extremity's circumference (Figure 27-14). The length of the sphygmomanometer bladder should be twice the width. Table 27-6 recommends bladder sizes based on different arm circumferences. A falsely elevated reading will result if the bladder is too narrow, and a falsely low reading will result if it is too wide.

Electronic sphygmomanometers are used by clients for self-measurements. A stethoscope is not required because the device electronically inflates and deflates the cuff while simultaneously reading and displaying the systolic and diastolic pressures. The electronic device is useful for clients who must monitor their own pressure at home. However, it must be recalibrated routinely to ensure an accurate reading.

Figure 27-14 Measure width of arm by holding cuff against client's upper arm.

TABLE 27-6
Guidelines for Sphygmomanometer Selection

Midpoint* Arm Circumference**	Bladder Cuff Width**	Bladder Length**
5–7.5 (newborn)	3	5
7.5–13 (infant)	5	8
13–20 (child)	8	13
24–32 (average adult)	13	24
32–42 (large adult)	17	32

* Distance between the acromion and olecranon processes.

** Measurement in centimeters (cm).

Auscultation

A stethoscope is used to auscultate the blood pressure (hear the sounds created by blood flowing through the artery). As discussed in Procedure 27-4, the blood pressure cuff is inflated 30 mm Hg higher than the palpated pressure so that the inflated pressure causes the artery to collapse; blood flow ceases, and sound is absent on auscultation. As the pressure is released from the bladder, blood begins to flow through the artery and creates the first sound, which is the systolic pressure.

The Korotkoff sounds, described in the accompanying display and Procedure 27-4, are named after the Russian surgeon who first identified the five distinct phases of sound heard with a stethoscope during

KOROTKOFF SOUNDS CORRELATED TO PRESSURE DYNAMICS

<i>Phase</i>	<i>Pressure Dynamics</i>
I. Clear, soft tapping that increases to a thud or loud tap (systolic sound).	1. Ventilation
II. Tapping changes to a soft, swishing sound.	2. Circulation
III. Clear tapping sound returns.	3. Diffusion
IV. Muffled, blowing sound (diastolic sound in children or physically active adults).	4. Transport
V. Disappearance of muffled, blowing sound (second diastolic sound).	5. Regulation

auscultation. Korotkoff's sounds are correlated to the pressure dynamics of measurement.

Bilateral readings should be done with the initial blood pressure assessment. A pressure variance of 5 to 10 mm Hg normally exists between arms. The arm with the higher reading should be used for routine measurements.

When measuring a popliteal blood pressure, the nurse should select a cuff wide and long enough to fit the girth of the thigh. Although the American Heart Association does not specify cuff sizes for thigh BP readings, the association emphasizes that the cuff should be wider and longer than an arm cuff to allow for the greater girth. Place the client in a supine position with the legs in a nondependent position for at least 10 minutes. (A prone position is also acceptable.) Apply the bladder cuff to the client's thigh with the center of the bladder over the popliteal artery. Wrap the cuff snugly, and place it far enough above the popliteal fossa to allow for auscultation of arterial sounds. Help the client slightly flex the knee and abduct the hip, this position will facilitate palpation of the pulse and placement of the stethoscope. Place the diaphragm of the stethoscope over the area where the pulse was palpated and follow the same procedure as presented for brachial artery auscultation (see Procedure 27-4). When the BP cuff is removed, inspect the area, and note abnormalities such as bruising, hematoma, or skin tear. Document in the medical record the systolic and diastolic BP, the site, and the size of the BP cuff. "Systolic readings in the

thigh may be 10 to 40 mm Hg higher than in the arm, but diastolic readings are generally the same" (Rice, 1999, p. 58).

Palpation

When the client's hemodynamic regulation is compromised to the degree that Korotkoff sounds cannot be heard, such as occurs with myocardial infarction or shock, the blood pressure has to be monitored by palpation or direct measurement. To palpate the systolic blood pressure, apply the cuff over the brachial artery, inflate the cuff, place the fingers over the radial artery, slowly release the pressure, and note the reading on the manometer when the first pulse (systole) is felt. With palpation, it is difficult to assess the diastolic pressure. Direct measurement is obtained with insertion of an intravenous catheter.

Hypotension

Hypotension refers to a systolic blood pressure less than 90 mm Hg or 20 to 30 mm Hg below the client's normal systolic pressure. Hypotension is caused by a disruption in hemodynamic regulation, such as:

- Decreased blood volume (e.g., hemorrhage)
- Decreased cardiac output (e.g., myocardial infarction [heart attack])
- Decreased peripheral vascular resistance (vascular dilation) (e.g., shock)

A hypotensive client manifests symptoms relative to the degree of hypotension regardless of the cause.

One of the initial compensatory responses to a falling blood pressure is an increased pulse rate. For example, if a blood vessel cauterized during surgery begins to bleed internally at the point at which the circulating blood volume is compromised, the heart will automatically beat faster to compensate for the decreased circulating volume. If the falling pressure is untreated, the body's compensatory mechanisms will fail and the client will exhibit the symptoms of shock: cool, clammy skin; fast, thready pulse; a gradual decrease in urinary output; and disruption to cerebral blood flow that causes confusion, progressing to coma.

Orthostatic hypotension (postural hypotension) refers to a sudden drop of 25 mm Hg in systolic pressure and 10 mm Hg in diastolic pressure when the client moves from a lying to a sitting or a sitting to a standing position. Orthostatic hypotension usually occurs with aging and is a common antiadrenergic side effect of several medications, such as chlorpromazine hydrochloride. When measuring orthostatic blood pressure:

1. Place the client in a supine position for 5 minutes to allow for equilibration of the blood pressure, and measure the pulse and blood pressure.

2. Assist the client to a standing position and wait 1 minute to obtain a full evaluation of the initial orthostasis, then recheck the pulse and blood pressure.
3. Reassess the vital signs after 2 minutes to allow for an evaluation of the client's mechanisms to compensate for the presence of any orthostasis (Wilson & Kneisl, 1996).

Clients with orthostatic hypotension should be advised to rise slowly from a supine position and to sit down immediately if they feel faint.

Hypertension

Hypertension refers to a persistent systolic pressure greater than 135 to 140 mm Hg and a diastolic pressure greater than 90 mm Hg. Diagnosis of hypertension is based on the average of two or more readings taken at each of two or more visits after an initial screening. Classifications of hypertension for adults have been developed with recommended medical follow-up; see the accompanying display.

A number of physiological changes occur as a result of hypertension. The arterial walls thicken and lose their elasticity, which, in turn, increases resistance to blood flow. Hypertrophy of the left ventricle develops. These changes place the client at risk for a myocardial infarction or stroke. Malignant hypertension is a diastolic pressure higher than 120 mm Hg. With this condition, the client complains of severe headaches, blurred vision, and confusion.

Nursing Considerations

Before checking a blood pressure, review the client's chart for brachial artery contraindications and make sure that the client has not exercised or eaten for

the past 30 minutes. Clients who have recently eaten, ambulated, or experienced an emotional upset will have a falsely high blood pressure reading. When the vital signs are taken correctly in sequence (T-P-R and BP), the client should be calm from sitting or lying quietly.

Faulty techniques that constrict blood flow will produce a false high pressure reading:

- A cuff too narrow for the extremity
- A cuff that does not fit snugly around the extremity
- A cuff that is deflated too slowly

Other false high readings occur when the mercury column in the manometer is not positioned flat on a firm surface or is read above eye level or the extremity is below the heart's apex level.

False low readings occur when the extremity is above the heart's apex level, the cuff is too wide for the extremity, or the mercury column in the manometer is read below eye level. If the nurse fails to recognize the **auscultatory gap**, the temporary disappearance of sounds at the end of Korotkoff phase I and beginning of phase II, the systolic pressure is read at a false low pressure.

Documentation

The nurse should record the blood pressure measurement on the appropriate form. If the brachial artery is not used for the measurement, indicate the site when recording the results. If the pressure was obtained by palpation, record "80 systolic by palpation."

Monitoring blood pressure changes in relation to T-P-R measurements is one of the major responsibilities of the registered nurse. One element of critical thinking is having concrete, objective clinical data, as provided by vital sign measurements, to direct decision making.

CLASSIFICATION OF BLOOD PRESSURE FOR ADULTS AGES 18 AND OLDER, WITH RECOMMENDED FOLLOW-UP (FOR PERSONS NOT TAKING ANTIHYPERTENSIVE DRUGS AND NOT ACUTELY ILL)

Category	Systolic (mm Hg)		Diastolic (mm Hg)	Follow-up recommended
Optimal	<120	and	<80	Recheck 2 years
Normal	<130	and	<85	Recheck 2 years
High normal	130–139	or	85–89	Recheck 1 year
Hypertension				
Stage 1	140–159	or	90–99	Confirm within 2 months
Stage 2	160–179	or	100–109	Evaluate within 1 month
Stage 3	180 or higher	or	110 or higher	Evaluate immediately or within 1 week depending on clinical situation

Data from the National High Blood Pressure Education Program; National Heart, Lung, and Blood Institute; National Institutes of Health. (1997): The Sixth Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure. *Archive of Internal Medicine*, 157, 2413, 2.

THINK ABOUT IT

Vital Signs Measurement

What happens when we do anything routinely? Do we recognize the significance of a routine action? Vital signs are taken routinely. Can you identify possible negative consequences of this routine nursing action?

PHYSICAL EXAMINATION

The physical examination is performed in all health care settings (home, outpatient facilities, extended care institutions, and acute care facilities) for all age groups to gather comprehensive, pertinent assessment data. The physical examination provides a complete picture of the client's physiological functioning. When combined with a health and psychosocial assessment, it forms a database to direct decision making. See Chapter 6 for a discussion of psychosocial assessment and health history. The nurse uses information from the assessment, health history, and physical examination to develop a client profile. Health history ascertains the client's chief complaint and directs the focus of physical examination. The critical elements of a medical, family, and psychosocial history are contained in each chapter of Unit VII, specific to the functional health pattern; this chapter provides a health history to assess sexual function and demonstrates how health history data are incorporated into the physical examination. The complete assessment data are used to:

- Ascertain the client's level of health and physiological function
- Identify factors placing the client at risk and to determine areas of preventive nursing
- Confirm alterations, disease, or inability to perform the activities of daily living
- Identify the need for additional testing or examination
- Evaluate the outcomes of treatment and therapy

The examination should be performed according to the agency's policy. Policy may vary from one agency to another.

The physical examination is done in a sequential, head-to-toe fashion to ensure a thorough assessment of each system. This method not only prevents the nurse from forgetting to examine an area, it should also decrease the number of times the nurse and the client have to change positions.

After gaining proficiency in performing the physical examination, nurses should be able to integrate assessment into daily care activities. For example, while weighing the client, observe posture, motor activity, and gait.

Preparation

The client and the environment require special consideration. Because the client will experience some anxieties regarding the examination, it is important for the nurse to keep the client informed while performing the examination. The nurse needs to be organized and demonstrate respect for the client's apprehension about physical exposure during the examination.

Although some uneasiness may be experienced when learning how to perform a physical examination, it is important that the nurse appear calm, organized, and competent at the bedside. Review the agency's physical examination/assessment form before meeting with the client. This process ensures that the nurse can fully explain the actions that will be performed and prevents omission of any area required to be assessed. The nurse usually takes the assessment form to the bedside to record the data to ensure accuracy of documentation.

Environment

The nurse should review the health and psychosocial assessment data before visiting the client so that the environment will accommodate any special needs of the client. Adjust the environment to allow for placement of the equipment on a surface that is clean and free from movement at the bedside. Check to make sure that nothing is on the floor that would place the client at risk for falling.

The room needs to be quiet, warm, without drafts, and adequately lit. Depending on the setting, make the necessary adjustments to ensure privacy. Inform other personnel about the time of the examination to avoid interruptions, which are frustrating to both the client and the nurse.

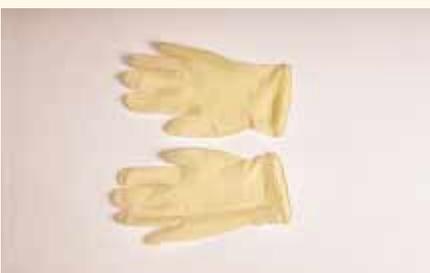

Equipment

Wash hands and gather the necessary equipment. The nurse should review the protocol relative to a physical examination and secure the forms required for documenting the assessment findings. Table 27-7 discusses the common equipment needed to conduct a physical examination. Secure enough clean gloves to change as needed throughout the examination to avoid cross-contamination.

Positioning and Draping

The nurse should position the client to ensure accessibility to the body part being assessed. Table 27-8 presents the positions used in conducting a physical examination and discusses what areas are assessed with the client in each position. Although all the positions for a complete physical examination are included in Table 27-8, it is not the expectation of this chapter for the beginning nursing student to perform a complete physical examination. For example, the lithotomy position is included in Table 27-8 for performing a vaginal examination; however, the discussion of the assessment of the female genitalia does not explain how

TABLE 27-7
Equipment and Supplies Used for a Physical Examination

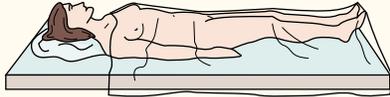

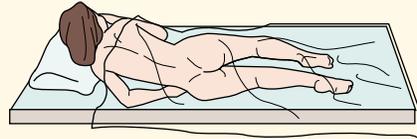

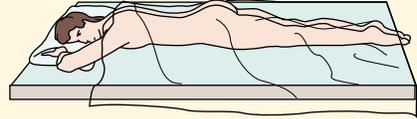

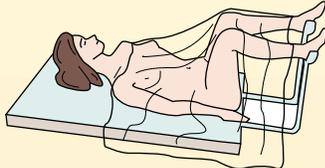

Instrument	Description/Usage
Aromatic substances (vanilla, coffee)	Test first cranial nerve (olfactory)
	
Cotton balls	Assess sensory system for light touch
	
Gloves	Reduce risk for transmission of microorganisms
	
Laryngeal mirror	Metal instrument with mirror to inspect pharynx and oral cavity
	
Ophthalmoscope	Lighted instrument attached to a battery tube to visualize the eye's interior
	
Otoscope	Special ear speculum that attaches to an ophthalmoscope to visualize external and middle ear (eardrum)
	

(continues)

TABLE 27-7 (continued)
Equipment and Supplies Used for a Physical Examination

Instrument		Description/Usage
Penlight		Flashlight to test pupillary reaction to light and third, fourth, and sixth cranial nerves (oculomotor, trochlear, and abducens)
Percussion hammer		Instrument with rubber head to test reflexes
Safety pin		Disposable sharp object to assess pain, sensory system
Tape measure		Calibrated in cm to measure circumference
Tongue depressor		Wooden tongue blade to inspect oral cavity and stimulate gag reflex to assess ninth and tenth (glossopharyngeal and vagus) cranial nerves
Tuning fork		Metal fork that vibrates when tapped and is used to perform Rinne test to assess eighth (acoustic) cranial nerve
Lubricant		Facilitates insertion of instruments into body cavities
Drape		Covers exposed body parts

TABLE 27-8
Positioning for a Physical Examination

Position	Body Part Assessed	Key Points/Contraindications
Sitting 	Head, neck, back, posterior thorax and lungs, anterior thorax and lungs, breast, axillae, heart, extremities	Client can expand lungs; nurse can inspect symmetry. <i>Institute risk precautions for elderly and debilitated clients.</i>
Supine 	Head, neck, anterior thorax and lungs, breast, axillae, heart, abdomen, extremities	Client relaxed; decreases abdominal muscle tension; nurse can palpate all peripheral pulses. <i>Contraindicated in clients with cardiopulmonary alterations.</i>
Dorsal recumbent 	Head, neck, anterior thorax and lungs, breast, axillae, heart	Client comfortable; increases abdominal muscle tension. <i>Contraindicated in abdominal assessment.</i>
Sims' 	Rectum and vagina	Relaxes rectal muscles. <i>Painful for clients with joint deformities.</i>
Prone 	Posterior thorax and lungs, hip	Assessment of hip extension. <i>Contraindicated in clients with cardiopulmonary alterations.</i>
Knee-chest 	Rectum	Maximal rectal exposure. <i>Contraindicated in clients with respiratory alterations.</i>
Lithotomy 	Female genitalia, rectum, genital tract	Maximal genitalia exposure; embarrassing and uncomfortable for client. <i>Contraindicated in clients with joint disorders.</i>

to insert a vaginal speculum because that is usually within the scope of advanced practice nursing.

The primary purpose of draping the client is to prevent unnecessary exposure during the examination. Feelings of embarrassment elicit tension and restlessness and will decrease the client's ability to cooperate. The drapes also prevent the client from being chilled.

The drape may be cloth or paper; for example, a bath blanket, sheet, or towel. The client's gown can be rearranged to expose and cover different body parts. When the client is in a sitting, supine, dorsal recumbent, Sims', or prone position, use a gown or towel to cover the upper chest and a bath blanket or sheet to cover the rest of the body.

Although you will not be expected to place the client in the lithotomy position to conduct an internal vaginal examination, you may be expected to assist another practitioner with this examination. Draping a client in the lithotomy position requires a sheet and boots. The nurse should apply the boots, if available, to cover each of the client's feet and legs. Fold and place the sheet in a diamond-shaped arrangement over the body: top diamond under chin with opposite corner pointing toward the toes and lateral corners pointing toward the sides of the table. Ask the client to flex her knees, and with the lateral corners of the sheet, wrap it in a spiral fashion around the legs and feet. The bottom corner covers the perineum and is folded back over the abdomen to expose the perineum when the examination begins.

General Survey

Assessment begins at the initial contact with the client. Proper terminology and agency-approved abbreviations should be used when recording assessment data.

Assess the following areas during a general survey:

1. Observe for signs of distress: labored breathing, pallor or cyanosis, protection of a painful part, sweating or cold moist palms, anxious face.
2. Observe the client's state of health, stature, and sexual development.
3. Weight, height, and vital signs are measured during the survey.
4. Note posture, motor activity, and gait; dress, grooming, and personal hygiene; and any odors of body and breath.
5. Observe client's facial expressions and behaviors; note manner, affect, and reaction to persons and things in environment.
6. Listen to the quality of speech and note the level of consciousness. See Chapter 36 for a complete discussion about assessing consciousness.

Document your general survey data in an organized fashion to portray a clinical picture of the client. Certain clients such as the elderly, disabled, and abused will require special consideration during the physical examination.

Sexual History

Prior to performing a physical examination of the genitalia, the nurse should refer to the information obtained from the client's sexual history. Illness and medical interventions can interfere with sexual functioning; for example, antihypertensive medication can cause men to experience ejaculation or erection difficulties. Sexual responsiveness can be altered in both men and women who are taking narcotics, sedatives, antidepressants, and antispasmodic medications. Prolonged therapies such as chemotherapy or radiation may cause physiologic changes that affect sexual desire and function; refer to the accompanying display for a sample of a sexual history.

SEXUAL HISTORY

- Age at which sexual history began
- History of sexual activity with women, men, or both
- Number of current sexual partners
- Satisfaction in current relationship
- Concerns regarding sexuality or sexual identity
- History of sexually transmitted diseases (STDs)
- Desire for parenting, at present or in the future
- Current or past contraceptive methods
- History of childhood or adult sexual trauma, rape, or domestic abuse

Adapted from Warner, P. H., Rowe, T., & Whipple, B. (1999). Shedding light on the sexual history. *American Journal of Nursing*, 99(6), 34–41.

Older Adults

When nurses assess older clients, it is important to know the normal changes that result from aging. See Chapter 18 for a complete discussion about caring for elderly clients. Aging may reduce the body's resistance to illness, tolerance of stress, and ability to recuperate from illness (Firth & Watanabe, 1996). Make sure the client understands and can follow instructions and allow extra time if the client has difficulty changing positions quickly.

THINK ABOUT IT

Cultural Values and Assessment

Cleanliness is highly valued by mainstream American society. However, in some cultures, a daily bath is not perceived as necessary or desirable. In fact, some cultures do not define natural body odors as offensive. It is important to consider the client in the context of cultural beliefs before labeling a client. Think of the terms "dirty," "unkempt," or "foul-smelling." These value-laden terms can certainly cloud the assessment process and subsequently the care provided to the client.

Disabled Clients

When assessing disabled clients, nurses should adapt their interactions to the client's ability; for example, a hearing-impaired client should be given a written questionnaire. An intellectually impaired client might require simple, direct sentences and questions or use of pictures. Determine the client's ability to participate before conducting the examination. To allay the disabled client's fears and anxiety, allow a family member to remain with the client during the examination. The nurse should ascertain the client's level of independence and feelings about the disability (Firth & Watanabe, 1996).

Abused Clients

Nurses need to be observant for signs of abuse, especially in children and the elderly. The symptoms may be psychologic as well as physical; for example, not wanting to be touched, unable to maintain eye contact, or unwillingness to talk about bruises, burns, or other injuries. Bruises or lacerations usually appear on breasts, buttocks, thighs, or genitalia. The nurse should also inspect for healed scarring or burns. The nurse needs to know state laws and agency policies for reporting possible abuse.

THINK ABOUT IT

Caring for Abused Clients

What would you do if a child in the emergency room in which you were practicing showed signs of abuse? How would you conduct the physical examination?

Techniques

Chapter 6 introduced the assessment techniques of inspection, palpation, percussion, and auscultation; this section demonstrates how these techniques are used in performing a physical examination. The specific techniques used to assess each body system are identified and explained within the context of the assessment. While practicing how to conduct a physical examination, refer to the following assessment tables to reinforce appropriate techniques for each system.

The nurse should use the senses of sight, hearing, smell, and touch when gathering information during the physical examination pertinent to the client's clinical status. The nurse uses the sense of sight by visually inspecting the client's body parts and assessing the client's normal behaviors and adaptive coping behaviors to alterations in functions. For example, the skin is inspected for color, tone, and texture, as well as scars, lesions, abrasions, and rashes. Throughout the examination the nurse should visually observe the client's general body appearances, such as movement, motor dexterity, contour and symmetry of the body, and deformities.

The nurse uses the sense of touch when performing palpation. The skin is thinner on the backs of the hands and more sensitive to temperature changes. The back of the hand can be used to assess skin temperature over an inflamed joint or a leg with impaired circulation. The fingerpads are also sensitive and are used to palpate the size, position, and consistency of various body parts, such as lymph nodes and breast tissue. Figure 27-15 demonstrates how to perform light palpation.

Learning the technique of percussion is challenging; it can be practiced on any surface. Refer to Figure 27-16 and practice percussion as follows:

1. Hyperextend the middle (pleximeter) finger of the nondominant hand and press its distal phalanx and joint firmly on the surface to be percussed (Figure 27-16A). Only the distal phalanx and joint should be touching the surface. Having other parts of the hand in contact with the surface will damp the vibrations.
2. Position the forearm of the dominant hand close to the surface, with the hand cocked upward, as shown in Figure 27-16B, with the middle finger partially flexed, relaxed, and poised to strike.
3. With a quick, sharp, but relaxed *wrist* motion, strike the pleximeter finger with the tip of the right plexor finger of the dominant hand, as shown in Figure 27-16C. Only the wrist joint is flexed, not the finger or elbow.
4. Quickly withdraw the plexor finger to avoid damping the vibration.
5. Strike one or two blows in one location, then move on, using the lightest percussion that will produce a clean note.

If the client becomes fatigued, encourage frequent rest periods. Adjust the client's position for comfort without compromising the ability to visualize the area of assessment.

The nurse uses the sense of hearing during the physical examination when performing auscultation. A stethoscope allows the nurse to listen to sounds produced in the heart, lungs, abdomen, and blood vessels.

Figure 27-15 Light Palpation

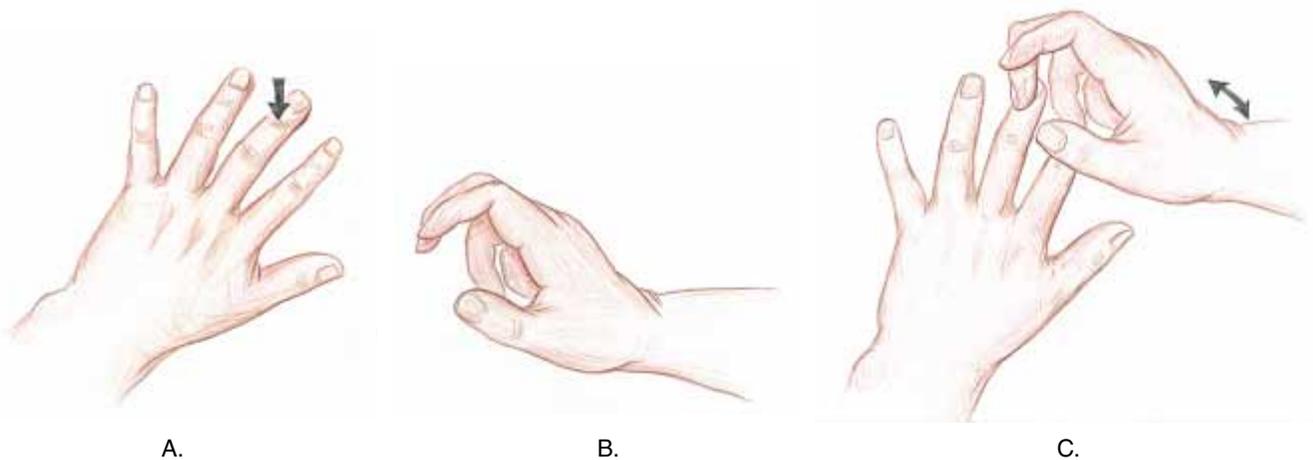

Figure 27-16 Percussion. A. Hyperextend the pleximeter finger and press the distal phalanx and joint firmly on the surface to be percussed. B. Cock the hand upward with the middle finger partially flexed and poised to strike. C. Strike the pleximeter finger with the tip of the right plexor finger.

Throughout the entire examination the nurse uses the senses of hearing and smell. Besides auscultation, the nurse should listen to what clients say relative to their health status during the examination. Smell is used to investigate any environmental, body, or fluid odors, such as drainage from a wound.

Integument

The **integumentary system** (skin, hair, scalp, and nails) provides the body with external protection, regulates temperature, and is a sensory organ for pain, temperature, and touch. The sebaceous and sweat glands are

considered appendages of the skin. Nurses should routinely assess the skin of elderly and debilitated clients for primary lesions that can lead to the development of secondary lesions such as pressure ulcers. See Chapter 35 for a complete discussion about skin integrity.

To facilitate learning and psychomotor proficiency, the integumentary system is assessed separately. However, once skills are established, the integumentary system assessment can be integrated into the examination of other systems. Table 27-9 presents the specific areas of the integumentary system to be examined and the normal and key findings of this assessment.

COMMON ALTERATIONS IN SKIN COLOR

- Melanin (naturally occurring brown pigment) is *increased* in exposed areas or points of pressure, for example, nipples, palmar creases, recent scars, with Addison's disease and some pituitary tumors. It is *decreased* in albinism (congenital inability to form melanin) and vitiligo (acquired loss of melanin).
- Cyanosis (bluish discoloration in the lips, mucous membranes, and nails) results from an increased amount of reduced hemoglobin in the blood caused by a cold environment or heart or lung disease.
- Jaundice (yellowish discoloration) results from increased bilirubin levels caused by red blood cell hemolysis in liver disease as observed first in the sclera and mucous membranes and then generalized.
- Carotenemia (yellowish discoloration) is described as normal as a result of increased levels of carotenoid pigments in the palms, soles, and face from a diet high in carotene. Also occurs in diseases such as myxedema, hypopituitarism, and diabetes.

NURSING TIP

Skin Palpation

When palpating the skin, wear gloves to prevent the transmission of microorganisms *because lesions are not always visible on general inspection.*

Skin

The skin is the largest organ system of the body, its surface area covering approximately 20 square feet in the average adult. The skin's thickness, influenced by age, varies from 0.2 to 1.5 mm. Skin assessment provides a noninvasive window to observe the body's physiological functions.

Lesions of the skin vary from superficial, involving only the epidermis, to penetrating the dermis or subcutaneous layers of the skin. Table 27-11 describes the common skin lesions.

TABLE 27-9
Assessment of Integumentary System: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
Skin: Inspect and Palpate	
<p>1. Color: inspect variations in skin color under natural sunlight to ensure accuracy in findings. <i>Color varies from light to ruddy pink or dark brown, or is yellow with olive overtones, with uniform skin color except in sun-exposed areas or normally lighted pigmented areas (nail beds, palms, lips) in dark-skinned people.</i></p> <p>2. Lesions: note color, size, and anatomic location and distribution; palpate the lesions with fingerpads for mobility, contour (flat, raised, or depressed), and consistency (soft or durable). <i>Freckles, skin tags in elderly, and some types of birthmarks and moles are normal.</i></p> <p>3. Moisture (wetness and oiliness): note amount and distribution. <i>Moisture varies with activity, body and environmental temperature, and humidity in skinfolds and the axillae.</i></p> <p>4. Temperature: palpate with back (dorsum) of hand, noting uniformity of warmth. <i>Temperature should be uniform and within normal range.</i></p> <p>5. Texture (quality, thickness, suppleness): palpate with fingerpads in different areas. <i>Texture is not uniform, for example, palms and soles are usually thicker than other areas, which are smooth, soft, and flexible. Wrinkled, leathery skin in the elderly results from the normal aging process, with decreased collagen, subcutaneous fat, and sweat glands.</i></p> <p>6. Mobility and turgor (elasticity): assessing mobility and turgor measures the elasticity of skin to determine the degree of hydration:</p> <p>a. Palpate dependent areas (sacrum, feet, ankles) for mobility by applying pressure with fingers, noting degree of indentation (Figure 27-17). If indentation occurs, firmly apply pressure with your thumb for 5 seconds: note the degree of edema based on the depth of indentation (pitting) in centimeters (see the accompanying display that follows at the end of this table).</p>	<p>1. The presence or absence of certain substances in the circulatory system or the deposition of substances in the skin are indications of disease processes. See the accompanying display for common alterations in skin color.</p> <p>2. Vascular and purpuric lesions are discussed in Table 27-10. Primary skin lesions, such as a vesicle, can give rise to secondary lesions, for example, erosion and crusting, as in chickenpox. See Table 27-11 for the different types of primary and secondary skin lesions.</p> <p>3. Excessive moisture or perspiration (hyperhidrosis) is usually caused by hyperthermia, infection, hyperthyroidism, strong emotions, menopause; excessive dryness often occurs in dehydration. Bromidrosis (body odor) is usually caused by bacterial decomposition of perspiration on the skin.</p> <p>4. Generalized hyperthermia is seen in fever; generalized hypothermia is seen in shock; localized hyperthermia is seen with an infection; localized hypothermia is characteristic of arteriosclerosis.</p> <p>5. Generalized roughness is seen in hypothyroidism.</p> <p>6. Dependent edema gives the skin a stretched, shiny appearance. The degree of pitting edema reflects the depth of indentation in centimeters (1+ to 5+). Edema is usually caused by direct trauma or impairment of venous return. Failure of the skin to reassume its normal contour or shape after being pinched indicates dehydration, which places the client at risk for skin breakdown. <i>Tenting</i> is the term used to describe skin that remains in a pinched position.</p>

Figure 27-17 Assessing for Edema

PITTING EDEMA SCALE

1+	Indentation of 1 cm or less
2+	Indentation of 2 cm
3+	Indentation of 3 cm
4+	Indentation of 4 cm
5+	Indentation of 5 cm or more

(continues)

Assessment of Integumentary System: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>b. Pinch a fold of skin on the sternal area using your thumb and forefinger (Figure 27-18). Note the speed with which it returns into place (turgor).</p>	
	
<p>Figure 27-18 Assessing Skin Turgor</p> <p><i>Absence of indentation in dependent areas and the resilience of the skin to spring back to its previous state after being pinched.</i></p>	
<p>Hair: Inspect and Palpate</p>	
<ol style="list-style-type: none"> 1. Quality, distribution, pattern of hair loss, if any, over the scalp. <i>Thick, evenly distributed hair.</i> 2. Texture and oiliness. <i>Silky, normally resilient hair.</i> 3. Body hair for amount, and note infestation. <i>The amount of body hair varies; hair should be free from infestation.</i> 	<ol style="list-style-type: none"> 1. Thin, brittle hair occurs with hypothyroidism. 2. Alopecia (hair loss), for example, effects from chemotherapeutic agent. Hirsutism (excessive body hair). 3. <i>Pediculus capitis</i>, <i>P. corporis</i>, and <i>P. pubis</i> are lice that adhere to head, body, and pubic hair. The eggs are white ovoid nits.
<p>Scalp: Inspect and Palpate</p>	
<ol style="list-style-type: none"> 1. Part the hair repeatedly all over the scalp and inspect for scaliness and scars. <i>The scalp should be shiny and smooth without lesions, lumps, or masses.</i> 2. Place the fingerpads on the scalp at the front and palpate down the midline and each side for tenderness, lesions, lumps, or masses. <i>Absence of redness or scaliness.</i> 	<ol style="list-style-type: none"> 1. Sebaceous cysts or trauma deformities. 2. Dry flaking, scaling occurs in seborrhea (dandruff) and psoriasis (red patches covered by thick, dry, silvery, adherent scales that result from excessive development of epithelial cells).
<p>Nails: Inspect and Palpate</p>	
<ol style="list-style-type: none"> 1. Note the nail color, shape, and texture. <i>Nail bed is highly vascular with a pink color in light-skinned clients and longitudinal streaks of brown or black pigmentation in dark-skinned clients. Angle between the fingernail and base is about 160°. When palpated the nail base is firm.</i> 	<ol style="list-style-type: none"> 1. Refer to Table 27-12 for abnormalities and variations of the nail bed.

(continues)

TABLE 27-9 (continued)
Assessment of Integumentary System: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
2. Test for capillary refill by pressing two or more nails between your thumb and index finger. Note the degree of blanching and return to normal color. <i>When pressure is released from the nail, it promptly returns to its normal color.</i>	2. Delayed return of nail bed color may indicate circulatory impairment.
3. Inspect the tissue surrounding nails for lesions. <i>Tissue surrounding the nail is intact.</i>	3. Paronychia (inflammation of the skin around the nail) is described in Table 27-12.

(From Estes, M. E. Z. [2002]. *Health assessment and physical examination*. Albany, NY: Delmar Publishers)

TABLE 27-10
Vascular and Purpuric Lesions of the Skin

Findings	Body Area Assessed	Key Points
Vascular		
		
Cherry angioma: Ruby red, 1–3 mm, round lesion.	Trunk and extremities	Pressure with a pinpoint edge causes partial blanching. Increase in size and number and may become brownish with age.
Spider angioma: Fiery red lesion up to 2 cm with a central body surrounded by erythema and radiating legs.	Face, neck, arms, and upper trunk	Occurs normally in some people. May occur with pregnancy, vitamin B deficiency, or liver disease.
		

(continues)

TABLE 27-10 (continued)
Vascular and Purpuric Lesions of the Skin

Findings	Body Area Assessed	Key Points
<p>Vascular</p> <p>Venous star: Bluish, varying in size from small to 1–2 inches, may resemble a spider or be linear, irregular, and cascading.</p>	Areas with superficial veins: legs and anterior chest	Indicates an increased pressure in superficial veins, for example, varicose veins.
<p>Purpuric</p> 		
<p>Petechia: Reddish purple, flat round lesion, 1–3 mm in size.</p> 	Variable distribution in areas with superficial blood supply	May indicate vitamin C deficiency, blood clotting disorders, liver disease, or drug reactions.
<p>Ecchymosis (bruise): Purplish blue, fading to green, yellow, and brown in time.</p>	Area of blood vessel trauma	Results from injury or with bleeding disorders.

(From Bates, B. (1994). *A guide to physical examination and history taking* (6th ed.). Philadelphia: Lippincott.

Hair

Hair is distributed over the body except for the palmar and plantar surfaces, lips, nipples, and the glans penis. The amount and texture of hair vary with age, sex, race and body part.

- Vellus: Fine, unpigmented hair that covers most of the body.
- Terminal hair: Coarser, darker hair of scalp, eyebrows, and eyelashes; axillary and pubic hair becomes terminal with the onset of puberty.

Men have coarser, thicker chest and facial hair growth than women.

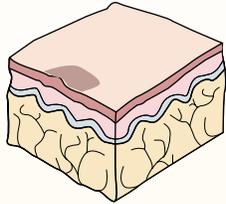

Nails

The nail plate (translucent tissue that covers the distal portion of the digits and provides protection) changes with many disease processes, as discussed in Table 27-12.

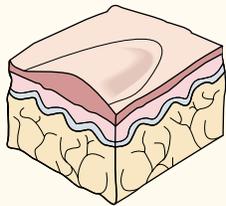

TABLE 27-11
Common Skin Lesions

Primary Lesions

Nonpalpable

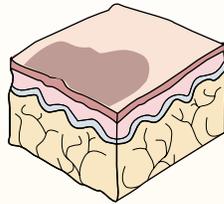

Macule: localized changes in skin color <1 cm in diameter (e.g., freckle)

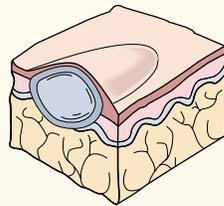

Patch: localized changes in skin of <1 cm (e.g., vitiligo, stage 1 of pressure ulcer)

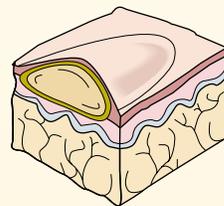

Palpable

Papule: solid, elevated lesion <0.5 cm in diameter (e.g., elevated nevi)

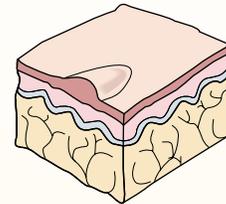

Plaque: solid, elevated lesion >0.5 cm in diameter (e.g., psoriasis)

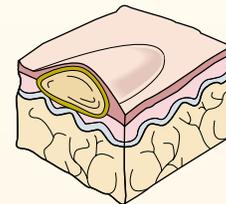

Nodule: solid and elevated; extends deeper than papule into the dermis or subcutaneous tissues, 0.5–2.0 cm (e.g., lipoma, erythema, cyst)

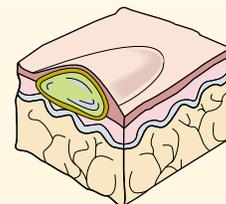

Fluid-Filled Cavities within the Skin

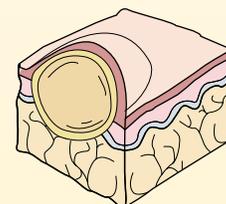

Vesicle: elevated mass containing serous fluid accumulation between the upper layers of the skin (e.g., herpes simplex and zoster, chickenpox, second-degree burns)

Bullae: same as vesicle only >0.5 cm (e.g., contact dermatitis, large second-degree burns, bulbous impetigo, pemphigus)

Pustule: pus-filled vesicle or bullae, <0.5 cm in diameter (e.g., acne, impetigo, carbuncles)

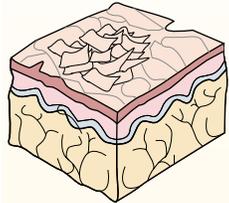

Cyst: subcutaneous or dermis mass (e.g., sebaceous or epidermoid cyst)

(continues)

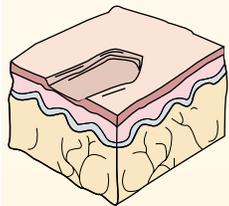

TABLE 27-11 (continued)
Common Skin Lesions

Secondary Lesions

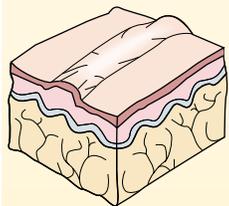

Above the Skin Surface

Scales: flaking of the skin's surface (e.g., dandruff, psoriasis)

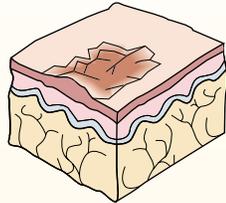

Crust: dried serum, blood, or pus on skin's surface (e.g., impetigo)

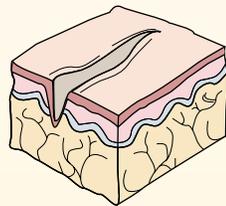

Atrophy: thinning of skin surface and loss of markings (e.g., striae, aged skin)

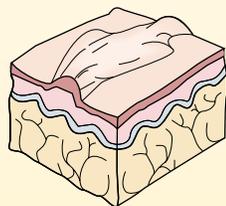

Below the Skin Surface

Erosion: loss of epidermis (e.g., ruptured chickenpox vesicle)

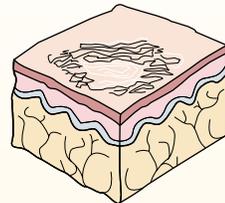

Fissure: linear crack in the epidermis that can extend into the dermis (e.g., chapped hands or lips, athlete's foot)

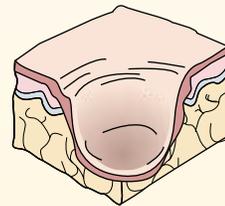

Ulcer: depressed lesion of the epidermis and upper papillary layer of the dermis (e.g., stage 2 pressure ulcer)

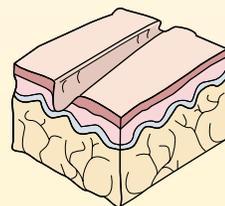

Below the Skin Surface

Scar: fibrous tissue that replaces dermal tissue after injury (e.g., surgical incision)

Keloid: enlarging of a scar past wound edges due to excess collagen formation (more prevalent in dark-skinned persons) (e.g., scar)

Excoriation: loss of epidermal layers exposing the dermis (e.g., abrasion)

Head and Neck

Areas to be included in the head and neck examination are the skull, face, eyes, ears, nose, mouth, pharynx, and neck. The carotid artery assessment is conducted either as part of the neck examination or with peripheral artery assessment. Inspection and palpation are used throughout this assessment. Auscultation is used if the carotid arteries are assessed as part of this examination. Table 27-13 containing Figures 27-20 through 27-34 presents the specific areas of the head and neck to be examined and the normal and key findings of this assessment.

Skull and Face

Assessment of the skull and face involves inspection and palpation. The client's face has its own unique charac-

teristics influenced by factors such as race, state of health, emotions, and environment.

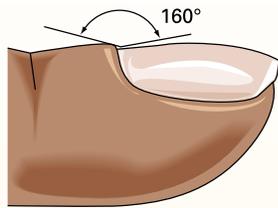

Eyes

Active client participation is needed for the various eye tests. To prevent client weakness or discomfort, the eye tests are separated by assessment of the eye's external anatomic structures. The nurse should practice holding and using the index finger to rotate the dial for the five lens settings of the ophthalmoscope before conducting the examination.

The assessment of visual acuity is a simple, noninvasive procedure that is performed with the use of a **Snellen chart** (a chart that contains various-sized letters with standardized numbers at the end of each line of letters) (Figure 27-19). The standardized numbers (called the denominator) indi-

TABLE 27-12
Variations of the Nail Bed

Normal nail angle

Normal nail: Has an angle of approximately 160° between the fingernail and nail base; nail feels firm when palpated.

Clubbing: Hypoxia causes an angle greater than 180° between the fingernail and nail base; nail feels springy when palpated.

Koilonychia (Spoon nail): Characterized by concave curves; associated with iron deficiency anemia.

Beau's line: Characterized by transverse depression in the nails; associated with injury and severe systemic infections.

Paronychia: Characterized by an inflammation at the nail base (may be swollen, red, or tender); associated with trauma and local infection.

PUPIL SIZE IN MILLIMETERS

COMMON ABNORMAL FACIES

- Exophthalmos is the protrusion or bulging of the eye that results from an increased pressure in the eye's orbit (e.g., from tumor or inflammation).
- Acromegaly is characterized by an elongated head with prominent forehead, nose, and lower jaw and enlarged nose, lips, and ears resulting from excessive growth hormone.
- Cushing's syndrome is a round or "moon" face with excessive hair growth (mustache and sideburns); it occurs in clients with excessive production of adrenal hormones or in clients taking adrenal hormone medications.
- Clients with chronic renal failure have pale, swollen tissue around their eyes.
- Parkinson's disease causes decreased facial mobility and expressions, producing a masklike face; results from progressive, degenerative, neurologic disorders.

COMMON REFRACTIVE ERRORS

- Myopia (nearsightedness): elongation of the eyeball or an error of refraction that causes the parallel rays to focus in front of the retina.
- Hyperopia (farsightedness): an error of refraction in which rays of light entering the eye are brought into focus behind the retina.
- Presbyopia (farsightedness): an error of refraction resulting from a loss of elasticity of the lens of the eye.
- Astigmatism: an unequal spherical curve of the cornea that prevents the light rays from being focused directly in a point on the retina.

COMMON ABNORMAL BREATH ODORS

- Acetone breath ("fruity" smell) is common in malnourished or diabetic clients with ketoacidosis.
- Musty smell is caused by the breakdown of nitrogen and presence of liver disease.
- Ammonia smell occurs during the end stage of renal failure from a buildup of urea.

COMMON LIP LESIONS

- Herpes simplex (cold sores or fever blisters) are painful vesicular lesions that rupture and crust over.
- Chancre (primary lesion of syphilis) is a reddish round, painless lesion with a depressed center and raised edges that appears on the lower lip.
- Squamous cell carcinoma (most common form of oral cancer) usually involves the lower lip and may appear as a thickened plaque, ulcer, or warty growth.

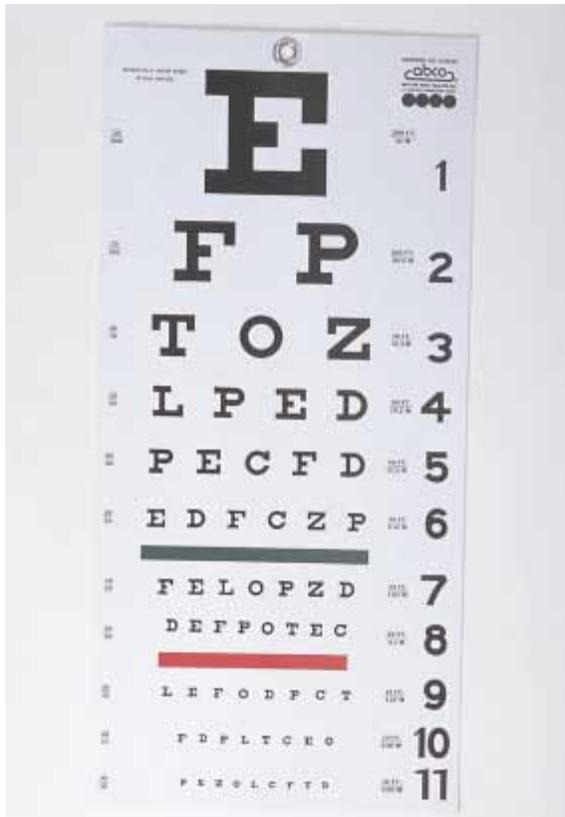

Figure 27-19 Snellen Chart

cate the degree of visual acuity when the client is able to read that line of letters at a distance of 20 feet.

Ears

Physical assessment of the ears consists of auditory screening, inspection and palpation of the external ear, and otoscopic assessment. The nurse should observe the client for signs of hearing difficulty during the physical examination, such as turning the head, lipreading, and speaking in a loud voice. If the client is wearing a hearing aid, ask if it is turned on, when the batteries were last changed, and if the device causes any irritation to the ear canal.

Nose and Sinuses

Assessment is limited to inspection and palpation of the external nose and nasal passages using a penlight. An examination with a nasal speculum to inspect the nasal chambers is usually performed only by an advanced nurse practitioner because the nasal chambers are lined with respiratory mucosa. Clients with nasal impairments are at risk of developing respiratory infections. Sinus assessment is limited to palpation of the frontal and maxillary sinuses. Transillumination of the sinuses is usually limited to advanced practitioners.

TABLE 27-13

Assessment of Head and Neck: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>Skull and Face: Inspect</p> <ol style="list-style-type: none"> 1. Observe shape and general size of skull and size of head in proportion to body. <i>Rounded, smooth skull contour.</i> 2. Inspect facial features for symmetry, involuntary movements, edema, and masses. <i>Symmetrical facial features and movement.</i> 	<ol style="list-style-type: none"> 1. Enlarged skull size is indicative of hydrocephalus and Paget's disease. 2. a. Sunken temples, eyes, and cheeks are indicative of dehydration and malnutrition (see accompanying display for a description of common facies [expression or appearance of face]). <ol style="list-style-type: none"> b. Puffy, swollen appearance anterior to ear lobes and above angles of the jaw may indicate parotid gland enlargement (e.g., mumps).
<p>Eyes: Inspect and Palpate</p> <ol style="list-style-type: none"> 1. Assess visual acuity. <ol style="list-style-type: none"> a. Position Snellen chart 20 feet in front of client. b. Remove corrective lenses. c. Instruct client to cover one eye and read lines, starting with top of chart from left to right (Figure 27-20); note the line where the client correctly reads more than half the letters. d. Record results as a fraction sc (without correction), 20/distance number, and the number of letters missed for the eye test. e. Repeat steps a–d for other eye. f. If appropriate, repeat steps a–e with client wearing corrective lenses, record result cc (with correction). <i>Normal vision, based on the Snellen chart, is 20/20 (at a distance of 20 feet the normal eye can read the chart).</i> 	<ol style="list-style-type: none"> 1. A value of 20/40 means that a client can read at a distance of 20 feet what a person with normal vision can read at a distance of 40 feet (see the accompanying display for common refractive errors).

TABLE 27-13 (continued)
Assessment of Head and Neck: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>2. Test extraocular muscle function:</p> <ol style="list-style-type: none"> Instruct client to follow your finger held 6 to 12 inches in front of eyes. Move your finger through the eight vision fields of gaze (Figure 27-21). Observe for parallel eye movement. Pause during upward and lateral gaze fields to detect involuntary movement of the eyes. Note position of the upper eyelid in relation to the iris and eyelid lag as the client's eyes move from up to down. Record results. <i>Eye movements should be symmetrical as both eyes follow the direction of the gaze. The upper eyelids cover only the uppermost part of the iris and are free from nystagmus (involuntary, rhythmical oscillation of the eyes).</i> <p>3. External anatomic structures (Figure 27-22).</p>	<p>2. Asymmetrical movement or the presence of nystagmus results from local injury to eye muscles and supporting structures or a cranial nerve disorder.</p>

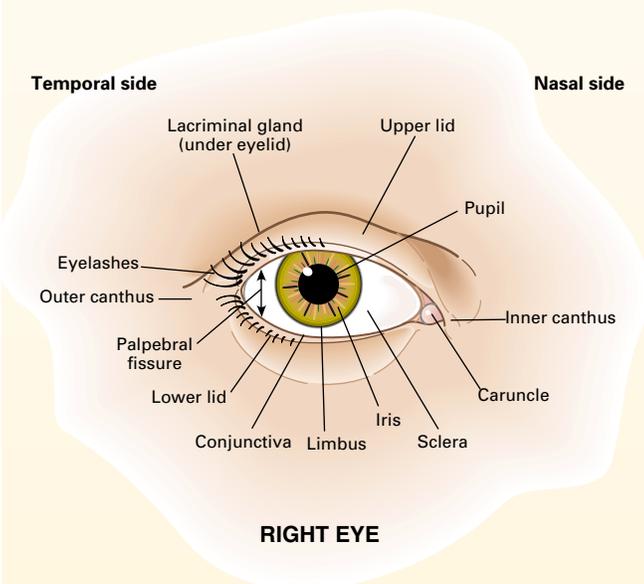

Figure 27-22 External Structures of the Eye

- Observe upper eyelid. *Upper eyelid should overlap iris.*
 - Check eyes and eyelids for inflammation, crusting, edema, or masses. *Eyes and eyelids should be free from inflammation, crusting, edema, or masses.*
 - Inspect and palpate lacrimal glands and sacs for swelling. If lachrimation is excessive:
 - Check for blockage of the nasolacrimal duct by pressing against inner orbital rim of lacrimal sac.
 - Inspect duct blockage by palpating on the lacrimal sac and observing for regurgitation of fluid. *Lacrimal*
- Upper eyelid should not overlap pupil.
 - Red lid margins with yellowish scales result from an inflammation of the eyelids (blepharitis). Presence of inflammation, crusting, edema, or masses may indicate acute hordeolum (sty), a painful, red infection of a hair follicle of the eyelashes; chalazion (chronic inflammatory lesion of the meibomian gland); or basal cell carcinoma (papule with a pearly border and a depressed or ulcerated center) of the lower lid.
 - Swelling of lacrimal sac indicates dacryocystitis (inflammation) or tumor. Regurgitation of tears through the puncta indicates blockage of lacrimal duct.

(continues)

TABLE 27-13 (continued)
Assessment of Head and Neck: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p><i>gland should not be palpable. Tears flow freely from the lacrimal gland over the cornea and conjunctiva to the lacrimal duct.</i></p> <p>d. Inspect conjunctiva and sclera by instructing client to look upward while you depress lower lid with your thumb. <i>Conjunctiva and lens should be transparent and the sclera should be a light yellow color in dark-skinned clients and a white porcelain color in light-skinned clients.</i></p> <p>e. Inspect cornea, lens, pupil, and iris. <i>Pupils are black, round, and equal in size, 3–7 mm in diameter (see the accompanying display). The margins of the iris should be intact.</i></p> <p>f. Test pupillary responses to light and reaction to accommodation in a dimly lit room.</p> <ol style="list-style-type: none"> (1) Instruct client to look straight ahead. (2) Bring the penlight from the side of the client's face to directly in front of the pupil (Figure 27-23A). (3) Note the quickness of response to light. (4) Shine light into same eye, observing response of opposite pupil for equality of size (Figure 27-23B). 	<p>d. Bright red conjunctiva with crusty drainage occurs with conjunctivitis (contagious infection of the conjunctiva). A pale conjunctiva usually indicates anemia. Bright red patch on the exposed bulbar conjunctiva is a subconjunctival hemorrhage that may result from trauma or sudden increase in venous pressure (e.g., cough or bleeding disorder).</p> <p>e. Opacity of the lens (loss of transparency) occurs with cataracts caused most commonly by aging (senile cataract). Cloudy pupils occur with cataracts.</p> <p>f. Altered pupillary reaction time and equality occur with increased intracranial pressure, lesions involving the third cranial nerve, trauma, or some medications. Pupillary constriction occurs with inflammation of the iris or in response to medication (e.g., pilocarpine or morphine). Pupillary dilation may occur with trauma, neurologic disorders, glaucoma, or in response to medication (e.g., atropine).</p>

A.

B.

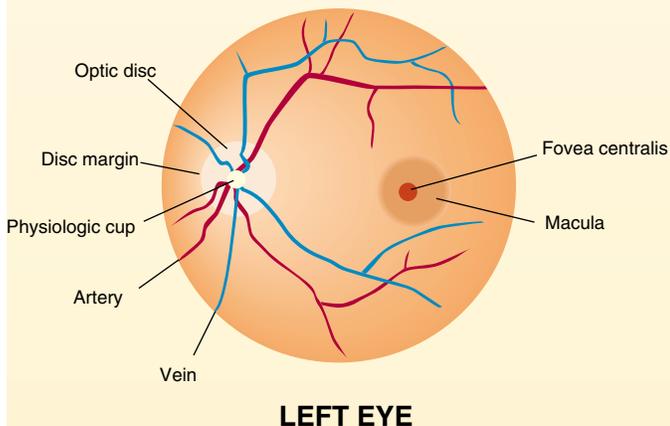

Figure 27-23 A. Move penlight from side of client's face to eye. B. Shine penlight into the eye and observe response of the opposite pupil.

- (5) Repeat steps 2–4, opposite eye.
- (6) Instruct client to gaze at your finger held 4–6 inches from her nose, then to glance at a distant object while you note pupillary reflex.
- (7) Move the finger toward the bridge of the client's nose, noting response of both pupils.

(continues)

TABLE 27-13 (continued)
Assessment of Head and Neck: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>(8) Record results PERRLA (pupils equal, round, reactive to light and accommodation). <i>Pupil should constrict quickly in direct response to light and the opposite pupil should also constrict. Pupils should be equal in size. Pupillary accommodation causes constriction in response to objects that are near, and dilation occurs to accommodate distant vision, with symmetrical convergence of eyes.</i></p> <p>4. Test visual fields.</p> <ol style="list-style-type: none"> Stand 2 feet in front of the client. Instruct client to cover the right eye, while you cover your left eye, and ask client to look into your eye directly opposite to create one vision field. Using the eight directions of gaze (see Figure 27-21), move your finger outside the vision field and slowly bring your finger back midpoint into the vision field for each direction of gaze. When testing the temporal field, bring your finger from behind the client. Instruct client to tell you when your finger becomes visible. Note if you see the finger before the client does. Repeat steps c and d for each field of vision. Record results, indicating eye tested. Repeat steps b–g with other eye. <i>Consensual peripheral vision should occur when the nurse's finger comes into the client's visual field.</i> <p>5. Inspect fundus with ophthalmoscope.</p> <ol style="list-style-type: none"> Set ophthalmoscope at 0 diopters. Instruct client to gaze at a designated point on the far wall, keeping both eyes open during the examination. With your right hand, hold the ophthalmoscope 10 inches from the client and use your right eye to examine the client's right eye. Rest your left hand on client's forehead. Shine the light on the pupil and locate the red reflex (bright, orange glow). Slowly move the ophthalmoscope closer until the retina is seen. While rotating the lens, dial to focus on the internal structures (Figure 27-24). 	<p>4. Loss of peripheral vision occurs in glaucoma (a circulatory disturbance that causes an increase in intraocular [aqueous fluid] pressure).</p> <p>5. Changes in color, size, or clarity of the margins of the optic disc or the identification of lesions should be recorded and reported; a follow-up examination by an ophthalmologist should be scheduled.</p>

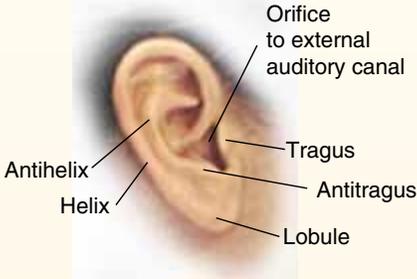

LEFT EYE

Figure 27-24 Landmarks of the Retina

(continues)

TABLE 27-13 (continued)
Assessment of Head and Neck: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<ul style="list-style-type: none"> f. Assess the size, color, and clarity of the optic disc. g. Carefully follow the blood vessel central to the optic disc into each of the four quadrants, observing for lesions (hemorrhages or exudates). h. Inspect the appearance of the macula, lateral to optic disc. i. Repeat steps a–h using your left eye and left hand to examine the client’s left eye. j. Record findings. 	
<p>Ears: Inspect and Palpate</p>	
<p>1. Examine external ears for placement, symmetry, and color (Figure 27-25). <i>Symmetrical, with upper attachment at level of eye’s corner (lateral canthus), flesh color.</i></p>	<p>1. Ears set below lateral canthus occur with congenital anomalies (e.g., Down syndrome). Redness indicates inflammation or fever. Clear or bloody drainage may indicate leakage of cerebrospinal fluid; if present, stop the examination and notify the nursing supervisor immediately.</p>
	
<p>Figure 27-25 External Structures of the Ear</p>	
<ul style="list-style-type: none"> 2. Observe auricle for discharge, swelling, and redness, and palpate for lesions or tenderness by moving auricle and pressing on tragus and mastoid process. <i>Firm, smooth, free from lesions and pain.</i> 3. Select largest ear speculum to accommodate the client’s ear canal. Attach speculum to otoscope to inspect the ear canal and eardrum. <ul style="list-style-type: none"> a. Tip client’s head and straighten ear canal by grasping and pulling the auricle upward, back, and slightly outward. b. Insert the speculum and examine the canal for ear wax, foreign bodies, discharge, scaliness, redness, or swelling. If wax or a foreign body is present, stop the examination and notify the nursing supervisor. c. Inspect the tympanic membrane by sliding speculum slightly down and forward. If membrane is not visible, gently pull the tragus slightly farther to straighten the canal. d. Identify the color, light reflex, umbo, the short process, and long handle of the malleus. Note perforations, lesions, bulging or retraction of the membrane, dilatation of blood vessels, bubbles or fluid level (Figure 27-26). e. Gently withdraw the speculum and repeat procedure in opposite ear. <i>Cerumen, a waxy yellow or brown substance is normal. Ear canal is pinkish and dry. Intact tympanic</i> 	<ul style="list-style-type: none"> 2. Flaky, scaly skin is seen with seborrhea. Sebaceous cysts are common behind the ear. Keloids (scar tissue) on the ear lobe may result from ear piercing. Yellow or green discharge, itching, or pain occurs with an ear infection (otitis media). 3. Buildup of cerumen, a normal moist, waxy yellow substance that turns hard, dry, and dark yellow-brown when impacted, may cause temporary hearing loss. Swollen or reddened canal with discharge occurs with infection. Nontender, nodular swelling deep in the ear canal suggests osteoma (usually a benign tumor composed of bone tissue). Red, bulging membrane indicates acute purulent otitis media; whitish appearance on tympanic membrane results from pus in the middle ear. Perforations of the eardrum result from infection.

(continues)

TABLE 27-13 (continued)
Assessment of Head and Neck: Normal and Key Findings

Area of Assessment/Normal Findings

Key Findings

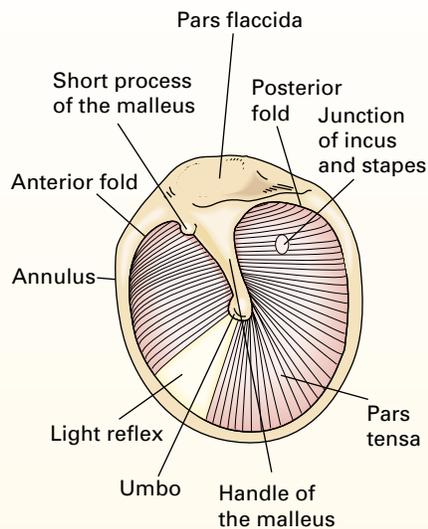

Figure 27-26 Tympanic Landmarks

membrane, translucent or pearly gray. Light reflex is seen at 5 o'clock in right ear and 7 o'clock in left ear.

4. Test auditory acuity.

a. Whispered voice test:

- (1) Instruct client to occlude one ear with finger and repeat the words when heard.
- (2) Nurse stands 1–2 feet away from client, out of view to avoid client lipreading, and softly whispers numbers on side of open ear. Increase voice volume until client identifies words correctly.
- (3) Repeat procedure on other ear.
- (4) Record results. *Client should be able to repeat whispered words.*

b. Weber test:

- (1) Strike tuning fork against your fist or pinch the prongs together.
- (2) Hold the base of the vibrating fork with your thumb and index finger and place the base of the fork on center of top of client's head (Figure 27-27).
- (3) Ask client to describe the sound.
- (4) Record results. *Sound perceived equally in both ears; results indicate a "negative" Weber test.*

c. Rinne test:

- (1) Vibrate prongs of tuning fork and place base of fork on mastoid process of ear being tested and note the time on your watch until the client no longer hears sound (Figure 27-28A)
- (2) Move the vibrating fork in front of the ear canal, noting the length of time sound is heard (Figure 27-28B).
- (3) Record results.
- (4) Repeat test, opposite ear.

Sound heard longer in front of the right auditory meatus than on the mastoid process because air conduction is twice as long as bone.

- a. Inability to hear words may indicate a high-frequency hearing loss (e.g., resulting from excessive exposure to loud noises).

- b. Results "positive" from Weber test when sound lateralizes to affected ear with a unilateral conductive hearing loss. Occurs with impacted cerumen, perforated tympanic membrane, serum or pus in the middle ear, or fusion of the ossicles. Sound can also lateralize to unaffected ear with sensorineural hearing loss. Occurs with inner ear disorders, auditory nerve damage, or results from repeated, prolonged loud noise or effects of ototoxic drugs.

- c. Bone conduction is equal to or greater than air conduction. Occurs with conductive hearing loss resulting from diseases, obstruction, or damage to outer or middle ear.

(continues)

TABLE 27-13 (continued)
Assessment of Head and Neck: Normal and Key Findings

Area of Assessment/Normal Findings

Key Findings

Figure 27-27 Weber test: Place the base of the tuning fork on the top of the client's head.

Nose and Sinuses: Inspect, Palpate, and Percuss

1. Inspect the nose for symmetry, deformity, flaring, or inflammation and discharge from the nares. *Located symmetrically, midline of the face and is without swelling, bleeding, lesions, or masses.*
2. Test patency of each nostril.
 - a. Instruct the client to close the mouth and apply pressure on one naris and breathe.
 - b. Repeat test on opposite naris. *Each nostril is patent.*
3. Inspect the nasal cavities with a penlight.
 - a. Tilt the client's head in an extended position.
 - b. Place nondominant hand on client's head. Using your thumb, lift the tip of the nose.
 - c. With the lit penlight, assess each nostril: note color of anterior nares, nasal septum for deviation, perforation, lesions, or bleeding, and inspect for swelling, discharge. *Mucosa is pink or dull red without swelling or polyps. Septum is midline and intact. A small amount of clear watery discharge is normal.*
4. Palpate the nasal sinuses (Figures 27-29 and 27-30) by applying gentle, upward pressure on frontal and maxillary areas, avoiding pressure on the eyes. Percuss area with

A.

B.

Figure 27-28 Rinne test. A. Place the base of the fork on the mastoid process. B. Place tuning fork in front of ear canal.

1. Swollen or broken as a result of trauma or surgery.
2. Air cannot move through the nostril. May occur with a deviated septum, foreign body, upper respiratory infection, allergies, or nasal polyps.
3. Rhinitis, red, swollen mucosa with copious clear, watery discharge occurs with a cold. Discharge becomes purulent if a secondary bacterial infection develops. Pale, edematous mucosa with clear, watery discharge occurs with allergies or hay fever. A normal mucosa with clear, watery nasal discharge that tests positive for glucose following head injury or nasal, sinus, or dental surgery usually indicates the leakage of cerebrospinal fluid. If present, stop the exam and notify the nursing supervisor immediately.
4. Pain or tenderness may be caused by viral, bacterial, or allergic processes that cause inflammation and obstruction, eliciting a dull sound. *(continues)*

TABLE 27-13 (continued)
Assessment of Head and Neck: Normal and Key Findings

Area of Assessment/Normal Findings

Key Findings

Figure 27-29 Palpating Frontal Sinuses

Figure 27-30 Palpating Maxillary Sinuses

middle or index finger and note the sound. *Nontender, air-filled cavities, resonant to percussion.*

Mouth and Pharynx: Inspect and Palpate

- Stand 12–18 inches in front of client and smell the breath. *Breath should smell fresh.*
 - Observe the lips for color, moisture, swelling, or lesions. Instruct client to open mouth. With a tongue depressor, retract the buccal mucosa and note color, hydration, inflammation, or lesions (Figure 27-31). Invert lower lip with your thumbs on inner oral mucosa, note muscle tone; repeat with upper lips using thumbs and index fingers. *Lips and mucosa should be pink, firm, and moist without inflammation or lesions.*
 - If present, remove dentures. Retract the cheeks with a tongue depressor and inspect gums (gingivae). Note color, edema, retraction, bleeding, and lesions. Palpate the gums with the tongue blade for texture. *Gums are pink, smooth, moist, and firm.*
- Halitosis (foul-smelling breath) occurs with tooth decay or disease of gums, tonsils, or sinuses or with poor oral hygiene (see the accompanying display for common abnormal breath odors).
 - Pale or cyanotic lips may indicate systemic hypoxemia. Dry, cracked lips occur with dehydration or exposure to weather. Swollen lips (angioneurotic edema) result from allergic reactions (e.g., medication or food; see the accompanying display for common lip lesions).
 - Pale gums that bleed easily may indicate periodontal disease or vitamin C deficiency.

(continues)

TABLE 27-13 (continued)
Assessment of Head and Neck: Normal and Key Findings

Area of Assessment/Normal Findings

Key Findings

Figure 27-31 Inspecting Buccal Mucosa

4. Instruct client to clench teeth. Note position and alignment. Inspect teeth: use tongue depressor to expose the molars. Note tartar, cavities, extraction, and color. *Properly aligned, smooth, white, and shiny.*
5. Instruct client to protrude the tongue.
 - a. Inspect dorsum of tongue. Note color, hydration, texture, symmetry, presence or absence of fasciculations (Figure 27-32).

4. Chalky white discoloration of teeth's enamel indicates early formation of dental caries (cavities). Brown or black discoloration indicates formation of caries.
5. Enlarged tongue may indicate glossitis or stomatitis or may occur with myxedema, acromegaly, or amyloidosis. Deep red, smooth surface occurs with glossitis caused by vitamin B₁₂, iron, or niacin deficiency or as a side effect from chemotherapy. Thick white coating with red, raw surface is candidiasis (thrush) indicating immunosuppression. Lesions on ventral surface or hardened areas or ulcerations on the lateral surface may indicate cancer.

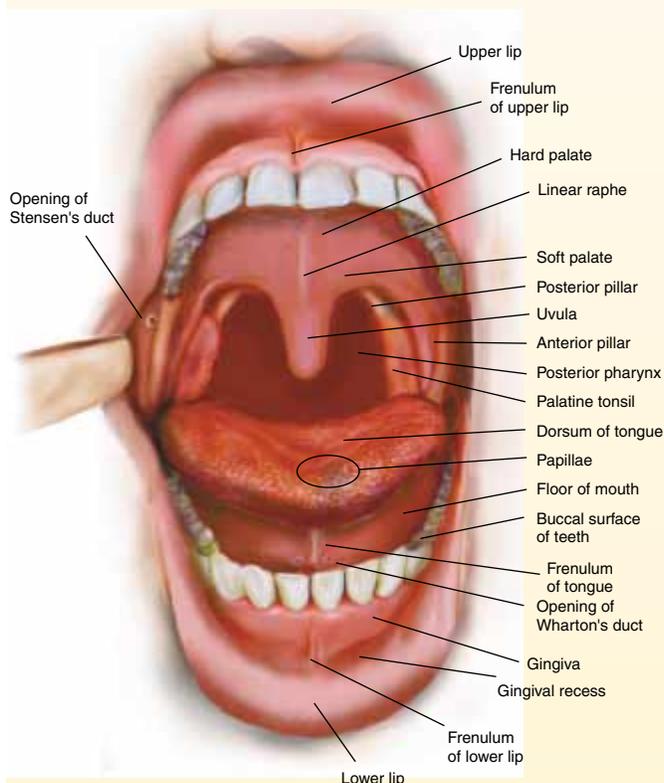

Figure 27-32 Structures of the Tongue

- b. With penlight, inspect sides and ventral surface. Note size, texture, nodules, or ulcerations.
- c. Grasp tongue with gauze. Gently pull it to one side and palpate the full length of tongue.

TABLE 27-13 (continued)
Assessment of Head and Neck: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>d. With penlight, inspect floor of mouth, salivary glands, and duct openings. <i>When protruded, tongue lies midline, medium red or pink in color, moist and smooth along lateral margins, with free mobility. Ventral surface is slightly rough (taste buds), and dorsum is highly vascular.</i></p> <p>6. Inspect the hard and soft palate with penlight.</p> <p>a. Instruct client to extend head backward and hold mouth open.</p> <p>b. Inspect the hard palate (roof of mouth), located anteriorly, and the soft palate, which extends posteriorly to pharynx. Note color, shape, lesions. <i>Palates are concave and pink. Hard palate has ridges; soft palate is smooth.</i></p> <p>7. Inspect the pharynx using a tongue depressor and penlight.</p> <p>a. Explain procedure to the client.</p> <p>b. Instruct client to tilt head back and open mouth.</p> <p>c. With your nondominant hand, place tongue depressor on middle third of tongue. With dominant hand, shine light into back of throat.</p> <p>d. Instruct client to say “ah.” Note the position, size, and appearance of tonsils and uvula.</p> <p>e. If palate and uvula fail to rise symmetrically with phonation, inform client about eliciting gag reflex (touch the posterior one-third of tongue with blade to stimulate the gag reflex) and inspect as stated in step 7d. <i>With phonation, the soft palate and uvula rise symmetrically. The pharynx is pink, vascular, lesion-free.</i></p>	<p>6. Cleft palate (maxillary processes fail to fuse prenatally) is a congenital defect. Red, swollen, tender palates indicate infection. Eroded lesion on hard palate may indicate cancer.</p> <p>7. Reddened, edematous uvula and tonsillar pillars with yellow exudate indicate pharyngitis. Swollen, gray membranes and tonsillar enlargement may result from acute tonsillitis, infectious mononucleosis, or diphtheria.</p>
<p>Neck: Inspect, Palpate, and Auscultate</p>	
<p>1. Inspect for symmetry and musculature. Instruct client to:</p> <p>a. Flex chin to chest and to each side and shoulder to test anterior sternocleidomastoid muscle.</p> <p>b. Hyperextend the neck backward to test posterior trapezia. <i>Muscles are symmetrical with head in central position. Movement through full range of motion without complaint of discomfort or limitation.</i></p> <p>2. Palpate lymph nodes. Instruct the client to relax and flex neck slightly forward.</p> <p>a. Stand in front of client.</p> <p>b. Methodically palpate anterior cervical nodes (Figure 27-33A) and posterior cervical nodes (Figure 27-33B) with fingerpads of middle three fingers in small circles with gentle pressure.</p> <p>c. Note size, shape, mobility, consistency, and tenderness. <i>Lymph nodes should not be palpable. Small, movable nodes are insignificant.</i></p> <p>3. Inspect and palpate trachea.</p> <p>a. Note position.</p> <p>b. Place thumbs and index fingers on sides of trachea. Apply gentle pressure and palpate. <i>Midline position above the suprasternal notch.</i></p>	<p>1. Pain with flexion or rotation of head is associated with muscle spasm that may be caused by inflammation of muscles, meninges, or diseases of the vertebrae. Prominent lateral deviation of sternocleidomastoid muscles (torticollis) is commonly associated with inflammation of viral myositis or trauma (e.g., sleeping with head in unusual position). Decreased range of motion is commonly associated with degenerative osteoarthritis.</p> <p>2. Palpable nodes may result from a variety of diseases, most commonly an infectious process or malignancy.</p> <p>3. Lateral displacement may be caused by a neck or mediastinum mass or pulmonary disorders.</p>

TABLE 27-13 (continued)
Assessment of Head and Neck: Normal and Key Findings

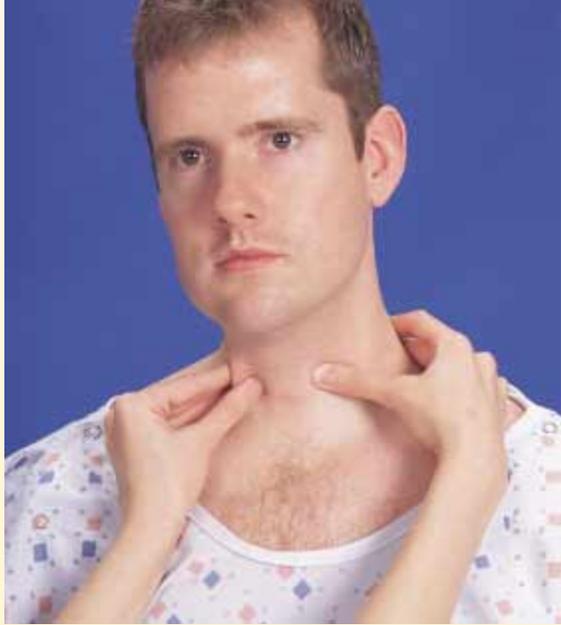

Area of Assessment/Normal Findings	Key Findings
<p>c. Ask client to swallow. You should feel the isthmus rising under your fingers and feel each lateral lobe before and while client swallows.</p> <p>d. Ask client to flex neck forward and to left, and displace thyroid cartilage to right with tips of your left fingers. Note any bulging of gland.</p> <p>e. Palpate with your right hand, placing thumb deep into and behind sternocleidomastoid muscle with index and middle fingers in front. Ask client to swallow. Note any enlargement of gland.</p> <p>f. Repeat steps 4d and e on opposite side.</p> <p>g. If gland appears enlarged, place the diaphragm of stethoscope over gland. Note on auscultation a vibration (soft, rushing sound, or bruit). <i>Thyroid cannot be visualized. It should be smooth, soft, nontender, and should not be enlarged.</i></p>	
<p>(From Estes, M. E. Z. (2002). <i>Health assessment and physical examination</i>. Albany, NY: Delmar Publishers.</p>	

Mouth and Pharynx

Physical assessment of the oral cavity includes the breath, lips, tongue, buccal mucosa, gums and teeth, hard and soft palate, and pharynx. If the client is wearing dentures or removable orthodontia, remove these devices before examination to visualize and palpate the gums. The oral cavity can yield significant information regarding the client's health because systemic diseases may manifest initially in the oral cavity.

Neck

Physical examination of the neck includes the neck muscles, lymph nodes of the head and neck, thyroid gland, and trachea. The lymph nodes are normally not easily palpable. If the client has an enlarged thyroid gland, the blood supply will be increased, causing a fine vibration that can be auscultated with the diaphragm of the stethoscope.

Thorax and Lungs

Physical assessment includes inspection, palpation, percussion, and auscultation of the posterior, lateral, and anterior thorax and lungs. Figure 27-35 depicts the landmarks of the thorax. Landmarks are imaginary lines that are based on anatomic structures such as the spine and sternum. These landmarks assist with visualizing the underlying organs for percussion and auscultation and

for accurate documentation of findings. The angle of Louis is a landmark for identifying the ribs in the mid-clavicular line. Each intercostal space is named for the number of the rib directly above it; that is, the space between the third and fourth ribs is the third intercostal space. When used together, landmarks and intercostal spaces identify the specific lobes of the lungs for percussion and auscultation.

Respiratory auscultation reveals the presence of normal and abnormal breath sounds. During auscultation, the client should be instructed to breathe only through the mouth because mouth breathing decreases air turbulence that could interfere with an accurate assessment. Figure 27-36 shows the anterior, posterior, and right lateral positions of the lung lobes. Table 27-14 (containing Figures 27-37 through 27-42) presents the specific areas of the thorax and lungs to be examined and the normal and key findings of this assessment. See the accompanying display for common terms associated with respiratory assessment.

There are three distinct types of normal breath sounds with their own unique pitch, intensity, quality, location, and relative duration in the inspiratory and expiratory phases of respiration:

- **Vesicular sounds:** soft, breezy, and low-pitched sounds heard longer on inspiration than expiration that result from air moving through the smaller airways over the lung's periphery, with the exception of the scapular area

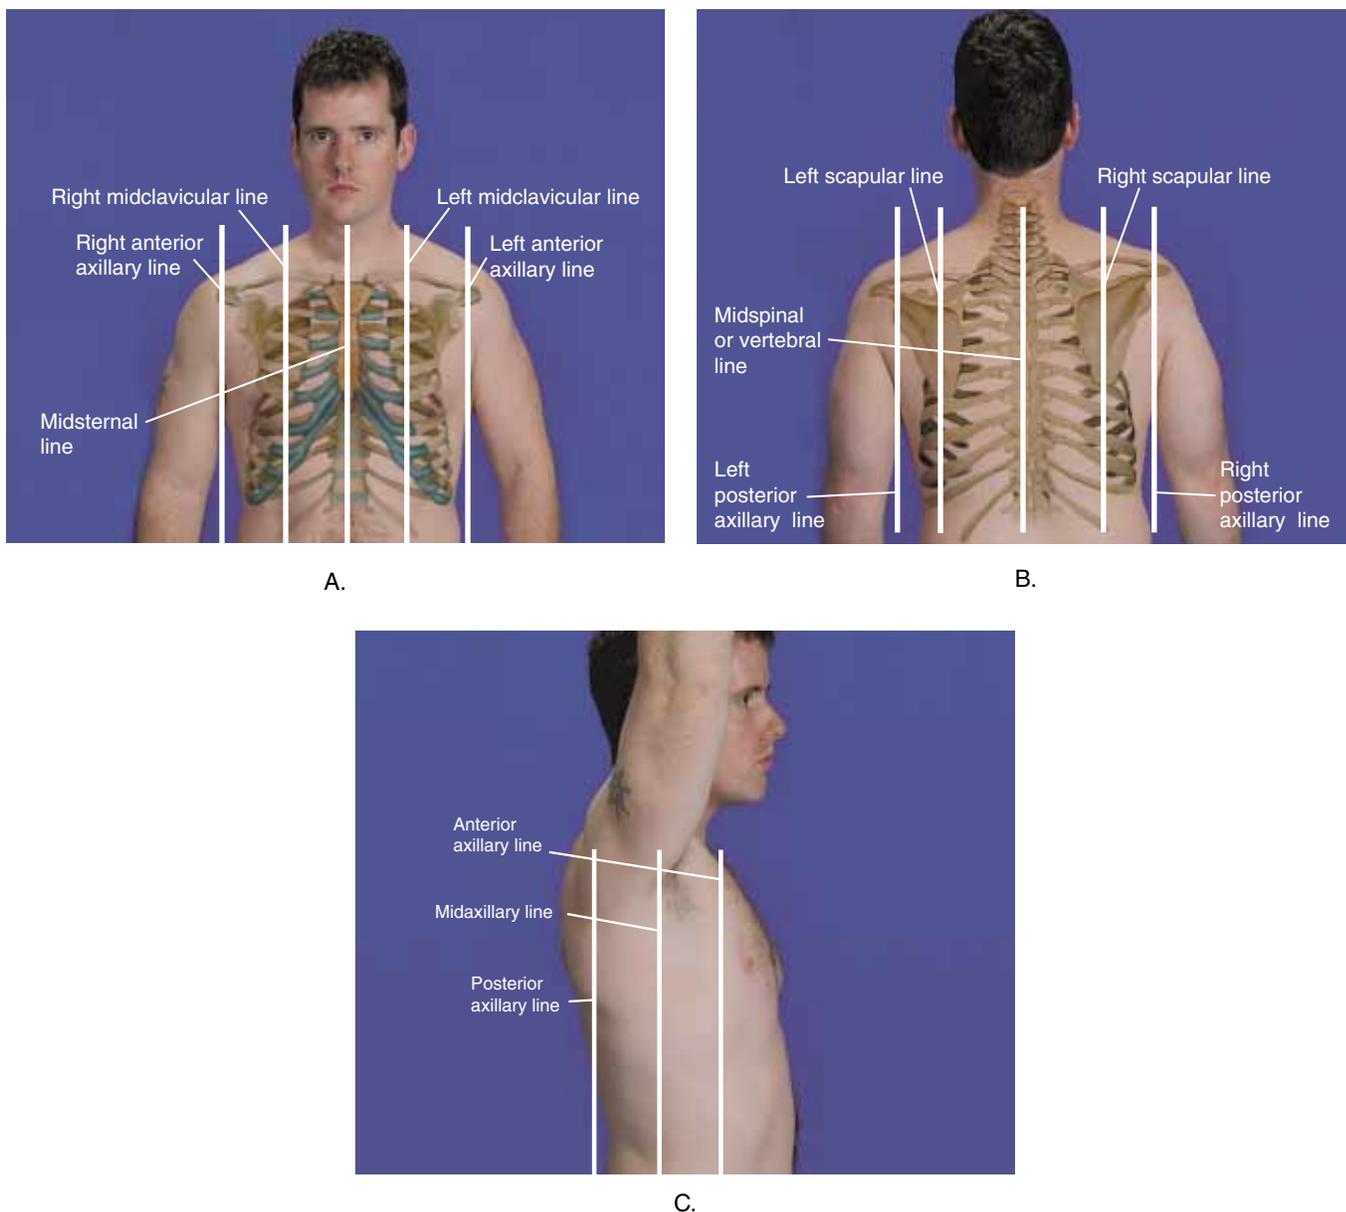

Figure 27-35 Landmarks of the Thorax: A. Anterior Thorax; B. Posterior Thorax; C. Right Lateral Thorax.

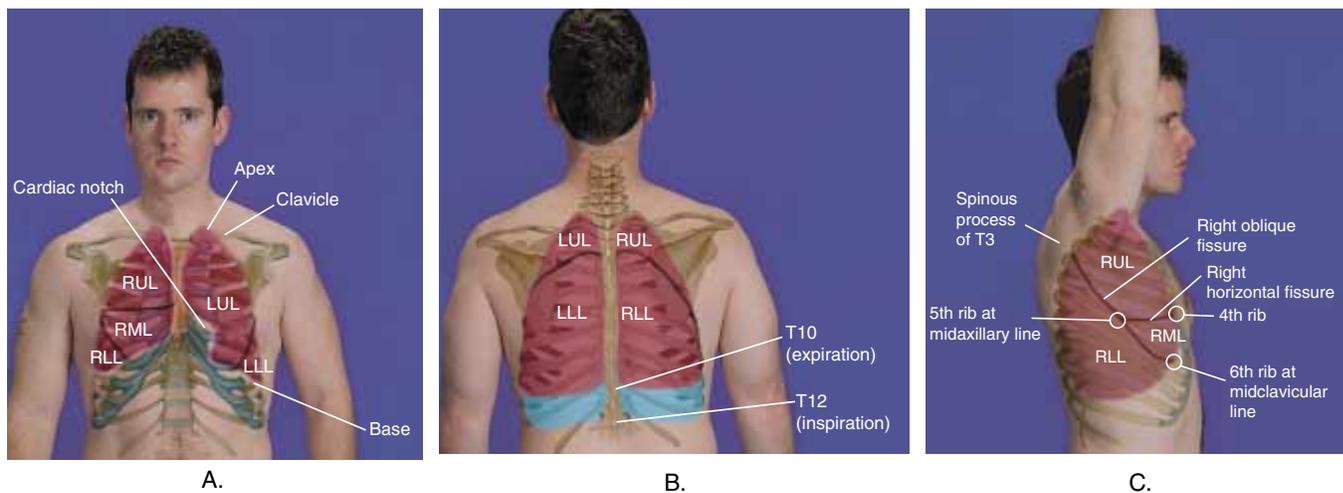

Figure 27-36 Positions of the Lung Lobes: A. Anterior View with Ribs; B. Posterior View with Ribs; C. Right Lateral View with Ribs.

- **Bronchovesicular sounds:** medium-pitched and blowing sounds heard equally on inspiration and expiration from air moving through the large airways, posteriorly between the scapula and anteriorly over bronchioles lateral to the sternum at the first and second intercostal spaces
- **Bronchial sounds:** loud and high-pitched sounds with a hollow quality heard longer on expiration than inspiration from air moving through the trachea

These normal breath sounds must be auscultated over the correct location, for example, bronchial sounds over the trachea. Otherwise, bronchial sounds in clients with emphysema are heard in the peripheral lung areas where normal vesicular sounds should be heard.

Breath sounds that are not normal are described as either abnormal or **adventitious breath sounds** (superimposed sounds on the normal vesicular, bronchovesicular, and bronchial breath sounds). Abnormal breath sounds are characterized by decreased or absent sounds. See the accompanying display for a description of the five types of adventitious breath sounds.

During the assessment of the thorax and lungs the nurse should monitor the client for symptoms of hyper-ventilation (light-headedness or dizziness). If this occurs, assist the client in restoring a normal breathing pattern. Continue with the assessment when the client's dizziness is gone and breathing is normal.

COMMON TERMS ASSOCIATED WITH RESPIRATORY ASSESSMENT

- Aortic aneurysm: localized dilatation of the aortic wall
- Asthma: recurring episodes of labored breathing, wheezing on expiration, and a productive cough of viscous mucoid bronchial secretions
- Atelectasis: collapse of lung tissue and decreased gas exchange
- Bronchiectasis: dilatation and destruction of the bronchial walls
- Emphysema: loss of alveolar elasticity and decreased gas exchange
- Empyema: accumulation of pus in a body cavity such as a pleural cavity
- Hemothorax: accumulation of blood and fluid in the pleural cavity
- Pleural effusion: accumulation of fluid in interstitial and air spaces of lungs
- Pleurisy: inflammation of the pleura
- Pneumonia: inflammation of the lungs
- Pneumothorax: collection of air in the pleural space that causes lungs to collapse

ADVENTITIOUS BREATH SOUNDS

- **Crackles:** heard predominantly on inspiration over the base of the lungs as an interrupted fine crackle (dry, high-pitched crackling, popping sound of short duration) that sounds like a piece of hair being rolled between the fingers in front of the ear or a coarse crackle (moist, low-pitched crackling, gurgling sound of long duration) that sounds like water going down the drain after the plug has been pulled on a full tub of water
- **Rhonchi:** heard predominantly on expiration over the trachea and bronchi as a continuous, low-pitched musical sound
- **Wheezes:** heard predominantly on expiration all over the lungs as a continuous sonorous wheeze (low-pitched snoring) or sibilant wheeze (high-pitched musical sound)
- **Pleural friction rub:** heard on either inspiration or expiration over the anterior lateral lungs as a continuous creaking, grating sound
- **Stridor:** heard predominantly on inspiration as a continuous crowing sound

Heart and Vascular System

Heart and vascular system assessment techniques consist of inspection, palpation, and auscultation. The nurse should review the client's profile relative to the health history for cardiac risk factors such as family history, cigarette smoking, and dietary and exercise habits.

Heart

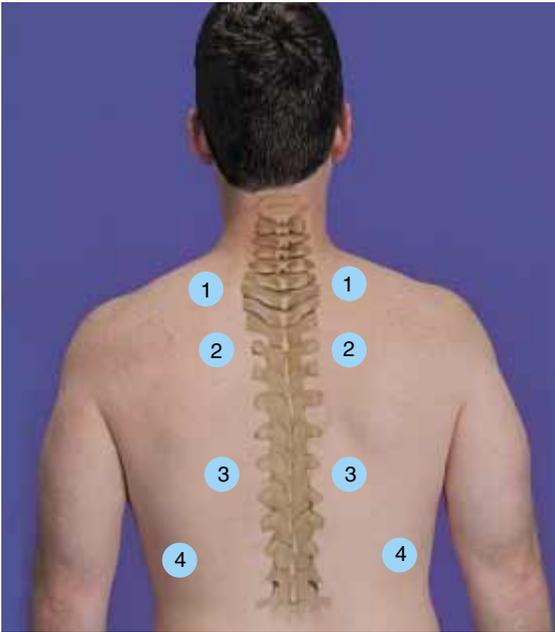

Inspection, palpation, and auscultation are performed in a systematic manner using certain cardiac landmarks. The cardiac landmarks, as seen in Figure 27-43, are defined as follows:

1. Aortic area is the second intercostal space (ICS) to the right of the sternum.
2. Pulmonic area is the second ICS to the left of the sternum.
3. Erb's point is located in the third ICS to the left of the sternum.
4. Tricuspid area (right ventricular area or septal area) is the fifth ICS to the left of the sternum.
5. Mitral area (left ventricular or apical area) is the fifth ICS at the left midcavicular line.

Whereas the mitral area is correlated anatomically with the apex of the heart, the aortic and pulmonic areas are correlated anatomically with the base of the heart. Assessment proceeds either from the base of the heart to the apex or from the apex to the base. When auscultating for cardiac sounds (S_1 and S_2) listen for:

TABLE 27-14
Assessment of Thorax and Lungs: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>Posterior Chest: Inspect, Palpate, Percuss, and Auscultate Place client in a sitting position, arms folded across chest (separates scapulae), back exposed. Refer to Figure 27-35 to review landmarks.</p> <ol style="list-style-type: none"> 1. Inspect posterior thorax. <ol style="list-style-type: none"> a. Assess shape and symmetry. Note rate and rhythm of respirations, movement of chest wall with deep inspiration and full expiration, and signs of distress. b. Estimate the anteroposterior diameter in proportion to lateral diameter. <i>Respirations are quiet, effortless, and regular, 12–20 breaths per minute. Thorax rises and falls in unison with respiratory cycle. Ribs slope across and down, without movement or bulging in the intercostal spaces. The adult ratio of anteroposterior to lateral diameter ranges from 1:2 to 5:7.</i> 2. Palpate. <ol style="list-style-type: none"> a. Lesions or areas of pain; palpate and note tenderness. b. Thoracic expansion at 10th rib: place thumbs close to client’s spine and spread hands over thorax (Figure 27-37). Note divergence of thumbs, feel for range and symmetry of movement during deep inhalation and full exhalation. 	<ol style="list-style-type: none"> 1. Structural changes that occur in the thorax are discussed in Chapter 31. Defined horizontal slope of ribs occurs with emphysema. Bulging in the intercostal spaces indicates increased effort of breathing (e.g., emphysema). Retraction of intercostal spaces during inspiration indicates airway obstruction (e.g., asthma). Impairment in respiratory movement occurs with lung or pleural disease. 2. Tenderness may result from a fractured rib. Unilateral decreased thoracic expansion occurs on the affected side (e.g., pneumonia or pneumothorax). Bilateral decreased expansion occurs when alveoli do not fully expand (e.g., emphysema or pleurisy). Absent or decreased fremitus occurs when voice is decreased, in presence of bronchus obstruction, or by fluid, air, or solid tissue in the pleural space. Fremitus is increased over areas of consolidated lung.
	
<p>Figure 27-37 Palpating Posterior Thoracic Expansion</p> <ol style="list-style-type: none"> c. Place ulnar aspect of your open hand at right apex of lung and place the hand at each location as shown in Figure 27-38. Instruct client to say “99” and palpate for tactile fremitus (vibrations created by sound waves). Note areas of increased or decreased fremitus. d. Move hands from side to side, from right to left, with client repeating the words with the same intensity every time you place your hands on the back. <i>Thumbs should separate an equal distance (3–5 cm) and in the same direction during thoracic expansion and meet in the midline on expiration. Posterior thorax is free from tenderness, lesions, and pulsations. Fremitus is equal on both sides of thorax, strongest at the level of tracheal bifurcation.</i> 	<p>(continues)</p>

TABLE 27-14 (continued)**Assessment of Thorax and Lungs: Normal and Key Findings****Area of Assessment/Normal Findings****Key Findings****Figure 27-38** Palpation Pattern for Tactile Fremitus: Posterior Thorax

3. Percuss chest systematically (Figure 27-39).

**Figure 27-39** Percussion Pattern of Posterior Thorax

- a. Start at lung apices. Move hands from side to side across the top of each shoulder. Note sound produced from each percussion strike and compare with contralateral sound.
- b. Continue downward and posterolateral every other intercostal space as shown in Figure 27-40. Note inten-

3. Hyperresonance in adults occurs in pneumothorax, emphysema, or asthma. Dull sound is created in solid or fluid-filled structures (e.g., pneumonia, pleural effusion, or tumors). Pleural fluid sinks to lowest part of pleural space (posteriorly in a supine client).

(continues)

TABLE 27-14 (continued)
Assessment of Thorax and Lungs: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>sity, pitch, duration, and quality of percussion. <i>Air-filled lungs create a resonant sound. Identify contralateral sound; bones (e.g., ribs or spine, create a flat sound). Thorax is more resonant in children and thin adults.</i></p> <p>4. Auscultate posterior and lateral surfaces.</p> <ol style="list-style-type: none"> Place diaphragm of stethoscope on right lung apex. Instruct client to inhale and exhale deeply and slowly when the stethoscope is felt on the back. Repeat on left lung apex. Move downward every other intercostal space and auscultate, placing stethoscope in the same position on both sides. Auscultate the lateral aspect by placing the stethoscope directly below the right axilla, instructing the client to breathe only through the mouth and to inhale and exhale deeply and slowly. Proceed downward, every other intercostal space on the same side. Repeat step c on left side. <i>Posterior sounds: bronchovesicular and vesicular sounds; lateral: vesicular sounds. A large chest will produce decreased breath sounds.</i> 	<p>4. Decreased breath sounds caused by an inability to inhale and exhale deeply (e.g., emphysema or by an obstruction; atelectasis or foreign object). Absent breath sounds (e.g., empyema, hemothorax, pneumothorax, or pneumonectomy). See the display for a description of adventitious breath sounds.</p>
<p>Anterior Chest: Inspect, Palpate, Percuss, and Auscultate</p> <p>Place client in a sitting or supine position.</p> <ol style="list-style-type: none"> Instruct client to inhale deeply and exhale fully. Inspect anterior thorax for: <ol style="list-style-type: none"> Symmetry and depth of movement Rhythm of respirations Slope of ribs and musculoskeletal deformities <i>Scapula at same height. Thorax rises and falls in unison with respiratory cycle, ribs at a 45° angle with sternum. Inspiratory breath sounds are not audible at a distance of more than 2–3 cm from the mouth.</i> Palpate. <ol style="list-style-type: none"> Place fingerpads on right apex, above the clavicle. Proceed downward to each rib and intercostal space and note tenderness, pulsation, masses, and crepitation. Repeat on left side. Assess respiratory excursion by placing your thumbs along each costal margin with hands on lateral rib cage (Figure 27-40). Instruct client to inhale deeply; note divergence of thumbs on expansion; feel range and symmetry of respiratory movement. Palpate for tactile fremitus as shown in Figure 27-41. Repeat steps discussed above for posterior palpation for tactile fremitus, gently displacing female breasts as necessary. Note that fremitus is usually decreased or absent over the precordium. <i>Same as normal findings for posterior palpation.</i> Symmetrically percuss anterior surface as shown in Figure 27-42. 	<ol style="list-style-type: none"> One scapula higher than the other occurs with scoliosis. Rib angle less than 45° occurs with emphysema, bronchiectasis, and cystic fibrosis. Bulging of intercostal spaces on expiration occurs with an expiratory obstruction (e.g., emphysema, tension pneumothorax, and tumors). Retraction on inspiration obstructs free inflow of air (e.g., asthma, tracheal/laryngeal obstruction, or tumor). Pulsations may indicate a thoracic aortic aneurysm. Tenderness may result from a fractured rib. Unilateral decreased thoracic expansion occurs on the affected side (e.g., pneumonia or pneumothorax). Bilateral decreased expansion occurs when alveoli do not fully expand (e.g., emphysema or pleurisy). Crepitus (a grating or crackling sensation caused by two rough surfaces rubbing together, as in subcutaneous emphysema) occurs when air escapes the lung and is trapped in subcutaneous tissue. It is palpated as a crackling sound from any condition that interrupts the pleurae (e.g., pneumothorax or thoracic surgery). Dullness over lung tissue indicates fluid-filled or solid areas (e.g., pneumonia or tumors). Because pneumonia typically occurs in right middle lobe, unless you displace the breast, you may miss the abnormal percussion note. <p style="text-align: right;"><i>(continues)</i></p>

TABLE 27-14 (continued)
Assessment of Thorax and Lungs: Normal and Key Findings

Area of Assessment/Normal Findings

Key Findings

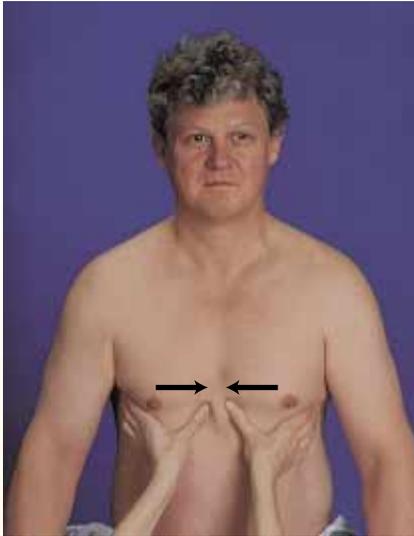

Figure 27-40 Palpating Anterior Thoracic Expansion

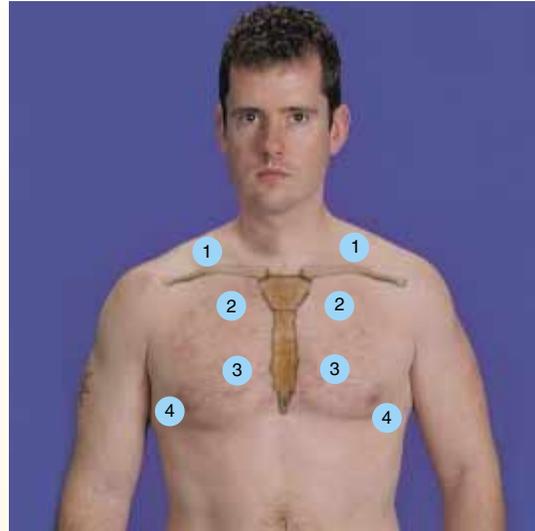

Figure 27-41 Palpation Pattern for Tactile Fremitus: Anterior Thorax

- a. Percuss 2–3 strikes along right lung apex, repeat on left lung apex. Proceed downward, percussing in every other intercostal space going from right to left in same position on both sides. Displace breast tissue as necessary.
- b. Assess in each thoracic area.
 - (1) Resonant-lung field
 - (2) Cardiac dullness: third to fifth intercostal spaces left of sternum
 - (3) Liver dullness: place your pleximeter finger parallel to upper border of expected liver dullness in right midclavicular line; percuss downward.
 - (4) Gastric air bubble: repeat procedure performed for liver dullness on left side. *Resonant sound over lung tissue (hyperresonance in children and thin adults). Cardiac, liver, and gastric silhouettes emit dull sound. Ribs are flat.*

Figure 27-42 Percussion Pattern for Anterior Thorax

4. Auscultate anterior surface: instruct client to breathe through mouth and compare symmetrical areas of the lungs, from above downward.
 - a. Listen to breath sounds. Note intensity and identify variations from normal.
 - b. Identify any added sounds by location on chest wall and time in the respiratory cycle.
 - c. If breath sounds are diminished, ask client to breathe hard and fast with mouth open. *Anterior sounds: bronchial, bronchovesicular, and vesicular sounds. A large chest will produce decreased breath sounds.*
4. Decreased breath sounds caused by an inability to inhale and exhale deeply (e.g., emphysema or by an obstruction; atelectasis or foreign object). Absent breath sounds (e.g., empyema, hemothorax, pneumothorax, or pneumonec-tomy). See the display for a description of adventitious breath sounds.

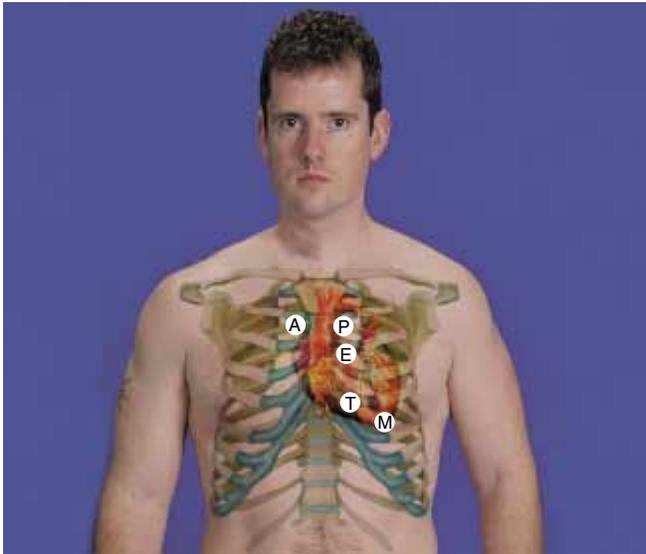

Figure 27-43 Cardiac landmarks: A, aortic area; P, pulmonic area; E, Erb's point; T, tricuspid area; and M, mitral area.

- S_1 , which is usually a quieter sound than S_2 in the aortic and pulmonic areas
- A split S_2 sound that may be heard in the pulmonic area during inspiration
- S_1 , which is usually louder than S_2 in the tricuspid and mitral areas
- A split S_2 sound that may be heard in the tricuspid area

Additional heart sounds (S_3 and S_4) may be heard during auscultation. S_3 (also called a ventricular gallop)

may be heard in the tricuspid and mitral areas during the early to mid-diastole following the S_2 sound. S_3 is heard best when the client is in the left lateral recumbent position, and the sound resembles the pronunciation of the word “Kentucky” (lub-dub-by). S_4 (also called atrial diastolic gallop) may be heard in the tricuspid and mitral areas during the late phase of diastole, before S_1 of the next cardiac cycle. S_4 is heard best when the client is in the supine position, and the sound resembles the pronunciation of the word “Tennessee” (le-lub-dub).

An S_3 can be a normal physiological sound in children and young adults; in adults it may be indicative of cardiac dysfunction (Estes, 2002). An S_4 may occur with or without any evidence of cardiac decompensation or it can be indicative of decompensation that is seen in conditions that increase the resistance to filling because of poorly compliant ventricles such as coronary artery disease and heart failure (Estes, 2002).

There are distinct abnormal findings found on palpation and auscultation. During palpation the nurse should assess for **thrills** (vibrations that feel similar to what one feels when a hand is placed on a purring cat) and **heaves** (lifting of the cardiac area secondary to an increased workload and force of left ventricular contraction). Abnormal heart sounds relative to **stenosis** (a narrowing or constriction of a blood vessel or valve) or **regurgitation** (the backward flow of blood through a diseased heart valve, also known as insufficiency) can be heard during auscultation as a **click** (a high-pitched systolic sound created by the opening of the valve) or a **murmur** (swishing or blowing sounds of long duration heard during the systolic and diastolic phases created by turbulent blood flow through a valve). Other abnormal sounds heard on auscultation are a pericardial friction rub (high-pitched, multiphasic, scratchy or grating sound that does not change with respirations) and **bruits** (blowing sounds that are heard when the blood flow becomes turbulent as it rushes past an obstruction).

Murmurs are characterized by their:

- Location: area where the murmur is heard loudest (e.g., mitral, pulmonic).
- Radiation: transmission of sound from a specific valve to other adjacent structures (mitral murmurs can radiate to the axilla).

COMMON TERMS ASSOCIATED WITH CARDIAC ASSESSMENT

- **Aneurysm:** localized (aortic) abnormal dilation of a blood vessel wall
- **Angina:** pain in the chest, neck, and/or arm resulting from myocardial ischemia
- Arteriosclerosis: buildup of plaques in the inner layers of the walls of large-to-medium-sized arteries
- Atrial fibrillation: rapid, random contractions of the atria with irregular ventricular beats
- Buerger's disease (thromboangiitis obliterans): an occlusion of a medium to small artery in the leg or foot that becomes inflamed and thrombotic
- Bundle branch block: conduction abnormality of the cardiac impulse through the bundle of His fibers
- Congestive heart failure: circulatory congestion caused by a cardiac disorder
- Coronary artery disease: any abnormal condition that may affect the arteries of the heart
- **Ischemia:** local and temporary lack of blood supply to the heart
- **Myocardial infarction:** necrosis of the heart muscle
- Thrombophlebitis: inflammation of a vein with a formed blood clot

GRADES AND CHARACTERISTICS OF MURMURS

Grade I:	Barely audible
Grade II:	Audible immediately
Grade III:	Moderate intensity
Grade IV:	Loud, may be associated with a thrill
Grade V:	Loud, with palpable thrill, audible with stethoscope in contact with chest wall
Grade VI:	Louder, heard without stethoscope, palpable thrill

(From Estes, M. E. Z. [2002]. *Health assessment and physical examination*. Albany, NY: Delmar Publishers.)

- Timing: phase in the cardiac cycle. If the murmur occurs simultaneously with the pulse, it is a systolic murmur. If the murmur is not related to the pulse, it is a diastolic murmur.
- Intensity: the loudness or intensity (see the display for a grading of murmurs).
- Quality: sound produced (harsh, rumbling, blowing, or musical).
- Pitch: high, medium, or low (auscultated with the bell of stethoscope for low-pitched murmurs and the diaphragm for high-pitched murmurs).
- Configuration: pattern that the murmur makes over time; described as crescendo (soft to loud), decrescendo (loud to soft), crescendo-decrescendo (soft to loud to soft), and plateau (sustained sound) (Estes, 2002).

Table 27-15 presents the specific areas to be examined and the normal and key findings of assessment of the heart and vascular system. See the accompanying display for common terms associated with cardiac assessment.

Vascular System

To assess blood perfusion of peripheral vessels and skin, the nurse should note changes in skin temperature, color, and sensation and in the pulses. Feeling the toes for warmth and color provides important information relative to peripheral circulation and tissue perfusion. Because the position of the extremities can affect the skin temperature and appearance, always assess extremities at heart level and at normal room and body temperature. Peripheral pulses should be compared bilaterally, and changes in strength and quality should be noted (Bosley, 1995).

TABLE 27-15
Assessment of Heart and Vascular System: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>Heart: Inspect, Palpate, and Auscultate</p> <p>Place client in supine or slightly elevated position. Expose anterior thorax using a drape. Stand at client's right side with light shining from opposite side to eliminate shadows.</p> <ol style="list-style-type: none"> 1. Inspect anterior thorax, precordium area: note pulsations, heaves, or retractions. <i>Absence of visible pulsations, heaves, or retractions.</i> 2. Inspect and palpate each of the cardiac landmarks for apical impulses. Use fingerpads to palpate pulsations and ball of the hand to palpate thrills or heaves (see Figure 27-43, for landmarks). <ol style="list-style-type: none"> a. Aortic area (second intercostal space to right of sternum): note pulsation, thrill, or vibration of aortic valve closure. b. Pulmonic area (second left intercostal space): note pulsation, thrill, or vibration of pulmonic valve closure. c. Third left intercostal space: note pulsation, thrill, or vibration of pulmonic valve closure. d. Right ventricular area (left, lower half of sternum and parasternal area): assess for a diffuse lift, heave, or thrill. e. Apex of heart (fifth intercostal space just medial to mid-clavicular line): note pulsation, thrill, or heave. <i>No pulsations, thrills, or heaves should be palpated in aortic, pulmonic, Erb's point, or tricuspid areas. An apical impulse (heard after first heart sound, lasting for half of systole) occurs in 50% of adult population. Mitral thrill or heave is absent.</i> 3. Palpate high in epigastric region for pulsations. <i>Strong pulsations thrusting upward against the fingerpads are caused by the aorta.</i> 4. Begin auscultation using the diaphragm of stethoscope for transmission of high-frequency sounds. Listen to several "lub dub" cycles in all five cardiac landmarks twice: first 	<ol style="list-style-type: none"> 1. Visible pulsations, heaves, or retractions require additional inspection with palpation to identify exact location and timing in relation to cardiac cycle (systole or diastole). <ol style="list-style-type: none"> a. Thrill may indicate aortic stenosis or regurgitation. b. Thrill may indicate pulmonic stenosis or regurgitation. c. Erb's point pulsations may indicate a left ventricular aneurysm or enlarged right ventricle. d. Thrill may indicate a tricuspid stenosis or regurgitation; a heave may also be present. e. Thrill may indicate mitral stenosis or regurgitation. A heave (sustained apex beat) may result from left ventricular hypertrophy. 3. Large pulsations and a mass may indicate an abdominal aortic aneurysm. Notify the nursing supervisor immediately if you detect signs of an aneurysm. 4. Diminished S₂ may indicate aortic stenosis and an intensified S₂ may indicate arterial hypertension. Ejection click

Assessment of Heart and Vascular System: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>identify S_1 and S_2, then listen for S_3 and S_4 and murmurs and friction rubs.</p> <ol style="list-style-type: none"> Locate aortic valve landmark (second intercostal space, right sternal border) and listen for S_2. Auscultate pulmonic valve (second intercostal space, left sternal border), listening for S_2. <i>Regular intervals of time occur with a regular rhythm: time between S_1 and S_2 (systole) and then the time between S_2 and the next S_1 (diastole) with a distinct silent pause between S_1 and S_2. Aortic S_2 heralds onset of diastole, corresponds with “dub” sound, and is louder than S_1. In the pulmonic area a split of the S_2 sound is usually heard every fourth or fifth beat (aortic and pulmonic components). Splitting of S_2 occurs on inspirations because of a greater negative intrathoracic pressure when the venous return to the right side of the heart increases; thus, pulmonic closure is delayed because of the extra time needed for increased blood volume to pass through the valve. Aortic S_2 is louder than pulmonic S_2 because of the greater pressures in the left side of the heart.</i> Erb’s point (third left intercostal space): auscultate for murmurs. Tricuspid area (fifth intercostal space, left sternal border): assess for S_1. Instruct client to hold his or her breath. <i>S_1 is split because the mitral valve closes slightly before the tricuspid valve. When the client holds his or her breath, the splitting disappears.</i> Mitral area (fifth intercostal space, left midclavicular line): assess for S_1. If you are unable to distinguish between S_1 and S_2, palpate carotid artery while assessing mitral landmark; you will hear S_1 with each carotid pulse beat. <i>S_1 heralds the onset of systole (“lub” sound) and is louder than S_2 at this landmark.</i> <ol style="list-style-type: none"> Place client on left side. Use the bell of stethoscope (low-pitched sounds) and assess all five anatomic areas for extra heart sounds (S_3 and S_4 gallops, clicks, and rubs). <i>S_3 is heard in children and young adults under the age of 30 or in the third trimester of pregnancy. S_4 may occur without any evidence of cardiac decompensation. Gallops, clicks, and rubs are absent.</i> Epigastric area: place client in supine position. Place bell of stethoscope over visible aortic pulsations and auscultate for 10–15 seconds. <i>Bruits are absent.</i> 	<p>following S_1 can be heard with aortic stenosis caused by calcified valve.</p> <ol style="list-style-type: none"> A split S_2 that is abnormally wide on inspiration indicates delayed closure of the pulmonic valve resulting from a delay in the electrical stimulation of the right ventricle (e.g., right bundle branch block). A pulmonic ejection click (heard loudest on expiration) is caused by the opening of a diseased pulmonic valve. A loud pulmonic S_2 is caused by an elevated pressure in the pulmonary artery. A diminished pulmonic S_2 occurs with a calcified or thickened valve (e.g., pulmonic stenosis). A split pulmonic S_2 that is abnormally wide or occurs with every S_2 is usually indicative of an abnormality. Murmurs may indicate stenosis or regurgitation of a valve. A wide split S_1 during inspiration that is still heard on expirations is due to an electrical malfunction (e.g., right bundle branch block or a structural alteration, mitral stenosis). A variable S_1 sound (soft or loud) occurs when diastolic filling time varies (e.g., tachycardia or atrial fibrillation). <ol style="list-style-type: none"> S_3 (ventricular gallop) occurs after S_2 at the end of ventricular diastole and may be one of the earliest clinical findings of cardiac dysfunction (e.g., congestive heart failure). S_4 may indicate cardiac decompensation (e.g., coronary artery disease or myocardial infarction). A bruit in the epigastric area indicates turbulent blood flow as seen in the presence of an aneurysm.
<p>Vascular System: Inspect, Palpate, and Auscultate Place client in supine position with head of bed elevated 30° to 45°. Use a drape and uncover only those areas that are being assessed. If skin is not assessed as a separate system, inspect the skin for color, texture, temperature, and edema during this part of the examination.</p> <ol style="list-style-type: none"> Assess carotid pulse: <ol style="list-style-type: none"> Inspect right carotid artery along margin of the sternocleidomastoid muscle. <i>Absence of kinks or bulging.</i> 	<ol style="list-style-type: none"> Kinking or bulging may indicate hypertension or arteriosclerotic artery. <i>(continues)</i>

TABLE 27-15 (continued)
Assessment of Heart and Vascular System: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>b. Palpate carotid artery at lower half of neck (to avoid carotid sinus) by instructing client to turn head toward right side (relaxes sternomastoid muscle) and placing fingerpads of index and middle fingers around medial edge of sternocleidomastoid muscle.</p> <p>c. Auscultate carotid artery with diaphragm or bell of stethoscope. Instruct client to hold breath and listen for bruits.</p> <p>d. Repeat steps 1a–c on left side. <i>Pulses are equal in rate and rhythm with a strong, thrusting quality. No blowing or swishing sound is heard on auscultation.</i></p> <p>2. Identify bilateral external and internal (deep, along carotid artery) jugular veins with head of bed elevated 45° (avoid hyperextension or flexion of neck).</p> <p>a. Inspect right internal jugular vein.</p> <p>b. Measure the vertical distance in centimeters from the sternal angle (angle of Louis) to top of distended neck vein to obtain an indirect jugular venous pressure.</p> <p>c. Repeat steps 2a and b on left side. <i>Measurement of 1–2 cm above the angle of Louis with head of bed elevated 45°.</i></p> <p>3. Assess blood pressure; refer to Procedure 27-4.</p> <p>4. Inspect and palpate bilateral peripheral pulses (locate pulse points as discussed in Figure 27-1 and Table 27-5. Starting with the temporal artery, proceed in a sequential pattern with the upper extremities (brachial, radial, and ulnar pulses), then the lower extremities (femoral, posterior tibial, and dorsalis pedis pulses). Note rate, quality, rhythm, and volume of pulses. If you are unable to palpate a pulse, use a Doppler or ultrasound stethoscope to amplify the sound. <i>Bilateral equality and symmetry of peripheral pulses.</i></p>	<p>b. Decreased pulsations may indicate arterial narrowing or occlusion.</p> <p>c. Bruits may indicate distribution of blood flow from arterial narrowing or occlusion.</p> <p>2. Distended jugular veins (>2 cm) with client in a sitting position may be related to fluid volume overload (rapid infusion of an intravenous solution). Elevated jugular venous pressure, when accompanied with a third heart sound are the most specific signs of heart failure (Agency for Health Care Policy and Research, 1994).</p> <p>4. Markedly diminished or absent pulses may indicate arterial occlusion; e.g., Buerger’s disease (thromboangiitis obliterans).</p>
<p>5. Assess tissue perfusion:</p> <p>a. Perform the Allen test to determine patency of radial and ulnar arteries. Instruct client to rest hands in lap (Figure 27-44).</p> <ol style="list-style-type: none"> (1) Compress both the radial and ulnar arteries. (2) Firmly compress arteries and instruct client to open the hand. (3) Note color of palms. (4) Release one artery and note the color of the palm. (5) Then steps 1–4 are repeated for the other artery on the same hand. Then the procedure is performed on the other hand. <i>Palms should turn pink promptly.</i> <p>b. Inspect both legs from the groin and buttocks to feet. Note venous enlargement, redness or discoloration, and ulcers over saphenous veins. <i>Skin intact, free from venous engorgement and pain.</i></p> <p>c. Check for Homan’s sign by slightly bending client’s knee and sharply dorsiflexing the client’s foot. If client feels pain in calf area of leg, the test is positive. Repeat on opposite leg. <i>Absence of calf pain.</i></p>	<p>a. Persistence of pallor when one artery (e.g., radial) is manually compressed indicates occlusion of the other artery; e.g., ulnar.</p> <p>b. Edema or ulceration are indicative of venous stasis. Tenderness or pain, warmth, redness, or discoloration indicates superficial thrombophlebitis. Dilated and tortuous veins are varicosities.</p> <p>c. A positive Homan’s sign may indicate thrombophlebitis or deep vein thrombosis (DVT).</p>

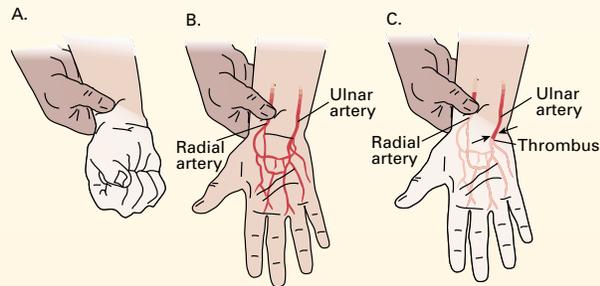

Figure 27-44 Allen Test. A. Pallor is initiated by compressing the radial artery with the client’s fist clenched. B. A patent ulnar artery reveals the return of palm perfusion despite radial artery compression. C. An occluded ulnar artery results in continued pallor of the hand while the radial artery is still compressed.

Breasts and Axillae

Breast cancer is the most commonly occurring cancer in women (one out of eight) in the United States according to the National Cancer Institute; all women should be considered at risk for developing breast cancer because 80% of women with breast cancer fail to exhibit the specific risk factors associated with cancer (Firth & Watanabe, 1996).

Long-term survival rates for breast cancer have a direct correlation to early detection of the disease. Nurses play a major role in women’s health by teaching breast self-examination (BSE) and by supporting women in achieving healthier lifestyles believed to decrease the risk factors of breast cancer (Estes, 2002).

Table 27-16 presents the specific areas of the breast and axillae to be examined and the normal and key findings of this assessment. This table *does not* describe the changes that occur with pregnancy. Inspection and palpation are used to assess the female and male breasts and axillae, and palpation is used for the axilla and lymph nodes.

The breasts are divided into four quadrants, inclusive of the tail of Spence, by lines crossing at the nipples as shown in Figure 27-45. These quadrants are used in a sequential fashion during assessment. Figure 27-46 shows a cross section of breast tissue.

Palpation of the supraclavicular, infraclavicular, and axillary nodes is included in the assessment of the breasts. The pattern of lymph drainage is illustrated in Figure 27-47. Note that not all the lymphatics drain into the axilla; therefore, depending on the location of a malignant lesion, the spread of cancer cells may occur directly to the infraclavicular nodes, deep into the chest or abdomen, or even to the opposite breast.

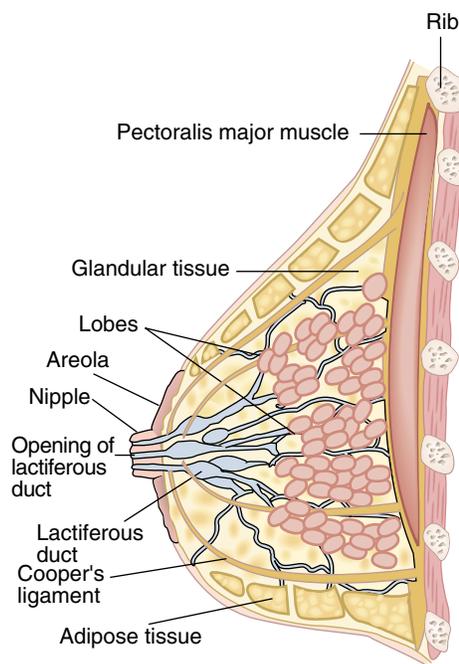

Figure 27-46 Cross Section of the Left Breast

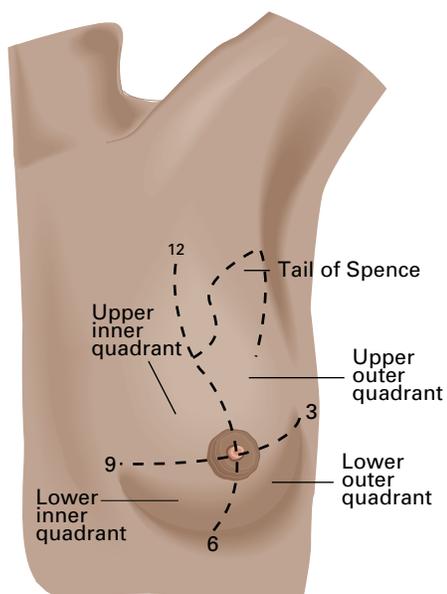

Figure 27-45 Quadrants of the Left Breast

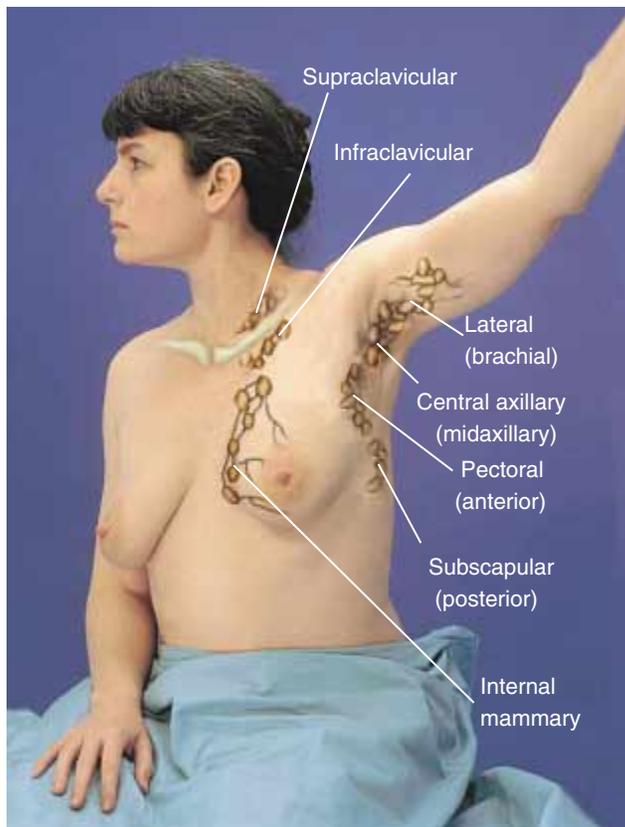

Figure 27-47 Drainage Patterns of the Left Breast

Breast Self-Examination

The nurse should use the time during the assessment to educate the client about BSE and encourage the client to ask questions. Figure 27-51 demonstrates the procedures that the client should perform in conducting a BSE. The American

TABLE 27-16
Assessment of Breasts and Axillae: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>Female Breasts and Axillae: Inspect and Palpate</p> <p>Assist client to a sitting position on the edge of examining table or bed facing you. Uncover to waist.</p> <ol style="list-style-type: none"> Inspect the breasts, areolar areas, nipples, and axillae. Note color, vascularity, thickening or edema, size, symmetry, contour, lesions or masses, and exudates. <ol style="list-style-type: none"> Instruct client to place arms at sides. Proceed with assessment in step 1. Instruct client to raise arms over head (will accentuate any retraction if present). Repeat step 1. Instruct client to press hands into hips (will contract the pectoral muscles and will accentuate any retraction if present). Repeat step 1. Instruct client to lean forward to allow breasts to hang freely away from chest, provide support as necessary; repeat step 1. <i>Breasts and areolae are flesh-colored, the areolar areas and nipples are darker in pigmentation. Moles and nevi and terminal hair may be present on the areolar areas. Superficial vascular patterns are diffuse and symmetrical. Breast on the same side as the dominant arm is usually larger. Nipples should point upward and laterally or outward and downward. Nipples may be inverted from puberty, making breastfeeding difficult. Supernumerary nipples (extra nipples) appear as pigmented moles along the “milk line.” Convex breast without flattening, retractions, or dimpling.</i> Palpate in a sequential manner. Stand in front of the client. Instruct client to place arms at side. Place client’s head in a flexed position (relaxes sternocleidomastoid muscle). <ol style="list-style-type: none"> Assess simultaneously bilateral supraclavicular nodes as demonstrated in Figure 27-49A by placing your fingerpads over client’s clavicles, lateral to tendinous portion of the sternocleidomastoid muscle, and proceed with a rotary motion of the palmar surfaces of index fingers. Probe deeply into scalene triangles to palpate the nodes. Using same rotary motion of palmar surface of index and middle fingers, palpate infraclavicular nodes as shown in Figure 27-49B. <i>Palpable lymph nodes should be less than 1 cm in diameter without additional enlargement of axillary lymph nodes.</i> Palpate breasts: stand at right side facing the client. Instruct client to place arms at side. <ol style="list-style-type: none"> Support the inferior aspect of left breast with nondominant hand. Use palmar surface of dominant hand: <ol style="list-style-type: none"> Begin palpation at outer quadrant of breast. (Small-breasted clients: use dominant hand to palpate tissue against chest wall; pendulous breasts, use both hands to palpate.) 	<ol style="list-style-type: none"> Reddened areas of breasts, areolar areas, nipples, or axillae may be an indication of inflammation, infection, or inflammatory carcinoma. Striae (red or silver-white streaks over the breasts or axillae) are caused by rapid stretching of the skin and damage to the elastic fibers of the dermis (Figure 27-48A). Focal or unilateral superficial vascular patterns result from an increased blood supply and may indicate tumor formation (Figure 27-48B). Thickening or edema of breast tissue or nipple causes enlarged skin pores that give the appearance of an orange rind (peau d’orange), which may be indicative of obstructed lymphatic drainage (e.g., a tumor, Figure 27-48C). Significant differences in size or symmetry of breasts, axillae, areolar areas, or nipples may be indicative of a tumor (Figure 27-48D). Asymmetrical nipple direction or recent nipple inversion, flattening, or depression is indicative of nipple retraction (Figure 27-48E). Thickening of a previously inverted nipple may indicate a tumor. Unilateral reduction of breast tissue or structures may result from trauma or surgery. Scaly, eczema-like nipple erosion or persistent dermatitis of the areola and nipple may indicate Paget’s disease (malignant neoplasm of breast tissue). Nipple discharge in nonpregnant or nonlactating woman may be caused by tranquilizers, oral contraceptives, manual stimulation, infection, or malignant or benign breast disease. Fixed firm, immobile lymph nodes greater than 1 cm in diameter may be indicative of metastasis (spread of tumor cells to other parts of the body). Enlarged, painful, or tender nodes that are matted together may be indicative of a systemic infection or carcinoma. Significant tenderness may indicate mammary duct ectasia (benign, inflamed lactiferous duct). Hard, poorly circumscribed nodules, loss of elasticity, and bloody discharge usually indicate cancer. Augmentation (saline or silicone implants or transposition of chest wall muscles) produces a feeling of being fluid-filled or of firmness throughout the tissue, with inferior suture line scars.

TABLE 27-16 (continued)
Assessment of Breasts and Axillae: Normal and Key Findings

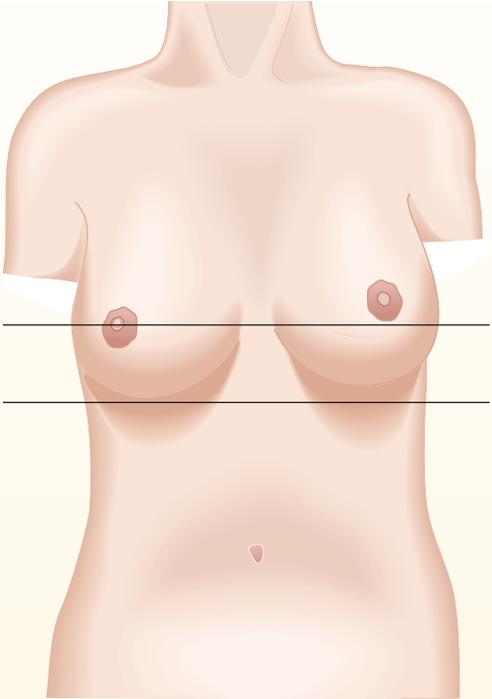

Area of Assessment/Normal Findings	Key Findings
<p>(2) Palpate in a downward, sweeping fashion from outer quadrants to the sternal border of each breast.</p> <p>b. Repeat steps (1) and (2) with client's arms raised over head (enhances retraction). <i>Consistency or elasticity of tissue varies with age, menses or pregnancy, and size: firm elasticity of young breasts and a less-firm granular feel of older breasts. Premenstrual fullness, nodularity, and tenderness are common. Large breasts may have a firm transverse (inframammary) ridge of compressed tissue along the lower edge, which should not be confused with a tumor.</i></p> <p>4. Maintain client in a sitting position. Inspect and palpate the axillary lymph nodes. Note any rash, infection, unusual pigmentations, and nodes.</p> <p>a. Instruct client to take a deep breath and relax shoulders and arms. Use your left hand to adduct client's left arm close to chest wall (relaxes axillary muscles) and place client's left forearm on your right forearm.</p> <p>b. Place fingerpads of your right hand into apex of the client's axilla (behind the pectoral muscles) and gently roll the tissue against the chest wall and axillary muscles, working downward as you locate and palpate the four axillary lymph node groups (Figure 27-50):</p> <ol style="list-style-type: none"> (1) Posterior (subscapular) at anterior edge of latissimus dorsi muscle (2) Central (midaxillary) at thoracic wall of axilla (3) Anterior (pectoral) behind lateral edge of pectoralis major muscle (4) Lateral (brachial) on inner aspect of upper part of humerus close to axillary vein 	<p>4. Rashes may indicate allergic response to deodorant. Redness and inflammation may indicate hidradenitis suppurative (infection of sweat glands). Enlarged, painful, or tender nodes that are matted together may be indicative of a systemic infection or carcinoma. Fixed firm, immobile, irregular lymph nodes greater than 1 cm in diameter are considered suspicious for metastasis.</p>

Figure 27-50 Palpation of the Axillary Lymph Nodes

TABLE 27-16 (continued)
Assessment of Breasts and Axillae: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>c. Repeat steps 4a and b on client's right axilla using same technique with your opposite hand. <i>Painless palpation of 1 or 2 soft, nontender nodes less than 1 cm in diameter without additional enlarged lymph nodes found in other regions.</i></p> <p>5. Place client in a supine position (spreads breast tissue thinly and evenly over chest wall). Stand to right of client and place left arm above head:</p> <p>a. With fingerpads, palpate left breast by compressing mammary tissue gently against chest wall by either concentric circles that migrate from periphery to nipple or in wedge sections from periphery to nipple.</p> <p>b. Proceed with palpation to include tail of Spence, periphery, and areola.</p> <p>c. Compress the nipple to express any discharge. If noted, palpate breast along wedge radii to distinguish from which lobe the discharge is originating.</p> <p>d. Repeat steps a, b, and c on opposite breast. <i>See steps 2 and 3 for normal breast tissue findings on palpation.</i></p>	<p>5. Loss of nipple elasticity or nipple thickening may indicate tumor formation. White-milky discharge in nonpregnant, nonlactating client may indicate nonpuerperal galactorrhea (hormonally induced discharge from lesions of anterior pituitary, or drug induced). Nonmilky discharge from nipple may be indicative of benign or malignant breast disorder.</p>
<p>Male Breasts and Axillae: Inspect and Palpate</p>	
<p>Assist client to a sitting position on the edge of examining table or bed facing you. Uncover to waist.</p>	
<p>1. Inspect the nipple and areola. Note nodules, swelling, or ulcerations. <i>The areolar areas and nipples are darker than surrounding breast tissue. Absence of edema.</i></p> <p>2. Palpate the areola and note nodules. <i>Small breasts, nipple and areola overlie a thin disc of undeveloped breast that is indistinguishable from surrounding tissues. Adolescent boys may develop temporary breast enlargement on one or both sides.</i></p> <p>3. Inspect and palpate the axillae; note any rash, infection, unusual pigmentation, and nodes.</p> <p>a. Assess left axilla, instruct client to relax with left arm down; support client's left wrist with your left hand.</p> <p>b. Cup fingers of your right hand and palpate the apex of the axilla with fingerpads.</p> <p>c. Proceed downward over the surface of ribs and serratus anterior and palpate for central nodes by compressing them against the chest wall.</p> <p>d. Stand behind client (ensuring safety from falling forward) and probe the anterior and posterior axillary fold by pressing against the humerus for pectoral, subscapular, and axillary nodes. If enlarged or tender nodes are detected, palpate for infraclavicular nodes and reexamine supraclavicular nodes.</p> <p>e. Repeat steps 3a–d, using your left hand to examine the client's right axilla. <i>One or two soft, small, nontender central nodes without additional enlarged lymph nodes found in other regions.</i></p>	<p>1. Distorted nipple and areola may indicate cancer.</p> <p>2. A firm disc of glandular enlargement may indicate gynecomastia (glandular enlargement of the male breast). Hard, irregular nodule, frequently fixed to both nipple and underlying tissue, may indicate breast cancer.</p> <p>3. Rashes may indicate a deodorant allergy. Reddened and inflamed area occurs with infected hidradenitis suppurative. Enlarged tender nodes may indicate lymphadenitis from hand or arm infection or axillary metastasis of breast cancer.</p>

Cancer Society (1997) recommends that the following guidelines be used for early detection of breast cancer:

1. BSE performed monthly by women age 20 years and older.
2. From ages 20 to 40, examination every 3 years by a practitioner and yearly after 40 years of age.
3. Regardless of age, women with a family history should have a yearly examination by a practitioner.
4. A baseline mammogram should be performed for women aged 35 to 39. The frequency of diagnostic mammograms is determined by family history and symptoms: yearly for women 35 years of age with a family history and yearly for all women over 40 years of age (American Cancer Society, 1997).

If time permits during the examination, have the client demonstrate to you how she performs the BSE.

Abdomen

Physical examination of the abdomen provides significant data relative to the various functions of the gastrointestinal and genitourinary systems and the abdominal aorta. The order of abdominal assessment is inspection,

auscultation, percussion, and palpation. Auscultation is performed second because palpation and percussion can alter the bowel sounds. The abdominal landmarks used for assessment are presented in Figure 27-52.

Auscultate the four quadrants, as shown in Figure 27-53, when assessing bowel sounds and listening for vascular bruits. Assessment should always begin in the right lower quadrant (RLQ). Table 27-17 presents the specific areas of the abdomen to be examined and the normal and key findings of this assessment.

The nurse should percuss all four quadrants in the same systematic fashion. Visualize each organ in the corresponding quadrant; note when **tympany** (a low-pitched sound of long duration) changes to **dullness** (a high-pitched sound of short duration).

Light palpation of the abdomen is done in all four quadrants, beginning in the RLQ for resistance, tenderness, and rebound tenderness. Deep palpation is not addressed in Table 27-17 because this assessment technique usually requires supervision during the learning process. If any of the abdominal organs (gallbladder, liver, spleen, fecal-filled colon, or flatus-filled cecum) can be palpated, it is abnormal and should be reported to the nursing supervisor.

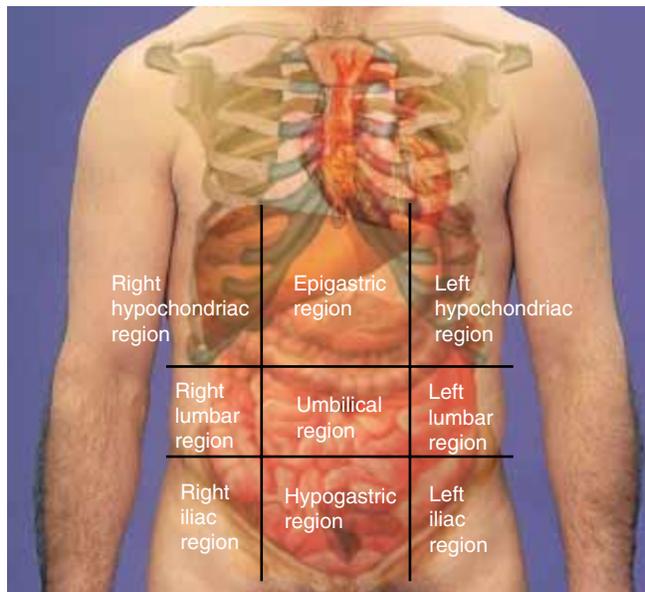

Figure 27-52 Abdominal Landmarks

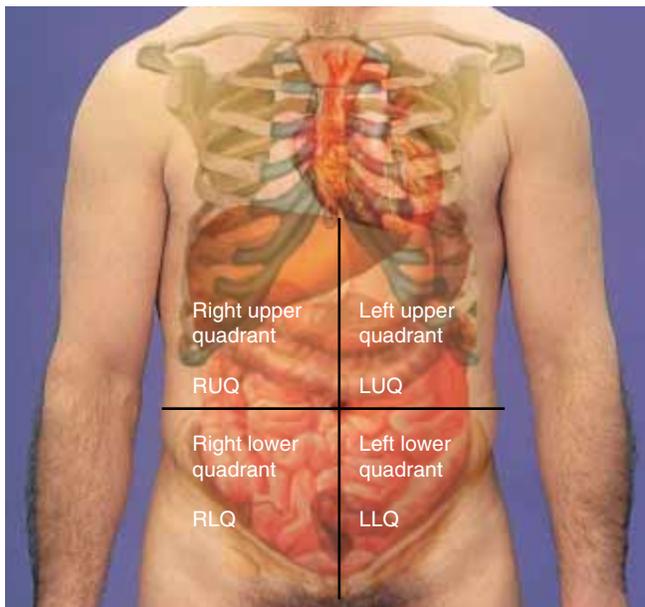

Figure 27-53 Abdominal Quadrants

Female Genitalia and Anus

Assessment of the female genitalia uses the techniques of inspection and palpation for the external genitalia and anus. Table 27-18 presents the specific areas of the female external genitalia and anus to be examined and the normal and key findings of this assessment. Speculum assessment of the internal genitalia is not presented in Table 27-18 because this function is usually within the scope of advanced practice registered nurses or registered nurses prepared in expanded roles.

Assessment of the genitalia may produce feelings of fear, anxiety, indignity, and loss of control in many women. These feelings may be reduced by the sensitivity of the nurse before, during, and after the assessment. The nurse must respect the client's wishes regarding privacy and take

COMMON ABNORMAL LESIONS OF THE EXTERNAL FEMALE GENITALIA

- **Chancere:** a reddish, round ulcer with a depressed center and raised edges that appears during the primary phase of syphilis at the site where the treponema enters the body. It lasts for 4 weeks, then disappears.
- **Condyloma acuminatum:** white, dry, painless growth (wart) that has a narrow base that is caused by the human papillomavirus.
- **Condylomata lata:** raised, round, wartlike plaque with a moist surface covered by a gray exudate that appears during the secondary stage of syphilis.
- **Herpes simplex:** small, red vesicles that fuse together to form a large ulcer that may be painful and itchy.

into consideration cultural issues concerning this aspect of health assessment. For example, many Middle Eastern women will remain veiled during an assessment. By using techniques to diminish client discomfort and by empowering the client through education and participation in the assessment process, the nurse offers a path for the client in the management of her own health care. Most states require that a male nurse be accompanied by a female nurse or assistant during a gynecologic examination.

Male Genitalia, Anus, and Rectum

Assessment of the male genitalia includes the essential organs (testes and male gonads), the accessory organs (seminal vesicles and bulbourethral glands), several ducts (epididymis, ductus [vas] deferens, ejaculatory), and the urethra. The supporting structures include the scrotum, penis, and spermatic cord. The anorectal examination allows for assessment of both the rectum and prostate gland. Table 27-19 presents the specific areas of the male genitalia, anus, and rectum to be examined and the normal and key findings of this assessment.

Female nurses may feel anxious about examining the male genitalia. If a nurse feels uncomfortable about this assessment, she needs to work through her feelings about sexuality and reproduction before she can talk comfortably with the client.

Some health care agencies do not allow nurses to perform a digital examination of the anus and rectum. Nurses must check the agency's policies relative to this part of the physical examination. Nursing students should have a qualified registered nurse with them the first time they perform a digital examination. After this procedure has been done, the color of feces on your gloved finger should be noted. Bright red or tarry, black stools are indicative of bleeding and should be reported. Usually a sample of the feces is tested for occult blood.

Middle-aged white men are at risk for testicular cancer; early detection and treatment decrease

TABLE 27-17
Assessment of Abdomen: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>Abdomen: Inspect, Auscultate, Percuss, and Palpate Place client in a supine position with knees flexed over a pillow, hands at sides or across chest. Drape the client from xiphoid process to symphysis pubis to expose the abdomen.</p> <ol style="list-style-type: none"> Stand at right side of client. <ol style="list-style-type: none"> Inspect abdomen from rib margin to pubic bone. Note contour and symmetry (observing for peristalsis, pulsations, scars, striae, or masses). Inspect umbilicus for contour, location, signs of inflammation, or hernia. Observe the abdomen for smooth, even respiratory movement. Observe for surface motion (visible peristalsis). Inspect epigastric area for pulsations. <i>Contour is flat or rounded and bilaterally symmetrical. Umbilicus is depressed and beneath the abdominal surface. Abdomen rises with inspirations and falls with expirations, free from respiratory retractions. Visible peristalsis slowly traverses the abdomen in a slanting downward movement as observed in thin clients. Pulsations of the abdominal aorta are visible in the epigastric area in thin clients.</i> Auscultate the four abdominal quadrants (see Figure 27-53) using the diaphragm of the stethoscope for bowel sounds (high-pitched). <ol style="list-style-type: none"> Begin by placing the diaphragm on the right lower quadrant (RLQ). Listen for a full minute to the frequency and character of the bowel sounds. Repeat step a, proceeding in sequence to right upper quadrant (RUQ), left upper quadrant (LUQ), and left lower quadrant (LLQ). Listen at least 5 minutes before concluding the absence of bowel sounds. <i>High-pitched sounds, heard every 5 to 15 seconds as intermittent gurgling sounds in all four quadrants as a result of air and fluid movement in the gastrointestinal tract. Bowel sounds should always be heard at the ileocecal valve area.</i> Auscultate with bell of stethoscope over the aorta, epigastric area, renal arteries, and femoral arteries. Note bruits over each area. <i>Free from audible bruits.</i> Percuss all four quadrants in a systematic fashion (Figure 27-54). Begin percussion in RLQ, move upward to RUQ, cross over to LUQ, and down to LLQ. Note when tympany changes to dullness. <i>Tympany is heard because of air in the stomach and intestines. Dullness is heard over organs (e.g., the liver).</i> Perform light palpation. Never palpate over areas where bruits are auscultated. <ol style="list-style-type: none"> Instruct client to cough. If client experiences a sharp twinge of pain in a quadrant, palpate that area last. With client's hands and forearms on a horizontal plane (see Figure 27-15), use fingerpads to depress the abdominal wall 1 cm in all four quadrants. Begin palpation in RLQ, move upward to RUQ, cross over to LUQ, and down to LLQ. Note texture and consistency of underlying tissue. <i>Should feel smooth with consistent softness.</i> 	<p>Promotes relaxation of the abdominal muscles.</p> <ol style="list-style-type: none"> A convex symmetrical profile reveals either a protuberant abdomen (results of poor muscle tone from inadequate exercise or obesity) or distension (taut stretching of skin across abdominal wall). Asymmetry may indicate a mass, bowel obstruction, enlargement of abdominal organs, or scoliosis. Umbilicus bulging may indicate a hernia. Old scars are flat with a shiny appearance, blending with client's pigmentation; new scars are raised and reddened. Atrophic lines or streaks reveal lineae albicantes (striae) that occur with tumors, obesity, ascites, and pregnancy. Engorged or dilated veins around the umbilicus are associated with circulatory obstruction of superior or inferior vena cava. Uneven respiratory movement with retractions may indicate appendicitis. Strong peristaltic movement may indicate intestinal obstruction. Marked pulsations in epigastric area may indicate an aortic aneurysm. Hypoactive or diminished bowel sounds are soft and low and widely separated so that only one or two are heard in a 2-minute interval. Hypoactive is normal the first few hours after general anesthesia. Hypoactive sounds may indicate decreased motility of the bowel, such as occurs with peritoneal irritation or paralytic ileus. Absent bowel sounds (none heard for 3–5 minutes) may signal paralytic ileus, peritonitis, or an obstruction. Hyperactive (loud, audible, gurgling sounds similar to stomach growling; sounds also called borborygmi) may occur with diarrhea or hunger. Rushed, high-pitched or tingling sounds suggest air or fluid under pressure; this may occur in the early stages of an intestinal blockage when heard in the portion of the bowel that precedes the obstruction (Kirton, 1997). A bruit over an abdominal vessel reveals turbulent blood flow suggestive of an aortic aneurysm or partial obstruction (e.g., renal or femoral stenosis). Dullness over the stomach or intestines may indicate a mass or tumor; ascites (excessive fluid accumulation in the abdominal cavity) or full intestines. Tenderness and increased skin temperature may indicate inflammation. Large masses may be due to tumors, feces, or enlarged organs.

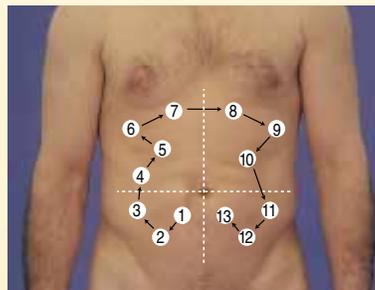

Figure 27-54 Directional Pattern of Abdominal Percussion

TABLE 27-18
Assessment of Female External Genitalia and Anus: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>Female External Genitalia and Anus: Inspect and Palpate</p> <p>Place client in lithotomy position with knees flexed perpendicular to bed. Instruct client to relax thighs to allow each leg to abduct to side. The client's head may be elevated for comfort. Place drape over client's torso and thighs to expose external genitalia. Don gloves.</p> <ol style="list-style-type: none"> 1. Inspect the mons pubis and vulva. Touch the thigh before advancing to the perineum (extremely sensitive and tender). <ol style="list-style-type: none"> a. Observe skin coloration and condition of mons pubis and vulva. b. Separate the labia majora with thumb and index finger of dominant hand. Note color, lesions, or trauma. c. Palpate the labium between thumb and index finger of dominant hand for swelling, induration, pain, or discharge from a Bartholin gland. <i>Skin over the mons pubis is clear except for nevi and hair distribution. The labia majora and minora are symmetrical, with a smooth to wrinkled, unbroken, slightly pigmented skin surface, free from ecchymosis, excoriation, nodules, swelling, rash, and lesions. Sebaceous cysts (nontender, yellow-colored nodules less than 1 cm) may be present.</i> 2. Inspect the clitoris using the dominant thumb and index finger: separate the labia minora laterally to expose the prepuce of the clitoris. Note the size and condition. <i>Approximately 2 cm long and 0.5 cm in diameter; free from lesions.</i> 3. Using dominant thumb and index finger, separate the labia minora laterally to expose the urethral meatus to inspect the shape, color, and size. Avoid touching the meatus because touching it may cause pain and urethral spasm. <i>Midline, slit-like opening, free of discharge, swelling, or redness; about the size of a pea.</i> 4. Keeping the labia minora retracted laterally, inspect the vaginal introitus: instruct the client to bear down while you note patency and bulging. <i>Introitus mucosa is pink and moist with a clear to white discharge that contains white clumps of epithelial cells. Free of foul odor and bulging.</i> 5. Inspect the perineum and anus. Note texture and color of perineum and color and shape of anus. <i>Perineum is smooth, intact, and slightly darkened. The anus is dark pink to brown and puckered, usually with skin tags.</i> 	<p>If client has difficulty assuming the lithotomy position, place in a left lateral or Sims' position with buttocks near the edge of bed with right knee flexed.</p> <ol style="list-style-type: none"> 1. Ecchymosis over mons pubis or labia may be due to blunt accidental trauma or intentional abuse. Rashes over the mons pubis or labia have multiple origins (e.g., contact dermatitis or infestations). Labial swelling may be due to a hematoma, Bartholin's cyst, or obstruction of lymphatic system. Broken areas of the skin may be due to ulcerations or abrasions secondary to infections or trauma (see the display on common abnormal lesions of the external female genitalia). A painless mass with pruritus or a cauliflower-like growth is suspicious of malignancy. Venous prominence (varicose veins) of the labia may be due to a congenital predisposition, prolonged standing, or pregnancy. 2. Enlarged (hypertrophy) clitoris may indicate female pseudohermaphroditism caused by androgen excess. The clitoris is the common site for a chancre lesion. 3. Discharge of any color indicates a urinary tract infection. Swelling or redness around the urethral meatus indicates a possible infection of the Skene's glands, urethral caruncle or carcinoma, or prolapse of the urethral mucosa. 4. Pale color and dryness reveal atrophy from topical steroids or aging. Foul-smelling discharge of any color may indicate vaginitis or cervicitis. External tear of the vaginal introitus may indicate trauma from sexual activity or abuse. Bulging of the anterior wall may indicate a cystocele (protrusion of the urinary bladder through the wall of the vagina) due to weakness of supporting tissues and ligaments. 5. Fissure or tear results from area trauma, abscess, or unhealed episiotomy. Venous prominence of anal area indicates external hemorrhoids (varicose dilatation of a vein of the inferior hemorrhoidal plexus covered with modified anal skin).

RESEARCH FOCUS

Title of Study

“Something to Talk About: Sexual Risk Communication Between Young Women and Their Partners”

Author

Hutchinson, M. K.

Purpose

To describe sexual risk communication between young women and their male sexual partners, and examine its impact on women’s perceptions of sexual risks.

Methods

The study and results reported were part of a larger descriptive, retrospective study in which data were collected from young women and their male partners via telephone interviews. Participants of this study included 93 unmarried, sexually active heterosexual women between the ages of 17 and 26 years, and 82 of their male sexual partners. The sample was predominantly white; all other ethnic groups were underrepresented.

Findings

Nearly all of the women described their partners as “no risk” or “low risk,” despite the fact that nearly half never discussed their partner’s sexual risk histories. Women gave three primary reasons why sexual risk was not discussed: did not know the partner well enough/too embarrassed to ask; “knew” the partner was low risk/no need to discuss it; and did not think of it.

Implications

Nurses should adopt and promote the premise that all sexually active women are at some risk for sexually transmitted diseases (STDs), including human immunodeficiency virus (HIV). Furthermore, sexually active women should be advised to distinguish between what they think they know about their partners and what they actually know. As client advocates, nurses should help women recognize the need to protect themselves from STD/HIV.

Hutchinson, M. K. (1998). Something to talk about: Sexual risk communication between young women and their partners. *Journal of Obstetric, Gynecologic, and Neonatal Nursing*, 27(2), 127–133.

COMMON ABNORMAL LESIONS OF THE EXTERNAL MALE GENITALIA

- **Candidiasis:** multiple, discrete, flat pustules with scaling and surrounding edema that are superficial mycotic infections of moist cutaneous sites associated with diabetes mellitus, deficiencies in systemic immunity, and antibiotic therapy
- **Chancroid:** tender, ulcerated, exudative, papular lesion with an erythematous halo surrounding edema and a friable base that results from small breaks in epidermal tissue and inoculation of *Hemophilus ducreyi*
- **Tinea cruris:** erythematous plaques with scaling, papular, lesions with sharp margins caused by fungal infections of the groin

Note: Chancre, condyloma acuminatum, and herpes simplex are common abnormal lesions of the external male genitalia. These lesions are described in the display for common abnormal lesions of the external female genitalia.

THINK ABOUT IT

Examination of the Male Genitalia

What would you do if a client, who is the same age as you, had an erection during the examination? How would you feel?

NURSING CHECKLIST

Testicular Self-examination

- Ask the client if monthly TSE is performed.
- Explain to the client that monthly TSE will allow for early detection of testicular cancer.
- Review the anatomy of the scrotum by describing that the testicles are ovoid structures that feel firm and rubbery and that the epididymis, located behind the testicles, is softer and feels rope-like.
- Instruct the client to perform the examination during a warm shower using the thumb and first two fingers to gently feel each testicle and the epididymis. The testicles should move freely within the scrotum and have a smooth surface; the epididymis should be softer.
- Instruct the client to report any findings that deviate from normal such as lumps and nodules, especially if they are nonmobile.

(From Estes, M. E. Z. [2002]. *Health assessment and physical examination*. Albany, NY: Delmar Publishers.)

mortality rates. Monthly testicular self-examination (TSE) allows for early detection of testicular cancer. The nurse should teach the client during the scrotal examination about TSE (see the accompanying Teaching Checklist, “Testicular Self-Examination”).

TABLE 27-19
Assessment of Male Genitalia, Anus, and Rectum: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>Male External Genitalia and Anus: Inspect and Palpate: Place client supine, with legs spread slightly, or in standing position. Don gloves.</p> <ol style="list-style-type: none"> 1. Assess the glans penis, urethral meatus, and scrotum. <ol style="list-style-type: none"> a. Instruct uncircumcised clients to retract the foreskin. Inspect the anterior and posterior surfaces by lifting the penis. Note lesions, swelling, or inflammation (client can replace the foreskin). b. Palpate the shaft of the penis using thumb and first two fingers to assess the entire length of penis. Note pulsations, tenderness, swelling, masses, or plaques. c. Inspect the urethral meatus. Note location and color, and observe for discharge (culture any discharge). d. Inspect the scrotum by displacing the penis to one side to assess the scrotal skin. Lift up the posterior side. Note lesions, inflammation, and swelling. e. Begin scrotal palpation by gently palpating the right testicle between your thumb and first two fingers. Proceed to the epididymis, then to the spermatic cord from the epididymis, and to the external ring, noting consistency, presence of tenderness or masses. Repeat on left side. f. Teach testicular self-examination. <i>Foreskin retracts easily. Glans penis varies in size and shape. A small amount of smegma (white “cottage cheese” substance) may be present. Pulsations are present on the dorsal sides of the penis. The meatus is centrally located and pink. Scrotal skin appears rugated and thin and hugs the testicles firmly in the young male and becomes elongated and flaccid in the elderly. The left scrotal sac is lower than the right. Testicles are sensitive to pressure, firm, ovoid, smooth, and equal in size bilaterally. The epididymis should be distinguishable from the testicle, and the spermatic cord feels smooth and round.</i> 	<p>If the client has difficulty in the supine position, elevate the head of the bed.</p> <ol style="list-style-type: none"> 1. a. Uncircumcised men can develop phimosis (foreskin cannot be retracted over the glans penis). Paraphimosis occurs when retracted foreskin causes proximal constriction to glans and the penis distal to the foreskin becomes swollen and gangrenous. Priapism is a continuous and pathologic erection of the penis. b. Absent pulsations indicate vascular insufficiency associated with systemic disease, localized trauma, or disease that interrupts blood flow. See the display on common abnormal lesions of the external male genitalia. c. Meatus that opens dorsally on penis (epispadias) occurs mainly with chordee (a congenital defect that results in ventral curvature of penis). Congenital defects, epispadias, and hypospadias (congenital defect in which the meatus opens on the underside of the penis) cause displacement of the meatus. d. and e. Painless swelling that is unilateral with a hard, fixed nodule may indicate a cancerous mass. An extremely sensitive, enlarged testicle may indicate a testicular torsion (twisting). Swollen, indurated, tender epididymis indicates epididymitis (inflammation). Warm scrotal skin, tenderness, and an acute onset of swelling indicates orchitis (inflammation of the testes) that is associated with mumps. Enlarged, reddened scrotum with taut skin and nonpalpable contents is scrotal edema. A large pear-sized mass in the scrotum (hydrocele) causes the skin to stretch with a shiny, erythematous appearance from the accumulation of fluid between the two layers of the tunica vaginalis. A bluish discoloration of the scrotal mass that disappears with supine positioning is a varicocele. Undescended testicle (cryptorchidism) is usually unilateral. The testicle remains in the inguinal canal. f. Provides for early detection and treatment of testicular cancer.

TABLE 27-19 (continued)
Assessment of Male Genitalia, Anus, and Rectum: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>2. Inspect and palpate the inguinal and femoral areas with client standing.</p> <ol style="list-style-type: none"> Instruct the client to strain down. Observe for bulges. Begin palpation on the client's right side. <ol style="list-style-type: none"> Using your right hand, invaginate (telescope) loose scrotal skin with index finger. Follow spermatic cord upward to opening of external inguinal ring. Ask client to cough or strain down. If mass is present, it will touch your finger. Repeat palpation on client's left side with your left hand. <i>Inguinal area is smooth, free from swelling or bulges.</i> <p>3. Examine the anal and rectal area with the client in a side-lying position. Spread the buttocks with your nondominant hand.</p> <ol style="list-style-type: none"> Inspect sacrococcygeal and perineal areas. Observe for excoriation, rashes, inflammation, and nodes. Palpate any nodules for tenderness. Lubricate gloved index finger of dominant hand. Instruct client to strain down while inspecting anus for hemorrhoids, fissures, excoriation, and growths. As client strains down, place pad of index finger over anus. As sphincter relaxes, insert finger pad into the anal canal, pointing toward umbilicus. Note sphincter tone, tenderness, or nodules. Insert finger further and palpate as much of rectal wall as possible in sequence (right lateral, posterior, left lateral surfaces), noting nodules, irregularities, or undue tenderness. Palpate surface of prostate gland (lateral lobes and median sulcus). Extend fingerpad above prostate gland and instruct client to strain down. Note size, shape, consistency, and mobility of prostate. Withdraw finger and wipe anal area. <i>Perineum and sacrococcygeal area is smooth, intact, and free of feces and mucus. Anal mucosa is deeply pigmented, coarse, moist, and hairless. Anal opening should be closed. Rectal sphincter has good tone, and rectal wall is smooth. Prostate gland is small (about the size of a chestnut), smooth, mobile, and median sulcus is palpable.</i> 	<p>2. Oval swelling at the pubic tubercle just above the inguinal ligament indicates an inguinal hernia (portions of the bowel or omentum protrude through the external inguinal ring). A mass medial to the femoral vessels and inferior to the inguinal ligament is indicative of a femoral hernia (portions of the bowel or omentum protrude through the femoral wall).</p> <p>3. Fissure or tear results from trauma or abscess. Venous prominence of anal area indicates external hemorrhoids. A soft, nontender, enlarged prostate may reveal benign prostatic hypertrophy that occurs with the loss of androgens (e.g., as with aging). Firm, hard, or indurated nodules on prostate may indicate acinar adenocarcinoma. A firm, tender, or fluctuant mass may reveal a prostatic abscess that has a high occurrence with diabetes mellitus clients and is caused mainly by <i>Escherichia coli</i>. A tender, warm prostate may indicate acute bacterial prostatitis associated with a bladder infection (e.g., <i>E. coli</i>).</p>

(From Estes, M. E. Z. [2002]. *Health assessment and physical examination*. Albany, NY: Delmar Publishers.)

Musculoskeletal System

The musculoskeletal system provides clients with the ability to maintain and change their position in response to both internal and external stimuli. Muscle tone and bone strength allow the client to maintain an upright and erect position. The musculoskeletal system consists of bones, joints, skeletal muscles, and supportive connective tissue (Figure 27-55).

Inspection, palpation, range of motion (ROM), and muscle testing are performed on the major skeletal muscles and joints by comparing paired muscles and joints. Table 27-20 presents the specific areas of the musculoskeletal system to be examined and the normal and key findings of this assessment. This table is not meant to be a complete examination to assess complaints or musculoskeletal disease.

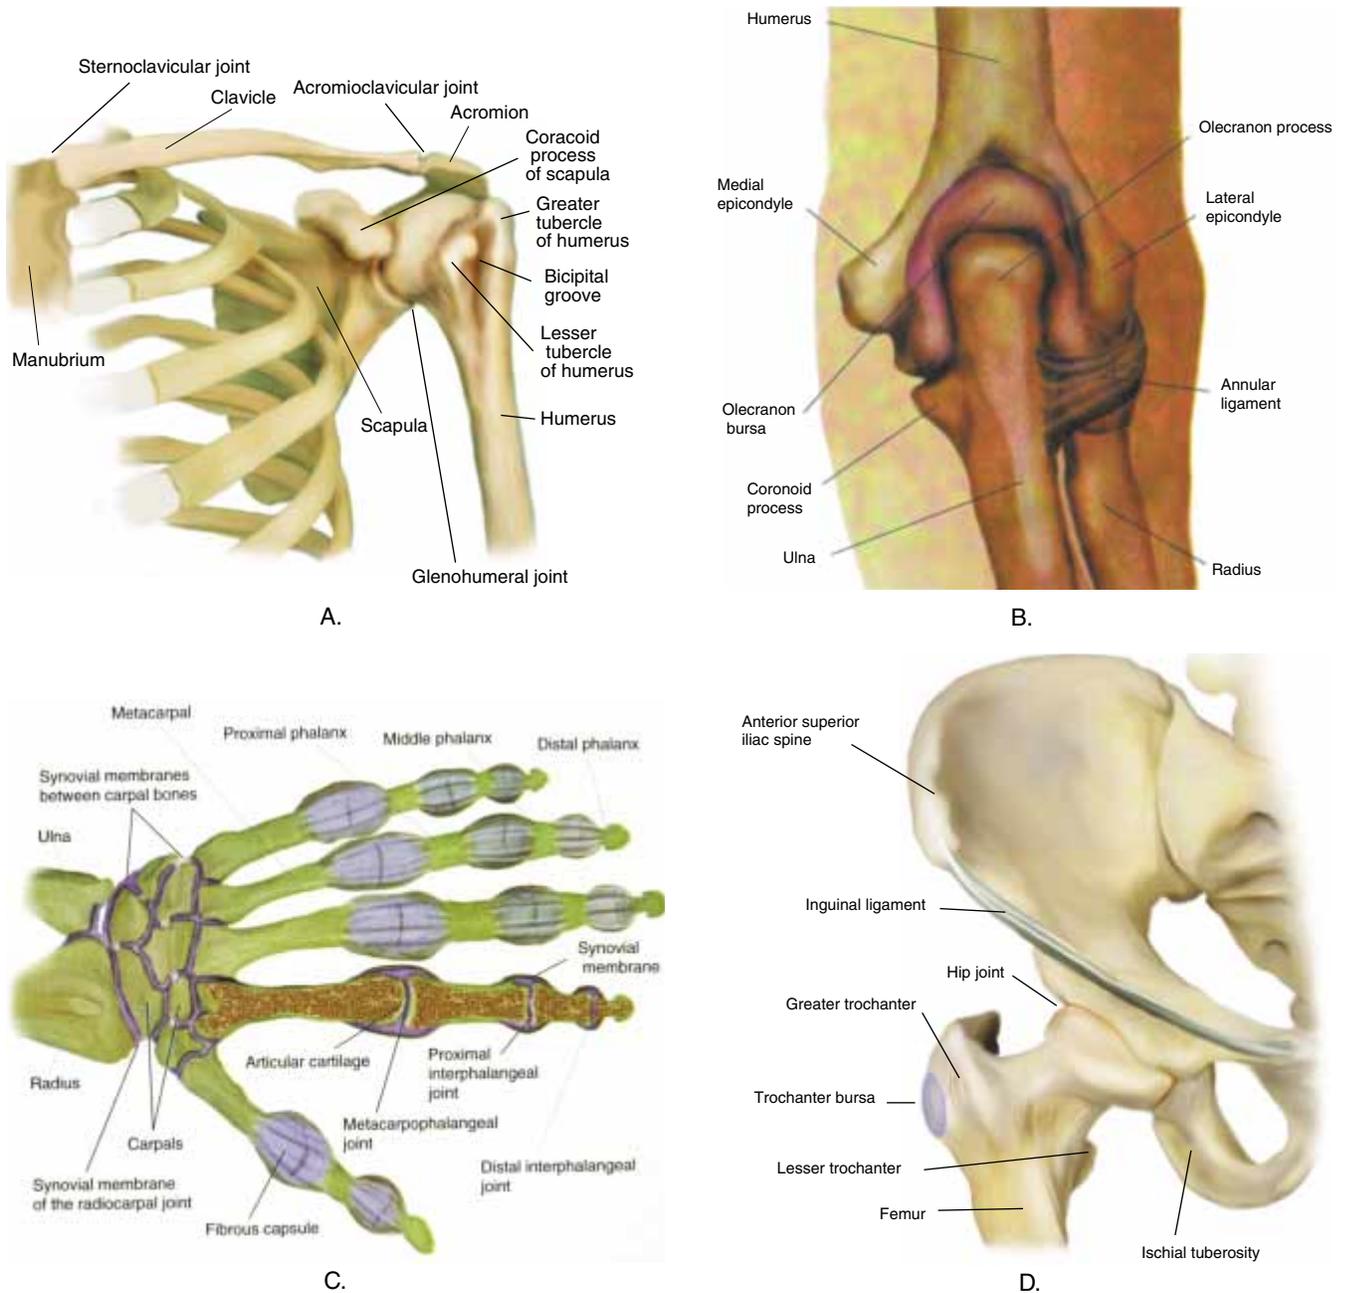

Figure 27-55 The Musculoskeletal System: A. Shoulder; B. Elbow; C. Wrist and Hand; D. Hip.

A complete musculoskeletal examination requires the full assessment of range of motion. A **goniometer** is a protractor with two movable arms (Figure 27-57) used to measure the angle of a skeletal joint during range of motion.

Skeletal muscles provide contour for the body and promote joint mobility. Muscle contour is affected by the exercise and activity patterns of the client. **Hypertrophy** refers to an increase in muscle size and shape due to an increase in muscle fiber. **Atrophy** refers to thin, flabby muscles due to a reduction in muscle size and shape. Increased muscle tone (**hypertonicity**) causes resistance with joint movement. **Hypotonicity** refers to a flabby muscle with poor tone.

Joints are normally nontender and move freely. **Arthritis** is an inflammation of the joints that causes

pain and swelling. Degenerative joint disease or **osteoarthritis** (the most common type of degenerative arthritis, in which the joints become stiff and tender to touch) causes the joints to undergo degenerative changes. ROM and activities of daily living are compromised by the loss of joint mobility. Crepitus is often palpated in joints affected by degenerative joint disease.

Neurologic System

A complete neurologic examination includes an assessment of mental status, sensation, cranial nerves, motor functioning, cerebellar function, and reflexes. See Chapter 36 for a complete discussion of cranial nerve

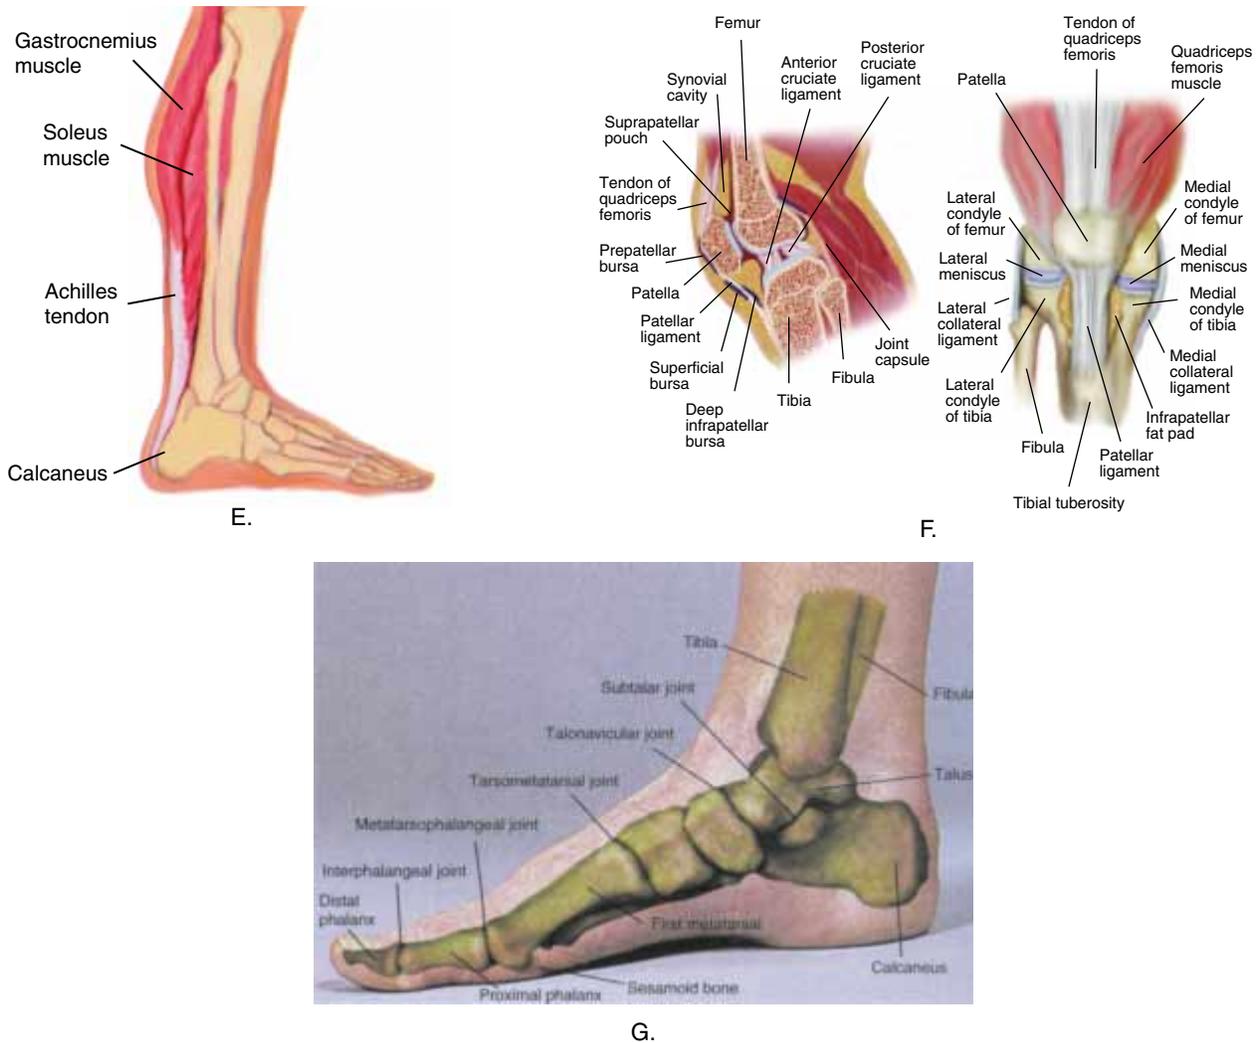

Figure 27-55 (continued) The Musculoskeletal System: E. Leg; F. Knee; G. Ankle and Foot.

TABLE 27-20
Assessment of Musculoskeletal System: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>Inspect and Palpate</p> <p>Place client in a sitting position to provide comfort.</p> <p>1. Assess the head and neck.</p> <p>a. Ask client to open mouth as you apply light pressure with fingerpads of dominant hand 2–3 inches away from the temporomandibular joint. Listen for crepitation and note any limitation of range of motion of jaw.</p> <p>b. Inspect neck, noting symmetry, deformities, and abnormal posture.</p> <p>c. Palpate cervical spine, paravertebral muscles, and trapezii for tenderness.</p> <p>d. Assess ROM of neck. <i>A click occurs when mouth opens. Lower jaw protrudes without deviating to the side and moves 1 to 2 cm with lateral movement. Head and neck are erect and straight. Alignment is straight in the cervical spine. Movements done with ease.</i></p>	<p>1. a. Tenderness, limited range of motion (ROM), and crepitus reveal temporomandibular joint dysfunction that occurs secondary to arthritis, malocclusion, dislocation, poorly fitting dentures, and myofascial dysfunction.</p> <p>b. Lateral tilting of the head and neck indicates degenerative joint disease.</p> <p>c. Aching pain and tightness of muscles may be associated with chronic postural strain, tension, or depression.</p> <p>d. Pain and limited movement may be caused by herniation of a cervical intervertebral disc, arthritis, or degenerative joint disease.</p>

(continues)

TABLE 27-20 (continued)
Assessment of Musculoskeletal System: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>2. Assess hands and wrists.</p> <p>a. Inspect for swelling, redness, nodules, deformity, or muscular atrophy.</p> <p>b. Test ROM.</p> <p>c. Assess strength of hand grasp.</p> <p>(1) Place your dominant index and middle fingers in the client's dominant hand and your nondominant index and middle fingers in the client's nondominant hand.</p> <p>(2) Instruct the client to squeeze your fingers as hard as possible.</p> <p>(3) Release grasp on client's hands.</p> <p>d. Palpate medial and lateral aspects of each interphalangeal joint between your thumb and index finger. Note tenderness, bony enlargement, swelling, or bogginess.</p> <p>e. Use your thumb to palpate the metacarpophalangeal joints, just distal to and on each side of knuckles.</p> <p>f. Palpate each wrist joint with your fingers underneath the client's hands and your thumbs on the dorsum of client's hand. <i>Move your thumbs from side to side. Fingers, hands, and wrists are straight. Joints are smooth, movement is easy, and strength is felt on grasp.</i></p> <p>3. Assess elbows.</p> <p>a. Support the client's forearm, elbow partially flexed:</p> <p>(1) Inspect and palpate each elbow, extensor surface of ulna, and olecranon process. Note tenderness, swelling, or nodules.</p> <p>(2) Palpate both sides of olecranon groove for tenderness or swelling.</p> <p>(3) Palpate the lateral epicondyle for tenderness.</p> <p>b. Assess ROM. <i>Elbows are at the same height and symmetrical in appearance. Movements should be done with ease.</i></p> <p>4. Assess shoulders.</p> <p>a. Inspect anterior shoulder and girdle for symmetry. Note swelling, atrophy, or deformity.</p> <p>b. Inspect and palpate scapulae and related muscles posteriorly.</p> <p>c. Palpate the following areas on each side and note tenderness:</p> <p>(1) Sternoclavicular joint</p> <p>(2) Acromioclavicular joint</p> <p>(3) Shoulder</p> <p>(4) Biceps groove</p> <p>(5) Greater tubercle of humerus</p> <p>d. Assess ROM. <i>Shoulders are equal in height, and movements should be done with ease.</i></p>	<p>2. a. Hard, painless nodules on the dorsolateral aspects of the distal interphalangeal joints (Heberden's nodes) are the main sign of degenerative joint disease or osteoarthritis.</p> <p>b. Flexion contracture that affects the little, ring, and middle fingers (Dupuytren's contracture) may limit full extension of the fingers. Limited movement of all fingers is associated with arthritis.</p> <p>c. Weakness of opposition of thumb and ipsilateral finger against resistance indicates median nerve disorders.</p> <p>d. Enlargement of interphalangeal distal joints is associated with degenerative joint disease. Bony enlargement with tender, swollen interphalangeal proximal joints is associated with acute rheumatoid arthritis.</p> <p>e. Painful, swollen, and boggy metacarpophalangeal joints, with ulnar deviation of deformed fingers, are associated with chronic rheumatoid arthritis.</p> <p>f. Bilateral swelling of wrist suggests rheumatoid arthritis. Round, nontender swelling near the tendon sheaths or joint capsules that is more prominent on the dorsum of the hand and wrist when flexed is a ganglia (cystic growth).</p> <p>3. Painful, asymmetrical elbow with forearm out of alignment is associated with a dislocation or subluxation of the elbow. Red, warm, swollen, and tender olecranon process indicates arthritis. A boggy, soft, or fluctuant swelling with tenderness in the grooves between the olecranon process and the epicondyles on either side indicates a synovial inflammation. Localized tenderness and pain during ROM indicate epicondylitis (inflammation of muscle tissue surrounding elbow) that results from repetitive motion (e.g., swinging a racquet, tennis elbow).</p> <p>4. Increased outward prominence of scapula is indicative of a serratus anterior muscle injury or weakness. Painful, decreased movement with swelling and asymmetry are associated with degenerative joint disease, arthritis, or injury, which may trigger bursitis (an inflammation of the bursa). Pain with swelling at the distal end of clavicle is associated with an acromioclavicular joint separation (separated shoulder). Shoulder subluxation and dislocation are common athletic injuries that result when the glenohumeral joint pops out of the socket.</p>

(continues)

TABLE 27-20 (continued)
Assessment of Musculoskeletal System: Normal and Key Findings

Area of Assessment/Normal Findings	Key Findings
<p>5. Assess feet and ankles with client in a supine position.</p> <ol style="list-style-type: none"> Inspect for swelling, calluses, corns, nodules, or deformity. Palpate anterior surface of ankle joint. Note tenderness, bogginess, or swelling. Palpate the Achilles tendon for nodules. Palpate metatarsophalangeal joints and metatarsal head in sole of each foot, compressing joint between thumb and finger for tenderness. Assess ROM. <i>Foot is in alignment with lower leg.</i> <p>6. Assess knees.</p> <ol style="list-style-type: none"> Inspect for contour, alignment, and deformity; atrophy of quadriceps muscles; and loss of normal hollows around patella. Palpate suprapatellar pouch on each side of quadriceps. Note tenderness, thickening, or bogginess. Compress suprapatellar pouch. Palpate each side of patella over joint space and near femoral epicondyles for structural abnormalities, tenderness, thickening, or edema. <i>Knees are in alignment with each other and do not protrude medially or laterally.</i> <p>7. Assess hips and spine with the client in a standing position.</p> <ol style="list-style-type: none"> Inspect for symmetry of the iliac crests and buttocks. Observe the client's posture and gait. Note position of trunk in relation to legs; foot drop; shuffling or limp; cervical, thoracic, and lumbar curves. Place client in supine position and palpate the hips (Figure 27-56). Test ROM. <i>Iliac crests and buttocks are symmetrical with each other. Stance is upright, with parallel alignment of hips and shoulders. Gait is natural, with arms swinging freely at sides and head leading the body. Spine has a cervical concavity, thoracic convexity, and lumbar concavity.</i> 	<p>5. Nontender thickening of skin on sole of foot is a callus, which is caused by pressure. Painful, conical thickening of skin over bony prominences is a corn (also caused by pressure). Painful, swollen, red, and warm first metatarsophalangeal joint usually indicates acute gouty arthritis. Ankle pain, decreased ROM, and crepitation occur with a sprain or fracture secondary to injury.</p> <p>6. Bilateral inward deviation toward midline of the knees is genu valgum (knock knees). Bilateral outward deviation away from the midline is genu varum (bow legs). Thickening, bogginess, or swelling indicates synovial effusion (excessive synovial joint fluid).</p> <p>7. Unequal iliac crests and lateral curvature of the thoracic or lumbar vertebrae is scoliosis. The chin tilted downward onto the chest, with abdominal protrusion, indicates kyphosis (excessive convexity of the thoracic spine). Excessive concavity of the lumbar spine is lordosis.</p>

Figure 27-56 Palpation of the Hips

(From Estes, M. E. Z. [2002]. *Health assessment and physical examination*. Albany, NY: Delmar Publishers.)

function. Clients with minor or intermittent neurologic symptoms may require only a screening assessment, as outlined in Table 27-21.

