quad (22)$$

where  $E^\circ = -\Delta_r G^\circ / |v_e|F$  is the standard electromotive force, that is the electromotive force when all of the species are in their standard states, but at the ionic strength specified for  $\Delta_r G^\circ$ . The electromotive force for a cell is equal to the difference in the electromotive forces of the half cells.

The standard Gibbs energy and enthalpy of reaction can be calculated from the formation properties of the species.

$$\Delta_r G^\circ = \sum v_i \Delta_f G^\circ(i) \quad (23)$$

$$\Delta_r H^\circ = \sum v_i \Delta_f H^\circ(i) \quad (24)$$

where the  $v_i$  is the stoichiometric numbers of species  $i$ . The standard entropy of formation of species  $i$  can be calculated using

$$\Delta_f S^\circ(i) = [\Delta_f H^\circ(i) - \Delta_f G^\circ(i)] / T \quad (25)$$

Two special needs of biochemistry are illustrated by considering the seven species in Table I. The first part of Table I gives the standard thermodynamic properties as they are found in the standard thermodynamic tables (see Appendix). The standard

**Table I: Standard Formation Properties of Aqueous Species at 298.15 K.**

	$\Delta_f H^\circ / \text{kJ mol}^{-1}$	$\Delta_f G^\circ / \text{kJ mol}^{-1}$

thermodynamic tables give the standard formation properties for the standard state, which is the state in a hypothetical ideal solution with a concentration of 1 M but the properties of an infinitely dilute solution and the activity of the solvent equal to unity. This means that the tabulated thermodynamic properties apply at *I* = 0. Since many biochemical reactions are studied at about *I* = 0.25 M, the tabulated values of  $\Delta_f G^\circ(i)$  and  $\Delta_f H^\circ(i)$  in *The NBS Tables of Chemical Thermodynamic Properties* and the *CODATA Key Values for Thermodynamics* have to be corrected to ionic strength 0.25 M, as described in Section 5.3. The values at *I* = 0.25 M are given in the second part of Table I. No adjustments are made for H<sub>2</sub>O, MgHPO<sub>4</sub>, and glucose because the ionic strength adjustment is negligible for neutral species. We will see in Section 5.1 that the transformed Gibbs energy *G'* is the criterion of equilibrium at specified pH and pMg. In Section 5.4 we will see that the calculation of transformed thermodynamic properties involves the adjustment of the standard formation properties of species to the desired pH and pMg by use of formation reactions involving H<sup>+</sup> and Mg<sup>2+</sup>. The standard transformed formation properties of species can be calculated at any given pH and pMg in the range for which the acid dissociation constants and magnesium complex dissociation constants are known. However, for the purpose of making tables, it is necessary to choose a pH and pMg that is of general interest. For the tables given here, pH = 7 and pMg = 3 are used because they are close to the values in many living cells. Table II shows the result of these calculations for the species in Table I. The ions H<sup>+</sup> and Mg<sup>2+</sup> do not appear in this table because it applies at pH = 7 and pMg = 3. These methods have been applied to calculate the transformed formation properties

**Table II: Standard Transformed Formation Properties of Species at 298.15 K, pH = 7, pMg = 3, and *I* = 0.25 M.**

	$\Delta_f H'^\circ / \text{kJ mol}^{-1}$	$\Delta_f G'^\circ / \text{kJ mol}^{-1}$

of P<sub>i</sub> (ref. 4); glucose 6-phosphate (ref. 5); adenosine, AMP, ADP, and ATP (ref. 7).

Tables I and II can be extended by use of measured equilibrium constants and enthalpies of reaction for enzyme-catalyzed reactions. For example, the species of glucose 6-phosphate can be added to these two tables because the equilibrium constant for the hydrolysis of glucose 6-phosphate has been measured at several temperatures, and because the acid dissociation constant and magnesium complex dissociation constant for glucose 6-phosphate are known at more than one temperature. However, as the standard thermodynamic properties are not known for any species of adenosine, AMP, ADP, or ATP, it is necessary to adopt the convention that  $\Delta_f G^\circ = \Delta_f H^\circ = 0$  for adenosine in dilute aqueous solution at each temperature. This convention was introduced for H<sup>+</sup> a long time ago. This method has been used to calculate the standard enthalpies and standard Gibbs energies of formation of adenosine phosphate species relative to H<sub>2</sub>ADP<sup>-</sup> at 298.15 K (ref. 8). When this convention is used, it is not possible to calculate the enthalpy of combustion of adenosine, but it is possible to calculate  $\Delta_f G^\circ$  and  $\Delta_f H^\circ$  for reactions of adenosine that do not reduce it to CO<sub>2</sub>, H<sub>2</sub>O, and N<sub>2</sub>. If the standard thermodynamic properties of all of the species of a reactant are known,  $\Delta_f G^\circ$  and  $\Delta_f H^\circ$  can be calculated at any specified pH and pMg, as described in the next section. When  $\Delta_f G^\circ$  and  $\Delta_f H^\circ$  are eventually determined for adenosine in dilute aqueous solution, the values of  $\Delta_f G^\circ$  and  $\Delta_f H^\circ$  of the other species in the ATP series can be calculated, but this will not alter the equilibrium constants and enthalpies of reaction that can be calculated using the tables calculated using the assumption that  $\Delta_f G^\circ = \Delta_f H^\circ = 0$  for adenosine.

In making these calculations, the pH has been defined by  $\text{pH} = -\log_{10}([\text{H}^+]/c^\circ)$ , rather than in terms of the activity, as it is in more precise measurements. The reason for doing this is that approximations are involved in the interpretation of equilibrium experiments on biochemical reactions at the electrolyte concentrations of living cells. Even Na<sup>+</sup> and K<sup>+</sup> ions are bound weakly by highly charged species of biochemical reactants, like ATP. As an approximation the acid dissociation constants and magnesium complex dissociation constants are taken to be functions of the ionic strength and the different effects of Na<sup>+</sup> and K<sup>+</sup> are ignored. These approximations can be avoided in more precise work, but only at the cost of a large increase in the number of parameters and the amount of experimental work required.

## 4.2 Recommendations concerning biochemical reactions

When pH and pMg are specified, a whole new set of transformed thermodynamic properties come into play (ref. 4, 5). These properties are different from the usual Gibbs energy *G*, enthalpy *H*, entropy *S*, and heat capacity at constant pressure *C<sub>p</sub>*, and they are referred to as the transformed Gibbs energy *G'*, transformed enthalpy *H'*, transformed entropy *S'*, and transformed heat capacity at constant pressure *C<sub>p</sub>'*. The standard transformed Gibbs energy of reaction  $\Delta_r G'^\circ$  is made up of contributions from the standard transformed enthalpy of reaction  $\Delta_r H'^\circ$  and the standard transformed entropy of reaction  $\Delta_r S'^\circ$ .

$$\Delta_r G'^\circ = \Delta_r H'^\circ - T\Delta_r S'^\circ \quad (26)$$

The standard transformed enthalpy of reaction is given by

$$\Delta_r H'^\circ = RT^2 \left( \frac{\partial \ln K'}{\partial T} \right)_{P, \text{pH}, \text{pMg}, I} \quad (27)$$

If  $\Delta_r H^\circ$  is independent of temperature in the range considered, it can be calculated using

$$\Delta_r H^\circ = [RT_1 T_2 / (T_2 - T_1)] \ln (K_2' / K_1') \quad (28)$$

where  $K_2'$  and  $K_1'$  are measured at the same  $P$ , pH, pMg, and  $I$ . If  $\Delta_r H^\circ$  is dependent on temperature, a more complicated equation involving an additional parameter  $\Delta_r C_p^\circ$ , the standard transformed heat capacity of reaction at constant pressure, can be used with the assumption that

$$\Delta_r H^\circ(T) = \Delta_r H^\circ(298.15 \text{ K}) + (T - 298.15 \text{ K})\Delta_r C_p^\circ \quad (29)$$

This more complicated equation is analogous to equation 16. The standard transformed reaction entropy can be calculated from the standard transformed molar entropies of the reacting species:

$\Delta_r S^\circ = \sum v_i' \bar{S}^\circ(i)$ , where the  $v_i'$  are the apparent stoichiometric numbers (positive for products and negative for reactants) of the reactants  $i$  in a biochemical reaction written in terms of reactants (sums of species) (for example, reaction 6).

The standard transformed enthalpy of reaction  $\Delta_r H^\circ$  can also be calculated from calorimetric measurements. When that is done it is necessary to make corrections for the enthalpies of reaction caused by the change  $\Delta_r N(\text{H}^+)$  in the binding of  $\text{H}^+$  and in the change  $\Delta_r N(\text{Mg}^{2+})$  in the binding of  $\text{Mg}^{2+}$  in the reaction (see equation 38 below). The change in binding of an ion in a biochemical reaction is equal to the number of ions bound by the products at the specified pH and pMg minus the number of the ions bound by the reactants. Note that  $\Delta_r N(\text{H}^+)$  and  $\Delta_r N(\text{Mg}^{2+})$  are dimensionless.

The change in binding of  $\text{H}^+$  and  $\text{Mg}^{2+}$  in a biochemical reaction can be calculated if the acid dissociation constants and magnesium complex dissociation constants for the reactants are known; the equilibrium constant for the biochemical reaction itself does not have to be known for this calculation. Earlier calculations of the production of  $\text{H}^+$  and  $\text{Mg}^{2+}$  used a different sign convention (ref. 9). The changes in binding  $\Delta_r N(\text{H}^+)$  and  $\Delta_r N(\text{Mg}^{2+})$  are given by

$$\Delta_r N(\text{H}^+) = \sum v_i' \bar{N}_{\text{H}}(i) \quad (30)$$

$$\Delta_r N(\text{Mg}^{2+}) = \sum v_i' \bar{N}_{\text{Mg}}(i) \quad (31)$$

where the  $v_i'$  are the apparent stoichiometric numbers of the reactants  $i$  in a biochemical reaction.  $\bar{N}_{\text{H}}(i)$  is the number of H bound by an average molecule of reactant  $i$  at  $T$ ,  $P$ , pH, pMg, and  $I$ .  $\bar{N}_{\text{H}}(i)$  is calculated from  $\sum r_i N_{\text{H}}(i)$  where  $r_i$  is the mole fraction of species  $i$  in the equilibrium mixture of the species of the reactant at the specified pH and pMg.  $N_{\text{H}}(i)$  is the number of hydrogen atoms in species  $i$ . The average numbers  $\bar{N}_{\text{H}}(i)$  and  $\bar{N}_{\text{Mg}}(i)$  can be included in tables of transformed thermodynamic properties at specified pH and pMg so that  $\Delta_r N(\text{H}^+)$  and  $\Delta_r N(\text{Mg}^{2+})$  can be readily calculated for biochemical reactions. The sign and magnitude of  $\Delta_r N(\text{H}^+)$  and  $\Delta_r N(\text{Mg}^{2+})$  are important because they determine the effect of pH and pMg on the apparent equilibrium constant  $K'$ . It can be shown (ref. 9, 10) that

$$\Delta_r N(\text{H}^+) = - \left( \frac{\partial \log_{10} K'}{\partial \text{pH}} \right)_{T, P, \text{pMg}, I} \quad (32)$$

$$\Delta_r N(\text{Mg}^{2+}) = - \left( \frac{\partial \log_{10} K'}{\partial \text{pMg}} \right)_{T, P, \text{pH}, I} \quad (33)$$

where the logarithms are  $\log_{10}$ . A pHstat can be used to measure  $\Delta_r N(\text{H}^+)$  directly.

Since the standard transformed thermodynamic properties  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  apply to the change from the initial state with the separated reactants at  $c^\circ$  to the final state with separated products at  $c^\circ$ , it is of interest to calculate the changes in the transformed thermodynamic properties under conditions where the reactants and products have the concentrations they do in a living cell. The change in transformed Gibbs energy  $\Delta_r G'$  in an isothermal reaction in which the reactants and products are not all in their standard states, that is, not all at 1 M, is given by

$$\Delta_r G' = \Delta_r G^\circ + RT \ln Q' \quad (34)$$

where  $Q'$  is the apparent reaction quotient of specified concentrations of reactants (sums of species). The change in transformed Gibbs energy  $\Delta_r G'$  in an isothermal reaction at specified pH and pMg is related to the change in transformed enthalpy  $\Delta_r H'$  and change in transformed entropy  $\Delta_r S'$  by

$$\Delta_r G' = \Delta_r H' - T\Delta_r S' \quad (35)$$

The corresponding changes in transformed entropy and transformed enthalpy are given by

$$\Delta_r S' = \Delta_r S^\circ - R \ln Q' \quad (36)$$

$$\Delta_r H' = \Delta_r H^\circ \quad (37)$$

The calorimetrically determined enthalpy of reaction  $\Delta_r H(\text{cal})$  includes the enthalpies of reaction of  $\text{H}^+$  and  $\text{Mg}^{2+}$  (consumed or produced) with the buffer at the specified  $T$ ,  $P$ , pH, pMg, and  $I$ . The standard transformed enthalpy of reaction  $\Delta_r H^\circ$  can be calculated using (ref. 11)

$$\begin{aligned} \Delta_r H^\circ = & \Delta_r H(\text{cal}) - \Delta_r N(\text{H}^+) \Delta_r H^\circ(\text{HBuff}) \\ & - \Delta_r N(\text{Mg}^{2+}) \Delta_r H^\circ(\text{MgBuff}) \end{aligned} \quad (38)$$

$\Delta_r H^\circ(\text{HBuff})$  is the standard enthalpy for the acid dissociation of the buffer, and  $\Delta_r H^\circ(\text{MgBuff})$  is the standard enthalpy for the dissociation of the magnesium complex formed with the buffer. The values of  $\Delta_r N(\text{H}^+)$  and  $\Delta_r N(\text{Mg}^{2+})$  can be determined experimentally using equations 32 and 33, or they can be calculated if sufficient data on acid and magnesium complex dissociation constants are available.

When the pH is specified, the electromotive force of an electrochemical cell can be discussed in terms of the concentrations of reactants (sums of species) rather than species. When this is done the electromotive force of the cell or of a half cell is referred to as the apparent electromotive force  $E'$ . When this is done equation 34 becomes

$$E' = E^\circ - \frac{RT}{|v_e|F} \ln Q' \quad (39)$$

where  $E^\circ = -\Delta_r G^\circ / |v_e|F$  is the standard apparent electromotive force at that pH. The symbol  $E^\circ$  is also used for the standard apparent reduction potential for an electrode reaction.

Biochemists have not had the advantage of having tables of standard formation properties of reactants at some standard set of conditions involving pH and pMg. Currently, information on biochemical reactions is tabulated as standard transformed Gibbs energies of reaction  $\Delta_r G^\circ$  and, in some cases, standard transformed enthalpies of reaction  $\Delta_r H^\circ$  at specified,  $T$ ,  $P$ , pH, pMg, and  $I$ . Standard transformed formation properties have not

been calculated because of lack of thermodynamic information to connect reactants in aqueous solution with the elements in their standard states and because of lack of knowledge as to how to calculate standard thermodynamic properties for a reactant like ATP that is made up of an equilibrium mixture of species at a given pH and pMg. The solution to the first problem is to assign zeros to a minimum number of species. This is what is done with  $H^+(aq)$  a long time ago. The solution to the second problem is that when pH and pMg are specified, the various species  $ATP^{4-}$ ,  $HATP^{3-}$ ,  $MgATP^{2-}$ , etc. of ATP become pseudoisomers. That is, the relative concentrations of the various species are then a function of temperature only. At a given  $T$ ,  $P$ , pH, pMg, and  $I$ , the relative concentrations can be calculated, and the standard transformed thermodynamic properties of ATP (sum of species) can be calculated. The equations for doing this are given in Section 5.2. Thus, ATP at a given pH and pMg can be treated like a single species with the properties  $\Delta_f G'^{\circ}$ ,  $\Delta_f H'^{\circ}$ , and  $\Delta_f S'^{\circ}$ .