Mental Status

The mental status assessment should be done during the interview and health history. A complete assessment should be performed if the client exhibits any signs of neurologic deficit (see the display).

Physical Appearance and Behavior

Pertinent information relative to mental status is assessed by observing the client's posture and movements, dress and grooming, facial expressions, and

affect. The nurse should observe the client's ability to wait patiently. Note the gait and posture (relaxed, slumped, or stiff).

The client should appear relaxed but with the appropriate amount of concern regarding the assessment. The client should exhibit an erect posture, smooth gait, and symmetrical body movements.

Dress and grooming are influenced by the client's economic status, age, home situation, and cultural background. Information obtained from the health history assists the nurse in determining appropriate dress and grooming for each client. It is also helpful to ask clients directly about their grooming routines and clothing choices.

Facial expressions should be symmetric and appropriate to the content of the conversation. Facial expres-

Figure 27-57 Use of Goniometer to Measure Joint ROM

NEUROLOGIC DEFICITS REQUIRING A COMPLETE ASSESSMENT

- Known brain lesion (stroke, tumors, trauma)
- Suspected brain lesion (new seizures, headaches, behavioral changes)
- Memory deficits
- Confusion
- Vague behavioral complaints (by significant others if client unaware or denies behavioral changes)
- Aphasia
- Irritability
- Emotional lability
- Change in level of consciousness

sions may demonstrate anxiety or depression. The nurse should observe the client's verbal and nonverbal behaviors and note if the client's affect appears labile, blunted, or flat.

TABLE 27-21
Neurologic Screening Assessment

Area of Assessment	Assessment Parameter	Outcome Findings
Mental status/level of consciousness	Note general appearance, affect, speech content, memory, logic, judgment, and speech patterns during the health history. Perform the Glasgow Coma Scale (GCS) (see Chapter 36) with motor assessment component and pupil assessment.	If any abnormalities are evident, perform a full mental status assessment. If the GCS < 15, perform a full assessment of mental status. If motor assessment is abnormal or asymmetrical, perform a complete motor and sensory assessment.
Sensation	Assess pain and vibration in the hands and feet with light touch on the limbs.	If deficits are identified, perform a complete sensory assessment.
Cranial nerves (CNs)	Assess CN II, III, IV, VI: visual acuity, gross fields, funduscopy, pupillary reactions, and extraocular movements. Assess CN VII, IX, X, XII: facial expression, gross hearing, voice, and tongue.	If any abnormalities exist, perform complete assessment of all 12 CNs.
Motor system	Assess muscle tone and strength, abnormal movements, and grasps.	If deficits are noted, perform a complete motor assessment.
Cerebellar function	Observe the client's gait and ability to walk heel-to-toe and to perform shallow knee bends. Perform Romberg's test: ask the client to stand erect, feet together and arms at side, first with eyes open, then closed. The nurse should stand close to the client to catch the client in the event of a fall. Note the client's ability to maintain balance with eyes open and closed for 20 seconds with minimum swaying.	If any deficits exist, perform a complete cerebellar assessment.
Reflexes	Assess the muscle stretch reflexes and the plantar response.	If an abnormal response is elicited, perform a complete reflex examination.

Communication

Communication skills should be assessed throughout the entire interview, health history, and physical examination. The client should be able to produce spontaneous, coherent speech with an effortless flow and normal inflections, volume, pitch, articulation, rate, and rhythm. The message should make sense. Comprehension of language should be intact, and the client's ability to read and write should be commensurate with educational level.

Aphasia is an impairment of language functioning that results from injury to the cortex. Aphasia is classified as sensory (receptive), motor (expressive), or global (mixed sensory and motor). In receptive aphasia, auditory comprehension is impaired as well as the content of speech. The client is unaware of the deficits, and his ability to name people and objects is severely impaired. With expressive aphasia, speech is slow and hesitant, the client has difficulty selecting and organizing words, and writing is impaired. Phrases are repeated. Oral and written comprehension are severely impaired with global aphasia.

Level of Consciousness

Consciousness is the level of awareness of the self and the environment. Conscious behavior requires arousal, or wakefulness, and awareness, or cognition and affect. Awareness is a higher-level function of the cerebral cortex that includes judgment and thinking, which are usually assessed as part of the cognitive assessment.

The **Glasgow Coma Scale** (GCS) is an international scale used in grading neurologic responses to determine the client's level of consciousness; see Chapter 36 for a detailed discussion.

Cognitive Abilities and Mentation

Assessment of cognitive function includes testing for attention, memory, judgment, insight, spatial perception, calculation, abstraction, thought process, and thought content. See Chapter 36 for a complete discussion about assessment of these abilities.

Sensory Assessment

Sensation should be tested early in the neurologic assessment because of the detail involved and the need for client cooperation. If the client becomes fatigued, the findings may be unreliable. The assessment is divided into three sections:

- Exteroceptive sensations: superficial sensations that originate in the sensory receptors in the skin and mucous membranes (light touch, pain, heat, and cold)
- Proprioceptive sensations: deep sensations that originate in the sensory receptors in the muscles, joints, tendons, and ligaments (motion, position, and vibration sense)
- Cortical sensations: sensations that compose cerebral integration and discrimination abilities—**stereognosis**

(ability to identify objects by manipulation and touch); **graphesthesia** (ability to identify numbers, letters, or shapes drawn on the skin); two-point discrimination (a test to determine at a given site how close two points can be brought together before being felt as one); and **extinction** (ability to discriminate the points of distance when two body parts are simultaneously touched)

The sensory **dermatome map** (cutaneous area whose sensory receptors and axons feed into a single dorsal root of the spinal cord) is used to assess the major sensory nerves (Figure 27-58). The map of dermatomes is helpful in identifying the areas of pain and altered sensation. Although several dorsal roots may receive inputs from a single dermatome, the map is helpful in identifying where a neurologic lesion may exist. For example, pain localized in the posterior area of the neck would suggest a possible lesion in the third cervical spinal cord segment.

The assessment is carried out with the client's eyes closed to note the client's ability to perceive the sensation. The nurse should observe the client's reactions by watching for facial grimacing or withdrawal of the stimulated extremity. Compare the client's sensation on the corresponding areas bilaterally. The nurse should note

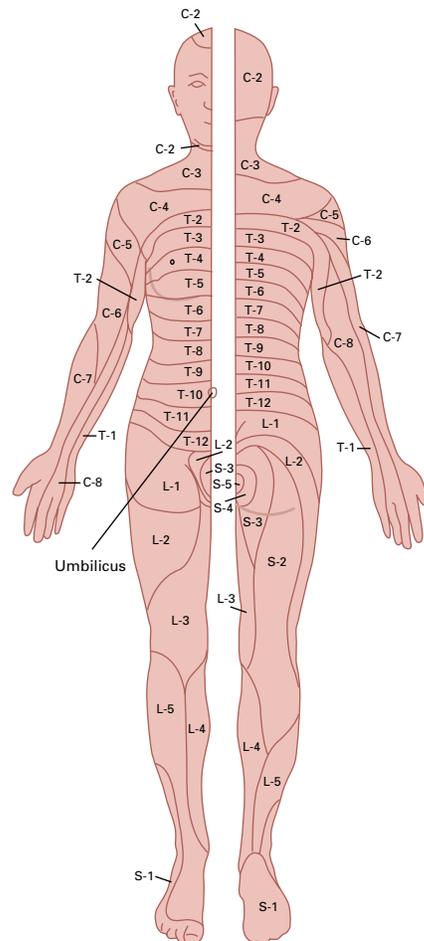

Figure 27-58 Dermatome Map

the proximal to distal sensory differences on all four extremities, evaluate whether any sensory deficits follow a dermatome distribution, and map the borders of any area exhibiting changes in sensation.

Cranial Nerves Assessment

A complete assessment of the 12 cranial nerves is necessary for a baseline assessment, if a tumor of a specific cranial nerve is suspected, or when periodic assessment is required after surgery or radiation treatments. An abbreviated cranial nerve assessment is an integral part of a neurologic screening as presented in Table 27-21.

Pupil assessment (cranial nerve III, oculomotor) is included in the screening assessment and is tested with the trochlear and abducens (cranial nerves IV and VI) because all three cranial nerves supply the muscles of the eye, as previously discussed in Table 27-13.

Motor Assessment

The assessment of the motor system involves testing for muscle size, tone, and strength under voluntary movements (see Table 27-20). Cerebellar assessment can be done either with motor testing or separately as follows.

Cerebellar Assessment

Cerebellar assessment includes observation of coordination, station or balance, and gait. Cerebellar muscular activity requires the motor coordination of various muscle groups to execute smooth, precise, and harmonious movements. Coordination is an integrated process that involves complicated neural integration of the motor and premotor cortex, basal ganglia, cerebellum, vestibular system, posterior columns, and peripheral nerves.

Coordination

Equilibratory coordination is concerned with maintenance of an upright stance and depends on the vestibular, cerebellar, and proprioceptive systems. Nonequilibratory coordination is concerned with smaller movements of the extremities and involves the cerebellar and proprioceptive mechanisms.

To test coordination the nurse should position the client comfortably with eyes open. Clients who wear glasses should be wearing their glasses before coordination is assessed. Instruct the client to first touch the index finger to the nose, then to alternate rapidly with the index finger of the opposite hand. Ask the client to close her eyes and continue to rapidly touch her nose with alternate index fingers. Tell the client to open her eyes and ask her to touch her finger to her nose and to touch the nurse's index finger, which is held about 18 inches away from the client. The test is repeated with the client using the opposite hand. Throughout testing, the nurse should observe for intention tremor or overshooting of the client's finger.

To assess rapid alternate movements of the upper extremities, ask the client to alternately pat her knees with rapid supinating and pronating of the hands. Test the lower extremities for rapid alternating movement by asking the client to rapidly extend the ankle ("tap your foot") and to place the heel just below the knee on the shin of the opposite leg and slide it down to the foot.

The client should be able to rapidly alternate touching finger to nose and moving finger from nose to the nurse's finger in a coordinated fashion. Also, the client should be able to perform alternating movements in a purposeful, rapid, coordinated manner. The client should demonstrate the ability to purposefully and smoothly run her heel down the shin.

Station and Gait

The performance of Romberg's test is described in Table 27-21. A positive Romberg sign exists if the client becomes unsteady and tends to fall with the eyes closed.

The assessment of gait begins when the client enters the room and continues throughout the examination. The nurse must consider the client's age, activity level, and degree of alertness. The tandem walk is tested by having the client walk in a straight line touching the ground heel-to-toe. The arms should be held at the side and the eyes should be open. Note the client's posture and ability to maintain balance. Posture should be upright with a narrow base and the gait smooth with arms swinging opposite the movement of the legs. Heel-to-toe walk should be in a straight line without losing balance.

Reflex Assessment

A reflex action is a specific response to an adequate stimulus that occurs without conscious control. The stimulus can occur in a joint, muscle, or skin and is transmitted through the sensory and motor pathways of the reflex arc and specific spinal cord segments. Each muscle contains a muscle spindle (small sensory unit) that controls muscle tone and detects changes in the length of the muscle fibers.

To elicit a muscle stretch reflex, the nurse should briskly tap the client's tendon with a reflex hammer, thereby stretching the muscle and tendon and lengthening the spindle. The spindle transmits the signal along the afferent neurons to the dorsal roots where it synapses. Following synapse in the cord, the anterior motor neurons trigger an impulse on efferent neurons to the endplates of the skeletal muscle, causing the reflex response.

Normal reflexes are classified into two main categories: muscle stretch (deep tendon) reflexes (DTR) and superficial (cutaneous) reflexes. When testing reflexes, clients should be relaxed and positioned so that their extremities are symmetrical. The nurse should hold the reflex hammer loosely between the thumb and index finger and strike the tendon with a brisk motion from the wrist. The reflex hammer should make contact with the correct point on the tendon in a quick, direct manner.

TABLE 27-22
Assessment of Common Deep Tendon Reflexes

Type	Assessment	Normal Reflex
<p>Biceps</p> 	<p>Flex client's arm between 45° and 90°. Place your thumb firmly on the biceps tendon just above the crease of antecubital fossa and tap thumb with reflex hammer.</p>	Flexion of arm at elbow
<p>Triceps</p> 	<p>Flex client's arm between 45° and 90°. Tap triceps tendon just above elbow.</p>	Extension of elbow
<p>Brachioradialis</p> 	<p>Flex client's arm 45° and place in lap with the arm in semipronation. Tap brachioradialis tendon on thumb side of wrist.</p>	Flexion of forearm
<p>Patellar</p> 	<p>Ask client to sit in a chair or on edge of bed with legs hanging freely or in a supine position with knee flexed. Tap patellar tendon just below the patella.</p>	Extension of leg below the knee

(continues)

TABLE 27-22 (continued)
Assessment of Common Deep Tendon Reflexes

Type	Assessment	Normal Reflex
Achilles 	Ask client to sit with feet dangling and partially dorsiflexed or in a supine position with leg flexed at knee and thigh externally rotated. Tap the Achilles tendon just above heel.	Plantar flexion of foot
Plantar (Babinski) 	Position the client's ankle firmly against the bed and slowly stroke client's sole with the handle of the reflex hammer.	Bending of the toes downward

REFLEX GRADING SCALE

Scale	Response
0	Absent
+	Present but diminished
++	Normal
+++	Mildly increased but not pathologic
++++	Markedly hyperactive; clonus may be present

Table 27-22 discusses the assessment of common DTRs: biceps, triceps, brachioradialis, patellar, Achilles, and plantar (Babinski). When testing the reflexes the nurse should observe the degree and speed of response of the muscle after the reflex hammer makes contact. Grading of reflexes is presented in the accompanying display. The reflex responses between the right and left sides should be compared. The normal response to taps in the correct area should elicit a brisk (++ or +++) contraction of the muscles involved.

Care of the Client after the Examination

A physical examination is taxing on the client, especially if the complete assessment is performed in one session.

The nurse should assess the client's needs after this process and respond appropriately. The nurse should also dispose of soiled articles in the proper container, clean and store equipment appropriate for the setting, and put all furniture back in its original place. Thanking the client for cooperating during the physical examination demonstrates concern and caring.

Home or Outpatient Setting

If the physical examination is conducted in the home environment, the nurse should acknowledge the client's need to rest before dressing. The client should be offered assistance with either toileting or dressing. If a family member is in the home, the nurse should notify that person that the assessment is completed. If the client is home alone the nurse should verify that the client is capable of caring for his or her own needs before leaving. The nurse should telephone the client within 2 hours after leaving to answer any questions about the examination.

In an outpatient setting, assess whether the client needs assistance in dressing. After the client is dressed, discuss the experience by inviting questions and comments. Listen carefully to the client's remarks and provide information regarding the assessment. The nurse should make certain that the client is capable of driving home or should secure safe transportation if needed.

Acute or Extended Care Setting

Nursing students should check with their instructors or supervisors before conducting the assessment to ascertain the amount of information that they can share with the client during and after the examination. This varies in different agencies and according to the admitting physician. It is best to secure this information before beginning the examination.

After concluding the assessment, the nurse should dispose of soiled articles and clean and store the equipment. The bed should be returned to a low position, side rails up, and call light in place. Quietly check on the client several times within the 2 to 3 hours after assessment to monitor the client's condition.

Data Documentation

Health care agencies have specific forms for recording the assessment findings. Review these forms before initiating the assessment and record the findings on the appropriate form as the data are gathered. This practice ensures accuracy in documentation of findings. Some data (e.g., vital signs) may need to be recorded on two or more forms.

THINK ABOUT IT

Physical Examination: Benefit and Implications

With the emphasis on cost containment in health care and the expanding roles of nurses as case managers for managed care companies, what do you think are the implications for accurate assessment data? Can you relate the health care implications of preventive nursing to assessment and cost controls? How does performance of thorough physical examination ensure the holistic care of the client?

Reporting information is a critical part of documentation. If findings that require immediate attention—for example, bright red blood or a change in the nature and character of a previous symptom—are detected, report the findings to the nursing supervisor and document in the medical record the actions taken.

Documentation should reflect the objective data obtained from the examination regarding the client's current condition. Avoid phrases such as the *client appears lethargic*; rather, record the GCS score. If the data identify areas in which the client is at risk, such as a 35-year-old woman with a family history of breast cancer, use the appropriate resources for prevention; for example, BSE and the American Cancer Society's guidelines for early detection of breast cancer. Likewise, abnormal findings should be addressed in planning the nursing care and client outcomes.

KEY CONCEPTS

- Baseline values establish the norm; variations from normal may indicate possible problems with the client's health status.
- The assessment of physiological functioning provides specific data regarding the client's current condition.
- Thermoregulation is the body's physiological function of heat regulation to maintain a constant internal body temperature.
- Hemodynamic regulation is the body's physiological function of blood circulation to maintain an appropriate environment in all the tissue fluids.
- The pulse is caused by the stroke volume ejection and distension of the walls of the aorta, which creates a pulse wave as it travels rapidly toward the distal ends of the arteries.
- Blood pressure is the measurement of pressure pulsations exerted against the blood vessel walls during cardiac systole and diastole. It is measured in terms of millimeters of mercury (mm Hg).
- There are several factors that cause changes in one or more of the vital signs: age, sex, exercise and metabolism, anxiety and stress, postural and diurnal variations, hormones, pain, medications, and alterations in physiological functions.
- The normal values and variations in vital signs measurement are usually based on age.
- All pieces of equipment used to measure the vital signs and perform a physical assessment should be maintained to function accurately.
- Clinical data regarding the efficacy of blood circulation to an extremity are obtained by assessing all the characteristics (rate, quality, rhythm, and volume) of the peripheral pulses.
- When assessing ventilation, ascertain the rate, depth, and rhythm of ventilatory movement.
- Before checking a blood pressure, review the client's chart for brachial artery contraindications and make sure that the client has not exercised or eaten for the past 30 minutes.
- The physical examination provides a complete picture of the client's physiological functioning; when combined with a health and psychosocial assessment it forms a database to direct decision making.
- Because the client will experience some anxieties regarding the examination it is important for the nurse to keep the client informed while performing the examination.
- The primary purpose of draping the client is to prevent unnecessary exposure during the examination; feelings of embarrassment will elicit tension and restlessness and will decrease the client's ability to cooperate.
- The physical examination is done in a sequential, head-to-toe fashion to ensure a thorough assessment of each system; when you gain proficiency in per-

forming the physical examination, you will be able to integrate assessment into routine care.

- Assessment begins from the moment you come in contact with the client; data obtained from the health history will assist in identifying areas of alteration.
- Know the agency's policies relative to performing and documenting a physical assessment.
- Use the landmarks and visualize the internal organs when assessing the thorax, heart, and abdomen.
- The order of abdominal assessment is inspection, auscultation, percussion, and palpation because palpation and percussion can alter the bowel sounds.
- Nurses play a major role by teaching breast self-examination (BSE), testicular self-examination (TSE), and by supporting clients in achieving healthier lifestyles believed to decrease the risk factors of cancer.
- If you feel uncomfortable about assessing the genitalia you need to work through your own feelings about sexuality and reproduction before you can talk comfortably with the client; work through any reluctance you may have about discussing sexual situations.
- Reporting information is a critical part of documentation; if you assess findings that require immediate attention, report the findings to your supervisor and document your action in the medical record.
- Documentation should reflect the objective data obtained from the examination regarding the client's current condition.

CRITICAL THINKING ACTIVITIES

1. Ms. Reynolds is 33 years old; her vital signs measurements are: OT-37.0°C (98.6°F), P-96/min., R-22/min., and BP 144/90. Which of these measurements are outside the normal ranges?
2. You are assigned to care for Mr. Warren, a 77-year-old client in a long-term care facility. When you enter his room to take his vital signs, you note that the fan is on high speed and blowing directly over him. He is sweating, and the bed linens are damp. What type of reading would you expect to find when you take his temperature? Why is the fan on? What type of heat loss from the skin surface is being increased: radiation, conduction, convection, or evaporation?
3. Mrs. Gray is 55 years old and had a right mastectomy 9 months ago. What implications would the mastectomy have on your assessment (vital signs and examination)?
4. What hemodynamic function is compromised when the lips and nail beds have a bluish discoloration?
5. What normal sounds should you hear when you percuss the posterior aspect of the apex of the right lung?
6. Are bronchial breath sounds upon auscultation of the lung periphery normal?

7. What type of palpating technique should you use to assess an obese client or a client with large breasts?
8. Match the adventitious breath sound in Column A with the description that best describes it in Column B.

COLUMN A

- ___ 1. Fine crackle
- ___ 2. Coarse crackle
- ___ 3. Sonorous wheeze
- ___ 4. Sibilant wheeze
- ___ 5. Pleural friction rub
- ___ 6. Stridor

COLUMN B

- a. Moist, low-pitched crackling, gurgling sound of long duration
- b. Creaking, grating sound
- c. Crowing sound
- d. Dry, high-pitched crackling, popping sound of short duration
- e. Low-pitched snoring sound
- f. High-pitched musical sound

Chapter 28

Diagnostic Testing

If the nurse is an intelligent being, and not a mere carrier of diets to and from the patient, let her exercise her intelligence in these things.

—Nightingale (in Skretkowicz, 1992)

COMPETENCIES

1. Discuss the relevant client teaching guidelines for the care of the client before, during, and after diagnostic testing.
2. Describe the common specimen collection methods.
3. Describe common invasive and noninvasive diagnostic procedures.
4. Discuss nursing interventions for the common diagnostic procedures.

KEY
TERMS

agglutination	angiography	oliguria
agglutinin	disseminated intravascular coagulation	oral cholecystography
agglutininogen	Doppler	paracentesis
Allen test	echocardiogram	Papanicolaou test
amniocentesis	electrocardiogram	phagocytosis
analyte	electroencephalogram	phlebotomist
aneurysm	electrolyte	pneumothorax
angiography	endoscopy	polyp
anions	enzyme	port-a-cath
antibody	erythrocyte	predictive value
antigens	fluoroscopy	radiofrequency ablation
arteriography	general anesthesia	radiography
ascites	hematuria	red cell indices
aspiration	hemoconcentration	regional anesthesia
atherosclerotic plaque	hemoglobin electrophoresis	sensitivity
bacteremia	hemolysis	signal-averaged electrocardiography
barium	incidence	specificity
barium enema	intravenous pyelogram	spherocytes
barium swallow	invasive	stress test
biopsy	ketone	thallium
bronchography	late potentials	thrombus
cardiac catheterization	leukocytes	thoracentesis
cations	lipoproteins	transducer
central line	local anesthesia	trocar
cholangiography	lumbar puncture	T-tube
cholinesterase	lymphangiography	type and crossmatch
computed tomography	mammography	ultrasound
conscious sedation	magnetic resonance imaging	urobilinogen
contrast medium	myelography	venipuncture
culture	necrosis	venography
cystography	noninvasive	void
cytology	occult	
digital subtraction		

With the arrival of health care reform, reimbursement practices such as managed care, and medicolegal concerns, health care is redefining the importance of history taking and physical examinations with a decreasing reliance on diagnostic tests. In the last two decades, before reform acts, health care relied heavily on the use of diagnostic testing to determine the nature of the client's condition.

Health care providers are using the findings from a thorough history and physical to determine the need for diagnostic testing. The client's history and presenting symptoms determine which diagnostic procedures are necessary to formulate a medical diagnosis and the course of treatment. The challenge of cost-effective health care pushes practitioners to rely on basic assessment and to be selective with expensive diagnostic tests. To reflect the emphasis on cost containment, the nurse's role has changed from doing for the client to teaching clients to do for themselves. The role of the nurse is to teach the client, family, and significant others about the procedures involved with diagnostic testing, the steps to be taken in preparation for the specific test, and the care

that will follow the procedure. Although the primary focus is on teaching, the nurse may assist in performing various noninvasive and invasive procedures. Nurses must be aware of the implications of diagnostic testing so as to deliver appropriate nursing care to the client.

This chapter discusses the most common diagnostic tests. The terms *test* and *procedure* are used interchangeably throughout the chapter. The term *practitioner* is used in this chapter to refer to either the physician or other authorized prescribers. Most state boards of nursing allow advanced practice registered nurses to order and perform certain diagnostic tests. See Chapter 22 for a discussion of professional responsibility.

UNDERSTANDING DIAGNOSTIC TESTING

To understand the nature of diagnostic tests, nurses need to review anatomy and physiology. Knowing the anatomical and physiological functions of the body will assist nurses in relating certain diagnostic tests to specific disease processes.

NURSING TIP

Client Assessment and Diagnostic Testing

Mr. Simon, a 57-year-old man, goes to a primary care clinic for treatment of an infected ingrown toenail that continues to bleed when pressure is released. This is his first visit in 7 years. While performing the history and physical, the nurse practitioner learns that for the past 2 months Mr. Simon has had repeated colds with fever, fatigue, weakness, and a 20-lb weight loss. He has multiple bruises on his extremities and trunk. He complains of pain when his bones and joints are moved. The nurse practitioner orders a white blood cell differential. The staff nurse cleans the toenails and applies a pressure dressing.

What did Mr. Simon's physical and history and reveal? Why did the nurse practitioner order a white blood cell differential as opposed to a white blood cell count? What are the possible medical diagnoses for Mr. Simon's ailment? Infected ingrown toenail? Anemia? Diabetes? Or could it be something else? Relate the symptoms as presented in the history and physical to the physiological functions of white blood cells.

As you gain in nursing knowledge and clinical experience, you will be exposed to a wide range of diagnostic tests. As with Mr. Simon, always ask yourself "Why is this diagnostic test being done?" Answer the question of "why" from the relational perspective of the client's symptomatology and the physiological functions of the body's organs and tissues.

NONINVASIVE AND INVASIVE DIAGNOSTIC TESTING

Diagnostic tests are either noninvasive or invasive. **Noninvasive** means the body is not entered with any type of instrument. The skin and other body tissues, organs, and cavities remain intact. **Invasive** means accessing the body's tissue, organ, or cavity through some type of instrumentation procedure.

Nursing Care of the Client

Diagnostic testing is a critical element of assessment. See Chapters 6 and 27 for a complete discussion. Assessment data are used to formulate nursing diagnoses, a plan of care, and outcome measures in collabo-

NURSING ALERT

Diagnostic Testing: Safety Measures

Use Standard Precautions whenever performing invasive and noninvasive testing to protect your health and safety, as well as that of other health care providers and the client.

ration with the client. Ongoing client assessment and evaluation of the client's expected outcomes requires the incorporation of diagnostic findings.

Preparing a Client for Diagnostic Testing

The nurse plays a key role in scheduling and preparing the client for diagnostic testing. "The emphasis of pretest is on appropriate test selection, proper patient preparation, individualized patient education, and emotional support" (Fischbach, 2000, p. 9). When tests are not scheduled correctly, the client is inconvenienced. It may also delay interventions, which places the client's health status at risk. The institution is also at risk to lose money. Table 28-1 presents a sample protocol of the nursing care to prepare a client for diagnostic testing.

The nursing care contained in the protocol provides a systemic format, based on the nursing process, to prepare the client for most diagnostic studies. During the assessment of the client, make sure the client is wearing an identification band (Figure 28-1). The identification band is a key factor to ensure client safety in all health care settings.

Other key nursing measures to ensure client safety are to establish baseline vital signs, identify known allergies, and assess the effectiveness of teaching. In the ambulatory and outpatient centers, the nurse might have only one opportunity to assess and record the vital signs; it is

Figure 28-1 Nurse and client prepare for diagnostic testing.

TABLE 28-1
Protocol: Preparing the Client for Diagnostic Testing

<i>Purpose</i>	To increase the reliability of the test by providing client teaching on why the test is being performed, what the client can expect during the test, and the outcomes and side effects of the test To decrease the client's anxiety about the test and the associated risk
<i>Level</i>	Independent
<i>Supportive Data</i>	Increasing the client's knowledge promotes cooperation, enhances the quality of the testing, decreases the time required to perform the study with an outcome of increased cost-effectiveness. Proper physical preparation prevents delays.
<i>Assessment</i>	Check to be sure the client is wearing an identification band. Review the medical record for allergies and previous adverse reactions to dyes and other contrast media, a signed consent form, and the recorded findings of diagnostic tests relative to the procedure. Assess for presence, location, and characteristics of physical and communicative limitations or preexisting conditions. Monitor the client's knowledge of why the test is being performed and what to expect during and after testing. Monitor vital signs for clients scheduled for invasive testing to establish baseline data. Assess client outcome measures relative to the practitioner's preferences for preprocedure preparations. Monitor level of hydration and weakness for clients who are NPO (nothing by mouth), especially geriatric and pediatric populations.
<i>Report to Practitioner</i>	Notify practitioner of allergy, previous adverse reactions, or suspected adverse reaction following administration of drugs. Notify practitioner of any client or family concerns you were not able to alleviate.
<i>Interventions</i>	Clarify with practitioner if regularly scheduled medications are to be administered. The NPO status is determined by the type of test. Administer cathartics or laxatives as denoted by the test's protocol; however, there must be a specific practitioner order to give children and infants a laxative. Instruct clients who are weak, especially geriatric clients, to call for assistance to bathroom. Teach relaxation techniques, such as deep breathing and imagery. Establish intravenous (IV) access if necessary for procedure.
<i>Evaluation</i>	Evaluate client's knowledge of what to expect. Evaluate client's anxiety level. Evaluate client's level of safety and comfort. Monitor that someone will accompany a child to the department where the test is to be performed and remain with the child during the tests if not at risk of harmful exposure.
<i>Client Teaching</i>	Discuss the following with the client and family as appropriate to the specific test: <ul style="list-style-type: none"> • Explain reason for test and what to expect • An estimation of how long the test will take • NPO (If oral medication to be taken, how much water to drink) • Cathartics or laxative: how much, how often • Sputum: cough deeply, do not clear throat • Urine: voided, clean-catch specimen, time to collect • No objects (jewelry or hair clips) to obscure x-ray film • Barium: taste, consistency, aftereffects (stools lightly colored for 24–72 hours, can cause obstruction/impaction) • Iodine: metallic taste, delayed allergic reaction (itching, rashes, hives, wheezing and breathing difficulties) • Positioning during the test • Positioning posttest (e.g., angiography)—immobilize limb • Post-test, encourage fluids if not contraindicated
<i>Documentation</i>	Record the following in the client's medical record: <ul style="list-style-type: none"> • Practitioner notification of allergies or suspected adverse reaction to contrast media • Presence, location, and characteristics of symptoms • Teaching and the client's response to teaching • Response to interventions (client's outcomes)

important for the nurse to confirm that these findings are *normal values* for the client. To accurately assess the client's response to anesthetic agents and the procedure, the nurse has to compare the vital signs taken during and after the procedure with the baseline data.

The client needs to know what to expect during the procedure. Teaching can increase the client's level of cooperation and should decrease the degree of anxiety. The client's family should also know what will happen during the procedure and approximately how long the procedure normally lasts.

Reference is made to Table 28-1 throughout this chapter. This protocol provides you with the direction and guidance needed to plan nursing care. Nurses must also know the institution's protocols and procedures because these are not standardized in all practice settings.

Care of the Client During Diagnostic Testing

Although the care of the client needs to be individualized for a specific procedure, general guidelines for client care during a procedure are given in Table 28-2. Protocols are used to assist the nurse with client care.

Standard Precautions are initiated when exposure to body fluids presents a threat to the safety of the caregiver. Protective barriers, such as gloves and a gown, should be used during invasive procedures. The nurse is responsible for labeling any specimen with the client's name, room number (hospitalized clients), date, time, and source of the specimen. Some specimens may need to be taken immediately to the laboratory or placed on ice (e.g., arterial blood gases).

In order to promote the client's comfort and cooperation during diagnostic tests, nurses must consider the management of procedural pain. Although not all procedures are painful, advances in diagnostic and therapeutic studies have placed clients at risk for painful procedures. Clients who are repeatedly subjected to painful procedures without adequate analgesia become anxious and anticipate pain; if pain is experienced during one procedure, the client is reluctant to return for the same procedure or other tests. "Unrelieved procedural pain also can have adverse physiologic effects, even if the pain is temporary" (Pasero, 1998, p. 18).

Recognizing that diagnostic procedures are performed in various settings, intravenous conscious sedation (conscious sedation) is often used to manage pain during diagnostic testing.

Conscious sedation is a minimally depressed level of consciousness during which the client retains the ability to maintain a continuously patent airway and respond appropriately to physical stimulation or verbal commands (Fischbach, 2000). The nurse managing conscious sedation is usually functioning in an expanded role that requires additional education and demonstrated ability beyond basic education.

DIAGNOSTIC PROCEDURES THAT MAY REQUIRE ANALGESIA OR SEDATION

- Bone marrow aspiration or biopsy
- Cardioversion
- Endoscopy
- Lumbar puncture
- Paracentesis
- Placement of catheters, lines, and tubing
- Radiologic procedures (CT and MRI)
- Thoracentesis
- Tissue biopsies
- Venipuncture

Adapted from Pasero, C. L. (1998). Procedural pain management. *American Journal of Nursing*, 98(7), 19–20.

See the accompanying display for some procedures that may require analgesia or sedation.

Ongoing assessment of the client's status is required during the procedure. Always assess the patency of the client's airway, which may be compromised by the client's position, anesthesia, or the procedure itself. During an invasive procedure the nurse needs to monitor for signs and symptoms of accidental perforation of an organ (e.g., sudden changes in vital signs).

The nurse has additional responsibilities:

- Preparing the room (e.g., adequate lighting).
- Gathering and charging for supplies used during the procedure
- Testing the equipment to ensure it is functional and safe
- Securing proper containers for specimen collection

Practitioners usually have *preference cards* within the diagnostic testing area that specify the type of equipment to be used, the position to place the client, and the type of sedation or anesthesia.

Care of the Client After Diagnostic Testing

Nursing care postprocedure is directed toward restoring the client's prediagnostic level of functioning (Table 28-3). Nursing assessment and interventions are based mainly on the nature of the test and whether or not the client received anesthesia. Anesthesia can be administered in one of three ways:

- **Local anesthesia**—client loses sensation to a localized body part—spraying the back of the throat with lidocaine to decrease the gag reflex
- **Regional anesthesia**—client loses sensation in an area of the body—laparoscope for a tubal sterilization
- **General anesthesia**—client loses all sensation and consciousness—major surgical procedures

TABLE 28-2
Protocol: Care of the Client During Diagnostic Testing

<i>Purpose</i>	To increase cooperation and participation by allaying the client's anxiety and to provide the maximum level of safety and comfort during a procedure
<i>Level</i>	Interdependent
<i>Supportive Data</i>	Increasing the client's participation and comfort encourages relaxation of muscles to facilitate instrumentation. Proper preparation of the client ensures efficient use of time during the test and reliable results.
<i>Assessment</i>	Check the client's identification band to ensure the correct client. Review the medical record for allergies. Assess the preprocedure sedatives administered to the client before the administration of anesthesia during the procedure. Assess airway maintenance and gag reflex if a local anesthetic is sprayed into the client's throat. Assess vital signs throughout the procedure and compare with baseline data. Assess the client's ability to maintain and tolerate the prescribed position. Assess the client's comfort level to ensure the effectiveness of the anesthetic agent. Assess for related symptoms indicating complications specific to the procedure (e.g., accidental perforation of an organ).
<i>Report to Practitioner</i>	Notify the practitioner if the client has any concerns or questions that you were not able to resolve. Notify the practitioner if the client has family members present and where they are waiting during the procedure. Notify the practitioner when the client is positioned properly and the anesthetic agent has been administered to the client.
<i>Interventions</i>	Institute Standard Precautions or appropriate aseptic technique for the specific test. Report to all personnel involved with the test any known client allergies. Place client in the correct position, drape, and monitor to ensure that breathing is not compromised. Remain with the client during the administration of anesthesia. If the procedure requires the administration of a dye, ensure the client is not allergic to the dye; if the client has not received the dye before, perform the skin allergy test according to the drug manufacturer's instructions that accompany the medication. Maintain the client's airway and keep resuscitative equipment available. Assist the client to relax during insertion of the instrument by telling the client to breathe through the mouth and to concentrate on relaxing the involved muscles. Explain what the practitioner is doing so that the client will know what to expect. Label and handle the specimen according to the type of materials obtained and the testing to be done. Report to the practitioner any symptoms of complications. Secure client transport from the diagnostic area. Post-test in the diagnostic area: <ol style="list-style-type: none"> 1. Assist client to a comfortable, safe position. 2. Provide oral hygiene and water to clients who were NPO for the test if they are alert and able to swallow. 3. Remain with the client awaiting transport to another area.
<i>Evaluation</i>	Evaluate client's ventilatory status and tolerance to the procedure. Evaluate client's need for assistance. Evaluate client's understanding of what was performed during the procedure. Evaluate client's understanding of findings identified during the procedure. Evaluate client's knowledge of what to expect after the procedure.

(continues)

TABLE 28-2 (continued)
Protocol: Care of the Client During Diagnostic Testing

<i>Client Teaching</i>	<p>Discuss the following with the client and family as appropriate to the specific test:</p> <ul style="list-style-type: none"> • Explain what occurred during the procedure. • Answer questions and concerns of the client or family member. • Explain what to expect during the immediate recovery phase. • Explain what to report to the nurse during the immediate recovery phase.
<i>Documentation</i>	<p>Record in the client's medical record:</p> <ul style="list-style-type: none"> • Who performed the procedure • Reason for the procedure • Type of anesthesia, dye, or other medications administered • Type of specimen obtained and where it was delivered • Vital signs and other assessment data, such as client's tolerance of the procedure or pain/discomfort level • Any symptoms of complications • Who transported the client to another area (designate the names of persons who provided transport and place of destination)

See Chapter 30 for additional discussion of anesthesia.

The client is monitored closely for signs of respiratory distress and bleeding. Some diagnostic procedures require that the vital signs be measured every 15 minutes for the first hour, then gradually decreased in frequency until the client is stable (alert and vital signs within the client's normal range).

Some diagnostic tests require the use of medications that are excreted through the kidneys; the nurse monitors the client's intake and output for 24 hours. The client is taught how to monitor intake and output. Instruct the client to report **hematuria** (presence of blood in the urine). Clients receiving radioactive iodine must have their urine collected and properly discarded in a special container, according to agency policy for handling radioactive medical wastes.

When clients are discharged after diagnostic tests, they should receive written instructions. Most agencies have discharge forms for the nurse to document teaching regarding medications, dietary and activity restrictions, and signs and symptoms to be reported immediately to the practitioner. Clients may also need to have follow-up appointments made for them.

LABORATORY TESTS

Common laboratory studies are usually simple measurements to determine how much or how many **analytes**, (a substance dissolved in a solution, also called a solute) are present in a specimen. Laboratory tests are ordered by practitioners to:

- Detect and quantify the risk of future disease
- Establish and exclude diagnoses
- Assess the severity of the disease process and determine the prognosis
- Guide the selection of interventions

- Monitor the progress of the disorder
- Monitor the effectiveness of the treatment

Nurses are often the first to view results of laboratory studies and they need to know the terminology regarding laboratory tests: purpose, process, procedure, and normal test values. The clinical value of a test is related to (Fischbach, 2000):

1. **Specificity**—the ability of a test to correctly identify those individuals who do not have the disease
2. **Sensitivity**—the ability of a test to correctly identify those individuals who have the disease
3. **Incidence**—the prevalence of a disease in a population or community. the predictive value of the same test can be different when applied to people of differing ages, genders, and geographic locations.
4. **Predictive value**—the ability of screening test results to correctly identify the disease state—a true-positive correctly identifies persons who actually have the disease, whereas a true-negative correctly identifies persons who do not actually have the disease.

Laboratory test results are based on *normal range values*. Le Système International d'Unités (SI), the International System of Units, is an international normal range reference established for reporting laboratory results (Pagana & Pagana, 1999). For example, the SI reference range for reporting red blood cell count for a woman is 4.0 to $5.2 \times 10^{12}/L$, the conventional range would appear as 4,000,000 to 5,200,000/ mm^3 of blood.

Specimen Collection

The scheduling and sequencing of laboratory tests is an important function of the nurse. All tests requiring **venipuncture** (the puncturing of a vein with a needle to aspirate blood) are grouped together so that the client

TABLE 28-3
Protocol: Care of the Client After Diagnostic Testing

<i>Purpose</i>	To restore the client's prediagnostic level of functioning by providing care and teaching relative to what the client can expect after a test and the outcomes or side effects of the test
<i>Level</i>	Interdependent
<i>Supportive Data</i>	Increasing the client's participation and knowledge of expected outcome measures after a diagnostic test Proper postprocedure care and client teaching alerts the client to what signs and symptoms need to be reported to the practitioner.
<i>Assessment</i>	Check the identification band and call the client by name. Assess the client closely for signs of airway distress, adverse reactions to anesthesia or other medications, and other signs that may indicate accidental perforation of an organ. Assess body area(s) where a biopsy was performed for bleeding. Assess the client's color and skin temperature. Assess vascular access lines or other invasive monitoring devices. Assess the client's ability to expel air if air was instilled during a gastrointestinal test. Assess the client's knowledge of what to expect during the recovery phase.
<i>Report to Practitioner</i>	Notify the practitioner of any signs of respiratory distress bleeding or changes in vital signs; adverse reactions to anesthetic, sedative, or dye; and other signs of complications. Notify the practitioner regarding client or family concerns or questions that you are not able to answer. Notify the practitioner when any results are obtained from the diagnostic test. Notify the practitioner when the client is fully alert and recovered for an order to discharge.
<i>Interventions</i>	Implement the practitioner's orders regarding the postprocedure care of the client. Institute Standard Precautions or surgical asepsis as appropriate to the client's care needs. Position the client for comfort and accessibility to perform nursing measures. Monitor vital signs according the frequency required for the specific test. Observe the insertion site for a hematoma or blood loss; replace pressure dressing, as needed. Monitor the client's urinary output and drainage from other devices. Enforce activity restrictions appropriate to the test. Schedule client appointments as directed by the practitioner.
<i>Evaluation</i>	Evaluate the client's respiratory status to any anesthetic agents. Evaluate the client's tolerance of oral liquids. Evaluate the client's understanding of procedural findings or the time frame that written results should be reported to the practitioner. Evaluate the client's knowledge of what to expect after discharge.
<i>Client Teaching</i>	Based on client assessment and evaluation of knowledge, teach the client or family about the following: <ul style="list-style-type: none"> • Dietary or activity restrictions • Signs and symptoms that should be reported immediately to the practitioner • Medications
<i>Documentation</i>	Record in the client's medical record on the appropriate forms: <ul style="list-style-type: none"> • Assessment data, nursing interventions, and achievement of client expected outcomes • Client or family teaching and demonstrated level of understanding • Written instructions given to the client or family members

is subjected to only one venipuncture. Fasting laboratory and radiologic studies are scheduled on the same day so that the client has to fast for only one day. Appropriate scheduling increases the client's comfort level and satisfaction.

“Communication errors account for more incorrect results than do technical errors” (Fischbach, 2000, p. 13). Accuracy in laboratory testing requires that:

- The practitioner's order is transcribed onto the correct requisition form.
- All information requested should be written onto the form (e.g., the client's full name and medical number).
- Pertinent data that could influence the test's results, such as medication taken, must be included.
- Collection of the specimen from the correct client is confirmed by the identification band.
- Laboratory results are placed on the correct client's medical record.

The risk for errors increases when clients have the same last name. Always check the full name of the client and the medical record number before placing the laboratory results report onto a chart.

NURSING ALERT

Documentation

Document on the laboratory requisition slip and in your nurses' notes any difficulty you experience while collecting the specimen. Such problems may be indicative of adverse effects that clients may experience due to the nature of the test and are conditions that must be reported and treated immediately.

Point of care testing (POCT) is a common practice in critical care settings and is proving to be a cost-effective, quality intervention for both clients and agencies. With advances in POCT technology over the past two decades, critical care nurses can perform a blood analysis and within seconds to minutes have a measurement upon which to change or implement an intervention. Schallom (1999) suggests that nurses be involved in the implementation and evaluation process of POCT since accuracy of the test is contingent on correct calibration and correct usage by the test performer. The following advantages are inherent in POCT (McConnell, 1999; Schallom, 1999):

- Prompt client diagnosis, treatment, and monitoring by decreasing turnaround time (TAT)
- Decreasing the risk for error by eliminating many of the steps in conventional laboratory testing
- Decreasing prolonged hospital stays and avoiding unnecessary hospitalizations by facilitating appropriate triage from emergency departments and prehospital settings

- Decreasing delays or cancellations of surgical procedures due to unavailable laboratory results, and the actual time the client spends in surgery;
- Minimizing blood loss due to phlebotomy since POCT devices usually require only a few microliters or drops of blood versus 25 to 125 microliters per day for the critically ill client due to laboratory testing

Studies regarding POCT's clinical and financial value have revealed positive results: improved overall day-stay unit operations and client services; and earlier therapeutic decision-making time that required blood test results for emergency room clients (McConnell, 1999). Although studies have proven positive results in settings where the client's condition is acute and unstable, critical care applications may be quite different from that on a general medical/surgical unit. Studies will need to document the usefulness of POCT as a quality intervention in nonacute care settings.

Venipuncture

Venipuncture can be performed by various members of the health care team. Laboratories employ a **phlebotomist** (an individual who performs venipuncture) to collect blood specimens; however, it is the responsibility of a nurse to know *how* to perform a venipuncture. Nurses routinely perform venipuncture in the home, long-term care settings, and hospital critical care units.

Venipuncture can either be performed by using a sterile needle and syringe or a vacuum tube holder with a sterile two-sided needle. Test tubes are used to collect blood specimens. Test tubes have different colored stoppers to indicate the type of additive in the test tube. Collecting tubes are universally color coded as follows:

- Red—no additive
- Lavender—EDTA (ethylenediaminetetraacetic acid)
- Light blue—sodium citrate
- Green—sodium heparin
- Gray—potassium oxalate
- Black—sodium oxalate

Noe and Rock (1994) address three sources of venipuncture variability that can cause inaccurate results. **Hemoconcentration** is the reduced volume of plasma water and the increased concentration of blood cells, plasma proteins, and protein-bound constituents. It occurs with increased capillary hydrostatic pressure that causes water to shift from the intravascular into the interstitial space.

Hemoconcentration can be caused from prolonged standing or a prolonged time of application of a tourniquet during venipuncture. Alterations in the circulating blood volume can also cause hemoconcentration, such as occurs with dehydrated and burned clients.

Hemolysis is the breakdown of red blood cells and the release of hemoglobin. Hemolysis occurs with the rapid

NURSING ALERT

Preventing Hemoconcentration

Keep to a minimum both the length of time a client stands before venipuncture and the length of time of tourniquet application during venipuncture. These actions lower the risk of hemoconcentration and increase the rate of accuracy in laboratory tests.

flow of blood through small-bore needles and exposure to large negative pressures. A negative pressure exists inside the collecting test tubes and syringe. To minimize the possibility of hemolysis use a large-bore needle, moderate flow rates, and moderate negative pressures.

NURSING ALERT

Contraindications to Conducting Laboratory Tests

Health care providers with weeping dermatitis or other exudative lesions should avoid handling all invasive equipment, because the pathogens from these conditions can contaminate the equipment and spread infection to clients.

The third source of variability occurs when a blood specimen is drawn from a site above an intravenous infusion. The specimen is contaminated with intravenous solutions. Blood should be drawn from the client's other arm or below the infusion site.

Venipuncture is an invasive procedure. Health care providers performing venipuncture are at risk for the transmission of blood-borne organisms, such as human immunodeficiency virus (HIV) and hepatitis. HIV is the causative agent for acquired immunodeficiency syndrome (AIDS).

THINK ABOUT IT

Determining Needle Gauge

The gauge of the needle should be appropriate to the size of the vessel to prevent hemolysis.

Correct selection and preparation of equipment and vein provides for a safe and efficient venipuncture (Procedure 28-1). Review of the client's health history and physical assessment data will assist in identifying special client considerations. If the client has a bleeding

PROCEDURE 28-1

Venipuncture

Equipment

- | | |
|---|--|
| <ul style="list-style-type: none"> ■ Sterile packages of 70% isopropanol (antiseptic) and povidone-iodine (topical anti-infectant) ■ Sterile needle and syringe or vacutainer system (20- or 21-gauge needle for cubital vein puncture on an adult) | <ul style="list-style-type: none"> ■ Sterile 2 × 2 cotton gauze and povidone-iodine ■ Tourniquet ■ Nonsterile gloves ■ Bandage or sterile adhesive bandage ■ Collecting tubes |
|---|--|

Action

1. Check identification band.
2. Wash hands.
3. Explain procedure to client.
4. Place client in a sitting or supine position; lower side rail.
5. Prepare supplies:
 - Open sterile packages.
 - Label specimen tubes with the client's data.
6. Position arm straight. If possible place extremity in dependent position.
7. Apply the tourniquet 6 to 10 cm above the elbow. Tourniquet should only obstruct venous blood flow, not arterial. Check for a distal pulse.

Rationale

1. Ensures correct client.
2. Decreases transmission of microorganisms.
3. Reduces anxiety; promotes cooperation.
4. Promotes client comfort; provides access to the site.
5. Promotes efficiency; ensures accuracy of specimen collection regarding the client's identifying data, date and time of collection.
6. Provides access to vein. Increases venous dilation and visibility.
7. Restricted arterial blood flow prevents venous filling.

(continues)

PROCEDURE 28-1

Venipuncture (continued)

Action

8. Select a dilated vein (Figure 28-2). If a vein is not visible, instruct client to open and close a fist; or stroke extremity from proximal to distal, tap lightly over a vein, apply warmth.

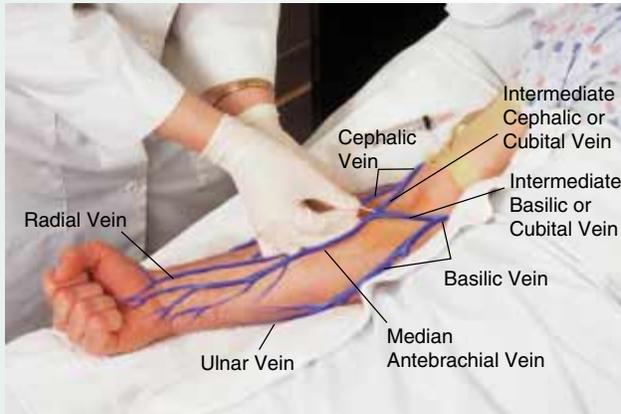

Figure 28-2 Nurse selects site for venipuncture and holds skin taut over site with needle held at 30° angle.

Rationale

8. Commonly used veins are the basilic or median cubital. Alternate sites are lower arm veins (cephalic or median antebrachial) and hand veins (basilic). Methods to increase venous dilation.

9. Palpate the vein for size and pliancy; be sure it is well seated.
 10. Release the tourniquet.
 11. Cleanse puncture site with isopropanol, let dry and cleanse with povidone-iodine, let dry or wipe with sterile gauze, do not touch site after cleansing. If the client is allergic to iodine, only use isopropanol and cleanse skin for 30 seconds.
 12. Place equipment in easy reach and position yourself to access the puncture site.
 13. Reapply the tourniquet (time should not exceed 3 minutes).
 14. Don gloves.
 15. Perform venipuncture:
 - Remove cap from 20- or 21-gauge needle.
 - With nondominant hand, stabilize the vein by holding the skin taut over the puncture site (apply downward tension on the forearm with your thumb).
 - With dominant hand, hold the needle bevel facing upward at an approximate 30° angle to the arm (see Figure 28-2).
 - Puncture the skin into the straightest part of vein with a steady, moderately fast movement. (When the vein is entered you will feel
9. Locates a well dilated vein; vein does not roll.
 10. Prevents hemoconcentration.
 11. Povidone-iodine reduces bacteria on the skin's surface; it must dry to be effective.
 12. Promotes efficiency.
 13. Restricts blood flow, distends vein.
 14. Decreases exposure to blood-borne organisms.
 15.
 - Large-bore needle prevents hemolysis.
 - Prevents the vein from rolling when the needle is pushed against the outer wall of the vein.
 - Provides for a downward movement toward vein.
 - Decreases risk of going through the vein, decreases discomfort.

(continues)

PROCEDURE 28-1

Venipuncture (continued)

Action	Rationale
<p>a slight give and can see blood at the needle's hub.)</p> <ul style="list-style-type: none"> Apply moderate negative pressure by puncturing the vacuum tube or by gently retracting the syringe plunger. (When first performing a venipuncture, use a syringe. It takes greater dexterity to puncture the vacuum tube with a two-sided needle; if you apply too much pressure you will go through the vein.) 	
16. Remove the tourniquet once blood is flowing into the tube or syringe; collect the specimen(s).	16. Prevents hemolysis.
17. Remove the needle and immediately apply pressure to site for 2 to 3 minutes or 5 to 10 minutes if client is taking anticoagulant medication. Keep the arm straight.	17. Decreases bleeding. Bending the arm can reopen the puncture site.
18. Have the client maintain pressure on the puncture site. <ul style="list-style-type: none"> <i>Note:</i> Green stoppers contain sodium heparin (anticoagulant); they must be mixed promptly after collection. 	18. Facilitates clotting. <ul style="list-style-type: none"> Prevents coagulation of blood in test tube.
19. Apply a sterile bandage or adhesive bandage to puncture site.	19. Facilitates clotting.
20. If using a needle and syringe, transfer the blood into test tube under moderate pressure.	20. Prevents hemolysis.
21. Dispose the needle or needle/syringe into a sharps container.	21. Prevents needle stick.
22. Remove gloves; wash hands.	22. Decreases transmission of microorganisms.

disorder or is taking anticoagulant therapy, apply pressure to the puncture site for 3 to 5 minutes after the removal of the needle.

Nursing Process Highlight

INTERVENTION

Clients with a depressed white blood cell count are susceptible to infection. Whenever you have to puncture the skin of a client with a depressed white blood cell count, cleanse the puncture site for 2 to 3 minutes.

Arterial Puncture

Assessment of arterial blood gases (ABG) reveals the ability of the lungs to exchange gases by measuring the partial pressures of oxygen (PO_2), carbon dioxide (PCO_2), and evaluates the pH of arterial blood. Blood gases are ordered to evaluate:

- Oxygenation
- Ventilation and the effectiveness of respiratory therapy
- Acid-base level of the blood

Arterial blood samples are drawn from a peripheral artery (e.g., radial or femoral) or from an arterial line. The arterial blood sample is collected in a 5-ml heparinized syringe. The syringe is then rotated to mix the blood with the heparin to prevent clotting. The

THINK ABOUT IT

Diagnostic Testing and Confidentiality

Mr. Takahashi comes to the Ambulatory Surgery Clinic for his preoperative diagnostic testing. You overheard the staff saying that Mr. Takahashi has had a history of hepatitis. Your instructor gathers all the student nurses and says “Who needs the experience of performing a venipuncture?” Two of your classmates indicate to the instructor that they have not had the opportunity to perform this procedure. Should you say anything to the instructor? Would you share with your classmates Mr. Takahashi’s history? If you said something, would this be a breach of client confidentiality?

blood sample is placed on ice to reduce the rate of oxygen metabolism.

In some agencies it is within the scope of nursing practice to perform radial artery puncture; however, femoral artery puncture is usually performed only by an advanced practitioner. An increased risk of hemorrhage exists with a femoral puncture. Although it is not common practice for student nurses to draw ABG samples, students often have to assist with the procedure and care for the client after the procedure.

Arterial punctures should not be performed:

- If the client is hyperthermic
- Immediately after breathing and suctioning treatments
- If there have been changes on ventilator settings

NURSING ALERT

Arterial Blood Gases

Arterial blood gases should not be drawn within 20 minutes after any respiratory treatment; *ensures accurate determination of the client’s actual blood gases.*

Arterial samples are also contraindicated in the following conditions:

- Anticoagulant therapy
- Clotting disorders
- Symptomatic peripheral vascular disease
- Negative Allen test

An **Allen test** is performed to measure the collateral circulation to the radial artery. See Chapter 27 for the Allen test procedure.

Regardless of who performs the arterial puncture, the nurse is responsible for assessing the client for symptoms of bleeding or occlusion postpuncture. Direct pressure must be applied to the puncture site until all bleeding has stopped, a minimum of 5 minutes. Ensure

NURSING ALERT

Postarterial Puncture

Instruct the client to notify you immediately if any pain or numbness occurs in the arm or leg after arterial puncture, symptoms indicate impaired circulation.

that all bleeding has stopped before releasing the pressure. Symptoms of impaired circulation include:

- Numbness and tingling
- Bluish color
- Absence of a peripheral pulse

Capillary Puncture

Skin punctures are performed when small quantities of capillary blood are needed for analysis or when the client has poor veins. Capillary puncture is also commonly performed for blood glucose analysis, discussed later in this chapter.

The common sites for capillary punctures are the:

- Heel—most common site for neonates and infants
- Fingertip—the inner aspect of palmar fingertip used most commonly in children and adults
- Earlobe—when the client is in shock or the extremities are edematous

To perform a skin puncture, assemble the equipment, prepare the client, and select the appropriate site (Procedure 28-2). Figure 28-3 shows a capillary puncture of a fingertip.

Central Lines

Blood samples can be collected from central lines. A **central line** refers to a venous catheter inserted into the superior vena cava through the subclavian, internal, or external jugular vein. Central lines are used to treat alterations in fluid or electrolytes. The client’s nursing diagnoses may include the following: *Deficient Fluid Volume related to nausea and/or vomiting or Imbalanced Nutrition, Less than Body Requirement related to anorexia.*

A central line is inserted when a peripheral route cannot be obtained, for treatment, and to withdraw blood for analysis.

Nurses need to know the type and location of the central line catheter. There are various types of central lines. Central lines can have either one or more lumens inside the catheter. For example, a central venous catheter has either one or two lumens, whereas a Hickman multilumen catheter, may have either two or three catheters contained in one sheath (Figure 28-4).

It is standard practice to mark each lumen of a multilumen catheter with the name of the infusion (e.g., fluid or medication). Lumens are marked to prevent the mixing of medications. Lumens without continuous

PROCEDURE 28-2

Skin Puncture

Equipment

- Antiseptic—70% isopropanol or povidone-iodine
- Sterile 2 × 2 gauze
- Sterile lancet
- Hand towel or absorbent pad
- Microhematocrit tubes or micropipette (collection tubes)
- Nonsterile gloves

Action

1. Wash hands.
2. Check client's identification band.
3. Explain procedure to client.
4. Prepare supplies:
 - Open sterile packages.
 - Label specimen collection tubes.
 - Place in easy reach.
5. Don gloves.
6. Select site:
 - Lateral aspect of the fingertips in adults/children
7. Place the hand or heel in a dependent position; apply warm compresses if fingers or heel are cool to touch.
8. Place hand towel or absorbent pad under the extremity.
9. Cleanse puncture site with an antiseptic and allow to dry; use 70% isopropanol if client is allergic to iodine.
10. With nondominant hand apply light pressure by gently squeezing the area above/around the puncture site. Do not touch puncture site.
11. With the sterile lancet at a 90° angle to the skin, use a quick stab to puncture the skin (about 2 mm deep) (Figure 28-3).

Rationale

1. Decreases transmission of microorganisms.
2. Ensures correct client.
3. Allays anxiety and encourages cooperation.
4. Ensures efficiency.
5. Decreases the health care provider's exposure to blood-borne organisms.
6. Avoids damage to nerve endings and calloused areas of the skin.
7. Increases the blood supply to the puncture site.
8. Prevents soiling the bed linen.
9. Reduces skin surface bacteria; povidone-iodine must dry to be effective.
10. Increases blood supply to puncture site; maintains asepsis.
11. Provides a blood sample with minimal discomfort to the client.

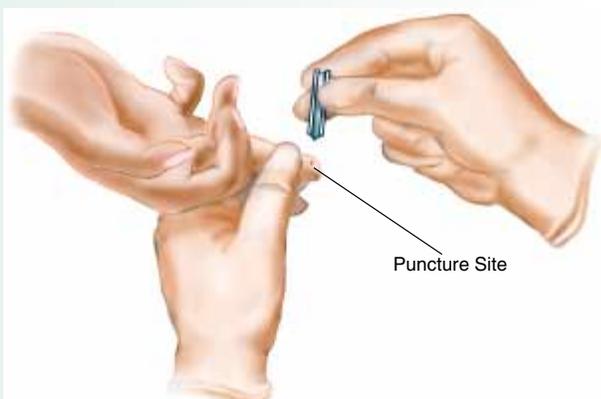

Figure 28-3 Capillary Puncture of Fingertip

(continues)

PROCEDURE 28-2

Skin Puncture (continued)

Action	Rationale
12. Wipe off the first drop of blood with a sterile 2 × 2 gauze; allow the blood to flow freely.	12. Pressure at the puncture site can cause hemolysis.
13. Collect the blood into the tube(s). If a platelet count is to be collected, obtain this specimen first.	13. Allows blood collection; avoids aggregation of platelets at the puncture site.
14. Apply pressure to the puncture site with a sterile 2 × 2 gauze gauze.	14. Controls bleeding.
15. Place contaminated articles into a sharps container.	15. Reduces risk for needle stick.
16. Remove gloves; wash hands.	16. Reduces transmission of microorganisms.
17. Position client for comfort with call light in reach.	17. Provides for comfort and communication.

Figure 28-4 Hickman Catheter®. (Photo provided by Bard Access Systems. Hickman is a registered trademark of Bard Access Systems.)

NURSING ALERT

Central Line

Clients in the home environment usually have a central line in place for prolonged therapy. Because one of the primary complications of central venous catheter insertion is infection, the nurse must be alert for signs of infections (e.g., fever) exhibited by the client.

infusion of fluids are capped with an infusion plug and flushed with a heparin solution every 8 hours according to agency protocol. Heparin prevents obstruction of the catheter lumen with a blood clot. The first sample of blood drawn from the central line cannot be used for diagnostic testing; it must be discarded. The amount of discard volume is directly related to the dead space (catheter size). The agency's protocol should indicate the volume to discard relative to the type and size of catheter.

The nursing care of central lines requires strict sterile technique. See Chapter 30 for a discussion of sterile technique. The practitioner has to write an order to allow a blood sample to be obtained from a central line. Refer to the Nursing Checklist for how to draw a blood sample from a central line.

Implanted Port

Some clients have a **port-a-cath** (a port that has been implanted under the skin) over the third or fourth rib.

NURSING CHECKLIST

Obtaining a Blood Sample From a Central Line

- Gather equipment (the sizes of the needle and syringe to obtain the blood sample are determined by the amount of blood needed for the test and the type and size of central line catheter).
- Check the client's identification band.
- Wash hands and don gloves to prevent exposure to blood-borne organisms.
- Select a port that is not used routinely for an infusion.
- Cleanse the port of the lumen with an antiseptic.
- Insert the needle into the port and aspirate the discard volume according to agency protocol; dispose of the syringe containing the discard blood into a sharps container.
- Access the port and withdraw the blood sample.
- Apply the same principles used in venipuncture to prevent the hemoconcentration and hemolysis of blood when withdrawing the sample.
- Transfer the sample into the correct collection tubes and discard the contaminated needle and syringe into the sharps container.
- Instill the required heparin solution to prevent the lumen from clotting.
- Transport specimen to the laboratory.
- Remove gloves, wash hands.

The port has a catheter that is inserted into the superior vena cava or right atrium through the subclavian or internal jugular vein. The implanted port is used for the same purpose as the central lines.

Blood can be withdrawn for sampling by accessing the port using strict sterile technique. Accessing a port should only be performed by a nurse with proper education. Students are not usually taught how to access an implanted port.

Urine Collection

The kidneys are responsible for maintaining homeostasis of the body's buffering systems and the volume, and ionic and osmotic composition of its fluid compartments; refer to Chapter 37 for a complete discussion of the composition of fluid compartments. "Although the results of kidney functions are reflected in analyses of blood, the mechanisms by which normalcy of body fluids is preserved can be understood only through studies of urine" (Kirschbaum, Sica, & Anderson, 1999, p. 597).

Urine can be collected for various studies. The type of testing determines the method of collection. The different methods of urine collection are:

- Random collection (routine analysis)
- Timed collection
- Collection from a closed urinary drainage system
- Clean-voided specimen

The urine from a closed urinary drainage system is a sterile specimen. Client teaching depends on the client's age and the method of collection. Initiate the protocol for preparing the client for testing (see Table 28-1). The method of collection should be written on the laboratory requisition.

NURSING ALERT

Urine Collection

As with blood, all urine collection requires the use of Standard Precautions to prevent the transmission of microorganisms among nurses, clients and other health care providers.

Random Collection

The practitioner usually writes the order for a UA (routine urine analysis), which is also called a random collection. It can be collected at any time using a clean cup. The urine does not have to be collected in a sterile container. Instruct the client to urinate into the specimen cup or into a clean bedpan or urinal. Wearing gloves, transfer the urine into a clean container. Seal the lid tightly, label, and place in a biohazard bag for transport to the laboratory. Submit the specimen immediately to the laboratory to prevent the growth of bacteria or changes in the urine's analytes (substances).

NURSING TIP

Urine Collection in the Home

Instruct clients in the home to place the urine container in a Zip Lock bag and refrigerate until it is delivered to a laboratory; this prevents the growth of bacteria and promotes accuracy of results.

Timed Collection

Timed collection is done over a 24-hour period. The urine is collected in a plastic gallon container that contains preservative(s), some of which are caustic. The laboratory usually adds the preservatives to the container. If the analyte to be studied is light sensitive, a dark plastic container is necessary.

Provide the client with specific instructions. The client is told to **void** (the process of urine evacuation) and discard the specimen at the beginning of the collection. The 24-hour collection begins with the first discarded voiding. For example, if the client is instructed to void at 1000 hours (24-hour clock time frame), discard the urine, save all other voided specimens until 1000 hours the following day. The client can void throughout the test into a clean container, then pour the urine into the collection bottle. Toilet tissue should not be dropped into the container used to catch the urine.

The collection container should be refrigerated or kept on ice throughout the 24 hours. This retards bacterial growth and stabilizes the analytes. The last urine collection, 1000 hours, should be a complete, forced voiding at the exact timed period. Seal the labeled container tightly and take immediately to the lab.

Collection from a Closed Drainage System

A sterile specimen can be collected from a client with an indwelling Foley catheter with a closed drainage system. A sterile specimen is used to culture the urine. *The urine specimen should not be obtained from the drainage bag.* The analytes in the urine drainage bag change; this will cause inaccurate results. Bacteria grow quickly in the drainage bag.

The catheter's closed drainage tubing has an aspiration port that is used for a sterile specimen collection (Procedure 28-3).

Clean-Voided Specimen

Clean-voided (clean-catch, or midstream) specimen collection is done to secure a specimen uncontaminated by skin flora. A clean-voided specimen should be obtained on first voiding in the morning. Most adult clients are capable of following instructions to perform this test.

PROCEDURE 28-3

Urine Collection—Closed Drainage System

Equipment

- Rubber band or catheter clamp
- Tape and sign
- Examination gloves
- Sterile specimen container and label
- Sterile packages of 70% isopropanol (anti-infective) or povidone-iodine (antiseptic)
- Sterile 10-ml syringe with 23- or 25-gauge needle

Action

1. Check client's identification band.
2. Gather equipment.
3. Explain procedure to client.
4. Manipulate the drainage tubing so that the urine in the tubing goes into the bag.
5. Clamp the drainage tubing below the aspiration port; leave clamped 10 to 15 minutes.
6. Tape a sign over the client's bed that the Foley catheter's drainage tubing is temporarily clamped for a specimen.
7. Wash hands, don gloves.
8. Provide for privacy.
9. Cleanse the aspiration port with an anti-infective or antiseptic solution; let dry.
10. Remove all air from the needle and syringe.
11. Insert needle into aspiration port at a 45° angle, aspirate 10 ml, from port, remove needle.
12. Transfer urine into sterile labeled container, secure lid on container, and place container in a biohazard bag.
13. Place needle and syringe unit into sharps container, *never recap a contaminated needle*.
14. Remove the notice from above the bed.
15. Transport specimen to laboratory.
16. Remove and dispose of gloves, wash hands.

Rationale

1. Ensures accuracy.
2. Promotes efficiency.
3. Allays anxiety, increases participation.
4. Facilitates urine to flow into the drainage bag; provides a fresh urine sample.
5. Traps fresh urine in the tubing above the level of the aspiration port.
6. Communicates to other personnel that the drainage tube is clamped.
7. Decreases transmission of microorganisms.
8. Decreases embarrassment.
9. Inhibits growth and reproduction of microorganisms; povidone-iodine must dry to be effective antiseptic.
10. Allow for withdrawal of the correction amount of urine.
11. Prevents accidental puncture of the catheter wall on distant side of port; provides sufficient urine for analysis.
12. Prevents contamination of sterile specimen, ensures client accuracy, prevents spillage.
13. Prevents accidental needle sticks.
14. Clamp is no longer in place.
15. Prevents growth of bacteria or changes in the urine's analytes.
16. Decreases transmission of microorganisms.

Different aseptic techniques are used for women and men. Poor technique in cleaning the perineum can contaminate the specimen. Instruct the female client to cleanse from the front to the back (Procedure 28-4).

Instruct the male client to perform the same procedure except for the cleansing of the perineal area; men should cleanse from the tip of the penis downward. The Nursing Checklist describes the procedure for obtaining a clean-voided specimen from a man.

PROCEDURE 28-4

Urine Collection—Clean Catch, Female

Equipment

- Examination gloves
- Sterile collection container and lid, label
- Sterile midstream kit
- 3 antiseptic towelettes or 3 cotton balls saturated with an antiseptic solution

Action

1. Gather equipment.
2. Check client's identification band.
3. Wash hands and don gloves.
4. Provide for privacy.
5. Instruct the female client:
 - To sit with legs separated on the toilet.
 - Open the sterile container, placing the lid up on a firm surface in easy reach.
 - Using thumb and forefinger separate the labia.
 - With the labia separated, using a downward stroke, cleanse one side of the labia with the towelette, discard the towelette, repeat procedure on the other side with the second towelette, make sure the labia stay separated throughout the procedure (Figure 28-5).

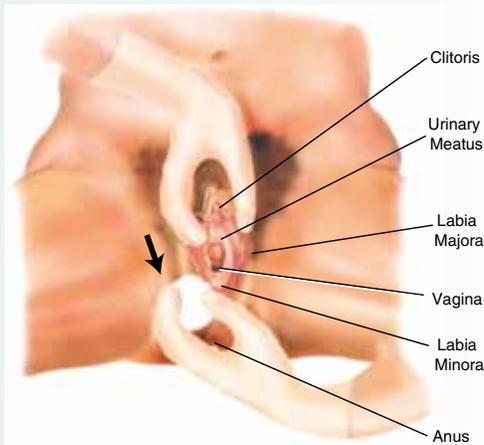

Figure 28-5 Cleansing Labia

Rationale

1. Promotes efficiency.
2. Ensures accuracy.
3. Decreases transmission of microorganisms.
4. Decreases embarrassment.
5. Allays anxiety, increases participation.
 - Comfortable position, provides access to cleansing the labia.
 - Prevents the inside of the container's lid from touching a soiled surface; prevents contamination of specimen.
 - Provides access for cleansing the labia.
 - Prevents contamination of clean area.
6. Begin to urinate into the toilet, place the collection cup under the stream of urine after a good flow of urine has been started. Fill the container half-way with urine.
6. Initial flow of urine is *not* collected, can contain bacteria.
6. Place sterile lid back onto the container, close tightly, label and transport to laboratory.
6. Prevents contamination of sterile specimen, prevents spillage, ensures client accuracy.
7. Remove and dispose of gloves; wash hands.
7. Decreases transmission of microorganisms.

✓ NURSING CHECKLIST

Clean-Voided Specimen, Male

- Check the client's identification band.
- Instruct the client on the procedure.
- Wash hands and don gloves if the client needs assistance with the procedure.
- If uncircumcised, retract the foreskin, hold retracted.
- Cleanse the head of the penis with a towelette using a circular motion. Cleanse the meatus and glans beginning with the urethral opening and make one complete circle around the penis, moving down the glans shaft.
- Discard the towelette.
- Repeat the procedure until all three towelettes have been used.

THINK ABOUT IT

Overcoming Embarrassment

You are cleansing the genitals of a client to obtain a clean catch urine sample. How would you feel about performing this type of procedure if the client were a man? A woman? What methods would you use to maintain your professional role while still respecting and caring for the client? How would you maintain your nurse-client relationship without becoming too personal? Or without depersonalizing the client so that he or she becomes uncomfortable?

When obtaining a clean-voided specimen from infants and small children, secure assistance. Follow the Nursing Checklist.

Stool Collection

Explain to the client why the stool specimen is being collected. Instruct the client to defecate into a clean bedpan or container, discarding tissue into the toilet. Stools can be collected for either a one-time defecation or over 24, 48, or 72 hours. If a specimen is needed over a pro-

NURSING ALERT

Stool from a Client with Hepatitis

When collecting a stool specimen from a client with hepatitis, write on the lab requisition form that the client has hepatitis. This increases the laboratory personnel's awareness to be extra careful when handling the specimen.

✓ NURSING CHECKLIST

Clean-Voided Specimen, Infant and Child

- Check the identification band.
- Explain the procedure to family member present with infant or child. If the child can cooperate, tell child what to do before having someone hold him or her in position.
- Wash hands and don gloves.
- Place in a supine position with hips externally rotated.
- Have parent or assistant flex and abduct the knees, hold the knees throughout the procedure.
- Cleanse the perineal area as you would for an adult.
- Place a sterile collection bag over the perineum or penis and scrotum, apply a diaper.
- Remove the collection bag immediately after voiding.
- Transfer the urine into the labeled collection container, close lid tightly, place in biohazard bag for immediate transport to the laboratory.

longed period of time, all stools must be placed into a container and refrigerated. Once collected, label the container with the client's name, date, time, and the test to be performed on the specimen. All stool specimens are placed in a biohazard bag before transport to the laboratory.

Hematologic System

Understanding the hematologic system requires a knowledge of the blood's composition and its functions. Table 28-4 discusses the origin, normal range values, and the major function for each of the three types of cells found in blood:

- Red blood cells (**erythrocytes**)
- White blood cells (**leukocytes**)
- Platelets

Forty to 45% of the blood's volume is composed of blood cells; the remaining blood volume is plasma as shown in Figure 28-6. Plasma is part of the body's extracellular fluid system, consisting of water and analytes. Blood proteins form the largest portion of the plasma analytes. The average plasma volume for a normal adult is 3 L.

Red Blood Cells

Red blood cells (RBCs), in embryonic life, are produced first in the yolk sac until the middle trimester; then the liver becomes the main organ of RBC production. RBC

TABLE 28-4
Types of Blood Cells

Cell	Origin	Range SI Units*	Major Function
Erythrocytes	Bone marrow	F: $4.0\text{--}5.2 \times 10^{12}/\text{L}$ M: $4.5\text{--}5.9 \times 10^{12}/\text{L}$	Transport hemoglobin
Leukocytes	Granulocytes Monocytes Bone Marrow Lymphocytes Plasma cells Lymph tissue	$4.5\text{--}11.0 \times 10^9/\text{L}$	The body's protective system
Platelets	Bone Marrow from megakaryocytes	$150\text{--}300 \times 10^9/\text{L}$	Vascular repair

*Data for normal range SI units from Noe, D., & Rock, R. (1994). *Laboratory medicine*. Baltimore: Williams & Wilkins.

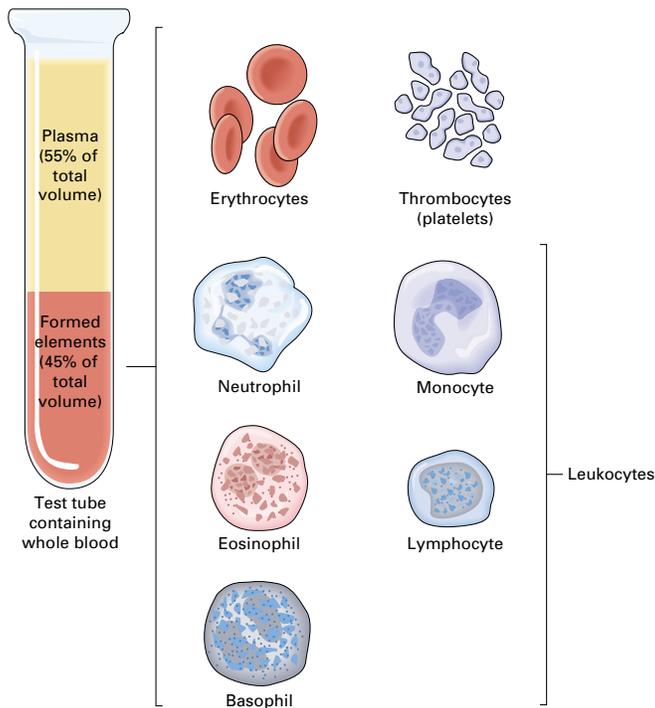

Figure 28-6 Blood Cells

production becomes the exclusive function of the bone marrow by the end of gestation, after birth, and throughout life. RBC bone marrow site production changes with age:

- From birth to age 5—all bone marrow
- Five to 20 years—the shaft of the long bones (tibia and femur)
- After 20 years—the membranous bones (ilia, ribs, sternum, and vertebrae). As part of the normal aging process, the production of RBCs decreases with age.

Functions of the RBCs include:

- Transporting oxygen carrying hemoglobin
- Transporting carbon dioxide in the form of sodium bicarbonate
- Being an acid-base buffer for whole blood

White Blood Cells

There are six types of white blood cells (WBCs, leukocytes) found in the blood.

- Neutrophils
- Basophils
- Lymphocytes
- Eosinophils
- Monocytes
- Plasma cells

The polymorphonuclear cells, neutrophils, eosinophils, and basophils have a granular appearance, hence the name granulocytes or polys. The granulocytes and monocytes are responsible for **phagocytosis** (process by which certain cells engulf and dispose of foreign bodies). The lymphocytes and plasma cells function mainly as the body's immune system.

The WBCs are formed and stored in the bone marrow until needed by the body. Table 28-5 presents laboratory studies for a complete blood count with SI values and when each analyte is either increased or decreased in clinical situations.

Red Cell Indices

Red cell indices measure the size and hemoglobin content of the RBCs. The RBC indices are:

- Mean red cell hemoglobin (MCH)
- Mean red cell hemoglobin concentration (MCHC)
- Mean red cell volume (MCV)

The indices are diagnostic in determining the type of anemia. For example, an elevated MCHC means that

TABLE 28-5
Complete Blood Count with Clinical Significance

Analyte	SI Range	Increased	Decreased
Red blood cell count	F: $4.0\text{--}5.2 \times 10^{12}/\text{L}$ M: $4.5\text{--}5.9 \times 10^{12}/\text{L}$	Dehydration, induced hypoxia, polycythemia	Anemias, hypothyroidism, leukemias
Hemoglobin (Hb): Whole blood Fetal Plasma	F: 120–150 g/L, M: 139–163 g/L 0–75mg/L < 0.01	Chronic obstructive lung disease, polycythemia, high altitudes burns, shock	Anemia, severe hemorrhage
Hematocrit (Hct)	F: 0.36–0.46 M: 0.41–0.53	Dehydration, polycythemia	Leukemia, hemorrhage
Mean red cell Hb	26–34 pg/RBC	Macrocytosis	Microcytic hypochromic anemia
Mean red cell Hb concentration	310–370 g/L	Spherocytosis	Chronic iron deficiency anemia
Mean red cell volume	80–100 fl	Aplastic anemia, cirrhosis, folic acid & vitamin B ₁₂	Chronic iron deficiency, thalassemias, chronic anemia
White blood cell (WBC): Total count	$4.5\text{--}11.0 \times 10^9/\text{L}$	Acute leukemia, infections, surgery, trauma	Acute chronic leukemias, aplastic anemia, agranulocytosis
WBC Differential	% of total WBC		
Band Neutrophils	0–0.06%	Severe bacterial disease	
Segmented neutrophils	0.31–0.76%	Diabetic acidosis, infarctions, inflammatory diseases, malignancies	
Lymphocytes	0.14–0.44%	Chronic lymphocytic leukemia	Lupus erythematosus, Hodgkin's disease
Monocytes	0.02–0.11%	Chronic inflammatory diseases	
Eosinophils	0–0.04%	Allergies, parasites	
Basophils	0–0.02%	Myelofibrosis	

Data for normal range SI units from Noe, D., & Rock, R. [1994]. *Laboratory medicine*. Baltimore: Williams & Wilkins.

spherocytes (smaller, thicker red cells) are present; this occurs in acquired hemolytic anemia.

Platelets

Platelets are fragments of a seventh type of WBC found in the bone marrow, the megakaryocytes. Platelets maintain hemostasis and blood coagulation by being the active mechanism of the blood in vascular repair. The active factors necessary for blood to coagulate are found in the cytoplasm of platelets. Blood coagulation is a

comprehensive, sequential process of the body's response to injury.

The blood coagulation flow chart (Figure 28-7) reviews the key elements of vascular constriction and coagulation. Prothrombin (factor II) is a plasma protein, formed in the liver, and requires vitamin K for synthesis. It is activated when blood vessels are damaged. Prothrombin activator causes the conversion of prothrombin into thrombin, which then causes fibrinogen to form threads. This whole process takes 10 to 15 seconds.

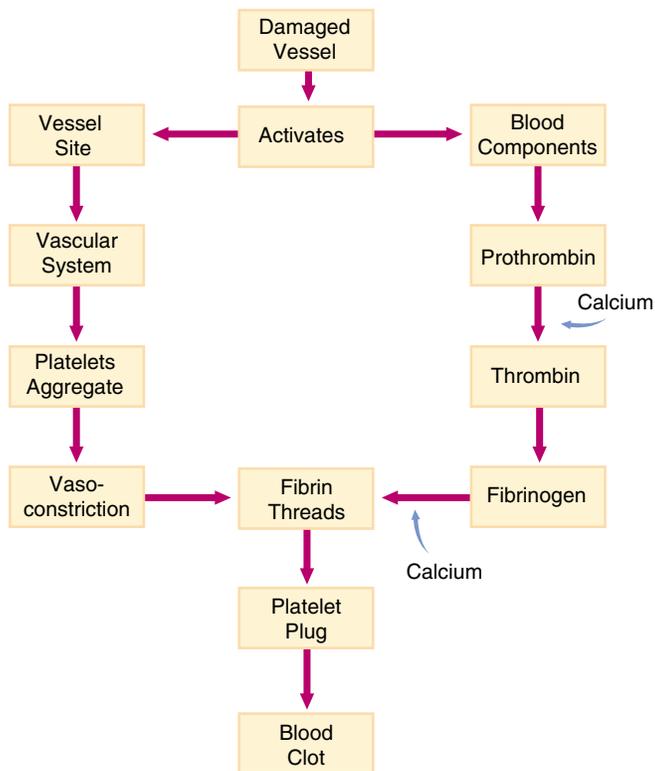

Figure 28-7 Blood Coagulation Flow Chart

Prothrombin activator is the governing element in blood coagulation. Prothrombin time (PT) measures the defects in this extrinsic clotting mechanism, specifically fibrinogen (factor I), prothrombin (factor II), and factors V, VII, and X (Pagana & Pagana, 1999).

NURSING ALERT

Drug Effect on Prothrombin Time

Be sure to list the drugs the client is taking on the laboratory requisition for the PT test; some drugs affect the PT.

Drugs can either increase or decrease the PT. Common drugs that increase the PT include salicylates, steroids, sulfonamides, oral anticoagulants, antibiotics, quinidine, Dilantin, Aldomet, Tagamet, cathartics, and alcohol. Other drugs can decrease the PT: digitalis, oral contraceptives, corticosteroids, chloral hydrate, barbiturates, vitamin K, Placidyl, Doriden, griseofulvin, Alupent, and rifampin.

Partial thromboplastin (PTT) or activated partial thromboplastin time (aPTT) measures the intrinsic clotting mechanism factors (I, II, V, X, XI, XII). There are five primary screening tests to diagnose suspected coagulation disorders (Pagana & Pagana, 1999; Fischbach, 2000):

1. Platelet count, size, and shape
2. Bleeding time—the ability of platelets to function normally and the ability of capillaries to constrict their walls, prolonged with deficiencies in platelets and other clotting factors
3. PTT—measures the ability of the blood to clot, prolonged with any intrinsic factor deficiencies such as hemophilia A (factor VIII) and hemophilia B (factor X)
4. PT—measures the total quantity of prothrombin in the blood, monitors the effectiveness of coumarin therapy, prolonged with deficiencies in the extrinsic factors and vitamin K
5. Fibrinogen level—investigates abnormal PT and APTT and to screen for **disseminated intravascular coagulation (DIC)** (an acquired hemorrhagic syndrome characterized by uncontrolled formation and deposition of thrombi) and fibrin-fibrinogenolysis; levels increase with acute inflammatory reactions, trauma, coronary heart disease and cigarette smoking and decrease in liver disease, DIC, cancer, primary fibrinolysis and congenital hypofibrinogenemia.

Thrombin time (TT) measures the fibrinogen portion of the hemostatic mechanism; it is infrequently used today to evaluate the fibrinogen-to-fibrin reaction. Direct measurements of fibrinogen level and the increasing use of other tests have decreased the usefulness of TT (Pagana & Pagana, 1998).

Sickle Cell Test

Sickle cell test (hemoglobin S) is used to identify the sickle cell trait and sickle cell disease. A negative result, which is normal, indicates the absence of hemoglobin S. The presence of sickle cells causes a positive result, thus requiring hemoglobin electrophoresis to determine the presence of the genetically transmitted deficit. Figure 28-8 shows the difference in the shape between a normal RBC and a sickle-shaped RBC.

Hemoglobin electrophoresis refers to a laboratory test that uses an electromagnetic field (an anode [+], and a cathode [-], which are separated by cellulose acetate or starch gel) to identify various types of hemolytic anemia.

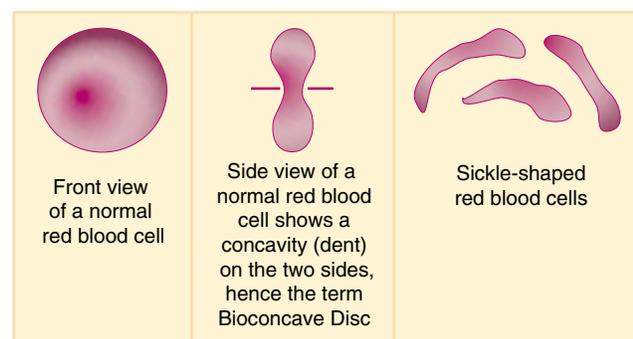

Figure 28-8 Differences in shape are apparent in a normal red blood cell (biconcave disc) and a sickle-shaped red blood cell (crescent-shaped).

Electrophoresis distinguishes between genetically transmitted homozygous and heterozygous hemoglobin S, which is responsible for sickle cell anemia. For example, if both genes carry hemoglobin S, it is called homozygous and the client has sickle cell disease; however, if only one gene has the abnormal hemoglobin S and the other gene has the normal hemoglobin A, the client is heterozygous, having the sickle cell trait. Electrophoresis is also used to identify fetal hemoglobin and distinguishes between thalassemia minor and major.

Sickle cell anemia is a blood disorder with multiple, recurring symptoms that not only causes the client pain from the clumping of RBCs in the joints but has widespread effects on other systems. Figure 28-9 demonstrates the pathologic changes in the body and the resulting effects of sickle cell anemia.

Other common laboratory tests that measure hematologic functions are presented in Table 28-6.

Type and Crossmatch

A **type and crossmatch** is a laboratory test that identifies the client's blood type and determines the compatibility of blood between a potential donor and recipient (client). There are four basic blood types: A, B, AB, and O that are determined by the presence or absence of A or B antigens as seen in Figure 28-10. **Antigens** are substances, usually proteins, that cause the formation of and react specifically with antibodies. **Antibodies** are immunoglobulins produced by the body in response to bacteria, viruses, or other antigenic substances. Type A and type B are antigens that are classified as **agglutinogens**, which are substances that cause **agglutination** (clumping of RBCs). **Agglutinins** are specific kinds of antibodies whose interaction with antigens is manifested as agglutination.

Blood types are also designated as either positive or negative, depending on the presence or absence of the

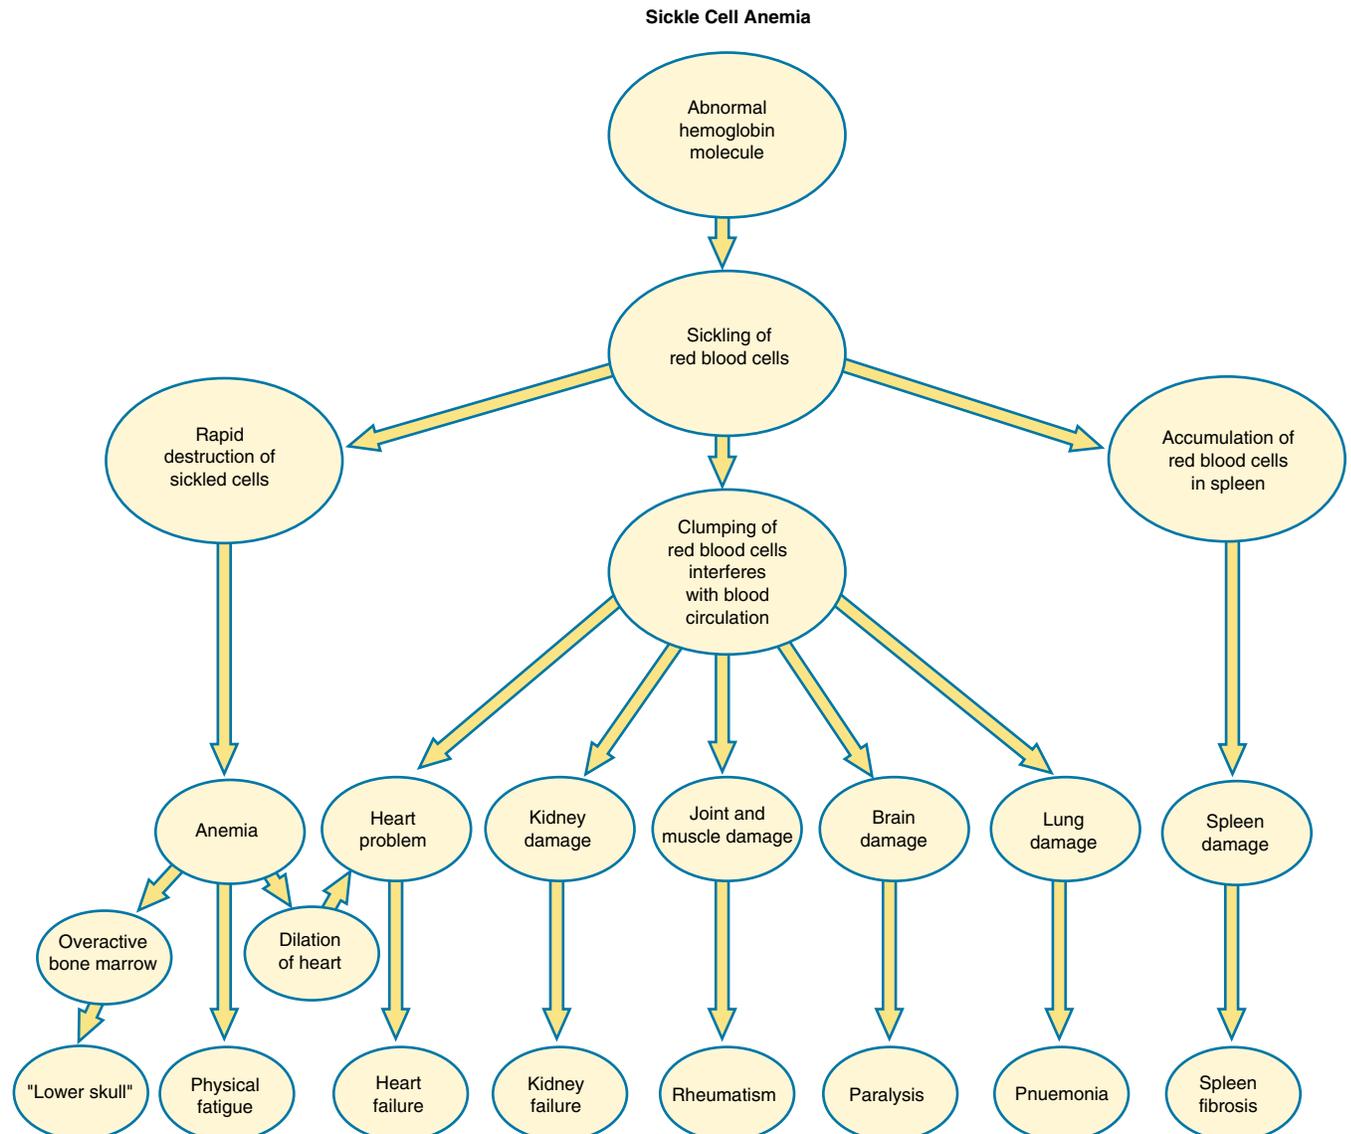

Figure 28-9 Sick cell anemia: the clumping of red blood cells with their resulting effects on the body are shown.

TABLE 28-6
Hematologic Function Studies

Test/Normal Range	Diagnostic Value
Erythrocyte sedimentation rate (ESR or sed rate) Westergren: F: < 50 yr 0–25 mm/h > 50 yr 0–30 mm/h M: < 50 yr 0–15 mm/h > 50 yr 0–20 mm/h	Alterations in the plasma proteins cause aggregation of the RBCs with an elevated ESR: moderately, with inflammatory diseases; high, with multiple myeloma, macroglobulinemias, hyperfibrinogenemias.
Haptoglobin 0.10–0.30 g/L 12–35 μ mol/L	Haptoglobins bind with free hemoglobin released from the destruction of RBCs, conserving iron, <i>decreased</i> in any condition causing hemolysis of RBCs: hemolytic anemias (sickle cell anemia, hereditary spherocytosis, erythroblastosis fetalis), thalassemia, liver disease, transfusion reactions, systemic lupus erythematosus, prosthetic heart valve implants; <i>increased</i> with acute and chronic infections, inflammation, malignancies, steroid therapy, rheumatoid arthritis, ulcerative colitis, peptic ulcer, oral contraception, pregnancy.
Glucose-6-phosphate dehydrogenase (G6PD) (red blood cell) F: 7.4–9.4 IU/g hemoglobin Whites 6.5–9.3 IU/g hemoglobin African-Americans M: 7.4–9.4 IU/g hemoglobin Whites 6.6–10.8 IU/g hemoglobin African-Americans	G6PD is an enzyme in RBCs that metabolizes glucose. The test measures enzyme deficiencies that are hereditary, sex-linked conditions carried on the female X chromosome, which causes hemolytic anemia. Clinical disease traits are found in males.
Osmotic fragility 0.30%–0.45% saline < 0.30% saline > 0.50% saline	Test measures the fragility of RBCs to aid in the diagnosis of hereditary spherocytosis. <i>Increased</i> in hereditary spherocytosis, spherocytosis resulting from autoimmune hemolytic anemia, severe burns, chemical poisoning, erythroblastosis fetalis, transfusion reactions, prosthetic heart valve transplantation. <i>Decreased</i> in sickle cell and iron deficiency anemia, polycythemia vera, hemoglobin C disease, thalassemia major, liver disease, obstructive jaundice, or splenectomy
Reticulocyte count (results reported in % of total erythrocytes) Adults 0.5–2.0% Children 0.5–2.0% Infants 0.5–3.5% Newborns 2.5–6.0%	Used to differentiate between hypoproliferative and hyperproliferative anemias; to assess blood loss and bone marrow response to therapy. <i>Increased</i> in hemolytic and sickle cell anemia; hereditary spherocytosis; treatment of anemias from iron, vitamin B ₁₂ , and folic acid deficiencies. <i>Decreased</i> in aplastic, iron deficiency and untreated pernicious anemias; chronic infection; radiation therapy

Rh factor. Rh factor refers to an antigen found on the RBC. Rh positive means the antigen is present; Rh negative means the antigen is absent.

When factoring the four basic blood types with either Rh positive or Rh negative factor there are eight possible combinations (see accompanying box). An individual's blood type is determined by heredity.

Crossmatch determines the compatibility of the donor's blood with that of the recipient. In the laboratory, a sample of the recipient's blood is mixed with the blood of a possible donor. If the blood sample is compatible, the mixed sample does not agglutinate. For example, blood type A negative means that the person's blood

BASIC BLOOD TYPES

- A positive
- B positive
- AB positive
- O positive
- A negative
- B negative
- AB negative
- O negative

contains the A antigen but does not contain the anti-Rh agglutinins. The first time the person is exposed to A-positive blood, either through a transfusion or by giving birth to an Rh-positive child, agglutination does not occur because the body has no antibodies against the

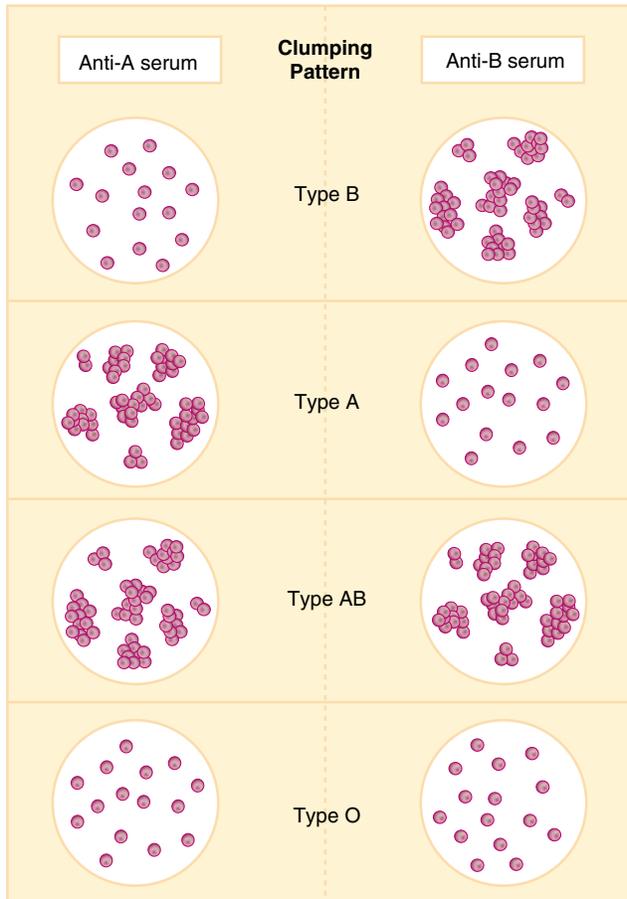

Figure 28-10 Blood Types

antigen. However, once the body has had time to build up antibodies (agglutinins), agglutination will occur.

Blood Chemistry

Blood chemistry analytes can be ordered separately or as profile groups (panels) that consist of 4 to 20 biochemical tests performed on a few milliliters of serum with an instrument called a sequential multiple analyzer (SMA). The studies are referred to as SMA panels based on the number of analytes being tested; refer to accompanying display.

Blood Glucose

Glucose is a simple sugar formed from the digestion of carbohydrates and used by the cells for energy. Insulin is needed to transport glucose into the cells.

Glucose measurement is performed by either skin puncture or venipuncture, fasting blood sugar (FBS) or nonfasting (usually 2-hours postprandial). The normal fasting value is 70 to 115 mg/dl and less than 120 mg/dl postprandial. The 2-hour postprandial blood sugar is drawn 2 hours after the client eats a meal. This test is used to screen for diabetes mellitus; if the results are abnormal, the practitioner may order a glucose tolerance test.

SMA PANELS

Data from Jaffe, M. S., & McVon, B. F. (1997). *Laboratory and diagnostic test handbook*. Philadelphia: F. A. Davis Company.

A glucose tolerance test is the most accurate test for diagnosing hypoglycemia and hyperglycemia (diabetes mellitus). The client is asked to fast until the test begins. The test is conducted as follows:

- Initial blood and urine specimens are obtained.
- An oral loading dose of glucose is administered.
- Blood and urine specimens are obtained at 30 minutes, 1 hour, 2 hours, 3 hours, and sometimes 4 hours after loading dose.

Figure 28-11 is a graphic presentation of the results of a glucose tolerance test, showing results that indicate hyperglycemia, normal glucose, and hypoglycemia.

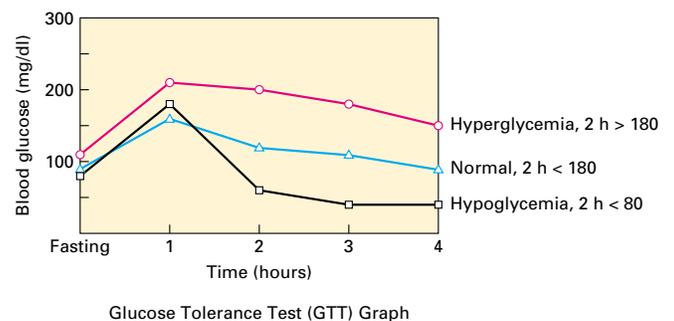

Figure 28-11 Glucose Tolerance Test (GTT) Graph

Title of Study

“Diurnal Variation in Fasting Plasma Glucose: Implications for Diagnosis of Diabetes in Patients Examined in the Afternoon”

Authors

Troisi, R. J., Cowie, C. C., & Harris, M. I.

Purpose

To document diurnal variation in fasting plasma glucose levels in adults not known to have diabetes, and to examine the applicability to afternoon-examined clients based on the diagnostic criteria for diabetes.

Methods

Participants were selected from the U.S. population-based Third National Health and Nutrition Examination Survey (1988–1994). All participants were 20 years of age or older who had no previously diagnosed diabetes. The participants were randomly assigned to morning or afternoon examinations, and fasted prior to blood sampling.

Findings

The two groups did not differ in age, body mass index, waist-to-hip ratio, physical activity index, and other factors. The mean fasting plasma glucose levels were higher in the morning group than in the afternoon group.

Implications

The results of this study indicate that, if current diabetes diagnostic criteria are applied to clients seen in the afternoon, approximately half of all cases of undiagnosed diabetes in these clients will be missed.

Troisi, R. J., Cowie, C. C., & Harris, M. I. (2000). Diurnal variation in fasting plasma glucose: Implications for diagnosis of diabetes in patients examined in the afternoon. *Journal of the American Medical Association*, 284(24), 3157–3159.

Glucose results reveal deficits in either the digestion of carbohydrates or glucose metabolism (e.g., diabetes mellitus). Drugs, especially diuretics and steroids, can cause physiological changes resulting in elevated blood glucose values. Clients receiving intravenous fluids with a high glucose content need to have their glucose levels monitored for hyperglycemia.

Serum Electrolytes

An **electrolyte** is an element or compound that, when dissolved in water or another solvent, separates into ions and provides for cellular reactions. Some electrolytes act on the cell membrane allowing for the transmission of electrochemical impulses in nerve and muscle fibers. Other electrolytes determine the activity of different enzymatically catalyzed reactions that are necessary for cellular metabolism.

Cations are ions that have a positive charge: sodium (Na^+), potassium (K^+), calcium (Ca^{++}), and magnesium (Mg^{++}). **Anions** are ions that have a negative charge: chloride (Cl^-) and phosphate (HPO_4^{--}).

The routine electrolyte laboratory tests are presented in Table 28-7. These tests measure the serum concentration of sodium, potassium, calcium, chloride, magnesium, and phosphate. See Chapter 37 for a detailed discussion of the intracellular and extracellular functions of electrolytes.

Blood Enzymes

Enzymes are globular proteins produced in the body that catalyze chemical reactions within the cells by promoting the oxidative reactions and synthesis of various chemicals, such as lipids, glycogen, and adenosine triphosphate (ATP). Enzyme tests play a key role in diagnosing the degree of tissue damage mainly to the myocardium and, to a lesser degree, to the brain.

Elevations in plasma levels of intracellular enzymes occur during myocardial **necrosis** (tissue death as the result of disease or injury). Enzymes are released into the bloodstream in proportion to the degree of cellular damage. Table 28-7 discusses the common alterations of electrolytes and their clinical significance.

Enzymes are not used as single diagnostic values in determining a diagnosis but are viewed in relation to other diagnostic studies. The results from several diagnostic procedures will assist the practitioner in determining the cause of clinical symptoms.

Creatine phosphokinase (CPK) is an enzyme used to convert creatine to phosphocreatine and adenosine diphosphate (ADP) to ATP. ATP provides energy to the cells to carry on metabolism. CPK levels indicate the degree of normal tissue catabolism. Elevated values of CPK reflect the damage that has occurred in tissue with a high CPK content. For example, the myocardium has a high CPK content; when the client has a myocardial infarction, CPK is elevated because the heart's tissue has been damaged, requiring ATP to repair the damaged myocardium.

Creatine phosphokinase has three isoenzymes of differing molecular structure that are present in different tissue (Table 28-8). The isoenzymes provides clinical data to the practitioner in diagnosing the site and extent of tissue injury.

Aspartate aminotransferase (AST) is one of two enzymes that catalyze the transfer of the nitrogenous por-

TABLE 28-7
Routine Serum Electrolytes

Electrolyte/Normal Range*	Clinical Significance
Sodium 135–148 mEq/L, adult 138–144 mEq/L, children 133–144 mEq/L, newborns	<i>Increased:</i> excessive intake of sodium without water; salt water drowning; high solute concentration (tube feeding, IV, hyperalimentation) without fluid correction; diarrhea; diabetes insipidus; primary aldosteronism; renal failure. <i>Decreased:</i> excessive intake of water without sodium (oral, IV therapy, tap water enemas); heart failure, cirrhosis; nephrosis and massive diuretic therapy.
Potassium (serum) 3.5–5.0 mEq/L, adult 3.4–4.7 mEq/L, children 3.7–5.9 mEq/L, newborns	<i>Increased:</i> high potassium intake (oral, IV therapy, rapid infusion of aged blood); renal disease; drugs (adrenal steroids, potassium-conserving diuretics, potassium penicillin, chemotherapeutic agents); Addison's disease; burns and other massive tissue trauma; metabolic and respiratory acidosis. <i>Decreased:</i> drugs (diuretics, digitalis); metabolic alkalosis; primary aldosteronism; Cushing's disease; vomiting and gastric suction.
Calcium Total 8.4–10.5 mg/dl Ionized 1.13–1.32 mmol/L	<i>Increased:</i> hyperparathyroidism; bone catabolism (multiple myeloma, leukemia, bone tumors); immobility. <i>Decreased:</i> renal failure; sprue; pancreatitis; Crohn's disease; hyperphosphatemia; drugs (aminoglycosides, antacids containing aluminum, caffeine, cisplatin, corticosteroids, loop diuretics, mithracin, phosphate).
Chloride 96–109 mEq/L, adult 98–105 mEq/L, children 94–112 mEq/L, newborn	<i>Increased:</i> hyperparathyroidism; drugs (ammonium chloride, ion exchange resin, phenylbutazone); metabolic acidosis; respiratory acidosis; dehydration. <i>Decreased:</i> prolonged vomiting and gastric suction; diarrhea; diuretics (ethacrynic acid and furosemide).
Magnesium 1.3–2.0 mEq/L, adult 1.6–2.6 mEq/L, children 1.4–2.9 mEq/L, newborn	<i>Increased:</i> chronic renal failure, drugs (magnesium sulfate, antacids, enemas containing magnesium, sedatives); acute adrenal cortical insufficiency. <i>Decreased:</i> chronic diarrhea and alcoholism, nontropical sprue, steatorrhea, hereditary malabsorption, starvation, bowel resection, diuretics (mannitol, urea, glucose); hypoparathyroidism.
Phosphate 2.7–4.5 mg/dl, adult 4.5–5.5 mg/dl, children 4.5–6.7 mg/dl, newborn	<i>Increased:</i> renal insufficiency; intake, IV solutions and enemas; blood transfusion; muscle necrosis; hypoparathyroidism. <i>Decreased:</i> alcohol withdrawal; hyperventilation; diabetic ketoacidosis; phosphate-binding antacids.

*Data for normal ranges from Noe, D., & Rock, R. [1994]. *Laboratory medicine*. Baltimore: Williams & Wilkins.

TABLE 28-8
CPK Isoenzymes

Isoenzyme	Normal Range*	Tissue Source
CPK ₁ (BB)	0 IU/l	Primarily in brain/indicative of cerebrovascular accident
CPK ₂ (MB)	0–7 IU/l	Exclusively in myocardium/indicative of myocardial infarction
CPK ₃	5–70 IU/l	Found in skeleton and myocardium/skeletal muscle disorders

*Data for normal range values from Noe, D., & Rock, R. [1994]. *Laboratory medicine*. Baltimore: Williams & Wilkins.

tion of an amino acid to an acid residue. It is an intracellular enzyme found mainly in the liver, heart, skeletal muscles, kidney, pancreas, and RBCs. The normal range is:

- Adults/children 4–36 IU/L
- Newborns 4 times as high as those of adults.

Blood for AST is drawn to determine:

- A recent myocardial infarction (together with the CPK and lactic dehydrogenase levels)
- Acute hepatic disease
- The client's progress and prognosis in cardiac and hepatic diseases

Certain drugs may increase the AST (see the accompanying box). Remember to note drugs on the laboratory

DRUGS THAT CAN ELEVATE ASPARTATE AMINOTRANSFERASE (AST)

- Antibiotics
- Contraceptives
- Cortisone
- Digitalis
- Flurazepam
- Guanthidine
- Indomethacin
- Isoniazid
- Mithramycin
- Narcotics
- Pyridoxine
- Rifampin
- Salicylate
- Theophylline
- Vitamin A

requisition when a client is taking a drug that can influence the results of testing.

Lactic dehydrogenase (LDH), a cellular enzyme that contributes to carbohydrate metabolism, catalyzes the reversible conversion of muscle pyruvic acid into lactic acid. The diagnostic value of serum LDH is limited because it is present in almost all body tissue; however, through electrophoresis, five isoenzymes can be related to specific tissue (Table 28-9).

The percent of isoenzymes changes with tissue damage. For example, in an acute myocardial infarction the LDH₁ becomes greater than LDH₂ 12 to 48 hours postinfarction.

α -Hydroxybutyrate dehydrogenase (HBD) is the total LDH forced to act on α -ketobutyric acid rather than lactic or pyruvic acid. It is a serum measurement used when the assay of isoenzymes of LDH is not available in the laboratory. Once a myocardial infarction has been diagnosed, the HBD has clinical significance by indicating the duration of tissue injury. HBD will remain elevated up to 2 weeks after infarction.

TABLE 28-9
LDH Isoenzymes

Isoenzyme	Range of % of Total LDH	Tissue Source
LDH ₁	17–33	Primarily in heart, kidneys, RBCs
LDH ₂	27–37	Primarily in heart, kidneys, RBCs
LDH ₃	18–25	Primarily in lungs, to a lesser extent in pancreas, thyroid, adrenal glands, lymph nodes
LDH ₄	3–8	Liver and skeletal tissue
LDH ₅	0–5	Liver and skeletal tissue

(Data for normal range values taken from Noe, D., & Rock, R. [1994]. *Laboratory medicine*. Baltimore: Williams & Wilkins.)

Alkaline phosphatase (a zinc-dependent enzyme) influences bone calcification and lipid and metabolite transport. The normal plasma range is 30 to 120 IU/L. Alkaline phosphatase is used to detect:

- Osteoblastic activity
- Hepatic tumors or abscess
- Impaired zinc status
- The response of vitamin D in the treatment of deficiency-induced rickets

Certain drugs can cause a mild to moderate elevation in the alkaline phosphatase (see the accompanying box).

DRUGS THAT CAN ELEVATE ALKALINE PHOSPHATASE

- Allopurinol
- Antibiotics
- Ergosterol
- Estrogen
- Isoniazid
- Methyldopa
- Methyltestosterone
- Oral contraceptives
- Phenothiazine tranquilizers
- Procainamide
- Propranolol
- Sulfonamides
- Tolbutamide

Acid phosphatase is an enzyme found primarily in the adult male prostate gland. It is used clinically to distinguish between encapsulated and metastatic carcinoma of the prostate gland. If the cancer cells are contained within a capsule, the acid phosphatase levels remain normal (0.2 to 0.8 IU/L).

Glucose-6-phosphate dehydrogenase is a RBC enzyme. The normal range and the clinical significance were shown in Table 28-6.

The main proteolytic enzymes for digestion are contained in the pancreatic juices (trypsin, chymotrypsin, and carboxypeptidase). The common laboratory tests for measuring the digestive enzymes are presented in Table 28-10.

NURSING ALERT

Blood Enzyme Tests

Client must be fasting 1 to 2 hours before having a serum amylase drawn. If the client has eaten and received a narcotic at the same time, the serum results could be invalidated.

Cholinesterase is an enzyme, manufactured in liver, that is responsible for the breakdown of acetylcholine and other choline esters. The normal range for cholinesterase in adults and children is 8 to 18 IU/L. It is elevated in diabetes, hyperthyroidism, and nephrotic syndrome. Decreases in cholinesterase can result from

TABLE 28-10
Digestive Enzymes

Enzymes	Reference Range	Clinical Significance
Alanine aminotransferase	0–30 IU/L	Hepatocellular damage
Aldolase	0–8 IU/L	Anemia (hemolytic and megaloblastic); granulocytic leukemia; metastatic carcinoma; skeletal muscle tissue damage
Amylase	Total: 40–220 IU/L	Pancreatitis
Aspartate aminotransferase	0–35 IU/L	Hepatitis; infectious mononucleosis; cirrhosis
Lipase	0–1 Cherry-Crandell U/L	Acute pancreatitis
5'-Nucleotidase	0–17 U/L	Biliary cirrhosis; extrahepatic obstruction; hepatic carcinoma

(Data for normal range values taken from Noe D., & Rock, R. [1994]. *Laboratory medicine*. Baltimore: Williams & Wilkins.)

severe anemias and infections, exposure to some insecticides, liver disease, malnutrition, shock, and uremia (Cavanaugh, 1999).

Blood Lipids

Coronary heart disease (CHD) is the number one killer of both men and women in the United States. According to the National Center for Health Statistics (NCHS), some 7 million Americans suffer from CHD and more than 500,000 Americans die of heart attacks each year caused by CHD (NCHS, 1999). The National Cholesterol Education Program (NCEP) and the American Heart Association have published guidelines and recommendations regarding the need to improve laboratory detection of hypercholesterolemia and treatment. Total blood cholesterol is the most common measurement of blood cholesterol. Cholesterol is measured in milligrams per deciliter of blood (mg/dl). Blood cholesterol for adults is classified by levels.

Exogenous cholesterol is present in the diet and absorbed into the gastrointestinal tract. Endogenous cholesterol is formed in the liver and other cells in the body. As much as 80% of cholesterol is converted into cholic acid to form bile salts. Cholesterol is also needed:

- Throughout the body for the formation of membranes
- By the adrenal glands to form adrenocortical hormones
- By the ovaries to form progesterone and estrogen
- By the testes to form testosterone
- By the skin to provide a water-soluble barrier

Cholesterol and other fats cannot dissolve in the blood; they have to be transported to and from the cells by special carriers called **lipoproteins** (blood lipids bound to protein). The types of lipoproteins are described below, but the ones to be most concerned about are low-density lipoprotein (LDL) and high-density lipoprotein (HDL).

- Chylomicrons—mainly ingested triglycerides
- Very low-density lipoproteins (VLDLs)—mainly endogenous triglycerides
- Low-density lipoproteins (LDLs)—moderate amounts of phospholipids with 50% cholesterol
- High-density lipoproteins (HDLs)—50% protein

LDL is the major cholesterol carrier in the blood. When too much LDL circulates in the blood, it can slowly build up in the walls of the arteries feeding the heart and brain. The build up of LDL and other substances causes the formation of **atherosclerotic plaque**, a thick, hard deposit that can clog the arteries in the heart and brain. A **thrombus** (a blood clot) can develop around the plaque that blocks the flow of blood to part of the heart muscle and causes a myocardial infarction (MI). If the thrombus blocks the flow of blood to part of the brain, it results in a cerebrovascular accident (CVA). High levels of LDL cholesterol (more than 130 mg/dl) increase the risk for CHD; this type of cholesterol is often called bad cholesterol.

HDL accounts for one-third to one-fourth of blood cholesterol and carries the cholesterol away from the arteries and back to the liver, where it is removed from the blood. HDL removes excess cholesterol from atherosclerotic plaques, slowing their growth. HDL is known as good cholesterol because a high level of HDL seems to decrease the risk of CHD.

Triglycerides are the chemical form in which most fat exists in food as well as in the body; they account for more than 90% of dietary intake and comprise 95% of fat stored in tissues (Fischbach, 2000). Triglycerides are insoluble in water and are the main plasma glycerol ester. An increase in triglyceride levels can be detected by plasma measurements; this test evaluates suspected atherosclerosis and measures the body's ability to metabolize fat.

Table 28-11 shows the relationship of lipids to a client being at risk for CHD. The practitioner must examine all of the lipid levels together. For instance, a client whose total cholesterol, LDL cholesterol, and triglycerides are all slightly elevated and whose HDL is slightly decreased is at a greater risk for CHD than

TABLE 28-11
Relationship of Lipids to Coronary Heart Disease Risk

Lipid	Desirable Level	Borderline CHD Risk	High CHD Risk
Cholesterol	< 200 mg/dl	200–239 mg/dl	> 240 mg/dl
LDL Cholesterol	< 130 mg/dl	130–159 mg/dl	> 160 mg/dl
HDL Cholesterol	> 40 mg/dl	35–40 mg/dl	< 35 mg/dl
Triglyceride	< 250 mg/dl	250–500 mg/dl	> 500 mg/dl

(Data from Fischbach, F. [2000]. *A manual of laboratory and diagnostic tests* [6th ed.]. Philadelphia: Lippincott.)

someone whose cholesterol is elevated but whose HDL is also high.

The nurse must prepare clients for the lipid level testing by teaching them to:

- Eat a regular diet 3 to 7 days before the test
- Fast 12 to 14 hours before the test
- Refrain from vigorous exercise 24 hours before the test
- Refrain from caffeine and nicotine 24 hours before the test
- Per practitioner order, withhold drugs 24 hours before the test (many drugs affect the serum triglycerides level)
- Be aware that repeat tests may be necessary to confirm elevated levels because results can vary 15% or more from day to day.

Diurnal variation causes triglycerides to be lowest in the morning and highest around noon (Fischbach, 2000).

Several factors can affect the test results. The client's position, such as lying down, causes a redistribution between vascular and extravascular compartments. For instance, after 5 minutes in a recumbent position, total plasma cholesterol may be significantly reduced (10–15% decrease after 20 minutes). Recent trauma and severe infections may decrease the cholesterol level by 10% to 30%. Because pregnancy increases the HDL, LDL, VLDL levels 20% to 30%, postpone testing 3 to 4 months postdelivery.

Therapeutic Drug Monitoring

Therapeutic drug monitoring is performed when a quantitative relationship exists between the drug concentration and drug response or toxicity is known. For a drug concentration to be significant:

- It must be determined in a blood sample drawn after the drug has been completely absorbed from the oral or intramuscular route.
- It has had an opportunity to be distributed to its site of action.
- Its steady state has been reached (e.g., four to five half-lives must have passed).

For instance, with digoxin (a cardiac medication, administered on a daily schedule) the absorption and distribution phases may take 6 to 12 hours to complete. For a meaningful interpretation, the blood specimen should be drawn at least midway through the elimination phase (6 hours before the next dose). If the specimen is drawn just before the next dose, one obtains a trough concentration, whereas a specimen drawn 6 to 12 hours after dosing yields a peak concentration. For digoxin, the swing between peak and trough would be expected to be minimal because the drug is given at intervals that are less than the drug's terminal half-life (42 ± 19 hours). Generally, such sampling is most significant after steady state has been reached (about 8 days for digoxin). Trough and peak sampling help the practitioner to determine the dose rate, keeping the drug level below toxic value.

Arterial Blood Gases

Blood gas results are reported in millimeters of mercury (Hg). Normal ABG ranges are:

- PO_2 75–100 mm Hg
- PCO_2 35–45 mm Hg
- pH 7.35–7.45

The clinical interpretation of gases studies the relationship between the gasses. For example, a low PO_2 combined with a high PCO_2 may indicate bronchiole obstruction or that the alveoli are filled with fluid. In both situations, there is an impairment of gaseous exchange. See Chapter 32 for a complete discussion.

Urine Tests

The primary function of the kidneys to rid the body of waste products and to maintain homeostasis through regulation of the acid-base balance, fluid and electrolyte balance, and arterial blood pressure. Urine leaves the kidneys through the ureters. Peristaltic waves move the waste products through the ureters to the bladder. Normally, the bladder stores 200 to 400 ml of urine; however, its capacity is greater.

NORMAL URINE VALUES

• pH	4.6–8.0	Adults and children
	5.0–7.0	Newborns
• Color	Amber-yellow	
• Specific gravity	1.010–1.025	
• Protein:		
Qualitative	None	
Quantitative	10–100 mg/24h	
• Glucose	None	
• Ketones	None	
• Blood	0–2 RBCs	

(Data from Noe D., & Rock, R. [1994]. *Laboratory medicine*. Baltimore: Williams & Wilkins.)

Urinalysis (UA) is an essential part of an examination for both diagnostic and preventive purposes. UAs are easy to collect and can be a valuable screening procedure. The kidneys have the ability to regulate sodium and urine concentration and dilution in accordance with the needs of the individual. The main urine constituents are water, urea, uric acid, creatinine, ammonia, sulfates, sodium, potassium, chloride, calcium, magnesium, and phosphate. Other kidney filtrates found in the urine include hormones, vitamins, and medications. The urine may also contain other constituents indicative of disease such as RBCs and WBCs, casts, crystals, mucus, bacteria, protein, glucose, and ketones. See the accompanying box for normal values.

Although laboratories provide a wide range of urine tests, some types of tablet, tapes, and dipstick tests for UA can be performed outside the laboratory setting. Kerr, Marshall, and Sinclair (1999) conducted a study to determine if there was a difference in the urine results obtained by the emergency department physician as compared with the results obtained by a trained laboratory technician. On comparison, the results were similar for both dipstick and microscopic components of urinalysis: red blood cell urinalysis and microscopy, leukocyte esterase, and nitrite testing; however, emergency physicians were not able to consistently perform UA for microscopic white cells and bacteria, and testing for proteinuria.

Urine pH

The pH is governed by the hydrogen ion concentration of the urine. Disorders such as diabetes mellitus, dehydration, diarrhea, emphysema, and starvation make the urine acidic. Chronic renal failure, renal tubular acidosis, urinary tract infections, and salicylate poisoning cause the urine to be alkaline.

Specific Gravity

Specific gravity measures the number of solutes in a solution. Urea and uric acid (the byproducts of nitrogen

metabolism) have the greatest influence on the specific gravity of urine. A urinometer and cylinder are used to measure the specific gravity (Figure 28-12). The urinometer has a specific gravity scale and a weighted mercury bulb. A fresh urine specimen is poured into the cylinder. The nurse inserts and twirls the urinometer into the cylinder. The depth of the urinometer is determined by the concentration of dissolved analytes. When the urinometer stops spinning, the nurse reads the urinometer at eye level.

The specific gravity increases with conditions that increase the loss of fluids from the body, such as diabetes mellitus, gastrointestinal fluid losses, third-space fluid accumulation, and fear or anxiety. Decreases in the specific gravity result from renal disease. When the amount of urine increases and the specific gravity decreases there is an absence of the antidiuretic hormone (ADH), usually triggered by diabetes insipidus (a disorder of the posterior pituitary gland).

Urine Glucose

When the blood levels of glucose exceed the renal threshold (180 mg/dl), glucose spills into the urine. Multiple agents are available for measuring the glucose content of urine. These agents are not as accurate a test method as blood glucose levels.

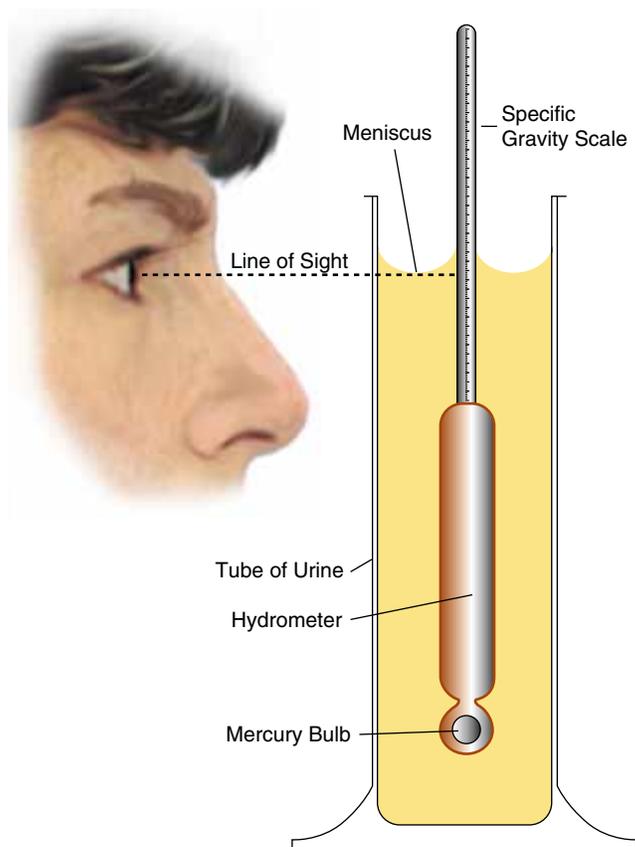

Figure 28-12 Urinometer

Some of the reducing agents can measure other products, such as protein and blood, along with the glucose (Clinitest and Clinistix). Each product has specific step-by-step instructions for performing the test and reading the results. Teach the client how to perform these urine tests.

Urine Ketones

Ketones are products of fatty acid metabolism and are completely metabolized by the liver under normal conditions. The most common cause of ketonuria is diabetes. However, with strenuous exercise, starvation, and sustained febrile and hypoxic conditions an increase in fatty acid metabolism causes ketoacidosis, resulting in ketone bodies in the urine.

Urine Cells and Casts

Normally the urine is free from blood cells and casts. When the renal system is impaired as in renal damage or failure, nephritis, and stones and infections in the urinary tract, the following can occur:

- Bleeding with resulting RBCs in the urine
- Accumulation of epithelial cells with cast formation
- WBCs, which indicate infections

Stool Tests

Stool analysis is used to determine the various constituents of the stool for diagnostic purposes such as diseases of the gastrointestinal tract, the liver, and the pancreas. Normal constituents of the stool are urobilinogen, porphyrins, sodium, chloride, potassium, and small amounts of nitrogen and lipids. The most frequent tests ordered on feces include leukocytes, blood, fat, ova and parasites, and pathogens.

Urobilinogen

Urobilinogen is derived from the normal bacterial action of intestinal flora on bilirubin. It is increased with severe hemolysis of RBCs and decreased with most biliary obstructions.

Occult Blood

When blood is invisible on inspection it is said to be **occult**; it is blood that can only be detected through a microscope or by chemical means. In the gastrointestinal tract, the digestive process acts on blood, making it occult. Random sampling for occult blood is done to diagnose gastrointestinal bleeding, ulcers, and malignant tumors. Colorectal cancer is a leading cause of cancer deaths in the United States. Most colorectal cancers begin as a **polyp**, a small abnormal growth of tissue, in the wall of the colon. As the polyp grows, it may cause bleeding from the rectum, blood in the stool, or a

change in the shape of the stool. Screening for colorectal cancer begins with fecal occult blood testing. Cancer screening guidelines recommend annual fecal occult blood testing for adults aged 50 years and older (Mandelson, LaCroix, Anderson, Nadel, & Lee, 1999). Any person age 50 years or older but asymptomatic are considered average risk for colorectal cancer. The risk factors increase when one or more of the following exist:

- Close relative(s) who have had colorectal cancer or an adenomatous polyp
- Family history of familial adenomatous polyposis
- Family history of hereditary nonpolyposis colorectal cancer
- History of adenomatous polyps
- History of colorectal cancer
- Inflammatory bowel disease

See the accompanying box for the complete set of guidelines for colorectal screening as developed by the

GUIDELINES FOR COLORECTAL SCREENING

Risk Category	Recommendations
Average	Fecal occult blood screening yearly, starting at 50 years of age Flexible sigmoidoscopy every 5 years or colonoscopy every 10 years or double-contrast barium enema every 5 to 10 years
Increased Risk	Same as above, but screening is initiated when the client is 40 years of age Genetic counseling/testing In a gene carrier, flexible sigmoidoscopy every 12 months, beginning at puberty Genetic counseling/testing Examination of the entire colon every 1 to 2 years, starting when the client is 20 to 30 years old Examination of the entire colon yearly after the client is 40 years old Colonoscopy 3 years after initial examination, with subsequent examinations, depending on the types of polyps detected Complete examination 1 year after colon surgery; if normal, reexamination of colon in 3 years; if still normal, reexamination in 5 years Surveillance colonoscopy every 1 to 2 years, beginning after 8 years of disease in the client with pancolitis and after 15 years in the client with left colon involvement only

From Johnson, B. A. (1999). Flexible sigmoidoscopy for colorectal cancer. *American Family Physician*, Jan 15., 1999.

American Cancer Society, the American College of Gastroenterology, and the American Society of Gastrointestinal Endoscopists. See Table 28-12 for the diagnostic procedures: colonoscopy and proctosigmoidoscopy.

When the practitioner is using occult blood to confirm suspicions of a gastrointestinal disorder, the client is placed on a 3-day diet free of meat, poultry, and fish to decrease the possibility of a false-positive result. Common drugs that can cause a positive test for occult blood are salicylate, steroids and indomethacin.

Parasites

The gastrointestinal tract can harbor parasites and their eggs (ova). Some of these parasites are harmless, whereas others cause clinical symptoms. With the exception of pinworms (which can enter the body through both the oral and anal routes), all other common parasites gain portal entry through the mouth by ingesting contaminated water or food. Roundworm, hookworm, whipworm, tapeworm, *Trichinella spiralis*, and *Entamoeba histolytica* are common parasites found in the United States.

Culture and Sensitivity Tests

Culture refers to the growing of microorganisms to identify the pathogen. Culture and sensitivity (C&S) tests are performed to identify both the nature of the invading organisms and their susceptibility to commonly used antibiotics. Sensitivity allows the practitioner to select the appropriate antibiotic therapy. All C&S specimens should be taken immediately to the laboratory.

NURSING ALERT

Cultures

All culture tests should be performed before initiating antibiotic therapy so as to identify the type of pathogen and its sensitivity to specific antibiotics.

Blood Culture

Bacteremia is bacteria in the blood. The blood culture should be obtained while the client is experiencing chills and fever. A series of three venipuncture collections are performed using strict sterile technique; change the needle after the specimen is collected before injecting the blood sample into the test tube.

Swab (Throat) Culture

The throat normally colonizes many organisms. Throat cultures serve to isolate and identify such pathogens as β -hemolytic streptococci; *Staphylococcus aureus*; meningococci; gonococci; *Bordetella pertussis*; and *Corynebacterium diphtheria*. A throat swab is commonly done to identify streptococcal infections, which, if untreated, can cause rheumatic fever or glomerulonephritis.

To obtain a throat swab, use a wooden blade to depress the tongue and swab the white patches, exudate, or ulcerations of the throat with a sterile applicator. Avoid touching other parts of the mouth with the swab. Once obtained, place the applicator in a sterile container.

Sputum Culture

Sputum tests are done for culture, smear, and cytology. Sputum is created by the mucous glands and goblet cells of the tracheobronchial tree and is raised by coughing. Sputum is sterile until it reaches the throat and mouth where it comes in contact with normal flora. Sputum can be obtained by tracheobronchial suctioning and transtracheal aspiration, producing a more accurate identification of pulmonary organisms.

A sputum smear will identify the same organism found in a culture plus eosinophils, epithelial cells, and other substances. Smears are helpful in diagnosing asthma (eosinophils) and fungal infection. The specimen needs to be refrigerated if it cannot be taken immediately to the laboratory.

Sputum can also be examined for **cytology** (the study of cells). It is performed to diagnose cancer of the lungs. The specimen should be collected early in the morning after a deep cough.

Urine Culture

Urinary C&S tests are performed whenever a urinary tract infection is suspected. Organisms enter the urinary system by one of two ways:

1. Ascending urinary tract infections are associated with *Escherichia coli* and *Candida albicans* from the rectum, vagina and catheterization.
2. Descending sources are caused from *Staphylococcus* and *Streptococcus* entering the urinary system from the blood.

Stool Culture

Stool C&S is performed to identify bacterial infections. If the client has diarrhea, a rectal swab can be taken as a specimen; fecal material must be visible on the swab for the laboratory to perform the test.

Wound Culture

Clinical specimens taken from abscesses or infected wounds reveal a variety of aerobic and anaerobic microorganisms. "Because anaerobic microorganisms are the preponderant microflora in humans and are

consistently present in the upper respiratory, gastrointestinal, and genitourinary tracts, they are also likely to invade other parts of the body to cause severe, and sometimes fatal, infections” (Fischbach, 2000, p. 554). Pathogens are likely to be present in the following wound specimens: pus, necrotic tissue, debrided material, postoperative wound drainage, lower-extremity ulcers, and pressure ulcers. Use standard precautions when obtaining a wound culture. Most wounds require some form of preparation prior to culturing a wound (see Procedure 35-1, Culturing a Wound).

Bone Marrow

Bone marrow specimens are examined by either culture or smear for identification of microorganisms. Smear slides are prepared at the client’s bedside by the nurse.

Papanicolaou Test

Papanicolaou test (smear method of examining stained exfoliative cells), commonly called a Pap smear, is done to evaluate the cell maturity, metabolic activity, and morphologic variations of the cervical tissue. Papanicolaou testing can also be used for tissue specimens from other organs, such as bronchial aspirations and gastric secretions.

Cervical Pap smear testing is recommended every 2 to 3 years after the onset of sexual activity. Annual testing is indicated for women:

- Over 40 years of age
- With a family history of cervical cancer
- With a previous positive test

To increase the accuracy of a cervical specimen, the client should be told to avoid intercourse, douches, and vaginal creams for 24 hours before the test. The vaginal speculum should not be lubricated. This test should not be performed if the client is menstruating because the specimen will be unsuitable for cytologic study.

RADIOLOGIC STUDIES

Radiography (the study of x-rays or gamma ray-exposed film through the action of ionizing radiation) is used by the practitioner to study internal organ structure. **Fluoroscopy** (the immediate, serial images of the body’s structure and function) is used to demonstrate the motion of organs when used with **contrast medium** (a radiopaque substance that facilitates roentgen imaging of the body’s internal structures). X-rays are valuable to the practitioner in either formulating a diagnosis (e.g., pneumonia) or as a tool to determine if other studies are necessary (e.g., lung lesion requiring biopsy to differentiate between a benign or malignant tumor).

Certain radiologic tests will require a contrast medium that could interfere with other diagnostic studies. Barium and iodine are commonly used contrast media. Laboratory blood samples measuring the thyroid function should be drawn before an intravenous pyelogram (IVP) where radioactive iodine dye is administered. If the client needs both an IVP and barium enema, the IVP is done first because the barium is likely to decrease the visualization of the kidneys.

Precautions need to be taken to ensure client safety. It is essential during history taking that the client is questioned about the possibility of pregnancy, asthma, and allergic reactions to contrast media (iodine) as well as to other foods and drugs. If the client has never received iodine, this should be noted on the requisition.

NURSING ALERT

Contrast Media

Carefully monitor clients who are scheduled for dye injection studies when they have a history of allergies to any foods or drugs (particularly fish or iodine) because this condition may predispose them to allergic reactions to contrast media.

Chest X-Ray

The most common radiologic study is the noninvasive, non-contrasted chest x-ray. The best results are obtained when the films are taken in the radiology department; however, a portable chest x-ray can be performed at the bedside.

Radiographic projection positions of chest x-ray films are taken from various views (Figure 28-13). Multiple views of the chest are necessary for the practitioner to assess the entire lung field. To prepare the client for a chest x-ray, remove metal objects (jewelry) and all clothing from the waist up and replace with a gown. Metal will appear on the x-ray film thereby obscuring visualization of parts of the chest. Pregnant women are draped with a metal apron to protect the fetus.

Chest films can indicate the following alterations and diseases:

- Lesions (tumors, cysts, masses) in the lung tissue, chest wall, bony thorax or heart
- Inflammation of lung tissue (pneumonia, atelectasis, abscesses, tuberculosis); pleura (pleuritis); and pericardium (pericarditis)
- Fluid accumulation in the lung tissue (pulmonary edema, hemothorax); pleura (pleural effusion); and pericardium (pericardial effusion)
- Bone deformities and fractures of the rib and sternum
- Air accumulation in the lungs (chronic obstructive pulmonary disease, emphysema), and pleura (pneumothorax)
- Diaphragmatic hernia

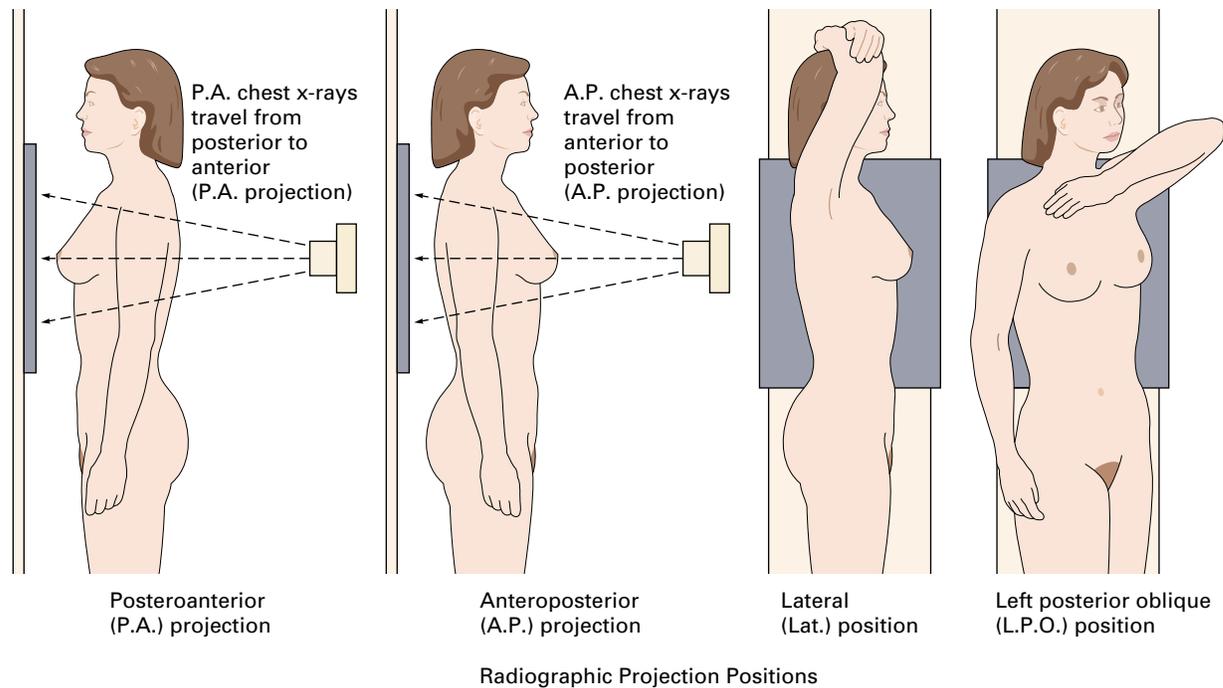

Figure 28-13 Radiographic Projection Positions

RESEARCH FOCUS

Title of Study

“Financial Impact of Elimination of Routine Chest Radiographs in a Pediatric Intensive Care Unit”

Authors

Price, M. B., Grant, M. J., & Welkie, K.

Purpose

To determine the change in chest radiograph use if each chest radiograph requires a separate order and clinical indications.

Methods

A prospective, nonrandomized, controlled design with an intervention study was conducted in a pediatric intensive care unit (PICU) at a children’s hospital. The study comprised 3,727 PICU clients treated between 1992 and 1996. The study’s interventions were a change in ordering practice: no standing orders for routine daily morning chest radiographs; each radiograph required a written order and clinical indication for ordering the chest radiograph. During a 29-month control phase when routine daily chest radiographs were obtained for all intubated clients, 1.026 chest radiographs per client day were performed. After the intervention, the ratio dropped to 0.653 chest radiographs per client day, a decrease of 36.4% and a cost savings of \$45,476.

Findings

The study results demonstrated the outcome of an evaluation and subsequent change in radiology ordering practice; the change resulted in decreased variability in ordering practice, fewer chest radiographs per client, and a cost savings to the clients and payors.

Implications

This study is the beginning effort to validate the need for diagnostic testing versus standing orders for routine testing. Other routine tests need to be studied regarding outcome measures that include client safety and health promotion.

Price, M. B., Grant, M. J., & Welkie, K. (1999). Financial impact of elimination of routine chest radiographs in a pediatric intensive care unit. *Critical Care Medicine*, 27(8), 1588–1593.

Kidney-Ureter-Bladder

A kidney-ureter-bladder, also known as a KUB (x-ray of the abdomen), is used to visualize the kidney, ureter, and bladder and sometimes the gallbladder, liver, and spleen. The results can reveal congenital abnormalities, enlarged organs, lesions, and obstructions.

Mammography

Mammography (a low-dose radiographic study of breast tissue) is used to reveal congenital abnormalities and lesions. The American Cancer Society (1997) recommends a baseline mammogram by age 40, followed by a mammogram every 2 years until age 50, and every year after age 50.

Skeletal X-Rays

Skeletal x-rays are taken of any bony processes to reveal congenital abnormalities, fractures, joint and spine abnormalities, and degeneration (arthritis).

Computed Tomography

Computed tomography (CT) is the radiologic scanning of the body with x-ray beams and radiation detectors that transmit data to a computer that transcribes the data into quantitative measurement and multidimensional images of the internal structures. Figure 28-14 demonstrates the directions of sagittal, transverse, and coronal planes taken during CT scanning.

This procedure requires the client's written consent. Because the client will be positioned on the scanning table and told to remain motionless, the client's cooperation is essential during the scanning. Prepare the client with an explanation and pictures of what to expect. Figure 28-15 shows the direction of CT scan waves. A simple drawing of this figure can be used in client teaching to increase understanding of the test. Assess the client's ability to relax and review imagery relaxation. See Chapter 14 for a discussion of relaxation techniques. Sedation can be administered with an order from the practitioner.

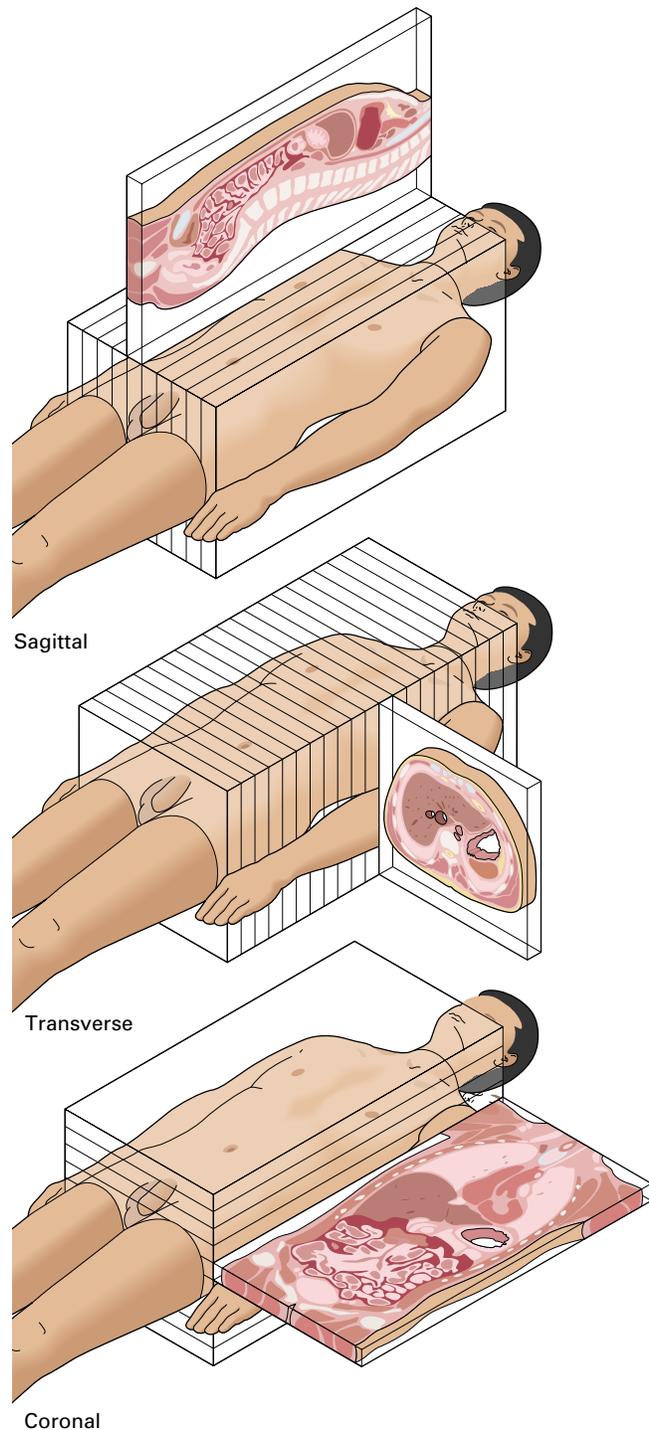

Figure 28-14 Computed Tomography (CT)

Clients who will receive a contrast medium need to be kept NPO 2 to 4 hours before the test. The client should void before the test unless the pelvic area is to be studied. A full bladder enhances visualization of the pelvic area.

Barium Studies

Barium (a chalky white contrast medium) is an oral preparation that allows for roentgenographic visualization of the internal structures of the digestive tract. The results of

NURSING ALERT

Computed Tomography

Because of the use of contrast media during CT to improve the images yielded by the equipment, the nurse must observe the client after the procedure for indicators of allergic dye reactions such as: respiratory distress, urticaria, hives, nausea, vomiting, decreased production of urine (oliguria) and decreased blood pressure.

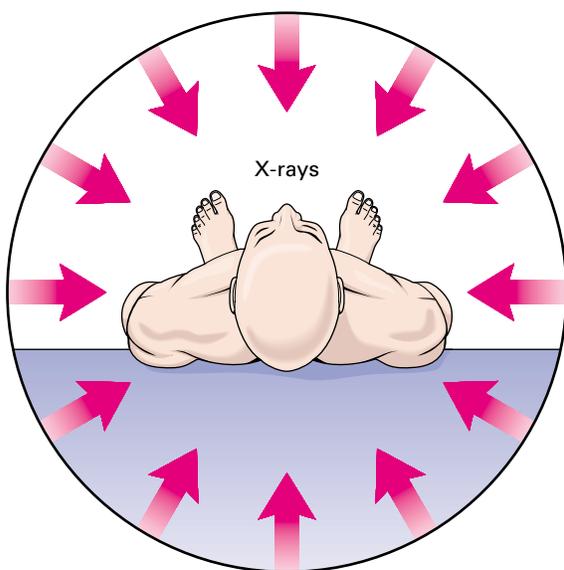

Figure 28-15 Direction of Computed Tomography Scan Rays

barium studies can reveal: congenital abnormalities; lesions; spasm, reflux, stricture, and obstruction; inflammation and ulceration; varices; and fistula. General client preparation for barium studies should include:

- Placing the client on NPO status after midnight
- Administering a laxative the evening before and enemas the morning of the test
- Forcing fluid postprocedure
- Follow-up 2 to 3 days postprocedure to ensure the client has had a normal brown stool

Postprocedure barium will be expelled in the stool, making it milky white. Fluids are forced to help with the excretion of barium. If the barium is not completely excreted, it can cause an intestinal obstruction.

Barium Swallow

Barium swallow (also called esophography) is a fluoroscopic visualization of the esophagus following the ingestion of barium sulfate. Implement the nursing care discussed above for client having a barium study.

Upper Gastrointestinal Study

Upper gastrointestinal (UGI) study is a fluoroscopic visualization of the stomach and small bowel following the ingestion of barium sulfate. In addition to the general preparation of the client for a barium study, also instruct the client:

- Not to smoke 24 hours before the procedure (smoking causes an increased production of gastric juices)
- That during the procedure (which will last approximately 2 hours) pictures will be taken at 30-minute intervals with the client in different positions

Barium Enema

Barium enema (a rectal infusion of barium sulfate) is the roentgenographic study of the lower intestinal tract. The colon should be free of all fecal material to allow for maximum visualization. Instruct the client:

- To eat a low residue diet 2 days prior to the test
- That during the procedure various positions will need to be assumed on the table to facilitate movement of the barium in the intestines
- The test will take about 1 hour.
- The postprocedure cleansing enemas will be given to help remove the barium

NURSING ALERT

Enema

Clients with severe abdominal pain, ulcerative colitis, or a history of a megacolon should have a written order before enemas can be administered because these conditions would normally prohibit the use of standard bowel preparation procedures such as administration of laxatives and cleansing enemas.

Angiography

Angiography allows visualization of the vascular structures through the use of fluoroscopy with a contrast medium. It is performed in radiology or diagnostic studies departments. The test reveals the blood flow to the heart, lungs, brain, kidneys, and lower extremities. It is also useful in diagnosing an **aneurysm** (weakness in the wall of a blood vessel).

Arteriography

Arteriography is the radiographic study of the vascular system following the injection of a radiopaque dye through a catheter. The practitioner uses fluoroscopy to thread the catheter through a peripheral artery into the area to be studied, such as the aorta or the cerebral, coronary, pulmonary, renal, iliac, femoral, or popliteal arteries. The client is placed on a cardiac monitor. Dye is injected in a vascular catheter with a rapid sequence of films to visualize the vasculature.

Cardiac Catheterization

Cardiac catheterization is a radiographic study with the use of a contrast medium injected into a vascular catheter that is threaded into the heart and coronary or pulmonary vessels. The client is placed in a supine position and connected to a cardiac monitor.

The peripheral site, either the groin or brachial area, is prepped and injected with xylocaine. A catheter is inserted and threaded:

- Right-sided catheterization—into the right atrium, ventricle and pulmonary artery
- Left-sided catheterization—into the aorta to the coronary arteries or the left ventricle

The study includes pressure measurements, blood gas sampling, and viewing the integrity of the heart's valves. Postcatheterization the nurse should:

- Place the client on telemetry.
- Apply manual pressure (for 30 minutes or longer) when the catheter sheath is removed, then apply a pressure dressing.
- Keep the client on bed rest with the involved extremity straight and immobile.
- Monitor and record vital signs to include the presence, quality, and character of peripheral pulses; and the color, temperature and tactile sensation of the involved extremity.
- Encourage oral fluids and record intake and output.
- Instruct the client to report any warm, tickling sensations at the puncture site that would indicate bleeding.
- Monitor for procedural complications: bleeding or hematoma formation at the site; allergic reactions; and cardiovascular, pulmonary, and neurologic changes.

Digital Subtraction Angiography

Digital subtraction angiography is a computerized imaging of the vasculature with visualization on a monitor screen after the intravenous injection of iodine through a catheter. The results reveal the presence of vascular malformations (stenosis, occlusion, obstruction, ulceration, plaques, and aneurysms), lesions, and emboli.

Lymphangiography

Lymphangiography is a radiographic study of the lymphatic system after a catheter injection of an oil-based dye. A lymphatic vessel is first identified with an intradermal injection of a blue dye into either the foot or hand depending on the area to be studied. The results reveal the presence of a lymphoma, metastatic disease, and the degree of edema in lymphatic tissue.

Venography

Venography is a radiographic study of the venous system of the lower extremities after the injection of an iodine contrast agent. A venogram reveals both the presence and degree of trauma or disease (e.g., incompetent valves) to a vein, soft tissue compression, and the presence of thrombi.

Dye Injection Studies

Iodine is a common dye used in radiographic studies. Iodine injection might cause the client to experience temporary symptoms of shortness of breath, nausea, and a warm, hot flushed sensation. Most dye injection studies are invasive, requiring written consent. General guidelines for a client receiving a dye injection study should include:

- Preprocedure—NPO 6 to 12 hours before testing.
- Postprocedure—drink 2500 ml of water daily to encourage dye excretion. Notify the practitioner of decreased urinary output, bleeding, and signs of infection.

Test findings can reveal congenital abnormalities, lesions, inflammation, stones, obstruction, and organ-specific disorders.

Cholangiography

Cholangiography is the roentgenographic procedure visualizing the integrity of the biliary system by a radiopaque contrast medium. There are three methods of performing a cholangiogram: intravenous, percutaneous, and direct injection into a **T-tube** (an artificial drain placed in common bile duct during surgery). The client is placed NPO 8 to 12 hours before the test with a cleansing enema the evening before.

Intravenous Cholangiography

Intravenous Cholograffin (contrast agent) is administered with photographs taken every 15 to 30 minutes until the common bile ducts are visualized. If the gallbladder has not been removed, a fatty meal is given the evening before. The x-ray films are taken to show the contraction of the dye in the gallbladder.

Percutaneous Cholangiography

The percutaneous method for performing a cholangiogram requires the contrast agent to be injected directly into the liver tissue. A venous catheter or long needle is inserted into the liver tissue during fluoroscopy. For this method, the client must have a normal prothrombin time and platelet count before the procedure.

Postprocedure the client is placed on bed rest. Assess the insertion site for bleeding. Clients are at risk for bile peritonitis. Instruct the client to report immediately to the practitioner if any of the following symptoms occur: abdominal pain, distension and rigidity; chills and fever; and nausea or vomiting.

T-Tube Cholangiography

T-tube cholangiography requires the instillation of iodine to visualize the patency of the hepatic and common bile ducts. The client is at risk for bile peritonitis.

Oral Cholecystography

Oral cholecystography is the visualization of the gallbladder and presence of stones through the administration of radiopaque iodine tablets. The evening before the test the client eats a fatty meal and takes the iodine tablets 5 minutes apart with 8 ounces of water. The number of tablets administered is based on weight.

Cystography

Cystography is a radiographic study that uses an aqueous iodine contrast agent instilled into the bladder through a urinary catheter. It is used to visualize the bladder, urethra, and ureteral openings. Postprocedure, instruct the client on how to monitor urinary output and to notify the practitioner of bleeding, decreased output, and signs of infection.

Intravenous Pyelogram

An **intravenous pyelogram (IVP)** is a series of x-ray films of the kidneys, ureters, and bladder following the administration of an intravenous iodine preparation. The test may reveal organ specific disorders such as hydronephrosis, polycystic disease, chronic pyelonephritis, and acute renal failure.

Bronchography

Bronchography is a radiographic study of the trachea and bronchi following the injection of a contrast agent through a catheter. Before the insertion of the catheter, the client is given a local anesthetic agent to sedate the gag and swallow reflex. The test may reveal bronchiectasis.

NURSING ALERT

Gag and Swallow Reflexes

The client is maintained on an NPO status until the return of the gag and swallowing reflexes; prevents aspiration.

Myelography

Myelography is the study of the spinal cord and its surrounding subarachnoid spaces through the use of radiography and Pantopaque (contrast agent). *Strict aseptic technique is used throughout the procedure.* This test is performed in the radiology department with the client on a tilt table.

To inject the Pantopaque dye, the practitioner has to access the subarachnoid space by performing a posterior lumbar puncture. The procedure for performing a lumbar puncture is presented later in this chapter.

The practitioner inserts a needle with a stylet between the vertebrae to access the subarachnoid

space. The stylet is removed and a pressure reading is taken of the cerebrospinal fluid (CSF). If the CSF pressure is elevated, the test is stopped. Otherwise the dye is injected. The table is tilted into various up and down positions. Changing position allows the dye to flow within the subarachnoid space. X-ray films are taken to reveal compression or herniated intervertebral discs and tumors.

ULTRASONOGRAPHY

Ultrasound (echogram) is a noninvasive study that uses high-frequency sound waves to visualize deep body structures. This test should be scheduled before any studies using a contrast medium or air to ensure accuracy because an ultrasound *does not* require any contrast medium. The client is instructed to lie still during the procedure.

Ultrasound is used to evaluate the brain, thyroid gland, heart, vascular structure, abdominal aorta, spleen, liver, gallbladder, pancreas, and pelvis. An ultrasound is commonly done during pregnancy to evaluate the size of the fetus and placenta; a full bladder is needed to ensure visualization. Instruct the mother to drink 6 to 8 glasses of water and to avoid urination before testing.

A coupling agent (lubricant) is placed on the surface of the body area to be studied to increase the contact between the skin and the **transducer** (instrument that converts electrical energy to sound waves). The transducer emits waves that travel through the body tissue and are reflected back to the transducer and recorded. The varying density of body tissues deflects the waves into a differentiated pattern on an oscilloscope. Photographs can be taken of the sound wave pattern on the oscilloscope.

Echocardiograms

An **echocardiogram** is an ultrasonographic procedure used to reveal abnormal structure or motion of the heart wall and thrombi. This test is also used after **radiofrequency ablation** (the delivery of low-voltage, high-frequency alternating electrical current to cauterize the abnormal myocardial tissue) to identify the potential complications of pericardial effusion.

Doppler Ultrasonography

Doppler (a hand-held transducer) transmits high-frequency sound waves to the artery or vein being studied. The sound waves strike the moving RBCs and are reflected back to the transducer, which amplifies the sound and produces a graphic recording. Doppler ultrasonography reveals blood clots and peripheral vascular disease.

MAGNETIC RESONANCE IMAGING

Magnetic resonance imaging (MRI) is an imaging technique that uses radiowaves and a strong magnetic field to make continuous cross-sectional images of the body. The client is instructed to wear earphones to decrease the discomfort from the machine's clanging sound. A noniodine intravenous paramagnetic contrast agent may be used during the study. The study reveals lesions and changes in the body's organs, tissues, vascular, and skeletal structures.

RADIOACTIVE STUDIES

Radionuclide imaging (nuclear scanning) uses radionuclides (or radiopharmaceuticals) to image the morphologic and functional changes in the body's structure. A scintigraphic scanner is placed over the area of study to detect the radiation emission and to produce a visual image of the structure on film. Radiopharmaceutical agents are administered by various routes with consideration given to time delays of absorption. The results reveal congenital abnormalities, lesions, skeletal changes, infections, and gland and organ enlargement.

ELECTRODIAGNOSTIC STUDIES

These diagnostic tests use devices to measure the electrical activity of the heart, brain, and skeletal muscles. Electrical sensors (electrodes) are placed at certain anatomic points to measure the tone, velocity, and direction of the impulses. The impulses are then transmitted to an oscilloscope or printed on graphic paper.

Electrocardiography

An **electrocardiogram (ECG or EKG)** is a graphic recording of the heart's electrical activity. The client may be asked not to smoke or drink caffeinated beverages 24 hours before the test. Nicotine and caffeine can affect the heart rate.

Electrodes are applied to the chest wall and extremities. A lubricating gel applied to the electrodes increases the conduction of electrical activity between the skin and electrode. The client is instructed to lie still during the pain-free test. The test can reveal abnormal transmission of impulses and electrical position of the heart's axis.

A portable cardiac monitor (Holter monitor) is a device that records the heart's electrical activity. It produces a continuous recording over a specified period of time (e.g., 24 hours). The portable unit allows the client to ambulate and perform regular activities. Clients are

instructed to maintain a log of activities that occur when they feel their heart beating faster or irregularly. The practitioner reviews the ECG tracing in relation to the client's log to determine if certain activities, such as walking, are associated with abnormal transmission of impulses.

Signal-Averaged Electrocardiography

Signal-averaged electrocardiography (SAECG) is a surface ECG that amplifies **late potentials** (the electrical activity that occurs after normal depolarization of the ventricles). The test requires a specialized ECG machine and small computer to detect the late potentials. It is performed on clients who have had a myocardial infarction. The test reveals the client's risk for ventricular tachycardia.

Stress Test

A **stress test** measures the client's cardiovascular response to exercise tolerance. It demonstrates the ability of the myocardium to respond to increased oxygen requirements (the result of exercise) by increasing the blood flow to the coronary arteries.

The client is connected to an ECG machine and asked to walk on a treadmill. Continuous ECG recordings are made of the client's heart response (rate, electrical activity, and cardiac recovery time) to frequent changes in the treadmill's speed and slope. The test is stopped immediately if the client experiences any symptoms of decreased cardiac output (chest pain, dyspnea, fatigue, or ischemic changes on the ECG monitor).

Thallium Test

Thallium (a radionuclide that is the physiological analogue of potassium) is normally absorbed into normal myocardial tissue from the circulating blood. During the test, thallium is administered intravenously to detect damaged myocardial tissue (necrotic or ischemic). Because thallium is not absorbed by the damaged tissue, the degree of heart damage can be estimated.

There are two types of thallium tests: resting imaging or stress imaging. Resting imaging is performed a few hours after myocardial infarction. The thallium is injected and an ECG tracing is performed. Stress imaging (thallium stress test) is performed while the client is on the treadmill with ECG monitoring. At peak stress the intravenous thallium is injected; scanning is done 3 to 5 minutes postinjection. The test is stopped immediately if the client becomes symptomatic for ischemia.

Electroencephalography

An **electroencephalogram (EEG)** is the graphic recording of the brain's electrical activity. The procedure is painless and takes about an hour. The test is performed

in a quiet, nonstimulating environment. It can reveal the presence and type of seizure disorder and intracranial lesion. The absence of brain's electrical activity is used to confirm death.

During the procedure, electrodes are placed on the client's scalp. The electrodes transmit the impulses from the brain to an EEG machine. The machine amplifies the brain's impulses and makes a recording of the waves on strips of paper.

ENDOSCOPY

Endoscopy is the visualization of a body organ or cavity through a scope. The procedure is performed with an endoscope (a metal or fiberoptic tube) being inserted directly into the body structure to be studied (see Figure 28-16). A light at the end of the scope allows the practitioner to assess for lesions and structural problems. The endoscope has an opening at the distant tip that allows the practitioner to administer an anesthetic agent, lavage, suction, and biopsy tissue. Common endoscopic procedures are presented in Table 28-12.

THINK ABOUT IT

Participating in Diagnostic Testing

A client comes to an outpatient clinic for a laparoscopy to retrieve an egg for in vitro fertilization. You are to assist the practitioner with this procedure. How would you handle this situation if your own religious beliefs were in conflict with the procedure being performed? Would it make any difference if the client had had an abortion as a teenager?

General client preparation and positioning depend on the structure being studied as discussed in Table 28-12. As with all invasive procedures, the client needs to sign a consent form and the nurse needs to establish baseline vital signs before administering sedative agents.

Postprocedure the nurse monitors the vital signs, observes for bleeding, and assesses for procedural risks (e.g., return of the gag and swallowing reflexes following an esophagogastroduodenoscopy with local anesthesia).

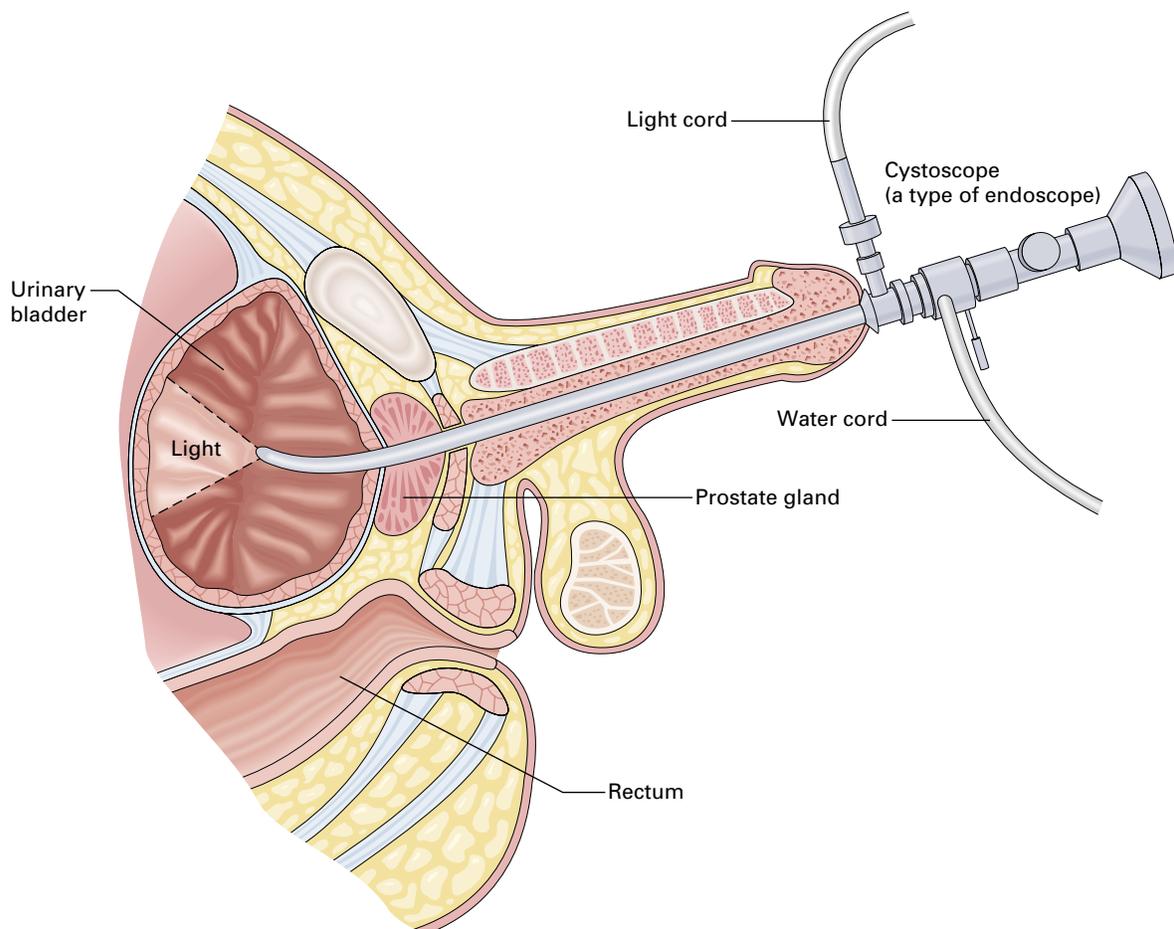

Figure 28-16 Cystoscopy

TABLE 28-12
Endoscopic Procedures

Procedure/Area Studied	Preparation/Position	Clinical Significance
Arthroscopy—examine joint structures, primarily the knee	Instruct client to fast after midnight; test is usually performed under local anesthesia, may be done under spinal or general anesthesia if surgery is necessary. Position the joint for accessibility.	Diagnose a torn meniscus, patellar, condylar, and synovial disorders; perform surgery. Also used to monitor the progression of a disease or effectiveness of therapy.
Bronchoscopy—examine the bronchus and bronchial tree	Instruct client to fast 6–12 hours before the test; test is usually done under local anesthesia. Position client supine or sitting upright.	Identify the origin of bleeding, lesions, or obstruction; collect a specimen for bacteriologic and cytologic examination (diagnosis abnormal cells); remove foreign bodies, lesions, mucus plugs, or excessive secretions.
Colonoscopy—examine the large intestine	Instruct client to maintain a clear liquid diet for 48 hours before the test, take the prescribed laxative the evening before the examination; place client on left side with knees flexed and drape.	Identify origin of bleeding or lesions; evaluate inflammatory and ulcerative bowel disease and recurrence of polyps or malignant lesions.
Colposcopy—examine the cervix and vagina following a positive Pap smear	No restriction on food or liquids. Place client in lithotomy position.	Evaluate abnormal cytology or grossly suspicious lesions and to perform a biopsy or take photographs of suspicious lesions.
Cystoscopy (see cystourethroscopy)		
Cystourethroscopy—uses two instruments: a cystoscope to examine the bladder and ureter openings, urethroscope to examine the bladder neck and the urethra	Food and fluids are restricted only if the client is to receive general anesthesia; regional anesthesia is usually given. Place client in a lithotomy position.	Identify bladder lesions and urethral strictures, ulcers, inflammation, and an enlarged prostate gland.
Esophagogastroduodenoscopy (EGD)—examine the esophagus, stomach, and upper duodenum	Instruct client to fast 6–12 hours before the test. An intravenous tranquilizer may be given, then a local anesthetic is sprayed into the back of the throat to decrease the gag reflex (swallowing will seem difficult). Place client in a sitting position.	Identify diverticula, varices, Mallory-Weiss syndrome, esophageal rings and hiatal hernia, and esophageal and gastric stenoses. When combined with histologic and cytologic tests may indicate acute or chronic ulcers, benign or malignant tumors, and inflammatory disease.
Laparoscopy—examine the peritoneal cavity: pelvis and abdomen	Instruct client to fast 8 hours before the surgery; the test is performed either with a local or general anesthetic agent. Place the client in a lithotomy position; catheterize the client to ensure the bladder is empty (avoids puncture of the bladder during the test with the laparoscope).	Used to detect cysts; adhesions; fibroids; and infections of the uterus, fallopian, tubes and ovaries; ectopic pregnancies; liver lacerations and cirrhosis. May also be used for lysis of adhesions, ovarian biopsy, tubal sterilization, foreign body removal, and fulguration of endometriotic implants.
Proctosigmoidoscopy—three steps: 1. Digital examination to dilate the anal sphincters to detect obstruction that might hinder passage of the endoscope 2. A sigmoidoscope to examine the distal sigmoid colon and rectum. 3. A proctoscope to examine the lower rectum and anal canal	Instruct client according to physician orders relative to dietary restrictions and bowel preparation (these are usually based on physician preference). If the client has rectal inflammation a local anesthetic agent is applied to decrease discomfort. Secure the client to a tilting table that rotates into horizontal and vertical positions.	Identify internal hemorrhoids, hypertrophic anal papillae, polyps, fissures, fistulae, and rectal and anal abscesses.

ASPIRATION/BIOPSY

Aspiration is performed to withdraw fluid that has abnormally collected or to obtain a specimen. Aseptic technique and Standard Precautions are used during aspiration. Aspiration diagnostic studies are invasive; implement the protocols for diagnostic tests. A local anesthetic is administered in the area being studied to decrease the client's discomfort when the skin is pierced by the needle.

A stylet needle with an outer, hollow-bore needle is used to pierce the skin. Once the needle is in place, the stylet is withdrawn, leaving only the outer needle to aspirate the fluid. A tissue **biopsy** (excision of a small amount of tissue) can be obtained during aspiration or with other diagnostic tests (e.g., bronchoscopy). A biopsy can be taken from most of the body's tissue.

Amniocentesis

Amniocentesis is the withdrawal of amniotic fluid to obtain a sample for specimen examination. The amniotic fluid increases during pregnancy from 50 ml at the end of the first trimester to an average of 1000 ml near term. This test is indicated when:

- Maternal age exceeds 35
- A spontaneous abortion occurred with a previous pregnancy
- There is a family history of genetic, chromosomal, or neural tube defects

The amniocentesis is performed when the amniotic fluid volume reaches 150 ml, usually after the 16th week of pregnancy.

There are no restrictions on fluids or food. The procedure usually lasts 10 to 15 minutes. Instruct the mother to void to prevent the risk of puncturing a full bladder. Position the client supine and assesses the fetal heart tones.

The abdomen is prepped and injected with lidocaine hydrochloride (a local anesthetic agent). The practitioner withdraws 10 to 20 ml amniotic fluid by transabdominal needle aspiration. Postprocedure the nurse monitors the client's vital signs, fetal heart tones, and assesses for signs of labor. Instruct the client to notify the practitioner of any signs of labor or infection.

Bone Marrow Aspiration/Biopsy

The sternum and iliac crest are the common sites for bone marrow puncture. During a bone marrow puncture a fluid specimen (aspiration) or a core of marrow cells (biopsy) can be obtained. Both tests are commonly done concurrently to obtain the best marrow specimen. The test can reveal anemias or cancer, such as leukemia, multiple myeloma, or Hodgkin's disease, or the client's response to chemotherapy.

There are no restrictions on fluids or food before the puncture. The nurse should explain the procedure to elicit the client's support during the procedure. The client must lay perfectly still throughout the procedure. The client is usually fearful; allay the client's fear with relaxation methods or sedation. Infants and small children are restrained by holding them throughout the procedure.

Client positioning is determined by the site to be used, supine (sternum) or side-lying (iliac crest). The site is prepped for puncture to decrease the skin's normal flora. Explain to the client that pressure may be experienced as the specimen is withdrawn. The client should not move when the specimen is being withdrawn; a sudden movement may dislodge the needle.

Postprocedure the client should be on bed rest for an hour. The nurse monitors vital signs to assess for bleeding (rapid pulse rate, low blood pressure). Instruct the client to report to the practitioner any bleeding or signs of inflammation.

Paracentesis

Paracentesis is the aspiration of fluid from the abdominal cavity. This test can either be diagnostic, therapeutic, or both. For instance, with end-stage liver or renal disease there is **ascites** (an accumulation of fluid in the abdomen). Pressure caused from the ascites can interfere with breathing and gastrointestinal functioning. Aspiration in this instance is therapeutic. If a culture specimen is taken, it is also diagnostic.

Have the client void and obtain a body weight before the procedure. Place the client in a high Fowler's position in a chair or sitting on the side of the bed. The skin is prepped, anesthetized, and punctured with a **trocár** (a large-bored abdominal paracentesis needle). The trocar is held perpendicular to the abdominal wall and advanced into the peritoneal cavity. When fluid appears, the trocar is removed, leaving the inner catheter in place to drain the fluid. Observe the client for pressure changes that can result from the rapid removal of fluid.

Postprocedure apply a sterile dressing to the puncture site. Monitor the client for changes in vital signs and electrolytes. Instruct the client to record the color, amount, and consistency of drainage on the dressing after discharge.

Thoracentesis

Thoracentesis is the aspiration of fluids from the pleural cavity. The pleural cavity normally contains a small amount of fluid to lubricate the lining between the lungs and pleura. Infection, inflammation, and trauma may cause an increased production of fluid, which can impair ventilation.

Position the client with arms crossed and resting on a bedside table to allow access to the rib cage (Figure 28-17). Instruct the client not to cough during insertion

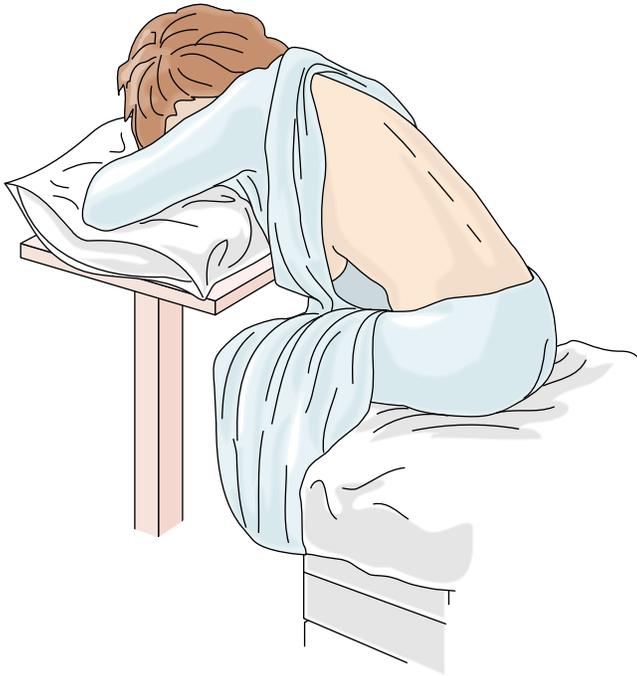

Figure 28-17 Client Position for Thoracentesis

of the needle. The practitioner selects, preps, and anesthetizes the puncture site. The needle is usually inserted into the intercostal space at the location of maximum dullness to percussion. Posteriorly, the site should be above the ninth rib, and laterally, above the seventh rib.

During the procedure, monitor the client for symptoms of a **pneumothorax** (collection of air or gas in the pleural space causing the lungs to collapse), such as dyspnea, pallor, tachycardia, vertigo, and chest pain. Postprocedure observe for cardiopulmonary changes and a mediastinum shift as assessed by vital signs and bloody sputum.

Cerebrospinal Fluid Aspiration

Lumbar puncture (“spinal tap”) is the aspiration of CSF from the subarachnoid space. The specimen is examined for organisms, blood, and tumor cells. A spinal tap is also performed:

- To obtain a pressure measurement when blockage is suspected
- During a myelogram, as discussed earlier
- To instill medications (anesthesia, antibiotics, or chemotherapy)

A spinal tap is contraindicated in clients with increased intracranial pressure, hemorrhagic diathesis, and an infection at the proposed puncture site.

Place the client in a lateral recumbent position with the craniospinal axis parallel to the floor and flat of the back perpendicular to the procedure table. Have the client assume a flexed knee-chest position to bow the

back. This position separates the vertebrae. Most clients will require assistance in maintaining this position throughout the procedure. To assist, the nurse stands facing the client with one hand across the client’s posterior shoulder blades and the other hand over the buttocks.

The practitioner selects, preps, and anesthetizes the puncture site (usually interspace L3-L4, L4-L5, or L5-S1). The needle and stylet are inserted into the mid-sagittal space and advanced through the longitudinal subarachnoid space (Figure 28-18).

Once in the subarachnoid space, the stylet is removed, leaving the needle in place. An initial CSF pressure reading is taken:

- A three-way stopcock with a manometer (calibrated column) is securely connected to the spinal needle.
- The stopcock is opened toward the manometer to allow the CSF to rise in the column. Under normal conditions, the CSF will fluctuate in the column with respirations.
- When the CSF stabilizes, a pressure reading is taken.

If the pressure reading is greater than 200 mm H₂O or falls quickly, only 1 or 2 ml CSF is obtained for analysis. If the pressure is less than 200 mm H₂O, an adequate specimen sampling is withdrawn slowly.

NURSING ALERT

Taking the Pressure Reading

The client should be relaxed and quiet during the initial pressure reading; *straining increases the CSF*.

After the pressure reading is taken, the stopcock is turned to allow the CSF to slowly flow into a sterile test tube. A sterile cap is placed on the test tube, and the

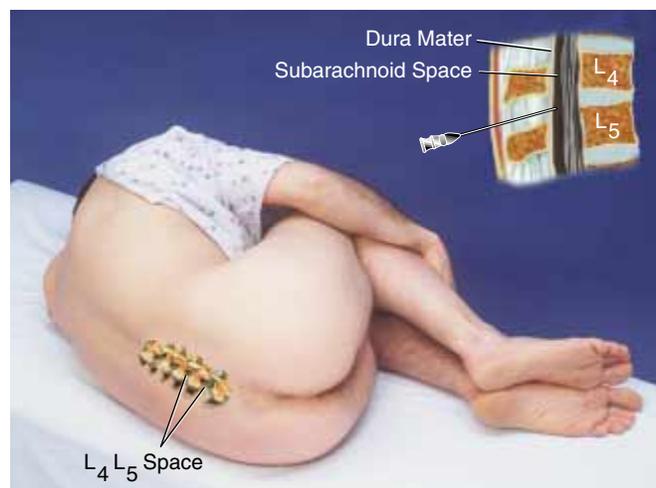

Figure 28-18 Lumbar puncture: position of client and insertion of the needle into the subarachnoid space are shown.

sample is transported to the laboratory for analysis. Rapid withdrawal of CSF can cause a transient postural headache. Throughout the procedure, monitor the client's cardiorespiratory status.

Postprocedure, pressure is applied and then a sterile bandage. Assess the bandage for leakage of CSF and the client's neurologic and cardiorespiratory status. A postural headache is the most common complication of a lumbar puncture; using a small-bore spinal needle minimizes the chances of a headache.

KEY CONCEPTS

- Most invasive procedures require the client's written consent and a thorough understanding of the reasons the test is being performed. Nurses explain the purpose of the diagnostic test and the reasons it has been ordered.
 - Nurses prepare clients for diagnostic testing by ensuring client understanding and compliance to preprocedural requirements.
 - Clients, families, and significant others need to be involved in the testing process; advise them of the estimated time the procedure requires.
 - Nurses teach the client how to perform relaxation and imagery techniques to cope with the discomfort and anxiety experienced during procedures.
 - After a procedure, the nurse provides care and teaches the client what to expect following a diagnostic test and the outcomes or side effects of the test.
 - Specimen collection methods include punctures such as venipuncture, arterial puncture, capillary puncture, catheter insertion, and bone marrow aspiration. Specimens collected by noninvasive methods include urine, stool, sputum, throat tissue, and cervical tissue.
 - Invasive procedures include endoscopy, angiography, aspiration, biopsy, and other procedures in which body cavities are punctured.
 - Noninvasive procedures include radiography, fluoroscopy, mammography, computed tomography, radioisotope scanning, ultrasonography, magnetic resonance imaging, and electrodiagnostic studies.
 - The role of the nurse in diagnostic procedures is to facilitate the scheduling of diagnostic test, perform client teaching, perform or assist with procedures, and assess the client for adverse responses to the procedures.
 - Nurses should schedule diagnostic procedures to promote client comfort and cost containment.
 - Standard Precautions are used when obtaining a specimen for diagnostic examination or assisting with an invasive procedure
 - Before the procedure the nurse is responsible for obtaining baseline vital signs and assessing the client's preparation for testing.
- Nurses may assist the practitioner in performing invasive procedures.
 - After the procedure the nurse assesses the client for secondary procedural complications and provides any necessary nursing interventions.

CRITICAL THINKING ACTIVITIES

1. In reference to the nursing tip about Mr. Simon, what did his history and physical reveal? Why did the nurse practitioner order a white blood cell differential as opposed to a white blood cell count? What do you think Mr. Simon's medical diagnosis will be: an infected ingrown toenail, anemia, diabetes, or something else? Relate the symptoms as presented in the history and physical to the physiological functions of white blood cells.
2. With invasive procedures the body is entered with some type of instrumentation; there is a puncture site. If you fall down and a nail pierces your leg, you have a puncture site. What are you at risk for immediately after the incidence and 48 to 72 hours postinjury? Can you relate the body's physiological response to an invasive procedure to a puncture injury?
3. Explain how the three sources of venipuncture variability can cause inaccurate laboratory results.
4. What is a normal prothrombin time (PT)? PT is a comparative test that measures the client's PT to the control time. Both the PT and control time results are reported. One example of the use of a PT is to measure the effectiveness of prescribed anticoagulant therapy. In this case, the therapeutic range is 2 to 2.5 times the control time, which is 12 to 14 seconds. If the control time is 12 seconds, what would you expect the client's PT to be?
5. If your blood type is AB positive, what are the possible blood types of your parents? Can you receive Rh-negative blood? Explain your answer.
6. What are the physiological effects of acetylcholine on the nervous system? Why should the practitioner be notified about a decreased level of cholinesterase for a client scheduled to receive succinylcholine for either major surgery or electroconvulsive therapy?
7. Which client is more at risk for coronary heart disease? Mrs. Smith, a 59-year-old who is postmenopausal with a cholesterol of 185 mg/dl, LDL of 131 mg/dl, HDL of 25 mg/dl, and triglycerides of 250 mg/dl. Mr. Jones, a 55-year-old who smokes occasionally with a cholesterol of 220 mg/dl, LDL of 157 mg/dl, HDL of 37 mg/dl, and triglycerides of 249 mg/dl.
8. You are counseling Maria Rodriguez regarding the symptoms and risk factors of large radiation exposures. She is receiving radiation therapy for breast cancer. Where in her medical record should the potential risk factors be addressed?

9. What specific teaching should be done for a client undergoing arteriography? Evaluate the need for teaching based on the procedure. Refer to the protocol on preparing the client for diagnostic testing for appropriate teaching interventions.
10. Plan the postprocedural care for a cardiac catheterization client using the protocol for care of the client after diagnostic testing.
11. Relate the laboratory and diagnostic tests to the functional health patterns. Consider the special diagnostic teaching needs for each of the functional health patterns.
12. Select interventions, based on the functional health pattern(s) affecting the results, when planning nursing care for your assigned clients.

Chapter 29

Medication Administration

Words are the most potent drug that mankind uses.

—Kipling (in Edlin & Golanty, 1988)

COMPETENCIES

1. Define the key terms and abbreviations frequently used in medication administration.
2. Describe the influence of drug standards and legislation on medication administration.
3. Discuss the nurse's legal responsibilities in preparation and administration of medications.
4. Explain the principles of pharmacokinetics, including absorption, distribution, and metabolism, and excretion of drugs.
5. Describe the factors that can affect a drug's action.
6. Identify the responsibilities of the nurse for each type of medication order.
7. Differentiate between allergic reaction, side effects, toxic effect, and idiosyncratic reaction to medications.
8. Correctly calculate appropriate dosage for medications as prescribed.
9. Discuss principles of safe medication administration including the five rights of medication administration.
10. Correctly explain procedures for the different methods of medication administration including the choice of route and site.
11. Discuss potential liabilities for the nurse administering medications.
12. Develop teaching guidelines for clients regarding medication in the home.

KEY
TERMS

absorption	excretion	phlebitis
addiction	half-life	plateau
adverse reaction	idiosyncratic reaction	prn orders
aspiration	infiltration	trough
bioavailability	intra dermal (ID)	side effects
buccal	intramuscular (IM)	stat order
dependence	intravenous (IV)	stock supply
dissolution	metabolism	subcutaneous (SC/SQ)
distribution	onset of action	sublingual
drug allergy	parenteral	therapeutic range
drug incompatibility	patency	toxic effect
drug tolerance	peak plasma levels	trough
duration	pharmacognosy	unit-dose form
enteral instillation	pharmacokinetics	Z-track technique

Alteration in health related to acute or chronic conditions lead clients to seek relief of their symptoms through various treatment options. One modality frequently used to help alleviate symptoms and restore health is a medication regime. Medications are substances prescribed by the client's health care practitioner to help in the treatment, relief, or cure of the cause of the client's health alteration or in the prevention of an alteration.

Medication management requires the collaborative efforts of many health care providers. Medications may be prescribed by a physician, dentist, or other authorized prescriber such as advanced practice registered nurses as determined by individual state licensing bodies. Pharmacists are licensed to prepare and dispense medications. Nurses are responsible for administering medications. Dietitians are often involved in identifying possible food and drug interactions.

Nurses play an essential role in the administration of, education about, and evaluation of the effectiveness of prescribed medications. The nurse's role changes with the setting of the client. In the home or community setting, referred to as primary care, clients take their own medication as prescribed by the health care practitioner. Nurses are responsible for educating the client about his or her medications and its possible side effects as well as for evaluating the outcome of the prescribed therapy in restoring and maintaining the client's health. In the acute care setting, nurses spend a great deal of time administering medications and evaluating their effectiveness. Nurses are responsible for teaching clients how to take their medications safely when they are discharged.

Medication administration requires specialized knowledge, judgment, and nursing skill based on the principles of pharmacology. The focus of this chapter is to assist the student in applying knowledge of pharmacology and in acquiring skills in the safe administration of medications. The nursing process is used to direct nursing decisions relative to safe drug administration and to ensure compliance with standards of practice.

DRUG STANDARDS AND LEGISLATION

A drug is a chemical substance intended for use in the diagnosis, treatment, cure, mitigation, or prevention of a disease. When a drug is given to a client, there is an intended specific effect. An assumption made by nurses before administration of any medication is that the drug will be safe for the client to consume if the dose, frequency, and route are within the therapeutic range for that drug. This assumption is implied in accord with standards that are set to ensure drug uniformity in strength, purity, efficacy, safety, and **bioavailability** (readiness to produce a drug effect).

Standards

Standards have been developed to ensure drug uniformity so that effects are predictable. The *United States Pharmacopeia* and *National Formulary* (USP and NF) are books of drug standards for usage in the United States. The USP and NF list drugs that have been recognized as being in compliance with legal standards of purity, quality, and strength.

The USP has been providing standards for pharmaceutical preparations since its first edition in 1820. The NF was published in 1898 by the American Pharmaceutical Association to provide a listing of drugs that complied with established standards. The *British Pharmacopoeia* is the Canadian complement to the USP, and the *Canadian Formulary* provides a listing of drugs commonly used in Canada.

Federal Legislation

The Pure Food and Drug Act of 1906 designated the USP and the NF as the official references to establish drug standards. It also gave the federal government the authority to enforce these standards.

The federal Food, Drug, and Cosmetic Act of 1938 empowered the Food and Drug Administration (FDA) to

test all new drugs for toxicity before granting a pharmaceutical company approval to market a drug. The federal Food, Drug, and Cosmetic Act of 1938 was amended in 1952 to distinguish prescription (legend) drugs from nonprescription (over-the-counter) drugs and to regulate the dispensing of prescriptions. Testing for drug effectiveness materialized with the Kefauver-Harris Act of 1962 (Lehne, 1994).

The Harrison Narcotic Act of 1914 classified habit-forming drugs as narcotics and began regulating these substances. This law and other drug abuse laws have been replaced with the Comprehensive Drug Abuse Prevention and Control Act (Controlled Substance Act) of 1970. This act defines a *drug-dependent person* in terms of physical and psychological dependence and provides for strict regulation of narcotics and other controlled drugs such as barbiturates through the establishment of five categories of scheduled drugs (see the accompanying display on controlled substances). Any controlled substance must be recorded by the dispensing pharmacist. The Drug Enforcement Administration (DEA) employs pharmacists to inspect all types of records, including prescriptions, to detect the illicit distribution of these substances.

State and Local Legislation

Within an individual state, the nurse's functions and responsibilities are defined by the state nurse practice act. The wording of a state's practice act may be general so that it gives the nurse a broad range of responsibilities, or it may be very specific in the limitations it sets. The nurse is responsible for knowing the boundaries set by the state practice act in the particular state of practice. A health care institution may develop policies that are more restrictive than the nurse practice act but cannot expand the scope of practice outlined by the state legislation. The primary intent of all state practice acts is to protect the public by defining required education and skill levels of all state-licensed nurses.

State and local regulations of medications must conform with federal legislation. States, however, have the

power to enforce additional regulations that impose stricter control of substances. For example, the Controlled Substance Act has codeine in antitussives as a schedule V drug, but an individual state that identifies abuse of antitussives with codeine may place this drug in the schedule II category, which is more restrictive.

Health Care Institution Regulations

All health care institutions are required to meet minimum standards set by federal, state, and local agencies. In addition to these standards, most institutions have established specific policies that regulate administration of medication within the institution. Institutional policies are typically more restrictive and more specific than federal and state regulations. Health care institutions are trying to prevent problems stemming from medication administration. For example, institutional policies may set the times for medication administration (for example, medications ordered for every eight hours are given at 0600 [6 AM], 1400 [2 PM], and 2200 [10 PM] or may mandate discontinuation of medications unless reordered by the health care provider (for example, antibiotics must be reordered every five days).

PHARMACOKINETICS

For a drug to achieve a therapeutic effect, it must proceed from the point of entry into the body to the tissue with which it will react. The effectiveness is further affected by the dosage of the drug and the amount of time the drug spends in the body before it is excreted.

Pharmacokinetics refers to the study of the absorption, distribution, metabolism, and excretion of drugs to determine the relationship between the dose of a drug and the drug's concentration in biological fluids. The knowledge of pharmacokinetics is used by health care providers in medication management.

The physician, when ordering a drug, is concerned mainly with dose and route to produce the most therapeutic effects; physicians, pharmacists, and nurses are all involved in identifying appropriate times for drug administration and for avoiding interactions with other substances that could alter the drug's actions. Physicians and nurses monitor the client's response to the drug's action. Drug actions are dependent on four properties: absorption, distribution, metabolism, and excretion.

Absorption

The degree and rate of **absorption**, or passage of a drug from the site of administration into the bloodstream, depend on several factors: the drug's physicochemical effects, its dosage form, its route of administration, its interactions with other substances in the digestive system, and various client characteristics such as age. Oral preparations, such as tablets and capsules, must first disintegrate into smaller particles for gastric juices to

CONTROLLED SUBSTANCES

- Schedule C-I: High abuse potential, no current accepted medical use (e.g., heroin, marijuana, and LSD)
- Schedule C-II: High abuse potential for severe dependence (e.g., narcotics, amphetamines, dronabinol, and some barbiturates)
- Schedule C-III: Less abuse potential than schedule II drugs for moderate dependence (e.g., nonbarbiturate sedatives, nonamphetamine stimulants, and limited amounts of certain narcotics)
- Schedule C-IV: Lower abuse potential than schedule III drugs for limited dependence (e.g., sedatives, antianxiety agents, and nonnarcotic analgesics)
- Schedule C-V: Limited abuse potential (e.g., codeine used as antitussive and antidiarrheals)

dissolve and prepare the drug for absorption in the small intestines. **Dissolution** is the rate at which a drug becomes a solution. After ingestion, a pill, capsule, or caplet must disintegrate before it can be dissolved and then absorbed by the body for therapeutic use. The more rapid the rate of dissolution, the more quickly the drug can be absorbed. Oral drugs in liquid form are more readily absorbed by the gastrointestinal tract than are tablets. Figure 29-1 shows the process of absorption of solid drugs.

Drugs administered intramuscularly are absorbed through the muscle into the bloodstream. Suppositories are absorbed through the mucous membranes into the blood. Intravenous drugs are immediately bioavailable because of their direct injection into the blood to produce a drug effect.

Blood flow to the absorption site is a major factor in drug absorption. A rich blood supply facilitates absorption, whereas a poor blood supply will slow absorption. **Sublingual** (under the tongue) medications, such as Nitrostat (for angina), are absorbed more quickly than are medications such as insulin that are injected into subcutaneous tissue. A person in shock, which results in poor peripheral circulation, may not absorb intramuscular medications as well as a person with normal circulation. Circulation is enhanced by exercise, so a diabetic who has exercised hard may experience low blood sugar (hypoglycemia) because of more rapid absorption of the insulin from increased peripheral circulation.

The solubility of the drug is also a factor in absorption. To be absorbed, the drug must be in a liquid form. The more soluble the drug, the faster it will be absorbed. Because cells have a fatty acid layer, drugs that are more lipid in content are absorbed more rapidly. Chemicals and minerals that are insoluble in the gastrointestinal tract, such as barium salts, are not absorbed. When given parenterally, drugs with an oily base such as streptomycin (anti-infective) are absorbed more slowly than are drugs dissolved in a water base.

The pH of the drug is another factor in absorption. A drug that is acidic (such as aspirin) can be more easily absorbed in an acidic environment such as gastric content. A drug that is more basic in composition is not

absorbed in the stomach but passes on to the small intestine, where it is absorbed.

Drugs that are highly concentrated (such as epinephrine) tend to be absorbed more quickly than do drugs that are lower in concentrations. Less well researched is the effect ethnicity and culture have on the therapeutic effects of medications. Some studies have identified differences in required drug levels as well as response to medications (such as antihypertensive drugs and the African-American client). Drugs do not have the same effect in all people. Diet is a factor as well as adherence to herbal and homeopathic remedies (for example, the herb ginseng can act as an accelerant or inhibitor of certain medications). Health care providers need to be aware of and sensitive to these cultural variations that may affect clients in their care (Kudzma, 1999).

Another factor affecting absorption is the ingestion of food before taking oral medications. Interactions of some medications with food change the chemical structure of the drug, thereby affecting absorption. For example, tetracycline (an anti-infective) should not be taken with dairy products. Clients taking warfarin (an anticoagulant) should avoid or limit their intake of food high in vitamin K, which is an antidote for warfarin. Some medications, when given together, interact with each other to impair absorption.

The administration time of dosages needs to be regulated to ensure adequate absorption of drugs. For example, it may be best to take certain medications a half-hour before meals. The nurse needs to use this knowledge to be sure prescribed medications are administered properly.

Distribution

Distribution refers to the movement of drugs from the blood into various body fluids and tissues. The rate at which the drug reaches the specific site of action is affected by blood flow, cell membrane permeability, and the protein-binding capacity of the medication.

How fast the drug reaches the organs and tissues depends on the cardiac output (blood flow) of the person. When conditions exist that decrease blood flow (as in cardiogenic shock) or when circulation to the tissue is poor (as in peripheral vascular disease from atherosclerosis) the distribution of the drug will be slowed. When conditions exist that increase blood flow (such as strenuous exercise) distribution will be facilitated.

To be distributed to the tissue, the drug must cross the cell membrane. Some membranes act as a barrier for distribution of medications. The blood brain barrier, for example, allows only fat-soluble medications to pass through (for example alcohol, general anesthetics, penicillin G).

Once the drug enters the circulation, it may become attached to proteins, mostly albumin. This protein binding decreases the amount of free drug available to reach the site of action. This is because the protein-drug molecule is trapped in the blood flow because it is too large to diffuse through the cell membrane. While medications vary in the extent to which they bind with proteins, most drugs have some protein binding properties. Some diseases (such as malnutrition or liver disease) cause a decrease in circulating

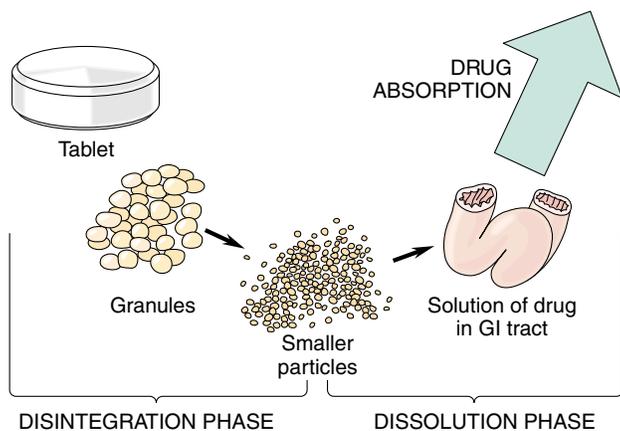

Figure 29-1 Phases of Solid Drug Absorption

albumin which results in more free drug. This can result in increased distribution of the drug (enhanced pharmacological effect) and toxicity if not carefully monitored.

The body composition also affects the distribution of medications. Many drugs are prescribed based on body weight. An increase in body fat (in an obese person for example) causes longer drug duration because of slower distribution. The less a person weighs the higher the concentration of medication in the circulation which results in a more powerful drug effect. This needs to be monitored very closely in the elderly who have changes in body composition naturally related to aging and often lose weight due to a decreased appetite.

Metabolism

After the medication is absorbed and distributed, the body eliminates the drugs. The process of **metabolism** (also known as biotransformation) refers to the physical and chemical processing of the drug. In metabolism, the drug is inactivated and changed into a water-soluble compound that can be excreted by the body. The liver is the primary source of biotransformation. The rate of metabolism is determined by the presence of enzymes in the liver cells that detoxify the drugs. Diseases that affect the liver (such as cirrhosis) affect the body's ability to biotransform medications. Other conditions that affect metabolism are blood flow to the liver, the presence of other substances that affect liver function, and age. If drug metabolism is inhibited, there will be a buildup of the medication, causing a cumulative effect. This will be exhibited as prolonged response to a normal dose of medication. If metabolism is enhanced (as in high blood flow states), the medications will be inactivated faster than expected, resulting in a shorter response to medications.

Excretion

Excretion is the process in which drugs are eliminated from the body. Excretion occurs primarily through hepatic biotransformation and renal excretion. "Drug excretion refers to the movement of a drug or its metabolites from the tissues back into circulation and from the circulation into the organs of excretion" (Springhouse, 1997, p. 7).

Factors that affect the kidneys' ability to excrete drugs include maturity of the kidneys, circulation, and disease. As kidney function decreases, there can be an accumulation of drugs, which can result in toxicity. If the kidneys are not functioning normally, a decreased dosage of medications may be needed. Adequate fluid intake aids in the elimination of drugs in a healthy individual. Other organs, such as exocrine glands, the skin, the gastrointestinal tract, and the lungs contribute to the elimination of some drugs.

DRUG NOMENCLATURE

A drug may be used as an aid in the diagnosis, treatment, or prevention of disease; or in other abnormal

SAMPLE TRADE AND GENERIC DRUG NAMES

Trade Name	Generic Name
Bayer	Aspirin
Benadryl	Diphenhydramine hydrochloride
Robitussin	Guiafenesin
Zovirax	Acyclovir

conditions for the relief of pain or suffering; or to improve any physiological or pathologic condition. The terms *drug*, *medication*, and *medicine* are often used interchangeably by health care providers and laypersons.

Drugs can be identified by their chemical, generic, official, or trade names. The *chemical name* is a precise description of the drug's composition (chemical formula). The *nonproprietary*, or *generic, name* in the United States is the name assigned by the United States Adopted Names Council to the manufacturer who first develops the drug. When the drug is approved, it is given an *official name* that may be the same as the nonproprietary name (Lehne, 1994). Drugs with a proven therapeutic value are listed in the USP and NF by their official names. When pharmaceutical companies market the drug, they assign a *proprietary name*, also called a *trade*, or *brand, name*; therefore, one generic drug may have several trade names based on the number of companies marketing the drug. For example, ibuprofen is a generic name; common trade names for this drug are Advil, Excedrin IB, Motrin, and Nuprin. See the accompanying display for additional examples of trade and generic drug names.

DRUG ACTION

Drug action refers to a drug's ability to combine with a cellular drug receptor. Depending on the location of different cellular receptors affected by a given drug, a drug can have a local effect, systemic effect, or both local and systemic effects. For example, when diphenhydramine hydrochloride (Benadryl) cream is applied to the skin, it elicits only a local effect; however, when this drug is administered in a tablet or injectable form, it causes both systemic and local effects.

Pharmacology

Pharmacology is the study of the effects of drugs on living organisms. This section discusses the pharmacologic activities of drug action as it relates to medication management, drug classification, drug preparation, and routes of administration.

Medication Management

The purpose of medication management is to produce the desired drug action by maintaining a constant drug level. Drug action is based on the half-life of a drug.

A drug's **half-life** refers to the time it takes the body to eliminate half of the blood concentration level of the original drug dose. For example, if a drug has a half-life of 6 hours, 50% of the drug's original dose is present in the blood 6 hours after administration; in 12 hours after administration, 25% of the original drug is present. Because of a drug's half-life, repeated doses are often required to maintain the drug level over a 24-hour interval.

The nurse should understand other terms used to describe drug action: onset, peak plasma level, trough, duration, and plateau. **Onset of action** is the time it takes the body to respond to a drug after administration. Onset is affected by route of administration and pharmacokinetic factors already discussed. A **peak plasma level** is the highest blood concentration of a single drug dose before the elimination rate equals the rate of absorption. Once the peak plasma level is achieved, the blood concentration level will decrease steadily unless another drug dose is given. **Trough** is the lowest blood serum concentration of a drug in a person's system. This is measured immediately before the next scheduled dose. Trough levels help adjust dosage to prevent toxicity or drug buildup. **Duration** is the time a drug remains in the system in a concentration great enough to have a therapeutic effect. Table 29-1 defines the common terms associated with the medical management of medication administration. If a series of scheduled drug doses are administered, the blood concentration level is maintained; maintenance of a certain level is called a **plateau**.

Classification

Drugs are commonly classified by the body system that they interact with (e.g., cardiovascular) or in accord with the drug's approved therapeutic usage (e.g., antihypertensive). Drugs with multiple therapeutic uses are usually classified in accordance with their most common usage.

TABLE 29-1
Common Terms Associated
with Medical Management

Half-life	The time it takes the body to eliminate half the blood concentration level of the original drug dose
Onset	The time it takes the body to respond after medication administration
Peak plasma level	The time it takes for a drug to reach the highest blood concentration after a plasma level single dose before elimination rate equals the rate of absorption
Trough	The lowest blood serum concentration immediately before the next scheduled dosage
Duration	The time a drug remains in the system in a therapeutic concentration
Plateau	Blood concentration level maintained after a series of scheduled drug doses is administered

Preparation and Route

Drugs are available in many forms for administration by a specific route (see Drug Preparations). The route refers to how the drug is absorbed: oral, buccal, sublingual, rectal, parenteral (hypodermic routes), topical, and inhalation.

Drugs prepared for administration by one route should not be substituted by other drug forms. For example, when a client has difficulty swallowing a large tablet or capsule, *the nurse should not administer an oral solution or elixir of the same drug without first consulting the physician because a liquid may be more easily and completely absorbed, producing a higher blood level than a tablet.*

The nurse should be aware of the various drug forms and how they are administered. Certain drug preparations require special consideration regarding administration. For example:

- Chewable tablets are designed to be chewed before swallowing because chewing enhances gastric absorption.
- Buccal and sublingual medications must be allowed to dissolve completely before the client can drink or eat.
- Suspensions and emulsions should be administered immediately after shaking and pouring from the bottle.

Oral Route

Most drugs are administered by the oral route because it is the safest, most convenient, and least expensive method. The disadvantage of the oral route is that it is slower acting than the other routes, such as injectables. Drugs may not be given orally to clients with gastrointestinal intolerance or those on NPO (nothing by mouth) status. Oral drugs should be given with caution to clients who have difficulty swallowing, such as a patient who has had a cerebrovascular accident (stroke). Oral administration is also precluded by unconsciousness.

When small amounts of drugs are required, the **buccal** (cheek) or sublingual route is used. Drugs administered through these routes act quickly because of the oral mucosa's thin epithelium and large vascular system, which allows the drug to quickly be absorbed by the blood.

Certain oral drugs are prepared for sublingual or buccal administration to prevent their destruction or transformation in the stomach or small intestines. Buccal drugs are designed to be placed in the buccal pocket (superior-posterior aspect of the internal cheek next to the molars) for absorption by the mucous membrane of the mouth. Sublingual medications are designed to dissolve quickly when placed under the tongue. For example erythrityl tetranitrate (an anti-anginal) can be given either sublingually or buccally as prescribed, whereas isoproterenol hydrochloride (a bronchodilator) and nitroglycerin (an anti-anginal) are given sublingually, and methyltestosterone (an androgen) is given only buccally.

Parenteral Route

By definition, **parenteral** means introduction of a medication by any route other than the oral-gastrointestinal

DRUG PREPARATIONS

Oral Solids

- Tablets: compressed or molded substances, to be swallowed whole, chewed before swallowing, or placed in the buccal pocket or under the tongue (sublingual)
- Capsules: substances encased in either a hard or a soft soluble container or gelatin shell that dissolves in the stomach
- Caplets: gelatin-coated tablets that dissolve in the stomach
- Powder and granules: finely ground substances
- Troches, lozenges, and pastilles: similar preparations of drugs designed to dissolve in the mouth
- Enteric-coated: coated tablets that dissolve in the intestines
- Time-release capsules: encased substances that are further enclosed in smaller casings that deliver a drug dose over an extended period of time
- Sustained-release: compounded substances designed to release a drug slowly to maintain a steady blood medication level

Topical

- Liniments: substances mixed with an alcohol, oil, or soapy emollient that is applied to the skin
- Ointments: semisolid substances for topical use
- Pastes: semisolid substances, thicker than an ointment, absorbed slowly through the skin
- Transdermal patches: contain medication that is absorbed through the skin over an extended period of time
- Suppositories: gelatin substances designed to dissolve when inserted in the rectum, urethra, or vagina

Inhalants

- Inhalations: drugs or dilution of drugs administered by the nasal or oral respiratory route for a local or systemic effect

Solutions

- Solutions: contain one or more soluble chemical substances dissolved in water
- Enemas: aqueous solutions for rectal instillation
- Douches: aqueous solutions that function as a cleansing or antiseptic agent that may be dispensed in the form of a powder with directions for dissolving in a specific quantity of warm water
- Suspensions: particle or powder substances that must be dissolved in a liquid (shaken vigorously) before administration
- Emulsion: a two-phase system in which one liquid is dispersed in the form of small droplets throughout another liquid
- Syrups: substances dissolved in a sugar liquid
- Gargles: aqueous solutions
- Mouthwashes: aqueous solutions that may contain alcohol, glycerin, and synthetic sweeteners and surface-active flavoring and coloring agents
- Nasal solutions: aqueous solutions in the form of drops or sprays
- Optic (eye) and otic (ear) solutions: aqueous solutions that are instilled as drops
- Elixirs: nonaqueous solutions that contain water varying alcohol content, and glycerin or other sweeteners

route. However, medical usage of this term refers to injecting medication into body tissue. Sterile technique is always used for any medication injection. The four routes that nurses commonly use to administer parenteral medications are:

- **Intradermal (ID)** is an injection into the dermis.
- **Subcutaneous (SC or SQ)** is an injection into the subcutaneous tissue.
- **Intramuscular (IM)** is an injection into the muscle.
- **Intravenous (IV)** is an injection into a vein.

Other parenteral routes, such as intrathecal or intraspinal, intracardiac, intrapleural, intra-arterial, and intra-articular, are used by physicians and in some cases by advanced practice registered nurses for medication administration.

Topical Route

Most topical drugs are given to deliver a drug at, or immediately beneath, the point of application. Although a large number of topical drugs are applied to the skin, other topical drugs include eye, nose and throat, ear, rectal, and vaginal preparations. Drugs directly applied to the skin are absorbed through the epidermal layer into the dermis, where they create local effects or are absorbed into the bloodstream. Drug action varies with the vascularity of the skin, usually requiring several applications over a 24-hour period to cause the desired therapeutic effect.

Transdermal patches, another type of topical preparation, are used to deliver medications such as nitroglycerin (anti-anginal) and certain supplemental hormone replacements for absorption by the blood to produce systemic effects. An adhesive disk secures the

medication ointment to the skin. The frequency for changing the patch varies with the specific drug. The medication can last from 24 hours to 7 days.

Some topical drugs, such as eye and nasal drops and vaginal and rectal suppositories, can be applied directly to the mucous membranes. These drugs are absorbed quickly into the bloodstream, and, depending on the drug's dose (strength and quantity), may cause systemic effects.

The client may complain of a burning sensation when the nurse instills eye or nasal drops because the cornea of the eye and nasal mucous membranes are often sensitive to medications. Eyedrops should never be applied onto the sensitive cornea.

Inhalants

Inhalants such as oxygen and most general anesthetics deliver gaseous or volatile substances that are almost immediately absorbed into the systemic circulation. The inhalants are delivered into the alveoli of the lungs, which promote fast absorption owing to:

- The permeability of the alveolar and vascular epithelia
- An abundant blood flow
- A very large surface area for absorption

Oropharyngeal hand-held inhalers deliver topical drugs to the respiratory tract to create local and systemic effects. There are three types of inhaler: metered-dose inhaler or nebulizer, turbo-inhaler, and nasal inhaler. They are explained later in this chapter.

Intraocular Route

Intraocular medications are administered by applying a clear, flexible, elliptical-shaped disk similar to a contact lens to the conjunctival sac. This provides continuous treatment of diseases such as open-angle glaucoma. Pilocarpine, a medication to treat glaucoma, can be administered in this manner. The disk can remain in the patient's eye for up to a week. This route increases compliance and decreases the number of times a client must administer medication.

Drug Interaction

Drug interaction refers to the effect one drug can have on another. Drug interactions may occur when one drug is administered in combination with a second drug or when a short time interval exists between the administration of two different drugs. Drugs can be combined deliberately to produce a positive effect, as when hydrochlorothiazide (a potassium-depleting diuretic) is combined with spironolactone (a potassium-sparing diuretic) to maintain a normal blood level of potassium. A positive drug combination can also occur when one drug, such as a preoperative medication, is deliberately given to potentiate the action of another drug.

Not all drug combinations are therapeutic. Some drug combinations can interfere with the absorption,

effect, or excretion of other drugs. For example, calcium products and magnesium-containing antacids can cause inadequate absorption of tetracycline (antibiotic) in the digestive tract.

Side Effects and Adverse Reactions

Drug effects other than those that are therapeutically intended and expected are called **adverse reactions**. A nontherapeutic effect may be mild and predictable (**side effect**) or unexpected and potentially hazardous (adverse effect). There are several types of adverse reactions: drug allergy, drug tolerance, toxic effect, and idiosyncratic reactions.

Drug allergy (hypersensitivity) is an antigen-antibody immune reaction that occurs when an individual who has been previously exposed to a drug has developed antibodies against the drug. The type of reaction may be mild (skin rash, urticaria, headache, nausea, or vomiting) or severe (anaphylaxis). Drug reactions are often manifested in the skin because of its abundant blood supply.

Anaphylaxis is an immediate, life-threatening reaction to a drug, such as penicillin, characterized by respiratory distress, sudden severe bronchospasm, and cardiovascular collapse. If emergency measures (administration of epinephrine, bronchodilators, and antihistamines) are not instituted immediately, anaphylaxis can be fatal.

Drug tolerance occurs when the body becomes so accustomed to a specific drug that larger doses are needed to produce the desired therapeutic effect. For example, cancer clients with severe pain may require larger and larger doses of morphine (narcotic analgesic) to control the pain as the body builds up a tolerance to the morphine.

A **toxic effect** occurs when the body cannot metabolize a drug, causing the drug to accumulate in the blood. Toxic reactions can result after prolonged intake of high doses of medication or after only one dose.

An **idiosyncratic reaction** is a highly unpredictable response that may be manifested by overresponse, underresponse, or an atypical response. For example, 1 of 40,000 clients will develop aplastic anemia after receiving chloramphenicol (antibiotic) (Springhouse, 1997).

Food and Drug Interactions

Medication management requires avoidance of possible food and drug interactions. There are three primary types of food and drug interaction:

1. Certain drugs may interfere with the absorption, excretion, or use in the body of one or more nutrients.
2. Certain foods may increase or decrease the absorption of a drug into the body.
3. Certain foods may alter the chemical actions of drugs, preventing their therapeutic effect on the body.

COMMON FOOD AND DRUG INTERACTIONS

Drug Effects on Nutritional Status

- Abuse of antacids can lead to phosphate depletion, which can cause a vitamin D deficiency, resulting in osteomalacia, or softening of the bones due to loss of calcium.
- Excessive use of diuretics may result in the loss of electrolytes, especially potassium, that places clients with cardiac conditions at a higher risk for serious rhythm problems. Potassium loss is greatest in clients taking digitalis as well as diuretics, making the heart more sensitive to the drug.
- Prolonged use of oral contraceptives by women may cause folacin and vitamin C deficiencies if their diets are inadequate in these nutrients.
- Hydralazine (antihypertensive drug) can deplete the body's supply of vitamin B₆.

Food Effects on Drug Absorption

- Calcium in milk and milk products may decrease the absorption of certain antibiotics such as tetracycline.
- Certain liquids such as soda pop or high-acid fruit or vegetable juices can cause an increase in the stomach acidity that can dissolve some drugs before they reach the intestine. Because most drugs are absorbed in the intestines, this interaction will decrease the amount of drug that can be absorbed into the body.
- Certain foods such as fatty foods can increase the rate of absorption of some drugs; (e.g., griseofulvin, an antifungal).

Food Effects on Drug Utilization

- The effects of anticoagulants can be decreased by certain foods in the liver such as green leafy vegetables that contain vitamin K, which is used by the body to promote blood clotting.
- Aged or fermented foods such as aged cheese, chicken livers, and other foods can decrease the metabolism in the body of monoamine oxidase inhibitors that are used to treat depression and high blood pressure.
- Long-term use of licorice and licorice-flavored candy or drugs can counteract the effect of high blood pressure medication.

Most interaction problems occur with the use of diuretics, oral antibiotics, and anticoagulant and antihypertensive drugs (see the accompanying display on common food and drug interactions). Clients on sodium-restricted diets should be advised to consult with a pharmacist regarding the sodium content in prescription and over-the-counter drugs. Some drugs can contain almost one-half the total daily allowance of

sodium. Alcohol is also considered a drug. Small amounts of alcohol interact with many drugs, such as antibiotics, antihistamines, anticoagulants, and sleeping pills. Food and drug interactions can vary depending on the dose and the form in which the drug is taken and the client's age, sex, body weight, nutritional status, and specific medical condition.

FACTORS INFLUENCING DRUG ACTION

Individual client characteristics such as genetic factors, age, height and weight, and physical and mental conditions can influence the action of drugs on the body. Sometimes mistaken for drug allergies, genetic factors can interfere with drug metabolism and produce an abnormal sensitivity to certain drugs.

The nurse should consider age-related factors that can influence drug action and dosing. For example, neonates and infants have underdeveloped gastrointestinal systems, muscle mass, and metabolic enzyme systems and inadequate renal function; elderly clients often experience decreased hepatic or renal function and diminished muscle mass.

The physician often correlates the client's age, height, and weight when determining the dosage for many drugs. The nurse should make sure that this information is accurately recorded in the client's medical record. The amount of body fat may also alter drug distribution because some drugs such as digoxin (inotropic) are poorly distributed to fatty tissues.

The client's physical condition can also alter the effects of drugs. For example, in an edematous client the drug must be distributed to a larger volume of body fluids than for a nonedematous client; therefore, the edematous client may require a larger drug dose to produce the drug action, whereas a dehydrated client would require a smaller dosage. Diseases that affect liver and renal functions can alter the metabolism and elimination of most drugs.

PROFESSIONAL ROLES IN MEDICATION ADMINISTRATION

The health care practitioner determines the therapeutic drug plan and conveys the plan to others by initiating orders or a prescription. In health care settings (long-term care facilities and hospitals), medication orders are written on a health care practitioner's order form. Health care practitioners can also write medication orders on legal prescription pads or through the computer terminal. When allowed by organizational policy, the health care practitioner may also give medication orders via telephone or as a verbal order.

If the health care practitioner gives a medication order orally, either directly or over the telephone, the nurse enters the information on the medical record. This information includes the name of the health care practitioner who ordered the medication, the name of the medication, the dosage, the frequency, the route of administration, and the nurse's name. Most institutions require the health care practitioner to confirm oral orders within 24 hours; the nurse is responsible for ensuring that the verbal order is clear. It often helps for the nurse to repeat the order to the health care practitioner to make sure it was interpreted as intended. See Chapter 26 for a complete discussion of written and verbal orders and the role of the nurse in transcribing orders.

The pharmacist processes the health care practitioner's orders, clarifies any entries that are unclear, and prepares the medications for administration. The pharmacist is responsible for filling prescriptions and for making sure they are valid entries. Pharmacists also assess medication plans monitoring for incompatibilities and, at times, recommending the best time to administer a medication to obtain therapeutic benefit such as Lovastatin (cholesterol lowering drug) which is most effective if taken in the evening. The pharmacist participates in calculating the appropriate dosage of certain medications such as anti-infective drugs (e.g., gentamycin). These dosages are based on the patient's body weight and kidney function and may be adjusted during the course of therapy by the pharmacist with the health care practitioner's consent. Nurses frequently consult with pharmacists in determining compatibility if intravenous medications are to be administered simultaneously. Pharmacists also answer medication-related questions for both nurses and patients.

Nurses spend a great deal of time with their patients and have specific knowledge and skills that qualify them to administer medication and to evaluate a medication's effectiveness. Nurses understand why particular medications are ordered for clients and what physiological changes may result from the medication that cause a therapeutic effect. Because of their knowledge, skills, and frequent client contact, nurses can readily assess changes in a client's condition and can determine whether it is appropriate to administer a medication on the basis of the client's condition.

Nurses are responsible for teaching patients to self-administer medications such as insulin and for assessing the patient's ability to self-administer correctly. Before discharge, nurses teach clients about the medications they will be taking at home and how to assess for side effects and adverse reactions. Using the nursing process, nurses help clients incorporate their medication regimen into their plan of care.

When a client is admitted to an inpatient health care facility, the drug order form is stamped with the

COMMON ABBREVIATIONS USED IN MEDICATION ORDERS

Abbreviation	Meaning
a.c.	before meals
ad lib	freely, as desired
b.i.d.	two times a day
̄	with
cap	capsule
DC	discontinue
elix	elixir
h	hour
hrly	hourly
h.s.	at bedtime
ID	intra dermal
IM	intramuscular
IV	intravenous
IVPB	intravenous piggyback
OD	right eye
od	every day
OS	left eye
OU	each eye
p.c.	after meals
PO	by mouth
per	by
prn	as needed
q	every
qd	every day
q2h	every 2 hours
q.i.d.	four times a day
qod	every other day
qs	sufficient quantity
SC or SQ	subcutaneous
stat	immediately
supp	suppository
susp	suspension
tab	tablet
t.i.d.	three times a day
Tr or tinct	tincture

client's name, room number, age, and weight. The client's weight is used by the pharmacist in compounding and dispensing drugs.

Most agencies have policies relative to medication administration, such as stop dates for certain types of drugs, regularly scheduled times to administer medications as specified in the drug order, and a listing of abbreviations officially accepted for use in the agency. The agency's medical records department maintains the official listing of abbreviations adopted by the medical staff; only abbreviations from the official list can be used in any part of the client's medical record. See the accompanying display for a list of common abbreviations used in medication orders.

NURSING TIP

Therapeutic Levels

Some medications require monitoring of blood levels to determine their effectiveness. When reviewing these laboratory values, notice if the levels are higher (toxic) or lower (subtherapeutic) than the recommended therapeutic range for that medication. Adjustments in the medication dose by the health care practitioner may be warranted to reach the recommended therapeutic level.

Types of Medication Orders

The health care practitioner prescribes medications in different ways, depending on their purpose. Medications can be prescribed as stat, single-dose, standing, and prn orders.

Stat Orders

When the health care practitioner writes orders, the nurse should read all of the orders to determine if any stat orders have been prescribed. A **stat order** is an order for a single dose of medication to be given immediately. Stat drugs are often prescribed in emergency situations to modify a serious physiological response; a stat dose of nitroglycerin may be ordered for a client experiencing chest pain. The nurse should assess and document the client's response to all stat medications.

Single-dose Orders

Single-dose orders are one-time medications or may require the administration of drops or tablets over a short period of time. The nurse should administer single-dose orders only once, either at a time specified by the health care practitioner or at the earliest convenient time. These drugs are often prescribed in preparation for a diagnostic or therapeutic procedure; for example, radiopaque tablets may be administered in preparation for a gallbladder test, or a one-time order may be given for a preoperative medication.

Standing Orders

Standing orders are also referred to as *scheduled orders* because they are administered routinely as specified until the order is canceled by another order. The standing orders stay in effect until the health care

practitioner discontinues or modifies the dosage or frequency with another order or until a prescribed number of days has elapsed as determined by agency policy. The purpose of a standing medication order is to maintain the desired blood level of the medication.

Agency policy determines the actual times for administering medications for a 24-hour time interval. For example, t.i.d. drugs may be administered at 0800, 1400, and 2000 or at 0900, 1500, and 2100. Medications ordered qd may have a specified time identified in the order, such as Isophane (NPH) Insulin 10 U SC qd at 0600, or they may be given at the agency's designated time, for example, Lanoxin 0.25 mg PO qd 0900.

When the order specifies the number of days or the number of dosages of the drug the client is to receive, the order has an automatic stop date to discontinue the drug. For example, the order may read tetracycline 250 mg PO q6h for 5 days. The nurse should execute this order by administering 250 mg tetracycline orally every 6 hours for 5 days for a total of 20 doses. Day one begins with the administration of the drug and the time the first dose is given. If the first dose of tetracycline is given on a Tuesday at 1200, then every 6 hours, the last dose will be given on Sunday at 0600. Although the medication is given over 6 consecutive days, it totals 20 doses as ordered. Most agencies have an automatic stop date to discontinue certain medications, such as 5 or 7 days for antibiotics and 48 or 72 hours for narcotics.

prn Orders

A drug may be ordered on a prn (as needed) basis as circumstances indicate. The drug is administered when, in the nurse's judgment, the client's condition requires it. Before administering a prn medication, the nurse must thoroughly assess the client, using both objective and subjective data in determining the appropriateness of administering the medication. This type of order is commonly written for analgesics, antiemetics, and laxatives.

The order written by the health care practitioner indicates how frequently a prn medication can be given. A nurse cannot administer a prn medication more frequently than the order indicates without consulting with the health care practitioner for a change in that order. Examples of prn orders are meperidine (a narcotic analgesic) 75 mg IM q3–4 hours prn incisional pain and Tylenol 650 mg q4 hours prn headache. When the prn medication has been administered, the nurse documents the assessment and the time of administration. In addition, the nurse is responsible for monitoring the effectiveness of the medication and documenting the effect in the client's medical record. The nurse administers the pain medication on the basis of the assessment of the client's pain and as specified in the order.

Parts of the Drug Order

All orders should be written clearly and legibly, and the drug order should contain seven parts:

1. The name of the client
2. The date and time when the order is written
3. The name of the drug to be administered
4. The dosage
5. The route by which it is to be administered and special directives about its administration
6. The time of administration and frequency
7. The signature of the person writing the order, such as the physician or advanced practice registered nurse

Drug prescriptions written in settings other than acute care facilities may also specify whether the generic or trade name of the drug is to be dispensed, the quantity to be dispensed, and how many times the prescription can be refilled.

SYSTEMS OF WEIGHT AND MEASURE

Medication administration requires the nurse to have a knowledge of weight and volume measurement systems. In North America there are three systems of measurement used in medication management: metric, apothecary, and household.

Metric System

The metric system of weights and measures was adopted by the USP in 1890 and the British Pharmacopoeia in 1914 to the exclusion of all other systems except for equivalent dosages. The Council on Pharmacy and Chemistry of the American Medical Association adopted the metric system exclusively in 1944. Resistance to changing established customs interfered with the exclusive adoption of the metric system. Today, the metric system is used in every major country of the world and is used almost exclusively in the U.S. medical practice (*Remington's Pharmaceutical Sciences*, 1990).

The metric, or decimal, system is a simple system of measurement based on units of 10. The basic units can be multiplied or divided by 10 to form secondary units. The decimal point is moved to the right for calculating multiples, and the decimal point is moved to the left for division.

The basic units of measurement in the metric system are the meter (linear), the liter (volume), and the gram (mass). The metric system uses prefixes derived from Latin to designate subdivisions of the basic units and prefixes derived from Greek to designate multiples of the basic units (see the accompanying display). When the metric system is used, a zero is always placed in front of the decimal for values less than 1 (e.g., 0.5) to prevent error.

METRIC SYSTEM PREFIXES

Latin Prefixes—Subdivisions of the Basic Unit

deci (1/10, or 0.1)
centi (1/100, or 0.01)
milli (1/1000, or 0.001)

Greek Prefixes—Multiples of the Basic Unit

deka (10)
hecto (100)
kilo (1000)

Apothecary System

The apothecary system, which originated in England, is based on the weight of one grain of wheat. Therefore, the basic unit of weight is the grain (gr), and the basic unit of volume is the minim (the approximate volume of water that weighs a grain). The grain is expressed in fractions such as morphine gr 1/4. The minim (*m*) is the smallest unit of volume, followed in ascending order by the fluid dram (*D*), fluid ounce (*Z*), pint (pt), quart (qt), and gallon (gal).

Household System

The household system of measurement is similar to the apothecary system of liquid measures and is the least accurate of the three systems. The units of liquid measure are drop (gtt), teaspoon (tsp), tablespoon (Tbsp), cup, and glass. Household units are often used to inform clients of the size of a liquid dose.

The USP recognizes the use of the teaspoon as the ordinary practice for household medication administration and states that the teaspoon may be regarded as representing 5 ml (American Hospital Formulary Service, 1996). Household spoons are not appropriate when accurate measurement of a liquid dose is required; therefore, the USP recommends that a calibrated oral syringe or dropper be used for accurate measurement of liquid drug doses.

APPROXIMATE DOSE EQUIVALENTS

The conversion of metric doses with the apothecary and household systems are *approximate dose equivalents* (see the accompanying display). The approximate dose equivalents represent the quantities usually ordered by health care practitioners when using either the metric or apothecary system of weights and volumes for drug doses (American Hospital Formulary Service, 1996). If the prepared dosage form is prescribed in the metric system, the pharmacist may dispense the corresponding approxi-

mate equivalent in the apothecary system and vice versa. For example, if the health care practitioner prescribes morphine gr 1/4, the pharmacist may dispense morphine 15 mg. The USP and NF reference *exact equivalents* that must be used to calculate quantities in pharmaceutical formularies and prescription compounding.

Converting Units of Weight and Volume

The nurse has to apply the knowledge of measurement systems and their conversions when the health care practitioner prescribes a drug dosage in one system and the pharmacy dispenses the equivalent dose in another. Given the above example of morphine, if the health care practitioner orders morphine gr 1/4 and the pharmacist dispenses morphine 15 mg, the nurse is responsible for ensuring the correct dose. The nurse knows that 1 grain equals 60 milligrams; to convert the ordered dose to milligrams, the nurse should use the following calculation:

$$\begin{aligned} 1 \text{ gr} &= 60 \text{ mg} \\ x &= 1/4 \text{ gr} \times 60 \text{ mg/gr} \\ &\text{(the grains cancel out)} \\ x &= 60/4 \text{ mg} \\ x &= 15 \text{ mg} \end{aligned}$$

Measurement Conversions within the Metric System

Because the metric system is based on units of 10, dose equivalents within the system are computed by simple arithmetic, either dividing or multiplying. For example, to change milligrams to grams (1,000 mg equals 1 g) or milliliters to liters (1,000 ml equals 1 L), divide the number by 1000:

$$\begin{aligned} 250 \text{ mg} &= x \text{ g} \\ &\text{(move the decimal point three places to the left)} \\ x &= 0.25 \text{ g} \\ &\text{or} \\ 500 \text{ ml} &= x \text{ L} \\ &\text{(move the decimal point three places to the left)} \\ x &= 0.5 \text{ L} \end{aligned}$$

To convert grams to milligrams or liters to milliliters, the nurse multiplies the number by 1000:

$$\begin{aligned} 0.005 \text{ g} &= x \text{ mg} \\ &\text{(move the decimal point three places to the right)} \\ x &= 5 \text{ mg} \\ &\text{or} \\ 0.725 \text{ L} &= x \text{ ml} \\ &\text{(move the decimal point three places to the right)} \\ x &= 725 \text{ ml} \end{aligned}$$

The nurse may need to convert the volumes of liters and milliliters for enemas and irrigating solutions such as for bladder and wound irrigations. Intravenous solutions are sterile, prepackaged solutions dispensed in volumes as ordered by the health care practitioner, such as 50 ml, 100 ml, 250 ml, 500 ml, and 1,000 ml (1 liter).

APPROXIMATE METRIC SYSTEM EQUIVALENTS

Liquid Measure (Volume)

Metric	Apothecary	Household
5 ml	= 1 fluid dram	= 1 teaspoonful
10 ml	= 2 fluid drams	= 1 dessertspoonful
15 ml	= 4 fluid drams	= 1 tablespoonful
30 ml	= 1 fluid ounce	= 1 ounce
60 ml	= 2 fluid ounces	= 1 wineglassful
120 ml	= 4 fluid ounces	= 1 teacupful
240 ml	= 8 fluid ounces	= 1 tumblerful
500 ml	= 1 pint	= 1 pint
1000 ml	= 1 quart	= 1 quart
4000 ml	= 1 gallon	= 1 gallon

Weight

Metric	Apothecary
1 mg	= 1/60 grain
4 mg	= 1/15 grain
10 mg	= 1/6 grain
15 mg	= 1/4 grain
30 mg	= 1/2 grain
60 mg	= 1 grain
1 g	= 15 grains
4 g	= 1 dram
30 g	= 1 ounce
500 g	= 1.1 pound
1000 g (1 kg)	= 2.2 pounds

Measurement Conversions between Systems

When converting grains to milligrams, the nurse must multiply by 60. For example, if the physician orders nitroglycerin (anti-anginal) 1/150 gr PO for chest pain, the dispensed dose will be 0.4 mg:

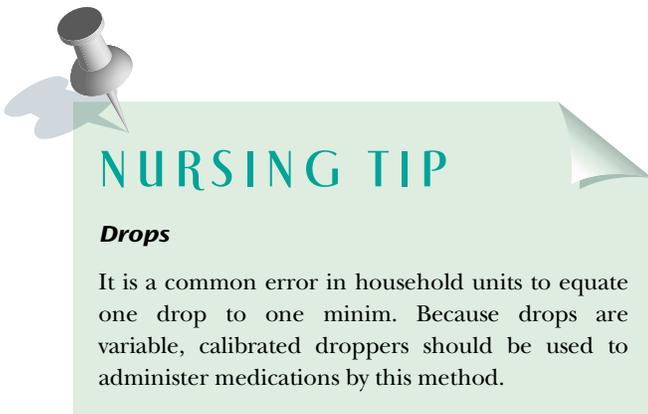

$$\begin{aligned} 1 \text{ gr} &= 60 \text{ mg} \\ x &= 1/150 \text{ gr} \times 60 \text{ mg/gr} \\ &\text{(the grains cancel out)} \\ x &= 1/150 \times 60/1 \text{ mg} \\ x &= 60/150 \text{ mg} \\ &\text{(divide 60 by 150)} \\ x &= 0.4 \text{ mg} \end{aligned}$$

The nurse converts between pounds and kilograms (2.2 lb = 1 kg) by dividing or multiplying by 2.2. For example, if the ordered dose is 10 mg/kg and the client weighs 150 lb:

$$\frac{150 \text{ lb}}{2.2 \text{ lb/kg}} \times \frac{10 \text{ mg/kg}}{x}$$

$$\begin{aligned} &\text{(the lb and kg cancel out)} \\ x &= 68.2 \times 10 \text{ mg} \\ x &= 682 \text{ mg} \end{aligned}$$

In clinical settings, household measures are used for bedside recording of intake so that the client or family member can record the volume ingested by the client. Agencies have a legend on their intake form with the approximate conversions from household to metric volume measures based on the type of containers used in that specific agency. See Chapter 37 for the procedure for measuring intake and output. Home health nurses often have to convert a liquid dose to an approximate household unit.

NURSING TIP

Drops

It is a common error in household units to equate one drop to one minim. Because drops are variable, calibrated droppers should be used to administer medications by this method.

Drug Dose Calculations

Several formulas may be used by the nurse when calculating drug doses. One formula uses ratios based on the *dose on hand* and the *dose desired*. For example, cephalexin (anti-infective cephalosporin) 500 mg PO q.i.d. (dose desired) is ordered by the health care practitioner; the dose on hand is 250 mg/5 ml. The formula is as follows:

$$\frac{250 \text{ mg (dose on hand)}}{5 \text{ ml (dose on hand)}} = \frac{500 \text{ mg (dose desired)}}{x \text{ (dose desired)}}$$

(cross-multiply)

$$250 x = 5 \times 500$$

$$x = \frac{5 \times 500}{250}$$

$$x = 10 \text{ ml}$$

The ratio formula can be used in calculating dosages. For example, the health care practitioner orders heparin (anticoagulant) 10,000 units SC; the dose on hand is 40,000 units/ml:

$$\frac{40,000 \text{ units}}{1 \text{ ml}} = \frac{10,000 \text{ units}}{x}$$

(units cancel out)

$$40,000 x = 10,000$$

$$x = \frac{10,000}{40,000}$$

$$x = \frac{1}{4}$$

$$x = 0.25 \text{ ml}$$

Pediatric Dosages

“Children are sometimes more susceptible than adults to certain drugs” (*Remington’s Pharmaceutical Sciences*, 1990, p. 91). Several rules have been devised to calculate infants’ and childrens’ dosages such as *Young’s Rule*, *Clark’s Rule*, and *Fried’s Rule*, but these rules give only approximate dosages. Even when pediatric drug dosages are calculated on body surface area, weight, and age of the child, they are based on a proportion of the usual adult dose (approximate). Regardless of the method used in calculating pediatric drug dosages, the nurse should realize that dosages are approximate and often need adjustment based on the child’s response.

The body surface area method of determining pediatric doses is based on the body surface area of an adult weighing 150 lb. The body surface area of an adult weighing 150 lb. is 1.73 square meters. The approximate child dose is calculated as follows:

$$\frac{\text{Body surface area of child}}{\text{Body surface area of adult}} \times \text{adult dose} \\ = \text{approximate child dose}$$

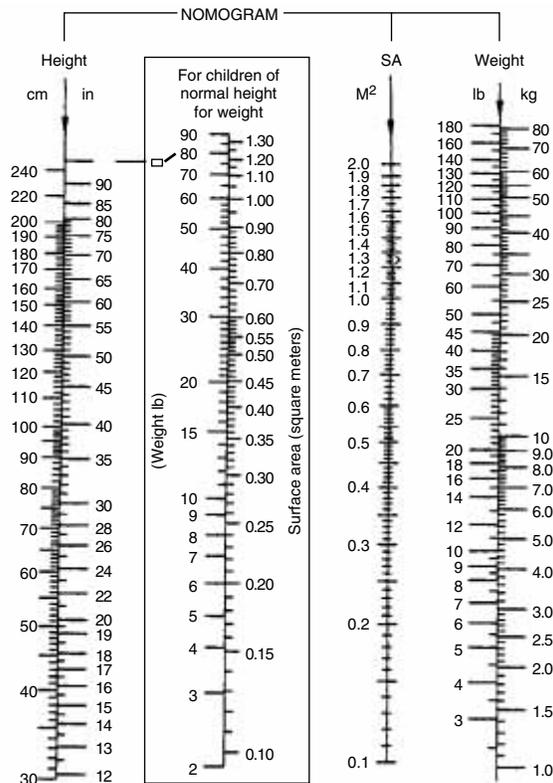

$$\frac{\text{Body surface area of child (m}^2\text{)}}{1.73 \text{ m}^2} \times \text{adult dose} \\ = \text{approximate child dose}$$

Nomograms based on height and weight are used to compute the body surface area (Figure 29-2). A straight line is drawn from the client’s height in the left column to the client’s weight in the right column. The point at which this line intersects the body surface area column (designated SA) indicates the body surface area. Nomograms are used primarily in calculating pediatric drug dosages; however, they are also used when calculating some adult drug dosages such as aminoglycosides and antineoplastic agents.

SAFE DRUG ADMINISTRATION

Nurses must administer numerous drugs daily in a safe and efficient manner. The nurse should administer drugs in accord with nursing standards of practice and agency policy. The safe storage and maintenance of an adequate supply of drugs are other responsibilities of the nurse.

The nurse documents the actual administration of medications on the medication administration record, or MAR. The MAR is a medical record form that contains the drug’s name, dose, route, and frequency of administration. Drug data are entered either by the nurse when transcribing the order (handwritten onto the form) or by the pharmacist when dispensing the order (a computer-generated pharmacy MAR form is shown in Figure 29-3).

Directions for use: (1) Determine client height. (2) Determine client weight. (3) Draw a straight line to connect the height and weight. Where the line intersects on the SA line is the derived body surface area (m²).

Figure 29-2 Nomogram for Estimating Body Surface Area. Reprinted with permission from Behrman, R.E., Kliegman, R., & Arvin, A. M. (Eds.). (1996). *Nelson textbook of pediatrics* (15th ed.). Philadelphia: Saunders

Guidelines for Medication Administration

To protect the client from medication errors, nurses have traditionally used as a guideline the “five rights” of drug administration (see the accompanying display).

Right Drug

Before administering any medication the nurse compares the medications listed on the MAR, other recording forms, or computer orders against the health care practitioner’s order. When administering a medication, the nurse should check the label written on the container against the MAR at least three times before giving the drug. The nurse should:

1. Check the label when removing the drug container from the client’s medication drawer.
2. Check the drug when removing it from the container.
3. Check the drug before returning it to the client’s medication drawer.

Some medications come in a unit-dose prepackaged form. The nurse should check the medication a third

time even though there would be no container to return to the drawer. This third check should be done at the bedside before opening the unit-dose medication.

The nurse should give only medications that the nurse has prepared and checked. The nurse who administers the medication is the responsible party should an error occur. If a client questions a medication to be administered, the nurse should never ignore the question. Clients are active participants in their care and usually know when a medication is different from that usually taken. The nurse should withhold this medication until the order can be rechecked. Frequently, the medication order has changed, but the client question can stop an error before it occurs.

If the client refuses a medication, it should be discarded rather than returned to the original container. Unit-dose medications that have not been opened can be saved.

FIVE RIGHTS OF DRUG ADMINISTRATION

1. Right drug
2. Right dose
3. Right client
4. Right route
5. Right time

Right Dose

The unit-dose system was implemented to help decrease medication errors. However, there are times when medications on hand are in a larger volume or strength than needed. Careful calculation is especially important when the health care practitioner orders a unit of measurement different from what is supplied by the pharmacy.

The nurse must know how to reduce the risk of error by correctly calculating doses and having them double-checked before administration. Policy in some agencies, for instance, mandates that two nurses check insulin dosages to ensure accuracy. After calculations have been completed, the nurse should prepare the medication using appropriate measurement devices such as graduated measuring cups, syringes, and droppers.

To prepare scored or crushed medications, the nurse should make sure scored tablets are broken evenly. This practice will prevent overdosage or underdosage of a medication. If the medication has to be crushed with a mortar and pestle, the nurse should thoroughly cleanse the pestle after each use. Cleansing the pestle will avoid mixing of different medications and will prevent the client from receiving minute amounts of a medication that may cause serious adverse effects.

Right Client

The nurse should correctly identify the client by asking the client to state his or her full name and checking the client’s

Figure 29-3 Computerized Pharmacy Medication Administration Record

identification armband (Figure 29-4). Never identify a client solely by calling the person's name because some clients may be confused and will answer to any name. Identification bracelets that become blurred or are missing for any reason should be replaced. The nurse needs to obtain a new identification band for the client. Verify the identification by asking the client to state his or her full name before placing the new band on the client's arm.

Right Route

The route of the medication is specified in the written order. The nurse should consult the health care practitioner whenever a route is not identified in the prescription, when the route indicated differs from the recommended one, or when the nurse questions the choice of route prescribed. For example, the nurse should not substitute an oral medication for an intramuscular medication simply because the oral medication is available and the intramuscular one is not.

Figure 29-4 Check a client's identification band before administering medication.

Injecting a medication designed to be administered orally can cause adverse reactions such as a sterile abscess at the injection site. Medications for parenteral injections should be prepared from medications designed for this purpose. Manufacturers of medications label medications that can be used for parenteral injections as “for parenteral use only.”

Right Time

Medications are generally ordered on a schedule. Nurses are responsible for knowing why a medication is ordered on a certain schedule and for following that schedule as closely as possible. A drug should not be given more than a half-hour before or after the scheduled time (according to organizational policy) without first checking with the health care practitioner. To maintain the drug’s effect, the nurse has to give the medication in a timely manner. Some medications must be given at a certain time for proper therapeutic effect; for example, insulin should be given at a set time before meals. These types of drugs should be administered as ordered. See the Nursing Checklist for guidelines that ensure the safe administration of medications.

In the home health and community care settings, such as a retirement home, the nurse has different responsibilities regarding drug safety (Figure 29-5). The nurse should promote drug safety measures that are appropriate to the environment and inherent risk factors (see the accompanying display).

Documentation of Drug Administration

A critical element of drug administration is documentation. The standard is “if it was not documented it was not done.” Many drug errors can be avoided with appropriate documentation. The nurse responsible for administering the medication must initial the medication on the MAR near the time the drug is scheduled. Usually there is a space available for a full signature on the record. The nurse should document that a drug has been given after the client has taken the drug.

Figure 29-5 A pill box correlated to the days of the month can help the client follow her medication regimen.

NURSING CHECKLIST

Guidelines for Safe Administration of Medications

- Never administer medications that are prepared by another nurse. You are responsible for a medication error if you administer a medication that was inaccurately prepared by another nurse.
- Nurses should listen carefully to the client who questions the addition or deletion of a medication. Most clients are aware of their prescribed medications. If a client questions the drug or dose you are preparing to administer, recheck the order.
- If a medication is withheld, indicate the exact reason why in the client’s record. Legally you are accountable for giving ordered medications to the client; however, circumstances may prevent you from giving a medication as ordered. Medications may be held for some diagnostic tests, or the client receiving antihypertensive medications may have a blood pressure that is lower than normal. If you gave the antihypertensive, the blood pressure would decrease, causing further hypotension.
- *Do not leave medications at the client’s bedside for any reason.* The client may forget to take the medication, medications can accumulate, and the client could take two or more of the same medication, causing an overdose, or another client who is confused could take the medicine.
- Initial the MAR only for those medications you actually have administered. This practice ensures accurate charting by clearly indicating which actions you have performed.
- Advise clients not to take medications belonging to others and not to offer their medications to others. Medications are ordered for each client on the basis of the history, physical examination, and effectiveness of the medication.

If the client refuses to take a medication once it has been prepared, the nurse must indicate that a dose was missed. In some hospitals, a circle is placed around the time the medication was scheduled to be given. The nurse should write in the record why the dose was missed and notify the health care practitioner. The client may have refused because the tablet was too large. The medication may be supplied as a liquid so an alternate form of the medication can be given; the nurse must request that the health care practitioner change the order to a liquid. Clients do have the right to refuse medications. However, if clients understand the actions of the medication, they may be willing to take the

DRUG SAFETY CONSIDERATIONS IN HOME HEALTH AND COMMUNITY CARE SETTINGS

- Help the client remove outdated prescriptions and over-the-counter drugs from medication cabinets. The chemical composition may change over time, causing a different drug action. Over-the-counter drugs may interact with prescription drugs, either by decreasing or potentiating the effects of the prescription medication.
- Encourage the client or caregivers to maintain drug refills to decrease the risk of missing scheduled medications.
- Use a mechanism such as a paper clock, reminder calendar, or pill box to help the client or caregiver remember to take or administer prescribed medications as scheduled.

medication. Clients who are scheduled for various diagnostic tests or treatments at the time the medication is to be administered will need to have the medication times rescheduled.

Drug Supply and Storage

Drugs are dispensed by the pharmacy to nursing units through various methods to accommodate the agency's medication system. Once the pharmacy delivers the drugs to a nursing unit, the nurse is responsible for their safe storage.

Scheduled drugs for each client are usually dispensed in a **unit-dose form**. Unit dose is a system of packaging and labeling each dose of medication by pharmacy, often to supply a 24-hour time period. The pharmacy usually delivers the drugs and stores the drugs in the designated area for each client. Unit-dose drugs are usually stored in a medication cart that contains individual drawers for each client's medication supply or in the medication room in a separate, organized container for each client. The unit-dose system has made it easier for nurses to administer the correct dose, thereby reducing the number of medication errors.

The nurse, usually at the beginning of each shift, checks the medications in each client's drawer. Some medication carts are locked, and the nurse keeps the key. Medication drawers should be removed only one at a time from the cart when the nurse is preparing the medication for administration. The client's drawer should never be left unattended on top of the cart. Drugs should not be removed from one client's supply for administration to another client.

Certain drugs are **stock supplied** (dispensed and labeled in large quantities) and stored in the medication room or other area on the nursing unit. Stock supplies are kept together in a secured area.

Certain intravenous fluids and medications must be stored in the medication refrigerator to preserve the integrity of the drug. The Public Health Department and accrediting agencies mandate that only drugs can be stored in the medication refrigerator.

Narcotics and Controlled Substances

Health care agencies have forms to record the supply on hand and the administration of narcotics and controlled substances in accord with federal regulations. These forms usually require the recording of the following information for each drug administered:

- Name of the client receiving the drug
- Amount of the drug used
- Time the drug was administered
- Name of the prescribing health care practitioner
- Name of the nurse administering the drug

Nursing practice usually requires that nurses count the narcotics and controlled substances at specified intervals. For example, at the change of shifts, one nurse who is going off duty counts the drugs with a nurse coming on duty. Each drug used must be accounted for on the narcotic record. When the narcotic count does not check, the nurse must report the discrepancy immediately. Narcotics and controlled substances are kept in a double-locked drawer, box, room, or medication-dispensing cart. The law requires these safety precautions in the use of narcotics and controlled substances to aid in the control of drug misuse. If for any reason a narcotic has to be discarded, a second person should act as a witness and that person should also sign the narcotic sheet.

Drug Abuse

Federal, state, and local rules regulate the appropriate use of drugs. Despite these rules, some people use drugs for purposes other than their proper use, seriously jeopardizing their health. Misuse of drugs also creates problems for family members and the community as a whole.

"The American Medical Association and the World Health Organization have both recognized addiction as an illness, not a lack of willpower" (Dossey, Keegan, & Guzzetta, 2000, p. 514). **Addiction** is defined as a physiological or psychological dependence on a substance, such as alcohol or morphine, or a behavior such as eating, gambling, working, or engaging in sexual intercourse. The rest of this discussion focuses only on substance abuse.

Nursing practice requires the nurse to be knowledgeable about the addictive process in order to assess and care for clients with drug toxicity or overdose and withdrawal. Continual or periodic use of drugs may lead to **dependence** (reliance on or need to take a drug). The term *chemical dependence* is often used as a more inclusive term than *drug dependence* because it includes problems with *all mind-altering substances that have the potential of creating dependence* (Crosby & Bissell, 1989).

Addiction implies more than a physical dependence alone, and it does not refer exclusively to illicit drugs. Illicit drugs are substances sold illegally, such as cocaine, PCP (angel dust), hallucinogenic agents (LSD and peyote), and cannabinoids (marijuana and hashish). There are two types of drug dependence that can occur separately or together:

- **Physiological dependence:** the biochemical changes in body tissues that occur when the tissue depends on a substance for normal functioning; cessation of the substance causes physical withdrawal symptoms.
- **Psychological dependence:** the emotional reliance on a substance to maintain a sense of well-being; the degree of psychological dependence can vary from a mild desire to an intense craving or compulsion for the substance.

Although there are many types of addictions to various substances, alcohol addiction is the most prevalent one in the United States, afflicting at least 11 million people (Dossey et al., 2000). The nurse should be able to identify the characteristics of substance abuse (see the accompanying display) and work together with other health team members in planning the care for clients experiencing the disorder.

COMMON CHARACTERISTICS OF ALCOHOLISM

- Denial that there is a drinking problem
- Rationalization
- Restlessness, impulsiveness, anxiety
- Selfishness, self-centeredness, lack of consideration
- Irritability, anger, rage
- Physical cruelty; child, spouse, or elder abuse
- Depression, isolation, self-destruction
- Low self-esteem, shame, guilt, remorse, loneliness
- Susceptibility to disease

(From Dossey, B. M., Keegan, L., & Guzzetta, C. E. [2000]. *Holistic nursing: A handbook for practice* [3rd ed.]. Gaithersburg, MD: Aspen)

Nurses and other health care providers (physicians, dentists, and pharmacists) are at risk for substance abuse because of their access to drugs such as benzodiazepines (Valium, Librium), sedative hypnotics (Nembutal, Placidyl), amphetamines (Dexedrine, Benzedrine), and narcotics (meperidine, morphine). The actual incidence of chemical dependence among nurses and other health care professionals is difficult to document; however, it is estimated that 6% to 16% of registered nurses in the United States are chemically dependent (Crosby & Bissell, 1989). The difficulty of obtaining factual data for the number of chemically addicted nurses is often related to the reluctance of professionals to report one another.

Although it may be uncomfortable to report an addicted colleague, nurses have a moral responsibility to report the situation to the appropriate authority. Nurses who are addicted may display suspicious behaviors such as insisting on carrying the narcotic keys and volunteering to administer all of the narcotics during the shift (see the accompanying display for other behavioral characteristics).

CHARACTERISTICS OF DRUG-ADDICTED NURSES IN THE WORKPLACE

- Exhibit extreme and rapid mood swings
- Always wear long sleeves
- Sign out more controlled drugs than anyone else
- Report frequent spills and breakage of controlled drugs
- Commit multiple medication errors
- Practice illogical or sloppy charting
- Are frequently absent from work
- Come to work early and stay late
- Frequently use sick leave

In 1983, Florida was the first state to enact a “diversion” law as an alternative to disciplinary proceedings against substance abusers. Florida’s diversion program is called the Intervention Project for Nurses and has served as a model for other states to create similar programs such as impaired nurse programs. These programs provide support, confidentiality, and stringent on-the-job monitoring and allow the nurse to maintain licensure as long as the nurse complies with the program. An impaired nurse program is a welcomed alternative for nurses with addictive behaviors and has increased the reporting of nurses with addiction problems. (Contact your state board of nursing office to inquire about alternative programs to disciplinary measures.)

More recently, some hospitals have taken a proactive role in combating the problem of drug abuse among nurses with the use of a computer-controlled dispensing system (Figure 29-6). With this system, the likelihood of

Figure 29-6 Computer-controlled Dispensing System

the nurse's abusing narcotics is markedly decreased. The nurse enters a private security code. The system will provide the nurse with a printout of the medications given to the client and will charge the client. This dispensing system eliminates stock supplies of narcotics and controlled drugs, decreasing the nurse's access to these drugs.

MEDICATION COMPLIANCE

Medication compliance can be associated with the client's understanding of why a medication was ordered and how a medication can decrease the likelihood of getting a disease or how it can lessen the effects of an existing disease. When clients do not consistently take their prescribed medications, or when they adjust the scheduling or dose of the medication, they are *noncompliant*.

THINK ABOUT IT

Chemical Dependence

Addicted health care practitioners are rehabilitated, whereas addicted nurses are punished! If you were practicing in a state where the only action from the state board of nursing were license suspension or revocation, would you report a fellow nurse? If you did not, what could happen to the clients under the nurse's care, and what would be the legal implications for you? Likewise, if you were addicted, what would be the implications for your continued nursing practice?

There are several reasons why clients choose not to take ordered medications. If a hypertensive client is asymptomatic (without distress), it may be difficult for the client to understand the need to take prescribed medications. If medications are taken, the dose may be altered at the discretion of the client. Medications are costly, and the client may be on a fixed income or unemployed. If the medication does not provide prompt relief, the client may consider the medication useless and discontinue it. The medication may be discontinued if the client experiences undesirable side effects, such as dizziness, impotence, or weight gain.

Compliance can be enhanced if the client is given information on the medication to take home when discharged from the hospital. If the client is elderly, large-type print or illustrations should be used. Caregivers should be included when educating the client. Scheduling the medications around certain activities of daily living may serve as a reminder to the client that the medication must be taken. Providing the client with a telephone number and a name of a nurse to call if questions arise can ensure compliance.

The nurse in the community has an opportunity to see how medications are arranged in the client's home.

Outdated medications must be discarded. After consulting with the client and caregiver, the nurse can make suggestions that may improve compliance.

Nurses have to remember that many elderly clients take a multitude of drugs. Some drugs actually cancel each other out when taken together, thus eliminating the therapeutic response. A client taking BuSpar and digoxin may experience digoxin toxicity. BuSpar may displace the serum binding of digoxin and increase the toxic levels of that drug (Shannon & Wilson, 1995). Nurses must sort through the medications with the client and report back to the health care practitioner the drugs taken in addition to those ordered by that health care practitioner.

LEGAL ASPECTS OF ADMINISTERING MEDICATIONS

Clients are awarded settlements in malpractice suits when nurses are negligent in their practice. Negligence exists any time the nurse fails to do something that a reasonable nurse would do under similar circumstances or does something that a reasonable nurse would not do. Malpractice is any professional misconduct or unreasonable lack of skill in professional duties. See Chapter 23 for related information on legal issues.

Medication Errors

Nurses have learned the "five rights" as a guideline to safe administration of medications. If the nurse gives the wrong medicine to the wrong person, an error has been made. If the nurse has the right medicine but wrong dose or wrong route, a medication error has been made. If the nurse gives the medication at the wrong time, an error has been made. Nurses must inform the health care practitioner of the error made. If an antidote must be given, the health care practitioner needs accurate information to make appropriate care decisions.

Medication errors must be reported in a timely manner. Knowing the actions and the side effects of drugs will help the nurse assess the client's response and health status. Incident reports are required in some agencies to document medication errors. A report of a medication error must include the name of the medication, the dose given, the route, the time the medication was administered, the specific error that occurred, the time the health care practitioner was contacted about the error, and what countermeasures were taken.

Sometimes nurses discover errors made by other nurses. These must also be documented.

Questioning the Medication Order

The nurse is responsible and held accountable for questioning any medication order if, in the nurse's judg-

ment, the order is unclear or in error. The nature of the error may be in any part of the drug order, and the nurse should seek clarification from the health care practitioner. A drug error has serious legal implications if the nurse involved could have been expected, on the basis of knowledge and experience, to have noted the error.

If the health care practitioner disregards the nurse's query, another line of authority must be pursued by the nurse to prevent a drug error. The medication in question should not be administered until the order has been clarified. The nurse should withhold any drug when the client's health may be jeopardized. Notify the health care practitioner of the need to withhold the medication and the reason withholding it is necessary. Document the reason for withholding the drug (such as withholding a dose of an antihypertensive medication due for a patient who is currently experiencing hypotension) on the medication administration record (MAR) and the nurse's notes.

When the nurse is not able to read or understand the order, the prescriber should be contacted for clarification. The nurse should not *guess* what the person who wrote the order is trying to communicate; the only safe nursing action is to validate the order with the health care practitioner.

ASSESSMENT

Drug administration is based on assessment data obtained by reviewing the client's medical history, eliciting a drug history, performing a physical examination, and obtaining and interpreting relevant laboratory results. Assessment is an ongoing process and requires the knowledge, skills, and abilities of a licensed professional.

THINK ABOUT IT

Medication Error

While monitoring a client who has an order for Solu-Cortef (anti-inflammatory drug) intravenously, you notice that Solu-Medrol (anti-inflammatory drug) is in the client's room. You recheck the order to make sure that the original order was for Solu-Cortef and that the order was not changed. What should your next action be? How do you feel about the nurse who made the medication error but did not recognize it?

Medical History

The client's medical history is obtained by the nurse when conducting the interview assessment and by reviewing the client's medical record. The nurse should identify all chronic diseases and disorders and correlate

these data with the drugs prescribed by the health care practitioner. Because the client may have more than one health care practitioner, the admitting health care practitioner might not be aware of all the drugs the client is taking, including over-the-counter medications. It is the nurse's responsibility to gather this information and document it on the client's chart.

Preexisting conditions such as liver and kidney dysfunction may require drug alteration because they prolong drug action, thereby increasing the potential for toxicity. The nurse needs to elicit this type of information during the medical history so that these clients can be closely monitored for signs of adverse reactions to drugs.

Drug History

A drug history is obtained on admission to a health care facility. The drug history should contain specific questions about the client's background: allergies, prescription and over-the-counter drugs, medical history, biographical data, lifestyle and beliefs, and sensory and cognitive status. See Chapter 16 for a complete discussion of taking a health history. If the client is unable to answer the questions, the nurse should contact a family member to obtain the data. Drug history data are used by nurses in determining the client's plan of care and learning needs.

Allergies

The nurse should inquire about all food and drug allergies. If the client has had an allergic reaction to a drug, the nurse should have the client describe the details of the reaction: name of the drug; dosage, route, and number of times the drug was taken before the reaction; onset of the reaction; and manifestations of the reaction. The nurse should question the client about possible contributing factors to the allergic reaction, such as concurrent use of stimulants (tobacco, alcohol, or illegal drugs) or significant changes in nutritional status.

The nurse should also ask about allergies to foods because drugs may contain the same elements or nutrients that cause allergic reactions to some foods. For example, clients who are allergic to shellfish may also experience a reaction to drugs containing iodine. Vaccines are commonly derived from chick embryos and would be contraindicated in clients with allergies to eggs.

Allergies to food and drugs, including over-the-counter drugs, should be noted in the client's record, in the admission note, on the medication administration record, and on the history and physical examination forms. The pharmacy should be notified of any drug or food allergies. In hospitals, clients wear allergy alert bands that list all medications to which the person is allergic. Nurses in all settings should discuss the use of medical alert bracelets by clients with allergies. These

bracelets would inform health care providers of allergies should the person not be able to speak for himself or herself.

Prescription Drugs

The nurse should have the client identify all current prescription drugs and describe:

- Why the drug was prescribed and by whom
- The drug's dosage, route, and frequency
- The client's knowledge of the drug's action: side and adverse effects, when to notify the health care practitioner, and special administration considerations such as with or without foods

If the client is receiving any drug that requires monitoring before administration such as insulin (antidiabetic hormone), the nurse needs to make sure the client is checking blood sugar and that the results are within normal limits.

Over-the-Counter Drugs

Clients usually have to be questioned separately about nonprescription drugs because they often fail to identify these drugs when asked to list all the medications they take routinely. For example, the nurse must determine if the client takes aspirin, antacids, or laxatives routinely. The client should describe the dosage, route, and frequency of these drugs. Because many drugs are available in topical form, the nurse should also inquire about the use of creams, ointments, patches, or sprays. Clients admitted to inpatient facilities should be asked if they have any over-the-counter drugs with them.

The nurse should explain to the client in a sensitive manner why these questions are necessary in order to allay any anxieties that might arise from this nature of questioning. Depending on the dosage and frequency, nonprescription drugs may have a profound effect on the client's treatment.

Biographical Data

The client's biographical data, including age, education, occupation, and insurance coverage, may influence the nursing care plan and teaching plan. These data are also used by the nurse when helping a client develop a drug regimen that complements the client's daily routine.

Lifestyle and Beliefs

The client's lifestyle and beliefs affect attitudes toward health, use of the health care system, and daily activity patterns. These factors often determine the client's dietary habits and nontherapeutic use of drugs such as tobacco, alcohol, and illegal drugs.

Sensory and Cognitive Status

The nurse should assess for and inquire about sensory deficits such as vision or hearing impairments, weakness or paralysis, or loss of sensation in one or more extremities. These deficits may impair a client's ability to comply with a prescribed drug plan, administer a subcutaneous injection, break a scored tablet, or open a medication container.

The nurse should assess the client's cognitive abilities throughout the drug history interview by noting whether the client is alert and oriented and interacts appropriately. Clients who are not able to express their thoughts coherently or who exhibit impaired memory function will require special consideration by the nurse when planning the client's care and teaching plan. See Chapter 36 for a complete discussion of sensory and cognitive impairments.

Physical Examination

The nurse conducts a physical assessment to identify those body systems that may be affected by a particular drug the client is currently taking or will be taking. The nurse assesses the client's condition before administering any drug to establish the client's baseline, or normal, health status. For example, the nurse assesses the client's apical pulse before administering Lanoxin (inotropic) so that the heart rate after receiving the drug can be compared with the baseline measurement.

Diagnostic and Laboratory Data

Common laboratory values, such as electrolytes, blood urea nitrogen, creatinine, glucose, complete blood count, and a white blood cell count, are usually monitored over a period of time to identify trends and to measure the body's response to medications. Laboratory results are evaluated on the basis of the client's clinical condition, physical assessment, and drug therapies. See Chapter 28 for a complete discussion of laboratory testing.

NURSING DIAGNOSIS

The nurse analyzes the assessment data to determine the client's ability to self-administer medications and to identify any potential or actual drug-related problems. Once the nurse identifies the actual or potential problems, relevant nursing diagnoses can be formulated. The common nursing diagnoses specifically related to medication administration are:

- *Deficient Knowledge*
- *Ineffective Therapeutic Regimen Management*
- *Ineffective Health Maintenance*
- *Impaired Physical Mobility*
- *Disturbed Sensory Perception*
- *Impaired Swallowing*

The addictive client may have a different set of nursing diagnoses, such as:

- *Imbalanced Nutrition*
- *Impaired Verbal Communication*
- *Interrupted Family Processes*
- *Impaired Social Interaction*
- *Social Isolation*
- *Spiritual Distress*
- *Readiness for Enhanced Spiritual Well-Being*
- *Ineffective Coping*

Selecting the most appropriate nursing diagnosis will identify the client's teaching needs.

PLANNING

Nurses need to carefully plan nursing care activities to ensure safe administration of medications. Reviewing scheduled diagnostic tests, laboratory results, and the overall plan of care helps to ensure that clients receive medications at the appropriate time and that medications that should not be given are withheld until their administration can be clarified with the health care practitioner. For example, digoxin might be withheld if the lab test indicates an above-normal level. Medication administration is a good time for nurses to incorporate client teaching. Adequate planning provides for questions and discussion by the client and demonstration of skills learned (as in self-administration of insulin injections). Planning ahead ensures that enough time is allocated for the client to accomplish all the desired tasks in a timely manner.

OUTCOME IDENTIFICATION

The nurse develops goals and plans the care on the basis of the nursing diagnosis. Inherent in the plan of care is client teaching based on medications prescribed. Nursing interventions are identified and incorporated into the plan of care to promote the attainment of goals and to assist the client in achieving expected outcomes. For example, the client with deficient knowledge related to a newly prescribed drug, insulin, may have the following expected outcomes:

- Client will correctly state the actions of insulin in the body before self-administering insulin.
- Client will prepare the correct dose of insulin in a syringe three times before discharge.
- Client will state the reasons for rotating the injection sites and demonstrate by self-administering insulin to three different sites before discharge.
- Client will correctly identify the onset of action, peak plasma level, and half-life of the insulin preparation prescribed before self-administering insulin.

- Client will correctly perform glucometer testing to ensure a normal range of blood sugar before administering the insulin injection.
- Client will correctly describe the signs of hyperglycemia and hypoglycemia and the appropriate actions to take before discharge.

Most clients admitted to a hospital or a long-term care facility have one or more nursing diagnoses related to alterations that precipitated the admission. Inherent in their nursing care plans are expected outcomes related to medication administration. For example, the nursing diagnosis *Ineffective breathing pattern* related to decreased energy may have as a client outcome, demonstrates correct use of a metered-dose inhaler. See the sample Nursing Care Plan at the end of this chapter for additional examples of client expected outcomes related to medication administration.

IMPLEMENTATION

The primary nursing interventions related to medication management are assessment, administration, and teaching. The nurse should use the time spent with the client during medication administration to assess the client's knowledge and response to the drug's action.

The administration of medication requires the implementation of safety guidelines, following the five rights. Medications are administered in accordance with set procedures based on the prescribed route. This section presents procedures and guidelines for medication administration by the following routes: oral, including sublingual, buccal, and enteral; parenteral; site-specific topical applications; and inhalation.

Once the teaching plan has been developed, the nurse should initiate discharge teaching of drug therapy. Assessment data, especially the client's history, help the nurse in determining who should be included in the teaching session. For example, an elderly client living alone is physically capable of self-administering but may have short-term memory loss. In this situation the nurse should obtain the client's permission to include a family member, neighbor, or friend in the teaching session.

Drug teaching usually occurs in two phases. The first phase involves a formal teaching session. The nurse explains the drug's action, route, side and adverse effects, and the specific signs of a drug reaction that require physician notification. Clients often need assistance in developing a drug schedule that promotes compliance and complements their lifestyle. Self-administration may require the nurse to teach the client specific procedural techniques, such as subcutaneous injection.

The second phase of client teaching is ongoing, occurring whenever the nurse administers a drug. The nurse should assess and reinforce the client's knowledge of drugs at each interaction. If the client is being taught self-administration, the drug teaching plan should

Nursing Process Highlight

Implementation: Client Teaching

The American Nurses Association and various governing bodies support written medication information for clients that is “scientifically accurate, unbiased in content and tone, sufficiently specific and comprehensive, presented in an understandable and legible format, timely, up to date, and useful.” Written medication information should:

- Be appropriate to client literacy levels
- Reflect print size appropriate to client’s visual abilities
- Give straightforward instructions
- Include brand and trade names
- Prominently display drug warnings
- Outline indications for use, contraindications, and precautions
- List possible adverse reactions and risks, storage, and use

(From American Nurses Association. [1997, March/April]. *The American Nurse*, 29 [2], 11)

identify the dates for teaching, and expected outcomes should identify a date for client achievement of targeted goals.

Administer Oral Drugs

Oral administration of drugs is the most common route; however, there are potential risk factors that the nurse must consider. Before administering oral drugs, the nurse should assess the client’s ability to take the medication as prescribed. This assessment includes the client’s gag reflex, state of consciousness, and presence of nausea and vomiting.

Figure 29-7 Check the client’s mouth to ensure that medications have been swallowed.

The nurse should protect the client against aspiration when administering any form of oral drug. **Aspiration** refers to the inhalation of regurgitated gastric contents into the pulmonary system. If a client has a weak gag reflex or difficulty swallowing water, medication can be inhaled during medication administration. To prevent aspiration, the nurse confirms the client’s gag reflex and ability to swallow. When administering an oral drug, the nurse prepares the medication, correctly identifies the client, and provides some form of liquid. See Procedure 29-1 for administering an oral medication. The nurse should remain with the client until *all* of the medications have been swallowed. If there is doubt that the client has swallowed the pill, the nurse should don a nonsterile glove and visually inspect the client’s mouth with a tongue depressor (Figure 29-7).

Sublingual and Buccal Drug Administration

Sublingual and buccal drugs are types of oral medications. Certain drugs are given by these routes to prevent their destruction or transformation in the stomach or small intestines. The nurse should assess the integrity of

PROCEDURE 29-1

Administering an Oral Medication

Equipment

- | | |
|--|--|
| <ul style="list-style-type: none"> ■ Medication administration record (MAR) ■ Medication cart or tray ■ Glass of water or juice | <ul style="list-style-type: none"> ■ Medication cup ■ Medication properly labeled ■ Straw |
|--|--|

Action

1. Assess the client for potential problems (e.g., absence of a gag reflex).
2. Check the MAR against the health care practitioner’s written orders.

Rationale

1. Decreases the risk of aspiration.
2. Ensures accuracy in the administration of the medication.

(continues)

PROCEDURE 29-1

Administering an Oral Medication (continued)

Action	Rationale
<ol style="list-style-type: none"> 3. Check for drug allergies. 4. Wash your hands. 5. Prepare the medications for <i>one client at a time</i>: <ul style="list-style-type: none"> • Select the correct medication and double-check against MAR. • Calculate the medication dose, if necessary. Double-check calculations for accuracy. • Avoid touching the drug while pouring in cup. If unit-dose is available leave drug in the wrapper until at the bedside. • Prepare liquids by placing the label side of the medicine bottle against the palm of your hand and pouring the liquid at eye level (Figure 29-8). Liquids should be measured at fluid level at the surface or the meniscus not the edges. • Recheck medications prepared with MAR. • Check MAR to make sure all medications to be administered have been prepared. • Place on the tray or medication cart. 6. Check client's armband before administering the medications. 7. Identify the drug for the client and its therapeutic purpose. 8. Perform any assessment required before the administration (such as apical pulse rate before administration of digoxin.) 9. Assist client to a sitting position. 	<ol style="list-style-type: none"> 3. Decreases risk of allergic reactions such as hives, urticaria, or anaphylactic shock. 4. Decreases transmission of microorganisms. 5. Ensures that the right client receives the right medications. <ul style="list-style-type: none"> • Increases accuracy and reduces chance of error. • Determines the correct amount of medication to be given. • Decreases possibility of contaminating the medication and helps ensure accuracy. • Prevents soiling and maintains legibility of the label. Ensures accurate measurement. 6. Ensures right dose, route, and time. 7. Promotes efficiency and decreases risk of error. 8. Prevents spillage. 6. Ensures right client. 7. Encourages client cooperation and increases client awareness of what to expect from the medication. 8. Provides data to determine if the medication should be given. 9. Prevents aspiration and promotes swallowing of the medication.

Figure 29-8 Measure oral medications at eye level to ensure accurate measurement.

(continues)

PROCEDURE 29-1

Administering an Oral Medication (continued)

Action

10. Offer liquids before and during ingestion; encourage the patient to drink 5–6 oz of water.
 - If the client is unable to hold the medication cup, assist the client by using the medication cup to introduce the pills to the person's mouth one at a time.
 - If a medication falls on the floor, discard the pill and start over.
11. Remain with the client until all medications have been swallowed.
12. Wash your hands.
13. Record the administered medications on the MAR.
14. Observe the client for side effects or adverse reactions.

Rationale

10. Facilitates downward movement of the medication in digestive system and helps absorption.
 - Prevents contamination of the medication; single-pill administration assists swallowing and helps prevent aspiration.
 - Medication that falls on floor is contaminated.
11. Ensures that all medications have been taken.
12. Decreases the transmission of microorganisms.
13. Provides documentation of the administration.
14. Assess for potential problems related to the medications administered.

the mucous membranes by inspecting underneath the client's tongue and in the buccal cavity. If the membranes are excoriated or painful, the nurse should withhold the medication and notify the health care practitioner. Some buccal drugs may irritate the mucosa, requiring the nurse to use alternate sides of the mouth to prevent irritation of the mucosa.

Sublingual and buccal administration of drugs (Figure 29-9) requires the nurse to use Standard Precautions because the nurse's hand may come into contact with oral secretions. See the Nursing Checklist for administering sublingual and buccal drugs. Drugs given by these routes are quickly absorbed by the mucosa's thin epithelium and the abundant blood supply.

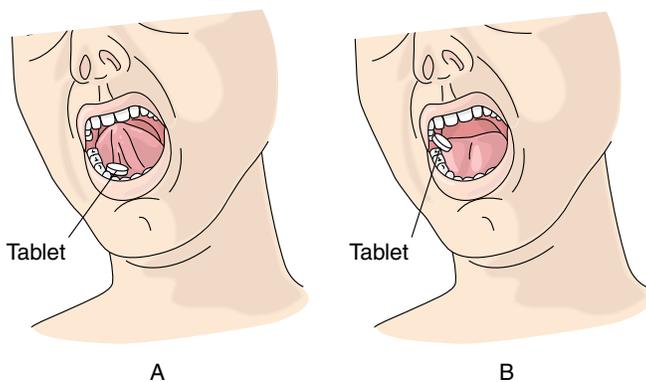

Figure 29-9 A. Sublingual Administration of a Tablet; B. Buccal Administration of a Tablet.

Enteral Instillation of Drugs

Enteral instillation refers to the delivery of drugs through a gastrointestinal tube. Enteral tubes provide a means of direct instillation of medications into the gastrointestinal system of clients who cannot ingest it orally. See Chapter 38 for a complete discussion of the purpose, insertion, and nursing care of clients with enteral tubes. Once the tube's position has been radiographically verified, the nurse may administer drugs or nutrients as prescribed.

There are several types of enteral tubes. A *nasogastric tube* (NG) is a soft rubber or plastic tube that is inserted through a nostril and into the stomach. The *gastrostomy tube* is surgically inserted into the stomach through the creation of an artificial fistula. The physician uses an endoscope to insert a *percutaneous endoscopic gastrostomy* (PEG) tube into the stomach.

The nurse should assess the client for the presence of bowel sounds and check the tube for **patency** (openness) and placement before administering a medication. The instillation of drugs is contraindicated when the tube is obstructed or improperly placed, when the client is vomiting, or if bowel sounds are absent.

The nurse prepares the medication for instillation as prescribed by the health care practitioner once the patency and placement of the tube have been determined. It is preferable to instill liquid medications into tubes, especially PEG tubes that have a small lumen. Tablets can clog the tube unless they are finely crushed. When the health care practitioner orders a drug in the

NURSING CHECKLIST

Administering Sublingual and Buccal Drugs

- Follow the five rights of safe drug administration.
- Wash your hands and don nonsterile gloves.
- Assess the client's knowledge of the drug and its action.
- Explain the procedure to the client, and allow the client time to ask questions.
- Offer the client a sip of water and explain to the client that liquids cannot be taken until the tablet is completely dissolved.
- To give a drug sublingually, ask the client to open the mouth and lift the tongue; place the drug under the client's tongue. Give the client the following instructions:
 - Keep the medication under the tongue until it dissolves completely to ensure absorption.
 - Avoid chewing the tablet or touching the tablet with the tongue to prevent accidental swallowing.
 - Do not smoke before the drug has completely dissolved because nicotine has a vasoconstriction effect that slows absorption.
- To give a drug buccally, instruct the client to open the mouth wide, and place the tablet between the client's cheek and teeth. Give the client the following instructions:
 - Keep the medication in place until it dissolves completely to ensure absorption.
 - Do not drink liquids for an hour because some tablets take up to an hour to dissolve.
 - Do not smoke before the drug has completely dissolved because nicotine has a vasoconstriction effect that slows absorption.
- Remove gloves and dispose in a proper receptacle; wash hands.
- Document the medication administration on the MAR. When the client is receiving repeated doses of a buccal medication, the nurse should indicate the site, such as right buccal cavity, to prevent irritation of the same site.

tablet or capsule form, the nurse should crush the tablet into minute particles and dissolve the crushed tablet in 15 to 30 ml of warm water before instillation. Some tablets cannot be crushed without altering their therapeutic effect. The nurse should check with the pharmacist if unsure. The instillation of cold solution may cause abdominal cramps. Capsules are prepared for administration by opening the capsule and emptying the con-

NURSING CHECKLIST

Verifying Placement of an Enteral Tube

- The nurse checks the patency and placement of a nasogastric tube before adding any water or medications by performing the following actions:
- Wash hands and don nonsterile gloves.
 - Unclamp the tube.
 - Create a 20-ml air space in a 50- or 60-ml syringe.
 - Attach the syringe to the free end of the tube.
 - Place the stethoscope on the left upper quadrant, 3 inches (7.5 cm) below the sternum.
 - Gently instill 20 ml of air into the tube while simultaneously listening for a gastric bubble. (The gastric bubble is the “swish” sound heard as the air moves into the stomach.)
 - When sound is heard, draw back on the piston of the syringe. (The appearance of gastric contents in the syringe may imply the tube is in the stomach.)

If the nurse fails to hear the swish sound and aspirates gastric contents, the tube may have risen into the client's esophagus. *Do not administer the medication until placement in the stomach is verified.* If allowed by policy, advance the tube into the stomach and check its placement by instilling air and aspirating or by obtaining a physician's order to confirm the tube's placement with an X-ray.

NURSING ALERT

Risk for Aspiration

Clients, especially those with an NG tube, are at risk for aspiration from esophageal reflux. Position the client as directed in the nursing checklist to minimize the risk of esophageal reflux and aspiration.

tents into a liquid. When the drug is prepared, the nurse is ready to instill the medication (see the Nursing Checklist for instilling drugs into enteral tubes).

The nurse should question the health care practitioner if oily medications and enteric-coated or sustained-release tablets are ordered because these drug forms should not be given through a tube. Oily preparations may cling to the sides of the tube and resist mixing with the irrigating solution. Crushing enteric-coated or sustained-release tablets destroys their intended effect. Do not crush buccal or sublingual tablets. Never attempt to give whole or undissolved medications through an enteral tube. See the accompanying display for special considerations.

NURSING CHECKLIST

Instilling Drugs into Enteral Tubes

- Wash hands and don nonsterile gloves.
- Place the client in a high or semi-Fowler's position, as the client's condition allows; for an NG tube, unpin the tube from the client's gown to allow manipulation of the tube's free end. Place a linen saver over the bed linens to prevent soilage during administration of the medication.
- Attach the syringe to the free end of the tube, pour 30 ml of medication into the syringe barrel, and open the clamp; for NG tube instillation, hold the NG tube at the client's nose level.
- Hold the syringe barrel at a slight angle and allow the medication to flow at a steady, slow rate; add more medication before the syringe empties to prevent air from entering the stomach. If necessary, adjust the height of the NG tube to achieve a steady flow rate. Never push medications into the tube.
- Observe the client while instilling the medication. If the client experiences any discomfort, slow the rate by lowering the height of the syringe.
- As the syringe barrel begins to empty with the last of the medication, slowly add 30 to 50 ml of room-temperature water into the syringe to clear the medication from the sides and distal end of the tube to prevent clogging.
- Before the syringe empties of water, clamp the tube, and detach and dispose of the syringe.
- Position the client as appropriate; clients with an NG tube should be placed on the right side with the head of the bed slightly elevated for at least 30 minutes after the instillation.
- Clean area, remove and dispose of gloves in the proper receptacle, and wash hands.
- Document the instillation of the medication on the MAR and record on the intake and output sheet the total amount of fluid instilled

SPECIAL CONSIDERATIONS FOR ENTERAL TUBE MANAGEMENT

- When a client is receiving intermittent tube feedings, schedule the medications to prevent the two solutions from being given together.
- An adult client should not receive more than 400 ml of liquid at one time. If the administration of feedings and medication coincide, give the medication first to ensure that the client receives the prescribed dosage on time; the feeding may not be given in its entirety.
- When the client is receiving a continuous feeding, stop the feeding and aspirate the gastric contents. If the gastric contents are greater than 150 ml, withhold the medication and notify the health care practitioner.
- Never put tablets into tube feeding bags.
- For clients who have an NG tube for decompression (removal) of gastric contents, turn off the suction for 20 to 30 minutes after the instillation of the medication to allow time for the gastric contents to be emptied into the intestines, where most drugs are absorbed.
- For clients who have a nasogastric tube, never use the pigtail air vent for irrigation or administration of fluids.

enteral medications the nurse must have knowledge of the special equipment, use manual dexterity and sterile technique, and follow Standard Precautions. An injection is an invasive procedure because it breaks the skin barrier. As such, it must be performed using proper aseptic technique to prevent risk of infection.

Equipment

Nurses use special equipment such as syringes, needles, ampules, and vials when administering parenteral medications.

Syringes

A syringe has three basic parts: the hub, which connects with the needle; the barrel, or outside part, which contains measurement calibrations; and the plunger, which fits inside the barrel and has a rubber tip (Figure 29-10). The nurse must ensure that the hub, inside of the barrel, and shaft and rubber plunger tip are kept sterile. When handling the syringe, the nurse should touch only the outside of the barrel and the plunger's handle.

Most syringes are disposable, made of plastic, and individually packaged for sterility. There are several types of syringes, such as the hypodermic, insulin, and tuberculin syringes (Figure 29-11A–C). When a medication is incompatible with plastic, it is usually prefilled in a single-dose glass syringe. Syringes are often prepackaged with the commonly used needle size and gauge and are referred to as *disposable plastic syringes* (Figure 29-11D).

Administer Parenteral Drugs

Parenteral medications are given through a route other than the alimentary canal; these routes are intradermal, subcutaneous, intramuscular, or intravenous. The angle of injection and the depth of penetration will indicate the type of injection. Many clients have broadly classified the parenteral route into one category: "injections" or "shots." The nurse should provide the client with an explanation of the various routes used when administering parenteral drugs. To prepare and administer par-

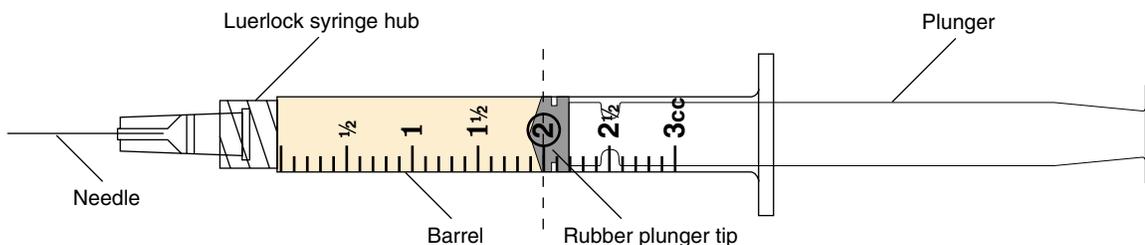

Figure 29-10 The Parts of a Syringe

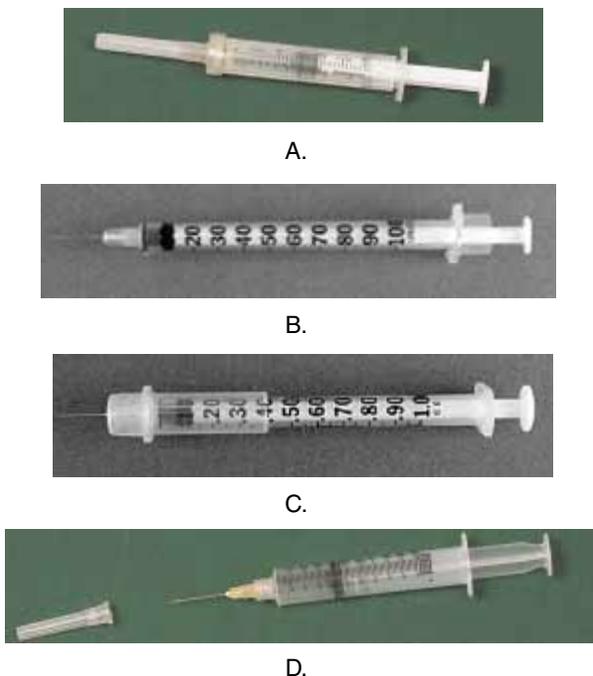

Figure 29-11 Types of Syringes. A. Hypodermic B. Standard U-100 Insulin. (Courtesy of Becton Dickinson and Company) C. 1-ml Tuberculin (Courtesy of Becton Dickinson and Company) D. Disposable Plastic

The *hypodermic syringe* comes in 2-, 2.5-, and 3-ml sizes. The measurement calibrations (scales) are usually printed in milliliters and minims. Most syringes are marked in cubic centimeters (cc), and most drugs are ordered in milliliters; these are equivalent measurements (1 cc = 1 ml). The hypodermic syringe is used most often when a medication is ordered in milliliters. When the order is written in minims, it is safer to prepare the drug in a tuberculin syringe.

The *insulin syringe* is designed specially for use with the ordered dose of insulin. For example, if the health care practitioner writes the order for 30 units of U-100 insulin, the nurse will use an insulin syringe that is calibrated on the 100-unit scale. Insulin syringes are calibrated on the U-100 (100-unit) scale, which is based on 100 units of insulin contained in 1 ml of solution. Insulin syringes come in sizes that hold 0.5 ml (50 units) to 1.0 ml (100 units). Insulin syringes that hold 0.5 ml are the easiest to read and are therefore used for low dosages.

There are other sizes of insulin syringes that complement the ordered dose, such as U-30 and U-50, although these dosages are seldom prescribed. The nurse should always compare the size of insulin syringe and the dose indicated on the insulin bottle with the health care practitioner's order; all three unit doses must be the same.

The *tuberculin syringe* is a narrow syringe, calibrated in tenths and hundredths of a milliliter (up to 1 ml) on one scale and in sixteenths of a minim (up to 1 minim) on the other scale. Originally this syringe was designed to administer the tuberculin drug, but it is commonly used today to administer small or precise doses, such as pediatric dosages. The tuberculin syringe should be used for doses 0.5 ml or less.

Prefilled single-dose syringes should not be confused with a unit dose. The nurse must be careful to check the prescribed dose against that in the prefilled syringe and discard excess medication. For example, if the health care practitioner orders diazepam (Valium) 5 mg IM as a preoperative sedative and the prefilled single-dose contains 10 mg/2 ml, the nurse must calculate dosage (5 mg/1 ml) and destroy 1 ml from the syringe before administration.

Needles

Most needles are disposable, made of stainless steel, and individually packaged for sterility. Reusable needles are seldom used, except in certain areas such as surgery and special procedure rooms; reusable needles require frequent inspection to ensure that the needle is sharp, and resterilization is necessary between uses.

The needle has three basic parts: the hub, which fits onto the syringe; the cannula, or shaft, which is attached to the hub; and the bevel, which is the slanted part at the tip of the shaft. Needles come in various sizes, from 1/4 inch to 5 inches, and with gauges that range from 28 to 14 (Figure 29-12).

Figure 29-12 Various Lengths and Gauges of Needles. Gauge from left to right: 18, 20, 22, 25.

The *gauge* of the needle refers to the diameter of the shaft; the larger the gauge number, the smaller the diameter of the shaft. Large-gauge needles produce less trauma to the body's tissue; however, the nurse has to consider the viscosity of a solution when selecting the gauge.

The *shaft of the needle* determines its length. The nurse selects the length of the needle on the basis of the client's muscle development and weight and the type of injection, such as intradermal versus intramuscular.

The needle may have a short or long *bevel*. The length of bevel selected is based on the type of injection. Long bevels are sharp and produce less pain when injected into the subcutaneous or muscle tissues; however, a short-bevel needle must be used for intradermal and intravenous injections to prevent occlusion of the bevel either by the tissue or by a blood vessel wall.

When the nurse removes a needle from its sterile wrapper, the hub of the needle should be immediately attached to the hub of the syringe to prevent contamination. Likewise, the protective cover should remain on the needle's shaft until the nurse is ready to use the needle.

After an injection, the nurse should not recap the needle; used needles should be disposed of in the proper receptacles, such as a sharps container, to prevent needle sticks. See Chapters 31 and 37 for details on how to prevent needlestick injuries. Most agencies have sharps con-

tainers in all client care areas. Chapter 37 provides a complete discussion of the needle-less system.

Ampules and Vials

Drugs for parenteral injections are sterile preparations. Drugs that deteriorate in solution are dispensed as tablets or powders and dissolved in a solution immediately before injection. Drugs that remain stable in a solution are dispensed in ampules and vials in an aqueous or oily solution or suspension.

Ampules are glass containers of single-dose drugs (Figure 29-13). The glass container has a constriction in the stem to facilitate opening the ampule. See Procedure 29-2 for removing a drug from an ampule. Because many drugs are irritating to the subcutaneous

Figure 29-13 Ampules

PROCEDURE 29-2

Withdrawing Medication from an Ampule

Equipment

- | | |
|--|---|
| <ul style="list-style-type: none"> ■ Medical administration record (MAR) ■ Sterile syringe and needle ■ Extra needle of proper gauge and length in accord with site | <ul style="list-style-type: none"> ■ Ampule of prescribed medication ■ Sterile gauze or alcohol swab ■ Filter needle |
|--|---|

Action

1. Wash your hands.
2. Hold the ampule and quickly and lightly tap the top chamber until all fluid flows into the bottom chamber.
3. Place a sterile gauze or alcohol wipe around the neck of the ampule (Figure 29-14).
4. Firmly grasp the neck of the ampule and quickly snap the top off away from your body. Place the ampule on a flat surface.
5. Withdraw the medication from the ampule, maintaining sterile technique.
 - Check connection of needle to syringe by turning barrel to right while holding needle guard.

Rationale

1. Decreases transmission of microorganisms.
2. Moves the fluid trapped above the neck of the ampule to the lower chamber of the ampule.
3. Contains the glass fragments and shields the nurse's fingers from the broken ampule.
4. Directs shattered glass fragments away from the nurse's face and fingers. Prevents spillage of medication.
5. Prevents the transmission of microorganisms.
 - Ensures an airtight system.

(continues)

PROCEDURE 29-2

Withdrawing Medication from an Ampule (continued)

Action

Figure 29-14 Snap open the ampule while holding a wipe or gauze around the neck of the ampule, to protect against glass fragments.

- Use a filter needle if recommended.
- Remove needle guard, and hold syringe in dominant hand.
- With nondominant hand grasp ampule and turn upside down, or stabilize ampule on a flat surface.
- Insert the needle into the center of the ampule; do not allow the needle tip or shaft to touch the rim of the ampule.
- Keep needle tip below level of meniscus (Figure 29-15).

Rationale

- Filters out fine glass particles.
- Promotes dexterity.
- Provides access to medication.
- Prevents contamination of needle tip or shaft.
- Prevents air from entering syringe and fluid from leaking out while the ampule is inverted.

A

B

Figure 29-15 A. Invert ampule and draw fluid into the syringe. B. Remove filter needle and replace with injection needle.

(continues)

PROCEDURE 29-2

Withdrawing Medication from an Ampule (continued)

Action

- Aspirate the medication by gently pulling on the plunger.
 - If air bubbles are aspirated, remove the needle from the ampule. Hold syringe with needle pointing up and tap sides of the syringe. Draw back slightly on plunger, and gently push the plunger upward to eject air. Reinsert the needle in the middle of the ampule and continue to withdraw the medication.
6. Remove excess air from the syringe and check the dosage of medication in the syringe. Recap.
 7. Discard any unused portion of the medication, and dispose of the ampule top in a suitable container after comparing with MAR.
 8. Change needle and properly discard used needle. Secure needle to syringe by turning the barrel to right while holding the needle guard.
 9. Wash hands.

Rationale

- Allows medication to enter the syringe.
 - Prevents loss of medication from the ampule caused from air pressure. Moves air bubbles above the fluid level in the syringe. Pulls medication from needle so only air is ejected from the syringe.
6. Allows for accurate measurement of medication dose. Prevents contamination of the needle and protects the nurse against inadvertent needlesticks.
 7. Sterility of a medication is lost in an open ampule.
 8. Reduces the risk that the drug will cause irritation to subcutaneous tissue.
 9. Prevents spread of microorganisms.

NURSING TIP

Expiration Dates

Manufacturers are required by law to put the expiration date on all drugs. The nurse should check the expiration date to ensure that the drug is current. Outdated drugs should be returned to the pharmacy for proper disposal.

Figure 29-16 Vials

tissue, the nurse should change the needle on the syringe after withdrawing a drug from an ampule.

The nurse should consider the use of a needle filter when withdrawing medication from an ampule or vial. Beyea and Nicoll (1996) suggest that the last few drops of the drug be left in an ampule or vial; some studies have found foreign substances, such as glass and rubber, in the containers that could be drawn into the syringe.

Glass, single- or multiple-dose rubber-capped drug containers are called vials (Figure 29-16). The vial is usu-

ally covered with a soft metal cap that can be easily removed. See Procedure 29-3 for removing a drug from a vial. The nurse should change the needle on the syringe after withdrawing a drug from a vial. Inserting the needle through the rubber cap of the vial can dull the needle or remove the needle coating that helps it glide through the skin (Beyea & Nicoll, 1996).

Compatible medications can be mixed in the same syringe. Refer to compatibility charts or check with the pharmacist to determine if the medications can be mixed. If medications are going to be mixed, care must be exercised not to contaminate one medication with the other in their respective vials. See Procedure 29-4 for mixing insulins in one syringe. The nurse must calculate and measure carefully to be sure the final dose is accurate.

PROCEDURE 29-3

Withdrawing Medication from a Vial

Equipment

- | | |
|--|----------------------|
| ■ Medication administration record (MAR) | ■ Vial of medication |
| ■ Sterile syringe and needle | ■ Sterile needle |
| ■ Alcohol swab | |

Action

1. Wash your hands.
2. Prepare the vial.
 - Open the alcohol wipe.
 - New vial, remove metal cap from vial of medicine and cleanse the rubber top of the vial.
 - Used vial, cleanse the rubber top of the vial.
3. Prepare syringe.
 - Choose a syringe of appropriate size to accommodate the volume of medication to be withdrawn.
 - Grasp needle and turn barrel of syringe to the right.
 - Remove the needle cap and pull back on plunger to fill syringe with an amount of air equal to amount of solution to be withdrawn from the vial.
4. Insert the needle into the center of the upright vial and inject air into the vial.
5. Invert vial; keep the vial at eye level and the needle's bevel below the fluid level, and remove the exact amount of medicine while touching only the syringe barrel and plunger tip (Figure 29-17).

Rationale

1. Reduces transmission of microorganisms.
2. Provides access to vial. Removes surface contamination. (*Note:* Manufacturers do not ensure sterility of rubber top.)
3. Ensures a closed system.
 - Ensures withdrawing all the medication at one time.
 - Displaces the solution with air to prevent the formation of a vacuum in the sealed vial.
4. Creates positive pressure inside vial to allow accurate withdrawal of medicine.
5. Prevents contamination of the plunger, barrel, and medicine.

Figure 29-17 Invert the vial, and keep the needle below the fluid level.

Withdrawing Medication from a Vial (continued)

*Action**Rationale*

- | | |
|--|---|
| <ol style="list-style-type: none"> 6. Expel air from the syringe while needle remains within the inverted vial by tapping the side of the syringe with your finger. 7. Check the amount of medicine in the syringe. 8. Turn vial upright and remove the needle. 9. Replace the needle cap. Open the sterile package of the new needle. Remove used needle, and dispose in the sharps container. 10. Attach the new needle to the syringe by turning the barrel to the right. 11. Compare the medication in the syringe with the prescribed dosage. | <ol style="list-style-type: none"> 6. Removes air bubbles created by the dead space in the needle's hub; allows for accurate measurement of the solution. 7. Ensures accurate dose. 8. Prevents the leakage of solution from the vial. 9. Prevents needlestick. 10. Provides a sharp needle for injection that decreases the client's discomfort. 11. Complies with safety standards for ensuring the correct dosage. |
|--|---|

PROCEDURE 29-4

Mixing Insulins in One Syringe

Equipment

- | | |
|---|--|
| <ul style="list-style-type: none"> ■ Medication administration record (MAR) ■ Insulin vials | <ul style="list-style-type: none"> ■ Alcohol swabs ■ Insulin syringe |
|---|--|

*Action**Rationale*

- | | |
|---|---|
| <ol style="list-style-type: none"> 1. Check with the client and the chart for known allergies or medical conditions that would contraindicate the use of the drug. 2. Gather necessary equipment. 3. Check the MAR against written health care orders. 4. Wash your hands. 5. Follow the five rights of medication administration. Check the client's identification band. 6. Remove caps from insulin vials (if not already off). 7. Slowly rotate each bottle of insulin. Never shake. Make sure suspensions are thoroughly mixed. (Cloudy insulin such as NPH should be completely mixed.) 8. Clean the rubber stoppers of the vials with an alcohol swab. | <ol style="list-style-type: none"> 1. Prevents occurrence of adverse reactions. 2. Promotes efficiency. 3. Ensures accuracy in identification of medication. 4. Reduces transmission of microorganisms. 5. Ensures correct client. 6. Permits access to solution. 7. Ensures complete mixture of suspension. Make sure there are no crystals on the bottom of the vial. 8. Helps remove surface contaminants. |
|---|---|

(continues)

PROCEDURE 29-4

Mixing Insulins in One Syringe (continued)

Action

9. Remove cap from the needle. Draw air into the syringe equal to the dose of insulin to be given. Insert needle into vial of the suspension, being careful not to touch the needle to the medication in the vial. Inject the air into the vial and remove the needle. Do not withdraw any insulin yet.
10. Fill syringe with air equal to dose of regular insulin. Insert needle into bottle and inject air into vial. Invert bottle and pull plunger down to withdraw the appropriate dose of insulin.
11. With needle in the bottle, hold it up to the light and look for air bubbles. To remove air bubbles, tap or flick the syringe with your finger to cause air to rise. Push plunger to push air and some insulin back into the vial. Pull back to get the appropriate dose of insulin free of air. Remove the needle.
12. Insert needle into the vial of longer-acting insulin; be sure the tip of the needle is below the surface of the fluid level. Invert the bottle, and slowly draw back to dose of insulin required. Remove needle.
 - Have another nurse check the prescribed dose.
13. Store insulin vials according to your agency policy.
14. Wash your hands.

Rationale

9. Injected air will displace the insulin to be removed.
10. Injected air displaces insulin and facilitates withdrawal. Inverting the vial allows the air to rise and the solution to settle on the bottom of the vial.
11. Air displace the medication in the syringe and can cause errors in dosage. Air bubbles must be removed to ensure that an accurate dose of insulin is in the syringe.
12. Drawing back slowly helps prevent air from being drawn into the syringe.
 - Ensures accuracy.
14. Reduces transmission of microorganisms.

Angle of Injection

The angle of insertion depends on the type of injection. Figure 29-18 illustrates the angle of insertion for each type of parenteral injection.

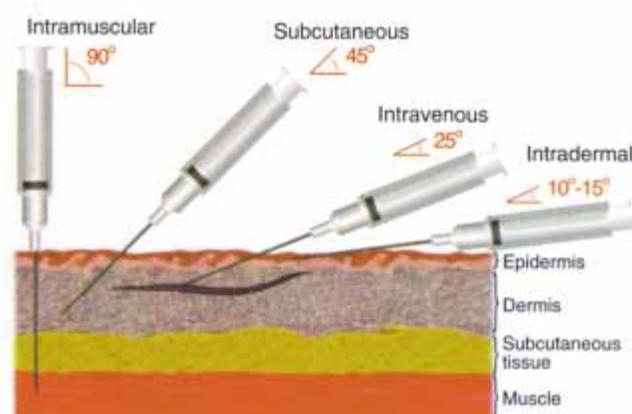

Figure 29-18 Angles of Insertion for Parenteral Injections.

Intradermal Injection

Intradermal (ID) or intracutaneous injections are typically used to diagnose tuberculosis, identify allergens, and administer local anesthetics. The site below the epidermis is the location for administering ID injections; drugs are absorbed slowly from this site. The sites commonly used for ID injection are the inner aspect of the forearm (if it is not highly pigmented or covered with hair), upper chest, and upper back beneath the scapula (Figure 29-19). Only small amounts of water-soluble medication should be used for subcutaneous injections.

The drug's dosage for an ID injection is usually contained in a small quantity of solution (0.01 to 0.1 ml). A 1-ml tuberculin syringe with a short bevel, 25 to 27 gauge, 3/8- to 1/2-inch needle is used to provide accurate measurement. If repeated doses are ordered, the site should be rotated. ID injections are administered into the epidermis layer by angling the needle 10° to 15° to the skin. See Procedure 29-5 for administering intradermal injections.

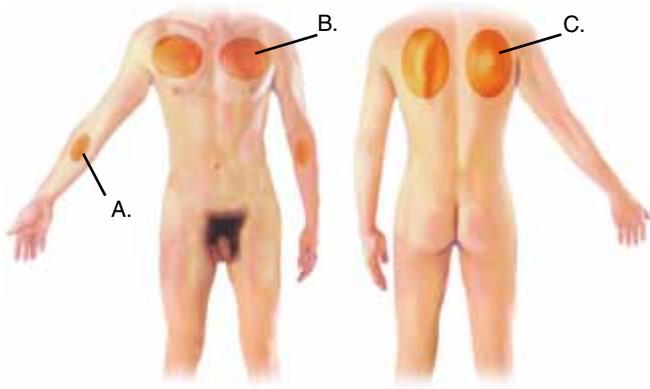

Figure 29-19 Intradermal Injection Sites: A. Inner Aspect of the Forearm; B. Upper Chest; C. Upper Back

Subcutaneous Injection

Subcutaneous (SC or SQ) injections are commonly used in the administration of medications such as insulin and heparin because these drugs are absorbed slowly, to produce a sustained effect. SC injections place the medication into the subcutaneous tissue, between the dermis and the muscle. Clients who administer frequent subcutaneous injections should rotate sites regularly. An administration chart can help them keep track of the sites used. The amount of medication given varies but should not exceed 1.0 ml; if repeated drug doses are given, rotate the sites. Subcutaneous tissues are sensitive to irritating medications. Hard painful lumps can develop beneath the skin if the sites are not rotated.

PROCEDURE 29-5

Administering an Intradermal Injection

Equipment

- | | |
|--|---|
| <ul style="list-style-type: none"> ■ Medication administration record (MAR) ■ Sterile tuberculin syringe and short bevel, 25 to 27 gauge, $\frac{3}{8}$- to $\frac{1}{2}$-inch needle. | <ul style="list-style-type: none"> ■ Medication ■ Alcohol swab and sterile 2 × 2 gauze pad ■ Disposable gloves |
|--|---|

Action

1. Check with the client and the chart for any known allergies.
2. Wash hands.
3. Follow the five rights.
4. Prepare the medication from an ampule or vial; refer to Procedure 29-2 or 29-3 as appropriate. Take the medication to the client's room and place on a clean surface.
5. Check the client's identification armband.
6. Explain the procedure to the client.
7. Place the client in a comfortable position; provide for privacy.
8. Wash hands and don nonsterile gloves.
9. Select and clean the site.
 - Assess the client's skin for bruises, redness, or broken tissue.
 - Select an appropriate site using appropriate anatomic landmarks.
 - Cleanse the site with an alcohol wipe using a firm circular motion; cleanse from inside to outside; allow alcohol to dry.

Rationale

1. Prevents the occurrence of hypersensitivity reactions such as hives, urticaria, or anaphylactic shock.
2. Reduces transmission of microorganisms.
3. Promotes client safety.
5. Accurately identifies the client.
6. Reduces the client's anxiety and enhances cooperation.
7. Promotes comfort. Promotes absorption of the medication. Decreases anxiety.
8. Decreases contact with blood and body fluids.
9. Promotes absorption of the drug; reduces trauma to the body's tissue.
 - Aids in the removal of microorganisms on the skin.

(continues)

PROCEDURE 29-5

Administering an Intradermal Injection (continued)

Action

10. Prepare the syringe for injection.
 - Remove the needle guard.
 - Express any air bubbles from the syringe.
 - Check the amount of solution in the syringe.
11. Inject the medication.
 - Hold the syringe in dominant hand.
 - With nondominant hand, grasp the client's dorsal forearm and gently pull the skin taut on ventral forearm (Figure 29-20).

Figure 29-20 Spread the skin taut for an intradermal injection.

- Place the needle close to the skin, bevel side up. Insert the needle at a 10° to 15° angle until resistance is felt, and advance the needle approximately 3 mm below the skin surface; the needle's tip should be visible under the skin.
 - Administer the medication slowly; observe the development of a bleb (large flaccid vesicle that resembles a mosquito bite). If none appears, withdraw the needle slightly.
 - Withdraw the needle.
 - Pat area gently with a dry 2 × 2 sterile gauze pad.
 - Do not massage the area after removing the needle.
12. Discard the needle and syringe in a sharps container.
 13. Remove gloves, dispose of in appropriate receptacle, and wash hands.
 14. Observe for signs of an allergic reaction.
 15. Draw a circle around the perimeter of the bleb with a ball point pen.
 16. Document medication and site of injection on the MAR.

Rationale

10. Ensures correct dosage of medication in the syringe.
 - Taut skin facilitates needle insertion.
- Ensures that medication is injected into the intradermal tissue; initial resistance indicates the needle's tip is in the subcutaneous region.
- Indicates that the medication was injected into the dermis.
- Prevents spreading the medication beyond the point of injection.

 12. Prevents needlesticks.
 13. Reduces the spread of microorganisms.
 14. Ensures client safety.
 15. Allows for easy recognition and observation of the injection site.
 16. Provides a written description of the injection site and states the time the medication was administered.

Common sites for SC injections are the abdomen, the lateral and anterior aspects of the upper arm or thigh, the scapular area on the back, and upper ventrodorsal gluteal areas (Figure 29-21). The nurse should select a sterile 0.5- to 3-ml syringe with a 25- to 29-gauge, 3/8- to 1/2-inch needle. The medication is administered by angling the needle 45° or 90° to the skin. The client's body weight will influence the angle used for injection. As a general rule, to reach subcutaneous tissue, if you can grasp 2 inches of tissue between two fingers, insert the needle at a 90° angle. If only 1 inch of tissue can be grasped between the fingers, use a 45° angle to administer the medication.

The length of the needle may also vary with body weight. Normally for SC injections, a 25-gauge, 5/8-inch needle is used. A child will require a short needle, and an obese person may require a longer needle to ensure placing the medication in the subcutaneous tissue. The length of the needle should be approximately half the

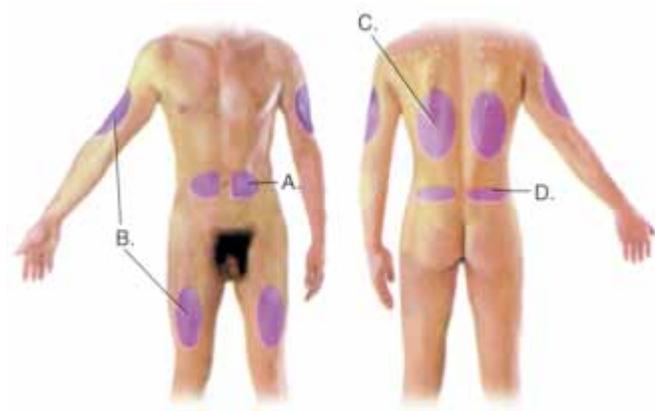

Figure 29-21 Subcutaneous Injection Sites: A. Abdomen; B. Lateral and Anterior Aspects of Upper Arm and Thigh; C. Scapular Area on Back; D. Upper Ventrodorsal Gluteal Area.

width of the pinched skinfold. See Procedure 29-6 for the technique used in administering an SC injection.

NURSING ALERT

Aspirating the Syringe

Do not aspirate on the plunger when giving heparin; *doing so may cause tissue damage.*

Intramuscular Injection

Intramuscular (IM) injections are used to promote rapid drug absorption and to provide an alternate route when the drug is irritating to subcutaneous tissue. The IM route enhances the absorption rate because there

PROCEDURE 29-6

Administering a Subcutaneous Injection

Equipment

- Medication administration record (MAR)

are more blood vessels in the muscles than in subcutaneous tissue; however, the absorption rate may be affected by the client's circulatory status.

Since the 1920s over 90 research studies related to IM injections have been reported in the literature (Beyea & Nicoll, 1995). Researchers have studied the medication volume and appropriate size of the syringe and needle for administering an IM injection to a particular site. "Research on the maximum volume to be drawn up for a single injection is still inconclusive" (Beyea & Nicoll, 1996, p. 34). The nurse should determine the maximum volume to inject on the basis of the site and the client's muscle development:

- 4 ml for a large muscle (gluteus medius) in a well-developed adult
- 1 to 2 ml for less developed muscles in children, elderly, and thin clients
- 0.5 to 1.0 ml for the deltoid muscle

When more than 4 ml is ordered, the medication can be divided into two different sites.

There are four common sites for administering IM injections (see the accompanying display). Injection sites are identified by using appropriate anatomic landmarks (Figure 29-22).

COMMON INTRAMUSCULAR INJECTION SITES AND MUSCLES

Site	Muscle
Dorsogluteal	Gluteus maximus
Ventrogluteal	Gluteus medius
Anterolateral aspect of thigh	Vastus lateralis
Upper arm	Deltoid

The primary site for administering an IM injection in clients over 7 months old is the ventrogluteal (VG) site. The gluteus medius is a well-developed muscle, free of major nerves and large blood vessels. Research shows that injuries—including fibrosis, nerve damage, abscess, tissue necrosis, muscle contraction, gangrene, and pain—have been associated with all the common sites (dorsogluteal, deltoid, and vastus lateralis, for example) *except* the VG site (Beyea & Nicoll, 1996, p. 35).

The nurse should avoid using the deltoid and dorsogluteal sites in infants and children. There is a risk of striking the sciatic nerve when using the dorsogluteal site. The deltoid muscle is not well developed in infants and children.

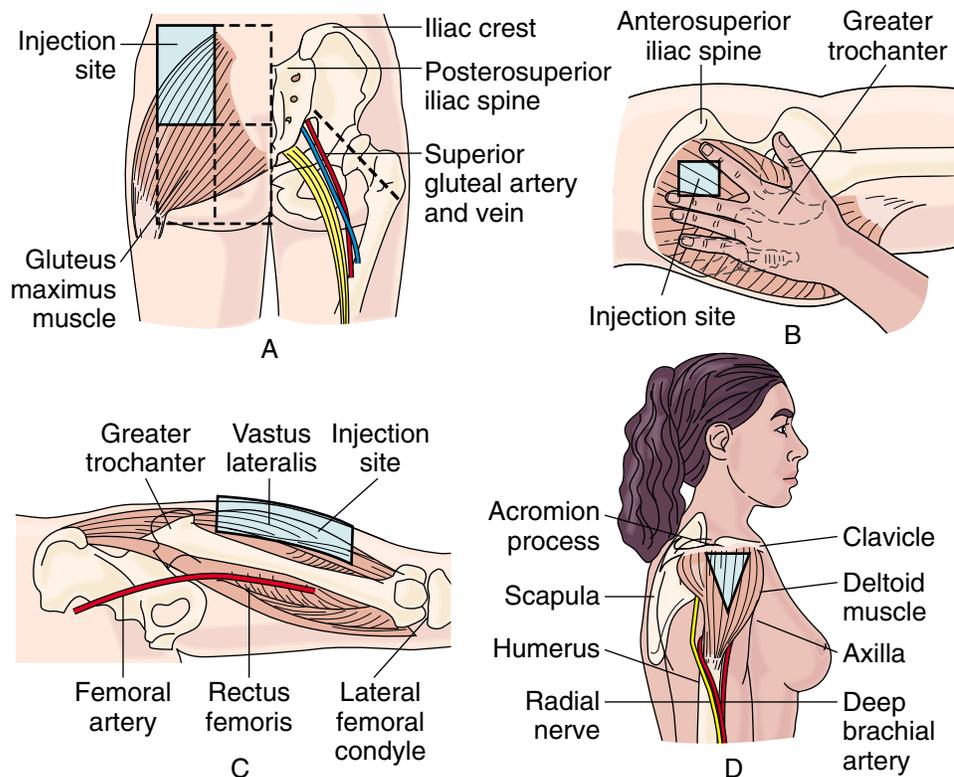

Figure 29-22 Intramuscular Injection Sites. A. Dorsogluteal: Place hand on iliac crest and locate the posterosuperior iliac spine. Draw an imaginary line between the trochanter and the iliac spine; the injection site is the outer quadrant. B. Ventrogluteal: Place palm of left hand on right greater trochanter so that index finger points toward anterosuperior iliac spine; spread first and middle fingers to form a V; injection site is the middle of the V. C. Vastus lateralis: Identify greater trochanter; place hand at lateral femoral condyle; injection site is middle third of anterior lateral aspect. D. Deltoid: Locate the lateral side of the humerus from two to three fingerwidths below the acromion process in adults or one fingerwidth below the acromion process in children.

The nurse will need to decide on the gauge and length of the needle on the basis of the consistency of the solution, the site, and how far the needle must be injected to reach the muscle. A 21- to 23-gauge needle will accommodate the consistency of most drugs and will minimize tissue injury and subcutaneous leakage. The needle's length is determined by the site:

- 1 ½-inch needle, VG site for average-sized adults
- 1-inch needle, VG site for children
- 1-inch needle, deltoid or vastus lateralis

An obese client usually requires a 2-inch needle to ensure that the needle will reach a large muscle such as the gluteal muscle. For example, for a client weighing 100 pounds, use a needle 1 to 1 ½ inches long; usually

for a child use only a 1-inch needle. It is important to consider the size of the client when determining the needle length; some children are large, and some adults are small. The nurse should administer an IM injection at a 90° angle. See Procedure 29-7 for administering an intramuscular injection.

Z-Track Injection

The *Z-track* (zigzag) *technique* refers to a method used in administering IM injections (see Procedure 29-7). This technique was traditionally used when administering imferon, an iron preparation, which can cause permanent discoloration in the subcutaneous tissue. Today, the technique is used commonly when administering ventrogluteal and dorsogluteal injections.

PROCEDURE 29-7

Administering an Intramuscular Injection

Equipment

- | | |
|--|----------------------------|
| ■ Medication administration report (MAR) | ■ Medication as prescribed |
| ■ Sterile 3-ml syringe and long bevel, 20 to 22 gauge, 1- to 2-inch needle (average-sized, adult client receiving a drug in an aqueous solution) | ■ Alcohol swab |
| | ■ Nonsterile gloves |
| | ■ Sterile 2 × 2 gauze pad |

Action

1. Check with client and the chart for any known allergies.
2. Wash hands.
3. Follow the five rights.
4. Prepare the medication from an ampule or vial; refer to Procedure 29-2 or 29-3 as appropriate.
 - Add 0.1 to 0.2 ml of air to the syringe.
 - Take medication to the client's room and place on a clean surface.
5. Check the client's identification armband.
6. Explain the procedure to the client; provide for privacy.
7. Place the client in an appropriate position to expose the site.
 - Deltoid: sitting position.
 - Ventrogluteal:
 - Side-lying: flex the knee, pivot the leg forward from the hip about 20° so it can rest on the bed.
 - Supine: flex the knee on the injection side.
 - Prone: point toes inward toward each other to internally rotate the femur.

Rationale

1. Prevents the occurrence of hypersensitivity reactions.
2. Reduces the transmission of microorganisms.
3. Promotes client safety.
 - Ensures that all the medication is expelled from the needle's shaft.
5. Accurately identifies the client.
6. Reduces the client's anxiety and enhances cooperation.
7. Provides access to the site, promotes relaxation of muscles, and decreases the discomfort from the injection.

(continues)

PROCEDURE 29-7

Administering an Intramuscular Injection (continued)

<i>Action</i>	<i>Rationale</i>
<p>8. Don nonsterile gloves.</p> <p>9. Select and clean the site.</p> <ul style="list-style-type: none"> • Assess the client's skin for redness, scarring, breaks in the skin, and palpate for lumps or nodules. • Select site using the anatomic landmarks. • Cleanse the area with an alcohol swab, cleanse from inside outward using friction; wait 30 seconds to allow to dry. <p>10. Prepare for the injection.</p> <ul style="list-style-type: none"> • Remove the needle cap by pulling it straight off, and expel any air bubbles from the syringe. • Pull the skin down or to one side (Z-track technique) with nondominant hand. <p>11. Administer the injection.</p> <ul style="list-style-type: none"> • Deltoid: quickly insert the needle with a dart-like motion at a 90° angle (Figure 29-23). 	<p>8. Decreases contact with blood and body fluids.</p> <p>9. Avoids potential problems that may decrease the rate of the drug's absorption.</p> <ul style="list-style-type: none"> • Avoids tissue containing large nerves and blood vessels. • Removes the surface microorganisms and prevents the introduction of alcohol into subcutaneous tissue to avoid irritation. • Maintains the sterility of the needle; ensures the correct dosage in the syringe. • Decreases the risk of medication's leaking into needle track and the subcutaneous tissue; reduces complications and discomfort. <p>11. Ensures that the needle is injected into the muscle.</p>

Figure 29-23 Administering Intramuscular Injection into the Deltoid Muscle

- Ventrogluteal: quickly insert the needle using a dartlike motion and steady pressure at a 90° angle to the iliac crest in the middle of the V (Figure 29-24).
- Aspirate by pulling back on the plunger, and observe for blood.
- If blood appears, remove the needle and discard.

(continues)

PROCEDURE 29-7

Administering an Intramuscular Injection (continued)

Action

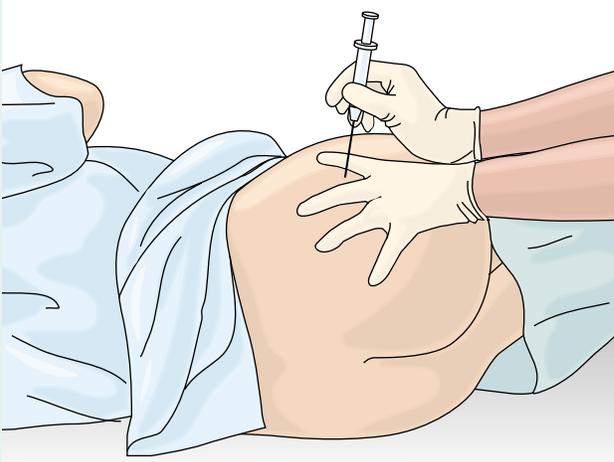

Figure 29-24 Administering Intramuscular Injection into the Ventrogluteal Site

- | | |
|---|--|
| <ul style="list-style-type: none"> • If blood does not appear, inject the medication slowly, about 10 sec/ml. • Wait 10 seconds after the medication has been injected, then smoothly withdraw the needle at the same angle of insertion. • Apply gentle pressure at the site with a dry, sterile 2 × 2 gauze; do not massage the injection site. Swab using gentle pressure. • Discard the needle and syringe in a sharps container; do not recap the needle. <ol style="list-style-type: none"> 12. Position client for comfort; encourage client receiving ventrogluteal injections to perform leg exercises (flexion and extension). 13. Remove gloves, wash hands. 14. Record on the MAR the dosage, route, site, and time. 15. Inspect the injection site within 2 to 4 hours and evaluate the client's response to the medication. | <div style="text-align: center;"><i>Rationale</i></div> <hr/> <ul style="list-style-type: none"> • Promotes comfort and allows time for the tissues to expand and begin absorbing the medication. • Allows the medication to diffuse through the muscle. • Decreases tissue irritation. • Prevents needlesticks. <ol style="list-style-type: none"> 12. Promotes the absorption of the medication. 13. Prevents transmission of microorganisms. 14. Provides documentation that the medication was administered. 15. Alerts the nurse to hypersensitivity reactions; the peak plasma level is dependent on the drug's half-life. |
|---|--|

When administering a Z-track injection, the nurse should place the client in the prone position (Figure 29-25A); then pull the skin to one side (Figure 29-25B), insert the needle at a 90° angle and administer the medication (Figure 29-25C). Spreading the skin, a common method formerly used for IM injections, increases the risk

that medication will leak into the needle track and the subcutaneous tissue; this risk is virtually eliminated using the Z-track technique, making it the technique of choice (Beyea & Nicoll, 1996). The nurse waits 10 seconds and withdraws the needle at the same angle of insertion; the site should not be massaged because massaging could cause tissue irritation.

NURSING TIP

Air Bubble in Syringe

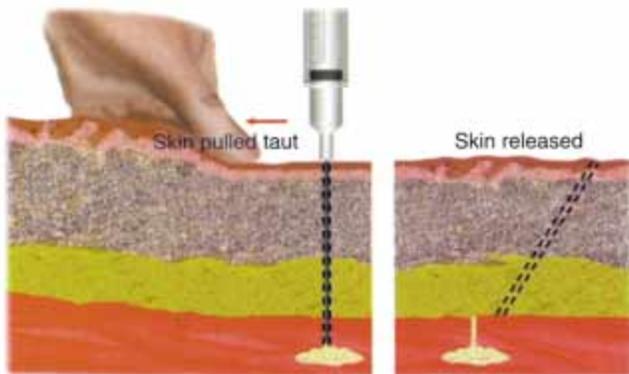

The nurse should not draw an air bubble when using a plastic disposable syringe, as doing so can dramatically affect the medication dosage (Beyea & Nicoll, 1996).

A.

B.

C.

Figure 29-25 Administering Intramuscular Injection Using Z-Track Technique. A. Client lies prone with buttocks exposed. B. Grasp and pull the muscle laterally before injecting medication. C. Pulling skin taut and then releasing it after the needle is withdrawn seals the site.

Table 29-2 summarizes the basics of intradermal, subcutaneous, and intramuscular injections.

Intravenous Injections

The intravenous (IV) route is used when a rapid drug effect is desired or when the medication is irritating to tissue. IV administration provides immediate release of medication into the bloodstream; consequently, it can be dangerous. IV medications are administered by one of the following methods:

- Intravenous fluid container
- Volume-control administration set
- Intermittent infusion by piggyback or partial fill
- Intravenous push (IVP or bolus)

See Chapter 37 for a discussion of other IV delivery systems.

Adding Drugs to an Intravenous Fluid Container

When administering IV medications, regardless of the method used, the nurse should assess the patency of the infusion system and the condition of the injection site for signs of complications such as **infiltration** (swelling and discomfort at the IV site) and **phlebitis** (inflammation of a vein). See Chapter 37 for a complete discussion of these IV complications. Some IV medications or solutions with high or low pH or high osmolarity are irritating to veins and can cause phlebitis.

Before administering any IV medication, the nurse should note the client's allergies, drug or solution incompatibilities, the amount and type of diluent needed to mix the medication, and the client's general condition to establish a baseline for administering medication.

Examples of drugs that can be added to an IV fluid container that is infusing are potassium chloride, an electrolyte, and Solu-B, a vitamin (Figure 29-26). The nurse should check for drug compatibilities of drug additives before injecting a medication into an infusion bag. **Drug incompatibilities** cause an undesired chemical or physical reaction between a drug and a solution, between two drugs, or between a drug and the container or tubing. For example, diazepam (Valium) and chlorthalidone hydrochloride (Librium) must not come into contact with a saline solution; insulin should not be added to an infusion bag because the insulin adheres to the inside of the solution bag.

Adding Drugs to a Volume-Control Administration Set

A volume-control set is used to administer small volumes of IV solution (Figure 29-27). These devices have various names as determined by the manufacturer, such as

TABLE 29-2
Summary of Intradermal, Subcutaneous, and Intramuscular Injections

Type of Injection	Purpose	Site	Needle Size	Maximum Dose	Angle of Insertion
Intradermal	Injects medication below the epidermis; drugs are absorbed slowly; typically used for diagnosis of tuberculosis and allergens	Inner aspect of forearm; upper chest; upperback	Syringe with short bevel; 25- to 27-gauge; 3/8 to 1/2-inch	0.01 to 0.1 ml	10°–15° 
Subcutaneous	Injects medication between dermis and muscle; absorbed slowly; typically used for insulin and anticoagulants	Abdomen; lateral and anterior aspects of upper arm and thigh; scapular area on back; ventrogluteal area	25-gauge, 5/8-inch needle (varies by size of person)	0.5–1.0 ml	45° or 90° 
Intramuscular	Used to promote rapid drug absorption and to provide an alternate route when drug is irritating to SC tissue	Ventrogluteal; dorsogluteal; anterolateral aspect of thigh (vastus lateralis); upper arm (deltoid)	The gauge and length of needle are selected on the basis of medication volume and viscosity and client's body size	Well-developed adult: 4 ml in a large muscle; infant and small child: 0.5–1.0ml; children and elderly: 1–2 ml; deltoid muscle: 0.5–1 ml	90° 

Figure 29-26 Adding a Medication to an Intravenous Fluid Container

Soluset, Metriset, VoluTrol, or Buretrol. To administer a drug by this method, the nurse should:

- Withdraw the prescribed amount of medication into a syringe that is to be injected into the volume-control set.

- Cleanse the injection port of a partially filled volume-control set with an alcohol swab.
- Inject the prepared medication into the port of the volume-control set (Figure 29-28).
- Gently mix the solution in the volume-control chamber.

After injecting the medication into the volume-control chamber, the nurse should check the infusion rate and adjust as necessary to the prescribed rate of infusion.

Administering Medications by Intermittent Infusion

A common method of administering IV medications is by using a secondary, or partial-fill additive bag, often referred to as an IV piggyback (IVPB). A secondary line is a complete IV set (fluid container and tubing with either a microdrip or a macrodrip system) connected to a Y-port of a primary line (see Procedure 29-8). The primary line maintains venous access. The IVPB is used for medication administration. See Chapter 37 for a complete discussion of primary and secondary lines. When the IVPB medication is incompatible with the primary IV solution, the nurse must flush the primary IV tubing with normal saline before and after administering the medication.

Intermittent Infusion Devices When the client requires only the administration of IV medications without the infusion of solutions, an intermittent infusion device is inserted into a peripheral needle or catheter in

Figure 29-27 Volume-control set is connected to a continuous infusion line.

Figure 29-28 Injecting a Medication into a Partially Filled Volume-Control Set

PROCEDURE 29-8

Administering Medications by IV Piggyback to an Existing IV

Equipment

- Medication administration record (MAR)
- Prepared and labeled medication 50-ml solution bag from pharmacy
- Alcohol swab
- Secondary administration set
- Needle-less locking cannula

Action

1. Gather prepared equipment (medication labeled with the client's name, and time tape for fluids to infuse per hour).
2. Wash hands.
3. Check the client's armband.
4. Explain the procedure to the client.
5. Assess the puncture site.
 - Observe for redness and puffiness.
 - Palpate for tenderness.
6. Check patency of infusion site.
 - Observe fluid infusing.
 - Remove IV container from the pole and lower the container below the level of infusion site.

Rationale

1. Ensures correct fluids to be administered to the right client at the infusion rate prescribed by the health care practitioner.
2. Decreases risk of transmission of microorganisms.
3. Ensures correct client.
4. Elicits client's support and decreases anxiety.
5. Indicates signs of infiltration or infection.
6. Verifies patency of IV system with venous access device in the client's vein.

(continues)

PROCEDURE 29-8

Administering Medications by IV Piggyback to an Existing IV (continued)

Action	Rationale
<ul style="list-style-type: none"> Observe for backflow of blood into the hub of the venous access device. Replace container on IV pole. 	
7. Secure medication bag prepared and labeled by pharmacy and check health care practitioner's prescription and the MAR.	7. Ensures the correct client, medication, dosage, route, and frequency.
8. Check the client's chart for allergies, and check the drug compatibility chart.	8. Ensures that the client is not allergic to the drug and that the prescribed drug is compatible with the primary IV solution.
9. Hang the secondary bag on IV pole.	9. Provides easy access for preparation.
10. Add the administration set to the secondary bag and prime the tubing.	10. Removes the air from the tubing.
11. Affix a needle-less locking cannula to the end of tubing (Figure 29-29A).	11. Reduces risk of exposure to IV needles.

Figure 29-29A Administering Medications by IV Piggyback. Connect a needle-free locking cannula to a secondary infusion line.

12. Cleanse needle-less Y-site injection port of primary IV tubing closest to infusion site with an alcohol swab; allow to dry.	12. Reduces risk of transmission of microorganisms.
13. Insert needle-less locking cannula of secondary bag set into Y-site injection port of primary set and secure in place with tape (Figure 29-29B).	13. Provides access for infusion and prevents dislodgement of needle-less locking cannula.
14. Affix the extension hook to the primary bag on the IV pole so that the primary bag hangs below the level of the secondary bag.	14. Ceases flow of primary solution because of an increased hydrostatic pressure in secondary bag.
15. Open clamp of secondary tubing and adjust drip rate to desired infusion rate. <ul style="list-style-type: none"> Slowly close the regular clamp while observing the drip chamber until the fluid is dripping at a slow, steady pace (Figure 29-29C). Count the drops for a 15-second interval and multiply by 4 (e.g., if the drop factor of 	15. Allows solution in the secondary bag to infuse at the prescribed drip rate. <ul style="list-style-type: none"> Determines number of drops falling per minute.

(continues)

PROCEDURE 29-8

Administering Medications by IV Piggyback to an Existing IV (Continued)

Action

Figure 29-29B Connect locking cannula to a Y-site injection port of primary infusion set.

Figure 29-29C Monitor the infusion rate.

tubing is 10 drops/ml then the drop rate should be 10 drops/minute to infuse 50 ml in 50 minutes).

- Recount the drop rate in 5 minutes.
 - Detects changes in rate due to expansion and contraction of tubing.
16. Observe client for any signs of adverse reactions to the medication.
 16. Provides for immediate intervention if client has an adverse reaction.
 17. When secondary bag and drip chamber are empty, close the clamp on secondary system, readjust drip rate of primary solution as indicated, and remove the secondary system.
 17. Allows the primary solution to infuse at prescribed drip rate.
 18. Record medication infusion on the MAR and note any client responses in the nurses' notes
 18. Documents the nursing intervention.

Rationale

the client's vein (Figure 29-30). This device is commonly referred to as a heparin or saline lock depending on the agency's policy regarding the device's maintenance. A lock provides continuous access to venous circulation, eliminating the need for a continuous IV, and it increases the client's mobility.

The device can be used to infuse intermittent IVPB or IV push medications, or it can be converted to a primary IV. A major consideration for inserting a heparin lock device is that it provides venous access in case of an emergency. Lock devices are routinely used with cardiac clients.

Locks are generally flushed every 8 hours to maintain patency (patency refers to being freely opened). Some agencies require a diluted dose of heparin (100 units/ml) to be injected into the lock; other agencies use normal saline to keep the device patent. See Chapter 37 for a complete discussion of heparin and saline locks. When heparin is used, the device must be flushed with normal saline solution before and after administration of a medication.

Administering IV Push Medications

The method of medication administration by IV bolus or IV push injection is determined by the type of IV system. For example, an IV push medication can be injected into a saline or heparin lock (Figure 29-31) or into a continuous infusion line. When giving an IV push medication into a continuous infusion line, the nurse must stop the fluids in the primary line; the nurse usually pinches the IV tubing closed to inject the drug (see Figure 29-32). This technique is safe and prevents the nurse from having to recalculate the drip rate of the primary infusion line.

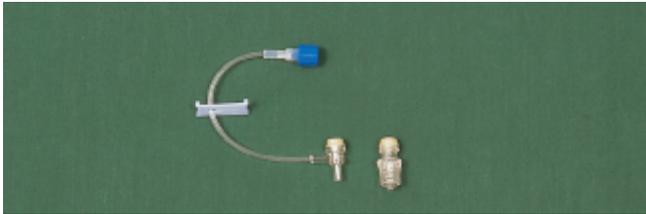

Figure 29-30 Heparin Locking Device

Figure 29-31 Pinch closed the IV tubing of a primary infusion line to administer an IV push medication.

Figure 29-32 Injecting a Bolus of Medication into a Peripheral Saline Lock

IV push medications can also be given into a central line or directly into the vessel by venipuncture. The five rights of medication administration are implemented when administering an IV bolus. The nurse must know the specific time interval to inject the medication and the specific reactions of the infused drug. The client must be monitored closely during and after injection for drug reactions.

Administer Topical Medications

Topical medications may be administered to the skin, eyes, ears, nose, throat, rectum, and vagina. The medication generally provides a local effect but can also cause systemic effects. Drugs directly applied to the skin to produce a local effect include lotions, pastes, ointments, creams, powders, and aerosol sprays. The rate and degree of the drug's absorption are determined by the vascularity of the area.

Topical drugs are usually given to provide continuous absorption to produce different effects: to relieve pruritus (itching), to protect the skin, to prevent or treat an infection, to provide local anesthesia, or to create a systemic effect. Topical medications are usually ordered two or three times a day to achieve their therapeutic effect.

Before applying a topical preparation, the nurse should assess the condition of the skin for any open lesions, rashes, or areas of erythema and skin breakdown. Because secretions are produced by the skin and mucous membranes, the nurse should always implement Standard Precautions when applying a topical drug. The medication can be transferred to the nurse if gloves are not worn or an applicator, such as a sterile tongue depressor, is not used. The nurse should check with the client and the medical record for any known allergies.

Body oils may interfere with the adhesive properties of the patch, disk, or tape. The skin harbors microorganisms, and lesions can cause encrustation. The nurse should cleanse the area by washing with soap and warm water, unless contraindicated by a specific order. The

skin should be thoroughly dry before a topical medication is applied. Open wounds require the nurse to use surgical asepsis. See Chapter 28 for a complete discussion of surgical asepsis.

When the skin is dry, the nurse can apply the medication. When applying a paste, cream, or an ointment, the nurse should use a sterile tongue depressor to remove the medication from the container; this method prevents cross-contamination. The medication is transferred from the tongue blade to a gloved hand for application. The medication should be applied in long, smooth strokes in the direction of the hair follicles to prevent the medication from entering the hair follicles. A new sterile tongue depressor should be used whenever more medication is removed from the container. Two to 4 hours after the application, the nurse should assess the area for signs of an allergic reaction.

Eye Medications

Eye medications, often referred to as ophthalmic medications, refer to drops, ointments, and disks. These drugs are used for diagnostic and therapeutic purposes—to lubricate the eye or socket for a prosthetic eye and to prevent or treat eye conditions such as glaucoma (elevated pressure within the eye) and infection. Diagnostically, eyedrops can be used to anesthetize the eye, dilate the pupil, and stain the cornea to identify abrasions and scars.

The nurse should review the abbreviations used in medication orders to ensure that the medication is instilled in the correct eye. Cross-contamination is a potential problem with eyedrops. The nurse should adhere to the following safety measures to prevent cross-contamination:

- Each client should have his or her own bottle of eyedrops. Clients should never share eye medications.
- Discard any solution remaining in the dropper after instillation.
- Discard the dropper if the tip is accidentally contaminated, as by touching the bottle or any part of the client's eye. The risk of transferring infection from one eye to the other is increased if the tip touches any part of the client's eye.

See Procedure 29-9 for administering eye medications. The nurse should insert medication disks at bedtime because they usually cause blurring of the eyes on insertion. Standard Precautions are used when eye care and medications are being administered because of the potential contact with bodily secretions.

Ear Medications

Solutions ordered to treat the ear are often referred to as *otic* (pertaining to the ear) drops or irrigations. Eardrops may be instilled to soften ear wax, to produce anesthesia, to treat infection or inflammation, or to facilitate removal of a foreign body, such as an insect. External auditory canal irrigations are usually performed for cleaning purposes and less frequently for applying heat and antiseptic solutions. The internal ear is very sensitive to changes in temperature. Sudden changes can cause nausea and dizziness. Eardrops and irrigation fluids should be at room temperature.

Before instilling a solution into the ear, the nurse should inspect the ear for signs of drainage, an indication of a perforated tympanic membrane. Eardrops are usually contraindicated when the tympanic membrane is perforated. If the tympanic membrane is damaged, all procedures must be performed using sterile aseptic technique; otherwise, medical asepsis is used when instilling medications into the ear (see Procedure 29-10). Medication should never be forced into the ear canal especially if it is occluded (as by wax). Forcing medication into an occluded eardrum can injure the eardrum.

Certain conditions have contraindications for specific drugs; for example, hydrocortisone eardrops are contraindicated in clients with a fungal infection or a viral infection such as herpes.

Nasal Instillations

Nasal instillations can be performed with different preparations: drops or nebulizers (atomizer or aerosol). Nasal drugs are administered to produce one or more of the following effects: to shrink swollen mucous membranes, to loosen secretions and facilitate drainage, to treat infections of the nasal cavity or sinuses. Because many of these products are nonprescription drugs, clients should be taught their correct usage. For example, nasal decongestants are common over-the-counter drugs used to shrink swollen mucous membranes; however, when these drugs are used in excess, they may have a reverse or rebound effect by increasing nasal congestion.

The nasal sinuses (frontal, ethmoid, maxillary, and sphenoid sinuses) communicate with the nasal fossae and are lined with mucous membranes similar to those that line the nose. Nose drops can be instilled to remain in the nasal passage, to reach the ethmoid and sphenoid sinuses, or to reach the frontal or maxillary sinuses. Location is determined by the degree of hyperextension and position of the

NURSING ALERT

Systemic Effects of Eyedrops

The nurse should apply pressure to the inner canthus when instilling eyedrops that have potential systemic effects such as atropine and timolol maleate (Timoptic). Gentle pressure over the inner canthus prevents the medication from flowing into the tear duct, thereby decreasing the absorption rate of the drug.

PROCEDURE 29-9

Administering an Eye Medication

Equipment

- Medication administration record (MAR)
- Tissue or cotton ball

- Eye medication
- Nonsterile gloves

Action

1. Check with the client and the chart for any known allergies or medical conditions that would contraindicate use of the drug.
2. Check the MAR against the written orders.
3. Gather the necessary equipment.
4. Follow the five rights of drug administration.
5. Take the medication to the client's room and place on a clean surface.
6. Check client's identification armband.
7. Explain the procedure to the client; inquire if the client wants to instill his or her own eye-drops.
8. Wash hands, don nonsterile gloves.
9. If the eye has crust or drainage along the margins or inner canthus, gently wash the eye. Always wipe from inner canthus to outer. Use warm soaks to soften material if necessary.
10. Place client in a supine position with the head slightly hyperextended.

Instilling Eyedrops

11. Remove cap from eye bottle and place cap on its side.
12. Squeeze the prescribed amount of medication into the eyedropper.
13. Place a tissue below the lower lid.
14. With dominant hand, hold eyedropper 1/2 to 3/4 inch above the eyeball; rest hand on client's forehead to stabilize.
15. Place nondominant hand on cheekbone and expose lower conjunctival sac by pulling on cheek while applying slight pressure to the inner canthus.
16. Instruct the client to look up, and drop prescribed number of drops into center of conjunctival sac (Figure 29-33 on the following page).

Rationale

1. Prevents occurrence of adverse reactions.
2. Ensures accuracy in identification of the medications.
3. Promotes efficiency.
4. Promotes safety.
5. Decreases risk of contamination.
6. Accurately identifies client.
7. Reduces client's anxiety and enhances collaboration; some clients are used to instilling their own eyedrops.
8. Decreases contact with bodily fluids.
9. Crust and drainage harbor microorganisms. Cleansing from inner to outer aspects of eye avoids pushing microorganisms into the lacrimal duct. Soaking allows crusted material to soften and facilitates removal without pressure on the eye.
10. Minimizes drainage of medication through the tear duct.
11. Prevents contamination of the bottle cap.
12. Ensures correct dose.
13. Absorbs the medication that flows from the eye.
14. Reduces risk of dropper's touching eye structure.
15. Stabilizes hand and prevents systemic absorption of eye medication.
16. Reduces stimulation of the blink reflex; prevents injury to the cornea.

(continues)

PROCEDURE 29-9

Administering an Eye Medication (continued)

Action*Rationale*

Figure 29-33 To administer an eye medication, gently press the lower lid down and have the client look upward while instilling drops into the lower conjunctival sac.

- | | |
|---|--|
| <ul style="list-style-type: none"> 17. Avoid instilling medication directly into the cornea. 18. If the client blinks and the drops land on the outer lid or eyelash, repeat the procedure. 19. Instruct client to gently close eyes and move eyes. 20. Remove gloves; wash hands. 21. Record on the MAR the route, site (which eye), and time administered. | <ul style="list-style-type: none"> 17. Pain fibers in the cornea make it very sensitive to anything applied to it. 18. Therapeutic effect achieved only if the drop enters the conjunctival sac. 19. Distributes solution over conjunctival surface and anterior eyeball. 20. Reduces the transmission of microorganisms. 21. Provides documentation that the medication was given. |
|---|--|

Eye Ointment

- 22. Repeat steps 1–10.
 - 23. Lower lid:
 - With nondominant hand, gently separate client's eyelids with thumb and finger, and grasp lower lid near margin immediately below the lashes; exert pressure downward over the bony prominence of the cheek.
 - Instruct the client to look up.
 - Apply eye ointment along inside edge of the entire lower eyelid, from inner to outer canthus.
- Provides access to the lower lid.
 - Reduces stimulation of the blink reflex, and keeps cornea out of way of medication.
 - Ensures that drug is applied to entire lid.

(continues)

PROCEDURE 29-9

Administering an Eye Medication (continued)

<i>Action</i>	<i>Rationale</i>
<p>24. Upper lid:</p> <ul style="list-style-type: none"> • Instruct client to look down. • With nondominant hand, gently grasp client's lashes near center of upper lid with thumb and index finger, and draw lid up and away from eyeball. • Squeeze ointment along upper lid starting at inner canthus. 	<ul style="list-style-type: none"> • Keeps cornea out of way of medication. • Ensures medication applied to entire length of lid.
<p>25. Repeat steps 19–21.</p>	
Medication Disk	
<p>26. Repeat steps 1–10.</p> <p>27. Open sterile package and press dominant, gloved finger against the oval disk so that it lies lengthwise across fingertip (Figure 29-34A).</p>	<p>27. Promotes sticking of disk to fingertip. Allows nurse to inspect disk.</p>
<p>28. Instruct the client to look up.</p>	
<p>29. With nondominant hand, gently pull the client's lower eyelid down and place the disk horizontally in the conjunctival sac. It should float on the sclera between the iris and the lower eyelid (Figure 29-34B,C).</p> <ul style="list-style-type: none"> • Then pull the lower eyelid out, up, and over the disk. 	<p>29. Allows the disk to automatically adhere to the eye. Ensures proper absorption of medication.</p>

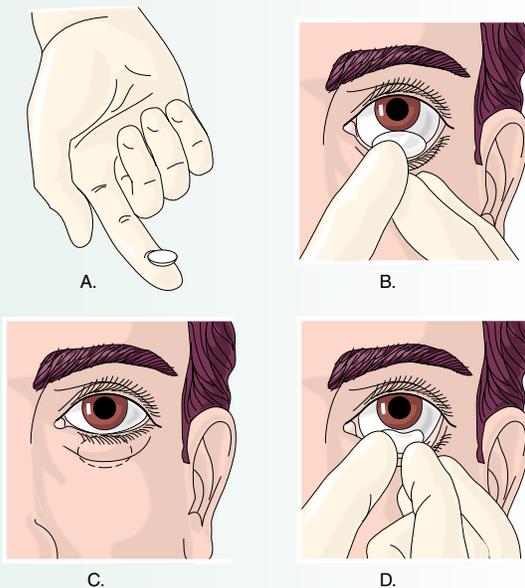

Figure 29-34 Insertion of an Intraocular Medication Disk (Steps A–D)

(continues)

PROCEDURE 29-9

Administering an Eye Medication (continued)

*Action**Rationale*

- Instruct the client to blink several times.
 - If disk is still visible, repeat steps.
 - Once the disk is in place, instruct the client to gently press his fingers against his closed lids; do not rub eyes or move the disk across the cornea.
 - If the disk falls out, rinse it under cool water and reinsert.
30. If the disk is prescribed for both eyes (OU), repeat steps 27–29.
31. Repeat steps 19–21.

30. Ensures both eyes are treated at the same time.

Removing an Eye Medication Disk

32. Repeat steps 4 and 6–10.
33. Remove the disk.
- With nondominant hand, invert the lower eyelid and identify the disk.
 - If the disk is located in the upper eye, instruct the client to close the eye, and place your finger on closed eyelid. Apply gentle, long, circular strokes; instruct client to open the eye. Disk should be located in corner of eye. With your fingertip, slide the disk to the lower lid, then proceed (Figure 29-34D).
 - With dominant hand, use the forefinger to slide the disk onto the lid and out of the client's eye.
34. Remove gloves; wash hands.
35. Record on the MAR the removal of the disk.

- Exposes the disk for removal.

34. Reduces transmission of microorganisms.
35. Provides documentation that the disk was removed.

head during instillation (Figure 29-36). Although the nose is considered a clean (not sterile) cavity, because of its connection with the sinuses, the nurse uses medical asepsis when performing nasal instillations. See Procedure 29-11 for administering nasal instillations.

Nebulizers (inhalers) are used to deliver a fine mist containing medication droplets. The nurse should administer or assist clients with the usage of atomizers and aerosols:

- Instruct the client to clear the nostrils by blowing the nose.
- Client should be in an upright position with head tilted back slightly.

Atomizer

- Occlude one nostril to prevent air from entering the nasal cavity and to allow the medication to flow freely in the open nostril.

- Insert the atomizer tip into the open nostril and instruct the client to inhale, then squeeze the atomizer once, and instruct the client to exhale.

Aerosol

- Shake the aerosol well before each use.
- Grasp between thumb and index finger and insert the adapter tip into one nostril while occluding the other nostril with a finger, then press the adapter cartridge firmly to release one measured dose of medication.
- Repeat the above steps as ordered for the other nostril.
- Instruct the client to keep head tilted backward for 2 to 3 minutes and to breathe through the nose while the medication is being absorbed.

PROCEDURE 29-10

Instilling an Ear Medication

Equipment

- Medication administration record (MAR)
- Cotton-tipped applicator
- Cotton balls

- Medication
- Nonsterile gloves
- Tissue

Action

1. Check with client and chart for any known allergies.
2. Check the MAR against the health care practitioner's written orders.
3. Wash your hands.
4. Calculate the dose.
5. Use the identification armband to properly identify the client.
6. Explain the procedure to the client.
7. Place the client in a side-lying position with the affected ear facing up.
8. Don nonsterile gloves.
9. Straighten the ear canal by pulling the pinna down and back for children or upward and outward for adults (Figure 29-35).

Rationale

1. Prevents the occurrence of hypersensitivity reactions
2. Ensures accuracy in identification of the medication.
3. Reduces the transfer of microorganisms.
4. Ensures the administration of the correct dose.
5. Ensures correct client.
6. Enhances cooperation.
7. Facilitates the administration of the medication.
8. Decreases contact with body fluid.
9. Opens the canal and facilitates introduction of medication. The external ear structures of adults and children are different. If the ear canal is not straightened properly, medication may not reach the deep inner ear structures.

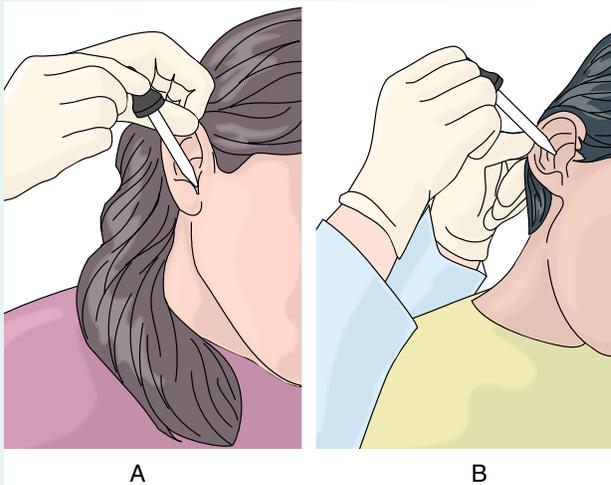

Figure 29-35 To instill eardrops, position client on the side. A. For an adult, pull the pinna up and outward. B. For a child, pull pinna down and back.

10. Instill the drops into the ear canal by holding the dropper at least 1/2 inch above the ear canal.
11. Ask the client to maintain the position for 2 to 3 minutes.

10. Prevents injury to the ear canal.
11. Allows for distribution of the medication.

(continues)

PROCEDURE 29-10

Instilling an Ear Medication (continued)*Action*

12. Place a cotton ball on the outermost part of the canal.
13. Wash hands.
14. Document the drug, number of drops, time administered, and the ear medicated.
15. Evaluate the condition of the skin in the outer ear between instillations.

Rationale

12. Prevents the medication from escaping when the client changes to a sitting or standing position.
13. Reduces the transmission of microorganisms.
14. Documenting the actions of the nurse will reduce the number of medication errors.
15. Determines possible skin reaction.

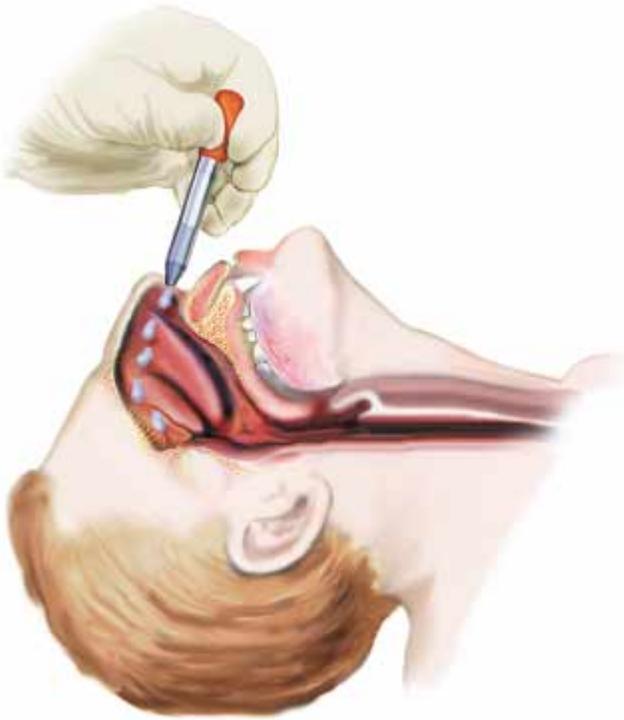

Figure 29-36 Positioning a Client for Nose Drop Instillation

When the client is discharged with a nasal inhaler, the nurse should teach the client how to store and use the device.

Teach Use of Respiratory Inhalants

Respiratory inhalants are delivered by devices that produce fine droplets that are inhaled deep into the respiratory tract. These medication droplets are absorbed almost immediately through the alveolar epithelium into the bloodstream. This chapter addresses only oropharyngeal hand-held inhalers. See Chapter 28 for general anesthetic inhalants and Chapter 31 for a complete discussion of oxygen.

Oropharyngeal hand-held inhalers deliver medications that produce both local and systemic effects, such

as bronchodilators and mucolytics. Bronchodilators improve airway patency and are used to prevent or treat bronchospasms, asthma, and allergic reactions. Mucolytics are used to liquify tenacious (thick) bronchial secretions. There are three types of oropharyngeal hand-held inhalers: metered-dose inhaler, turbo-inhaler, and the nasal inhaler (previously discussed).

Clients must be able to form an airtight seal around the inhaling devices and be able to assemble the turbo-inhaler. This requirement prevents some clients, such as clients with visual or coordination impairments, from using these devices. Bronchodilators are contraindicated in clients who have a history of tachycardia.

The nurse should ensure that the client knows how to use the inhaler correctly so that the prescribed medication dose is delivered. See Procedure 29-12 for teaching a client how to use a metered-dose inhaler.

A metered-dose inhaler delivers a measured dose of the medication with each push of the canister. The nurse needs to evaluate the client's ability to adequately compress the inhaler to deliver a full dose and to inhale at the same time as the dose is expressed. Failure to do either could prevent the client from receiving the full benefit of the inhaler. The ability to compress the inhaler for dose delivery can be affected by hand strength (which diminishes with age), flexibility (as in arthritic changes), and disease related to weakness (such as chronic respiratory disease). Careful discharge instructions and observation of the client performing the task are important to continued therapeutic effect at home (see the accompanying display for home care application).