When pH and pMg are specified, the transformed formation properties (indicated by a subscript f) of reactants are defined by (ref. 4)

$$\Delta_f G'^{\circ} = \sum v_i' \Delta_f G'^{\circ}(i) \quad (40)$$

$$\Delta_f H'^{\circ} = \sum v_i' \Delta_f H'^{\circ}(i) \quad (41)$$

where the  $v_i'$  are the apparent stoichiometric numbers of the reactants  $i$  in a biochemical reaction written in terms of reactants. These formation properties apply to reactants like ATP (that is, sums of species) at a specified  $T$ ,  $P$ , pH, pMg, and  $I$ . The corresponding standard transformed entropy of formation of a reactant like ATP can be calculated using

$$\Delta_f G'^{\circ}(i) = \Delta_f H'^{\circ}(i) - T \Delta_f S'^{\circ}(i) \quad (42)$$

Table III gives standard transformed enthalpies of formation and standard transformed Gibbs energies of formation that have been calculated at 298.15 K, pH = 7, pMg = 3, and  $I = 0.25$  M (ref. 7). The values for creatine phosphate are based on the recent work of Teague and Dobson (ref. 12). The adjustment of standard formation properties of species to standard transformed formation properties at the desired pH and pMg has been mentioned in connection with Table II. When a reactant exists as a single species at pH = 7 and pMg = 3, the transformed formation properties of the species in Table II go directly into Table III. Water has to be

**Table III: Standard Transformed Formation Properties of Reactants (sums of species) at 298.15 K, pH = 7, pMg = 3, and  $I = 0.25$  M. This Table Uses the Convention that  $D_f G^{\circ} = D_f H^{\circ} = 0$  for Adenosine in Dilute Aqueous Solution**

	$\Delta_f H'^{\circ}/\text{kJ mol}^{-1}$	$\Delta_f G'^{\circ}/\text{kJ mol}^{-1}$
ATP	-2981.79	-2102.88
ADP	-2000.19	-1231.48
AMP	-1016.59	-360.38
A (adenosine)	-5.34	529.96
Glc-6-P	-2279.09	-1318.99
Glc (glucose)	-1267.11	-426.70
CrP	-1509.75	-750.37
Cr (creatine)	-540.08	107.69
$P_i$	-1299.13	-1059.55
$H_2O(l)$	-286.65	-155.66

included in this table because its formation properties must be used in equations 40 and 41, even though it does not appear in the expression for the apparent equilibrium constant. When a reactant exists at pH = 7 and pMg = 3 as an equilibrium mixture of species, isomer group thermodynamics (see Section 5.2) has to be used to calculate standard transformed formation properties (Table III) for that reactant.

The large number of significant figures in Table I might appear to indicate that these thermodynamic properties are known very accurately, but this is misleading. The values in such a table are used only by subtracting them from other values in the table, and so the only things that are important are differences between values. The values have to be given in the table with enough significant figures so that thermodynamic information in the differences is not lost. The following examples illustrate uses of this table.

This kind of table will make it easier to make thermodynamic calculations on systems of enzymatic reactions, like glycolysis. Currently, to calculate  $\Delta_r G'^{\circ}$  for the net reaction of glycolysis, 10 reactions must be added and  $\Delta_r G'^{\circ}$  must be multiplied by 2 for some of them.

Example 1. Calculate  $\Delta_r G'^{\circ}$ ,  $\Delta_r H'^{\circ}$ ,  $\Delta_r S'^{\circ}$ , and  $K'$  for the glucokinase reaction (EC 2.7.1.2) (ref. 13) at 298.15 K, pH = 7, pMg = 3, and  $I = 0.25$  M.

$$\Delta_r G'^{\circ} = (-1231.48 - 1318.99 + 2102.88 + 426.70) \text{ kJ mol}^{-1} \\ = -20.89 \text{ kJ mol}^{-1}$$

$$\Delta_r H'^{\circ} = (-2000.19 - 2279.09 + 2981.79 + 1267.11) \text{ kJ mol}^{-1} \\ = -30.38 \text{ kJ mol}^{-1}$$

$$\Delta_r S'^{\circ} = (-30.38 + 20.89) \cdot 10^3 \text{ J mol}^{-1}/298.15 \text{ K} = -31.83 \text{ J K}^{-1} \text{ mol}^{-1}$$

$$K' = \exp\left(\frac{20890 \text{ J mol}^{-1}}{8.3145 \text{ J K}^{-1} \cdot 298.15 \text{ K}}\right) = 4.57 \cdot 10^3$$

Example 2. Calculate  $\Delta_r G'$ ,  $\Delta_r H'$ , and  $\Delta_r S'$  for the glucokinase reaction at 298.15 K, pH = 7, pMg = 3, and  $I = 0.25$  M when the reactant concentrations are  $[ATP] = 10^{-5}$  M,  $[ADP] = 10^{-3}$  M,  $[Glc] = 10^{-4}$  M, and  $[Glc-6-P] = 10^{-2}$  M.

$$Q' = (10^{-3})(10^{-2})/(10^{-5})(10^{-4}) = 10^4$$

$$\Delta_r G' = \Delta_r G'^{\circ} + RT \ln Q' = -20.89 + (8.3145 \times 10^{-3})(298.15) \ln 10^4 \\ = 1.94 \text{ kJ mol}^{-1}$$

Since  $\Delta_r G'$  is positive, the glucokinase reaction cannot occur in the forward direction under these conditions.

$$\Delta_r H' = \Delta_r H'^{\circ} = -30.38 \text{ kJ mol}^{-1}$$

$$\Delta_r S' = \Delta_r S'^{\circ} - R \ln Q' = -108.41 \text{ J K}^{-1} \text{ mol}^{-1}$$

Note that

$$\Delta_r G' = \Delta_r H' - T \Delta_r S' = -30.38 - (298.15)(-0.10841) = 1.94 \text{ kJ mol}^{-1}$$

### 4.3 The importance of distinguishing between chemical equations and biochemical equations

Both types of equations are needed in biochemistry. Chemical equations are needed when it is important to keep track of all of the atoms and charges in a reaction, as in discussing the mechanism of chemical change. Biochemical reactions are needed to answer the question as to whether a reaction goes in the forward or backward direction at specified  $T$ ,  $P$ , pH, pMg, and  $I$ , or for calculating the equilibrium extent of such a reaction. Therefore, it is essential to be able to distinguish between these two types of equations on sight. The reaction equations in *Enzyme Nomenclature* [ref. 13] are almost exclusively biochemical equations. In the case of the hydrolysis of adenosine

triphosphate to adenosine diphosphate and inorganic phosphate, it is clear that equation 9 is a chemical equation and equation 6 is a biochemical equation. Equation 6 does not indicate that hydrogen ions or magnesium ions are conserved, but it is meant to indicate that C, O, N, and P are conserved. Equation 6 indicates the form of the expression for the apparent equilibrium constant  $K'$  at specified  $T$ ,  $P$ , pH, pMg, and  $I$ . Equation 9 indicates that electric charge is conserved, and the abbreviations  $\text{ATP}^{4-}$  and  $\text{ADP}^{3-}$  can be replaced by the atomic compositions of these ions to show that C, H, O, N, and P are conserved. Equation 9 indicates the form of the expression for the equilibrium constant  $K$  at specified  $T$ ,  $P$ , and  $I$ . Currently, the hydrolysis of ATP is often represented by  $\text{ATP} + \text{H}_2\text{O} = \text{ADP} + \text{Pi} + \text{H}^+$  in textbooks and research papers, but this is a hybrid of a chemical equation and a biochemical equation and does not have an equilibrium constant. Furthermore, this "equation" does not give the correct stoichiometry. The correct stoichiometry with respect to  $\text{H}^+$  is obtained by use of equation 32 and is  $\Delta_r N(\text{H}^+) = 0.62$  at 298.15 K, 1 bar, pH = 7, pMg = 3, and  $I = 0.25$  M. The convention is that  $\text{H}_2\text{O}$  is omitted in the equilibrium expression for  $K$  or  $K'$  when reactions in dilute aqueous solutions are considered.

In writing biochemical equations, words are often used to avoid the implication that hydrogen atoms and charge are being balanced, but it is important to understand that all other atoms are balanced. For example,

is a biochemical equation and

is a chemical reaction. There is no unique way to write a chemical reaction; for example, this equation could be written with  $\text{H}_2\text{PO}_4^-$  and no  $\text{H}^+$  on the right hand side. It can also be written with  $\text{CO}_2$  on the left-hand side, but then it is necessary to be clear about whether this  $\text{CO}_2$  is in the solution or gas phase. In equation 43 the word carbonate refers to the sum of the species  $\text{CO}_2$ ,  $\text{H}_2\text{CO}_3$ ,  $\text{HCO}_3^-$ , and  $\text{CO}_3^{2-}$  in aqueous solutions.

It is important to realize that  $K' = K$  for reactions where the reactants are nonelectrolytes (ref. 14). An example is the hydrolysis of sucrose to glucose and fructose. Of course sugars do have ionizable groups, but we are usually not interested in the dissociations that occur above pH = 12. For racemases,  $K' = K$ . There are other reactions for which  $K'$  is approximately equal to  $K$  because a product has very nearly the same acid dissociation constant as a reactant.

The need to clearly distinguish between biochemical equations and chemical equations raises problems with some abbreviations that are widely used. For example, the use of  $\text{NAD}^+$  in a biochemical equation makes it look like this charge should be balanced.  $\text{NAD}^+$  is also not a suitable abbreviation for use in a chemical equation because it is actually a negative ion.

Chemical equations and biochemical equations should not be added or subtracted from each other because their sum or difference does not lead to an equation that has an equilibrium constant. On the other hand, chemical equations can be added to chemical equations, and biochemical equations can be added to biochemical equations.

The net equation for a system of biochemical reactions can also be written as a chemical equation or a biochemical equation, but the equilibrium constants are, of course, in general different. Net

equations in the form of biochemical equations are especially useful for determining whether the system of reactions goes in the forward or backward direction at specified  $T$ ,  $P$ , pH, pMg, and  $I$ .

These recommendations apply also to reactions catalyzed by RNA enzymes (ref. 15), catalytic antibodies (ref. 16), and synthetic enzymes (ref. 17) (sometimes called ribozymes, abzymes, and synzymes, respectively). The reactions catalyzed have apparent equilibrium constants  $K'$  that are functions of pH and free concentrations of certain metal ions. Both biochemical equations and chemical equations can be written for these reactions if the reactants are weak acids or bind metal ions.

#### 4.4 Experimental matters

In reporting results on equilibrium measurements on biochemical reactions it is extremely important to give enough information to specify  $T$ ,  $P$ , pH, pMg (or free concentration of any other cation that is bound by reactants), and  $I$  at equilibrium. The most difficult of these variables are pMg and  $I$ . The calculation of pMg in principle requires information on the composition of the solution in terms of species, and this requires information on the dissociation constants of all of the weak acids and magnesium complex ions. However, if the metal ion binding constants of the buffer are known and the reactants are at low concentrations compared with the buffer, the concentrations of free metal ions can be calculated approximately. It is important to specify the composition of the solution and calculate the ionic strength, even if it can only be done approximately. Other important issues are the purities of materials, the methods of analysis, the question as to whether the same value of apparent equilibrium constant was obtained from both directions, and assignment of uncertainties. For calorimetric measurements, it is important to measure the extent of reaction. An important part of any thermodynamic investigation is the clear specification of the substances used and the reaction(s) studied. It is very helpful to readers to give *Enzyme Nomenclature* (ref. 13) identification numbers of enzymes and Chemical Abstracts Services registry numbers for reactants. IUPAC has published a "Guide to the Procedures for the Publication of Thermodynamic Data" (ref. 18), and CODATA has published a "Guide for the Presentation in the Primary Literature of Numerical Data Derived from Experiments" (ref. 19).

It is recommended that equilibrium and calorimetric measurements on biochemical reactions be carried out over as wide a range of temperature, pH, pMg, and  $I$  as is practical. For the study of biochemical reactions under "near physiological conditions," the following set of conditions is recommended:  $T = 310.15$  K, pH = 7.0, pMg = 3.0, and  $I = 0.25$  M. It is also recognized that there is no unique set of physiological conditions and that for many purposes it will be necessary and desirable to study biochemical reactions under different sets of conditions.

For the purpose of relating results obtained on biochemical reactions to the main body of thermodynamic data (NBS Tables and other tables listed in the Appendix) the results of experiments should be treated so as to yield results for a chemical (reference) reaction at  $T = 298.15$  K and  $I = 0$ . If this calculation is done, the method of data reduction and all auxiliary data used should be reported. It is also recognized that while a standard state based upon the concentration scale has been widely used in biochemistry, the molality scale has significant advantages for many purposes and can also be used for the study of biochemical reactions and for the calculation of thermodynamic properties.

## 5. Thermodynamic background

### 5.1 Transformed thermodynamic properties

The definition of a transformed Gibbs energy is a continuation of a process that starts with the first and second laws of thermodynamics, but is not always discussed in terms of Legendre transforms. The combined first and second law for a closed system involving only pressure-volume work is

$$dU = TdS - PdV \quad (45)$$

where  $U$  is the internal energy and  $S$  is the entropy. The criterion for spontaneous change at specified  $S$  and  $V$  is  $(dU)_{S,V} \leq 0$ . That is, if  $S$  and  $V$  are held constant,  $U$  can only decrease and is at a minimum at equilibrium. To obtain a criterion at specified  $S$  and  $P$ , the enthalpy was defined by the Legendre transform  $H = U + PV$  so that  $(dH)_{S,P} \leq 0$ . To obtain a criterion at specified  $T$  and  $V$ , the Helmholtz energy was defined by the Legendre transform  $A = U - TS$  so that  $(dA)_{T,V} \leq 0$ . To obtain a criterion at specified  $T$  and  $P$ , the Gibbs energy was defined by the Legendre transform  $G = H - TS$  so that  $(dG)_{T,P} \leq 0$ . The Gibbs energy is especially useful because it provides the criterion for equilibrium at specified  $T$  and  $P$ . Two Legendre transforms can be combined. For example, the internal energy can be transformed directly to  $G$  by use of  $G = U + PV - TS$ . Alberty and Oppenheim (ref. 20, 21) used a Legendre transform to develop a criterion for equilibrium for the alkylation of benzene by ethylene at a specified partial pressure of ethylene. Wyman and Gill (ref. 22) have described the use of transformed Gibbs energies in describing macromolecular components in solution.

In 1992, Alberty (refs. 4, 5) used the Legendre transform

$$G' = G - n'(H^+) \alpha(H^+) - n'(Mg^{2+}) \mu(Mg^{2+}) \quad (46)$$

to define a transformed Gibbs energy  $G'$  in terms of the Gibbs energy  $G$ . Here  $n'(H^+)$  is the total amount of  $H^+$  in the system (bound and unbound) and  $\alpha(H^+)$  is the specified chemical potential for  $H^+$ , which is given for an ideal solution by

$$\mu(H^+) = \mu(H^+)^\circ + RT \ln ([H^+]/c^\circ) \quad (47)$$

where  $\mu(H^+)^\circ$  is the chemical potential of  $H^+$  at 1 M in an ideal solution at specified  $T$ ,  $P$ , and  $I$ . The transformed Gibbs energy  $G'$  is defined in order to obtain a criterion of spontaneous change at  $T$ ,  $P$ , pH, and pMg. It can be shown that  $(dG')_{T,P,pH,pMg} \leq 0$ , so that  $G'$  is at a minimum when  $T$ ,  $P$ , pH, and pMg are held constant. This is the fundamental justification for the use of  $G'$  in biochemistry. Under the appropriate circumstances, the magnesium term can be left out or be replaced by a term in another metal ion. The reaction is generally an enzyme-catalyzed reaction, but these concepts apply to any reaction involving a weak acid or metal ion complex when the pH and concentration of free metal ion at equilibrium are specified.

A consequence of equation 46 is that the chemical potential  $\mu_i$  of each species in the system is replaced by the transformed chemical potential  $\mu_i'$  given by

$$\mu_i' = \mu_i - N_H(i) \mu(H^+) - N_{Mg}(i) \mu(Mg^{2+}) \quad (48)$$

where  $N_H(i)$  is the number of hydrogen atoms in species  $i$  and  $N_{Mg}(i)$  is the number of magnesium atoms in species  $i$ .

Although thermodynamic derivations are carried out using the chemical potential, in actual calculations, the chemical potential  $\mu_i$  of species  $i$  is replaced by the Gibbs energy of formation  $\Delta_f G_i^\circ$

and the transformed chemical potential  $\mu_i'$  of species  $i$  is replaced by the transformed Gibbs energy of formation  $\Delta_f G_i'^\circ$ , where

$$\Delta_f G_i = \Delta_f G_i^\circ + RT \ln ([i]/c^\circ) \quad (49)$$

$$\Delta_f G_i' = \Delta_f G_i'^\circ + RT \ln ([i]/c^\circ) \quad (50)$$

for ideal solutions. The calculation of  $\Delta_f G_i'^\circ$  for a species is discussed in Section 5.4 and the calculation of  $\Delta_f G_i'^\circ$  for a reactant is discussed in Section 5.5.

Once the  $\Delta_f G_i'^\circ$  for the species ( $H_2PO_4^-$ ,  $HPO_4^{2-}$ ,  $MgHPO_4$ ) of  $P_i$ , for example, have been calculated, the next question is how can these values be combined to obtain the value of  $\Delta_f G_i'^\circ$  for  $P_i$ ? The equations for this calculation are given in the next section.

### 5.2 Isomer group thermodynamics

A problem that has to be faced in biochemical thermodynamics at specified pH and pMg is that a reactant may consist of various species in equilibrium at the specified pH and pMg. Fortunately, a group of isomers (or pseudoisomers) in equilibrium with each other have thermodynamic properties just like a species does, but we refer to the properties of a pseudoisomer group as transformed properties. The problem of calculating a standard transformed Gibbs energy of formation of a reactant like ATP also arises when a reactant exists in isomeric forms (or hydrated and unhydrated forms), even if it is not a weak acid and does not complex with metal ions, so first we discuss a simple isomerization. The thing that characterizes an isomer group in ideal solutions is that the distribution within the isomer group is a function of temperature only. For such solutions, the standard Gibbs energy of formation of an isomer group  $\Delta_f G^\circ(\text{iso})$  can be calculated from the standard Gibbs energies of formation  $\Delta_f G_i^\circ$  of the various isomers using (ref. 23)

$$\Delta_f G^\circ(\text{iso}) = -RT \ln \sum_{i=1}^{N_i} \exp(-\Delta_f G_i^\circ/RT) \quad (51)$$

where  $N_i$  is the number of isomers in the isomer group. The standard enthalpy of formation  $\Delta_f H^\circ(\text{iso})$  of the isomer group can be calculated using (ref. 24)

$$\Delta_f H^\circ(\text{iso}) = \sum_{i=1}^{N_i} r_i \Delta_f H_i^\circ \quad (52)$$

where  $r_i$  is the equilibrium mole fraction of the  $i$ th species within the isomer group that is given by

$$r_i = \exp\{[\Delta_f G^\circ(\text{iso}) - \Delta_f G_i^\circ]/RT\} \quad (53)$$

The standard entropy of formation of the isomer group  $\Delta_f S^\circ(\text{iso})$  is given by

$$\Delta_f S^\circ(\text{iso}) = \sum_{i=1}^{N_i} r_i \Delta_f S_i^\circ - R \sum_{i=1}^{N_i} r_i \ln r_i \quad (54)$$

These equations can be used for pseudoisomer groups (for example, the species of ATP at specified pH and pMg) by using the transformed thermodynamic properties of the species.

For pseudoisomer groups, equations 51, 52, and 53 become

$$\Delta_f G^{\text{iso}}(\text{reactant}) = -RT \ln \sum_{i=1}^{N_i} \exp(-\Delta_f G_i^{\text{iso}}/RT) \quad (55)$$

$$\Delta_f H'^{\circ}(\text{reactant}) = \sum_{i=1}^{N_i} r_i \Delta_f H_i^{\circ} \quad (56)$$

$$r_i = \exp\{[\Delta_f G'^{\circ}(\text{reactant}) - \Delta_f G_i^{\circ}]/RT\} \quad (57)$$

where  $i$  refers to a species at specified pH and specified free concentrations of metal ions that are bound.

### 5.3 Adjustment for ionic strength

The ionic strength has a significant effect on the thermodynamic properties of ions, and the extended Debye-Huckel theory can be used to adjust the standard Gibbs energy of formation and the standard enthalpy of formation of ion  $i$  to the desired ionic strength (ref. 25-28). At 298.15 K these adjustments can be approximated by

$$\Delta_f G_i^{\circ}(I) = \Delta_f G_i^{\circ}(I=0) - 2.91482z_i^2 I^{1/2}/(1 + BI^{1/2}) \quad (58)$$

$$\Delta_f H_i^{\circ}(I) = \Delta_f H_i^{\circ}(I=0) + 1.4775z_i^2 I^{1/2}/(1 + BI^{1/2}) \quad (59)$$

where  $\text{kJ mol}^{-1}$  are used,  $z_i$  is the charge on ion  $i$ , and  $B = 1.6 \text{ L}^{1/2} \text{ mol}^{-1/2}$ . Since for  $\text{H}^+$ ,  $\Delta_f G^{\circ} = 0$  and  $\Delta_f H^{\circ} = 0$  at each temperature at  $I = 0$ ,  $\Delta_f G^{\circ}(\text{H}^+, 298.15 \text{ K}, I = 0.25 \text{ M}) = -0.81 \text{ kJ mol}^{-1}$  and  $\Delta_f H^{\circ}(\text{H}^+, 298.15 \text{ K}, I = 0.25 \text{ M}) = 0.41 \text{ kJ mol}^{-1}$ . For the purpose of these recommendations,  $\text{pH} = -\log_{10}([\text{H}^+]/c^{\circ})$  and  $\text{pMg} = -\log_{10}([\text{Mg}^{2+}]/c^{\circ})$ , as discussed above Section 4.1.

The adjustment of thermodynamic quantities from one solution composition to another using ionic strength effects alone is an approximation that works well at low ionic strengths ( $< 0.1 \text{ M}$ ) but it can fail at higher ionic strengths. Rigorous treatments require the use of interaction parameters (ref. 29) and a knowledge of the composition of the solution. While a substantial body of information on these parameters exists for aqueous inorganic solutions, there is very little of this type of data available for biochemical substances. Therefore, it is important that complete information on the compositions of the solutions used in equilibrium and calorimetric measurements be reported so that when values of these interaction parameters eventually become available, the results can be treated in a more rigorous manner. Specific ion effects are especially important when nucleic acids, proteins, and other polyelectrolytes are involved (refs. 30, 31).

### 5.4 Adjustment of standard thermodynamic

#### properties of species to the desired pH and pMg

When pH and pMg are specified, the various species of ATP, for example, become pseudoisomers; that is their relative concentrations are a function of temperature only. The procedure for calculating the transformed chemical potential  $\mu_i'$  of a species has been indicated in equation 48. For actual calculations the chemical potentials  $\mu_i$  of species are replaced with  $\Delta_f G_i$  (see equation 49), and the transformed chemical potentials  $\mu_i'$  of species are replaced with  $\Delta_f G_i'$  (see equation 50). Thus equation 48 for a species can be written

$$\Delta_f G_i'^{\circ} = \Delta_f G_i^{\circ} - N_{\text{H}}(i)[\Delta_f G^{\circ}(\text{H}^+) + RT \ln([\text{H}^+]/c^{\circ})] - N_{\text{Mg}}(i)[\Delta_f G^{\circ}(\text{Mg}^{2+}) + RT \ln([\text{Mg}^{2+}]/c^{\circ})] \quad (60)$$

where  $N_{\text{H}}(i)$  is the number of hydrogen atoms in species  $i$ . The corresponding equation for the standard transformed enthalpy of formation of species  $i$  is

$$\Delta_f H_i'^{\circ} = \Delta_f H_i^{\circ} - NH(i) \Delta_f H^{\circ}(\text{H}^+) - NMg(i) \Delta_f H^{\circ}(\text{Mg}^{2+}) \quad (61)$$

since the enthalpy of an ion in an ideal solution is independent of its concentration.

In adjusting standard Gibbs energies of formation to a specified pH, there is the question as to whether to count all of the hydrogens or only those involved in the reaction under consideration. However, the recommendation here is to adjust for all of the hydrogens in a species because all of them may be ultimately removed in biochemical reactions. This has been done in Tables II and III.

There is a simple way to look at the standard transformed Gibbs energy of formation  $\Delta_f G_i'^{\circ}$  and the standard transformed enthalpy of formation  $\Delta_f H_i'^{\circ}$  of species  $i$ , and that is that they are the changes in formation reactions of the species with  $\text{H}^+$  at the specified pH and  $\text{Mg}^{2+}$  at the specified pMg on the left-hand side of the formation reaction (ref. 32). For  $\text{H}_2\text{PO}_4^-$ ,

$$\Delta_f G'^{\circ}(\text{H}_2\text{PO}_4^-) = \Delta_f G^{\circ}(\text{H}_2\text{PO}_4^-) - 2\{\Delta_f G^{\circ}(\text{H}^+) + RT \ln 10^{-\text{pH}}\} \quad (63)$$

$$\Delta_f H'^{\circ}(\text{H}_2\text{PO}_4^-) = \Delta_f H^{\circ}(\text{H}_2\text{PO}_4^-) - 2\Delta_f H^{\circ}(\text{H}^+) \quad (64)$$

The quantities  $\Delta_f G^{\circ}(\text{H}^+)$  and  $\Delta_f H^{\circ}(\text{H}^+)$  are included because they are equal to zero only at zero ionic strength. The electrons required to balance the formation reaction are assigned  $\Delta_f G^{\circ}(\text{e}^-) = \Delta_f H^{\circ}(\text{e}^-) = 0$ . This calculation can be made with either the standard thermodynamic properties at  $I = 0$  or at some specified ionic strength.

The calculation of  $\Delta_f G'^{\circ}$  and  $\Delta_f H'^{\circ}$  for  $\text{HPO}_4^{2-}$  and  $\text{MgHPO}_4$  follow this same pattern, with  $\text{Mg}^{2+}(\text{pMg} = 3)$  also on the left-hand side of the formation reaction of  $\text{MgHPO}_4$ .

For a pseudoisomer group in which  $\Delta_f G^{\circ}$  and  $\Delta_f H^{\circ}$  are not known for any species, zero values have to be assigned to one of the species, as described in Section 4.1.

### 5.5 Calculation of the standard formation properties of a pseudoisomer group at specified pH and pMg

$\text{H}_2\text{PO}_4^-$ ,  $\text{HPO}_4^{2-}$  and  $\text{MgHPO}_4$  form a pseudoisomer group when pH and pMg are specified. Therefore, equations 55-57 can be used to calculate  $\Delta_f G'^{\circ}(\text{P}_i)$  and  $\Delta_f H'^{\circ}(\text{P}_i)$  for inorganic phosphate at the desired pH and pMg. These calculations have been made for inorganic phosphate and glucose 6-phosphate at  $\text{pH} = 7$  and  $\text{pMg} = 3$  by Alberty (ref. 4), and for adenosine, AMP, ADP, and ATP by Alberty and Goldberg (ref. 7) using the convention that  $\Delta_f G^{\circ} = \Delta_f H^{\circ} = 0$  for neutral adenosine.

For less common and more complicated reactants, the acid dissociation constants and magnesium complex dissociation constants may not be known. The  $\Delta_f G_i'^{\circ}$  values of the reactants at  $\text{pH} = 7$  and  $\text{pMg} = 3$  can, however, be calculated if  $K'$  has been measured at  $\text{pH} = 7$  and  $\text{pMg} = 3$  for a reaction in which  $\Delta_f G_i'^{\circ}$  is known for the other reactants. For example, this approach can be used to calculate  $\Delta_f G_i'^{\circ}$  for the reactants in glycolysis.

### 5.6 The actual experiment and thought experiments

In the laboratory, a biochemical equilibrium experiment is actually carried out at specified  $T$  and  $P$ , and the pH is measured at equilibrium. Buffers are used to hold the pH constant, but there may be a change in the pH if the catalyzed reaction produces or consumes acid. pMg at equilibrium has to be calculated, and this can be done accurately only if the acid dissociation constants and magnesium complex dissociation constants are known for all of the reactants and buffer components (ref. 12, 33). In the absence of this information pMg can be calculated approximately if the buffer binds  $\text{H}^+$  and  $\text{Mg}^{2+}$ , these

dissociation constants are known, and the concentrations of the reactants are much smaller than the concentration of the buffer components that are primarily responsible for the binding of  $\text{Mg}^{2+}$ . We can hope that some day there will be a pMg electrode as convenient as the pH electrode.

When we interpret the thermodynamics of a biochemical equilibrium experiment, we use an idealized thought experiment that is equivalent to the laboratory experiment. In the laboratory experiment, the buffer determines the approximate pH, but the pH will drift if  $\text{H}^+$  is produced or consumed. The pH should be measured at equilibrium because the composition and  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  depend on this pH. Since the experimental results depend on the final pH, we can imagine that the experiment was carried out in a reaction vessel with a semipermeable membrane (permeable to  $\text{H}^+$  and an anion, and impermeable to other reactants) with a pH reservoir on the other side. If the binding of  $\text{H}^+$  by the products is greater than that of the reactants,  $\text{H}^+$  will diffuse in from the pH reservoir as the reaction proceeds. If the binding of  $\text{H}^+$  by the reactants is greater,  $\text{H}^+$  will diffuse out of the reaction vessel as the reaction proceeds. Thus hydrogen ion is not conserved in the reaction vessel in this idealized thought experiment. Similar statements can be made about  $\text{Mg}^{2+}$ . In calorimetric experiments, corrections have to be made for the enthalpies of reaction due to the production of  $\text{H}^+$  and  $\text{Mg}^{2+}$  to obtain  $\Delta_r H^\circ$ , as mentioned earlier.

The thermodynamic interpretation of the apparent equilibrium constant  $K'$  uses  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$ . These quantities correspond with another thought experiment in which the separated reactants, each at 1 M at the specified  $T, P$ , final pH, final pMg, and  $I$  react to form the separated products, each at 1 M at the specified  $T, P$ , final pH, final pMg, and  $I$ .

### 5.7 Linear algebra

It is generally understood that chemical equations conserve atoms and charge, but it is not generally known how the conservation equations for a chemical reaction system can be calculated from a set of chemical equations or how an independent set of chemical equations can be calculated from the conservation equations for the system. Nor is it well known that conservation equations in addition to atom and charge balances may arise from the mechanism of reaction. The quantitative treatment of conservation equations and chemical reactions requires the use of matrices and matrix operations (ref. 10, 23). When the equilibrium concentrations of species such as  $\text{H}^+$  and  $\text{Mg}^{2+}$  are specified, these species and electric charge are not conserved, and so a biochemical equation should not indicate that they are conserved. The current practice of using words like acetate and symbols like ATP and  $\text{P}_i$  is satisfactory provided that people understand the reason for using these words and symbols. It should be possible to distinguish between chemical equations and biochemical equations on sight, and this means that different symbols should be used for the reactants in these two types of equations.

A set of simple chemical equations has been discussed from the viewpoint of linear algebra (ref. 34). The hydrolysis of ATP to ADP and  $\text{P}_i$  at specified pH has also been discussed from the viewpoint of linear algebra which shows why the 4 chemical equations reduce down to a single biochemical equation (ref. 35).

The conservation matrix for a biochemical reaction is especially useful for the identification of the constraints in addition to element balances (ref. 36).

## 6. Recommendations on thermodynamic tables

The papers by Alberty (ref. 5) and Alberty and Goldberg (ref. 7) show four types of tables of thermodynamic properties of biochemical reactants: (1)  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for species at 298.15 K, 1 bar (0.1 MPa),  $I = 0$ . (2)  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for species at 298.15 K, 1 bar,  $I = 0.25$  M. (3)  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for species at 298.15 K, 1 bar, pH = 7, pMg = 3, and  $I = 0.25$  M. (4)  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for reactants (sum of species) at 298.15 K, 1 bar, pH = 7, pMg = 3, and  $I = 0.25$  M. Table 1 contains the most basic information for calculating  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for reference reactions at  $I = 0$  and corresponds with the NBS and CODATA Tables. Table 4 is the most convenient for calculating  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  under normal experimental conditions of 298.15 K, 1 bar, pH = 7, pMg = 3, and  $I = 0.25$  M. Currently, thermodynamic information in biochemistry is stored as  $K'$  and  $\Delta_r H^\circ$  when pH and pMg are specified and as  $K$  and  $\Delta_r H^\circ$  for reactions in terms of species. In order to calculate  $K'$  and  $\Delta_r H^\circ$  or  $K$  and  $\Delta_r H^\circ$  for a reaction that has not been studied, it is currently necessary to add and subtract known reactions. It would be more convenient to be able to look up reactants in a table and add and subtract their formation properties to calculate  $K'$  and  $\Delta_r H^\circ$  or  $K$  and  $\Delta_r H^\circ$ , as is usually done for chemical reactions. One reactant can be involved in hundreds of reactions, and so it is more economical to focus on the reactants. The usefulness of such a table increases rapidly with its length. As mentioned in Section 4.3 columns for  $\bar{N}_{\text{H}}(i)$  and  $\bar{N}_{\text{Mg}}(i)$  can be included so that the change in binding of H and Mg at specified  $T, P, \text{pH}, \text{pMg}$ , and  $I$  can be readily calculated by use of equations 30 and 31.

The choice of 298.15 K, 1 bar, pH = 7, pMg = 3, and  $I = 0.25$  M is arbitrary, but these conditions are often used. Tables can be constructed for other conditions ( $T$ , pH, pMg, and  $I$ ) if sufficient information is available.  $\text{H}_2\text{O}$  has to be included in this table because its  $\Delta_r G^\circ(\text{H}_2\text{O})$  and  $\Delta_r H^\circ(\text{H}_2\text{O})$  have to be included in the summations in equations 40 and 41 when it is a reactant, even though  $\text{H}_2\text{O}$  is omitted in the expression for the apparent equilibrium constant.