Rectal Instillations

Rectal instillations can be in the form of enemas, suppositories, and ointments. See Chapter 39 for a complete discussion of enema administration. Rectal ointments are used to treat local conditions and

PROCEDURE 29-11

Instilling Nose Drops

Equipment

- | | |
|--|---------------------|
| ■ Medication administration record (MAR) | ■ Nonsterile gloves |
| ■ Medication with dropper | ■ Tissue |
| ■ Emesis basin (optional) | |

*Action**Rationale*

- | | |
|---|---|
| <ol style="list-style-type: none"> 1. Check with the client and chart for any known allergies. 2. Check the MAR against health care practitioner's written order. 3. Wash hands. 4. Check client's identification armband. 5. Explain the procedure to the client and provide privacy. 6. Instruct client to blow nose unless contraindicated by client condition (such as recent nosebleed). 7. Explain that the client may feel a burning sensation to the mucosa or a choking sensation, or both, as the drop trickles back into the throat. 8. Place the client in a supine position and hyperextend the neck. Position the head to the site that facilitates the drops' reaching the expected site, as shown in Figure 29-36. 9. Instruct the client to breathe through his or her mouth. 10. Squeeze some medication into the dropper. 11. Insert the nasal drops about 3/8 inch into nostril, keeping the tip of the dropper away from the sides of the nares. Instill the prescribed dosage of medication and observe the client for signs of discomfort. 12. Instruct the client to remain supine for 5 minutes. 13. Discard any unused medication remaining in the bottle. 14. Return the client to a comfortable position and provide the client with the emesis basin and tissue to expectorate any medication that flows into the oropharynx and mouth. 15. Remove gloves and wash hands. 16. Record on the MAR the drug given, number of drops instilled, and nostril medicated. 17. Observe the patient for side effects for 30 minutes after administration. | <ol style="list-style-type: none"> 1. Prevents the occurrence of hypersensitivity reactions. 2. Ensures accuracy in identification of medication. 3. Reduces transfer of microorganisms. 4. Accurately identifies client. 5. Reduces anxiety and enhances collaboration. 6. Removes mucus and secretions that might block medication absorption. 7. Understanding what to expect reduces anxiety and enhances cooperation. 8. Proper position provides access to passages and helps medication reach the appropriate site. 9. Helps prevent aspiration of drops into the lungs. 11. Prevents contamination of the dropper. 12. Prevents medication from leaking out of the nose prematurely. 13. Prevents contamination of medication in the the dropper. 14. Restores client comfort. 15. Reduces spread of microorganisms. 16. Provides documentation that the medication was given. 17. Drugs given onto the mucosa can be systemically absorbed, causing an adverse reaction. |
|---|---|

PROCEDURE 29-12

Teaching Self-administration with a Metered-dose Inhaler

Equipment

- | | |
|--|-------------------------------------|
| ■ Medication administration record (MAR) | ■ Wash basin or sink to rinse mouth |
| ■ Inhaler | ■ Tissue (optional) |
| ■ Nonsterile gloves | |

Action

1. Check with the client and the chart for known allergies or medical conditions that would contraindicate the use of the drug.
2. Gather necessary equipment.
3. Check the MAR against written health care practitioner orders.
4. Wash your hands.
5. Follow the five rights of medication administration. Check the client's identification band.
6. Review with the client the purpose of each prescribed medication.
7. Allow the client to hold and manipulate the canister. Explain how the canister fits into the inhaler. Have the client demonstrate insertion of the canister.
8. Explain metered-dose concept to client, and discuss frequency of prescribed medications.
9. Explain that the inhaler must be shaken before each use.
10. Remove the mouthpiece and cap from the bottle and insert the stem into the small hole on the flattened portion of the mouthpiece.
 - Client should grasp the inhaler with thumb and first two fingers.
11. Instruct the client to exhale, place the mouthpiece into the mouth, and ensure that the lips form a tight seal around the mouthpiece (Figure 29-37A).
12. Instruct the client to firmly push the cylinder down against the mouthpiece only once (Figure 29-37B), while slowly inhaling until the lungs feel full.
13. Ask the client to remove the mouthpiece while holding breath for about 10 seconds and then to exhale slowly through pursed lips.

Rationale

1. Prevents occurrence of adverse reactions.
2. Promotes efficiency.
3. Ensures accuracy in identification of medication.
4. Reduces the transmission of microorganisms.
5. Ensures correct client.
6. Some clients have several inhalants ordered and need to be taught the correct sequence. For example, fast-acting bronchodilators (albuterol sulfate) are taken before slower acting bronchodilators (ipratropium bromide).
7. Nurse can assess client's ability to manipulate inhaler, and client can become more comfortable with task.
8. Client needs to understand dangers of overuse related to adverse reactions.
9. Medication must be mixed with aerosol propellant to ensure correct dosage of medication.
 - Proper hand position facilitates use of the inhaler.
11. Tight seal prevents escape of medication.
12. Releases the medication; as client inhales medication is distributed into the airway.
13. Allows the medication to reach the alveoli.

(continues)

PROCEDURE 29-12

Teaching Self-administration with a Metered-dose Inhaler (continued)

Action

Rationale

A.

B.

C.

Figure 29-37 Self-administration with a Metered-dose Inhaler. A. Insert mouthpiece into mouth, forming a tight seal with the lips. B. Push the cylinder down and inhale. C. Aerochamber and Nebulizer Medications

- If the client had difficulty coordinating the inhalation and medication dispensing, an aerochamber may be added (Figure 29-37C).
14. Repeat doses as ordered, waiting 1 minute between puffs.
 15. Inform client that a mouthwash can be used to remove the taste of the medication.
- An aerochamber provides dead space for the medicated mist while the client inhales slowly and deeply.
14. Allows for maximal absorption and effect of first dose before another is taken.
 15. Promotes client comfort.

(continues)

PROCEDURE 29-12

Teaching Self-administration with a Metered-dose Inhaler (continued)

Action

16. Show client how to wash the mouthpiece under tepid running water to remove secretions.
17. If two or more metered-dose medications are ordered, wait 5–10 minutes between inhalations or as specifically ordered by the health care practitioner.
18. Record on the MAR the drug's name, dose, date, and time of medication.
19. Observe for effectiveness of the medication and relief of client symptoms.

Rationale

16. Accumulation of medication around mouthpiece can interfere with delivery of next metered dose.
17. Drugs must be inhaled sequentially to maximize therapeutic effect.
18. Provides documentation that medication was given.
19. Evaluates effectiveness of medication.

APPLICATION: HOME CARE

Considerations for Use of Nasal Inhalers

- Provide the client with the manufacturer's directions for the specific type of inhaler, such as how to replace a medication cartridge for a nasal aerosol.
- Inhalers should be stored at room temperature.
- Aerosols are prepared under pressure and should not be punctured or placed in an incinerator.
- Instruct the client not to allow other people to use the inhaler.
- Caution the client about overuse that could cause a rebound effect, making the condition worse.
- Ensure that the client is knowledgeable about the expected and adverse effects of the drug. Some of these drugs do not produce therapeutic effects for several days, and some require 2 weeks of continuous use before the drug effects appear.
- Provide the client with a telephone number to call if assistance is needed.

symptoms such as pain, inflammation, and itching caused from hemorrhoids. Rectal suppositories are cone-shaped masses of substances designed to melt at body temperature and to produce the intended effect at a slow and steady rate of absorption.

Suppositories provide a safe and convenient route for administering drugs that interact poorly with digestive enzymes or have a bad taste or odor. They are also used to provide temporary relief for clients who cannot tolerate oral preparations: for example, to relieve nausea and vomiting. Suppositories are also used to induce relaxation, relieve pain and local irritation, reduce fever, and stimulate peristalsis and defecation in clients who are constipated.

Rectal suppositories are contraindicated in cardiac clients because insertion may stimulate the vagus nerve,

causing cardiac dysrhythmias (abnormal heart patterns). These drugs are also avoided in clients recovering from rectal or prostate surgery because they may cause pain on insertion and trauma to the tissues.

The nurse should assess the rectum for irritation or bleeding and check sphincter control. Some clients may experience problems in retaining the suppository. The nurse should instruct such a client to remain in the Sims' position for at least 15 minutes or should place the client on the abdomen, if the condition allows, and hold the buttocks closed. The health care practitioner should be notified when the client is unable to retain a suppository so that another route can be ordered.

Suppositories are often stored in the refrigerator to preserve the integrity of the drug form. A softened suppository is difficult to insert; to harden a suppository, place it under cold running water while it is still in its original wrapper. The nurse should follow the five rights of medication administration and Standard Precautions when administering rectal instillations. See the Procedure 29-13 for the procedure on inserting a rectal suppository.

Vaginal Instillations

Medications inserted into the vagina are in the form of suppositories, creams, gels, ointments, foams, or douches. These medications may be used to treat inflammation, infections, and discomfort, or as a contraceptive measure.

NURSING ALERT

Tampon Use

Clients should be instructed not to use tampons after the insertion of vaginal medications because the tampon can absorb the medication and decrease the drug's effect.

PROCEDURE 29-13

Administering a Rectal Suppository

Equipment

- | | |
|---|---------------------|
| ■ Medication administration record (MAR) | ■ Nonsterile gloves |
| ■ Prescribed rectal suppository | ■ Tissue |
| ■ Water-soluble lubricant (such as K-Y jelly) | ■ Bedpan (optional) |

Action

Rationale

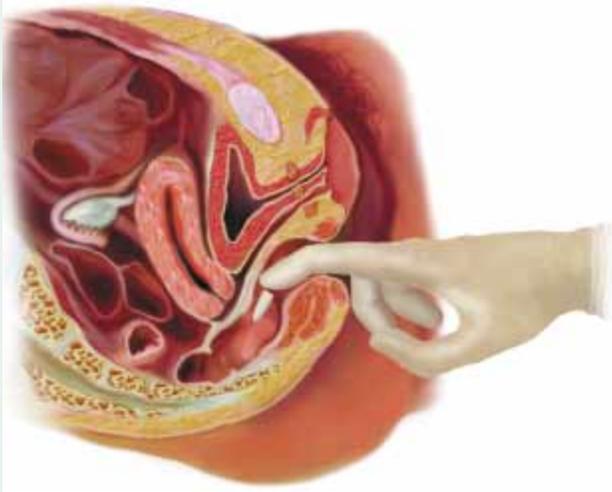

- | | |
|--|--|
| <ol style="list-style-type: none"> 1. Check with client and the chart for any known or medical conditions that would contraindicate use of the drug. 2. Gather necessary equipment. 3. Check MAR against written health care practitioner orders. 4. Wash your hands 5. Check the client's identification armband. 6. Ask client if he or she needs to void. 7. Explain procedure to client. 8. Don nonsterile gloves. 9. Place the client in the Sims', left-lateral position, with the upper leg flexed. 10. Fold back the bed linen to expose the rectum. 11. Open the package of lubricant and remove the foil wrapper from the suppository. Read the manufacturer's instructions on the wrapper for the recommended time interval the client should retain the suppository after insertion. 12. Apply a small amount of lubricant to the smooth rounded end of the suppository to reduce mucosal irritation. Lubricate the gloved index finger. 13. Instruct the client to breathe through the mouth. 14. Insert the suppository into the rectal canal beyond the internal sphincter, about 4 inches (10 cm) for an adult and 2 inches (5 cm) for a child (Figure 29-38). Avoid inserting the suppository into feces. 15. Withdraw the finger and wipe the anal area with tissue. 16. Instruct the client to remain in bed for 15 minutes and to resist urge to defecate. 17. Remove gloves, turning them inside out; dispose of gloves; wash hands. | <ol style="list-style-type: none"> 1. Prevents occurrence of adverse drug reaction. 2. Promotes efficiency. 3. Ensures accuracy in identification of the medication. 4. Reduces the transmission of microorganisms. 5. Ensures correct client. 6. Client will have to remain in bed after insertion of suppository. 7. Enhances cooperation. 8. Decreases contact with body fluids. 9. Exposes anus and helps rectal sphincter relax. 10. Provides privacy. 11. Manufacturer's instructions provide important information as part of the instructions for the client. 12. Lubricant facilitates insertion and reduces friction or pain as the suppository is inserted into rectum. 13. Relaxes sphincter and reduces chance of pain. 14. Prevents the suppository from slipping out. Suppository must be placed next to mucosa to facilitate absorption and enhance therapeutic action of the drug. 15. Provides comfort. 16. Allows medication to be absorbed and prevents expulsion of the suppository. 17. Reduces transmission of microorganisms. |
|--|--|

(continues)

PROCEDURE 29-13

Administering a Rectal Suppository (continued)

Action

Rationale

Figure 29-38 Administering a Rectal Suppository

- | | |
|--|--|
| <p>18. Record on the MAR the name of the drug, dosage, route, and time of administration.</p> <p>19. Observe for effect of suppository after administration.</p> | <p>18. Provides documentation that medication was given.</p> <p>19. Evaluates effectiveness of medication.</p> |
|--|--|

Vaginal creams, gels, or ointments usually come with a disposable tubular applicator with a plunger to insert the drug. Standard Precautions are always used by the nurse when inserting suppositories. Body temperature causes the suppository to melt and be absorbed. Suppositories are usually inserted with the index finger of a gloved hand; however, small suppositories may come with an applicator and the suppository is placed in the applicator's tip. Many clients prefer to insert their own vaginal suppository. In this case, provide privacy for the client. See Procedure 29-14 for the procedure on instilling a vaginal suppository. After insertion of these preparations, the client may notice drainage and should be informed that this is expected. If a suppository is given to treat infection, tell the client that the drainage may be foul smelling. The nurse should advise the client to wear a perineal pad to prevent soiling of the underpants.

Sterile technique is usually required by agency policy, especially if there is an open wound when administering a vaginal douche (irrigation). Douches are ordered to apply antimicrobial solutions, to remove offensive or irritating discharge, to reduce inflammation, and to prevent hemorrhage with warm or cold irrigations. The nurse should ensure that the client does not have an allergy to iodine because many vaginal preparations contain povidone-iodine.

Complementary Therapy

The practice of healing has always incorporated the use of herbs as medicines. The World Health Organization recognizes that of 119 plant-derived pharmaceutical medicines, about 74% are used in modern medicine in ways that are correlated directly with their traditional uses as plant medicines by native cultures (Goldberg, 1999). An estimated 25% of all pharmaceuticals are derived directly from plants (White & Foster, 2000): for example, quinine (an extract from the South American *cinchona*) is used to treat malaria; digitalis, which comes from foxglove, is an inotropic drug used to treat congestive heart failure; the active components of periwinkle, vinblastine and vincristine, are used in the treatment of certain cancers (Cassileth, 1998).

Herbal medicine, also known as botanical medicine or, in Europe, as phytotherapy or phytomedicine, refers to the use of a plant or plant part to make medicine, food flavors, or aromatic oils for soaps and fragrances. An herbal medicine can come from a leaf, a flower, a stem, a seed, a root, a fruit, bark, or any other plant part. Herbs are often used to season foods (culinary herbs) or to maintain or restore health (medicinal herbs).

The traditional use of herbs was based on trial and error. The process of discovery produced both positive

|---|--|

and negative results since many herbs contain poisonous substances that counteract the main ingredients for which they might be taken (Cassileth, 1998). **Pharmacognosy** (the study of the biochemical aspects of natural products) seeks to standardize herbal products so that they consistently include the same amount of

active ingredients and are free of any harmful components that the plant may contain.

Herbs are classified by the U.S. government as dietary supplements (vitamins, minerals, enzymes, hormones, amino acids, and other nutritional products). Congress passed the Dietary Supplement Health and Educational

NURSING CARE PLAN**The Client with Deep Vein Thrombosis****Case Presentation**

Mrs. Landry, a 45-year-old, was admitted to your floor with a diagnosis of deep vein thrombosis. The client noticed swelling of her left leg about a week ago but decided to treat it at home. Four days later, the lower leg was very edematous, warm, and painful to move. After an office visit, the client was admitted to the hospital. This is Mrs. Landry's first hospitalization. On examination you find that the left leg is warmer than the right. The left thigh circumference is 3 inches larger than the right. The physician ordered a heparin IV drip after a loading dose bolus was given. The drip contained 10,000 units heparin in 500 ml of D5W at 10 ml/h (200 units/h). The physician anticipates that Mrs. Landry will be weaned off of the heparin drip and started on subcutaneous heparin within 5 days. At the time of discharge she will be given coumadin.

Assessment

- Edematous left thigh
- Left leg warmer to touch than right
- Left thigh circumference 3 inches larger than right

Nursing Diagnosis #1

Ineffective Tissue Perfusion related to the development of venous thrombi in the deep femoral vein.

Expected Outcomes

The client will:

1. Report an absence of pain.
2. Demonstrate an absence of edema.
3. Experience the same degree of skin temperature in both legs.

Interventions/Rationales

1. Maintain on bed rest.
Reduces the possibility of embolus; may decrease the pain and swelling.
2. Elevate the legs above the heart.
Elevation facilitates venous return and decreases the edema.
3. Measure the circumference of the left thigh and compare with that of the right thigh.
Measuring the circumference provides a quantitative reference point that can be used to evaluate the swelling.
4. Apply moist heat to the affected extremity.
Heat provides an analgesic effect; it decreases venospasms and pain.
5. Administer the heparin drip at 200 units/h.
Heparin prevents the conversion of fibrinogen to fibrin and prothrombin to thrombin, thereby limiting the extension of the thrombus.
6. Monitor the partial thromboplastin time (PTT).
The partial thromboplastin time is used to monitor heparin therapy because heparin, a short-acting anticoagulant, increases the PTT.

Nursing Diagnosis #2

Injury, Risk for, bleeding related to the administration of an oral anticoagulant.

Expected Outcomes

The client will:

1. Not demonstrate evidence of bleeding from gums or nose, in urine or stool, or under the skin.
2. Maintain the prothrombin time (PT) or international normalized ratio (INR) within therapeutic range.

(continues)

NURSING CARE PLAN

The Client with Deep Vein Thrombosis (continued)

Interventions/Rationales

1. Advise the client to withhold the medication in the event that bleeding occurs and to notify the physician immediately. *The dose may need to be adjusted.*
2. Encourage the client to discontinue smoking. *Smoking has a tendency to increase the metabolism of the medication necessitating an increase in the dose.*
3. Advise the client to watch food intake. *Foods high in fat and foods rich in vitamin K can interfere with the PT.*
4. Warn against taking oral contraceptive medication. *There may be a decrease in anticoagulant effect due to the increased production of clotting factors with oral contraceptives.*
5. Warn against taking aspirin and other over-the-counter medications. *Aspirin may increase the risk of bleeding; it inhibits platelet formation.*

Evaluation

Resolution of the signs and symptoms of deep vein thrombus is a measurement of success. The client will be able to ambulate without difficulty, and the swelling, temperature difference, and pain will disappear. The client will be knowledgeable about taking the oral anticoagulant on discharge. Discharge follow-up will be needed to monitor the client's progress on the oral anticoagulant.

Act of 1994 (DSHEA) and “grandfathered” most botanical products as a new class of products known as dietary supplements. Although dietary supplements are not regulated by the FDA, product labeling of herbal medicines is restricted to structure and function claims. Manufacturers can indicate on a product label how the herb can affect a normal body structure or function, but promotional material and packaging cannot claim to treat or prevent a disease. For example, a product label for ginkgo can say “increases microcirculation in the brain,” but it cannot say “cures early-stage Alzheimer’s” or “alleviates tinnitus” even though there is research to support the effectiveness of standardized ginkgo extracts in the treatment of these diseases.

Herbs and supplements are regulated by other organizations such as the American Botanical Council (ABC), the American Herbal Products Association (AHPA), and the Natural Nutritional Foods Association (NNFA). The ABC promotes the safe and effective use of medicinal plants by educating the public, government agencies, research institutions, industry, and the media on the scientific research that can guide decisions about producing and consuming herb-based products that benefit health and well-being. The AHPA is a group of herbalists, researchers, and manufacturers that created a code of ethics that members adhere to and releases product safety alerts regarding adulteration—that is, contamination with an unlabeled substance—of herbal products. The AHPA publishes the *Botanical Safety Handbook*, a reference on the safe and effective use of herbs. The NNFA is a group of manufacturers and retailers concerned with product quality and truth in packaging and advertising. The NNFA supports a True Label Program to ensure that products produced by its members actually contain what their labels claim.

It is estimated that 1 out of every 3 Americans uses one or more herbal products (White & Foster, 2000). Although herbal medicines generally have fewer and far milder side effects than drugs, problems can arise if they are used improperly or in combination with drugs. Nurses need to know which herbs can alter the activity of certain drugs. For example, garlic and ginkgo may increase the effects of blood thinners, whereas goldenseal, Oregon grapefruit, and barberry may counteract short-acting blood thinners. Refer to Chapter 14 for additional information on the safe, effective use of herbal medicines.

EVALUATION

The nurse is responsible for the ongoing evaluation of the client's response to medication. This evaluation requires knowledge of the therapeutic action of drugs and of the side effects and adverse reactions that can occur. Changes in a client's health status can change the way a client responds to medications. For example, clients who develop renal failure do not excrete medications well, and medications can build up within their system. Nurses need to assess for changes in clients' responses to medication. Nurses in the community setting need to evaluate their clients' ongoing ability to manage their own medication regimens. They can discuss the regimen with the client and the family, observe client technique (as in self-administration of injections), and take physiological measures such as blood pressure readings. The nurse uses all information gathered through any source as a way of determining if the intended interventional outcomes are met.

The nurse who identifies a potential medication risk and initiates actions to prevent client injury is perform-

ing another form of evaluation. For example, if the client in the home setting cannot remember if the prescribed medications have been taken, providing the client with a daily or weekly pill box that is filled when the nurse is present prevents the client from taking too much medication or failing to take the dose as ordered.

KEY CONCEPTS

- The *United States Pharmacopeia and National Formulary* outline drug standards for usage in the United States.
- The Food and Drug Administration tests all drugs for toxicity before granting a company the right to market a drug.
- Drugs are usually referred to by their trade (company) or generic (nonproprietary) name.
- The oral administration route is the safest and least expensive administration route, although it is also the slowest to act.
- Parenteral drugs are injected through intradermal (ID), subcutaneous (SC or SQ), intramuscular (IM), or intravenous (IV) routes and are typically fast-acting drugs.
- The pharmacokinetics of drugs includes absorption, distribution, metabolism, and excretion.
- Safe drug administration is facilitated by following the five rights: right drug, right dose, right client, right route, and right time.
- Nurses are both morally and legally responsible for correct administration of medications; this includes following institutional policy, considering clients' desires and abilities, fostering compliance, and correctly documenting all actions related to medication administration and medication errors.
- Drug abuse is a common problem, both in society and in the health care professions; nurses have a responsibility to report addicted colleagues so that they can find resources to help overcome their addictions.
- Before administering medications, the nurse must thoroughly assess the client's drug history, medical history, and psychosocial factors that may affect drug acceptance and compliance.
- Oral medications should be poured and measured at eye level to ensure accuracy.
- Although the health care practitioner will determine the dose and route of a parenteral drug, the nurse is responsible for choosing the correct gauge and length of the needle to be used.
- The nurse must always carefully monitor client reactions to medications and ensure that clients are appropriately educated as to the actions, side effects, and contraindications of all medications they are receiving.

CRITICAL THINKING ACTIVITIES

1. Mrs. Adams is a 76-year-old client being discharged from the hospital with cancer of the lungs. Mrs.

Adams elected not to have surgery and was given her first chemotherapy before discharge. She is not accustomed to taking medications. Before the onset of symptoms that necessitated her admission to the hospital, Mrs. Adams considered herself in good health, only bothered with the discomfort of arthritis in her hands. She is being discharged on the following medications:

- Sulfamethoxazole (sulfonamide anti-infective) 500 mg/5 ml susp PO b.i.d.
- Ganisetron (antiemetic) 1 mg PO q12h
- Morphine 30 mg PO q4h, prn for pain

Describe the nursing interventions that should be included in Mrs. Adams's discharge teaching relative to medication self-administration and other appropriate nursing actions.

2. A client receiving doxycycline, a tetracycline, 100 mg PO daily should avoid which of the following food groups?

Group A	Group B	Group C
Beef liver	Almonds	Aged meat
Brussels sprouts	Buttermilk	Avocados
Cabbage	All cheese	Caffeine
Oils	Pizza	Chicken liver
Kale	Yogurt	Cola drinks
Arugula	Ice cream	Raisins
Spinach	Milk	Soy sauce

3. The health care practitioner writes the order for the client to drink 2 L/24 h. How should the nurse explain this volume of liquid to the client?
4. How would you solve the following problem? The health care practitioner wrote the following medication order: Dilantin 100 mg, PO, t.i.d. In the process of preparing the medication, the nurse noticed that the medication was available in 50-mg tablets only. To calculate the correct dosage the nurse used the following formula:

$$\frac{\text{Dose ordered}}{\text{Dose on hand}} \times \text{Amount on hand} = \text{Amount to administer}$$

$$\frac{100 \text{ mg}}{50 \text{ mg}} \times 1 \text{ tablet} =$$

5. A health care practitioner orders Tylenol PO for an elevated temperature. The child weighs 22 lb (10 kg). The body surface area is 0.30 m². The normal adult dose is 325 mg. Use the nomogram to calculate the following problem.

$$\text{Child's dose} = \frac{\text{Surface area of child}}{1.7 \text{ m}^2} \times \text{Adult dose}$$

$$\text{Child's dose} = \frac{0.30 \text{ m}^2}{1.7 \text{ m}^2} \times 325 \text{ mg} =$$

Chapter 30

Responding to the Needs of the Perioperative Client

Life's not just living, it's living in health.

—Guterman (1960)

COMPETENCIES

1. Discuss the three phases of the perioperative experience in relation to the client's expected outcomes and the major functional roles of the nurse.
2. Assess the physiological, psychological, social, cultural, spiritual, and age-related aspects of the perioperative client's health status.
3. Recognize sociocultural and ethical factors that affect decision making in planning care with the perioperative client.
4. Demonstrate an awareness of age-related functions and values when assessing and teaching clients.
5. Plan, implement, and evaluate the nursing care outcomes for perioperative clients in various health care settings.
6. Document nursing interventions that achieve the individualized expected outcomes for perioperative clients.
7. Describe essential components of discharge teaching for the perioperative client.

KEY
TERMS

anesthesia
arthroplasty
continuous passive motion
(CPM) device
Cullen's sign
extubation
incentive spirometers
intraoperative

intubation
lock-out interval
malignant hyperthermia
patient-controlled analgesia
(PCA)
perioperative
pneumatic compression
device

postoperative
preoperative
pulse oximeter
transcutaneous electrical
nerve stimulation (TENS)
urgency

Periodic **perioperative** refers to the management and treatment of the client during the three phases of surgery: preoperative, intraoperative, and postoperative. The three perioperative phases are designated by time intervals, interventions, and settings, using the word roots of *pre*—before; *intra*—during, and *post*—after. **Preoperative** (before surgery) refers to the time interval that begins when the decision is made for surgery until the client is transferred to the operating room (OR). The **intraoperative** (during surgery) phase begins when the client is transferred to the OR and ends with client transfer to a postanesthesia care unit (PACU). When the client leaves the OR and is taken to a PACU, the **postoperative** (after surgery) phase begins; this phase continues until the client is discharged from the care of the surgeon.

Changes have occurred in perioperative services as a result of advances in technology (such as lasers) and limited resources such as cost-containment measures in health care. These changes have challenged health care providers to be more responsive and cost-effective in delivering perioperative services.

Surgery is a major source of a hospital's income. Although major surgical interventions still occur in the hospital setting, the 1980s introduced a trend to perform surgery in ambulatory settings. Many of the services of the hospital's perioperative departments are now performed in outpatient settings. This change has had a positive impact on decreasing health care costs related to surgery. At the same time, health care providers are challenged to work in greater collaboration to decrease the client's length of stay in the hospital, increase satisfaction with the services, and prevent complications.

Ambulatory surgery clinics (free-standing facilities) also began in the 1980s as an outgrowth of federally regulated reforms from the Health Care Financing Administration (HCFA). HCFA's goal in health care reform was to decrease inpatient costs of services. Except for inpatient hospitalization, ambulatory surgery clinics provide all the services offered by hospitals.

In 1989, HCFA developed a listing of urgent and elective surgeries that require preauthorization for Medicare clients. Preauthorization means the surgery must be approved before surgery is performed to ensure that Medicare and other third-party payers will reimburse the facility for incurred surgical costs.

SURGICAL INTERVENTIONS

Surgery is performed to correct an anatomical or physiological defect or to provide therapeutic interventions. Surgeries are categorized according to the degree of **urgency** (timely intervention of surgery):

1. Emergency surgery requires immediate intervention to sustain life.
2. Urgent surgery dictates intervention as necessary to maintain health in situations that are not life-threatening.
3. Elective surgery is usually performed at a time convenient to the client, with the delay presenting no physiological harm.

Once the degree of urgency is established, the reason for performing the surgical intervention is categorized according to the expected outcome (see Table 30-1).

TABLE 30-1
Surgical Interventions Based on Expected Outcomes

Intervention	Expected Outcome
Diagnostic/exploratory	Determine the origin of presenting symptoms and extent of a disease process (e.g., biopsy)
Reconstructive	Correct a disease process or improve cosmetic appearance (e.g., arthroplasty and rhinoplasty)
Curative	Repair or remove a diseased organ or restore normal physiologic functioning (e.g., amputation or aneurysm repair)
Palliative	Decrease the spread of the disease process to prolong life or to alleviate pain (e.g., colostomy or partial tumor removal)
Transplant	Remove diseased tissue or organ and replace with functioning tissue or organ (e.g., kidney)

In a true emergency, saving the client's life is the primary goal. Stat blood work, including a type and cross-match, is performed while the client and the operating room are prepared for the surgery. Urgent and elective surgeries allow the client and physician time to discuss the setting and scheduling of the surgery.

SETTING

Ambulatory care centers and physician offices are the usual settings for minor surgical procedures, such as removal of skin lesions and laparoscopy for inspection and biopsy. Outpatient surgery areas (one-day surgery centers or free-standing ambulatory clinics) provide the client and physician with alternative services for urgent and elective surgeries.

Outpatient surgical units focus on the needs of the client and strive to expedite the rendering of services with a preadmission visit. Preauthorization documents for Medicare or third-party insurance payers should be processed and approved before the preadmission visit.

During the preadmission visit, the nurse and anesthesiologist perform the preoperative assessment and initiate teaching. Diagnostic tests are performed in the outpatient surgical unit as opposed to the traditional process of having a client go to the various hospital departments for testing. Performing diagnostic testing in this fashion promotes a sense of caring for the client's needs and decreases the preadmission time.

On the day of surgery, clients who have been preadmitted go directly to an outpatient surgical unit, where they are prepared for surgery. Family members are encouraged to remain with the client while the client awaits transfer to the operative area.

Perioperative care is initiated for the hospitalized client when the decision is made for surgery. The client is reassessed and the nurse collaborates with the client in planning the care. Client and family teaching is begun as soon as possible to allow time to reinforce the teaching.

Preparing a client for a surgical procedure requires the collaboration of many professionals. Specific role responsibilities focus on assessment, client and family teaching, and interventions to promote client achievement of expected outcomes.

PERIOPERATIVE MANAGEMENT OF CARE

Effective perioperative management is directed by a multidisciplinary team in accordance with recognized standards of care and individualized expected client outcomes. Institutional protocol, which defines how procedures will be performed, is initiated in the preoperative phase and continues throughout the other phases.

Each member of the health care team (surgeon, anesthesiologist, and nurse) has a specific role and responsi-

bility toward the perioperative client. Collaboration between all health care providers is essential in planning client care. "Collaboration means that people with different areas of expertise are working as equals to define issues, design solutions, and achieve high quality outcome" (Rubenfeld & Scheffer, 1999, p. 352).

Surgeon Responsibilities

Physicians are credentialed by health care facilities to perform surgery. The surgeon is the primary physician the nurse communicates with regarding client care needs. Before surgery, the surgeon:

- Determines the need for the surgical intervention on the basis of the client's medical diagnosis and findings from the medical history and physical examination
- Determines the surgical setting in collaboration with the client
- Orders diagnostic tests only if directly correlated to the procedure or client diagnosis (see the accompanying display)
- Obtains client's consent for the surgical procedure
- Teaches the client about the outcomes and risks of the procedure

COMMON DIAGNOSTIC TESTS

- Urinalysis
- Complete blood count (CBC)
- Prothrombin time (PT) and partial thromboplastin time (PTT): Clients with known or suspected coagulation defects or to establish baseline information
- Chemistry profile: Clients with diseases that can alter electrolytes
- Electrocardiogram (ECG)
- Human immunodeficiency virus (HIV) testing: In accordance with agency policy
- Chest x-ray films: Clients over age 60 years, smokers, or those scheduled for general anesthesia

A major role function of the surgeon is *explaining and documenting evidence that the client understands the nature of the surgical procedure, the risk factors, and expected outcomes of the surgery*. This is done with a surgical consent form, the client's written permission to allow the surgeon to provide surgery. Many states, through statutory provisions, require physicians to perform and document client teaching. Once the client demonstrates understanding, the client signs the form, giving permission for the specific surgical intervention.

Anesthesia Provider Responsibilities

The anesthesia provider (anesthesiologist or certified registered nurse anesthetist) actively participates in each perioperative phase. The main role of the

anesthesia provider is to ensure client safety relative to the administration of anesthesia. The anesthesia provider:

- Obtains informed consent for anesthesia services
- Performs a preanesthesia evaluation that includes a thorough history, such as complications from previous anesthesia, and physical examination (American Association of Nurse Anesthetists [AANA], 1999a)
- Selects anesthetic agents
- Teaches the client regarding the anesthetic medications, their side effects, and risk factors
- Performs **intubation** (the insertion of an endotracheal tube into the bronchus through the nose or mouth to ensure an airway) and **extubation** (the removal of an endotracheal tube)

Most surgical procedures have predetermined anesthetic agents based on policy; if there is a variance from the norm, the anesthetist seeks agreement with the surgeon. The decision to use particular anesthetic agents is based on the client's health status, the surgical procedure, and anticipated duration of the surgery.

During the client interview, the anesthesiologist inquires about previous anesthesia experiences that can place the client at risk such as connective tissue abnormalities that suggest the presence of the autosomal dominant malignant hyperthermia (MH) gene. **Malignant hyperthermia** is a potentially lethal syndrome caused by a hypermetabolic state that is precipitated by the administration of certain anesthetic agents, for example, succinylcholine. When appropriate and feasible, medical records from previous surgeries are reviewed as part of the preanesthesia examination.

Nurse Responsibilities

The Association of periOperative Registered Nurses (AORN), formerly called the Association of Operating Room Nurses, promotes quality client care through the development of guidelines and standards of nursing practice. AORN has also developed the Perioperative Nursing Data Set (PNDS) to standardize nursing terminology regarding the perioperative client experience from preadmission until discharge to promote evidence-based practice. The PNDS is the first nursing language developed by a specialty organization that has been recognized by the American Nurses Association.

Perioperative nurses perform critical functions that vary with specific surgical procedures and the unique needs of individual clients to achieve positive client outcomes (Parker, Mimick, & Kee, 1999). Rubenfeld and Scheffer (1999) identified three guiding principles for implementing care based on professional standards: maintain client safety; provide effective care; and provide care as efficiently as possible. These principles are incorporated into each phase of the perioperative standards of nursing practice.

The nurse coordinates the client's care in a timely fashion to ensure safety and avoid surgical delays. Activities include:

- Scheduling the diagnostic tests
- Verifying that all the necessary documents (e.g., signed consent form) are on the client's medical record
- Reporting abnormal diagnostic results to the surgeon. Depending on the test results, treatment may be instituted to correct any abnormalities or the surgery may be canceled

A major part of the nurse's time is spent in preparing and teaching the client. Preoperative teaching is structured to provide planned educational activities to presurgical clients or family (significant others) according to assessed anxiety and fear levels, as discussed later in this chapter.

As technology becomes more sophisticated and health care resources become more limited, ethical issues have become more complex (Schroeter, 1999). Ethical dilemmas are inherent in perioperative nursing such as lack of respect for the client's dignity, withholding information or lying to clients, inadequate consents, incompetent health care providers, and do-not-resuscitate (DNR) orders. These issues have implications for the management of care in perioperative settings. Schroeter (1999) studied the aspects of informed consent and the impaired or incompetent colleague in the perioperative practice setting, and determined that perioperative nurses can accurately identify ethical situations occurring in the environment and that the majority of the participants reported that they would take action. The ethical competency of perioperative nurses is paramount to ensure that safe, competent, and ethical care is provided to all surgical clients.

ANESTHESIA

Anesthesia means the absence of pain. Anesthetic agents render a person insensible to pain during surgical, obstetric, and therapeutic or diagnostic procedures. Anesthesia requires a balancing of several agents to provide sedation, analgesia, muscle relaxation, and anesthesia for procedures of varying complexity. The types of anesthesia and their effects are listed in Table 30-2.

General Anesthesia

General anesthesia refers to the drug-induced state of analgesia, amnesia, muscle relaxation, and unconsciousness. General anesthesia represents a critical experience for surgical clients. The needs of these clients require that perioperative nurses possess knowledge of the basic principles of general anesthesia.

TABLE 30-2
Effects of Anesthetic Agents

Type of Anesthesia	Effects
General anesthesia	<p>Expected result Total unconscious state, placement of a tube into the trachea</p> <p>Technique Intravenous injection or inhalation</p> <p>Risks Mouth or throat pain, hoarseness, injury to mouth or teeth, awareness under anesthesia, injury to blood vessels, aspiration, pneumonia</p>
<i>Regional Anesthesia</i>	
Spinal or epidural analgesic/anesthesia	<p>Expected result Temporary decreased sensation or loss of feeling and movement to lower part of the body</p> <p>Technique Drug injected through a needle or catheter placed either directly into the spinal canal (spinal or subarachnoid) or immediately outside the spinal canal (epidural)</p> <p>Risks Headache, backache, buzzing in the ears, convulsions, infection, persistent weakness, numbness, residual pain, injury to blood vessels, complete spinal</p>
Major/minor nerve block	<p>Expected result Temporary loss of feeling or movement of a specific limb or area</p> <p>Technique Drug injected near multiple nerves or a plexus (major) or into or around a nerve or small nerve group (minor) providing loss of sensation to the area of the procedure</p> <p>Risks Infection, convulsions, weakness, persistent numbness, residual pain, injury to blood vessels</p>
Intravenous regional anesthesia	<p>Expected results Temporary loss of feeling and movement of an extremity</p> <p>Technique Drug injected into veins of arms or leg while using a tourniquet</p> <p>Risks Infection, convulsions, persistent numbness, residual pain, injury to blood vessels</p>

(Adapted with permission from the American Association of Nurse Anesthetists. [1999b]. *Informed consent in anesthesia*. Park Ridge, IL: Author.)

INHALATION GENERAL ANESTHETIC AGENTS

Volatile Liquids

- Halothane (Fluothane, Somnothane)
- Methoxyflurane (Penthrane)
- Enflurane (Ethrane)
- Isoflurane (Forane)

The common routes for administering general anesthetics are inhalation and parenteral; other routes used less frequently are oral and rectal. Inhalation agents are administered in the form of gases or as vapors of volatile liquids through an anesthesia delivery system and a face mask or endotracheal tube. Commonly used inhalation agents that can produce all of the elements of general anesthesia are listed in the accompanying display; these agents are absorbed by the lungs. Nitrous oxide (compressed gas) is both absorbed and eliminated by the lungs, whereas the percentage of volatile liquids varies in their excretion between the lungs and kidneys.

COMMON INTRAVENOUS AGENTS USED FOR GENERAL ANESTHESIA

- Barbiturates: methohexital sodium, thiamylal sodium, thiopental sodium
- Benzodiazepines: diazepam and midazolam
- Narcotics: alfentanil hydrochloride, fentanyl, and sufentanil citrate
- Neuromuscular blocking agents: atracurium bresylate, doxycarium chloride, gallamine triethiodide, metocurine iodide, mivacurium chloride, pancuronium bromide, pipecuronium bromide, succinylcholine chloride, tubocurarine chloride, and vecuronium bromide

Although anesthesia is administered parenterally, it takes several intravenous drugs to produce all of the elements of general anesthesia. Injectable agents used for induction or maintenance of anesthesia are from one of the following drug classifications: barbiturates, benzodiazepines, narcotics, and neuromuscular blocking agents. See the accompanying display for common drugs for each of these classifications.

Barbiturates provide a rapid induction of short duration and are therefore used for invasive diagnostic and obstetric procedures and minor surgery. When barbiturates are contraindicated, other short-acting agents are used: ketamine or a nonbarbiturate drug (etomidate or propofol). Neuromuscular blocking agents produce muscle relaxation required for select surgical procedures; these drugs vary in their duration of action.

The client's individualized plan for balanced anesthesia may involve the concurrent or sequential use of many agents. For instance, thoracic muscle relaxation that is required for lung surgery can be provided by intravenous administration of a neuromuscular blocking agent. During the surgery, various types of vapors and gases may also be administered with oxygen to provide anesthesia. For abdominal surgery, muscle relaxation can be achieved by injecting a local anesthetic into the cerebrospinal fluid; after the abdominal anesthesia level is established, a short-acting barbiturate may be infused to provide general anesthesia during the surgical procedure.

Although the incidence of drug toxicity in anesthesia is rare, clients need to be informed about these inherent risk factors. General anesthetic agents can induce anaphylactic reactions; the incidence is 1:4,500, with a mortality rate of 6%, according to Khrais and Ouellette (1995).

Regional Anesthesia

The increased use of balanced anesthesia for surgical procedures has made it increasingly important for perioperative nurses to be knowledgeable about regional and local anesthetic agents. Regional anesthesia blocks nerve impulse conduction to a specific area or region of the body to decrease intractable pain or to produce an anesthetic field without the loss of consciousness.

An analgesic/anesthetic state is obtained by injecting a local anesthetic solution along a specific nerve path (see the accompanying display for a list of commonly used local anesthetic agents). Regional anesthesia can be administered with or without sedation (refer to Table 30-2 for the various techniques used in administering regional anesthesia).

Local Anesthesia

Local anesthesia refers to use of an anesthetic agent that disrupts sensation at the nerve endings. The two techniques used for administering local anesthesia are topical and infiltration. Topical anesthesia is the direct application of local anesthetics to tissues in the form of ointments, lotions, solutions, or sprays. After the use of oral anesthetic solutions (e.g., viscous lidocaine), *fluids and foods must be withheld until the gag reflex returns.*

Infiltrate anesthesia refers to intradermal, subcutaneous, or submucosal injection to provide a circumscribed area of anesthesia. This technique provides a local nerve block that is used for suturing lacerations or extracting teeth.

COMMONLY USED LOCAL ANESTHETIC AGENTS

- Bupivacaine hydrochloride (Marcaine, Sensorcaine)
- Chloroprocaine (Nesacaine, Nesacaine MPF)
- Etidocaine hydrochloride (Duranest)
- Lidocaine hydrochloride (Xylocaine)
- Mepivacaine hydrochloride (Carbocaine, Polocaine)
- Procaine hydrochloride (Novocain)
- Tetracaine hydrochloride (Pontocaine)

PREOPERATIVE PHASE

The primary goal of preoperative nursing care is to place the client in the best possible condition for surgery through careful assessment and thorough preparation. Assessment of the client's status before surgery establishes baseline data to direct interventions throughout the perioperative phases. Each member of the health care team has identified functions relating to the assessment of the client's physiological, psychological, social, cultural, and spiritual status. *The findings from the client's assessment must be documented throughout the surgical experience.*

Assessment

Assessment of the perioperative client includes a nursing history and physical examination. A complete assessment is performed on the outpatient client during the preadmission visit. On the day of surgery, the nurse conducts a focused assessment to ensure current, accurate data.

During the assessment process, the nurse evaluates the client's level of anxiety and fear. Bulechek and McClosky (1995) describe these feelings:

- Anxiety is a vague, uneasy feeling whose source is often nonspecific or unknown to the client.
- Fear is a feeling of dread related to an identifiable source that the client validates.

Anxiety also has well-defined physiological changes, such as an increased heart rate, clammy hands, muscular tension (especially in the neck muscles), and behavioral manifestations, such as rapid speech and irritability.

Nursing History

The perioperative nursing history provides information relative to factors that can increase a client's risk or influence the expected surgical outcomes. Pertinent data are obtained from the client interview: medical history including family history of anesthesia complications (malignant hypertension); medications; allergies; age-related factors; social, cultural, and spiritual concerns; and psychologic status. See Chapter 6 for more details.

Nurses should conduct the interview in a quiet room, free from background noise. Many elderly clients have some degree of high-tone hearing loss (Eiseman, 1996), so it is necessary to speak in a strong, clear voice.

Clients who have difficulty comprehending the surgical procedure should have a responsible family member present during the interview. A third person can help clarify precisely what the nurse said and can interpret such instructions to other family members.

Medical History

The nurse reviews the client's medical record. The surgeon's history and physical findings provide pertinent data regarding the reasons for surgery. If the client was previously hospitalized, the nurse obtains the previous medical records to have available on the nursing unit. Hospitalization records are reviewed to gain an overview of the client's health status because preexisting medical conditions can increase the client's surgical risks.

During the interview, the nurse questions the client regarding past illnesses and the main reason for seeking surgical treatment. The client is asked to describe prior surgeries and their dates. Any complications from a previous surgery or anesthesia should be recorded.

It is important to note if the client has had prior blood transfusions or reactions. At this time the nurse can ascertain whether the client has objections to receiving blood or blood products or has made arrangements for blood replacement. Some clients prefer to donate their own blood in advance so that it can be held in reserve if the need for it arises during surgery. Family members or friends may also donate blood to decrease the cost to the client.

Medications

During the nursing history, the nurse needs to assess exactly what drugs the client has been taking. The client's response to questions about the use of alcohol, tobacco, "street drugs," prescription, over-the-counter drugs, and herbs should be documented because these substances have surgical implications.

DRUGS THAT PLACE SURGICAL CLIENTS AT RISK

- Aspirin: May increase bleeding
- Antidepressants: May lower blood pressure during anesthesia
- Bromide in medications (e.g., Sominex): Can accumulate and produce signs and symptoms of dementia
- Drugs with anticholinergic effects: Increase the potential for confusion
- Steroids: Suppress immunity
- Nonsteroidal anti-inflammatory medications: Increase the risk of stress ulcers and displace other drugs from blood proteins

Certain prescription drugs (antihypertensives, tranquilizers, steroids, and diuretics) can increase the client's anesthesia risks. Clients with chronic diseases are likely to be taking numerous medications that can cause complications during the perioperative period (see the accompanying display).

Herbs

Question clients regarding their use of herbal products and supplements as part of the preoperative assessment. Certain herbal products and supplements may place the client at risk if taken before surgery such as *Ephedra sinica* (Chinese ephedra or Ma Huang), St. John's wort, and Feverfew.

Ephedra can produce the same side effects of ephedrine such as increased blood pressure and heart rate, insomnia and anxiety. St. John's wort is used widely as a mild to moderate antidepressant because of its ability to inhibit monoamine oxidase (MAO). MAO inhibitors may interact with various types of anesthetic agents. Feverfew inhibits platelet aggregation and may affect the client's clotting time.

Although some herbal products may place the client at risk during surgery, other herbs such as *Bromelain* can reduce healing time and pain following various surgical procedures. Bromelain is obtained from the pineapple plant and refers to a group of sulfur-containing enzymes that digest protein (proteolytic enzymes or proteases). Murray (1995) addresses a double-blind study of persons undergoing oral surgery; bromelain reduced edema, inflammation, and pain when taken preoperatively.

Allergies

Allergies and sensitivities to foods, drugs, or other substances should be documented on the assessment record. Of special importance is questioning the client about allergies to iodine. Povidone-iodine, a common antiseptic, is used to prepare the skin for surgery. The nurse places a note regarding the client's allergies on the front of the chart to alert perioperative team members.

Age-Related Considerations

Age-related considerations are critical aspects of assessment (Eiseman, 1996). The client's age and developmental stage can influence the ability to cope with surgery. Age-related factors can also influence existing health care problems and the client's response to surgery. For instance, infants are at risk during surgical interventions because their physiological functions are immature. The infant's ability to respond to stress is also altered.

Morbidity and mortality rates for surgical clients over the age of 90 are much higher than for those in the 70 to 75 age group (Hogstel, 2001). Older clients may be fearful of death, especially if this is their first hospitalization or surgery. The risk of surgery for many older clients is complicated by chronic disease processes; more than 100,000 clients over 65 years of age die

postoperatively each year (Corey-Plett, 1995). Age-related risk factors for the older adult should be assessed on an individual basis. Hogstel (2001) contends that age should no longer be a major factor in deciding whether or not surgery should be performed to prolong life or to provide comfort for elderly clients. When elderly clients are adequately prepared for a noncomplicated surgical procedure, they can tolerate many types of surgeries as well as younger clients (Cory-Plett, 1995; Hogstel, 2001). However, studies have shown that, when elderly clients are subjected to emergency surgeries or long, complicated surgeries, their decreased ability to adapt to physical and psychological stress may have a negative surgical outcome (Eiseman, 1996). Since 50% of all emergency surgeries are on clients over 65 years of age (Eiseman, 1996), nurses need to provide psychological support to assist the elderly client in coping with the stress of surgery.

Social and Cultural Considerations

Data relative to the client's social and cultural orientation are incorporated into care. These data assist the nurse in selecting appropriate teaching methods. Many facilities provide interpreters to prevent language from being a communication barrier.

Cultural beliefs can influence a client's perception of surgery. Listen to a client's concerns expressed during the interview. Surgeries that cause changes in body image can alter self-esteem. The client may worry about being sexually attractive or active after surgery. The nurse may initiate discussion regarding sexual outcomes of surgery; encourage the client to verbalize fears in order to increase adaptive coping.

Spiritual Considerations

Clients must be provided the opportunity to express their spiritual values and beliefs. Religious beliefs are discussed and incorporated into the client's plan of care. A client may ask to see a member of the clergy before surgery. The beliefs of the client should be respected. The client has the right to refuse certain

types of interventions. For example, some religions do not allow the administration of blood products as treatment. When the client indicates that religious beliefs prevent blood administration, the health care team should identify alternative methods of treatment and discuss these with the client during the preoperative phase. Collaborating with the client preoperatively helps prevent ethical dilemmas from arising during the other perioperative phases in the event that the client loses a large quantity of blood.

Psychosocial Status

A psychosocial evaluation is conducted with the client and family by assessing their degree of understanding and anxiety regarding the surgical procedure (see the accompanying display). Assess the client's knowledge of the surgical procedure and the expected surgical outcomes. It is important that the client express agreement with the surgical plan of care.

ASSESSMENT QUESTIONS: PSYCHOSOCIAL STATUS

- Why are you having surgery?
- When did this problem start?
- What do you think caused this problem?
- Has this caused any problems with your relationships with others?
- Has your problem prevented you from working?
- Are you able to take care of your own needs?
- Are you experiencing any discomfort or pain?
- What are you expecting from this surgery?
- Is there anything that you do not understand regarding your surgery?
- Are you worried about anything?
- Will someone be available to assist you when you return home?

Physical Assessment

The nurse assesses the client's physiological health status by performing either a partial or a complete physical examination. The decision to conduct a partial or complete physical depends on the client's health status relative to the surgical procedure, the setting, and the amount of time available to gather pertinent data.

The nurse in an outpatient setting, on the day of surgery, usually performs a partial examination. The client's medical record should be reviewed to ensure that a complete nursing physical was conducted during the preadmission visit. The nurse should focus on obtaining pertinent assessment data to establish baseline parameters for prioritizing the client's care. The client's neurologic assessment is integrated throughout the interview and physical examination.

THINK ABOUT IT

Responding to Client Altered Self-Image

As a student nurse, how can you assist the client in verbalizing fears about alterations in body image that have sexual implications? A 30-year-old woman is admitted for removal of a cancerous breast. Her mother died at age 30 from breast cancer. The client has been married for 5 years and has a 3-week-old infant. Her husband is with her. You have to admit and interview the client for the nursing history. How would you approach the medical diagnosis? Would you feel comfortable helping this client verbalize her fears?

General Survey

Observe the client's condition starting with the initial contact. For instance, if the client walks into the unit, observe and note the client's gait; note if assistance is needed with ambulation. Does the client need assistance when transferred to a bed? When shaking the client's hand, note the strength and sensation of the hand grasp and the skin temperature. Coldness of the hand may indicate impaired circulation.

During the interview, assess the level of consciousness and orientation. Does the client respond appropriately to your questions? Observe for signs of hearing impairment or loss of vision. Note if the client is wearing glasses.

Head and Neck

While talking with the client, assess if eye contact is maintained. Note the color of the sclera and inspect for drainage from the eyes. Inspect the general condition of the scalp, noting alopecia or seborrheic dermatitis. Inspect the oral cavity, check for any loose teeth, and assess the tongue and mucous membranes (note color and moisture). Observe the client's lips and tongue (especially if client has a history of cardiac disease). Note if the client has dentures.

Inspect the neck and verify the strength of the carotid pulses, one at a time; palpate jugular veins for distension. If the client is a child or has cancer, palpate the cervical lymph nodes. Assess for range of motion.

Upper Extremities

Palpate the client's brachial and radial pulses bilaterally; note the rate and character of each pulse. Check the capillary refill. Assess the skin; note the temperature, texture, and integrity. Assess for range of motion.

Anterior and Posterior Chest and Abdomen

Inspect and palpate the chest wall, noting the breathing pattern and expansion of the chest wall. Auscultate heart sounds and listen to anterior and posterior breath sounds; note crackles, gurgles, or wheezing.

Inspect the abdomen for distension and listen for bowel sounds in all four quadrants. Palpate the abdomen for rigidity, enlarged organs, or rebound tenderness.

Lower Extremities

Assess the length and position of each leg. Palpate the bilateral strength of femoral, popliteal, and pedal pulses, noting the rate and character of each pulse. Assess the skin; note the temperature, texture, integrity, and the presence of edema. Check the capillary refill. Inspect the bony prominences of the ankles and feet. Assess for strength and sensation by having the client bend the leg and push the foot against your hand. Assess for range of motion. Clients scheduled for spinal anesthesia should be assessed for gross motor function and strength.

NURSING ALERT

Spinal Anesthesia

Spinal anesthesia causes temporary paralysis of the lower extremities. Preoperative weakness or impaired movement of the lower extremities should be reported to nurses caring for clients recovering from spinal anesthesia; postoperatively this report prevents the recovery nurse from making the wrong decisions when full motor function fails to return.

The nurse documents on the medical record and communicates to the health care team all significant assessment data. This information establishes baseline parameters to direct decision making throughout the perioperative phases.

Nursing Process Highlight

ASSESSMENT

Mrs. Broussard, 69, was admitted to an outpatient surgical unit for a total hip replacement (**arthroplasty**). The surgeon explained the surgical procedure during her last office visit. Preauthorization has been granted for the surgery. Diagnostic testing, a comprehensive history and physical examination, and postoperative exercise instructions were performed during the preadmission visit. Mrs. Broussard has been suffering for 10 years with chronic degenerative arthritis. She has experienced increasing pain and loss of mobility in her left hip for the past 6 months.

- In collecting data from Mrs. Broussard during the focused assessment, what types of information are essential for the development of a plan of care for her on the day of surgery?
- Which baseline data should be obtained from Mrs. Broussard during the partial physical examination?
- What further data should be collected at this time?

Diagnosis

The nurse formulates nursing diagnoses based on an analysis of assessment data and the nature of surgery. Physical assessment findings are compared against diagnostic test results; for example, cardiovascular findings are analyzed with blood chemistry and ECG results.

Selection of the most appropriate nursing diagnosis should focus on the specific perioperative phase (see the accompanying display). The diagnosis may be pertinent to all three perioperative phases or to one or more phases.

For instance, as described in the Nursing Process Highlight, Mrs. Broussard is experiencing pain that is caused from the degenerative changes in the hip joint as a result of arthritis. Although the surgeon will remove the diseased joint, Mrs. Broussard will continue to experience pain. In fact, the pain may worsen for several weeks postoperatively (Barrows, 1995). The most appropriate diagnosis for Mrs. Broussard is *Pain*. Preoperatively, the pain is related to the degeneration of the hip joint; postoperatively, the pain is related to swelling at the surgery site.

Common nursing diagnoses for the preoperative client are *Deficient Knowledge* related to the surgery, *Anxiety*, and *Fear*. Clients and families view the perioperative experience differently on the basis of prior experiences and coping skills (Bulechek & McCloskey, 1995). Some clients are threatened; others consider the experience to be a challenge. Some clients are highly anxious, whereas others experience a moderate degree of anxiety. Besides the primary threat of surgery, clients also have to deal with separation from family and loss of independence.

Associated nursing diagnoses address the client's pre-existing health condition. For instance, an associated diagnosis for Mrs. Broussard is *Impaired Physical Mobility* related to musculoskeletal impairment. This nursing diagnosis would be initiated preoperatively and throughout the perioperative experience.

Outcome Identification and Planning

The nurse develops goals with client-focused expected outcomes based on relevant nursing diagnoses. Nurses collaborate with other health care team members and the client in establishing the goals and outcomes. The overall goal is to protect the client from injury related to anesthesia and surgery. The plan of care directs the selection of specific nursing interventions that promote the client's achievement of expected outcomes, for example, client teaching.

The current health care system challenges the perioperative nurse to be responsive to surgical clients who may enter and exit the health care setting at various points and with different experiences (Bulechek & McCloskey, 1995). Some clients are admitted to the hospital the day of surgery, some the evening before; some have surgery as an outpatient. Some clients with general anesthesia may be discharged the day of surgery.

Discharge planning needs are incorporated into the plan of care on admission. The following considerations are included in discharge planning:

- Psychosocial and spiritual support systems and community resources
- Financial aspects of the illness
- The degree of illness or disability
- Rehabilitation
- Preventive care
- Client teaching needs

Some clients need the services of a home health agency on discharge. The perioperative nurse usually coordinates home care with the social worker.

Implementation

Preparing the client for surgery requires the nurse to perform multiple interventions within specific time constraints. However, the nurse must remain responsive to the client's needs, demonstrating a caring attitude (see Figure 30-1). Documentation tools are available to assist the nurse in providing safe, timely preoperative care (e.g., the consent form and preoperative checklist). Active planning and intervention are necessary to reduce the risk for complications (Eliopoulos, 1999).

Surgical Consent Form

Although surgeons are responsible for obtaining informed consent, nurses should verify that consent has been obtained before treatment begins. Consent is given only for the extent of action documented on the informed consent. Nurses can identify problems with consent when the client:

- Cannot explain the procedure or identify the risks
- Signed the form more than 30 days before surgery
- Had an unauthorized person sign the consent form
- Did not sign the consent form

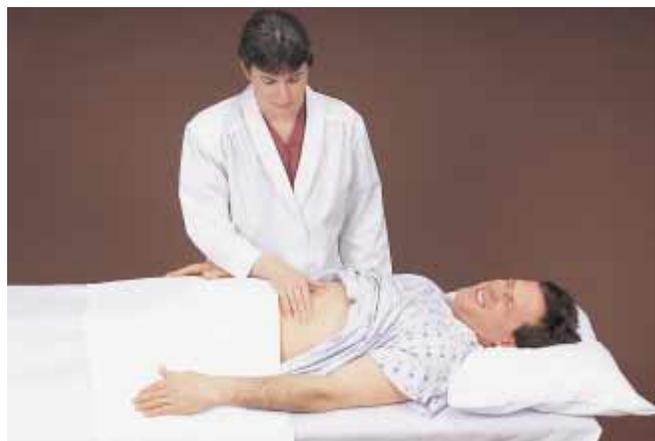

Figure 30-1 The nurse prepares a client for surgery. While the nurse was performing preoperative assessment, the client demonstrated pain through facial expression. What implications might the client's pain have on the surgery? What actions should the nurse take, considering the potential effects on the client's perioperative experience?

PERIOPERATIVE NURSING DIAGNOSES

Preoperative Phase

Deficient Knowledge related to:

- Nature and purpose of the surgical procedure
- Preoperative preparation to decrease postoperative risks

Anxiety related to:

- Deficient knowledge of a new experience
- Inherent risk factors of the surgical procedure and anesthesia

Fear related to:

- The unknown
- Effects of surgery on economic and employment status

Intraoperative Phase

Risk for Perioperative Positioning Injury related to:

- Sensory/perceptual disturbances due to anesthesia
- Edema

Risk for Injury related to:

- Physical (equipment or sponge count)
- Environmental
- Positional

Risk for Infection related to:

- Invasive procedure
- Imbalanced nutrition

Hypothermia related to:

- Exposure to cool environment
- Decreased metabolic rate

Postoperative Phase

Ineffective Airway Clearance related to:

- Anesthesia (diminished cough reflex)
- Increased pulmonary congestion

Ineffective Breathing Pattern related to:

- Pain
- Decreased energy/fatigue

Ineffective Tissue Perfusion (Cardiopulmonary) related to:

- Anesthesia
- Position or immobility

Deficient Fluid Volume related to:

- Active fluid volume loss
- Inadequate fluid intake

Imbalanced Nutrition: Less Than Body Requirements related to:

- Anesthesia
- Surgical manipulation of intestines

(continues)

PERIOPERATIVE NURSING DIAGNOSES (continued)

Urinary Retention related to:

- Anesthesia
- Surgical manipulation of the bladder

Acute Pain related to:

- Surgical incision

Risk for Infection related to:

- Impaired skin integrity from surgical wound
- Deficient knowledge of wound or drainage tube care

Situational Low Self-Esteem related to:

- Altered body image, effects of surgery
- Dependence on others during recuperation from surgery

(From North American Nursing Diagnosis Association. [2001]. *Nursing diagnoses: Definitions & classification*. 2001–2002. Philadelphia: Author.)

The nurse should notify the surgeon in the event that any problems with consent are identified.

If the surgeon proceeds without appropriate consent, nursing administration should be notified and the nurse should make personal notations outside the medical record. This practice protects the nurse should the situation be brought to court. If the client reverses a decision and decides against surgery, the nurse is obligated to inform the surgeon in order to prevent unwanted treatment.

Preoperative Checklist

A checklist is a form that allows the nurse to insert a checkmark (✓) beside symptoms or to fill in one or two words in answer to a cue or a question. Although some variations exist in how agencies format the preoperative checklist, the forms usually have similar content. Nursing activities are usually designated by time intervals: “night before surgery” and “day of surgery.” Time designations help to prevent surgical delays that can increase the client’s anxiety and the agency’s costs. Table 30-3 presents a sample preoperative checklist.

Although clients in outpatient settings arrive the day of surgery, the nurse prepares the client’s medical record the day before for necessary documentation as itemized in Table 30-3. This preparation ensures that assessment, diagnostic tests, and teaching were done on the preadmission visit and allows time to obtain missing information and to assess the need for reinforcement or reevaluation as necessary.

On the day of surgery, the nurse focuses on the immediate physical interventions to prepare the client for surgery. While admitting and preparing the client for surgery, the nurse uses this time to encourage the client to

verbalize any concerns. Allowance should be made for family members or significant others to remain with the client as the client awaits transfer to the operating room.

Client Teaching

Most clients view surgery as a threatening and anxiety-provoking event (Bulechek & McCloskey, 1995). Client teaching reduces anxiety. The risks of surgical complications are decreased when the client knows what to expect and receives instruction in postoperative exercises (Lindeman & Van Aernam, 1971).

Teaching the client and family members (significant others) is the responsibility of the multidisciplinary team. The nurse verifies that the client or family member is able to describe, in his or her own words, the reason for the surgery, what will be done during the surgical procedure, the side effects of the anesthetic agents, and the possible complications of both the surgery and the anesthesia.

The nurse plays a major role in relieving the client's anxiety by facilitating communication between physicians and the client and family and by reinforcing teaching regarding preoperative care. The client's family should be involved in the teaching sessions. Table 30-4 presents an overview to perioperative teaching activities with the client's expected outcomes.

Teaching aids (videotapes and pamphlets) are resources for client instruction during the perioperative processes. The nurse selects teaching materials based on the client's ability to read and understand. The nurse provides accurate, consistent information throughout the teaching process. The teaching aids must reinforce the

verbal instructions of the nurse, anesthetist, and surgeon. Informational materials should explain what will happen in each of the perioperative areas (such as the holding area) to foster client cooperation. Refer to Chapter 13 for additional information on client teaching.

Types of Surgical Incisions

Nurses need to be knowledgeable about common surgical incisions to reinforce the surgeon's teaching and to answer the client's questions. Two main factors govern incisions: direction and location. Incisions may be vertical, horizontal, transverse, or oblique. Figure 30-2 illustrates and describes the location of common surgical incisions.

Postoperative Exercise Instruction

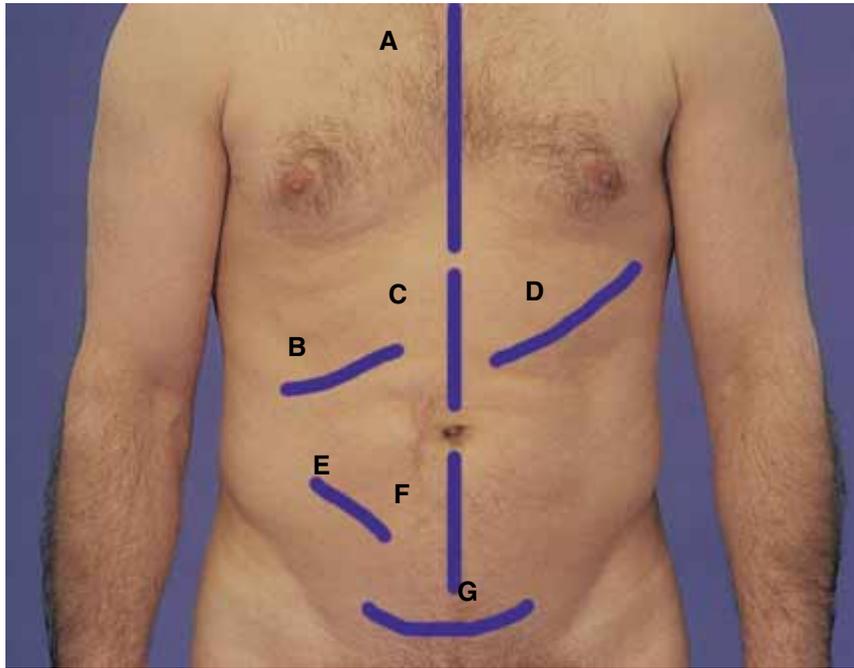

As early as 1941, nurses were challenged to participate in preoperative instruction (Bulechek & McCloskey, 1995). In 1983, Leventhal and his colleagues suggested that the effectiveness of existing preoperative instruction could be increased by assisting clients to assume self-regulation after surgery.

Preoperative teaching of postoperative exercises prepares the client physically and emotionally for the impending surgery (Bulechek & McCloskey, 1995; Eiseman, 1996). Language barriers, identified during assessment, are considered when teaching the client. The goal of instruction is to have the client demonstrate the performance of exercises while verbalizing why the exercises are used during the postoperative phase (Procedure 30-1).

Clients may experience their worst postoperative pain while coughing, deep breathing, and exercising. Clients with abdominal or chest surgery may avoid using muscles

TABLE 30-4
Preoperative Teaching Interventions and Expected Client Outcomes

Intervention	Expected Client Outcomes
Preparation activities	<p>The client can:</p> <ul style="list-style-type: none"> Describe in own terms the purpose, risk factors, and outcomes of surgery and anesthesia. Explain restrictions on food the evening before, identifying the time frame (6–8 hr) when no food and drink are allowed by mouth, NPO Explain the meaning and purpose of skin and bowel preps. Identify medications to be taken or omitted the day of surgery. Describe activities that will occur in each perioperative area: holding area, fluids will be started in a vein; position on the operating room table; stay in recovery until awake, then be transferred to an intensive care unit.
Postoperative exercise instructions	<ul style="list-style-type: none"> Demonstrate on two consecutive occasions postoperative exercises: deep breathing, coughing and pillow splinting, turning and proper body alignment; leg and foot exercises; and out-of-bed transfers.
Proper application and usage of medical devices	<ul style="list-style-type: none"> For example, demonstrate proper use of incentive spirometer, application of TED hose, and self-medicating pain infusion pump.
Physical or environmental changes following surgery	<ul style="list-style-type: none"> Demonstrate knowledge of the rehabilitation process: daily physical therapy for 2 weeks and a home health nurse for 10 days to administer prophylactic antibiotics and to monitor and refill the patient-controlled analgesia pump.

INCISION	LOCATION	ORGAN
A. Sternal Split	Begins at the top of the sternum and extends downward to the sternal notch.	Heart
B. Oblique Subcostal	Begins in the epigastric area and extends laterally and obliquely below the lower costal margin.	Right side: Gallbladder, Biliary Left side: Spleen
C. Upper Vertical Midline	Begins below the sternal notch and distally around the umbilicus.	Stomach, Duodenum, Pancreas
D. Thoracoabdominal	Begins midway between the xiphoid process and the umbilicus and extends across the seventh or eighth intercostal space, to the midscapular line.	Thorax, Heart
E. McBurney	Begins below the umbilicus, goes through McBurney's point, and extends toward the right flank.	Appendix
F. Lower Vertical Midline	Begins below the umbilicus, downward toward the symphysis pubis.	Bladder, Uterus
G. Pfannenstiel	Begins 1.5 inches above the symphysis pubis with a curved transverse cut across the lower abdomen.	Uterus, Fallopian tubes, Ovaries

Figure 30-2 Common Surgical Incisions

in the affected areas to take deep breaths or to cough effectively. Deep breathing and coughing facilitate removal of accumulated pulmonary secretions. Certain anesthetic agents depress the central nervous system, causing some clients to experience shallow respirations. Inhaled gases and oxygen have a direct drying effect on the respiratory mucosa, which increases the viscosity of mucus, making the secretions difficult to raise with coughing. These factors place the client at risk for respiratory complications (see the accompanying display).

To prevent respiratory complications, the nurse teaches clients to use a breathing technique in which the client turns, coughs, and deep breathes to achieve sustained max-

COMMON RESPIRATORY COMPLICATIONS AFTER SURGERY AND ANESTHESIA

- Pulmonary embolism: A blood clot that has moved to the lungs, causing pulmonary obstruction
- Atelectasis: Decreased ventilation caused from the pooling of secretions in dependent areas of the bronchiole
- Pneumonia: Inflammation of lung tissue
- Hypoxemia: Lowered oxygen level in the blood

PROCEDURE 30-1

Postoperative Exercise Instruction (continued)

Action

have the client grasp the pillow against the abdomen with clasped hands (see Figure 30-3).

- Have client take a deep breath and begin coughing immediately after inspiration is completed by bending forward slightly and producing a series of soft, staccato coughs.
- Have a tissue ready.

Figure 30-3 Splinting

10. Instruct the client on the use of an incentive spirometer (see Figure 30-4). Have the client:
 - Hold a volume-oriented incentive spirometer upright.

Figure 30-4 Incentive Spirometer

Rationale

muscles and reduces pain when coughing if the client has an abdominal incision.

- Removes secretions from the main bronchus.
- Provides a tissue for sputum disposal.

10. Reinflates the alveoli and removes mucus secretions.
 - Promotes proper functioning of the device.

(continues)

PROCEDURE 30-1

Postoperative Exercise Instruction (continued)

Action

- Take a normal breath and exhale, then seal lips tightly around the mouthpiece; take a slow, deep breath to elevate the balls in the plastic tube, hold the inspiration for at least 3 seconds.
 - The client simultaneously measures the amount of inspired air volume on the calibrated plastic tube.
 - Remove the mouthpiece, exhale normally.
 - Take several normal breaths.
 - Repeat the procedure four to five times.
 - Have the client cough after the incentive effort; repeat Step 9. Have a tissue ready.
 - Have client clean mouthpiece under running water and place in clean container (disposable mouthpiece changed every 24 hours).
11. The nurse explains leg and foot exercises (Figure 30-5).

Rationale

- Allows for greater lung expansion; holding the inspiration increases the pressure, preventing immediate collapse of the alveoli.
 - Encourages the client to do respiratory exercises.
 - Allows normal expiration.
 - Provides client the opportunity to relax.
 - Encourages sustained maximal inspiration and loosens secretions.
 - Facilitates removal of secretions.
 - Prevents transmission of microorganisms.
11. Elicits client cooperation.

PROCEDURE 30-1

Postoperative Exercise Instruction (continued)

Action	Rationale
15. Reverse instructions (use left side instead of right) for the client with a right-sided incision according to step 14.	15. Same as step 14.
16. Instruct clients with orthopedic surgery (e.g., hip surgery) how to use a trapeze bar.	16. Facilitates movement in bed without putting pressure on a leg or hip joint.

imum inspiration (SMI). SMI promotes the reinflation of the alveoli and the removal of mucus secretions.

Several devices help encourage clients to perform SMI exercises. The breathing devices, called **incentive spirometers**, measure the client's ventilatory volume and provide the user with a tangible reward for generating an adequate respiratory flow. Devices range from simple types, a Ping-Pong ball in a plastic tube, to sophisticated models (see Figure 30-4). When the client takes a deep breath, the ball moves upward and the amount of air is measured, making the results visible to the client.

Turning, deep breathing, coughing, and using spirometry prevent respiratory complications by:

- Promoting pulmonary circulation
- Promoting the exchange of gases by increasing lung compliance
- Facilitating the removal of mucus secretions from the tracheobronchial tree

Postoperatively the client is encouraged to move in bed and perform leg exercises as explained in Procedure 30-1. These exercises assist in preventing circulatory complications that can arise from anesthetic agents that depress the metabolic and heart rates; see the accompanying display. Early ambulation also increases respiratory function and the return of peristalsis.

COMMON CIRCULATORY COMPLICATIONS AFTER SURGERY AND ANESTHESIA

- Thrombophlebitis: Inflammation of a vein with the formation of a blood clot
- Thrombus: A blood clot in the circulatory system
- Embolus: A blood clot or air that moves in the circulatory system from its place of origin

Other Devices

Besides exercises, other devices are used to prevent postoperative circulatory complications, namely, antiembolism stockings and pneumatic compression. Another device, continuous passive motion (CPM),

increases range of motion for immobilized clients after surgery. The CPM device also stimulates healing of articular cartilage by reducing swelling and adhesions.

Pain is managed with devices such as transcutaneous electrical nerve stimulation (TENS) and patient-controlled analgesia (PCA). The client needs to be informed about the use of such devices preoperatively to promote achievement of postoperative pain outcomes. All medical devices require a physician's order.

Antiembolism Stockings

Antiembolism stockings are elastic hose that compress leg veins to facilitate the return of venous blood. Depending on the surgical site, these stockings can be applied either preoperatively (e.g., abdominal surgery) or postoperatively (e.g., cardiac catheterization).

Elastic stockings are available in a variety of lengths, colors, and sizes to accommodate specific needs. One type of hose goes from the foot to the knee; another type goes from the foot to midhigh. Some stockings have partial openings on the foot to expose either the toes or heel so that the nurse can assess circulation.

The physician usually specifies the size and style of the hose and the frequency of application. If the physician does not indicate the size, the nurse uses a tape to measure the circumference of the calf and thigh and the length of the client's leg from the heel to the gluteal furrow. Stockings are removed for 20 to 30 minutes three times a day to allow for assessment and hygienic care. Assessment should include inspection for redness, palpation for tenderness or increased temperature, and testing for Homans' sign.

NURSING TIP

Client Safety

Instruct the client with antiembolism stockings to wear slippers or shoes to avoid slipping.

Pneumatic Compression Device

A **pneumatic compression device** provides intermittent compression cycles to the veins of the extremities to promote circulation. The device consists of either vinyl surgical sleeves that slide over each calf or Velcro-secured vinyl compression hoses that are applied under the thigh and leg with a knee-opening site that is placed over each popliteal area (see Figure 30-7). Both types of vinyl appliances have tube connectors that attach to an air pump machine. Observe the client applying the stockings, connecting the tubes to the air pump, and setting the correct pressure.

The air pump has an on-off switch and a dial to set the desired pressure. Turning on the pump initiates compression cycles, which cause the vinyl sleeves to automatically inflate and deflate. The nurse assesses the circulation to the extremities and placement of the stockings every 2 to 3 hours. The stockings are removed three times a day for 20- to 30-minute intervals to allow for hygiene care. Instruct the client on how to clean the vinyl stockings by disconnecting the stockings from the air pump and wiping off with tepid, soapy water.

Continuous Passive Motion Device

The **continuous passive motion (CPM) device** increases range of motion and stimulates healing of the articular cartilage by decreasing swelling and the formation of adhesions. It is used for clients with a nursing diagnosis of either *Impaired Physical Mobility* related to the surgical intervention or *Altered Tissue Perfusion* related to surgical intervention and immobility. The goal is to increase tolerance to the CPM device. The expected client outcome is to maintain maximum mobility of the joint.

Before initiating CPM, the nurse:

- Assesses the client's neurovascular status (skin color and temperature, pulses, capillary refill, sensation, and movement) of the extremity
- Applies the disposable soft goods to the CPM device according to the manufacturer's instructions

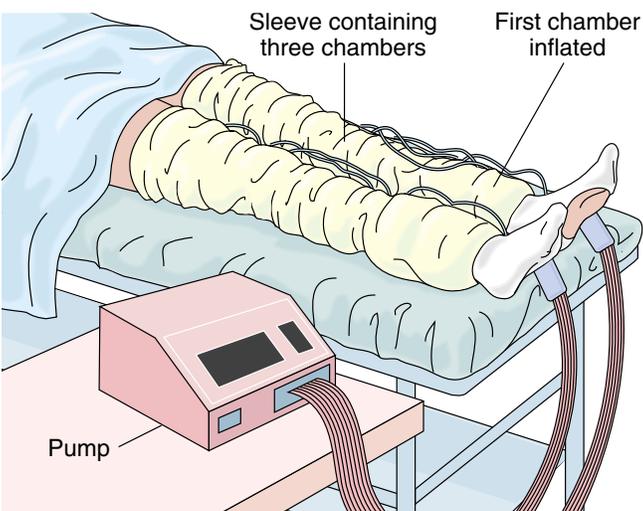

Figure 30-7 Pneumatic Compressed Device

NURSING CHECKLIST

Application of Antiembolism Stockings

- Wash hands and obtain the stockings, making sure the type and size are correct.
- Check the client's identification band.
- Show the client the stockings and explain the procedure to elicit cooperation. Make sure the client knows that the stockings are to be removed routinely and washed daily according to package directions.
- Provide for privacy. The client should be in a comfortable position to observe your technique while you apply one of the stockings.
- Wash, rinse, and dry the legs; stockings should only be applied to clean, dry skin.
- Talcum powder can be applied to the feet and legs to allow the stocking to move more easily over the skin.
- Turn the stocking inside out, except the foot portion.
- Place the foot of the stocking over the client's toes and on the foot; with your nondominant hand supporting the client's ankle, use your dominant hand to pull the heel pocket over the client's heel (see Figure 30-8).

Figure 30-8 When applying antiembolism stockings, support client's ankle while pulling stocking up.

- Slide the stocking up the leg, straightening as you apply; make sure that kinks and wrinkles are smoothed out to provide even pressure.
- Knee-length stockings should end 1 inch (2.5 cm) below the knees.
- If the stocking goes to midthigh, have the client flex the knee while you pull the stocking over the knee and thigh; the stocking should be 1 to 3 inches (2.5 to 7.5 cm) from the groin.
- The top of the stockings should not be folded over because additional constriction can occur.
- Have the client apply the other stocking, and assess the client's learning.
- Document client learning.

- Sets the machine to provide the degree of flexion and extension according to the physician's orders (e.g., 0° extension and 35° flexion)
- Adjusts the speed to control movement

When the device is readied, the client is positioned in the middle of the bed to accommodate the CPM unit. The nurse places the client's legs in the padded CPM device, making sure that the knees are at the hinged joint of the machine. The nurse measures the angle of flexion with a goniometer when the device has reached its greatest height. The client is taught how to operate the "go/stop" button and is instructed to report any discomfort or pain that occurs with motion.

Transcutaneous Electrical Nerve Stimulation Unit

A **transcutaneous electrical nerve stimulation (TENS)** unit controls pain by delivering electrical impulses to nerve endings that block the passage of pain signals from entering the

NURSING CHECKLIST

Instructing the Client on the Use of the TENS Device

- Place electrodes on the skin in the area of pain (e.g., on both sides of an incision).
- Connect the lead wires to the electrodes and portable battery-powered transmitter.
- Turn on and regulate for comfort by working with one lead at a time, beginning with a zero setting.
- Gradually increase the level of stimulation until the client feels discomfort, indicating that maximum stimulation has been achieved to block pain sensation; then reduce the volume slightly to prevent continued contraction of muscles.
- Repeat the same process with the other lead; this time allow the client to perform the actions.
- Ensure that the client knows to apply the electrodes to clean, unbroken skin.

Figure 30-9 Transcutaneous Electrical Nerve Stimulation (TENS) Unit

dorsal spinal root. The TENS unit is effective in reducing pain and the amount of pain medication required to maintain comfort after surgery. The unit consists of a transmitter, lead wires, and electrodes (see Figure 30-9).

Patient-Controlled Analgesia Pump

The **patient-controlled analgesia (PCA)** pump is a device that allows the client to control the delivery of intravenous or subcutaneous pain medication in a safe, effective manner. The client self-regulates the delivery of the medication. Several different types of PCA devices are available; the manufacturers provide instructions for setting up the infusion pump. The pain medication is contained within an infusion pump and set according to the physician's order: type and concentration of pain medication, loading dosage, and **lock-out interval** (minimum time allowed between doses for the client to self-medicate).

Before initiating the PCA pump, the nurse assesses the client's level of consciousness, orientation, reading ability, and ability to learn and comprehend. PCA is used most frequently in adolescents and adults. Family members are also taught how to recognize the signs of drug overdose in home-bound clients. Instruct the client on the PCA unit:

- To self-administer the medication as needed
- That the amount of the drug the machine delivers within a particular time frame is regulated to prevent overdose
- On the use of the control button

The advantages of a PCA unit are rapid pain relief, increased client satisfaction, and often the use of less medication than with the traditional intramuscular analgesia method.

Physical Preparation

Nursing activities related to the physical preparation of the client must be performed. These nursing functions are individualized to the client's needs as determined by health status and the type of surgical procedure scheduled. Activities such as restricting fluids, bowel preparation, or the removal of nail polish are done the evening before, regardless of the setting. Other activities occur the day of surgery in various perioperative settings.

Skin Preparation

The skin and hair follicles harbor microorganisms that can contaminate a surgical wound. The skin around the operative site is prepared to reduce the number of organisms present and to inhibit rebound growth. Preparation of the skin to reduce contamination of the surgical wound occurs in two phases. The evening before or the day of surgery, the client washes the area involved in the surgical procedure with an antimicrobial soap. The client is usually instructed to wash the surgical area vigorously several times to decrease the chance of wound infection.

Most agencies follow the recommendation of the Centers for Disease Control and Prevention (CDC) and the Association of periOperative Registered Nurses regarding the second phase. During the second phase, the skin is surgically prepared by removing hair in the operative site. The CDC and AORN recommend that this be done in the operating room. Shaving with a razor may cause cuts and nicks in the skin that promote the growth of microorganisms; therefore, performing this function immediately before surgery in the operating room, which is basically a controlled and germ-free environment, reduces the risk of wound contamination. Methods used to prep the skin are discussed in the intraoperative phase.

Nutrition

Nutrition and fluid considerations are determined by the client's health status and the nature of the surgical procedure and anesthesia. Clients scheduled for surgical procedures requiring only local anesthetic agents may be allowed a light breakfast or clear liquids the day of surgery. However, clients scheduled for regional or general anesthesia are instructed not to eat or drink (NPO) for 6 to 8 hours before surgery. Restricting food and fluids decreases the risk of aspiration of gastric contents into the lungs during anesthesia.

Clients at risk for dehydration are infants, the elderly, those with preexisting nutritional imbalances, and those having surgical procedures that cause extensive loss of blood and other body fluids. These clients are usually given intravenous fluids preoperatively to maintain fluid and electrolyte balances. Measurement of intake and output allows the nurse to monitor the client's fluid and electrolyte status.

Gastrointestinal Preparation

Gastrointestinal surgeries usually require special procedures to prepare the stomach or intestines.

Nasogastric Tube Some clients may require a nasogastric tube to facilitate stomach decompression to prevent postoperative abdominal distension. Insertion of a nasogastric tube causes client discomfort and can increase apprehension regarding surgery; therefore, the tube is usually inserted during the intraoperative phase when the client is under anesthesia. Inform clients that the tube can cause irritation to the nasal mucosa and may result in a sore throat.

Bowel Preparation The surgeon prescribes the type of bowel preparation on the basis of the surgical procedure. Enemas and laxatives are not routinely administered unless the client is having abdominal surgery. Intestinal surgeries require a bowel preparation to cleanse the intestines of fecal material by administering either a cathartic or enema to empty the bowel. Antibiotics are given to reduce the bacterial content. Cleansing the bowel is necessary because surgical manipulation of the intestines interrupts normal peristalsis. Also, incision of any portion of the gastrointestinal tract places the client at risk for peritonitis if fecal material enters the abdominal cavity.

The client is usually instructed to eat a light meal the evening before, avoiding high-fat foods, and is given a laxative. The morning of surgery, enemas may be given. If the surgeon orders "enemas until clear" (no fecal return), refer to the agency's policy. Administering enemas until clear can place the NPO client at risk for fluid and electrolyte imbalances. The client's stress response may already be compromised by the fear of surgery; administering repeated enemas may further decrease the client's coping mechanisms.

Urinary Elimination

The client is instructed to void before receiving the preoperative medication or being transferred to the operating room. The bladder needs to be empty to prevent distension and incontinence during the surgery.

Some surgeries can require continuous decompression of the bladder; the operating room nurse usually inserts a Foley catheter before or during surgery. See Chapter 39 for details on catheterization. If this occurs, the client should be informed about the catheter and how long the catheter will be left in place. Inform the client that a Foley catheter causes a sensation of pressure and an urge to urinate.

THINK ABOUT IT

Nursing Intervention

What should a nurse do if a client refuses a treatment? You are caring for a 16-year-old boy who was in an automobile accident and is scheduled for bladder surgery. The parents are present for perioperative teaching. You explain what will happen during the surgical procedure and that the boy will have a catheter after surgery. The boy gets upset, saying he does not want a tube. What type of age-related teaching materials might you use in this situation?

Safety Precautions

Outpatient clients are instructed to leave their jewelry at home and to avoid the use of makeup the day of surgery for safety reasons. Jewelry and other metal objects can cause burns when electrocautery is used during surgery. Rings can compromise circulation. Hairpins can injure the scalp when the head is positioned for anesthesia. Makeup and nail polish can interfere with the practitioner's assessment of oxygenation.

Unnecessary prosthetic devices should also be left at home to prevent client injury or loss. Outpatient areas have limited space to secure valuables. Contact lenses should always be removed and stored before surgery to avoid corneal ulceration and displacement. Partial dentures and other orthodontic devices must be removed to prevent displacement into the throat during anesthesia.

If the client feels helpless without certain devices, such as glasses and hearing aids, it should be documented on

the preoperative checklist that the client is wearing such devices. The operating room nurse removes such devices immediately before or after anesthesia induction.

Hospitalized clients are usually instructed to give their valuables to a family member before surgery. Otherwise these items are removed from the client's room and placed in a safe area according to hospital policy. The nurse documents on the preoperative checklist the disposition of valuables and prosthetic devices.

Medications

Efforts are made to continue routine medications throughout the perioperative experience. The physician instructs outpatient clients on which medications to take the day of surgery. The nurse is responsible the day of surgery to document which medications were taken and to notify the surgeon when drugs were omitted.

Clients scheduled to receive only local anesthesia are usually instructed to wait until after the procedure to take their medications unless there may be a time delay that could have a negative effect on the client. The following medications that increase a client's risk are withheld:

- Anticoagulants, ibuprofen, and aspirin: May increase blood loss. Clients routinely taking oral anticoagulants are given subcutaneous heparin to ensure prompt reversal with intravenous protamine sulfate should the need arise; oral anticoagulants are not reversed by protamine sulfate.
- Monoamine oxidase inhibitors: May interact with anesthetic agents and are discontinued 2 weeks before surgery.
- Aminoglycosides: Potentiate the effect of neuromuscular blockers.
- Oral hypoglycemic agents: Are continued until the evening before surgery except for chlorpropamide, which is discontinued 48 hours before surgery; to prevent intraoperative fluctuations in blood sugar, an intravenous infusion of glucose and insulin is begun before surgery.

The medication dosage can be adjusted preoperatively for certain drugs. For instance, corticosteroid therapy should be continued when clients have been maintained on the drug for 2 months or more; the dose to be given the day of surgery depends on the client's daily therapy.

Medications to reduce anxiety and facilitate the induction of anesthesia are administered as prescribed. To prevent client discomfort with traditional intramuscular preanesthetic injections, facilities with a "holding area" use this setting to initiate intravenous therapy and administer the pre-anesthetic drugs intravenously.

Evaluation

Evaluation of actual and expected outcomes of the perioperative client is done over the three phases. Preoperative evaluation focuses on the client's ability to verbalize and demonstrate the exercises. The outcome

is evaluated when the client successfully performs the exercises after surgery. Measurement of the client's ability to perform postoperative exercises should first be assessed during the teaching session and again an hour later to evaluate learning. If the client needs coaching to perform the exercises, reinforce teaching until the client demonstrates the exercises appropriately.

Assessment of the client's knowledge regarding the nature, purpose, and risks of the surgical procedure is measured preoperatively. Likewise, the nurse listens to the client's comments and monitors physiological indicators (e.g., vital signs) to measure fears and anxieties regarding the surgery.

The evaluation of a client's preoperative preparation for surgery should include understanding of the procedure, verbalization and return demonstration of postoperative exercises, and postoperative expectations resulting from the surgery. Refer to the accompanying Nursing Process Highlight to understand how the nurse evaluates achievement of client expected outcomes.

Documentation

Documentation of preoperative activities must be entered in the client's medical record on the appropriate forms. The preoperative checklist is used to document accurate completion of preoperative activities. Documentation on this form means that all aspects of care have been performed as ordered. When the operating room (OR) personnel come to transfer the client, the preoperative nurse signs the checklist, entering the time and mode of transportation to the OR (e.g., by stretcher).

Nursing Process Highlight

EVALUATION

In evaluating the nursing care of Mrs. Broussard during the preoperative phase of her total hip replacement surgery, the following questions should be considered:

- What methods can be used to determine whether Mrs. Broussard understands the events that will occur during the surgery?
- What postoperative exercises should Mrs. Broussard be asked to demonstrate for the evaluation of her ability to perform these measures?
- What types of information should Mrs. Broussard be able to share about the postoperative course of treatment?
- What methods can be implemented to elicit Mrs. Broussard's concern or anxiety about the surgery itself or the expectations for her recovery?

INTRAOPERATIVE PHASE

The intraoperative phase begins when the client is transferred to the OR and ends with the client's discharge from the OR. The goal of nursing care during this phase is to ensure client safety. Maintaining a safe environment includes protecting the client from injury, infection, and complications arising from anesthetic agents, hazards, and the surgical procedure (see the accompanying Research Focus).

Surgical Environment

The surgical area usually consists of three zones: unrestricted, semirestricted, and restricted. The unrestricted area is designed for personnel to enter in street clothes: receiving desk, holding area, and locker rooms. Surgical attire (scrub clothes, disposable shoe covers, and caps) is required in the semirestricted and restricted zones. Hallways and storage areas constitute the semirestricted area. Restricted zones (controlled and germ-free areas) include the OR and rooms where sterile instruments are prepared.

Holding Area

The holding area is a unit where the surgical team prepares the client for surgery (Figure 30-10). The anesthesiologist usually starts the intravenous infusion and administers the preoperative intravenous medication. The nurse confirms that aspects of care on the preoperative checklist have been performed. A family member is usually encouraged to remain with the client while the client awaits transfer to the OR.

Surgical Team

The surgical team consists of the surgeon, anesthesiologist, OR nurses, surgical assistants, and other members of the health care team. The roles and responsibilities of the

Figure 30-10 Holding Area. What is this nurse doing to prepare this client for surgery?

RESEARCH FOCUS

Title of Study

“Clinical Decision-Making Process in Perioperative Nursing”

Authors

Parker, C., Minick, P., & Kee, C.

Purpose

The purpose of this phenomenological study was to reveal the processes of clinical decision-making by expert perioperative nurses.

Methods

Six expert nurses from five different hospitals in a large southern metropolitan area participated in the study. Expert nurses were defined as having worked a minimum of 5 years and considered themselves to be expert circulating nurses in the OR. Based on an interview guide, the participants were asked to describe any perioperative clinical situation in which they intervened on the patient's behalf and affected the patient's outcome by doing so. The interviews were transcribed verbatim; data were loaded into a software program to categorize, sort, and manage the data.

Findings

The predominant pattern contributing to the clinical decision-making process among the expert nurses was “seeing the big picture: engendered through caring.” Multiple decisions were identified within each nurse's practice, and within each decision, certain characteristics were identified and categorized into themes. Data analysis identified three themes as requisite for expert clinical decision-making: connecting with patients; advocating for patients; and embodied knowing.

Implications

This study demonstrates that positive patient outcomes depend on the ability of the perioperative nurse to integrate all nursing knowledge, make rapid decisions, and constantly advocate for the patient. These data also suggest that nurses and nursing students would both benefit if personal care experiences were shared so that the taken-for-granted knowledge of clinical practice could be examined and caring practices could be made explicit.

Parker, C., Minick, P., & Kee, C. (1999). Clinical decision-making process in perioperative nursing. *AORN Journal*, 70(1), 45–62.

surgeon and anesthetist have already been discussed. The OR team usually consists of:

- Surgeon: Scrubbed and in surgical attire to perform the surgery
- Anesthesia provider: Masked and in clean scrub attire to administer the anesthesia
- Surgical assistant (first assistant): Can be another physician, a nurse, or physician's assistant (PA) who is scrubbed, in sterile attire, and assists the surgeon to ligate, suction, and suture
- Scrub nurse or technician: Scrubbed and in sterile attire; prepares the instrument tray and passes the instruments, sponges, needles, and sutures to the surgeon
- Circulating nurse: In clean scrub attire and mask; obtains supplies, delivers materials, pours solutions, handles specimens, positions the client and surgical drapes, and disposes of soiled items

Both the scrub and circulating nurses are responsible for counting the number of used instruments, needles, and sponges. Before the surgeon closes the incision, these items are counted to ensure that nothing is being left in the operative site.

Occupational Hazards

Perioperative personnel are at risk of exposure to harmful pathogens and other dangers. Dangers of a particular concern to perioperative nurses are latex allergies, needlesticks, eye splashes, back injuries, and indoor pollution. Precautions should be in place that are in compliance with Occupational Safety and Healthcare Administration (OSHA) standards regarding blood-borne pathogens, medical waste and hazards materials, including personal protection devices, disposal of needles and syringes, and contaminated supplies. See Chapter 31 for a complete discussion of latex allergy and OSHA's standards.

Health care agencies need to have a process in place to document compliance with OSHA requirements. Akdumann (1999) studied the compliance of OR personnel with universal precautions during surgical procedures in four subspecialties: orthopedic, gynecologic, cardiothoracic, and general surgery. Personnel were informed in advance about data collection regarding the use of protective equipment. The study revealed that only 39% of the personnel wore protective goggles, 5% wore face shields, 32% wore regular glasses, and nearly one-fourth wore no eye protection. Although double-gloving was higher in orthopedics than other areas, only 28% of the observed personnel double-gloved. A 22% rate of exposure was observed during 76 cases with three percutaneous injuries (two scalpel, one needle-stick) and 14 cutaneous blood and bodily fluid exposures. The study proposed the need for consistent training in and reinforcement of OSHA's guidelines.

Slattery (1998) refers to the hospital environment as a "chemical soup" and addresses the agents that compro-

mise the quality of indoor air. Pollution in the OR is caused by fumes from high levels of disinfectants, surgical smoke from tissue being cut, vaporized, or coagulated, and waste gases from anesthetic agents. Disinfectants such as glutaraldehyde used to sterilize instruments are not regulated, and the fumes may cause serious respiratory and dermatologic problems. OR nurses are also at risk with respect to laser plume or surgical smoke, which can lead to respiratory problems, burning, watery eyes, nausea, and viral contamination and regrowth. To decrease the exposure to these dangerous pollutants, agencies should have policies in place that require clients and personnel to wear high-filtration masks and to provide the rooms with smoke evacuators.

Assessment

The first activity of assessment for the OR nurse is to check the client's identification band and confirm the surgical site. Agency protocol and standards of care from the AORN establish the focus areas of assessment for the client and the environment.

Assessment of proper positioning to ensure comfort and safety includes:

- Checking for client alterations that can affect positioning during the procedure, such as previous skeletal or joint surgery, presence of a joint or vascular prosthesis, poor nutrition, and skin integrity
- Making sure the OR bed is prepared to receive the client: for example, warming mattress on bed, proper orientation of bed, bed wheels locked
- Ensuring that accessories are clean and readily available for a specific position: for example, Wilson frame, chest rolls, pillows, headrest

Throughout the surgical procedure, the nurse assesses for pressure areas of the extremities, joints, or any body surface; skin discoloration; and temperature. Whenever the client's position is changed during surgery, the nurse reassesses for signs of circulatory impairment from positioning and equipment in contact with the skin.

Nursing Diagnoses

Common intraoperative nursing diagnoses promote client comfort, safety, and support during the surgical procedure. See the previous display of nursing diagnoses in the section on Perioperative Nursing Diagnoses.

Outcome Identification and Planning

The focus of intraoperative care planning is on nursing activities that promote the client's achievement of expected intraoperative outcomes (see the accompanying display).

COMMON INTRAOPERATIVE CLIENT OUTCOMES

- The client demonstrates knowledge related to the physical environment and surgical intervention.
- The client's needs are met while in a dependent state from the anesthesia.
- The client is maintained in a safe germ-free environment during the surgical procedure.
- The client is free from infection 72 hours postoperatively.
- The client's skin integrity is maintained by proper positioning on the operating room table.
- The client is maintained in proper body alignment to prevent injury from positioning.
- The client is free from injury related to exposure from heat loss.
- The client is free from injury related to chemical, electrical, and physical hazards.
- The client's fluid and electrolyte balance is maintained.

These outcomes are directed at placing the client in a safe environment free from injury. The OR team monitors the client throughout the surgical procedure for complications.

Specific nursing care is planned to encompass the surgeon's specifications for positioning and to alleviate or prevent any individual client problem. Surgeons have preference cards that identify the type of equipment and instruments for various surgical procedures (e.g., indications and use of electrical equipment). Planning also involves determining the appropriate mode of client transfer, determining equipment and positioning aids, or determining the need for ancillary personnel to accom-

THINK ABOUT IT

Nursing Care and Client Populations

What options are available to nurses who have personal objections to caring for certain client populations?

A Special Committee on Ethics of the AORN conducted a study to elicit the acquired immunodeficiency syndrome (AIDS)-related knowledge, attitudes, and practices of perioperative nurses. The findings revealed that:

Nurses continue to be reluctant to provide care to HIV-positive patients if given a choice. Sixty percent of perioperative nurse respondents said they "somewhat agreed" or "strongly agreed" with this sentiment compared with 62% of the respondents in the original study. One AORN respondent said, "I don't believe anyone should be legally required to care for any patient with any illness/disease (Reeder, Hamlet, Killen, King, & Uruburu, 1994, p. 456).

What is your reaction to the AORN respondent? Read the American Nurses Association Code of Ethics in reviewing your own values toward HIV-positive clients.

plish the positioning. The plan of care should be individualized to include needs relative to the client's health status such as diabetes, malnourishment, or paralysis.

Interventions

Nursing interventions are selected to facilitate caring and to achieve the expected outcomes, such as the client is free from infection 72 hours postoperatively. Because anesthesia inhibits the client's ability to protect self, the OR staff implements surgical asepsis, safe positioning, and other interventions that promote client safety (e.g., the client is never left unattended).

Nursing care includes communication skills to reduce the client's anxiety. The OR staff communicates a caring attitude, functioning under the assumption that anesthetized clients will be able to recall comments made during surgery.

Surgical Asepsis

Surgical asepsis is used to decrease the client's risk for an infection. Surgical asepsis refers to handwashing, wearing surgical attire, handling sterile instruments and equipment, and establishing and maintaining sterile fields. The sterile field is free of microorganisms and only sterile items can be placed inside the field. See Chapter 31 for a complete discussion of surgical asepsis.

Surgical handwashing is performed to remove soil and microorganisms from the skin. The skin on the hands and arms should be intact (free of lesions). Agency policy determines how the scrub is to be performed (e.g., method and timing).

Once the scrub nurse is properly attired for surgery, strict adherence to aseptic principles guides all actions. The hands and arms are held above the waist at all times. Only attire from the waist to the gown's collar and the anterior surface of the sleeves is considered sterile. The scrub nurse sets up the instrument table, using sterile drapes and instruments. Only the tops of instrument tables are considered sterile. Items placed within a sterile field are opened, dispensed, and transferred using technique to maintain the item's sterility. Soiled or contaminated articles are removed immediately from the room by the circulating nurse.

Skin Preparation

Skin preparation (prep) is performed to decrease the risk for infection by reducing the resident microbial count on the skin and inhibiting rebound growth of microbes when the skin is incised during surgery. The second phase of the surgical skin preparation is usually done by OR personnel before surgery to prevent the growth of microorganisms.

Guidelines for when and where the skin is to be prepped for the surgical procedure differ according to agency policy, surgeon's preference, and incision site. The preference card usually indicates the type of preparation. The OR nurse ensures that the operative site is clean.

The skin preparation should comply with the CDC recommendations to avoid unnecessary hair removal

and to shave immediately before an operation. Hair can be removed by clipping, depilatory, and shaving with a razor. A dry shave refers to the removal of hair by clipping or the use of a depilatory. Shaving with a razor and a warm, antiseptic solution is often called a wet shave. Figure 30-11 designates the body surfaces to be prepared for surgical procedures involving the head, neck, ear, and upper thorax. Preparation of the upper extremities, chest, and abdomen are illustrated in Figure 30-12.

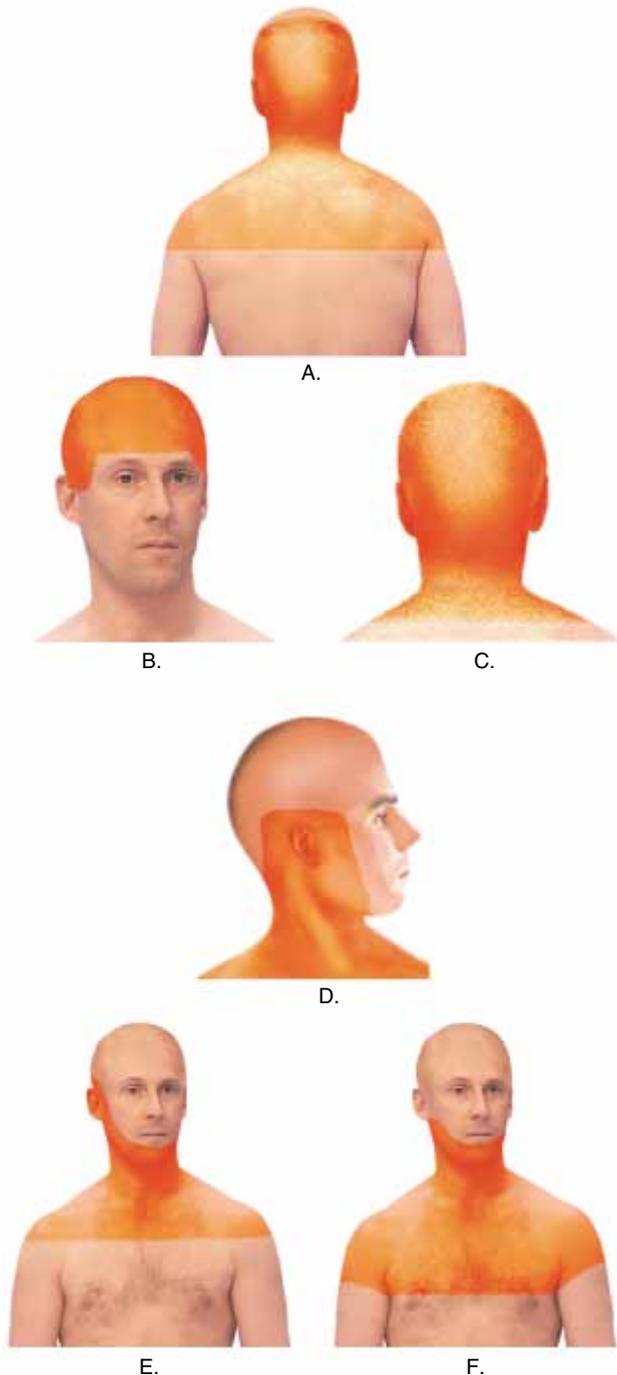

Figure 30-11 Preparation of the Head for Surgery: A.–C. Head for a Craniotomy; D. Neck for Otological Surgery; E., F. Upper Thorax for Thyroidectomy

Figure 30-12 Surgical Preparation of Upper Extremities and Trunk for Surgery, Anterior and Posterior Views

NURSING ALERT

Chemical Burns

After the skin preparation, remove all solution that has pooled under the client; chemical skin burns can result from prolonged exposure to antiseptic solutions.

When performing a skin prep, the nurse should provide the client with an explanation of the procedure, privacy, comfort, and safety. Common agents for prepping the skin include povidone-iodine, chlorhexidine, alcohol, and hexachlorophene. If the client has any adverse reactions to the prep, the nature of the reaction should be documented and the physician notified.

Positioning and Draping

The surgical client is usually sedated or anesthetized and therefore is unable to communicate any discomfort. Proper positioning ensures client comfort and safety, preserves vascular supply, and prevents neuromuscular damage to tissue. At the same time, positioning also provides access to the surgical site, airway, intravenous lines, and all monitoring devices.

All sharp surfaces in contact with the client's skin are padded to prevent injury from positioning. Bony prominences (e.g., sacrum and heels) are padded to avoid excessive pressure on these points. The nurse ensures that skin surfaces are insulated from metal bed attachments (e.g., padded arm boards, headrest, stirrups). Appropriate devices are made available to support extremities to prevent compression of vital structures, such as the ulnar nerve or Achilles tendons.

The circulating nurse ensures that at least four persons are available for positioning clients under general anesthesia. Restraints (or belts) are available to secure the client to the operating bed; sufficient soft padding is used to maintain anatomical alignment of the head and neck with the spine.

Once the client is positioned properly and the site has been prepped, the circulating nurse applies the sterile drapes. OR drapes are designed to expose specific operative sites. The staff keeps the sterile drapes dry and in place.

Electrical Hazards

During surgery the client can be exposed to an electrical surgical generator (electrocautery device to eliminate bleeding and reduce contamination). Electricity cannot flow unless a circuit is complete; thus, electricity introduced into the body has to find a pathway back to the generator. A ground pad is provided for that purpose.

Proper grounding technique is essential for the safe and effective use of the generator. The circulating nurse ensures that the selected ground site is free of skinfolds,

scar tissue, erythema, skin lesions, or bony protuberances. The site should be as close as possible to the operative area. Throughout the surgery, the circulating nurse inspects the ground pad site for any unusual skin discoloration, burns, or skin reaction.

Lasers provide another method for cutting and coagulating tissue during the surgical procedure. Lasers deliver high energy-beams directly onto the tissue and reduce tissue damage and scarring that can inhibit healing. To prevent injury to the skin and eyes, the staff and conscious clients wear special high-filtration masks when the laser produces smoke.

Heat Loss

Injury from hypothermia is prevented by measures implemented to minimize heat loss. During surgery, body heat is lost by positioning on a cold OR table (conduction); administration of cold gases (convection); exposure of large operative sites, such as thoracic and abdominal areas (evaporation); and exposure to cold OR temperatures (radiation). Anesthetic agents can also alter thermoregulation and lower metabolism. Body temperature is maintained by applying warming mattresses or warmed blankets, warming and humidifying inhaled gases, warming irrigating and intravenous solutions, and increasing room temperature when the client is exposed, for example, for skin preparation and positioning.

Monitoring Physiological Functioning

After intubation and induction of anesthesia, the client is monitored for:

- Ventilation and circulation
- ECG and oxygen analyzer alterations
- Fluid intake, urinary output, and calculated blood loss
- Behavioral changes
- Body temperature
- Diagnostic testing (collection of specimens and cultures, x-rays and fluoroscopy)
- Placement of medical devices (ground pad, position support, drains, catheters, implants, packings, and dressings)

These measures assist in identifying and correcting any serious problems before they can result in client injury.

Evaluation

Before the client is transferred to the recovery room, the OR nurse evaluates and documents achievement of client outcomes. Evaluation is based on reassessment findings of the client during and after surgery. The nurse documents the specific data on the OR record,

which usually reflects AORN standards of intraoperative care and other direct care issues pertinent to client outcomes.

Transfer to Postanesthesia Care Unit

While the surgeon is closing the incision, the OR nurse gives a telephone report to a recovery room or PACU nurse regarding the client's health status, surgical outcomes, special equipment needs, and nursing interventions. This information allows the PACU staff time to prepare to receive the client.

Planning for personnel and equipment needed to safely transfer the client is usually handled by the circulating nurse. Moving the semianesthetized client from the OR table to the PACU stretcher for transport requires coordinated effort of at least four persons. Assurance is made that a sufficient number of staff are available to move the client while maintaining proper body alignment and preventing the dislodgement of any tubes, drains, or monitoring devices.

Safety measures are implemented to prevent injury to both client and staff members. The staff uses good body mechanics and assistive devices, such as draw sheets or body rollers, to allow proper weight distribution of the client. The stretcher wheels are locked to prevent movement. The client is always lifted from the table, as opposed to being dragged or pulled with draw sheets, to prevent skin irritation or shearing. The nurse applies stretcher belts (restraints) prior to transport. Also, the head of the stretcher is elevated, side rails are raised, and the placement of tubes and drains is confirmed.

Once on the stretcher, the client is quickly transported by a nurse and anesthetist to the PACU. The client at this time is at high risk for injury related to the effects of residual anesthesia: airway distress, vomiting and aspiration, and circulatory alterations. The anesthetist stays with the client while the OR nurse gives a report to the PACU nurse assigned to the client. The report should include all pertinent anesthesia and surgery information (refer to the Nursing Checklist).

After giving the report, the OR nurse documents the time of discharge, method and disposition of transfer, and a general statement regarding the client's status. The client usually remains on the same PACU stretcher throughout the stay in the unit.

POSTOPERATIVE PHASE

The primary goal of nursing care during the immediate postoperative phase is to maintain the "A-B-Cs": airway, breathing, and circulation. Ongoing care is directed toward restoring the client to the preoperative health status. Clients receiving local anesthetics, without sedation, are usually transferred to the outpatient ambulatory care setting for observation while awaiting discharge. Their postoperative care is usually nonemergent in nature and is discussed later in the section titled Ongoing Postoperative Care.

General anesthesia requires intubation. Extubation is performed by the anesthetist before the client leaves the OR or in the PACU when assessment data confirm adequate gas perfusion. Clients with heart and other major surgeries are not extubated immediately. The endotracheal tube is usually removed on the first postoperative day. Intubated clients are usually transferred to intensive care units for 2 or 3 days.

NURSING CHECKLIST

Preparing the Postanesthesia Report

- Brief history of client's health status: preexisting conditions and medical diagnoses requiring surgery
- Baseline and OR vital signs
- Results of diagnostic testing (e.g., blood gases)
- Administration of anesthetic agents and other medications
- Estimated blood loss
- Total volume of output from all tubes and drains
- Total volume of infused intravenous fluids and blood products
- Presence and status of devices (e.g., tubes, drains, antiembolism hose)
- Any other problems treated during the surgery or other special nursing interventions

Assessment

Following the initial assessment of the client's respiratory status, the nurse performs a total assessment (see Table 30-5). The postoperative nursing care protocol, based on AORN's standards of care, is initiated. The protocol identifies those areas requiring immediate assessment and reassessment as discussed in Table 30-5. Focused assessment is performed relative to the surgical procedure as discussed in the Nursing Process Highlight.

Nursing Diagnosis

Refer to the earlier display of perioperative nursing diagnoses. Clients with preexisting conditions, identified during the preoperative period, will continue to require special nursing care. Depending on the individual client's needs, other nursing diagnoses can be included in the plan of care.

Nursing Process Highlight

ASSESSMENT

During surgery Mrs. Broussard was placed in a lateral position and given a general anesthetic. She was extubated before leaving OR with an oral airway in place on arrival to PACU. Following assessment and management of the “A-B-Cs” the nurse assessed: alignment of the left hip; the client’s level of pain; incision dressing for drainage, inspecting posteriorly where drainage can pool; and circulatory, motor, and sensory status below the site of surgery.

- What immediate assessment parameters must the nurse address to ascertain the status of the postoperative client?
- What priority areas must the nurse assess?
- What measures should be implemented to determine the client’s level of pain?
- What are the nurse’s priorities when inspecting the incision?
- What signs or manifestations should the nurse be alert for regarding the incision?

Some surgeries have unpleasant outcomes. The loss of an extremity or other body part or function can cause the client and family to experience ineffective coping. These situations require compassion and consideration to assist those involved to work through and express their feelings. Support needs to be given not only to the client but also to the family. Physical healing can occur before emotional or spiritual healing does. Learning to cope with a loss sometimes extends beyond the postoperative phase. See Chapters 11 and 21 for more information.

Outcome Identification and Planning

Planning the care for postanesthesia clients addresses the development of nursing interventions to achieve the client’s expected outcomes during recovery from anesthesia and surgery. Care planning is done in two parts: immediate care rendered in the PACU area and ongoing post-PACU care. Nursing care in PACU usually lasts 1 to 3 hours and is directed toward returning the client to a safe physiological level of functioning after anesthesia. Care is prioritized according to the type of anesthesia and surgical interventions through the assistance of appropriate agency protocols (e.g., care of the client following extubation).

TABLE 30-5
Initial Postoperative Assessment: Normal and Abnormal Findings

Area of Assessment	Normal Findings	Abnormal Findings
Airway and Respiratory Status <ul style="list-style-type: none"> • Adequacy of airway and return of gag, cough, and swallowing reflexes • Type of artificial airway • Rate, rhythm, and depth of respirations • Symmetry of chest wall movements and use of accessory muscles • Breath sounds • Color of mucous membranes • Pulse oximeter readings • Amount and method of oxygen administration • If awake, ability to deep breathe and cough 	The client is able to: <ul style="list-style-type: none"> • Expel an oral airway; gag reflex has returned • Breathe deeply and cough freely with normal rate for age, even, without use of accessory muscles, and chest wall symmetry; breath sounds present in all lobes; mucous membranes pink • Pulse oximeter reading between 95% and 100% • If awake, demonstrates proper use of incentive spirometer 	<ul style="list-style-type: none"> • Upper airway obstruction: stridor, retractions, asymmetrical chest movement • Laryngospasm: high-pitched squeaky sounds • Dyspnea: shortness of breath or difficulty in breathing • Diminished breath sounds, wheezing, rales, or rhonchi • Residual neuromuscular blockage: weak inspiratory effort, inability to lift head, or inadequate muscle strength
Circulatory Status <ul style="list-style-type: none"> • Apical and peripheral pulses • Blood pressure (BP) • Nail bed and skin color and temperature • Capillary refill • Homans’ sign Monitoring devices: <ul style="list-style-type: none"> • Cardiac monitor (ECG) 	The client has: <ul style="list-style-type: none"> • Normal apical rate and peripheral pulses • BP within 20 mm of baseline measurements • Pink nail beds; skin warm and dry • Capillary refill <3 seconds • Negative Homans’ sign • Normal ECG rhythm 	<ul style="list-style-type: none"> • Hypotension: BP <20 mm of baseline; rapid, weak pulse; nail beds bluish; capillary refill >3 seconds • Hemorrhage/hypovolemic shock: rapid, weak pulse; increasing respirations; restlessness; hypotension; cold, clammy skin; pallor; urinary output <30 ml/hr

TABLE 30-5 (continued)
Initial Postoperative Assessment: Normal and Abnormal Findings

Area of Assessment	Normal Findings	Abnormal Findings
<ul style="list-style-type: none"> Pressure readings (arterial blood pressure or central venous pressure) 		<ul style="list-style-type: none"> Positive Homans' sign (calf pain present on dorsiflexion of foot) ECG pattern: dysrhythmias; signs of cardiac ischemia
Neurologic Status <ul style="list-style-type: none"> Level of consciousness (Glasgow Coma Scale) Eye opening Verbal response Motor response 	The client: <ul style="list-style-type: none"> Spontaneously opens eyes Is orientated Obeys commands (Glasgow Coma Scale of 15, highest rating) 	Glasgow Coma Scale <15 indicates some alteration in consciousness; a score of 7 is considered coma
Fluid and Metabolic Status <ul style="list-style-type: none"> Intake and output Palpate for bladder distention Patency of intravenous (IV) infusion (type, rate, and amount) Signs of dehydration (skin integrity and turgor) or overload (edema) Patency, amount, and character of drainage (catheters, drains, or tubes) Inspect operative dressing (type, color and amount of drainage) Auscultate for bowel tones in all four quadrants and inspect for abdominal distension 	Fluid intake balanced with total output, electrolytes within normal limits, considering replacement of blood volume lost during surgery: <ul style="list-style-type: none"> IV fluids infusing per surgeon's order Absence of bladder distension Good skin turgor Absence of edema Drains and other tubing patent and intact Dressing dry and intact Bowel tones faint or absent during the immediate recovery phase Absence of nausea and vomiting 	<ul style="list-style-type: none"> Signs of deficient fluid volume (thirst, poor skin turgor, low-grade temperature, tachycardia, respirations ≥ 30, a 10–15 mm decrease in systolic blood pressure, slow venous filling, urinary output <25 ml/hr) Bright red blood on operative dressing Signs of excess fluid volume (increased central venous pressure and edema, pulmonary or peripheral)
Level of Discomfort or Pain <ul style="list-style-type: none"> Location, intensity, and duration Type, amount of analgesia administered and client's response 	Client free from pain	Pain not relieved by analgesia
Wound Management <ul style="list-style-type: none"> Inspect the dressing Note type and amount of drainage If drainage is present, reassess in 15-minute intervals 	Dressing dry and intact	Clot dislodged: bright red drainage on the dressing

After discharge from PACU, the nurse ensures that the client is knowledgeable about home care. Post-PACU care is begun for outpatients in the ambulatory setting. The nursing interventions reinforce client safety and teaching for discharge. For clients who are hospitalized postoperatively, the nursing care plan encompasses both inpatient and discharge needs.

Interventions

Care in the recovery unit is directed by standards of care and protocols. These tools assist the nurse in determining the most effective interventions for specific client populations, type of anesthesia, and surgical procedure. Postoperative nursing interventions are based on assessment and reassessment findings.

Safety measures are initiated immediately on arrival into the recovery unit (see Figure 30-13). Intubated clients require the constant attendance of a nurse at the bedside. The head of the stretcher is maintained in a high Fowler's position. Stretcher belts and side rails are left in place from transfer; wheels on the stretcher are locked. Lifesaving equipment is at the client's bedside.

Maintaining Respiratory Status

On arrival to the recovery area the client is placed on high-humidity oxygen and attached to a **pulse oximeter** (sensor device to measure the oxygen saturation level of the blood). The client is at risk for ineffective breathing patterns resulting from the anesthesia. At least every 15 minutes the nurse monitors the reading on the pulse

Figure 30-13 Postanesthesia Care Unit (PACU). What is the most essential action the nurse should implement with the client in this situation?

oximeter along with respirations. A patent airway can be maintained with an endotracheal tube, nasal or oral airways, and suctioning when needed. See Chapter 32 for a complete discussion of airway devices.

If the client is extubated and experiences difficulty in breathing, reestablish the upper airway: bring the chin forward, hyperextend the neck, and turn the head to the side. If the obstruction is unrelieved, insert either a nasal or an oral airway and suction. If these measures fail to relieve the obstruction, notify the anesthetist. The anesthetist is responsible for treating any physiological impairments related to anesthesia.

The nurse tapes the endotracheal tube on intubated clients to ensure proper placement. The client is maintained in a high Fowler's position to optimize breathing and lung expansion, unless contraindicated. Bronchial secretions are removed by suctioning the intubated client. Suctioning is performed on the basis of assessment findings:

- Rhonchi (low-pitched gurgling sounds in large airways)
- Low-pitched, musical wheezes despite bronchodilator therapy
- Increased peak airway pressure in clients receiving mechanical ventilation

The lungs are usually hyperinflated and hyperoxygenated before, between, and after suctioning to prevent hypoxemia and cardiac dysrhythmias. The nurse observes the ECG monitor while suctioning to observe for signs of hypoxemia.

Hypoxemia can be caused by inadequate lung ventilation from the depressant effects of anesthesia or narcotics. The PACU client is at risk for hypoxemia from the effects of general anesthesia, which reduces the inspiratory effort, and the presence of pain, which reduces ventilatory effort. Older or obese clients are especially vulnerable to postoperative hypoxemia (McCaffigan, 1996).

The early symptoms of hypoxemia are drowsiness and confusion. These symptoms are usually present in

PACU clients recovering from anesthesia. A blood oxygen level measurement less than 95% is an indication of hypoxemia.

Extubation

The agency's protocol is implemented to determine the parameters for extubation, such as the client being able to lift the head for 5 seconds and produce strong bilateral hand grasps. The nurse obtains a tidal volume, negative inspiratory force, and vital capacity (if the client can cooperate) before extubation. See Chapter 32 for further discussion. The anesthetist is notified when the oxygen saturation percent is within safe limits to allow extubation.

The nurse confirms the presence of bilateral breath sounds immediately before and after extubation by auscultation. The procedure is explained to elicit client cooperation and to allay anxiety. Before extubation, the pharynx and trachea are suctioned. The client is instructed to inhale deeply while the anesthetist deflates the cuff and removes the endotracheal tube at maximal lung inflation to encourage initial gas flux outward, allowing the forceful exhaling of secretions.

The client is placed immediately on humidified oxygen for at least 30 minutes and monitored with a pulse oximeter for an hour after extubation. Ventilation is maintained by encouraging deep breathing, coughing, turning, and taking deep breaths every 5 to 10 minutes.

Maintaining Circulatory Status

The client is monitored carefully for the signs of hypotension (Table 30-5), which can occur from the myocardial depressant effects of residual anesthesia or hypovolemia. The cardiac monitor displays the client's heart rhythm; it is used to detect and treat tachycardia, bradycardia, dysrhythmias, and cardiac ischemia.

Hypovolemic shock (marked reduction in circulating blood volume) is caused from hemorrhage. The symptoms of hemorrhage are presented in Table 30-5. A rapid pulse rate can indicate pain, bleeding, dehydration, or shock. Impaired capillary refill indicates inadequate tissue perfusion to extremities.

Passive range of motion and the application of antiembolism hose or other devices promote circulation of the intubated or semiconscious client. Postoperative leg exercises are begun as soon as the client recovers from the effects of anesthesia. These measures prevent circulatory complications such as thrombophlebitis, thrombus, and embolus formation.

Maintaining Neurologic Status

Monitoring the client's level of consciousness is done in relation to how the airway is maintained:

- The unconscious client with an absence of the cough and gag reflex will have an endotracheal tube or airway.

- The semiconscious client with partial return of all reflexes will have an oral or nasal airway.
- The conscious client with full return of all reflexes will breathe without assistance from an artificial airway.

The Glasgow Coma Scale is used to measure the client's level of response. See Chapter 36 for a description of the Glasgow Coma Scale.

The nurse monitors clients who had spinal anesthesia for return of reflexes, sensation, and movement of extremities below the level of anesthesia. Extremities are assessed for color, temperature, and pedal pulses.

Nursing care of clients with spinal anesthesia includes the prevention of a postspinal headache. The postspinal headache is thought to be caused by the leakage of cerebrospinal fluid from the puncture site in the dura. Measures to prevent a headache include strict bed rest for 24 to 48 hours, adequate hydration with intravenous saline, and injection of 5 to 20 ml autologous blood into the epidural space at the puncture site.

Maintaining Fluid and Metabolic Status

During the immediate postoperative phase, gastrointestinal and genitourinary assessment and interventions are considered from a fluid and metabolic perspective. The client is maintained on intravenous infusions as prescribed by the surgeon. The goal of intravenous therapy is to maintain the circulating fluid volume. Infusion sites are inspected for patency immediately when the client arrives in the PACU. Frequent inspection of these sites is necessary throughout recovery; intravenous access must be maintained in the event of complications (e.g., hemorrhage) that warrant emergency administration of intravenous fluids or medications. Secretions from tubes, drains, and the incision site are measured to determine output. The client's total output is compared against the volume of intravenous replacement fluids.

After surgery, the muscle tone of the bladder is compromised by analgesic or anesthetic agents. Assess for bladder distension by palpating the contour of the lower abdomen for a rounded mass above the symphysis pubis. When clients cannot void within 8 hours, the surgeon is notified for an order to catheterize. If the client has a Foley catheter, it should flow freely with urine.

Postoperative nausea and vomiting can be caused by multiple factors. Anesthetic agents and opiates can stimulate the chemoreceptors of the inner ear and the vomiting center in the brain. Deficient fluid volume, electrolyte imbalances, drugs, and general anesthesia by mask technique can also cause nausea and vomiting. Nausea and vomiting are treated with antiemetics.

Anesthetic agents can decrease peristalsis, resulting in diminished or absent bowel tones. Manipulation of the intestines further decreases the loss of bowel tones. The nurse auscultates for bowel tones and inspects for abdominal distension. A nasogastric tube is usually in place for clients with abdominal surgery and clients at risk for nausea and vomiting postoperatively.

With abdominal surgery, the nurse also monitors for abdominal distension to detect internal hemorrhage. **Cullen's sign** (a bluish discoloration around the umbilicus in postoperative clients) can indicate intra-abdominal or perineal bleeding.

Clients are kept on an NPO status until the gag reflex returns, they are free from nausea, and the presence of bowel tones is detected. Certain drugs (analgesic/anesthetic agents) have a drying effect on the oral mucous membranes. Dehydration from loss of body fluids also causes dryness and thirst. Oral hygiene is performed frequently to promote comfort and prevent infections.

Managing Pain

Nurses assess for pain by allowing the client to rate the intensity of pain. Studies comparing nurses' and clients' ratings of pain have found little similarity between the two (Pasero, 1996). One study compared the pain ratings of 119 postoperative clients and their nurses. The ratings matched only 35% of the time; nurses underassessed pain in 45% of the cases and overassessed pain in 20% of the cases.

Pain management is monitored and treated by intravenous narcotics in titrated doses until the client is fully conscious. Once the client is fully conscious, pain is managed according to physician order: PCA, continuous epidural anesthesia, intravenous or intramuscular injection, TENS.

The nurse should institute comfort measures such as splinting the incision line and positional changes to decrease the client's pain response. Besides incisional pain, the client can experience pain for other reasons, such as positioning during surgery, presence of tubes (endotracheal, nasogastric, chest, or Foley), and tight dressings or casts. Skin care and back rubs are done to promote comfort and circulation.

The Agency for Health Care Policy and Research (AHRQ) has clinically relevant practice guidelines for the management of postoperative pain. Three interdisciplinary panels, chaired by nurses, developed guidelines to inform the public on pain management:

- The provider should anticipate the pain.
- It is least therapeutic to be medicated when in pain.
- There are alternatives to pharmacologic management of pain.

NURSING ALERT

Abdominal Distension

When clients with abdominal surgery develop abdominal distension, inspect the tape over the incision dressing; tension on the tape can cause disruption of skin integrity (irritation and blisters). This can also increase the client's risk for a wound infection.

Relaxation techniques, distraction, environmental manipulation, massage, and positioning are optional therapies. See Chapter 14 for additional information on complementary therapies for pain management.

Evaluation and Discharge from the PACU

The anesthetist is responsible for releasing the client from the PACU. Agencies have specific standards of care that have to be met before discharge. These standards address achievement of specific client outcomes with inherent parameters for evaluation, such as:

- The client is conscious, oriented, and can move all extremities.
- The client demonstrates full return of reflexes.
- The client can clear the airway and cough effectively.
- Vital signs have been stable or within baseline ranges for 30 minutes.
- Intake and urinary output are adequate to maintain the circulating blood volume.
- The client is afebrile, or a febrile condition has been treated accordingly.
- Dressings are dry or have only minimal drainage.

The surgeon manages the client's treatment throughout the remainder of the postoperative phase.

Ongoing Postoperative Care

The postoperative phase continues until the client is released from the surgeon's care. The primary goal during this phase is to restore physiological functioning, promote healing, and prevent complications. When the client is discharged from the PACU, the client goes either directly to an inpatient hospital bed or to the outpatient ambulatory unit for observation. The surgeon will later decide whether to admit the client to an inpa-

tient 24-hour observation room or to discharge the client. When clients are discharged to their residence, they often require the services of a home health nurse to assist with their postoperative care. The home health nurse will continue to assess and provide necessary care until the client achieves the expected outcomes.

Postoperative nursing care after discharge is based on the nursing diagnoses and expected outcomes that still have not been met (see the accompanying display). Clients who are discharged without the services of a home health agency assume their own care or have a family member or significant other serve as the care provider. In this situation, specific written discharge instructions are explained to the client or care provider.

Ineffective Airway Clearance

Ineffective Airway Clearance during this phase can result from a diminished cough reflex or increased pulmonary congestion. The nurse monitors skin color and respiratory rate and depth and auscultates breath sounds to determine the adequacy of oxygenation and to identify complications (e.g., atelectasis). Deep breathing and coughing and the use of the incentive spirometer are continued until the client demonstrates achievement of respiratory outcomes.

Ineffective Tissue Perfusion

Ineffective Tissue Perfusion (Cardiopulmonary) related to inadequate circulation is a possible nursing diagnosis. The nurse monitors pulse rate and quality, blood pressure, skin and nail bed color and condition, and temperature for indications of decreased oxygenation at the cellular level. Capillary refill and peripheral pulses are checked for adequate circulation to the extremities. The nurse monitors the lower extremities for signs of superficial vein thrombosis (local warmth, swelling, pain, redness) and deep vein thrombosis (a positive Homans' sign).

Postoperative leg exercises are performed until the client is able to ambulate and resume activities of daily living. Antiembolism hose are usually worn until the client returns for the first office visit. At that time the surgeon assesses the need to continue use of the hose.

Other devices, pneumatic compression, and CPM are maintained according to the physician's order. Clients are encouraged to ambulate while these devices are in place to promote respiratory, circulatory, and gastrointestinal functions. The CPM device is used until signs of incision swelling have decreased, healing is evident, and range of motion is achieved.

Deficient Fluid Volume

Deficient Fluid Volume can be related to active fluid volume loss, inadequate fluid intake from being NPO, or nausea and vomiting. The client is monitored for intake and output that includes secretions from drainage tubes, drains, and dressings. If oral fluids are restricted, the client is

DISCHARGE TEACHING

Client Expected Outcomes

Before discharge, the client can:

- List the symptoms to be reported to the physician on occurrence.
- Describe limitations in activity.
- Explain dietary limitations.
- Explain the meaning and purpose of medications.
- Explain potential food or drug interactions.
- Describe the use of Standard Precautions as appropriate.
- Demonstrate aseptic technique in changing dressings.
- Demonstrate use or application of prescribed medical devices (identify appropriate device).

maintained on intravenous infusions as ordered by the surgeon. The nurse monitors the patency of the intravenous line, observes for signs of infiltration, and records the amount and type of fluids infused. The nurse assesses for signs of dehydration or fluid overload. See Chapter 37 for a discussion of fluid balance.

Home health clients with continuous intravenous therapy are maintained on an infusion pump. The caregiver is taught how to add infusions to the line under sterile technique. The home health nurse visits the client daily to assess for intravenous patency. A nurse is usually on call 24 hours for clients receiving continuous infusions.

Imbalanced Nutrition

Imbalanced Nutrition: Less Than Body Requirements is usually related to anesthesia or surgical manipulation of the intestines. Until peristalsis returns and nausea, anorexia, or vomiting subsides, the client is maintained on intravenous therapy to maintain fluid and electrolyte balance. Nasogastric tube drainage is measured, and color and consistency are documented. See Chapter 38 for more information.

Clients with abdominal surgery can take up to 2 to 3 days or longer for return of normal gastrointestinal function. The nurse auscultates the abdomen for gurgling and rumbling sounds in all four quadrants to indicate return of peristalsis. Early ambulation promotes the return of peristalsis. When bowel tones return and nausea subsides, the client's diet is progressive: first ice chips, then clear to full liquids; if tolerated, the diet is progressed to soft or regular. Some clients are on a regular diet within hours after surgery. See Chapter 38 for a discussion of types of modified diets.

Urinary Retention

Urinary Retention is related to anesthesia or surgical manipulation that causes temporary loss of bladder tone. Efforts are made to promote urination (e.g., male clients are more prone to void if they can stand). If the client does not void within 8 hours after surgery, assess for bladder distension and notify the surgeon. The surgeon can order a straight or Foley catheter. *Clients must void before they can be released from the ambulatory setting.*

Acute Pain

Position changes and splinting are continued to relieve pain. Clients can be discharged to home with a PCA pump. Before discharge the nurse ensures that the client is able to correctly self-administer using the PCA. Efforts are made to provide adequate rest by scheduling procedures that do not interfere with sleep.

Risk for Infection

The client with a surgical incision is at risk for infection. Wound healing begins as early as 2 hours after surgery.

The nurse ensures that the dressing is clean, dry, and intact; dressings promote rapid re-epithelialization and protect against infection. Various types of dressings are used: conventional absorbent nonocclusive, semioclusive hydroactive, and occlusive hydrocolloid.

In a study of 250 heart surgery clients, Wikblad and Anderson (1995) found that hydroactive dressings were not as effective as occlusive hydrocolloid and absorbent nonocclusive dressings in preventing wound infections. Hydroactive dressings were difficult to remove and painful to the client. An earlier study by Bolton and van Rijswijk (1991) showed that epithelialization can be delayed by repeated trauma or removal of dressings that have aggressive adhesives.

Nurses use Standard Precautions when caring for clients and sterile technique when changing a dressing. The incision line is assessed when the nurse changes the dressing. For some clients, the surgeon usually orders prophylactic antibiotics and removes any catheters or drains as soon as possible to prevent an infection. If the client were to develop a deep wound infection, it could necessitate prosthesis removal.

To monitor for signs of an infection, the nurse notes the type and amount of drainage on the dressing and the stage of wound healing. Vital signs are measured, recorded, and analyzed against laboratory results, especially the white blood cell count and differential. The client is taught to care for the wound and to observe for the complications of wound healing: hemorrhage, hematoma formation, infection, dehiscence, and evisceration. See Chapter 35 for a discussion of these complications.

NURSING CHECKLIST

Postoperative Documentation

- The client's respiratory function has returned to baseline level within 1 week after surgery as demonstrated by respirations 16 to 20/minute, deep and regular, skin color pink, lungs sounds clear on auscultation; oxygen saturation greater than 95%.
- The client's cardiopulmonary function has returned to baseline level within 1 week after surgery as demonstrated by: blood pressure with 10 to 20 mm Hg of baseline measurement; absence of dysrhythmias; pulse rate 60 to 90 beats per minute; skin pink, warm, and dry; capillary refill less than 3 seconds; peripheral pulses present; negative Homans' sign; output is within 500 ml of intake.
- The client is free from signs of a wound infection within 72 hours after surgery as demonstrated by: afebrile; pulse and respirations at baseline level; sutures intact; incision line without swelling, redness, or purulent exudate; scab sloughing.

Evaluation

Evaluation is based on client-specific postoperative nursing diagnoses and achievement of outcomes. The time frame for the client's achieving the outcomes can vary with the client's health status, surgical procedure, and other factors, such as age. The nurse documents achievement of outcome criteria data (see the Nursing Checklist on the previous page).

KEY CONCEPTS

- The major role of nursing functions in caring for the perioperative client is to foster the achievement of expected outcomes of care.
- Outpatient surgical clinics decrease the client's length of stay in the hospital and health care costs.
- Management of the perioperative client occurs in various health care settings.
- Effective perioperative management is directed by a multidisciplinary team on the basis of recognized standards of care, protocols, and individualized expected client outcomes.
- Assessment of the client's status before surgery establishes baseline data to direct interventions throughout the perioperative phases.
- Interventions of the health care team focus on decreasing the perioperative client's risks for complications.
- Documentation of the client's response to interventions and achievement of expected outcomes provides the framework for evaluation.
- Coordination of discharge care begins in the preoperative phase and is reinforced throughout the other two phases.

CRITICAL THINKING ACTIVITIES

1. Mrs. G is a 45-year-old wife and mother who needs an emergency hysterectomy; however, she has no health insurance. Where should Mrs. G seek surgical intervention? With emergency surgery there is little time for client teaching. How does the nurse handle this challenge? What type of support should the family receive?

2. An 11-year-old child is hospitalized for surgical repair of an ankle injury. The child lives with a single parent, a 5-year-old brother, and a 3-year-old sister. What age-related considerations need to be incorporated into planning the discharge care of the child, keeping in mind the implications on the family unit?
3. Mr. S is an 86-year-old inpatient client scheduled for heart surgery. The evening before surgery he requests the sacrament of Anointing of the Sick. What nursing activities should the nurse institute?
4. Although the primary activity of perioperative nursing is client-centered care, nurses must also have an awareness of inherent "cost" challenges. Discuss how nurses can have a positive or negative impact on health care costs related to surgery.
5. You are working the evening shift on a surgical unit. You assess a client on his second postoperative day; he is receiving morphine, 2 to 4 mg/hr, with a PCA pump. He has had 17 mg morphine during the past 6.5 hours. During your assessment you observe that he is nodding and unable to tell you the day of the week, his color is pale, the vital signs are: T-37°C, P-94, R-12, BP 144/92. What nursing actions should you initiate to determine if the client's symptoms are caused from a lack of sleep, the morphine, or hypoxemia?
6. Identify the ongoing postoperative nursing diagnoses, expected outcomes, interventions, and evaluation criteria in planning the discharge care for Mrs. Broussard from the hospital the second postoperative day.

Chapter 31

Safety, Infection Control, and Hygiene

We are not sensible of the most perfect health, as we are of the least sickness.

—De Montaigne

COMPETENCIES

1. Describe factors affecting environmental safety.
2. Describe the chain of infection.
3. Explain the principles of medical and surgical asepsis.
4. Contrast various types of isolation precautions.
5. Discuss factors that influence a client's personal hygiene practices.
6. Explain the role of assessment in maintaining a safe environment.
7. Discuss the nursing interventions that can be used to resolve environmental hazards in institutional and home settings.
8. Describe the nursing interventions that promote a client's personal hygiene.

**KEY
TERMS**

acquired immunity	disinfectant	physical agent
agent	disinfection	physical restraints
airborne transmission	equipment accidents	poison
anthropogenic	erythema	prodromal stage
antibody	flora	pyorrhea
antigens	germicide	resident flora
asepsis	gingivitis	restraints
aseptic technique	halitosis	risk for infection
autoimmune disorder	handwashing	sebum
biological agent	host	self-care deficit
body image	humoral immunity	sensory overload
cavities	hygiene	spores
chain of infection	illness stage	sterilization
chemical agent	incubation period	stomatitis
chemical restraints	infection	surgical asepsis
clean object	infectious agent	susceptible host
cleansing	inflammation	systemic infection
client behavior accidents	localized infection	therapeutic procedure
colonization	lymphokine	accidents
communicable agent	medical asepsis	transient flora
communicable disease	mode of transmission	vaccination
compromised host	nosocomial infection	vectorborne transmission
contact transmission	pathogen	vehicle transmission
convalescent stage	pathogenicity	virulence
dirty object	perineal care	

Safe care is a basic need of all clients regardless of the setting. Nurses are responsible for providing the client with a safe environment through the delivery of professional, quality nursing care that incorporates safety precautions, infection control practices, and hygiene assistance. This chapter describes the nurse's role in each of these areas.

SAFE ENVIRONMENT

Safety has a positive association with health promotion and illness prevention. A safe environment reduces the risk of accidents, subsequent alterations in health and lifestyle, and the cost of health care services. There are many factors in the environment that can threaten safety (Figure 31-1).

FACTORS AFFECTING SAFETY

Client safety is influenced by several factors such as age, lifestyle, sensory and perceptual alterations, mobility, and emotional state.

Age

Risk for injury varies with chronological age and developmental stage. Health education about preventive

measures can facilitate injury prevention for various age groups (Figure 31-2).

As infants mature, their potential for injury increases. Infants, toddlers, and preschoolers are explorers of their environment. Most accidents involving these age groups are preventable with careful adult supervision to prevent falls from bed, burns, electrical hazards, choking on small objects, and drowning.

As school-age children explore their environment outside the home, their risk for injury increases. Prevention measures during this stage focus on not accepting candy, food, gifts, or rides from strangers; bicycle, skating, and swimming safety; and substance abuse.

Adolescents and young adults usually enjoy good physical health; however, their lifestyles put them at risk for injury. Since this age group spends much time away from home, collaborative educational efforts among parents, schools, and community health care providers need to focus on environmental safety. High-risk factors for injury and death are automobile accidents, substance abuse, violence, unwanted pregnancies, and sexually transmitted diseases.

Studies indicate that adolescents who initiate substance use in middle school and continue into high school are likely to become multisubstance users (tobacco, alcohol, and drugs). The progression from lighter to heavier use of illicit substances during adolescence leads to more serious multisubstance use careers.

Adult risk for injury is generally related to lifestyle, work practices, and behaviors. Prevention measures

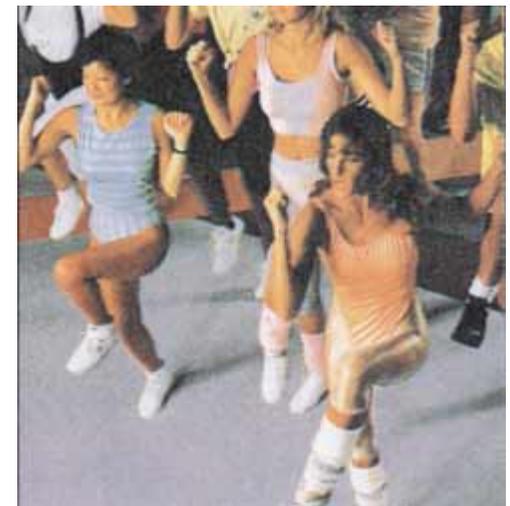

Figure 31-1 Minimization of risks for injury. These photos show various methods by which people in different age groups can lessen or prevent their risk of injury. Can you identify other risks that may be more prevalent in certain age groups than others? What measures can be taken to prevent them?

during this period emphasize nutrition, exercise, and occupational safety. High-risk factors for this age group include fatigue, anxiety, sleep pattern disturbances, caregiver role strain, and altered health maintenance.

The older adult is prone to falls, especially in the bathroom, bedroom, and kitchen, because of a loss of agility and visual acuity, predisposition to dizziness and syncope, and side effects of medications. Prevention measures for this age group emphasize slow position changes, good lighting, hand rails, and skidproof strips in the bathtub or shower and under rugs and carpets.

Each year, approximately one-third of people over the age of 65 who live at home fall; 15% of falls cause serious

injuries, half of which are fractures that cost about \$10 billion for hospital care (Winslow, 1998). Two Maryland hospitals worked together to implement a fall precaution program in their medical-surgical units and within 1 year lowered their fall rates from 9.3 falls per 1,000 client days to 7.3 per 1,000 client days (Sullivan & Badros, 1999). (See Chapter 18 for a complete discussion of the older adult).

Lifestyle

Lifestyle practices can increase a person's risk for injury and potential for disease. Individuals who operate machinery; experience stress, anxiety, and fatigue; use

alcohol and drugs (prescription and nonprescription); and live in high-crime neighborhoods are at risk for injury. Risk-taking behaviors such as daredevil activities, driving vehicles at high speeds, and smoking are factors associated with accidents (Figure 31-2).

Sensory and Perceptual Alterations

Sensory functions are essential for accurate perception of environmental safety. If one of the senses is altered, then the other senses compensate to facilitate perception of the environment. For instance, a blind person usually will develop a keen sense of touch and hearing. Clients who have visual, hearing, taste, smell, communication, or touch perception impairments are at increased risk for injury. These clients are often not able to perceive a potential danger. See Chapter 36 for a complete discussion on sensory or perceptual alterations.

Mobility

Clients who have impaired mobility are at increased risk for injury, especially falls. Mobility impairments may be a result of poor balance or coordination, muscle weakness, or paralysis. Immobility may also precipitate physiological and emotional complications such as decubitus and depression, respectively. See Chapter 34 for a complete discussion on mobility.

Emotional State

Emotional states such as depression and anger affect a client's perception of environmental hazards and degree of risk-taking behavior. These emotional states alter a client's thinking patterns and reaction time. Usual safety precautions may be forgotten during periods of emotional stress. Self-confidence decreases when an elderly person falls; they tend to limit their activities because they fear falling again (Winslow, 1998).

Types of Accidents

In the health care setting, accidents are categorized by their causative agent: client behaviors, therapeutic procedures, or equipment:

1. **Client behavior accidents** occur when the client's behavior or actions precipitate the incident; for example, poisonings, burns, and self-inflicted cuts and bruises.
2. **Therapeutic procedure accidents** occur during the delivery of medical or nursing interventions; for example, medication errors, client falls during transfers, contamination of sterile instruments or wounds, and improper performance of nursing activities.
3. **Equipment accidents** result from the malfunction or improper use of medical equipment; for example, electrocution and fire.

Figure 31-2 Lifestyle practices that can either increase or decrease a client's risk of injury. Can these practices be easily reversed, in terms of risky behavior, or adopted, in terms of promoting healthy approaches, by clients?

National and institutional policies establish safety standards; for example, the risk for equipment accidents can be reduced by having the biomedical engineering department check the equipment inspection label prior to use. All accidents and incident reports must be fully documented according to institutional protocol.

Potential Occupational Hazards

Nurses and other health care providers are at risk for injury in the workplace. Every day in the United States, 9,000 health care workers sustain a disabling injury on the job, according to the National Institute for Occupational Safety and Health (NIOSH) (Slattery, 1998). The Occupational Safety and Health Administration (OSHA), a division of the Department of Labor, has the power to enforce safety standards, and to cite and discipline agencies that are not in compliance with the standards (Bending, 2000).

Numerous hazards exist in today's workplace such as latex allergy, blood-borne pathogens, work-related musculoskeletal disorders (MSDs), chemotherapeutic agents, environmental pollution, and violence. Findings from studies indicate that nurses who prepare or administer chemotherapeutic agents are exposed to occupational hazards from dermal absorption, ingestion, and inhalation from aerosolization of powder or liquid during reconstitution or from spillage (DelGaudio & Menonna-Quinn, 1998). According to the Bureau of Labor, almost two-thirds (64%) of nonfatal workplace assaults occur in nursing homes and hospitals (Slattery, 1998). The salient points regarding latex allergy and MSDs are discussed here; blood-borne pathogens are discussed later in this chapter.

Latex Allergy

NIOSH (1997) issued an *Alert* entitled *Preventing Allergic Reactions to Natural Rubber Latex in the Workplace*. Latex products are manufactured from a milky fluid derived from the Brazilian rubber tree, *Hevea brasiliensis*. The allergic response is attributed to the proteins contained in the milky fluid and to the chemicals that are added during the processing and manufacture of commercial latex. There are three types of latex reactions: irritant contact dermatitis; allergic contact dermatitis, the most common type of reaction; and immediate hypersensitivity, a systemic reaction also called type 1 IgE-mediated reaction.

Since 1992, when OSHA issued regulations requiring health care workers to wear gloves and other protective devices such as surgical masks and goggles as a safeguard against blood-borne pathogens, health care workers were placed at risk for developing latex allergy. Commercial latex is in more than 20,000 medical products (Burt, 1999) such as blood pressure cuffs, stethoscopes, catheters, and wound drains, to name a few, as well as many household items. Reports indicate that 1–6% of the general population and about 8–12% of regularly exposed health care workers are sensitized to latex (NIOSH, 1997).

NOISH'S RECOMMENDATIONS TO PREVENT LATEX EXPOSURE

Employers

- Provide workers with nonlatex gloves.
- Provide appropriate barrier protection for workers handling infectious materials; if latex gloves are chosen, provide reduced protein, powder-free gloves to protect workers from infectious materials.
- Provide good housekeeping to remove latex-containing dust, and ensure that workers change ventilation filters and vacuum bags frequently in latex-contaminated areas.
- Provide education programs regarding latex allergy.
- Periodically screen high-risk workers for latex allergy symptoms.
- Evaluate current policies whenever a worker is diagnosed with latex allergy.

Workers

- Use nonlatex gloves for contact with noninfectious materials.
- Use CDC-appropriate barrier protection when handling infectious materials; if latex gloves are chosen, use reduced protein, powder-free gloves to reduce exposure and reactions to latex chemical additives (allergic contact dermatitis).
- Use appropriate work practices when wearing latex gloves: avoid oil-based hand creams or lotions that can cause glove deterioration unless they have been shown to reduce latex-related problems and maintain glove barrier protection; wash hands with a mild soap and dry thoroughly after removing latex gloves; use good housekeeping practices to remove latex-containing dust.
- Attend latex allergy educational programs to be knowledgeable of procedures and to recognize the symptoms of latex allergy: skin rashes; hives; flushing; itching; nasal, eye, or sinus symptoms; asthma; and shock.
- Avoid direct contact with latex gloves and other products if you develop symptoms until you have been seen by a physician experienced in treating latex allergy.
- If you have latex allergy, consult your physician regarding exposure precautions, contact with gloves and other latex-containing products, and areas that contain latex powder from gloves worn by other workers; inform your employer and health care providers that you have latex allergy.
- Carefully follow your physician's instructions regarding allergic latex reactions.

Adapted from: National Institute for Occupational Safety and Health Centers for Disease Control and Prevention. (1997). *Preventing allergic reactions to natural rubber latex in the workplace*. (DHHS [NIOSH] Publication No. 97-135) U.S. Department of Health and Human Services, Public Health Service, Centers for Disease Control and Prevention, National Institute for Occupational Safety and Health.

NIOSH (1997) recommends that employers and employees take a common sense approach based on current knowledge to protect workers from latex exposure and allergy in the workplace; refer to the accompanying display for NIOSH's recommendations. NIOSH recommends that, if latex gloves are worn, they should be powder free and low allergen because these gloves are less likely than powdered ones to produce allergic responses (Gritter, 1998).

Work-Related Musculoskeletal Disorders

One-third of all occupational injuries reported by employers every year to the Bureau of Labor Statistics are work-related MSDs. Employers reported a total of 626,000 lost workdays in 1997, with these disorders costing workers' compensation more than \$15-\$20 billion (OSHA, 2000).

According to OSHA (2000), it is estimated that only 28% of all workplaces in general industry have voluntarily implemented ergonomics programs. In response to these workplace hazards, OSHA has issued mandatory standards that require all employers to set up ergonomic programs to prevent work-related MSDs such as back injuries.

Work-related back pain affects 38% of nurses. The predominant cause of nurse back pain is lifting clients (Slattery, 1998). OSHA ergonomic standards state that a 51-pound stable object with handles is the heaviest amount that can be safely lifted. Health care providers are being challenged, in the midst of personnel cutbacks, to develop and implement safety policies that protect the provider and support OSHA's ergonomic regulations.

The ergonomic standards require that all employers must provide workers the following information: common MSD hazards; signs and symptoms of MSDs, and the importance of reporting them early; how to report MSD signs and symptoms; and a summary of the requirement of the OSHA standard. The standards require the employer to ensure pay and benefits in the event that an employee needs to take time off or go on lighter duty because of a work-related MSD.

INFECTION CONTROL PRINCIPLES

Client safety in the health care environment requires the reduction of microorganism transmission. Infection control practices are directed at controlling or eliminating sources of infection in the health care agency or home. Nurses are responsible for protecting clients and themselves by using infection control practices. Nurses and clients must be educated on the types of infections, modes of transmission, risks for susceptibility, and infection control practices required to control or prevent further transmission.

Pathogens, Infection, and Colonization

Pathogenicity is the ability of a microorganism to produce disease. Microorganisms that cause diseases in humans are called **pathogens**. There are five types of microorganisms that can be pathogenic: bacteria, viruses, fungi, protozoa, and *Rickettsia*. **Virulence** is the degree of pathogenicity of an infectious microorganism (pathogen).

Infection and colonization are not synonymous. **Infection** is an invasion and multiplication of microorganisms in body tissue that results in cellular injury. These microorganisms are called **infectious agents**. Infectious agents that are capable of being transmitted to a client by direct or indirect contact, through a vehicle (or vector), or airborne route are also called **communicable agents**. Diseases produced by these agents are referred to as **communicable diseases**. **Colonization** is the multiplication of microorganisms on or within a host that does not result in cellular injury. However, microorganisms that are colonized on a host may be a potential source of infection, especially if host susceptibility declines or the microorganism's virulence increases.

Some microorganisms reside on the human body as normal flora. This is synonymous with colonization. **Flora** are microorganisms on the human body. There are two types of flora: resident and transient. **Resident flora** are microorganisms that are always present, usually without altering the client's health. Handwashing with soap and water alone is not sufficient to remove resident flora; there must be considerable friction, which is created by rubbing the hands and scrubbing the nails. **Transient flora** are microorganisms that are episodic. They attach to the skin for a brief period of time but do not continually live on the skin. Transient flora are usually acquired from direct contact with the microorganisms on environmental surfaces. Handwashing with soap and water is an effective means of removing transient flora.

Chain of Infection

A susceptible host or presence of a pathogen alone does not mean that an infectious process will occur. The **chain of infection** describes the phenomenon of developing an infectious process. There must be an interactive process that involves the agent, host, and environment. This interactive process must involve several essential elements, or "links in the chain," for transmission of microorganisms to occur. Figure 31-3 identifies the six essential links (elements) in the chain of infection. Without the transmission of microorganisms, an infectious process cannot occur. Therefore, knowledge about the chain of infection for an infectious process permits control or elimination of the microorganism by breaking the links in the chain of infection. Breaking the chain of infection occurs by altering the interactive process of agent, host, and environment, as shown in Figure 31-3.

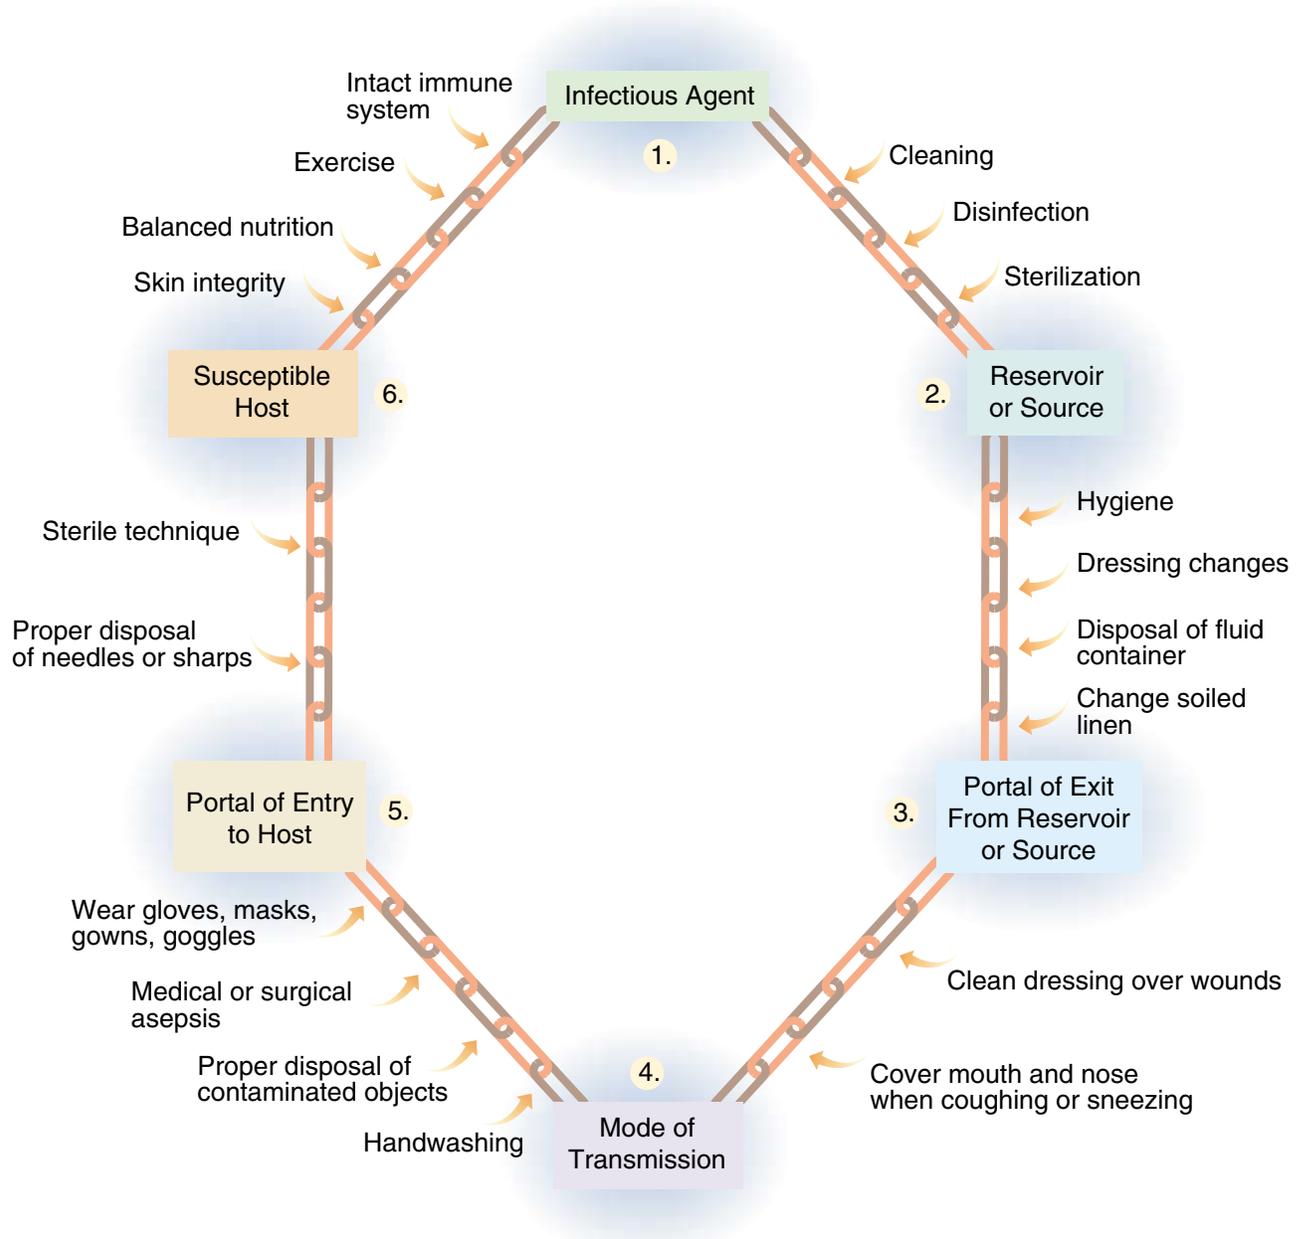

Figure 31-3 Breaking the chain of infection. Preventive measures follow each critical link in the chain of infection.

Agent, Host, and Environment

An **agent** is an entity that is capable of causing disease. Agents that cause disease may be:

- **Biological agents:** Living organisms that invade the host, such as bacteria, viruses, fungi, protozoa, and *Rickettsia*
- **Chemical agents:** Substances that can interact with the body, such as pesticides, food additives, medications, and industrial chemicals
- **Physical agents:** Factors in the environment that are capable of causing disease, such as heat, light, noise, radiation, and machinery

In the chain of infection, the main concern is biological agents and their effect on the host.

A **host** is a simple or complex organism that can be affected by an agent. Generally, a human being is considered a host. A **susceptible host** is a person who lacks resistance to an agent and is thus vulnerable to disease. A **compromised host** is a person whose normal defense mechanisms are impaired and who is therefore susceptible to infection.

Interaction between agent and host occurs in the environment; the environment consists of everything other than the agent and host. Environmental factors that affect the chain of infection are water, food, plants, animals, housing conditions, noise, meteorological conditions, and environmental chemicals. Many of the conditions that promote the transmission of microorganisms are **anthropogenic**, reflecting

changes in the relationship between humans and their environments.

The causes of most emerging infectious diseases are the same today as throughout recorded history: the transfer and dissemination of existing agents to new host populations (a process called “global microbial traffic”). For instance, cholera probably originated in Asia in ancient times; in the 19th century it spread to Europe and the New World because of increased global travel. Cholera entered South America for the first time this century (1992) through the possible contaminated bilge water released from a Chinese freighter. The causes of emerging infectious diseases and outbreaks require careful consideration of environmental changes and especially of anthropogenic factors.

Modes of Transmission

The **mode of transmission** is the process that bridges the gap between the portal of exit of the biological agent from the reservoir or source and the portal of entry of the susceptible “new” host. Most biological agents have a primary mode of transmission; however, some microorganisms may be transmitted by more than one mode. Almost anything in the environment can become a potential means of transmitting infection, depending on the agent.

The most important and frequent mode of transmission is **contact transmission**, which involves the direct physical transfer of an agent from an infected person to a host through direct contact with a contaminated object or close contact with contaminated secretions. Sexually transmitted diseases are examples of diseases spread by direct contact.

Airborne transmission occurs when a susceptible host contacts droplet nuclei or dust particles that are suspended in the air. Vehicle and vectorborne transmission are indirect modes of transmission, because transmission occurs by an intermediate source. **Vehicle transmission** occurs when an agent is transferred to a susceptible host by contaminated inanimate objects such as water, food, milk, drugs, and blood. **Vectorborne transmission** occurs when an agent is transferred to a susceptible host by animate means such as mosquitoes, fleas, ticks, lice, and other animals.

Breaking the Chain of Infection

Nurses focus on breaking the chain of infection by applying proper infection control practices to interrupt the mode of transmission. The chain of infection can also be broken by interrupting or blocking the agent, portal of exit, or portal of entry or by destroying the agent or decreasing the host’s susceptibility. Refer to Figure 31-3, which shows preventive measures that break the chain of infection. Host susceptibility is dependent on the immune system to function as a defense mechanism.

Normal Defense Mechanisms

A host’s immune system serves as a normal defense mechanism to resist the transmission of infectious agents. A unique feature of the immune system is its ability to recognize “self” and “nonself”; that is, the immune system recognizes which agents are not consistent with the genetic composition of the host (self). These agents are usually referred to as antigens (non-self). **Antigens** are foreign proteins. An immune response is mounted against an antigen, which is recognized as nonself, to protect the body from infection. The immune defenses are categorized as nonspecific and specific immune defenses. Nonspecific and specific immune defenses work in harmony to defend the host from pathogens.

Nonspecific Immune Defense

The nonspecific immune defense mounts a response to protect the host from all microorganisms; it is not dependent on prior exposure to the antigen. Nonspecific immune defenses are skin and normal flora; mucous membranes; sneeze, cough, and tearing reflexes; elimination and acidic environment; and inflammation.

Skin and Normal Flora

Intact skin is the first line of defense against infection, serving as a physical barrier to infectious agents. Skin cells are shed along with potentially harmful microorganisms. **Sebum** is produced by the skin and contains fatty acids that kill some bacteria. The normal flora that reside on the skin compete with pathogenic flora for food and inhibit their multiplication. The balance of normal flora may become disrupted as a result of the inappropriate use of antibiotics, which allows pathogenic organisms to proliferate and cause infection or superinfection.

Mucous Membranes and Sneeze, Cough, and Tearing Reflexes

Mucous membranes also function as a physical barrier to infectious agents. Mucus produced by these membranes entraps infectious agents and contains substances such as antibodies, lactoferrin, and lysozyme, which inhibit bacterial growth. Cilia of the respiratory tract trap and propel mucus and microorganisms away from the lungs. The sneeze and cough reflexes physically expel mucus and microorganisms from the respiratory tract and oral cavity with force. Tears protect the eyes by continually flushing away microorganisms.

Elimination and Acidic Environment

Elimination patterns and an acidic environment normally prevent microbial growth of pathogenic organisms. Resident flora of the large intestines prevent the growth of pathogens. The mechanical process of defe-

cation evacuates the bowel of feces and microorganisms. Acidity of the urine prevents microbial growth. The flushing action of urination cleanses the bladder neck and urethra of microorganisms and prevents microorganisms from ascending into the urinary tract.

Normal vaginal flora prevent growth of several pathogens. At puberty, lactobacilli ferment and produce sugars in the vagina that lower the pH to an acidic range. The acidic environment of the vagina prevents pathogenic growth. Inappropriate use of antibiotics destroys the lactobacilli and its protective function.

Inflammation

Inflammation is a nonspecific cellular response to tissue injury or infection. Tissue injury caused by bacteria, trauma, chemicals, heat, or any other phenomenon releases multiple substances that produce dramatic secondary changes in the injured tissue. This entire complex of tissue changes and response to injury is referred to as the inflammatory process (see Table 31-1). The inflammatory process has five stages, which facilitate the localization, neutralization, and resolution of the offending agent within the damaged tissue. The result of the body's response to injury produces the characteristic local and systemic signs of inflammation, discussed in the assessment section of this chapter.

The intensity of the inflammatory process is usually in proportion to the degree of tissue injury. For example, when staphylococci invade the tissues, they release lethal

cellular toxins that cause the inflammatory process to develop quickly; the staphylococcal infection is characteristically walled off rapidly before the organism can multiply and spread. Streptococci, on the other hand, do not cause such intense local tissue destruction, and the walling-off process develops slowly, allowing the organism to reproduce and migrate. Therefore, the streptococci have a far greater tendency than do staphylococci to spread throughout the body and cause death, even though staphylococci are far more destructive to the tissue.

Specific Immune Defense

The specific immune defense mounts an immune response that is specific to the invading antigen. Unfortunately, the specific immune defense sometimes inappropriately reacts to the host's own tissue (**auto-immune disorders**).

The specific immune defense is activated by the failure of phagocytes to completely destroy the antigen; this causes the production of T lymphocytes (T cells), which regulate the immune response by activating other cells. Stimulated T cells are referred to as sensitized T cells. T cells migrate to the area of injury and release chemical substances called **lymphokines**. Lymphokines attract other phagocytes and lymphocytes to the area of injury and assist in antigen destruction.

T cells also stimulate the production of B cells that differentiate into plasma cells, producing antibodies specific

TABLE 31-1
Stages of the Inflammatory Process

Stage	Description	Result
1	Initial injury precipitates release of chemicals: histamine, bradykinin, serotonin, prostaglandins (reaction products of the complement and blood-clotting systems), and lymphokines (hormonal substances released by sensitized T cells).	Activates the inflammation process.
2	Increased blood flow to the inflamed area (erythema).	Produces characteristic signs of redness and increased warmth.
3	Increased capillary permeability with leakage of large quantities of plasma out of the capillaries into the damaged tissue; tissue spaces and lymphatics blocked by fibrinogen clots.	Initiates the inflammation process; infection is "walled off," and nonpitting edema occurs.
4	Damaged tissue infiltrated by leukocytes, which engulf the bacteria and necrotic tissue. After several days, these leukocytes eventually die and form a cavity of necrotic tissue and dead leukocytes (mainly neutrophils and some macrophages).	Produces purulent exudate (pus).
5	Destroyed tissue cells are replaced with identical or similar structural and functioning cells and/or fibrous tissue.	Promotes tissue healing or the formation of fibrous (scar) tissue, which may reduce the functional capacity of the tissue.

to the antigen. **Antibodies** are protein substances that counteract and neutralize the effects of antigenic toxins and destroy bacteria and other cells. Antibodies destroy the antigen. Stimulation of B cells and antibody production are referred to as **humoral immunity**.

B cell activation causes formation of memory B cells. Memory B cells remember the antigen and prepare the host for future antigen invasion. Therefore, when the antigen enters the body again, the immune response will occur more rapidly by producing antibodies faster. The formation of these antibodies is referred to as **acquired immunity**, which protects the individual against invading agents such as lethal bacteria, viruses, toxins, and even foreign tissues from other animals.

The process of **vaccination** provides acquired immunity against specific diseases. There are three ways an individual can be vaccinated:

1. By injection of dead organisms that are no longer capable of causing disease but still have their chemical antigens, such as typhoid fever, whooping cough, and diphtheria.
2. By toxins that have been treated with chemicals so that their toxic nature has been destroyed even though their antigens for causing immunity are still intact, such as tetanus and botulism.
3. By infection with live organisms that have been attenuated (grown in a special culture media or passed through a series of animals for mutation; the organisms then do not cause the disease but still carry the specific antigen). Attenuated vaccines protect against poliomyelitis, yellow fever, measles, smallpox, and many other viral diseases.

Although 10,000 new cases of hepatitis B virus (HBV), formerly called serum hepatitis, are reported each year in the United States; HBV is considered one of the most underreported diseases in the country (Marx, 1998). Risk factors associated with HBV infection among health care workers include the frequency of blood and needle exposures. In order to protect health care workers against HBV infections, the Occupational Safety and Health Administration (OSHA) has established standards relative to vaccination programs.

Stages of the Infectious Process

Activation of the immune response indicates the occurrence of infection. Infection results from tissue invasion and damage by an infectious agent. There are two types of infectious responses:

1. **Localized infections** are limited to a defined area or single organ with symptoms that resemble inflammation (redness, tenderness, and swelling).
2. **Systemic infections** affect the entire body and involve multiple organs.

Localized or systemic infections progress through four stages of infection:

- Incubation
- Prodromal
- Illness
- Convalescence

The **incubation period** is the time interval between entry of an infectious agent in the host and the onset of symptoms. During this time period, the infectious agent invades the tissue and begins to multiply to produce an infection.

NURSING ALERT

Incubation Period

Always check the incubation period of an infection. Depending on the infectious agent, a client may be able to transmit the infection to another person.

The **prodromal stage** is the time interval from the onset of nonspecific symptoms until specific symptoms of the infectious process begin to manifest. During this period, the infectious agent continues to invade and multiply in the host. A client may also be infectious to other persons in this time period.

The **illness stage** is when the client is manifesting specific symptoms of an infectious process. The period of time from the beginning of the disappearance of acute symptoms until the client returns to the previous state of health is referred to as the **convalescent stage**.

Nosocomial Infections

Nosocomial infections are infections acquired in the hospital or other health care facilities that were not present or incubating at the time of the client's admission. Nosocomial infections are also referred to as hospital-acquired infections. Nosocomial infections include those infections that become symptomatic after the client is discharged as well as infections among medical personnel. Most nosocomial infections are transmitted by health care personnel who fail to practice proper handwashing procedures or change gloves between client contacts.

Hospitalized clients are at risk for nosocomial infections because the environment provides exposure to a variety of virulent organisms that the client has not been exposed to in the past; therefore, the client has not developed any resistance to these organisms. In addition, illness, often the reason for hospital admission, impairs the body's normal defense mechanisms.

According to the Centers for Disease Control and Prevention (CDC), the rate of hospital nosocomial infections per 1,000 patient days has increased 36%

from 7.2 in 1975 to 9.8 in 1995. It is estimated that in 1995, nosocomial infections cost \$4.5 billion and contributed to more than 88,000 deaths, one death every 6 minutes (Weinstein, 1998).

Nicolle and Garibaldi (1995) discuss the increased risk of infections in long-term care facilities. The most common endemic infections in this setting affect the urinary tract, upper and lower respiratory tracts, gastrointestinal tract, conjunctiva, and skin. Hospitalized clients have multiple comorbidities that increase their risk of infection. For example, urologic abnormalities (prostatic hypertrophy) are associated with urinary tract infections. Chronic obstructive lung disease and congestive heart failure increase a client's risk of developing pneumonia. Diabetes or vascular insufficiency may lead to more frequent and severe skin infections (pressure ulcers, cellulitis, and vascular ulcers). Since these high-risk clients are housed together, the transmission of pathogens is increased among residents. For instance, organisms may be transmitted through the air (e.g., tuberculosis, influenza), on the hands of staff members (e.g., *Staphylococcus aureus* or uropathogens), and by contaminated items (e.g., *E. coli*).

Nosocomial infections are receiving increased attention because of the development of multiple-drug-resistant organisms (MDROs). The two most common MDROs are bacteria—methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant enterococcus (VRE)—in both hospital and long-term care clients; other drug-resistant organisms include tuberculosis bacilli and *Clostridium difficile* (Davis & Madigan, 1998).

Overuse of antibiotics has increased the prevalence of MDROs (CDC, 1996). “Annually, as many as 150 million outpatient prescriptions written to treat viral upper respiratory tract infections have no effect” (Wolgin & Olmsted, 1999, p. 7). The indiscriminate use of antibiotics has given once-susceptible bacteria the chance to develop resistant strains to antibiotics (Sheff, 1999). MRSA and VRE are spread by infected or colonized clients or colonized health care workers. The most effective way to prevent the spread of MDROs is proper handwashing.

Blood-Borne Pathogens

The risk for blood-borne pathogens in the health care setting is an increasing concern for health care providers. In the fall of 1999, OSHA issued an update that supersedes the one issued in 1992 regarding the risk for blood-borne pathogens to health care providers. OSHA's 1999 directive recognizes the advances made in medical technology such as improved safety equipment and devices, better methods of treatment following exposure and more concise policy interpretations; these advances decrease the risks of health care workers exposed to blood-borne pathogens, specifically the human immunodeficiency virus (HIV), and hepatitis B and C (Bending, 2000).

The major hepatitis viruses in humans in the United States and the world are HAV, HBV, HCV, HDV, HEV, and HGV. HCV is prevalent in the United States, with over 3,000 new cases reported each year; however, it is also underreported, as is HBV (Marx, 1998). Henderson (1999) and Howell (1999) refer to hepatitis C as the “sleeping giant” of occupational infections in the health care settings; unlike for HBV, there is no vaccine for HCV. According to the CDC (1996), 85% of infected persons who contact HCV become chronically infected, and 70% of the infected persons develop chronic hepatitis.

HYGIENE

Hygiene is the science of health. Hygienic care promotes cleanliness, provides for comfort and relaxation, improves self-image, and promotes healthy skin. Client hygiene is an extension of providing client safety and protecting the client's defense mechanisms. The health of the body's first line of defense (skin and mucous membranes) is promoted by client hygiene. Nurses are responsible for assuring that the client's hygienic needs are met. The type of hygienic care provided depends on the client's ability, needs, and practices.

Factors Influencing Hygienic Practice

Hygienic needs and practices are unique to each client; nurses should provide individualized care based on these needs and practices. Hygienic practices are influenced by several factors: body image, social and cultural practices, personal preferences, socioeconomic status, and knowledge.

Body Image

Body image is the client's subjective belief about his or her own physical appearance. Body image is associated with the client's emotions, mood, attitude, and values. See Chapter 19 for a complete discussion of this concept. A client's body image directly affects the type of personal hygiene practiced; this may change if the client's body image is altered because of illness or surgical procedures. During this time, the nurse should help the client maintain hygienic practices in accordance with the client's pre-illness level of hygiene and personal preferences.

Social and Cultural Practices

Social and cultural practices also directly influence hygienic practices. Clients are socialized to their hygienic practices by family practices in early childhood. As a person ages, hygienic practices are influenced by maturational development and socialization with

people outside of the family. For example, teenagers are usually concerned with peer acceptance and follow the latest trends in personal hygiene. In later adulthood, hygienic practices may be influenced by coworkers and social networks.

Cultural practices and beliefs are derived from family, religious, and personal values developed during maturation. See Chapter 16 for a complete discussion of cultural diversity. Clients from diverse cultural backgrounds will have differing hygienic practices. For example, some cultures do not permit women to submerge their bodies in water during the time of menstruation because there is fear that the woman may drown. In North America, people typically bathe daily and use numerous deodorant products. In Europe, people do not bathe daily and seldom use deodorant products. Europeans do not consider the smell of human perspiration as offensive as do North Americans. Nurses should have a nonjudgmental attitude when assessing or providing hygienic care to clients from different social or cultural backgrounds.

Personal Preferences

Personal preferences influence when bathing occurs, what products are used, and what type of bath is performed. For example, some male clients may shave before bathing, while others prefer to wait until after the bath. Some clients prefer to bathe in the morning to facilitate waking, while others prefer to bathe before bedtime to encourage relaxation and sleep. Unless a client's health is affected, the nurse should permit clients to practice their usual routine and use the hygienic products that they prefer. Individualized nursing care should incorporate the client's personal hygiene preferences.

THINK ABOUT IT

Hygiene and Personal Preferences

What role do values have in relation to self-care needs? Do you believe that a client's hygienic activities demonstrate personal preferences and idiosyncrasies that are based on family, culture, religion, and other factors? What should you do to avoid projecting your own values onto the client? If the client states, "I feel uncomfortable about you bathing me," what should you do? Another area that requires sensitivity on your part deals with a client's use or failure to use hygienic products, for example, deodorant. How do you feel about caring for a client who does not use deodorant or whose hygiene habits differ greatly from your own?

Socioeconomic Status

A client's hygienic practices may be influenced by socioeconomic status. Limited economic resources may affect the type, frequency, and extent of hygiene prac-

ticed. Assessment of socioeconomic status provides information about the availability of hygiene supplies. Some clients may not be able to afford deodorants, perfumes, soaps, shampoo, and toothpaste. The nurse can function as an advocate for the client by making referrals to community agencies that provide assistance to needy persons, for example, Catholic Charities or a local chapter of the American Association of Retired Persons (AARP).

Knowledge

Knowledge level influences the client's understanding about the relationship between hygiene and health. Thus, knowledge should influence a client's hygienic practices. In addition to being knowledgeable, before clients perform basic hygiene, they must be motivated and believe that they are capable of self-care.

Frequently, an illness or surgical procedure results in deficient knowledge about basic hygienic practices. In these situations, the client may not know the correct procedures or types of hygiene that can be performed. The nurse is responsible for providing the necessary education about hygiene during an illness. Sometimes, the nurse may have to perform all hygienic practices for a client during an illness until the client is able to regain this ability.

ASSESSMENT

The nursing process facilitates an understanding of the scope of challenges inherent in the nursing care of clients at risk for injury, infections, or a self-care deficit. The assessment data should direct the prioritization of the client's problem and accompanying nursing diagnoses. Clients at risk for injury or infection require frequent reassessment of their status with appropriate changes in the plan of care and expected outcomes.

The assessment and physical examination data are correlated with the laboratory indicators to identify those clients who are at risk for problems relating to safety, infection, or hygiene. One of the assessment models should be used to provide structure to the assessment. See Chapter 6 for a complete discussion of assessment models. Appropriate risk appraisals may be incorporated into the nursing health history interview. These core elements of assessment are discussed in relation to clients in ambulatory, institutional, and home settings. Refer to the accompanying display for a sample format for developing minimum safety standards applicable to all health care settings.

Health History

The nursing health history interview is the first part of assessment; it provides the client's subjective specific

STANDARD OF CARE: SAFETY

Client Outcome

The client will receive care in a safe health care environment and remain free of preventable injuries.

Nursing Practice Standards

1. Perform a client injury risk appraisal on admission and prior to therapeutic nursing interventions. Risk factors for injury include but are not limited to age, altered mental status, previous history of falls, impaired mobility, sensory deficits, perceptual deficits, and inability to communicate.
2. Eliminate or modify risk elements when possible, such as assisting with mobility and placing bed rails up with bed in the lowest position.
3. Implement environmental precautions such as hand rails, nonslip mats or rugs, and adequate lighting.
4. Use infection control practices that prevent or control the transmission of pathogens.
5. Maintain intravenous access according to intravenous protocols.
6. Implement emergency measures in accordance with American Heart Association guidelines for cardiopulmonary resuscitation (CPR) and advanced life support.
7. Know and comply with the institution's Environmental Health and Safety guidelines.
8. Implement emergency measures during fires and disasters.
9. Use mechanical, radiant, chemical, and thermal equipment according to the manufacturer's guidelines and institution's policy and procedures.
10. Use a multidisciplinary approach to enhance client safety as indicated.

health data. Key elements of relevant data regarding the client at risk for safety and infection are obtained in the health history. See Chapter 6 for a sample of a nursing health history tool.

The client is often asked to complete a health history questionnaire; however, depending on the client's status, the nurse may have to perform an interview to obtain these data. If the client is unable to provide the subjective data, the nurse must designate on the questionnaire or in the nursing progress notes who provided the information.

During the nursing health history interview, assess the client's general health perception and management status to determine how the client manages self-care. This information will provide data regarding the client's routine self-care and health promotion needs. Sample questions that relate specifically to habits that foster safe, healthy patterns of behavior are presented in the accompanying display. These questions are appropriate for home health and ambulatory care settings as well as inpatient settings.

KEY INTERVIEW QUESTIONS ABOUT SAFETY, INFECTION CONTROL, AND HYGIENE

- Describe the things you do to stay healthy.
- How do you typically spend a day (e.g., home or work)?
- What are your health care concerns?
- Do you need assistance with bathing and dressing?
- Do you regularly visit the dentist and eye doctor?
- Do you use dental floss on a regular basis?
- Have you recently come in contact with someone who has an infectious disease?
- Do you wash your hands when preparing food?
- Do you keep meats and dairy products refrigerated until ready to use?
- Is there a smoke detector or fire extinguisher in your home?
- Are emergency phone numbers readily available?

Physical Examination

A complete health assessment includes a systematic physical examination, generally conducted from head to toes, in order to obtain objective data relative to the client's health status and presenting problems. See Chapter 27 for a complete discussion of a physical examination.

When assessing the client to determine the level of risk for injury or infection and hygienic deficits, focus the physical examination on the following areas and signs:

- Level of consciousness: Use the Glasgow Coma Scale to evaluate this attribute (see Chapter 36 for discussion of this tool).
- Range of motion or total immobilization of an extremity.
- Localized infection: Redness, swelling, warmth, tenderness, pain, and loss of movement in a specific body part.
- Systemic infection: Fever, with a corresponding increase in pulse and respirations; weakness; anorexia, with possible accompanying findings of nausea, vomiting, and diarrhea; enlarged and/or tender lymph nodes.
- Secretions or exudate of the skin or mucous membranes and detection of crackles, rhonchi, or wheezes in the lungs on auscultation.

The condition of the skin is a good indicator of a client's general health status. Assessment of skin integrity provides data concerning a client's nutritional and hydration status, continuity of intact skin, hygienic practices, and overall physical abilities. Similarly, a client with limited mobility is at risk for developing joint contractures, skin breakdown, and muscle atrophy.

SKIN INTEGRITY RISK APPRAISAL

Area of Assessment	Score
General Physical Condition (Health Problem)	
Good (minor)	0
Fair (major but stable)	1
Poor (chronic/serious, not stable)	2
Mental State/Level of Consciousness (to Commands)	
Alert (responds readily)	0
Lethargic (slow to respond)	1
Semicomatose (responds only to verbal or painful stimuli)	2
Comatose (no response to stimuli)	3
Activity	
Ambulate without assistance/infant	0
Ambulate with assistance	2
Chairfast/out-of-bed to chair	4
Bedfast/confined to bed	6
Mobility (Extremities)	
Full active range	0
Restricted movement (slightly limited)	2
Moves only with assistance	4
Immobile	6
Incontinence (Bowel and/or Bladder)	
None	0
Occasional (less than twice in 24 hours)	2
Usually (greater than twice in 24 hours)	4
Total (no control)	6
Nutrition (for Age and Size)	
Good (eats/drinks adequately)	0
Fair (eats/drinks inadequately)	1
Poor (unable/refuses to eat/drink)	2
Totally depleted	3

Assess the client's risk status for each indicator on the skin integrity risk appraisal form, then total the numbers from all six indicators. The risk rating is as follows:

- 0–8: low risk
- 9–16: moderate risk
- 17–27: high risk

Usually a rating greater than 8 requires implementation of special skin measures; for example, a protocol to prevent skin breakdown.

(Patient Care Admission Sheet courtesy of Tulane University Hospital & Clinic, New Orleans, LA)

The client's self-care abilities, used for determining the level of assistance needed in providing hygienic care, are appraised during the health history. The analysis of relevant risk factors alerts the nurse to actual or possible risks. Skin integrity is usually compromised when a person is placed on bed rest. A skin integrity risk appraisal such as the one shown in the accompanying display should be completed to assist with planning care.

Client in an Inpatient Setting

Inpatient clients should be assessed for fall and infection risk factors. The hospitalized or institutionalized client's risk for falls is identified after compiling specific assessment data that are correlated with contributing factors. Each of these indicators carries a specific weight, as shown in the accompanying Fall Risk Appraisal, to determine the client's risk. The inpatient client should be assessed for falls every shift or as designated by institutional policy. To minimize the chance of falls, make sure the client's environment is safe: the bed is kept in a low position, side rails are up, personal belongings are in easy reach, and assistive devices (e.g., walker) are nearby, as shown in Figure 31-4.

To determine risk for infection, review or listen to the client's response to the health history and inter-

Figure 31-4 This client's risk of falls has been assessed and responded to through the measures shown here. Do all clients within the hospital setting need to be assessed for the risk of falls, regardless of their health status or reason for hospitalization?

Risk Factors

A comprehensive nursing assessment involves using specifically developed risk assessment tools and appraising the client's environment to detect potential hazards.

FALL RISK APPRAISAL

Area of Assessment	Score
General Factors	1
Restraint (posey, arm, leg)	
Orthostatic changes	
History of falls/crawling out of bed/syncope (brief loss of consciousness)	
Seizure disorder	
Elimination Function	2
Decreased bladder/bowel tone	
Urgency/frequency	
Incontinence	
Nocturia (excessive urination at night)	
Age	3
Over 65	
Level of Consciousness/Mental Status	4
Lethargic (slow to respond)	
Inability or refusal to follow directions	
Inability or refusal to call for help	
Impaired judgment, memory, awareness	
Confused, disoriented	
Sensory Deficits	5
Diminished visual acuity, blind, blurred vision	
Slow reaction time	
Mobility/Physical Limitations	6
Decreased mobility in lower extremities	
Up with assistance	
Amputee/joint difficulties	
Weakness, dizziness, fatigability, vertigo (dizziness), syncope	
Cast, splint	
Use of crutches, cane, walker	
Hemiparesis (one-sided paralysis), paraparesis (loss of function), hemiplegic, paraplegic (loss of function in lower limbs)	
Ataxia (unsteady gait)	
Improper fitting/smooth soled/no footwear	
Unsteady gait, decreased balance, imbalance	
Medications	7
Sedatives/hypnotics/tranquilizers	
Diuretics/antihypertensives/laxatives	
Narcotics/analgesics/anesthetics	
Antihistamines	
Antiseizures	
Barbiturates/phenothiazines	
Eye drops	
Antipsychotics/antidepressants	
Scoring: If the client is over 65 years of age, the indicator has a weight of 3. If the client is also receiving a diuretic, which has a weight of 7, the total risk factor for this client is 10. This would place the client at high risk for falls and would require the implementation of special fall measures. (Patient Care Admission Sheet courtesy of Tulane University Hospital & Clinic New Orleans, LA)	

view questions related to “exposure to infectious diseases,” “invasive procedures,” and “behaviors you think you should change.” An infection risk appraisal is based on the defining characteristics that place a client at risk for an infection. These factors are listed in the section entitled Nursing Diagnosis.

Client in the Home

An injury risk appraisal will provide the nurse with assessment data to determine the client’s level of safety knowledge as previously discussed in the standard of care for safety. Injuries in the home are primarily the result of falls, fires, electrical malfunctions, suffocation, weapons, and household and medication poisonings. Home health nurses may use a safety risk appraisal; refer to the accompanying display.

The safety risk data assessed in the home environment direct the nurse in planning for the client and caregiver’s education. The home health nurse needs to prioritize these data when planning the client’s care. Assessment, teaching, and outcome evaluation of all safety hazards can take several home visits.

Diagnostic and Laboratory Data

Appraising the client’s risk for injury should also include an evaluation of laboratory findings relative to an abnormal blood profile (e.g., altered clotting factors, anemic conditions, or leukocytosis). See Chapter 28 for a complete discussion of abnormal blood profiles. Malnourished clients are at risk for injury.

The laboratory indicators for an infection are:

1. An elevated leukocyte (white blood cell [WBC]) and WBC differential:
 - Neutrophils: Increased in acute, severe inflammation
 - Lymphocytes: Increased in chronic bacterial and viral infections
 - Monocytes: Increased in some protozoan and rickettsial infections and tuberculosis
 - Eosinophils and basophils: Unaltered in an infectious process
2. An elevated erythrocyte sedimentation rate (ESR): Increased in the presence of inflammation
3. An elevated pH of involved body fluids (gastric, urine, or vaginal secretions): Indicates the presence of microorganisms
4. Positive cultures of involved body fluids (blood, sputum, urine, or other drainage): Indicates the growth of microorganisms

Refer to Chapter 28 for the age-related normal laboratory values for each of the preceding tests.

HOME SAFETY RISK APPRAISAL

Infant

- Crib has side rails that stay in the up position while infant is in the crib.
- Infants are not left unattended, especially on elevated surfaces or in the bath.
- Bath water temperature is 37.8°–40.6°C (100°–105°F). Check temperature for comfort with wrist.
- Environment is kept warm and draft-free at bath time.
- Bottles are sterilized and formula refrigerated.
- Toys are soft without detachable pieces.
- Car seat has restraint strap and is used consistently.
- Stroller and carry seat are sturdy with a restraint strap.
- Fire, police, and poison control numbers are posted by telephones.
- Caregivers know infant CPR.

Toddler/Preschooler

- Sharp objects are placed out of reach and out of sight.
- Poisons are labeled and placed in a locked cabinet.
- Medications and other toxins have childproof lids and are stored in a locked cabinet.
- Small, hard food objects (peanuts, candy) are kept in locked cabinets.
- Stairs and floor furnaces have gates or barriers.
- Safety locks are on doors and windows.
- Electrical outlets are covered.
- Burners on the stove are not left on and unattended.
- Pots with hot liquids are placed on back burners with handles facing toward the back wall.
- Home and yard are free from poisonous plants.
- Play equipment is kept in proper functioning condition; toys have no small parts; crayons are nontoxic.
- Outdoor play is supervised in a fenced area with locks on gates.
- Car seat/belt is used consistently.
- Supervision is given child when crossing the street.
- Caregivers know child CPR and Heimlich maneuver.

School-Age Child

- Play and sports are supervised.
- Play equipment kept in proper functioning condition and free from hazards.
- Outdoor play limited to soft surfaces.
- Bicycle helmet worn consistently.
- Taught not to open the door or speak with strangers while at play.
- Firearms are kept unloaded in locked cabinets.
- Caregivers know child CPR and the Heimlich maneuver.
- Seat belt is worn at all times.

Adolescent

- Firearm safety is taught.
- Seat belt is worn at all times.
- Teenagers take drivers' education; cautioned about drinking and driving.
- Caregivers know adult CPR and the Heimlich maneuver.

HOME SAFETY RISK APPRAISAL (continued)

Adult

- Firearms have safety latches.
- Smoke detector and fire extinguisher installed in the home.
- Sharp-edged objects are safely stored.
- A nondrinking designated driver is chosen.
- Emergency phone numbers are readily available.
- Caregiver knows adult CPR and Heimlich maneuver.

Older Adult

- Stairs have adequate lighting and nonskid surfaces, and rails are in good condition.
- Throw rugs are not present.
- Hallways are uncluttered.
- Carpets are free from frayed ends/pieces.
- Phone and other cords are behind furniture.
- Bathtub has rails and nonslip surface.
- Shower stall has seat.
- Bathroom is free from drafts.
- Shoes fit properly with nonskid soles.
- Home is adequately ventilated and heated.
- Home is free of space heaters.
- Pilot lights are functional for gas appliances.
- Electrical appliances are in good working condition.
- Food is properly refrigerated.
- Medications are kept in properly labeled containers with readable print.
- Emergency phone numbers are readily available.
- Fire and police departments aware of older adult at home alone.
- Caregiver knows adult CPR and Heimlich maneuver.

NURSING DIAGNOSIS

After data collection and analysis, the nurse is able to formulate a nursing diagnosis. If Gordon's Functional Health Patterns model is used to conduct the assessment, the nurse can use the classification of nursing diagnoses by functional health patterns that relate to safety, infection, and hygienic deficits; for example:

- I. Health perception–health management pattern
 - Risk for injury
 - Risk for infection
- II. Activity-exercise pattern
 - Bathing/hygiene self-care deficit
 - Dressing/grooming self-care deficit
 - Toileting self-care deficit

Risk for Injury

The primary nursing diagnosis *Risk for Injury* exists when the client is at risk of injury as a result of environmental conditions interacting with the individual's adaptive and defen-

sive resources (NANDA, 2001). Although this diagnostic label does not have defining characteristics as set forth by NANDA, it is categorized as having either internal or external potential hazards. An internal biochemical risk factor for a client with impaired vision would be stated as *Risk for Injury* related to sensory dysfunction. In contrast, a home health nurse's assessment data that identify drugs on a nightstand with a toddler in the home as creating an external chemical risk factor for the toddler would be stated as *Risk for Injury* related to drugs (pharmaceutical agents).

NANDA (2001) has six defined subcategories of specific risk factors for this diagnostic labeling:

1. *Risk for Suffocation*: An accentuated risk of accidental suffocation
2. *Risk for Poisoning*: An accentuated risk of accidental exposure to, or ingestion of, drugs or dangerous products in doses sufficient to cause poisoning
3. *Risk for Trauma*: An accentuated risk of accidental tissue injury (e.g., wound, burn, fracture)
4. *Risk for Aspiration*: Risk for entry of gastrointestinal secretions, oropharyngeal secretions, or solids or fluids into the tracheobronchial passages
5. *Risk for Disuse Syndrome*: Risk for deterioration of body or body systems as the result of prescribed or unavoidable musculoskeletal inactivity
6. *Latex Allergy Response*: A response to natural latex rubber products

These six subcategories of nursing diagnoses provide the nurse with the opportunity to relate specific nursing interventions to the diagnosed problem. For example, the specific nursing diagnosis for the situation of a toddler in the home environment encountering medications on a nightstand would be *Risk for Poisoning* related to medicines not stored in locked cabinets and accessible to children. The level of risk would be increased if the medications on the client's nightstand were in open containers or the closed containers failed to have child-proof caps. The subcategory diagnosis provides specific nursing interventions directed at the level of risk for the toddler and the need for client teaching.

Risk for Infection

Risk for infection is the state in which an individual is at increased risk for being invaded by pathogenic organisms (NANDA, 2001). The risk factors that increase the client's vulnerability to infections are:

- Inadequate primary defenses (broken skin, traumatized tissue, decrease in ciliary action, stasis of body fluids, change in pH of secretions, and altered peristalsis)
- Inadequate secondary defenses, acquired immunity, and immunosuppression
- Tissue destruction and increased environmental exposure
- Chronic diseases and malnutrition

- Invasive procedures and pharmaceutical agents
- Trauma
- Rupture of amniotic membranes
- Insufficient knowledge to avoid exposure to pathogens (NANDA, 2001)

Self-Care Deficits

A **self-care deficit** exists when the client is not able to perform one or more of the activities of daily living. NANDA (2001) identifies three self-care deficits related to hygienic practices. These diagnostic labels, together with their defining characteristics and related factors, are presented in Table 31-2.

Other Nursing Diagnoses

Clients who are at risk for injury and infection or have a self-care deficit may have other problems. These associated physiological and psychological problems are discussed in detail in other chapters in this unit. The common nursing diagnoses that often accompany diagnostic labels for risk or self-care deficits are:

- *Imbalanced Nutrition* (specify less than body requirements or more than body requirements)
- *Ineffective Protection*
- *Impaired Tissue Integrity*
- *Impaired Oral Mucous Membrane*
- *Impaired Skin Integrity*
- *Social Isolation*
- *Risk for Loneliness*
- *Ineffective Coping*
- *Impaired Physical Mobility*
- *Hopelessness*
- *Powerlessness*
- *Deficient Knowledge* (specify)
- *Acute Pain*
- *Anxiety*
- *Fear*

This list is not all-inclusive but gives an indication of the number of related problems that need to be considered when planning care.

THINK ABOUT IT

Experiencing Self-Care Deficits

Imagine that you are unable to feed yourself, you cannot dress yourself, and you are incontinent and must rely on others to clean you. You are completely dependent on caregivers since you have no family or friends to assist you. How do you feel about being dependent on caregivers to meet your basic needs? What happens if the caregivers do not respond when you ask for help? How do you feel when others make decisions for you?

TABLE 31-2
Self-Care Deficits

Nursing Diagnosis and Definition	Defining Characteristics	Related Factors
<i>Bathing/Hygiene Self-Care Deficit:</i> A state in which the individual experiences an impaired ability to perform or complete bathing/hygiene activities for self	Inability to wash body or body parts, obtain or get water from a water source, or regulate the temperature or flow of water	Intolerance to activity; decreased strength and endurance; pain, discomfort; impairment of perception or cognition, neuromuscular activity, and musculoskeletal function; depression, severe anxiety
<i>Dressing/Grooming Self-Care Deficit:</i> A state in which the individual experiences an impaired ability to perform or complete dressing and grooming activities for self	Impaired ability to put on or take off necessary items of clothing, obtain or replace articles of clothing, fasten clothing, or maintain appearance at a satisfactory level	Intolerance to activity; decreased strength and endurance; pain, discomfort; impairment of perception or cognition, neuromuscular activity, and musculoskeletal function; depression, severe anxiety
<i>Toileting Self-Care Deficit:</i> A state in which an individual experiences an impaired ability to perform or complete toileting activities for self	Unable to get to toilet or commode, sit on or rise from toilet or commode, manipulate clothing for toileting, carry out proper toilet hygiene, or flush toilet or commode	Impaired transfer ability and mobility status; intolerance to activity; decreased strength and endurance; pain, discomfort; impairment of perception or cognition, neuromuscular activity, and musculoskeletal function; depression, severe anxiety

(From North American Nursing Diagnosis Association. [2001]. *Nursing Diagnoses: Definitions and Classification 2001–2002*. Philadelphia: Author.)

OUTCOME IDENTIFICATION AND PLANNING

The primary nursing goal is to provide safe care through the identification of actual or potential hazards and the implementation of safety measures. The assessment data are reviewed with the client, and the nurse records the areas in which the client indicates a need for change and health teaching, for example, age-related exercise or maintaining a safe environment. These findings are incorporated into the plan of care, reflecting the individualized needs of each client.

During the planning phase, the nurse collaborates with the client and other health care providers to determine the goals, outcomes, and interventions and manipulates the external environment to reduce the risk of injury and infection. Identified outcomes provide direction for the nursing care that is implemented to reduce the risk of injury and infection.

Another critical element of the care plan is client/caregiver education related to the identification of potential hazards and health promotion practices. The nursing care plan should include safety measures that educate clients about preventive actions and modification of an unsafe environment, for example, proper use of a call light or the side effects of medications.

Table 31-3 discusses the basic components of care planning and outcome measurements for clients at risk or with a self-care deficit. Sample statements of goals

and expected outcomes are included in Table 31-3. The nursing interventions are statements taken from the Nursing Intervention Classification System. For each of these nursing interventions, there are specific actions taken by the nurse to individualize the care for each client. The nurse could use Gordon's Functional Health Patterns to plan care. Gordon's Functional Health Patterns that may be used for clients at risk or with a self-care deficit are health perception–health management; activity-exercise pattern; and cognitive-perceptual pattern. Nursing actions are discussed in detail in the following section.

IMPLEMENTATION

Nursing care implemented for clients with alterations in health perception–health management or activity and exercise involves continual assessment of client health risks and prioritization of risk reduction nursing interventions, such as:

- Administration of prescribed medications (refer to Chapter 29)
- Provision of balanced nutritional intake (refer to Chapter 38)
- Promotion of adequate rest and exercise (refer to Chapters 33 and 34)
- Decreasing the spread of infection

TABLE 31-3
Planning the Care of Clients at Risk for Injury or Infection and/or with a Self-Care Deficit

Nursing Diagnosis and Definition	Goals	Expected Outcomes	Nursing Interventions
<i>Risk for Injury</i>	1. The client will identify factors that increase the potential for injury.	1. The client will identify internal and external factors that will increase the risk for injury.	Risk identification: Analysis of potential risk factors, determination of health risks, and prioritization of risk reduction strategies for an individual
	2. The client will remain free of bodily injury.	2. The client will identify and implement safety measures to decrease the risk for injury.	Fall prevention: Instituting special precautions with client at risk for injury
<i>Risk for Infection</i>	1. The client will remain free of nosocomial infection.	1. The client will remain afebrile during hospitalization.	Infection protection: Prevention and early detection of infection in a client at risk
	2. The client will reduce exposure to known infectious agents.	2. The client will not engage in unprotected sexual intercourse.	Infection control: Minimizing the acquisition and transmission of infectious agents
<i>Bathing/Hygiene Self-Care Deficit</i>	1. The client will maintain an optimum functional level in hygienic practices in a safe and effective manner.	1. The client will participate physically and/or verbally in bathing, dressing, and toileting activities.	Bathing: Cleaning of the body for the purpose of relaxation, cleanliness, and healing Dressing: choosing, putting on, and removing clothes for a person who cannot do this for self
	2. The client's skin will remain clean and intact.	2. The client's skin will be free from drainage or secretion, intact, and without redness.	Skin surveillance: Collection and analysis of client data to maintain skin and mucous membrane integrity Perineal care: Maintenance of perineal skin integrity and relief of perineal discomfort
<i>Deficient Knowledge: related to health hazards</i>	The client will not sustain injuries.	The client will verbalize feedback of instructions and willingness to comply.	Teaching individual: Planning, implementation, and evaluation of a teaching program designed to address a client's particular needs

From McCloskey, J. C., & Bulechek, G. M. (Eds.). (1996). *Nursing Interventions Classification (NIC)* (2nd ed.) St. Louis, MO: Mosby Yearbook.

Implementation of safety measures may require an alteration in the physical environment as directed by the fall prevention protocol or Standard Precautions; refer to Table 31-4. Chapter 34 provides additional information on fall prevention.

Nursing measures to counter common physical hazards that impair environmental safety are maintaining electric beds in the low position with side rails up and call light within easy reach and keeping the bedroom and bathroom uncluttered to prevent falls. Some states consider side rails a form of restraint. Nurses must be knowledgeable about statutory provisions relative to health care in their state.

The implementation of standard precautions is the most effective nursing measure to prevent and control the spread of infections. Standard Precautions are discussed in detail later in this chapter.

Raise Safety Awareness and Knowledge

Nurses in all settings must demonstrate an awareness of safety hazards and teach clients accordingly. Clients must be aware of and knowledgeable about safety

TABLE 31-4
Adult Fall Prevention Protocol

Purpose

To direct the nursing management of the client at risk for falls

Level

Interdependent nursing function

Supportive Data

Falls account for nearly 90% of injuries reported in hospitalized clients (Whedon & Shedol, 1989). Risk factors for falls include age, dizziness, confusion, use of medications, and physical or mental alterations. Fall prevention is used to increase staff awareness of clients at risk for falls and to provide preventive safety measures.

Content

Assessment

1. Perform client injury risk appraisal and identify fall risks. Update status of fall risks daily and as needed on nursing care plan.
2. Assess effects of medications administered that increase risk of falling.
3. Implement institution's fall prevention program.

Report to Physician

4. Notify physician of previous fall history and identify risk factors for a fall.
5. Notify physician of adverse effects of medications that may increase the client's risk of falling.

Client Teaching

6. Orient client to environmental surroundings on admission and as necessary.
7. Instruct client and significant others on safety measures.
8. Instruct client and significant others on correct use of hospital equipment.
9. Instruct client with risk for falls to call for assistance when ambulating or performing activities of daily living (ADL).

Environmental Interventions

10. Keep bed in lowest position, brakes locked, and side rails up.
11. Keep call light and frequently used objects within easy reach at the bedside.
12. Keep environment clean and clutter-free.
13. Provide adequate lighting at all times.
14. Lock wheels on wheelchair, bed, and stretcher at all times.
15. Provide nonslip footwear, mats, and rugs.
16. Keep hospital furniture in the same place throughout hospital stay.
17. Provide call cord in bathroom.
18. Encourage use of handrails in bathroom and hallways.
19. Provide nonslip mats in the tub or shower.
20. Place high-risk clients in a room near the nurse's station.

Direct Nursing Care

21. Respond promptly to call lights and verbal requests for assistance.
22. Provide assistance with ADL.
23. Maintain close supervision by performing hourly safety assessments.
24. Encourage significant others to stay with high-risk clients.
25. Provide proper equipment for ambulation and elimination needs.
26. Communicate client's injury risk status in shift report.
27. Provide protective devices such as restraints for client safety (physician's order necessary).

Evaluation

28. Evaluate client's knowledge of safety measures.
29. Evaluate effectiveness of environmental interventions.
30. Evaluate changes in client's injury risk status.
31. Evaluate effectiveness of direct nursing care.

(continues)

TABLE 31-4 (continued)
Adult Fall Prevention Protocol**Content***Documentation*

32. Document the following in the client's medical record:
- Assessment of client's injury risk status
 - Nursing plan of care
 - Safety measures implemented
 - Client education performed
 - Client outcomes

(From Whedon, M. B., & Shedol, P. [1989]. Prediction and prevention of patient falls. *Image: Journal of Nursing Scholarship*, 21(2), 108–114.)

precautions in order to prevent injuries. Clients may also need specific safety information on oxygen, intravenous equipment, use of heating devices, and automatic bed controls.

A Food and Drug Administration (FDA) safety alert addressed entrapment hazards with side rails on hospital beds. The FDA received 102 reports of head and body entrapment incidents that resulted in 68 deaths, 22 injuries, and 12 entrapments without injury that occurred in hospitals, long-term care facilities, and private homes. All reported entrapments occurred in one of the four ways identified in Figure 31-5.

Prevent Falls

Falls occur among clients who are weak, fatigued, uncoordinated, paralyzed, confused, or disoriented. The data obtained from the client's fall risk appraisal will identify which clients require special nursing measures to prevent falls. The risk for falls can be reduced by:

- Good supervision
- Orienting clients to the environment and call system

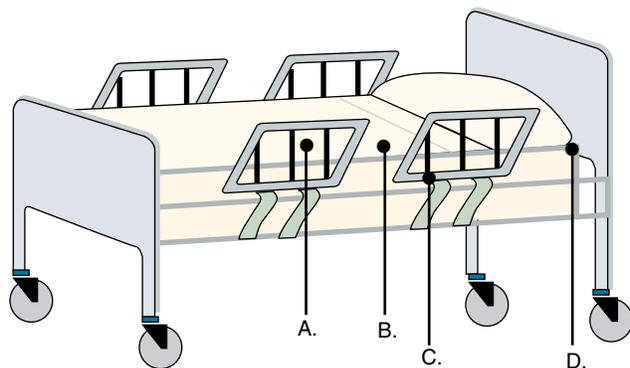

Figure 31-5 Entrapment hazards with hospital bed side rails. A. Through the bars of an individual side rail; B. through the space between split side rail; C. between the side rail and mattress; or D. between the headboard or footboard, side rail, and mattress. (From Food and Drug Administration, *Safety Alert*, August 23, 1995.)

- Providing ambulatory aids (wheelchairs or walkers)
- Placing personal belongings on tables near the bed
- Keeping hospital beds in lowest position with side rails up
- Using nonslip mats and rugs
- Illuminating the environment

Although falls do not necessarily constitute malpractice, they are a major reason why nurses are involved in lawsuits (Ignatavicius, 2000). Sullivan and Badros (1999) and Ignatavicius (2000) identify the need for registered nurses to assess patients' risk of falls and implement evidence-based interventions. The concept of evidence-based practice (EBP) refers to health care based on research findings, expert consensus, or both (Davis & Madigan, 1999).

Apply Restraints

Restraints are protective devices used to limit the physical activity of a client or to immobilize a client or extremity. Restraints are used to protect the client, allow for treatment in a safe environment, and reduce the risk of injury to others.

The use of restraints has become very controversial because of client injuries from restraints. The Omnibus Budget Reconciliation Act (OBRA) of 1987 and the Health Care Financing Administration regulations of 1999 governing client's rights are forcing a reexamination of how clients are cared for in acute and critical care settings (Bower & McCullough, 2000). In response to more individualized care regarding the use of restraints, the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) revised their standards for restraint use with nonpsychiatric clients; see the accompanying display for JCAHO-revised standards.

Nurses must document, according to the institutional protocol, the application and care of the client in restraints (see the accompanying display). Refer to

RESEARCH FOCUS

Title of Study

“Nursing Outcome Indicator: Preventing Falls for Elderly People”

Authors

Benzon, J., et al.

Purpose

To identify people at risk of falling and to mitigate that risk through established nursing interventions.

Methods

The study included 115 participants. Each participant received a comprehensive nursing assessment and a fall risk appraisal, which included the client's history of falling, episodes of confusion, diminished eyesight or hearing, and number and types of medications. Interventions were determined by each person's risk factors and included reducing medications or teaching about side effects, correcting vision and hearing, providing walkers and canes to persons who had previously fallen, and promoting improved strength and endurance through exercise. Homes were surveyed, and environmental changes were made: lighting was increased; loose carpet edges were taped; and grab rails were installed in showers, in tubs, and by toilets.

Findings

Only 4 (3%) of the 115 participants fell during the first year of the fall prevention program as opposed to 30 (or 26%) prior to the implementation of the program. Two of the four participants who fell were under the influence of alcohol, and the other two persons fell while they were away from their homes.

Implications

This study demonstrates that it is possible to prevent falls when the risk factors are identified and proper interventions are implemented to counter the risk factors.

Benzon, J., et al. (1999). Nursing outcome indicator: Preventing falls for elderly people. *Outcomes Management Nursing Practice*, 3(3), 132–137.

KEY ELEMENTS OF RESTRAINT DOCUMENTATION

- Reason for the restraint
- Method of restraint
- Application: Date, time, and client's response
- Duration
- Frequency of observation and client's response
- Safety: Release from restraint with periodic, routine exercise and assessment for circulation and skin integrity
- Assessment of the continued need for restraint
- Client outcome

through the application of a device. Most states require a physician's order for the application of physical restraints. **Chemical restraints** are medications used to control the client's behavior. Commonly used chemical restraints are anxiolytics and sedatives.

This chapter limits discussion to the common types of physical restraints:

- **Jacket (body restraint):** A sleeveless vest with straps that cross in front or back of the client and are tied to the bed frame or chair legs (Figure 31-6A).
- **Belt:** Straps or belts applied across the client to secure him or her to the stretcher, bed, or wheelchair (Figure 31-6B).
- **Mitten or hand:** Enclosed cloth material applied over the client's hand to prevent injury from scratching (Figure 31-6C).
- **Elbow:** A combination of fabric and plastic or wooden tongue blades that immobilize the elbow to prevent flexion (Figure 31-6D).
- **Limb or extremity:** Cloth devices that immobilize one or all limbs by securely tying the restraint to the bed frame or chair (Figure 31-6E).
- **Mummy:** A blanket or sheet that is folded around the child to limit movement. Mummy restraints are used to perform procedures on children (Figure 31-6F).

The nursing plan of care should include safety measures to reduce the potential for injury from restraints (Procedure 31-1). Additional safety measures to observe when using restraint devices are:

- Restraints can be changed and released easily, using only a clove hitch knot, as shown in Procedure 31-1.
- Restraints should not interfere with any treatments (e.g., intravenous therapy) or aggravate the client's health problem.
- There should be enough slack on the straps so that the client can move both arms and legs and for range-of-motion exercises.
- At least once every 2 hours, the nurse must perform circulation and neurological exams, assessing the

Chapter 29 for additional information regarding the use of restraints and their legal implications.

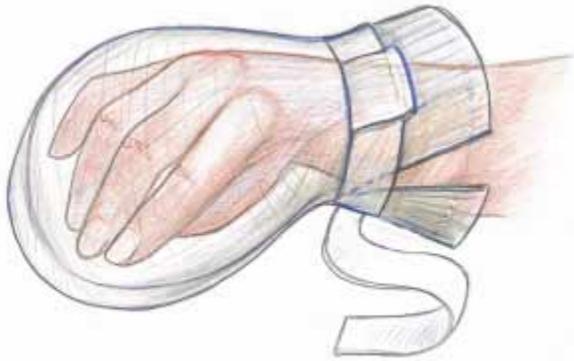

Restraints used to either limit physical activity or immobilize a client can be physical or chemical. **Physical restraints** reduce the client's movement

JCAHO RESTRAINT STANDARDS FOR NONPSYCHIATRIC CLIENTS

Organizational Perspective:

- Be individualized for each institution
- Demonstrate clinical justification
- Demonstrate the use of innovative alternatives
- Delineate preventive strategies
- Identify ways to reduce risks associated with restraint use

Policies/Procedures/Protocols:

- Be clearly stated
- Advocate use of least restrictive measures

Preventive Strategies:

- Identify potentially harmful client behaviors
- Identify effective and tried alternatives

Plan of Care

- Individualized and ensure client's assessed needs are met
- Preserve client's rights, dignity, and well-being

Education:

- Be ongoing for staff and client
- Be provided to families when appropriate

Initiation and Monitoring of Restraint Use:

- Based on state law
- Initiated based on individual orders or approved protocols with written physician order obtained within 12 hours
- Applied/monitored/assessed/reassessed by qualified staff
- Monitored at least every 2 hours
- Renewed every 24 hours when continuous restraint is used

Special Conditions When Restraint Is Applied:

- Based on significant change in the client's condition with the physician notified immediately and written orders obtained within 24 hours
- Initiated by a registered nurse
- Based on protocols established for situations where clients may harm themselves if staff initiate, maintain, and terminate restraint without an order from independent practitioner

Documentation:

- Include all restraint episodes according to organizational policies and procedures
- Occur, at a minimum, every 2 hours
- Indicate alternatives were tried before restraints were applied
- Be entered into the client's medical record

Adopted from: The Joint Commission on Accreditation of Healthcare Organizations for Restraint Use. (1999). *Introduction to the restraint standards in acute medical and surgical (nonpsychiatric) care. Comprehensive accreditation manual for hospitals*. Oakbrook Terrace, IL: Author.

NURSING ALERT

Restraints

Jacket or belt restraints should not restrict respiratory effort. Placing a restraint too tight on the diaphragm will inhibit the expansion of the lungs.

color, sensation, temperature, motion, and capillary refill in the area distal to the restraint.

- There should be a provision for psychological support of client and significant others.

Figures 31-7 and 31-8 demonstrate how to make a clove hitch knot used in applying restraints. Note how the clove hitch restraint, made from a strip of gauze, does not tighten when force is applied against it. The restraint strap is secured to the bed frame, *not to the side rail* so as to avoid accidental injury to the extremity in the event that the side rail is released while the restraint strap is attached to it.

THINK ABOUT IT

Use of Restraints

Gloria Hernandez is an 83-year-old widow who fractured her hip when she fell in the bathtub. She had hip replacement surgery yesterday. Tonight she is very confused and is trying to dislodge the bandage and stitches. Mrs. Hernandez is now being restrained for protection. What other nursing activities could have been implemented prior to the use of restraints? Do you think that restraints will affect Mrs. Hernandez's mental status? If so, in what ways? What are some other effects Mrs. Hernandez may experience as a result of being restrained? How would you feel about the use of restraints if Mrs. Hernandez were your grandmother?

Ensure Adequate Lighting

Adequate lighting assists in the visualization of environmental hazards. Rooms should be adequately lighted so that the client can safely perform ADL and health care providers can perform procedures. Lighting can be supplemented by lamps and nightlights. Lighting can also assist in protecting the home against crime.

Remove Obstacles

Obstacles in heavily traveled areas of health care facilities or homes are a risk to the client's safety. Older adults or persons who are unfamiliar with the environment are at greatest risk of injury from obstacles. The risk that obstacles pose can be reduced by keeping hallways clear, removing excess furniture from heavily traveled areas, removing all electrical cords or taping cords securely to the floor, removing throw rugs, applying

PROCEDURE 31-1

Application of Restraints

Equipment

■ Restraint

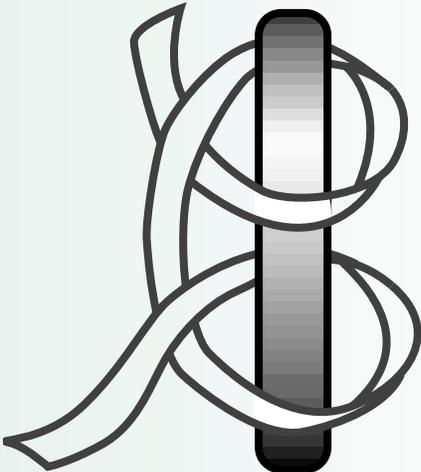

<i>Action</i>	<i>Rationale</i>
<ol style="list-style-type: none"> 1. Explain rationale for application of restraint. Repeatedly reinforce rationale. 2. Select the proper type of restraint. 3. Assess skin for irritation. 4. Apply restraint to client assuring some movement of body part. One to two fingers should slide between restraint and client's skin. Tie straps securely with clove hitch knot as shown in Figure 31-7. To make a clove hitch: make a figure-eight (Figure 31-8A); pick up the loops (Figure 31-8B); put the limb through the loops and secure (Figure 31-8C). Pad bony prominences. 	<ol style="list-style-type: none"> 1. Explanations facilitate cooperation. 2. Least restrictive restraint that does not interfere with client's health status but provides safety should be selected. 3. Provides baseline skin assessment. 4. Maintains adequate circulation and mobility. Prevents skin breakdown. Restraint should be easy to release.
	
<ol style="list-style-type: none"> 5. Secure restraint to bed frame; do not tie the straps to the side rail. 6. Assess restraints and skin integrity every 30 minutes. Release restraints at least every 2 hours. 7. Continually assess the need for restraints (at least every 8 hours). 	<ol style="list-style-type: none"> 5. Prevents accidental injury to client from moving side rails and decreases client's ability to untie restraints. 6. Permits muscle exercise. Promotes circulation. 7. Assist in evaluating client's progress and response to restraints.

Figure 31-7 Clove Hitch Knot

(continues)

PROCEDURE 31-1

Application of Restraints (continued)

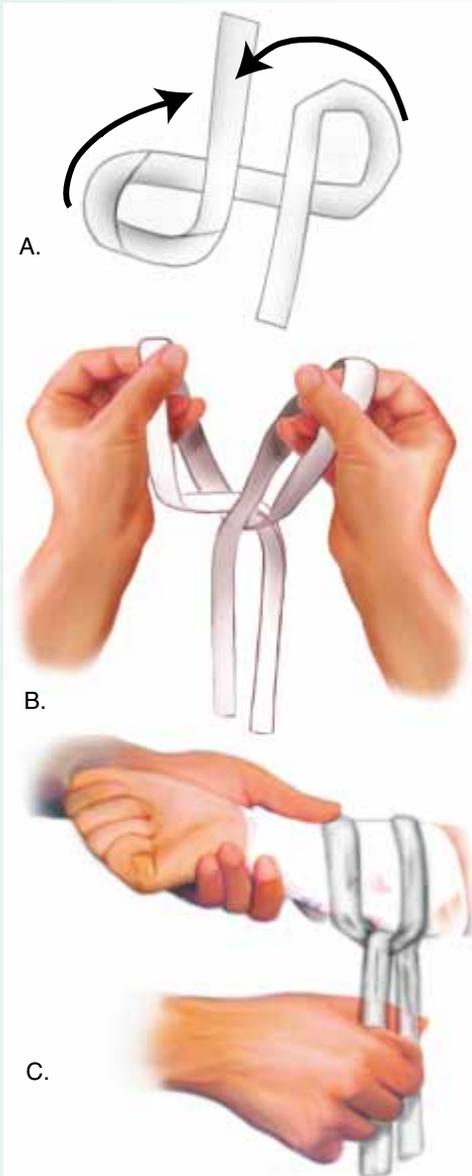

*Action**Rationale*

Figure 31-8 Making a Clove Hitch Knot: A. Make a figure-eight; B. Pick up the loops; and C. Put the limb through the loops and secure.

nonslip pads to rugs, cleaning up spills immediately, and removing objects that could fall from the tops of appliances.

Reduce Bathroom Hazards

Bathrooms pose a threat to the client in the home because of the presence of water and storage of medication. Common bathroom accidents are falls, scalds or

burns, and poisonings. Bathroom accidents can be reduced by the use of grab bars near the tub, shower, and toilet; nonslip mats in the tub and shower; and a secured bathroom rug near the tub or shower. Other safety measures include checking the temperature of the water before entering tub or shower; checking the thermostat setting on the water heater; and storing medications in a locked cabinet, out of reach of children or disoriented or confused adults.

Prevent Fire

Fire is a potential danger to all people in an institutional or home environment. Immobilized or incapacitated clients are at increased risk during a fire. Common causes of fire are smoking in bed, discarding cigarette butts in trash cans, and faulty electrical equipment. Fire occurs with the interaction of three elements: sufficient heat to ignite the fire, combustible material, and oxygen to support the fire.

Nursing goals are fire prevention and protection of clients during a fire. Nursing interventions aimed at preventing or reducing the risk of fire include:

- Clearly marking fire exits
- Knowing locations of fire extinguishers and their operation
- Practicing fire evacuation procedures
- Posting emergency phone numbers by all telephones
- Keeping open spaces and hallways clear of clutter
- Checking electrical cords and outlets for exposed or damaged wires
- Reporting identified electrical hazards
- Educating clients about fire hazards

In the event of a fire, follow institutional policy and procedures for fire containment and evacuation. Nursing interventions during a fire are directed at *protecting the client from injury and containing the fire*. Nurses should be familiar with the location of fire alarm pull boxes. If a fire occurs, the nurse should utilize the nearest fire box for notification and move clients to safety.

Nurses should be familiar with the use of fire extinguishers and their locations. The fire extinguisher should be directed toward the base of the fire. The four types of fire extinguishers used are water, carbon dioxide, regular dry chemical, and multipurpose dry chemical. Each type of fire extinguisher is used for a specific class of fire, as discussed in Table 31-5.

Ensure Safe Operation of Electrical Equipment

Clients have contact with a variety of electrical equipment in the hospital environment, such as bed controls

and intravenous and patient-controlled analgesia (PCA) pumps. All electrical equipment should have a three-pronged electrical plug that is grounded. A grounded plug transmits any stray electrical current from equipment to the ground. To protect the client from electrical injury, the nurse should read the warning labels on all equipment, use only grounded electrical equipment, check for frayed electrical cords, avoid overloading circuits, and report any shocks received from equipment to the biomedical department (see Figure 31-9).

If a client receives an electrical shock, the nurse should turn off or remove the electric source before touching the client. Then, the client's pulse should be checked. If the client has no pulse, CPR should be initiated. If the client has a pulse, the nurse should assess vital signs, mental status, and skin integrity for burns. A physician should be notified of the event. The nurse should note points of entry and exit of electrical current to assess for potential complications.

Reduce Exposure to Radiation

Clients are exposed to radiation during diagnostic testing and therapeutic interventions. Injury can occur from radiation if there is overexposure or exposure to untargeted tissues. Exposure to untargeted tissues can occur with radiation implants that become dislodged. General principles of radiation exposure and protection are based on time, distance, and shielding. Protection from radiation therapy includes:

- Minimizing time in contact with radiation source (implants or client)
- Maximizing distance from radiation source (implants or client)
- Using appropriate radiation shields
- Monitoring radiation exposure with a film badge
- Labeling all potentially radioactive material
- Never touching dislodged implants or body fluids of client

Both the client and the nurse are at risk for radiation injury. The client's risk for injury can be reduced by educating the client about radiation treatment and

TABLE 31-5
Fire Extinguishers

Type	Class of Fire
Water (type A)	Paper, wood, draperies, upholstery, or rubbish
Carbon dioxide or dry chemical (types B and C)	Flammable liquids, flammable gases, or electrical fires
Multipurpose dry chemical (types A, B, and C)	Any type of fire

Figure 31-9 Warning Label on Electrical Equipment

necessary precautions, placing the client in a private room, and providing a lead apron when necessary to protect nontargeted body tissues. The nurse's risk for injury can be reduced by observing all radioactive labels, wearing gloves when handling radioactive body discharges, washing hands, wearing lead aprons, disposing of radioactive substances in special containers, reducing time of client contact, and wearing badges that measure the amount of radiation exposure.

Prevent Poisoning

A **poison** is any substance that causes an alteration in the client's health, such as injury or death, when inhaled, injected, ingested, or absorbed by the body. Antidotes and treatments are available for some but not all types of poisonings. Direct and indirect causes of poisonings are:

- Inadequate supervision of children
- Ingestion of household plants
- Improper storage of toxic substances
- Insect or snake bites
- Accidental ingestion of a toxic substance or medication overdose

The poison control center should be notified when poisoning is suspected. The person reporting the poisoning should be prepared to state the amount and type of poison ingested, inhaled, or injected, client's age, and symptoms. Clients who have ingested poison should be turned on their side to prevent aspiration while awaiting further treatment. Client education about safety measures can prevent some accidental poisonings. The following Client Teaching Checklist provides some safety measures to prevent accidental poisoning. Keep syrup of ipecac available at all times.

CLIENT TEACHING CHECKLIST

Safety Measures to Prevent Accidental Poisonings

- Store medications in child-resistant containers (Figure 31-10).
- Do not take medications in front of children.
- Never call medicine candy.
- Limit the number of tablets in a medicine container.
- Place toxic substances in a locked cabinet out of reach of children.
- Never remove labels from containers.
- Do not place poisonous substances in food or beverage containers.
- Place poison stickers on toxic substances.
- Display poison control center phone numbers near telephones.

Figure 31-10 Poison Prevention Measure: Medications Stored in Child-Resistant Containers.

Reduce Noise Pollution

Noise pollution, a situation that results when the noise level becomes uncomfortable for the client or staff, frequently occurs in the health care setting as a result of visitor traffic, medical equipment, and personnel. It can result in an unorganized environment, hearing loss, and **sensory overload**. Sensory overload is an increased perception of the intensity of auditory and visual stimuli. Sensory overload can alter a client's recovery by increasing anxiety, paranoia, hallucinations, and depression. Safety measures include maintaining a quiet environment, traffic control, and providing earplugs. See Chapter 36 for a discussion of sensory overload.

THINK ABOUT IT

Noise Pollution

A client who you think is experiencing sensory overload has several visitors, including her grandchildren. How would you manage this situation? What explanation would you provide to the family as a rationale for restricting visitation? What explanation would you provide to the client as a rationale for restricting visitation?

Ensure Asepsis

Nurses are responsible for providing the client with a safe environment, which includes preventing the transmission of nosocomial infections. **Asepsis** is the absence of microorganisms. Providing nursing care using aseptic technique decreases the risk and spread of nosocomial infections. **Aseptic technique** is the infection control practice used to prevent the transmission of pathogens. Two types of asepsis are medical and surgical.

Medical Asepsis

Medical asepsis uses practices to reduce the number, growth, and spread of microorganisms. Medical asepsis

is also referred to as “clean technique.” Objects are generally referred to as “clean” or “dirty” in medical asepsis. **Clean objects** are considered to have the presence of some microorganisms that are usually not pathogenic. **Dirty** (soiled) **objects** are considered to have a high number of microorganisms, with some that are potentially pathogenic. Common medical aseptic measures used for clean or dirty objects are handwashing, gloves, changing linens daily, and cleaning floors and hospital furniture daily. Refer to Appendix D for *Your Guide to Gloves*, based on the CDC’s standard precautions.

Handwashing

Handwashing is the rubbing together of all surfaces and crevices of the hands using a soap or chemical and water.

Handwashing is a component of all types of isolation precautions and is the most basic and effective infection control measure that prevents and controls the transmission of infectious agents. The CDC (2000) recommends vigorous scrubbing with warm, soapy water for at least 15 seconds to prevent the transfer of germs.

The three essential elements of handwashing are soap or chemical, water, and friction (see Procedure 31-2 for the proper steps of handwashing). Soaps that contain antimicrobial agents are frequently used in high-risk areas such as emergency departments and nurseries. Friction is the most important element of the three because it physically removes soil and transient flora.

Handwashing should be performed after arriving at work, before leaving work, between client contacts, after

PROCEDURE 31-2

Handwashing

Equipment

- Soap
- Sink

- Paper or cloth towels
- Running water

Action

1. Remove jewelry. Wristwatch may be pushed up above the wrist (midforearm). Push sleeves of uniform or shirt up above the wrist at midforearm level.
2. Assess hands for hangnails, cuts or breaks in the skin, and areas that are heavily soiled.
3. Turn on the water. Adjust the flow and temperature. Temperature of the water should be warm.
4. Wet hands and lower forearms thoroughly by holding under running water. Keep hands and forearms in the down position with elbows straight. Avoid splashing water and touching the sides of the sink.
5. Apply about 5 ml (1 teaspoon) of liquid soap. Lather thoroughly.
6. Thoroughly rub hands together for about 10 to 15 seconds. Interlace fingers and thumbs and move back and forth to wash between digits (Figure 31-11). Rub palms and back of hands with circular motion. Special attention should be provided to areas such as the knuckles and fingernails, which are known to harbor organisms (Figure 31-12).

Rationale

1. Provides access to skin surfaces for cleaning. Facilitates cleaning of fingers, hands, and forearms.
2. Intact skin acts as a barrier to microorganisms. Breaks in skin integrity facilitate development of infection and should receive extra attention during cleaning.
3. Running water removes microorganisms. Warm water removes less of the natural skin oils.
4. Water should flow from the least contaminated to the most contaminated areas of the skin. Hands are considered more contaminated than arms. Splashing of water facilitates transfer of microorganisms. Touching of any surface during cleaning contaminates the skin.
5. Lather facilitates removal of microorganisms. Liquid soap harbors less bacteria than bar soap.
6. Friction mechanically removes microorganisms from the skin surface. Friction loosens dirt from soiled areas.

(continues)

PROCEDURE 31-2

Handwashing (continued)

Action

Figure 31-11 Interlace fingers to wash between the digits.

7. Rinse with hands in the down position, elbows straight. Rinse in the direction of forearm to wrist to fingers.
8. Blot hands and forearms to dry thoroughly. Dry in the direction of fingers to wrist and forearms. Discard the paper towels in the proper receptacle.
9. Turn off the water faucet with a clean, dry paper towel (see Figure 31-13).

Figure 31-13 Turn off faucet with a clean, dry paper towel.

Rationale

Figure 31-12 Provide special attention to washing knuckles and fingernails.

7. Flow of water rinses away dirt and microorganisms.
8. Blotting reduces chapping of skin. Drying from cleanest (hand) to least clean area (forearms) prevents transfer of microorganisms to cleanest area.
9. Prevents contamination of clean hands by a less clean faucet.

NURSING ALERT

Handwashing

Wash hands before and after every client contact. The most common cause of nosocomial infections is contaminated hands of health care providers.

removing gloves, when hands are visibly soiled, before eating, after excretion of body waste (urination and defecation), after contact with body fluids, before and after performing invasive procedures, and after handling contaminated equipment. The exact duration of time required for handwashing is not known. A washing time of 10 to 15 seconds is recommended to remove transient flora from the hands. High-risk areas, such as

nurseries, usually require about a 2-minute handwash. Soiled hands usually require more time (CDC, 2000).

Surgical Asepsis

Surgical asepsis, or sterile technique, consists of those practices that eliminate all microorganisms and spores from an object or area. **Spores** are single-celled microorganisms or microorganisms in the resting or inactive stage. Surgical asepsis refers to handwashing, the donning of surgical attire (caps, masks, and eyewear), handling of sterile instruments and equipment, and establishing and maintaining sterile fields.

Surgical asepsis is practiced by the nurse in the operating room, during labor and delivery, and for many diagnostic and therapeutic interventions at the client's bedside. Common nursing procedures that require sterile technique are:

- All invasive procedures, either intentional perforation of the skin (injections, insertion of intravenous needles or catheters) or entry into a bodily orifice (tracheobronchial suctioning, insertion of a urinary catheter)
- Nursing measures for clients with disruption of skin surfaces (changing a surgical wound or intravenous site dressing) or destruction of skin layers (trauma and burns)

Sterile Field

The nurse needs to establish and maintain a sterile field when performing those procedures that require sterile technique such as changing burn dressings or large wound dressings. Agency policy and supplies vary in different health care settings. Review the agency's policy and gather all the necessary supplies before preparing the sterile field.

Sterile dressing packages can be either commercially prepared or agency wrapped. When opening the package, allow the edges of the wrapper to drop down and away from the package (see Procedure 31-3). The sterile field must be kept free of microorganisms by placing only sterile items inside the field. When adding additional supplies to the field, avoid reaching across a sterile field. Gently drop additional supplies onto the sterile field, making sure that the supply wrapper does not touch the field; always open packages away from the field to prevent crossover and contamination.

When the sterile field is prepared, always face the field and keep sterile objects above waist level to avoid the risk of field contamination. Behaviors such as talking, sneezing, and coughing should be avoided to maintain the field's sterility; if the client is unable to cooperate, explain why a face mask is needed and apply.

Care of a wound requires a sterile dressing change to promote wound healing and to prevent infection. Assess the wound during the dressing change for infection

PROCEDURE 31-3

Surgical Asepsis: Preparing and Maintaining a Sterile Field

Equipment

- | | |
|---|--|
| <ul style="list-style-type: none"> ■ Antimicrobial soap for handwashing ■ Sterile materials (antiseptic solution, bowl, dressing, instruments) ■ Additional sterile supplies (culture swab, gauze, or dressings to complement the type of procedure to be performed) | <ul style="list-style-type: none"> ■ Sterile drape (may be contained in dressing tray) ■ Sterile solution ■ Package of proper-sized sterile gloves ■ Container for disposal of waste materials (follow agency policy, colored bag that designates infectious waste products) |
|---|--|

Action

1. Gather equipment for the type of procedure:
 - a. Select only clean, dry packages marked sterile, and read listing of contents.
 - b. Check the package for integrity and expiration date.
2. Select a clean, easily accessible area in the client's environment to establish the sterile field.
3. Explain procedure to the client; provide specific instructions if client assistance is required during the procedure.

Rationale

1. Prevents break in technique during procedure. If the package is moist or outdated, it is considered contaminated and must be discarded.
2. Promotes access to the sterile field during the procedure.
3. Gains client's understanding and cooperation during the procedure.

(continues)

PROCEDURE 31-3

Surgical Asepsis: Preparing and Maintaining a Sterile Field (continued)

Action

4. Inquire about and attend to the client's toileting needs.
5. Hospital environment: If the procedure is to be performed at the client's bedside, the client should be in a private room or moved to a clean treatment room.
6. Home environment: Secure privacy and remove pets from the room.
7. Position client and attend to comfort measures; the client's position should provide you easy access to the area and facilitate good body mechanics during the procedure.
8. Wash hands; refer to Procedure 31-2.
9. Place sterile package (drape or tray) in the center of the clean, dry work area.
10. Remove the wrapper, pulling away from the body (see Figure 31-14).

Figure 31-14 Open the first flap of a sterile wrapped package.

Rationale

- | | | |
|--|--|--|
| <ol style="list-style-type: none"> 4. Prevents break in technique during the procedure. 5. Minimizes microorganisms in the environment. 6. Puts the client at ease and promotes a clean environment. 7. Helps the client relax and prevents movement during the procedure; prevents reaching, decreasing the risk of contamination and back strain. 8. Prevents transmission of infection. 9. Prevents reaching over exposed sterile items when wrapper is removed. 10. Prevents contamination. | <ol style="list-style-type: none"> 11. Grasp the folded top edge with fingertips of one hand. 12. Remove the drape by lifting up and away from all objects while it unfolds; discard the outer wrapper with other hand. 13. With free hand, grasp the other drape corner, keeping it away from all objects. 14. Lay the drape on the surface, with the drape bottom first touching the surface farthest from you; step back and allow the drape to cover the surface (see Figure 31-15). | <ol style="list-style-type: none"> 11. Edges are considered unsterile. 12. If the drape touches an unsterile object, it is contaminated and must be discarded. 13. Avoids contamination. 14. Prevents you from reaching over the sterile field; stepping back decreases risk that drape will touch your uniform. |
|--|--|--|

(continues)

PROCEDURE 31-3

Surgical Asepsis: Preparing and Maintaining a Sterile Field (continued)

Action

Figure 31-15 Place drape on the surface by first placing the bottom portion of drape farthest from oneself and then placing the top portion of drape over the work surface.

Rationale

- | | |
|--|---|
| <p>15. Open and place the tray on the work surface so that the top flap of the sterile wrapper opens away from you.</p> <p>16. Reach around the tray, with thumb and index fingertips grasping the wrapper's top flap, gently pull up, then down to open over the surface.</p> <p>17. Repeat the same steps to open the side flaps.</p> <p>18. Grasp the corner of the bottom flap with fingertips, step back, and pull flap down.</p> <p>19. While facing the sterile field, step back, remove the outer wrapper, and grasp the item in your nondominant hand so that the top flap will open away from you.</p> <p>20. With your dominant hand, open the flaps as previously described (Figure 31-16).</p> <p>21. With your dominant hand, pull the wrapper back and away from the sterile field and place the item onto the field (Figure 31-17).</p> <p>22. When adding additional gauze or dressings to the sterile field, open the package as directed; grasp the top flaps of the wrapper and pull downward as shown in Figure 31-16; then drop the contents onto the center of the field, as shown in Figure 31-17.</p> <p>23. Read the labels and strengths of all solutions three times prior to pouring.</p> | <p>15. Prevents reaching over the sterile items.</p> <p>16. Only the edges of the field can be contaminated; pulling up frees the top folded flap.</p> <p>17. Keeps the arm from reaching over the sterile field.</p> <p>18. Creates a sterile work surface.</p> <p>19. Keeps your dominant hand free; item remains sterile.</p> <p>20. Prevents reaching over the sterile item.</p> <p>21. Prevents the wrapper from touching the sterile field.</p> <p>22. Prevents contamination of item and sterile field.</p> <p>23. Ensures proper solution and strength.</p> |
|--|---|

(continues)

PROCEDURE 31-3

Surgical Asepsis: Preparing and Maintaining a Sterile Field (continued)

Action

Figure 31-16 Grasp the flaps of the wrapped supply and pull downward.

Figure 31-17 Add contents to the sterile field by holding the package 6 inches (15 cm) above the field and allowing the contents to drop onto the field.

Rationale

- | | |
|--|--|
| <p>24. Remove the lid from the bottle of solution and place the sterile side up onto a clean surface.</p> <p>25. Hold the bottle, label in palm of hand, 4 to 6 inches (10 to 15 cm) over the container on the sterile field; slowly pour the solution into the container to avoid splashing.</p> <p>26. Replace the lid on the container, label the container with the date and time, and initial the container if retained for reuse.</p> <p>27. Wash hands and don nonsterile gloves.</p> <p>28. With dominant hand, grasp forceps from the sterile field, making sure only the handles of the forceps are touched.</p> <p>29. Hold forceps above waist level throughout the procedure.</p> | <p>24. Inverting the lid prevents contamination of the inner surface.</p> <p>25. Prevents the label from getting wet; if the solution splashes onto the label, the field is contaminated because moisture conducts microorganisms from the nonsterile surface.</p> <p>26. Sterility of the solution will be lost if exposed to air for an extended period of time.</p> <p>27. Prevents transmission of infection to client.</p> <p>28. Prevents contamination of sterile items.</p> <p>29. Keeps forceps in your view and decreases the risk of contamination.</p> |
|--|--|

(continues)

PROCEDURE 31-3

Surgical Asepsis: Preparing and Maintaining a Sterile Field (continued)

<i>Action</i>	<i>Rationale</i>
30. Keep forceps tips pointing downward when adding, arranging, or removing items to the sterile field during the sterile procedure.	30. Gravity will prevent any liquids from flowing back and forth between forceps tips and handle held in ungloved hand.
31. Dispose of contaminated items in colored plastic bag.	31. Alerts other health care workers of contaminated waste, decreasing their risk of infection.
32. Wash hands and perform open gloving (Procedure 31-4).	32. Prevents transmission of infection.
33. Continue with procedure, keeping gloved hands above waist level at all times, touching only items on the sterile field.	33. Decreases chance of contamination. Any item below waist level and out-of-sight is considered contaminated.
34. If using a solution to cleanse a site, use the sterile forceps to prevent contamination of gloves; dispose of forceps after use.	34. Prevents field contamination.
35. Postprocedure, dispose of all contaminated items in colored plastic bag.	35. Decreases risk of transmission of infection to all health care workers.
36. Remove gloves by grasping the outside of one cuff with the other gloved hand; pull glove off, turning it inside out. Dispose in plastic bag with other contaminated items.	36. Minimizes your risk of contact with infectious wastes on the gloves.
37. Using the fingers of your ungloved hand, slip fingers, palm up, inside the cuff and peel the glove off, inside out. Dispose of glove in colored plastic bag.	37. Outside of the glove does not touch your skin and contaminate it.
38. Reposition the client.	38. Promotes client comfort.
39. Clean the environment; wash hands.	39. Prevents transmission of infection.
40. In the client's medical record, document the procedure, findings (description of infected area), and the response of the client.	40. Demonstrates compliance with sterile procedure and the effectiveness of therapy.

(redness, edema, pain at the incision line, and purulent drainage from the wound) and progression of healing. See Chapter 35 for a complete discussion of wound care.

Wound care often requires the use of a sterile solution to cleanse the wound during a dressing change. Maintain the sterility of the solution by handling the container to keep the inside of the container sterile. When the lid to the container is removed, place the sterile side up and pour some of the solution into a nonsterile container before adding to the sterile container on the field. Gently pour the sterile solution into the sterile container to avoid wetting the field. The sterile technique is maintained throughout wound care; if the sterile field becomes wet or damp, discard all supplies and prepare a new sterile field.

Donning Sterile Gloves

There are two methods for applying sterile gloves: open and closed. The open method is used most frequently when performing procedures that require the sterile technique such as dressing changes (see Procedure 31-4 for applying sterile gloves by the open method). The closed method is used when the nurse wears a sterile gown.

Donning Surgical Attire

Surgical nurses are required to wear a surgical mask and a clean cloth or paper cap that covers all of the hair. After the cap is applied, the nurse positions the mask to cover the nose and mouth (see Procedure 31-5). Protective eyewear (glasses or goggles) is worn during all procedures that pose a threat of splashing body fluids into the eyes.

PROCEDURE 31-4

Performing Open Gloving and Removal of Soiled Gloves

Equipment

- Package of proper-sized sterile gloves

Action

1. Wash hands; see Procedure 31-2.
2. Read the manufacturer's instructions on the package of sterile gloves; proceed as directed in removing the outer wrapper from the package, placing the inner wrapper onto a clean, dry surface.
3. Identify right and left hand; glove dominant hand first.
4. Grasp the 2-inch- (5-cm-) wide cuff with the thumb and first two fingers of the nondominant hand, touching only the inside of the cuff.
5. Gently pull the glove over the dominant hand, making sure the thumb and fingers fit into the proper spaces of the glove (see Figure 31-18).

Figure 31-18 Pull the glove over the dominant hand.

Rationale

- | | |
|---|---|
| <ol style="list-style-type: none"> 1. Wash hands; see Procedure 31-2. 2. Read the manufacturer's instructions on the package of sterile gloves; proceed as directed in removing the outer wrapper from the package, placing the inner wrapper onto a clean, dry surface. 3. Identify right and left hand; glove dominant hand first. 4. Grasp the 2-inch- (5-cm-) wide cuff with the thumb and first two fingers of the nondominant hand, touching only the inside of the cuff. 5. Gently pull the glove over the dominant hand, making sure the thumb and fingers fit into the proper spaces of the glove (see Figure 31-18). | <ol style="list-style-type: none"> 1. Prevents transmission of infection. 2. Manufacturers package gloves differently; the instructions will tell you how to properly open to avoid contamination of the inner wrapper; any moisture on the surface will contaminate the gloves. 3. Dominant hand should facilitate motor dexterity during gloving. 4. Maintains sterility of the outer surfaces of the sterile glove. 5. Prevents tearing the glove material; guiding the fingers into proper places facilitates gloving. |
|---|---|
-
- | | |
|---|---|
| <ol style="list-style-type: none"> 6. With the gloved dominant hand, slip your fingers under the cuff of the other glove, gloved thumb abducted, making sure it does not touch any part on your nondominant hand (see Figure 31-19). | <ol style="list-style-type: none"> 6. Cuff protects gloved fingers, maintaining sterility. |
|---|---|

(continues)

PROCEDURE 31-4

Performing Open Gloving and Removal of Soiled Gloves (continued)

Action

Figure 31-19 Slip the fingers under the cuff of the glove for the nondominant hand and abduct the thumb.

7. Gently slip the glove onto your nondominant hand, making sure the fingers slip into the proper spaces.
8. With gloved hands, interlock fingers to fit the gloves onto each finger.
If the gloves are soiled, remove by turning inside out as follows:
9. Slip gloved fingers of the dominant hand under the cuff of the opposite hand or grasp the outer part of the glove at the wrist if there is no cuff (Figure 31-20).

Figure 31-20 Insert gloved fingers under the cuff of the other glove.

Rationale

7. Contact is made with two sterile gloves.
8. Promotes proper fit over the fingers.
9. Contact is made with two sterile gloves.

(continues)

PROCEDURE 31-4

Performing Open Gloving and Removal of Soiled Gloves (continued)

Action

10. Pull the glove down to the fingers, exposing the thumb (see Figure 31-21).

Figure 31-21 Pull the glove down to the fingers and turn inside out.

11. Slip the uncovered thumb into the opposite glove at the wrist, allowing only the glove-covered fingers of the hand to touch the soiled glove.
12. Pull the glove down over the dominant hand almost to the fingertips and slip the glove onto the other hand.
13. With the dominant hand touching only the inside of the other glove, pull the glove over the dominant hand so that only the inside (clean surface) is exposed.
14. Dispose of soiled gloves according to institutional policy and wash hands.

Rationale

10. Frees the thumb for the next step.
11. Contact is made with two sterile gloves.
12. Removes glove without contact with soiled surfaces.
13. Exposes only the clean surface of the gloves.
14. Prevents the transfer of microorganisms.

NURSING ALERT

Disposable Equipment

Disposable equipment should be discarded after use. The materials used for disposable equipment cannot be thoroughly cleaned.

Surgical Handwashing

Surgical handwashing or scrub is used to remove soil and most transient microorganisms from the skin. Nurses working in the operating room perform surgical

handwashing to decrease the client's risk for an infection. The skin on the nurse's hands and arms should be intact (free of lesions). Agency policy determines how to perform the scrub with regard to method and timing (see Procedure 31-6 for the basic principles in performing surgical handwashing).

Gowning and Closed Gloving

Nurses in the operating room and special procedure areas such as cardiac catheterization labs use the closed gloved method when donning a sterile gown. After the surgical scrub, the nurse proceeds to don the sterile gown and gloves using the closed method (see Procedure 31-7). The sterile gown serves as a barrier to

PROCEDURE 31-5

Applying a Surgical Mask

Equipment

- Surgical mask

Action

1. Grasp the two top strings or loops of the mask (the top part of the mask usually has a light-weight metal strip that goes over the bridge of the nose).
2. Position mask to cover your nose and mouth.
3. Tie the top strings above your ears at the top-back of your head (Figure 31-22).

Figure 31-22 Tie the top strings of the mask at the top and back of the head.

Rationale

1. Metal strip fits snugly against the bridge of nose.
2. Establishes a respiratory barrier.
3. Provides for a tight fit of the mask.
4. Tie the bottom strings at the back-base of your neck so that the bottom part of the mask fits snugly around your chin.
5. Grasp and pinch the metal strip around bridge of nose.
4. Prevents irritation to the ears.
5. Minimizes number of microorganisms that can escape around nose.

PROCEDURE 31-6

Surgical Handwashing

Equipment

- Surgical scrub items (antimicrobial soap, two brushes, and nail file)
- Sterile towel
- Surgical shoe covers (booties) and cap, face mask, sterile gown, and proper-sized gloves

Action

Preparing for Surgical Handwashing

1. Remove rings, chipped nail polish, watch, and earrings that do not fit under a surgical cap.
1. Decreases resident and transient microorganisms.

(continues)

PROCEDURE 31-6

Surgical Handwashing (continued)

<i>Action</i>	<i>Rationale</i>
2. Use a deep sink with side or foot pedal to dispense antimicrobial soap and control water temperature and flow.	2. Prevents hands and forearms from touching a soiled surface.
3. Have two surgical scrub brushes and nail file.	3. Enhances mechanical friction during the scrub.
4. Apply surgical shoe covers and cap to cover hair and ears completely.	4. Prevents introduction of contaminants into environment.
5. Apply mask; refer to Procedure 31-5.	5. Provides a respiratory barrier.
6. Before beginning the surgical scrub: <ol style="list-style-type: none"> a. Open the sterile package containing the gown; using aseptic technique make a sterile field with the inside of the gown's wrapper. b. Open the sterile towel and drop it onto the center of field. c. Open the outer wrapper from the sterile gloves and drop the inner package of gloves onto the sterile field beside the folded gown and towel (see Procedure 31-7 for gowning and closed gloving). 	6. Preparing the sterile items prior to the scrub decreases the risk of contaminating scrubbed hands.
Surgical Handwashing	
7. At a deep sink with foot or knee controls turn on warm water; under flowing water, wet forearms and hands (from elbows to fingertips), keeping arms and hands above elbow level during entire procedure (do not allow uniform to get wet).	7. Water should flow from the least contaminated (forearms) to the most contaminated (hands).
8. Apply a liberal amount of soap onto hands and rub hands and arms to 2 inches above elbows.	8. Reduces number of microorganisms on hands.
9. Use nail file under running water, clean under each nail of both hands and drop file into sink when finished.	9. Removes dirt that harbors microorganisms.
10. Wet and apply soap to scrub brush, with brush in your dominant hand; using a circular motion, scrub nails and all skin areas of nondominant hand and arm (10 strokes to each of the following areas): <ol style="list-style-type: none"> a. Nails b. Palm of hand and anterior side of fingers c. Sides of thumb d. Posterior of thumb e. Sides and posterior surface of fingers f. Back of hand 	10. Removes resident bacteria from the skin's surfaces; the circular motion mechanically removes microorganisms. Scrubbing the nondominant hand first sets a routine you can remember if you should get interrupted during the scrub.

(continues)

PROCEDURE 31-6

Surgical Handwashing (continued)

<i>Action</i>	<i>Rationale</i>
11. Rinse brush thoroughly; reapply soap.	11. Decreases transfer of microorganisms.
12. Continue with scrub of nondominant arm with a circular motion for 10 strokes each to the lower, middle, and upper arm; drop brush into the sink.	12. Decreases transfer of microorganisms from the arm; dropping the brush avoids contamination.
13. Maintaining the hands and arms above elbow level, place the fingertips under running water and thoroughly rinse the fingers, hands, and arms (allow the water to run off your elbow into the sink); take care not to get your uniform wet.	13. Allows flow of water to cleanse from area of least to most contaminated. Water conducts microorganisms and keeping uniform dry aids in maintaining sterility of gown.
14. Take the second scrub brush and repeat steps 10 through 13 on your dominant hand and arm.	14. See steps 10 through 13.
15. Keep arms flexed and proceed to area (operating or procedure room) with sterile items.	15. Prevents water from flowing from least to most contaminated area.
16. Secure sterile towel by grasping it on one edge, opening the towel, full length, making sure it does not touch your uniform.	16. Maintains the sterility of the towel.
17. Dry each hand and arm separately; extend one side of the towel around fingers and hand and dry in a rotating motion up to the elbow.	17. Prevents contamination by drying from cleanest to least clean area.
18. Reverse the towel and repeat the same action on the other hand and arm, thoroughly drying the skin.	18. Prevents contamination of the gown.
19. Discard the towel into a linen hamper.	19. Keeps the environment clean.

PROCEDURE 31-7

Performing Gowning and Closed Gloving

<i>Equipment</i>	
■ Sterile gown	■ Sterile and proper-sized gloves
<i>Action</i>	<i>Rationale</i>
Gowning	
1. The sterile gown is folded inside out.	1. Allows ungloved hands to touch only the inside.
2. Grasp the gown inside the neckline, step back, and allow the gown to open in front of you; keep the inside of the gown toward you; do not allow it to touch anything.	2. Keeps the outside of the gown sterile.

(continues)

PROCEDURE 31-7

Performing Gowning and Closed Gloving (continued)

<i>Action</i>	<i>Rationale</i>
3. With hands at shoulder level, slip both arms into the gown; keep your hands inside the sleeves of the gown.	3. Prevents the gown from touching nonsterile objects; allows sterile items to come in contact only with other sterile items.
4. The circulating nurse will step up behind you and grasp the inside of the gown, bring it over your shoulders, and secure the ties at the neck and waist.	4. Prevents any part of the gown from touching a nonsterile object; provides complete coverage of undergarments.
Closed Gloving	
5. With hands still inside the gown sleeves, open the inner wrapper of the gloves on the sterile gown field.	5. Maintains sterility of the gloves.
6. With your nondominant sleeved hand, grasp the cuff of the glove for the dominant hand and lay it on the extended dominant forearm with palm up; place the palm of the glove against the sleeved palm, with fingers of the glove pointing toward elbow.	6. Only sterile items come in contact with each other.
7. Manipulate the glove so that the sleeved thumb of your dominant hand is grasping the cuff; with your nondominant hand, turn the cuff over the end of dominant hand and gown's cuff.	7. Prevents the hands from contaminating the sterile glove.
8. With sleeved nondominant hand, grasp the cuff of the glove and the gown's sleeve of the dominant hand; slowly extend the fingers into the glove, making sure the cuff of the glove remains above the cuff of the gown's sleeve.	8. Provides a closed sterile method for gloving; the glove cuff over the gown prevents contamination of the operative field with microorganisms.
9. With the gloved dominant hand, repeat steps 7 and 8.	9. Only sterile items can touch each other.
10. Interlock gloved fingers, secure fit.	10. Promotes dexterity of gloved hands.

decrease the risk of wound contamination. The sterile gown also allows the nurse to move freely in the environment with sterile drapes and objects.

Reduce or Eliminate Infectious Agents

Transmission of microorganisms to clients may also occur through contact with inanimate objects. Cleansing, disinfecting, and sterilizing can break this link in the chain of infection by reducing or destroying microorganisms on objects. Cleansing, disinfection, and sterilization are usually the responsibility of nursing, housekeeping, and central supply departments. These infection control practices can and should also be practiced in the home care setting.

Cleansing

Cleansing is the removal of soil or organic material from instruments and equipment used in providing client care. Nurses are involved in cleansing instruments after assisting or performing an invasive procedure. Reusable objects are cleansed prior to sterilization and disinfection to reduce the amount of contamination and loosen the material on the object. Cleansing involves the use of water, mechanical action, and sometimes a detergent. Contaminated objects are cleaned using a soft-bristled brush to scrub the surface. The steps for proper cleansing are:

1. Rinse object under cold water since warm water causes proteins in organic material to coagulate and stick.

2. Apply detergent and scrub object under running water with soft-bristled brush.
3. Rinse the object under warm water.
4. Dry the object prior to sterilization or disinfection.

Cleansing presents a potential hazard to the nurse through splashing of contaminated material onto the body. Nurses should wear gloves, masks, and goggles during cleansing.

Disinfection

Disinfection is the elimination of pathogens, except spores, from inanimate objects. **Disinfectants** are chemical solutions used to clean inanimate objects. Bedpans, blood pressure cuffs, linens, stethoscopes, thermometers, and some types of endoscopes are disinfected in the hospital setting. The U.S. Environmental Protection Agency (EPA) licenses (registers) disinfection products and monitors the products to ensure they work as claimed on the label. Common disinfectants are alcohol, sodium hypochlorite, quaternary ammonium, phenolic solutions, and glutaraldehyde. In the home, Lysol and bleach are common disinfectants that are capable of eliminating several pathogens. A **germicide** is a chemical that can be applied to both animate and inanimate objects for the purpose of eliminating pathogens. Antiseptic preparations such as alcohol and silver sulfadiazine are germicides and may be used on skin.

Sterilization

Sterilization is the total elimination of all microorganisms including spores. Instruments that are used for invasive procedures must be sterilized. Methods of achieving sterilization are moist heat or steam, radiation, chemicals, and ethylene oxide gas. The method of sterilization depends on the type of contamination, amount of contamination, and object to be sterilized.

Autoclaving sterilization, which uses moist heat or steam, is the most common sterilization technique used in the hospital setting. Boiling water is not an effective sterilization measure as some viruses and spores can survive boiling water. Objects that have been boiled in water for 15 to 20 minutes at 121°C (249.8°F) are considered clean but not sterilized (Department of Labor, 1991). However, boiling water is still the best and most common sterilization measure used in the home. For example, boiling baby bottles and nipples makes them safe for use.

Home Health Care

“While many home care policies and procedures are developed with the best of intentions, they frequently lack a scientific basis and have been perpetuated over the years” (Friedman & Rhinehart, 2000, p. 99). Home care and hospice nurses are faced with significant chal-

NURSING SUPPLY BAG TECHNIQUE PROCEDURE

- Place the bag on a clean, dry surface.
- Wash hands with soap and running water prior to direct client contact. For MRSA or VRE clients, wash hands with antibacterial soap and running water. Cleanse hands with a waterless product if running water is not available.
- Remove the necessary supplies from the nursing bag, and place them on a clean, dry surface.
- Perform client care.
- Clean and disinfect semicritical equipment such as an oral thermometer with a 70% isopropyl alcohol prep pad, and return the equipment to the supply bag.
- Clean noncritical equipment such as a blood pressure cuff, stethoscope, or scale if soiled and return to the bag. If the client is infected or colonized with MDR bacteria, and equipment has not been designated for the client’s individual use, clean and disinfect the equipment with a disinfectant of the home care or hospice organization’s choice prior to replacing the noncritical items in the bag.
- Remove personal protective items such as a gown and gloves if worn.
- Wash hands with soap and running water prior to direct client contact. For MRSA or VRE clients, wash hands with antibacterial soap and running water. Cleanse hands with a waterless product if running water is not available, and wash hands with soap and running water as soon as possible.

Adopted from Friedman, M., & Rhinehart, E. (2000). Improving infection control home care: From ritual to science-based practice. *Home Healthcare Nurse*, 18(2), 99–106.

lenges when adapting acute care infection control practice to the home care setting such as cleaning and disinfecting equipment and using clean versus sterile technique. Common practice of home care organizations requires special practice regarding the handling of the *nursing supply bag*; see the accompanying display of a basic nursing bag technique procedure that may be followed in the home.

Disposal of Infectious Waste

All health care facilities must have guidelines for the disposal of infectious waste materials as deemed by the OSHA Act of 1991 (see the accompanying display). Always observe the biological hazard symbol and handle all infectious materials as a hazard. OSHA regulations mandate that “immediately after use, sharps shall be disposed of in closable, puncture-resistant, disposable containers that are leakproof on the sides and bottom and are labeled or color coded.” Dispose of soiled and infectious items in the home; do not place in car to dispose elsewhere.

DISPOSAL OF BIOLOGICAL MATERIALS

- Laboratory wastes
- Blood, blood products, and all other body fluids
- Client care items: soiled bed linen and protection pads soiled with visible blood, urinals, and bedpans
- Disposable instruments
- Medication and soiled treatment items
- Surgical wastes

When disposing of infectious waste:

- Wear gloves.
- Use the proper containers (red or one labeled with the biological hazard symbol as required by the facility), leakproof plastic bags for waste from client areas (soiled dressings, gloves, linen), and sharps containers for needles, scalpels, and other sharp instruments or devices (Figure 31-23).
- Ensure that all infectious waste is properly labeled.
- Use care when handling plastic bags to avoid punctures and tearing.
- Disinfect carts used to carry infectious waste.
- Dispose of waste in designated areas only.
- Wash hands after disposing of hazardous materials.

Containers for contaminated sharps should be readily accessible to personnel and maintained in an upright position.

NURSING ALERT

Needle Disposal

Used needles should not be recapped, bent, or broken. Needles should be placed in a puncture-resistant marked or color-coded container close to the work site. Correct disposal decreases the risk of needle punctures to caregivers.

Weltman, Short, and Mendelson (1995) studied disposal-related sharps injuries in a teaching hospital. Of the 361 persons in the study who reported sharps injuries, 72 of the injuries were related to sharps disposal. The majority of exposures to hepatitis B virus (HBV) and human immunodeficiency virus (HIV) were caused by sharp objects. Never attempt to place syringes in a full container.

Practice Standard and Isolation Precautions

The CDC revised the Guidelines for Isolation Precautions in Hospitals in 1996. The new guidelines

Figure 31-23 Sharps Disposal and Infectious Waste Containers

combined the major features of Universal Precautions and Body Substance Isolation into a single set of Standard Precautions (Satterfield, 1995). Refer to the Standard Precautions on the end pages. The Standard Precautions apply to:

- Blood
- All body fluids, secretions, excretions, and contaminated items regardless of whether or not they contain visible blood
- Nonintact skin
- Mucous membranes

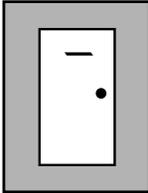

Barrier precautions are used to minimize the risk of exposure to blood and body fluids. Barrier precautions consist of using personal protective equipment, such as masks, gowns, and gloves, to create a barrier between the person and the microorganism that prevents transmission of the microorganism.

The 1996 CDC guidelines eliminated the previous category-specific isolation precautions and condensed the former disease-specific precautions into three sets of precautions based on routes: contact, droplet, and airborne transmission (Figure 31-24). The new

CONTACT PRECAUTIONS

(In addition to Standard Precautions)

VISITORS: Report to nurse before entering

Patient Placement

Private room, if possible. Cohort if private room is not available.

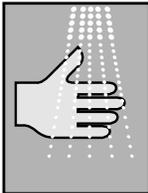

Gloves

Wear gloves when entering patient room.

Change gloves after having contact with infective material that may contain high concentrations of microorganisms (**fecal** material and **wound drainage**).

Remove gloves before leaving patient room.

Wash

Wash hands with an **antimicrobial** agent immediately after glove removal.

After glove removal and handwashing, ensure that hands do not touch potentially contaminated environmental surfaces or items in the patient's room to avoid transfer of microorganisms to other patients or environments.

Gown

Wear gown when **entering** patient room if you anticipate that your clothing will have substantial contact with the patient, environmental surfaces, or items in the patient's room, or if the patient is **incontinent**, or has **diarrhea**, an **ileostomy**, a **colostomy**, or **wound drainage** not contained by a dressing. **Remove** gown before leaving the patient's environment and ensure that clothing does not contact potentially contaminated environmental surfaces to avoid transfer of microorganisms to other patients or environments.

Patient Transport

Limit transport of patient to essential purposes only. During transport, ensure that precautions are maintained to minimize the risk of transmission of microorganisms to other patients and contamination of environmental surfaces and equipment.

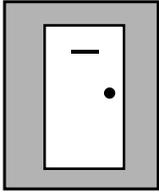

Patient-Care Equipment

Dedicate the use of noncritical patient-care equipment to a single patient. If common equipment is used, clean and disinfect between patients.

DROPLET PRECAUTIONS

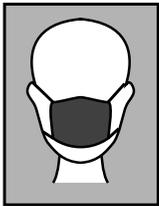

(In addition to Standard Precautions)

VISITORS: Report to nurse before entering

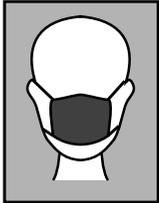

Patient Placement

Private room, if possible. Cohort or maintain spatial separation of **3 feet** from other patients or visitors if private room is not available.

Mask

Wear mask when working within **3 feet** of patient (or upon entering room).

Patient Transport

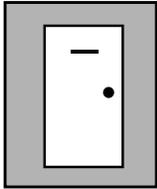

Limit transport of patient to essential purposes only.
Use **surgical mask** on patient during transport.

Figure 31-24B Transmission-Based Precautions: Droplet Precautions (Courtesy of the Brevis Corporation, 3310 S. 2700, Salt Lake City, UT 84109.)

AIRBORNE PRECAUTIONS

(In addition to Standard Precautions)

VISITORS: Report to nurse before entering

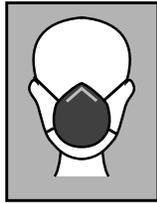

Patient Placement

Private room that has:

Monitored negative air pressure,
6 to 12 air changes per hour,

Discharge of air outdoors or HEPA filtration if recirculated.

Keep room door closed and patient in room.

Respiratory Protection

Wear an **N95 respirator** when entering the room of a patient with known or suspected infectious pulmonary **tuberculosis**.

Susceptible persons should not enter the room of patients known or suspected to have **measles** (rubeola) or **varicella** (chickenpox) if other immune caregivers are available. If susceptible persons must enter, they should wear an **N95 respirator**. (Respirator or surgical mask not required if immune to measles and varicella.)

Patient Transport

Limit transport of patient from room to essential purposes only.

Use **surgical mask** on patient during transport.

precautions are called transmission-based precautions and are to be used in addition to Standard Precautions. Transmission-based precautions are to be used for specific syndromes that are highly suspicious for infections until a diagnosis is confirmed (see Table 31-6).

In addition to the Standard Precautions these temporary precautions are to be used for suspicious infections. Immunosuppressed clients, like Mary Evans with neutropenia, require transmission-based precautions, as described in Table 31-6.

NURSING ALERT

Standard Precautions

Standard Precautions must be practiced with all clients since this is the most effective method to decrease the risk of infection for clients and caregivers.

Nurses use isolation precautions to protect the host's normal defense mechanisms by preventing the transmission of pathogens (nosocomial infections). Isolation precautions include barrier protection that breaks the chain of infection.

When the nurse cares for a client in isolation, additional precautions are used along with handwashing and gloves. A mask and eye protection (or face shield) are worn to protect the mucous membranes of the eyes, nose, and mouth during interventions that are likely to produce splashes or sprays of blood, body fluids, secretions, and excretions. A nonsterile gown is also worn to protect the skin and clothing against splashes or sprays. Procedure 31-8 describes isolation precaution techniques.

Nurses caring for clients with tuberculosis (an infectious disease caused by the tubercle bacillus *Mycobacterium tuberculosis*) are required to wear special masks since transmission occurs between individuals through respiratory contact. There are two types of tuberculosis masks: high-efficiency particulate air (HEPA) mask used for suspected or confirmed multi-drug-resistant (MDR) tuberculosis and the disposable submicrometer mask used for confirmed tuberculosis. These masks form a tight-fitting seal against particulates 1 to 5 μm .

Isolation precautions are usually ordered by the physician; however, nurses may initiate these precautions whenever there is a nursing diagnosis related to the infectious process, for example, *Risk for Infection* related to decreased resistance of immune system. Most agencies require nurses to obtain a culture from a draining body area and to initiate isolation precautions when positive cultures are reported. Once isolation precautions have been instituted, visitors and all personnel should comply with the agency's policy regarding isolation precautions. Signs should be posted in a prominent location outside the client's room indicating the type of isolation precautions, preparation prior to entering the room, and the necessary supplies that should be readily available.

Clients should be placed in a private room with adequate ventilation and have their own supplies. Personal belongings should be kept to a minimum, and health care providers should use disposable supplies and equipment. All articles leaving the room, such as soiled linen and collected specimens, should be labeled and either placed in impermeable bags or double bagged (see Procedure 31-8 for the double-bagging technique). Home health nurses should provide the client and

TABLE 31-6
Transmission-Based Precautions

Category	Private Room	Gloves	Gowns	Masks
Contact precautions	If possible; cohort if not available	Required	If anticipate contact with soiled items; patient is incontinent; diarrhea, ileostomy, colostomy, wound drainage	Not required
Droplet precautions	If possible; cohort or maintain separation of 3 feet	Not required	Not required	Required when within 3 feet
Airborne precautions	Required. Negative air pressure, 6–12 air changes per hour, keep door closed, discharge air outdoors or HEPA filter	Not required	Not required	N95 respirator required for known or suspected tuberculosis and measles or varicella if not immune

PROCEDURE 31-8

Initiating Strict Isolation Precautions

Equipment

- | | |
|---|---|
| <ul style="list-style-type: none"> ■ Isolation sign ■ Disposable gowns ■ Gloves (nonsterile and sterile) ■ Tape or bag ties ■ Room with sink and running water ■ Paper towels ■ Water pitcher, cups, and fresh water ■ Other supplies relative to client's condition, for example, dressings for wound care | <ul style="list-style-type: none"> ■ Disposable caps ■ Disposable masks ■ Impermeable bags (linen and trash) ■ Disposable vital signs equipment (single-use thermometers, stethoscope, and sphygmomanometer) ■ Linen ■ Specimen containers and labels |
|---|---|

Action

1. Review physician orders and agency protocols relative to the type of isolation precautions:
 - a. Implement protocol about the type of disinfectants needed to eliminate specific microorganism.
 - b. Alert housekeeping regarding the room number and type of isolation supplies needed in the room.
 - c. Make sure the room has proper ventilation (the door will have to remain closed at all times) and that the bed and other electrical equipment are functioning properly.
2. Place appropriate isolation supplies outside the client's room and place isolation sign on the door.
3. Gather appropriate supplies to take in the room:
 - a. Soap and paper towels
 - b. Linen
 - c. Impermeable bags
 - d. Disposable vital signs equipment
 - e. Wound care, if appropriate
4. Remove jewelry, lab coat, and other items not necessary in providing client care.
5. Wash hands and don disposable clothing:
 - a. Apply cap to cover hair and ears completely.
 - b. Apply gown to cover outer garments completely: Hold gown in front of body and place arms through sleeves (Figure 31-25A). Pull sleeves down to wrist. Tie gown securely at neck and waist (Figure 31-25B, C).

Rationale

1. Ensures compliance without unnecessary stress being placed on the client and family. Allows housekeeping to have the necessary supplies on their cleaning carts. Provides for client comfort and decreases the spread of microorganisms. Limits the number of personnel coming into the client's room and the client's exposure to microorganisms.
2. Ensures staff follows isolation protocol and alerts visitors to check with the nurses' station before entering the room.
3. Provides for organized care, handwashing, proper isolation, and client care materials. Decreases the spread of microorganisms and the number of times you have to go into and out of the room.
4. Decreases the spread of resident and transient microorganisms.
5. Disposable garments act as a barrier in preventing the transmission of microorganisms from nurse to client and protect the nurses from contact with pathogens.

Initiating Strict Isolation Precautions (continued)

Action

Rationale

A.

B.

PROCEDURE 31-8

Initiating Strict Isolation Precautions (continued)

Action

C.

Figure 31-25 Donning disposable gown: A. Hold gown in front of the body and place arms through the sleeves. B. Fasten neck ties. C. Fasten waist ties.

Rationale

- c. Don nonsterile gloves and pull gloves to cover gown's cuff.
 - d. Apply mask by placing the top of the mask over the bridge of your nose (top part of mask has a lightweight metal strip) and pinch the metal strip to fit snugly against your skin.
6. Enter client's room with all gathered supplies; if client is to receive medications, bring them with you at this time. Arrange and store supplies and equipment.
 7. Assess client and family knowledge relative to client's diagnosed infection and isolation:
 - a. Reason isolation initiated
 - b. Type of isolation
 - c. Duration of isolation
 - d. How to apply cap, gown, gloves, and mask
- 6. Prevents trips into and out of client room and keeps supplies clean.
 - 7. The physician usually informs the client and family of the reasons isolation is required. Client's and family's understanding of isolation procedures will increase their participation in care.

(continues)

PROCEDURE 31-8

Initiating Strict Isolation Precautions (continued)

*Action**Rationale*

- | | |
|---|--|
| <p>8. Assess vital signs, administer medications if appropriate, and perform other functions of nursing care to meet the needs of the client. Record assessment data on a piece of paper, avoiding contact with any articles in the client's room.</p> <p>9. Dispose of soiled articles in the impermeable bags, which should be labeled correctly according to contents. If soiled reusable equipment is removed from the room, label bag accordingly.</p> <p>10. Bag soiled linen according to agency policy either in an impermeable bag or in plastic linen bags, double bagging.</p> <p>11. Replenish supplies before leaving the client's room by having another staff member bring the clean supplies and transfer at the door. Ask client if anything is needed (juice or personal care items).</p> <p>12. Before leaving, let the client know when returning; make sure call light is accessible.</p> <p>13. Exiting the isolation room:</p> <p>a. Untie gown at waist.</p> <p>b. Remove one glove by grasping the glove's cuff and pulling down so that the glove turns inside out (glove on glove) and dispose of it. With your ungloved hand, slip your fingers inside the cuff of the other glove, pull it off, inside out, and dispose of it.</p> <p>c. Grasp and release the ties of the mask, and dispose of it.</p> <p>d. Release neck ties of the gown and allow the gown to fall forward. Place fingers of dominant hand inside cuff of other hand and pull down over other hand (Figure 31-26A). With gown covered hand, pull gown over the dominant hand (Figure 31-26B). While gown is still on arm, fold outside of gown together, remove, and dispose of it (Figure 31-26C).</p> <p>e. Remove cap by slipping your finger under the cap and removing from the front to back and dispose of it.</p> | <p>8. Allows for data collection and the performance of client care measures.</p> <p>9. Impermeable bags prevent the leakage of contaminated materials, thereby preventing the spread of infection. Labeling is a warning to other personnel that the contents are infectious.</p> <p>10. Double bagging allows the washing of soiled linen without human contact: When linen is double bagged, the first bag is removed prior to washing; the second bag goes into the machine with the dirty linen and dissolves.</p> <p>11. Decreases the number of times staff members have to go in and out of the room and client exposure to microorganisms.</p> <p>12. Decreases feeling of abandonment; provides client with a means of communication.</p> <p>13. Gloves are removed inside out to avoid contact with skin. The gown is removed and folded with hands touching only the inside of the garment. Only the ties and the inside of the cap are touched with your hands. All articles are disposed of as soon as they are removed.</p> |
|---|--|

PROCEDURE 31-8

Initiating Strict Isolation Precautions (continued)

Action

A.

Rationale

B.

C.

14. Wash hands for 10 minutes. Don nonsterile gloves and remove bags from the client's room. Exit room and close door. Dispose of bags according to agency protocol. Remove gloves and wash hands.

Figure 31-26 Removing disposable gown: A. Place fingers of dominant hand inside the cuff of other hand and pull gown down over other hand. B. With the gown-covered hand, pull gown down over dominant hand. C. As the gown is removed, fold the outside of the gown together and dispose of it.

14. Decreases transmission of microorganisms.

NURSING CHECKLIST

Psychological Interventions for Clients Requiring Isolation Precautions

- Explain isolation procedure and rationale.
- Discuss client's feelings about isolation procedures.
- Convey a sense of empathetic understanding.
- Permit visitors in accordance with isolation precautions.
- Support existing coping mechanisms.
- Visit with the client.

family with appropriate written isolation instructions relative to the specific precautions.

Isolation precautions are for the client's protection; however, clients who are placed on isolation precautions may experience psychological discomfort (Figure 31-27). Nurses should be alert for symptoms of anxiety, depression, rejection, guilt, or loneliness. Clients should be educated on which isolation precautions will be practiced and their purposes. Nurses should encourage clients to verbalize their feelings regarding the isolation precautions and provide the client with intellectual stimulation. Visitors should be encouraged to prevent the client's feelings of isolation and loneliness. The following Nursing Checklist lists some psychological interventions.

Alternative Therapies

The American Nurses Association, in its 1995 *Social Policy Statement*, recognizes holistic, complementary, and alter-

Figure 31-27 This nurse is interacting with a client who requires isolation precautions. Although both the client and nurse are observing isolation precautions, they are still able to communicate with one another. In planning the care of this client, what would the expected outcomes of these interventions be?

native practices for the client. More and more clients are seeking alternative therapy for common medical conditions, mainly chronic conditions (Springhouse, 1999). Hospitals are becoming more responsive to client demands by incorporating new practice models to allow the client choices and requests for alternative options as part of a holistic approach to both curing and healing. The Massachusetts and Louisiana state boards of nursing have issued statements regarding the role and scope of registered nurse practice and holistic care.

Documentation of the client's alternative or complementary practices should be included in the health history to ensure an integration of alternative and conventional care. Nurses need to have a knowledge of herbal products and their effects to avoid possible adverse reactions when prescribed drugs are used in combination with the client's herbal regimen. A brief discussion regarding herbal baths and the use of herbs for infections is presented; refer to Chapter 14 for a complete discussion of complementary therapies.

THINK ABOUT IT

Isolation Precautions

Where were the nurses? Pugliese (1995) cited a nursing home that was fined \$75,000 for isolating a 36-year-old stroke client with human immunodeficiency virus (HIV) for 9 months. The client filed a complaint with the division of human rights. Who should have been the advocate for this client? What would you have done if you had been working in this nursing home?

Herbal Baths

Herbal baths are a safe home method of treatment for all clients, especially infants and the elderly, and can be made just for the specific part of the body, such as the hands, hips, or feet, or can be a full body bath (Tierra, 1997). A bath made from freshly grated ginger root tea stimulates circulation, alleviates aches and pains and breaks a cold, helps arthritis, and warms the body. To calm the mind and relax the body, combine equal parts of lavender, rose, chamomile, and skullcap in the bath water. To stimulate circulation and relieve fever and chill, combine equal parts bayberry bark, ginger, and prickly ash, and one-fourth part cayenne pepper in the bath water. Clients using herbs in bath water for the first time should do a simple patch test to rule out a possible allergic response.

Herbs for Infections

Herbs are used in two ways for infections. Through their antimicrobial action, they work directly against

microbes. They also augment and vitalize the body's own defenses. Although research may not always be available to explain exactly how herbs work, many plants have a direct toxic effect upon microbes. "The best anti-microbials that can be used safely to combat infections include *Echinacea*, *Eucalyptus*, *Garlic*, *Myrrh*, *Nasturtium*, *Thyme*, *Wild Indigo*, and *Wormwood*" (Hoffmann, 1998, p. 115).

Provide for Client Bathing Needs

Bathing of clients is an essential component of nursing care. Whether the nurse performs the bath or delegates the activity to another health care provider, the nurse retains the responsibility for assuring that the hygienic needs of the client are met. The type of bath provided will depend on the purpose of the bath and the client's self-care ability. The two general categories of baths are cleaning and therapeutic.

NURSING TIP

Bathing

- Baths are an excellent time to perform a complete skin assessment.
- The bathing process provides time for the nurse to meet the client's psychosocial needs through assessment and counseling.
- Bathing provides time to educate the client on basic and special hygienic needs.

Cleaning Baths

Cleaning baths are provided as routine client care. The purpose of a cleaning bath is personal hygiene. The five types of cleaning baths are shower, tub, self-help, or assisted bed bath, complete bed bath, and partial bath.

Shower

Most ambulatory clients are capable of taking a shower. Clients with limited physical ability can be accommodated by placing a waterproof chair in the shower (Figure 31-28). The nurse provides minimal assistance with a shower. The Nursing Checklist discusses guidelines for helping clients with tub or shower baths.

NURSING CHECKLIST

Tub or Shower Bath

- Schedule use of tub or shower and provide necessary equipment.
- Assist with ambulation to and from tub or shower.
- Place bath mat in tub or shower. Provide shower chair if necessary.
- Place "occupied" sign on door.
- Adjust room temperature and temperature of water.
- Half-fill tub with water. Do not allow client to soak longer than 20 minutes.
- Assist client with getting into and out of tub or shower. Provide with a call system.
- Assist with cleaning as necessary.
- Clean tub or shower after use according to agency policy.

Figure 31-28 Shower Chair

Tub Bath

Clients frequently prefer and enjoy tub baths. A tub bath permits washing and rinsing in the tub. Tub baths can also be therapeutic. Clients with limited physical ability should be assisted with entering and exiting the tub.

Self-Help Bath

A self-help, or assisted, bed bath is used to provide hygienic care for clients who are confined to bed. In the self-help (assisted) bed bath, the nurse prepares bath equipment but provides minimal assistance. This assistance is usually limited to washing difficult-to-reach body areas such as the feet and back.

Complete Bed Bath

A complete bed bath is provided to dependent clients confined to bed. The nurse washes the client's entire body during a complete bed bath. Procedure 31-9 outlines the actions involved in giving a complete bed bath.

Partial Bath

A partial (or abbreviated) bath consists of cleaning only body areas that would cause discomfort or odor if not washed thoroughly. These areas are the face, axillae, hands, and perineal area. The nurse or client may perform a partial bath depending on the client's self-care

ability. Partial baths may be performed with the client lying in bed or standing at the sink.

Therapeutic Bath

Therapeutic baths require a physician's order stating the type of bath, temperature of water, body surface to be treated, and the type of medicated solutions to use. A therapeutic bath is usually performed in a tub and lasts about 20 to 31 minutes. Therapeutic baths are classified as hot or warm water, cool or tepid water, soak, sitz, oatmeal or Aveeno, cornstarch, or sodium bicarbonate, depending on the prescribed type of bath.

Hot- or warm-water tub baths are used to reduce muscle spasms, soreness, and tension. Hot- or warm-water baths, however, have the potential for causing skin burns. Cool or tepid baths are used to relieve tension or lower body temperature. The nurse needs to prevent chilling and rapid temperature fluctuations during a cool or tepid bath.

A soak can include the entire body or be limited to only one body part. A soak consists of applying water, with or without a medicated solution, to reduce pain, swelling, or irritation or to soften or remove dead tissue.

Sitz baths cleanse and reduce inflammation in the perineal and anal areas. Sitz baths are commonly used for hemorrhoids or anal fissures and after perineal or rectal surgery. Skin irritations can be soothed with oatmeal or Aveeno, cornstarch, or sodium bicarbonate baths.

PROCEDURE 31-9

Adult Complete Bed Bath

Equipment

- | | |
|----------------|---------------------|
| ■ Bath towels | ■ Washcloths |
| ■ Bath blanket | ■ Washbasin |
| ■ Soap | ■ Soap dish |
| ■ Lotion | ■ Deodorant |
| ■ Powder | ■ Clean gown |
| ■ Clean linen | ■ Disposable gloves |

Action

1. Assess client's preferences about bathing.
2. Explain procedure to client.
3. Prepare environment. Close doors and windows, adjust temperature, provide time for elimination needs, and provide privacy.
4. Wash hands. Apply gloves. Gloves should be changed when emptying water basin.

Rationale

1. Provides client opportunity to participate in care.
2. Enhances cooperation.
3. Protects from chills during bath and increases sense of privacy.
4. Reduces potential for transmission of pathogens.

(continues)

PROCEDURE 31-9

Adult Complete Bed Bath (continued)*Action*

5. Lower side rail on the side close to you. Position client in a comfortable position close to the side near you.
6. If bath blankets are available, place bath blanket over top sheet. Remove top sheet from under bath blanket (see Figure 31-29). Remove client's gown. Bath blanket should be folded to expose only the area being cleaned at that time. (Top sheets may also be used for bath blankets.)

Figure 31-29 Place a bath blanket over the top sheet and remove the sheet from under the blanket.

Rationale

5. Prevents unnecessary reaching. Facilitates use of good body mechanics.
6. Prevents exposure of client. Promotes privacy. Protects from chills.
7. Fill washbasin two-thirds full. Permit client to test temperature of water with his or her hand. Water should be changed when a soap film develops or water becomes soiled.
8. Make a bath mitten with the washcloth. To make a mitten: grasp the edge of the washcloth with the thumb; fold a third over the palm of the hand; wrap remainder of cloth around hand and across palm, grasping the second edge under the thumb; fold the extended end of the washcloth onto the palm and tuck under the palmar surface of the cloth.
9. Wash the face. Ask the client about preference for using soap on the face. Use a separate corner of the washcloth for each eye, wiping from inner to outer canthus (see Figure 31-30). Wash neck and ears. Rinse and pat dry. Male clients may want to shave at this time. Provide assistance with shaving as needed.
7. Prevents accidental burns or chills.
8. Prevents ends of washcloth from dragging across skin. Promotes friction during bath.
9. Some clients may not use soap on their face. Using separate corners of washcloth reduces risk of transmitting microorganisms. Patting dry reduces skin irritation and drying.

(continues)

PROCEDURE 31-9

Adult Complete Bed Bath (continued)

Action

Figure 31-30 Clean the eye with the corner of the washcloth, wiping from the inner to the outer canthus.

10. Wash arms, forearms, and hands. Wash forearms and arms using long, firm strokes in the direction of distal to proximal (Figure 31-31). Arm may need to be supported while being washed. Wash axilla. Rinse and pat dry. Apply deodorant or powder if desired. Immerse client's hand into basin of water. Allow hand to soak about 3 to 5 minutes. Wash hands, interdigit area, fingers, and fingernails. Rinse and pat dry.

Figure 31-31 Wash forearms and arms in the direction of the wrist to upper arm.

11. Wash chest and abdomen. Fold bath blanket down to umbilicus. Wash chest using long, firm strokes. Wash skinfold under the female client's breast by lifting each breast. Rinse and pat dry. Fold bath blanket down to suprapubic area. Use another towel to cover chest area. Wash abdomen using long, firm strokes. Rinse and pat dry. Replace bath blanket over chest and abdomen. Cover chest or abdomen area in

Rationale

10. Long strokes promote circulation. Soaking hands softens nails and loosens soil from skin and nails. Strokes directed distal to proximal promote venous return. Powder removes excess moisture.

11. Promotes privacy and prevents chills. Long strokes promote circulation. Perspiration and soil collect within skin folds.

(continues)

PROCEDURE 31-9

Adult Complete Bed Bath (continued)*Action*

between washing, rinsing, and drying to prevent chilling.

12. Wash legs and feet. Expose leg farthest from you by folding bath blanket to midline. Bend the leg at the knee. Grasp the heel, elevate the leg from the bed and cover bed with bath towel. Place washbasin on towel. Place client's foot into washbasin. Allow foot to soak while washing the leg with long, firm strokes in the direction of distal to proximal (ankle to thigh; Figure 31-32). Rinse and pat dry. Clean soles, interdigits, and toes. Rinse and pat dry. Perform same procedure with the other leg and foot.

Figure 31-32 Wash the leg and foot in the direction of distal to proximal.

Rationale

12. Supports joints to prevent strain and fatigue. Soaking foot loosens dirt, softens nails, and promotes comfort.

13. Wash back. Assist client into prone or side-lying position facing away from you. Wash the back and buttocks using long, firm strokes. Rinse and pat dry. Give back rub and apply lotion.
 14. Perineal care: Assist client to supine position. Perform perineal care.
 15. Apply lotion and powder as desired. Apply clean gown.
 16. Document skin assessment, type of bath given, and client outcomes and responses.
13. Exposes back and buttocks for washing. Back rub promotes relaxation and circulation.
 14. Removes genital secretions and soil.
 15. Lotion lubricates skin. Powder absorbs excess perspiration.
 16. Provides evidence of nursing care.

Provide Clean Bed Linen

After a bath, clean linens are placed on the bed to promote comfort. If the client is able to get out of the bed, assist the client to a chair and proceed with making the bed. Procedure 31-10 describes the steps

involved with making an unoccupied bed. After surgery, the client should be returned to a clean bed with the linens folded to the foot of the bed to promote easy client transfer.

If the client is unable to get out of the bed, refer to Procedure 31-11 for a description of the steps involved

PROCEDURE 31-10

Bedmaking: Unoccupied Bed

Equipment

- | | |
|--|---|
| ■ Bottom sheet (fitted, if available) | ■ Top sheet |
| ■ Draw sheet (regular top sheet may be used) | ■ Pillowcase (each pillow on the bed) |
| ■ Mattress pad | ■ Antiseptic solution, washcloth, and towel |
| ■ Linen bag hamper outside the room | ■ Nonsterile gloves |

Action

1. Wash hands.
2. Place hamper by client's door if linen bags are not available. Explain procedure to client. Assess condition of blanket and/or bedspread.
3. Gather linen and gloves. Place linen on a clean, dry surface in reverse order of usage at the client's bedside (pillowcases, top sheet, draw sheet, bottom sheet).
4. Don gloves.
5. Inquire about the client's toileting needs and attend as necessary.
6. Assist client to a safe, comfortable chair.
7. Position bed: flat, side rails down, adjust height to waist level.
8. Remove and fold blanket and/or bedspread. If clean and reusable, place on clean work area.
9. Remove soiled pillowcases by grasping the closed end with one hand and slipping the pillow out with the other. Place soiled cases on top of soiled sheet and pillows on clean work area.
10. Remove soiled linens: Start on the side of the bed closest to you; free the bottom sheet by lifting the mattress and rolling soiled linens to the middle of the bed. Go to the other side of the bed, repeat action.
11. Fold soiled linens: head of bed to middle, foot of bed to middle. Place in linen bag or hamper, keeping soiled linens away from uniform.

Rationale

1. Reduces transmission of microorganisms.
2. Provides for proper disposal of soiled linens. Encourages client cooperation. Allows for organization of supplies.
3. Provides easy access to items.
4. Decreases risk of infection from soiled, contaminated linens.
5. Provides for client comfort and prevents interruptions during bedmaking.
6. Increases client's comfort and decreases risk for falls.
7. Promotes good body mechanics and decreases back strain.
8. Keeps reusable bed linens clean.
9. Allows easy removal of the pillowcases without contamination of uniform by soiled linens and keeps pillows clean.
10. Prevents tearing and fanning of linens. Linens are folded from cleanest area to most soiled to prevent contamination.
11. Fanning linens increases number of microorganisms in air. Folding linens decreases the risk of transmission of infection to others.

(continues)

PROCEDURE 31-10

Bedmaking: Unoccupied Bed (continued)

<i>Action</i>	<i>Rationale</i>
<p>12. Check mattress and pad. If the pad is soiled, replace. If the mattress is soiled, clean with an antiseptic solution and dry thoroughly.</p> <p>13. Remove gloves, wash hands, and don second pair of clean gloves.</p> <p>14. Open clean bottom sheet lengthwise onto the bed with the seamed side of the sheet toward the mattress. Unfold half of the sheet's width to center crease and smooth the sheet flat (refer to action 15 for placing sheet onto mattress).</p> <p>15. Proceed with placing bottom sheet onto the mattress:</p> <p>a. Fitted sheet</p> <ul style="list-style-type: none"> • Position yourself diagonally toward the head of the bed. • Start at the head with seamed side of the fitted sheet toward the mattress. • Lift the mattress corner with your hand closest to the bed; with your other hand, pull and tuck the fitted sheet over the mattress corner; secure at the head and sides. • Repeat action at foot of bed. <p>b. Flat regular sheet</p> <ul style="list-style-type: none"> • Lay the bottom of the sheet on the top edge of the mattress at the foot of the bed. • Allow the sheet to hang 10 inches (25 cm) over the mattress on the side and at the top of the bed. • Position yourself diagonally toward the head of the bed. Lift the top of the mattress corner with the hand closest to the bed and smoothly tuck the sheet under the mattress (Figure 31-33). 	<p>12. Reduces transmission of microorganisms.</p> <p>13. Reduces transmission of microorganisms to clean linens.</p> <p>14. Facilitates making bed in an organized, time-saving manner by not having to go from one side of the bed to the other.</p> <p>15. Prevents back strain. Placement of seamed side toward mattress prevents irritation to the client's skin. Proper placement of linens ensures adequate sheeting for all sides of the bed.</p> <p>Ensures proper placement of the sheet so that it can be tightly secured at the top and on both sides of the bed.</p> <p>Prevents straining of back muscles; decreases the chance that the sheet will pull out from under the mattress.</p>

Figure 31-33 Tuck the sheet under the mattress corner.

(continues)

PROCEDURE 31-10

Bedmaking: Unoccupied Bed (continued)*Action**Rationale*

16. Miter the corner at the head of the bed.
 - a. Face the side of bed and lift and lay the top edge of the sheet onto the bed to form a triangular fold (Figure 31-34A).
 - b. With your palms down, tuck lower edge of sheet (hanging free at side of mattress) under mattress.
 - c. Grasp the triangular fold, bring it down over the side of the mattress and tuck the sheet smoothly under the mattress (see Figure 31-34B). Straighten the free hanging sheet on mattress side.

16. Secures sheet tightly to the mattress, with the triangular fold providing a smooth tuck to keep the linen in place.

A.

B.

Figure 31-34 A. Lay the top edge of the sheet onto the bed to form a triangular fold. B. Bring the triangular fold down over the side of the mattress and tuck the sheet under the mattress.

17. Place draw sheet on top of bottom sheet and unfold to middle crease. Both sheets should hang 10 inches (25 cm) over the side of the mattress.
 17. Provides a sheet to lift and move the client in bed without having to use the bottom sheet and remake the bed. Helps to keep bottom sheet clean.
18. Face the side of the bed, palms of hands down. Tuck both the bottom and draw sheets under the mattress. Ensure that the bottom sheet is tucked smoothly under the mattress all the way to the foot of the bed.
 18. Keeps sheet taut, in place, and wrinkle-free, decreasing the risk of skin irritation.
19. Go to the other side of the bed, unfold the bottom sheet, repeating steps 14 to 16.
 19. Unfolding decreases air current, which can spread microorganisms.
20. Unfold the draw sheet and grasp the free hanging sides of both the bottom and draw sheets. Pull toward you, keeping your back straight, and with a firm grasp (sheets taut) tuck both sheets under the mattress. Use your arms and
 20. Uses your body's weight in pulling the sheet taut and prevents strain on your back muscles.

(continues)

PROCEDURE 31-10

Bedmaking: Unoccupied Bed (continued)

<i>Action</i>	<i>Rationale</i>
with a firm grasp (sheets taut) tuck both sheets under the mattress. Use your arms and open palms to extend the linen under the mattress.	
21. Place the top sheet on top of bed and unfold lengthwise, placing the center crease (width) of the sheet in the middle of the bed. Place the top edge of the sheet (seam up) even with the top of the mattress at the head of the bed. Pull the remaining length toward the bottom of the bed.	21. Saves time and movement, making one side of the bed at a time. Seam will be folded down to prevent contact with the client's skin, which can result in irritation.
22. Unfold and apply the blanket or spread; repeat action 21.	22. Provides warmth.
23. Miter the bottom corners as described in action 16.	23. Secures linen at the foot of the bed.
24. Face the head of the bed and fold the top sheet and blanket over 6 inches (15 cm). Fan-fold the sheet and blanket (from the foot to the middle of the bed).	24. Allows the client easy access to the bed.
25. Apply clean pillowcase on each pillow. With one hand, grasp the closed end of the pillowcase. Gather case and turn it inside out over hand. With same hand, grasp the middle of one end of the pillow. With the other hand, pull the case over the length of the pillow. The corners of the pillow should fit snugly into the corners of the case.	25. Keeps clean pillowcase away from your uniform.
26. Return the bed to the lowest position and elevate the head of the bed 31 to 45 degrees. Put side rails up on side, farthest from client.	26. Provides for client safety.
27. Inquire about toileting needs of the client; assist as necessary.	27. Saves client energy and provides time to care for the client's needs.
28. Assist the client back into the bed and pull up the side rails; place call light in reach; take vital signs.	28. Promotes client safety and a means to call for assistance. Sitting up in a chair and movement may cause changes in the client's vital signs.
29. Remove gloves and wash hands.	29. Prevents transmission of microorganisms.
30. Document your actions and the client's response during the procedure and to being up in a chair.	30. Documents completion of procedure and assessment findings of client's tolerance.

in making an occupied bed. Assistance will be needed if the client is in traction or cannot be turned. Care must be taken to avoid disturbing the traction weights. If the client cannot be turned, change the linen from head to toe. Place a waterproof draw sheet on the beds of clients who are incontinent or have profuse drainage.

Provide Skin Care

The skin functions as a protective barrier between the internal and external environments. In addition, the skin functions to regulate body temperature, secrete sebum, excrete sweat, transmit sensations, and facilitate absorption of vitamin D.

PROCEDURE 31-11

Bedmaking: Occupied Bed*Equipment*

- Linen hamper
- Pillowcase
- Bath blanket

- Top sheet, draw sheet, bottom sheet
- Blanket

Action

1. Explain procedure to client.
2. Remove top sheet and blanket. Loosen bottom sheet at foot and sides of bed. Lower side rail on side of nurse. Client may be covered with a bath blanket.
3. Position client on side, facing away from you. Reposition pillow under head.
4. Fan-fold or roll bottom linens close to client toward the center of the bed (Figure 31-35).

Figure 31-35 Fan-fold the bottom linens close to the client toward the center of the bed.

Rationale

1. Promotes client cooperation.
2. Facilitates easy removal of linen. Lowering only side rail close to nurse reduces client's risk of falls. Bath blanket prevents exposure and chills.
3. Provides space to place clean linen.
4. Maintains soiled linen together. Promotes comfort when client later rolls to other side.
5. Smooth wrinkles out of mattress. Place clean bottom linens with the center fold nearest the client. Fan-fold or roll clean bottom linens nearest client and tuck under soiled linen (Figure 31-36). Maintain an adequate amount of sheet at head and foot of bed for tucking.
6. Miter bottom sheet at head of bed, then at foot of bed. To miter, lift mattress and tuck sheet over the edge of the mattress, lift edge of sheet that is hanging to form a triangle, and lay upper part of sheet back onto bed; tuck the lower hanging section under the mattress. Repeat for each corner. Tuck the sides of the sheet under

5. Provides for maximum fit of sheets and decreases chance of wrinkles.
6. Holds linens firmly in place.

(continues)

PROCEDURE 31-11

Bedmaking: Occupied Bed (continued)*Action*

Figure 31-36 Fan-fold the clean bottom linens nearest the client and tuck under the soiled linens.

Rationale

- part of sheet back onto bed; tuck the lower hanging section under the mattress. Repeat for each corner. Tuck the sides of the sheet under the mattress.
7. Fold draw sheet in half. Identify the center of the draw sheet and place close to the client. Fan-fold or roll draw sheet closest to client and tuck under soiled linen (Figure 31-37). Smooth linen. Tuck draw sheet under mattress, working from the center to the edges. Draw sheet should be positioned under the lower back and buttocks.
 8. Log roll client over onto side facing you. Raise side rail.
 9. Move to other side of bed. Remove soiled linens by rolling into a bundle and place in linen hamper without touching uniform.
 10. Unfold/unroll bottom sheet; then draw sheet. Look for objects left in the bed. Grasp each sheet with knuckles up and over the sheet and pull tightly while leaning back with your body weight (Figure 31-38). Client may be positioned supine.
7. Draw sheet facilitates moving and lifting clients while in bed.
 8. Positions client off soiled linen. Protects client from falling.
 9. Prevents cross-contamination.
 10. Tight sheets keep linens wrinkle-free and decrease risk of skin irritation. Leaning back uses body weight for good body mechanics.

(continues)

PROCEDURE 31-11

Bedmaking: Occupied Bed (continued)*Action*

Figure 31-37 Fan-fold the draw sheet close to the client and tuck under the soiled linen.

Rationale

Figure 31-38 Grasp the bottom and draw sheets and pull tightly.

- | | |
|---|--|
| <ol style="list-style-type: none"> 11. Place top sheet over client with center of sheet in middle of bed. Unfold top of sheet over client. Remove bath blankets left on client to prevent exposure during bedmaking. Place top blanket over client, same as the top sheet. 12. Raise foot of mattress and tuck the corner of the top sheet and blanket under. Miter the corner. Repeat with other side of mattress. 13. Grasp top sheet and blanket over client's toes and pull upward, then make a small fan-fold in the sheet. 14. Remove soiled pillowcase. Grasp center of clean pillowcase and invert pillowcase over hand/arm. Maintain grasp of pillowcase while grasping center of pillow. Use other hand to pull pillowcase down over pillow. Place pillow under client's head. While changing pillowcase, client can be instructed to rest head on bed, or place a blanket under client's head. 15. Document procedure used to change linen and client's condition during the procedure. | <ol style="list-style-type: none"> 11. Provides client with top sheet and blanket to prevent chilling. 12. Secures top sheet and blanket in place. 13. Permits client to move feet under the sheets. Provides room under the tight top sheet and blanket. 14. Provides clean pillowcase without shaking pillow or pillowcase. Promotes comfort. 15. Provides documentation of nursing care and assessment of client's status. |
|---|--|

Skin care provides cleansing and conditioning to promote the optimal functioning of the skin. It consists of providing adequate nutrition, baths, perineal care, and back rubs. Excessive or abrasive skin care can damage skin and result in loss of function. Performing skin care provides an excellent opportunity for the nurse to assess skin integrity.

Perineal Care

Perineal care is cleansing of the external genitalia, perineum, and surrounding area. Perineal care is also referred to as “peri-care” or “perineal-genital” care. The purposes of perineal care are to prevent or eliminate infection and odor, promote healing, remove secretions, and provide comfort. Perineal care can be provided alone or as part of the bed bath.

Perineal care may be an embarrassing procedure for both the client and the nurse, especially if the client is of the opposite sex. Clients who are embarrassed may elect to perform their own perineal care. In this situation, the nurse should provide the client with warm water, moistened washcloth, soap, a dry towel, and privacy. If the client is unable to perform perineal care, the nurse is responsible for providing this care in a professional and private manner (see Procedure 31-12).

THINK ABOUT IT

Perineal Care

How would you approach providing perineal care to someone of the opposite sex or similar age? If the client were embarrassed and unable to perform perineal care, how would you handle this situation? How would you feel if someone of the opposite sex or similar age were going to provide perineal care for you?

Offer Back Rubs

Back rubs and massages stimulate the client’s circulation, relax muscles, and relieve muscle tension as well as provide the nurse with an opportunity for skin assessment. Emollient creams and lotions are used to facilitate the rubbing and lubrication of the skin during a back rub or massage.

The client is positioned prone or side-lying. Nurses create friction and pressure by rubbing their hands on the client’s skin. The friction creates heat, which dilates the peripheral circulation and increases the blood supply to the skin. The pressure provides manual stimulation to muscle fibers, which relaxes the

PROCEDURE 31-12

Perineal Care

Equipment

- | | |
|---------------------------|----------------------|
| ■ Bath basin | ■ Waterproof pads |
| ■ Soap | ■ Toilet tissue |
| ■ Two or three washcloths | ■ Lotion or ointment |
| ■ Dry bath towel | ■ Disposable gloves |
| ■ Bath blanket | |

Action

1. Explain procedure and purpose to client. Obtain permission. Close door and pull curtain around bed.
2. Wash hands and apply gloves.
3. Place waterproof pad under client’s buttocks. Client may be placed on a bedpan for perineal care. Females usually assume the dorsal recumbent position. Males may assume the dorsal recumbent or supine position with knees and hips flexed.

Rationale

1. Promotes cooperation. Provides privacy.
2. Reduces transmission of pathogens.
3. Waterproof pad prevents wetting of linen. Dorsal recumbent position provides maximal visualization of genital area.

(continues)

PROCEDURE 31-12

Perineal Care (continued)

Action

4. Expose perineal area. Fold client's gown up above the genital area. Place a bath blanket over the client using a "diamond" draping technique. Corners of bath blanket should point toward the head, sides of body, and between the client's legs. Fold top linen down to the end of the bed. Tuck side corners of bath blanket around client's legs. Lift corner between client's legs to expose perineal area (Figure 31-39).

Figure 31-39 Drape the client for perineal care.

5. Moisten and lather washcloths.

Female: Clean perineal area in the downward direction (from pubic area to rectum). Clean and dry upper thighs. Use separate quarters of the washcloth for each cleaning stroke. Discard soiled washcloths as necessary. Clean the labia majora. Separate the labia majora to clean between the labia majora and labia minora. With the labia separated, clean the clitoris, urethral meatus, and vaginal orifice (Figure 31-40). Rinse the area well with warm water. Pat perineal area dry. Apply lotion to upper thighs.

Male: Gently raise penis. Place a bath blanket under the penis. If the client develops an erection, delay perineal care. Gently grasp the shaft of the penis. If the client is uncircumcised, retract the foreskin. Use a circular motion to clean the meatus of the penis and glans in an outward direction (Figure 31-41). Replace the foreskin after cleansing the glans. Clean the shaft of the penis. Rinse penis. Pat glans and shaft of penis dry. Clean and dry scrotum. Scrotum may need to be lifted during cleaning. Discard soiled washcloths as necessary.

Rationale

4. Draping promotes a sense of privacy and decreases exposure.
5. Cleaning in the direction of the pubic area to rectum reduces risk of transmitting fecal material to the urinary tract. Using clean area of washcloth for each stroke reduces risk of transmitting organisms. Cleaning between the labia removes accumulated smegma.

Gentle handling reduces chance of an erection. Smegma accumulates around the foreskin. Replacing of foreskin prevents phimosis. Cleaning moves from area of least to most soiled.

PROCEDURE 31-12

Perineal Care (continued)

Action

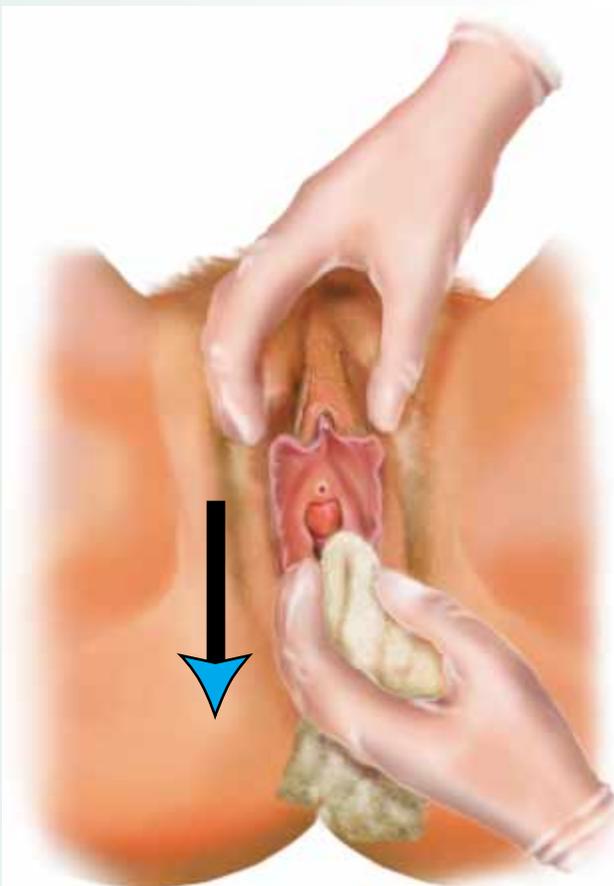

Figure 31-40 Clean the female perineal area.

6. Perform anal care. First remove any fecal material with toilet tissue. Clean perineal area by wiping from genitals to anus with one stroke. Discard soiled washcloths as necessary. Clean anus in circular motion. Rinse anal area. Pat dry. Apply lotion.
7. Remove gloves. Wash hands. Remove bath blanket. Place gown down over genitals. Place top linen on client.
8. Document procedure performed, client's response, and assessment findings.

Rationale

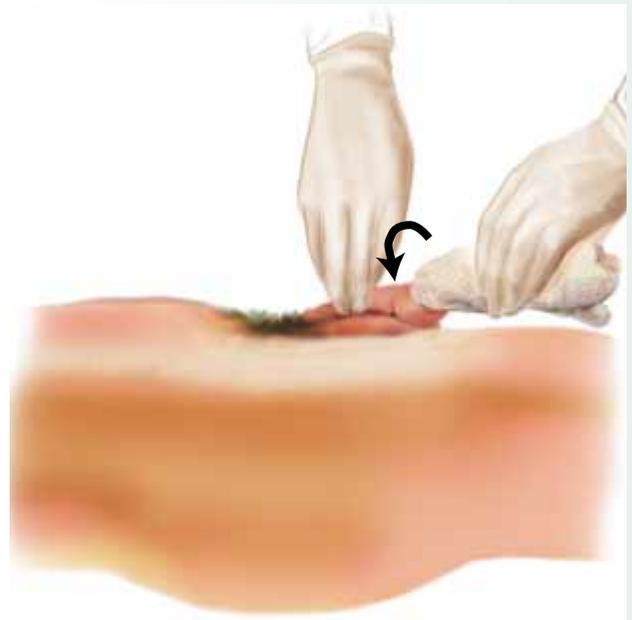

Figure 31-41 Clean the male perineal area.

6. Cleaning fecal material with toilet tissue removes the bulk of soil prior to washing. Cleaning from genitals to anus reduces chances of transmitting fecal microorganisms to urinary tract. Patting dry reduces skin irritation.
7. Reduces transmission of microorganisms. Covering genitals maintains client's privacy.
8. Provides evidence of nursing care.

NURSING ALERT

Massage

Do not massage red, tender areas since such signs may indicate a thrombus.

muscles. Chapter 14 presents the technique for performing a back rub.

Prior to performing a back rub or massage, the nurse must assess for contraindications. Caution should be exercised when massaging limbs. Massaging limbs, especially the lower limbs, could dislodge a thrombus (blood clot), creating an embolus (circulating blood

clot). Bony prominences should be massaged lightly to avoid damaging underlying tissue.

Provide Foot and Nail Care

Proper foot and nail care are essential for ambulation and standing. Foot and nail care are often ignored until problems exist. Common problems with feet and nails may be a direct result of abuse and neglect, such as from inadequate foot and nail hygiene, fingernail and cuticle biting, incorrect nail trimming, poorly fitted shoes, and exposure to harsh chemicals. These problems result in alterations of skin integrity with the potential for infection.

The first signs of foot and nail problems are usually pain or tenderness. These symptoms affect a client's posture and may result in limping with subsequent strain on certain muscle groups. Clients with illnesses such as diabetes mellitus need special foot and nail care. Clients with diabetes mellitus experience alterations in circulation that predispose them to foot problems.

The purposes of foot and nail care are to prevent infection and soft tissue trauma from ingrown or jagged nails and to eliminate odor. Hygienic care of feet and nails consists of regular trimming of nails; cleaning under nails; cleaning, rinsing, and drying feet and nails; and wearing properly fitted shoes. The following Nursing Checklist discusses the specific interventions that should be taken in providing foot and nail care.

Soaking of nails assists with their cleaning if nails are dirty or thickened. An orangewood stick is used to clean under nails since a metal instrument can roughen the nail and cause it to harbor dirt. The safest instrument to trim nails is the nail clipper; however, some clients feel that cutting the nails makes them brittle. If the client chooses not to cut the nails, the nails should be filed straight across. Special attention should be given to drying the areas between the toes.

NURSING CHECKLIST Foot and Nail Care

- Soak feet in warm water and a detergent or in warm oil.
- Use an orangewood stick to clean the nails and release the cuticle growth from the nail.
- File or cut the nails straight across to prevent ingrown nails.
- Trim the cuticles as necessary.
- Pat all areas dry with a clean towel.
- Apply an emollient.

An emollient, such as cold cream, helps to keep nails and cuticles soft.

Callused areas should never be cut. Repeated soaking usually facilitates the removal of calluses. Lotion should be applied to the foot to maintain moisture and soften callused areas. If the client's feet maintain excessive moisture (sweat), water-absorbent powder should be applied between the toes.

The client should wear clean, properly fitted shoes. The fit should not be extremely tight but should be snug enough to provide support to the foot. An arch support should be in each shoe. Shoe size should be large enough so that the shoe is one-half inch longer than the longest toe. Common foot problems can often be alleviated by assessing footwear and providing proper education on footwear and foot and nail care.

Provide Oral Care

The oral cavity functions in mastication, secretion of mucus to moisten and lubricate the digestive system, secretion of digestive enzymes, and absorption of essential nutrients. Common problems occurring in the oral cavity are:

- Bad breath (**halitosis**)
- Dental caries (**cavities**)
- Plaque
- Periodontal disease (**pyorrhea**)
- Inflammation of the gums (**gingivitis**)
- Inflammation of the oral mucosa (**stomatitis**)

Poor oral hygiene and loss of teeth may affect a client's social interaction and body image as well as nutritional intake. Daily oral care is essential to maintain the integrity of the mucous membranes, teeth, gums, and lips (see Procedure 31-13). Through preventive measures, the oral cavity and teeth can be preserved. Preventive oral care consists of fluoride rinsing, flossing, and brushing.

Fluoride

Researchers have determined that fluoride can prevent dental caries. This finding has led to the fluoridation of water supplies in many communities. Fluoride is a common component of mouthwashes and toothpastes. However, persons with excessive dryness or irritated mucous membranes should avoid commercial mouthwashes because of the alcohol content, which causes drying of mucous membranes.

Fluoride supplements are available without a prescription. Infants can be given fluoride drops as early as 2 weeks of age to prevent dental caries. Nurses should educate clients about fluoride being an excellent preventive measure against dental caries.

However, excessive fluoride usage can affect the color of tooth enamel. To prevent discoloration of the tooth enamel, fluoride should be administered with a drop-per directed toward the back of the throat.

Flossing

Flossing should be performed daily in conjunction with brushing of teeth. Flossing prevents the formation of plaque, removes plaque between the teeth, and removes food debris. Dental caries and periodontal disease can be prevented by regular flossing. Flossing is best performed after toothpaste is applied to the teeth but before brushing (see Procedure 31-13). This order permits the fluoride in the toothpaste to have direct contact with the tooth surfaces, thus preventing dental caries.

Flossing can also be performed after brushing, but brushing first does not maximize the fluoride’s contact with the tooth surfaces.

Brushing

Brushing of teeth should follow flossing. Teeth should be brushed after each meal. Brushing should be performed using a dentifrice (toothpaste) that contains fluoride to aid in preventing dental caries. An effective homemade dentifrice is the combination of two parts salt with one part baking soda. Brushing removes plaque and food debris and promotes blood circulation of the gums. Dentures should be brushed using the same brushing motion as that used for brushing teeth. Refer to Procedure 31-13 for brushing of teeth and denture care.

PROCEDURE 31-13

Oral Hygiene

Equipment

Brushing and Flossing

- Toothbrush
- Toothpaste
- Emesis basin
- Towel
- Cup of water
- Nonsterile gloves
- Dental floss
- Dental-floss holder
- Mirror
- Lip moisturizer

Denture Care

- Denture brush
- Denture cleaner
- Emesis basin
- Towel
- Cup of water
- Nonsterile gloves
- Tissue
- Denture cup

Special Care Items for Clients with Impaired Physical Mobility or Who Are Unconscious (comatose)

- Soft toothbrush or toothette
- Tongue blade
- 3 × 3 gauze sponges
- Suction machine and catheter
- Prescribed solution and/or milk of magnesia
- Cotton-tip applicators
- Plastic Asepto syringe

Action

Rationale

Self-Care Client

Flossing and Brushing

(continued)

PROCEDURE 31-13

Oral Hygiene (continued)

<i>Action</i>	<i>Rationale</i>
7. Assist client with rinsing mouth.	7. Removes toothpaste and oral secretions.
8. Reposition client, raise side rails, and place call button within reach.	8. Promotes comfort, safety, and communication.
9. Rinse, dry, and return articles to proper place.	9. Promotes a clean environment.
10. Remove gloves, wash hands, and document care.	10. Prevents the transmission of microorganisms and documents nursing care.
Denture Care	
11. Assemble articles for denture cleaning.	11. Promotes efficiency.
12. Provide privacy.	12. Relaxes the client.
13. Assist client to a high-Fowler's position.	13. Facilitates removal of dentures.
14. Wash hands and don gloves.	14. Reduces microorganism transfer and exposure to body fluids.
15. Assist client with denture removal:	15. Breaks seal created with dentures without causing pressure and injury to oral membranes.
a. Top denture:	
• With tissue, grasp the denture with thumb and forefinger and pull downward.	
• Place in denture cup.	Prevents breaking of dentures.
b. Bottom denture:	
• Place thumbs on the gums and release the denture. Grasp denture with thumb and forefingers and pull upward.	
• Place in denture cup.	
16. Apply toothpaste to brush and brush dentures either with cool water in the emesis basin or under running water in the sink.	16. Facilitates removal of microorganisms.
17. Rinse thoroughly.	17. Removes toothpaste.
18. Assist client with rinsing mouth and replacing dentures.	18. Freshens mouth and facilitates intake of solid food.
19. Reposition client, with side rails up and call button within reach.	19. Promotes comfort, safety, and communication.
20. Rinse, dry, and return articles to proper place.	20. Maintains a clean environment.
21. Remove gloves, wash hands, and document care.	21. Prevents the transmission of microorganisms and documents nursing care.
Full-Care Client	
Brushing and Flossing	
22. Assemble articles for flossing and brushing.	22. Promotes efficiency.
23. Provide privacy.	23. Relaxes client.

(continues)

PROCEDURE 31-13

Oral Hygiene (continued)

<i>Action</i>	<i>Rationale</i>
24. Wash hands and don gloves.	24. Reduces microorganism transfer and exposure to body fluids.
25. Position client as condition allows: high-Fowler's, semi-Fowler's, or lateral position, head turned toward side.	25. Decreases risk of aspiration.
26. Place towel across client's chest or under face and mouth if head is turned to one side.	26. Catches secretions.
27. Moisten toothbrush, apply small amount of toothpaste, and brush teeth and gums.	27. Moistens mouth and facilitates plaque removal.
28. Grasp the dental floss in both hands or use a floss holder and floss between all teeth, holding floss against tooth while moving floss up and down sides of teeth (Figure 31-42).	28. Removes plaque and prevents gum disease.

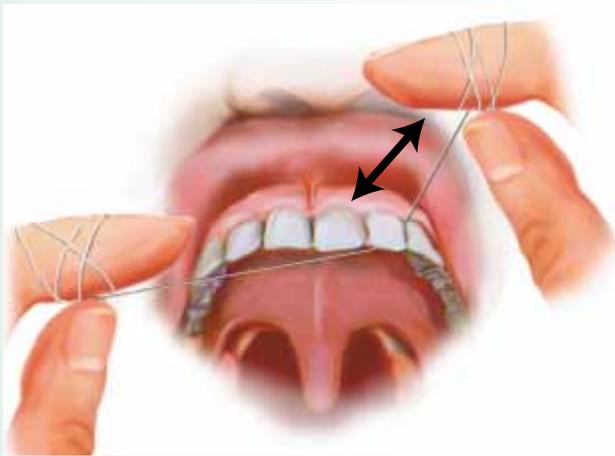

Figure 31-42 Floss teeth.

29. Assist the client in rinsing mouth.	29. Removes toothpaste and oral secretions.
30. Reapply toothpaste and brush the teeth and gums using friction in a vertical or circular motion. On inner and outer surfaces of teeth, hold brush at 45 degree angle against teeth and brush from sulcus to crowns of teeth. On biting surfaces, move brush back and forth in short strokes. All surfaces of teeth should be brushed from every angle (Figure 31-43).	30. Permits cleaning of back and sides of teeth and decreases microorganism growth in mouth.
31. Assist the client in rinsing and drying mouth.	31. Removes toothpaste and oral secretions.
32. Apply lip moisturizer, if appropriate.	32. Maintains skin integrity of lips.
33. Reposition client, raise side rails, and place call button within reach.	33. Promotes comfort, safety, and communication.
34. Rinse, dry, and return articles to proper place.	34. Provides an orderly environment.

PROCEDURE 31-13

Oral Hygiene (continued)

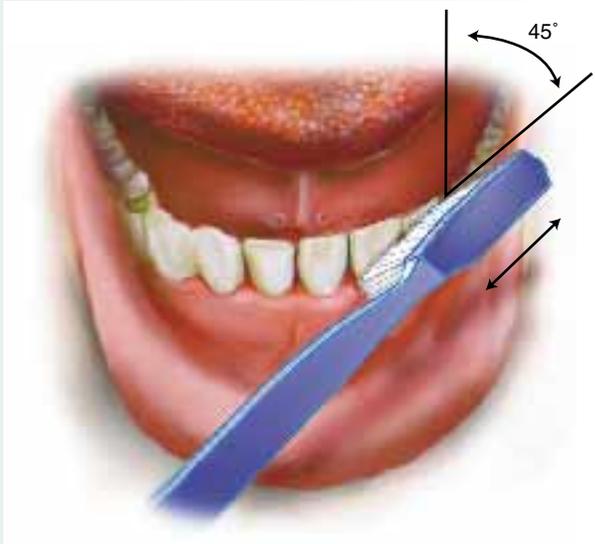

Action*Rationale*

Figure 31-43 Brush teeth.

35. Remove gloves, wash hands, and document care.

35. Prevents transmission of microorganisms and documents nursing care.

Clients at Risk for or with an Alteration of the Oral Cavity

Follow steps 22 through 24.

36. Bleeding:

- a. Assess oral cavity with a padded tongue blade and flashlight for signs of bleeding.
- b. Proceed with the actions for oral care for a full-care client, except:
 - Do not floss.
 - Use a soft toothbrush, toothette, or a tongue blade padded with 3 × 3 gauze sponges to gently swab teeth and gums.
 - Dispose of padded tongue blade into a biohazard bag according to institutional policy.
 - Rinse with tepid water.

36. Determines if bleeding is present, amount, and specific areas.

Decreases risk of bleeding.

Promotes proper disposal of contaminated waste.

Cleanses mouth.

37. Infection:

- a. Assess oral cavity with a tongue blade and flashlight for signs of infection.
- b. Culture lesions as ordered.

37. Determines appearance, integrity, and general condition.

Identifies growth of specific microorganisms.

|--|--|

Oral Care for the Unconscious Client

Oral care for the unconscious client maintains a clean oral cavity and intact mucous membranes. Special care should be exercised when performing oral care to unconscious clients to prevent client aspiration or injury to the nurse (client biting because of gag reflex). The accompanying Nursing Checklist provides essential safety guidelines for providing oral care to unconscious clients.

**NURSING CHECKLIST***Oral Care for the Comatose Client*

- Never place your fingers in the client's mouth. A bite block or padded tongue blade can be used to hold the client's mouth open. Assess for gag reflex.
- Client's head should be turned to one side with a basin placed under the mouth. Oral suctioning facilitates the removal of secretions. Only a small amount of liquids should be used.
- Flossing and brushing of teeth and tongue can be performed in the usual manner. Caution should be exercised to prevent aspiration.

Provide Hair Care

Hair affects a client's personal appearance and body image. Hair functions to maintain the body temperature and as a receptor for the sense of touch. Assessment of hair texture, growth, and distribution provides information on a client's general health status.

Common hair problems are dandruff, hair loss, tangled or matted hair, and infestations such as pediculosis and lice. Hair problems can be reduced by daily hair care, which helps to promote hair growth, prevent hair loss, prevent infections or infestations, promote circulation of the scalp, evenly distribute oils along hair shafts, and maintain the client's physical appearance. Hair care consists of brushing and combing, shampooing, shaving, and mustache and beard care.

Brushing and Combing

Hair should be brushed or combed daily according to the client's preferred hairstyle. Brushing and combing stimulate circulation to the scalp, distribute oils along hair shafts, and arrange the placement of hair. A clean brush or comb should be used. Hair should be brushed from the scalp toward the hair ends. Sensitive scalps should be brushed or combed gently. Wetting the hair with water before brushing or combing can prevent damage to the hair and painful pulling of the scalp.

NURSING TIP

Cultural Influences on Hygiene

Keep in mind that all self-care and hygiene practices are influenced by the client's background and cultural values. Always ask clients about preferences prior to performing care and show sensitivity to those practices that may differ from your own.

Clients who are immobilized may have tangled or matted hair. Care should be taken to prevent pain when combing tangled or matted hair by holding the tangled hair near the scalp while combing. If the client permits, the hair can be braided to avoid tangling or matting, but braiding the hair tightly should be avoided since tight braids may cause pain and hair loss. A nurse must receive written informed consent to cut a client's hair.

Shampooing

When soiled, hair should be shampooed according to the client's usual routine. The purposes of shampooing are to stimulate scalp circulation, remove soil from hair, and facilitate brushing and combing. Hair can be shampooed in the tub, in the shower, at the sink, or in the bed depending on the client's abilities and preferences.

Clients confined to bed can have their hair shampooed with water or with shampoos that do not require water (see Nursing Checklist: Shampooing Hair in Bed). Hair is shampooed by thoroughly wetting all hair, applying about a teaspoon of shampoo, lathering shampoo, and gently massaging the scalp with the pads of the fingertips. Hair should be rinsed thoroughly after shampooing. Hair should be dried with an absorbent towel, then brushed or combed in the preferred hairstyle.

Shaving

Shaving is the removal of hair from the skin surface. Males often shave to remove facial hair, and women may shave to remove leg and/or axillary hair. Operative procedures may also require skin preparation that requires shaving of an area of the body.

Shaving may be performed before, during, or after the bath. Care should be used to avoid cutting the skin. Prior to shaving, the area should be washed with soap and warm water to soften the hair. A warm washcloth may be placed over the area for a few minutes to assist with softening the hair. A shaving cream or mild soap is applied to the area to ease hair removal. To shave, the skin should be pulled taut. The razor is held at a 45

NURSING CHECKLIST

Shampooing Hair in Bed

- Remove pillow. Position client with head and shoulders near edge of bed. Cotton may be placed in the external ear canal.
- Place a linen protector or plastic head-washing tray under the head to protect the bed from becoming wet and to facilitate the draining off of water and shampoo.
- Offer the client a towel to cover eyes, if desired (Figure 31-44).
- Shampoo hair beginning at the hair line and working toward the back of the head.
- Rinse thoroughly to remove all residue from the scalp. Repeat washing and rinsing until hair squeaks when fingers move through hair.
- Squeeze excess water from hair. Wrap a towel around client's head and rub hair and scalp with towel. Remove linen protector or plastic tray and complete drying of hair.

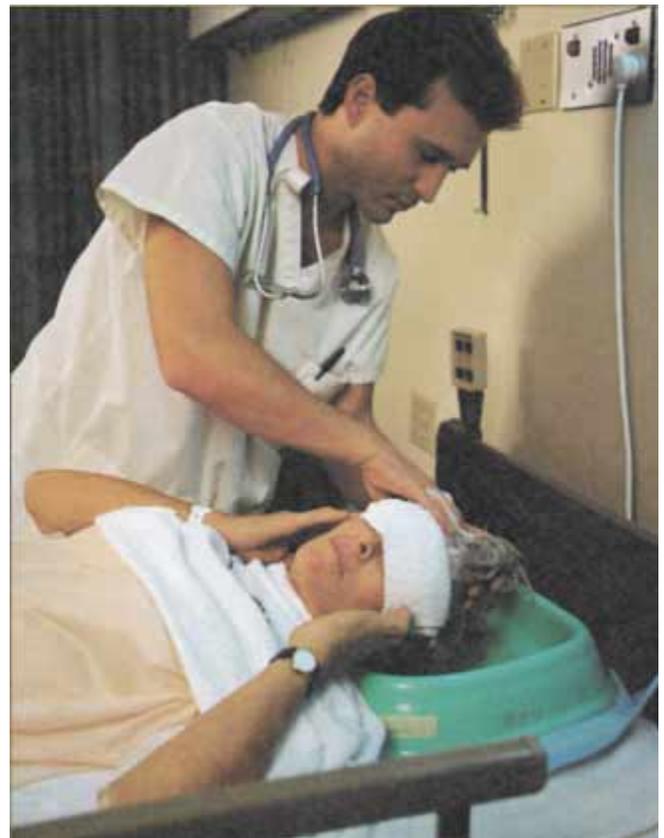

Figure 31-44 Shampooing Hair in Bed

degree angle and moved over the skin in short, firm strokes in the direction of hair growth. After the skin is shaved, it should be washed, rinsed, and patted dry.

Mustache and Beard Care

Mustaches and beards require daily care. Mustache and beard care consists of keeping the hair clean, trimmed, and combed. Mustaches and beards can be washed with soap or a shampoo. Frequently, mustaches and beards require only gentle wiping with a moist washcloth. A mustache or beard should never be shaved by the nurse without written informed consent.

NURSING ALERT

Shaving

Review the client's medical record and the facility's policy regarding the use of razors for shaving. Clients prone to bleeding, such as those on anticoagulants, should be instructed to use only electrical razors for shaving.

Provide Eye, Ear, and Nose Care

Eye, ear, and nose care should be included in routine hygienic care.

Eyes

Eyes are continually cleansed by the production of tears and movement of eyelids over the eyes. Eyelids should be washed daily with a warm washcloth from the inner to outer canthus. Eyelashes function to prevent foreign material from entering the eyes and conjunctival sacs. Eyelashes and eyebrows should be washed as necessary.

A client's artificial eye (prosthetic) may require daily cleaning, which requires that the eye be removed from the eye socket and washed (see Procedure 31-14). Some artificial eyes are permanently implanted.

Comatose clients have special eye care needs since they lack a blink reflex. These clients require frequent instillations of lubricants or eyedrops to prevent corneal abrasions. The accompanying Nursing Checklist describes eye care for the comatose client.

Contact Lenses

The nursing history should indicate if the client wears contact lenses, and the routine care and level of assistance should be recorded on the client's care plan. Clients who can insert, remove, and manage the care of their lenses will require minimal assistance from the nurse. If the client is unable to assist with lens care and also has corrective eyeglasses, suggest to the client that he or she wear the eyeglasses during hospitalization. There are two types of contact lenses: hard and soft. Each type requires different cleaning and care (see Procedure 31-14). During emergency situations, the nurse should remove the lenses and place them in the appropriate solution.

NURSING CHECKLIST

Eye Care for the Comatose Client

- Cleanse eyelids, eyelashes, and eyebrows with warm washcloth at least every 4 hours. Clean from inner to outer canthus.
- If eyes remain open and blink reflex is absent, liquid tear solutions should be applied to prevent corneal drying and ulcerations.
- Eyes can be closed and covered with an eye patch or protective shield. The eye patch or protective shield should be removed at least every 4 hours to assess eyes and provide eye care.

Ears

Hearing can be affected by foreign material or wax in the external ear canal. Cleaning of the ears involves cleaning of the external ear canal and auricles. Objects should not be inserted into the ear canal. Excess wax or foreign material should be removed by gently washing the external ear and auricles with a warm washcloth while pulling the ear downward in the adult client. Irrigation of the ear may be necessary to remove dried wax. The physician should be notified prior to irrigation of the ear.

Hearing Aids

Hearing aids amplify sound. The health history should indicate if the client is wearing a hearing aid and the plan of care should discuss the cleaning schedule of this aid. Clients with hearing aids should clean the ear mold regularly to ensure proper functioning. There are four types of hearing aids:

- Body-worn
- Eyeglass
- Behind the ear
- In the ear

Some hearing aids have a telephone switch that can be turned on and off.

If the hearing aid is not functioning properly, check the on-off switch and volume control, battery (replace as necessary), plastic tubing for cracks and loose connections, and telephone switch, which should be in the off position unless the client is using the phone. Hearing aids should be handled carefully since dropping or bumping the hearing aid can damage its delicate mechanisms. When not in use, the hearing aid should be stored in a container because dust and dirt can damage the mechanism.

When communicating with a client who has a hearing aid, you should address the client by name and then wait for the client to face you before speaking further. Always face the client and speak in a slow, natural voice.

PROCEDURE 31-14

Eye Care: Artificial Eye and Contact Lens Removal

Equipment

Artificial Eye

- Storage container
- Mild soap
- 3 × 3 gauze sponges
- Cotton balls
- Towel
- Emesis basins
- Eye irrigation syringe (optional)
- Running water
- Nonsterile gloves
- Biohazardous bag
- Saline solution

Contact Lenses

- Lens container
- Soaking solution (type used by client)
- Towel
- Suction cup (optional)
- Scotch tape (optional)
- Nonsterile gloves

Action

Artificial Eye Removal

1. Inquire about client's care regimen and gather equipment accordingly.
2. Provide privacy.
3. Wash hands; don gloves.
4. Place client in a semi-Fowler's position.
5. Place the cotton balls in emesis basin and half fill with warm tap water.
6. Place 3 × 3 gauze sponges in bottom of second emesis basin, and half-fill with mild soap and tepid water.
7. Grasp and squeeze excess water from a cotton ball. Cleanse the eyelid with the moistened cotton ball, starting at the inner canthus and moving outward toward the outer canthus. After each use, dispose of cotton ball in biohazard bag. Repeat procedure until eyelid is clean (without dried secretions).
8. Remove the artificial eye:
 - a. Using dominant hand, raise the client's upper eyelid with index finger and depress the lower eyelid with thumb (Figure 31-45).
 - b. Cup nondominant hand under the client's lower eyelid.
 - c. Apply slight pressure with index finger between the brow and the artificial eye and remove it.
9. Place the artificial eye in the emesis basin that has soap and water.

Rationale

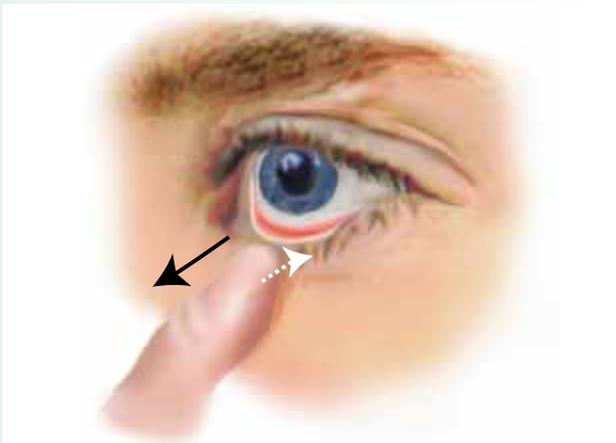

1. Promotes continuity of care.
2. Relaxes the client.
3. Prevents transmission of microorganisms.
4. Facilitates procedure and client participation.
5. Dry cotton balls could cause irritation.
6. Gauze serves as padding to prevent breakage of the prosthesis.
7. Eliminating the excess water prevents water from running down the client's face. Cleansing the eyelid prevents contamination of the lacrimal system (inner canthus area). Disposal of cotton balls prevents transmission of microorganisms to other health care workers.
8. Promotes removal of artificial eye. Cupping prevents dropping and possible breaking of the eye. Applying pressure will help the prosthesis to slip out.
9. Prevents secretions from adhering to the prosthesis.

PROCEDURE 31-14

Eye Care: Artificial Eye and Contact Lens Removal (continued)

Action

Rationale

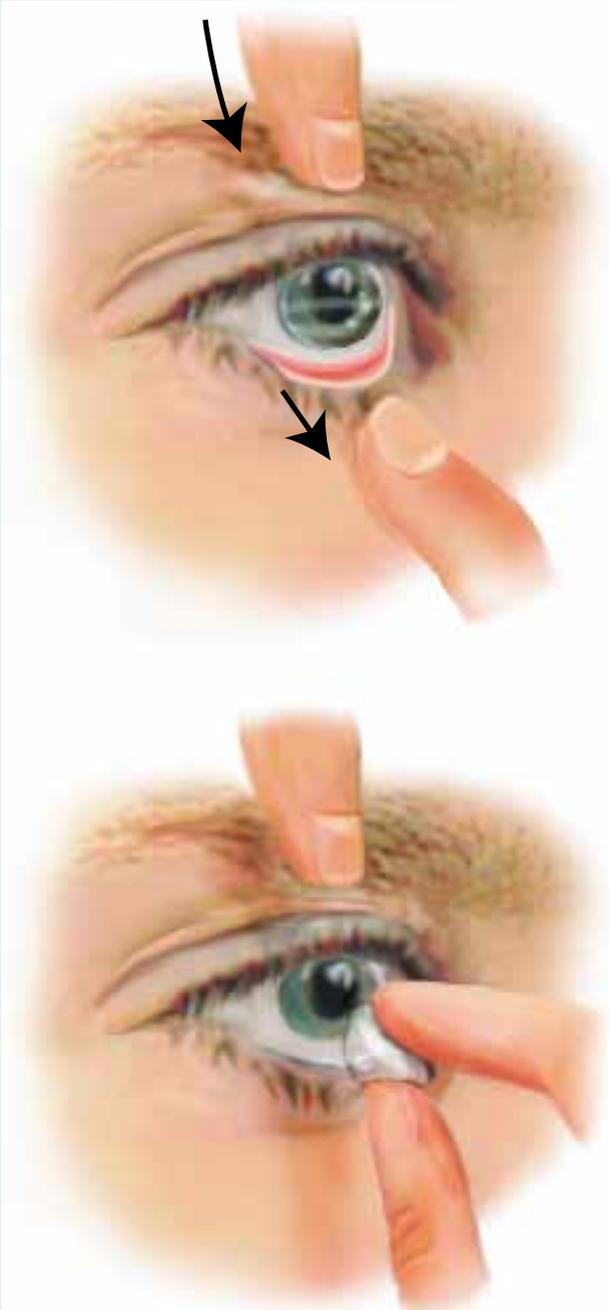

Figure 31-47 Removal of a Soft Contact Lens

Shouting causes distortion of sound and usually makes the client feel uncomfortable.

Nose

The nose provides the sense of smell, prevents entrance of foreign material into the respiratory tract, humidifies

inhaled air, and facilitates breathing. Excessive or dried secretions may impair nasal function. Excessive nasal secretions are removed by inserting a cotton-tipped applicator moistened with water or saline into the nostrils. The applicator should not be inserted beyond the cotton tip. Infants may have excessive nasal secretions removed by a suction bulb. Clients with a nasogastric

NURSING CARE PLAN**Client at Risk for Injury****Case Presentation**

Mr. Simon, age 75, is admitted to the hospital with coronary heart disease (CHD). He has a family history of CHD. He smokes two packs of cigarettes per day, has diabetes mellitus, and is obese.

Assessment

- Weight gain of 7 pounds in past month
- Blood cholesterol 320 mg/dl
- High-density lipoproteins (HDL) 28 mg/dl
- Blood pressure 186/116
- Diminished visual acuity
- Decreased bladder tone
- Weakness and syncope
- Glasgow Coma Scale (GCS) score of 12

Nursing Diagnosis #1

Risk for injury related to sensory dysfunction and altered level of consciousness.

Expected Outcome

The client will be protected from injury during the hospitalization.

Interventions/Rationales

1. Initiate the fall prevention protocol.
Identifies and reduces risk for injury.
2. Reassess the client's injury status every 4 hours.
Identifies changes and highlights need to modify plan of care.
3. Place the client in a room as close as possible to the nurses' station.
Facilitates faster response time to client's needs.
4. Place fall alert signs on the client's door and head of bed.
Alerts other health care workers to client's risk status.
5. Put the bed alarm on.
Helps monitor client status and facilitates prompt response if client tries to get out of bed unassisted.
6. Monitor the client and the environment every 2 hours and whenever a caregiver goes by the client's room.
Provides information on status, progress, and needs of client; encourages team approach to client care.
7. Instruct all caregivers to respond promptly to call light.
Ensures rapid response to client's needs.
8. Teach the client to use the call light; reinforce teaching each time before leaving the client alone.
Ensures that client has means and knowledge to call for assistance if necessary.

Evaluation

Fall prevention protocol implemented; client discharged on third day of hospitalization free from injury.

tube should receive meticulous skin care to the nose area to prevent skin breakdown.

EVALUATION

Evaluation is based on the achievement of goals and client expected outcomes, regardless of the setting. Clients with alterations in health perception–health management pattern or activity-exercise pattern are at

risk for injury, infection, and self-care deficits. Keeping the client free from injury and infection requires frequent reassessment, through the use of risk appraisals, with timely adjustments made in the plan of care in order for nursing interventions to be effective.

It is imperative that the client not only be free of injury during hospitalization but also develop a true awareness of the internal and external factors that increase the risk for injury. Achievement of this outcome measure is directly related to the behaviors the

Nursing Process Highlight

INTERVENTION

The use of restraints or other protective devices on confused clients usually increases their confusion, placing them at a greater risk for injury. Implementation of the fall protocol with frequent reassessment and visual observations and special beds with alarms that notify the staff when the client is trying to get out of the bed are actions that support client safety. Restraints should be used only when all other nursing measures are ineffective in providing client safety.

client observes while in the hospital and through client teaching. Modification of a home to a safe environment is evidence for the home health nurse that learning has taken place.

Adherence to barrier precautions is critical in preventing the spread of infectious agents, especially nosocomial infections to clients, self, and other health care workers. The nurse needs to correlate the client's diagnostic laboratory results and temperature in evaluating the expected outcome of remaining free of signs and symptoms of infection. If the nurse is caring for a client with an infection, the evaluation should indicate the stage of the inflammatory process (refer to Table 31-1).

The therapeutic value of hygiene is maximized when the client can participate and is kept free from infection and alterations in skin integrity. Evaluation should identify the client's level of functioning in self-care activities.

At the time of discharge from the hospital, appropriate referrals should be made to home health care agencies to assist the client in achieving optimum functioning levels for safety and hygienic practices. Clients at risk for infection should have follow-up visits by the home health nurse to measure the effectiveness of client teaching and resources in the home to prevent the transmission of infections.

KEY CONCEPTS

- Factors influencing client safety are age, lifestyle, sensory and perceptual alterations, mobility, and emotional state.
- Types of accidents that can occur in the health care setting are client behavior, therapeutic procedure, and equipment accidents.
- Assessment of a safe environment consists of performing an injury risk appraisal.
- Nurses can help clients in maintaining a safe environment by resolving or alleviating hazards related to

falls, lighting, obstacles, bathroom hazards, fire, electricity, radiation, poisoning, and noise pollution.

- The chain of infection involves a biological agent, a reservoir of the agent, a portal of exit, a mode of transmission, a portal of entry of the agent into the host, and a susceptible host.
- Medical and surgical asepsis prevent the transfer of microorganisms by implementation of practices that reduce the number, growth, or spread of microorganisms from an object or area.
- The new guidelines from the CDC require that transmission-based precautions be used for specific syndromes that are highly suspicious for infections until a diagnosis is confirmed.
- Hygienic practices are influenced by body image, social and cultural practices, personal preference, socioeconomic status, and knowledge.
- Basic hygienic practices include bathing, skin care, perineal care, back rubs, foot and nail care, oral care, hair care, and eye, ear, and nose care.

CRITICAL THINKING ACTIVITIES

1. Write a description of the typical hospital room. From this description, describe what nursing interventions would be implemented to provide a safe client environment.
2. Develop a safety protocol for a 65-year-old client who is confused and has severe arthritic contractures of the hands.
3. A client admitted to the intensive care unit has been diagnosed with methicillin-resistant *Staphylococcus aureus* (MRSA). The MRSA is transmitted by direct contact. What isolation precautions are necessary to break the chain of infection?
4. Several factors are known to affect a client's personal hygiene practices. List these factors. Describe how these factors may influence a client's personal hygiene practices.

Oxygenation

And what nursing has to do in either case, is to put the patient in the best condition for nature to act upon him.

—Florence Nightingale (in Skretkowicz, 1992)

COMPETENCIES

1. Describe the basic physiological mechanisms of ventilation, circulation, and oxygenation.
2. Assess the client's ventilatory, circulatory, and oxygenation status.
3. Explain potential client outcomes when oxygenation is impaired.
4. State common client knowledge deficits related to oxygenation impairment.
5. Develop nursing interventions that promote oxygenation.
6. Describe actions for emergency support of airway, ventilation, and circulation.

Oxygenation (the delivery of oxygen to the body's tissues and cells), is necessary to maintain life and health. Clients with compromised oxygenation status need careful assessment and thoughtful nursing care to achieve an adequate and comfortable level of oxygenation function. The purpose of this chapter is to explore the elements of the process of oxygenation, common mechanisms by which it may be impaired, and interventions that are aimed at improving oxygen delivery to the cells.

PHYSIOLOGY OF OXYGENATION

The delivery of oxygen to the body's cells is a process that depends upon the interplay of the pulmonary, hematologic, and cardiovascular systems. Specifically, the processes involved include ventilation, alveolar gas exchange, oxygen transport and delivery, and cellular respiration. The basic anatomy of the lungs is shown in Figure 32-1.

Ventilation

The first step in the process of oxygenation is **ventilation**, which is the movement of air into and out of the lungs for the purpose of delivering fresh air into the lung's alveoli (Figure 32-2). Ventilation is regulated by respiratory control centers in the pons and medulla oblongata, which are located in the brain stem. The rate and depth of ventilation are constantly adjusted in response to changes in the concentrations of hydrogen ion (pH) and carbon dioxide (CO₂) in the body's fluids. For instance, an increase in carbon dioxide in the blood or a decrease in pH in the body's fluids will stimulate

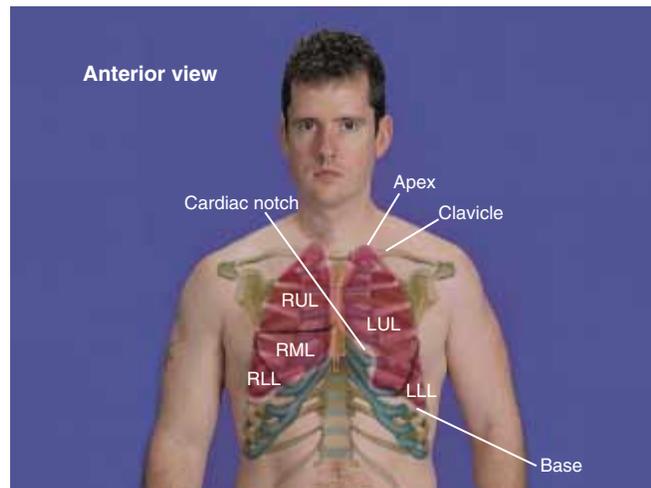

Figure 32-1 Lungs. RUL=right upper lobe, RML=right middle lobe, RLL=right lower lobe, LUL=left upper lobe, LLL=left lower lobe.

faster and deeper ventilation. A decrease in blood oxygen concentration (**hypoxemia**) will also stimulate ventilation, but to a lesser degree.

Inhalation of air is initiated when the diaphragm contracts, pulling it downward and thus increasing the size of the intrathoracic space (Figure 32-3). This space is also increased by contraction of the external intercostal muscles, which elevate and separate the ribs and move the sternum forward. The effect of increasing the space inside the thorax is to decrease the intrathoracic pressure, so that air will be drawn in from the atmosphere. Stretch receptors in the lung tissue send signals back to the brain to cause cessation of inhalation, preventing overdistension of the lungs. Exhalation occurs when the respiratory muscles relax, thus reducing the size of the intrathoracic space, increasing the intrathoracic pressure, and forcing air to exit the lungs. Under normal conditions, exhalation is a passive process.

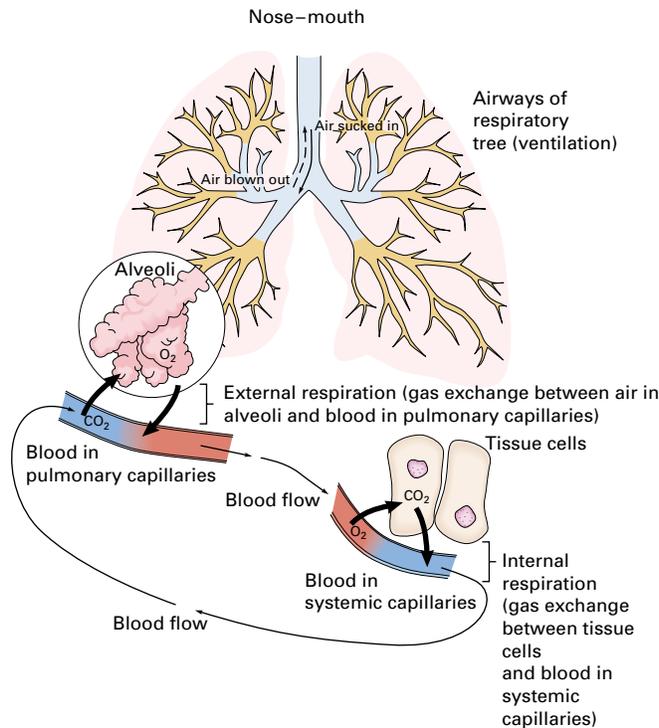

Figure 32-2 Elements of Oxygenation of the Pulmonary and Hematologic Systems

When the movement of air is impeded, additional muscles may be used to increase the ventilatory ability. These accessory muscles of ventilation include the sternocleidomastoid muscle, the abdominal muscles, and the internal intercostal muscles. In some disease states,

exhalation is impaired, requiring that the individual actively force air out of the lungs rather than passively exhaling. Forced expiration is aided by the intercostal muscles and the abdominal recti. When additional muscular force is required for breathing, the **work of breathing** is said to be increased.

Several mechanisms exist to keep the airways clear of microorganisms and debris. As air is inhaled through the nose, the larger particles are filtered out through hairs lining the nasal passages. The mucous membranes of the nasopharynx and sinuses warm and humidify the inspired air, and the film of mucus lining these membranes traps smaller particles. Closure of the glottis protects the airway from aspiration of food and fluids during swallowing. In the trachea and larger bronchi, tiny hairlike cilia continually produce wavelike movements to propel mucus and particles upward, where they can be coughed out. If any invaders manage to reach the alveoli, specialized alveolar macrophages will engulf and destroy the offending organism. Disease processes can interfere with any of these protective mechanisms, increasing the individual's vulnerability to infection and injury.

Alveolar Gas Exchange

Once fresh air reaches the lung's alveoli, the next step in the process of oxygenation begins. The exchange of oxygen from the alveolar space into the pulmonary capillary blood is referred to as **oxygen uptake**; it may also be called **external respiration**. Oxygen diffuses across

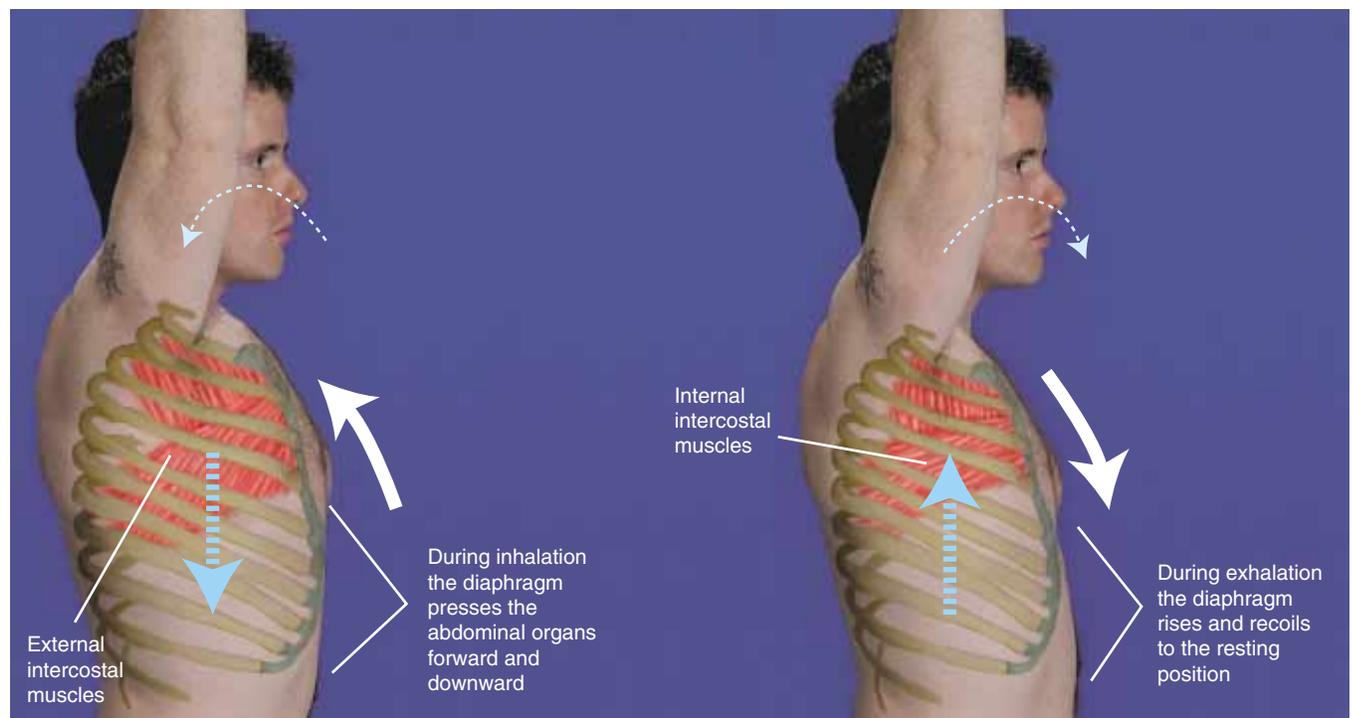

Figure 32-3 Mechanics of breathing. Inhalation increases the volume of the thorax by diaphragmatic excursion and elevation of the sternum. Exhalation is normally accomplished by passive elastic recoil.

the alveolar membrane in response to a concentration gradient; that is, it moves from an area of higher concentration (the alveoli) to an area of lower concentration (the pulmonary capillary blood), seeking equilibrium. At the same time, carbon dioxide diffuses from the blood to the alveolar space, also in response to a concentration gradient (Figure 32-4).

Oxygen Transport and Delivery

Oxygen Transport in the Blood

Once the diffusion of oxygen across the alveolar-capillary membrane occurs, the oxygen molecules are dissolved in the blood plasma. Three factors influence the capacity of the blood to carry oxygen: the amount of dissolved oxygen in the plasma, the amount of hemoglobin, and the tendency of the hemoglobin to bind with oxygen. However, the plasma is not able to carry nearly enough dissolved oxygen to meet the metabolic needs of the body. The oxygen-carrying capacity of the blood is greatly enhanced by the presence of hemoglobin in the erythrocytes.

The amount of oxygen carried in a sample of blood is measured in two ways. Oxygen dissolved in plasma is expressed as the partial pressure of oxygen (PaO_2). The normal PaO_2 in arterial blood is about 80 to 100 mm Hg. The oxygen dissolved in plasma, however, represents only about 1% to 5% of the total oxygen content of the blood. The vast majority of oxygen in the blood is carried bound to the hemoglobin molecule. The amount of oxygen bound to hemoglobin is expressed as the percentage of hemoglobin that is saturated with oxygen (SaO_2), with 100% being fully saturated. Since the SaO_2 is a percentage indicating the relationship

between oxygen and hemoglobin, the nurse should interpret the client's SaO_2 measurement with the hemoglobin level. Normal saturation of arterial blood (SaO_2) is about 96% to 98%.

Hemoglobin molecules have the ability to form a reversible bond with oxygen molecules, so that the hemoglobin readily takes up oxygen in the lungs, while it also readily releases oxygen to the body's cells in the systemic capillary beds. This seemingly paradoxical shift in hemoglobin's affinity for oxygen is represented by the **oxyhemoglobin dissociation curve**, which is a graphic representation of the relationship between the partial pressure of oxygen and oxygen saturation.

The affinity of hemoglobin for oxygen is highest when the PaO_2 (the measure of oxygen dissolved in the arterial blood plasma) is 70 mm Hg or higher; in this portion of the curve, further increases in PaO_2 result in very little change in SaO_2 (Figure 32-5A). This characteristic of the oxyhemoglobin dissociation curve accounts for the rapid uptake of oxygen by hemoglobin in the pulmonary circulation and allows for some decrease in PaO_2 (such as might occur with disease or in high altitudes) without significantly sacrificing SaO_2 .

As the oxygen-saturated blood is circulated to the peripheral capillary beds, dissolved oxygen diffuses out of blood. This decrease in dissolved oxygen causes hemoglobin to lose its affinity for oxygen, so the oxygen is then released to the body's cells. Once the partial pressure of oxygen in the blood drops below 60 mm Hg, hemoglobin releases oxygen very easily. This release is represented in the lower left portion of the curve, also known as the venous portion, and permits rapid unloading of oxygen to the cells (Figure 32-5B).