The most basic principle is that thermodynamic tables on biochemical reactants at pH = 7 and pMg = 3 should be consistent with the usual thermodynamic tables to as great an extent as possible. A great deal is already known about the thermodynamics of reactions in aqueous solution, and this is all of potential value in biochemistry. The standard transformed formation properties of inorganic phosphate and glucose 6-phosphate at pH = 7 and pMg = 3 can be calculated since the standard formation properties of inorganic phosphate and glucose are well known and the properties of glucose 6-phosphate can be calculated from  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for the glucose 6-phosphatase reaction. This is true for many other biochemical reactants. Sometimes it is necessary to use the convention that  $\Delta_r G^\circ = \Delta_r H^\circ = 0$  for a reference species, as described in the discussion of the ATP series. It is difficult and expensive to obtain these missing data because biochemical reactants are often rather large molecules and contain a large number of elements. The methods described here make it possible to calculate  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for  $\text{P}_i$ , glucose 6-phosphate, adenosine, AMP, ADP, and ATP at temperatures in the approximate range 273–320 K, pH in the approximate range 3–10, pMg in the range above about 2, and ionic strengths in the approximate range 0–0.35 M. Since the choice of reference species is arbitrary to a certain extent, it is desirable to have international agreement on these choices. This agreement is required so that thermodynamic properties in different tables of this type can be used together.

For many biochemical reactants, the acid and magnesium complex dissociation constants have not been measured, but this does not mean that these reactants cannot be included in a table

of  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  at 298.15 K, pH = 7, pMg = 3, and  $I = 0.25$  M. What is required is that the apparent equilibrium constant  $K'$  for a reaction involving this reactant (or pair of reactants) with reactants with known properties has been determined at pH = 7, pMg = 3, and  $I = 0.25$  M at more than one temperature. If the pKs of a reactant are unknown, there is a problem in calculating the equilibrium pMg, but this uncertainty may not be large if the concentration of  $\text{Mg}^{2+}$  is controlled by a buffer with known binding properties and the equilibrium concentration of the reactants is low.

The fact that biochemical reactions are often organized in series will facilitate the construction of thermodynamic tables. When a series starts or ends with a reactant with known formation properties, knowledge of the apparent equilibrium constants in the series makes it possible to calculate  $\Delta_r G^\circ$  for reactants in the series at pH = 7. For example, consider glycolysis for which the apparent equilibrium constants for the 10 reactions have been known for some time. Since the standard transformed thermodynamic properties of glucose in aqueous solution are known, the  $\Delta_r G^\circ$  values for the 17 reactants at pH = 7, including pyruvate, can be calculated with just one problem. Since  $\Delta_r G^\circ$  is not known for NAD or NADH, one of the species has to be assigned  $\Delta_r G^\circ = \Delta_r H^\circ = 0$ . Since the thermodynamic properties of pyruvate are known, this provides a check on the calculation of  $\Delta_r G_i^\circ$  of the reactants in glycolysis.

The following conventions are recommended:

- When a reactant exists only in an electrically neutral form at pH = 7 and pMg = 3 and  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for that form in dilute aqueous solution are known, the values of  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  are calculated by adjusting for the content of H. An example is glucose.
- When a reactant exists in a single ionized form in the neighborhood of pH = 7 and pMg = 3, the values of  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for that form in the usual tables (which apply at  $I = 0$ ) have to be adjusted to  $I = 0.25$  M with the extended Debye-Hückel theory and adjusted for H to obtain the entry to the table of  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  values. Obviously, thermodynamic properties of  $\text{H}^+$  and  $\text{Mg}^{2+}$  will not be found in the table of  $\Delta_r G^\circ$  values. Also, ions like  $\text{Ca}^{2+}$  which bind significantly with multiply charged negative species of biochemical reactants cannot be put in the table because they require treatment like  $\text{Mg}^{2+}$ . Values of  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for Krebs cycle intermediates that exist at pH = 7 and pMg = 3 in a single ionic form calculated by Miller and Smith-Magowan (Appendix, ref. 8) can be adjusted for H and Mg and used in the proposed table after the values have been corrected to  $I = 0.25$  M. An example is succinate.
- When a reactant exists in several ionized or complexed forms that are at equilibrium at pH = 7 and pMg = 3 and the standard thermodynamic properties of all of the ionized and complexed forms are known, the values of  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  of reactants at pH = 7, pMg = 3,  $I = 0.25$  M can be calculated using isomer group thermodynamics. Examples are inorganic phosphate ( $\text{P}_i$ ), pyrophosphate, carbonate, citrate, and glucose 6-phosphate.
- When a reactant exists in several ionized or complexed forms with known dissociation constants and  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  are not known for any species of the reactant,  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  for the species can only be calculated by assigning one of them  $\Delta_r G^\circ = \Delta_r H^\circ = 0$  in dilute aqueous solution. The  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  values of the various species have to be adjusted to an ionic strength of 0.25 M and adjusted for H and Mg, so that  $\Delta_r G^\circ$  and  $\Delta_r H^\circ$  can be calculated for the reactant (sum of species) by use of isomer group thermodynamics, as illustrated here for the ATP series. NAD and NADH also provide an example, which is a little different because the acid and magnesium complex dissociation constants are believed to be identical.
- If acid dissociation and magnesium dissociation constants are not known for a reactant, it can still be put into a table at pH = 7 and pMg = 3 if apparent equilibrium constants have been measured under these conditions for a reaction involving this reactant with other reactants whose transformed thermodynamic properties are known. Examples are the many reactants in glycolysis other than glucose, ATP, ADP, Pi, NAD, NADH, and  $\text{H}_2\text{O}$ .
- It is not necessary to have columns in tables for  $\Delta_r S^\circ$  and  $\Delta_r S^\circ$  because these can be treated as dependent properties and can be calculated from equations 25 and 42.

## 7. Nomenclature

Symbol	Name	Unit
$A$	extensive Helmholtz energy of a system	kJ
$B$	parameter in the extended Debye-Hückel theory	$\text{L}^{-1/2} \text{mol}^{-1/2}$
$c_i$	concentration of species $i$	$\text{mol L}^{-1}$
$c^\circ$	standard state concentration (1 M)	$\text{mol L}^{-1}$
$\Delta_r C_p^\circ$	standard heat capacity at constant pressure of reaction at $T, P$ , and $I$	$\text{J K}^{-1} \text{mol}^{-1}$
$\Delta_r C_p^{\circ\prime}$	standard transformed heat capacity of reaction at constant $T, P$ , pH, pMg, and $I$	$\text{J K}^{-1} \text{mol}^{-1}$
$E$	electromotive force	V
$E^\circ$	standard electromotive force of a cell or half cell	V
$E'$	apparent electromotive force at specified pH	V
$E^{\circ\prime}$	standard apparent electromotive force of a cell or half cell at specified pH	V
$F$	Faraday constant (96 485.31 C mol <sup>-1</sup> )	C mol <sup>-1</sup>
$G$	extensive Gibbs energy of a system	kJ
$G'$	extensive transformed Gibbs energy of a system	kJ
$\Delta_r G$	reaction Gibbs energy for specified concentrations of species at specified $T, P$ , and $I$	$\text{kJ mol}^{-1}$
$\Delta_r G^\circ$	standard reaction Gibbs energy of a specified reaction in terms of species at specified $T, P$ , and $I$	$\text{kJ mol}^{-1}$
$\Delta_r G^{\circ\prime}$	transformed reaction Gibbs energy in terms of reactants (sums of species) for specified concentrations of reactants and products at specified $T, P$ , pH, pMg, and $I$	$\text{kJ mol}^{-1}$
$\Delta_r G^{\circ\prime}$	standard transformed reaction Gibbs energy of a specified reaction in terms of reactants (sums of species) at specified $T, P$ , pH, pMg and $I$	$\text{kJ mol}^{-1}$
$\Delta_r G(i)$	Gibbs energy of formation of species $i$ at a specified concentration of $i$ and specified $T, P$ , and $I$	$\text{kJ mol}^{-1}$
$\Delta_r G^\circ(i)$	standard Gibbs energy of formation of species $i$ at specified $T, P$ , and $I$	$\text{kJ mol}^{-1}$

Symbol	Name	Unit	Symbol	Name	Unit
$\Delta_f G'(i)$	transformed Gibbs energy of formation of species $i$ or reactant $i$ (sum of species) at specified concentration and specified $T, P, \text{pH}, \text{pMg},$ and $I$	$\text{kJ mol}^{-1}$	$\Delta_f N(\text{H}^+)$	change in binding of $\text{H}^+$ in a biochemical reaction at specified $T, P, \text{pH}, \text{pMg},$ and $I$	dimensionless
$\Delta_f G^\circ(i)$	standard transformed Gibbs energy of formation of species $i$ or reactant $i$ (sum of species) at specified $T, P, \text{pH}, \text{pMg},$ and $I$	$\text{kJ mol}^{-1}$	$\Delta_f N(\text{Mg}^{2+})$	change in binding of $\text{Mg}^{2+}$ in a biochemical reaction at specified $T, P, \text{pH}, \text{pMg},$ and $I$	dimensionless
$H$	extensive enthalpy of a system	$\text{kJ}$	$N_i$	number of isomers in an isomer group	dimensionless
$H'$	extensive transformed enthalpy of a system	$\text{kJ}$	$\text{pH}$	$-\log_{10}([\text{H}^+]/c^\circ)$	dimensionless
$\Delta_f H(\text{cal})$	calorimetrically determined enthalpy of reaction that includes the enthalpies of reaction of $\text{H}^+$ and $\text{Mg}^{2+}$ (consumed or produced) with any buffer in solution	$\text{kJ mol}^{-1}$	$\text{pMg}$	$-\log_{10}([\text{Mg}^{2+}]/c^\circ)$	dimensionless
$\Delta_f H$	enthalpy of reaction of a specified reaction in terms of species at specified $T, P,$ and $I$	$\text{kJ mol}^{-1}$	$\text{pX}$	$-\log_{10}([\text{X}]/c^\circ)$	dimensionless
$\Delta_f H^\circ$	standard enthalpy of reaction of a specified reaction in terms of species at specified $T, P,$ and $I$	$\text{kJ mol}^{-1}$	$P$	pressure	bar
$\Delta_f H'$	transformed enthalpy of reaction of a specified reaction in terms of reactants (sums of species) for specified concentrations of reactants and products at specified $T, P, \text{pH}, \text{pMg},$ and $I$	$\text{kJ mol}^{-1}$	$Q$	reaction quotient of specified concentrations of species in the same form as the equilibrium constant expression	dimensionless
$\Delta_f H^\circ$	standard transformed enthalpy of a specified reaction in terms of reactants (sums of species) at specified $T, P, \text{pH}, \text{pMg}$ and $I$	$\text{kJ mol}^{-1}$	$Q'$	apparent reaction quotient of specified concentrations of reactants and products (sum of species) in the same form as the apparent equilibrium constant expression	dimensionless
$\Delta_f H(i)$	enthalpy of formation of species $i$ at specified $T, P,$ and $I$	$\text{kJ mol}^{-1}$	$R$	gas constant ( $8.31451 \text{ J K}^{-1} \text{ mol}^{-1}$ )	$\text{J K}^{-1} \text{ mol}^{-1}$
$\Delta_f H^\circ(i)$	standard enthalpy of formation of species $i$ at specified $T, P,$ and $I$	$\text{kJ mol}^{-1}$	$r_i$ or $r(i)$	equilibrium mole fraction of $i$ within a specified class of molecules	dimensionless
$\Delta_f H'(i)$	transformed enthalpy of formation of species $i$ or reactant $i$ (sum of species) at specified $T, P, \text{pH}, \text{pMg},$ and $I$	$\text{kJ mol}^{-1}$	$S$	extensive entropy of a system	$\text{J K}^{-1}$
$\Delta_f H^\circ(i)$	standard transformed enthalpy of formation of species $i$ or reactant $i$ (sum of species) at specified $T, P, \text{pH}, \text{pMg},$ and $I$	$\text{kJ mol}^{-1}$	$S'$	extensive transformed entropy of a system	$\text{J K}^{-1}$
$I$	ionic strength	$\text{mol L}^{-1}$	$\bar{S}^\circ(i)$	standard molar entropy of species $i$ at specified $T, P,$ and $I$	$\text{J K}^{-1} \text{ mol}^{-1}$
$K$	equilibrium constant for a specified reaction written in terms of concentrations of species at specified $T, P,$ and $I$ (omitting $\text{H}_2\text{O}$ when it is a reactant)	dimensionless	$\bar{S}^\circ(i)$	standard molar transformed entropy of species $i$ or reactant $i$ at specified $T, P, \text{pH}, \text{pMg},$ and $I$	$\text{J K}^{-1} \text{ mol}^{-1}$
$K'$	apparent equilibrium constant for a specified reaction written in terms of concentrations of reactants (sums of species) at specified $T, P, \text{pH}, \text{pMg},$ and $I$ (omitting $\text{H}_2\text{O}$ when it is a reactant)	dimensionless	$\Delta_f S$	entropy of reaction of a specified reaction in terms of species at specified $T, P,$ and $I$	$\text{J K}^{-1} \text{ mol}^{-1}$
$m_i$	molality of $i$	$\text{mol kg}^{-1}$	$\Delta_f S^\circ$	standard entropy of reaction of a specified reaction in terms of ionic species at specified $T, P,$ and $I$	$\text{J K}^{-1} \text{ mol}^{-1}$
$n_i$ or $n(i)$	amount of species $i$	$\text{mol}$	$\Delta_f S'$	transformed entropy of reaction of a specified reaction in terms of reactants (sums of species) for specified concentrations of reactants and products at specified $T, P, \text{pH}, \text{pMg},$ and $I$	$\text{J K}^{-1} \text{ mol}^{-1}$
$n'(i)$	amount of species (bound and unbound) or amount of reactant $i$ (that is, sum of species)	$\text{mol}$	$\Delta_f S^\circ$	standard transformed entropy of a specified reaction in terms of sums of species at specified $T, P, \text{pH}, \text{pMg}$ and $I$	$\text{J K}^{-1} \text{ mol}^{-1}$
$N_{\text{H}}(i)$	number of H atoms in species $i$	dimensionless	$\Delta_f S^\circ(i)$	standard entropy of formation of species $i$ at specified $T, P,$ and $I$	$\text{J K}^{-1} \text{ mol}^{-1}$
$N_{\text{Mg}}(i)$	number of Mg atoms in species $i$	dimensionless	$\Delta_f S^\circ(i)$	standard transformed entropy of formation of species $i$ or reactant $i$ (sum of species) at specified $T, P, \text{pH}, \text{pMg},$ and $I$	$\text{J K}^{-1} \text{ mol}^{-1}$
$\bar{N}_{\text{H}}(i)$	average number of H atoms in reactant $i$ at specified $T, P, \text{pH}, \text{pMg},$ and $I$	dimensionless	$T$	temperature	$\text{K}$
			$U$	extensive internal energy of a system	$\text{kJ}$
			$V$	volume	$\text{L}$
			$z_i$	charge of ion $i$ with sign	dimensionless
			$\rho$	density	$\text{kg m}^{-3}$
			$\mu(i)$	chemical potential of species $i$ at specified $T, P,$ and $I$	$\text{kJ mol}^{-1}$
			$\mu'(i)$	transformed chemical potential of species $i$ or reactant (sum of species) at specified $T, P, \text{pH}, \text{pMg},$ and $I$ [can be replaced by $\Delta_f G'(i)$ ]	$\text{kJ mol}^{-1}$

Symbol	Name	Unit
$\mu^\circ(i)$	standard chemical potential of species $i$ at specified $T$ , $P$ , and $I$ [can be replaced by $\Delta_f G^\circ(i)$ ]	$\text{kJ mol}^{-1}$
$\nu_e$	number of electrons in a cell reaction	dimensionless
$\nu_i$ or $\nu(i)$	stoichiometric number of species $i$ in a specified chemical reaction	dimensionless
$\nu'(i)$	apparent stoichiometric number of reactant $i$ in a specified biochemical reaction	dimensionless

# STANDARD TRANSFORMED GIBBS ENERGIES OF FORMATION FOR BIOCHEMICAL REACTANTS

Robert N. Goldberg and Robert A. Alberty

This table contains values of the standard transformed Gibbs energies of formation  $\Delta_f G'^{\circ}$  for 130 biochemical reactants. Values of  $\Delta_f G'^{\circ}$  are given at pH 7.0, the temperature 298.15 K, and the pressure 100 kPa for three ionic strengths:  $I = 0$ ,  $I = 0.1$  mol/L and  $I = 0.25$  mol/L. The table can be used for calculating apparent equilibrium constants  $K'$  and standard apparent reduction potentials  $E'^{\circ}$  for biochemical reactions. Such a listing is more compact than tabulating the actual apparent equilibrium constants or standard apparent reduction potentials, which would require a very large number of reactant–product combinations. In the table, all reactants are in aqueous solution unless indicated otherwise.

A biochemical reactant is a sum of species. For example, ATP consists of an equilibrium mixture of the aqueous species  $\text{ATP}^+$ ,  $\text{HATP}^{3-}$ ,  $\text{H}_2\text{ATP}^{2-}$ ,  $\text{MgATP}^{2-}$ , etc. Similarly, phosphate refers to the equilibrium mixture of the aqueous species  $\text{PO}_4^{3-}$ ,  $\text{HPO}_4^{2-}$ ,  $\text{H}_2\text{PO}_4^-$ ,  $\text{H}_3\text{PO}_4$ ,  $\text{MgHPO}_4$ , etc. Biochemical reactions are written using biochemical reactants in terms of an apparent equilibrium constant  $K'$ , which is distinct from the standard equilibrium constant  $K$ . This subject is discussed in an IUPAC report (see Reference 1 below).