Several physiological factors may alter the affinity of hemoglobin for oxygen, and these shifts can be represented on the oxyhemoglobin dissociation curve. A shift to the left occurs when affinity is increased so that, for a given PaO_2 , the associated SaO_2 will be higher. This means that, although the arterial blood may be carrying adequate oxygen, little of it is being released to the tissues. A shift to the left may be caused by increased pH (alkalosis), hypothermia, or a decrease in the red blood cell enzyme 2,3-diphosphoglycerate (2,3-DPG), which may occur after massive transfusions of banked blood.

A shift to the right of the oxyhemoglobin dissociation curve means that, for a given PaO_2 , the SaO_2 will be lower. This phenomenon represents a decreased affinity of hemoglobin for oxygen so that oxygen is more readily released to the tissues. This shift occurs in response to acidosis, hyperthermia, and hypoxia (which induces increased production of 2,3-DPG) and results in improved delivery of oxygen to the tissues.

Circulation

Once oxygen is bound to hemoglobin, the oxygen is delivered to the cells of the body by the process of circulation. Circulation of the blood is the function of the heart and blood vessels.

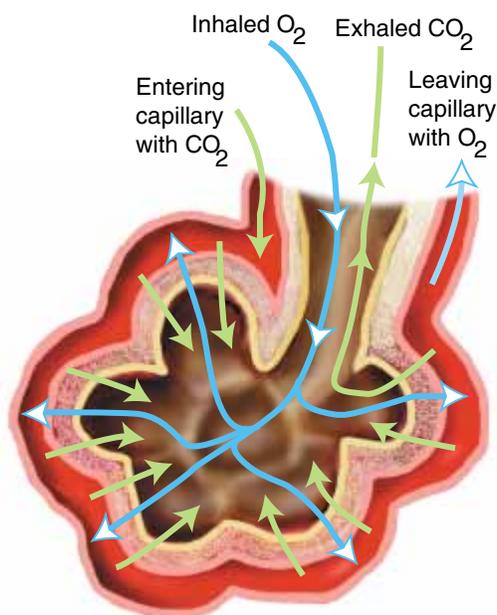

Figure 32-4 Alveolar Gas Exchange

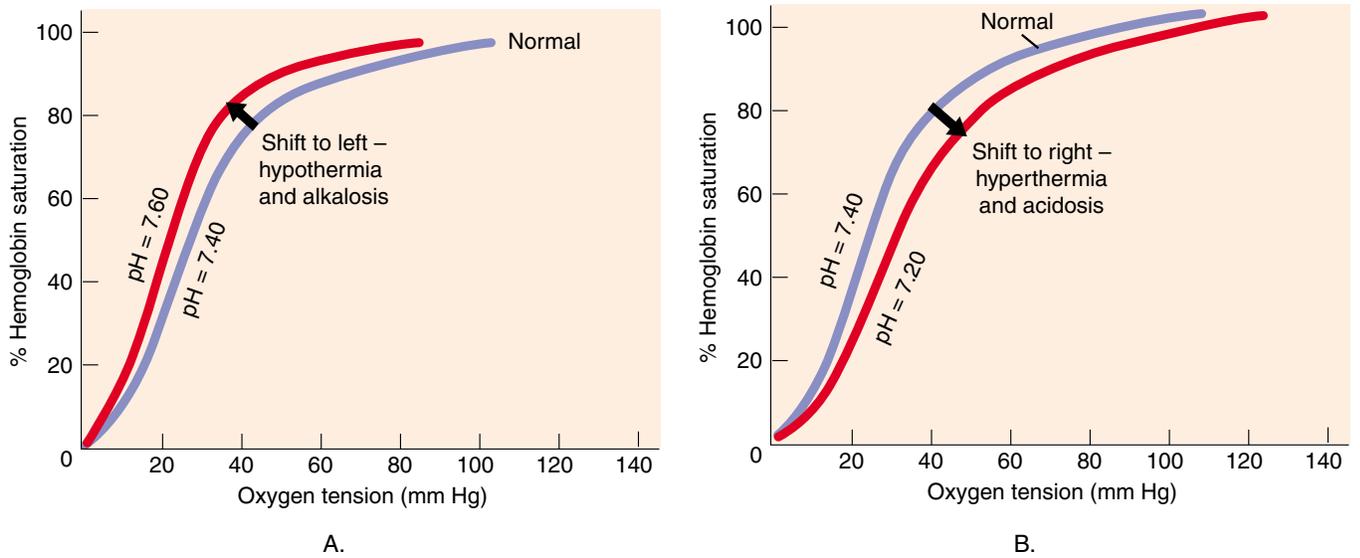

Figure 32-5 Oxyhemoglobin Dissociation Curve: A. Effect of increase in pH; B. Effect of decrease in pH

The heart is a muscular pump that is divided into four chambers: the right and left atria and the right and left ventricles (Figure 32-6). A series of valves allows for unidirectional blood flow through the chambers, which is driven by the sequential contraction and relaxation of the heart muscle.

A single cycle of atrial and ventricular contraction and relaxation is referred to as a **cardiac cycle**, which is the product of the interplay of electrical and mechanical events. The electrical activity of the heart involves the generation and transmission of electrical current by specialized cardiac cells known as the **cardiac conduction**

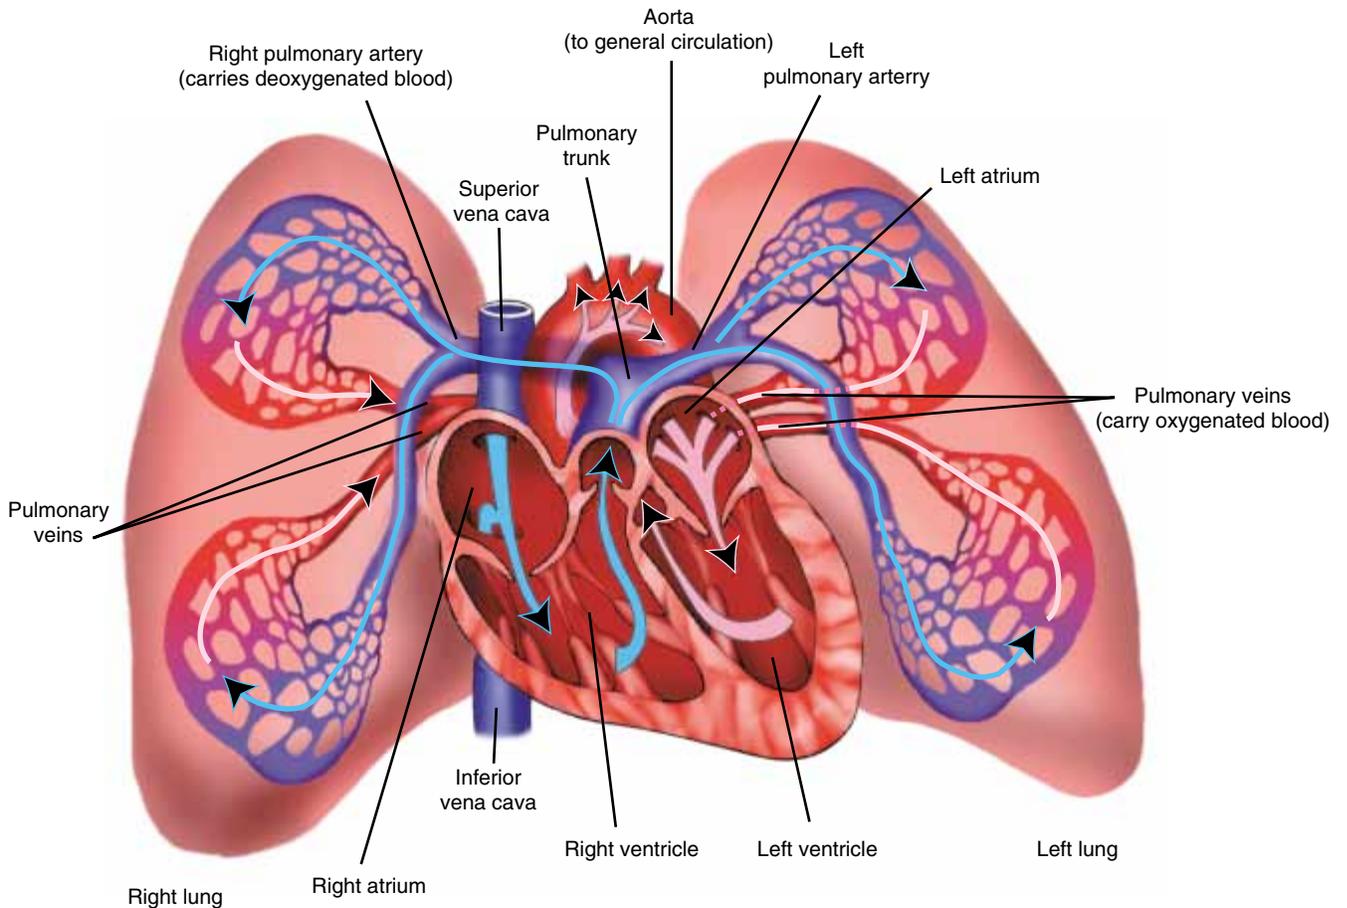

Figure 32-6 Major Structures of the Heart and Pulmonary Circulation

system (Figure 32-7). A small mass of cells in the right atrium, the *sinoatrial node*, or *SA node*, normally controls the heart rate by rhythmically generating electrical impulses. For this reason, the SA node is often referred to as the heart's "pacemaker." The impulses created by the SA node travel along specialized internodal pathways to spread throughout the atria, resulting in mechanical muscular contraction. The electrical activity is then transmitted down to the ventricles via the *atrioventricular (AV) node* and spreads through the ventricular tissue along the *bundle of His*, *right and left bundle branches*, and *Purkinje fibers*. Again, the result is muscular contraction. The sequential contraction and relaxation of the atria and ventricles is an essential factor in the cyclical filling and emptying of the chambers, which produce circulation.

The process of chamber filling is referred to as **diastole**, and the process of a chamber emptying is **systole**. Atrial diastole occurs as the right and left atria relax and blood flows into the right and left atrial chambers from the venae cavae and pulmonary veins, respectively. As pressure rises in the atria, the atrioventricular valves (the mitral and tricuspid) open, permitting the blood to begin flowing into the ventricles. Ventricular filling is further augmented by contraction of the atrial muscle (atrial systole), forcing additional blood into the ventricles. This contribution to ventricular filling is sometimes called "atrial kick."

Filling of the ventricles causes the intraventricular pressure to rise. When the intraventricular pressure exceeds the pressure in the atria, the atrioventricular

valves close. The ventricular muscle then begins to contract, further increasing intraventricular pressure until it is sufficient to force open the two semilunar valves (the pulmonic and aortic valves). As contraction of the ventricular walls proceeds, blood is forced out of the ventricles and into the circulation (ventricular systole).

Blood leaving the right ventricle is pumped into the pulmonary artery, which quickly branches into right and left pulmonary arteries. Further division of the pulmonary arterial tree culminates in the pulmonary capillary bed. Blood in the pulmonary capillaries is in very close contact with the alveolar air; it is here that alveolar-capillary gas exchanges take place. From the pulmonary capillaries, the freshly oxygenated blood flows into the pulmonary veins and to the left atrium, which delivers it to the left ventricle (Figure 32-8).

Blood leaving the left ventricle enters the aorta. The aorta serves as the "trunk" of the arterial tree, with branches leading to every organ and tissue group in the body. Blood flow through the arterial system is driven by the pressure generated during ventricular systole and is influenced by the volume and viscosity of the blood and the amount of resistance within the arterial system. Blood flow to specific organs and tissues may be increased or reduced by the relaxation or contraction of **precapillary sphincters**, which are rings of smooth muscle surrounding the arterioles. This mechanism allows for redistribution of blood flow to the areas of greatest need, a process known as **autoregulation**.

Blood return through the venous system is also driven by pressure gradients, although the venous sys-

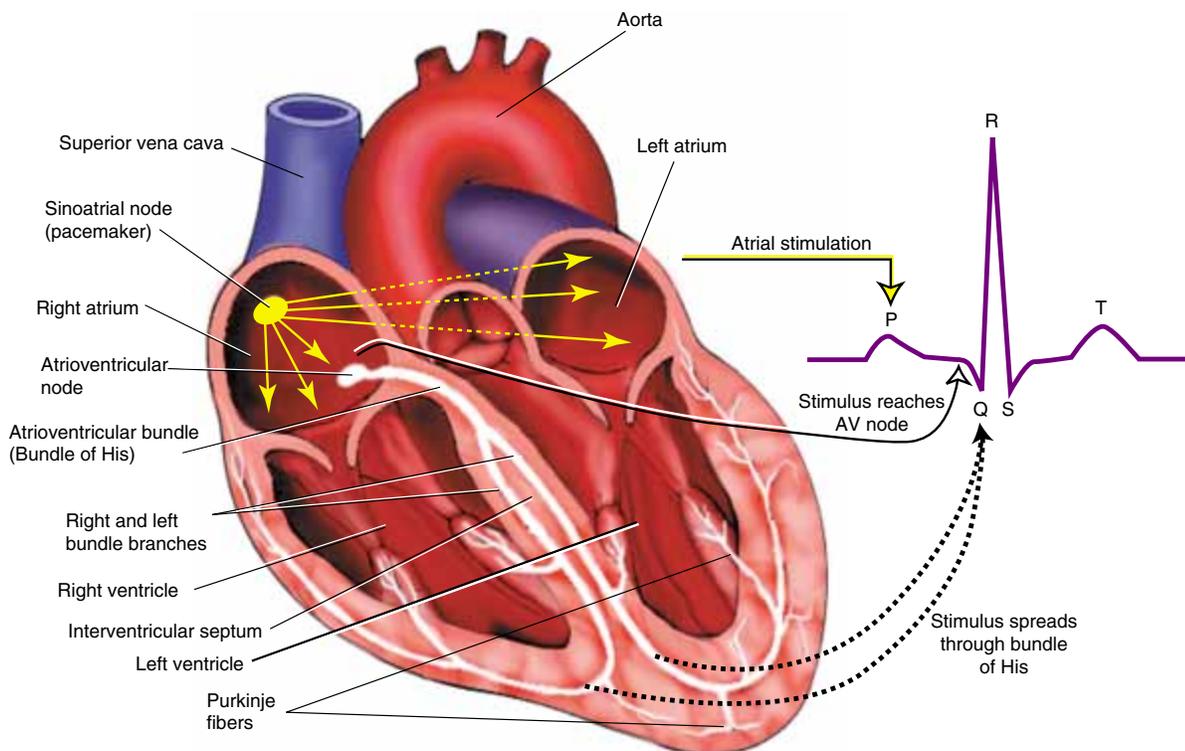

Figure 32-7 Cardiac Conduction System

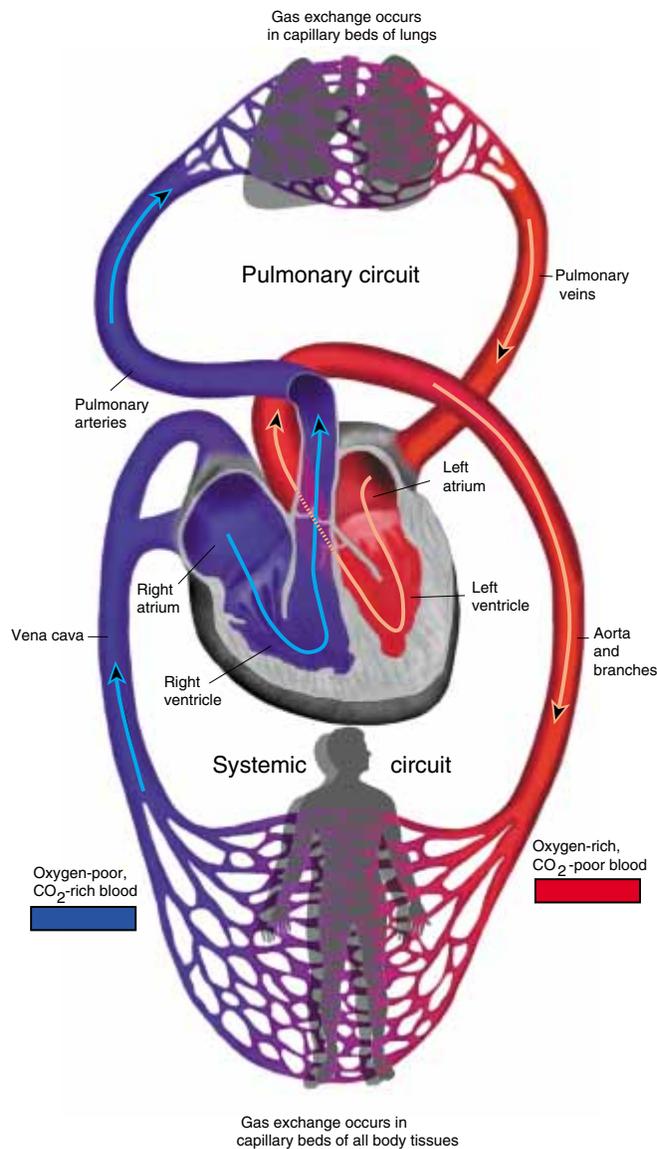

Figure 32-8 Systemic and Pulmonary Circuits

tem operates under lower pressure than the arterial system does. In order to boost venous return, many veins (particularly in the lower extremities) are equipped with valves that prevent backward flow of blood (regurgitation); as the veins are compressed by their surrounding skeletal muscles, blood is forced along toward the vena cava and ultimately to the right atrium.

Cellular Respiration

Gas exchange at the cellular level, like that at the alveolar level, takes place via diffusion in response to concentration gradients. Oxygen diffuses from the blood to the tissues, while carbon dioxide moves from the tissues to the blood; the blood is then reoxygenated by the heart. This process is referred to as **internal respiration**.

FACTORS AFFECTING OXYGENATION

Adequate oxygenation is influenced by many factors, including age, environmental and lifestyle factors, and disease processes.

Age

Oxygenation status can be influenced by age. Older adults may exhibit a barrel chest and require increased effort to expand the lungs. Loss of alveolar gas exchange is accompanied by a decrease in the partial pressure of oxygen. Older adults are also more susceptible to respiratory infection because of decreased activity in the cilia, which normally are an effective defense mechanism.

THINK ABOUT IT

Tobacco Use

If you are a smoker, would you feel comfortable suggesting that your clients avoid smoking in order to maintain a healthy oxygenation status? Imagine that a client smelled cigarette smoke on your breath when you returned from your break. How would you respond?

Environmental and Lifestyle Factors

Environmental and lifestyle factors can significantly affect a client's oxygenation status. Clients who are exposed to dust, animal dander, asbestos, or toxic chemicals in the home or workplace are at increased risk for alterations in oxygenation. Individuals who experience

NURSING TIP

Maintaining Healthy Oxygenation

Encourage clients to:

- Leave windows open for ventilation instead of using an air conditioner or humidifier.
- Change filters on furnaces, heaters, and range hoods as recommended by manufacturer.
- Wear a mask when working with hazardous materials, such as asbestos.
- Limit physical exertion if it causes shortness of breath.
- Refrain from smoking.

significant physical or emotional stress or who are obese or underweight are also subject to changes in oxygenation status. Smokers and those exposed to second-hand smoke should be questioned as to the type and amount of tobacco and number of years of exposure.

Disease Processes

Oxygenation alterations can often be traced to disease states related to alterations in ventilation, alveolar gas exchange, oxygen uptake, or circulation. There are many disease states that may affect oxygenation, including obstructive pulmonary disease, restrictive pulmonary disease, diffusion defects, ventilation-perfusion mismatching, atherosclerosis, heart failure, anemia, and alterations in oxygen uptake.

Obstructive Pulmonary Disease

Alterations in ventilation may be related to obstructive or restrictive pulmonary disease. **Obstructive pulmonary disease** occurs when the airways become partially or completely blocked, diminishing airflow, or the lungs lose some of their elastic recoil, trapping stale air, which should be exhaled. In both cases, the end result is impaired exhalation, air trapping, and difficulty bringing fresh air into the alveoli (Figure 32-9). The most common obstructive pulmonary diseases are asthma, emphysema, and chronic bronchitis, collectively known as **chronic obstructive pulmonary disease (COPD)**.

Restrictive Pulmonary Disease

Restrictive pulmonary disease represents pathologies that impair the ability of the chest wall and/or lungs to expand during the inspiratory phase of ventilation. This impairment increases the work of breathing and also reduces airflow to the alveoli. A wide variety of disorders cause restrictive lung disease, including pneumonia and pulmonary fibrosis (scarring).

NURSING ALERT

Risk Factors for Pneumonia

The following compromise a client's respiratory health, increasing the susceptibility to pneumonia:

- Smoking
- Emphysema
- Intoxication
- Weak cough reflex
- Immunosuppressed status
- Medicated or unconscious status

Traumatic injury to the thorax or a break in the pleural membrane that surrounds the lungs may also produce restrictive pulmonary dysfunction. The stability of the chest depends upon the rib cage; multiple rib fractures may produce a type of paradoxical chest wall movement called “flail chest” that impedes normal airflow. The dual-layer pleural membrane also has an important structural function; it helps maintain a negative pressure between its two layers that keeps the lungs from collapsing upon themselves. A break in either layer of the membrane or an abnormal collection of fluid between them interferes with this function, permits alveoli to collapse, and increases the work of breathing. Common pleural defects are described in Table 32-1.

Alveolar collapse, known as **atelectasis**, can be caused by pleural defects as described above, by compression from a mass such as a tumor, or by occlusion of the small airways by secretions, which prevents air movement into the associated alveoli. Failure of a client to breathe deeply after abdominal surgery may result in atelectasis. Regardless of the cause, atelectasis results in restrictive pulmonary dysfunction and reduces the amount of alveolar-capillary surface area engaged in gas exchange.

Diffusion Defects

Another mechanism of oxygenation impairment is a decrease in the efficiency of gas diffusion from the alveolar

TABLE 32-1
Common Pleural Defects

Pleural Defect	Description
Pleural effusion	Collection of fluid between the pleural layers. May consist of serous fluid (hydrothorax), purulent fluid (empyema), or chyle (chylothorax).
Hemothorax	Collection of blood between the pleural layers.
Pneumothorax	A collection of air between the pleural layers caused by a hole in one or both layers of the pleural membrane. May be classified as <i>open</i> (communicating with a chest wall wound) or <i>closed</i> (no exterior wound).
Tension pneumothorax	A pneumothorax that rapidly expands with each respiratory cycle, compressing the lungs and heart and pushing the great vessels and trachea toward the opposite side of the chest. A <i>tension pneumothorax</i> is a medical emergency requiring immediate intervention.

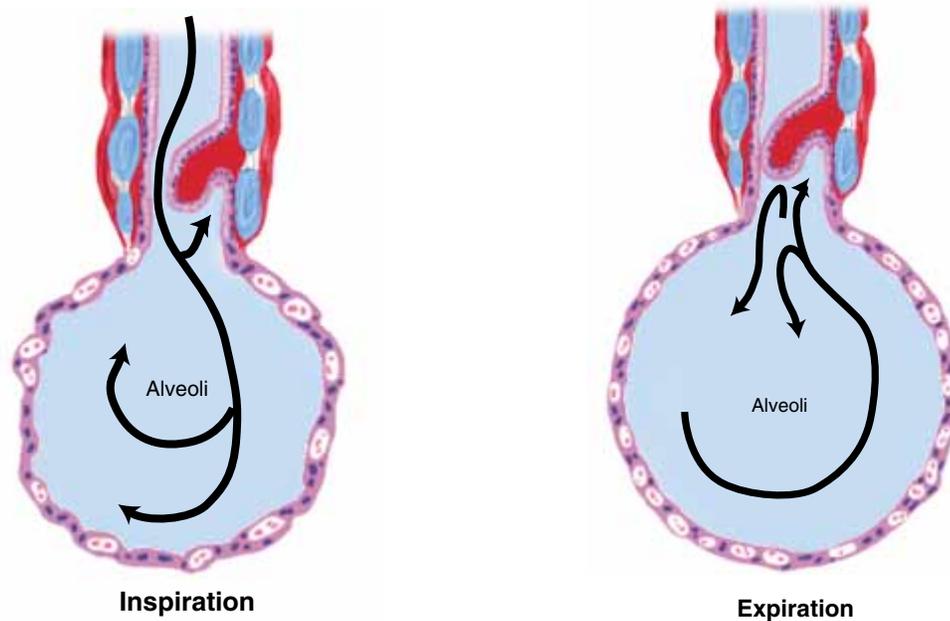

Figure 32-9 One mechanism of air trapping in COPD. During inspiration, the airway widens and opens. During exhalation, the airway closes, trapping air distal to the obstruction and preventing fresh air from entering the alveoli.

space into the pulmonary capillary blood, known as a **diffusion defect**. This may be caused by thickening of the alveolar-capillary basement membrane or by marked increases in the speed of blood flow through the pulmonary capillary beds, which reduce contact time with the alveoli. Diffusion defects by themselves are uncommon but may coexist with obstructive or restrictive pulmonary disease such as emphysema, pulmonary edema, or fibrosis.

Ventilation-Perfusion Mismatching

Gas exchange across the alveolar-capillary membrane is also influenced by **ventilation-perfusion (V/Q) mismatching**, or the balance between ventilation and perfusion. The amount of fresh air entering the alveoli (alveolar ventilation) and the amount of blood flow to various regions of the pulmonary capillary network (perfusion) are not uniform throughout the lungs. Due to alterations in position and the effect of gravity, certain zones of lung tissue may have better ventilation or perfusion than others at any given time.

An important mechanism of compensation in healthy lung tissue is to produce vasoconstriction or bronchoconstriction as needed to better match ventilation to perfusion or vice versa. Many disease states, however, produce areas of ventilation-perfusion mismatching that cannot be overcome by compensatory responses. When mismatching occurs, some alveolar regions will be well ventilated but poorly perfused (a condition known as **dead space**), while others may be well perfused but poorly ventilated (known as **shunting**). This phenomenon is illustrated in Figure 32-10.

Alterations in circulation may occur in either the pulmonary or the systemic vasculature and may be localized or generalized. Generalized decreases in pulmonary circulation may be caused by right-sided heart failure or by

pathologies in the pulmonary vascular system such as pulmonary hypertension and the resultant pulmonary artery sclerosis. Regional decreases in pulmonary circulation may be related to blockage of a pulmonary artery by an embolus or by regional vasoconstriction.

Atherosclerosis

Alterations in systemic circulation may also be generalized or localized. A common cause of altered arterial circulation is **atherosclerosis**. This disease is characterized by narrowing and eventual occlusion of the lumen (opening of the arteries) by deposits of lipids, fibrin, and calcium on the interior walls of the arteries (Figure 32-11). The

NURSING TIP

Reducing Risk for Atherosclerosis

Because accumulation of fats is a primary cause of atherosclerosis, encourage your clients to reduce their risk of this disease by:

- Monitoring cholesterol intake
- Lowering fat intake to less than 30% of daily calories
- Increasing intake of carbohydrates to compensate for loss of calories not consumed in fat
- Exercising according to a plan outlined by a health care provider

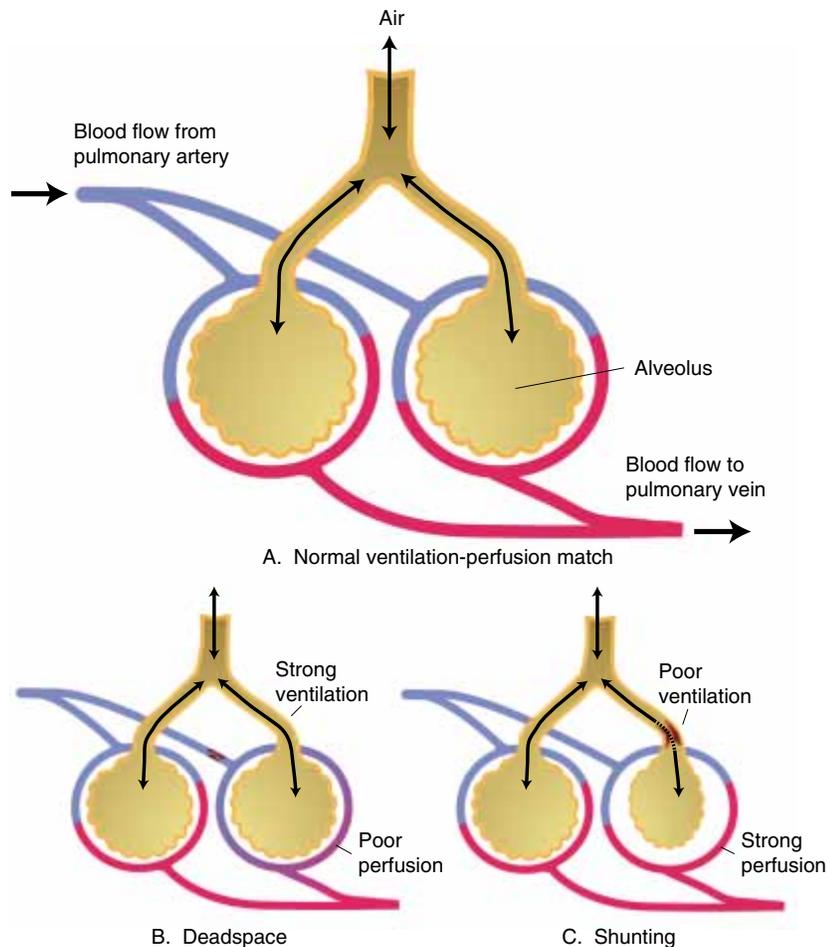

Figure 32-10 Types of Ventilation-Perfusion Abnormalities

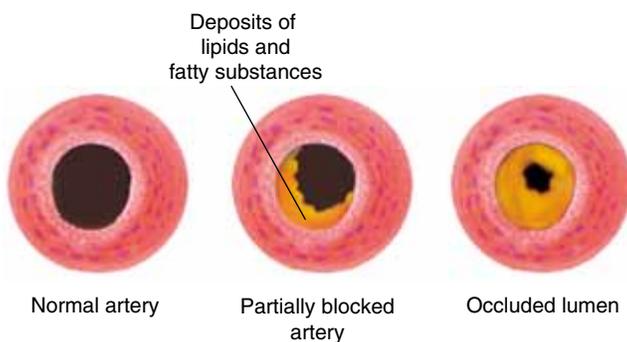

Figure 32-11 Progression of Atherosclerosis

reduction in blood flow with accompanying oxygen deprivation leads to **ischemia** (deprivation of blood flow) and eventual **infarction** (necrosis or death) of the affected tissue. Atherosclerosis in the coronary arteries (coronary heart disease) and the arteries of the brain (cerebral vascular disease) causes myocardial infarction and stroke, respectively, two of the leading causes of death in our society.

Heart Failure

Generalized decreases in tissue perfusion may be caused by left-sided heart failure or by loss of circulating blood volume

as may occur with shock or hemorrhage. **Heart failure** is a condition in which the heart is unable to pump enough blood to meet the metabolic needs of the body; typically, this is accompanied by a backup of blood in the venous circuits (pulmonary and systemic veins), leading to the condition known as congestive heart failure. The increased pressure of the blood in the engorged veins causes fluid to leak out of the associated capillary beds, causing edema in the tissue, including the lungs (pulmonary edema).

Congestive heart failure results in poor arterial perfusion to the body's tissues. This reduction in **cardiac output** (amount of blood pumped by the heart) may be mild, causing only vague symptoms, or may be profound enough to cause death. Causes of congestive heart failure include myocardial infarction, hypertensive heart disease, and valvular disorders, among others.

Loss of circulating blood volume (hypovolemia) may result from massive bleeding, loss of fluid through a wound (such as an extensive burn injury), or severe dehydration.

Anemia

Another factor that influences oxygenation is the amount of hemoglobin in the blood available to bind with oxygen. A deficiency of hemoglobin (**anemia**) may decrease the oxygen-carrying capacity of the blood. A

SPECIAL CONSIDERATIONS

Sexuality

Clients who are recovering from acute cardiac compromise, such as congestive heart failure or myocardial infarction, will need sensitive nursing care and education regarding sexual activity. Help alleviate their concerns by sharing the following American Heart Association (AHA) recommendations:

- Check with your health care provider.
- Resume sexual activity when you feel ready; most cardiac-compromised clients can safely resume sexual activity within 2 to 4 weeks.
- Take it slow and establish your comfort level; begin with lower energy forms of sexual expression, such as touching and holding.
- Continue taking prescribed cardiac medications; report to your health care provider any impact of these medications on sexual desire and performance.
- Experiencing an increased awareness of breathing, heartbeat, and muscle tightening during sexual activity is normal.

person who is anemic may have normal SaO₂ levels but still continue to experience inadequate tissue oxygenation at the cellular level. Certain poisoning syndromes, most notably carbon monoxide poisoning, mimic anemia in that they reduce oxygenation by competing with oxygen for binding sites on the hemoglobin molecule.

Alterations in Oxygen Uptake

A final factor to consider in the process of oxygenation involves the uptake of oxygen by the body's cells. Certain conditions may impair the cells' ability to take up and utilize oxygen, particularly when the mitochondria are damaged. Cyanide poisoning and severe sepsis impair mitochondrial functioning, rendering the oxygen in arterial blood useless to the cells.

Physiological Responses to Reduced Oxygenation

When oxygen delivery is inadequate to meet the metabolic needs of the body, various responses to this deficit can be expected, including changes in metabolic pathways and efforts to increase the extraction of available oxygen. If these efforts fail, cells will be damaged and ultimately die.

Increased Oxygen Extraction

Under normal conditions, the cells of the body do not extract all of the oxygen carried in the arterial blood. In fact, blood returning to the heart via the venous circulation

is typically about 75% saturated with oxygen. In response to poor oxygen delivery or increased oxygen need, the cells can extract more oxygen from the arterial blood.

Anaerobic Metabolism

The utilization of food (glucose) for cellular energy occurs via metabolic pathways that use oxygen; this is known as **aerobic metabolism**. Many cells are also capable of utilizing alternate metabolic pathways in the absence of oxygen for short periods of time; this is referred to as **anaerobic metabolism**. Anaerobic metabolism is limited by several factors:

1. Not all cells are capable of significant anaerobic metabolism (most notably brain cells).
2. Anaerobic metabolism yields less energy per unit of fuel than does aerobic metabolism.
3. Anaerobic metabolism results in the accumulation of acid byproducts, such as lactate, which upset the chemical environment of the cell and induce the release of cell-damaging (lysosomal) enzymes.

Tissue Ischemia and Cell Death

Prolonged oxygen deprivation (**hypoxia**) will lead to a syndrome ending in cellular death. The decreased production of adenosine triphosphate (ATP) resulting from anaerobic metabolism reduces the amount of energy available for cellular metabolic functions and results in a breakdown in all cellular functions. The integrity of the cell membrane becomes impaired, and the cell begins to swell. Cellular organelles may become damaged and lysosomal enzymes released, killing the cell. The destruction of tissues or organs as a result of oxygen deprivation is known as an infarction. Widespread cellular death resulting from oxygenation disturbances is the underlying characteristic of a devastating syndrome known as *multiple-organ-system failure*.

Carbon Dioxide Transport and Excretion

Carbon dioxide is a natural byproduct of glucose metabolism. Like oxygen, it exists normally as a gas and can be dissolved in the plasma as well as loosely bound to the hemoglobin molecule (although carbon dioxide attaches to a different binding site on the hemoglobin molecule than does oxygen). In the lungs, carbon dioxide is released into the alveoli by diffusion, and when the individual exhales, the carbon dioxide exits to the atmosphere.

In the body fluids, carbon dioxide functions as an acid because, combined with water, it produces carbonic acid. The hydrogen ions that are liberated in this process stimulate the respiratory control centers in the pons and medulla to increase the rate and depth of breathing; more carbon dioxide is then released by the lungs and the pH of the body is brought back to normal. Likewise,

increased production of carbon dioxide, as may be associated with fever or exercise, is often a cause of increased ventilatory rate (**tachypnea**) and depth. Elevated blood levels of carbon dioxide (**hypercapnea**) indicate inadequate alveolar ventilation.

ASSESSMENT

Health History

The health history of the individual experiencing oxygenation deficits is important in the development of the plan of care. The health history should begin with a thorough exploration of the presenting problem (Table 32-2), including how long it has been present and whether it has recently gotten worse, then should proceed to explore the medical history, impact of the illness on activities of daily living, and the client's knowledge level and coping abilities.

Physical Examination

Inspection will begin when the nurse first encounters the client. This is a time to make general notes of the client's

TABLE 32-2
Health History Related to Oxygenation

Presenting Problem	Qualifiers
Cough	Onset: sudden or gradual, how long ago Nature: dry, moist, barking, hacking, productive, nonproductive Pattern: continuous, occasional, related to time of day, position or activity, weather Severity Associated symptoms: pain, shortness of breath, wheezing Alleviating factors: vaporizers, OTC medications
Sputum	Amount, color, odor Presence of blood in sputum
Shortness of breath	Onset: sudden or gradual Nature: precipitated by choking or gagging Pattern: associated with activity or position; continuous or intermittent Associated symptoms: pain, cough, diaphoresis Alleviating factors
Pain	Location/radiation Nature: stabbing, dull, aching, burning, squeezing, crushing Associated symptoms: dizziness, nausea, diaphoresis, palpitations Aggravating factors Alleviating factors

efforts at ventilation, especially anxious or distressed appearance, flaring of nostrils, position preferences, and general chest configuration (Figure 32-12). While counting the respiratory rate, also note the rhythm or pattern of the breathing for regularity or irregularity (Figure 32-13). The signs and symptoms of hypoxia are relative to the onset. Early clinical manifestations of hypoxia include restlessness, apprehension, anxiety, dizziness, inability to concentrate, confusion, agitation, increased pulse rate, increased rate and depth of respiration, and elevated blood pressure (unless the hypoxia is caused by shock). If the hypoxia goes untreated, the respiratory rate may decline and changes in the level of consciousness progress to stupor, or coma indicating ischemia of neuronal cells resulting from oxygen deprivation. Perfusion deficits resulting in poor circulation can be visually noted in mottled skin, **cyanosis** (bluish coloration of the skin), and edema. The bluish discoloration of cyanosis is the result of the presence of desaturated hemoglobin in capillaries that may occur from either hypoxia or stagnant blood flow. When cyanosis is observed in the tongue, soft palate, and conjunctiva of the eye, it indicates hypoxemia, whereas cyanosis of the extremities, nail beds, and earlobes is often a result of vasoconstriction and stagnant blood flow. Clubbing of the fingers, which manifests as a flattened angle of the nailbed and a rounding of the fingertips, is a sign of chronic hypoxia (Figure 32-14).

Common palpation findings related to compromised ventilation include vocal fremitus and displacement of

NURSING ALERT

Cyanosis

Regardless of the mechanism behind it, it is important to remember that cyanosis is often a late development in clients with poor oxygenation and may be further delayed in those with dark skin pigmentation or low blood hemoglobin (anemia). *Therefore, the absence of cyanosis should not be taken as an assurance that oxygenation is adequate.* However, the presence of cyanosis, especially central cyanosis, should be considered to be an indicator of a hypoxic emergency.

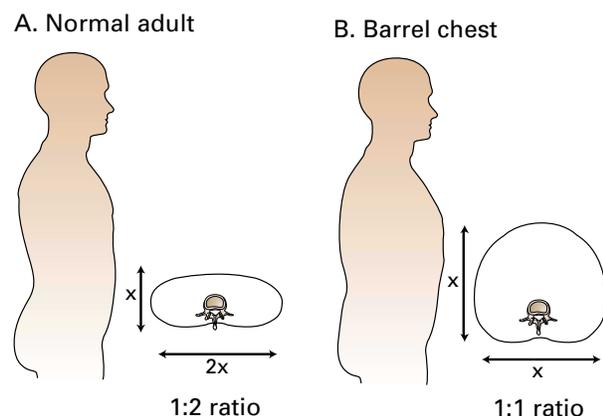

Figure 32-12 Changes in chest configuration and posture. The normal ratio of the anterior posterior diameter to the lateral diameter is 1:2. With a barrel chest, the ratio between the diameters is 1:1.

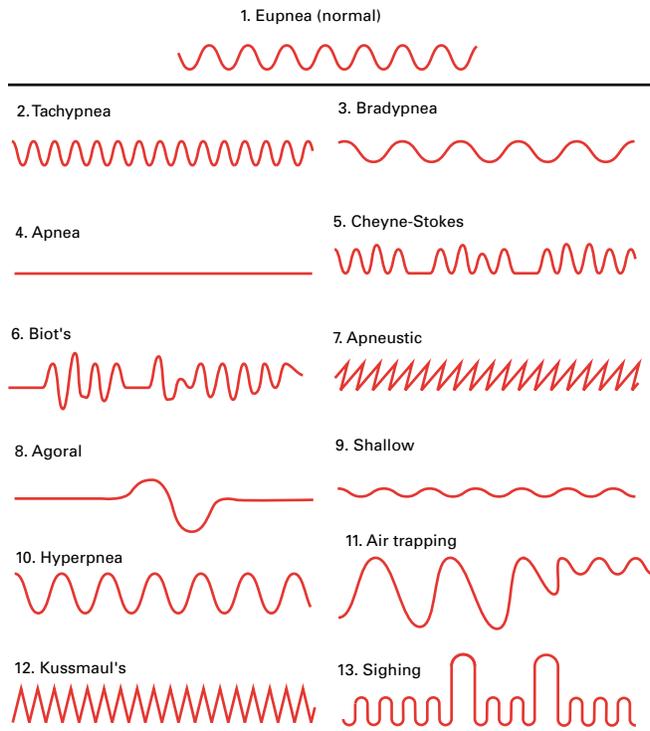

Figure 32-13 Respiratory Patterns

the trachea. Perfusion deficits are noted in changes in pulse rate or character, clammy skin, and ulcers in the lower extremities.

Percussion may reveal hyperresonance, dull percussion tone, or changes in the density of the lungs and surrounding tissues.

Figure 32-14 Clubbing of the Fingers as a Result of Chronic Hypoxia (Courtesy of Robert A. Silverman, M.D., Clinical Associate Professor, Department of Pediatrics, Georgetown University.)

NURSING TIP

Percussion Hint

Sound waves travel better through a solid medium than through an air-filled medium. Therefore:

- The more solid a structure, the higher its pitch, the softer its intensity, and the shorter its duration.
- The more air-filled a structure, the lower its pitch, the louder its intensity, and the longer its duration.

Auscultation may reveal adventitious breath sounds such as rales (crackles) or wheezes (rhonci), pleural friction rub, or stridor, all indicators or alterations in ventilation (Table 32-3). Circulation deficits will be noted upon auscultation by **gallops**, or extra heart

TABLE 32-3
Characteristics of Adventitious Breath Sounds

Breath Sound	Respiratory Phase	Description	Conditions
Fine crackle	Predominantly inspiration	Dry, high-pitched crackling, popping; short duration; roll hair by ears between your fingers to simulate this sound	Chronic obstructive pulmonary disease, congestive heart failure, pneumonia, pulmonary fibrosis, atelectasis
Coarse crackle	Predominantly inspiration	Moist, low-pitched crackling, gurgling; long duration	Pneumonia, pulmonary edema, bronchitis, atelectasis
Sonorous wheeze	Predominantly expiration	Low-pitched; snoring	Asthma, bronchitis, airway edema, tumor, bronchiolar spasm, foreign body obstruction
Sibilant wheeze	Predominantly expiration	High-pitched; musical	Asthma, chronic bronchitis, emphysema, tumor, foreign body obstruction
Pleural friction rub	Inspiration and expiration	Creaking, grating	Pleurisy, tuberculosis, pulmonary infarction, pneumonia, lung abscess
Stridor	Predominantly inspiration	Crowing	Croup, foreign body obstruction, large airway tumor

sounds, and **murmurs**, or sounds produced by blood flowing through a malfunctioning valve.

Diagnostic and Laboratory Data

There are many tests to measure oxygenation status. Pulse oximetry uses light waves to measure oxygen saturation (SaO_2) noninvasively (Figure 32-15). Arterial blood gases (ABGs) measure a number of indicators that can affect oxygenation status; these factors and their values are listed in Table 32-4. Sputum collection is another valuable tool in assessing a client's oxygenation functioning; this procedure is outlined in Table 32-5, and common findings and their indications are listed in Table 32-6. Measurements of lactic acid, hemoglobin,

Figure 32-15 Client with Pulse Oximeter

TABLE 32-4
Arterial Blood Gases

Measurement	Normal Arterial Values	Clinical Significance
pH	7.35–7.45	Indicates acid-base balance
Pco_2	35–45 mm Hg	Partial pressure of carbon dioxide; indicates adequacy of alveolar ventilation; represents respiratory component of acid-base balance
HCO_3^-	22–26 mEq/L	Bicarbonate level; indicates metabolic component of acid-base balance
PaO_2	80–100 mm Hg	Partial pressure of oxygen; represents oxygen dissolved in plasma
SaO_2	96%–98%	Saturation of hemoglobin with oxygen

TABLE 32-5
Protocol: Assisting a Client with Sputum Collection

Purpose	To collect an adequate sample of sputum for laboratory analysis and/or culture; To minimize contamination of the sample with oral or other secretions.
Level	Independent
Supportive data	Increasing the client's knowledge promotes cooperation and increases the diagnostic value of the sample obtained.
Assessment	Verify the type of test to be performed (cytology studies should be collected into a cup containing a preservative solution; cultures must be collected into a sterile container). Assess the client's level of consciousness and ability to follow instructions. Assess the client's breath sounds; coarse rales indicate the presence of sputum in the airways.
Interventions	Obtain correct specimen container. Wash hands and don clean gloves. Assist the client to rinse the mouth with water (not mouthwash). Instruct client to raise sputum from the lungs, not the throat or nose. Instruct client to expectorate sputum into the cup without touching the inside of the container. Replace cap on container as soon as sample is obtained. Label container and wash the outside if indicated. Place in a bag with a biohazard label for transport. Provide mouth care for the client and assist to a comfortable position. Remove gloves and wash hands. Send specimen to lab immediately.
Documentation	Document amount, color, character, and odor of sputum obtained and time the specimen was sent to the lab.

and hematocrit are also useful in determining the effectiveness of the body's oxygen delivery to tissues.

Selected tests to determine oxygenation status are discussed in Table 32-7. (See also Figure 32-16 for ventilatory function.) Clients undergoing these tests are often apprehensive and need nursing care and education directed at their knowledge levels. Refer to Chapter 28 for further diagnostic information.

TABLE 32-6
Pathologies Associated with Different Colors of Sputum

Sputum Color	Pathology
Mucoid	Tracheobronchitis, asthma
Yellow or green	Bacterial infection
Rust or blood-tinged	Pneumonia, pulmonary infarction, tuberculosis
Black	Black lung disease
Pink	Pulmonary edema

TABLE 32-7
Selected Tests for Oxygenation Status

Test	Indications/Possible Findings
Ventilatory function tests	<ul style="list-style-type: none"> Volume of air in the lungs at various phases of the ventilatory cycle Speed and ease of airflow through the airways Strength of the respiratory muscles
Chest x-ray	<ul style="list-style-type: none"> Areas of fluid accumulation (infiltrates) Solid masses (suggestive of tumors) Abnormal accumulations of calcium, areas of necrosis (as seen in tuberculosis) Excessive air trapping (suggestive of emphysema) Abnormal accumulations of air or fluid in the pleural space (suggestive of pleural effusion or pneumothorax) Gross abnormalities in size, shape, position of thoracic structures
Computerized tomography (CT) scan, magnetic resonance imaging (MRI)	<ul style="list-style-type: none"> Detailed pictures of thoracic structures
Ventilation scan	<ul style="list-style-type: none"> Areas of impaired airflow (suggestive of pulmonary emboli)
Bronchoscopy	<ul style="list-style-type: none"> Sputum collection Examination of tissue
Thoracentesis	<ul style="list-style-type: none"> Tissue sample collection
Echocardiography	<ul style="list-style-type: none"> Size and motion of cardiac structures Accumulation of fluid in the pericardial sac (suggestive of pericardial effusion)
Electrocardiography	<ul style="list-style-type: none"> Heart rate and rhythm Abnormal sites of impulse formation (ectopic pacemakers) Areas of blocked or delayed impulse transmission Chamber enlargement (as seen in heart failure) Areas of ischemia, injury or infarction
Stress test	<ul style="list-style-type: none"> Changes in ECG tracings (may indicate ischemic heart disease)

NURSING DIAGNOSIS

Nursing care of the client experiencing oxygenation problems should be prioritized on the basis of the A-B-C format used in basic life support; that is, consider the

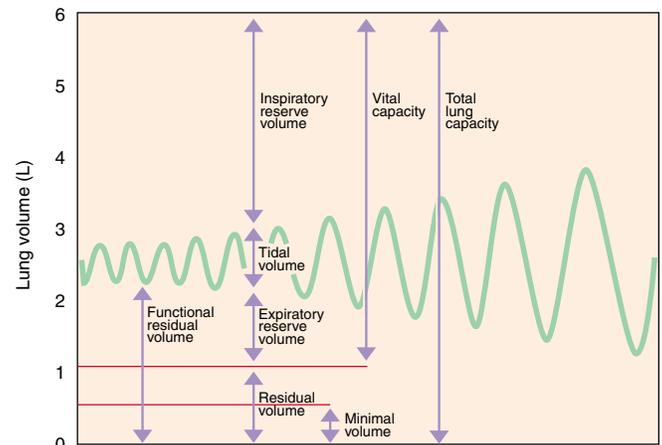

Figure 32-16 Graphic Representation of Lung Volumes and Capacities

airway, breathing, and circulation first and foremost. The primary nursing diagnoses are related to these priorities.

Ineffective Airway Clearance

Ineffective airway clearance exists when the client has difficulty maintaining a patent (open) airway at any point along the airway. This occlusion of the airway may be partial or complete. Causes of ineffective airway clearance include:

- Obstruction of the airway by the tongue (as may occur in the comatose or anesthetized client)
- Obstruction of airway by secretion (as may occur with excessive sputum production, and ineffective or absent cough)
- Upper airway obstruction caused by edema of the larynx or glottis
- Obstruction of the trachea or a bronchus by foreign body aspiration
- Partial occlusion of the bronchi and bronchioles by infection (bronchitis, bronchiolitis), inflammation and smooth muscle spasm (asthma), or occlusion or compression by a tumor mass
- Occlusion of the more distal airways by the changes associated with emphysema

Assessment findings in the client with ineffective airway clearance include a complaint of feeling short of breath or suffocating, a condition sometimes referred to as “air hunger.” The use of accessory muscles of ventilation may be noted, and the client may complain of fatigue. Shortness of breath may be noted on observation, and the client may have difficulty speaking because of it. A cough may be noted, and on auscultation rales and rhonchi may be heard. Poor aeration of the alveoli, as can occur with emphysema and severe asthma, will cause diminished breath sounds over the peripheral lung fields. Complete obstruction of a large or medium-sized airway will result in a loss of breath sounds over the affected lung segment.

Ineffective Breathing Patterns

Ineffective breathing pattern is commonly a problem for clients with restrictive pulmonary disease or central nervous system disorders that affect breathing. Those with restrictive pulmonary disease, in an effort to decrease their work of breathing, tend to adopt a pattern of rapid, shallow respirations. This respiratory pattern does not deliver adequate fresh air to the alveoli, resulting in chronic air hunger while contributing to muscle fatigue. Central nervous system disorders, including the effects of anesthetics and narcotics, may reduce both the rate and the depth of ventilation. Lesions affecting the brain stem in particular may reduce ventilation to dangerous levels.

Another group of clients at risk for ineffective breathing patterns are those who have had major abdominal or thoracic surgery or whose mobility is restricted. These individuals have a tendency to take shallow breaths and to avoid sighing and coughing, both necessary to maintain airway integrity.

Neuromuscular diseases that weaken the respiratory muscles may also result in ineffective breathing patterns as well as impaired airway clearance. Examples of such disorders include Guillain-Barré syndrome and myasthenia gravis. Alterations in thoracic structures that interfere with breathing patterns include abnormal curvatures of the spine (scoliosis, kyphosis), chest wall injury, and pleural defects.

Impaired Gas Exchange

Impaired gas exchange occurs when, despite the delivery of fresh air to the alveoli, adequate oxygen does not enter the arterial blood and/or carbon dioxide is not removed from the venous blood. Often this condition is the result of ventilation-perfusion mismatching or overall decreases in the amount of alveolar-capillary surface area available for gas exchange, a characteristic of emphysema. Another cause of impaired gas exchange is widespread shunting, as may occur with atelectasis (alveolar collapse) and pneumonia. Impaired gas exchange is assessed by measuring the oxygen and carbon dioxide content in the arterial blood via arterial blood gas analysis or pulse oximetry or both.

Decreased Cardiac Output

Decreased cardiac output impairs oxygen delivery to the tissues and may also be a factor in impaired gas exchange, as when congestive heart failure causes pulmonary edema. Causes of decreased cardiac output include heart failure and various types of shock. The assessment findings associated with decreased cardiac output may include low blood pressure; cool, clammy skin; weak, thready pulses; low urine output; and a diminished level of consciousness. If pulmonary edema is present, crackles will be heard over the lung bases and the client may produce frothy pink or white sputum.

Ineffective Tissue Perfusion

Ineffective (decreased) tissue perfusion may be widespread, as in the case of decreased cardiac output, or it may be confined to one or more tissues or organs of the body. A common cause of regional decreases in tissue perfusion is atherosclerosis, which may impair perfusion to the heart, brain, kidneys, or extremities. Assessment findings depend upon the organ or tissue involved, but one common finding is pain. The tissue that is deprived of oxygen will in many cases be painful, as the accumulation of lactic acid and the chemical mediators of the inflammatory response stimulate local pain receptors.

Other Nursing Diagnoses

The relationship between the primary nursing diagnoses discussed above and the secondary nursing diagnoses in the client with oxygenation problems is reciprocal; that is, the primary diagnoses both influence and are influenced by the secondary diagnoses. A holistic approach to nursing care requires that all diagnoses affecting the patient be considered and prioritized in developing the plan of care.

Deficient Knowledge

Deficient knowledge may exist to varying degrees in the client with either acute or chronic oxygenation problems. Involving the client in the plan of care requires that the client be informed regarding the disease process, diagnostic procedures, and treatment modalities. Assessment for deficient knowledge involves questioning the client and family with regard to their understanding and perceptions of these subjects. It is a mistake to assume that a client with a long-standing chronic illness has a good understanding of that illness.

Activity Intolerance

Activity intolerance reflects the impact of the illness on the client's ability to perform activities of daily living; the degree of this impairment may range from mild to severe, but it is important that this judgment be based on the client's, not the nurse's, perception of the activity intolerance. Activity restrictions that may be a mere annoyance for one individual can be viewed as catastrophic by another.

To assess activity intolerance, both interview and observation are useful. Ask the client to compare the current level of activity with the previous level and desired level. In addition, observe the client performing activities such as moving about in bed, ambulating, and performing personal care activities; note the point at which fatigue and/or dyspnea occurs and the amount of rest required. Objective tests of exercise tolerance, such as stress tests, may be performed in certain cases.

Disturbed Sleep Pattern

Disturbed sleep pattern is common in people with both cardiac and pulmonary disease. As mentioned earlier, many people with restrictive and obstructive pulmonary diseases find that breathing is easiest in an upright position; this position is also more comfortable for those with congestive heart failure. Sudden attacks of dyspnea during sleep, called **paroxysmal nocturnal dyspnea**, may interrupt the sleep of these clients, resulting in chronic fatigue. Complaints of poor sleep, along with daytime sleepiness and fatigue, are common assessment findings. Severe sleep deprivation can result in personality changes, hallucinations, and delusions.

A particular sleep problem associated with airway obstruction is **sleep apnea**. It is often seen in males who are overweight and have short, thick necks and is commonly associated with loud, heavy snoring. The soft tissues of the upper airways collapse during sleep, resulting in periods of absence of breathing (apnea). The individual then rouses enough to resume breathing, interrupting the normal sleep cycle. These individuals may complain of persistent daytime fatigue despite what seems to be adequate nighttime sleep.

Imbalanced Nutrition

Nutritional alterations are also commonly associated with both cardiac and pulmonary disease. The client with dyspnea may have difficulty consuming adequate food because of the effort involved; in turn, the malnutrition contributes to respiratory muscle weakness. The client with a productive cough may have an unpleasant taste in the mouth, interfering with appetite. Congestive heart failure may cause a poor appetite (anorexia) because of decreased perfusion to the gut. On the other hand, obesity can affect oxygenation by increasing the work of breathing as well as the cardiac workload.

Acute Pain

Acute pain may be present in the client with ischemia to the heart or to the extremities due to inadequate perfusion; chest wall or pleuritic pain may also be a feature of many pulmonary disorders. Adequate pain control can influence the effectiveness of breathing patterns and coughing, making pain control a priority in these cases. Pain assessment should address the nature of the pain, its intensity, its location and radiation, factors that make it better or worse, and any associated symptoms. For instance, pain caused by myocardial ischemia is called **angina pectoris** and is often described as crushing or squeezing in nature; it may be confined to the chest or it may radiate to the neck, shoulder, jaw, arm, or hand. Ischemia to the extremities (most often the legs) produces a pain known as **intermittent claudication**, which is typically brought on by exercise and relieved by rest. See Chapter 33 for further discussion of pain assessment.

Anxiety

Anxiety is often a prominent finding in individuals who are experiencing breathing difficulties or acute cardiac problems, such as chest pain. The anxious client may have difficulty answering questions and focusing on the instructions being given and may expend excessive amounts of precious energy in the process. Therefore, recognition and control of anxiety bring both psychological and physiological benefits.

OUTCOME IDENTIFICATION AND PLANNING

In identifying goals and planning nursing care for the client with oxygenation disorders, carefully consider individual goals for each nursing diagnosis and each client; the goals should be individualized to reflect the client's capabilities and limitations. In many cases, identifying desired outcomes of care is best accomplished in small steps, progressing from one level of functioning to the next until the ultimate objective is attained. Such an approach prevents the client from feeling overwhelmed with the magnitude of the task at hand while allowing for the satisfaction of reaching intermediate outcomes. Outcomes may be based on physiological parameters such as respiratory rate or arterial blood gas values, on activity tolerance and client comfort levels, or on identified learning needs.

The outcomes for a particular client should be based upon the assessment findings that led to the nursing diagnoses at hand. For example, if a respiratory rate of 30 breaths per minute with a shallow breathing pattern and suprasternal retraction led to a diagnosis of ineffective breathing pattern, then the desired outcome of intervention might be a respiratory rate of 20 breaths per minute or less and the absence of retractions. Achievement of the outcome indicates resolution of the problem.

IMPLEMENTATION

Interventions to Promote Airway Clearance

Interventions to promote airway clearance focus on clearing the airways of secretions, relieving bronchospasm, and, when necessary, bypassing the natural airway structures with an artificial airway. All of these procedures are facilitated when the client has been well informed of the purpose for the interventions and knows what to expect.

Teach Effective Coughing

Effective coughing techniques may need to be taught to the client experiencing either short-term or chronic airway obstruction. Coughing is an important element of postoperative care in order to prevent pulmonary complications. Effective coughing should be preceded by a series of slow, deep breaths. One technique that may be useful is "huffing," or delivering a series of short, forceful exhalations, prior to actual coughing. The intent is to raise the sputum to the level where it can then be coughed out. If the client is recovering from thoracic or abdominal surgery, splinting the incision by holding a pillow firmly against it will reduce the pain caused by coughing. In most cases, assisting the client to a sitting position will increase the effectiveness of the cough.

Assess the sputum produced by coughing, noting the amount, color, and odor. Recognize that the client may become fatigued after coughing and need a rest period; also offer oral care such as a mouth rinse after sputum has been expectorated.

Initiate Postural Drainage and Chest Physiotherapy

Postural drainage and **chest physiotherapy (CPT)** are techniques intended to promote the drainage of secretions from the lungs. Positioning for drainage of each of the lung lobes is accompanied by percussion and/or vibration applied to the chest wall to loosen secretions (Figure 32-17). Percussion involves using a cupped hand to beat firmly on the chest wall (Figures 32-18 A,

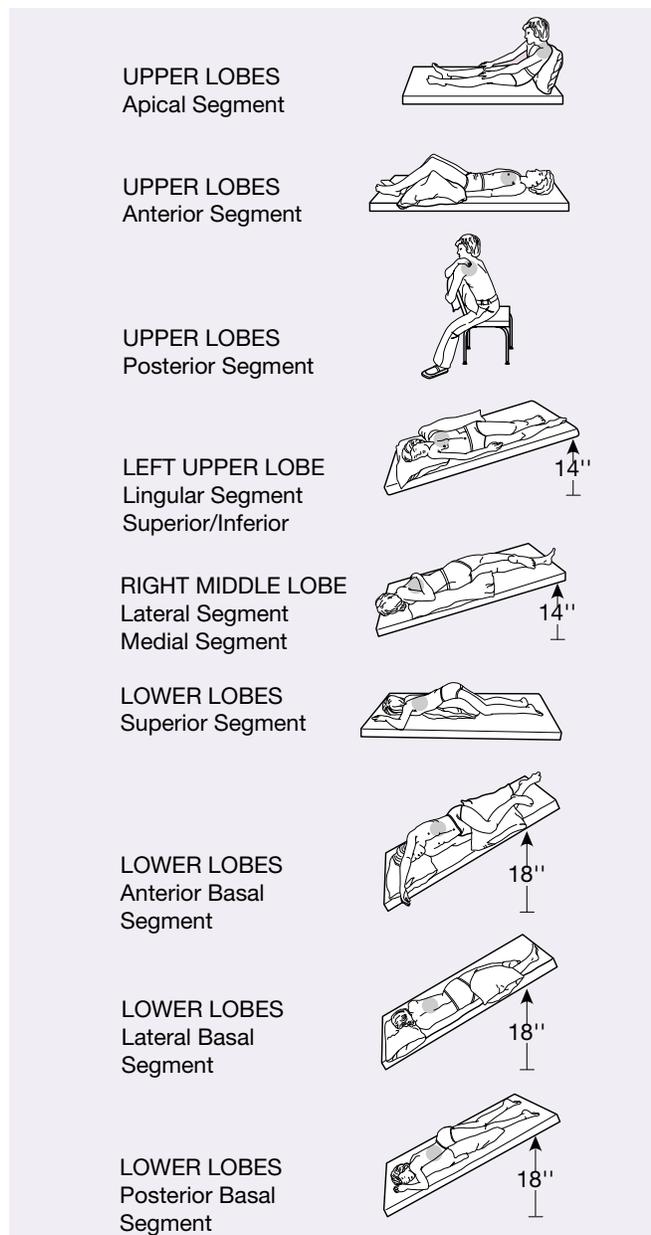

Figure 32-17 Postural Drainage Positions

B); a firm rubber cup of a size appropriate to the client's body size may also be used. Vibration is done using a special vibrator applied to the chest wall. Inhalation treatments containing bronchodilator or mucolytic drugs may be administered before chest physiotherapy and postural drainage.

Measures should be taken to minimize the client's anxiety and discomfort during these procedures. Pain medications, if indicated, should be timed so that their effectiveness peaks at the time of the treatment. Also, the nurse must recognize that some clients may be unable to tolerate certain postural drainage positions, and the treatment must be modified. Those with congestive heart failure or increased intracranial pressure particularly will not be able to tolerate a head-down position.

Monitor Hydration

Hydration, that is, the provision of adequate fluid intake, is important in thinning the pulmonary secretions so that they may be more easily expectorated. This may be beneficial in cases of pneumonia, bronchitis, and asthma. Clients experiencing congestive heart failure, on the other hand, may require limitation of fluid intake to reduce pulmonary congestion due to fluid volume overload.

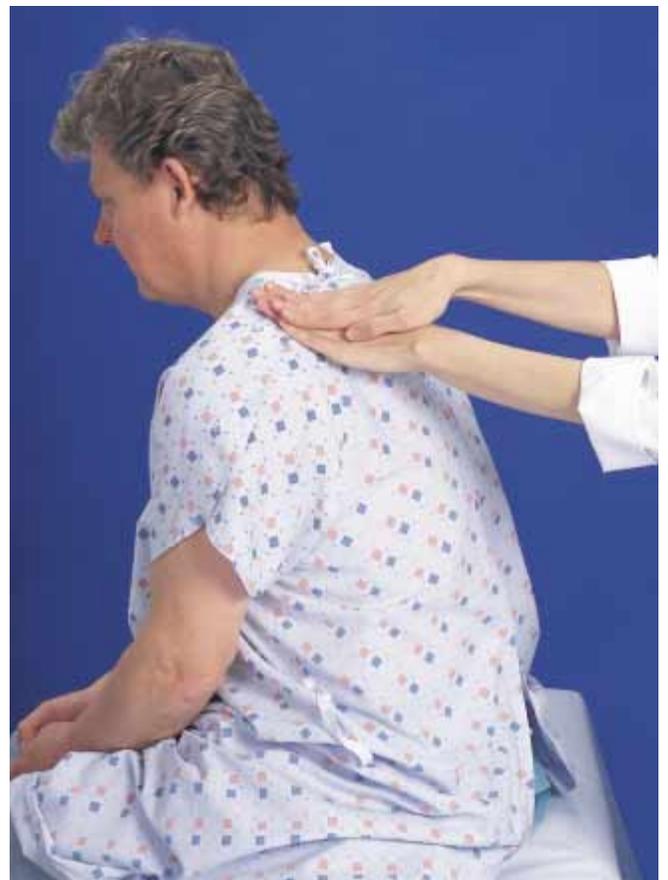

Each exhalation contains not only carbon dioxide and other gases but also water vapor. This "insensible fluid loss" will be increased in those who are tachypneic as well as in clients receiving supplemental oxygen if the oxygen is not adequately humidified. Artificial airways that bypass the natural humidification processes of the nose and oropharynx also contribute to increased insensible fluid losses. Drying and inflammation of the respiratory mucosa may result. For this reason, humidification of inspired oxygen, especially that which is delivered through an artificial airway, is very important.

Administer Medications

Medications that assist in airway clearance include expectorants, mucolytics, and bronchodilators. It may be beneficial to administer the medications before chest physiotherapy or postural drainage treatments in order to maximize the treatment's effectiveness. Clients must be taught the name of the medications they are receiving, the purpose of the medication, the dose, and how it is to be taken. The most common and/or most significant side effects should also be reviewed with the client. A summary of medications for airway clearance is presented in Table 32-8.

A.

B.

Figure 32-18 Chest Wall Percussion: A. Positions of hands to strike; B. Strike completed.

TABLE 32-8
Medications Used for Airway Clearance

Drug Type	Common Examples	Actions
Mucolytic/expectorant	Mucomyst (acetylcysteine) Guaifenesin	Thins respiratory secretions by increasing the amount of fluid produced
Methylxanthine	Aminophylline Theophylline	Dilates bronchi Increases ciliary movement
Beta-adrenergic sympathomimetic	Epinephrine Isoproterenol Albuterol Metaproterenol Terbutaline	Causes bronchial smooth muscle relaxation (dilates bronchi)
Mast cell stabilizer	Cromolyn sodium	Prevents histamine release from mast cells
Corticosteroid	Beclomethasone Prednisone Prednisolone Hydrocortisone	Anti-inflammatory action

Monitor Environmental and Lifestyle Conditions

Environmental and lifestyle conditions may greatly influence the client's long-term recovery. Allergic conditions such as asthma may improve dramatically if the allergens to which the client is sensitive are identified and removed from the client's environment. Certain allergens such as animal dander or feather pillows may be relatively easy to eliminate; others, such as house dust and pollen, may be impossible to eliminate but can be reduced using devices such as air filters.

Smoking is a significant contributing factor in both heart and lung disease. Smoking cessation may not reverse advanced disease but will often reduce the client's symptoms and improve the quality of life. Smoking cessation programs and support groups, along with nicotine replacements such as transdermal patches, may help the client succeed in quitting smoking.

Introduce Artificial Airways

Artificial airways (Figure 32-19A–D) may be used for clients with significant airway obstruction that cannot be relieved by more conservative means or who require mechanical ventilatory support. Nasal airways, also known as nasal trumpets, may be placed in conscious adults who have adequate breathing ability but require assistance in keeping their upper airways open. These airways are usually fairly well tolerated and can provide a conduit for frequent nasotracheal suctioning while minimizing trauma to the nasal mucosa.

The oral airway is used to maintain the tongue away from the posterior oropharynx in the unconscious client. It is essential to choose the correct size, since an airway that is too large may actually cause occlusion, while one that is too small may compress the tongue, stimulating the vomiting center. Oral airways are not well tolerated in conscious individuals, who may gag and vomit if an oral airway is in place.

Endotracheal tubes bypass the upper airway structures altogether; they may be inserted via the nose or mouth and are passed beyond the vocal cords into the trachea. An inflatable cuff near the distal end of the tube serves to seal off the airway, allowing for mechanical ventilatory assistance and protecting the airway from aspiration.

Since endotracheal tubes bypass the filtration and humidification normally provided by the nose and oropharynx, care must be taken to humidify the inspired air and to prevent introduction of pathogenic organisms into the lungs. Meticulous attention to aseptic technique when caring for clients with endotracheal tube and ventilator circuits is mandatory.

NURSING TIP

Cigarette Smoking

Cigarette smoking is the primary risk factor for chronic bronchitis, emphysema, and lung cancer. Lung cancer is the primary cause of cancer deaths among men and now surpasses breast cancer as the number one cancer killer in women.

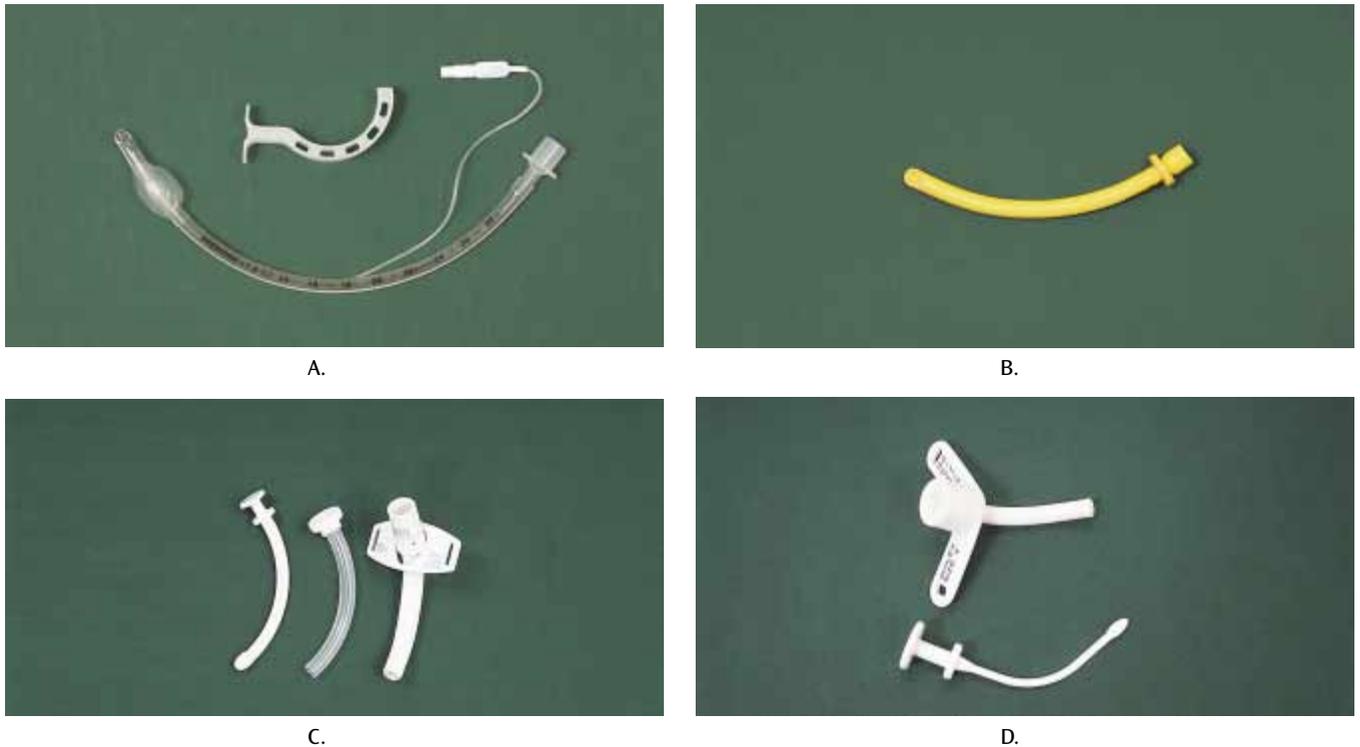

Figure 32-19 Types of Artificial Airways: A. Oral airway and endotracheal tube; B. Nasal trumpet; C. Tracheostomy tube; D. Pediatric tracheostomy tube.

Mouth care must be provided for the client with an endotracheal tube. The tube prevents adequate swallowing, so the client will be unable to eat. Frequent cleansing and suctioning of the oral cavity (every 2 hours) reduces discomfort and the risk of breakdown and infection of the oral mucosa.

Nutritional needs for the client with an endotracheal tube must be addressed by providing enteral feeding (via nasogastric or gastrostomy tube) or total parenteral nutrition (hyperalimentation). Whatever the means, adequate nutrition is necessary to maintain and improve respiratory muscle strength.

A **tracheotomy** is a surgical procedure done to provide long-term airway support or as an emergency procedure when an endotracheal tube cannot be passed successfully. An opening (stoma) is made in the trachea below the cricoid cartilage, and a semirigid plastic tube (tracheostomy tube) is passed through the opening and

into the trachea. A cuff, similar to that in an endotracheal tube, is inflated near the distal airway.

Many tracheostomy tubes consist of two tubes or *cannulae*: an outer cannula that stays in place and an inner cannula that can be removed to be cleaned or replaced. This permits thorough removal of encrusted secretions to prevent occlusion of the airway. The outer cannula is connected to a flange that permits the tubes to be secured around the neck with twill tape or a cloth strap. See Procedure 32-1 for tracheostomy care.

Like an endotracheal tube, a tracheostomy tube bypasses the upper airways, so humidification and prevention of infection must be considered. Because both types of airways prevent the movement of air through the vocal cords, which produce speech, the client will not be able to talk while these tubes are in place (some long-term tracheostomy clients may be outfitted with a tracheostomy tube that has slits, or “fenestrations,” that permit speech). If possible, reviewing an alternate method of communication prior to tube insertion can reduce the anxiety and isolation that may be felt by the intubated client. Writing of messages and use of an alphabet board are two possible methods of communication. Significant others should also be advised that the intubated client will not be able to speak but can hear and understand what is being said.

NURSING ALERT

Artificial Airways

The cuff of an endotracheal tube or tracheostomy tube must be deflated before removing the tube; removal of a tube with an inflated cuff may cause laryngeal edema and damage to the vocal cords. For this reason, the tube must be taped securely in place, and confused or agitated clients may require sedation and/or wrist restraints to prevent them from pulling at the tube.

Suction the Airway

Suctioning of the airway, whether a natural or artificial airway, may be necessary to clear secretions the client cannot remove by coughing. Suctioning becomes

PROCEDURE 32-1

Performing Tracheostomy Care

Equipment

- Tracheostomy care kit (includes two sterile containers, sterile cotton-tip applicators, sterile pipe cleaner, sterile nylon brush, sterile 4 × 4 gauze pads, tweezers, sterile drapes, and tracheostomy ties)
- Two pairs of sterile gloves
- Plastic bag or biohazard container for disposal
- Sterile 0.9% sodium chloride solution
- Hydrogen peroxide solution
- Suction kit and suction equipment (see Procedure 32-2)
- Sterile precut 4 × 4 drain sponges
- Personal protective devices: gown, mask, and goggles or face shield

Action

1. Explain procedure to the client and assist the client to a semi-Fowler's position. Remove pillows from behind the client's head.
2. Place plastic bag or disposal container within easy reach. Position in an area that does not require crossing over the sterile field or stoma to discard soiled items.
3. Place additional items on a clean overbed table or other easily accessible work space.
4. Wash your hands.
5. Loosen the caps on the bottles of sterile saline and hydrogen peroxide.
6. Put on goggles and mask or face shield and gown and don sterile gloves (see Procedure 31-4).
7. Suction the client's tracheostomy tube (see Procedure 32-3); then remove the soiled tracheostomy dressing. Note the amount, color, and odor of any drainage around the stoma. Remove the gloves by pulling them over the discarded dressing, and discard the gloves and dressing.
8. Open the tracheostomy care kit, taking care to avoid touching the inside of the kit.
9. Using sterile gloving technique (see Procedure 31-4), put on the gloves supplied in the tracheostomy care kit (if included) or a separate pair of sterile gloves.
10. Open the inner wrapper of the tracheostomy care kit to form a sterile field. Separate the two sterile containers and place them on the field. Lay the cotton applicators, pipe cleaners, nylon brush, and sterile 4 × 4's pads on the field. Place the sterile drape on the patient's chest, with its upper edge as near to the tracheostomy tube as possible. Fold a tuck of the drape over your fingers as you position the drape.

Rationale

1. Reduces anxiety and increases client's ability to cooperate. Semi-Fowler's position allows comfortable access to the tracheostomy site, and removal of pillows reduces neck flexion.
2. Prevents contamination of sterile field or stoma.
3. This space will be used to set up a sterile field for the tracheostomy care supplies.
4. Prevents the transmission of pathogens.
5. Permits easy opening of the bottles when ready.
6. Protects you from splattering with body fluids (sputum).
7. Suctioning clears the airway of loose secretions. Inspection of the exudate reveals signs of possible peristomal infection. The old dressing and gloves used for suctioning are discarded to prevent reintroduction of pathogens. Removing the gloves over the old dressing permits containment of infectious exudate (if present).
8. Prevents contamination of sterile items in the kit.
9. Maintains sterility of the supplies in the kit.
10. Provides a sterile area in which to work. Prevents contamination of your sterile gloves.

(continues)

PROCEDURE 32-1

Performing Tracheostomy Care (continued)

Action

11. Designate one hand as *sterile* (able to touch only sterile items) and the other as *clean* (able to touch only nonsterile items).
12. *Using your clean hand*, open the bottles of sterile saline and peroxide, laying the caps outside of the sterile field. Pour about 100 ml of saline into one sterile container and about 100 ml of hydrogen peroxide into the other container. Set the bottles down outside of the sterile field.
13. *Using your sterile hand*, pick up a sterile cotton swab and saturate the tip with hydrogen peroxide. Swab the peristomal skin, including the area under the tracheostomy tube's faceplate. If you must touch the tracheostomy tube or the client, do so with your *clean* hand (Figure 32-20).

Figure 32-20 Clean stoma under faceplate.

14. *Using your clean hand*, gently loosen the inner cannula of the tracheostomy tube by twisting the outer ring counterclockwise; then withdraw the inner cannula in a smooth motion. Place the inner cannula into the basin of peroxide.
15. *Using your sterile hand*, pick up the cannula. Using your clean hand, pick up the nylon brush and scrub to remove any visible crusts or secretions from inside and outside the cannula (Figure 32-21).
16. Place the cannula into the container of sterile saline. Agitate so that all surfaces are bathed in saline.
17. Inspect the inner cannula again to be sure it is clean; then remove excess saline from the lumen by tapping the cannula against a sterile surface.

Rationale

11. Usually, the dominant hand is the sterile hand, while the nondominant hand is clean. This system prevents contamination of sterile supplies while allowing you to handle unsterile items.
12. These solutions will be used to clean the tracheostomy tube's inner cannula. Since the bottles and caps are unsterile, they should not be placed in the sterile field.
13. This action removes exudate and other material from the skin to maintain skin integrity.
14. Minimizes trauma to the client's tracheal tissues and reduces reflexive coughing. The hydrogen peroxide serves to dissolve crusted secretions. *Note:* Some tracheostomy tubes use disposable inner cannulae that would be replaced at this point in the procedure. If replacing a disposable inner cannula, skip to step 18.
15. Any secretions retained on the inner cannula may be aspirated into the client's lungs, causing infection and possible airway obstruction. In some cases, the pipe cleaners may be needed to gain access to the inner surface of the cannula.
16. Rinses the peroxide off of the cannula before it is returned to the client.
17. Fluid trapped in the lumen of the cannula can be aspirated by the client.

(continues)

PROCEDURE 32-1

Performing Tracheostomy Care (continued)

Action

Figure 32-21 Clean lumen and inner cannula.

Rationale

- | | |
|--|--|
| <p>18. Gently replace the inner cannula, following the curve of the tube. When fully inserted, lock the inner cannula in place by rotating the external ring clockwise until it clicks into place.</p> <p>19. Place a new precut sterile gauze dressing around the stoma, between the faceplate and the skin.</p> <p>20. Inspect the ties or strap securing the faceplate. If damp or soiled, carefully cut the ties (or loosen the Velcro to remove a strap). Remove the ties or strap and inspect the underlying skin for redness or breakdown.</p> <p>21. To replace ties (Figure 32-22), cut a length of twill tape about as long as the circumference of the client's neck. Fold over one end to 1 inch and cut a small ($\frac{1}{2}$ inch) slit into the folded end.</p> | <p>18. Minimizes tissue trauma and unintentional displacement.</p> <p>19. Protects the skin from irritation and breakdown due to friction with the faceplate and absorbs exudate if present. Using <i>precut</i> gauze dressings is important because cutting a regular 4×4 gauze will create loose fibers that may be inhaled by the client.</p> <p>20. Ties or straps that are wet contribute to skin breakdown and infection. <i>Note:</i> Tracheostomy ties should not be removed or changed for the first 24 hours after tracheostomy tube insertion to prevent dislodgement of the tube and bleeding from the stoma.</p> <p>21. Creates a slit through which the end of the tie can be threaded and secured.</p> |
|--|--|

Figure 32-22 Change tracheostomy ties.

(continues)

PROCEDURE 32-1

Performing Tracheostomy Care (continued)

Action	Rationale
22. Thread the slit end of the tape through the eye of one side of the tracheostomy faceplate from the underside of the faceplate. Thread the end of the tie through the cut slit and secure it with a knot.	22. Creates a secure knot that can be easily cut when the tape needs to be removed and changed.
23. Slip the tape under the client's neck, keeping it smooth and flat against the skin.	23. Prevents excessive looseness or bunching of the tape.
24. Bring the loose end of the tape around to the other side of the faceplate. Ask the client to flex his or her neck and slip one of your fingers under the tape as you measure the desired tightness of the tie.	24. Flexion of the neck simulates the increase in neck circumference that occurs with coughing. The tape should be secure but not tight. <i>Caution: clients who have had neck surgery or injury should be monitored frequently for tightening of the tape due to neck swelling.</i>
25. Fold the end of the tape and cut a slit as in step 21, then tie the end as in step 22. Trim off excess tape from the end and knot the cut ends of the tape.	25. Prevents fraying of tape ends.
26. To replace a Velcro™ strap: Place new strap behind client's neck and thread ends through faceplate eyelets. Adjust tightness as above and secure Velcro™.	26. Velcro™ straps may be more comfortable for some clients and are easier to adjust for proper fit.
27. Reconnect the patient to oxygen and reposition for comfort.	27. Restores supplemental oxygen and humidification to the patient. <i>Note:</i> Some clients may not tolerate removal from supplemental oxygen during the entire tracheostomy care procedure. In this case, an assistant may be needed to intermittently replace and remove oxygen throughout the procedure. Always work quickly, and continuously assess your client's response to the procedure.
28. Discard soiled items in the appropriate container. Remove and discard soiled gloves. Wash hands.	28. Prevents cross-contamination.
29. Document the procedure, noting the appearance of the stomal site and any exudate.	29. Increasing exudate or a change in its color or character may indicate infection.

especially important when an endotracheal tube or tracheostomy tube is present because coughing is significantly impaired by these devices.

Nasotracheal suctioning involves passing a suction catheter or nasal trumpet through the nare, down the pharynx, through the larynx, and into the trachea. See Procedures 32-2 and 32-3 regarding suctioning. Once

the tip is in the trachea, a strong cough reflex will often be elicited. At this time suction is applied to the catheter and it is withdrawn while a twisting motion is applied to the catheter.

Endotracheal suctioning involves passing the suction catheter through the endotracheal tube or tracheostomy into the trachea and applying suction as the

PROCEDURE 32-2

Performing Nasopharyngeal and Oropharyngeal Suctioning

Equipment

- Suction source (wall suction regulator with collection bottle or portable suction machine)
- Sterile suction kit (contains suction catheter, sterile gloves, sterile solution container; may contain a small container of sterile normal saline)
- Sterile water-soluble lubricant
- Extension tubing connected to suction device
- Small bottle of sterile water or normal saline if not included in kit
- Personal protective devices: gown, mask and goggles or face shield if splattering is likely (e.g., a client with a vigorous productive cough)

Action

1. Assess the client's need for suctioning: inability to effectively clear the airway by coughing and expectoration; coarse bubbling or gurgling noises with respiration.
2. Choose the most appropriate route (nasopharyngeal or oropharyngeal) for your client. If nasopharyngeal approach is considered, inspect the nares with a penlight to determine patency. Alternatively, you may assess patency by occluding each nare in turn with finger pressure while asking the client to breathe through the remaining nare.
3. Explain the procedure to the client. Advise that suctioning may cause coughing or gagging but emphasize the importance of clearing the airway.
4. Wash your hands.
5. Position the client in a high Fowler's or semi-Fowler's position.
6. If the client is unconscious or otherwise unable to protect his or her airway, place in a side-lying position.
7. Connect extension tubing to suction device if not already in place, and adjust suction control to between 110 and 120 mm Hg.
8. Put on gown and mask and goggles or face shield if indicated.
9. Using sterile technique (Figure 32-23), open the suction kit. Consider the inside wrapper of the kit to be sterile, and spread the wrapper out carefully to create a small sterile field.
10. Open a packet of sterile water-soluble lubricant and squeeze out the contents of the packet onto the sterile field.

Rationale

1. Suctioning is an uncomfortable and traumatic procedure and should be used only when needed.
2. The oropharyngeal approach is easier but requires that the client cooperate; it may also produce gagging more readily in some persons. The nasopharyngeal route is more effective for reaching the posterior oropharynx but is contraindicated in clients with a deviated nasal septum, nasal polyps, or any tendency toward excessive bleeding (low platelet count, use of anticoagulants, recent history of epistaxis or nasal trauma).
3. Promotes cooperation and reduces anxiety.
4. Reduces the transmission of pathogens.
5. Maximizes lung expansion and effective coughing.
6. Protects the client from aspiration in the event of vomiting.
7. Excessive negative pressure can cause tissue trauma, whereas insufficient pressure will be ineffective.
8. Protects you from splattering with body fluids.
9. Produces an area in which to place sterile items without contaminating them.
10. Lubricant will be used to further lubricate the catheter tip if the nasopharyngeal route is used.

(continues)

PROCEDURE 32-2

Performing Nasopharyngeal and Oropharyngeal Suctioning (continued)

Action

Figure 32-23 Sterile Technique

Rationale

- | | |
|--|--|
| <ol style="list-style-type: none"> 11. If sterile solution (water or saline) is not included in the kit, pour about 100 ml of solution into the sterile container provided in the kit. 12. Carefully lift the wrapped gloves from the kit without touching the inside of the kit or the gloves themselves. Lay the wrapped gloves down next to the suction kit, and open the wrapper. Put on the gloves using sterile gloving technique (see Procedure 31-4). 13. If a cup of sterile solution is included in the suction kit, open it. 14. Designate one hand as <i>sterile</i> (able to touch only sterile items) and the other as <i>clean</i> (able to touch only nonsterile items). 15. <i>Using your sterile hand</i>, pick up the suction catheter. Grasp the plastic connector end between your thumb and forefinger and coil the tip around your remaining fingers. 16. Pick up the extension tubing <i>with your clean hand</i>. Connect the suction catheter to the extension tubing, taking care not to contaminate the catheter (Figure 32-24). 17. Position your clean hand with the thumb over the catheter's suction port. 18. Dip the catheter tip into the sterile solution, and activate the suction. Observe as the solution is drawn into the catheter. | <ol style="list-style-type: none"> 11. This solution will be used to lubricate the catheter and to rinse the inside of the catheter to clear secretions. 12. The gloves should be kept sterile for handling the sterile suction catheter to avoid introducing pathogens into the client's airway. 13. This solution will be used to lubricate the catheter and to rinse the inside of the catheter to clear secretions. 14. Usually, the dominant hand is the sterile hand, while the nondominant hand is clean. This prevents contamination of sterile supplies while allowing you to handle unsterile items. 15. Prevents accidental contamination of the catheter tip. 16. The extension tubing is not sterile. 17. Suction is activated by occluding this port with the thumb. Releasing the port deactivates the suction. 18. Tests the suction device as well as lubricates the interior of the catheter to enhance clearance of secretions. |
|--|--|

(continues)

PROCEDURE 32-2

Performing Nasopharyngeal and Oropharyngeal Suctioning (continued)

Action

Figure 32-24 Attach catheter to tubing.

19. For oropharyngeal suctioning, ask the client to open his or her mouth. Without activating the suction, gently insert the catheter and advance it until you reach the pool of secretions or until the client coughs.
20. For nasopharyngeal suctioning, estimate the distance from the tip of the client's nose to the earlobe and grasp the catheter between your thumb and forefinger at a point equal to this distance from the catheter's tip.
21. Dip the tip of the suction catheter into the water-soluble lubricant to coat catheter tip liberally.
22. Insert the catheter tip into the nare with the suction control port uncovered. Advance the catheter gently with a slight downward slant. Slight rotation of the catheter may be used to ease insertion. Advance the catheter to the point marked by your thumb and forefinger (Figure 32-25).

Figure 32-25 Insert catheter into nostril.

Rationale

19. To minimize trauma, do not apply suction while the catheter is being advanced.
20. Ensures placement of the catheter tip in the oropharynx and not in the trachea.
21. Promotes the client's comfort and minimizes trauma to nasal mucosa.
22. Guides the catheter toward the posterior oropharynx along the floor of the nasal cavity.

(continues)

PROCEDURE 32-2

Performing Nasopharyngeal and Oropharyngeal Suctioning (continued)

<i>Action</i>	<i>Rationale</i>
23. If resistance is met, <i>do not force the catheter</i> . Withdraw it and attempt insertion via the opposite nare.	23. Forceful insertion may cause tissue damage and bleeding.
24. Apply suction intermittently by occluding the suction control port with your thumb; at the same time, slowly rotate the catheter by rolling it between your thumb and fingers while slowly withdrawing it. Apply suction for no longer than 15 seconds at a time.	24. Prolonged suction applied to a single area of tissue can cause tissue damage.
25. Repeat step 24 until all secretions have been cleared, allowing brief rest periods between suctioning episodes.	25. Promotes complete clearance of the airway.
26. Withdraw the catheter by looping it around your fingers as you pull it out.	26. Allows you to maintain control over the catheter tip as it is withdrawn.
27. Dip the catheter tip into the sterile solution and apply suction.	27. Clears the extension tubing of secretions that would promote bacterial growth.
28. Disconnect the catheter from the extension tubing. Holding the coiled catheter in your gloved hand, remove the glove by pulling it over the catheter. Discard catheter and gloves in an appropriate container.	28. Contains the catheter and secretions in the glove for disposal.
29. Discard remaining supplies in the appropriate container.	29. Follow institutional policy regarding the disposal of patient care supplies.
30. Wash your hands.	30. Prevents the transmission of pathogens.
31. Provide the client with oral hygiene if indicated or desired.	31. Suctioning and coughing may produce an unpleasant taste.
32. Document the procedure, noting the amount, color, and odor of secretions and the client's response to the procedure.	32. Changes in the amount, color, or odor of pulmonary secretions may indicate infection.

catheter is withdrawn. In both types of suctioning procedures, the guidelines listed in the Nursing Tip on page 897 should be followed.

Interventions to Improve Breathing Patterns

Properly Position Client

Client positioning to improve breathing patterns may begin by taking cues from the client. If the client finds that breathing is easier in an upright or sitting position, you should allow that position to be maintained. Supporting the client with elevation of the head of the bed or with pillows can reduce the

client's workload and minimize fatigue. Maintaining proper body alignment and preventing slouching or slumping in the bed increase the efficiency of ventilatory efforts.

As previously stated, clients with obstructive respiratory disease may find that leaning forward, with the clavicles elevated, is most comfortable. Providing an

NURSING ALERT

Safety

Clients with oxygenation impairment may be confused or agitated, making safety a vital concern of the nurse.

PROCEDURE 32-3

Performing Tracheostomy Suctioning

Equipment

- Suction source (wall suction regulator with collection bottle or portable suction machine)
- Sterile suction kit (contains suction catheter, sterile gloves, sterile solution container; may contain a small container of sterile normal saline)
- Extension tubing connected to suction device
- Small bottle of sterile water or normal saline if not included in kit
- Personal protective devices: gown, mask and goggles or face shield

Action

1. Assess the client's need for suctioning: inability to effectively clear the airway by coughing and expectoration; coarse rales auscultated over the upper airways.
2. Explain the procedure to the client. Advise that suctioning may cause coughing; emphasize the importance of clearing the airway.
3. Wash your hands.
4. Position the client in a high Fowler's or semi-Fowler's position.
5. Connect extension tubing to suction device if not already in place, and adjust suction control to between 80 and 100 mm Hg.
6. Put on gown and mask and goggles or face shield if indicated.
7. Using sterile technique (see Figure 32-23), open the suction kit. Consider the inside wrapper of the kit to be sterile, and spread the wrapper out carefully to create a small sterile field.
8. If sterile solution (water or saline) is not included in the kit, pour about 100 ml of solution into the sterile container provided in the kit.
9. Carefully lift the wrapped gloves from the kit without touching the inside of the kit or the gloves themselves. Lay the wrapped gloves down next to the suction kit, and open the wrapper. Put on the gloves using sterile gloving technique.
10. If a cup of sterile solution is included in the suction kit, open it.
11. Designate one hand as *sterile* (able to touch only sterile items) and the other as *clean* (able to touch only nonsterile items).

Rationale

1. Suctioning is an uncomfortable and traumatic procedure and should be used only when needed.
2. Promotes cooperation and reduces anxiety.
3. Reduces the transmission of pathogens.
4. Maximizes lung expansion and effective coughing.
5. Excessive negative pressure can cause tissue trauma, hypoxemia, and atelectasis, whereas insufficient pressure will be ineffective.
6. Protects you from splattering with body fluids.
7. Produces an area in which to place sterile items without contaminating them.
8. This solution will be used to lubricate the catheter and to rinse the inside of the catheter to clear secretions.
9. The gloves should be kept sterile for handling the sterile suction catheter to avoid introducing pathogens into the client's airway.
10. This solution will be used to lubricate the catheter and to rinse the inside of the catheter to clear secretions.
11. Usually, the dominant hand is the sterile hand, while the nondominant hand is clean. Prevents contamination of sterile supplies while allowing you to handle unsterile items.

(continues)

PROCEDURE 32-3

Performing Tracheostomy Suctioning (continued)

Action	Rationale
12. Using your sterile hand, pick up the suction catheter. Grasp the plastic connector end between your thumb and forefinger and coil the tip around your remaining fingers.	12. Prevents accidental contamination of the catheter tip.
13. Pick up the extension tubing with your clean hand. Connect the suction catheter to the extension tubing, taking care not to contaminate the catheter (see Figure 32-24).	13. The extension tubing is not sterile.
14. Instruct the patient to take several slow, deep breaths.	14. Promotes optimal opening of airways and reduces suction-induced hypoxemia. <i>Note:</i> Clients who are especially prone to suction-induced hypoxemia may be preoxygenated by taking several deep breaths with supplemental oxygen set at 100% or by delivery of 100% oxygen via manual resuscitation bag. Always return oxygen flow to the prescribed rate after the suctioning procedure is completed.
15. Using your clean hand, remove the oxygen delivery device from the tracheostomy tube and place it on a clean surface.	15. Permits access to the tracheostomy tube. Placing the oxygen device on a clean surface reduces contamination (the sterile glove wrapper may be used for this purpose).
16. Position your clean hand with the thumb over the catheter's suction port.	16. Suction is activated by occluding this port with the thumb. Releasing the port deactivates the suction.
17. Dip the catheter tip into the sterile solution, and activate the suction. Observe as the solution is drawn into the catheter.	17. Tests the suction device as well as lubricating the interior of the catheter to enhance clearance of secretions.
18. Without occluding the suction control port, insert the catheter tip into the tracheostomy tube and advance it until the patient coughs (Figure 32-26).	18. To minimize trauma, do not apply suction while the catheter is being advanced.

Figure 32-26 Suction tracheostomy.

(continues)

PROCEDURE 32-3

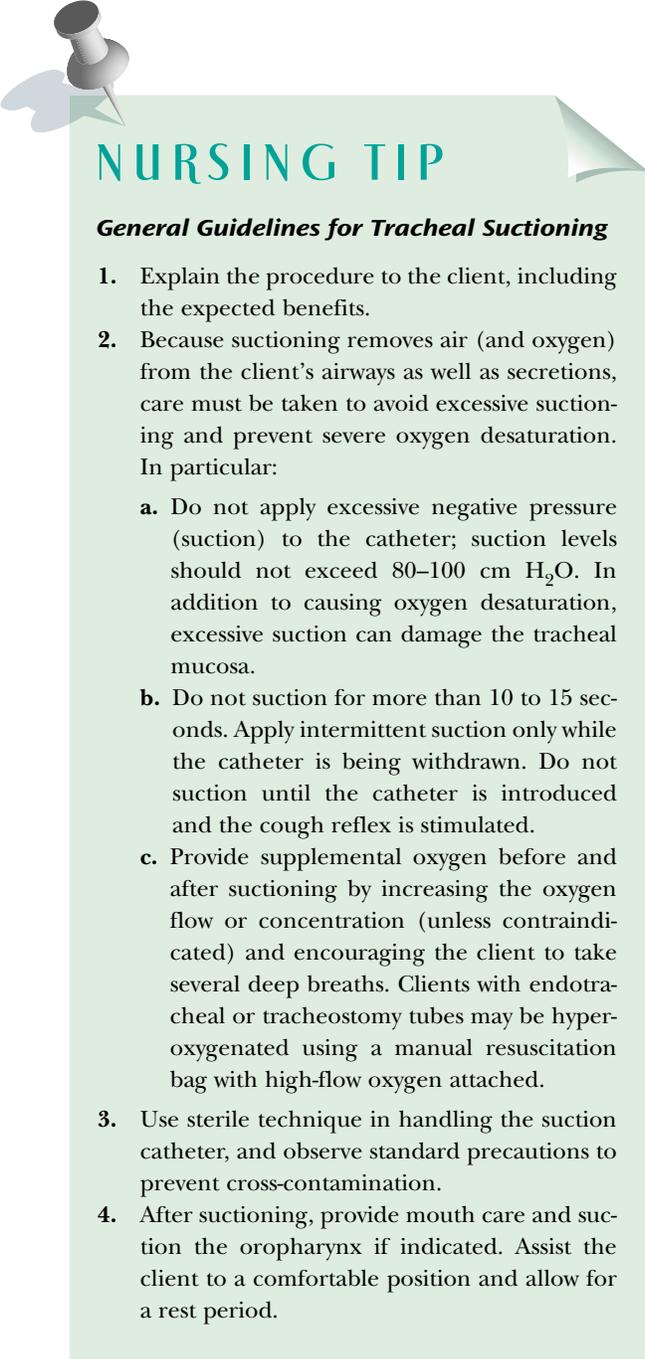

Performing Tracheostomy Suctioning (continued)

Action	Rationale
19. If extremely strong coughing occurs, withdraw the catheter slightly.	19. The tracheal tissue at the point of bifurcation (the <i>carina</i>) is extremely sensitive to touch and produces a vigorous cough.
20. Apply suction intermittently by occluding the suction control port with your thumb; at the same time, slowly rotate the catheter by rolling it between your thumb and fingers while slowly withdrawing it. Apply suction for no longer than 15 seconds at a time.	20. Prolonged suction can cause tissue damage, atelectasis, and hypoxemia.
21. Repeat step 20 until all secretions have been cleared, allowing brief rest periods between suctioning episodes. Encourage client to breathe deeply between suctioning episodes.	21. Promotes complete clearance of the airway.
22. Withdraw the catheter by looping it around your fingers as you pull it out.	22. Allows you to maintain control over the catheter tip as it is withdrawn.
23. Ask the client to open his or her mouth. Insert the catheter and advance it along the oropharynx until resistance is felt. Apply suction and slowly withdraw the catheter.	23. Removes pooled secretions above the cuff of the tracheostomy, which may provide a source of infection if aspirated. <i>Note:</i> At this point the catheter is contaminated. If another suctioning pass into the tracheostomy is needed, a new sterile catheter must be used.
24. Dip the catheter tip into the sterile solution and apply suction.	24. Clears the extension tubing of secretions, which would promote bacterial growth.
25. Disconnect the catheter from the extension tubing. Holding the coiled catheter in your gloved hand, remove the glove by pulling it over the catheter. Discard catheter and gloves in an appropriate container.	25. Contains the catheter and secretions in the glove for disposal.
26. Reapply oxygen delivery device.	26. Restores supplemental oxygen and humidification.
27. Discard remaining supplies in the appropriate container.	27. Follow institutional policy regarding the disposal of patient care supplies.
28. Wash your hands.	28. Prevents the transmission of pathogens.
29. Provide the client with oral hygiene if indicated/desired.	29. Suctioning and coughing may produce an unpleasant taste.
30. Document the procedure, noting the amount, color, and odor of secretions and the client's response to the procedure.	30. Changes in the amount, color, or odor of pulmonary secretions may indicate infection

overbed table for the client on which to rest his or her elbows may facilitate this position, *provided the wheels are locked or removed to prevent the table from rolling away and placing the client at risk for a fall.*

Teach Controlled Breathing Exercises

Controlled breathing exercises may also improve breathing efficiency for the client with obstructive respiratory disease. One technique that is especially useful is *pursed-lip breathing*. This technique involves forced exhalation against pursed (partially closed) lips, which

NURSING TIP

General Guidelines for Tracheal Suctioning

1. Explain the procedure to the client, including the expected benefits.
2. Because suctioning removes air (and oxygen) from the client's airways as well as secretions, care must be taken to avoid excessive suctioning and prevent severe oxygen desaturation. In particular:
 - a. Do not apply excessive negative pressure (suction) to the catheter; suction levels should not exceed 80–100 cm H₂O. In addition to causing oxygen desaturation, excessive suction can damage the tracheal mucosa.
 - b. Do not suction for more than 10 to 15 seconds. Apply intermittent suction only while the catheter is being withdrawn. Do not suction until the catheter is introduced and the cough reflex is stimulated.
 - c. Provide supplemental oxygen before and after suctioning by increasing the oxygen flow or concentration (unless contraindicated) and encouraging the client to take several deep breaths. Clients with endotracheal or tracheostomy tubes may be hyperoxygenated using a manual resuscitation bag with high-flow oxygen attached.
3. Use sterile technique in handling the suction catheter, and observe standard precautions to prevent cross-contamination.
4. After suctioning, provide mouth care and suction the oropharynx if indicated. Assist the client to a comfortable position and allow for a rest period.

maintains positive pressure in the lungs during the expiratory phase and prevents collapse of the smaller airways. This in turn reduces the amount of air trapping characteristic of obstructive disease.

Deep-breathing exercises encourage the client to take slow, deep breaths instead of the rapid, shallow breathing pattern that may be present in restrictive lung disease and in those who are anxious. Abdominal breathing involves the use of the abdominal muscles to pull the diaphragm downward. Placing your hand on the client's abdomen and instructing the client to watch it rise give a visual aid to teaching the technique.

Apical and basal expansion exercises direct the client to focus on achieving maximal expansion of the upper lung

lobes (apices) and lower lobes (bases), respectively. To perform these techniques, place your hands flat against the chest wall just below the clavicles for apical exercises or over the lower ribs along the midaxillary lines for basal exercise and apply gentle pressure. Instruct the client to push your hands away with the chest wall by breathing. These exercise should be repeated several times a day.

Incentive spirometry is another technique used to encourage deep breathing. The client draws air through the spirometry device, which measures the volume of air displaced by moving a float ball or similar device up a column. Goals (incentives) can be marked on the spirometer and the client can compare his or her progress, with the desired goal. Incentive spirometry is often performed in the care of postoperative clients and is usually done every 1 to 2 hours while awake.

Deep breathing may also be augmented using intermittent positive-pressure breathing (IPPB). An IPPB machine delivers a volume of air under pressure through a mouthpiece when the client draws air through the mouthpiece. IPPB requires the client's cooperation, so preparatory teaching is essential. IPPB may include the administration of aerosolized medications and may be followed by coughing exercise, CPT, and postural drainage.

Introduce Chest Drainage Systems

Chest drainage systems (chest tubes) improve breathing patterns by removing accumulations of air and/or fluid from the pleural space, permitting the lungs to return to normal expansion. The tubes are inserted through the chest wall via a stab wound; multiple holes in the tip of the tube collect drainage from the pleural space. This drainage is then collected into a drainage system by either suction control or gravity. A special feature called a water seal prevents the reintroduction of air into the pleural space through the chest tube.

Interventions to Improve Oxygen Uptake and Delivery

Administer Oxygen

Oxygen uptake in the pulmonary capillary beds can be improved by increasing the concentration of oxygen in the alveolar air; this increase in the partial pressure of oxygen in the alveoli (PaO₂) increases the driving pressure for gas diffusion across the alveolar-capillary membrane.

The percentage of oxygen in the inspired air is referred to as the fraction of inspired oxygen, or FiO₂, expressed as a percentage; normal atmospheric air has an FiO₂ of 21%. Supplemental oxygen delivery systems are capable of increasing the FiO₂ to anywhere from 24% to nearly 100% oxygen (Figures 32-27 and 32-28). See Procedure 32-4.

Oxygen administration, like the administration of any drug, is not without hazards. Clients who have chronic pulmonary disease associated with carbon dioxide retention (**hypercapnia**) may become insensitive to carbon dioxide levels to drive their respiratory rate. Instead,

Figure 32-27 Oxygen Delivery Systems: A. Nasal cannula; B. Single face mask; C. Open face tent; D. Reservoir mask; E. Venturi mask.

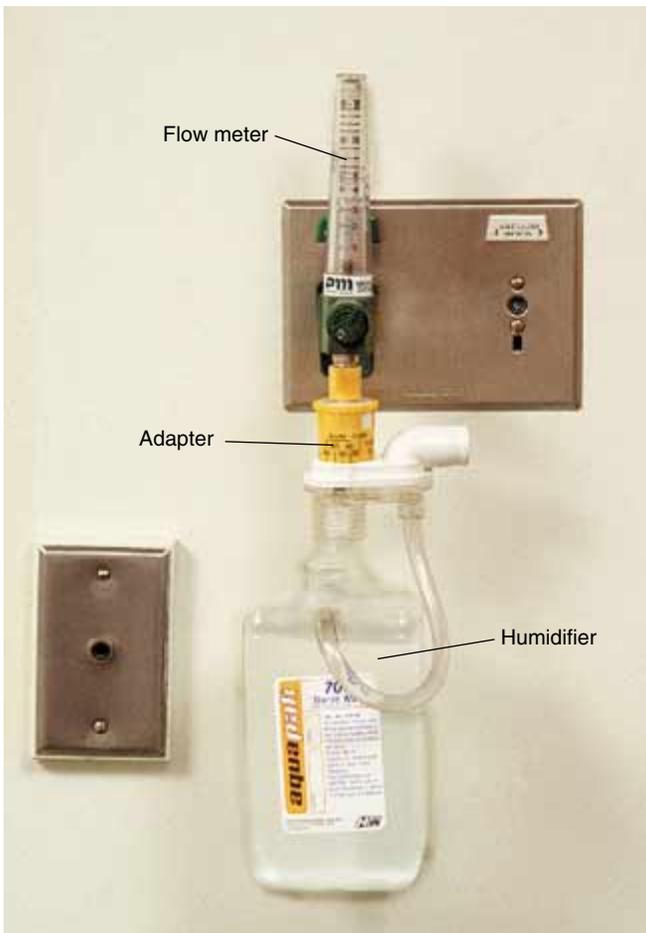

Figure 32-28 Oxygen Flowmeter Attached to Wall

these clients may depend upon a chronic low oxygen level in the blood (hypoxemia) to stimulate their respiratory drive. While low-flow oxygen may be beneficial to these clients, excessive oxygen administration may obliterate that hypoxic drive, resulting in apnea.

Another possible hazard of oxygen administration is oxygen toxicity. Prolonged administration of high FiO_2 (greater than 50% for more than 24 hours) may actually damage lung tissue and produce severe respiratory difficulties. The mechanisms by which oxygen toxicity occurs are twofold. First, it should be understood that 78% of the inspired air consists of the gas nitrogen. Although nitrogen is (under normal conditions) physiologically inert, it does serve an important function in the lung: it keeps the alveoli open simply by occupying space. High concentrations of oxygen displace nitrogen from the alveoli; as this oxygen is absorbed by the alveolar capillary blood, the volume of gas in the alveolar space is reduced and the alveoli collapse. Once the alveoli have collapsed (atelectasis), no airflow occurs and the work of breathing increases dramatically.

Second, oxygen in high concentrations is toxic to the type II alveolar cells, which are responsible for the production of **surfactant**. Surfactant is a substance that assists in keeping the alveoli open by reducing the alveolar surface tension (the tendency of the alveolar walls to collapse upon themselves). Atelectasis results when surfactant is insufficient.

Widespread atelectasis due to oxygen toxicity may result in a syndrome known as the adult respiratory distress syndrome (ARDS), which is characterized by diffuse pulmonary edema, severe stiffness of the lung tissue, and profound hypoxemia.

PROCEDURE 32-4

Administering Oxygen

Equipment

- Oxygen source (wall outlet or tank)
- Humidifier bottle, if used
- Nasal cannula and tubing

- Oxygen regulator or flowmeter
- Nipple adapter for flowmeter, if humidification is not used

Action

1. Verify written order for oxygen therapy, including methods of delivery and flow rate.
2. Wash hands.
3. Explain procedure to client. If oxygen is being given in a facility where smoking is permitted, instruct the patient and any other persons in the room to refrain from smoking or lighting matches while oxygen is in use. Check that all electrical equipment in use in the room has been inspected for electrical safety. Post appropriate signs in the room and on the door.
4. Assess the client for obstruction of the nasal passages by observing of breathing patterns and, if indicated, inspecting of nasal passages with a pen light. Notify physician if significant obstruction is present.
5. If using a wall outlet as oxygen source, plug flowmeter into outlet by pushing until it snaps into place. If a lock-release button is present, depress it as you insert the flowmeter.
6. If a tank is used as the oxygen source, the flowmeter should already be attached.
7. If humidification is used, remove the cover from the humidifier bottle to expose the adapter that connects the bottle to the flowmeter. Attach the bottle to the flowmeter by screwing the plastic nut on the adapter to the threaded outlet of the flowmeter.
8. If no humidification is used, attach the nipple adapter to the flowmeter by screwing it onto the threaded outlet of the flowmeter.
9. Attach oxygen tubing to the port on the humidifier bottle or the pointed end of the nipple adapter. Turn on oxygen flow by turning the thumbscrew (wall outlet) or knob (tank).

Rationale

1. Oxygen is a drug, and its use must be ordered by a physician. Oxygen delivered by nasal cannula is prescribed in flow rates expressed as liters per minute (L/min).
2. Prevents transmission of pathogens.
3. Explanation reduces anxiety. Oxygen, while not itself flammable, makes fires burn more readily than they otherwise would, so strict fire safety must be observed. Faulty electrical equipment may produce sparks that could ignite materials nearby.
4. If nasal passages are obstructed, oxygen delivery by nasal cannula will be ineffective and another route should be chosen.
5. Wall outlets are sealed by heavy steel valves that prevent the escape of oxygen from the system. If you hear hissing from the valve, the flowmeter is not fully engaged.
6. Special tools are used to attach valves to oxygen tanks.
7. If long-term oxygen therapy is anticipated, if flow is 6 L/min or higher, or if drying of the respiratory mucosa and/or thick secretions are present, humidification of oxygen is indicated. Short-term and/or low-flow oxygen use, such as during a medical procedure, may not require humidification.
8. This adapter allows the oxygen tubing to be connected directly to the flowmeter.
9. Establishes proper functioning of equipment. If humidifier bottle is used, bubbling of oxygen through the bottle will be noted. In addition, verify flow by feeling for the flow of air from the cannula's nasal prongs.

(continues)

PROCEDURE 32-4

Administering Oxygen (continued)

Action

10. Adjust flow rate to the prescribed amount.
11. Gently position nasal prongs into client's nares, with curves of prongs pointing toward the floor of the nostrils (Figure 32-29).

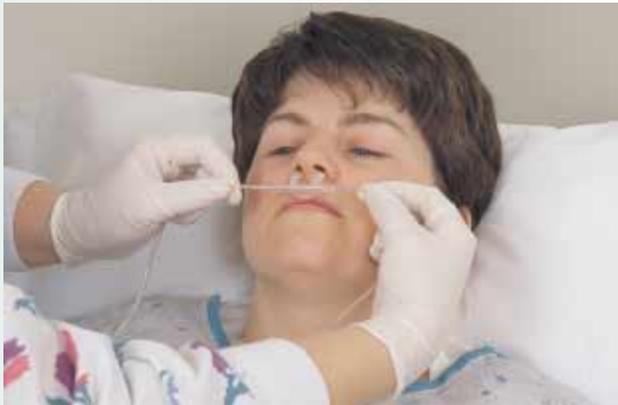

Figure 32-29 Insert cannula prong into nostrils.

12. Loop the cannula tubing over the client's ears; adjust the fit of the tubing by sliding the adjuster upward to hold the cannula in place (Figure 32-30).

Figure 32-30 Adjust tubing.

13. Assess the client's nares, face, and ears every 4 hours for signs of skin irritation or breakdown and document your findings. At the same time, inspect the nasal prongs for the presence of nasal secretions or crusts. If needed, wipe the prongs clean with a gauze pad.

Rationale

10. As for any drug, correct dosing of oxygen is essential. Both insufficient and excessive amounts can be harmful to the client.
11. Directs the flow of oxygen into the nasal cavity, where it will mix with inspired room air.

12. The fit of the cannula should be secure but not tight. A too-tight fit is uncomfortable, may cause skin breakdown (especially above the ears), and can occlude oxygen flow.

13. Pressure from the tubing or cannula may cause skin breakdown. Accumulated secretions can impair the flow of oxygen.

APPLICATION: HOME SETTING

Oxygen increases the risk of fire. Although oxygen itself is not a flammable gas, it is a necessary catalyst for fire to occur. The presence of any fuel (bed linens, paper) along with any source of ignition (a lighted cigarette, an electrical spark) will lead to fire more rapidly, and the fire will burn more vigorously, in an oxygen-rich environment. Instruct clients on oxygen administration to caution all family members and visitors to the home to avoid lighting matches, cigarettes, or any other substances in the presence of the oxygenation equipment. Also advise clients receiving therapy in the home to inspect all electrical equipment prior to use.

Administer Blood Components

Blood component administration is indicated when the client's oxygenation is impaired because of decreased circulating blood volume, decreased hemoglobin concentration in the blood (anemia), or hemorrhage. Red blood cells, plasma, clotting factors, proteins, or whole blood may be administered. Since a blood transfusion is really a type of tissue transplant, extreme care must be taken to decrease the possibility of an immune system rejection response known as a transfusion reaction.

NURSING ALERT**Blood Administration**

To minimize the risk of a serious transfusion reaction when administering blood components, be sure to:

- Follow institutional policy regarding client identification for each transfusion.
- Assess and record client vital signs (temperature, pulse, blood pressure, respirations) before initiating the transfusion and within 1 hour of completing the transfusion.
- Instruct the client to report any unusual feelings, including flushing, itching, headache, or back pain.
- Reassess vital signs after the first 10 to 15 minutes of slowly infusing the blood component. Stop the transfusion immediately if fever, tachycardia, hypotension, dyspnea, or any reports of the above symptoms occur. Notify the client's physician and the blood bank for further instructions.

Interventions to Increase Cardiac Output and Tissue Perfusion

The client with impaired cardiac output and tissue perfusion is likely to be experiencing edema of the lower extremities and/or the lungs, fatigue, activity intoler-

ance related to poor tissue oxygenation, and possibly angina and/or intermittent claudication. Interventions are aimed at reducing symptom severity while optimizing cardiac performance.

Manage Fluid Balance

Management of fluid balance is a cornerstone in the care of the client with reduced cardiac output. If congestive heart failure is present, fluid intake may be restricted to prevent edema and circulatory overload. Often, sodium intake is also limited because sodium promotes fluid retention. Diuretics may also be given to increase fluid excretion by the kidneys.

Monitoring of fluid balance by the nurse may involve the measurement of fluid intake and output (I&O) and measurement of daily weights. I&O measurement involves teaching the client the importance of accounting for all intake and output and providing a container for the measurement of urine. Daily weights should be performed at the same time each day (usually early in the morning) with the same amount of clothing on, and on the same scale, to maximize accuracy.

Clients receiving diuretics may also require monitoring for electrolyte imbalances. Potassium, particularly, may become depleted in the client receiving loop diuretics such as furosemide. Encouraging the consumption of potassium-rich foods such as bananas, and perhaps potassium supplementation, is often required.

Suggest Activity Restrictions and Assistance with Activities of Daily Living

Activity restrictions and assistance with activities of daily living (ADL) should be based upon the client's activity tolerance. The purpose of activity assistance is to decrease the oxygen demands of the body. The client's activity tolerance may be gradually increased through a sequence of exercise protocols as part of a cardiac rehabilitation program. Such a program incorporates careful monitoring of the client as the exercise level increases over time.

Position Client Properly

Positioning of the client with decreased cardiac output is done to decrease the fluid load to the heart and to decrease the development of pulmonary edema. The venous system is able to pool blood when aided by gravity; this "venous capacitance" is increased when the client's head and upper body are elevated and the legs are in a dependent position. Although it is customary in the hospital environment to place clients in a supine position, this position may be detrimental for the client with congestive heart failure, as evidenced by worsening dyspnea, tachycardia and tachypnea, and decreased arterial oxygen saturation.

Administer Medications

Medications to improve cardiac output and perfusion include diuretics as mentioned above, cardiac glycosides, and other inotropic agents. Antihypertensives, nitrates, and vasodilators may also be given to increase cardiac oxygen supply and/or reduce the myocardium's demand for oxygen. Table 32-9 lists the drugs most commonly used.

Emergency Interventions

Complete airway obstruction, cardiac arrest, and respiratory arrest are emergency situations that will result in death if not immediately rectified. Nurses receive regular training in the basic life support techniques described below; hands-on practice is an essential component of that training, and this text is not intended to serve as a substitute.

Remove Airway Obstruction

Complete airway obstruction is often the result of aspiration of food or some other foreign object into the trachea. The presence of a complete airway obstruction is characterized by an inability to speak or cough; the victim may also raise his or her hands to the throat and will likely appear very

anxious. The rescuer should verify that obstruction is present by asking the victim, "Are you choking?"

Relief of the obstruction is attempted by way of the **Heimlich maneuver**, which is described in Procedure 32-5.

Initiate Cardiopulmonary Resuscitation

Cardiac and respiratory arrest require artificial support of circulation and ventilation if the victim is to survive. **Cardiopulmonary resuscitation (CPR)** is the accepted technique of basic life support, as described in Procedure 32-6.

The technique described above is used for adult victims; different techniques are applied for children and infants and can be learned through courses such as those offered by the American Heart Association or the American Red Cross.

Interventions to Address Associated Nursing Diagnoses

Explore Lifestyle and Activity Adaptations

Lifestyle and activity adaptations may be necessary for the client with chronic alterations in oxygenation.

TABLE 32-9
Medications Used to Improve Cardiac Function

Drug Type	Common Examples	Actions
Diuretic	Furosemide (Lasix) Bumetanide (Bumex) Hydrochlorothiazide (Hydro-diuril, HCTZ) Spironolactone (Aldactone)	Affects renal tubules, resulting in increased excretion of water and certain electrolytes Lowers blood pressure and decreases cardiac workload
Cardiac glycoside	Digoxin (Lanoxin)	Increases force of cardiac contraction and slows heart rate
Inotropic agent	Dobutamine (Dobutrex) Amrinone (Inocor) Dopamine (Intropin) Isoproterenol (Isuprel)	Increases force of cardiac contraction
Antihypertensive	ACE inhibitors (captopril, enalapril) Beta-adrenergic blockers (labetolol, propranolol, atenolol) Calcium channel blockers (nicardipine, diltiazem) Centrally acting alpha-adrenergics (clonidine, methyldopa) Ganglionic blockers (trimethaphan) Peripherally acting anti-adrenergics (guanethidine, prazosin) Vasodilators (minoxidil, hydralazine)	Lowers blood pressure by various mechanisms, decreasing the heart's workload
Nitrate	Nitroglycerin Isosorbide dinitrate (Isordil)	Dilates the coronary arteries and peripheral vessels, increasing cardiac oxygen supply while decreasing cardiac workload

PROCEDURE 32-5

Clearing an Obstructed Airway

Equipment

■ None required

Action

1. Recognize the signs of airway obstruction. In the conscious person, airway obstruction is signaled by the inability to cough, speak, or breathe and often occurs during eating. In the unconscious person, note the absence of respiratory movements and the absence of air movement. A partial obstruction, indicated by high-pitched noises while breathing, a weak ineffective cough, and cyanosis, should be treated as a complete obstruction.
2. If the victim is conscious, announce that you can help. Position yourself behind the victim and wrap your arms around the victim's waist.
3. Make a fist with one hand. Place the thumb side of the fist against the victim's abdomen just above the umbilicus and well below the xyphoid process. Grasp the fist with the other hand (Figure 32-31).

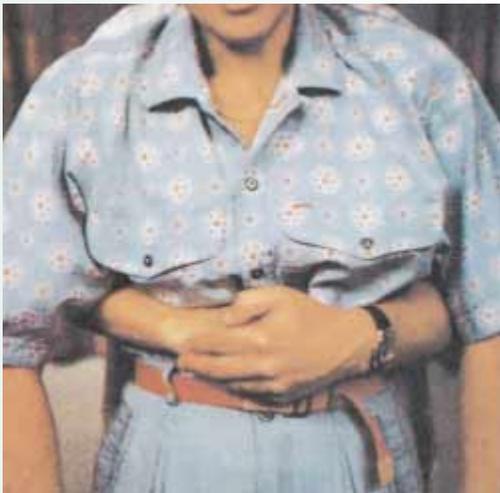

Figure 32-31 Placement of Fist into Abdomen

Rationale

1. Allows you to react quickly and effectively. If the person with a partial airway obstruction has an effective cough, you must observe closely for exacerbation. Prompt intervention is necessary if the person is unable to dislodge the obstruction.
2. A person who cannot breathe is likely to panic; announcing your intentions will elicit cooperation.
3. This position allows for rapid compressions of the diaphragm. Avoiding the xyphoid process (lowermost point of the sternum) reduces the risk of internal injury.
4. Press the fist into the victim's abdomen with quick, upward thrusts. Repeat thrusts until the object is expelled or the victim becomes unconscious.
5. If the victim become unconscious, lower him to the floor and call for help by activating the Emergency Medical System (EMS) if outside the
4. The thrusts should be of sufficient force to produce an artificial cough.
5. At this point Advanced Life Support equipment and personnel should be mobilized.

(continues)

PROCEDURE 32-5

Clearing an Obstructed Airway (continued)

Action

hospital or the internal emergency call system if inside the hospital.

6. Place the victim in a supine position. Kneel astride the victim with your body over the lower trunk or upper legs.
7. Place the heel of one hand on the victim's abdomen just above the umbilicus but well below the xyphoid process. Place the second hand on top of the first (Figure 32-32).

Figure 32-32 Placement of Hands on Abdomen for Unconscious Client

Rationale

6. This position allows you to apply abdominal thrusts to the unconscious victim.
7. This position allows for rapid compressions of the diaphragm. Avoiding the xyphoid process (lowermost point of the sternum) reduces the risk of internal injury. *Note:* If the rescuer is too short to reach around the victim from behind, this position may also be used for the conscious victim.

8. Press into the abdomen with quick, upward thrusts.
 9. If the victim is in the late stages of pregnancy or is markedly obese, the hand position may be changed. In this case, place the fist over the midportion of the sternum, avoiding the xyphoid process.
 10. After five abdominal thrusts in the unconscious victim, open the mouth and sweep with the index finger.
 11. Open the airway using the head tilt–chin lift method (see Procedure 32-6) and attempt to ventilate. If successful, proceed with cardiopulmonary resuscitation sequence. If unsuccessful, repeat steps 5 through 10 in sequence until successful.
8. The thrusts should be of sufficient force to produce an artificial cough.
 9. A very large abdomen will make effective abdominal thrusts impossible.
 10. Abdominal thrusts may have raised the foreign body up to a level where it can be removed manually.
 11. Until the obstruction is removed, no other resuscitation efforts will be successful.

PROCEDURE 32-6

Performing Adult Cardiopulmonary Resuscitation

Equipment

■ Backboard (optional)

■ Resuscitation mask or face shield (optional)

Action

1. Determine unresponsiveness in the victim by tapping or gently shaking and shouting, “Are you OK?”
2. If the victim is unresponsive, call out for help and activate the EMS if outside the hospital or the internal emergency paging system if inside the hospital.
3. Position the victim for CPR: Place supine on a firm surface. If in a bed, roll the victim onto his or her side and place firm backboard under the torso, then roll back into a supine position.
4. Open the victim’s airway using the head tilt–chin lift method (Figure 32-33). Once the airway is open, place your cheek very close to the victim’s mouth; look, listen, and feel for breathing.

Figure 32-33 Open airway by head tilt–chin lift.

Rationale

1. Quickly determines whether an emergency exists. *Note:* If the victim has sustained an injury to the head or neck, to avoid furthering a spinal cord injury, move the victim only if absolutely necessary.
2. Rapid initiation of Advanced Life Support techniques, particularly defibrillation, is associated with increased success of resuscitation.
3. Facilitates airway opening and chest compressions, and the firm surface increases the effectiveness of chest compressions.
4. Removal of the tongue from the posterior oropharynx may restore breathing in the unconscious adult victim. *Note:* If this maneuver restores breathing, place the victim in a side-lying position or continue to hold the airway open and monitor breathing until help arrives.
5. Minimizes neck movement but is more difficult to perform.
6. A mask or shield can be used to reduce the exposure of the rescuer to the oral secretions, blood, vomitus of the victim.
7. Slow breath delivery improves the distribution of air in the victim’s lungs and decreases the risk that air will enter the stomach. Uncovering
(continues)

PROCEDURE 32-6

Performing Adult Cardiopulmonary Resuscitation (continued)

Action

chest rise as the breath is given, and feel for exhalation after the breath is given.

8. Locate the carotid artery in the victim's neck (in the groove between the larynx and the large muscle of the neck). Palpate for at least 5 seconds to determine whether a pulse is present. If a pulse is present, continue to deliver breaths at a rate of 10 to 12 per minute, or a breath every 5 to 6 seconds.
9. If no pulse is present, begin chest compressions: Position yourself over the victim with your shoulders directly over the victim's chest (Figure 32-34). Place the heel of one hand over the lower half of the sternum, avoiding the xiphoid process. Place the second hand directly on top of the first, keeping the fingers up and off of the chest wall. Lock your elbows.

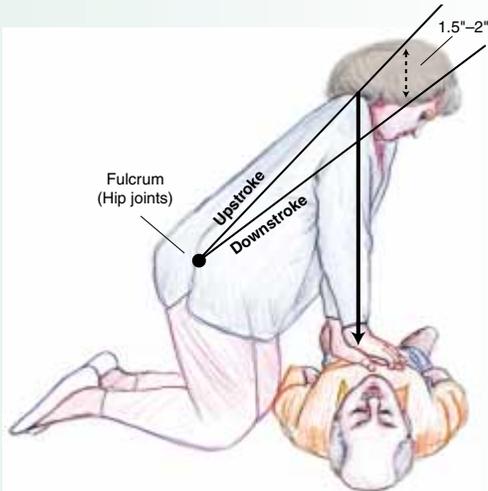

Figure 32-34 Proper Position of Rescuer

Rationale

mouth after breath delivery permits passive exhalation. Watching the chest rising and feeling exhalation verify successful delivery of breaths.

8. Too-rapid pulse assessment may cause the rescuer to miss a slow or weak pulse. If a pulse is present, chest compression should not be performed.
9. Correct hand position maximizes the effectiveness of compressions while minimizing the risk of injuries such as fractured ribs, pneumothorax, and lacerations of internal structures. Correct hand position may be achieved by running the middle finger along the bottom rib toward the sternum until the xiphoid process is felt. Place the opposite hand on the sternum two finger widths above this point.

10. Compress the sternum $1\frac{1}{2}$ to 2 inches; then release fully while maintaining correct hand position. Repeat the compression and release sequence 15 times at a rate equivalent to 80 to 100 compressions per minute.
11. After 15 chest compressions, return to the victim's head and open the airway as in step 4. Deliver two slow, full breaths as in steps 6 and 7. Repeat the sequence of 15 compressions to two breaths until help arrives or pulse and breathing are restored.
12. Reassess for the return of breathing and pulse every few minutes; then resume CPR.

10. Compression of the sternum forces blood to be ejected from the heart, mimicking normal ventricular systole. Release of the pressure moves blood into the heart, mimicking diastole.
11. Repeated cycles of breaths and compressions are necessary to deliver oxygenated blood to the vital organs.
12. In rare instances, breathing and circulation may be restored with CPR; in most circumstances, CPR sustains minimal tissue oxygenation until Advanced Life Support measures are available.

THINK ABOUT IT

Mouth-to-Mouth Breathing

In recent years, increased concern over the possibility of disease transmission during mouth-to-mouth breathing has led to the development of newer variations on this technique. Several styles of masks that fit over the victim's mouth and contain a one-way valve through which the rescuer breathes are available for both in-hospital and community use. Have you ever performed mouth-to-mouth breathing through one of these masks? Knowing that there is a possibility of disease transfer, would you be willing to administer mouth-to-mouth breathing without a mask?

Interventions related to lifestyle and activity have three general purposes:

- To minimize energy and oxygen consumption
- To reduce factors that contribute to the disease process
- To systematically increase activity tolerance

Measures to reduce energy and oxygen consumption are chosen after a careful assessment of the client's activity tolerance. Clients may need assistance with activities of daily living, including hygiene and toileting; however, it should be noted that complete bedrest is not always the best option. Many clients find that using a bedside commode or toilet is less physically taxing than using a bedpan, especially for bowel movements.

Occupational roles may also need to be modified. If the client is not able to continue working in the old job, it may be possible to take on a new job that is less taxing or to reduce the number of hours worked. If such changes are not possible, the client may have to quit working altogether. All of these possibilities may cause much distress to the client and family, who must grapple with role issues, authority and autonomy issues, and possibly financial con-

APPLICATION: HOME SETTING

Activity adaptations in the home setting may involve alterations in the physical environment of the home, changes in family roles, or changes in work roles. The client who cannot climb stairs may need to have his or her sleeping quarters moved to the first floor of the house. Clients may also need to give up household chores that cause distress and perhaps take on other, less physically taxing roles. Changes such as these can be trying for the entire family, and they will need support during the period of transition. Home health nurses are a tremendous resource for families facing role changes related to illness.

Title of Study

"Functional Status from the Patient's Perspective: The Challenge of Preserving Personal Integrity"

Authors

Leidy, N. K., & Haase, J. E.

Purpose

The purpose of this quantitative research was to explore how clients with chronic obstructive pulmonary disease (COPD) cope with the changes in their ability to perform day-to-day activities.

Methods

Twelve clients from a pulmonary outpatient clinic in the southeast with varying sociodemographic backgrounds and moderate to severe emphysema, chronic bronchitis, asthma (with underlying chronic airways obstruction), or COPD participated in the study. During recorded interviews, the clients were asked to describe a typical day and were then encouraged to self-direct the content of the interview. The interviews were transcribed, and theme clusters were identified and findings validated for credibility.

Findings

Clients with COPD experienced ongoing challenges in preserving a sense of wholeness as they faced physical changes that interfered with their daily activities. They wanted to maintain personal integrity, which was described as having a sense of effectiveness and connectedness through their daily activities.

Implications

This study identifies the need for further research in order to define nursing interventions that focus on individual, client needs, and support emotional expression, goal setting, and recollection.

Leidy, N. K., & Haase, J. E. (1999). Functional status from the patient's perspective: The challenge of preserving personal integrity. *Research in Nursing Health*, 22(2), 67–77.

cerns. Signs of inadequate family coping, such as marital discord, anger or hostility, sleep disturbances, and depression, should be noted and appropriate interventions, such as a referral for counseling, should be instituted.

Lifestyle adaptations aimed at reducing factors that contribute to the disease process include removal of allergens from the environment, smoking cessation, and control of modifiable risk factors for heart disease.

Allergen control and smoking cessation were discussed in the section Interventions to Promote Airway Clearance. Modification of cardiac risk factors includes smoking cessation as well as dietary alterations and weight control, control of diabetes and hypertension if present, exercise, and stress management. A comprehensive cardiac rehabilitation program addresses all of these issues while monitoring the client's progress toward his or her individualized goals.

Encourage Dietary and Nutritional Modifications

Dietary modifications for cardiovascular disease may include reduction of sodium intake and reduction of total fat, saturated fat, and cholesterol intake. Sodium consumption may be reduced by decreasing or eliminating salt used in cooking and added at the table and avoiding highly processed foods such as prepared meats, canned meat or fish, and many prepared sauces. The client should be taught to examine food labels for sodium content per serving.

The client who is not receiving adequate nutrient intake because of poor appetite or severe dyspnea will need assistance in finding ways to increase intake of calories and essential nutrients. Eating small, frequent

meals of high nutritional value and using dietary supplements are often helpful.

Promote Comfort

Promoting comfort for the client with oxygenation disturbances can be a challenge but is extremely important. Comfort influences the client's ability to eat, sleep, learn, and cope with the illness and the care being provided.

Altered comfort related to pain is best approached by removing or modifying the cause of the pain if possible and administering analgesics if indicated. The use of analgesics in the postoperative client is particularly important in allowing the client to participate fully in deep-breathing and coughing exercises. See Chapter 33 for more discussion of pain management.

Pain related to tissue ischemia is best relieved by improving the oxygen delivery to the tissues while reducing the oxygen demand. The first response to ischemic pain should be to rest the affected tissue. If the pain is in the legs, for example, the client should sit down. Improving delivery of oxygen to the legs in the client with peripheral vascular disease may involve positioning the legs lower than heart level (elevating the legs will often make the pain worse).

Heart pain related to ischemia (angina pectoris) should also be dealt with first and foremost by resting. Resting will decrease the heart's workload and in some cases is sufficient to relieve the pain. Improving oxygen delivery to the heart may be accomplished by providing supplemental oxygen or by using medications, such as nitrates, that improve coronary blood flow. In some cases, narcotic analgesics such as morphine are necessary.

CLIENT TEACHING CHECKLIST *Following a Healthy Diet*

Reduction of total dietary fat, saturated fat, and cholesterol can be a challenge and requires careful client teaching. Use food labels and reference charts to help clients follow these dietary outlines:

- Reduce fat intake to no more than 30% of the total caloric intake.
- Keep saturated fats down to no more than 10% of the total caloric intake. (Saturated fats include those from animal sources such as milk and dairy products. Palm and coconut oils, although from a vegetable source, have the same effect as animal fats in terms of raising serum cholesterol.)
- Limit cholesterol intake to no more than 300 mg per day.
- Eat less meat and dairy products and more fresh fruits, vegetables, and whole grains.
- Avoid processed foods, especially those with sauces or fillings. When eating out, choose baked or grilled dishes rather than fried, sautéed, or stewed.
- Enjoy treats such as rich desserts only occasionally; choose low-fat desserts such as low-fat frozen yogurt, fruit sorbets, or angel food cake whenever possible.

CLIENT TEACHING CHECKLIST *General Reminders*

- Assess the client's and family's level of knowledge.
- Focus on identifying misconceptions that need to be clarified.
- Ask open-ended questions, such as, "Tell me what your medications are for," instead of simple yes/no questions.
- Set goals with the client's input; base goals upon realistic expectations.
- State goals clearly: for example, "Mr. Jones will be able to name all of his medications, the dose, and frequency they are taken and list one major side effect of each."
- Individualize teaching methods, taking into account the client's particular needs and abilities.
- Involve the family in teaching sessions.

Complementary Therapies

Many complementary therapies that enhance oxygenation originate in ancient healing traditions of China and India. For example, the practice of meditation and yoga produces a sense of serenity and relaxation, and other positive physiologic benefits. Harvard Medical School professor Herbert Benson studied the effects of people who practiced transcendental meditation in the 1970s and showed that meditation decreases oxygen consumption and metabolism; lowers blood pressure, heart rate, and respiratory rate; increases the production of alpha brain waves; and relieves stress and enhances overall well-being. Dean Ornish, M.D., has successfully reversed coronary artery disease by using yoga with dietary changes, moderate exercise, and support groups.

Herbs

Herbs are often used with relaxation techniques, exercise, and diet to prevent diseases of the cardiovascular and respiratory systems; see the accompanying display for commonly used herbs for these systems. Respiratory stimulants are expectorants that loosen mucus from the

NURSING CARE PLAN

The Client with Pneumonia

Case Presentation

Mrs. Johnson is a 72-year-old woman hospitalized for left lower lobe pneumonia. She complains of a persistent cough and occasional pain in her left chest associated with coughing, fever, and shortness of breath. Prior to this admission, she has been healthy and independent. Upon assessment, you find her mildly dyspneic, occasionally pausing in the middle of a sentence to breathe. Her respiratory rate is 28 breaths per minute. Her pulse is 100 per minute and regular; blood pressure is 140/90 mm Hg. Her skin is warm, dry, and pale pink with brisk capillary refill. You do not note any edema. She is receiving oxygen by nasal cannula at 6 L/min.

Assessment

- Dyspnea, tachypnea, and tachycardia
- Cough, chest pain, fever

Nursing Diagnosis #1

Impaired Gas Exchange related to presence of infectious exudate in the left lower lobe of the lung.

Expected Outcomes

The client will:

1. Report relief of dyspnea.
2. Demonstrate return of respiratory rate to 20/minute or less and heart rate to 100/minute or less.
3. Be able to speak comfortably.

Interventions/Rationales

1. Teach client effective techniques for coughing, such as sustained maximal inspiration and “huffing.”
Increases the clearance of exudate.
2. Assist with chest physiotherapy and postural drainage as indicated. *Promotes the clearance of exudate by using gravity, percussion, and vibration of the chest wall.*
3. Humidify inspired oxygen, and encourage oral fluid intake. *Promotes liquefaction of pulmonary secretions, which facilitates expectoration.*
(continues)

NURSING CARE PLAN**The Client with Pneumonia (continued)**

4. Encourage client to lie on her right side while in bed. *Positioning with the unaffected lung down provides the best match of ventilation and perfusion.*
5. When assessing for dyspnea, do so not only with the client at rest but also during activities such as talking, eating, and moving. *Clients who appear to be breathing comfortably at rest may become dyspneic with minimal activity.*

Nursing Diagnosis #2

Imbalanced Nutrition: Less Than Body Requirements related to decreased oral intake and increased metabolic requirements.

Expected Outcomes

The client will:

1. Maintain usual body weight.
2. Consume at least 50% of food provided.

Interventions/Rationales

1. Provide oral care after coughing, after respiratory treatments, and before meals. *Coughing and the expectoration of secretions can create an unpleasant taste in the mouth, which interferes with appetite.*
2. Assess food intake and provide supplements if intake is insufficient to meet caloric needs. *Dietary supplements may provide increased calories and nutrients.*
3. Encourage liberal fluid intake. *Clients with fever and dyspnea lose excess body fluids through the skin and lungs. Adequate hydration will help liquefy pulmonary secretions and prevent decreases in circulating blood volume. Always check for contraindications such as heart failure, kidney disease, or a physician-ordered fluid restriction before encouraging increased fluids.*
4. Weigh daily. Monitors progress to goal so that plan can be modified as needed. *Daily gains or losses in excess of 1 pound are often due to fluid balance alterations. Slower gains or losses may be due to nutritional alterations.*

Evaluation

Success of the nursing interventions can be measured by a visible increase in the client's comfort and ease of speaking and a decreased effort at the work of breathing. The client will report that dyspnea has been relieved and will have respiratory and heart rates within the normal range. Ongoing evaluation will be needed to monitor client's weight to ensure that intake is adequate to meet client's caloric requirements.

respiratory system. *Lobelia* (Indian tobacco) contains lobeine, a nonaddicting substance similar to nicotine, and is often used to quit smoking.

revisit the initial plan of care to determine if each expected outcome was within reasonable expectations and then to revise the goals, interventions, and plan of care to reflect truly reasonable expectations.

EVALUATION

Clients with compromised oxygenation status need careful nursing care to address both their physical and psychological needs. Evaluation will be based on the outcomes and goals that the nurse and client have established together. In many instances, the evaluation of the success of the specific interventions will be a matter of degree, that is, the degree to which the client is or can be returned to a satisfactory state of respiratory functioning. It is important when evaluating progress to

KEY CONCEPTS

- Adequate tissue oxygenation is essential to survival and may be threatened by deficits in air movement through the lungs to deliver fresh air to the alveoli (ventilation), the exchange of oxygen and carbon dioxide across the alveolar-capillary membrane (diffusion or external respiration), oxygen transport in the blood, the delivery of oxygen to the tissues (circulation), or the uptake of oxygen by the cells (internal respiration).

- Impairment of oxygen delivery to the tissues results first in compensatory efforts such as anaerobic metabolism and increased oxygen extraction; when these efforts fail, tissue ischemia and infarction will ensue.
 - Client teaching related to oxygenation impairment involves teaching about the disease process, treatments, and lifestyle alterations that may be indicated; teaching should involve not only the client but also the family.
 - Nursing care related to oxygenation focuses on maintaining a patent airway, promoting effective ventilation, promoting optimal circulation and perfusion, and meeting the client's learning, nutritional, activity, and sleep needs.
 - A holistic approach to care recognizes that each of the problems experienced by the client with oxygenation deficits is interrelated.
 - Emergency support of airway, ventilation, and circulation is achieved by instituting the Heimlich maneuver for airway obstruction and cardiopulmonary resuscitation for cardiopulmonary arrest.
4. What is the difference between intermittent positive-pressure breathing (IPPB) and incentive spirometry?
 5. List two potential complications of oxygen administration.
 6. Artificial airways such as endotracheal tubes and tracheostomies bypass the upper airways. What is the significance of this?
 7. How does heart failure cause edema?
 8. When experiencing pain related to peripheral atherosclerosis (claudication), the client should position the extremity below heart level. Why?

CRITICAL THINKING ACTIVITIES

1. Which accounts for the greatest amount of oxygen carried in the arterial blood: the partial pressure of oxygen (PaO_2) or the hemoglobin saturation (SaO_2)?
2. Describe how positioning might affect the client with ineffective breathing patterns.
3. List two limitations of anaerobic metabolism.

Comfort and Sleep

“We cannot be a source of strength unless we nurture our own strength.”

—M. Scott Peck

COMPETENCIES

1. Describe types of pain.
2. Assess the nature of pain as it relates to onset, intensity, and duration.
3. Discuss the physiology of pain.
4. Describe nonpharmacologic interventions in pain control.
5. Discuss the use of pharmacologic interventions in pain control.
6. Describe the stages of sleep.
7. Discuss age-related sleep variations.
8. State the outcomes of sleep deprivation on an individual.
9. Discuss nursing interventions that promote comfort, rest, and sleep.

cutaneous pain	pain tolerance	trigger point
distraction	parasomnia	visceral pain
efferent pain pathway	paresthesia	withdrawal syndrome
endorphin	patient controlled-analgesia (PCA)	
gate control pain theory		

The experience of pain and the quality of rest and sleep are both factors that can have a significant impact on a client's health. Both are personal experiences that can affect all other aspects of an individual's health, including physical well-being, mental status, and effectiveness of coping mechanisms. This chapter explores the nature of pain, the importance of rest and sleep, and nursing care to help clients maintain their optimal health when the presence of pain or rest/sleep disturbances threaten to compromise their health status.

PAIN

Pain is a universal human experience; it is defined as “a state in which an individual experiences and reports the presence of severe discomfort or an uncomfortable sensation” (Carpenito, 1999, p. 51). Pain is a subjective experience that is often difficult for clients to describe and nurses to understand, yet it is among the most common complaints that cause individuals to seek health care. McCaffery and Pasero (1999) recognize the subjective nature of pain by stating “Pain is whatever the experiencing person says it is, existing whenever he says it does” (p. 17). Until recently, pain was viewed as a symptom that required diagnosis and treatment of the underlying cause. It is now clear that pain itself can be detrimental to the health and healing of clients. “Unrelieved pain is not only detrimental, it's avoidable” (Williams-Lee, 1999, p. 9). Pain is a stressor that can trigger both physiological and psychological discomfort. Untreated pain can lead to physical disorders related to undernutrition, immobility, and immune suppression.

Nature of Pain

Pain, a response to noxious stimuli, can be a protective mechanism to prevent further injury, as is seen in clients who guard or protect an injured body part. The sensation of pain as the warning of potential tissue damage may be absent in people with nerve/spinal cord abnormalities, diabetic neuropathy, multiple sclerosis, and nerve/spinal cord injury.

Common Myths About Pain

Because pain is subjective (dependent on client's perception) and cannot be objectively measured by another individual through a laboratory test or diagnostic data, pain is often misunderstood and misjudged. A client's reports of level of pain will vary on the basis of cultural and experiential backgrounds, and the nurse's interpretations of a client's pain will be filtered through the nurse's own biases and expectations. “Pain doesn't go untreated (or under-treated) because of cruelty or apathy by the staff, but because of lack of knowledge. Just as [long-term care] residents have preconceived notions and concerns regarding pain and pain management, so do staff members” (Loeb, 1999, p. 49). Incongruence of the nurse's view and the client's perception of pain can often lead to undermedication and unnecessary suffering on the client's part. The accompanying display outlines some of the common myths about pain, along with factual statements countering those beliefs.

Types of Pain

Pain can be qualified or described in two basic ways: by its cause or origin and by its description or nature.

Pain categorized by its origin is either cutaneous, somatic, or visceral. **Cutaneous pain** is caused by stimulation of the cutaneous nerve endings in the skin and results in a well-localized “burning” or “prickling” sensation; getting a knot in the hair that is pulled out during combing may cause cutaneous pain. **Somatic pain** is nonlocalized and originates in support structures such as tendons, ligaments, and nerves; jamming a knee or finger will result in somatic pain. **Visceral pain** is discomfort in the internal organs and is less localized and more slowly transmitted than cutaneous pain. Visceral pain is often difficult to assess because the location may not be directly related to the cause.

COMMON MYTHS ABOUT PAIN

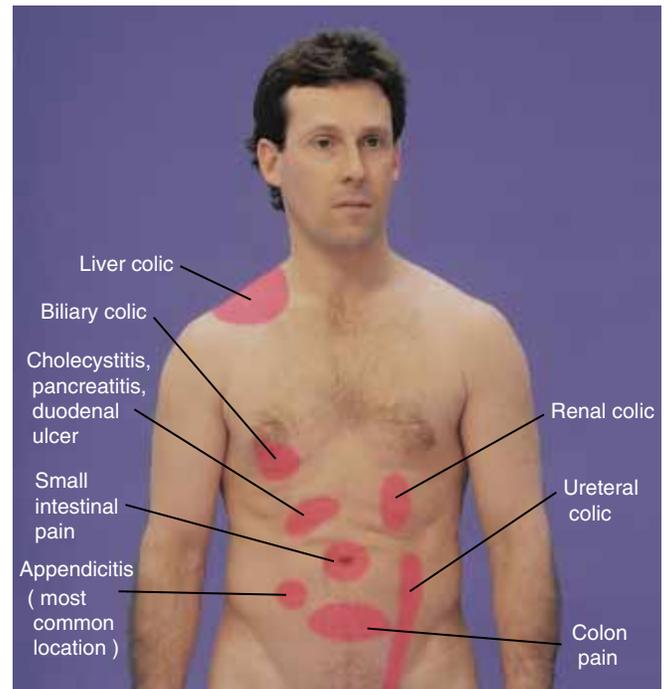

Myth

- The nurse is the best judge of a client’s pain.
- If pain is ignored, it will go away.
- Clients should not take any measures to relieve their pain until the pain is unbearable.
- Most complaints of pain are purely psychological (e.g., “it’s all in your head”); only “real” pain will manifest in obvious physical signs such as moaning or grimacing.
- Clients with severe tissue damage will experience significant pain; those with lesser damage will feel less pain.
- Clients taking pain medications will become addicted to the drug.

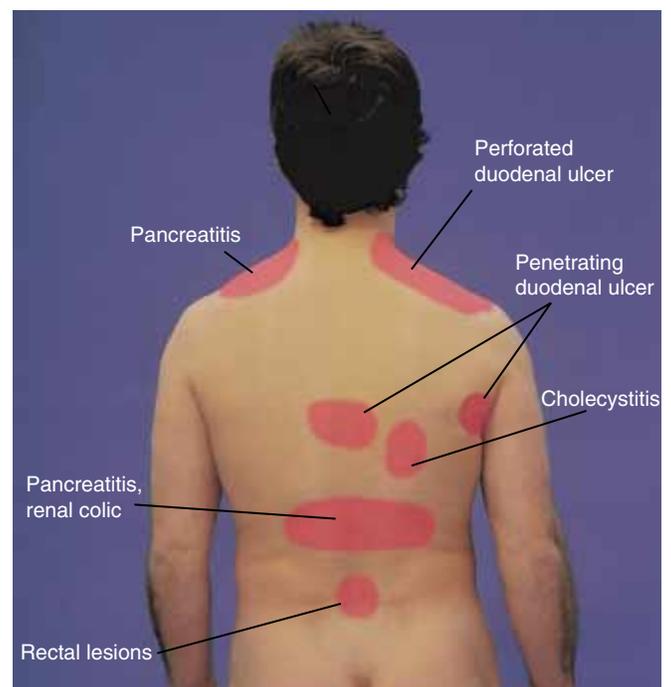

Fact

- Pain is a subjective experience; only the client can judge the level and severity of pain.
- Pain is a real experience that can be appropriately treated.
- Pain control and relief measures are effective in lowering pain levels, which will help clients function more normally and comfortably.
- Most clients honestly report their perception of pain.
- Physical responses to pain vary greatly depending on experience and cultural norms.
- Visible expressions of pain are not always reliable indicators of its severity.
- Individuals’ perceptions of pain are subjective; the extent of tissue damage is not necessarily proportional to the extent of pain experienced.
- Addiction is unlikely when analgesics are carefully administered and closely monitored.

Pain originating from the abdominal organs is often called **referred pain** because the sensation of pain is not felt in the organ itself but instead is perceived at the spot where the organs were located during fetal development. Figure 33-1 shows the cutaneous areas where visceral pain is often referred.

A.

B.

Figure 33-1 Areas of Referred Pain. A. Anterior view. B. Posterior view.

Acute pain is most frequently identified by its sudden onset and relatively short duration, mild to severe intensity, and a steady decrease in intensity over a period of days to weeks. Some forms of acute pain may have a slower onset. Once the noxious stimulus is resolved, the pain usually decreases. Examples of noxious stimuli are needle sticks, surgical incisions, burns, and fractures.

Recurrent acute pain is identified by repetitive painful episodes that may recur over a prolonged period or throughout the client's lifetime. These painful episodes alternate with pain-free intervals. Examples of recurrent pain include migraine headaches, sickle cell pain crises, and the pain of angina pectoris due to myocardial hypoxia.

Chronic pain is identified as long-term (lasting 6 months or longer), persistent, nearly constant, or recurrent pain that produces significant negative changes in the client's life. Unlike acute pain, chronic pain may last long after the pathology is resolved.

Chronic acute pain occurs almost daily over a long period, has the potential for lasting months or years, and has a high probability of ending. Severe burn injuries and cancer are examples of pathophysiology that leads to chronic acute pain, which may last for long periods before the condition is cured or controlled.

Chronic nonmalignant pain (CNP), occurs almost daily and lasts for at least 6 months, with intensity ranging from mild to severe.

Chronic pain, a primary motivator for individuals to seek health care intervention, can greatly influence a client's quality of life, including emotional, social, vocational, and financial areas.

There is a relationship between chronic conditions (including pain) and depression. Thus, the client experiencing chronic pain should always be assessed for the presence of depression. "Not only do patients with CNP have a higher rate of depression, but suicide potential is also a serious concern for this population" (McCaffery & Pasero, 1999, p. 487). Examples of pathophysiology leading to chronic nonmalignant pain include:

- Many forms of **neuralgia** (paroxysmal pain that extends along the course of one or more nerves)
- Low back pain
- Rheumatoid arthritis
- Ankylosing spondylitis
- **Phantom limb pain** (a form of neuropathic pain that occurs after amputation with pain sensations referred to an area in the missing portion of the limb)
- **Myofascial pain syndromes** (a group of muscle disorders characterized by pain, muscle spasm, tenderness, stiffness, and limited motion)

CNP may be associated with several problems, including:

- Activity intolerance, which leads to physical deconditioning

- Functional impairment with resultant changes in role performance (parent, breadwinner)
- Social isolation, which alters relationships
- Sleep deprivation
- Frustration, anxiety, anger, and depression

When CNP is severe enough to disable the client, nurses understand that in order "To improve your patient's quality of life, pain management becomes a priority" (Bral, 1998, p. 27).

Physiology of Pain

Noxious stimuli activate **nociceptors** (receptive neurons for painful sensations) that, together with the axons of neurons convey information to the spinal cord where reflexes are activated. The information is simultaneously transmitted to the brain supraspinally (Cleland & Gebhart, 1997). Long-lasting changes in cells within the spinal cord **afferent** (ascending) and **efferent** (descending) **pain pathways** may occur after a brief noxious stimulus.

Physiological responses (such as elevated blood pressure, pulse rate, and respiratory rate; dilated pupils; pallor; and perspiration) to even a brief acute pain episode will begin showing adaptation within a short period, possibly minutes to a few hours. Physiologically, the body cannot sustain the extreme stress response for other than short periods of time. The body conserves its resources by physiological adaptation (returning to normal or near normal blood pressure, pulse rate, and respiratory rate; normal pupil size, and dry skin) even in the face of continuing pain of the same intensity. Pain can be categorized into two types according to its pathophysiology; see Table 33-1.

Nociceptive Pain

The four fundamental processes involved in **nociception** (process by which individual becomes consciously aware of pain) are as follows (McCaffery & Pasero, 1999):

- **Transduction**—The changing of noxious stimuli in sensory nerve endings to energy impulses
- **Transmission**—Movement of impulses from site of origin to the brain
- **Perception**—Developing conscious awareness of pain
- **Modulation**—The changing of pain impulses

Transduction of Pain

When noxious stimuli occur, tissues are damaged. Cell damage releases the following sensitizing substances:

- Prostaglandins (PG)
- Bradykinin (BK)
- Serotonin (5HT)
- Substance P (SP)
- Histamine (H)

TABLE 33-1
Pathology-Based Pain Classification

Nociceptive Pain	Neuropathic Pain
<p><i>DESCRIPTION:</i> Normal processing of noxious stimuli May damage tissue if prolonged</p>	<p><i>DESCRIPTION:</i> Abnormal processing of stimuli by peripheral nervous system (PNS) or central nervous system (CNS)</p>
<p><i>EXAMPLES:</i> Somatic pain Visceral pain</p>	<p><i>EXAMPLES:</i> Centrally generated pain: <ul style="list-style-type: none"> • Phantom pain • Spinal cord injury Peripherally generated pain: <ul style="list-style-type: none"> • Diabetic neuropathy • Trigeminal neuralgia </p>
<p><i>THERAPY:</i> Nonsteroidal anti-inflammatory drugs (NSAIDs), opioids</p>	<p><i>THERAPY:</i> NSAIDs, opioids, adjuvant analgesics</p>
<p>(Data from McCaffery, M., & Pasero, C. [1999]. <i>Pain: Clinical manual</i> (2nd ed.). St. Louis: Mosby, p. 19.)</p>	

Release of these substances alters the electrical charge on the neuronal membrane. This change in electrical charge is a result of movement of Na⁺ and other ions into the cells. The impulse is then ready to be transmitted along the nociceptor fibers (McCaffery & Pasero, 1999).

Transmission of Pain

The specific action of pain varies depending on the type of pain. In cutaneous pain, cutaneous nerve transmissions travel through a reflex arc from the nerve ending (point of pain) to the brain at a speed of approximately 300 feet per second, with a reflex response causing an almost immediate reaction. This explains why, when a hot stove is touched, the person's hand jerks back *before* there is conscious awareness that damage is occurring (Figure 33-2). After a hot stove is touched, a sensory nerve ending in the skin of the finger initiates nerve transmission that travels through the dorsal root ganglion to the dorsal horn in the gray matter of the spinal cord. From there, the impulse travels through an interneuron that synapses with a motor neuron, which exits the spinal cord at the same level. This motor neuron, and the stimulation of the muscle it innervates, is responsible for the swift movement of the hand away from the hot stove.

In the case of the hot stove, the sensory neuron synapses not only with an interneuron but also with an afferent sensory neuron. The impulse travels up the spinal cord to the thalamus, where a final synapse conducts the impulse to the cortex of the brain. Efferent or descending motor neuron response is conducted from the brain through the spinal cord, where it synapses with a motor neuron that exits the spinal cord and innervates the muscle.

In visceral pain, transmission of pain impulses is slower and less localized than in cutaneous pain. The internal organs (including the gastrointestinal tract) have a minimal number of nociceptors, which explains why visceral pain is poorly localized and is felt as a dull aching or throbbing sensation. However, internal organs have extreme sensitivity to distension. The cramping pain of **colic** (acute abdominal pain), for example, results when:

- Flatus or constipation causes distension of the stomach or intestines
- There is hyperperistalsis, as in gastroenteritis
- Something tries to pass through a lumen (an opening) that is too small

The physiology of **ischemic pain**, or pain occurring when the blood supply of an area is restricted or cut off completely, also differs from that of cutaneous pain. The restriction of blood flow causes inadequate oxygenation of the tissue supplied by those vessels, as well as inadequate metabolic waste product removal. Ischemic pain has the most rapid onset in an active muscle and a much slower onset in a passive muscle. Examples of ischemic pain are muscle cramps, sickle cell pain crisis, angina pectoris, and myocardial infarction. When ischemic pain occurs in a muscle that continues to work, a muscle spasm (cramp) is the outcome. If the blood supply to the heart is severely restricted or completely cut off and is not restored quickly, a myocardial infarction will occur.

In acute pain episodes, substances released from injured tissue lead to stress hormone responses in the client. This causes an increased metabolic rate, enhanced breakdown of body tissue, impaired immune function, increased blood clotting and water retention,

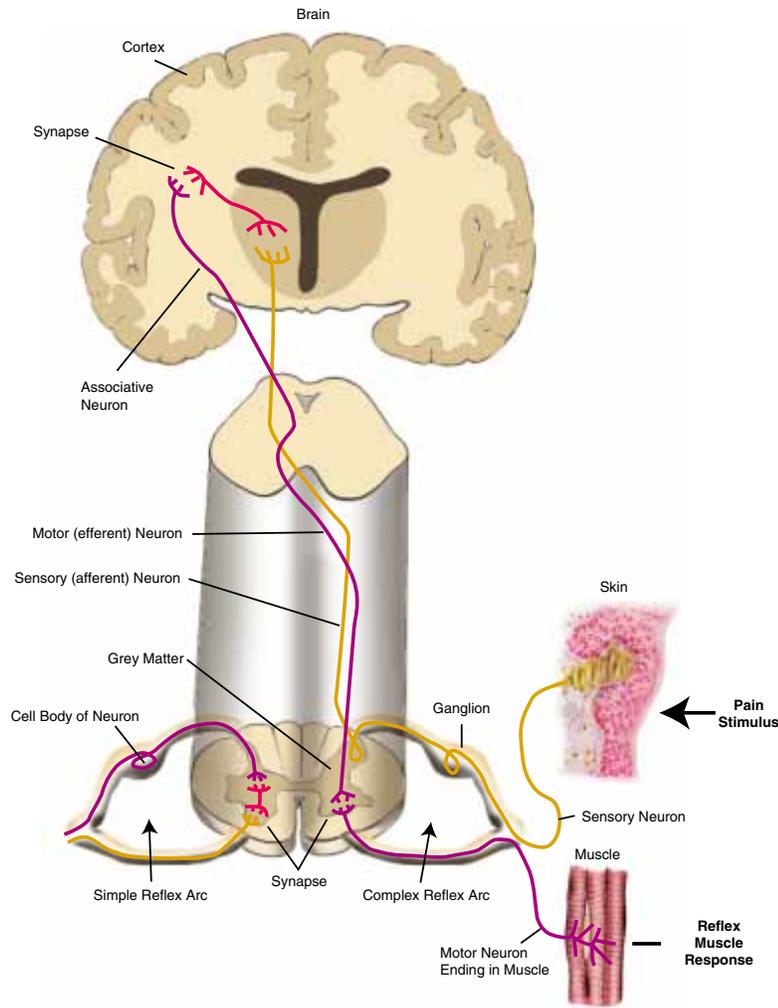

Figure 33-2 Reflex Arcs

NURSING ALERT

Ischemic Pain

Supplemental oxygen and pain medication must be administered quickly to clients with ischemic pain to minimize oxygen deprivation and prevent infarction (tissue death).

and it triggers the fight-or-flight reaction, leading to tachycardia and negative emotions.

Pain Perception

When the impulse has been transmitted to the cortex and is interpreted by the brain, the information is available on a conscious level. It is then that the person becomes aware of the intensity, location, and quality of pain. This information is interpreted in light of previous experience, adding the affective component to the pain experience.

Modulation

Modulation refers to activation of descending neural pathways that inhibit transmission of pain. “The path-

ways are described as descending because they involve neurons originating in the brain stem that descend to the dorsal horn of the spinal cord” (McCaffery & Pasero, 1999, p. 22). The descending fibers release substances that produce analgesia by blocking the transmission of noxious stimuli. Pain modulation is a result of the effects of endogenous opioids, also called enkephalins and endorphins.

Neuropathic pain arises from damage to portions of the peripheral or central nervous system. This pain is *not* nociceptive pain, nor that which is due to ongoing tissue injury or inflammation. It is important to differentiate neuropathic pain from other types of pain because the treatment differs significantly. Table 33-2 identifies some of the differences between nociceptive and neuropathic pain.

Neuropathic pain is a result of abnormal processing of sensory input by either the peripheral or central nervous system. Two types of neuropathic pain are **allodynia** (a nonpainful stimulus is felt as painful in spite of the tissue appearing normal) and **paresthesia** (abnormal sensation such as burning, prickling, or tingling).

Myofascial pain was first described by Travell and Rinzler (1952) as pain that occurs as a result of a small,

TABLE 33-2
Differences Between Nociceptive Pain and Neuropathic Pain

	Nociceptive Pain	Neuropathic Pain
Pain descriptors	Varied	Sharp, shooting, lancinating, tingling, pins and needles, strange <i>or</i> Dull, aching, burning
Pain pattern	Pain intensity decreases steadily over period of days to weeks in the absence of repeated injury or inflammation	Pain persists or even intensifies during weeks or months after injury
Response to opioids	Generally relieves pain with acceptable margin between comfort and sedation	“Resistant” to opioids, with significant pain remaining even when on opioid doses that lead to severe sedation
Response to nonsteroidal anti-inflammatory drugs (NSAIDs)	Generally effective at partial reduction of pain intensity	Rarely relieved by NSAIDs
Response to tricyclic antidepressants, anticonvulsants, local anesthetics	Generally ineffective	Often decreased significantly or relieved
Mechanical allodynia	Uncommon	Common even when no skin injury is present

(Modified from Olsson, G., & Berde, C. [1993]. Differences between nociceptive pain and neuropathic pain. In N. L. Schechter, C. B. Berde, & M. Yaster (Eds.), *Pain in infants, children, and adolescents* [p. 474]. Baltimore: Williams & Wilkins.)

hypersensitive region in a muscle, ligament, fascia, or joint capsule called a **trigger point**. The trigger point is a hypersensitive point that, when stimulated, causes a local twitch or “jump” response. Myofascial pain is often accompanied by a localized deep ache that is surrounded by a referred area of **hyperalgesia**, or extreme sensitivity to pain.

Gate Control Theory of Pain

Theories of pain transmission and interpretation attempt to describe and explain the pain experience. In 1965, Melzack and Wall proposed the **gate control pain theory**, which was the first to recognize that the psychological aspects of pain are as important as the physiological aspects. The gate control theory combines cognitive, sensory, and emotional components—in addition to the physiological aspects—and proposes that they can act on a gate control system to block the individual’s perception of pain. Bezkor and Lee (1997, p. 181) describe gate control as “regulation of pain perception through a gating mechanism at the dorsal horn of the spinal cord. Vasoconstriction and decreased nerve conduction velocity result in reduced transmission of noxious stimuli to the ‘gate.’” As a result, the level of conscious awareness of painful sensation is altered.

The gate control theory is based on the premise that pain impulses travel through either small-diameter nerve cells or large-diameter nerve cells, both of which

pass through the same gate. The large-diameter cells have the ability, when properly stimulated, to “close the gate” and thus block transmission of the pain impulse to the brain (Figure 33-3). Stimulants such as cutaneous massage, opioid release, and excessive stimulation all activate the large-diameter cells to close the gate. Clinically, the effectiveness of several nonpharmacologic modalities, such as massage, acupuncture, and acupressure, supports gate control theory.

Factors Affecting the Pain Experience

The subjective nature of pain varies from person to person and is influenced by several variables. Many factors account for the differences in a client’s individual response to pain, including age, previous experience with pain, and cultural factors.

Age

Age can greatly influence a client’s perception of the pain experience. Infants are sensitive to pain and typically exhibit discomfort through crying or physical movement. Toddlers also use crying and physical movement to indicate pain, and they begin to develop the skills needed to verbally describe pain or point to the area that is hurting. Children often do not understand why pain occurs and can therefore be frightened or

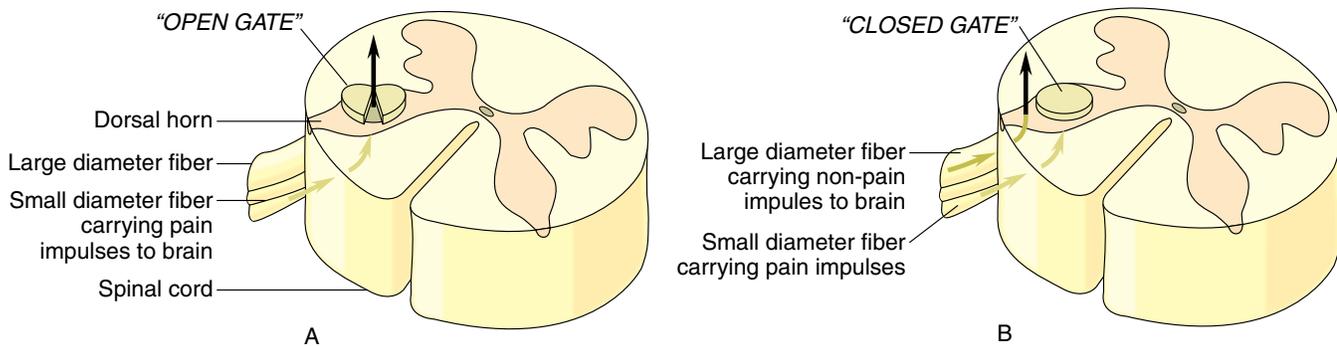

Figure 33-3 Gate Control Theory: Blocking Transmission of Pain

resentful of the pain experience; in some cases, children revert to habits of their younger years (regression) as a coping mechanism when faced with pain they cannot otherwise manage.

Adolescents often sense great peer pressure and may be reluctant to admit having pain for fear of being called weak or sensitive. Adults may continue pain behaviors they learned as children and may also be reluctant to admit pain or seek medical care because of fear of the unknown or fear of the impact that treatment may have on their lifestyle.

Older adults may often ignore their pain, viewing it as an unavoidable consequence of aging; family and health care members may inadvertently support this stereotype and be less than responsive to an older client's complaints of pain. Pain related to chronic disease is prevalent among the elderly population. Up to 70% of noninstitutionalized older adults report the occurrence of pain (Luggen, 2000, p. 281). Frequently, pain is undertreated in older people. Loeb (1999) states that there are three major factors which contribute to inadequate pain management in older clients:

1. Pain is underreported by older people who believe the myth that pain is a normal part of aging. Older adults with such misconceptions believe nothing can be done to relieve the pain.
2. Underdetection of pain may be a result of the client's cognitive-perceptual deficits.
3. Undertreatment of pain is a result of underreporting and underdetection.

Previous Experience with Pain

Clients' previous exposures to pain will often influence their reactions. Coping mechanisms that were used in the past may affect clients' judgments as to how the pain will affect their lives and what measures they can use to successfully manage the pain on their own. Client teaching about pain expectations and management methods can often allay client fears and lead to more successful pain management, especially in those clients who do not have previous pain experience or who have memories of a previous devastating pain experience that they do not wish to repeat.

Cultural Norms and Attitudes

Cultural diversity in pain responses can easily lead to problems in pain management. There are no significant differences among groups in the level of intensity at which pain becomes appreciable or perceptible. However, the level of intensity or duration of pain the client is willing to endure is culturally determined.

Expression of pain is also governed by cultural values. In some cultures, tolerance to pain, and therefore "suffering in silence," is expected; in others, full expression of pain may include animated physical and emotional responses. The nurse must be careful not to equate the level of expression of pain with the level of actual pain experienced, but to instead consider cultural influences that affect the expression of pain.

NURSING TIP

Remember that pain is not part of the normal aging process.

NURSING TIP

Recognizing Pain

Recognizing the potential for pain is the most effective step nurses can take in pain management.

Assessment

Assessment of pain includes collection of subjective and objective data through the use of various assessment tools and construction of a database to use in developing a pain management plan. Pain assessment should be performed for every client. “In the normal course of doing business, pain should be nursing’s fifth vital sign, as basic to practice as temperature, pulse, respiration, and blood pressure” (Joel, 1999, p. 9).

Data Collection

Cheever (1999) emphasizes the need to prevent pain rather than treat it. Prevention calls for accurate assessment in order to alleviate pain before it escalates. “Even if a patient fails to report pain, you must make efforts to detect it” (Loeb, 1999, p. 52). Gathering subjective information regarding the client’s pain is the first step in pain assessment. The client’s perception of the pain should cover a description of several qualifiers, including:

- Intensity
- Location
- Quality (radiating, burning, diffuse)
- Associated manifestations (factors that often accompany the pain, such as nausea, constipation, or dizziness)
- Aggravating factors (variables that worsen the pain, such as exercise, certain foods, or stress)
- Alleviating factors (measures the client can take that lessen the effect of the pain, such as lying down, avoiding certain foods, or taking medication)

Nurses must look for nonverbal signs of pain such as changes in motor activity or facial expression. It is also important to ask family members to share their observations; they may be the first ones to note subtle behavior changes indicative of pain. When assessing a client’s report of pain, the nurse should also determine a client’s pain threshold and pain tolerance level. **Pain threshold** is the level of intensity at which pain becomes appreciable or perceptible and will vary with each individual and type of pain. **Pain tolerance** is the level of intensity or duration of pain the client is willing or able to endure. A client’s perceptions and attitudes about pain are dramatically influenced by many factors, including previous experiences and cultural background.

Clients’ behavioral adaptation may yield no report of pain unless questioned specifically. **Distraction** (focusing attention on stimuli other than pain) may also be used by clients. McCaffery and Pasero (1999) recognize that clients often minimize the pain behaviors they are able to control for a number of reasons including:

- To be a “good” client and avoid making demands
- To maintain a positive self-image by not becoming a “sissy”
- By using distraction as a method of making pain more bearable (young children are particularly adept at this)
- Exhaustion

Pain is fatiguing as a significant amount of energy is used to deal with pain. The longer a person suffers from pain, the greater the level of fatigue. Although there is no conscious awareness of pain during sleep, there may be a dream-state awareness (McCaffery & Pasero, 1999). The stress response continues, and the body physiologically pays the price. Clients also wake up with considerably more pain than they had going to sleep, thereby requiring even more intervention (pharmacologic and nonpharmacologic) to reduce the pain.

NURSING CHECKLIST

Assessing the Effect of Pain on Sleep

Questioning clients about the effect pain has on their sleep habits will help clarify the intensity of the pain and its effect on the client’s patterns of daily living. Questions to ask include: Does the pain:

- Prevent you from falling asleep?
- Make finding a comfortable sleeping position difficult?
- Wake you up from a sound sleep?
- Keep you from falling back asleep once awakened?
- Leave you feeling tired and unrefreshed after a sleeping session?

Occasionally, there is a discrepancy between pain behaviors observed by the nurse and the client’s self-report of pain. Client pain behaviors (Acute Pain Management Guideline Panel, 1992) include splinting of the painful area, distorted posture, impaired mobility, insomnia, anxiety, attention seeking, and depression. Discrepancies between behaviors and the client’s self-report can be due to good coping skills (e.g., relaxation techniques or distraction), stoicism, anxiety, or cultural differences in expected pain behaviors. Whenever these discrepancies occur, they should be addressed with the client, and the pain management plan altered accordingly.

Assessment Tools

Pain assessment tools are the single most effective method of identifying the presence and intensity of pain in clients. These tools must be used, and the results must be believed. Tools used for assessing pain must be appropriate to the client’s age and cultural context. “Make sure your assessments are culturally appropriate, keeping in mind that cultural mores and personal values can affect both the patient’s beliefs and pain and her responses to it” (Acello, 2000, p. 53). See Table 33-3 for sample questions used in pain assessment.

NURSING TIP

Client self-report is the most accurate indicator of pain. Do not assume that clients who are laughing or sleeping are necessarily comfortable.

Initial Pain Assessment Tool

Figure 33-4 shows the Initial Pain Assessment Tool developed by McCaffery and Pasero (1999). This tool is particularly effective when clients have complex pain problems because it assesses location, intensity, quality, precipitating and alleviating factors, and how the pain affects function and quality of life. Once this tool is completed, another less detailed tool can be used for ongoing monitoring of the client's pain level.

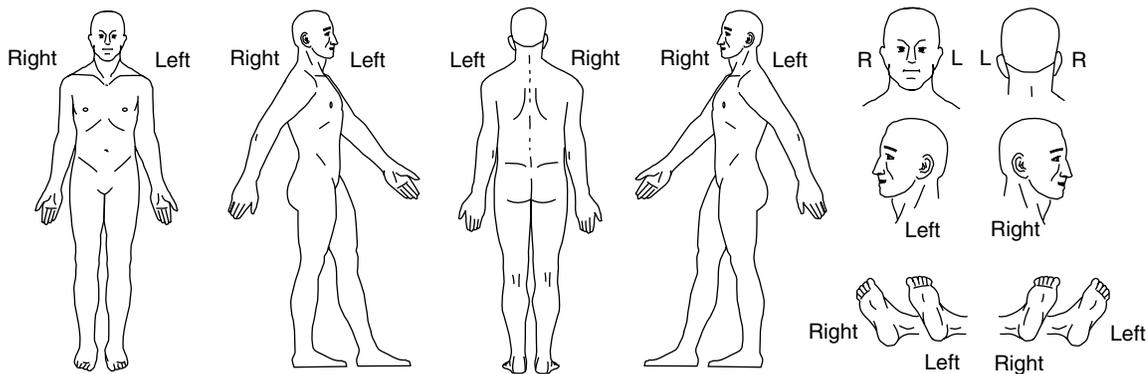

TABLE 33-3
Pain Assessment Questions

Characteristic	Question	Explanation
Quality	“How do you feel?”	Common descriptors: <ul style="list-style-type: none"> • Aching • Burning • Dull • Numb • Sharp • Throbbing
Intensity	“Using this scale, what number best describes your pain?” “Which picture best describes your pain?”	Use the Verbal Rating Scale (VRS) and the numeric rating (NRS) in combination. Use the Wong-Baker faces scale.
Location	“Where does it hurt?” “What part of your body is painful?”	Encourage client to point to the affected area. On a printed body outline, have client shade in the areas that correspond to painful areas of his or her body.
Duration	“Is the pain constant?” “Does the pain come and go?”	Instruct client to time painful episodes.
Triggers	“What makes the pain worse?” “What lessens the pain?”	Have client focus on triggers such as positions, activities, or situations.
Effects	“How has the pain affected your life?” “Do you have any symptoms in addition to pain?”	Include effects on: <ul style="list-style-type: none"> • Work/school • Relationships • Eating • Sleep • Energy level • Recreation/leisure • Moods Ask client about presence of: <ul style="list-style-type: none"> • Confusion • Constipation • Itching • Nausea/vomiting • Problems with urination • Sleepiness/drowsiness
Knowledge Level	“What do you understand about your pain and its causes?” “What have you been taught about your pain?” “Have you taken any medicine for pain? If so, what?”	Document the client's responses.

Figure 33-4 Initial Pain Assessment Tool (May be duplicated for use in clinical practice. Reprinted with permission from McCaffery, M., & Pasero, C. (1999). *Pain: Clinical manual for nursing practice* (2nd ed.). St. Louis, MO: Mosby.)

Nursing Process Highlight

Assessment

The client may exhibit any or all of the following indicators of pain:

- Reporting or complaining of pain
- Focusing on pain
- Crying or moaning
- Frowning or grimacing
- Rubbing or protecting painful areas
- Altering posture or movements to lessen pain
- Splinting painful areas by increasing muscle tension
- Reporting insomnia, fatigue, or depression

Pain Intensity Scales

Pain intensity scales are another quick, effective method for clients to rate the intensity of their pain (Figure 33-5). The verbal rating scale (VRS) and the numeric rating (NRS) are often used together to collect more accurate client input. The VRS uses adjectives ranging from “no pain” to “excruciating pain” in order to describe intensity. Frequent use of these tools will increase understanding of the pain severity. When using the NRS, clients are asked to assign their pain a number, with zero meaning no pain and 10 representing the worst possible pain. “On a scale of 0 to 10, with 0 being no pain at all and 10 being the worst pain you could ever have, how much do you hurt right now?” If there are multiple painful areas, this question can be asked regarding each area.

Pain Intensity Scales

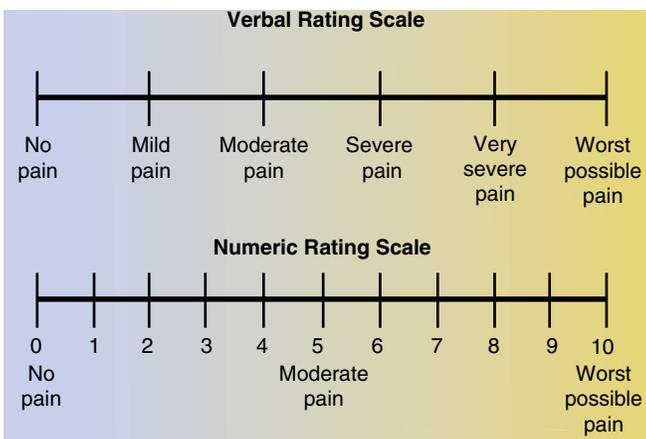

Figure 33-5 Pain Intensity Scales (From Acute Pain Management Guideline Panel. [1992]. *Acute pain management: Operative or medical procedures trauma*. Clinical practice guideline. [AHCPR Publication No. 92-0033]. Rockville, MD: Agency for Health Care Policy and Research.)

Pain Diary

Client input is essential if accurate assessment data are to be collected. Self-monitoring of symptoms can be promoted by having clients complete a pain diary; see the accompanying display.

PAIN DIARY

- Date/Time
- Intensity
- Situation
(What were you doing?)
- How did you feel?
- What were you thinking?
- What did you do to ease the pain?
- How effective was the pain control strategy?

Psychosocial Pain Assessment

Plaisance and Price (1999) state the following questions should be included on the psychosocial assessment of a client experiencing pain:

- Do the client and family/caregivers understand the diagnosis?
- How have previous experiences with pain affected the client and family?
- How does the client usually cope with pain and/or stress?
- What concerns do the client and family have about using certain medications such as opioids?
- Do the client and family understand the differences between tolerance, dependence, and addiction?

Developmental Considerations

Because pain experiences and reports can be influenced by age and developmental level, special consideration should be used to factor in those influences.

Children and Adolescents

Infants, children, and adolescents provide a special challenge in pain assessment because their pain behaviors often differ from those considered normal in the adult population. Certain myths hinder the accurate assessment and management of pain in children; see Table 33-4.

Two useful tools for assessing pain in children are the Wong/Baker Faces Rating Scale and the Poker Chip Tool. The Wong/Baker Faces Rating Scale can be used with children as young as 3 years, and it helps children express their level of pain by pointing to a cartoon face that most closely resembles how they are feeling (Figure 33-6).

The Poker Chip Tool consists of four red poker chips that can easily be carried in a pocket to be available when needed. The chips are aligned horizontally on a

TABLE 33-4
Myths About Pain and Children

Misconception	Fact
Infants do not feel pain.	Anatomic structures for pain processing reach adult maturity at 36 weeks after conception.
Children tolerate pain better than adults.	Even though children may not express pain as adults do, there are behavioral indicators of pain in children. Children as young as age 3 can use pain scales to communicate the level of pain experienced.
Children become accustomed to pain or painful procedures.	Some children show increased signs of discomfort with repeated painful procedures. Anxiety over impending procedures only exacerbates pain.
Narcotics are more dangerous for children than adults.	When used appropriately, opioids are not more dangerous for children than adults.

(Data adapted from McCaffery, M., & Pasero, C. L. [1999]. *Pain clinical manual* (2nd ed.). St. Louis, MO: Mosby, p. 627.)

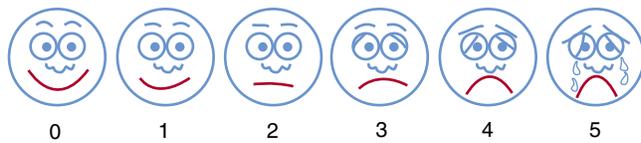

Figure 33-6 Wong/Baker Faces Pain Rating Scale (Reprinted with permission from Wong, D. L. [1998] *Whaley & Wong's nursing care of infants and children* [6th ed.]. St. Louis, MO: Mosby.)

hard surface in front of the child, and they are described as “pieces of hurt.” The chips are described from left to right as just a little bit of hurt, a little more hurt, more hurt, and the most hurt you could ever have. The child is then asked, “How many pieces of hurt do you have right now?” This tool can be used with children 4 to 13 years old.

The verbal 0 to 10 scale is also frequently used for school-age and adolescent clients in a number of settings. It is important to remember that any child under stress or with anxiety will regress, and regression may

make use of the verbal 0 to 10 scale in children under 8 to 10 years of age of questionable value.

Nursing Diagnosis

The two primary nursing diagnoses used to describe pain are *Acute Pain* and *Chronic Pain*. According to NANDA (2001), *Acute Pain* is defined as “an unpleasant sensory and emotional experience arising from actual or potential tissue damage or described in terms of such damage . . . (with) sudden or slow onset of any intensity from mild to severe, with an anticipated or predictable end and a duration of less than 6 months” (p. 72). *Chronic Pain* is defined as *Acute Pain*, with the last phrase replaced by “constant or recurring without an anticipated or predictable end and a duration of greater than 6 months.” Presenting characteristics of *Acute Pain* and *Chronic Pain* are listed in the Nursing Process Highlight.

If the client presents with problems in addition to pain, the nurse must be alert to the possibility that the pain may be the *cause* (not the effect) of another problem. For example, a client may be experiencing *Impaired Physical Mobility* or *Activity Intolerance* related to pain caused by a broken leg, as evidenced by verbal complaint, fatigue, and guarding of the affected leg.

Outcome Identification and Planning

When planning care for the client experiencing pain, mutual goal setting is of utmost importance. After assessing the client’s perception of the problem, work with the client in developing realistic outcomes. Be sure to use both nonpharmacologic and pharmacologic interventions in planning strategies to help clients achieve desired levels of functioning and pain control.

When asking about the client’s goal for pain relief, the nurse often has to state, “We can’t usually get rid of

THINK ABOUT IT

Pain Assessment Tools

After reviewing these brief case presentations, determine the type of pain assessment tool most appropriate for each:

1. A developmentally normal 42-year-old man during an overnight hospital stay after orthopedic surgery on the ankle
2. A developmentally normal 12-year-old oncology client with severe mucositis (inflammation of the mucous membrane) after chemotherapy for recurrent osteosarcoma (following an above-the-knee amputation) with metastases to multiple ribs and severe phantom limb pain

Nursing Process Highlight

Diagnosis Selected Defining Characteristics

- | | |
|---------------------|---|
| <i>Acute Pain</i> | <ul style="list-style-type: none"> • Verbalization of severe discomfort • Restlessness • Variations in vital signs indicative of autonomic responses • Guarding behavior • Sleep disturbances • Grimace • Self-focus • Distracted behavior • Changes in appetite and eating |
| <i>Chronic Pain</i> | <ul style="list-style-type: none"> • Verbalization of pain over an extended period of time • Impaired functional ability • Sleep disturbances • Guarding behavior • Irritability • Self-focus • Restlessness • Depression • Muscle atrophy of affected area • Weight changes • Fatigue • Fear of reinjury |

all your pain, but if we could get it down to a place that it didn't bother you so much, what would that be?" Thus, the family, and health care professionals involved will all be aware of a realistic goal for pain relief. "Providing the best possible pain relief to patients requires regular and consistent communication among all members of the health care team, including the patient" (Collins, Sparger, Richardson, Schriver, & Bergenstock, 1999, p. 20). Treatment goals for CNP clients include the following (McCaffery & Pasero, 1999):

1. Reduce pain level whenever possible.
2. Improve functioning.
3. Develop self-help skills for coping.
4. Alleviate psychopathology, including anxiety and depression.
5. Improve relationships with family members and health care providers in order to meet individual needs.

Terminally ill clients pose a special challenge in the area of pain management. According to Bral (1998), approximately 15% of deaths occur in people receiving hospice care. Thus, pain management is the responsibility of nurses who have no specialization in palliative

care. Joel (1999, p. 9) states "no death is a good or peaceful one if attended by suffering. Suffering can take the form of isolation, confusion, emotional deprivation, depersonalization, pain . . . All of this falls within the province of comfort and caring, and consequently becomes the work of nursing."

In its *Position Statement on Promotion of Comfort and Relief of Pain in Dying Patients*, the American Nurses Association (1991) states:

One of the major concerns of dying patients and their families is the fear of intractable pain during the dying process. Indeed, overwhelming pain can cause sleeplessness, loss of morale, fatigue, irritability, restlessness, withdrawal, and other serious problems for the dying patient. (p. 1)

The American Nurses Association (1991) advises nurses to administer doses of pain medication that are effective enough to manage pain in the dying client.

Planning of care leads to the development of an individual treatment plan for each client. When nurses understand that the existence of pain and its intensity is best defined by the client, "they acknowledge that every person with pain has a complex, multidimensional, and unique experience" (Bral, 1998, p. 7).

Implementation

The accompanying display lists AHRQ recommendations on caring for clients experiencing pain.

"Assessing and managing pain has long been a core nursing responsibility. Now, The Joint Commission on the Accreditation of Healthcare Organizations (JCAHO) is requiring accredited facilities and organizations to develop policies and procedures that formalize this obligation" (Acello, 2000, p. 52). The

PAIN ASSESSMENT AND MANAGEMENT TIPS

- Ask about pain regularly. Assess pain systematically.
- Believe the client/family's reports of pain and what relieves it.
- Choose pain control measures appropriate for the client, family, and setting.
- Deliver interventions in a timely, logical, and coordinated manner.
- Empower clients and families by encouraging them to control their treatment regime as much as possible.

(Data adapted from Jacox, A., Carr, D. B., Payne, R., et al. (1994). *Management of cancer pain: Clinical practice guideline no. 9* [Publication No. 94-0592]. Rockville, MD: Agency for Health Care Policy and Research (AHCPR), U.S. Department of Health and Human Services, Public Health Service.)

JCAHO calls for health care providers to (Williams-Lee, 1999):

- Recognize each client's right to pain assessment and treatment
- Monitor client responses to pain management strategies
- Educate staff and clients about pain management

Some key concepts of JCAHO's standard on pain management include the following (Acello, 2000, p. 52):

- Clients have the right to appropriate pain assessment.
- Pain is to be assessed and regularly reassessed.
- Clients will be treated for pain or referred for treatment.
- Clients will be taught the importance of effective pain management.
- Clients will be taught that pain management is a part of treatment.
- Clients will be involved in making health care decisions.
- Analgesics are to be administered as needed.
- Discharge planning and teaching will include continuing needs for pain management.

Nurse-Client Relationship

Establishment of a therapeutic relationship is the foundation for effective nursing care of the client experiencing pain. Clients who trust their nurses to be there, to listen, and to act, are the clients who are most likely to be comfortable. See Chapter 12 for information on developing a therapeutic relationship.

Client Education

Client education regarding pain management begins with defining pain, identifying the probable causes, introducing clients to pain assessment tools, and allowing them to choose the tool they would like to use. The importance of talking with health care providers about their pain and of using a preventive approach to pain management must also be emphasized. Provide written information to reinforce verbal explanations. Teach the importance of around-the-clock dosing instead of PRN administration of analgesic medications. Refer to the Client Teaching Checklist for pain management information.

When a client is to be discharged from a health care facility, discharge teaching should include pain management information with specific guidelines about the need for seeking follow-up advice/treatment. The accompanying display lists content for a comprehensive pain management teaching plan.

Both nonpharmacologic and pharmacologic interventions can be effective in caring for clients with pain. In some cases of mild pain, nonpharmacologic techniques may be the primary intervention, with medication available as "backup." In cases of moder-

CLIENT TEACHING CHECKLIST *Pain Management Information*

1. Help clients understand the importance of effective pain management. Explain the outcomes of unrelieved pain.
2. Teach at the client's level of comprehension. Assess literacy level.
3. Respect client's cultural beliefs related to pain.
4. Correct any misconceptions about the use of opioid analgesics. Teach about the low risk for addiction when these medications are used for pain relief.
5. Instruct on the use of complementary methods for relieving pain, including massage, application of heat and cold, and imagery.

CONTENT FOR PAIN MANAGEMENT TEACHING PLAN

1. General overview of pain
 - Definition
 - Causes/contributing factors
 - Pain assessment, including use of assessment tools
 - Importance of preventive approach
 - Family involvement
2. Pharmacologic pain management
 - Overview of drug management
 - Addiction, dependence, and tolerance
 - Respiratory depression
 - Communicating with health care providers about pain
 - Controlling accompanying symptoms (e.g., constipation, nausea)
3. Nonpharmacologic pain management
 - Importance of strategies
 - Review of past experience with nonpharmacologic methods
 - Demonstration of specific techniques

ate to severe pain, nonpharmacologic techniques can be an effective adjunctive, or complementary treatment.

Pharmacologic Pain Management

Listed below are principles for the care of clients experiencing pain:

- Assess the pain.
- Treat the contributing factors (pathology).

- Individualize analgesic therapy to each client.
- Choose the least invasive route of administration.
- Administer analgesics at regularly scheduled intervals (around-the-clock dosing) rather than on an as-needed (PRN) basis.
- Keep clients in control of their own analgesia as much as possible.
- Titrate doses to provide maximum pain relief and minimum side effects (Bral, 1998, p. 30). Know that the right dose is “whatever it takes to relieve the pain with the fewest side effects” (Newshan, 2000, p. 83).

Other general principles that guide practice are discussed below.

Combine Analgesics

Combining analgesics on the basis of the World Health Organization’s three-step analgesic ladder is imperative to provide effective pharmacologic intervention for clients with all types of pain. The use of adjuvant medication is recommended (Management of Cancer Pain Guideline Panel, 1994). **Adjuvant medications** are those drugs used to enhance the analgesic efficacy of opioids, to treat concurrent symptoms that exacerbate pain, and

to provide independent analgesia for specific types of pain. Adjuvant medication (medications without intrinsic analgesic properties) are often helpful in treating chronic pain. Adjuvant drugs include anticonvulsants, antidepressants, and sedatives. Gabapentin (Neurontin) is one anticonvulsant useful in treating older clients experiencing chronic pain (Luggen, 2000). Education for clients taking adjuvant medication must explain the need to continue to take the analgesic drug with the adjuvant medication.

Table 33-5 lists some common adjuvant medications used in pain management.

Maintain Therapeutic Serum Levels

Establishing and maintaining a therapeutic serum level is another important pain management strategy. Peaks and valleys of drug serum levels often occur when analgesics are administered in the traditional PRN manner. When the dose is administered on an intermittent schedule, a larger dose is often required, causing the client to have a peak serum drug level in the sedation range. The client must wait for the return of pain before requesting the next dose of analgesic. Depending on the length of time it takes to obtain the medication and,

TABLE 33-5
Adjuvant Medications for Pain Management

Medication	Type of Pain	Effects
<i>Tricyclic antidepressants</i> Amitriptyline Doxepin Imipramine Trazodone	Neuropathic pain frequently described as dull, aching, or throbbing	<ul style="list-style-type: none"> • Mood elevation, enhancement of opioid analgesia, direct analgesic effects • Anticholinergic side effects: dry mouth, constipation, urinary retention
<i>Anticonvulsants</i> Carbamazepine Phenytoin Clonazepam	Neuropathic pain frequently described as sharp shooting, burning, or lancinating	<ul style="list-style-type: none"> • Suppresses the spontaneous neuronal firing as sharp, that causes this type of pain
<i>Corticosteroids</i> Dexamethasone Prednisone	Pain due to cerebral or spinal cord edema or that in peripheral nerves caused by perineural edema	<ul style="list-style-type: none"> • Mood elevation, strong anti-inflammatory activity, appetite stimulation
<i>Antihistamine</i> Hydroxyzine	Pain or nausea in the anxious client	<ul style="list-style-type: none"> • Relief of complicating symptoms including anxiety, insomnia, nausea, and pruritus
<i>Neuroleptic</i> Methotrimeprazine	Alternative analgesic for clients who are opioid-tolerant or have opioid-limiting side effects, especially constipation	<ul style="list-style-type: none"> • Antiemetic and anxiolytic. • This is the one phenothiazine to date that has demonstrated analgesic properties: methotrimeprazine 15 mg IM was found to be equivalent to morphine 10 mg IM
<i>Psychostimulants</i> Dextroamphetamine Methylphenidate	Continued pain with opioid-induced sedation	Improves opioid analgesia and decreases sedation

(Adapted from Acute Pain Management Guideline Panel. [1992]. *Acute pain management: Operative or medical procedures and trauma. Clinical practice guideline*. [AHCPR Publication No. 92-0033]. Rockville, MD: Agency for Health Care Policy and Research.)

once taken, to reestablish an adequate blood level, there could be a period of up to an hour or so with inadequate pain control.

Patient-controlled analgesia (PCA) (client self-administration of intravenous pain medication via a programmable pump), with a loading dose when first started and a booster dose if needed, is a method to obtain a smooth analgesic level (Figure 33-7). PCA also allows the client to have control over pain management. The major advantage of PCA over the traditional, nurse-administered analgesia is that clients are enabled to seek pain relief whenever they feel it is necessary: “the best advice you can give your patients is to press the PCA button whenever they feel a need for pain medication” (Van-Couwenberghe & Pasero, 1998, p. 15). Requirements for the use of PCA are the cognitive ability to understand how to use the pump and the physical ability to push the button. The method is effective if the appropriate titrations are made on the basis of reassessment and client pain report.

Clients need to be taught that complete pain relief may be an unrealistic expectation. Instead, the goal of PCA is for the client to be comfortable and alert enough to participate in therapy. “The best time to teach patients about PCA is before it has started, when they’re lucid enough to understand your instructions” (Van-Couwenberghe & Pasero, 1998, p. 14).

Choose Appropriate Routes of Administration

Available routes of administration play an important role in choice of pain management technique. In general, the oral route (PO) of administration is preferred because it is the most convenient and cost-effective (Management of Cancer Pain Guideline Panel, 1994). When the oral route is not feasible, other routes (such as rectal or transdermal) can be used to administer analgesics.

The rectal route is effective when clients are nauseated and vomiting or when they are NPO. Suppositories of morphine, hydromorphone, and oxycodone are available. Contraindications to rectal administration include diarrhea, lesions of the rectum or anus, or immunosuppressed status. The transdermal route bypasses gastrointestinal absorption but has a slow onset and a slow decline in blood level after the patch is removed.

Figure 33-7 Client is using patient-controlled analgesia (PCA).

With continuing documentation of unreliable absorption of intramuscular (IM) injections of opioids, the prudent approach is to switch to subcutaneous or intravenous administration. Continuous infusions are possible by either intravenous (IV) or subcutaneous methods.

Analgesia using epidural, intrathecal (intraspinal), or intraventricular routes are reserved for settings in which experience, expertise, extensive support systems, and sophisticated follow-up are available (Management of Cancer Pain Guideline Panel, 1994). See Table 33-6 for an overview of administration routes; see Chapter 29 for a complete discussion of medication administration routes.

Nonsteroidal Anti-Inflammatory Drugs

The nonopioid class of pharmacologic agents consists of a group of medications classified as nonsteroidal anti-inflammatory drugs (NSAIDs). NSAIDs work by inhibiting the synthesis of prostaglandin, a class of chemicals that:

- Can be found in almost every body tissue
- Cause allodynia even in low concentrations
- Are always released when cells are damaged
- Contribute to edema and erythema
- Sensitize afferent nerve endings to bradykinin (a pain substance) (McCaffery & Pasero, 1999)

NSAIDs are useful in treating mild to moderate pain, especially painful conditions involving inflammation. NSAIDs are used frequently because of the following (Cleland & Gebhart, 1997, p. 32):

- They can be administered orally.
- They do not cause CNS or respiration depression.
- Several are available over-the-counter.

The widespread use of NSAIDs makes them the culprit in many adverse drug effects. The use of some NSAIDs can result in adverse gastrointestinal, hematologic, and renal effects. Aspirin is the standard NSAID against

NURSING TIP

Injections and Children

Because children lack the cognitive ability to weigh the pain of an injection against the pain relief from the medication, oral and rectal routes are preferred over injections.

TABLE 33-6
Advantages and Disadvantages of Selected Medication Administration Routes

Intervention	Advantages	Disadvantages
Oral NSAIDs	<ol style="list-style-type: none"> Useful for a wide variety of mild to moderate pains. Widely available, some over the counter. Additive analgesia when combined with opioids and other modalities. Can be administered by patient or family. Some are inexpensive. 	<ol style="list-style-type: none"> Ceiling effect to analgesia. Side effects, especially gastritis and renal toxicity, can be serious. May risk bleeding in severely thrombocytopenic patients. Only one NSAID (ketorolac) is available now for parenteral administration. Many are expensive.
Oral opioids	<ol style="list-style-type: none"> Effective for both localized and generalized pain. Ceiling to analgesic effectiveness imposed only by side effects. Multiple drug choices in the class. Sedative and anxiolytic properties useful in some acute treatment settings. Can be administered by patient or family. Some are inexpensive. Long-acting, controlled-release forms are available. 	<ol style="list-style-type: none"> Side effects may limit analgesic effectiveness. Prescription of these substances is regulated. Stigma or fears associated with use.
Transdermal opioids (fentanyl)	<ol style="list-style-type: none"> Long duration of action (48–72 h) from single patch. Allows use of a strong opioid (fentanyl) in outpatient settings for some patients who have not tolerated morphine and related drugs. Many patients find them easy to use. Provides continuous administration of an opioid without use of needles or pumps. Can be administered by patient or family. 	<ol style="list-style-type: none"> Side effects may not be as quickly reversible as in oral administration. Difficult to modify dosage rapidly. Relatively slow onset of action. Requires additional short-acting medicine for breakthrough pain. Expensive.
Rectal opioids	<ol style="list-style-type: none"> Relatively easy-to-use alternative route when the oral route is unavailable. Other opioid suppositories available for morphine-intolerant patients. Can be administered by patient or family. Less expensive than subcutaneous or intravenous infusions. 	<ol style="list-style-type: none"> Not widely accepted by patients or families. Side effects may limit analgesic effectiveness. Relatively slow onset of action. Contraindicated if low white blood cell or platelet count (risks of infection, bleeding).

TABLE 33-6 (continued)
Advantages and Disadvantages of Selected Medication Administration Routes

Intervention	Advantages	Disadvantages
Subcutaneous infusion	<ol style="list-style-type: none"> 1. Can provide rapid pain relief without intravenous access. 2. Morphine and hydromorphone are the preferred drugs for this route when administered in the home. 3. When used in PCA mode, allows for rapid individual dose titration and provides sense of control for patient. 	<ol style="list-style-type: none"> 1. Only a limited volume of infusate can be administered (e.g., 2–4 ml/h). 2. Induration, irritation at infusion site may be a complication. 3. Requires skilled nursing and pharmacy support. 4. Often requires expensive drug infusion pump and recurring charges for disposables.
Intravenous infusion	<ol style="list-style-type: none"> 1. Can provide rapid pain relief. 2. Almost all opioids can be given by this route. 3. Not limited to infusate volumes. 4. When used in PCA mode, allows for rapid individual dose titration and provides sense of control for patient. 	<ol style="list-style-type: none"> 1. Infection and infiltration of intravenous lines are potential complications. 2. Requires skilled nursing and pharmacy support. 3. Often requires expensive drug infusion pump and recurring charges for disposables.
Epidural, intrathecal, and intracerebral ventricular routes	<ol style="list-style-type: none"> 1. Useful for pain that has not responded to less-invasive measures. 2. Local anesthetics may be added to spinal opioids and may produce additive analgesia. 	<ol style="list-style-type: none"> 1. Tolerance may occur sooner than with oral or rectal administration. 2. Infection at catheter site can produce meningitis and/or epidural abscess. 3. Pruritus and urinary retention are more common than with oral or parenteral opioid administration. 4. Contraindicated in presence of acute spinal cord compression. 5. Requires special expertise. 6. Requires careful monitoring, especially when therapy begins and when doses are increased. 7. May require expensive drug infusion pump, intervention fees, and recurring charges for disposables.
Regional neurolytic blocks	<ol style="list-style-type: none"> 1. Effective for pain relief with certain diagnoses (e.g., pancreatic cancer). 2. May be useful for movement-related and abdominal visceral pain that is refractory to drug therapy. 3. Can allow dosage (and side effect) reduction of systemic drugs for localized pain. 	<ol style="list-style-type: none"> 1. Risk of postural hypotension, bowel and bladder incontinence, and leg weakness. 2. Procedure is irreversible. 3. Requires special expertise. 4. Expenses for specialized care and operating room costs.

(Adapted from Management of Cancer Pain Guideline Panel. [1994]. *Management of cancer pain: Clinical practice guideline*. [AHCPR Publication No. 94-0592, pp. 42–43]. Rockville, MD: Agency for Health Care Policy and Research.)

which the efficacy of all NSAIDs are measured due to its long history of relative safe usage, low cost, and availability without a prescription (Jones, 1997). In fact, aspirin is so commonly used that many individuals fail to consider it to be a drug. Clients must be taught about aspirin's adverse effects; see Table 33-7.

NSAIDs are also subject to the **ceiling effect** (as the dose of medication is increased above a certain level,

the analgesic effect remains the same), and only the adverse effects continue to increase.

For example, acetaminophen is relatively easy on the gastrointestinal tract and does not affect platelet aggregation, but large doses over time have caused liver damage, with extreme overdoses causing liver failure. The remaining NSAIDs all have significant multisystem side effects and adverse effects, with the most worrisome

TABLE 33-7

NURSING TIP

The Ceiling Effect

Educate clients and their families regarding the ceiling effect because they may feel that “If a little helps some, then more is better.” The risk for significant side effects and adverse reactions is increased by this misunderstanding.

being severe gastric irritation, gastric bleeding, and renal problems. NSAIDs must be used cautiously in elderly clients. The risk of gastrointestinal problems (such as peptic ulcer disease and gastrointestinal bleeding) increases with the use of NSAIDs in older clients (Pasero, Reed, & McCaffery, 1998). “Given the large number of NSAID users, protection against GI complications is a priority” (Peloso, 2000, p. 36).

Opioid Analgesics

The opioids and NSAIDs exert pain relief through different mechanisms. For example, the opioids act on several sites in the central nervous system (CNS) rather than on the peripheral nervous system as do the NSAIDs. Opioids alter the release of neurotransmitters, and, therefore, pain transmission is interrupted at several sites in the CNS. The result is an altered perception of and response to pain (Plaisance & Price, 1999).

The opioid analgesics fall into three classes: pure opioid agonists, partial agonists, and **mixed agonist-antagonists** (a compound that blocks opioid effects on one receptor type while producing opioid effects on a second receptor type). Pure agonists are those that produce a maximal response from cells when they bind to

the cells’ opioid receptor sites. Morphine (the gold standard against which all other opioids are measured), fentanyl, methadone, hydromorphone, and codeine are pure agonists. Meperidine, although classified as a pure agonist, is not recommended except in clients with a true allergy to all other narcotics, because of its neurotoxicity. Meperidine produces clinical analgesia for only 2.5 to 3.5 hours when given intramuscularly in adults. In pediatric clients receiving intravenous meperidine, analgesia may last for only 1.5 to 2.0 hours. In the elderly, most of whom show decreased glomerular filtration rates, there is generally a higher peak and longer duration of action as it takes longer to excrete the opioid as well as its toxic metabolite, normeperidine.

Meperidine should be reserved for very brief courses in otherwise healthy patients who have demonstrated an unusual reaction (e.g., local histamine release at the infusion site) or allergic response during treatment with other opioids such as morphine or hydromorphone. (Acute Pain Management Guideline Panel, 1992, p. 42)

Unlike the NSAIDs, pure agonist opioids are not subject to the ceiling effect. As the dosage is increased, there is increasing pain relief, with the only limiting factor being the degree of side effects, particularly respiratory depression and constipation. Many of the analgesic medications (especially opioids) can cause the unwanted effect of constipation. The accompanying display lists measures for prevention.

OPIOID-INDUCED CONSTIPATION: PREVENTIVE APPROACHES

- Eat high-fiber foods.
- Drink 8–10 glasses of fluid per day.
- Eat foods that have helped relieve constipation previously.
- Increase physical activity, such as walking.
- Consume a hot beverage about 30 minutes prior to the planned time for a bowel movement.
- Use laxatives or stool softeners only as advised by the health care provider.

Other side effects that occur frequently in clients on opioid medications are pruritus and nausea, but the degree to which they are present from each medication varies among individuals. Clients must be instructed regarding these *normal* responses to opioids and informed that it does not mean that they are allergic to them. A true allergy to opioids would be indicated by a rash or hives that starts after receiving the opioid, a local histamine release at the site of infusion, or anaphylaxis. Clients also need to know that the pruritus and nausea generally subside after 4 to 5 days of opioid therapy. In the meantime, an antihistamine such as diphenhydramine or hydroxyzine may be used for pruritus, and an antiemetic such as metoclopramide or trimethoben-

zamide can be used to treat the nausea. Almost all medications used to treat side effects have their own side effect of sedation. Thus, there is the possibility of a cumulative effect of severe sedation.

Mixed agonist-antagonist opioids are believed to be subject to the ceiling effect for pain relief, as well as a ceiling effect for respiratory depression. Mixed agonist-antagonist opioids activate one opioid receptor type while simultaneously blocking another type. Butorphanol, pentazocine, and nalbuphine are the most frequently used in pain management.

Addiction, Tolerance, and Physical Dependence

As a result of fears of addiction, family caregivers tend to undermedicate their relative's pain. Family/client education about addiction and pain medication should be a priority for those receiving opioid therapy. McCaffery and Pasero (1999) define **addiction**, or psychological dependence, as behavior of overwhelming involvement with obtaining and using a drug for other than approved medical reasons. Therefore, a client taking opioids for an appropriate medical reason is not addicted. "The fear of addiction is perhaps the single most persistent barrier to achieving pain relief with opioid analgesics . . . it may be the most challenging aspect of educating patient, their families, and even health care professionals" (McCaffery & Pasero, 1998, p. 18). **Tolerance** can occur after repeated administration of an opioid analgesic, when a specific dose loses its effectiveness and the client requires larger and larger doses to produce the same level of analgesia. The first indication of tolerance is decreased duration of action, then decreased analgesia. If this pattern is noted in clients with continuing opioid needs, the analgesic dose needs to be titrated higher immediately. **Physical dependence** is the reaction of the body, commonly known as withdrawal syndrome, to abrupt discontinuation of an opioid after repeated use.

Respiratory Depression

Titrating opioid analgesics to obtain optimal pain management with minimal side effects is a difficult task. See Table 33-8 for a list of risk factors predisposing to respiratory depression in clients receiving appropriate dosages of sedatives or opioid analgesics. This list should be used to identify clients of all ages who require increased vigilance, possible cardiac and pulse oximetry (determination of oxygen saturation of arterial blood) monitoring, and frequent assessment when taking opioid analgesics. It is not to be construed as a reason for denying the client adequate pain management. When caring for clients receiving opioid analgesics, the nurse should periodically identify the presence and intensity of risk factors.

Local Anesthesia

Local anesthetics are effective for pain management in a variety of settings. Topical anesthetics are available for teething, sore throats, denture pain, laceration repair, and intravenous catheter insertions. EMLA® cream is a

TABLE 33-8
Risk Factors Predisposing to Respiratory Depression With Use of Sedatives or Opioid Analgesics

1. Neurological impairment
 - Cerebral palsy
 - Altered level of consciousness
2. Respiratory compromise
 - Thoracic skeletal deformities (e.g., scoliosis, kyphosis, contracture)
 - Neurodegenerative disorders (e.g., muscular dystrophy, tuberous sclerosis, Werdnig-Hoffman disease, myasthenia gravis)
 - Pulmonary disease (e.g., cystic fibrosis, reactive airway disease, bronchopulmonary dysplasia, chronic obstructive lung disease)
 - Thoracic or high abdominal incision
 - Abdominal distension
3. Metabolic alteration
 - Liver dysfunction or failure
 - Metabolic disease
 - Sepsis
4. Renal compromise
 - Kidney dysfunction or failure
 - Single kidney
 - Hypovolemia
 - Urine output <1 ml/kg/h in children, <30 ml/h in adults, or elevated blood urea nitrogen (BUN) or creatinine
5. Other
 - Obesity (when drug is ordered on actual weight rather than estimated lean body weight)
 - Increasing sedation
 - Agitation
 - Preverbal or nonverbal client
6. Concurrent administration of other narcotics or sedatives
 - Opioid analgesics
 - Sedatives/hypnotics and tranquilizers
 - Anticonvulsants
 - Antihistamines
 - Psychotropics

(Data from: Pain Consultation Service, The Children's Hospital, Denver, 1995.)

mixture of local anesthetics, combining prilocaine and lidocaine. It produces complete anesthesia for at least 60 minutes when topically applied to intact skin.

Another topical anesthetic, TAC, is available for anesthesia during closure of lacerations. It is a combination of tetracaine 0.5%, adrenaline 1:2000, and cocaine 11.8% in a normal saline solution that can be applied directly to the open wound surface in place of local anesthetic infiltration with a needle. This allows pain-free cleansing of the laceration as well as suturing. Because both adrenaline (epinephrine) and cocaine cause vasoconstriction, TAC cannot be used in areas supplied by end-arteriolar blood supply such as digits, the ear, or the nose. It also is contraindicated on burned

or abraded skin because this could lead to increased systemic absorption of cocaine and tetracaine, thus placing the client at risk for seizures. See Chapter 29 for further discussion of topical medications.

Treatment of Neuropathic Pain

Neuropathic pain is often refractory to treatment with NSAIDs and opioids. When increasing doses of opioids are ineffective in controlling postoperative pain, an immediate search for the underlying cause should begin, and the diagnosis of neuropathic pain should be considered. Once diagnosed, the focus of treatment is optimizing functional abilities. Information on pharmacologic interventions for neuropathic pain found in the *Management of Cancer Pain Guideline* (1994) includes a number of options, which are discussed in the following paragraphs.

Trial of a tricyclic antidepressant is frequently the first step in a client who describes dull, aching, or throbbing pain. Amitriptyline is often the drug of choice because it has been the most widely studied. This class of medications is useful in pain management as a result of:

- Mood elevation
- Potentiation of opioid analgesia
- Direct analgesic effects

Clients with neuropathic pain often have significant sleep deprivation. Amitriptyline's action and the side effect of drowsiness improve the client's ability to fall asleep and to sleep for longer periods. Amitriptyline must be started at very low doses especially in children, the debilitated, or elderly clients, then increased slowly. It should be administered at bedtime to promote sleep and to minimize falls resulting from orthostatic hypotension. The onset of analgesic effects occurs within 1 to 2 weeks, and maximal effect can be seen in 4 to 6 weeks.

Anticonvulsants are often tried first for clients with burning, sharp, shocking, shooting, or **lancinating** (piercing or stabbing) pain. Carbamazepine is often the drug of choice, with other possibilities being clonazepam or phenytoin. These medications suppress spontaneous neuronal firing that leads to the lancinating pain of nerve injury. Carbamazepine may cause a transient bone marrow suppression and requires regular monitoring of serum drug levels, blood counts, and liver function. It should be avoided if possible in clients with any form of bone marrow suppression (e.g., those undergoing chemotherapy, radiation therapy, or taking immunosuppressants posttransplantation).

Corticosteroid effects include mood elevation, anti-inflammatory effects, and appetite stimulation. Corticosteroids are effective in reducing the neuropathic pain caused by pressure on nerves both centrally and peripherally. The two corticosteroids most frequently used in pain management are dexamethasone and prednisone.

If muscle spasms are a major contributor to the client's discomfort, baclofen can be tried for its antispasmodic effect. This is particularly effective for clients with spinal

cord injury or upper motor neuron dysfunction, including cerebral palsy.

For many individuals, the use of nonpharmacologic methods enhances pain relief. These nonpharmacologic strategies are often used in combination with medication. Complementary/alternative methods are being used with increasing frequency to treat pain. The use of such strategies is often influenced by the client's culture. The accompanying display lists some commonly used complementary treatment approaches.

COMPLEMENTARY/ALTERNATIVE THERAPY

Application of heat or cold
Acupuncture or acupressure
Focused breathing
Herbal remedies
Humor
Hypnosis
Imagery
Massage
Meditation
Music
Progressive muscle relaxation
Tai chi
Therapeutic touch
Yoga

(Data from Luggen, A. S. [2000]. Pain. In A. G. Leckenotte (Ed.), *Gerontologic nursing* [2nd ed.]. St. Louis, MO: Mosby, p. 286.

In some cases of mild pain, nonpharmacologic techniques may be the primary intervention, with medication available as "backup." In cases of moderate to severe pain, nonpharmacologic techniques can be an effective adjunctive, or complementary treatment.

Cognitive-Behavioral Interventions

Cognitive-behavioral interventions are designed to educate clients and to modify client attitudes and

NURSING TIP

Cognitive-Behavioral Interventions

Cognitive-behavioral interventions should be introduced as early as possible so that clients can learn and practice the techniques before experiencing intense pain, which impairs learning.

behaviors. These nonpharmacologic approaches are an important part of the multimodal approach to pain management and can be used in conjunction with appropriate analgesics. A major goal of these interventions is to help the client gain a sense of control over the pain. The effectiveness of selected therapies is outlined in Table 33-9.

Distraction

Distraction is a pain management strategy that focuses the client's attention on something other than the pain and associated negative emotions. Children and adolescents seem to be particularly adept at using distraction. As many parents know, interactive games or listening to music can be powerful distraction techniques for

TABLE 33-9
Advantages and Disadvantages of Nonpharmacologic Therapies

Intervention	Advantages	Disadvantages
Relaxation, imagery, biofeedback, distraction, and reframing	<ol style="list-style-type: none"> 1. May decrease pain and anxiety without drug-related side effects. 2. Can be used as adjuvant therapy with most other modalities. 3. Can increase patient's sense of control. 4. Most are inexpensive, require no special equipment, and are easily administered. 	<ol style="list-style-type: none"> 1. Patient must be motivated to use self-management strategies. 2. Requires professional time to teach interventions.
Patient education	<ol style="list-style-type: none"> 1. Effective in improving ability to follow medical regimen and in decreasing pain. 2. Multiple teaching aids available. 3. Promotes self-care in pain treatment and management of side effects. 	<ol style="list-style-type: none"> 1. Requires professional time to teach pain management regimens.
Psychotherapy, structured support, and hypnosis	<ol style="list-style-type: none"> 1. May decrease pain and anxiety for patients who have pain that is difficult to manage. 2. May increase patient's coping skills. 	<ol style="list-style-type: none"> 1. Requires skilled therapist.
Cutaneous stimulation (superficial heat, cold, and massage)	<ol style="list-style-type: none"> 1. May reduce pain, inflammation, or muscle spasm. 2. Can be used as adjuvant therapy with most other modalities. 3. Relatively easy to use. 4. Can be administered by patients or families. 5. Relatively low cost. 	<ol style="list-style-type: none"> 1. Heat may increase bleeding and edema after acute injury. 2. Cold is contraindicated for use over ischemic tissues.
Transcutaneous electrical nerve stimulation (TENS)	<ol style="list-style-type: none"> 1. May provide pain relief without drug-related side effects. 2. Can be used as adjuvant therapy with most other modalities. 3. Gives patient sense of control over pain. 	<ol style="list-style-type: none"> 1. Requires skilled therapist to initiate therapy. 2. Potential risk of infection, bleeding.
Acupuncture	<ol style="list-style-type: none"> 1. May provide pain relief without side effects. 2. Can be used as adjuvant with most other therapies. 	<ol style="list-style-type: none"> 1. Requires skilled therapist.

(Adapted from Acute Pain Management Guideline Panel. [1992]. *Acute pain management: Operative or medical procedures and trauma. Clinical practice guideline*. [AHCPR Publication No. 92-0033]. Rockville, MD: Agency for Health Care Policy and Research.)

NURSING TIP

Using Distraction

Distraction should never be used as the *only* pain management intervention, but it can be extremely helpful while waiting for other techniques to take effect.

children; they can also be effective for adults experiencing pain.

Reframing

Reframing is a technique that teaches clients to monitor their negative thoughts and replace them with ones that are more positive. Teaching a client to view pain by expressing not, “I can’t stand this pain, it’s never going away” but instead, “I’ve had similar pain before, and it’s gotten better” is an example of effective reframing.

Relaxation Techniques

Relaxation techniques (a variety of methods used to decrease anxiety and muscle tension), **imagery** (a strategy that uses mental images to assist with relaxation), and **progressive muscle relaxation** (a strategy in which muscles are alternately tensed and relaxed) are used to achieve both mental and physical relaxation. Physical relaxation leads to reduction of skeletal muscle tension; mental relaxation is used to alleviate anxiety.

Biofeedback

Biofeedback training is another method that may be helpful for the client in pain, especially one who has difficulty relaxing muscle tension. **Biofeedback** is a process through which individuals learn to influence their physiological responses. Through the use of biofeedback, clients can alter their pain experience. See Chapter 14 for a description of the biofeedback process.

Cutaneous Stimulation

Counterstimulation is the term used to identify techniques believed to activate the endogenous opioid and monoamine analgesia systems. These interventions are effective by decreasing swelling through cryotherapy (or cold applications), decreasing stiffness (heat applications), and increasing large-diameter nerve fiber input to block small-diameter pain fiber messages (cold, heat, pressure, vibration, or massage). Therapeutic heat and cold are effective pain management tools; they are readily available and easy to use. Both heat and cold can produce analgesia for pain. Heat therapy increases blood flow, increases tissue metabolism, decreases vasomotor

tone, and increases the viscoelasticity of connective tissue, making it particularly effective in easing joint stiffness/pain (Bezkor & Lee, 1997). The use of heat as therapy should be closely monitored as it can produce increased inflammation and edema.

NURSING ALERT

Use heat therapy cautiously in clients with sensory impairment as they may experience burns. Bony prominences are especially vulnerable to the potential for burns.

Cold therapy exerts many benefits, including the following:

- Alleviates edema by reducing vascular flow
- Counteracts inflammation
- Reduces fever
- Diminishes muscle spasms
- Elevates pain threshold as a result of decreasing the velocity of nerve conduction

Application of cold is inappropriate for clients with cold intolerance, vascular insufficiency, and conditions aggravated by cold (e.g., Reynaud’s phenomenon).

Transcutaneous Stimulation

Transcutaneous stimulation is achieved through use of transcutaneous electrical nerve stimulation, acupuncture, and acupressure. **Transcutaneous electrical nerve stimulation (TENS)** is a method of applying minute amounts of electrical stimulation to large-diameter nerve fibers via electrodes placed on the skin. Placement of the electrodes is determined by identifying which nerve innervates the painful area, then determining where that nerve is superficial, or where an anesthetic block would be placed to numb that nerve. Other modalities of pain management should *not* be abandoned while a trial of TENS occurs. Although TENS can be successful, there are two major contraindications:

1. No electrodes should be placed in the area over or surrounding demand cardiac pacemakers.
2. No electrodes can be placed over the uterus of a pregnant woman.

Acupuncture is another counterstimulation technique; it is performed by a specialist and accomplished by insertion of small solid needles into the skin and musculature at specific sites and at various depths. Acupressure accomplishes the same stimulation through cutaneous pressure over the selected site. When the client seeks acupressure, acupuncture, or TENS treatment, it is important to determine the efficacy of the present treatment regime.

Acupressure has been used in TCM since the 5th century B.C. Firm pressure is applied by the fingers to specific acupuncture points on the body to unblock the *chi* (energy); see Figure 33-8.

Encourage Exercise

Exercise is an important treatment for chronic pain because it strengthens weak muscles, helps mobilize joints, and helps restore balance and coordination. Passive range of motion should not be used if it increases pain or discomfort. Immobilization is frequently used for clients with episodes of acute pain or to stabilize fractures; however, prolonged immobilization should be avoided whenever possible because it can lead to muscle atrophy and cardiovascular deconditioning.

Nutrition

Dietary practices may affect pain by inhibiting biochemical events associated inflammation. Some foods may actually trigger a painful episode; for example, red wine,

cheese, citrus fruits, and cured meats often contribute to the onset of migraine headaches (Howell, 1997).

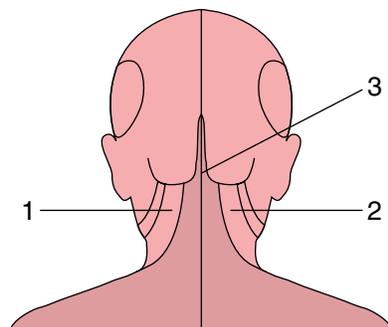

Other foods may help alleviate the pain associated with chronic diseases. For example, cherries and berries with red, blue, or black skins have high amounts of bioflavonoids, substances with antiinflammatory properties. Table 33-10 lists foods with properties that exert a pain reducing effect.

Herbals

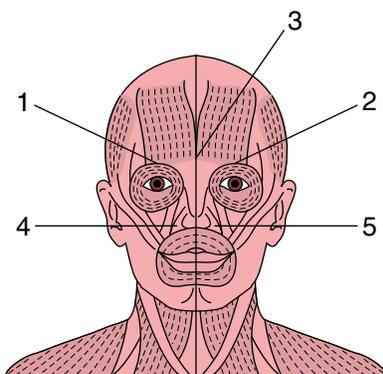

Many herbs are also useful in mediating pain; see Table 33-11. Howell (1997) reports treatment of mouth pain in cancer patients with candy that contains capsaicin.

Environment

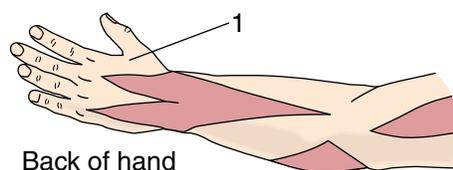

The environment can exert influence on the perception of pain; therefore, changes in one's environment may reduce pain levels. Pet therapy, consisting of interactive sessions between client and animals, is helpful for some people experiencing chronic pain.

Horticultural therapy (treatment that includes looking at, touching, and growing plants) has several therapeutic benefits, including pain reduction, relaxation, and improved energy level. Participation in gardening can provide distraction from chronic pain.

Music therapy may help ease pain by producing relaxation and providing distraction. See the Nursing Tips for suggestions on using music to alleviate pain.

NURSING TIP

Music as Pain Management

Let the client select the music. Throughout its use, continuously assess the affect of music on the client's pain intensity.

Pain may be manifested differently by older individuals. For example, pain may be referred (gallbladder pain is felt in the shoulder). Also, the intensity of pain in some elders may not accurately reflect the severity of the underlying pathology; (e.g., a myocardial infarction may be felt as a fluttering sensation, Eliopoulous, 1999).

Some of the outcomes of untreated pain in older adults include the following (Loeb, 1999):

- Sleep alterations
- Nutrition problems
- Impaired gait
- Cognitive impairments
- Decreased socialization
- Increased incidence of falls
- Decreasing ability to function independently

“Compared to race, site of pain, and intensity of pain, age is the most important variable influencing analgesic response” (Pasero, Reed, & McCaffery, 1998, p. 12.). The general guideline for administering analgesics to older clients is to *start low and go slow*.

Many elderly individuals receive health care in their homes. The accompanying display lists recommendations for home health nurse to use with clients experiencing pain.

Evaluation

Evaluating the efficacy of the pain management interventions is ongoing, with client input throughout the process. Evaluation focuses primarily on the client's subjective reports. Objective data used to evaluate pain management efficacy include:

- Client's facial expression and posture
- Presence (or absence) of restlessness
- Vital sign monitoring
- Ongoing use of pain assessment tools

HOME CARE: PAIN MANAGEMENT CONCEPTS

- On each visit, evaluate the client's pain.
- Assess factors influencing effective pain management (e.g., motor, cognitive, and functional alterations).
- Teach clients and family members adjunctive therapies to be used with analgesics to decrease pain.
- Identify barriers that hinder pain control.
- Encourage the homebound client to use around-the-clock dosing of analgesics.

(Data adapted from Luggen, A. S. [2000]. Pain. In A. G. Lueckenotte, (Ed.), *Gerontologic nursing* [2nd ed., p. 300.]. St. Louis, MO: Mosby)

Regular reassessment is an integral part of effective pain management. In addition to client self-report and nursing observation, family input is a valuable source of information for evaluating the effectiveness of care.

REST AND SLEEP

Rest and sleep are fundamental components of well-being. All individuals require certain periods of calm and lesser activity so that their bodies can regain energy and rebuild stamina. The need for rest and sleep varies with age, developmental level, health status, activity level, and cultural norms. Pain and impaired sleep are closely related in most people. According to Doghramji and Fredman (1999), 50–70% of clients experiencing pain also suffer sleep disturbance. On the other hand, sleep deprivation can decrease pain tolerance and, thus, may exacerbate pain (especially headaches).

Rest refers to a state of relaxation and calmness, both mental and physical. Activity during rest periods can range from lying down to reading a book to taking a quiet walk. When discussing a client's rest patterns, the nurse should try to understand what activities and environments the client defines as restful.

Sleep refers to a state of altered consciousness during which an individual experiences minimal physical activity and a general slowing of the body's physiological processes. Sleep generally occurs in a periodic cycle and usually lasts for several hours at a time; disruptions in the usual sleep routine can be distressing to clients and will most likely impair sleep further. As a restorative function, sleep is necessary for physiological and psychological healing to occur. It is important for clients, their significant others, and health care providers to understand the normal sleep-wake cycle and how sleep affects mood and healing.

Physiology of Rest and Sleep

The cycles of wakefulness and sleep are controlled by centers in the brain and influenced by routines and

environmental factors. An individual's biological clock also helps determine the specific cycles that will be followed for wakefulness and sleep.

Stages of Sleep

Electroencephalograph (EEG) patterns, eye movements, and muscle activity are used to identify stages of sleep. The stages of sleep are classified in two categories: non-rapid eye movement (NREM) and rapid eye movement (REM) sleep.

NREM Sleep

With the onset of sleep, the heart rate and respiratory rate slow slightly and remain regular. This first phase of sleep is referred to as non-rapid eye movement, or NREM, sleep. NREM sleep consists of four different stages. As the client enters *stage 1 sleep*, there is a general slowing of EEG frequency but an appearance of wave spikes; the eyes tend to roll slowly from side to side, and muscle tension remains absent except in the facial and neck muscles. In adult clients with normal sleep patterns, stage 1 sleep usually lasts only 10 minutes or so. Stage 1 NREM sleep is of a very light quality, which means that during this stage a sleeper can be easily awakened.

Stage 2 sleep is still fairly light sleep, with a further slowing of EEG patterns and loss of slow rolling eye movements. Fifty percent of normal adult sleep may be spent in stage 2. After an initial 20 minutes or so of stage 2 sleep, a deep form of sleep called stage 3 to 4 is entered.

Stage 3 and *stage 4* sleep are frequently discussed together because of the difficulty of identifying and separating the two. Stage 3 refers to medium-depth sleep, and stage 4 signals the deepest sleep. During these stages, all cortical brain cells appear to be firing at the same time, resulting in large slow waves on the EEG. When roused from stage 3 to 4 sleep, an adult can take 15 seconds or so to become fully awake. This difficulty

NURSING TIP

Night Terrors

Unlike nightmares, which occur during REM sleep, night terrors occur during NREM stage 3 to 4 sleep and are most common during childhood and adolescence. They are identified by an abrupt awakening, generally within the first hour of sleep, and the child appears to be in a panic state. The child may be only partially coherent and by the following morning typically has no memory of the event.

NURSING CARE PLAN

The Client with Chronic Pain

Case Presentation

Sally Atkinson, a 48-year-old woman, injured her back 3 years ago while lifting some boxes of paper at work. Since that time, she has had 4 epidural steroidal injections for the pain associated with 2 ruptured discs. Her pain has been intermittent with some alleviation from the epidural injections. Her last epidural was 3 months ago. She arrives at the clinic stating, “I just don’t know how I can go on like this. The pain has been tolerable until last night. I’m hurting so bad!” She is tearful and pacing, saying “It hurts too much when I sit down.”

Assessment

- Verbalization of pain (“9” on a 1 to 10 pain intensity scale)
- Anxious (as evidenced by pacing and tears)
- Blood pressure 148/90
- Pulse strong and regular at 92
- Guarded movement
- History of chronic pain

Nursing Diagnosis #1

Chronic Pain related to muscle spasm and ruptured discs.

Expected Outcomes

The client will:

1. Practice selected noninvasive pain relief measures.
2. Verbalize a decrease in pain.
3. Have increased ability to perform daily activities as evidenced by walking 1 mile every day and being able to work.

Interventions/Rationales

1. Assess the client’s level of pain, determining the intensity at its best and worst.
Determines a baseline for future assessment.
2. Listen to the client while she discusses the pain; acknowledge the presence of pain.
Acknowledging the client’s pain decreases anxiety by communicating acceptance and validating the client’s perceptions.
3. Discuss reasons why pain may be increased or decreased.
Helps the client determine a cause-and-effect relationship between pain and specific activities.
4. Teach relaxation techniques such as deep breathing, progressive muscle relaxation, and imagery.
Reduces skeletal muscle tension and anxiety, which potentiates the perception of pain.
5. Teach the client and family about treatment approaches (biofeedback, hypnosis, massage therapy, physical therapy, acupuncture, and exercise).
Makes the client and family aware of the availability of treatment options.
6. Teach the client about the use of medication for pain relief. Provide accurate information to reduce fear of addiction.
Lack of knowledge and fear may prohibit client from taking analgesic medications as prescribed.
7. Encourage the client to rest at intervals during the day.
Fatigue increases the perception of pain.
8. Explain the relationship between chronic pain and depression.
Knowledge decreases anxiety.

Evaluation

Ms. Atkinson demonstrates the use of deep breathing and progressive muscle relaxation. After practicing relaxation techniques, she rates her pain as a 2 to 3 on the pain intensity scale. Ms. Atkinson is able to walk for 1 mile, but she still has backache while sitting at her computer for extended periods of time.

(continues)

NURSING CARE PLAN**The Client with Chronic Pain (continued)****Nursing Diagnosis #2***Anxiety related to chronic pain.***Expected Outcomes**

The client will:

1. Verbalize an increase in psychological and physiological comfort level.
2. Demonstrate ability to cope with anxiety as evidenced by normal vital signs and a verbalized reduction in pain intensity.

Interventions/Rationales

1. Assess the client's level of anxiety.
To collect baseline data to be used in measuring a decrease or increase in anxiety level.
2. Speak slowly and calmly.
Avoids escalating client's anxiety level and increases the likelihood of client's comprehension.
3. Encourage Ms. Atkinson to verbalize angry feeling.
Anger is often a component of chronic conditions because of the prolonged sense of powerlessness. "Stuffing" anger can lead to increased anxiety.

Evaluation

Ms. Atkinson rates her pain as a 2 to 3 on the pain intensity scale after practicing relaxation techniques. She voices concern that the pain will soon come back. After a relaxation session, her vital signs returned to normal limits. She denies feeling angry.

in awakening is even more pronounced in children. Stage 3 to 4 sleep is where most sleepwalking, sleeptalking, enuresis, and night terrors occur.

Stage 3 to 4 sleep is felt to have restorative value, necessary for physical recovery. After sleep deprivation studies, stage 3 to 4 sleep is the first to be regained. The majority of growth hormone is secreted at night, peaking during stage 3 to 4 sleep near the beginning of a sleep period. Growth hormone is required not only for growth but also for normal tissue repair in clients of all ages. Stage 3 to 4 sleep accounts for approximately 25% of sleep in children, declines slightly in young adulthood, then gradually declines in middle age and may be absent in elderly clients.

REM Sleep

After the initial 90 minutes or so of NREM sleep in adults, the client enters rapid eye movement, or REM, sleep. The EEG pattern resembles that of the awake state; there are rapid conjugate eye movements; heart rate and respiratory rate are irregular and often higher than when awake; and muscles, including those of the face and neck, are flaccid, leaving the body immobilized. Dreams occur 80% of the time clients are in REM sleep. Unlike stage 3 to 4 sleep, which is most abundant during the early portion of a sleep period, REM sleep periods become longer as the night progresses and the individual becomes more rested. An adult typically has four to six REM sleep periods through the night, accounting for 20% to 25% of

sleep. REM sleep makes up 50% of sleep in the newborn, then gradually declines to 20% to 25% of sleep by early childhood and remains fairly constant throughout the remainder of the life span.

Sleep Cycle

A **sleep cycle** refers to the sequence of sleep that begins with the four stages of NREM sleep in order, with a return to stage 3, then 2, then passage into the first REM stage (Figure 33-9). The duration of a sleep cycle is generally between 70 and 90 minutes, and the typical sleeper will pass through four to six sleep cycles during an average sleep period of 7 to 8 hours.

The length of the NREM and REM periods of sleep will change as the overall sleep period progresses and the person becomes more relaxed and re-energized. There is less need for stage 3 to 4 sleep and more need for REM sleep as the sleep period progresses, and dreams during the REM phases of later sleep may become more vivid and intense. If the sleep cycle is broken at any point, a new sleep cycle will start, beginning again at stage 1 of NREM sleep and progressing through all the stages to REM sleep.

Biological Clock

The **biological clock** (an endogenous mechanism that measures time) controls the daily fluctuations in hun-

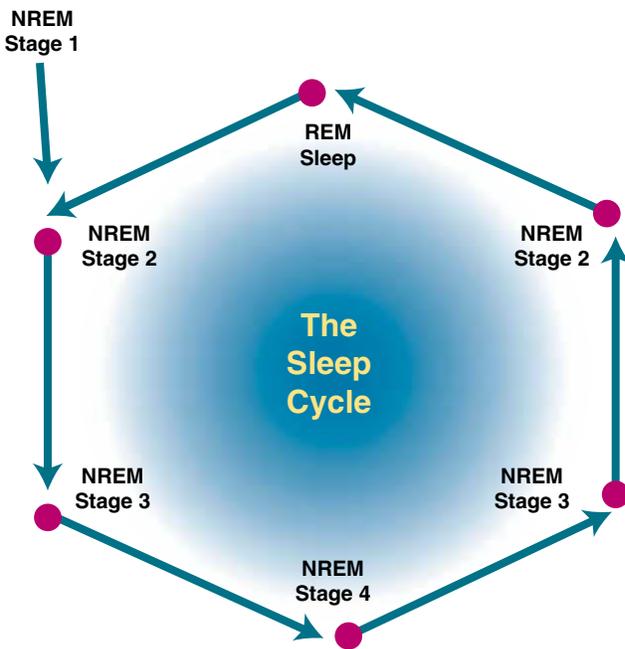

Figure 33-9 The Sleep Cycle

dreds of physiological processes, including body temperature, respiratory rate, performance, alertness, and hormone levels.

Chronobiology is a relatively new branch of science that studies these rhythms that are controlled by our biological clocks. The most widely studied are the **circadian rhythms**, or those that cycle on a daily basis. Other biological rhythms include:

- Ultradian—those much shorter than a day
- Infradian—those lasting a month or more
- Circannual—those requiring about 1 year to complete the cycle

When external time cues such as day-night, sleep-wake, and mealtimes are inconsistent, a desynchronization, or mismatching, of the circadian biological rhythms occurs. This internal desynchronization disrupts the timing of physiological and behavioral activity, which in turn causes chronic fatigue, disrupts sleep patterns, and causes decreased performance and coping abilities. An example of desynchronization is that of the newborn, whose biological rhythms are not established until 3 to 4 months of age. At this point, infants will start to develop longer sleep periods at night and become more predictable in their waking and sleeping patterns.

Factors Affecting Rest and Sleep

Several factors can influence the quality and quantity of both sleep and rest. Often, sleep problems result from a combination of many factors.

Degree of Comfort

Comfort is a highly subjective experience. The nurse must assess the degree to which the client's physical and psychological needs have been met. Whenever basic needs are unmet, the person experiences discomfort which leads to physiological tension, resultant anxiety, and potential impairments in sleep/rest.

Anxiety

A restless body and mind interfere with the ability to sleep. When trying to go to sleep, many individuals often have intrusive thoughts or muscular tension, which interfere with rest and sleep. Anxiety related to work pressures, family demands, and other stressors does not automatically cease when an individual attempts to go to sleep. Anxiety often results in difficulty falling or staying asleep.

Environment

Environmental factors can either enhance or impair sleep. Lighting, temperature, odors, ventilation, and noise level can all interrupt the sleep process when they differ from the norms of the client's usual sleep environment.

THINK ABOUT IT

Sleep Barriers in Institutions

Carefully observe a health care agency. Knowing that sleep promotes healing, identify the factors that promote rest and sleep. What are some barriers to sleep in the health care environment?

Lifestyle

A fast-paced life filled with multiple stressors can result in the person's inability to relax easily or to fall asleep quickly. Relaxation precedes healthy sleep.

Another lifestyle factor that interferes with sleep is having a work schedule that does not coincide with an individual's biological clock (e.g., working at times other than the day shift). Individuals who frequently change work shifts have a real challenge in trying to stabilize biological rhythms and rest comfortably.

Diet

The type of food consumed has an impact on the quality and quantity of sleep. Foods high in caffeine, such as coffee, colas, and chocolate, serve as stimulants and often disrupt the normal sleep cycle. Also, consuming a large, heavy, or spicy meal just before bedtime may cause indigestion, which will likely interfere with sleep.

Conversely, going to bed when hungry can also result in sleep problems because the individual may be preoccupied with food and hunger pangs instead of concentrating on sleep.

Drugs and Other Substances

Alcohol and nicotine use can impair sleep. Small amounts of alcohol may help some people fall asleep; however, in others alcohol may interfere with REM sleep, causing very restless and nonrefreshing sleep. Nicotine, which is a stimulant, can also impair the sleep cycle by stimulating the body, resulting in difficulty falling and staying asleep. Many medications (both prescription and over-the-counter) cause fatigue, sleepiness, restlessness, agitation, or insomnia, thus affecting the quality and quantity of rest and sleep.

Cultural Norms

Cultural and societal expectations also affect sleep. Some people perceive sleep as a luxury to be indulged in when they are not too busy with “important” activities. Others view sleep as an absolute necessity. The amount of sleep that a person considers to be necessary is partially determined by the attitudes of family and culture.

THINK ABOUT IT

Cultural Norms and Sleep

Which of the two descriptions of sleep (a luxury or a necessity) do you think is most congruent with our society? Which view is closest to your own? What approach would you take when discussing the rest and sleep needs of a client whose philosophy and views about sleep are in direct contrast to your own?

Life Span Considerations

A person’s need for sleep changes with age in a fairly predictable pattern. Although sleep and rest patterns are closely tied to lifestyle and other variables, there are some common variations:

- The *neonate* (birth to 1 month) sleeps in 3- to 4-hour intervals for a total of about 16 to 20 hours per day. The newborn usually is very passive, with little activity during sleep (“sleeping like a baby”), and typically sleeps very soundly. For the first few days or weeks of life, a baby’s biological clock is not attuned to regular day-night patterns, so there is often no difference in sleep patterns between day and night.
- The *infant* averages about 12 to 16 hours of sleep per day. As the infant ages, the amount of sleep needed decreases. At approximately 2 months of age, infants

can begin to sleep through the night and will typically nap two or three times during the day.

- During *toddlerhood* the daily average amount of sleep is 12 to 14 hours, which is usually broken down into 10 to 12 hours at night with one or two daytime naps. During this stage, bedtime rituals often develop and assume great importance in providing nighttime security. Repeated and predictable nighttime routines such as baths, brushing teeth, and reading books are helpful in establishing expectations and comfort.
- The *preschool* child sleeps approximately 10 to 12 hours per day. Daytime napping decreases or ceases, unless cultural norms dictate otherwise. Night sleep is often filled with vivid dreams and nightmares, which often awaken children several times during the night.
- A *school-age* child also averages about 10 to 12 hours of sleep daily. Resistance to bedtime and struggles for independence are hallmarks of the school-age child. During this time, the child may develop fear of the dark and will need reassurance and methods to handle this fear.
- *Adolescents* sleep about 8 to 10 hours per day and often decide themselves their bedtime routines and hours. High activity levels often interfere with regular sleep patterns and irregular sleeping habits often become the norm at this stage.
- The *young adult* averages about 8 hours of sleep per day. During this stage, sleep is often interrupted by young children in the home or work responsibilities. Lifestyle patterns cause many young adults to experience difficulties falling or staying asleep.
- The *middle-aged adult* sleeps about 6 to 8 hours a day. Daily stressors may continue to result in insomnia, and use of sleep-inducing medications is common.
- The sleep requirements for the *older adult* decrease to 5 to 7 hours per day, and often include a daytime nap. The quality of sleep often diminishes due to frequent waking, physical pain, and shortened REM sleep. Many elderly people misinterpret this decreased need for sleep as insomnia and are thus unduly concerned about not getting “enough” sleep.

Illness or Hospitalization

The stress imposed by illness usually disrupts sleep. Sleep is especially disrupted when a person is hospitalized. Some factors associated with hospitalization that lead to sleep impairment include:

- Physical or emotional pain
- Loss of familiar surroundings
- Loss of routine
- Fear of the unknown
- Timing of procedures and treatments
- Noise level (especially unfamiliar noises)
- Loss of privacy

Alteration in Sleep Patterns

Sleep disturbances can take many forms and are quite common. According to Carpenito (1999), sleep pattern disturbance is defined as:

The state in which an individual experiences or is at risk of experiencing a change in the quantity or quality of his or her rest pattern as related to the person's biological and emotional needs. (p. 291)

Alterations in sleep patterns are generally viewed as either primary sleep disorders (those in which the sleep alteration is the fundamental problem) or secondary sleep disorders (those in which the alteration has a medical or clinical cause that results in or contributes to the sleep alteration). The most common sleep alterations include insomnia, hypersomnia or narcolepsy, sleep apnea, sleep deprivation, and parasomnias.

Chronic insomnia is a widespread problem, affecting 10–20% of Americans; approximately 40–50% report occasional insomnia (Doghramji & Fredman, 1999). Listed below are problems associated with sleep disturbances:

- Decreased work productivity (more missed days of work)
- Increased utilization of health care services
- Greater risk of accidents
- Short-term memory problems
- Cognitive and motor performance impairments

Insomnia

Insomnia refers to the chronic inability to sleep or inadequate quality of sleep due to sleep prematurely ended or interrupted by periods of wakefulness. Insomnia is *not* a disease, but it may be a manifestation of many illnesses. The person experiencing insomnia often gets caught up in a vicious cycle of not being able to sleep, trying harder to fall asleep, increasing anxiety about not sleeping, which in turn increases the inability to fall asleep. Perception of sleep quantity can also be important; many insomniacs actually sleep significantly more than they think they do, so there is a discrepancy between perception and reality.

Sleep disturbances are common for individuals experiencing chronic pain. Sleep impairment can exacerbate pain, and, thus, a vicious cycle is established. “A poor night’s sleep contributes to depression, muscle soreness, difficulty thinking, and decreased motivation” (McCaffery & Pasero, 1999, p. 500). Treatment for insomnia is best directed at modifying those factors or behaviors that are causing it. It is impossible to force sleep.

Hypersomnia or Narcolepsy

Hypersomnia is an alteration in sleep pattern characterized by excessive sleep, especially in the daytime. Persons suffering from hypersomnia often feel that they cannot get enough sleep at night, and therefore they sleep very late into the morning and nap several times

throughout the day. Causes of hypersomnia can be physical or psychological; treatment depends on addressing the underlying cause.

Narcolepsy, another sleep alteration, manifests as sudden uncontrollable urges to fall asleep during the daytime. Individuals suffering from narcolepsy often achieve adequate sleep at night but are overwhelmed by sleepiness at unexpected and unpredictable periods during the day. Effective treatments for narcolepsy include avoiding substances or activities that cause sleepiness, taking short daytime naps, or taking prescribed stimulant medications.

Sleep Apnea

Sleep apnea refers to periods of sleep during which air-flow stops for 10 seconds or more. Sleep apnea gives rise to complications as a result of oxygen desaturation and carbon dioxide retention. Short-term consequences may include cognitive impairment (including memory changes), personality changes, and impotence. A major problem is daytime sleepiness, which may interfere with functional abilities such as driving and working. If untreated, sleep apnea can result in the following (Forth, 1998):

- Hypertension
- Cardiac arrhythmias
- Right-sided congestive heart failure
- Cerebral vascular accident (stroke)
- Cognitive dysfunction
- Death

The first line of defense against apnea is treating its cause (emotional, cardiac, or respiratory alteration). Use of a nasal continuous positive airway pressure (CPAP) device may also give relief. With some individuals, surgical intervention is required to correct the cause of the apnea.

Sleep Deprivation

Sleep deprivation is a term used to describe prolonged inadequate quality and quantity of sleep, either of the REM or the NREM type. Sleep deprivation can result from age, prolonged hospitalization, drug and substance use, illness, and frequent changes in lifestyle patterns. Sleep and dreaming have a restorative value necessary for mental and emotional recovery, and enhance the ability to cope with emotional problems. Therefore, sleep deprivation can cause symptoms ranging from irritability, hypersensitivity, and confusion to apathy, sleepiness, and diminished reflexes. Treating or minimizing the factors that cause the sleep deprivation is the most effective resolution.

Parasomnia

Parasomnias refer to sleep alterations resulting from “an activation of physiological systems at inappropriate times during the sleep-wake cycle” (American

Psychiatric Association, 1994, p. 579). **Somnambulism** (sleepwalking), sleepwalking, bed wetting, and **bruxism** (teeth grinding) are the most common parasomnias. Treatment for parasomnias varies, and care should be focused on helping the client and family understand the disorder and its potential safety risks.

Assessment

Discussion of sleep habits is included as part of the regular health history. Any client acknowledging a sleep disturbance should be thoroughly assessed to determine sleep routines, sleep alterations, type of disturbances, and impact of sleep problems. Typically the client is a reliable source for this information, but a spouse or partner who shares sleeping arrangements may be able to add valuable information to the client's report. Questions regarding the client's usual sleep patterns should include:

1. Nature of sleep (restful, uninterrupted)
2. Quality of sleep (usual sleep pattern, schedules, hours of sleep, feeling on waking)
3. Sleep environment (description of room, temperature, noise level)
4. Associated factors (bedtime routines, use of sleep medications or any other sleep inducers)
5. Opinion of sleep (adequate, restores energy adequately, inadequate, problematic)

Questions regarding altered sleep patterns are intended to discover such information as:

1. Nature of the problem (inability to fall asleep, difficulty remaining asleep, inability to fall asleep after awakening, restless sleep, daytime sleepiness)
2. Quality of the problem (number of hours of sleep versus number of hours spent trying to sleep, number of hours of sleep a night, duration and frequency of naps or other compensatory measures, number of wakings per sleep period)
3. Environmental factors (lighting, bed, noise level, surrounding stimulation, sleep partner)
4. Associated factors (relation to meals eaten, activity before retiring, life stressors, work stressors, anxiety level, pain, recent illness or surgery)
5. Alleviating factors (mild diet, warm drink before retiring, reading a book, listening to quiet music, taking a hot bath, taking sleeping pills)
6. Effect of problem (fatigue, irritability, confusion)

For clients whose sleep problems do not seem to be well defined, a daily journal of sleep patterns may prove useful. This written account can mirror the preceding outline.

Nursing Diagnosis

After information about the sleep impairment has been collected, data need to be analyzed to formulate appro-

priate nursing diagnoses. The primary diagnosis for individuals experiencing sleep problems is *Disturbed Sleep Pattern*.

According to NANDA (2001), *Disturbed Sleep Pattern* is defined as “a disruption of sleep time [that] causes discomfort or interferes with desired lifestyle” (p. 59). Alterations in sleep can manifest through verbal complaints of the client, physical signs such as yawning or dark circles under the eyes, or alterations in mood such as apathy or irritability.

If the client presents with problems in addition to the sleep disturbance, the nurse must be alert to the possibility that the sleep disturbance is the *cause* (not the effect) of another problem. For example, a client may be experiencing *Activity Intolerance* related to lack of sleep as evidenced by verbal complaint, extreme fatigue, disorientation, confusion, and lack of energy.

Outcome Identification and Planning

The plan of care for the sleep-disordered client must be individualized. For the nursing care to be effective, client input should be incorporated when developing expected outcomes. It is important to tailor the outcomes and plan of care to the true cause related to the sleep disturbance or alteration. For example, if the client is experiencing *Disturbed Sleep Pattern* because of bedwetting, then the bedwetting should be targeted for intervention.

Effective outcome identification and planning will also consider the fact that many sleep disturbances will require extended periods of time (weeks or months) to correct. Sleep patterns are by nature habitual and intertwined with lifestyle patterns, and these types of disturbances typically require interventions that have long-term goals. When planning care, the nurse should remember to perform procedures and treatments in a manner that disturbs sleep time and routines as little as possible.

Implementation

Several interventions can promote rest and sleep in clients. The interventions range from simple (e.g., correct bedmaking techniques) to complex (teaching clients about necessary lifestyle modifications). Several interventions that facilitate sleep are discussed here.

Establish a Trusting Nurse-Client Relationship

The quality of the nurse-client relationship can enhance a client's ability to rest and sleep. Knowing that the nurse is a trustworthy individual allows the client to relax and feel secure. The nursing checklist provides guidelines for communicating with the sleep-impaired

NURSING CHECKLIST

Communicating with the Sleep-Impaired Client

1. Thoroughly explain procedures before implementation.
2. Encourage client and significant others to verbalize feelings and to ask questions.
3. Answer questions honestly and completely.
4. Identify and support coping mechanisms of client and family.
5. Spend adequate time with the client to facilitate communication.
6. Ascertain and incorporate client preferences as much as possible into plan of care.

client. Anxiety can be decreased by the nurse's use of therapeutic communication skills. The *therapeutic use of self* helps allay client anxiety.

Create a Relaxing Environment

Arranging the immediate surroundings to promote sleep is important for the sleep-impaired client. A place to sleep should be inviting. Determine the type of environment the client finds relaxing, then provide this environment in the inpatient setting, or help the client establish this type of environment in the home setting.

THINK ABOUT IT

Relaxing Environment

Observe a client care area. What environmental factors encourage sleep? What factors interfere with sleep? If you were to design the ideal client care environment, how would you address the following variables:

- Colors
- Fabrics
- Lighting
- Noises
- Temperature
- Odors

Initiate Relaxation Techniques

The client's mood before sleep is of utmost importance. The *belief* that one can—and will—sleep greatly affects sleep quality and quantity. The client who is calm and relaxed is likely to fall asleep quickly and stay asleep all night. Relaxation techniques are useful sleep aids. Progressive muscle relaxation is especially therapeutic for the person who needs to lessen muscular tension and quiet the mind.

Ensure Appropriate Nutrition

Certain foods can actually enhance sleep. Tryptophan, a substance in milk, promotes sleep by stimulating the brain's production of the neurotransmitter serotonin. The old wives' tale that drinking warm milk promotes sleep is supported by scientific data. Other dietary considerations include avoiding large or heavy meals close to bedtime, refraining from eating spicy or other foods that cause gastrointestinal distress, and avoiding caffeine after noon.

COMPLEMENTARY/ALTERNATIVE MODALITIES THAT PROMOTE SLEEP

- Massage
- Imagery
- Meditation
- Herbal:
 - Chamomile
 - Hops
 - Lavender
 - Kava
 - Passion flower
 - Skullcap
- Aromatherapy:
 - Chamomile oil
 - Lavender oil

Initiate Pharmacologic Interventions

If unrelieved pain is a factor in the client's sleep disturbance, pain management should be the focus of initial interventions. Many of the nonpharmacologic relaxation and imagery interventions can be effective in clients with sleep disturbances.

Pharmacologic agents that may be therapeutic for clients with sleep disturbances include tricyclic antidepressants, antihistamines, and short-acting hypnotics (McCaffery & Pasero, 1999). The tricyclic antidepressants of choice are amitriptyline (Elavil®) or doxepin (Sinequan®). Amitriptyline improves the client's ability to fall asleep and stay asleep by causing sedation when given 1 to 3 hours before bedtime. Doses of amitriptyline for sleep disturbances are significantly lower than doses for treatment of depression, starting at 10 to 25 mg at bedtime and titrating up by 10 to 25 mg every 2 or 3 days until therapeutic effect is achieved.

Antihistamines such as hydroxyzine (Vistaril®, Atarax®) and diphenhydramine (Benadryl®) have mild sedative effects that could promote sleep if given at bedtime. If anxiety throughout the day is of concern, low doses of these medications at regular intervals throughout the day may be effective.

The final group of pharmacologic interventions for sleep disturbances are the short-acting hypnotics. These are *not* recommended for routine or long-term use, but

**CLIENT TEACHING CHECKLIST**
Managing Sleep Disturbance

To facilitate rest and sleep, the client should be encouraged to:

- Avoid stimulating activities such as strenuous exercise or demanding intellectual activity during the hour before bedtime. Use the time instead to wind down with relaxing activities such as taking a warm bath, reading a book, or sitting by the fire.
- Use bedtime rituals on a consistent basis.
- Practice relaxation techniques such as neck rolls and muscle relaxation to release tensions before going to bed.
- Do not watch television, study, or talk on the phone while lying in bed; accustom your body to using the bed only for sleeping.
- Follow dietary guidelines to avoid caffeine, spicy foods, and heavy meals in the several hours before bedtime.

they may be effective as a short-term intervention. When they are chosen, it is recommended that one with a short half-life be used.

Provide Client Education

Educating the client on sleep-promoting activities is a good investment of the nurse's time. By empowering clients to help themselves relax, the nurse helps them gain a sense of control over their sleep disturbance and boosts their confidence that they can successfully meet their sleep and rest needs.

Evaluation

The plan of care must be individualized for and negotiated with the client. It must be updated on a regular schedule and additional interventions initiated as needed. One of the strongest supportive activities nurses can perform is to make sure clients understand that there is help for sleep problems and that they are not alone in having difficulty successfully managing their sleep patterns. The Nursing Process Highlight lists

NURSING CARE PLAN**The Client Experiencing Altered Sleep Patterns****Case Presentation**

Jacques Porcheron, 6 years old, is brought to your clinic by his father, who states that Jacques has trouble sleeping at night. In the evenings after a dinner of hot dogs, corn or baked beans, and chocolate milk, Jacques reads some books, then watches his favorite superhero video. Afterward, he runs and plays, mimics the actions he sees in the video, and refuses to take a bath or cooperate when getting dressed for bed. Once put to bed at 9 PM, he is up several times for any number of reasons, and often is not asleep until midnight. When his father wakes him at 7 AM for school, Jacques is disagreeable, tired, and difficult to get moving.

Assessment

Client is experiencing:

- Inability to fall asleep
- Inability to remain asleep
- Inconsistent bedtime rituals that interfere with calm time needed before retiring

Nursing Diagnosis

Disturbed Sleep Pattern related to lack of sleep and disruption in lifestyle as evidenced by parental complaint, ineffective bedtime rituals, and insufficient hours of sleep for developmental age.

Expected Outcomes

The client will:

1. Identify behaviors that are helpful before bedtime.
2. Develop appropriate bedtime rituals to help Jacques wind down from the day.
3. Ensure that Jacques gets 10 to 12 hours of sleep per night.

Interventions/Rationales

1. Determine from the father and child what sleeping behaviors they would like to achieve.
Asking for client input in the desired outcomes will make the plan of care more effective and realistic.

(continues)

NURSING CARE PLAN

The Client Experiencing Altered Sleep Patterns (continued)

2. Teach the family about the effect that certain foods can have on digestion and sleep habits, and list with them foods that are good choices for dinners.
Educating the family about the potential adverse effects of certain foods will help them plan meals more appropriately.
3. Help client understand what bedtime activities can be detrimental to sleep induction.
Understanding which behaviors can interfere with falling asleep will help client and family identify and therefore modify prebedtime behaviors.
4. Explain why overstimulation close to bedtime, such as watching superhero movies and engaging in rowdy play, will prevent the body and mind from slowing down and preparing for sleep.
Understanding the psychological and physical implications of overstimulation before bedtime will help clients choose more appropriate bedtime activities.
5. Emphasize the importance of establishing a calming bedtime routine that is followed every night, especially for the school-age child.
Children Jacques' age are helped by ritual and knowing what is expected of them, and they need guidance in practicing routines that are appropriate for bedtime.
6. Suggest appropriate bedtime rituals, such as taking a bath, brushing the teeth, reading a book, or listening to calming music.
Focusing on quiet activities and routine will help the body and mind prepare for bedtime.
7. Help the family ensure an appropriate sleep environment for Jacques, such as a calm room at a comfortable temperature, lit only by a night light.
Promotes sleep and does not interfere with falling back asleep once awake.
8. Encourage the family through the preceding steps to work toward having Jacques get at least 10 to 12 hours of sleep a day, which is the normal requirement for a child his age.
Helping the family understand what factors may be interfering with Jacques' sleep habits, such as excessive daytime napping or repetitive waking during the night, and also ensuring that they understand what his sleep requirements are, will help them be more effective in their management of his bedtime and sleeping habits.

Evaluation

After 2 weeks, the father reports that Jacques eats the same type of meals but is no longer allowed to watch stimulating videos after 7 PM. Together they have established bedtime rituals that begin with quiet tablework (reading, arts and crafts, writing) or talks about the day, followed by a warm bath and reading three books together in the recliner in the living room. After this, they put on pajamas and brush teeth, then Jacques goes up to bed by himself. The father would like to modify Jacques' diet somewhat and is planning this as his goal for the next 2 weeks.

*Nursing Process Highlight***EVALUATION**

When evaluating the care of the sleep-disordered client, consider the following variables:

1. Client's basic needs were met.
2. Client education included the family or significant others.
3. An environment conducive to rest was maintained.
4. Therapeutic activities were balanced with the client's need for rest and sleep.
5. The client's bedtime rituals were followed as closely as possible.
6. Anxiety reduction techniques were used appropriately.

variables to be considered in evaluating the care of the sleep disturbed client.

KEY CONCEPTS

- Pain is a subjective and individualized experience.
- Pain is defined as whatever the client says it is.
- Pain is increased by anxiety and fatigue.
- Several factors influence the perception of pain, including developmental level, culture, previous experience.
- The amount of sleep required differs according to developmental stage.
- Nonpharmacologic interventions may be used in managing pain and promoting rest and sleep.
- Pharmacologic agents can be therapeutic for clients experiencing pain or sleep pattern disturbance. However, the medications should not be the only interventions used.

CRITICAL THINKING ACTIVITIES

1. Differentiate among the different types of pain (somatic, cutaneous, visceral, referred, ischemic, acute, chronic).
2. Describe nonpharmacologic interventions that would be appropriate for a 50-year-old woman suffering from arthritis; a 9-year-old oncology client; a couple going through childbirth.
3. Discuss the use of pharmacologic interventions in pain control.
4. Describe the stages of sleep and how they are related to the sleep cycle.
5. What age-related sleep variations would you need to consider when assessing the sleep habits of neonates, infants, toddlers, and the elderly?
6. State the outcomes that sleep deprivation may have on an individual.
7. Discuss nursing interventions that promote comfort, rest, and sleep.

Mobility

Worms will not eat living wood where the vital sap is flowing; rust will not hinder the opening of a gate when the hinges are used each day. Movement gives health and life. Stagnation brings disease and death.

—Ancient proverb in Traditional Chinese Medicine
(in Fontaine, 2000, p. 45)

COMPETENCIES

1. Explain the physiology of mobility.
2. Identify factors affecting mobility.
3. Identify health problems related to immobility.
4. Describe the process of activity and mobility assessment.
5. Discuss nursing diagnoses relevant to clients experiencing mobility impairments.
6. List client goals for activity and mobility in terms of lifestyle, age, and health promotion.
7. Describe specific nursing interventions that promote mobility and prevent complications due to immobility.
8. Identify evaluation procedures for client activity and mobility status.

KEY
TERMS

abduction	extension	myoneuronal junction
active range of motion	flexion	opposition
active-assistive range of motion	functional assessment	orthostatic hypotension
adduction	gait belt	passive range of motion
ambulation	hypertrophy	proprioception
atrophy	hypotonicity	range of motion
balance	incontinence	skin shear
base of support	line of gravity	spasticity
body alignment	logrolling	supination
body mechanics	mobility	thrombus
	muscle tone	

Movement is an activity most people take for granted. The ability to move and be active benefits health status, whereas immobility presents a threat to one's physical, mental, and social well-being. This chapter explores nursing responses to individuals with impaired ability to move.

OVERVIEW OF MOBILITY

Mobility refers to the ability to engage in activity and free movement which includes walking, running, sitting, standing, lifting, pushing, pulling, and performing activities of daily living (ADLs). Mobility is often considered an indicator of health status because it influences the correct functioning of many body systems, especially the respiratory, gastrointestinal, and urinary systems. Mobility enhances muscle tone, increases energy levels, and is associated with psychological benefits such as independence and freedom.

Body Alignment

Body alignment refers to the position of body parts in relation to each other. Proper body alignment (also called posture) results in **balance**, which is an individual's ability to maintain equilibrium. When the body is in good posture, the center of gravity (the center point of an object's mass) is evenly distributed over the foundation points. Good posture promotes balance, reduces strain and injury to support structures, facilitates respiratory effort, enhances gastrointestinal processes, and gives an appearance of confidence and health. A correct postural stance is maintained by a well-functioning musculoskeletal system. The normal alignment of the spine has a cervical concavity, a thoracic convexity, and a lumbar concavity; see Figure 34-1.

Proper standing body alignment (as noted in Figure 34-2) is characterized by the following:

- Head upright
- Face forward

- Shoulders squared
- Back straight
- Abdominal muscles tucked in
- Arms straight at side
- Hands palm forward
- Legs straight
- Feet forward

The sitting position in proper alignment has similar characteristics; however, the hips and knees are flexed. Figure 34-3 shows proper alignment and posture for the sitting position.

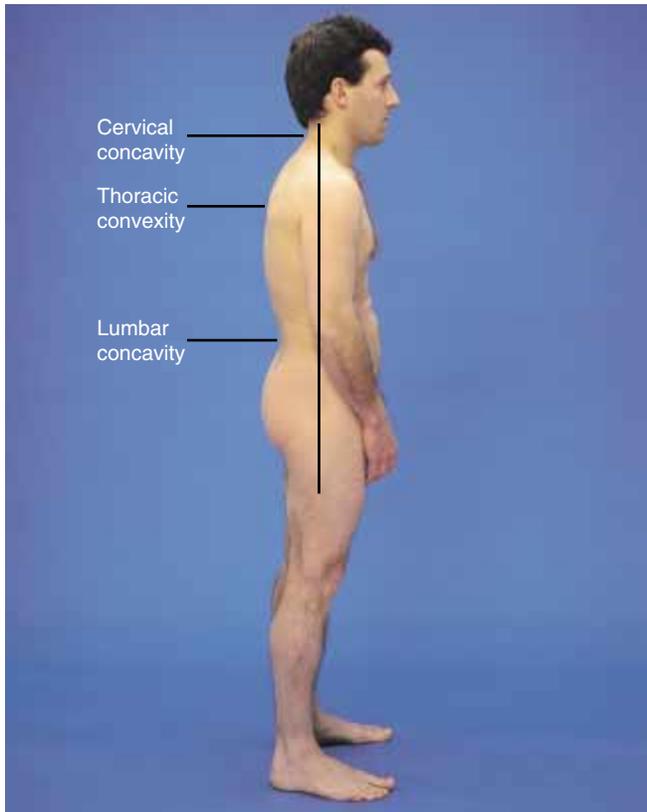

Proper alignment and posture of the client lying in bed appear similar to the standing position; however, the client is supine, as shown in Figure 34-4.

The benefits of proper alignment and posture include (1) client comfort; (2) prevention of contractures; (3) promotion of circulation; (4) less stress on muscle, tendons, nerves, and joints; and (5) prevention of foot drop (plantar flexion).

In a person standing upright, the center of gravity is located in the middle of the pelvis about halfway between the umbilicus and the symphysis pubis. The **line of gravity** (vertical line passing through the center of gravity) is shown in Figures 34-3 and 34-4. The **base of support** is the foundation on which a person or object rests. Stability of one's balance is promoted by a steady base of support and a low center of gravity.

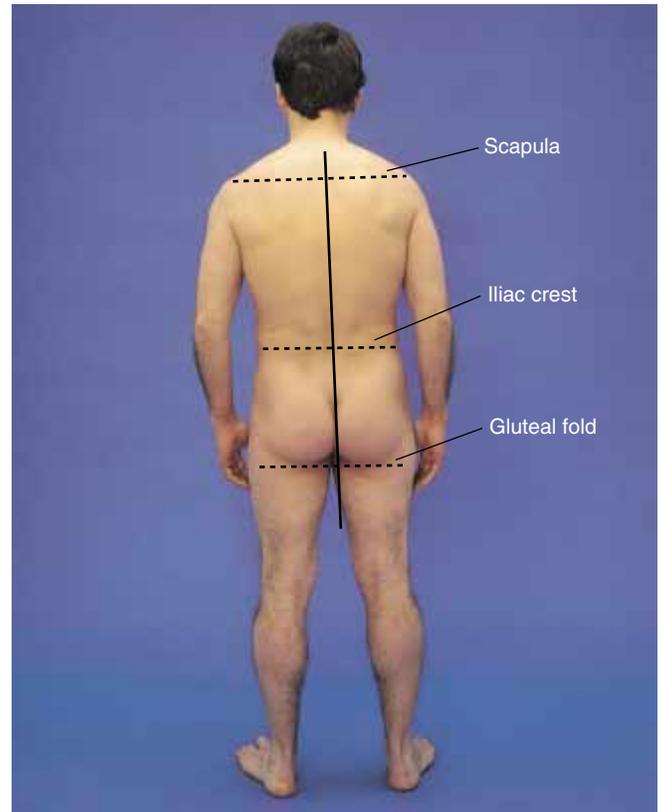

Muscle tone and bone strength allow a person to maintain an erect posture. Muscle contour is affected by the individual's exercise and activity patterns. **Muscle tone** is the normal state of balanced tension present in the body; it allows a muscle to respond quickly to stimuli. Two aberrations of muscle tone include **hypotonicity** (flaccidity), which is a decrease in muscle tone, and **spasticity**, which is an increase in muscle tension and is often noted with extreme flexion or extension.

Muscle shape should be symmetrical. There may be **hypertrophy** (increased muscle size and shape due to an increase in muscle fibers) or **atrophy** (a reduction in muscle size and shape) which manifests as thin, flabby muscles with indistinct contour; (Figure 34-5). Atrophy is usually a result of disuse, whereas hypertrophy occurs when the muscle is overworked.

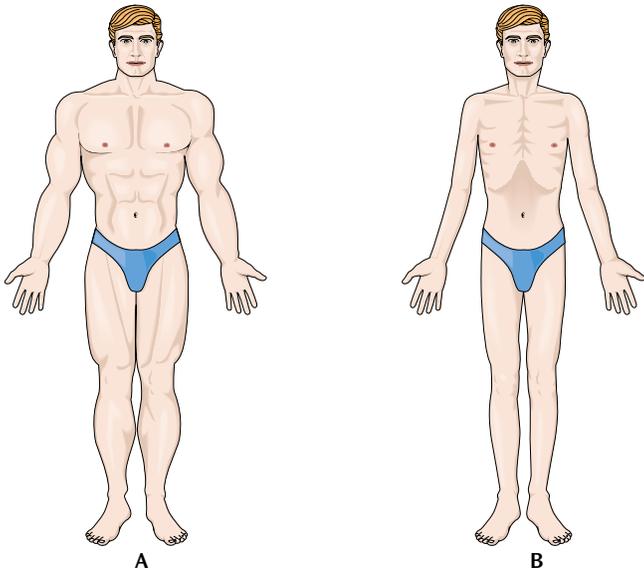

Figure 34-5 Variances of Muscle Size and Shape: A. Hypertrophy; and B. Atrophy

Body Mechanics

Functional mobility is governed by **body mechanics**, the purposeful and coordinated use of body parts and positions during activity. Use of proper body mechanics maximizes the effectiveness of the efforts of the musculoskeletal and neurological systems and reduces the body's exposure to strain or injury during movement.

Proper body mechanics are as important to the nurse as to the client. The purpose of proper body mechanics is prevention of strain and injury to the muscles, joints, and tendons.

Range of motion reflects the extent to which a joint can move. The ranges vary with each joint and are affected by several factors, including age, physical condition, and heredity. Parameters for range of motion are outlined in Tables 34-1 and 34-2.

The clinical application of body mechanics is described later in the implementation section of this chapter.

PHYSIOLOGY OF MOBILITY

Mobility is regulated by the coordinated effort of the musculoskeletal and neurological systems. The major functions of the musculoskeletal system are to maintain

body alignment and to facilitate mobility. The musculoskeletal system consists of a framework of bones, muscles, joints, tendons, ligaments, bursae, and cartilage.

The Musculoskeletal System

The musculoskeletal system (comprised of bones, cartilage, joints, tendons, ligaments, bursa, and muscles) serves several functions as described in Table 34-1.

Bone is the foundation of the musculoskeletal system. Mobility and weight-bearing capacity are directly related to the bone's size and shape. Joints work with muscles to provide motion and flexibility. Skeletal muscles overlying the joint exert opposing forces and, therefore, cause movement.

Muscles are basically machines that convert energy into mechanical work. Contractility is the common property among the three types of muscles: smooth, cardiac, and skeletal. Skeletal muscle fibers are innervated by somatic nerves, and, therefore are generally under voluntary control.

The muscles work in cooperation with the nervous system to maintain body alignment and cause movement. Muscles act in pairs to perform work. One muscle of the pair produces movement in a single direction. The other muscle of the pair produces movement in the opposite direction. When one muscle of the pair is contracted, the other is relaxed. The opposing actions of contraction and relaxation make motion possible. The position of the tendons upon the bones and the articulation of the bones make possible types of motion such as flexion, extension, circumduction, rotation, and gliding.

Muscles that maintain body alignment work together to stabilize surrounding body parts and to support the body's weight. Posture is maintained primarily by the muscles in the back, neck, trunk, and lower extremities.

Nervous System

Muscle contraction is controlled by the central nervous system (CNS) and is influenced by the transport of nutrients and oxygen and by the removal of waste products. An intact CNS is essential for coordinated movement to occur. Nerve impulses stimulate the muscles to contract. The **myoneuronal junction** is the point at which nerve endings come into contact with muscle cells. The afferent pathway conveys information from sensory receptors to the CNS; these neurons conduct impulses throughout the body. The CNS processes the sensory input and determines a response. The efferent pathway transmits the desired response to skeletal muscles via the somatic nervous system. If the nerve impulses are interrupted, the muscle is paralyzed and cannot contract.

Proprioception

Proprioception is the awareness of posture, movement, and changes in equilibrium and the knowledge of posi-

TABLE 34-1
Musculoskeletal System Components

Anatomical Structure	Description	Function
Bones	Ossified connective tissue	Facilitates mobility Protects body structures (e.g., brain, spinal cord) Produces blood cells
Joints	The site of a union between two bones	Facilitates motion Allows flexibility
Tendons	Cord or band of inelastic connective tissue	Causes movement of muscles
Ligament	Band of fibrous tissue connecting bones or cartilages	Supports and strengthens joints Facilitates mobility Protects structures (e.g., knee, hip)
Bursa	Fluid-filled sac or cavity	Prevents friction between bones and cartilage Facilitates gliding of muscles or tendons over bony surfaces
Cartilage	Dense connective tissue	Facilitates mobility

tion, weight, and resistance of objects in relation to the body. Nerve endings in muscles, tendons, and joints (proprioceptors) continuously provide input to the brain, which, in turn, regulates smooth coordinated involuntary movement.

Postural Reflexes

Postural tonus is maintained by postural or righting reflexes. Table 34-2 describes the major reflexes involved in maintaining posture.

EXERCISE

Exercise is any physical activity involving muscles that elevates the heart rate above resting levels. Exercise reduces joint pain and stiffness, and increases flexibility, muscle strength, and endurance. It also helps with weight reduction and contributes to an improved sense of well-being (National Institute of Arthritis and Musculoskeletal and Skin Diseases, 1997). Americans have become less active in recent years (Bray, 1998).

The U.S. Surgeon General's Report on Physical Health and Activity (Centers for Disease Control and Prevention, 1999) lists the following facts about exercise:

- People who are usually inactive can improve their health and well-being by becoming even moderately active on a regular basis.
- Physical activity need not be strenuous to achieve health benefits.
- Greater health benefits can be achieved by increasing the amount (duration, frequency, or intensity) of physical activity.

TABLE 34-2
Reflexes That Maintain Postural Tonus

Reflex	Description
Labyrinthine sense	Sensory organs in the inner ear activate impulses when the head is turned; impulses are transmitted to cerebellum
Tonic neck-righting reflexes	Affected by movement of head from side to side; neck muscle tonus is affected most when neck is hyperextended
Optic reflexes	Visual sensations affect posture by helping the person establish spatial relationships to surrounding objects
Proprioceptor or kinesthetic sense	Activated when nerve endings in muscles and tendons are stimulated by movements of the joints; informs the brain of the location of a body part
Antigravity (extensor) reflexes	When extensor muscles are stretched beyond a certain point, their stimulation causes a reflex contraction that counteracts the gravitational pull
Plantar reflexes	Reflexive contraction of the extensor muscles of the lower legs in response to pressure against the sole of the foot by the floor or ground

Table 20-9 in Chapter 20 describes the physiologic benefits of exercise.

Vigorous exercise stimulates an increased production of endorphins, which promote a sense of well-being. However, it is important to caution people not to overdo the exercise, especially when first starting a new regimen. The following may be signs of too much exercise: unusual or persistent fatigue, increased weakness, decreased range of motion, joint swelling, or continuing pain (pain that lasts more than 1 hour after exercising) (National Institute of Arthritis and Musculoskeletal System, 1997). Instruct clients, especially those with sedentary lifestyles, to consult their nurse practitioner or physician before beginning an exercise program.

Types of Exercise

There are several types of exercise that promote physical and psychologic health; see Table 34-3.

NURSING ALERT

Individuals with cardiovascular problems should be cautioned to exhale when performing isometric exercises to avoid increasing blood pressure.

Range-of-Motion Exercise

Active range-of-motion (ROM) activities are performed independently by the client. During active ROM exercises, the client moves various muscle groups. **Passive ROM** exercises are done by the nurse to help maintain or restore a client's mobility by achieving several outcomes; see the accompanying display.

OUTCOMES OF PASSIVE RANGE-OF-MOTION EXERCISES

- Prevention of contractures
- Improves muscle strength and tone
- Increases circulation
- Decreases vascular complications of immobility
- Facilitates client comfort

Physical Fitness

The ultimate outcome of regular physical activity is physical fitness that affects an individual's functional ability. There are four components of physical fitness: endurance and strength, joint flexibility, cardiorespiratory fitness, and body composition.

Endurance and Strength

Endurance is the ability to withstand movement in terms of duration and absence of fatigue. A physically fit

TABLE 34-3
Types of Exercise

Exercise Type	Function	Examples
Aerobic	Improve cardiovascular fitness Assist with weight control Improve general functional ability	Rowing Jumping rope Walking Running
Strengthening	Maintain or increase muscle strength	Weight training Calisthenics Physical labor
Isometric	Maintain muscle tone and strength	Quadriceps setting Gluteal setting Triceps setting
Isotonic	Increase and maintain muscle tone and strength Shape muscles Maintain joint mobility Improve cardiovascular fitness	Weight lifting Working with pulleys Range-of-motion exercises Performance of activities of daily living (ADL)
Isokinetic	Condition muscle groups	Exercise equipment Resistive water exercises
Range-of-Motion (ROM)	Maintain joint movement Maintain or increase flexibility	Adduction and abduction Flexion and contraction

individual has adequate muscular strength and endurance to accomplish one's goals.

Muscle strength is the amount of force exerted by the muscles against resistance. Good muscle strength allows an individual to lift more safely.

Joint Flexibility

The ability to use a muscle through its complete range of motion is referred to as flexibility; see Table 34-4 for a complete description of joint movement. People with limited flexibility are likely to experience shortened muscles and tendons with resultant imbalance in muscle strength and joint injury. Flexibility can be improved by stretching exercises such as yoga, tai chi, and dancing. Performance of ADLs also helps maintain flexibility. Walking, stooping, and lifting activities can promote and maintain flexibility.

Cardiorespiratory Fitness

Exercises that improve cardiorespiratory fitness are discussed in Table 34-3. To improve cardiorespiratory function, physical activity must be maintained for at least 20 minutes in order to raise the heart rate to the target level.

Body Composition

The recommended proportion of fat to lean body tissue is referred to as body composition. Having a body that falls within the normal range of body weight and percentage of body fat depends on balancing caloric intake and expenditure. Any type of physical activity can be useful in developing and maintaining physical fitness; see Table 34-5.

Fitness in Older Adults

Approximately 33% of those ages 65 and older fall each year (Lamb & Cummings, 2000). "No one is too old to enjoy the benefits of regular physical activity. Of special interest to older adults is evidence that muscle-strengthening exercises can reduce the risk of fall and fracturing bones and improve the ability to live independently" (Centers for Disease Control & Prevention, 1999, p. 5). The accompanying display lists benefits of physical exercise in older adults.

FACTORS AFFECTING MOBILITY

Mobility and activity level can be influenced by many factors, including overall health status, developmental stage, environment, attitudes, beliefs, and lifestyle.

Health Status

An individual's general health status will influence desire for exercise and activity tolerance. Compromised status of

BENEFITS OF EXERCISE

- Normalizes glucose tolerance
- Improves gait and balance
- Improves cardiovascular function
- Increases energy
- Promotes bone density
- Improves mobility
- Promotes weight loss
- Reduces blood pressure
- Lowers cholesterol
- Promotes rest and relaxation
- Improves sleep

[Data from Fleming, J. M. (2001). Successful aging. In M. O. Hogstel (Ed.), *Gerontology: Nursing care of the older adult* (p. 145). Albany, NY: Delmar Publishing.]

any of the body systems may affect an individual's mobility and may, in turn, be affected by a lack of activity. Physical conditioning will also influence mobility and stamina. Physical factors interfering with mobility or exercise include fatigue, muscle cramping, dyspnea, neuromuscular or perceptual deficits, and chest pain.

Mental status is often manifested as changes in mobility or appearance. For instance, a client who shuffles into the room, slumps down into a chair, and avoids eye contact may be sending a message of depression through low activity levels, poor posture, and a flattened affect.

Developmental Stage

An individual's developmental stage will affect the parameters of targeted mobility levels.

See Table 34-6 for examples of common age-related musculoskeletal trauma.

NURSING TIP

Some degree of physical activity is necessary regardless of age or health status.

Children

Developmental norms related to mobility have been established for the infant and toddler. Childhood development is monitored through achievement of milestones such as sitting, crawling, walking, running, and hopping. For *infants*, the mobility focus is on gross motor behavior such as posture, head balance, grasping, sitting, creeping, and standing. *Toddlers* are more active, with walking, running, jumping, kicking, and going up and down stairs. Activity

TABLE 34-4
Joint Range of Motion

Joint Movement	Range	Muscle Group(s)
1. Temporomandibular Joint (TMJ) (Synovial Joint)		
a. Open mouth.	1–2.5 in.	
b. Close mouth.	Complete closure	Masseter, temporalis
c. <i>Protrusion</i> : Push out lower jaw.	0.5 in.	Pterygoideus lateralis
d. <i>Retrusion</i> : Tuck in lower jaw.	0.5 in.	
e. <i>Lateral motion</i> : Slide jaw from side to side.	0.5 in.	Pterygoideus lateralis, pterygoideus medialis
2. Cervical Spine (Pivot Joint)		
a. <i>Flexion</i> : Rest chin on chest.	45° each side	Sternocleidomastoid
b. <i>Extension</i> : Return head to midline.	45°	Trapezius
c. <i>Hyperextension</i> : Tilt head back.	10°	Trapezius
d. <i>Lateral flexion</i> : Move head to touch ear to shoulder.	40° each side	Sternocleidomastoid
e. <i>Rotation</i> : Turn head to look to side.	90° each side	Sternocleidomastoid, trapezius
3. Shoulder (Ball-and-Socket Joint)		
a. <i>Flexion</i> : Raise straight arm forward to a position above the head.	180°	Pectoralis major, coracobrachialis, deltoid, biceps brachii
b. <i>Extension</i> : Return straight arm forward and down to side of body.	180°	Latissimus dorsi, deltoid, triceps brachii, teres major
c. <i>Hyperextension</i> : Move straight arm behind body.	50°	Latissimus dorsi, deltoid, teres major

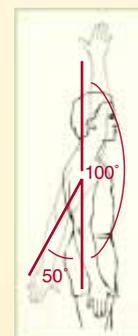

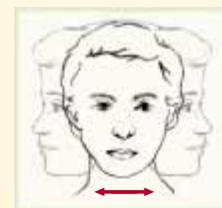

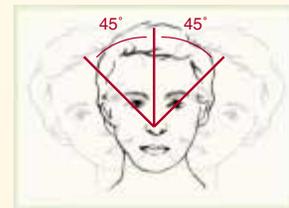

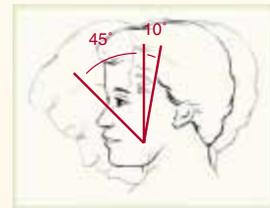

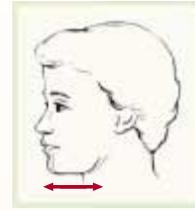

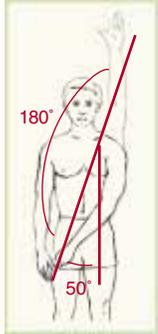

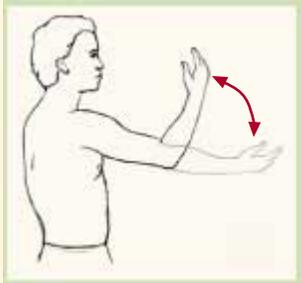

TABLE 34-4 (continued)
Joint Range of Motion

Joint Movement	Range	Muscle Group(s)	
d. <i>Abduction</i> : Move straight arm laterally from side to a position above the head, palm facing away from head.	180°	Deltoid, supraspinatus	
e. <i>Adduction</i> : Move straight arm downward laterally and across front of body as far as possible.	230°	Pectoralis major, teres major	
f. <i>Circumduction</i> : Move straight arm in a full circle.	360°	Deltoid, coracobrachialis, latissimus dorsi, teres major	
g. <i>External rotation</i> : Bent arm lateral, parallel to floor, palm down, rotate shoulder so fingers point up.	90°	Infraspinatus, teres minor, deltoid	
h. <i>Internal rotation</i> : Bent arm lateral, parallel to floor, rotate shoulder so fingers point down.	90°	Subscapularis, pectoralis major, latissimus dorsi, teres major	
4. Elbow (Hinge Joint)			
a. <i>Flexion</i> : Bend elbow, move lower arm toward shoulder, palm facing shoulder.	150°	Biceps brachii, brachialis, brachioradialis	
b. <i>Extension</i> : Straighten lower arm forward and downward.	150°	Triceps brachii	
c. <i>Rotation for supination</i> : Elbow bent, turn hand and forearm so palm is facing upward.	70°–90°	Biceps brachii, supinator	
d. <i>Rotation for pronation</i> : Elbow bent, turn hand and forearm so palm is facing downward.	70°–90°	Pronator teres, pronator quadratus

Dancing	250
House cleaning, scrubbing, vacuuming	227
Walking (4 mph)	312

(From Bray, G. A. [1998]. *Contemporary diagnosis and management of obesity*. Newtown, PA: Handbooks in Health Care Co.)

and mobility parameters for the toddler encompass gross and fine motor behaviors, manual dexterity, and exploration within environmental safety parameters. The *preschooler* increases strength and refines skills by walking, running, and jumping. During *middle childhood* (from 6 to 12 years of age) children have improved posture and locomotion abilities and increased muscle efficiency of the extremities and trunk; these children also have an increase in muscle tissue with a decrease of fat. For both preschool and middle childhood, activity and mobility expectations are centered on development of strength, coordination, and physical capacities.

Adolescents

The *adolescent* years (approximately ages 12 to 18) begin with onset of puberty and end with cessation of somatic growth. Changes are dramatic at this stage, with physical

TABLE 34-6
Common Age-related Musculoskeletal Trauma

Age Range	Common Trauma
0 to 18 months	Falls
18 months to 6 years	Falls
6 to 20 years	Sports-related injuries Motorcycle accidents High-impact falls (e.g., cycling, skiing)
20 to 50 years	Sports-related injuries Stress or overuse injuries (e.g., tendonitis) Pedestrian injuries
50 to 65+ years	Recreation-related injuries Falls Pathological fractures Pedestrian injuries

growth and development of secondary sex characteristics. Activity and mobility landmarks are development of muscles plus cardiac, respiratory, and metabolic functions through physical conditioning.

Adults

Adulthood is divided into young, middle, and elderly age groups. The *young adult* has well-developed myoskeletal and nervous systems which ideally function at peak efficiency.

The *middle-aged adult* has a gradual decrease in muscle mass, strength, and agility. The focus of activity and mobility for both these groups is on maintaining or developing tone, strength, and coordination of the musculoskeletal system.

Older adults often have progressive changes in the physiological systems. The rate of bone reabsorption (which affects bone density) increases with aging. Bone density loss accelerates in postmenopausal females due to estrogen deficiency. Decreased bone density makes a person more vulnerable to fractures, kyphosis, and a reduction in height.

Aging also negatively impacts muscles and connective tissue. The development of muscle atrophy is a gradual process in which muscle fibers deteriorate and are replaced by fibrous connective tissue. Muscle atrophy is accompanied by reduced muscle mass, a loss of muscle strength, and a reduction in overall body mass. The degree of muscle atrophy will be affected by the person's activity level. Staying physically active helps prevent disuse muscle atrophy and helps maximize muscle strength.

Cartilage ages better than bone or muscle; however, some changes occur that do affect joint flexibility. Aging leads to a loss of water content of hyaline cartilage and a reduction in the ability of cartilage to regenerate following trauma. Articulating cartilage may slightly deteriorate as a result of lifetime wear and tear.

Aging also affects the health of intervertebral disks. For example, the water content of the disks decreases which leads to less vertebral flexibility. Thinning of the disks causes older individuals to be more vulnerable to back pain and injury.

As a result of the age-related physical changes, older people often experience some functional alterations in mobility. Ambulation may be altered as a result of joint inflexibility and decreased muscle strength; such alterations are noticed as a reduction in step height and length as demonstrated in a shuffling gait. Vertebral inflexibility and reduced muscle strength may cause difficulty with client transfers in and out of a sitting position. The elderly client may need assistance in rising from a chair, ambulating, or climbing stairs. Table 34-7 provides an overview of age-related effects on mobility. Aging also affects the cardiovascular and respiratory systems, which directly affect endurance and stamina. Activity and mobility goals focus on maintenance of functional status and safety.

Environment

Environment can influence activity level in several ways. Home environments, for instance, can be considered safe and “mobility friendly” if they are free of hazards that can disrupt or endanger mobility and activity (see the accompanying display). Work environments can also affect mobility; repetitive handwork, such as key-stroking or sewing, can impair mobility and worsen arthritis. A sedentary lifestyle can lead to muscle atrophy, weakened bones, and a lack of motivation and energy to engage in physical activity.

TABLE 34-7
Effects of Aging on Musculoskeletal System

Physiological Changes	Results
Muscle cells replaced by fibrous connective tissue	Decreased muscle mass, tone, and strength
Decreased elasticity of ligaments, tendons, and cartilage	Weaker bones
Decreased bone mass	Weaker bones
Dehydration of intervertebral disks	Possible loss of height
Flattening of convex curvature of spine	Posture becomes more flexed Center of gravity shifts

(Data from Lamb, K. V. D., & Cummings, M. [2000]. Musculoskeletal function. In A. G. Luekenotte, (Ed.), *Gerontologic nursing* (2nd ed.). St. Louis, MO: Mosby.)

NURSING TIP

Ensuring Home Safety

To ensure a safe home environment, encourage clients (especially those who have an increased risk for injury in the home) to avoid:

- Loose or unsecured rugs (e.g., scatter rugs, rugs on stairways)
- Stairways without banisters or stairways with loose banisters or steps
- Stairs with a slippery surface
- Dim lighting, especially near stairways or steps
- Ill-fitting shoes, loose nonlaced shoes, shoes with high heels, or shoes with slippery soles
- Household clutter below waist level
- Electrical or phone cords that are too long and fall on the floor
- Wet or waxed floors
- Unleashed small pets
- Bathtubs or shower stalls without a nonskid surface
- Lack of grab bars in the bathroom near the toilet and tub or shower stall
- Wet or icy outdoor steps and sidewalks

Attitudes and Beliefs

Influential factors related to exercise are one's attitudes and beliefs, which are greatly affected by culture and family. Leisure activities provide a clue to the person's

value system. Individuals who engage in hiking, bicycle riding, or swimming for recreation value an active lifestyle. On the other hand, individuals who consider work to be the dominant area of life may view exercise as “a waste of time.” Does the individual go everywhere in a car, or is walking a part of normal transportation? Are elevators routinely used instead of climbing stairs? Activities enjoyed by the individual are less likely to produce fatigue than are activities that hold no interest for the person. Thus, preferences should be matched with capabilities when planning an exercise program.

Lifestyle

Modern lifestyles require little physical activity; thus, few adults in America are naturally fit. The use of many convenience items (e.g., fast food, remote controls) encourage little physical exertion. The sedentary lifestyles of many Americans result in loss of muscle strength, decreased endurance, inadequate cardiorespiratory function, and obesity. Individuals with active lifestyles value exercise and, therefore, are more likely to experience its therapeutic outcomes.

PHYSIOLOGICAL EFFECTS OF MOBILITY AND IMMOBILITY

Maintaining functional mobility and desired activity levels is important for both psychological and physiological reasons. Mobility and lack thereof will both affect the various systems of the body. Table 34-8 summarizes the major complications associated with immobility.

Neurological Effects/ Mental Status

As for mental status, mobility and activity can increase an individual's energy levels and sense of well-being. Activity and exercise are excellent means to relieve tension and reduce stress, which result in better sleep patterns and an enhanced sense of well-being.

Client inactivity and immobility are stressors that can lead to frustration, lower self-esteem, anxiety, helplessness, depression, general dissatisfaction, restlessness, unhappiness, and decreased competency self-rating. Immobility impacts cognitive abilities, affect, lifestyle, and social and family responsibilities. The fear of falls, pain, and sensory deficits such as visual problems, fatigue, and weakness are compounding factors that increase inactivity and immobility.

Cardiovascular Effects

The cardiovascular system reaps many benefits from mobility and exercise. The heart becomes more efficient as it adapts to increased demands for oxygen, and cardiac output increases. A healthy heart muscle leads

TABLE 34-8
Negative Outcomes of Immobility

Neurologic	Gastrointestinal
Sensory deprivation	Decreased appetite Stress ulcers Constipation Fecal impaction
Cardiovascular	Urinary
Increased cardiac workload Orthostatic hypotension Formation of thrombus	Urinary stasis Urinary tract infection Calculi
Respiratory	Integumentary
Increased respiratory effort Hypostatic pneumonia Altered gas exchange	Pressure ulcers Skin shearing
Musculoskeletal	Psychological
Decreased bone density (increased risk of fracture) Contractures Muscle atrophy Increased pain	Anxiety Depression Helplessness, hopelessness Increased dependency

to a decreased resting heart rate and decreased resting blood pressure, which mean that the heart does not have to work as hard in an individual who exercises regularly as it does in an individual who leads a sedentary lifestyle. Activity increases the oxygen supply to the heart and muscles and thereby benefits overall health.

Immobility increases the workload on the heart as the supine position increases the volume of blood circulating to the heart. This fluid shift increases central venous pressure along with left ventricular diastolic volume and stroke volume, and the cardiac workload increases. The cardiovascular system is prone to form **thrombi**, or blood clots, due to venous stasis related to lack of muscle contractions of the legs and pressure on veins, especially the popliteal areas (Figure 34-6). Thrombi are caused by increased coagulation of the blood due to free calcium from bone demineralization, stasis of venous blood, and intimal damage to veins (as from venipuncture).

Another cardiovascular problem related to immobility is **orthostatic hypotension**, or a decrease in blood pressure resulting from sudden position changes,

NURSING ALERT

Deep-vein Thrombosis

Deep vein thrombi have the potential of becoming pulmonary emboli, which are life-threatening.

Figure 34-6 Effect of Immobility on the Cardiovascular System

caused by decreased vessel tone. In orthostatic hypotension, the blood pressure parameters drop at least 25 mm systolic and 10 mm diastolic with the postural changes. Orthostatic hypotension is a result of several factors associated with immobility, including:

- Decreased circulating fluid volume
- Decreased autonomic nervous system response
- Blood pooling in lower extremities

These factors lead to decreased venous return which negatively affects cardiac output. Thus, the blood pressure is lowered. Orthostatic hypotension is an indication that the heart is working harder and less efficiently.

Clients who have experienced immobility (such as with bed rest) need to have blood pressure checked lying down, sitting, then standing. This is done to establish baseline parameters to assist in determining the presence of postural-related changes in blood pressure.

Respiratory Effects

The respiratory system response to activity and mobility is increased intake of oxygen, which results in increased overall respiratory capacity and an easing in the work of breathing. The effects of oxygenation to the tissues are enhanced and pooling of secretions in the bronchioles is less likely.

Immobility from sitting or lying limits chest expansion, which is compounded by the effects of respiratory muscle atrophy and ineffective cough (Figure 34-7). Stasis of respiratory secretions can be worsened by the use of CNS-depressant medications and dehydration, and can lead to hypostatic pneumonia and atelectasis.

Musculoskeletal Effects

Musculoskeletal responses to activity are numerous, including stronger and better-defined muscles, stronger bones, and increased mobility and range of motion of

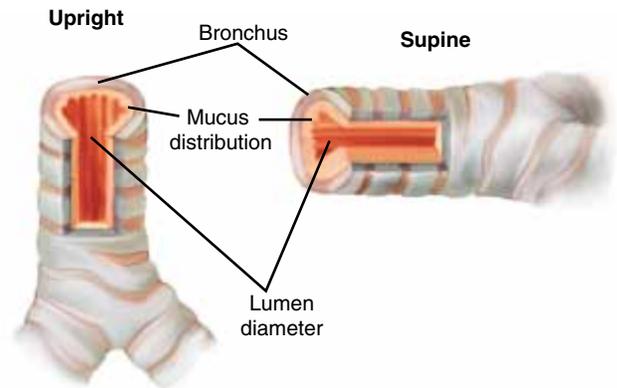

Figure 34-7 Effect of Immobility on the Respiratory System

the joints. Exercise can enhance endurance and tolerance of the muscle groups. Weight-bearing exercises such as walking (as opposed to swimming) are especially beneficial in preventing osteoporosis, or loss of strength and minerals in the bones.

Decreased physical mobility results in gross musculoskeletal impairment, especially when muscular atrophy occurs. Decreased mobilization alters muscle structure by reducing muscle mass and decreasing muscle cell diameter and the actual number of muscle cells. Clients experience rapid fatigue, decreased muscle strength and tone, decreased endurance, decreased mobility of joints, muscle stiffness, joint contracture, and negative nitrogen balance due to protein catabolism. Loss of calcium is a response to immobility and indicates an imbalance between bone formation and breakdown. The lack of pressure (e.g., weight bearing) on bones triggers calcium loss. Bone demineralization occurs as early as 2 or 3 days after onset of immobility and may lead to pathological fractures, renal calculi, and osteoporosis.

Digestive Effects

Digestive responses to activity include increased appetite and thirst, which indicate that the body's rate of processing nutritional intake is increased.

Loss of appetite is commonly related to lack of activity, negative nitrogen balance, and altered elimination patterns. Negative nitrogen balance occurs when the nitrogen output exceeds nitrogen intake. The causes of negative nitrogen balance include the increased need for protein in situations of extensive tissue damage, such as following surgery, and extended immobility. Extended periods of immobility cause muscle atrophy or muscle wasting; thus there is a need for extra protein intake to provide for muscle repair.

Elimination Effects

Elimination patterns are facilitated by mobility in that retention of wastes is usually prevented and the risk of constipation is reduced or avoided. The muscles become stronger and more efficient, thus enhancing the overall efficiency of elimination.

Constipation and fecal impaction are frequent complications of immobility. Variables contributing to these elimination problems are:

- Lack of activity, which decreases peristalsis
- Lack of privacy
- Inability to sit upright
- Improper diet
- Inadequate fluid intake
- Use of some medications, especially narcotics

Urinary stasis and urinary infections are related to the recumbent position of the immobile person. Decreased peristalsis of the ureters leads to stasis of urine, which is the etiology of urinary calculi (stones) and infection. Bladder distention occurs due to difficult relaxation of the external sphincter and decreased intra-abdominal pressure, thus causing overflow **incontinence** (loss of bladder control) and infection. The combination of increased urinary calcium, urinary stasis, and urinary infection leads to calculi formation.

Integumentary Effects

The integumentary system benefits from activity and exercise in that increased circulation and blood flow enhance oxygenation of tissues, maintaining the turgor and luster of the skin and hair.

Pressure ulcers are serious problems related to immobility. Prolonged pressure, shearing force, friction (rubbing), and moisture lead to tissue ischemia (impaired blood circulation), causing skin breakdown and decubiti. Moisture in the form of urine, feces, perspiration, and wound drainage can also lead to skin softening, which increases decubiti risk. Secondary factors contributing to pressure sore development are decreased nutrition, decreased arterial pressure, increased age, and edema. Refer to Chapter 35 for a discussion of pressure ulcers.

ASSESSMENT

During the assessment phase of the nursing process, data regarding activity and mobility of the client are gathered. Assessment data are used to initiate, individualize, plan, evaluate, and modify care on the basis of the client's strengths and limitations. Assessment of mobility status includes a health history and physical examination.

Health History

Taking a client's health history is the first step in determining the mobility needs and concerns of a client. Basic information about ADL, exercise patterns (type, frequency), lifestyle (active, sedentary), activity tolerance, and use of medications should be discussed. If an alteration or recent change in status is noted, then a detailed health history is in order. The nurse should ask what impact the mobility

Nursing Process Highlight

ASSESSING MUSCULOSKELETAL STATUS

1. Wash hands.
2. Provide an explanation to the client of the assessment procedure.
3. Assist the client to a comfortable position.
4. Use pillows or folded blankets to support painful body parts.
5. Provide assistance with disrobing as needed.
6. Adjust room temperature for client comfort.
7. Provide clear instructions to client (e.g., assuming a certain body position or performing a certain body movement).
8. Inform client before touching or moving a painful body part.
9. Assess skeletal muscles and joints in a cephalocaudal, proximal-to-distal manner. Always compare paired muscles and joints.
10. Examine nonaffected body parts before examining affected ones.
11. Avoid unnecessary or excessive manipulation of a painful body part. If the client verbalizes pain, stop the aggravating motion.
12. If needed, assist client in dressing after the physical examination is completed.

(Data adapted from Estes, M. E. Z. [2002]. *Health assessment and physical examination*. Albany, NY: Delmar Thomson Learning.)

impairment has had on the client's ADL and should have the client describe the exact nature of the problem (onset, duration, associated factors, aggravating factors, alleviating factors). The nurse should ask clients about the use (past and current) of medications, both prescription and over-the-counter, with the explanation that many drugs negatively affect the musculoskeletal system; see Table 34-9. It is also important to ask about the use of calcium supplements and estrogen replacement medication.

Physical Examination

The physical examination of mobility status typically covers three basic areas: musculoskeletal assessment, neurological assessment, and functional assessment.

Musculoskeletal Assessment

The nurse observes musculoskeletal functioning during every interaction with the client. Specific factors for objective assessment include the following:

- Body alignment
- Body mechanics

TABLE 34-9
Musculoskeletal Side Effects of Medications/Substances

Medication	Musculoskeletal Effect
Amphetamines	Muscle hyperactivity
Anticoagulants	Bleeding into the joints
Antipsychotics	Dystonic movements, altered gait
Caffeine	Muscle hyperactivity
Corticosteroids	Necrosis of femur head
Diuretics	Muscle weakness and cramping
Phenothiazines	Gait disturbances

(Data from Davison, M. A. [1998]. Antipsychotic medications. In M. E. Kuhn [Ed.], *Pharmacotherapeutics: A nursing process approach* [4th ed., p. 393]. Philadelphia: F. A. Davis; O'Hanlon-Nichols, T. [1998]. A review of the adult musculoskeletal system. *American Journal of Nursing*, 98[6], 49.)

- Posture (sitting and standing)
- Range of motion of joints
- Strength of muscles
- Endurance
- Muscle tone
- Size and contour of joints
- Inspection of the skin
- Palpation of skin, muscles, and joints

Subjective data include assessment of client's pain, joint stiffness, muscle cramping, fatigue, weakness, exercise habits, and environmental variables. Children should be evaluated by comparing physical development and abilities with normal values for the age. The elderly should be evaluated on functional abilities, strengths, weaknesses, joint limitations, and use of assistive devices such as canes or walkers to assist the client in ADLs.

A complete musculoskeletal assessment needs to include data related to client weakness, stiffness, and pain related to movement. A 0–10 intensity scale can be used to assess these subjective factors. When assessing weakness, zero represents complete absence of weakness and 10 represents weakness requiring complete bed rest. For determining stiffness, zero represents com-

plete absence of stiffness and 10 represents total inflexibility. See Chapter 32 for directions on using the 1–10 scale for measuring pain intensity.

Movement and Gait

Gait, the way that one walks, is assessed to determine a baseline. Normal gait is characterized by a smooth rhythmic movement of muscles when walking. Step height and length are symmetrical for each foot and the arms swing freely at each side of the torso in opposite movement of the legs. Normally, the lower limbs are able to bear full body weight during standing and ambulation. Gait is described in terms of smoothness, balance, arm movement, effectiveness, and the length and width of the step.

Alignment

When assessing body alignment, the nurse seeks to determine whether the movement results in fatigue, muscle stress, or strain. Structural deformities may interfere with body alignment and functional ability; see Table 34-10.

Endurance

When assessing a client's endurance during physical activity, look for reactions such as mood changes, indicators of pain, presence of fatigue, and changes in respiratory and circulatory status. Oxygen consumption increases during muscle activity, thus, assessment of vital signs is essential. The time required for vital signs to return to the normal (baseline) resting values is a significant factor to include in the assessment of mobility.

Pathological Alterations

Assessment to determine the presence of pathological alterations—such as bone disorders, joint impairment, impaired muscle development, postural abnormalities, musculoskeletal trauma, and neurological damage—can offer important data for the determination of mobility limitations.

Muscle Impairments

Overuse injuries are a common type of musculoskeletal problem, especially in people who exercise too much and/or incorrectly. Common overuse injuries are listed in Table 34-11.

Postural Abnormalities

In addition to the postural abnormalities described in Table 34-11, contractures may also affect body alignment.

Contractures

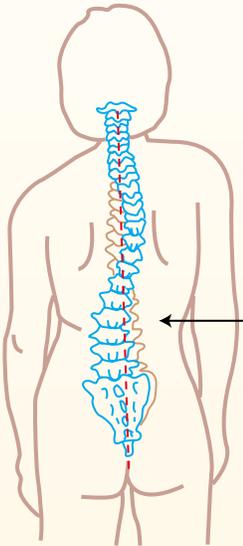

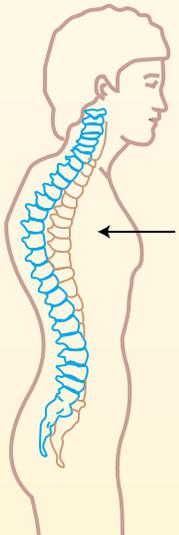

A contracture develops when the muscle fibers become unable to flex; see Figure 34-8. Each muscle has an antagonist that works in the opposite direction. If a muscle group is not moved for a period of time or if proper body alignment is not maintained, the stronger muscle will predominate, causing contracture deformities.

NURSING TIP

When assessing a client's musculoskeletal status, always warn the client if you think your action may cause discomfort.

TABLE 34-10
Spinal Misalignment

Anomaly	Description	Clinical Implications
<p>Scoliosis</p> <ul style="list-style-type: none"> • <i>Postural scoliosis</i>: no fixed rotation of vertebrae; can be corrected with exercise. • <i>Structural scoliosis</i>: fixed rotation of the vertebrae in the direction of the convexity of the curve. 	<ul style="list-style-type: none"> • Lateral deviation in the normally straight vertical line of the spine • More common in females, especially during adolescence • Some indicators: <ul style="list-style-type: none"> • One side higher than the other or one shoulder blade more prominent • Abnormal waistline tilt with more indentation on one side • Tilting of the hips with one hip more prominent • A prominence of the posterior chest or the shoulder when bending over. 	<ul style="list-style-type: none"> • Can progress to a severe curvature in a short period of time if untreated.
<p>Kyphosis</p> 	<ul style="list-style-type: none"> • Abnormally increased convexity in the curvature of the spine • Chin tilts downward onto chest with abdominal protrusion • Decreased interval between lower rib cage and iliac crests 	<ul style="list-style-type: none"> • In advanced stages, can interfere with lung expansion • Commonly seen: <ul style="list-style-type: none"> — elderly clients — osteoporosis • Paget's disease

TABLE 34-10 (continued)
Spinal Misalignment

Anomaly	Description	Clinical Implications
Lordosis	<ul style="list-style-type: none"> • Forward curvature of the lumbar spine 	<ul style="list-style-type: none"> • More pronounced in obesity and pregnancy (due to change in center of gravity)
List	<ul style="list-style-type: none"> • Lateral lean of the spine • Iliac crests are unequal in height • Decreased ROM, usually accompanied by pain 	<ul style="list-style-type: none"> • Commonly present in: <ul style="list-style-type: none"> —back injury —osteoarthritis —herniated vertebral disc

TABLE 34-11
Musculoskeletal Trauma, Common Overuse Injuries

Strain	Commonly referred to as “pulled muscles” Caused by overstretching, tearing, or ripping of a muscle and/or its tendon
Tendonitis	Inflammation of a tendon caused by chronic, low-grade strain of a muscle-tendon unit
Bursitis	Inflammation of the bursa (lubricating sac surrounding a joint) Caused by repeated low-grade strains of the joint’s supporting tissues
Sprain	Overstretching or tearing of ligaments

Figure 34-8 Hand-Wrist Contracture

Once a contracture occurs, the only corrective action is surgery to release the fibrous tissue. Prevention of contractures is a major nursing focus with immobile clients. Nursing interventions to prevent a muscle contracture include:

- Encouraging clients to be as active as possible
- Performing ROM exercises
- Positioning to maintain proper body alignment
- Repositioning every 2 hours or more often as needed

Musculoskeletal Trauma

Trauma to musculoskeletal tissues can result in many types of impairments (such as those described in the display on overuse disorders). Another common type of musculoskeletal trauma is a fracture (broken bone). The second type of trauma discussed below is surgical amputation.

Fractures

According to Lamb and Cummings (2000), hip fractures are the most disabling for older people. Hip fractures are usually a result of falls and approximately 24% of those with hip fracture die from complications within 1 year after the injury. Hip fracture complications result from immobility and include pressure ulcers, pneumonia, and sepsis from urinary tract infections.

When a fracture is suspected, the nurse should assess the area for mobility, pain, color, temperature, pulse, and sensation.

Amputation

Any condition in which circulation is inadequate to maintain cellular function can necessitate amputation.

NURSING TIP

The acronym RICE can be helpful in remembering the principles for emergency treatment of musculoskeletal injuries: **R**est, **I**ce, **C**ompression, and **E**levation.

For example, lower limb amputations are often required as a result of infection, peripheral vascular disease (PVD), neoplasm, and trauma. Pressure ulcers, if inadequately treated, can also lead to the loss of a limb. When the decubiti do not heal, infection and gangrene develop. Gangrene first manifests as a blackened area and is often accompanied by pain.

Lower limb amputation is either above the knee or below the knee; the level of amputation depends on the extent of the disease process. Below-the-knee amputation is the most commonly performed type. The goal of the surgery is to preserve the length of the extremity in order to assist with prosthetic fitting. Therefore, as much limb as possible is salvaged.

Central Nervous System Damage

As movement is a result of coordination between muscles and nerves, an intact central nervous system is necessary for mobility. Any disruption in the CNS, such as those occurring with spinal cord injury, can impair mobility. Spinal cord injury can lead to partial paralysis or complete loss of mobility.

Spinal Cord Injury

There are 15,000 to 20,000 traumatic spinal cord injuries each year in the United States (Huston, 1998). Damage to the spinal cord can be a result of hyperextension and/or compression. With hyperextension, the spinal cord is overstretched, leading to dislocation of the vertebrae or discs and possible compression of the spinal cord. Hyperextension can also completely dissect the spinal cord. In a complete spinal cord injury, voluntary motor activity, sensory function, and proprioception below the level of the injury are lacking.

Compression injuries occur when the force of impact fractures the vertebrae or ruptures the discs, forcing bony fragments or discs into the spinal canal. These particles can lacerate or compress the spinal cord, resulting in paralysis below the level of the injury. Prevention of spinal cord injuries is a major concern of nurses and may be addressed through educating the public on safety precautions related to driving, participation in sports, and leisure activities.

Neurological Assessment

An intact neurological system is essential for activity and mobility. Objective neurological assessment includes

(1) cranial nerves, (2) motor system, (3) sensory system, and (4) reflexes. The nurse assesses the motor system for the following variables:

- Size, strength, and tone of muscles
- Presence of involuntary movements
- Balance
- Gait
- Coordination
- Proprioception
- Fine motor function
- Gross motor function

The sensory system is assessed for integrity of peripheral nerves, pain, tactile discrimination (fine touch), and sensation of vibration. Assessment of deep tendon or stretch reflexes focuses on the biceps, triceps, brachioradialis, quadriceps, and Achilles reflexes. Refer to Chapter 27 for further details on physical assessment.

Functional Assessment

Functional assessment focuses on the client's abilities to perform ADL. The client's functional status is assessed in terms of the ability to feed, dress, toilet, move, transfer, and ambulate self independently or with some degree of required assistance; see Figure 34-9. Functional assessment data are used for initial planning, for discharge planning, for planning continuity of care in a nursing home or private home, and to provide baseline and ongoing data for rehabilitation.

Clients at high-risk for falls include those with prolonged hospitalization, those taking sedatives or tranquilizers, confused clients, or those with a history of physical restraint use. A great majority of falls:

Figure 34-9 Some mobility impairments significantly limit a person's ability to perform ADL.

- Occur in the evening
- Occur in the client's room
- Involve wheelchairs
- Involve unattended clients
- Involve clients with poor footwear
- Occur with poor lighting
- Involve clients with poor vision
- Occur with clients experiencing neuromuscular impairment

Awareness of these risk factors for falls allows the nurse to prevent many client injuries.

The nurse continually evaluates the client's strength and endurance during the entire ambulation process. The Risk Assessment Tool (RAT) for falls was developed to identify clients at high risk for falls and to individualize care (Brians, Alexander, Grota, Chen, & Dumas, 1991). See the accompanying Nursing Checklist for the RAT and Chapter 31 for further discussion of fall prevention.

NURSING DIAGNOSIS

Nursing diagnoses related to mobility focus primarily on activity and mobility levels, and the psychosocial impact that alterations in mobility can have on a client and the client's family. Common NANDA nursing diagnoses related to the physical adaptations or risks resulting from altered mobility include:

- *Activity Intolerance* related to bed rest and immobility, generalized weakness, sedentary lifestyle, and imbalance between oxygen supply and demand; see the Nursing Process Highlight.
- *Impaired Physical Mobility* related to intolerance to activity or decreased strength and endurance, pain, perceptual or cognitive impairment, neuromuscular impairment, musculoskeletal impairment, and depression or severe anxiety; see the Nursing Process Highlight.
- *Risk for Disuse Syndrome* per risk factors of paralysis, mechanical immobilization, prescribed immobilization, and severe pain
- *Self-Care Deficits* related to inability to wash body or body parts, inability to obtain or get to water source, activity intolerance, decreased strength and endurance, pain, and impaired transfer ability
- *Ineffective Health Maintenance* related to lack of or significant alteration in communication skills (written, nonverbal)
- *Risk for Falls* related to impaired mobility.

Alterations in family and social processes may also result from immobility and inactivity. Disruption in activity and mobility leads to impairment of the ability to perform one's usual social, vocational, educational, and family roles. There are often changes in the client's perception of role. *Disturbed Body Image* and *Situational Low Self-Esteem* can result from:

1. Changes in physical abilities
2. Changes in family responsibilities
3. Lack of knowledge regarding rehabilitation

NURSING CHECKLIST

Risk Management Tool (RAT) for Falls

Directions: Place a check mark in front of elements that apply to your patient. The decision of whether or not a patient is at risk for falls is based on your nursing judgment. **GUIDELINE:** A patient who has a check mark in front of an element with an asterisk (*) or four or more of the other elements would be identified as at risk for falls.

General Data

- Age over 60
- History of falls prior to admission*
- Postoperative/admit for operation
- Smoker

Physical Condition

- Dizziness/imbalance
- Unsteady gait
- Diseases/problems affecting weight-bearing joints
- Weakness
- Paresis
- Seizure disorder
- Impairment of vision
- Impairment of hearing
- Diarrhea
- Urinary frequency

Mental Status

- Confusion/disorientation*
- Impaired memory or judgment
- Inability to understand or follow directions

Medications

- Diuretics or diuretic effects
- Hypotensive or CNS suppressants (narcotic, sedative, psychotropic, hypnotic, tranquilizer, antihypertensive, antidepressant)
- Medication that increases GI motility (laxative, enema)

Ambulatory Devices Used

- Cane
- Crutches
- Walker
- Wheelchair
- Geri chair
- Braces

(From The development of the RISK for fall prevention, by L. K. Brians, K. Alexander, P. Grotta, R. W. H. Chen, & V. Dumas. [1991]. Reprinted from *Rehabilitation Nursing*, 16(2), pp. 67–69. With permission of the Association of Rehabilitation Nurses. Copyright 1991 by the Association of Rehabilitation Nurses.)

Nursing Process Highlight

DIAGNOSIS

Nursing Diagnosis: *Activity intolerance*—a state in which an individual has insufficient physiologic or psychologic energy to endure or complete required or desired daily activities.

Defining Characteristics

- Verbalization of weakness or fatigue
- Abnormal physiologic responses to activity (e.g., heart rate or blood pressure changes)
- Discomfort or dyspnea upon exertion

Related Factors

- Immobility, bed rest
- Generalized weakness
- Sedentary lifestyle
- Imbalance between oxygen supply and demand

Nursing Diagnosis: *Impaired physical mobility*—state in which the person experiences a limitation of ability for independent physical movement.

Defining Characteristics

- Inability to move purposefully
- Hesitant to attempt movement
- Limited range of motion
- Impaired coordination
- Decreased muscle mass, strength, and/or control

Related Factors

- Decreased strength and endurance
- Discomfort/pain
- Perceptual/cognitive impairment
- Musculoskeletal impairment
- Depression, marked anxiety

(Data from Carpenito, L. J. [1999]. *Handbook of nursing diagnosis* [8th ed. pp. 159–161]. Philadelphia: Lippincott; North American Nursing Diagnosis Association. [2001]. *Nursing diagnoses: Diagnoses and classification: 2001–2002*. [pp. 13, 117–118]. Philadelphia: Author)

4. Denial of abilities and strengths
5. Social insecurity
6. Feelings of worthlessness, hopelessness, or depression

PLANNING AND OUTCOME IDENTIFICATION

In the development of outcomes for clients with mobility needs, client involvement is essential. Realistic outcomes can be targeted by considering the client's (1) understanding of mobility status; (2) values, thoughts,

and concerns regarding mobility problems; (3) general health status; and (4) ability to solve problems.

The goal of the interdisciplinary health team during acute hospitalization and rehabilitation is to restore function, thus maximizing the level of the client's independence. Maximal independence includes the ability to function in ADL (eating, dressing, bathing, and moving). Independence in these activities contributes to self-reliance, self-care, self-determination, self-direction, and personal control. Personal client variables determining the maximal level of independence include extent of disability, competence, age, self-confidence, cognitive ability, knowledge level, and mood state. It is important to develop short-term goals that encourage clients to gain a sense of accomplishment. The nurse should recognize and praise the client's accomplishments that increase mobility.

The level of independence and ability for performance of ADL is enhanced or inhibited by the physical environment. Collaboration of the client, family, caregivers, nurses, physical therapists, and occupational therapists is essential for individualizing the physical environment to permit optimal activity and mobilization. Adaptive devices, such as those that follow, enhance independence for personal activities:

- Eating (e.g., plate guards and hand splints to hold utensils)
- Bathing (e.g., shower chairs and long-handled sponges)
- Dressing (e.g., Velcro closures and zipper pulls)
- Toileting (e.g., elevated toilet seats)
- Mobility (e.g., walkers)

Continued practice in self-care activities with adaptive devices promotes confidence. Interdisciplinary cooperation can be used to plan modifications for the home for activity and mobility, especially in the bathroom and kitchen. Physical modifications with adaptive equipment in home environments maximize client activity and mobility.

Bed Rest

Bed rest is a therapeutic intervention that achieves several objectives, including the following:

- Provide rest for clients who are exhausted.
- Decrease the body's oxygen consumption.
- Reduce pain and discomfort.

The planned duration of bed rest depends on the client's physical condition and ability to move.

Even though implemented for therapeutic reasons, bed rest can be counterproductive to a client's recovery. The inactivity imposed by bed rest causes structural changes in joints and shortens muscles. Such changes, which may lead to decreased range of motion and contractures, can occur within 48 hours of bed rest (Lamb

& Cummings, 2000). To prevent such complications, bed rest should be avoided as much as possible. For clients whose medical condition necessitates bed rest, range-of-motion exercises must be implemented. When planning care, it is important to "prevent immobility if possible; approximately 7 days are needed for the client to regain the function lost during 1 day of bedrest" (Eliopoulos, 1999, p. 278).

Restorative Nursing Care

Being able to move about independently is an important part of the recovery process and can determine whether the client is cared for at home or in a health care facility. Environmental evaluation is particularly important, with the focus on ease and safety of mobility. Promotion of activity through environmental modification increases the quality of life for the client whether injured, ill, or aging. Efforts by the client and the rehabilitation team to promote activity and mobility can be negated quickly by environmental barriers such as stairs and narrow passageways.

Clients who have limited mobility may be at risk for falls. To decrease the probability of falls at home, client education should focus on creating a safe environment for ambulation; see Client Teaching Checklist. The accompanying display lists some assistive devices for clients receiving care in the home setting. Other types of assistive devices are available to help clients perform ADL; see Figure 34-10.

CLIENT TEACHING CHECKLIST

Promoting Safety at Home

1. Avoid unsecured rugs or loose rugs.
2. Use banisters on stairways.
3. Install bright lights near steps and stairways.
4. Avoid wearing shoes that are ill-fitting, unlaced, or high-heeled, or have slippery soles.
5. Keep all walkways unobstructed (remove clutter).
6. Use caution with telephone lines; use a cordless phone if available to avoid tripping danger.
7. Do not walk on wet or waxed floors.
8. Use nonskid mats in shower/bathtub.
9. Use grab bars near toilet and shower/bathtub.
10. Keep commonly used objects within easy reach.

Health Promotion and Fitness

The client's long-term goals include the promotion of activity, mobility, and fitness. Therapeutic exercises maintain flexibility, strength of muscles, range of motion, and energy and increase endurance and sense

HOME HEALTH CARE: ASSISTIVE DEVICES IN THE HOME

The following devices may be rented and may qualify for reimbursement from Medicare or private insurance.

- Electric hospital bed with overhead trapeze (give client more control of environment)
- Portable commode (extend client's independence in elimination)
- Lifting device (assist with transferring dependent client from bed to chair)
- Portable telephone (for client safety and convenience)
- Shower chair and hand-held shower for bathtub (promote client independence and safety)
- Special mattresses for bed and cushions for chairs (promote comfort and help maintain skin integrity)
- Overbed table for eating or hand activities (promote client's ability to perform ADL)
- Comfortable chairs close to the bed (promote socialization by facilitating visits of family and friends)
- Remote control for client who enjoys television (provide leisure/diversion activity)

APPLICATION: HOME CARE

Increased accessibility and mobility can be achieved through planning home modifications such as:

1. Ramps (paths to freedom)
2. Wide doorways
3. Open-ended door handles replacing doorknobs
4. Remote-controlled lighting
5. Spacious room arrangements
6. Bare floor or low-level pile carpeting
7. Grab bars for bathrooms

Figure 34-10 Assistive devices, such as those shown here, help clients dress independently.

of well-being. Health promotion models stress the importance of cognitive and perceptual factors on exercise participation. Factors affecting targeted health promotion outcomes include perceived health status, perceived benefits of exercise, perceived barriers to exercise, and attitudes toward exercise. Perceived benefits of exercise and exercise attitudes held by the client have been identified as critical in goal setting for a program of health promotion and fitness.

IMPLEMENTATION

Interventions for clients with impaired mobility include meeting psychosocial needs, using body mechanics, maintaining body alignment, performing ROM exercises, transferring clients, assisting with ambulation, promoting wellness, using complementary treatment approaches, and documentation.

Meeting Psychosocial Needs

Nursing interventions for role change due to deficits in activity and mobility include (1) fostering open family communication, (2) providing opportunities for family role resumption, (3) prioritizing family roles and responsibilities, and (4) modifying family roles and responsibilities. The accompanying Nursing Process Highlight lists nursing interventions that encourage socialization.

Nursing Process Highlight

IMPLEMENTATION: PROMOTING SOCIALIZATION

- Foster client autonomy
- Encourage activities in collaboration with recreational therapist
- Involve client with successful role models
- Inform client of vocational, educational, recreational, and social resources
- Involve client and family in support groups
- Facilitate transportation resources

Applying Principles of Body Mechanics

Often nurses are required to have physical strength in order to assist clients in achieving mobility. Carrying, pulling, pushing, or lifting clients and/or equipment are all activities involved in the delivery of nursing care.

Nurses' implementation of correct body mechanics help minimize the following:

- Client injury
- Nurse work-related musculoskeletal injury
- Nurse fatigue

“Back injury is mainly caused by lifting unreasonable loads . . . the most stressful tasks involve the transferring of patients (from a bed to a chair, for example)” (Owen, 1999, p. 76). The following variables can increase the risk of nurse injury:

- Client weight
- Client weight-bearing ability
- Client combativeness and unpredictability
- Height of bed
- Confined work space
- Wheelchairs without adjustable arms

NURSING TIP

Body Mechanics

Think ahead to eliminate hazards and injuries.

- Consider the weight and bulk of a client or object before lifting.
- Take your time and lift properly.
- Watch your footing.
- Teach proper body mechanics to others.
- Ask for help as needed.

Educating staff about the use of proper body mechanics is essential in preventing injury; see Procedure 34-1. The U.S. Department of Labor Occupational Safety & Health Administration (OSHA) has implemented new standards for the prevention of musculoskeletal injuries. OSHA (2000) defines musculoskeletal disorders (MSDs) as injuries and disorders of the muscles, nerves, tendons, ligaments, joints, cartilage, and spinal discs. Examples of MSDs include carpal tunnel syndrome, tendonitis, sciatica, herniated disc, and low back pain. Work-related MSDs account for more than one-third of all occupational injuries and illnesses that are serious enough to result in days away from work (OSHA, 2000).

MSDs are preventable by educating the workers and modifying the work environment. The following recommendations are made by OSHA (2000) to prevent MSDs:

- Adjust the height of working surfaces to reduce long reaches and awkward postures.

- Reduce the weight and size of items that workers must lift.
- Provide mechanical lifting equipment.

NURSING TIP

Application of Body Mechanics

- When lifting objects from the floor, bend at the hips and knees while keeping the back straight and maintaining a wide base of support.
- Avoid bending from the waist as this will strain muscles of the lower back.
- Adjust the height of the client's bed to avoid back strain.
- Carry objects close to the midline of the body.
- Avoid stretching to reach objects.

Maintaining Body Alignment: Positioning

Clients cannot always move independently and reposition themselves in bed. In such instances, nurses must use proper turning and positioning techniques in order to achieve the following outcomes:

- Increase client comfort
- Prevent contractures
- Prevent decubiti (pressure sores)
- Make portions of the client's body accessible for procedures
- Help clients access their environment

Clients who cannot move independently must be repositioned every 2 hours. Repositioning must be done more often for clients who are uncomfortable or incontinent, or who have fragile skin, poor circulation, fragile skin, decreased sensation, poor nutritional status, or impaired mental status.

Nurses need to be aware of three essential concepts when positioning clients: pressure, friction, and skin shear. A pressure site is any skin surface area on which the client is lying or sitting. The force of the pressure

NURSING ALERT

To prevent the development of contractures and decubiti, change the client's position every 2 hours.

PROCEDURE 34-1

Practicing Proper Body Mechanics

Equipment

None required

Action

1. Get a firm footing by keeping your feet apart.
2. Bend at the knees; avoid bending at the waist. Hold the load close to your body (Figure 34-11).

Figure 34-11 Bend knees to lift.

3. Lift with the leg muscles.
4. Tighten abdominal muscles to lift.
5. Turn by pivoting your feet, not your trunk, while lifting (Figure 34-12).
6. If the load is heavy, get help or use a mechanical lift.
7. Push, do not pull.
8. Use wheeled objects (e.g., a wheelchair).
9. Perform health-promoting activities.

Rationale

1. Develops and maintains a stable base.
2. Provides greater leverage for lifting.

Figure 34-12 Pivot with feet.

3. Uses the strongest muscles, thereby reducing risk of injury.
4. Provides greater support to the back.
5. Maintains proper body alignment.
6. Avoids strain and possible injury.
7. Prevents back injury.
8. Eases mobility.
9. Exercising, maintaining normal weight for height, pacing activities, and relaxation promote good body conditioning.

can compromise circulation and lead to skin breakdown and ulceration. Tissue areas over bony prominences are more likely to experience impaired skin integrity. It is important to always inspect the skin and tissue areas under increased pressure for signs of irritation (i.e., redness).

Friction is caused when the skin is dragged across a rough surface such as bedsheets or stretcher surfaces. Friction causes heat, which damages the skin and may lead to decreased skin integrity with resultant infection and/or skin breakdown.

Skin shear is the result of dragging skin across a hard surface. The force of resistance to being dragged tears the deep layers of skin which can lead to skin ulceration.

NURSING ALERT

To prevent skin shear, avoid dragging a client across the bed or stretcher. Instead, lift the client or use assistive devices such as turning sheets or transfer boards.

For clients in bed, limit the number of pillows under the head in order to avoid neck flexion. Arms should be abducted from the body and straight with slight flexion. Hands should rest comfortably in a flat position with fingers open. The knees and hips should be aligned; use sandbags or pillows to prevent external hip rotation. Avoid flexing the knees by the use of pillows placed behind the knees. Ankles should be flexed at 90 degrees; use pillows or footboard if necessary.

To maintain proper positioning for a client seated in a chair, be sure the head is straight without bending the neck or head dangling. The trunk should be upright without bending or curving. Arms and hands are to be supported on armrests or the tabletop; avoid dangling the arms. The hands should be in a flat position with the fingers open. Hips and knees should be flexed. The feet are to be flat on the floor or footrest with the ankles at a 90 degree angle. If the legs are supported on leg rests and are straight, keep the ankles flexed at a 90 degree angle.

Table 34-12 provides a description of the most commonly used positions: Fowler's (elevated head and trunk), dorsal recumbent (back-lying with slight elevation of head and shoulders), prone (face down), lateral (side-lying), and Sim's (semi-prone).

Assisting clients to comfortable therapeutic positions requires much skill; see Procedure 34-2. Often the client is unable to assist in repositioning; in such cases, it is best to use two or more staff members to reposition the client in order to prevent injury.

Specialized equipment used for client positioning includes pillows, foam wedges, trochanter rolls, footboards, bed boards, hand-wrist splints, traction, side rails, restraints, and trapeze bars. Table 34-13 describes devices

NURSING ALERT

Before and after repositioning, assess the status of a client's skin and provide skin care as needed.

used to help maintain proper positioning.

Hand-wrist splints can facilitate extension of the wrist-hand-fingers, prevent contracture, and reduce spasticity. The goal for splint use is to maintain a functional hand for the client. Figure 34-13 shows hand-wrist splints. Clients must be taught the correct way to put on the

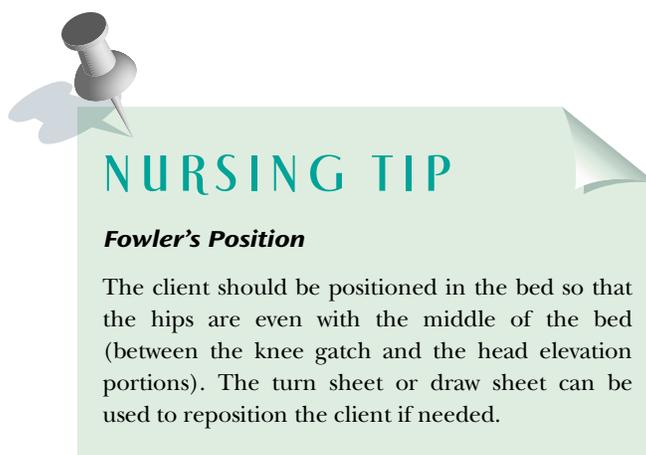

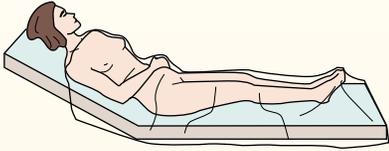

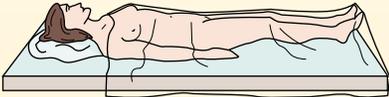

Figure 34-13 Hand-wrist Splints

TABLE 34-12
Positioning

Position	Description	Indications	Potential Complications	Corrective Measures
Fowler's	Semi-sitting position. Head of bed elevated to 45–60 degrees. Knees slightly elevated.	Promote comfort Improve respiratory problems (i.e., dyspnea, pneumonia) Encourage postoperative drainage	Flexion contracture of cervical spine Exaggerated flexion of lumbar spine Dislocation of shoulder Flexion contracture of wrist Finger contractures and thumb abduction External hip rotation Hyperextension of knees Foot drop (plantar flexion)	Rest head directly on mattress or support with small pillow only Firm support to back Pillow to support lower back Elevate forearms on pillows to avoid tension on shoulders Support hands on pillows to maintain natural alignment Hand-wrist splints Trochanter roll Flex knees with small pillow under the thighs Maintain dorsal flexion with footboard or high-top tennis shoes
				
Dorsal recumbent (Supine)	Back-lying position. Head and shoulders may be slightly raised.	Promote comfort NOTE: Head and shoulders are kept flat after procedures involving spinal anesthetics	Cervical hyperextension Posterior flexion of lumbar spine Clawhand deformities (extension of fingers and abduction of thumbs) Hyperextension of knees Footdrop (plantar flexion)	Maintain correct alignment with pillows under upper shoulders, neck, and head Small pillow or roll under lumbar curvature Hand-wrist splints Pillow under lower legs from below the knees to ankles or small pillow under thighs to slightly flex knees Maintain dorsal flexion with footboard or high-top tennis shoes
				

(continues)

TABLE 34-12 (continued)
Positioning

Position	Description	Indications	Potential Complications	Corrective Measures
Prone	Face-down position. Head is turned to one side.	Helps prevent contractures of hips and knees Promotes drainage from mouth	Cervical spine flexion Hyperextension of spine; respiratory impairment Footdrop	Small pillow under head Small pillow just below the diaphragm Allow feet to dangle over end of mattress Place lower legs on pillow to keep toes from resting on bed
Lateral	Side-lying position. Lateral aspects of lower scapula and lower ilium support most of body weight.	Promote comfort Relieves pressure on sacrum and heels	Lateral flexion of neck Internal rotation of arm; limited chest expansion leading to respiratory impairment Extension of fingers and abduction of thumbs Internal rotation and abduction of femur Twisting of spine	Pillow under head and neck Maintain alignment of upper arm with pillow underneath Slightly flex lower arm Hand-wrist splints Pillows to support leg from groin to foot Align both shoulders with both hips
Sim's	Semiprone position. Upper arm is flexed at shoulder and elbow; lower arm is positioned behind client. Both legs flexed in front of client with more flexion in upper leg. Promotes comfort especially in pregnant clients	Promotes drainage from mouth Prevents aspiration Reduces pressure on sacrum and greater trochanter of hip	Lateral flexion of cervical spine Damaged nerves and blood vessels of lower arm axillae Internal shoulder rotation and abduction Internal rotation and adduction of hip and leg; lumbar lordosis Footdrop	Support head with pillow unless drainage from mouth is necessary Position lower arm behind and away from the back Pillow between chest and upper arm Pillow under upper flexed leg from groin to foot Sandbag to dorsiflex lower foot

PROCEDURE 34-2

Positioning a Client in Bed

Equipment

- | | |
|--------------------------------|----------------------------|
| ■ Hospital bed with side rails | ■ Turn sheet or draw sheet |
| ■ Pillows or foam wedges | ■ Hand cones |
| ■ Foot board | ■ High-top tennis shoes |

Action

Rationale

1. Inform client of reason for the move and how to assist (if able).
2. Elevate bed to highest position.
3. Using two nurses, place turn (or draw) sheet under client's back and head.

1. Reduces anxiety; helps increase comprehension and cooperation; promotes client autonomy.
2. Avoids strain on nurse's back muscles.
3. Decreases shearing, which can lead to formation of pressure ulcers.

Fowler's Position

4. Place bed in a 15° to 30° angle for low-Fowler's position, 45° to 60° angle for Fowler's position, or 70° to 90° angle for high-Fowler's position.
5. Place pillows at small of back, under ankles, under the arms, and under head of client.
6. Slightly elevate the gatch of the lower portion of the bed.
7. Assess client for comfort.
8. Lower height of bed and elevate side rails.

4. The height of the head of the bed is determined by physician's order, client preference, client tolerance, or client's activity (e.g., eating).
5. Promotes client comfort. Pillows under ankles elevate heels to help prevent pressure ulcer formation. Pillows under the arms can assist with lung expansion.
6. Assists in maintaining correct client positioning.
7. Comfort is subjective.
8. Promotes client safety.

Supine Position

9. Repeat steps 1–3.
10. Place bed in a flat position.
11. Place small pillows at small of back, under head, and under ankles.
12. Assess client's comfort level.
13. Lower height of bed and elevate side rails.

11. Adds to client comfort; relieves pressure on heels.
12. Comfort is subjective.
13. Promotes client safety.

Side-Lying Position

14. Repeat steps 1–3.
15. Logroll client to side (Procedure 34-5).
16. Place a small pillow under client's head. Place pillow or foam wedges behind client's back. Place a pillow between client's legs. Put a pillow tucked by the client's abdomen.

15. Places client on side for the proper positioning; reduces flexion of neck and spine.
16. Pillows at back and abdomen help maintain side-lying positioning. Small pillow under head is for comfort. Pillow between legs is for back alignment, comfort, and pressure relief. Pillow at abdomen supports upper arm, thus protecting the upper arm-shoulder joint positioning.

(continues)

PROCEDURE 34-2

Positioning a Client in Bed (continued)

<i>Action</i>	<i>Rationale</i>
17. Run your hand under the client's dependent shoulder and move the shoulder slightly forward.	17. Removes pressure on upper arm-shoulder joint, promoting comfort.
18. Assess the client for comfort.	
19. Lower the bed and elevate the side rails.	19. Promotes client safety.
Prone Position	
20. Repeat steps 1–3.	
21. Assist the client to lie on abdomen.	21. Prepares client to assume prone position.
22. Place a small pillow under client's head; turn head to side. The client's arms can be extended near side or flexed toward head. Place a small pillow under chest for female clients and for clients with barrel chest.	22. Pillows at head and chest are for comfort. The arms are positioned according to client preference and flexibility. Pillow under chest protects breasts and promotes comfort.
23. Place a small pillow under ankles or allow toes to rest in space between foot of bed and the mattress.	23. Relieves pressure on toes.
24. Assess client for comfort.	
25. Lower the bed and elevate the side rails.	25. Promotes client safety.
General Guidelines for Client Positioning	
26. Use a hand cone for positioning the hand if needed. Place the cone in hand, with the wider portion near the little finger and the narrow portion nearer the index finger.	26. Helps prevent hand flexion contractures.
27. Assess the client's skin frequently (at least every 2 hours) for pressure marks.	27. Immobile clients are prone to tissue ischemia with subsequent development of pressure ulcers.
28. Turn client frequently, at least every 2 hours.	28. Promotes blood circulation and prevents skin breakdown.
29. Use a footboard or high-top tennis shoes for clients in Fowler's and supine position.	29. Assists in prevention of foot drop.
30. Prepare a turn schedule for each client. Place sign at head of client's bed.	30. Stresses to all nursing personnel the importance of turning client frequently.

device, as incorrect use of a splint or brace can cause joint damage, stiffness, or pain.

Falls are common types of injuries in hospitals and long-term care facilities. Side rails, which are placed on the sides of beds and stretchers to prevent falls, can be raised, lowered, and locked into place; see Figure 34-14. For clients who are at risk for falls, side rails should always be used; however, they should not give nurses a sense of security. Beds must still be placed in the lowest

position to reduce the force of a possible fall, should one occur. Also, clients identified as being at-risk for falls should be closely monitored.

Some clients resist the use of side rails because they feel their independence is altered. It is important that the nurse teach clients and families the purpose of side rails, focusing on safety promotion. Note that some health care agencies require signed notification consenting to the use of raised side rails.

TABLE 34-13
Maintaining Proper Position: Assistive Devices

Bed board	Plywood board placed under entire mattress; improves spinal alignment by providing support
Footboard	Board placed at end of bed to provide support for feet to maintain dorsiflexion
Hand-wrist splint	Individually contoured for each client; maintains thumb adduction and opposition to fingers
Pillow	Available in various thicknesses; provides support; elevates body parts
Restraint	Variety of types available (jacket or vest, wrist belt, ankle belt, waist belt); provides immobilization
Side rails	Bars attached to the sides of the bed. Assist with mobility and prevents falls
Trochanter roll	Folded blanket placed under client's buttocks and rolled inward toward client to place thigh in a neutral position; used when client is supine to avoid external rotation of hips and legs
Traction	Used for immobilization and to promote healing of fractures
Trapeze bar	Triangular device hanging from above-bed bar that is secured to bed frame; used by clients with upper extremity function to assist in repositioning and transferring

Figure 34-14 The use of side rails promotes safety.

Restraints are protective devices used to limit physical activity or to immobilize a client or body part. Restraints are used for the following purposes: to protect the client from falls; to protect a body part; to prevent the client from interfering with therapies (i.e., pulling out tubes or catheters); and to reduce the risk of injury to others. See Chapter 31 for a complete discussion of restraints and the procedure for applying restraints.

Traction may be used to maintain alignment, especially following injury or surgery. There are several traction techniques, including manual, skin, and skeletal; Figure 34-15. See Table 34-14 for a listing of key assessment data for clients using skeletal and skin trac-

tion. In addition to assessing, the nurse also documents the findings.

Performing Range-of-Motion Exercises

Range-of-motion exercises are performed several times a day by placing each joint through its full functional motion. The purposes of ROM exercises are to maintain full flexibility, maintain muscle tone and strength, prevent contractures, and improve circulation. Refer to Procedure 34-3.

Transfer Techniques

Planning plays a major role in safe effective client transfers; the nurse must determine to what extent the client

NURSING TIP

ROM Exercises

- Assess the motion of joints for every client.
- Do not flex, extend, rotate, abduct, or adduct a joint if the client complains of discomfort or stiffness.
- Encourage the client to perform range-of-motion exercises with as much independence as possible.
- Teach family members or caregivers to perform range-of-motion exercises with the client.

NURSING ALERT

Restraints are never to be used for staff convenience but instead to prevent injury to clients or others.

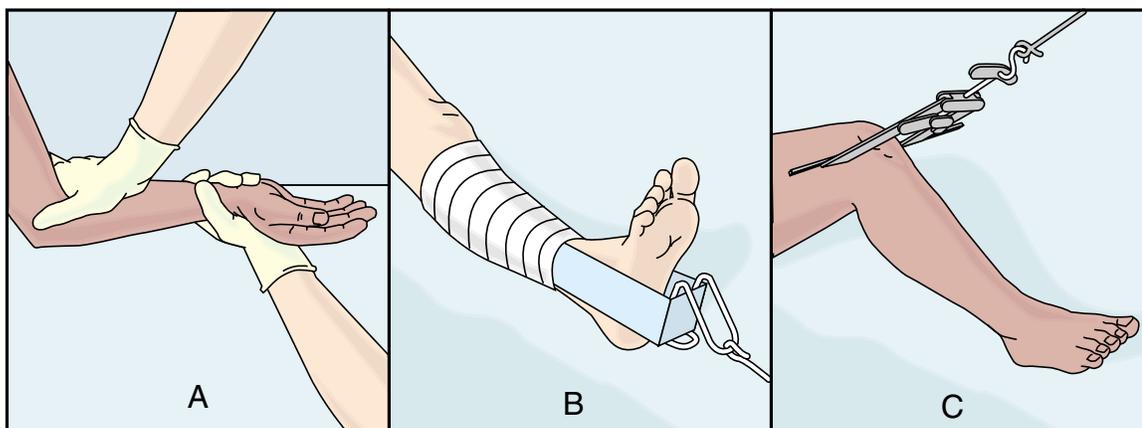

Figure 34-15 Traction Techniques: A. Manual; B. Skin; and C. Skeletal

TABLE 34-14
Skeletal and Skin Traction: Assessment Factors

Skeletal Traction	Skin Traction
Location of traction	Location of traction
Amount of traction being applied	Type of traction (e.g., cervical, Buck’s, Russell’s)
Countertraction applied	Amount of traction weight being applied to the affected body part
Body position to be maintained	Body position to be maintained
Duration of application (continuous, intermittent, or as-needed basis)	Duration of application (continuous, intermittent, or as needed basis)
Traction weights free falling	Traction weights free falling
Traction rope intact, taut, and unobstructed through the pulley	Traction rope intact, taut, and unobstructed through the pulley
Immobilized body part in alignment with rest of body	Immobilized body part in alignment with rest of body
Appearance of the skeletal pin or wire sites (e.g., dry, encrusted, reddened, edematous)	
Presence of drainage from the skeletal pin or wire sites	
Evidence of skin breakdown	

PROCEDURE 34-3

Performing Range-of-Motion (ROM) Exercises

Equipment

- Bed with side rails

Action

1. Explain the purposes of range-of-motion (ROM) exercises.
2. Elevate the bed.
3. Assist client to supine position in a warm, comfortable environment.
4. Start at head of client and perform ROM exercises down each side of the body.

Rationale

1. Reduces client anxiety and increases cooperation.
2. Decreases nurse’s muscle strain.
3. Promotes client’s comfort level.
4. Provides a systematic method to ensure that all body parts are exercised.

(continues)

PROCEDURE 34-3

Performing Range-of-Motion (ROM) Exercises (continued)

Action

- Repeat each range-of-motion exercise 5 times in a slow, firm manner.
- Cradle client's head with palms of hand while holding the extremities by the long bone areas.

Head: Rotation—Turn the head from side to side. Flexion and extension—Tilt the head toward the chest and then tilt slightly upward (Figure 34-16). Lateral flexion—Tilt the head on each side so as to almost touch the ear to the shoulder.

A.

B.

Figure 34-16 Passive ROM Exercises of Head. A. Flexion of Neck; and B. Extension of Neck

Neck: Rotation—Place the client in a sitting position and rotate the neck in a semicircle while supporting the head.

Trunk: Flexion and extension—Bend the trunk forward, straighten the trunk, and then extend slightly backward. Rotation—Turn the shoulders forward and return to normal position. Lateral flexion—Tip trunk to left side, straighten trunk, tip to right side.

Have the client resume a supine position.

Arm: Flexion and extension—Extend the arm in a straight position upward toward the head, then downward along the side. Adduction and abduction—Extend the arm in a straight position toward the midline (**adduction**) and away from the midline (**abduction**).

Shoulder: Internal and external rotation—Bend the elbow at a 90° angle with the upper arm parallel to the shoulder; rotate the shoulder by moving the lower arm upward and downward.

Elbow: Flexion and extension—Supporting the arm, flex and extend the elbow (Figure 34-17). Pronation and supination—Flex elbow, move the hand in palm-up and palm-down position.

Rationale

- Provides support to each body part, thus reducing strain on muscles and joints.

(continues)

PROCEDURE 34-3

Performing Range-of-Motion (ROM) Exercises (continued)

Action

A.

Rationale

B.

Figure 34-17 Passive ROM Exercises of Elbow. A. Flexion of Elbow; and B. Extension of Elbow

Wrist: Flexion and extension—Supporting the wrist, flex and extend the wrist. Adduction and abduction—Supporting the lower arm, turn wrist right to left, left to right, then rotate the wrist in a circular motion.

Hand: Flexion and extension—Supporting the wrist, flex and extend the fingers. Adduction and abduction—Supporting the wrist, spread fingers apart and then bring them close together. Opposition—Supporting the wrist, touch each finger with the tip of the thumb.

Thumb: Rotation—Supporting the wrist, rotate the thumb in a circular manner.

Hip and Leg: Flexion and extension—Supporting the lower leg, flex the leg toward the chest and then extend the leg (Figure 34-18). Internal and external rotation—Supporting the lower leg, angle the foot inward and outward.

Knee: Flexion and extension—Supporting the lower leg, flex and extend the knee.

Ankle: Flexion and extension—Supporting the lower leg, flex and extend the ankle.

Foot: Adduction and abduction—Supporting the ankle, spread the toes apart and then bring them close together. Flexion and extension—Supporting the ankle, extend the toes upward and then flex the toes downward.

A.

B.

Figure 34-18 Passive ROM Exercises of Hip and Leg. A. Flexion of Hip and Leg; and B. Extension of Hip and Leg

is able to help with the transfer. If the client is totally dependent or is heavy, the nurse will need other staff members to help. Table 34-15 lists potential hazards involved in client transfers with corresponding nursing interventions to promote safety.

Moving Clients

Prolonged immobility can cause discomfort, muscle wasting, clot formation, and skin breakdown. Also, the client who slides down toward the foot of the bed while the head is elevated can experience reduced lung capacity and impaired respiratory effort. Nurses often must move clients up in the bed or reposition them. Moving a client may sometimes be done by one person, but often requires two staff members to ensure safe transfer; see Procedure 34-4.

Logrolling the Client

Logrolling is a technique for moving a client whose body must remain in straight alignment. Situations requiring total alignment of the spine include spinal injury or recovery from spinal surgery. Logrolling is

TABLE 34-15
Client Transfer: Hazards and Safety Measures

Potential Hazard	Preventive Measures
Falling	<ul style="list-style-type: none"> Assess client's size and ability to assist Ask for help from other staff members if needed If client starts to fall, lower gently to the floor while protecting the head If client has fallen, assess thoroughly for signs of injury
Skin damage	<ul style="list-style-type: none"> Use a transfer board or draw sheet Lift client instead of sliding across surfaces Pad surfaces that may cause injury (e.g., bed rails)
Foot injury	<ul style="list-style-type: none"> Place nonskid slippers on client Do not tuck sheets/blankets tightly over feet Ensure that feet do not become tangled in side rails, chair legs, or other equipment
Dislodging client care equipment	<ul style="list-style-type: none"> Assess for presence of all tubes and lines (e.g., catheters, IV lines) Determine if equipment must be temporarily disconnected during the transfer Reconnect equipment promptly when transfer is completed Keep the urinary drainage bag at a level lower than the bladder

NURSING ALERT

Safety During Logrolling

For a very weak or immobile client, use extra personnel for logrolling. Two nurses should stand on each side of the client.

accomplished by two or three nurses working in a coordinated fashion; see Procedure 34-5.

Transferring from Bed to Chair

A client may need to be moved from the bed to a chair, commode, or wheelchair. Procedure 34-6 describes the steps involved in safely assisting a client from bed to chair. This procedure discusses moving a client to a wheelchair; however, the process is the same for transferring to a regular chair or bedside commode.

NURSING ALERT

Wheelchair Safety

Caution client to avoid leaning forward in the wheelchair because leaning forward can cause tipping and falling.

NURSING TIP

Wheelchair Technique

- When pushing a wheelchair, back into and out of elevators.
- Back slowly down wheelchair ramps.
- Push the wheelchair ahead of you when going up ramps.
- If going through a self-closing door, back the wheelchair out of the room. You can keep the door open by backing against the door. The wheelchair can then be guided out of the room.
- Lock brakes when the wheelchair is standing still.
- Intravenous infusion bags can be placed on portable IV poles attached to the wheelchair during transport.
- Urinary drainage bags can be placed on the lower body of the wheelchair during transport. Coil the drainage tubing so the catheter is not tugged during transport. Empty urinary drainage bag prior to wheelchair transfer. Keep the urinary drainage bag below the level of the client's urinary bladder.

PROCEDURE 34-4

Moving a Client in Bed

Equipment

■ Hospital bed with side rails

■ Turn sheet or draw sheet

*Action**Rationale*

1. Inform client of reason for the move and how to assist (if able).
2. Elevate bed to high position. Lower head of bed.
3. With two nurses, place draw sheet under client's back and head.
4. Nurses stand on each side of client. Position client with knees flexed to push with feet if able to assist with move (Figure 34-19).

1. Reduces anxiety; helps increase comprehension and cooperation; promotes client autonomy.
2. Lessens strain on nurse's back muscles.
3. Reduces shearing force, which can precipitate pressure sores.
4. Client assistance lessens strain on nurse's back muscles; promotes client autonomy.

Figure 34-19 Moving Client in Bed: Client Positioned with Knees Flexed

5. Have client use a bed trapeze, if available.
 6. The lead nurse gives the signal to move. Nurses lift up on the draw sheet. The move is coordinated to transfer the client up toward the head of the bed.
 7. Position in bed can be maintained using bed gatch, if tolerated by client.
 8. Elevate head of bed, if tolerated by client.
 9. Assess client for comfort.
 10. Lower bed and elevate side rails.
5. Lessens shearing force; decreases strain on both client and nurses.
 6. Lessens strain on client and nurses. Reduces shearing force.
 7. Elevated bed gatch maintains position by preventing client from sliding downward.
 8. Promotes comfort; facilitates eating and drinking; facilitates communication.
 9. Comfort is subjective.
 10. Promotes client safety.

PROCEDURE 34-5

Logrolling a Client

Equipment

- Hospital bed with side rails
- Pillows
- Turn sheet or draw sheet

Action

1. Inform client of reason for the move and how to assist (if able).
2. Elevate hospital bed to high position.
3. Using one or more staff members, place a turn/draw sheet under the client's back and head.
4. The lead nurse tells the client and other personnel the direction of the move.
5. One person stands on each side of bed. The lead nurse gives the signal for the move. The staff member on side of the bed in the direction of the move holds the turn/draw sheet to guide the move. The second staff member applies gentle pressure on client's back toward the direction of the move, assisting client to roll (Figure 34-20).

Figure 34-20 Logrolling: Two-Person Move

Rationale

- | | |
|---|--|
| <ol style="list-style-type: none"> 6. Tuck pillows at client's back and abdomen. 7. Assess the client for comfort and proper alignment. 8. Elevate side rails and lower the bed height. 9. This procedure can be reversed to reposition clients on their backs. | <ol style="list-style-type: none"> 1. Reduces anxiety; helps increase comprehension and cooperation; promotes client autonomy. 2. Avoids strain on nurse's back muscles. 3. Reduces shearing force, which can precipitate pressure ulcer formation. 4. Cooperation and coordination place less strain on client and personnel. 5. Two persons give more support to client than one person could and are better able to maintain proper alignment of client's spine and neck. 6. Maintains side-lying position. 7. Comfort is subjective. 8. Promotes client safety. 9. Repositioning can prevent development of pressure sores and promote circulation. |
|---|--|

A wheelchair is a means of transportation for clients unable to support their weight while standing; see Figure 34-21. Safety instructions for use of a wheelchair include the need to keep the wheels locked when not deliberately moving and to move the footrests out of the way when getting in and out of the wheelchair; see the previous Nursing Tip for other recommendations for wheelchair usage.

Transferring from Bed to Stretcher

Some clients (e.g., those who are too weak to sit upright, those who are unconscious, or those with injuries prohibiting the erect position) must lie flat during transfers. In such situations, a stretcher (gurney) is used to facilitate client transfer. Stretchers have several safety features, including side rails, safety belts/straps, and locking wheels. The nurse should caution clients to move carefully while on the stretcher as it is more narrow than the bed. Reassure the client that side rails will be used to prevent falls. Refer to Procedures 34-7 and 34-8 for instructions on moving clients who need minimal and maximal assistance.

Figure 34-21 Client education regarding wheelchair safety includes client and family.