The apparent equilibrium constant  $K'$  and the standard transformed Gibbs energy change  $\Delta_r G'^{\circ}$  for a biochemical reaction can be calculated from the  $\Delta_f G'^{\circ}$  values by using the relationship

$$-RT \ln K' = \Delta_r G'^{\circ} = \sum v'_i \Delta_f G'^{\circ},$$

where the summation is over all of the biochemical reactants. The quantity  $v'_i$  is the stoichiometric number of reactant  $i$  ( $v'_i$  is positive for reactants on the right side of the equation and negative for reactants on the left side);  $R$  is the gas constant. As an example, the hydrolysis reaction of ATP is

At pH 7.00 and  $I = 0.25$  M,  $\Delta_r G'^{\circ}$  and  $K'$  are calculated as follows:

$$\begin{aligned} \Delta_r G'^{\circ} &= \{-1424.70 - 1059.49 - (-2292.50 - 155.66)\} \cdot (\text{kJ mol}^{-1}) \\ &= -36.03 \text{ kJ mol}^{-1} \end{aligned}$$

$$\begin{aligned} K' &= \exp[-(-36030 \text{ J mol}^{-1}) / \{(8.3145 \text{ J mol}^{-1} \text{ K}^{-1}) \cdot (298.15 \text{ K})\}] \\ &= 2.05 \cdot 10^6 \end{aligned}$$

An example involving a biochemical half-cell reaction is

At 298.15 K, pH 7.00, and  $I = 0$ , the standard apparent reduction potential  $E'^{\circ}$  can be calculated as follows

$$E'^{\circ} = -(1/nF) \cdot \{\Delta_f G'^{\circ}(\text{ethanol}) - \Delta_f G'^{\circ}(\text{acetaldehyde})\},$$

where  $n$  is the number of electrons in the half-cell reaction and  $F$  is the Faraday constant. Then,

$$\begin{aligned} E'^{\circ} &= [-1 / (2 \cdot 9.6485 \cdot 10^4 \text{ C mol}^{-1})] \cdot (58.10 \cdot 10^3 \text{ J mol}^{-1} \\ &\quad - 20.83 \cdot 10^3 \text{ J mol}^{-1}) = -0.193 \text{ V} \end{aligned}$$

# OXIDATION-REDUCTION POTENTIALS, ABSORBANCE BANDS AND MOLAR ABSORBANCE OF COMPOUNDS USED IN BIOCHEMICAL STUDIES

Paul A. Loach

In addition to the references<sup>1-5,7,8</sup> in the table, other generally used sources of oxidation-reduction data are: *Biochemist's Handbook*, D. Van Nostrand Co., Princeton, N.J. (1961); *The Encyclopedia of Electrochemistry*, C. A. Hampel, Ed., Reinhold Publishing Corp. New York (1964); *Oxidation-Reduction Potentials in Bacteriology and Biochemistry*, sixth ed., L. F. Hewitt, McCorquodale and Co. Ltd., London, (1950); *Biochemisches Taschenbuch* part II, Springer-Verlag, New York, (1964).

The oxidation-reduction couples are listed according to decreasing values of  $E^\circ$  or  $E^\circ'$ . When both values are available, the order is according to  $E^\circ'$ . Unless otherwise indicated,  $E^\circ'$  is the mid-point potential for a particular couple at pH7. Temperatures are not listed; most of the data are relevant to room temperature (20°C to 30°C). When more exact conditions are desired (ionic strength, concentration, temperature, nature of data used to derive  $E^\circ$  or  $E^\circ'$ ) the reader should consult the reference listed.

# FREE ENERGIES OF HYDROLYSIS AND DECARBOXYLATION

William P. Jencks

One of the reasons that there has been so much confusion and disagreement regarding the free energies of hydrolysis of "energy-rich" compounds of biochemical interest is that it is uncommon for any two workers to express their results according to the same nomenclature and conventions. The following summary may be helpful in making use of these tables of free energies of hydrolysis and decarboxylation.

The equilibrium constant,  $K_1$ , for the hydrolysis of an ester may be expressed according to the Equation 1 and the free energy of hydrolysis according to Equation 2, using the convention that the concentration of water is expressed in the same units as the other reactants and pure water is 55.5 *M*. For glycine ethyl ester the values of  $K_1 = 0.43$  and  $\Delta G^\circ = +500$  cal/mol at 39° reflect

$$K_1 = \frac{[\text{RCOOH}][\text{HOR}']}{[\text{RCOOR}'][\text{HOH}]} \quad (1)$$

$$\Delta G_1^\circ = -RT \ln K_1 \quad (2)$$

the fact that  $-\text{OH}$  and  $-\text{OC}_2\text{H}_5$  have approximately the same affinity for the carbonyl group.

For biochemical reactions, which usually take place in dilute aqueous solution, it is generally more convenient to take the activity of pure water as 1.0, and this convention will be adopted here. For glycine ethyl ester the values of  $K_1 = 24$  and  $\Delta G_1^\circ = -1,970$  cal/mol according to this convention reflect the fact that the driving force toward hydrolysis which results from the high concentration of water compared to the other reactants is hidden in the equilibrium expression by the convention that the activity of liquid water is 1.0. This extra driving force amounts to  $-RT$  in  $55.5 \cong -2,400$  cal/mol and is one reason that free energies of hydrolysis expressed according to this convention are unlikely to be equal to heats of hydrolysis. The standard states of the other reactants according to this convention are ideal 1 *M* solutions of the non-ionized species. This commonly leads to difficulty for a compound such as glycine which does not exist in a non-ionized form in appreciable concentration and the standard state is commonly modified, as in the case of the values for glycine ethyl ester given here, to refer to a species in which the *reacting* groups are non-ionized; i.e., to  $\text{H}_3^+ \text{NCH}_2\text{COOH}$ . instead of  $\text{H}_2 \text{NCH}_2 \text{COOH}$ . This convention, which we shall call convention I, gives a single value of  $\Delta G^\circ$  which is true regardless of the pH. Its use requires that only the actual concentrations (or activities) of the *particular ionic species* which are given in the equilibrium expression be included in calculations. For example, in order to calculate the free energy of hydrolysis of glycine ethyl ester from the results of an experiment carried out at pH 3.0, it is necessary to insert the concentration of  $\text{H}_3^+ \text{NCH}_2 \text{COOH}$  which is present at equilibrium at this pH, not the stoichiometric concentration of total glycine.

It is often convenient, especially when the ionization constants of the reactants are not accurately known, to use convention II in which the concentrations (or activities) of the reactants are given in terms of some convenient ionic species that is present under

the conditions of the experiments and any hydrogen ions present in the equilibrium expression are included. For glycine ethyl ester this is shown in Equations 3 and 4 and the value of  $\Delta G_{\text{II}}^\circ$  is + 1,440 cal/mol. As in the case of convention I, this convention refers only to the concentrations of the particular

$$K_{\text{II}} = \frac{[\text{RCOO}^-][\text{H}^+][\text{HOR}']}{[\text{RCOOR}'][\text{HOH}]} \quad (3)$$

$$\Delta G_{\text{II}}^\circ = -RT \ln K_{\text{II}} \quad (4)$$

ionic species given in the equilibrium expression which may be present in a given solution. The  $G_{\text{II}}^\circ$  value of  $\Delta G_{\text{II}}^\circ$  is independent of pH.

To interconvert these pH-independent free energies with free energies which hold for stoichiometric concentrations of reactants and products at a given pH, which would be found experimentally, it is only necessary to substitute in Equation 5 the actual concentrations present at the desired pH of the particular ionic species of the reactants which are present at that pH,

$$\Delta G' = \Delta G^\circ + RT \ln \frac{[\text{products}]}{[\text{reactants}]} \quad (5)$$

including any hydrogen ions given off or taken up in the reaction. Equation 5 is the basic equation which relates concentrations (or activities) to free energies. When a reaction is at equilibrium  $\Delta G' = 0$  and the standard free energy is then a logarithmic function of the *equilibrium* concentrations of the reactants and products (Equation 6). When the reactants and products are all in the standard state of activity 1.0 the concentration term drops out and the free energy of the system is equal to the standard free energy of the reaction (Equation 7).

$$\Delta G^\circ = -RT \ln \frac{[\text{C}]_{\text{eq}}[\text{D}]_{\text{eq}}}{[\text{A}]_{\text{eq}}[\text{B}]_{\text{eq}}} = -RT \ln K \quad (6)$$

$$\Delta G' = \Delta G^\circ + RT \ln \frac{1 \cdot 1}{1 \cdot 1} = \Delta G^\circ \quad (7)$$

Thus, the standard free energy is the difference in free energy between a system in which all the reactants and products are in the standard states ( $\Delta G' = \Delta G^\circ$ ) and the same system at equilibrium ( $\Delta G^\circ = 0$ ).

A useful special case of Equation 5 is the situation in which the total concentrations of all reactants and products, except hydrogen ion, are 1.0 *M* at a given pH. This gives a value of  $\Delta G'^\circ$  which refers to 1.0 *M* total concentrations of all the ionic species of the reactants and products and is true only at the specified pH. This convention III is the convention which refers most directly to experimental results and is most useful in making comparisons of free energies of hydrolysis under physiological conditions.  $\Delta G'^\circ$

is also sometimes referred to as  $\Delta G'$ ,  $\Delta G'_{\text{anal}}$ ,  $\Delta G'_{\text{exp}}$  and (unfortunately) as  $\Delta G^\circ$ .

For example, the value of  $\Delta G'^{\circ}$  for glycine ethyl ester is calculated from the  $\Delta G^\circ$  of convention I by inserting the fraction of the 1 M total glycine that is present as the free acid at pH 7.0, as shown in Equation 8.

$$\begin{aligned}\Delta G'^{\circ} &= \Delta G_i^{\circ} + RT \ln \frac{[\text{RCOOH}][\text{HOR}']}{[\text{RCOOR}'][\text{HOH}]} \\ &= +500 + 1,420 \log \frac{(1 \cdot 10^{-4.6})(1)}{(0.85)(1)} \quad (8) \\ &= -8,400 \text{ cal/mol}\end{aligned}$$

The fact that glycine ethyl ester is only 85% in the protonated form at pH 7.0 introduces a further small correction. The same value of  $\Delta G'^{\circ}$  may be calculated from the  $\Delta G^\circ$  of convention II by inserting the hydrogen ion activity at pH 7.0 into the equilibrium expression (Equation 9), because at pH 7 glycine is entirely in the form of the carboxylate anion, which is the form which is used in the equilibrium expression according to this convention.

$$\begin{aligned}\Delta G'^{\circ} &= \Delta G_{\text{II}}^{\circ} + RT \ln \frac{[\text{RCOOH}^-][\text{H}^+][\text{HOR}']}{[\text{RCOOR}'][\text{HOH}]} \\ &= 1,440 + 1,420 \log \frac{(1)(10^{-7})(1)}{(0.85)(1)} \quad (9) \\ &= -8400 \text{ cal/mol}\end{aligned}$$

These interconversions between pH-independent and pH-dependent free energies may generally be carried out without difficulty if the following two simple rules are followed:

1. The equilibrium expression for the pH-independent equilibrium constant and free energy of hydrolysis may include any desired ionic species of the reactants, but must be based on a *balanced equation* for the reaction which includes any *hydrogen ions* which are given off or taken up.
2. The actual concentrations (or activities) of the *particular ionic species* given in this expression and which are present at a given pH value must be substituted in the expression for the pH-independent equilibrium constant or free energy.

A final convention gives the molar free energy of hydrolysis under conditions in which the reactants are at concentrations other than 1.0 M. For glycine ethyl ester at pH 7.0 under conditions in which the reactants and products, except for water and hydrogen ion, are present at a concentration of  $10^{-3}$  M, the free energy of hydrolysis is  $-12,660$  cal/mol, as shown in Equation 10. The importance of specifying and understanding the particular convention that is being used is illustrated by the range of values from  $+1,440$  to  $-12,660$  calories/mole for the free energy of hydrolysis of glycine ethyl ester according to the different conventions. At pH 7 and under physiological conditions, glycine ethyl ester has a free energy of hydrolysis which clearly places it in the category of "high-energy" or "energy-rich" compounds. All of these conventions are correct and are useful for different purposes.

$$\begin{aligned}\Delta G' &= \Delta G'_{\text{pH}7} + RT \ln \frac{[\text{gly}]_{\text{tot}}[\text{HOEt}]_{\text{tot}}}{[\text{glyOEt}]_{\text{tot}}[\text{HOH}]} \\ &= -8,400 + 1,420 \log \frac{(10^{-3})(10^{-3})}{(10^{-3})(1)} \quad (10) \\ &= 12,660 \text{ cal/mol}\end{aligned}$$

Complexation of the compounds which are involved in an equilibrium with other compounds which may be present in the solution is a common cause of difficulty in the determination of equilibria and free energies of hydrolysis. The most important example of this in biochemical reactions is the binding of magnesium and other ions to phosphate and polyphosphates. This problem may be dealt with in several ways:

1. The reaction may be carried out under conditions in which the complexing ions are present in negligible concentrations compared to the compounds involved in the equilibrium under study.
2. The concentrations of the free and complexed species of the reactants and ions may be calculated from equilibrium constants for complex formation, which must be determined in separate experiments or be obtained from the literature. There is still some disagreement in the literature as to the correct values for these complexing constants for many compounds and ions of biochemical importance.
3. The reaction may be carried out in the presence of an excess of ions under conditions in which most of the reactants exist in the form of the complex. The equilibrium constant and free energy are then obtained for this particular set of experimental conditions or may be expressed in terms of reactions of the complexed species. For example, the affinity of  $\text{Mg}^{2+}$  toward  $\text{ATP}^{4-}$  and toward  $\text{ATP}^{3-}$  is much larger than that toward  $\text{HPO}_4^{2-}$ , so that the equilibrium in the presence of excess  $\text{Mg}^{2+}$  may be expressed according to Equation 11. Most of the free energies of hydrolysis of polyphosphate compounds which are given in these tables refer to conditions in which  $\text{Mg}^{2+}$  is present in excess and most or all of the polyphosphates exist as the magnesium complexes. There is still no general agreement regarding these values.

$$K = \frac{[\text{Mg} \cdot \text{ADP}^-][\text{HPO}_4^-][\text{H}^+]}{[\text{Mg} \cdot \text{ATP}^-][\text{H}_2\text{O}]} \quad (11)$$

The free energies in these tables generally refer to concentrations rather than activities of the reactants. Thermodynamic values extrapolated to zero ionic strength are of theoretical interest, but have not often been obtained for reactions of biochemical importance.

It is worth noting that these equilibria refer only to aqueous solutions, and that a large fraction of a cell or cell particle is not aqueous. The perturbation of equilibria that may occur in non-aqueous systems is illustrated by the fact that esters of long chain fatty acids can be formed at equilibrium in a nonaqueous phase which is in contact with neutral buffer, although the equilibrium in the buffer solution is far toward hydrolysis.

It cannot be pointed out too often that thermodynamic measurements and conventions say nothing about the *pathway* by which a reaction takes place; i.e., the equilibrium state of a system under a given set of experimental conditions is the same regardless of the pathway by which equilibrium is attained. Thus, the common practice of calling a particular ionic species the "reactive" species from an observed change in the stoichiometric equilibrium position of a reaction with changing pH is incorrect. It is this independence of reaction pathway that makes it equally legitimate to specify the equilibrium constant of a reaction according to any of a number of equations which contain different ionic species of reactants and products; the only requirement is that the equations balance. Different equilibrium constants will be obtained, of course, from the different equations.

Further information regarding the methods for dealing with free energies of hydrolysis may be found in References 1–4. Carpenter<sup>5</sup> has prepared a useful summary of the dependence on pH of  $\Delta G^{\circ}$  for several classes of compounds of biochemical interest.

Ethyl acetate	1,660	4,720	4

Compiled by William P. Jencks.

<sup>a</sup> Standard free energy of hydrolysis based on a standard state of 1 *M* concentrations of the *uncharged* reactants and products and an activity of pure water of 1.0 (convention I).

<sup>b</sup> Standard free energy of hydrolysis at pH 7.0 based on a standard state of 1 *M* total stoichiometric concentration of reactants and products, except hydrogen ion, and on an activity of pure water of 1.0 (convention III). Values for derivatives of acetic acid are based on a thermodynamic  $pK_a$  of 4.76 for acetic acid and a  $\Delta G$  for ionization of acetic acid at pH 7.0 of 3,060 cal/mol. Values for  $\Delta G^{\circ}_{\text{pH}7}$  for acetate derivatives based on a  $pK'_a$  of  $4.63 \pm 0.02$  at ionic strength 0.2 to 1.0<sup>12</sup> are 180 cal/mol more negative.

<sup>c</sup> For the dianions of acetyl phosphate and phosphate.

<sup>d</sup> For hydrolysis of the ester.