PROCEDURE 34-6

Transferring a Client from Bed to Chair

Equipment

Bed

Action

1. Inform client about desired purpose and destination.
2. Assess client's ability to assist with the transfer and for presence of cognitive or sensory deficits.
3. Lower the bed.
4. Allow client to dangle for a few minutes.
5. Bring wheelchair close to the side of the bed, toward the foot of the bed.
6. Lock wheelchair brakes and elevate the foot pedals.
7. Assist client to side of bed until feet touch the floor.
8. Assess client for dizziness. Remain in front of client until dizziness has subsided.

Wheelchair

Rationale

1. Reduces client anxiety and increases cooperation.
2. Promotes safety.
3. Reduces distance client has to step down, thus decreasing risk of injury.
4. Allows time for assessing client's response to sitting; reduces possibility of orthostatic hypotension.
5. Minimizes transfer distance.
6. Provides stability.
7. Provides guidance and helps client maintain balance.
8. Reduces risk of falling.

(continues)

PROCEDURE 34-6

Transferring a Client from Bed to Chair (continued)

Action

9. Apply gait belt if necessary.
10. Reach under client's axillae and place hands on client's scapulae (or grasp gait belt).
11. Assist the client to a standing position and provide support.
12. Pivot client so client's back is toward the wheelchair (Figure 34-22).

Figure 34-22 Pivot client so back is toward wheelchair.

13. Instruct client to place hands on the arm supports of the wheelchair.
14. Bend at the knees, easing the client into a sitting position (Figure 34-23).

Figure 34-23 Ease client into wheelchair.

15. Assist client to maintain proper posture.
16. Secure the safety belt, place client's feet on feet pedals, and release brakes.

Rationale

9. Reduces risk of falling by maintaining client stability during transfer.
10. Maintains client stability and reduces pressure on axillae.
11. Helps client stand safely and gives time to assess status.
12. Moves client into proper position to be seated.

13. Allows client to gain balance and judge distance to seat.
14. Increases stability and minimizes strain on back.

15. Broadest, and therefore safest, base of support is with client seated as far back on the seat as possible.
16. Ensures client safety; prepares client for movement.

PROCEDURE 34-7

Transferring a Client from Bed to Stretcher with Minimum Assistance

Equipment

■ Bed

■ Stretcher

Action

1. Inform client about desired purpose and destination.
2. Raise the height of bed and lock brakes of bed.
3. Instruct client to move to side of bed close to stretcher. Have client use trapeze bar if available. Lower side rails of bed and stretcher.
4. Stand at outer side of stretcher and push it toward bed. Lock wheels of stretcher.
5. Instruct client to move onto stretcher with assistance as needed.
6. Cover client with sheet or bath blanket.
7. Elevate side rails on stretcher and secure safety belts about client. Release brakes of stretcher.
8. Stand at head of stretcher to guide it when pushing.

Rationale

1. Reduces client anxiety and increases cooperation.
2. Reduces distance nurse must bend, thus preventing back strain; prevents bed from moving.
3. Decreases risk of client falling.
4. Diminishes the gap between bed and stretcher; secures the stretcher position.
5. Promotes client independence.
6. Promotes comfort; protects privacy.
7. Prevents falls.
8. Pushing, not pulling, ensures proper body mechanics.

PROCEDURE 34-8

Transferring a Client from Bed to Stretcher with Maximum Assistance

Equipment

■ Bed

■ Stretcher

■ Pillows

■ Lift sheet

Action

1. Inform client about desired purpose and destination.
2. Elevate height of bed.
3. Assess amount of assistance required for transfer. Usually two to four staff members are required for the maximum assisted transfer.
4. Lock wheels of bed and stretcher (Figure 34-24).
5. Have one nurse stand close to client's head.
6. Logroll the client (see Procedure 34-5) and place a lift sheet under the client's back, trunk,

Rationale

1. Reduces client anxiety and increases cooperation.
2. Decreases amount of bending for nurse, thus reducing risk of back injury.
3. Promotes client independence; assures that enough staff are present before beginning transfer.
4. Prevents falls.
5. Supports client's head during the move.
6. Prevents flexion and rotation of client's hips and spine; maintains correct body alignment.

(continues)

PROCEDURE 34-8

Transferring a Client from Bed to Stretcher with Maximum Assistance (continued)

Action

Figure 34-24 Lock wheels on the stretcher.

and upper legs. The lift sheet can extend under the head if client lacks head control abilities.

7. If urinary drainage bag is present, empty it and move it to side of bed closest to stretcher.
8. Move client to edge of bed near stretcher.
9. Nurse on nonstretcher side of bed holds the lift sheet across the client's chest (Figure 34-25).

Figure 34-25 Transferring Client with Maximum Assistance: Grasping Lift Sheet

10. Place pillow overlapping the bed and stretcher.
11. Position client on stretcher and cover with a sheet or bath blanket (Figure 34-26).
12. Secure safety belts and elevate side rails of stretcher.
13. If IV pole is present, move it from bed IV pole to stretcher IV pole after client transfer.
14. Empty all drainage bags (e.g., T-tube, Hemovac, Jackson-Pratt). Secure drainage system to client's gown prior to transfer.

Rationale

7. Prevents risk of urinary infection.
8. Prevents dragging, which causes shearing force.
9. Protects the client from falling.

Figure 34-26 Transferring Client with Maximum Assistance: Moving Client from Bed to the Stretcher

10. Protects head from injury.
11. Promotes comfort and provides for privacy.
12. Prevents falls.
13. Prevents tubing from being pulled and IV from being dislodged.
14. Decreases possibility of spills; prevents dislodging of tubes.

NURSING TIP

Stretcher Transport Safety

- Use hall ceiling mirrors at intersections before turning corners.
- Lock elevator door open when entering or exiting.
- Stand at head of stretcher to push stretcher up a ramp.
- Back down a steep ramp while positioned at head of stretcher.
- Lock stretcher brakes when standing still.

NURSING ALERT

Transfers and Closed Chest Drainage System

The closed chest drainage system must remain vertical at all times, including during transfers, to maintain the water seal.

Assistive Devices

There are several devices available for helping with client transfers. Slide boards or transfer boards assist the bed-wheelchair transfer by bridging the same level space between the bed and the wheelchair. Note that specialized wheelchairs with removable armrests are used with

slide boards. As the client becomes more independent, the slide board can be used to transfer from wheelchair to car. Figure 34-27 shows a slide board transfer to a car.

Other transfer appliances include stretchers (gurneys) and hydraulic lifts. The hydraulic (Hoyer, mechanical) lift is used for moving immobile clients who are obese; see Procedure 34-9. A client may be transferred to a chair, wheelchair, bedside commode, stretcher, or scale using a hydraulic lift. The manufacturer's equipment instructions should be followed and the weight limits must not exceed the manufacturer's specifications. Two staff members are needed to safely operate a hydraulic lift. Hydraulic lifts are not for use with clients who have spinal cord injury as spinal alignment is not maintained during use of the lift.

Figure 34-27 Slide Board Transfer

PROCEDURE 34-9

Using a Hydraulic (Mechanical) Lift

Equipment

- Hydraulic lift with canvas sheet and bars
- Gloves (when applicable)

- Protective disposable cover or disinfectant

Action

1. Wash hands.
2. Check the written order to determine the length of time the client may sit.
3. Check the client's health status, including medical diagnosis and condition.
4. Ask the client how long ago he last sat.

Rationale

1. Reduces transmission of organisms.
2. The physician or other qualified practitioner may want the client to sit only for a specified time or for as long as possible.
3. Assists in determining any problems that sitting may cause or any necessary restrictions.
4. If the client has been bedridden for several days, dizziness or faintness may occur.

(continues)

PROCEDURE 34-9

Using a Hydraulic (Mechanical) Lift (continued)

Action

5. Lock the wheels of the bed.
6. Position the chair close to the bed.
7. Position all tubing (i.e., urine drainage, NG, and IV) on the side of the bed where the chair will be placed. Ensure slack in the tubing.
8. Clamp and disconnect any tubing permitted.
9. Roll the client onto side and position the sling on the bed behind the client (Figure 34-28).

Figure 34-28 Adjust the sling so it is smooth and flat under the client.

10. Roll the client onto his opposite side, pull the sling through, and position the sling smoothly on the bed.
11. Roll the client back onto the sling and fold his arms over his chest (Figure 34-29).

Figure 34-29 Roll the client back onto the sling. Position the client's arms across his chest.

Rationale

5. Prevents the bed from rolling when the client is moved.
6. Always transfer the client the shortest possible distance to minimize fatigue and possibility of injury.
7. Prevents the tubing from being dislodged.
8. NG suction tubing and tube-feeding tubing are often allowed to be clamped. This facilitates moving the client.
9. The sling is positioned behind the client to ease turning to the opposite direction so that the sling can be pulled through.

10. Prevents skin breakdown.
11. Protects client's arms during the transfer.

(continues)

PROCEDURE 34-9

Using a Hydraulic (Mechanical) Lift (continued)

Action

12. Make sure the sling is centered.
13. Lower the side rail and position the lift on the side of the bed with the chair. Be sure to spread the base of the hydraulic lift as indicated in manufacturer's instructions to provide stability (Figure 34-30). Protect client from falls while the side rail is down.

Figure 34-30 Spread the base of the hydraulic lift to provide stability.

14. Lift the frame and pass it over the client. Carefully lower the frame and attach the hooks to the sling (Figures 34-31 and 34-32).

Figure 34-31 Locate the correct hook for each corner of the sling.

Rationale

12. Evenly distributes the clients' weight.
13. The side rail must be down to use the lift. Always transfer the client the shortest possible distance. The wheels and base of the lift should be spread to provide a wide, stable base to prevent the lift from tipping.

14. Safely attaches sling to frame to facilitate safe transfer.

Figure 34-32 Attach the hooks to the sling.

(continues)

PROCEDURE 34-9

Using a Hydraulic (Mechanical) Lift (continued)

Action	Rationale
15. Raise the client from the bed by pumping the lift's handle.	15. Read the manufacturer's directions to determine the mechanism for raising the lift. Various models do not operate in the same way.
16. Secure the client with a safety belt and cover the client with a blanket.	16. Provides safety, comfort, and privacy.
17. Steer the client away from the bed and slide a chair through the base of the lift.	17. It is safer to slide the chair through the base than to slide the base around the chair.
18. The sling can be disconnected and the lift can be moved out of the way while the client is sitting in the chair. If the lift will be used to return the client to bed, leave the sling in place beneath the client.	18. Promotes comfort.
19. Reposition, reconnect, and unclamp any necessary tubing.	19. Tubing should not be left disconnected. The client may sit for a while and will need all the equipment to function properly.
20. Assess the client's tolerance of the move, determining whether dizziness was experienced.	20. The data are necessary for charting/reporting presence of any problems.
21. Place call light, appropriate covers, and padding as needed for comfort and position maintenance. Place protective restraints as needed. Cover feet with slippers/socks if in sitting position.	21. Ensures privacy, protection, and comfort.
22. Reverse the procedure to return the client to the bed.	22. Transfers client safely and comfortably.
23. Wash hands.	23. Reduces transmission of organisms.

(From G. B. Altman, [2000]. Using a hydraulic lift. In G. B. Altman, P. Buchsel, & V. Coxon. [Eds.], *Delmar's fundamental and advanced nursing skills*. Albany, NY: Delmar Thomson Learning.)

Assisting with Ambulation

Client **ambulation** (assisted or unassisted walking) is encouraged soon after the onset of illness or surgery to prevent the complications of immobility. In planning ambulation, the nurse assesses the client's strength, endurance, and mobility status. Can the client walk alone, or is assistance needed? The presence of equipment (e.g., urinary catheters, IV infusions, drainage tubes) requires assistance; see the Nursing Checklist.

In order to maintain client safety, ambulation must occur in progressive stages. First the client should be able to tolerate sitting on the bedside and dangling the feet. The next step is client tolerance of standing at the side of the bed. Then progressive ambulation can be initiated; see Procedure 34-10.

As ambulation activities are initiated, it is important to assess the client's blood pressure, respiratory rate, pulse, skin color and moisture, and subjective responses. While the client is walking, observe for signs

NURSING CHECKLIST

Assisting with Client Ambulation

- Determine the client's activity level and tolerance for physical exertion.
- Assess for factors that may negatively affect ambulation (e.g., mental status, fatigue, pain, medications).
- Evaluate the environment for safety (e.g., presence of obstacles in walkway, adequate lighting, nonslip floor, handrails; see Figure 34-33).
- Check assistive devices for safety hazards.
- Check client's clothing (e.g., nonslip shoes, adequate covering for privacy and warmth).
- During ambulation, assess client's tolerance of activity.
- Postambulation, assess client's recovery from the activity.

Figure 34-33 The use of handrails promotes safety and independence in ambulating.

of exertion, including diaphoresis, shortness of breath, or weakness. It is also important to assess for the presence of orthostatic hypotension in order to prevent falls. Depending on the client's physical conditioning and the effects of orthostatic hypotension, the client may need to slowly progress to independent ambulation. Once the activity is completed, the nurse evaluates the client evaluation focusing on progression of activity. Continuous evaluation of the client's strength and endurance is performed by the nurse.

Preparing the Client to Walk

One of the best ways to encourage ambulation is to help the client become and remain as independent as possible while lying in bed. This includes urging clients to participate in ROM exercises and perform self-care activities as much as possible.

Independent mobility, the goal of most clients, is the ability to walk, run, sit, and turn without mechanical or personal aid. Progressive exercises and activities that promote independent mobility include:

1. *Turning.* The client can turn in bed using side rails for stabilization and leverage.
2. *Sitting.* The client can raise the head of the bed and lower the height of the bed. Then the client turns to

PROCEDURE 34-10

Assisting a Client with Ambulation

Equipment

None required

Action

1. Inform client of the purposes and distance of the walking exercise.
2. Elevate the head of the bed and wait several minutes.
3. Lower the bed height.
4. With one arm under the client's back and one arm under the client's upper legs, move the client into the dangling position (Figure 34-34).
5. Encourage client to dangle at side of bed for several minutes.
6. Stand in front of client with your knees touching client's knees.
7. Place arms under client's axillae (Figure 34-35).
8. Assist client to a standing position, allowing client time to balance.

Rationale

1. Reduces client anxiety and increases cooperation.
2. Prevents orthostatic hypotension.
3. Reduces distance client has to step down, thus decreasing risk of injury.
4. Provides client support and reduces risk of fall.
5. Prevents orthostatic hypotension. Allows for assessing tolerance for the sitting position.
6. Prevents client from sliding forward if dizziness or faintness occurs.
7. Supports client's trunk.
8. Reduces risk of fall.

(continues)

PROCEDURE 34-10

Assisting a Client with Ambulation (continued)

Action

A.

Rationale

B.

Figure 34-34 Assist the client from a supine to a seated position. A. Place one arm under the client's back and one arm under the client's legs. B. Help the client move into the dangling position.

Figure 34-35 Assist client to a standing position by supporting the client's trunk with your arms under the client's axillae.

Figure 34-36 Assisting a Client with Ambulation

9. Help client ambulate desired distance or distance of tolerance by placing your hand under the client's forearm and ambulating close to the client (Figure 34-36).

9. Provides assistance in achieving ambulatory goals.

the side of the bed and swings legs over the side of the bed to assume the dangling position. Arms held in the tripod position give balance to the sitting position.

3. *Standing.* The client dangles for a few minutes to assure balance and then bears weight with both feet at the side of the bed. For additional stability and balance, the client can perch on the edge of the bed for several minutes.
4. *Walking.* The client assesses strength and balance while walking, thus allowing a gradual progression of

the duration of walking. Instruct clients to rest by sitting or standing still stabilized with a guide rail if fatigued.

Client Education

Prior to ambulation, clients who have been immobile need to be prepared adequately in order to prevent injury. Listing the therapeutic outcomes of ambulation is one way to teach clients the importance of ambulation. Clients should also be taught to sit down or use side rails if dizziness occurs.

Teach clients the technique for safe falling in order to minimize risk of injury; see Figure 34-37. Clients should be told that if they begin to feel faint they should fall toward the affected side of the body and to use the unaffected side to raise self from the floor or chair.

Preambulatory Exercise

Helping immobile clients to prepare for ambulation includes instruction of preambulatory exercises in order to strengthen and tone muscles. The quadriceps femoris is the major muscle used for walking, thus, clients should be directed to gently contract and release the leg muscles several times a day. Clients who will be walking with the assistance of walkers and crutches need upper body strength. Instruction in the safe use of ambulatory assistive devices is also necessary for many clients with impaired mobility.

Assistive Devices

Clients who are unable to ambulate independently can use devices designed to help them walk safely. Determination of which device to use is based on the following:

- Upper arm strength
- Endurance (stamina)
- Presence or absence of one-sided weakness
- Weight-bearing ability; see Table 34-16

See Table 34-17 for a comparison of the three most common devices used to assist in walking: canes, walkers, and crutches.

Figure 34-37 Support for Fainting Client

TABLE 34-16
Weight-bearing Status

Degree of Weight Bearing	Description
Non-weight bearing	Patient does not bear weight on the affected extremity. The affected extremity does not touch the floor.
Touchdown weight bearing	Patient's foot of the affected extremity may rest on the floor, but no weight is distributed through that extremity.
Partial weight bearing	Patient bears 30%–50% of his or her weight on the affected extremity.
Weight bearing as tolerated	Patient bears as much weight as can be tolerated on the affected extremity without undue strain or pain.
Full weight bearing	Patient bears weight fully on the affected extremity.

(Reprinted with permission from Maher, A. [1994]. *Orthopedic nursing*. Philadelphia: Saunders)

Canes

A cane is to be used by clients who can bear weight on both legs but have some weakness in one leg or hip. The straight (standard) cane is used most often; canes with three or four legs are used with clients who need more stability than provided by the straight cane. Quad canes provide more stability but are sometimes more awkward to use than the straight cane; see Figure 34-38.

NURSING ALERT

To promote safe ambulation using a cane, be sure that:

- the cane is appropriate for the client's height and that the cane has suction grips to prevent falls
- client is wearing flat shoes with nonskid soles

Walkers

A walker is a waist-high metal tubular device with a handgrip and four legs. Some walkers have rubber tips on all four legs, whereas others have wheels on the two front legs. The advantages of using a walker include provision of extra support, provision of a sense of security, and independence. The client first moves the walker forward and then takes a step while balancing his or her weight on the walker.

TABLE 34-17
Assistive Devices for Ambulation

Equipment Description		Directions for Use
Cane	<p>Widens base of support</p> <p>Various styles:</p> <p>(1) Regular (straight)—gives minimal support for balance</p> <p>(2) Three-point—provides broader base of support; more cumbersome</p> <p>(3) Four-point (quad)—broader base of support; more cumbersome</p>	<p>Use on unaffected side</p> <p>Advance cane simultaneously with affected limb</p> <p>Hold close to body; do not move cane forward beyond toes of affected foot</p>
Walker	<p>Provides more stability than canes due to broader base of support</p> <p>Various styles:</p> <p>(1) Pickup—assists with weight bearing; lifting may cause some strain for client</p> <p>(2) Rolling—pushed on wheels thus reduces physical strain on client</p>	<p>For clients with weight-bearing status: Advance walker and step normally</p> <p>For partial or non-weight bearing on one limb: Thrust weight forward, then lift walker and replace all four legs on floor</p>
Crutches	<p>Less stable than canes and walkers</p> <p>Requires upper body strength and ability to maintain balance</p>	<p>Use good posture</p> <p>Maintain proper foot position on affected side (footdrop can result from walking on toes or ball of foot)</p> <p>Eliminate obstacles in ambulatory path</p>

(Data adapted from Eliopoulos, C. [1999]. *Manual of gerontologic nursing* [2nd ed. pp. 286–287]. St. Louis, MO: Mosby.)

Figure 34-38 Nurse promotes safety of a client using a quad cane. Note the use of gait belt for added stability.

A walker is used by clients who need more support than that provided by a cane. Walkers are available with and without wheels. The walker without wheels provides more stability but also requires more client stamina in order to lift the walker. Walkers with wheels are intended for use by clients with limited upper body strength. The nurse should determine the following for clients using walkers:

1. Amount of weight bearing allowed on lower limb
2. Appropriateness for client's height
3. Type of walker (pick-up or rolling)
4. With pick-up walker: client's ability to grip, lift, and propel the walker forward
5. With rolling walker: client's ability to grip and propel the walker forward

When educating clients about the use of walkers, inform them when transferring from chair or commode they should back the walker to the toilet seat and use arms of chair or commode to assist in standing. Teach clients to always use both hands when using a walker to transfer from standing to sitting; see Figure 34-39.

Crutches

A crutch is a wooden or metal staff used to increase client mobility. There are two types of crutches: axillary and forearm. The most commonly used type, the axillary crutch, fits under the axilla with the weight being placed on the handgrips. The forearm crutch, which

Figure 34-39 Client Using a Walker

has a handgrip and a metal cuff that fits around the arm, is more convenient but provides less stability than the axillary crutch.

To prevent slipping, crutches have rubber tips, which must be kept dry. If the tips are worn or loose, they must be replaced. The crutch must be regularly inspected; if cracks or bends are present, the person's weight will not be properly supported.

Crutches can be used by clients who are unable to bear any weight on one leg, clients who can bear partial weight on one leg, as well as clients who have full weight bearing on both legs.

Several gaits are used with crutches: the four-point gait, three-point gait, two-point gait, and swing-through gait.

The *four-point gait* for weight bearing with both legs follows the pattern of right crutch forward, left foot forward, left crutch forward, then right foot forward. The four-point gait with crutches is very stable but slow. The *two-point gait* for weight bearing with both legs has the pattern of right crutch and left foot forward together, then left crutch and right foot forward together. The two-point gait requires more balance but is a faster gait. The *three-point gait* for weight bearing with one leg has the pattern of crutches and weak leg forward together, then weight-bearing leg forward. The *swing-through gait* has the pattern of crutches forward, then legs swing forward together. The swing-through gait has the advantage of speed; however, it requires good balance. See Procedure 34-11 for a description of crutch-walking techniques.

CLIENT TEACHING CHECKLIST

Crutch Walking

Climbing Stairs

This method of climbing stairs provides a broad base of support and stability for the weaker leg:

- Climb stairs using the stronger leg first.
- Bring the crutches to the level of the stronger leg.
- Bring the weaker leg to the level of the crutches and the stronger leg.
- Repeat to climb stairs. *This requires time, balance, and strength.*

Descending Stairs

This method of descending stairs provides a broad base of support and stability for the weaker leg:

- Support the body with the stronger leg.
- Move the crutches down to the first descending step.
- Move the stronger leg to the first descending step.
- Repeat to descend the staircase. *This requires time, balance, and strength.*

Sitting in a Chair

The client has greater stability using the stronger leg and chair arm for support:

- Stand in front of a chair.
- Hold the crutches on the side with the weaker leg.
- Grasp the chair arm using the arm on the side of the stronger leg.
- Flex knees and hips to sit in chair.
- Reposition self in chair using arms and stronger leg while sitting.

Rising from the Chair

The client has greater strength using the stronger leg to rise. More stability is provided by the chair arm and crutches for support. Rising requires more strength than sitting:

- Move forward in chair, placing strongest leg on the floor.
- Grasp the chair arm on the same side of the stronger leg.
- Hold the crutches with the hand on the side of the weaker leg.
- Use the chair arm and crutches for support while rising.
- Once standing, place the crutches in the position for ambulation.
- Weak clients may need assistance. The gait belt is useful in such situations.

PROCEDURE 34-11

Assisting a Client with Crutch Walking

Equipment

- One pair of crutches
- Gait belt (optional)

- Measuring tape

Action

1. Inform client that you will be assisting with ambulation using crutches.
2. Assess client for strength, mobility, range of motion, visual acuity, perceptual difficulties, and balance.
3. Adjust crutches to fit the client. With the client supine, measure from the heel to the axilla. With the client standing, set the crutch position at a point 4 to 5 in. lateral to the client and 4 to 6 in. in front of the client. The crutch pad should fit 1.5 to 2 in. below the axilla (Figure 34-40). The hand grip should be adjusted to allow for the client to have elbows bent at 30° flexion.

Rationale

1. Reduces anxiety; helps increase comprehension and cooperation; promotes client autonomy.
2. Helps determine the capabilities of client and amount of assistance required.
3. Provides broad base of support for client. Space between the crutch pad and the axilla prevents pressure on radial nerves. The elbow flexion allows for space between the crutch pad and axilla.

Figure 34-40 Adjusting Crutches to Fit Client

4. Lower the height of the bed.
 5. Dangle the client at the side of bed for several minutes. Assess for vertigo.
 6. Instruct client on method to hold the crutches; that is, with elbows bent 30° and pad 1.5 to 2 in. below the axilla. Instruct client to position crutches lateral to and forward of feet. Demonstrate correct positioning.
 7. Apply the gait belt around the client's waist if balance and stability are impaired.
4. Allows client to sit with feet on floor for stability.
 5. Allows for stabilization of blood pressure, thus preventing orthostatic hypotension.
 6. Increase client comprehension and cooperation.
 7. Provides support; promotes client safety.

(continues)

PROCEDURE 34-11

Assisting a Client with Crutch Walking (continued)

Action

8. Assist the client to a standing position with crutches. Support as needed.

Four-Point Gait

9. Position the crutches 4.5 to 6 in. to the side and in front of each foot. Move the right crutch forward 4 to 6 in. and move the left foot forward, even with the left crutch (Figure 34-41A). Move the left crutch forward 4 to 6 in. and move the right foot forward, even with the right crutch (Figure 34-41B). Repeat the four-point gait.

A.

B.

Figure 34-41 Four-Point Gait. A. Moving Right Crutch Forward and Left Foot Forward; and B. Moving Left Crutch Forward and Right Foot Forward, Even with Right Crutch

Rationale

8. Standing for a few minutes will assist in preventing orthostatic hypotension.
9. The four-point gait (used for partial or full weight bearing) provides greater stability. Weight bearing is on three points (two crutches and one foot or two feet and one crutch) at all times. The client must be able to bear weight with both legs.

Three-Point Gait

10. Advance both crutches and the weaker leg forward together 4 to 6 in. (Figure 34-42). Move the stronger leg forward, even with the crutches. Repeat the three-point gait.
10. The three-point gait (used for partial or non-weight bearing) provides a strong base of support. This gait can be used if the client has a weak or non-weight-bearing leg.

Figure 34-42 Crutch Walking: Three-Point Gait, Advancing Both Crutches and Weaker Leg Forward Together

(continues)

PROCEDURE 34-11

Assisting a Client with Crutch Walking (continued)

*Rationale***Two-Point Gait**

11. Move the left crutch and right leg forward 4 to 6 in. Move the right crutch and left leg forward 4 to 6 in. Repeat the two-point gait.

Swing-Through Gait

12. Move both crutches forward together 4 to 6 in. Move both legs forward together in a swinging motion, even with the crutches (Figure 34-43). Repeat the swing-through gait.

Figure 34-43 Crutch Walking: Swing-Through Gait

13. Set realistic goals and opportunities for progressive ambulation using crutches.
14. Consult with a physical therapist for clients learning to walk with crutches.

Rationale

11. The two-point gait (used for partial weight bearing) provides a strong base of support. The client must be able to bear weight on both legs. This gait is faster than the four-point gait.
12. The swing-through gait permits a faster pace. This gait requires weight bearing on both legs, greater balance, and more strength.

13. Crutch walking takes up to 10 times the energy required for unassisted ambulation.
14. The physical therapist is the expert on the health care team for crutch-walking techniques.

Wellness Promotion

Wellness promotion emphasizes the need for physical fitness, which increases well-being, increases sympathetic nervous system activity, improves cardiovascular functioning, and produces and maintains weight loss. “Increasing physical activity is beneficial for all ages and all groups” (Bray, 1998, p. 238). The nurse should identify activities enjoyed by the client and encourage increased participation. When planning an exercise program, the following elements should be considered:

- Health status (existing medical conditions)
- Physical condition
- Age
- Preferences for types of activities

NURSING ALERT

Exercise and Climate

Caution clients to consider the climate when exercising and replenish fluids accordingly.

Complementary Treatment Modalities

There are numerous complementary modalities that help improve musculoskeletal health; see the accompanying display. Also, physical activity and relaxation exercises help reduce muscular tension and improve functional abilities.

COMPLEMENTARY/ALTERNATIVE THERAPY

- The herb *Ginkgo biloba* may be used to promote circulation (Eliopoulous, 1999).
- Yoga increases circulation as a result of postural changes on the endocrine glands and nerve plexus (Eliopoulous, 1999).
- Acupuncture is a traditional Chinese medicine (TCM) method of pain relief in which a qualified practitioner inserts needles in certain body sites to promote the release of endorphins, (i.e., natural painkillers, National Institutes of Arthritis and Musculoskeletal and Skin Diseases, 1997).
- Acupressure is a technique similar to acupuncture; pressure instead of needles is applied to the acupuncture sites to relieve pain.
- Massage protects skin integrity by promoting circulation.
- Moist heat (warm towels, hot packs, bath/shower) promotes circulation.
- Cold (ice bag) helps reduce swelling.
- Transcutaneous electrical nerve stimulation (TENS) is used to decrease pain.
- Biofeedback is used to help clients decrease muscular tension.

EVALUATION

Family support for a client with activity or mobility deficits is a delicate balance between independence and dependence that is necessary for positive self-esteem and confidence. This healthy balance can be influenced by the client's family and friends. Healthy balance is fostered through support of the client as requested and needed, and through encouragement and positive acceptance and affection.

Family members are often unaware of the client's potential to improve. Thus, they give unnecessary assistance in activities and mobility rather than allow the client to function independently. The client then becomes resentful because there is a loss of self-control. Resentment can also occur with the family who has accepted the heavy responsibilities of caregiving.

For the client who overestimates his or her own cognitive and physical capabilities and energy level, safety becomes an important issue.

Actual long-term activity and mobility are the foci of evaluation as the client transfers skills and knowledge from the acute-care hospital or rehabilitation facility to home. Common areas of concern regarding activity include:

- Mobility status
- Activities of daily living capacity
- Use of appropriate adaptive devices

Title of Study

"Clinical Decision-Making Process in Perioperative Nursing"

Authors

Davis, G. C., and White, T. L.

Purpose

To develop and test an osteoporosis education program for older adults. The project was conducted to provide direction for developing a model program.

Methods

The study was conducted using a convenience sample of adults aged 65 and older living in a group residential setting. The pilot Osteoporosis Education Program (OEP) was advertised with mailed and posted flyers. A total of 26 residents participated in at least one session. The participants were tested for general knowledge of osteoporosis at the beginning of the program and at the end of the fourth session.

Findings

The OEP evaluation study suggests the use of the following in planning education for older adults:

- Sessions not to exceed 1 hour
- A minimum of four program sessions
- Use of prepared educational materials
- Use of an experiential activity (game) to reinforce learning
- Meeting time that does not conflict with other planned activities
- An informal teaching-learning environment

Implications

The pilot study provided direction for developing both the program format and content. The participant's interest in the program indicated that this type of intervention could be useful to help older adults, who are at greatest risk for osteoporosis, to adopt self-care behaviors. Such behaviors may help decrease the risk of fractures and help maintain the greatest possible level of independence.

Davis, G. C., & White, T. L. (2000). Planning an osteoporosis education program for older adults in a residential setting. *Journal of Gerontological Nursing*, 26(1), 16–23.

- Expansion of client activities
- Use of activities as a basis for building areas of competence and achievement

NURSING CARE PLAN**The Client with a Fractured Leg****Case Presentation**

Magda Constantin is a 15-year-old high school student who is recovering from a closed fracture of her right tibia suffered in a soccer game. She states that she is having trouble using crutches and getting around school, especially up and down the stairs. She is unhappy about not being able to play soccer and states, “People stare at me when I walk down the hall.”

Assessment

- Difficulty ambulating due to cast and crutches
- Verbalizations of discomfort about altered mobility and body image

Nursing Diagnoses

Impaired physical mobility related to inability to use legs normally and difficulty using crutches.

Disturbed body image related to change in lifestyle and appearance and fear of rejection by others.

Expected Outcomes

Client will:

1. Understand and demonstrate proper crutch technique.
2. Verbalize a more positive self-image and acceptance of her temporary condition.

Interventions/Rationales

1. Measure crutch height and fit for client. *Determines proper fit, which will relieve pressure, if any, and facilitate ambulation.*
2. Watch client as she walks across the room using the crutches. *Provides baseline assessment of crutch-walking skills.*
3. Demonstrate correct mechanics of crutch walking using three-point gait. *Allows for partial or non-weight-bearing ambulation.*
4. Ask client to return demonstrate crutch-walking technique. *Demonstrates client’s understanding and ability to execute technique.*
5. Suggest ways that crutch walking can be facilitated, such as wearing soft-soled flat shoes, carrying a backpack strapped over both shoulders, wearing nonbulky shirts to minimize clothing under arms, and taking frequent rest stops while walking. *Tips on facilitating crutch gait will remove barriers to effective walking and increase client comfort and confidence in technique.*
6. Help client understand that cast and crutches are a temporary measure to promote proper healing and are not a reflection of overall body health. *Client should learn to view situation as temporary and keep in mind that the broken leg is only one part of the whole person and need not detract from other positive qualities.*

Evaluation

Magda successfully demonstrates correct crutch-walking technique and decides to purchase a backpack to replace her shoulder bag. She is still somewhat shy about “people staring at me” but seems to be starting to accept the fact that the cast and crutches are temporary. She even jokes that “maybe this is an easy way to get noticed at school.”

Measures of physical assessment, functional assessment, and performance of ADLs are used for follow-up evaluation of the client’s status for activity and mobility. Ongoing assessment of the client’s activity and mobility is important because compliance with home exercise

programs may lessen over time after discharge. When evaluating long-term activity and mobility goal achievement, the nurse should observe the client in the home setting to note the client’s ability to function within his or her own environment.

KEY CONCEPTS

- The nurse must assess the client on an ongoing basis for activity and mobility during acute hospitalization, rehabilitation, and postdischarge.
- Collaboration between client, family, and members of the interdisciplinary health care team is essential for establishing and modifying goals for activity and mobility.
- Nursing interventions are individualized to maximize activity, mobility, and independence for the client and family.
- The nurse should be aware of the home environment and lifestyle of the client.
- Continuity of care among nurses and the interdisciplinary health care team is facilitated.
- The family or caregivers should be included in educational sessions regarding activity and mobility. Practice sessions of activities and mobility by client, family, and caregivers under the direction of the nurse are essential.
- The need for adaptive equipment should be assessed and acquisition of equipment facilitated.
- The client, family, and caregiver should be provided instructions in many forms: demonstrations, videos, pamphlets, handouts.
- The client and family should be informed of community resources to maximize activity, mobility, and independence.
- The nurse should be available to assist the client with problem solving after discharge.

CRITICAL THINKING ACTIVITIES

1. What factors would help the client ambulate independently 20 feet with the use of a walker within 2 days? What factors would hinder the client?
2. Think about persons of various age groups functioning normally in activities. Note the difference in the stages of growth and development.
3. Assess clients of various ages within the acute-care hospital setting. What are the alterations of activity and mobility of these clients as compared with normal expectations?
4. Evaluate your mobility and lifting habits. Do you have a backache or feel strained after work?
5. What equipment is available in your clinical setting to promote safe body mechanics?

Skin Integrity and Wound Healing

In dwelling upon the vital importance of sound observation, it must never be lost sight of what observation is for. It is not for the sake of piling up miscellaneous information or curious facts, but for the sake of saving life and increasing health and comfort.

—Nightingale (in Skretkowicz, 1992)

COMPETENCIES

1. Describe the normal process of tissue healing.
2. Differentiate between primary, secondary, and tertiary wound healing.
3. Discuss factors that may impair or promote wound healing.
4. Discuss common complications of wound healing.
5. Discuss the risk factors and pathogenesis of pressure ulcers.
6. Identify preventive and early treatment measures in clients at risk for pressure ulcer development.
7. Utilize the nursing process for a client with impaired skin integrity by:
 - a. Identifying appropriate assessment data
 - b. Formulating relevant nursing diagnoses
 - c. Developing a plan of care and identifying outcome criteria
 - d. Implementing appropriate nursing interventions
 - e. Evaluating a plan of care according to outcome criteria
8. Describe the principles of wound assessment and care.
9. Outline dressing products used to treat wounds.
10. Discuss the therapeutic uses of heat and cold therapy and their methods of application.

KEY
TERMS

angiogenesis	full-thickness wound	pyogenic bacteria
black wound	hematoma	red wound
blanching	hemorrhage	secondary intention healing
clean-contaminated wound	hemorrhagic exudate	serous exudate
clean wound	hemostasis	shearing
closed suction drainage system	homeostasis	superficial wound
collagen	inflammation	suppuration
contaminated wound	intentional wound	suture
dehiscence	ischemia	tertiary intention healing
dirty and infected wound	partial-thickness wound	unintentional wound
epithelialization	penrose drain	vasoconstriction
evisceration	phagocytosis	vasodilation
exudate	pressure ulcer	wound
friction	primary intention healing	yellow wound
	purulent exudate	

Maintaining skin integrity is an important aspect of nursing care. Impaired skin integrity, such as wounds, may occur as a result of trauma or surgery. The potential for skin breakdown and eventual pressure ulcer formation also exists whenever factors such as prolonged pressure, constant irritation of the skin, and immobility are present. Nurses, through constant and timely observations and interventions, can prevent or minimize skin breakdown.

WOUNDS

The skin is the body's largest organ and is the primary defense against infection. A disruption in the integrity of body tissue is called a **wound**.

Physiology of Wound Healing

When an injury is sustained, a complex set of responses is set into motion, and the body begins a three-phase process of wound healing. Understanding these physiological responses will assist the nurse in caring for clients with impaired skin integrity and promoting optimal wound healing.

Defensive (Inflammatory) Phase

The defensive phase occurs immediately after injury and lasts about 3 to 4 days. The major events that occur in this phase are hemostasis and inflammation. **Hemostasis**, or cessation of bleeding, occurs by vasoconstriction of large blood vessels in the affected area. Platelets, activated by the injury, aggregate to form a platelet plug and stop the bleeding. Activation of the clotting cascade results in the eventual formation of fibrin and a fibrinous meshwork, which further entraps platelets and other cells. The result is fibrin clot formation, which provides initial wound closure, prevents

excessive loss of blood and body fluids, and inhibits contamination of the wound by microorganisms.

Inflammation is the body's defensive adaptation to tissue injury and involves both vascular and cellular responses. During the vascular response, tissue injury and activation of plasma protein systems stimulate the release of various chemical mediators, such as histamine (from mast cells), serotonin (from platelets), complement, and kinins. These vasoactive substances cause blood vessels to dilate and become more permeable, resulting in increased blood flow and leakage of serous fluid into the surrounding tissues. The increased blood supply carries nutrients and oxygen, which are essential for wound healing, and transports leukocytes to the area to participate in **phagocytosis**, or the envelopment and disposal of microorganisms. The increased blood supply also removes the "debris of battle," which includes dead cells, bacteria, and **exudate**, or material and cells discharged from blood vessels. The area is red, edematous, and warm to touch, and it has varying amounts of exudate as a result.

During the cellular response, leukocytes move out of the blood vessel into the interstitial space. Neutrophils are the first cells to arrive at the injured site and begin phagocytosis. They subsequently die and are replaced by macrophages, which arise from blood monocytes. Macrophages perform the same function as neutrophils but remain for a longer time. In addition to being the primary phagocyte of debridement, macrophages are important cells in wound healing because they secrete several factors, including fibroblast activating factor (FAF) and angiogenesis factor (AGF). FAF attracts fibroblasts, which form collagen or collagen precursors. AGF stimulates the formation of new blood vessels. The development of this new microcirculation supports and sustains the wound and the healing process.

Reconstructive (Proliferative) Phase

The reconstructive phase begins on the third or fourth day after injury and lasts for 2 to 3 weeks. This phase con-

tains the process of collagen deposition, angiogenesis, granulation tissue development, and wound contraction.

Fibroblasts, normally found in connective tissue, migrate into the wound because of various cellular mediators. They are the most important cells in this phase because they synthesize and secrete collagen. **Collagen** is the most abundant protein in the body and is the material of tissue repair. Initially, collagen is gel-like, but within several months it cross-links to form collagen fibrils and adds tensile strength to the wound. As the wound gains strength, the risk of wound separation or rupture is less likely. The wound can resist normal stress such as tension or twisting after 15 to 20 days. During this time, a raised “healing ridge” may be visible under the injury or suture line.

Angiogenesis (formation of new blood vessels) begins within hours after the injury. The endothelial cells in preexisting vessels begin to produce enzymes that break down the basement membrane. The membrane opens, and new endothelial cells build a new vessel. These capillaries grow across the wound, increasing blood flow, which increases the supply of nutrients and oxygen needed for wound healing.

Repair begins as granulation tissue, or new tissue, grows inward from surrounding healthy connective tissue. Granulation tissue is filled with new capillaries that are fragile and bleed easily, thus giving the healing area a red, translucent, granular appearance. As granulation tissue is formed, **epithelialization**, or growth of epithelial tissue, begins. Epithelial cells migrate into the wound from the wound margins. Eventually, the migrating cells contact similar cells that have migrated from the outer edges. Contact stops migration. The cells then begin to differentiate into the various cells that compose the different layers of epidermis.

Wound contraction is the final step of the reconstructive phase of wound healing. Contraction is noticeable 6 to 12 days after injury and is necessary for closure of all wounds. The edges of the wound are drawn together by the action of myofibroblasts, specialized cells that contain bundles of parallel fibers in their cytoplasm. These myofibroblasts bridge across a wound and then contract to pull the wound closed.

Maturation Phase

Maturation, the final stage of healing, begins about the twenty-first day and may continue for up to 2 years or more, depending on the depth and extent of the wound. During this phase, the scar tissue is remodeled (reshaped or reconstructed by collagen deposition and lysis and debridement of wound edges). Although the scar tissue continues to gain strength, it remains weaker than the tissue it replaces. Capillaries eventually disappear, leaving an avascular scar (a scar that is white because it lacks a blood supply).

Types of Healing

Tissue may heal by one of three methods, which are characterized by the degree of tissue loss. **Primary intention healing** occurs in wounds that have minimal tissue

loss and edges that are well approximated (closed). If there are no complications, such as infection, necrosis, or abnormal scar formation, wound healing occurs with minimal granulation tissue and scarring.

Secondary intention healing is seen in wounds with extensive tissue loss and wounds in which the edges cannot be approximated. The wound is left open, and granulation tissue gradually fills in the deficit. Repair time is longer, tissue replacement and scarring are greater, and the susceptibility to infection is increased because of the lack of an epidermal barrier to microorganisms.

Tertiary intention healing, also known as delayed or secondary closure, is indicated when primary closure of a wound is undesirable. Conditions in which healing by tertiary intention may occur include poor circulation or infection. Suturing of the wound is delayed until the problems resolve and more-favorable conditions exist for wound healing.

Kinds of Wound Drainage

Chemical mediators released during the inflammatory response cause vascular changes and exudation of fluid and cells from blood vessels into tissues. Exudates may vary in composition but all have similar functions. These functions include:

1. Dilution of toxins produced by bacteria and dying cells
2. Transport of leukocytes and plasma proteins, including antibodies, to the site
3. Transport of bacterial toxins, dead cells, debris, and other products of inflammation away from the site

The nature and amount of exudate vary depending on the tissue involved, the intensity and duration of the inflammation, and the presence of microorganisms.

Serous exudate is composed primarily of serum (the clear portion of blood), is watery in appearance, and has a low protein count. This type of exudate is seen with mild inflammation resulting in minimal capillary permeability changes and minimal protein molecule escape (e.g., seen in blister formation after a burn).

Purulent exudate is also called pus. It generally occurs with severe inflammation accompanied by infection. Purulent exudate is thicker than serous exudate because of the presence of leukocytes (particularly neutrophils), liquefied dead tissue debris, and dead and living bacteria. The process of pus formation is called **suppuration**, and bacteria that produce pus are referred to as **pyogenic bacteria**. Purulent exudates may vary in color (e.g., yellow, green, brown) depending on the causative organism.

Hemorrhagic exudate has a large component of red blood cells (RBCs) due to capillary damage, which allows RBCs to escape. This type of exudate is usually present with severe inflammation. The color of the exudate (bright red versus dark red) reflects whether the bleeding is fresh or old.

Mixed types of exudates may also be seen, depending on the type of wound. For example, a serosanguineous exudate is clear with some blood tinge and is seen with surgical incisions.

Factors Affecting Wound Healing

Wound healing is dependent on multiple influences, both intrinsic and extrinsic. Wounds may fail to heal or may require a longer healing period when unfavorable conditions exist. Factors that may negatively influence healing include age, nutrition, oxygenation, smoking, drug therapy, and diseases such as diabetes. Such factors reduce local blood supply and, therefore, impair wound healing. Nutrition and diet can also have an impact on the healing process. See Tables 35-1 and 35-2 for a summary of factors that affect wound healing (these tables are compiled from information found in Cooper, 1990; Hottler, 1990; Jones & Millman, 1990; Levenson & Seifter, 1977; Schumann, 1979; and Sieggreen, 1987).

Hemorrhage

Some bleeding from a wound is normal during and immediately after initial trauma and surgery, but hemo-

stasis usually occurs within a few minutes. **Hemorrhage** (persistent bleeding) is abnormal and may indicate a slipped surgical suture, a dislodged clot, or erosion of a blood vessel. Swelling in the area around the wound or affected body part and the presence of sanguineous drainage from the surgical drain may indicate internal bleeding. Other evidence of bleeding may include the signs and symptoms seen in hypovolemic shock (decreased blood pressure, rapid thready pulse, increased respiratory rate, diaphoresis, restlessness, and cool clammy skin). A **hematoma** (localized collection of blood underneath the tissues) may also be seen and appear as a reddish blue swelling or mass. External hemorrhaging is detected when the surgical dressing becomes saturated with sanguineous drainage. It is also important to assess the linen under the client's wound site because it is possible for the blood to seep out from under the sides of the dressing and pool under the client. The risk for hemorrhage is greatest during the first 24 to 48 hours after surgery.

Infection

Bacterial wound contamination is one of the most common causes of altered wound healing. A wound can become infected with microorganisms preoperatively,

TABLE 35-1
Factors Affecting Wound Healing

Factor	Effect
Age	Blood circulation and oxygen delivery to the wound, clotting, inflammatory response, and phagocytosis may be impaired in the very young and the elderly; thus, the risk of infection is greater. Rate of cell growth and epithelialization of open wounds is lower with advancing age, so wound healing is slowed.
Nutrition	A balanced diet with adequate amounts of protein, carbohydrates, fats, vitamins, and minerals is needed to increase the body's resistance to pathogens and to decrease the susceptibility of skin and mucous membranes to infection and trauma. Surgery, severe wounds and infections, stress from burns and trauma, and preexisting nutritional deficits increase nutritional requirements. Malnutrition reduces humoral and cell-mediated factors, leading to immunocompromise, thus impairing wound healing and increasing the risk for infection. Obesity leads to fatty tissue, which has a decreased supply of blood vessels, that impairs delivery of nutrients and other elements needed for healing; also, suturing of fatty tissue is more difficult, and complications such as dehiscence or evisceration with subsequent infection may occur.
Oxygenation	Decreased arterial oxygen tension alters the synthesis of collagen and the formation of epithelial cells, causing wounds to heal more slowly. Reduced hemoglobin levels (anemia) decrease oxygen delivery to the tissues and interfere with tissue repair.
Smoking	Functional hemoglobin levels decrease, impairing oxygenation to tissues.
Drug therapy	Steroids reduce inflammatory response and slow collagen synthesis. Anti-inflammatory drugs suppress protein synthesis, wound contraction, epithelialization, and inflammation. Prolonged antibiotic use, with development of resistant strains of bacteria, may increase the risk of superinfection.
Diabetes mellitus	Small-vessel disease (microvascular changes) can impair tissue perfusion and oxygen delivery. Hemoglobin in poorly controlled diabetes has an increased affinity for oxygen, allowing less to be released to the wound bed. Elevated blood glucose levels impair leukocyte function and phagocytosis. The high-glucose environment is an excellent medium for the growth of bacterial, fungal, and yeast infections.

TABLE 35-2
Nutrients That Enhance Wound Healing

Nutrient	Function in Wound Repair
Proteins	
Amino acids	Neovascularization Lymphocyte formation Fibroblast proliferation Collagen synthesis Wound remodeling Cell-mediated responses (phagocytosis)
Albumin	Osmotic equilibrium control Edema prevention
Carbohydrates	
	Cellular energy Protein sparing
Fats	
	Cellular energy Component of cell membrane Prostaglandin production
Minerals	
Copper	Collagen cross-linking for scar strength
Iron	Collagen synthesis and enhanced leukocytic bacterial activity
Zinc	Cell proliferation and cell membrane stabilization
Vitamins	
A	Collagen synthesis Epithelialization
Pyridoxine, riboflavin, thiamine	Antibody and WBC formation Cofactors of enzyme systems
C	Resistance to infection Collagen synthesis Capillary formation and stabilization
K	Coagulation

intraoperatively, or postoperatively. During the preoperative period, the wound may become exposed to pathogens because of the manner in which the wound was inflicted, such as in traumatic injuries. Nicks or abrasions created during preoperative shaving may also be a source of pathogens. The risk for intraoperative exposure to pathogens increases when the respiratory, gastrointestinal, genitourinary, and oropharyngeal tracts are opened.

If the amount of bacteria in the wound is sufficient or the client's immune defenses are compromised, clinical infection may result and become apparent 2 to 11 days postoperatively. Infection slows healing by prolonging the inflammatory phase of healing, competing for nutri-

ents, and producing chemicals and enzymes that are damaging to the tissues.

Dehiscence and Evisceration

Wound healing may be disrupted by **dehiscence**, the partial or complete separation of the wound edges and the layers below the skin. **Evisceration** occurs when the client's viscera protrude through the disrupted wound. Factors that may predispose a wound to dehiscence include obesity, poor nutrition, problems with suturing, excessive coughing, vomiting, straining, and infection. Wound dehiscence is most likely to occur 4 to 5 days postoperatively, before extensive collagen is deposited in the wound. It may be preceded by sudden straining, such as that associated with coughing, sneezing, or sitting up in bed. Signs of impending dehiscence may include the sensation of "something giving way" and an increased flow of serosanguineous drainage on the wound dressing.

Wound Classification

A variety of terms are used to describe and classify wounds. Wounds are usually described based on their etiology since the treatment for the wound varies depending on the underlying disease process. Wound classification systems describe the cause of the wound, the status of skin integrity, the extent of tissue damage, cleanliness of wounds, or descriptive qualities of the wound such as color. The following are commonly used classification systems.

Cause of Wound

- **Intentional wounds** occur during treatment or therapy. These wounds are usually made under aseptic conditions. Examples include surgical incisions and venipunctures.
- **Unintentional wounds** are unanticipated and are often the result of trauma or an accident. These wounds are created in an unsterile environment and therefore pose a greater risk of infection.

Cleanliness of Wound

This classification system ranks the wound according to its contamination by bacteria and risk for infection (Sussman & Bates-Jensen, 1998).

- **Clean wounds** are intentional wounds that were created under conditions in which no inflammation was encountered and the respiratory, alimentary, genitourinary, and oropharyngeal tracts were not entered.
- **Clean-contaminated wounds** are intentional wounds that were created by entry into the alimentary,

respiratory, genitourinary, or oropharyngeal tract under controlled conditions.

- **Contaminated wounds** are open, traumatic wounds or intentional wounds in which there was a major break in aseptic technique, spillage from the gastrointestinal tract, or incision into infected urinary or biliary tracts. These wounds have acute nonpurulent inflammation present.
- **Dirty and infected wounds** are traumatic wounds with retained dead tissue or intentional wounds created in situations where purulent drainage was present.

Examples of classification systems that describe wound severity for different wound etiology are the National Pressure Ulcer Advisory Panel (NPUAP), discussed later in this chapter, the Wagner staging system, the partial-thickness and full-thickness skin loss criteria, and Marion Laboratories red/yellow/black (RYB) color system.

Wagner Ulcer Grade Classification

The Wagner staging system measures the depth and infection in a wound, mainly a dysvascular foot. It is the primary assessment tool used to evaluate diabetic foot ulcers. The classification ranges from 0 to 5, with 0 identifying the predisposing factors that may lead to grades 1 to 3 (superficial ulcer, deep ulcer, abscess osteitis). Grade 4 and 5, respectively, describe gangrene of the forefoot and gangrene of the whole foot.

Classification by Thickness of Skin Loss

The thickness classification system is based on the depth of the wound (Figure 35-1) and is used for wounds whose etiology is other than pressure wounds such as skin tears, donor sites, vascular ulcers, surgical wounds, or burns.

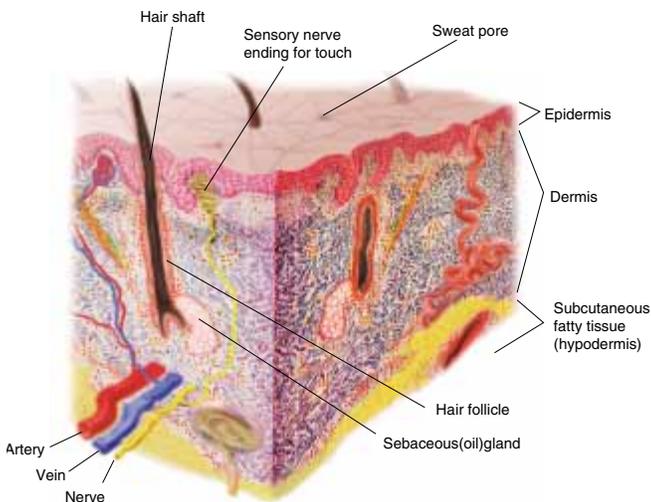

Figure 35-1 Structures of the Skin (From Estes, M. E. Z. [2002]. *Health assessment and physical examination*. Albany, NY: Delmar Publishers.)

THINK ABOUT IT

Impaired Skin Integrity Resulting from Abuse

A woman presents to your clinic with multiple bruises on her breasts, thighs, and abdomen; fresh abrasions on her hands and knees with gravel mixed in; and two puncture wounds on her left shoulder blade, surrounded by streaks of blue ink. Her injuries are highly suggestive of abuse, especially the puncture wounds, because these could not have been self-inflicted. How do you feel about caring for this client? What are the skin care priorities? What other issues should be addressed with this client once her wounds have been evaluated and any immediate physical needs attended to? What are the procedures for reporting suspected abuse at your clinical agency?

Superficial epidermal (first degree) are confined to the epidermis layer, which comprises the four outermost layers of skin. Partial-thickness (first to second degree) involves the epidermis and upper dermis, which is the layer of skin beneath the epidermis. Deep (second degree) involves the epidermis and deep dermis. Full-thickness (third degree) refers to skin loss that extends through the epidermis and the dermis, and into subcutaneous fat and deeper structures. Fourth degree are deeper than full-thickness loss, extending into the muscle and bone.

Types of wounds are described and illustrated in Figure 35-2, and burns are shown in Figure 35-3.

The RYB Wound Classification System

In 1988, the RYB classification system was introduced for use in conjunction with the other classification systems to assist the nurse in assessing the wound surface color. The three-color system is a tool to direct treatment of open wounds, with each color corresponding to specific therapy needs.

Red wounds are the color of normal granulation tissue and are in the proliferative phase of wound repair. These wounds need to be protected and kept moist and clean. **Yellow wounds** have either fibrinous slough or purulent exudate from bacteria. These wounds need to be cleansed of the purulent exudate, and nonviable slough needs to be removed. **Black wounds** contain necrotic tissue (eschar). Eschar may be either black, gray, brown, or tan. These wounds need debridement, which is the removal of nonviable necrotic tissue. Mixed color wounds often occur. The rule for treatment is to treat the worst color first. For example, a red and black wound would be debrided first. Then moisture and protection would be provided for the red portion.

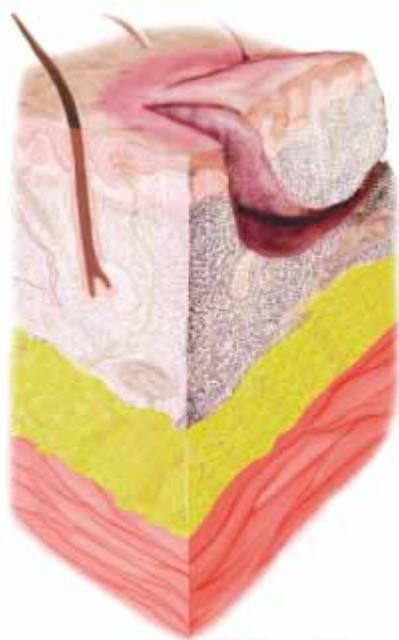

A. **Bruise**, also known as a contusion, results from damage to the soft tissues and blood vessels, which causes bleeding beneath the skin surface. A bruise in a light-skinned individual will change from red to purple to greenish yellow before fading; in a dark-skinned person, the bruise will first look dark red then darker red, brown, or purple, and slowly fade.

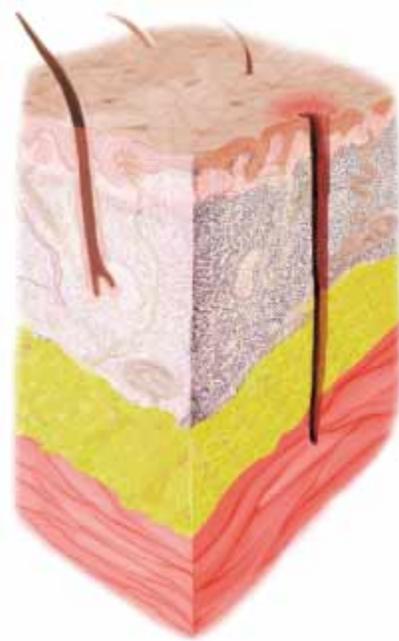

B. **Abrasion**, also known as a scrape or rug burn, results when the outer layer of skin is scraped or rubbed away. Exposure of nerve endings makes this type of wound painful, and the presence of debris from the scraped surface (rug fibers, gravel, sand) makes abrasions highly susceptible to infection.

C. **Laceration**, cut, or incision, is caused by sharp objects such as knives or glass: or from trauma due to a strike from a blunt object that opens the skin, such as a baseball bat. If the wound is deep, the cut may bleed profusely; if nerve endings are exposed, it may also be painful.

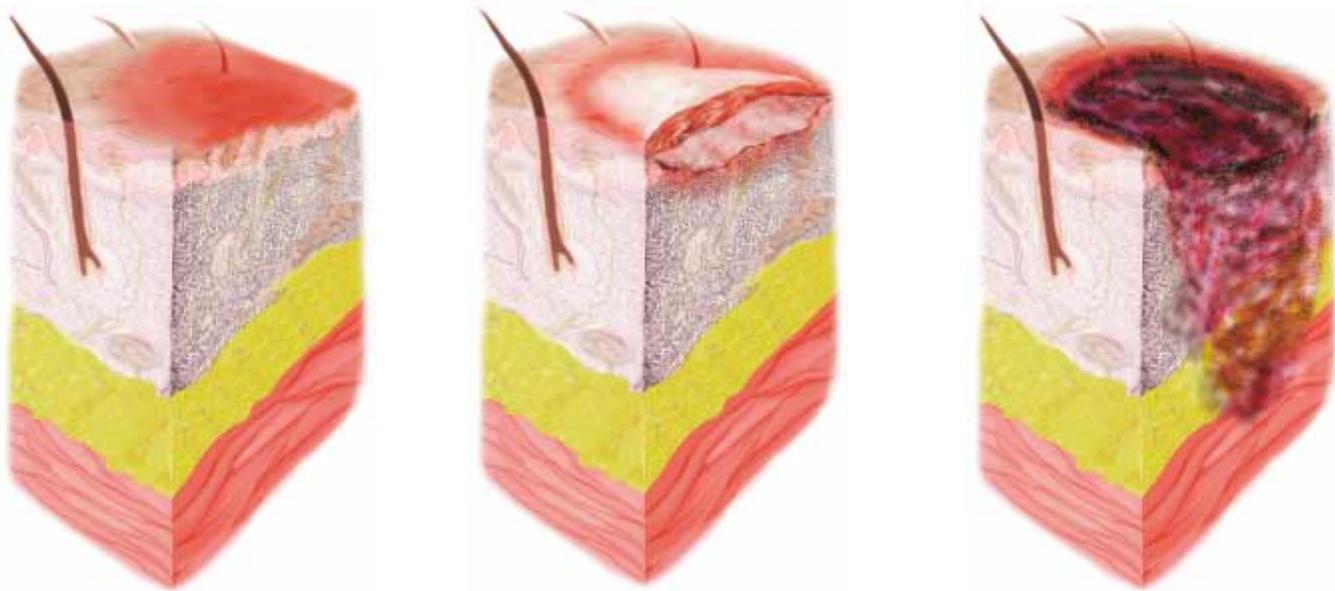

D. **Avulsion**, results when the skin or tissue is torn away from the body, either partially or completely. The bleeding and pain will depend on the depth of tissue affected.

E. **Puncture** results when the skin is pierced by a sharp object such as a pencil, nail, or bullet. If a piece of the object remains in the skin, or if there is little bleeding due to the depth and location of the puncture, infection is likely.

Figure 35-2 Types of Wounds. A. Bruise. B. Abrasion. C. Laceration. D. Avulsion. E. Puncture.

A. Superficial epidermal (first degree burn): Injury to the epidermis; skin is red, dry, and painful.

B. Deep (second degree burn): Injury to the epidermis and upper layers of the dermis, skin is red, moist or dry blisters, and extremely painful; exudate and swelling usually occur.

C. Full-thickness (third degree burn): Injury is to the epidermis, dermis, and subcutaneous tissue; skin is dry, pearly white to charred, inelastic, and leathery.

Figure 35-3 Types of Burns

Assessment

When it comes to wound care, the nurse is confronted with wounds that are extremely diverse. The wound may have occurred traumatically just before the client presents to the emergency room, or the wound may be a slow-healing chronic ulcer. Despite all this diversity, the nurse should approach assessment of the wound in a systematic manner, evaluating the wound's stage in the healing process. The nurse also needs to show sensitivity to the client's pain and tolerance levels during assessment and must always follow Standard Precautions to prevent transfer of pathogens. Following are some basic criteria for wound assessment.

Health History

The health history is conducted to elicit information regarding medical conditions or disease processes that are often associated with delayed or disrupted healing such as cardiovascular disease, diabetes, renal failure, immunosuppression, gastrointestinal disorders, collagen disorders, malignancy, septic shock, trauma, infection, liver disease, pulmonary disease, musculoskeletal disease, and depression/psychosis. It is important to obtain the data in chronological order: when and how the wound occurred, the initial location and size, and all associated symptoms such as pain and itching. The history should include aggravating and alleviating factors, such as radiation at the site of the wound, which can influence the healing process. The nurse should document allergies to tape, latex, medications, or other substances.

A personal and social history and a functional ability assessment is done to determine the client's ability to provide self-care and to identify support systems present in the home. A risk assessment tool, such as the Braden or Norton scale to assess the risk for pressure ulcers, is a part of the history.

Physical Examination

Although the focus of the assessment will be to accurately describe and/or stage the wound, the physical effects of any existing concurrent condition are evaluated. Stotts and Cavanaugh (1999) identify the defining physical areas to be assessed for three common types of ulcers:

Vascular ulcers—Evaluate the skin, nails, hair, color, capillary refill, temperature, pulses, edema of the extremity, and hemosiderin (an iron pigment that is a product of red blood cell hemolysis) in the peri-ulcer area

Arterial ulcers—Weak or absent pulses, thin skin, and lack of hair on the affected extremity

Neuropathic ulcers—Use of the Wagner scale previously discussed to evaluate diabetic ulcers

Wound Assessment

The following discussion will describe how to assess a wound, documenting location and size, noting length, width, and depth in centimeters. The appearance of the wound bed and surrounding skin are assessed for sinus tracts, undermining, tunneling, exudate, drainage,

necrotic tissue, and signs of infection. Some agencies may require a photograph of the wound on admission and documentation of the client’s response to therapy.

Location

Assessment begins with a description of the anatomical location of the wound; for example, “5-inch suture line on the right lower quadrant of the abdomen.” This task often becomes difficult if the client has multiple wounds close to each other, as is common in burn or multiple trauma victims. Use of a skin documentation form that incorporates drawings of the body (Figure 35-4) allows the nurse to draw circles and write numbers to depict the location of the various wounds.

Size

The length (head to toe), width (side to side), and depth of a wound are measured in centimeters. Single-use measurement guides (tape measures) often come with dressing supplies. To determine the depth of a wound, insert a sterile cotton swab into the deepest point of the wound and mark it at the skin surface level. Then the swab can be measured and the wound depth in centimeters can be documented. Tunneling, also called undermining, can be measured by using a cotton swab to gently probe the wound margins. If tunneling is noted, the location and depth are documented. For

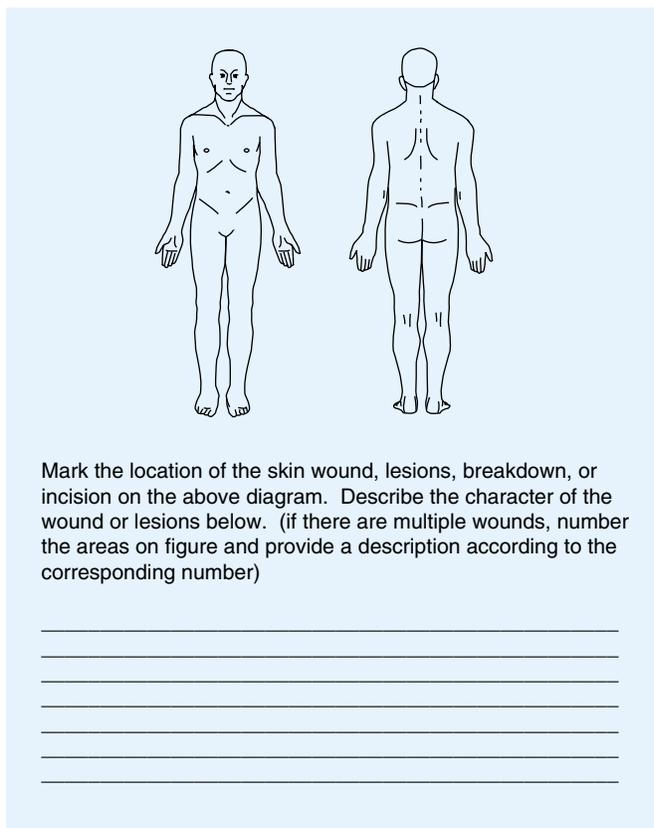

clarity in describing the location of the tunneling, refer to the tunnel location, using the hands of the clock as a guide, with 12 o’clock pointing at the client’s head. Example: “Tunneling occurs at 1 o’clock and its depth is 2 cm.”

For extremely irregularly shaped wounds, the wound edges can be traced on a plastic surface. A plastic bag or piece of plastic sheeting folded in half is placed on the wound, and the wound margins are traced. The side of the plastic that has been placed against the skin is cut off and discarded. The rest of the plastic can be placed in the chart.

General Appearance and Drainage

A general description of the color of the wound and surrounding area helps to determine the wound’s present phase of healing. Gently palpate the edges of the wound for swelling. Document the amount, color, location, odor, and consistency of any drainage.

Nurses who care for the client in the home must demonstrate the need for skilled nursing services by accurately describing all wounds (see the accompanying display). For example, for Medicare to reimburse nursing care, the care must be reasonable, necessary, and reflect a plan of care appropriate for the client’s diagnoses, prognosis, and rehabilitative potential (Baranoski, 1999).

DOCUMENTATION: HOME CARE

Document a clear, concise, and accurate picture of the client’s wound:

- Size, depth, and location of the wound
- Nature of drainage
- Condition and appearance of surrounding skin
- Specific individualized instructions for treatment

Pain

Document and notify the physician of any pain or tenderness at the wound site. Pain may indicate infection or bleeding. It is normal to experience pain at the incision site of a surgical wound for approximately 3 days. If there is any sudden increase in pain accompanied by changes in the appearance of the wound, be sure to notify the physician immediately. See Chapter 33 for more information on assessing pain.

Laboratory Data

Cultures of the wound drainage are used to determine the presence of infection and to identify the causative organism. The sensitivity results list the antibiotics that will effectively treat the infection. An elevated WBC

Figure 35-4 Documenting the Location and Character of Wounds

count is indicative of an infectious process. A decreased leukocyte count may indicate that the client is at increased risk for developing an infection related to decreased defense mechanisms. Albumin is a measure of the client's protein reserves; if decreased, there are decreased resources of protein for wound healing. Procedure 35-1 outlines the correct techniques for culturing a wound.

Nursing Diagnoses

Nursing diagnoses for clients with wounds focus on prevention of complications and promotion of the healing process through proper wound care and client teaching. Following are NANDA(2001)-approved nursing diagnoses with a partial list of related factors:

1. *Impaired Tissue Integrity* related to surgical incision, pressure, shearing forces, decreased blood flow, immobility, mechanical irritants, mechanical (pressure, shear, friction), radiation, nutritional deficit or excess, thermal, irritants, including body excretions, secretions, and medications.
2. *Risk for Infection* related to malnutrition, decreased defense mechanisms
3. *Pain* related to inflammation, infection
4. *Disturbed Body Image* related to changes in body appearance secondary to scars, drains, removal of body parts
5. *Deficient Knowledge* (wound care) related to lack of exposure to information, misinterpretation, lack of interest in learning.

Outcome Identification and Planning

After identifying the nursing diagnoses, the nurse establishes targeted outcomes for wound healing. When formulating outcomes, keep in mind that they should be based on the client's identified needs and should be individualized on the basis of the client's condition. Changes in the health care delivery system have brought about early discharge from the hospital, so clients are often sent home with wounds that need continued care. The goals for clients with wounds generally focus on promoting wound healing, preventing

PROCEDURE 35-1

Culturing a Wound

Equipment

- Disposable gloves
- Normal saline and irrigation tray
- Moisture-proof container or bag
- Sterile gloves and dressing supplies
- Culture tube and swab

Action

1. Wash hands, apply disposable gloves, and remove old dressing. Place old dressing in moisture-proof container, and remove and discard gloves. Wash hands again.
2. Open the dressing supplies using sterile technique, and apply gloves.
3. Assess the wound's appearance; note quality, quantity, color, and odor of discharge.
4. Irrigate the wound with normal saline prior to culturing the wound; do not irrigate with antiseptic.
5. Using a sterile gauze pad, absorb the excess saline, then discard the pad.

Rationale

1. Reduces the transmission of microorganisms. Makes the wound accessible for obtaining the culture.
2. Maintains sterile environment.
3. Provides assessment of the amount and character of the wound's drainage prior to irrigation. Reddened areas and heavy drainage suggest infection.
4. Irrigation decreases the risk of culturing normal flora and other exudates such as protein; irrigating with an antiseptic prior to culturing may destroy the bacteria.
5. Removal of excess irrigant prevents maceration of tissue due to excess moisture.

(continues)

PROCEDURE 35-1

Culturing a Wound (continued)

Action

6. Remove the culture tube from the packaging (see Figure 35-5). Remove the culture swab from the culture tube and gently roll the swab over the granulation tissue. Avoid eschar and wound edges (see Figure 35-6).

Figure 35-5 Remove culture tube from the packaging.

Figure 35-6 Roll the swab over the area to be cultural.

Rationale

6. Decreases the chance of collecting superficial skin microorganisms.
7. Replace the swab into the culture tube, being careful not to touch the swab to the outside of the tube. Recap the tube. Crush the ampule of medium located in the bottom or cap of the tube (see Figure 35-7).
8. Remove gloves, wash hands, and apply sterile gloves. Dress the wound with sterile dressing.
9. Label the specimen and arrange to transport the specimen to the laboratory according to agency policy.
7. Avoids contamination with microorganisms. Releases the medium to surround the swab.
8. Prevents contamination of the wound.
9. Ensures proper handling of specimen.

(continues)

PROCEDURE 35-1

Culturing a Wound (continued)

Action

Figure 35-7 Crush the ampule to release the medium inside the culture tube.

10. Remove gloves and wash hands.
11. Document all assessment findings and actions taken. Document that a specimen was obtained.

Rationale

10. Reduces the transmission of microorganisms.
11. Records information for evaluation and promotes continuity of care.

infection, and educating the client. An example of a goal for debilitated clients would be demonstrating no signs of infection and preventing pressure to certain skin areas for extended periods of time.

Implementation

Nursing interventions to promote wound healing and prevent infection include emergency measures to maintain **homeostasis** (state of internal constancy of the body), and cleansing and dressing of the wound.

Initiate Emergency Measures

The nurse assesses the type and extent of injury that the client has sustained. If hemorrhage is detected, sterile dressings and pressure should be applied to stop the bleeding. Standard Precautions are always implemented. The client's vital signs should be monitored frequently and the physician notified immediately.

When dehiscence or evisceration occurs, the client should be instructed to remain quiet and to avoid coughing or straining. The client should be positioned to prevent further stress on the wound. Sterile dressings, such as ABD pads soaked with sterile normal saline, should be used to cover the wound and abdominal contents. This will reduce the risk of bacterial contamination and drying of the viscera. The surgeon should be notified immediately and the client prepared for surgical repair of the area.

Cleanse the Wound

The goal of cleansing the wound is to remove debris and bacteria from the wound bed with as little trauma to the healthy granulation tissue as possible. Choice of cleansing agent depends on the physician's prescription as well as agency protocol. It is recommended that isotonic solutions such as normal saline or lactated Ringers be used to preserve healthy tissue. Much research has been conducted on the proper use of antiseptic solutions in open wounds. The results remain debatable, and continued research is needed to investigate the effects of antiseptic agents on leukocytes and fibroblasts. Many of the studies do show that commonly used agents such as povidone-iodine 10%, hydrogen peroxide 3%, sodium hypochlorite (Dakin's solution), and acetic acid are effective in destroying bacteria but at the same time destroy fibroblasts and healthy granulation tissue (Lineaweaver, Howard, & Saucy, 1985). Studies suggest that some of these antiseptic solutions at dilute concentrations remain bactericidal yet not cytotoxic to healthy fibroblasts (Doughty, 1994).

The major principles to keep in mind when cleansing a wound are:

1. Use Standard Precautions at all times.
2. When using a swab or gauze to cleanse a wound, work from the clean area out toward the dirtier area. (Example: When cleaning a surgical incision, start

Nursing Process Highlight

NURSING DIAGNOSIS

It is important to remember that, in addition to the physical risks of infection and further tissue damage, clients with wounds, pressure ulcers, and burns often have significant psychosocial needs that could benefit from your competent nursing attention. *Disturbed Body Image* is a common reaction to a severe alteration in one's appearance and needs to be managed sensitively and effectively through honest evaluation and prognosis. You may want to encourage a client to look at the wound and learn to accept it as only one part of the body; if that is too upsetting, encourage the client not to look at the wound until it is in more advanced stages of healing.

If *Deficient Knowledge* is a primary diagnosis, as is usually the case in first-time wound sufferers, then educating the client about wound care and health promotion is among your priorities. Make sure the client understands the healing process and the stages of recovery the wound will go through and what to expect in terms of pain and regrowth. Encourage the client to follow a healthy diet to provide the body with maximum ammunition for wound repair and to get plenty of rest, to allow the body's recuperative elements to do their work.

over the incision line, and swab downward from top to bottom. Change the swab and proceed again on either side of the incision, using a new swab each time (Figure 35-8).

3. When irrigating a wound, warm the solution to room temperature, preferably to body temperature, to prevent lowering of the tissue temperature. Be sure to allow the irrigant to flow from the cleanest area to the contaminated area to avoid spreading pathogens (Procedure 35-2).

Dressing the Wound

The three purposes of a wound dressing are to:

1. Keep the wound moist and therefore enhance epithelialization
2. Clean the wound or keep it clean
3. Protect the wound from physical trauma or bacterial invasion

Keeping these three purposes in mind, the nurse and physician are confronted with the daunting task of determining the appropriate dressing for the client's

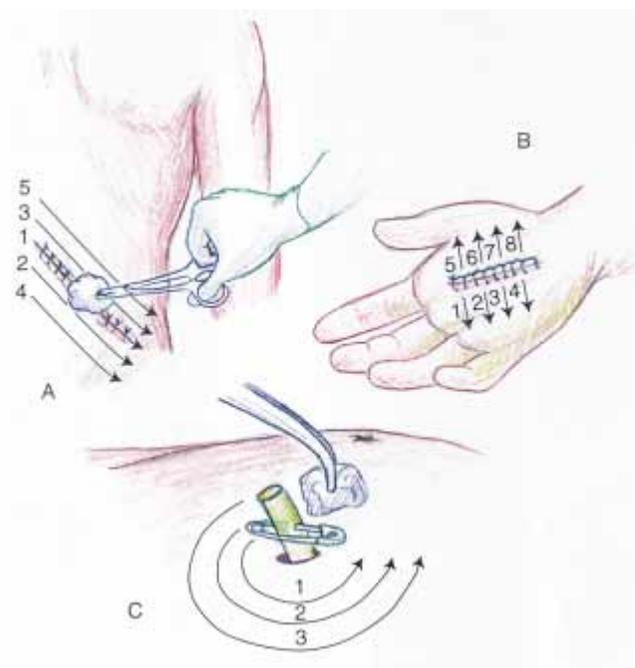

Figure 35-8 Cleaning a wound or surgical incision; use a clean sterile swab for each stroke. A. Begin in the center of the wound. B. Gently stroke the swab outward, away from the incision line. C. Clean around a drain site in a circular motion.

wound. There are literally thousands of different wound care products on the market, which fall into eight basic categories. In order to make an appropriate dressing choice, the nurse needs to be familiar with the proper use and indications for each of these categories and to select the one that meets the client's wound healing needs (Table 35-3). In addition, it is important to remember that the dressing plans must be modified as the wound changes. An excellent guide to help the nurse in the decision-making process is the RYB color code. Procedures 35-3 and 35-4 explain the proper technique for dry sterile dressing and wet to dry dressing changes.

Monitor Drainage of Wounds

During the inflammatory response, exudates develop within a wound. When excessive drainage accumulates in the wound bed, tissue healing is delayed. If the outer surface is allowed to heal while the drainage remains entrapped within the wound, infection and abscess formation may occur. To facilitate drainage of any excess fluid, the physician may insert a tube or drain.

When the drain is inserted by the surgeon at the time of surgery, one end of the drain is placed in the operative site and the other end is usually passed through a separate small stab wound near the main incision. Various types of drains exist on the market. Some flexible drains such as **Penrose drains** function by gravity and have an open end that drains onto dressings. **Closed suction drainage systems** commonly have a

TABLE 35-3
Wound Dressing Guidelines

Dressing Type	Examples*	Indications	Advantages	Disadvantages	Tips for Using
Transparent adhesive films	ACU-Derm	Minor burns, lacerations	Impermeable to external fluids and bacteria	Nonabsorptive	Defat surrounding skin with acetone or alcohol as needed
	Bioclusive	Skin donor sites	Conformable	Application can be difficult	
	OpSite	Transparent	Don't require secondary dressing	Can't be used on wounds with fragile surrounding skin, infected wounds or draining wounds	Shave surrounding hair
	Tegaderm	Pressure ulcers: stage I and some stage II (partial thickness, lightly exuding)	Promote autolytic debridement		Allow 1- to 2-inch margin around wound bed
	Transeal	Secondary dressing in certain situations	Reduce surface friction		Dressing change schedule varies with wound condition and location
	UniFlex	Dry necrotic wounds that need autolytic debridement			
	Polyskin				
Hydrocolloids	Comfeel	Partial-thickness wounds	Conformable	Not recommended for wounds with heavy exudate, sinus tracts, infections; wounds that expose bone or tendon; or wounds with fragile surrounding skin	Characteristic odor as well as yellow exudate that looks similar to pus is normal when dressing is removed from wound
	Cutinova hydro	Pressure ulcers: superficial stage III and some approved clean stage IV	Impermeable to external bacteria and contaminants		
	DuoDERM	Wounds with necrosis or slough	Support autolytic debridement	Not transparent	Allow 1- to 1 1/2-inch margin of healthy tissue around wound edges
	IntraSite	Wounds with mild to moderate exudate	Minimally to moderately absorptive	May curl or "seep" under edge	Taping edges will help prevent curling
	Restore		Can be used with compression (treatment of venous stasis ulcers)		Contour dressing to area to increase adhesion
	Tegasorb				Change every three to seven days and as needed with leakage
	Hydrocol				
	Ultec		"Thin" forms diminish friction Reduces pain

Wound Dressing Guidelines

Dressing Type	Examples*	Indications	Advantages	Disadvantages	Tips for Using
Collagens	Fibracol	Partial- and full thickness wounds	Comfortable	Contraindicated: sensitive to bovine products and third degree burns	Requires secondary dressing to secure
	Medifil	Pressure ulcers	Absorbent, nonadherent		
	Particles/Gel/Pads	Stage III and some IV	May be used in combination with topical agents	May require rehydration	
	Skin temp sheets	Dermal ulcers	necrotic wounds	Not recommended for	
		Donor sites			
		Surgical wounds			
Hydrogels	Aquasorb	Partial- and full-thickness wounds	Soothing, cooling	Most require secondary dressing	Sheet forms work best on superficial wounds
	Carrasyn Hydrogel Wound Dressing	Wounds with necrosis or slough	Fill dead space	Not used for heavily exuding wounds	Dressing change schedule varies from every eight to 48 hours
	ClearSite	Burns and tissue damaged by radiation	Rehydrate dry wound beds	May dry out, then adhere to wound bed (sheet form in particular)	Use skin barrier wipe on surrounding intact skin to decrease risk of maceration
	Elaso-Gel	Dermal ulcers	Promote autolytic debridement	May macerate surrounding skin	
	IntraSite Gel	Painful wounds	Provide minimal to moderate absorption		
	Normlgel		Conform to wound bed		
	Transorb		Transparent to translucent		
	Vigilon		Many are nonadherent		
		Can be used when infection is present			
Exudate absorbers	AlgiDERM	Wounds with moderate to large amounts of exudate	Absorb up to 20 times their weight in drainage	Require secondary dressing	Can use gauze pad or transparent film as secondary dressing
	Bard Absorption Dressing	Wounds with combination exudate and necrosis	Fill dead space	Not recommended for dry or lightly exuding wounds	Change schedule varies

TABLE 35-3 (continued)
Wound Dressing Guidelines

Dressing Type	Examples*	Indications	Advantages	Disadvantages	Tips for Using
Exudate absorbers (continued)	Debrisan	Wounds that require packing and absorption	Support debridement in presence of exudate	Can dry wound bed	(with type of product used and amount of exudate) from every eight hours to every three to
	DermaSORB Spiral Dressing	Easy to apply four days			
	Mesalt	Infected, exuding wounds			
	Kaltrostat				
	Sorbsan				
Polyurethane foams	Allevyn	Partial- and full-thickness wounds with minimal to moderate exudate	Nonadherent	Require secondary dressing, tape, or net to hold in place	Protect intact surrounding skin with skin sealant to prevent maceration
	Epi-Lock		Conformable		
	Hydrosorb	Secondary dressing for wounds with packing to provide additional absorption	Manage light to moderate amounts of exudate	Not for use with dry eschar, wounds with no exudate, or wounds with sinus tracts unless packed	Change schedule varies from one to five days
	Lyof foam		Easy to apply and remove		
	Mitraflex	Around draining tubes	May be used under compression		
			Can be used on wounds that have surrounding body hair		
			Can be used on infected wounds		
Lubricating sprays of emollients	Dermagran	Partial-thickness wounds	Easy to use	Apply two to three times daily to maintain moist wound environment	May stain clothing or sheets
	Granulex	Saturate gauze packing for use in full-thickness wounds	Inexpensive		
	Proderm	Moisturize wound and stimulate local circulation	Nonadhesive	May require secondary dressing	

(continues)

TABLE 35-3 (continued)
Wound Dressing Guidelines

Dressing Type	Examples*	Indications	Advantages	Disadvantages	Tips for Using
Enzymatic debriders	Accuzyme	Debride full thickness necrotic wounds, pressure ulcers, dermal ulcers, post-op wounds, infected wounds	Non-surgical debridement	Inactivated by soaps, detergents, acidic solutions, metallic ions	Requires daily or twice daily dressing changes
	Collagenase/Santyl				
	Elastase				
Nonadherent dressings	Adaptic	Skin donor sites	Readily available	Limited moisture retention	Change schedule varies from eight- to 24-hour intervals
	Exu-Dry	Abrasions, skin tears	Don't adhere	Require secondary dressing to retain moisture, protect from outside contaminants, and keep in place	
	Sofisorb	Lacerations	Cover partial- and full-thickness wounds without exudate		
	Telfa	Infected wounds, partial- and full-thickness wounds that require packing		May stick to wound if dressing dries out, causing wound damage with removal	
	Vaseline Gauze Xeroform		Can be used with topical antimicrobials, ointments, or creams		
Gauze dressings	Numerous products available	Exudative wounds	Readily available	Will disrupt wound healing if allowed to dry	Change schedule varies with amount of exudate
		Wounds with dead space, tunneling, or sinus tracts	Can be used with appropriate solutions such as gels, normal saline, or topical anti-microbials to keep wounds moist	Require secondary dressing	Pack loosely into wound; tight packing compromises blood flow and delays wound closure
		Wounds with combination exudate or necrotic debris	Can be used on infected wounds		If too wet, dressing will macerate surrounding skin; protect surrounding skin with moisture barrier ointment or skin sealant as needed

RESEARCH FOCUS

Title of Study

“A Study to Compare the Effects of a Thin Polyurethane Foam Dressing, a Hydrocolloid Dressing and a Nonadherent Dressing on the Healing Skin Tears in the Elderly”

Authors

Hart, D., Payne, R. L., Knox, D. M., & Neiheisel, M. B.

Purpose

The effects on the rate of wound healing in skin tears of three dressings were compared: thin polyurethane foam dressing; hydrocolloid dressing; nonadherent dressing.

Methods

This experimental design study used a convenience sample of 26 nursing home residents who had sustained a total of 45 skin tears. One of the three dressings were randomly assigned to the skin tears, and the rate of healing was measured by the number of days required to achieve a healed wound.

Findings

Although all skin tears showed evidence of healing, the thin polyurethane foam dressing and the hydrocolloid dressing healed faster than the nonadherent dressing and required less time to complete dressing changes.

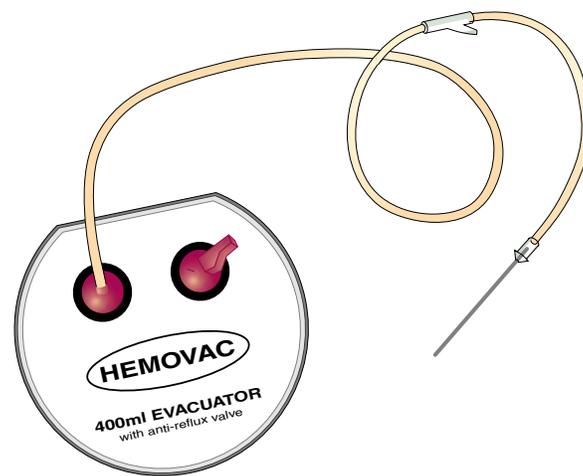

Implications

Choosing the type of dressing that supports healing for the specific type of wound decreases the client’s risk for infection as well as the cost to provide the care.

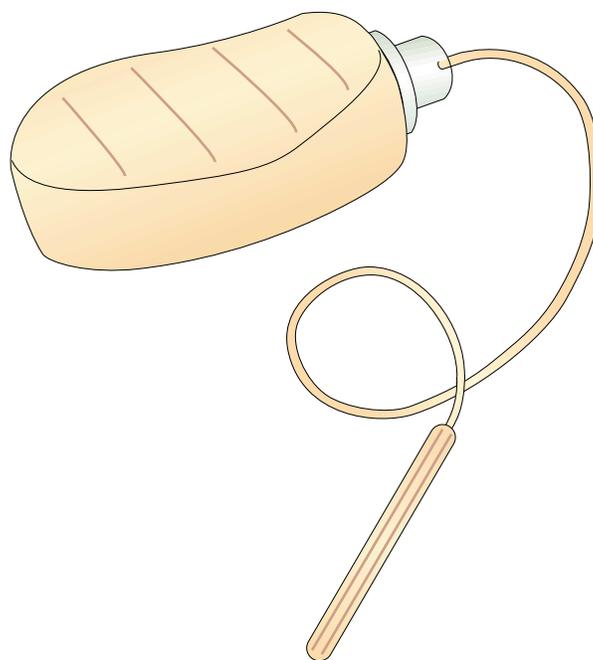

Hart, D., Payne, R. L., Knox, D. M., & Neiheisel, M. B. (1997). A study to compare the effects of a thin polyurethane foam dressing, a hydrocolloid dressing and a nonadherent dressing on the healing skin tears in the elderly. *Ostomy/Wound Management: The Journal for Extended Patient Care Management*, 43(3), 74.

reservoir that is capable of creating negative pressure or a vacuum. The gentle suction that is created draws exudate from the wound into the reservoir. As fluid enters the reservoir, suction is lost; therefore, the nurse must empty the reservoir when it is half full. Hemovac and Jackson-Pratt drains are examples of closed suction drainage systems (Figure 35-9).

Nurses are responsible for maintaining the patency of the system and for assessing the amount, type, and color of the drainage. It is important for the nurse to be

A. Closed System (Hemovac)

B. Tube and Reservoir System (Jackson-Pratt)

Figure 35-9 Drainage Systems

cautious when changing wound dressings to prevent accidental removal or dislodgement of drains.

Provide Suture Care

Sutures are a surgical means of closing a wound by sewing, wiring, or stapling the edges of the wound together. When placed deep within the tissue layers, sutures made of absorbable material are used so that the sutures will not need to be removed but rather can dissolve into the tissue. For surface closures, steel staples or sutures made of wire, nylon, cotton, or other materials are used; these need to be removed as the wound heals.

Nurses are often responsible for removing sutures and should therefore be familiar with different suturing

PROCEDURE 35-3

Applying a Dry Sterile Dressing

Equipment

- | | |
|---|---|
| <ul style="list-style-type: none"> ■ Clean disposable gloves ■ Moisture-proof bag ■ Sterile dressing set (if not available, gather the following): <ul style="list-style-type: none"> Sterile drape Gauze dressing and ABD pads (surgipads) Sterile container for cleansing solution Precut gauze if a drain is present | <ul style="list-style-type: none"> ■ Sterile gloves ■ Bath blanket ■ Cleansing solution (per MD order or agency protocol) ■ Adhesive remover ■ Tape or Montgomery straps |
|---|---|

Action

1. Review medical and nursing orders for dressing change procedure and list of needed supplies.
2. Prepare the client. Assess the client's comfort level and medicate as needed for pain.
3. Explain the procedure to the client. Wash hands, provide for privacy.
4. Position the client. Using a bath blanket, drape the client so that only the wound is exposed.
5. Place the moisture-proof bag within easy reach. Make a cuff on the bag by folding the top over.
6. Wash hands and don disposable gloves. Remove the soiled dressing.
 - a. If Montgomery straps or a binder were used, untie the tapes. If tape was used, gently remove tape by pulling up small sections at a time while holding down the skin in front of the tape (provides countertraction on the skin). If resistance is met, you may need to use adhesive remover (if skin is torn during tape removal, you have created another wound).
 - b. Carefully remove the outer protective dressing. Then remove the inner layers of gauze. If there is a drain present, use caution so that drains are not accidentally removed or dislodged.
 - c. Place the soiled dressings and disposable gloves in the moisture-proof bag.
7. Assess the wound; note the odor and presence of any drainage.

Rationale

1. A physician's order is needed to prescribe a cleansing solution. Nursing orders will describe individualized client needs, such as type and amount of dressing supplies needed.
2. Dressing changes may cause the client pain.
3. Client cooperation is necessary to avoid contamination of the wound. Explanation decreases anxiety and increases cooperation.
4. Provides privacy and prevents chilling.
5. Provides a receptacle for proper disposal of contaminated dressings.
6. Prevents transmission of microorganisms.
 - a. Careful removal of adhesive tapes prevents skin breakdown.
 - b. Exposes the wound.
 - c. Provides proper disposal and prevents contamination.
7. The wound needs to be assessed for signs of complications and healing.

(continues)

PROCEDURE 35-3

Applying a Dry Sterile Dressing (continued)

<i>Action</i>	<i>Rationale</i>
8. Open sterile dressing tray or set up sterile supplies and cleansing solution.	8. Maintains sterile technique.
9. Pour solution into sterile basin.	9. Keeps supplies sterile.
10. Don sterile gloves.	10. Sterile gloves are needed if the wound is open and if drains are present to prevent introduction of microorganisms.
11. Clean the wound with the cleaning solution and gauze. Gauze may be held with the forceps, or swabs may be used. Be sure to cleanse from the area least contaminated to the area more contaminated, and use a new swab for each stroke. If there is a drain present, cleanse this area last.	11. Always clean from the center of the wound to the outer area to avoid contamination of the wound by pathogens present on surrounding skin surfaces.
12. If a drain is present, apply precut dressing around the drain. Apply a thick second layer of gauze over the drain.	12. To absorb exudate and isolate drainage from the wound.
13. Apply sterile dressing over wound (Figure 35-10). Then cover with the surgipad.	13. Provides protection of the wound.
14. Secure the dressing with either tape or the ties from the Montgomery straps (Figure 35-11). Tape should be placed at the edges of the dressing so that the edges cannot be lifted to expose the wound. Paper tape should be used on clients with thin fragile skin and clients who have sensitive skin.	14. Montgomery straps are used when a wound needs to have frequent dressing changes to prevent skin breakdown.

Document all assessment findings and actions taken. | <ul style="list-style-type: none"> 15. Prevents transfer of pathogens. 16. Determines effect of dressing change; alerts to any client needs. 17. Records information for evaluation of progress of wound healing. |
|--|--|

NURSING ALERT

Removing Sutures

When removing sutures, never pull a suture back through the skin. Sutures beneath tissue are sterile, but those that are visible are considered contaminated, and pulling them through the tissue introduces a risk of infection. Instead, cut the suture as close to the skin as possible on one side, then pull it through the skin from the other side.

methods (Figure 35-12). Continuous sutures are made with one thread, tied at the beginning and end of the suture line. Intermittent sutures are each tied individually. In blanket continuous sutures, the single thread is grounded again in the last suture exit.

Checking Bandages, Binders, and Slings

Bandages and binders are applied over wound dressing sites: to secure, immobilize, or support a body part; to hold a dressing in place; or to prevent or minimize

PROCEDURE 35-4

Applying a Wet to Dry Dressing

Equipment

- Gather the equipment outlined in Procedure 35-3, plus:
- Sterile solution
- Fine mesh gauze
- Sterile forceps or sterile cotton swabs.

Action

Rationale

- | | |
|---|--|
| <ol style="list-style-type: none"> 1. Review medical and nursing orders for dressing change procedure and list of needed supplies. 2. Prepare the client. Assess the client's comfort level and medicate as needed for pain. 3. Explain the procedure to the client. Wash hands and provide for privacy. 4. Position the client. Using a bath blanket, drape the client so that only the wound is exposed. 5. Place the moisture-proof bag within easy reach. Make a cuff on the bag by folding the top over. 6. Remove the soiled dressing and assess the wound as outlined in Procedure 35-3, steps 6 and 7. 7. Open sterile dressing tray. Using aseptic technique, place fine mesh gauze in sterile container. Pour enough cleansing solution into the container to soak gauze. Don sterile gloves. 8. Clean the wound as described in Procedure 35-3, step 11. 9. Take one piece of fine mesh gauze and gently squeeze out the solution until the gauze is only slightly moist. 10. Open the gauze and <i>gently</i> pack the gauze into the wound, using either forceps or the top of a cotton swab stick. Continue until all surfaces of the wound are in contact with gauze. <i>Do not</i> pack the wound too tightly and <i>do not</i> overlap wound edges with wet packing. 11. Apply a layer of dry gauze over the wet gauze. Then cover with the ABD or surgipads. 12. Secure the dressing with either tape or Montgomery straps (see Procedure 35-3, actions 14–17). | <ol style="list-style-type: none"> 1. A physician's order is needed to prescribe a cleansing solution. Nursing orders will describe individualized client needs such as type and amount of dressing supplies needed. 2. Dressing changes may cause the client pain. 3. Client cooperation is necessary to avoid contamination of the wound. Explanation increases cooperation by decreasing anxiety. 4. Provides privacy and prevents chilling. 5. Provides a receptacle for proper disposal of contaminated dressings. 7. Sterile technique is used to prevent introduction of pathogens into the wound. 9. If the gauze is too moist, the wound bed can get too soupy, increasing the chance of bacterial growth (Wound-Care Update 91, [1991], p. 50). 10. If the wound is packed too tightly, capillaries can get compressed. If the wet packing overlaps the wound edges, it can cause maceration (softening and breakdown of tissue) (Wound-Care Update 91, [1991], p. 50). 11. Protects wound. |

swelling of a body part. Bandages are long rolls of material, such as gauze, webbing, or muslin, designed to be wrapped around body parts. Figure 35-13 illustrates several different methods of bandaging.

Binders are bandages made for specific body parts, usually the abdomen, perineal area, or arm (sling)

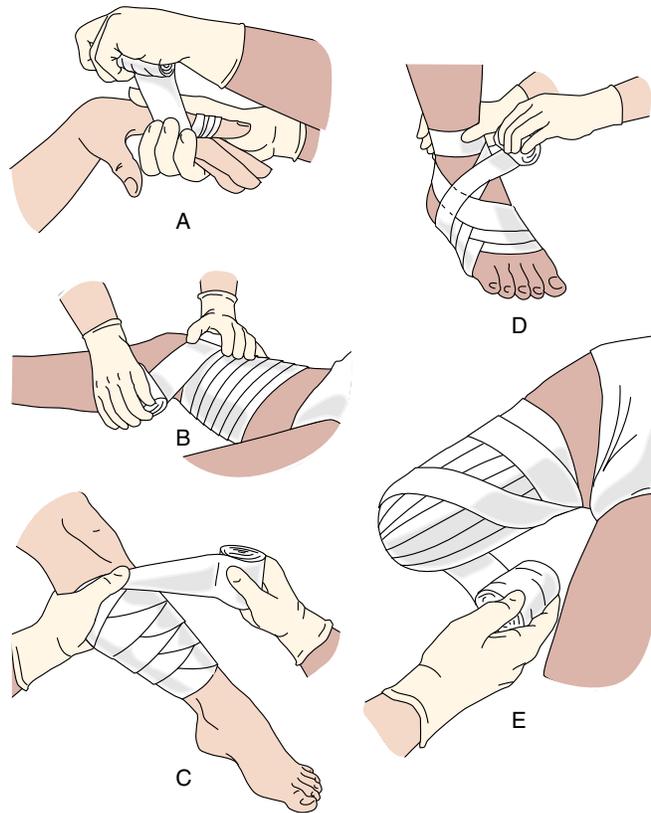

Figure 35-13 Common Bandaging Methods. A. *Circular turns* are wrapped around a body part several times to anchor the bandage or supply support; B. *Spiral turns* begin with a circular turn, then proceed up the body part, with each turn covering two-thirds the width of the preceding turn; C. *Spiral reverse turns* begin with a circular turn. Then the bandage is reversed, or twisted, once each turn to accommodate a limb that gets larger as the bandaging progresses; D. *Figure-eight turns* criss-cross in the shape of a figure eight and are used on a joint that requires movement. E. *Recurrent turns* are anchored with circular turns and follow a back-and-forth motion, and are completed with circular turns; used to cover a fingertip, head, or amputated stump.

APPLICATION: HOME CARE

Early discharge is one of the latest trends in health care. Clients are often being sent home with wounds that need special dressings. To facilitate an easy transition for the client from the hospital to the home, the nurse begins discharge planning during the admission assessment. At this time, the nurse determines the client's support system and availability to assist as caregivers, the home environment, and resources available to the client. Ongoing assessments provide the data for the identification of physical care and home environment needs. At times, a referral for home care nursing is necessary. Common areas for health teaching include:

- Wound care
- Diet therapy
- Medications
- Signs and symptoms of complications of wound healing

(Figure 35-14). Abdominal binders support the abdomen and are used following abdominal surgery or childbirth. Perineal binders, called T binders, are used to hold pads or dressings in the perineal area. Because of urination and defecation needs of clients, T binders must be changed regularly. A sling is a cloth support for an injured arm that wraps around the back of the neck to maintain the arm in a set position.

ADMINISTER HEAT AND COLD THERAPY

Cells in the hypothalamus act as a thermostat to regulate body temperature. When the hypothalamic thermostat detects that the body temperature is either too high or too low, it responds systemically by instituting appropriate temperature-decreasing (vasodilation, sweating) or temperature-increasing (vasoconstriction,

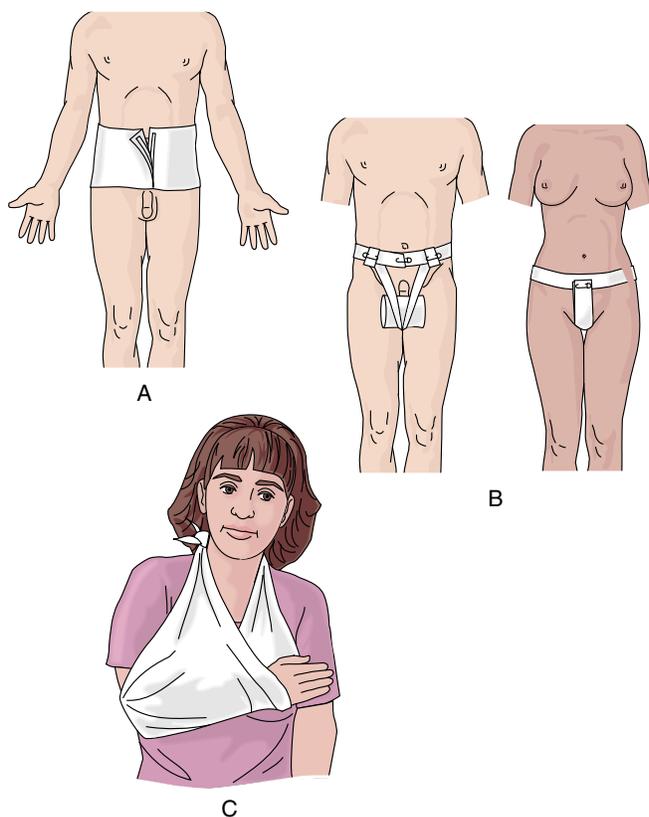

Figure 35-14 Common Binders. A. Abdominal. B. T binders: male and female. C. Arm sling.

NURSING CHECKLIST

Applying Bandages and Binders

When applying bandages and binders:

- Determine what type of support is needed for the wound and dressing.
- Note the appearance and condition of the skin and surrounding area, especially swelling, redness, excessive warmth, exudate, irritation, or uncovered wound areas.
- Ensure that the wound has a fresh sterile dressing *before* applying a bandage or binder to minimize intrusion and discomfort of the client for unnecessary dressing changes.
- Document the appearance of the skin that will be outside the bandage or binder, to monitor changes in circulation, temperature, color, or swelling that occur once the bandage or binder is in place.
- Replace soiled or damp bandages and binders promptly.

shivering) mechanisms to restore body temperature to the normal level.

Local responses to heat and cold occur through stimulation of temperature-sensitive receptors in the skin.

Impulses travel from the periphery to the hypothalamus and the cerebral cortex. The hypothalamus then initiates heat-producing or heat-reducing reactions of the body. The conscious sensations of temperature are aroused in the cerebral cortex.

Heat and cold receptors adapt to changes in temperature. On initial exposure, receptors are strongly stimulated by extremes in temperature, but, within a short time, this response declines as the receptors adapt to the new temperature variations. This adaptive ability of the body to temperature variations can be dangerous to clients insensitive to heat and cold extremes and may predispose them to serious injury. Nurses and clients need to understand this adaptive response when applying heat and cold.

Heat is one of the oldest nursing measures used to reduce pain and promote healing. Heat causes **vasodilation** and increases blood flow to the affected area, producing skin redness and warmth. Heat produces maximum vasodilation in 20 to 30 minutes; after this period, reflex vasoconstriction occurs along with tissue congestion. Periodic removal and reapplication of heat will restore vasodilation. Prolonged exposure to heat damages epithelial cells and results in redness, tenderness, and even blister formation.

The application of cold lowers the temperature of the skin and underlying tissues and causes **vasoconstriction**. Vasoconstriction reduces blood flow to the affected area and produces skin pallor or a bluish discoloration and coolness. Maximum vasoconstriction is achieved at 15°C (60°F); at temperatures below 15°C, the vessels begin to dilate. Prolonged exposure to cold results in a reflex vasodilation. Initially the skin is reddened, but later it takes on a bluish purple mottled appearance with numbness and pain because of impaired circulation and tissue ischemia. Vasodilation and vasoconstriction of the blood vessels in the skin result primarily from increased sensitivity of the vessels to nerve stimulation but also from a protective reflex response that passes to the spinal cord and then back to the vessels. The therapeutic effects of heat and cold applications are outlined in Table 35-4.

The body's response to the application of heat and cold is influenced by a number of factors. See the accompanying display for a discussion of the factors that affect tolerance to heat and cold.

The following conditions necessitate precautions in the use of heat and cold applications:

- **Neurosensory impairment:** Clients with reduced perception of sensory or painful stimuli (e.g., spinal cord injuries) are at an increased risk for tissue injury.
- **Impaired mental status:** Clients who are confused or unconscious need to be monitored and assessed frequently to ensure safety.
- **Impaired circulation:** Clients with cardiovascular and peripheral vascular problems or diabetes may not have the ability to dissipate heat through dilation of

TABLE 35-4
Therapeutic Effects of Heat and Cold Applications

Physiological Responses	Therapeutic Benefits
Heat Therapy	
Promotes vasodilation. Decreases blood viscosity. Increases tissue metabolism. Increases capillary permeability. Reduces muscle tension.	Improves blood flow. Increases delivery of oxygen and nutrients, leukocytes, antibodies to facilitate the inflammatory process. Facilitates removal of wastes and toxins. Produces a local warming effect. Decreases venous congestion in injured tissues. Increases absorption of fluid by capillaries and promotes removal of excess fluid from interstitial spaces, thereby reducing edema. Promotes muscle relaxation and decreases pain from spasm or stiffness.
Cold Therapy	
Promotes vasoconstriction. Increases blood viscosity. Decreases tissue metabolism. Has a local anesthetic effect. Decreases muscle tension.	Decreases blood flow to site of injury, thereby decreasing inflammation and edema formation. Decreases blood flow, facilitating clotting and control of bleeding. Reduces the tissues' oxygen consumption. Raises the threshold of pain receptors, thereby decreasing pain.

blood vessels and are at an increased risk for tissue injury.

- Skin and tissue integrity (open wounds, broken skin, scar formation, edema): Subcutaneous tissues are more sensitive to temperature variations than are superficial tissues (e.g., cold can decrease blood flow to an open wound, thereby inhibiting healing).

Heat and cold can be applied in dry and moist forms (Figure 35-15). The type of wound or injury, location, and presence of drainage or inflammation are considered when selecting moist or dry applications. See Table 35-5 for a discussion on the various forms of dry and moist heat and cold, their therapeutic effects, and general guidelines for their application.

FACTORS AFFECTING HEAT AND COLD TOLERANCE

- Body part: Certain areas of the skin have a sensitivity to temperature variations. The inner aspect of the wrist and forearm, the neck, and the perineal area are temperature-sensitive, while the back of the hand and the foot are not as sensitive.
- Duration of application: Therapeutic benefits of heat and cold applications are achieved with short periods of exposure to temperature variations. Tolerance increases as the length of exposure increases.
- Area of body exposed: The larger the area exposed to heat and cold, the lower the tolerance to temperature changes.
- Damage to body surface area: Injured skin areas are more sensitive than intact areas to temperature variations.
- Individual tolerance: Tolerance to temperature variations is affected by age and physical condition. The young and the aged are especially susceptible to heat and cold. Neurosensory impairments may interfere with the reception and perception of stimuli, increasing the risk of injury.
- Age: Thinner skin layers in children and elderly people increase the risk for burns from the heat and cold applications. Older adults have a decreased sensitivity to pain.

TABLE 35-5
Overview of Heat and Cold Applications

DRY	
Heat	Cold
<p>Hot water bag</p> <ul style="list-style-type: none"> • Fill two-thirds full with warm water and remove air at the top so the bag is easier to mold over the body part. • Cover bag with a towel or pillowcase (never apply directly on the skin surface). • Keep bag in place for 20–30 minutes and then remove. • Do not allow the client to lie on the hot water bag. <p>Hot packs</p> <ul style="list-style-type: none"> • Commercially prepared, disposable hot packs supply warm dry heat to an injured area. • Striking or squeezing the pack will release chemicals that create the heat. <p>Aquathermia pads</p> <ul style="list-style-type: none"> • Are useful in treating muscle sprains and for areas with mild inflammation or edema. • Unit consists of a waterproof plastic or rubber pad connected by two hoses to an electrical control unit that has a heating element and a motor. The reservoir of the unit is filled two-thirds full with distilled water. • The desired temperature is usually set with a key at 45°C for adults. • Cover the pad with a thin cloth or pillowcase prior to application. • Treatment usually continues for 20–30 minutes. • Do not have client lie on pad. <p>Electrical heating pads</p> <ul style="list-style-type: none"> • Provide constant, even heat, are lightweight, and can easily be molded to a body part. • Unit composed of electrical coil enclosed within a waterproof pad covered with cotton or flannel cloth. • Instruct the client to avoid using high setting, to prevent burns. • Do not insert sharp objects into the pad. • Do not allow the client to lie directly on the pad, because heat will not dissipate and the client may be burned. 	<p>Ice bag, ice collar</p> <ul style="list-style-type: none"> • Fill two-thirds full with crushed ice so bag is easier to mold over body part. • Cover bag with towel or pillowcase and apply to affected area for 30 minutes. • Provides cold to localized area (e.g., muscle sprain, hematoma) to prevent edema formation, control bleeding, and anesthetize body part. <p>Cold packs</p> <ul style="list-style-type: none"> • Commercially prepared single-use ice packs provide cold for designated period of time. • When the pack is squeezed or kneaded, an alcohol-based solution is released, creating the cold temperature.
MOIST	
Heat	Cold
<p>Warm compresses (gauze dressing moistened in a prescribed warmed solution)</p> <ul style="list-style-type: none"> • Applied to improve circulation, relieve edema, and hasten the suppurative process and healing. • For an open wound, use sterile technique. • Solution to moisten the gauze can be heated first to 40.5°C (105°F) or according to agency protocol, or procedure is similar to application of a wet to dry dressing and the use of a hot water bag or a heating pad to cover the dressing. • Remove compress after 20–30 minutes and redress wound. 	<p>Cold compresses</p> <ul style="list-style-type: none"> • Applied to either decrease or prevent bleeding and to reduce inflammation. • Procedure similar to that for warm compresses except cold compresses applied for 20 minutes at a temperature of 15°C (59°F). • Technique may be clean or sterile. • Observe for signs and symptoms of burning or numbness, mottling of the skin, redness, extreme paleness, or a bluish skin discoloration. <p style="text-align: right;"><i>(continues)</i></p>

TABLE 35-5 (continued)
Overview of Heat and Cold Applications

Heat	Cold
<p>Warm soaks</p> <ul style="list-style-type: none"> • Immersion of body part in warmed solution promotes circulation, decreases edema, increases muscle relaxation, and provides a means to debride wounds and apply medicated solution. • Can also be accomplished by wrapping body part in dressings and saturating them with warmed solution. • Position client comfortably, place waterproof pads under the area to be treated. • Sterile technique is generally indicated for open wounds, such as a burn. Check agency protocol regarding the temperature of the solution. <p>Sitz bath</p> <ul style="list-style-type: none"> • Used for clients who have had rectal surgeries, an episiotomy during childbirth, painful hemorrhoids, or vaginal inflammation. • Only the client's pelvic area is immersed in warm fluid; the client sits in a special tub or chair or in a basin placed on the toilet seat so that the legs and feet remain out of the water (immersing the entire body causes widespread vasodilation, negating the effect of local heat to the perineum or pelvic area). • Water temperature should be from 40° to 43°C (105° to 110°F). • Duration of the bath is usually 15–20 minutes. • Prevent overexposure and chilling by draping a bath blanket over the client's shoulders and thighs, and prevent drafts. • Assess the client during the bath for extensive vasodilation, faintness, dizziness, weakness, increased pulse rate, and pallor. 	<p>Cold soaks</p> <ul style="list-style-type: none"> • Procedure similar to that for warm soaks. • Desired temperature for a 20-minute soak is 15°C (59°F). • Take precautions (such as preventing drafts and draping shoulders) to prevent client from chilling.

(From Lehmann, J. F. [Ed.]. [1982]. *Therapeutic heat and cold* [3rd ed.]. Baltimore, MD: Williams & Wilkins.)

Evaluation

The nurse needs to evaluate the client's achievement of the goals established during the planning phase to achieve or maintain skin integrity. Goals for clients with wounds generally focus on wound healing, prevention of infection, and client education. If the goals are not achieved, the nurse will need to examine the nursing interventions and strategies that were employed and revise the nursing care plan accordingly. Reviewing techniques and procedures, especially those performed by the client or other caregivers in the client's support system, is especially important.

PRESSURE ULCERS

Pressure ulcers, also known as bedsores or decubitus ulcers, are localized areas of tissue necrosis that tend to develop when soft tissue is compressed between a bony prominence and an external surface for a prolonged period of time (National Pressure Ulcer Advisory Panel,

NURSING CHECKLIST *Heat and Cold Applications*

General guidelines to follow when using heat and cold applications include:

1. Obtain a physician's order that details the site to be treated, the type of therapy, and the frequency and duration of application.
2. Select temperature on the basis of client status and agency policy.
3. Thoroughly explain procedure and expected benefits to client.
4. Assess client's status before, during, and after treatment is performed to prevent injury.
5. Document effects of therapy.

1989). Pressure ulcers are due to **ischemia**, or decreased blood supply, and commonly occur in areas subject to high pressure from body weight on bony prominences.

Physiology of Pressure Ulcers

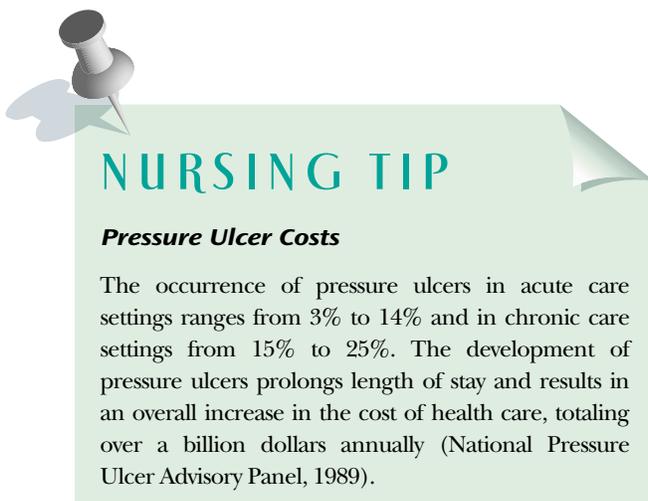

The reduction of blood flow causes **blanching** (white color) of the skin when pressure is applied. When pressure is relieved, the skin takes on a brighter color (reactive hyperemia) due to vasodilation, the body's normal compensatory response to the absence of blood flow. If this area blanches with fingertip pressure or if the redness disappears within an hour, no tissue damage is anticipated. If, however, the redness persists and no blanching occurs, then tissue damage is present.

Other forces acting in conjunction with pressure contribute to pressure ulcer formation. **Shearing** is the force exerted against the skin when a client is moved or repositioned in bed by being pulled or allowed to slide down in bed. The skin and subcutaneous tissue tend to adhere to the bed surface and remain stationary while deeper underlying tissues pull away and slide in the direction of movement. This action results in stretching and tearing of blood vessels, reduced blood flow, and necrosis. Shearing forces account for the high incidence of sacral ulcers.

Friction is the force of two surfaces moving across one another. When a client moves or is pulled up in bed, rubbing of the skin against the sheets creates friction. Friction can remove the superficial layers of the skin, making it more prone to breakdown.

Risk Factors for Pressure Ulcers

Pressure ulcers can be prevented if at-risk individuals and the specific factors placing them at risk can be identified. Many risk factors have been associated with pressure ulcer formation, including immobility and inactivity, incontinence, malnutrition, decreased mental status, diminished sensation, and age-related changes. Individuals should be assessed for pressure ulcer risk on admission to acute care hospitals, nursing homes, and other health care facilities (USDHHS, 1992). Validated risk assessment tools such as the Braden Scale (Braden, 1989) or the Norton Scale (Norton, 1989) can be used to predict who will or will not develop pressure ulcers (Tables 35-6 and 35-7).

NURSING TIP

Pressure Ulcer Costs

The occurrence of pressure ulcers in acute care settings ranges from 3% to 14% and in chronic care settings from 15% to 25%. The development of pressure ulcers prolongs length of stay and results in an overall increase in the cost of health care, totaling over a billion dollars annually (National Pressure Ulcer Advisory Panel, 1989).

Assessment

Pressure ulcers are staged to classify the degree of tissue damage (Figure 35-16). The revised National Pressure Ulcer Advisory Panel (USDHHS, 1998) recommends the following staging system:

- **Stage I.** Nonblanchable erythema of intact skin; the heralding lesion of skin ulceration. In individuals with darker skin, discoloration of the skin, warmth, edema, induration, or hardness may also be indicators.
- **Stage II.** Partial thickness skin loss involving epidermis or dermis. The ulcer is superficial and presents clinically as an abrasion, blister, or shallow crater.
- **Stage III.** Full-thickness skin loss involving damage or necrosis of subcutaneous tissue that may extend down to, but not through, underlying fascia. The ulcer presents clinically as a deep crater with or without undermining of adjacent tissue.
- **Stage IV.** Full-thickness skin loss with extensive destruction, tissue necrosis, or damage to muscle, bone, or supporting structures. Undermining and sinus tracts may also be associated with Stage IV pressure ulcers.

Nursing Diagnoses

Nursing diagnoses for clients with pressure ulcers will be similar to those for clients with wounds, because the type of injury and its consequences are similar. The emphasis is on gentle client care and client teaching to promote healing of the ulcer and to prevent its recurrence. Identifying the client's psychological needs as well, in terms of diagnoses such as *Disturbed Body Image* and *Anxiety*, will ensure that the client's symptoms are addressed holistically.

Outcome Identification and Planning

As with nursing diagnoses, the outcome identification and planning phase of the nursing process for relieving pressure ulcers is similar to that for clients with wounds. Individualized outcomes based on the client's overall physical condition, the stage of the wound, and the client's risk factors will help in identifying priority interventions. Client teaching should be included as an integral part of the planning process; if the client desires, family and support persons should be brought into the learning circle as well.

Implementation

Pressure ulcers can be prevented through a variety of measures. Early identification of high-risk individuals and contributing risk factors and an ongoing assessment of risk

TABLE 35-6
Braden Scale Risk Predictors for Skin Breakdown

Patient's Name _____		Evaluator's Name _____						
		Date of Assessment _____						
Sensory perception Ability to respond to discomfort	1. Completely limited: Unresponsive to painful stimuli, either because of state of unconsciousness or severe sensory impairment, which limits ability to feel pain over most of body surface.	2. Very limited: Responds only to painful stimuli (but not verbal commands) by opening eyes or flexing extremities. Cannot communicate discomfort verbally, OR has a sensory impairment which limits the ability to feel pain or discomfort over one-half of body surface.	3. Slightly limited: Responds to verbal commands by opening eyes and obeying some commands, but cannot always communicate discomfort or need to be turned, OR has some sensory impairment that limits ability to feel pain or discomfort in one or two extremities.	4. No impairment: Responds to verbal commands by obeying. Can communicate needs accurately. Has no sensory deficit that would limit ability to feel pain or discomfort.				
Moisture Degree to which skin is exposed to moisture	1. Very moist: Skin is kept moist almost constantly by perspiration and urine. Dampness is detected every time patient is moved or turned. Linen must be changed more than one time each shift.	2. Occasionally moist: Skin is frequently, but not always, kept moist; linen must be changed two to three times every 24 hours.	3. Rarely moist: Skin is rarely moist more than three to four times a week, but linen does require changing at that time.	4. Never moist: Perspiration and incontinence are never a problem; linen changed at routine intervals only.				
Activity Degree of physical activity	1. Bedfast: Confined to bed.	2. Chairfast: Ability to walk severely impaired or nonexistent and must be assisted into chair or wheelchair. Is confined to chair or wheelchair when not in bed.	3. Walks occasionally: Walks occasionally during day, but for very short distances, with or without assistance. Spends majority of each shift in bed or chair.	4. Walks frequently: Walks a moderate distance at least once every 1 to 2 hours during waking hours.				

(continues)

TABLE 35-6 (continued)
Braden Scale Risk Predictors for Skin Breakdown

Mobility Ability to change and control body position	1. Completely immobile: Unable to make even slight changes in position without assistance.	2. Very limited: Makes occasional slight changes in position without help but unable to make frequent or significant changes in position independently.	3. Slightly limited: Makes frequent though slight changes in position without assistance but unable to make or maintain major changes in position independently.	4. No limitations: Makes major and frequent changes in position without assistance.				
Nutrition Usual food intake pattern	1. Very poor: Never eats a complete meal. Rarely eats more than one-third of any food offered. Intake of protein is negligible. Takes even fluids poorly. Does not take a liquid dietary supplement, OR is NPO and/or maintained on clear liquids or IV for more than 5 days.	2. Probably inadequate: Rarely eats a complete meal and generally eats only about one-half of any food offered. Protein intake is poor. Occasionally will take a liquid dietary supplement, OR receiving less than optimum amount of liquid diet or tube feeding.	3. Adequate: Eats over half of most meals. Eats moderate amount of protein source one to two times daily. Occasionally will refuse a meal. Will usually take a dietary supplement if offered, OR is on a tube feeding or TPN regimen that probably meets most of nutritional needs.	4. Excellent: Eats most of every meal. Never refuses a meal. Frequently eats between meals. Does not require a dietary supplementation.				
Friction and shear	1. Problem: Requires moderate to maximum assistance in moving. Complete lifting without sliding against sheets is impossible. Frequently slides down in bed or chair, requiring frequent repositioning with maximum assistance. Either spasticity, contractures, or agitation leads to almost constant friction.	2. Potential problem: Moves feebly independently or requires minimum assistance. Skin probably slides against bedsheets or chair to some extent when movement occurs. Maintains relatively good position in chair or bed most of time but occasionally slides down.	3. No apparent problem: Moves in bed and in chair independently and has sufficient muscle strength to lift up completely during move. Maintains good position in bed or chair at all times.					
				Total Score				

Key: 16, minimum risk; 13–14, moderate risk; 12 or less, high risk; NPO nothing by mouth; IV, intravenously; TPN, total parenteral nutrition.

factors and skin integrity should be done to decrease the possibility of pressure ulcer formation. Other areas to focus on in the prevention of pressure ulcers include hygiene and skin care, positioning, and the use of support surface therapy. The following interventions may be used as guidelines by the nurse in caring for adult clients at risk for pressure ulcer development. They are based on recommendations developed by the Agency for Health Care Policy and Research (USDHHS, 1992).

Ensure Proper Hygiene and Skin Care

Proper skin care is essential to preventing skin breakdown. To maintain and improve tissue tolerance to pressure, the nurse should perform the following interventions:

- Assess the skin at least once a day, paying particular attention to bony prominences.

THINK ABOUT IT

Caring for Clients with Pressure Ulcers

Advanced-stage pressure ulcers can have extensive necrotic tissue, significant drainage, and very strong odor. Have you ever seen skin in an advanced stage of tissue deterioration? How would you feel about caring for a client with a stage IV pressure ulcer? Would your opinion be different if the client were an 8-year-old comatose child or an 80-year-old bedridden client?

- Cleanse the skin at routine intervals and at time of soiling. Keep the client's skin clean, dry, and free of irritation and maceration by urine, feces, and sweat. A moisture barrier cream can also be applied to the perineal area to protect the skin from moisture and toxins from urine and stool.
- Use warm water and mild cleansing agents so as not to irritate and dry the skin. Avoid the use of soaps and alcohol-based lotions, which may cause drying and leave an alkaline residue that discourages normal skin bacteria, leading to growth of opportunistic bacteria. Minimize the force and friction applied to the skin during cleansing so as not to disrupt the "natural barrier" to the skin.
- If the skin is dry, use moisturizing lotions and minimize exposure to cold and low humidity, which can cause dryness of the skin.
- Avoid massage over bony prominences. Current evidence suggests that massage may be harmful and cause deep tissue trauma (Maklebust, 1991; USDHHS, 1992).

Provide Proper Positioning

Positioning interventions prevent the adverse effects of pressure, friction, and shear. For most clients, maintaining current activity levels, mobility, and range of motion is sufficient to prevent pressure ulcers. For the immobilized client, the following interventions may help prevent the development of pressure ulcers:

- Turn and reposition client at least every 2 hours so that ischemic areas can recover. If a reddened area does not blanch when you press it, turn the client more often.
- When positioning, pay attention to body alignment. The position shown in Figure 35-17 relieves pressure on the sacrum and trochanters. There should be a 30° angle between the client's trochanters and the surface of the bed. The hips and knees should be flexed. To maintain this position, support the client's back with a pillow or foam wedge, and put a pillow between the knees.
- When turning the client, remove the pillows and wedges, lower the head of the bed, and use a draw

sheet to lift, not drag, the client to a new position. Maintain the head of the bed at 30° or less to prevent shearing.

- If the client is supine, make sure the heels are not resting on the mattress. Suspend them by placing a pillow or foam pad lengthwise under the lower legs.
- Place at-risk clients on pressure-reducing surfaces.
- Have clients who are able to sit up shift their weight every 15 minutes; those who can not do so need to be repositioned at least every hour.
- Use a pressure-reducing device such as a foam overlay on the seating surface to reduce pressure on the ischial tuberosities by redistributing weight over a much larger surface area. Do not use donut-shaped cushions, which reduce blood supply to the affected area, leading to even more ischemia.

Employ Support Surfaces

A variety of support surfaces are available to support the entire body and evenly distribute pressure. These devices can be used as adjunct therapy to help reduce pressure and prevent ulcers, but they are no substitute for frequent positioning and there is no scientific evidence that any one support surface works consistently better than any other (USDHHS, 1992).

In addition to pressure reduction or relief, many support surfaces reduce shear and friction and control moisture. Pressure-reducing support surfaces include overlays filled with foam, gel, or water (e.g., eggcrate mattresses, alternating air-filled mattresses) and replacement mattresses (replace standard mattresses). Pressure-relieving devices include specialty beds that replace hospital beds. Examples are low-air-loss (LAL) beds (e.g., Flexicair), air-fluidized beds (e.g., Clinitron), and beds that provide kinetic therapy. Kinetic beds (e.g., Rotorest) provide continuous passive motion or oscillation to counteract the effects of immobility. See Chapter 34 for a complete discussion of beds used to counteract the effects of immobility. See Table 35-8 for a list of selected support devices.

Complementary Therapies

Nature is rich in plants that promote healing of cuts, burns, and wounds. Herbalists recognize that skin problems may reflect a variety of internal conditions; therefore herbs used to treat wounds are selected based on

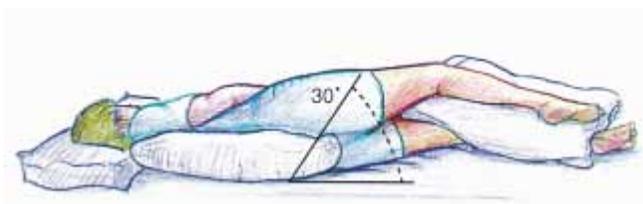

Figure 35-17 Avoiding Pressure Points with the 30° Lateral Position

Type	Examples	Manufacturer	Indications	Advantages	Disadvantages
Air fluidized	Clinitron Fluid Air Skytron	Support Systems International Kinetic Concepts Skytron	Patients who require minimal movement to prevent skin damage by shearing forces Pressure relief	Minimum pressure on bony prominences; fluidization makes turning easy. Facilitates drainage and substance in beads reduces risk of infection.	Heavy, transport difficult. Foam backrest provides limited head elevation. Drying effect may inhibit cough and may dehydrate.
Rotation	Tilt and Turn Paragon Keone Mobility Rotorest	SMI Patient Care Mediscus Group Kinetic Concepts	Patients who require frequent turning but have unstable spines Movement, skeletal stability	Skeletal stability. Mobilizes secretions. Supports traction.	Movement increases risk of friction and shearing and may cause motion sickness.
Bariatric	Burke	Kinetic Concepts	Management of morbidly obese	Supports independence; converts to chair.	Not wide enough to facilitate repositioning.

NURSING CARE PLAN**Client with Impaired Skin Integrity****Case Presentation**

Mr. Short is a 48-year-old client who was involved in a motor vehicle accident. Three days after abdominal surgery he develops fever, tenderness around incision, and purulent drainage from the wound. The physician opens the incision and orders normal saline wet to dry dressing changes three times a day.

Assessment

- Temperature 101.8°F
- Pulse 110
- Respirations 20
- BP 130/70
- Incision—red, tender, to touch, yellow purulent drainage
- Labs—WBC ↑

Nursing Diagnosis #1

Impaired Skin Integrity related to presence of contaminants.

Expected Outcomes

1. Within 1 week the client's wound will be free of infection as evidenced by:
 - a. Absence of fever
 - b. Absence of redness, exudate
 - c. Normal WBC count
2. Within 1–2 weeks the client's wound will exhibit signs of healing as evidenced by:
 - a. Presence of granulation tissue
 - b. Wound's being closed and without drainage

Interventions/Rationales

- 1a. Assess and document the wound for presence of redness, pain, exudate with every dressing change.
Exudate indicates infection.
- 1b. Assess VS q4h.
VS reflect client's overall condition.
- 1c. Assess WBC count.
WBC counts show progression of infection.
- 2a. Apply wet to dry dressing changes tid utilizing sterile technique.
Promotes clean environment, which encourages wound healing.
- 2b. Ensure good handwashing before and after all dressing changes.
Limits exposure of incision to pathogens.

Evaluation

The client should be free of infection, with no evidence of fever, redness, or exudate. WBC and VS should be within normal range within one week. The wound should exhibit beefy red granulation tissue, and the wound edges should be contracting 1 week after admission.

their internal and external actions (Hoffmann, 1998). Herbs that create the following actions are particularly useful for wound healing: vulneraries (promote healing of wounds and ulcers), alteratives (restore proper bodily function), diaphoretics (promote sweating and capillary dilation), antimicrobial (resist pathogenic microorganisms, usually by strengthening the immune system), and nervines (act on the nervous system as

either tonics, relaxants, or stimulants). Some of the vulnerary herbs discussed below also work as an astringent (bind to skin and mucous tissue, reduce irritation and inflammation, protect against infections) to arrest bleeding and to condense tissue.

Chickweed, a common garden weed, is a vulnerary and anti-microbial. It may be applied directly to an insect bite to relieve itching and irritation or used as an

ointment in combination with marshmallow for cuts and wounds (Tierra, 1998).

Comfrey contains a chemical, allantoin, that stimulates cell proliferation and promotes wound healing both inside and out. Although it can be used internally to treat gastric and duodenal ulcers, comfrey is often used externally as a compress or poultice to speed healing of wounds and fractures and reduce scarring. *Caution is given when using comfrey to treat deep wounds since it can lead to tissue forming over the wound before the wound heals from within, creating a risk for an abscess to form* (Goldberg, 1999). The anticancer action of this herb has been reputed and it should be used with caution in anyone with a family history of cancer.

Aloe vera is a common household plant. The juice from the plant is used externally to treat minor cuts and burns, sunburn, and insect bites. It has been used effectively to decrease the scarring from acne. Aloe is primarily a vulnerary herb that promotes wound healing and has an antimicrobial action. Internally this herb is used as a cathartic and emmenagogue (normalize and tone the female reproductive system) and should be used with *caution during pregnancy and should be avoided during breastfeeding since it is excreted in the mother's milk. Caution is given when taking dieter's teas containing aloe and other substances; they act as laxatives when consumed in large quantities, can disrupt potassium levels and contribute to cardiac arrhythmias* (Fontaine, 2000).

Woundwort is a vulnerary, antiseptic, antispasmodic, and astringent used primarily as a wound healer. It is equivalent to comfrey as a wound healer and may be used directly on the wound or as a ointment or compress (Hoffmann, 1998).

Other herbs that may be used to promote wound healing and relieve irritation and pain associated with an ulcer or wound are tea tree oil, lavender oil, colloid silver, *echinacea*, golden seal (refer to Chapter 31 for a complete discussion of their antimicrobial action), slippery elm, knitbone, and self-heal.

Although most wounds heal with a well-balanced diet, special attention should be given to the diet when wounds are at risk for infection. Avoid stressor foods such as refined sugars, excess caffeine, and alcoholic beverages because they may decrease the body's immune function and healing (Goldberg, 1999). The diet should be rich in essential fatty acids, vitamin A, zinc, and vitamin C to promote the skin's healing. Foods rich in these essential elements are: green and yellow vegetables, eggs, cold water fish, raw seeds and nuts, oysters.

Evaluation

Evaluation of the plan of care for a client with a pressure ulcer will consider the physical signs of healing and the status of the pressure ulcer, as well as the client's adapta-

tion to the altered skin integrity. Each intervention should be evaluated for its effectiveness, and the plan of care revised to reflect those actions that have proven the most beneficial in realizing the expected outcomes of care.

KEY CONCEPTS

- A wound is a disruption in the integrity of the body tissue that puts an individual at risk for infection.
- Wounds go through a three-step healing process that includes a defensive (inflammatory) phase, a reconstructive (proliferative) phase, and a maturation phase.
- The type of exudate from a wound can help determine the pathology of the infectious process.
- Wounds are often classified by their cause, level of cleanliness, depth, or color.
- Nursing diagnoses for clients with wounds and pressure ulcers focus on both the physical (pain, infection, impaired tissue integrity) and the psychosocial (anxiety, deficient knowledge, disturbed body image) aspects.
- A significant nursing intervention in all cases of impaired skin integrity is client education on wound care and promotion of healing; the client's support people are often included in this teaching.
- Heat and cold applications help the body's own systems respond to and therefore relieve the pain that accompanies wounds.
- Pressure ulcers, or bedsores, are a common problem in acute and chronic care settings, resulting in longer stays for clients and increased costs of health care.
- Pressure ulcers are classified into four stages, depending on the depth of tissue damage.
- Proper positioning is the most effective preventive measure for pressure ulcers.

CRITICAL THINKING ACTIVITIES

1. Describe the similarities and differences between wounds and pressure ulcers in terms of their formation, physiology, and care.
2. Define each of the three phases of wound healing, and outline the process that each represents.
3. Differentiate among primary, secondary, and tertiary intention healing.
4. What are the different types of exudate, and what does each indicate?
5. Describe measures the nurse and client can take to promote wound healing and to prevent complications that often hinder the wound-healing process.
6. Explain to a colleague the process of hot and cold therapeutic applications and the mechanics of how and why they work.
7. What steps should a nurse take to ensure that a comatose client will not develop pressure ulcers?

Chapter 36

Sensation, Perception, and Cognition

The question is not what you look at, but what you see.

—Henry David Thoreau

COMPETENCIES

1. Describe normal cognitive and sensory perceptual functioning.
2. Identify responses to sensory deprivation and overload.
3. Describe cognitive development across the lifespan.
4. Identify nursing diagnoses pertinent to clients experiencing cognitive and sensory perceptual impairments.
5. Describe the learning needs of clients experiencing alterations in cognition and sensory perception.
6. Explain the use of the nursing process with clients experiencing alterations in cognition and sensory perception.

KEY

sensory perception

Sensation is the ability to receive and process stimuli received through the sensory organs. There are two types of stimuli: external and internal. External stimuli are received and processed through the sight (visual), hearing (auditory), smell (olfactory), taste (gustatory), and touch (tactile) modes. Internal stimuli are received and processed through kinesthetic (an awareness of the position of the body) and visceral (feelings originating from large organs within the body) modes.

Perception is the ability to experience, recognize, organize, and interpret sensory stimuli. **Sensory perception** is the ability to receive sensory impressions and, through cortical association, relate the stimuli to past experiences and to form an impression of the nature of the stimulus.

Perception is closely associated with **cognition**, the intellectual ability to think. The processes of organizing and interpreting stimuli are dependent on a person's level of intellectual functioning. Cognition includes the elements of memory, judgment, and orientation. The well-being of an individual is dependent on the functions of sensation, perception, and cognition because it is through these mechanisms that the person fully experiences and interacts with his or her environment.

Sensory, perceptual, and cognitive alterations can be either temporary or progressive in their manifestations and can result from disease or trauma. Whatever the status or cause of the alterations, these conditions usually lead to social isolation and increased dependence on others. In addition, impairment in sensory, perceptual, and cognitive functions can place the individual at risk for injury to self or to others.

This chapter discusses the physiology of sensation, perception, and cognition and the common alterations in each functional area. Information on the nurse's role in caring for individuals with sensory, perceptual, or cognitive alterations is presented.

PHYSIOLOGY OF SENSATION, PERCEPTION, AND COGNITION

Sensation, perception, and cognition are neurological functions. The nervous system is composed of two major subsystems: the central nervous system (CNS) and the

peripheral nervous system (PNS), which consists of the somatic and autonomic nervous systems (Figure 36-1).

The CNS and PNS act in unison to accomplish three purposes: collection of stimuli from the receptors at the end of the peripheral nerves; transport of the stimuli to the brain for integration and cognition processing; and conduction of responses to the stimuli from the brain to responsive motor centers in the body.

The CNS is composed of the brain and spinal cord, which are protected by the bony structures of the skull and vertebral column. The brain, the most complex of the body's organs, is composed of three basic structures: the cerebrum (which consists of the temporal, frontal, parietal, and occipital lobes); the cerebellum, and the brain stem (Figure 36-2). Table 36-1 describes each of these structures. The structures of the brain serve as both receptors and reactors by collecting stimuli and effecting responses to those stimuli. The spinal cord links the advanced neurosensory mechanisms that occur in the brain to the rest of the body via a coordinated pathway of neurons.

Sensory perception involves the function of both the cranial and peripheral nerves. The cranial nerves arise from the three structures of the brain and govern the movement and function of various muscles and nerves throughout the body (Figure 36-3). The peripheral nerves connect the CNS to other parts of the body (Figure 36-4).

Components of Sensation and Perception

The sensory system is a complex network that consists of **afferent nerve pathways** (ascending pathways that trans-

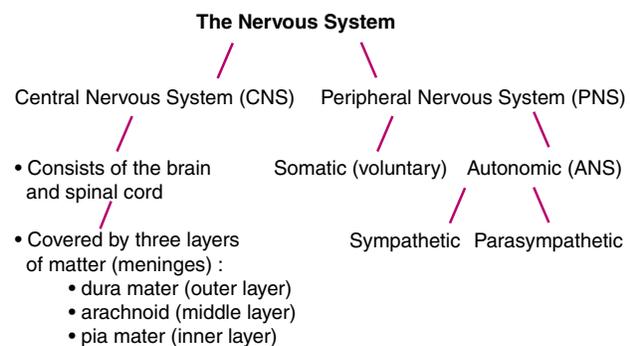

Figure 36-1 The Nervous System

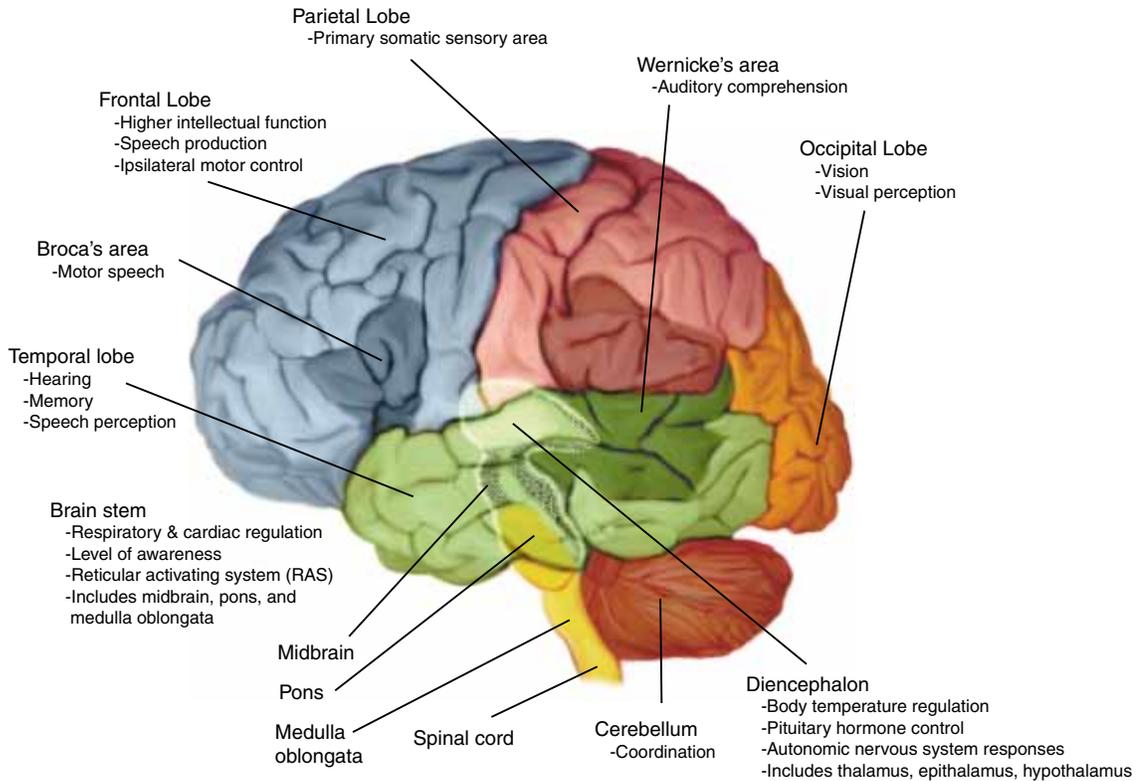

Figure 36-2 Cross-section of the Brain

TABLE 36-1
Structures and Functions of the Brain

Structure	Description	Primary Functions
Cerebrum	Composed of gray matter and white matter. Basal ganglia (masses of gray matter) are part of the extrapyramidal system.	Is responsible for: <ul style="list-style-type: none"> • Thinking • Memory • Learning. • Receives and interprets sensory input (stimuli); responds to sensory stimuli. • Helps control motor function.
Cerebellum	Located behind and under the cerebrum. Is a fissured mass consisting of a body that includes a narrow middle strip and two lateral lobes.	<ul style="list-style-type: none"> • Is concerned with unconscious functions. • Is responsible for smooth-muscle functioning. • Maintains equilibrium.
Brain stem	Composed of three structures: <ul style="list-style-type: none"> • The midbrain • The <i>pons</i> • The <i>medulla oblongata</i> 	Influences visual and auditory senses. Connects the upper and lower levels of the CNS. Affects respiratory rate. Prevents coma by maintaining wakefulness. Controls vital functions: <ul style="list-style-type: none"> • Heart rate • Respiratory rate • Swallowing • Coughing Processes sensory input from spinal tract

(From Guyton, A. C., & Hall, J. [2000]. *Textbook of medical physiology* [10th ed.]. Philadelphia: Saunders.)

mit sensory impulses to the brain), **effluent nerve pathways** (descending pathways that send sensory impulses from the brain), the spinal cord, the brainstem, and the higher cortex (cerebral lobes). Figure 36-5 shows the major sensory pathways.

Components of Cognition

Cognition includes the cerebral functions of memory, judgment, and emotion. In order for higher functions (such as memory, affect, judgment, perception, and language to occur) consciousness must be present.

Consciousness

Consciousness is a state of awareness of self, others, and the surrounding environment. It affects both cognitive (intellectual) and affective (emotional) functions. An

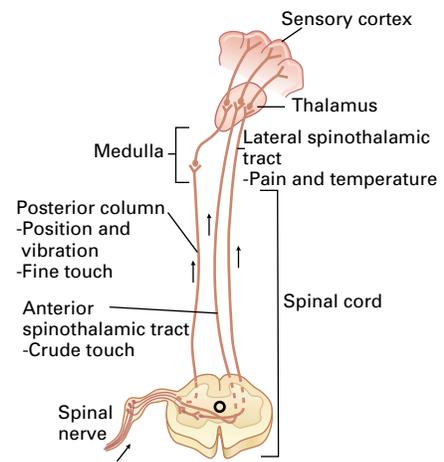

Figure 36-5 Major Sensory Pathways

alert individual (one who is aware of self and stimuli) is able to perceive reality accurately and to base behavior on those perceptions. The components of consciousness provide a foundation for behavior and emotional expression, thereby contributing to the uniqueness of each individual's personality.

Consciousness depends on the functioning of the reticular activating system (RAS), which is located within the midbrain and thalamus, as well as connective fibers between these structures and areas within the cerebral cortex. The RAS controls activities such as sleep and wakefulness and monitors the selective transmission of stimuli to other parts of the neurosensory system. Consciousness may be altered by various metabolic, traumatic, or other factors such as the pharmacological actions of drugs that affect mental status. The primary components of consciousness are arousal and awareness, both of which must be present before higher cognitive functioning occurs. "The reticular formation is the arousal or alerting system for the cerebral cortex; its functioning is crucial for maintaining consciousness" (Kuhn, Herlihy, & Herlihy, 1998, p. 208).

Arousal

The degree of **arousal** (a component linked closely to the appearance of wakefulness and alertness) is indicated by a person's general response and reaction to the environment.

People exhibit arousal, the state of being prepared to act, by behaving in an alert and aware manner and by experiencing periods of wakefulness. The degree of an individual's arousal is indicated by the general response and reaction to the environment. Impaired arousal can exist when a sleep pattern deficit is experienced; there may be an inability to take advantage of opportunities for activity because of limited periods of rest.

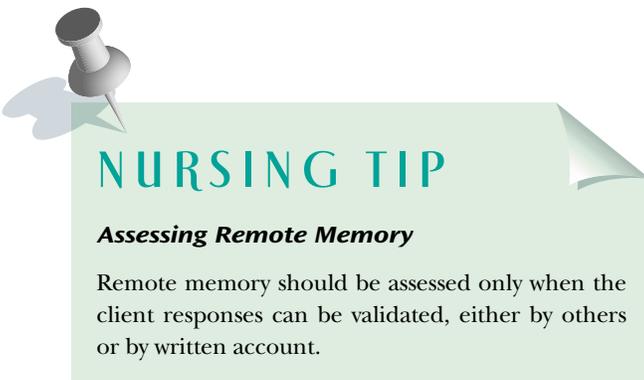

Awareness

Awareness is the capacity to perceive sensory impressions and react appropriately through thoughts and actions. An essential element in awareness is **orientation**

(perception of self in relation to the surrounding environment). According to Roy (1988), orientation is a person's ability to be cognitively aroused, to attend to the environment, and to recognize patterns. When awareness is impaired, orientation to time is frequently the first area affected. The degree of disorientation is worse when the individual loses awareness of place and self (person). Changes in a client's orientation to time, place, and person are often early indicators of an altered level of consciousness. Several tools have been developed to measure level of consciousness, which includes a measure of orientation.

Memory

There are three types of memory: immediate, recent, and remote. **Immediate memory** is the retention of information for a specified and usually short period of time. An example of this function is the recall of a telephone number long enough to dial it. **Recent memory** is the result of events that have occurred over the past 24 hours. An example of recent memory is the remembrance of foods eaten for dinner the previous night. **Remote memory** is the retention of experiences that occurred during earlier periods of life, such as an adult's memories of childhood or school days. The ability to learn is dependent on remote memory.

Affect

Affect (mood or feeling) is an important component of cognition, in that variations of mood can affect one's thinking ability. For example, depression may affect the client's concentration and attention. Also, anxiety narrows the perceptual field and interferes with the ability to concentrate by decreasing attention span.

Judgment

Judgment, the ability to compare or evaluate alternatives to life situations and arrive at an appropriate course of action, is closely related to reality testing and depends on effective cognitive functioning. When assessing logic and judgment, it is important to decide whether the client is

answering questions appropriately. The goal is to determine the use of reasoning and decision-making ability. It may be assessed by asking a question such as "What would you do if you were inside a burning building?" Answers that indicate impaired judgment may be given by clients experiencing frontal lobe damage, dementia, mental retardation, or psychosis. Behaviors indicative of impaired judgment include impulsiveness, unrealistic decision-making, and inadequate problem-solving ability.

Perception

Cognitive perceptions are considered in the context of the individual's awareness of reality. Misperceptions of reality can occur in the form of an **illusion** (an inaccurate perception or misinterpretation of sensory stimuli) or a **hallucination** (a sensory perception that occurs in the absence of external stimuli and is not based on reality).

Clients who are anxious and fearful or who are on therapeutic regimens involving the use of certain medications may experience misperceptions of environmental stimuli. For example, a postoperative client, after receiving analgesic medication for pain, sees a belt from his bathrobe lying on the floor and becomes terrified because he thinks there is a snake in the room. Once the nurse determines that the client is experiencing an illusion, appropriate reassurance and reality orientation can be implemented to reduce the client's anxiety.

Language

Language is one of the most complex cognitive functions, involving not only the spoken word but also reading, writing, and comprehension. Each of these skills is controlled by specific areas located in the cerebral cortex (Figure 36-6).

Characteristics of speech are **fluency** (ability to talk in a steady manner), **prosody** (melody of speech that conveys meaning through changes in the tempo, rhythm, and intonation), and content.

FACTORS AFFECTING SENSATION, PERCEPTION, AND COGNITION

The functions of sensation, perception, and cognition are influenced by many factors, including age, environment, lifestyle, stress, illness, and medications.

Age

Neurosensory pathways in infants and children are immature and do not allow for sophisticated discrimination among stimuli. As children mature they learn to apply their perceptions of the environment to different

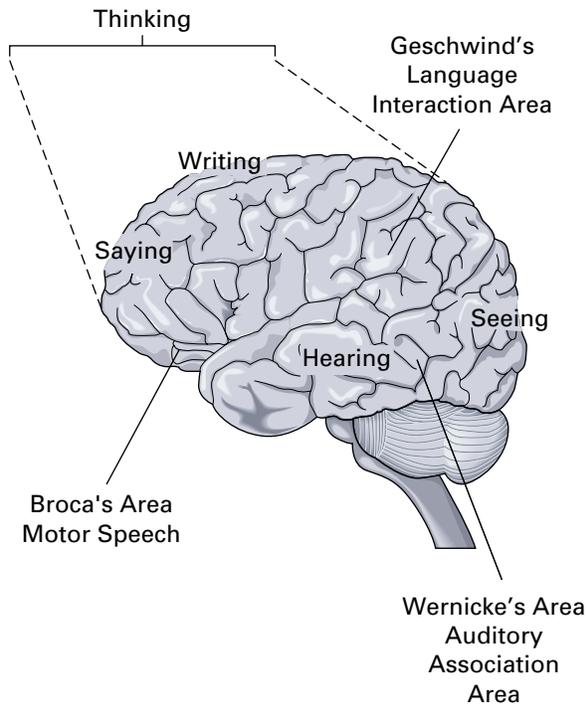

Figure 36-6 Language Perception Areas of the Brain. Note Broca's motor speech area in the frontal lobe, Wernicke's auditory association area in the temporal lobe, and Geschwind's language interaction area in the parietal lobe.

situations and can thus modify their behaviors accordingly. This process continues throughout the life cycle. For young adults, cognitive functioning is generally more advanced than during adolescence. According to Miller (1999):

The young adult uses systematic and sophisticated problem-solving techniques and achieves new levels of creative thought with less egocentrism than is seen in younger individuals. Thinking is more reality based and mental activities are proficient. (p. 386)

Intelligence is difficult to measure; intelligence quotient (IQ) tests (which are intended to predict academic achievement) are not very reliable indicators of adult intelligence. The measurement of intelligence in middle-aged adults is affected by several variables, including motivation, risk-taking and/or caution, and anxiety. "Middle age is considered . . . to be the height of intellectual endowment, as memory and problem solving are maintained and learning continues" (Miller, 1999, p. 391).

Intellectual functioning is maintained in part by a stimulating environment. **Crystallized intelligence** (the application of life experiences and learned skills to solve problems; also called acquired knowledge) generally increases with age as **fluid intelligence** (ability to acquire new concepts and adapt to unfamiliar situations; mental activities based on organizing information) decreases over time (Miller, 1999).

Cognitive development in older adults shows no decline in intellectual function. Memory loss is an area

of concern for many older adults. "The older person who is mentally active and well educated will not show the same problems with memory as will those adults without similar opportunities to use their minds" (Miller, 1999, p. 397). Memory impairments that occur in the elderly are usually the result of pathophysiological processes and are not a part of normal aging. Strategies such as list making and posting reminder notes can be helpful in compensating for minor memory losses. Some activities that encourage cognitive development in older people are reading, studying a new topic (such as language or computer skills), solving mathematical problems, and working word puzzles.

NURSING TIP

When assessing an older client's cognitive functioning, remember that aging does not occur in the same way in every individual.

Environment

The amount and type of environmental stimuli affects sensation, perception, and cognition. Excessive stimuli in the form of visual impressions and noise can create feelings of anxiety and disorientation within clients. Too few relevant stimuli decrease the client's response to people and the environment, thus leading to isolation.

Crowded living conditions, traffic congestion, or living where sound levels are high are stressors associated with negative physical and psychological health outcomes. "Environmental noise has been associated with delayed healing and other physical effects, as well as cognitive effects, including a diminished efficiency of prefrontal cortical regions of the brain resulting in a decrease in the variety and speed of cognitive responses" (Holmberg & Coon, 1999, p. 117).

Lifestyle

The amount and quality of sensory information that people feel comfortable in processing are based on their work and leisure habits. Some people may prefer quiet environments in which to think, whereas others derive energy and productivity from the activity around them.

Stress

Stress and anxiety can have a negative influence on a person's behavior and thought patterns. Depending on

the type and degree of stress, the person either finds ways to cope with the situation or becomes overwhelmed with the stimuli being received and can possibly become disoriented.

Illness

Specific conditions, such as diabetes mellitus and atherosclerosis, can impair neurosensory pathways and result in deficits in sensation, perception, and cognition. Diseases of the CNS can result in loss of sensory function and paralysis.

Medications

Certain medications have the potential to alter or depress the neurosensory system. For example, sedatives and narcotics can alter the perception of sensory stimuli. Medications such as analgesics can alter level of consciousness; see the accompanying display.

MEDICATIONS THAT ALTER LEVEL OF CONSCIOUSNESS: A PARTIAL LIST

- Analgesics
- Antidepressants
- Antidiuretics
- Antihypertensives
- Benzodiazepines (especially long-acting agents)
- Sedatives

SENSORY, PERCEPTUAL, AND COGNITIVE ALTERATIONS

An individual usually experiences discomfort and/or anxiety when subjected to a change in the type or amount of incoming stimuli. A person can become confused as a result of either overstimulation or understimulation. According to the individual's ability to process the stimuli, confusion (or disorientation) may occur. **Disorientation** is a mentally confused state in which the person's awareness of time, place, self, and/or situation is impaired; when awareness of these four factors is accurate, a person is said to be "oriented \times 4."

Sensory over-stimulation and sensory deprivation can lead to cognitive alterations in healthy adults. Such alterations include physical symptoms (i.e., nausea), altered time perceptions, paranoid ideation, and visual, auditory, and olfactory distortions (similar to hallucinations). A person admitted to a health care agency experiences stimuli that are different from those usually encountered. A change in environment can overwhelm one's ability to perceive and interpret sensory input. As a result, the treatment milieu itself can become a stressor

that negatively affects sensory, perceptual, and cognitive functions. If one or more of the factors just discussed causes an alteration in sensation, perception, or cognition, the client may experience problems with perceiving and interpreting stimuli. These problems are manifested by three types of alterations: sensory deficits, sensory deprivation, and sensory overload.

Sensory Deficits

A **sensory deficit** is a change in the perception of sensory stimuli. These deficits can affect all five senses. Examples of sensory deficits are vision and hearing losses such as those caused by cataracts, glaucoma, and presbycusis (steady loss of hearing acuity that occurs with aging).

The client's response to these losses usually depends on the time of onset and severity of the condition. If the problem occurs suddenly and without warning, the client may have difficulty in adjusting to the loss of sensory and perceptual function. If these alterations occur gradually, the client may be able to accommodate the change and actually compensate for it by strengthening one or more of the other senses.

The effects of hospitalization or intensive medical treatments can exacerbate the problems related to sensory deficits. For example, a client with acute hearing loss can feel alone and vulnerable when faced with an environment that does not provide an effective means (such as interpreters who sign) through which communication can occur. Because of these responses, clients with sensory deficits are at serious risk of experiencing either sensory deprivation or sensory overload.

Sensory Deprivation

Sensory deprivation is a state of reduced sensory input from the internal or external environment, manifested by alterations in sensory perception. Individuals can experience sensory deprivation as a result of illness, trauma, or isolation. A person experiencing sensory deprivation misinterprets the limited stimuli with a resultant impairment of thoughts and feelings. The following are factors contributing to sensory deprivation:

- Visual or auditory impairments that limit or prohibit perception of stimuli
- Drugs that produce a sedative effect on the CNS and interfere with the interpretation of stimuli
- Trauma that results in brain damage and decreased cognitive function
- Isolation (either physical or social) that results in the creation of a nonstimulating environment

Some contributing factors (such as brain damage or blindness) result in chronic sensory deprivation,

whereas others lead to acute, transient states of deprivation (e.g., an individual receiving analgesic medications).

Individuals who are sensory-deprived may exhibit any of the following characteristics:

- Inability to concentrate
- Poor memory
- Impaired problem-solving ability
- Confusion
- Irritability
- Emotional lability (mood swings)
- Depression
- Boredom and apathy
- Drowsiness
- Hallucinations (see accompanying display)

Sensory Overload

Sensory overload is a state of excessive and sustained multisensory stimulation manifested by behavior change and perceptual distortion. The individual experiencing this alteration is unable to process the amount or intensity of stimuli being received. The accompanying display lists factors contributing to sensory overload. Individuals experiencing sensory overload may exhibit any of the following characteristics:

- Anxiety and restlessness
- Irritability
- Disorientation
- Insomnia
- Fatigue
- Impaired problem-solving ability

A common type of stimulus that clients often experience is excessive noise; exposure to high noise levels interferes with the following:

FACTORS CONTRIBUTING TO SENSORY OVERLOAD

- Pain originating from a heightened quality or quantity of internal stimuli
- Invasive procedures that result in an increased amount of external stimuli
- Activity-filled, busy environment that contributes to the amount of stimuli being perceived
- Medications that stimulate the CNS and prohibit client from ignoring selective stimuli
- Presence of strangers (both health care professionals and others) who contribute to the quantity of stimuli
- Diseases that affect the CNS and that maximize the perception of stimuli

- Ability to shift attention
- Ability to perform complex tasks requiring sustained attention
- Verbal learning and memory
- Ability to make verbal associations

“Excessive sound affects cognitive processing activity in the prefrontal cortex” (Holmberg & Coon, 1999, p. 120).

ASSESSMENT

When caring for clients with sensory, perceptual, and cognitive alterations, the nurse must conduct a thorough health history and perform a complete physical examination of the client in order to identify existing or potential problems in this area of functioning. See

TYPES OF HALLUCINATIONS

Hallucination	Definition	Example
Visual	Perception of sights that are not actually present in the environment	“Do you see that little pink elephant at the foot of my bed?”
Auditory	Perception of sounds that are not present in the environment	“I hear the space aliens telling me that I’ll be in outer space soon.”
Tactile	Perception of being touched by things not actually present in the environment	“I feel bugs crawling underneath my skin.”
Olfactory	Perception of odors not present in the environment	“I can smell old rubber tires burning all the time.”
Gustatory	Perception of tastes that do not actually correspond to the foods being eaten	“That bitter taste is in all the food.”

Table 36-2 for an overview of assessing cognition and sensory perception.

Health History

In order to collect data that are used to develop the plan of care, the nurse collects the health history of the client experiencing alterations in sensation, perception, and cognition. Elements of the health history include the client's usual level of functioning, current sensory problems, and potential alterations. The nurse should also explore issues such as the client's current occupation, home environment, and ability to perform both daily routines and self-care activities. The accompanying display presents examples of questions that the nurse can ask the client during this part of the assessment process.

Physical Examination

During the physical examination, the nurse evaluates the client's visual, auditory, gustatory, olfactory, and tactile status. Physical examination focuses specifically on the client's ability to see, hear, taste, smell, perceive heat

HEALTH HISTORY: SAMPLE QUESTIONS

- Are you experiencing any difficulty in seeing objects, either near or far from you?
- Do you currently wear eyeglasses, bifocals, or contacts?
- Have you recently experienced any changes in your vision—for example, blurred vision, pain, sensitivity to light, or eye fatigue?
- Are you experiencing any changes in your hearing?
- Do you currently wear a hearing aid?
- Have you experienced any unusual sensations in the ears, such as a buzzing or ringing noise?
- Has your appetite or preference for certain foods changed recently?
- Are you experiencing any difficulty in your ability to smell particular odors?
- Do you experience unusual heat or cold in any of your extremities?
- Are you having any problems performing activities such as eating, brushing your hair, bathing, or toileting?
- Have you been exposed to loud noises or chemicals in your work environment or neighborhood?

TABLE 36-2
Neurological Screening Assessment

Assessment Parameter	Assessment Skill	Comments
Mental status/level of consciousness	Note general appearance, speech content, memory, logic, judgment, and speech patterns during history-taking Perform Glasgow Coma Scale (GCS) with motor assessment component and pupil assessment	If any abnormalities or inconsistencies are evident, perform full mental status assessment. If GCS is <15, perform full assessment of mental status and consciousness. If motor assessment is abnormal or asymmetrical, perform complete motor and sensory assessment.
Sensation	Assess pain and vibration in the hands and feet, light touch on the limbs	If deficits are identified, perform a complete sensory assessment.
Cranial nerves	Assess CN II, III, IV, VI: visual acuity, gross visual fields, fundoscopic examination, pupillary reactions, and extraocular movements. Assess CN VII, VIII, IX, X, XII: facial expression, gross hearing, voice, and tongue.	If any abnormalities exist, perform complete assessment of all 12 cranial nerves.
Cerebellar function	Observe the client's: <ul style="list-style-type: none"> • Initial gait • Ability to: (a) walk heel-to-toe, (b) walk on toes, (c) walk on heels, (d) hop in place, and (e) perform shallow knee bends 	If any abnormalities exist, perform complete cerebellar assessment.
Reflexes	Assess the muscle stretch reflexes and the plantar response.	If an abnormal response is elicited, perform a complete reflex assessment.

(Adapted from Estes, M. E. Z. [2002]. *Health assessment and physical examination*. Albany, NY: Delmar Thomson Learning.)

and cold, and perceive pain. See Chapter 27 for a complete discussion of assessing sensory and neurological status. Table 36-3 provides some guidelines helpful in assessing sensory perceptual status.

Assessment of Cranial Nerves

As stated earlier, there are 12 pairs of cranial nerves. Most of the cranial nerves have both sensory and motor functions (refer to Figure 36-3). Assessment of the cranial nerves is done to determine the presence of any neurological deficits. Chapter 27 provides a detailed discussion on assessing the cranial nerves.

TABLE 36-3
Assessing Sensory Perceptual Status

Sensation Being Assessed	Assessment Focus
Visual	Presence of visual problems, including: <ul style="list-style-type: none"> • Blurred vision • Double vision • Blind spots • Rainbows or halos around objects • Photosensitivity Difficulty seeing far or near Family history of visual problems (such as glaucoma, cataracts) Use of contact lenses or eyeglasses Date of last eye examination
Auditory	Presence of hearing problems Recent changes in hearing ability Ability to distinguish sounds (tone and pitch) Presence of buzzing or ringing noises Use of a hearing aid
Gustatory	Changes in ability to taste Difficulty in differentiating salty, sweet, sour, and bitter tastes Changes in appetite
Olfactory	Changes in ability to smell Ability to distinguish common smells (such as food, perfume, flowers)
Tactile	Difficulty in feeling temperature changes in extremities Impairment of pain perception in extremities Presence of unusual sensations in extremities (such as tingling or numbness)

NURSING ALERT

Level of Consciousness and Respiratory Function

Deterioration in a client's level of consciousness may indicate that intracranial pressure is increasing. This is a life-threatening condition that requires immediate intervention because it depresses respirations.

Mental-Status Assessment

A thorough mental-status examination includes a systematic assessment of all the emotional and cognitive functions. Mental status is usually assessed during the health history interview. See the Nursing Process Highlight for general guidelines on conducting a mental-status assessment.

The Mini-Mental Status Examination (MMSE) (Folstein, Folstein, & McHugh, 1975) was developed to determine one's baseline mental status; it includes several questions to assess orientation. The MMSE can be administered as a screening tool in acute, community-based, and long-term care settings. It is not intended to be used as a

Nursing Process Highlight

ASSESSMENT: MENTAL STATUS

1. Assessment begins as the client approaches. Observe gait, posture, mode of dress, involuntary movements, and voice to refine assessment priorities.
2. The history should be holistic because neurological disorders can affect all body systems.
3. The history should be age-sensitive:
 - Utilize other family members when client is a child.
 - Acknowledge adolescents' ability to speak for themselves.
 - Do not make assumptions regarding elderly clients' ability to relate their own health history.
4. Allow the client to remain clothed during the history and mental-status assessment.
5. Consider language and cultural norms when obtaining the history and performing the mental-status assessment.

(Adapted from Estes, M. E. Z. [2002]. *Health assessment and physical examination*. Albany, NY: Delmar Thomson Learning.)

diagnostic tool but rather to screen clients for the cognitive aspects of mental functioning: orientation, registration, attention and recall, and language (Folstein, Folstein, & McHugh, 1975). The highest possible score is 30, with a score of 21 or less usually indicating cognitive impairment (Figure 36-7). A more detailed mental-status assessment is warranted if the client presents with any of the following: memory deficit, confusion, aphasia (impairment in language functioning), mood swings, irritability, excessive headaches, behavioral changes, or seizures.

Levels of Consciousness

When assessing clients for sensory, perceptual, and cognitive alterations, the nurse should evaluate the level of consciousness (LOC). When describing assessment data relative to LOC, the nurse should include a brief description of the type of stimuli used to test LOC and the client's response. The accompanying display gives a list of terms commonly used in describing LOC.

The Glasgow Coma Scale (GCS) was developed as a standardized tool to assess LOC objectively (Table 36-4). The tool may be used in a variety of clinical situations and is meant to be used in conjunction with a complete neurological assessment.

TABLE 36-4
Glasgow Coma Scale

Behavior	Response	Score
Eye opening response	Spontaneous	4
	To verbal command	3
	To pain	2
	No response	1
Best verbal response	Oriented, conversing	5
	Disoriented, conversing	4
	Use of inappropriate words	3
	Incomprehensible sounds	2
	No response	1
Best motor response	Obeys verbal commands	6
	Moves to localized pain	5
	Flexion withdrawal to pain	4
	Abnormal posturing—decorticate	3
	Abnormal posturing—decerebrate	2
	No response	1
Total		3 to 15

With the GCS, a score of 15 indicates a fully oriented person. A score of 7 or less is considered a state of coma. A score of 3 is the lowest possible score and is indicative of deep coma.

DESCRIPTIVE TERMS FOR LEVELS OF CONSCIOUSNESS

Alert. Oriented and aware of stimuli; responds appropriately.

Lethargic. Responds appropriately to stimuli but may be slow to respond; may be drowsy and may drift off to sleep when not stimulated.

Obtunded. Sleeps most of the time; difficult to arouse with minimal response; requires constant stimulation; inconsistently follows commands.

Semicomatose. Responds with purposeful movements when stimulated, but does not follow commands and is nonverbal.

Comatose. Unconscious with no meaningful response to stimuli. Light coma may include reflex motor response to painful stimuli (decorticate or decerebrate posturing); deep coma includes no motor response to any stimuli.

Functional Abilities

The nurse needs to have an understanding of the client's ability to conduct self-care activities. Any sensory, perceptual, or cognitive impairments may interfere with the client's ability to perform activities of daily living (ADL). Also, such impairments can interfere with the client's ability to keep the home environment clean and safe. A thorough assessment of self-care abilities includes assessment of skills related to dressing, grooming, bathing, feeding, and toileting.

Environment

A person's environment can affect sensory, perceptual, and cognitive status in a variety of ways. For example, a nonstimulating environment can lead to sensory deprivation, whereas an environment that is excessively stimulating can result in sensory overload.

People who are at increased risk for sensory perceptual deficits include:

- The older adult
- Those who live alone
- Those who are institutionalized
- The homebound
- Those with chronic illness or physical handicaps
- Those who are mentally ill
- Those who have a developmental delay

The nurse assesses the type and quantity of stimuli in the client's environment (the health care facility or the home). See the accompanying display for information on assessing the client's home environment.

SCORE SHEET – MINI-MENTAL STATE

Name _____ Unit _____

Date _____

<u>Maximum Score</u>	<u>Score</u>									
<i>Orientation</i>										
5	()	What is the year (season, date, day, month)?								
5	()	Where are we: (state, county, town, hospital, floor)?								
<i>Registration</i>										
3	()	Name 3 objects: 1 second to say each. Then ask the patient all 3 after you have said them. Give 1 point for each correct answer. Then repeat them until he learns all 3. Count trials and record. Trials:								
<i>Attention and Calculation</i>										
5	()	Serial 7's. 1 point for each correct. Stop after 5 answers. Alternatively spell "world" backwards.								
<i>Recall</i>										
3	()	Ask for the 3 objects repeated above. Give 1 point for each correct.								
<i>Language</i>										
9	()	Name a pencil, and watch (2 points). Repeat the following: "No ifs, ands, or buts" (1 point). Follow a 3-stage command: "Take a paper in your right hand, fold it in half, and put it on the floor" (3 points). Read and obey the following: CLOSE YOUR EYES (1 point). Write a sentence (1 point). Copy design (1 point). Total score Assess level of consciousness along a continuum.								
<table border="0" style="width: 100%;"> <tr> <td style="border-top: 1px solid black; border-bottom: 1px solid black;">Alert</td> <td style="border-top: 1px solid black; border-bottom: 1px solid black;">Drowsy</td> <td style="border-top: 1px solid black; border-bottom: 1px solid black;">Stupor</td> <td style="border-top: 1px solid black; border-bottom: 1px solid black;">Coma</td> </tr> <tr> <td colspan="4">Examiner _____</td> </tr> </table>			Alert	Drowsy	Stupor	Coma	Examiner _____			
Alert	Drowsy	Stupor	Coma							
Examiner _____										

INSTRUCTIONS FOR ADMINISTERING MINI-MENTAL STATE EXAMINATION

Orientation

Ask for the date. Then ask specifically for parts omitted (e.g., "Can you also tell me what season it is?"). One point for each correct.
Ask in turn "Can you tell me the name of this hospital (town, county, etc)?" One point for each correct answer.

Registration

Ask the patient if you may test his memory. Then say the names of 3 unrelated objects (for example, car, house, book) clearly and slowly, about 1 second for each. After you have said all 3, ask him to repeat them. This first repetition determines his score (0-3), but keep saying them until he can repeat all 3, up to 6 trials. If he does not eventually learn all 3 recall cannot be meaningfully tested.

Attention and Calculation

Ask the patient to begin with 100 and count backwards by 7's. Stop after 5 subtractions (93, 86, 79, 72, 65). Score the total number of correct answers.
If the patient cannot or will not perform this task, ask him to spell "world" backwards. The score is the number of letters in correct order (e.g., dlrow = 5, dlrow = 3).

Recall

Ask the patient if he can recall the 3 words you previously asked him to remember. Score 0-3.

Language

Naming – Show the patient a wristwatch and ask him what it is. Repeat for pencil. Score 0-2.
Repetition – Ask the patient to repeat the sentence after you. Allow only one trial. Score 0-1.
3-Stage command – Give the patient a piece of plain, blank paper and repeat the command. Score 1 point for each part correctly executed.
Reading – On a blank piece of paper print the sentence "Close your eyes" in letters large enough for the patient to see clearly. Ask him to read it and do what it says. Score 1 point only if he actually closes his eyes.
Writing – Give the patient a blank piece of paper and ask him to write a sentence for you. Do not dictate a sentence: it is to be written spontaneously. It must contain a subject and verb and be sensible. Correct grammar and punctuation are not necessary.
Copying – On a clean piece of paper, draw intersecting pentagons, each side about 1 in. and ask him to copy it exactly to score 1 point. Tremor and rotation are ignored.
Estimate the patient's level of sensorium along a continuum, from alert on the left to coma on the right.

ASSESSING THE CLIENT'S HOME FOR ENVIRONMENTAL STIMULI

To determine the presence of sensory stimuli, the nurse assesses the presence of the following in the home:

- Adequate lighting
- Clock and calendar
- Odors
- Noise
- Other people (family members or frequency of visitors)
- Television, radio, or cassette player
- Books, magazines, newspapers

People with sensory, perceptual, and cognitive alterations are at increased risk of injury. Impairment of sensory perceptual and cognitive abilities can present the following hazards:

- Visual: Risk of tripping, falling
- Auditory: Lack of awareness of warning sounds (such as automobile horns, sirens, smoke alarms)
- Olfactory: Inability to perceive warning odors (such as burning food, escaping gas)
- Gustatory: Unawareness of spoiled or contaminated food or beverages
- Tactile: Lack of awareness of excessive pressure on a body part; at risk for exposure to extreme temperatures (frostbite, burns)

THINK ABOUT IT

Safety of the General Public versus Individual Liberty

Your 72-year-old neighbor, Mrs. Stafford, confides in you one afternoon at her home that she is becoming “more deaf by the minute.” She tells you, “Next week when I go in for my driver’s license renewal, I am not going to tell them about my little problem.” Your neighborhood has several small children who run into and out of the street playing. How do you respond to Mrs. Stafford?

DIAGNOSIS

Several nursing diagnoses are applicable to clients experiencing sensory, perceptual, and cognitive alterations. The nurse needs to establish a diagnosis that is most closely related to the client’s priority needs. The North American Nursing Diagnosis Association (NANDA) diagnostic label that is applicable for many clients experiencing altered sensory perception and cognition is *Disturbed Sensory Perception (specify)* (*visual, auditory, kinesthetic, gustatory, tactile, olfactory*). This condition is defined as “a state in which an individual

experiences a change in the amount or patterning of incoming stimuli accompanied by a diminished, exaggerated, distorted, or impaired response to such stimuli” (NANDA, 2001, p. 70). See Table 36-5 for other relevant diagnoses, with defining characteristics and related factors.

PLANNING AND OUTCOME IDENTIFICATION

Nurses understand the importance of promoting optimal sensory stimulation for clients in every area of care. The following goals will promote supportive, restorative care for clients experiencing sensory, perceptual, or cognitive alterations:

The client will:

- Remain safe and free from injury
- Experience a level of arousal that promotes the meaningful perception of stimuli
- Remain oriented to time, place, person, and situation
- Demonstrate intact functioning of senses (using assistive devices if necessary)
- Perform self-care activities appropriate to own functional capability

The current trend is to provide care for individuals experiencing cognitive deficits at home. “The goal of using creative strategies to manage dementia is to slow the rate of deterioration in order to prevent institutionalization for as long as possible” (Cacchione, 2000, p. 631). See the accompanying display for guidelines on planning the delivery of care in a long-term care facility.

APPLICATION: LONG-TERM CARE FACILITY: PROMOTING SENSORY STIMULATION

- Call the client by name.
- Introduce self by name.
- On every shift, inform the client of the year, month, day of month, day of week, name of facility, and name of health care provider.
- Have a calendar and clock that are easy to see near the client’s bed.
- Explain all procedures prior to implementation.
- Name and state the purpose of medications before administration.
- Have all necessary assistive devices (eyeglasses, dentures, hearing aid) accessible.
- Encourage client and family to personalize immediate environment with personal items (clothing, family photos, and personal possessions, such as quilts or furniture from home, if feasible).

TABLE 36-5
Nursing Diagnoses Related to Sensory, Perceptual, and Cognitive Impairments

Diagnosis	Defining Characteristics	Related Factors
<i>Disturbed Sensory Perception</i> (specify)	<p><i>Major</i></p> <ul style="list-style-type: none"> • Inaccurate interpretation of environmental stimuli • Negative change in amount or pattern of incoming stimuli <p><i>Minor</i></p> <ul style="list-style-type: none"> • Disoriented to time, place, or people • Impaired problem-solving ability • Changes in behavior or communication pattern • Restlessness • Disturbed sleep patterns • Hallucinations • Fear • Anxiety 	<ul style="list-style-type: none"> • Cerebrovascular accident • Meningitis or encephalitis • Fluid and electrolyte imbalance • Decreased oxygen transport • Medications • Physical isolation • Immobility • Social isolation • Stress
<i>Disturbed Thought Processes</i>	<p><i>Major</i></p> <ul style="list-style-type: none"> • Inaccurate interpretation of stimuli, internal and/or external <p><i>Minor</i></p> <ul style="list-style-type: none"> • Cognitive deficits, including memory deficits • Suspiciousness • Delusions • Hallucinations • Distractibility • Confusion, disorientation • Impulsivity 	<ul style="list-style-type: none"> • Mental disorders or personality changes resulting from biochemical changes • Hormonal changes • Depression • Anxiety • Fear • Loss • Isolation • Ambiguous communication • Abuse • Social isolation
<i>Social