<sup>e</sup> Based on (closely similar) equilibrium constants with several thiol esters and the  $\Delta G^{\circ}$  for *N,S*-dicetyl- $\beta$ -mercaptoethylamine.

<sup>f</sup> From the data of De la Mare in acetic acid containing traces of water<sup>13</sup> and an ionization constant of  $4.1 \cdot 10^{-8}$  for hypochlorous acid.<sup>14</sup>

<sup>g</sup> Based on Reference 10.  $\Delta G^{\circ}_{\text{pH}7.0} = -7,700$  for ATP ( $\rightarrow$  PP and AMP), and  $pK_a$  valine = 2.32.

#### FREE ENERGIES OF HYDROLYSIS OF THIOL ESTERS

Compound	$-\Delta G^{\circ a}$	$-G^{\circ}_{\text{pH}7^b}$	Reference
<i>N,S</i> -Diacetyl- $\beta$ -mercaptoethylamine	4,460	7,520	4

Compiled by William P. Jencks.

<sup>a</sup> Standard free energy of hydrolysis based on a standard state of 1 *M* concentrations of the *uncharged* reactants and products and an activity of pure water of 1.0 (convention I).

<sup>b</sup> Standard free energy of hydrolysis at pH 7.0 based on a standard state of 1 *M* total stoichiometric concentration of reactants and products, except hydrogen ion, and on an activity of pure water of 1.0 (convention III). Values for derivatives of acetic acid are based on a thermodynamic  $pK_a$  of 4.76 for acetic acid and a  $\Delta G$  for ionization of acetic acid at pH 7.0 of 3,060 cal/mol. Values for  $\Delta G^{\circ}_{\text{pH}7}$  for acetate derivatives based on a  $pK'_a$  of  $4.63 \pm 0.02$  at ionic strength 0.2 to 1.0<sup>12</sup> are 180 cal/mol more negative.

<sup>c</sup> Based on Reference 8 and 4-pyridinealdoxime acetate (see previous table).

<sup>d</sup> Based on Reference 7 and acetylimidazole (see following table).

<sup>e</sup> Based on *N,S*-diacetyl- $\beta$ -mercaptoethylamine.

<sup>f</sup> Based on the equilibria for the condensation of acetate and acetyl coenzyme A with oxaloacetate to give citrate with the correction for citrate ionization recalculated as described in the text above.

<sup>g</sup> Based on equilibria with acetyl phosphate and acetylimidazol.<sup>7,16</sup>

#### FREE ENERGIES OF HYDROLYSIS OF AMIDES

Compound	$-\Delta G^{\circ}_{\text{pH}7^a}$	Reference
Acetylimidazole	12,970	3
10-Formyltetrahydrofolic acid (pH 7.7, 37°)	5,830 <sup>b</sup>	17
Asparagine	3,600	18
Glutamine	3,400	18
<i>N</i> -Dimethylpropionamide	2,100 <sup>c</sup>	19
Propionamide	2,100 <sup>c</sup>	19
Hippurylanilide (pH 5.0, 39°)	1,470	20
Benzoyltyrosyl-glycylanilide (pH 6.5, 23°)	1,360	21
Benzoyltyrosyl-glycinamide	420 <sup>d</sup>	22
<i>N</i> -Acetyltyrosine hydroxamic acid	1,870	23
Acetohydroxamic acid	-200	23
<i>N</i> -Methylpropionamide	-300 <sup>c</sup>	19

Compiled by William P. Jencks.

<sup>a</sup> Standard free energy of hydrolysis at pH 7.0 based on a standard state of 1 *M* total stoichiometric concentration of reactants and products, except hydrogen ion, and on an activity of pure water of 1.0 (convention III).

<sup>b</sup> Based on Reference 17 and  $\Delta G^{\circ}_{\text{pH}7} 7.7 = -8,030$  cal/mol for ATP.

<sup>c</sup> Data for other simple amides at elevated temperatures are given in Reference 19.

<sup>d</sup> For cleavage of the peptide bond, to fully ionized products.

FREE ENERGIES OF HYDROLYSIS OF PHOSPHATES<sup>a</sup>

Compound	$-\Delta G^{\circ b}$	Reference
Phosphoenolpyruvate, pH 7.0	14,800	24
pH 7.4–8.4	12,800 <sup>b</sup>	2
$\beta$ -Aspartyl phosphate, pH 8.0, 15°	13,000 <sup>c</sup>	25
Carbamyl phosphate, pH 9.5	ca. 12,300 <sup>d</sup>	26
3-Phosphoglyceroyl phosphate, pH 6.9	11,800	2
Acetyl phosphate, pH 7.0	10,300	7, 3
Creatine phosphate, pH 7.0, 7.5, 37°	10,300	27
Phosphoarginine, pH 8.0, excess Mg <sup>++</sup>	7,700 <sup>e</sup>	28
Uridine diphosphate glucose (glycoside cleavage), pH 7.6	7,300	29
Adenosine triphosphate ( $\rightarrow$ AMP, PP), pH 7.0, excess Mg <sup>++</sup>	7,700 <sup>f</sup>	4, 9
pH 7.5, excess Mg <sup>++</sup>	10,300 <sup>g</sup>	30
Adenosine triphosphate ( $\rightarrow$ ADP, Pi), 37°, pH 7.0, excess Mg <sup>++</sup>	7,300	31–33
25°, pH 7.4, 10 <sup>-3</sup> M Mg <sup>++</sup>	8,800	44
25°, pH 7.4, 0 Mg <sup>++</sup>	9,600	44
Pyrophosphate, pH 7.0	8,000	24
pH 7.0, 0.005 M Mg <sup>++</sup>	4,500	24
Cytidine-2'-3'-phosphate (cyclic) $\rightarrow$ 3'-phosphate, pH 7.0	5,000	34
Glucose-1-phosphate, 25°, pH 7.0	5,000	35
N-Acetyethanolamine phosphate, pH 7.0	2,900	36
Glucose-6-phosphate, 25°, pH 7.0	3,300	35
$\alpha$ -Glycerophosphate, 38°, pH 8.5	2,200	37
pH 5.8	2,600	3
Hexose-6-phosphates, 38°, pH 8.5	2,800 $\pm$ 200	37
pH 5.8	3,200 $\pm$ 200	37

Compiled by William P. Jencks.

<sup>a</sup> For a more detailed compilation, see Reference 2.<sup>b</sup> Standard free energy of hydrolysis based on a standard state of 1 M total stoichiometric concentration of reactants and products, except hydrogen ion, and on an activity of pure water of 1.0 (convention III).<sup>c</sup> Based on Reference 25 and  $-\Delta G^{\circ}_{\text{pH } 8.0} = -8,400$  cal/mol for ATP.<sup>d</sup> Based on Reference 26 and  $\Delta G^{\circ}_{\text{pH } 9.5} = -10,440$  cal/mol for ATP.<sup>e</sup> Based on Reference 28 and  $\Delta G^{\circ}_{\text{pH } 8.0} = -8,400$  cal/mol for ATP.<sup>f</sup> Based on acetyl coenzyme A and the ATP-activated synthesis of acetyl coenzyme A.<sup>g</sup> Based on a series of equilibria and the assumption of the similarity of the terminal phosphates of ATP and ADP. This value is not consistent with the preceding estimate.

## FREE ENERGIES OF HYDROLYSIS OF GLYCOSIDES

Compound	$-\Delta G^{\circ}_{\text{pH } 7}$ <sup>a</sup>	Reference
Uridine diphosphoglucose (pH 7.6)	7,300 <sup>b,c,d</sup>	29
Sucrose	7,000 <sup>b</sup>	38
Levan (fructofuranoside 2-6-fructose)	5,000 <sup>b</sup>	39
Glucose-1-phosphate	5,000	35
Maltose	4,000	39
Glycogen	4,000	39
Amylose ( $\alpha$ (1-4)glucosidic)	3,400	39

Compiled by William P. Jencks.

<sup>a</sup> Standard free energy of hydrolysis at pH 7.0 based on a standard state of 1 M total stoichiometric concentration of reactants and products, except hydrogen ion, and on an activity of pure water of 1.0 (convention III).<sup>b</sup> Based on a corrected value for sucrose hydrolysis in Reference 38.<sup>c</sup> Recalculated from  $K = 1.6$ ,  $\Delta G^{\circ} = -300$  from the data of Reference 29.<sup>d</sup> The values for thymidine diphosphoglucose and adenosine diphosphoglucose are very similar.<sup>4,5,46</sup>

## FREE ENERGIES OF DECARBOXYLATION

Compound	$-\Delta G^{\circ a}$	Reference
Oxaloacetate <sup>-</sup> $\rightleftharpoons$ Pyruvate <sup>-</sup> + HCO <sub>3</sub> <sup>-</sup>	6,200	24
Methylmalonyl-CoA $\rightleftharpoons$ Propionyl-CoA + HCO <sub>3</sub> <sup>-</sup>		
30°	6,200 <sup>b</sup>	24,40
28°	7,510 <sup>c</sup>	41
Enzyme-biotin-CO <sub>2</sub> $\rightleftharpoons$ Enzyme-biotin + HCO <sub>3</sub> <sup>-</sup> (pH 7.0, 0°)	4,700	43

Compiled by William P. Jencks.

<sup>a</sup> Based on the indicated ionic species of reactants and products. Units are cal/mole.<sup>b</sup> Based on oxaloacetate decarboxylation and  $K$  for carbon dioxide transfer;  $K = [\text{pyruvate}][\text{D-methyl-malonyl-CoA}] / [\text{propionyl-CoA}] = 1.0$ .<sup>47</sup><sup>c</sup> Based on ATP-coupled carboxylation and  $-\Delta G^{\circ}_{\text{pH } 8.1} = -8.540$  for ATP hydrolysis. The corresponding value at 37° from the data of Reference 42 is  $-11.500$  cal/mol.<sup>42</sup>

## DECI-NORMAL SOLUTIONS OF OXIDATION AND REDUCTION REAGENTS

Atomic and molecular weights in the following table are based upon the 1965 atomic weight scale and the isotope C-12. The weight in grams of the compound in 1 cc of the following

deci-normal solutions is found by dividing the H equivalent in the last column by 1,000.

Name	Formula	Atomic or Molecular Weight	Hydrogen Equivalent	0.1 Hydrogen Equivalent in g
Antimony	Sb	121.75	$\frac{1}{2}$ Sb	6.0875
Arsenic	As	74.9216	$\frac{1}{2}$ As	3.7461
Arsenic trisulfide	As <sub>2</sub> S <sub>3</sub>	246.0352	$\frac{1}{2}$ As <sub>2</sub> S <sub>3</sub>	6.1509
Arsenous oxide	As <sub>2</sub> O <sub>3</sub>	197.8414	$\frac{1}{4}$ As <sub>2</sub> O <sub>3</sub>	4.9460
Barium peroxide	BaO <sub>2</sub>	169.3388	$\frac{1}{2}$ BaO <sub>2</sub>	8.4669
Barium peroxide hydrate	BaO <sub>2</sub> · 8H <sub>2</sub> O	313.4615	$\frac{1}{2}$ BaO <sub>2</sub> 8H <sub>2</sub> O	15.6730
Calcium	Ca	40.08	$\frac{1}{2}$ Ca	2.004
Calcium carbonate	CaCO <sub>3</sub>	100.0894	$\frac{1}{2}$ CaCO <sub>3</sub>	5.0045
Calcium hypochlorite	Ca(OCl) <sub>2</sub>	142.9848	$\frac{1}{4}$ Ca(OCl) <sub>2</sub>	3.5746
Calcium oxide	CaO	56.0794	$\frac{1}{2}$ CaO	2.8040
Chlorine	Cl	35.453	Cl	3.5453
Chromium trioxide	CrO <sub>3</sub>	99.9942	$\frac{1}{3}$ CrO <sub>3</sub>	3.3331
Ferrous ammonium sulfate	FeSO <sub>4</sub> (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> · 6H <sub>2</sub> O	392.0764	FeSO <sub>4</sub> (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> · 6H <sub>2</sub> O	39.2076

**Abstract:** An explanation of the origin and interpretation of the suspension effect (SE) is presented in accordance with “pH Measurement: IUPAC Recommendations 2002” [*Pure Appl. Chem.* **74**, 2169 (2002)]. It is based on an analysis of detailed schemes of suspension potentiometric cells and confirmed with experimental results. Historically, the term “suspension effect” evolved during attempts to determine electrochemically the thermodynamically defined activity of H<sup>+</sup> (aq) in suspensions. The experimental SE arises also in determining other pI<sub>on</sub> values, analogous to pH values.

The SE relates to the observation that for the potential generated when a pair of electrodes (e.g., reference electrode, RE, and glass electrode) is placed in a suspension, the measured cell voltage is different from that measured when they are both placed in the separate equilibrium solution (eqs). The SE is defined here as the sum of: (1) the difference between the mixed potential of the indicator electrode (IE) in a suspension and the IE potential placed in the separated eqs; and (2) the anomalous liquid junction potential of the RE placed in the suspension. It is not the consequence of a boundary potential between the sediment and its eqs in the suspension potentiometric cells as is stated in the current definition of the SE.

**Keywords:** operational definition of suspension effect; suspension effect; pH; suspension potentiometric cell; IUPAC Analytical Chemistry Division; pI<sub>on</sub>; boundary potential; mixed potential; soil pH; anomalous liquid junction potential.

## 1. The suspension effect explained on the basis of analysis of potentiometric cells

### 1.1 Introduction

Potentiometry is an electroanalytical technique based on the measurement of the potential of an electrochemical cell,

composed of a measuring and a reference electrode (RE), both immersed in the measuring solution to be measured.

In homogeneous solutions, direct potentiometry is used for the estimation of ion activities (e.g., pH) and potentiometric titrations for determination of the amount concentration of ionic species. These measuring techniques are also applied to suspensions or sols of different materials (containing positively or negatively charged particles) in aqueous dispersion media. Although pH measurement in soil suspensions is highly relevant to this work, ion exchanger suspensions were chosen preferentially as models due to their simplicity.

The most frequently applied direct potentiometric method is the measurement of pH. Therefore, the determination of pH is selected to explain the essential procedures and experimental set-up for the potentiometric techniques applied to suspensions or sols.

The most recent definitions, procedures, and terminology relating to pH measurements in dilute aqueous solutions in the temperature range 5–50 °C are given in the IUPAC Recommendations 2002 [1]. In this reference, the glass electrode cell V is proposed for practical pH measurements [1, p. 2187]:

Typically, the galvanic cells used for practical pH measurements conform to the characteristics of cell V; therefore, the results obtained in these practical pH measurements approximate results obtained by cell V.

Although “the quantity pH is intended to be a measure of the activity of hydrogen ions in [homogeneous] solutions” [1], and measurements using cell V include an unknown liquid junction potential, cell V is also used for practical measurement of pH in suspensions with the electrodes usually positioned in different phases.

When pH is measured in (i) a suspension (or its sediment) or (ii) in its equilibrium solution (eqs), the measured pH value in

each of these constituent parts is different, even though the total system is in equilibrium. None of these pH values represents the (thermodynamically) true  $H^+$  activity in a suspension. This observation has caused serious problems for the theory and practice of pH measurements, problems which remain unresolved.

### 1.2 Consideration of the “glass electrode cell” containing a suspension

The term “suspension” should mean a *uniform equilibrated multiphase system*. It can be separated into the eqs and the sediment. If, when separated, the eqs and the sediment remain in physical and electrical contact, they represent a *combined suspension system*. The separated supernatant, obtained by sedimentation, centrifugation, or filtration, does not necessarily give absolutely equivalent solutions, yet they can be considered eqs, because the differences between them can be neglected with respect to the characteristics of the measured values.

In this work, the term “suspension” means the dispersion of electrically charged solid particles in water or in an aqueous solution. The origin of the charges can be adsorption or ionization, or as a property of the ion exchanger beads. The positively or negatively charged particles of different sizes found in soils provide another example. However, for this document (and in the literature that it relies upon) ion exchanger particles (which, depending on solution pH lower than 7 will be mostly in the  $H^+$  form) were chosen as a representative example for the study of pH measurements in suspension. These particles reduce the experimental effort and make a simple approach possible. Experiments showed essentially the same results when particles of other types were used [2].

The bulk liquid (of any electrolyte concentration) in the suspension will be identical to the supernatant of this suspension, when it is separated in whatever manner into two parts. It is different from that in the diffusion layers of individual particles, which are responsible for the mixed electrode potential when they are in contact with the glass electrode part of the pH electrode (Section 1.4). The diffusion layer of individual particles contributes to the anomalous liquid junction potential observed in pH measurements in suspensions.

The two separated parts are (i) the *sediment*, which can be considered the most concentrated suspension possible, and (ii) the clear (homogeneous, non-turbid) solution above it. This solution is called the eqs, if the suspension is equilibrated before separation. It is proposed to call the combination of an eqs and sediment, which are in physical and electrical contact, a *combined suspension system*.

For pH measurement in a combined suspension system, the following specific positions for the glass and REs are possible:

1. both electrodes are positioned in the eqs;
2. both electrodes are in the sediment;
3. the glass electrode is in the sediment and the RE is in the eqs; or
4. the electrodes are in the reverse position from that in 3.

In addition, it is possible to measure the pH in each *separated suspension component*, which means that:

5. both electrodes are in the separated “eqs” or
6. both electrodes are in the separated sediment.

The pH measurement is possible also with

7. both electrodes in the original, (nonseparated) equilibrated suspension, the concentration of which should (ideally) be practically constant during the measurement.

In a suspension in equilibrium, the electrochemical potential  $\tilde{\mu}_{H^+}$  is equal throughout the system, therefore, the different electrode arrangements 1 to 7 could be expected to give the same pH values. Nevertheless, the electrode combinations 1 and 2 and the analogous pair 5 and 6 show large (and nearly equal) pH differences, as do the combinations 3 and 4. These pH differences were named the *suspension effect* (SE) for the first time in 1930 [5,6]. Subsequently, the nature of this effect has been studied intensively by many authors; a list of references may be found in reviews, e.g., [4,7–9]. However, there has been no consensus on the origin of, or explanation for, the SE.

An acceptable explanation of this phenomenon follows from a detailed analysis of the suspension cells (combinations 1 and 2, or 5 and 6) and from their cell potential differences,  $\Delta E$ , from which the corresponding pH differences can be calculated; this explanation is supported by recent experimental observations [3].

### 1.3 Detailed schemes for potentiometric cells used in suspensions

Scheme 1 shows both electrodes in the eqs (combined with sediment, system 1, or separated, system 5).

#### Scheme 1

Here, *S* indicates the separator (membrane) of the salt bridge and *G* the glass membrane of the glass electrode. The symbol  $\parallel$  represents the region of the KCl solution in the separator and that in the contact range of eqs with KCl solution diffused from the RE. (The extent of the KCl layer in eqs is exaggerated in the scheme.)  $E_{\text{ref}}$  is the potential of the RE,  $E_g$  is the potential of the glass electrode.  $E_j(S_A)$  and  $E_j(A)$  are the liquid junction potentials; these are of negligible magnitude due to the approximately equal transport numbers of  $K^+$  and  $Cl^-$ , as established by potentiometric measurements [3,13].

This scheme is equivalent to that for cell V (above), but considers the interphases in detail.

Scheme 2 shows both electrodes in the sediment (combined with eqs, or separated, systems 2 and 6, respectively).

#### Scheme 2

Again, *S*, *G*, and  $\parallel$  have the same meaning as in scheme [A]. The symbol  $\parallel$  represents the ion exchanger *X* (sediment of *X* in  $H^+$  form) bathed in KCl solution which diffuses from the RE, and the symbol  $\parallel$  means the ion exchanger *X* (in  $H^+$  form) dispersed in eqs. The sign  $\parallel$  represents the glass electrode in intimate contact with the suspension particles (HX) and entrained eqs; this evokes the mixed electrode potential.  $E_{j,\text{anomal}}$  is the anomalous liquid junction potential and  $E_{g,\text{mix}}$  is the mixed potential of the glass electrode.  $E_j(S_B)$  is negligible [3], and  $E_{\text{ref}}$  is defined as in [A].

When comparing cells [A] and [B], the first component of the potential difference arises from junction potentials, viz.  $E_j(A) + E_j(S_A) - E_{j,\text{anomal}}(B) - E_j(S_B)$ , which can be approximated to  $E_j(A) - E_{j,\text{anomal}}(B)$ , as  $E_j(S_A)$  and  $E_j(S_B)$  are negligible [3]. This difference occurs because in cell [B] the filling solution, which

diffuses from the salt bridge into the suspension, exchanges  $K^+$  for the  $H^+$  counter-ions of the particles, which changes the ion arrangement in the suspension and most importantly affects the approximate equality of ion transport numbers in the KCl diffusion front. This effect is termed an anomalous liquid junction potential and represents the *suspension effect of the second kind*, SE 2, as defined in [2,3,10]. The second component of the potential difference is  $E_{g,mix}(B) - E_g(A)$ ; this results from the small suspension particles making intimate contact with the electrode surface, and is called the *suspension effect of the first kind*, SE 1 [3,11]. This arises because the electrode is in contact with the (true) eqs and at the same time in intimate contact with charged particles. In the latter contact regions, an overlapping of the double layers of the particles and the electrode occurs and causes a different  $H^+$  activity in comparison with the activity existing in contacts of eqs with the electrode. This gives rise to a mixed potential [2,3,12], as discussed in Section 1.4.

It is evident that the cell potentials  $E_A$  and  $E_B$  will differ in two component potentials: (1)  $E_j(A)$  and  $E_{j,anomal}(B)$  and (2)  $E_g(A)$  and  $E_{g,mix}(B)$ . As both electrodes are in the same phase there can be no boundary potential component  $E_{boundary}$ , either in  $E_A$  or in  $E_B$ .

Scheme 3, System 3, shows the glass electrode in the sediment and RE in the eqs of a “combined suspension system” in equilibrium.

### Scheme 3

The boundary potential is represented by  $E_b (= E_{boundary})$ ; all other symbols have the analogous meanings as above. The cell potential  $E_C$  differs from the potential  $E_A$  (Scheme 1) only in the potential of the glass electrode because, as discussed below,  $E_b$  is negligible [3]. In [A] the potential of the glass electrode  $E_g(A)$  is a single potential, because the electrode is in contact with a homogeneous solution. However, in [C] it is a multiple or mixed electrode potential, as in [B].

The potential  $E_b$  (also known as a Donnan potential) at the eqs/sediment boundary is often considered, without foundation, as arising from an effective semipermeable membrane. It has been established experimentally [2,3] that when, for example, the movable electrode penetrates the sediment phase (“perforates” the “fictitious membrane”) no measurable step-change of the electrode potential occurs. Thus,  $E_b = 0$  and can be neglected. However, the electrode potential changes proportionately with progressive immersion of the electrode in the sediment. This is in accordance with the above interpretation that a mixed potential forms.

A Donnan potential exists at the solid–solution interface around individual particles (because the fixed ions inside the particles cannot cross the interfaces), but it does not exist where the bulk eqs is constricted in the interstitial eqs channels between the particles.

## 1.4 Analysis of the schemes and findings

### Potential at the eqs/sediment boundary.

Analysis of the above cell schemes shows that the effect of suspended sediment material on two electrochemical processes is responsible for the SE. The SE is not a result of a hypothetical membrane and the corresponding potential, which might be ascribed to the boundary between the eqs and the sediment. It

has been established experimentally that  $E_b \approx 0$  [2,3] both in control experiments, which included an appropriate agitation of the RE in the suspension, and in experiments in which a restrained flow of the solution filling the salt bridge was used or the direction of the flow was reversed.

### Liquid junction potential.

The liquid junction potential formed at the contact of the RE salt bridge with the sediment can show a much greater value than when in contact with the eqs.

The experiments carried out using a “movable electrode” to establish the existence of the “hypothetical membrane” between eqs and the sediment [10] showed that the *cause* of this change in liquid junction potential is, in fact, ion exchange between the sediment particles and the electrolyte solution flowing from the salt bridge [10]. This change in cell potential begins even before the tip of the salt bridge of the movable RE penetrates the interface [10]. This explanation is also accepted in Galster’s monograph on pH measurement [13].

The ions of the diffused filling solution may exchange with counterions (e.g.,  $H^+$ ) in the (colloid) particle double layers and change the solution composition in the particle environment, which will affect the *approximately equal ion transport numbers of the diffusing electrolyte solution*. This is the fundamental reason for the development and maintenance of the *anomalous liquid junction potential*, which can be regarded as the *nature* of the changed potential. This potential can be considered as a systematic error of measurement and can be eliminated (as described in Section 2.6). The magnitude of this potential is usually of the order of some tens of mV, but it can attain more than 100 mV [2,3,7,8].

### Indicator electrode (IE) potential and its duration.

The change of the IE potential when the electrode comes into intimate contact with the charged particles can also be followed by means of the above-mentioned movable electrode. Experiments confirm the interpretation that the overlapping of the electrode double layer with the double layers of particles is the *cause* of the potential change of the IE when introduced into a suspension [3,4,11,12]. If in the combined suspension system, a movable IE perforates the fictitious membrane, where a phase boundary potential difference between supernatant and the slurry phase should exist, an instantaneous electrode potential change would occur, but it does not! By a step-by-step movement of the electrode into the bulk of the suspension, a progressive increase of the electrode surface in contact with particles occurs and the electrode potential changes in parallel. This leads to the interpretation that the electrode potential change in the suspension depends on surface processes at the electrode and not on effects associated with a membrane. With further penetration of the electrode into the suspension, the contact regions on the electrode surface increase and with this the influence on the value of the mixed potential.

After the introduction of the electrode into the suspension and establishment of contacts with the particles, the electrode potential becomes an *irreversible mixed potential* [12], because two electrochemical reactions proceed simultaneously on the same electrode surface. This potential remains essentially constant for a period of time which exceeds the time required for a potentiometric measurement. This mixed potential can be regarded as the *nature* of the changed IE potential in suspensions, which cannot be eliminated from any measurement. The mixed potential in cells [B] or [C] depends on the species, smoothness of the electrode and the particles, the ionic strength of the solution, and

the particle charge and size [11,12]. Its value is usually not greater than some tens of mV.

The potentiometric cell, represented schematically by cell [C], is generally adopted as the most suitable for soil pH measurements. The analysis of its scheme shows that  $E_j(B)$  (required in cell [B]) is replaced by  $E_j(C)$  (which is  $\approx 0$ ) and  $E_b$  (which is  $= 0$ ). The cell potential  $E_C$  changes measurably only when the mixed potential of the IE  $E_g(C_{\text{mix}})$  changes. The systematic RE error is eliminated from the cell potential because the filling solution of the RE does not flow into the suspension. From the steady-state potential  $E_C$ , a useful approximation of the pH of a suspension can be calculated, because  $E_C$  depends on the contribution to the  $H^+$  activity from both the particles and the eqs. If the eqs is not completely free from colloidal particles, this may represent (at most) a small uncertainty which must be taken into account.

The interpretation of the experimental results obtained in the study of hydrogen ion activity in suspensions [12] is applicable in general to a potentiometric estimation of ion activities in suspensions measured with different ion-selective electrodes (ISEs) in combination with the RE. For the latter measurements, the symbol pH used in this work should be replaced by the symbol pIon.

## 1.5 Conclusions

In the publication "Measurement of pH: IUPAC Recommendations 2002" [1], cell V is recommended for practical pH measurement *in solutions*. Because this cell is identical to the pH cells most frequently used in laboratory measurements in the past, the results from both are equivalent and in accordance with the recommendations. Cell V and some other cells are used also for pH measurements *in suspensions*, with the electrodes positioned usually separately, the glass electrode in the sediment, and the RE in its eqs. The pH values measured separately in the suspension (or in its sediment) or in the eqs are different, even though the suspension and solution are in equilibrium. This pH difference, which can be expressed in terms of the corresponding differences in the cell potentials,  $\Delta E$ , is called the "suspension effect".

An analysis of the detailed schemes for the potentiometric cells used in such suspension measurements provides an acceptable explanation of the SE. The SE is the sum of two galvanic potential changes, which occur when the electrodes are transferred from the eqs to the suspension (or sediment):

1. The change in potential of the IE, which changes to an *irreversible mixed potential probe* (a consequence of the overlapping of the diffuse double layers of the electrode with the double layers of particles, when the electrode makes intimate contact with them).
2. The change in the liquid junction potential that exists between the salt-bridge solution of the RE and either the eqs or the suspension. In the latter case, contact of the flowing electrolyte from the salt bridge with the suspension particles gives rise to an *anomalous junction potential*.

Each of these phenomena has been confirmed with experiments [2–4, 10–12].

Measurements on the suspension potentiometric cell [B] shows no evidence for a potential boundary (as is also the case in cell [A]), characterized as a "semipermeable membrane". Experiments have established that there is *no measurable boundary potential* existing between the eqs and the sediment. Therefore, the SE does not include a measurable boundary potential; the SE cannot be interpreted as a boundary or Donnan potential.

## 2. Guidelines for practical pH measurements in soil suspensions

### 2.1 Introduction

The revised view of potentiometric measurements in suspensions (Section 1), which takes into account the currently presented definition of the SE and its interpretation in "Guidelines for potentiometric measurements in suspensions: Part B. Guidelines for practical pH measurements in soil suspensions (IUPAC Recommendations 2007)" [*Pure Appl. Chem.* **79**, 81 (2007)], provides an explanation for the results obtained by different potentiometric measurement techniques when applied to suspensions. This is important especially in the determination of soil pH.

Each of the different methods used provides a soil pH value, which is often neither clearly defined nor understood. The results can involve a large uncertainty and may only approximate the actual pH value. Only one experimental method is considered to provide a pH value with acceptable uncertainty in regard to the influence of soil solution components on a plant. However, a comparison of results obtained by several potentiometric methods can give a meaningful insight to the true  $H^+$  activity in the suspensions.

The SE that contributes to the measurement value should not be considered a very significant characteristic of a suspension, but rather it is a troublesome difference between two cell potentials, both of which affect the determination of the *actual pH value of the suspension*. The *thermodynamically defined  $H^+$  ion activity in a suspension* cannot be equated with any potentiometrically determined pH value.

The methods for pH measurement in dilute aqueous solutions, as in IUPAC Recommendations 2002 [6], are taken as the basis for pH measurements of suspensions. From the definition and interpretation of the SE presented here, a revised view of pH measurements in suspensions becomes possible. The effects, which occur in the measurement system due to the suspension characteristics, are analyzed below for five different measurement protocols applied to cells which contain the eqs or the suspension. These effects influence the potential difference measured in suspension potentiometric cells. Each of these measurement protocols is applicable to soil pH measurements. Advice is given on the reasonable choice and use of electrodes in suspension measurements.

To codify the different expressions of the suspension pH (soil pH), measured by cell [C] or cell V, some expressions can be proposed that specify the technique used.

The term "direct suspension pH" is used when the original sample is measured directly by cell V [1], with both electrodes in the original suspension (or soil), analogous to the pH measurement in solutions (noted as, e.g., "direct soil pH"). The term "modified direct pH" is used when the suspension is modified in any way before measurement (e.g., with water or electrolyte solution added to the original sample); this must be explicitly noted (e.g., "modified direct soil pH (1:2 w)") and the notation explained.

The term "effective suspension pH" can be used in the case where the original suspension is separated into two parts (combined suspension system) and the pH is measured with the IE in the sediment and the RE in the eqs of the cell [C], either without any prior modification of the suspension ("effective soil pH") or with a modification of the suspension ("modified effective" suspension pH). In this case, any water or solution added to the original sample must be noted explicitly (e.g., "modified effective soil pH (1:5 KCl)"). Each of these measurements is considered to give an approximation to the true pH in soil solution, that is the pH to which an object immersed in this suspension (e.g., a root) could be exposed.

The *true* pH means the pH value measured in the clear eqs separated from the equilibrated original suspension (e.g., “true soil pH”). Analogous to the above, the term “modified true” is used when the sample was modified before measurements (e.g., “modified true soil pH (1:2 CaCl<sub>2</sub>)”). These values, in combination with the direct pH values, are used for determination of the SE.

For routine work, the corresponding abbreviations are proposed:

- D soil pH, MD soil pH (1:2 w)
- E soil pH, ME soil pH (2:5 KCl)
- T soil pH, MT soil pH (1:5 CaCl<sub>2</sub>), etc.

The values should be valid for measurements at 20 °C; “w” means distilled water, “KCl” 1 mol kg<sup>-1</sup> solution and “CaCl<sub>2</sub>” 0.01 mol kg<sup>-1</sup> solution of salts, if not indicated otherwise.

## 2.2 Nature of suspensions and their relation to the pH electrode potential

In this report, the aqueous suspensions considered are defined as *charged solid particles* of not strictly determined sizes, which are dispersed in an aqueous *dispersing medium* (water or aqueous solution). This medium surrounds the particles permanently, even when they are settled and form a suspension *sediment*. In a suspension of, for example, ion exchanger beads (declared to be in H<sup>+</sup>-form), which are in equilibrium with the surrounding eqs, the particles together with their double layers may contain a larger or smaller concentration of H<sup>+</sup> than that existing in the bulk solution. These charged particles could be regarded as reservoirs of ions that are blocked from the eqs by an equilibrium Donnan potential. Thus, a suspension contains at least two phases of either similar or different activity of H<sup>+</sup>.

The electrochemical potential  $i_{H^+}$  is the same throughout the whole equilibrated suspension system. Therefore, *the pH of the eqs* can be considered to be the true pH value of the whole interstitial solution in a suspension or sediment (which is not disturbed by the measurement). The pH of the eqs can be measured practically by means of cell V, defined in IUPAC Recommendations 2002 [1]. In the case of an equilibrated soil suspension, it could be considered as the true soil pH value.

When the pH electrode is placed into the suspension, the particles do not influence its electrode potential during the measurement [7,10] until the reservoirs come into intimate contact with the electrode, resulting in an overlapping of the double layers of both. As a consequence of contact regions, the number depending on the particle size, the IE potential changes [12]. The change is proportional to the ratio of contact surfaces to the total electrode surface and to the double-layer thicknesses.

Whereas the potential of the pH glass electrode positioned in the eqs follows the Nernst equation, it changes to an *irreversible mixed (or corrosion) potential* when the electrode is transferred to the *corresponding suspension or sediment*, as described in Section 1.4. Different electrodes may show different mixed potentials in the same suspension, and the same electrode may show different mixed potentials when it contacts particles of different sizes in the same suspension.

The contents of reservoirs can be estimated approximately by selected methods given in Section 2.5.

## 2.3 Nature of suspensions and their relation to the reference electrode potential

The *heterogeneous character of suspensions* also influences the potential of the reference part of the potentiometric cell (represented by the RE connected with the salt bridge), which

is immersed in the suspension. The liquid junction potential between the RE and its salt bridge remains unchanged during the cell potential measurement. The liquid junction potential between the filling solution of the salt bridge (containing cations and anions of approximately equal transport numbers) and the eqs can practically be neglected. In contrast, the liquid junction potential between the diffused filling solution of the salt bridge and the suspension particles can be significant. It is called the *anomalous liquid junction potential*. In regard to the measurement technique, it represents a systematic error of measurement, and can be eliminated only by avoiding the salt-bridge filling solution from coming in contact with the suspension particles.

## 2.4 Relationship between the suspension–equilibrium solution–sediment and the positioning of the electrodes

Because the origin and cause of the SEs have not been clarified since the beginning of their study (in 1930), different modified techniques were introduced into routine determination of soil pH which give different and not clearly explained, nevertheless useful, results.

With regard to the electrode positioning in a uniform or in a combined system, the following classification of potentiometric techniques is possible: both electrodes placed (1) in the original suspension system, (2) in the eqs of the suspension, (3) in the suspension sediment, or (4) the IE in the sediment and RE in the eqs of the suspension, and (5) in the reverse mode to (4).

In these methods, the above-mentioned relations between the electrodes and the measured medium must be considered, and for 4 and 5 also the possible influence of the boundary between the sediment and the eqs on the measured cell potential. As described in Section 1.5 no measurable (Donnan) boundary potential exists at this interface; thus, it is not a “virtual continuous semipermeable membrane”, as has been shown in control experiments [3,12]. Nevertheless, in spite of this fact, in some recent publications it is erroneously assumed that a boundary potential between the eqs and the sediment is the main contributor to the SE [16–18].

## 2.5 Discussion of modified methods of pH measurements in soil suspensions

This part provides guidelines for pH measurement. With the aid of the proposed definition and interpretation of the SE in “Guidelines for potentiometric measurements in suspensions: Part B. Guidelines for practical pH measurements in soil suspensions (IUPAC Recommendations 2007)” [*Pure Appl. Chem.* **79**, 81 (2007)], processes and techniques are discussed and the significance of the results obtained is explained.

The *in situ “soil pH”* can be measured only in wet soil if it contains enough water so that the *water activity*  $a \approx 1$ . If this is not the case, deionized or rain water is added to the soil to obtain a homogenized wet *soil paste*, similar to the original wet soil. In these cases, the suspension is not separated into the eqs and the sediment. Measurements of pH with both electrodes in nearly dry soils are meaningless from a sheer physicochemical point of view.

In *routine pH measurements*, a greater amount of water is added to the soil to form a diluted aqueous suspension. This must be *equilibrated and separated into sediment and the corresponding eqs*. In laboratory measurements, a complete separation is performed by centrifugation, otherwise the separation is obtained by sedimentation, in which case the imperfect separation must be taken into account in assessing the uncertainty of the result.

For better-defined results, the air-dried pulverized soil is sieved, mixed with deionized water in known proportions by mass, and the pH is measured in the eqs after separation. The result for a 1:2 soil/water system can be given as "soil pH (1:2 w)". Different soil/water proportions show different pH values, which need a suitable interpretation to give useful information. Protocols for the sampling of soil populations are described in "Terminology in soil sampling (IUPAC Recommendations 2005)" [19].

### Method 1 (cell potential $E_1$ )

The direct pH measurement of the original suspension by means of cell V (analogous to IUPAC Recommendations 2002, which is recommended for measurement in homogeneous solutions), with both electrodes placed in the soil suspension, gives a result which is different from those obtained with other methods. This  $\text{pH}_1$  value has no reasonable pH meaning, because it is calculated from a cell potential  $E_1$ , which contains the unknown mixed potential of the IE and the anomalous liquid junction potential, the latter representing a systematic error of the measurement (Scheme 2 in Section 1.3). These two potentials are responsible for the SE. Nevertheless,  $\text{pH}_1$  can be used in comparison with other  $\text{pH}_n$  values as a repeatable suspension characteristic. Also, the pH of a soil paste can be considered as a result of Method 1 with the same significance.

### Method 2 (cell potential $E_2$ )

In this method, a known amount of water or of salt solution is added to the soil sample and the equilibrated suspension separated into the eqs and the sediment. For pH measurement, both electrodes are positioned in the eqs, which may, or may not, be in contact with the sediment. The cell potential  $E_2$  is equivalent to the difference of the electrode potentials  $E_A$  of the cell [A] in Section 1.3. The value  $\text{pH}_2$  calculated from  $E_2$  is not influenced by the diffuse layer of the suspended particles. This pH value can be adopted as the pH of the whole suspension system if the suspension is not disturbed by the measurement.

The amount of water added to the original suspension must be reported with the results. The air-dried soil-to-liquid mass ratio of the suspension should be reproducible with acceptable precision as it determines the measured cell potential. The ratio should be expressed explicitly; e.g., for the ratio 1:2 as  $E_2(1:2 \text{ w})$  for water, or  $E_2(1:2 \text{ KCl})$  for KCl solution and  $E_2(1:2 \text{ CaCl}_2)$  for  $\text{CaCl}_2$  solution, whichever is used as the dispersing medium. The comparison of  $E_2$  values, obtained in water-eqs and solution-eqs, respectively, allows an estimation of the amount of  $\text{H}^+$  set free from particles for different soil-to-liquid ratios after these were exchanged by  $\text{K}^+$  or  $\text{Ca}^{2+}$  [7]. In routine work, the measured  $E_2$  values are expressed as corresponding  $\text{pH}_2$  values. These can be regarded as the best defined, "true pH" value measured for a suspension.

### Method 3 (cell potential $E_3$ )

The measurement is performed with both electrodes in the separated sediment of a suspension and is equivalent to that in Method 1, except for the fact that the particle concentration is the maximum possible. The sediment may, or may not, be in contact with the separated part of eqs. The cell scheme is given in Section 1.3, Scheme 2. Both  $E_i$  and  $E_g$  contribute to  $\text{pH}_3$ , and it cannot be used for pH evaluation of a suspension, but it is used for the determination of the total SE as described in the definition of the SE.

### Method 4 (cell potential $E_4$ )

4(a) The electrode position in Method 4 is obtained by transferring the IE from the eqs, as it is positioned in Method 2, into the sediment, while the RE remains in eqs. As can be seen from the cell [C] (Scheme 3 in Section 1.3), the IE potential changes to a mixed

potential, the value of which depends on the pH of the eqs and on the  $\text{H}^+$  activity of the diffuse layer of the contacting suspension particles. Because the RE potential and the diffusion potential remain unchanged, the measured cell potential  $E_4$  differs from  $E_2$  by the potential difference  $\Delta E$  known as SE 1 (Section 1.3.) For an equilibrated suspension soil/water ratio of  $\frac{1}{2}$ , this is given by  $\Delta E_{4-2}(1:2 \text{ w}) = E_4 - E_2$ . The  $\text{pH}_4$  values obtained with the same IE in different (soil) suspensions allow an approximate comparison of the  $\text{H}^+$  activity to which a (charged) surface similar to that of the IE (e.g., of a root in the measured soil) could be exposed, when coming in contact with the particles of these soils. Any change in  $\text{pH}_4$  indicates a change of the electrode mixed potential, which depends on the particle contacts with the electrode surface.

Except for a method only applicable to the laboratory, where the filling solution of the salt bridge is exposed to a negative pressure [2], three other variations of Method 4 are used in routine practice, 4(b), (c), and (d). In these, the amount of the separated eqs is minimal and contact of the salt-bridge filling solution with the particles is avoided.

4(b) In this method, only a small amount of the eqs is needed for a measurement. It employs an RE connected with the suspension by two salt bridges in series (double salt bridge), of which the second one is filled with eqs.

4(c) In this modification, a strip of filter paper wetted with eqs is used for the electrolytic connection between the suspension and the salt bridge. When brought into contact with the suspension [9], a minimal amount of the clear eqs diffuses along the strip to the salt bridge.

4(d) In this method, a special combination electrode is used which, during the measurement, has only the pH sensing element in contact with the suspension. The eqs "climbs up" the specially prepared surface of the electrode stem to form the contact with the salt-bridge solution. In this case, the combination electrode does not measure pH without the SE, as it is often declared, because the presence of the SE 1 is unavoidable.

Method 4 is used very frequently in routine work, because the measured  $\text{pH}_4$  values, though not absolutely repeatable, depend on the sum of  $\text{H}^+$  activities contributed from the eqs and from the particles.

### Method 5 (cell potential $E_5$ )

In this method, the IE is placed in the eqs and the RE in the sediment. It is used solely when the anomalous liquid junction potential (i.e., the systematic error of measurement), equal to the cell potential difference  $\Delta E_{5-2} = E_5 - E_2$ , is to be determined. The derived  $\text{pH}_5$  value is not very relevant in routine work. From the methods discussed above, the most appropriate one can be used to obtain the information of interest. An illustration of the above methods applied to soil pH measurement is presented in [7]. It is seen that different soils show different  $\text{pH}_2$  values (and pH differences), which can be used for the characterization of these soils in agronomy. The treatise relating to soil pH measurement can be applied—*cum grano salis*—to the general potentiometric pIon measurement in soils and in other suspensions. It should be emphasized once more that, by measurement of the voltage of any suspension galvanic cell no thermodynamically defined quantity can be obtained.

## 2.6 Devices and their application in practical "soil pH" measurements

Because these guidelines are based on the IUPAC Recommendations 2002 [1], the definitions given in that Glossary for pH measurement in real solutions, are also valid when applied

to pH measurement in suspensions. Nevertheless, some additional points should be noted.

The *electrodes* used may be “single” or “combination”, but combination ones are suitable only in some cases.

*Single IEs* used in suspensions should be glass or other solid-state ISE, having smooth surfaces and providing fast responses and reproducible results. Electrodes of the second kind (e.g., Ag/AgCl, Sb/Sb<sub>2</sub>O<sub>3</sub>) do not have smooth surfaces, and for this and other reasons they show a greater or unexpected contribution to the SE [12].

The *single RE* may be constructed with one salt bridge which is filled with the same filling solution as the electrode (“half bridge”). Two salt bridges in series (a double salt bridge) are also feasible. The term “double salt bridge” in this case is more appropriate than the term “double junction” electrode. Both kinds of salt bridge are sealed with a separator (capillary, porous ceramic plug, frit, ground glass sleeve, or other). From the separator of the single salt bridge, which is in contact with the measured medium, its filling solution (e.g., saturated KCl solution of the RE half-cell) always flows or diffuses, even if the filling solution is gel-stabilized [10,14,15]. This can give rise to an anomalous liquid junction potential when it contacts the suspension particles. This can be minimized if the final half of the double salt bridge and the separator are filled with, for example, the eqs of the measured suspension for both the test solution measurements and the electrode calibration. It must be emphasized that the filling solution which flows from the separator to the sediment boundary can cause large systematic errors, even if the separator is placed in eqs near this boundary [10]. This can be minimized with a shielding tube, which is pulled onto the salt bridge and perforated by a small side-aperture (about 1.5 cm above the bottom of the tube), providing liquid and electrical contact between the two sides [11].

*Combination electrodes* are often used for measurements in suspensions. They are not suitable for measurements in *combined suspension systems*, except if the electrode is placed so that its indicator half-cell is connected with the sediment and the reference half-cell with the eqs so that SE 2 is minimized. The cell voltages measured with combination electrodes, the IE of which is immersed in a suspension, always include SE 1, notwithstanding that the electrodes are often declared to “measure soil pH without suspension effect”, as found in advertisements. Only some combination electrodes of special construction could possibly eliminate SE 2. *ISFET (combined) electrodes* also cannot avoid the SE in

suspension measurements as the experiments showed; the results are therefore equivalent to those obtained with method 1.

For measurements in suspensions, the electrodes must be *placed* in the suspension in such a way that any differentiation in particle sizes around the sensing element of the electrode is avoided and a stable position of the electrodes is assured.

The instruments for voltage measurement should have a high input resistance (as pH meters generally have). The potential differences of the suspension potentiometric cells, which have relatively small ohmic inner resistances (e.g., cells with the metal or solid membrane used as a halogenide IE), can be measured with voltmeters of smaller input resistance, but the readings are not stable and are difficult to interpret.

# IONIZATION CONSTANTS OF ACIDS AND BASES

W. P. Jencks and J. Regenstein

These  $pK'_a$  values were taken from the original literature and from several extensive compilations of such data, of which the most important are

- Albert, *Ionization Constants of Acids and Bases*, Methuen, London, 1962.  
 Bell, *The Proton in Chemistry*, 2nd ed., Cornell, Ithaca, New York, 1973.  
 Brown, McDaniel, and Häfliger, in Braude and Nachod, *Determination of Organic Structures by Physical Methods*, Academic Press, New York, 1955.  
 Kortum, Vogel, and Andrussov, *Dissociation Constants of Organic Acids in Aqueous Solution*, Butterworths, London, 1961.  
 Perrin, *Dissociation Constants of Organic Bases in Aqueous Solution*, Butterworths, London, 1965.  
 Yukawa, Ed., *Handbook of Organic Structural Analysis*, Benjamin, New York, 1965.

A particularly valuable source of dissociation constants obtained under a variety of experimental conditions is provided by Sillen, L. G. and Martell, A. E., Eds., *Stability Constants*, Special Publications No. 17 and 25, Chemical Society, London, 1964 and 1971. This compilation also lists association constants of metals for a variety of inorganic and organic ligands.

The compounds selected were those which were thought most likely to be useful to biochemists and chemists and these compilations should be consulted for information on compounds which are not included here.

All values are reported as  $pK'_a = -\log K'_a = 14 - pK'_b$ .  $K'_a$  is the ionization constant

$$\frac{[H^+][A^-]}{[HA]} \text{ or } \frac{[H^+][B]}{[HB^+]} \text{ or } \frac{[A^{n-1}][H^+]}{[HA^n]}$$

Temperatures are not indicated because variations of  $pK'_a$  with temperature are generally smaller than the variations of the data from different sources for other reasons, but most of the data were obtained at or near 25°. Ionization constants which are reported as thermodynamic values at 25° are indicated with an asterisk, \*, but some of these may only represent values measured at low ionic strength.

These  $pK'_a$  values and a measured pH should not be used to obtain an *exact* measure of the ratio of acid to base in a given solution. Ionic strength and specific salt effects, as well as possible errors in the reported  $pK'_a$  values, are likely to make such estimates inaccurate. It should be kept in mind that the effect of increasing ionic strength is generally to decrease the apparent  $pK'_a$  of neutral and anionic acids and to increase the  $pK'_a$  of cationic acids. These effects are particularly large for polyanions, such as phosphates.

There is some intentional redundancy in the tables to facilitate the location of listings for compounds that might be listed in several sections. The  $pK'_a$  values for amines refer to the ionization of the conjugate acids of the amines except for a few nitrogen acids, which undergo an acidic ionization.

The pH of a solution at a given ionic strength and temperature is given by

$$pH = pK'_a + \log \frac{(\text{base})}{(\text{acid})}$$

in which the  $pK'_a$  is measured under the same experimental conditions. The following relationships are useful to have readily available to estimate the ratio of acid to base at a given pH or to estimate the buffer ration of acid required to give a given pH; the compiler keeps a copy of these numbers on his desk.

For graphical plots of a large number of substituted phosphorus compounds see Ref. (83). For complex chelating agents of aliphatic amines, see also Reference 77.

Fraction Base or Acid	pH
5% or 95%	$pK'_a \pm 1.25$
10% or 90%	$pK'_a \pm 0.95$
15% or 85%	$pK'_a \pm 0.75$
20% or 80%	$pK'_a \pm 0.60$
25% or 75%	$pK'_a \pm 0.48$
30% or 70%	$pK'_a \pm 0.37$
35% or 65%	$pK'_a \pm 0.27$
40% or 60%	$pK'_a \pm 0.18$
45% or 55%	$pK'_a \pm 0.09$
50% or 50%	$pK'_a \pm 0$
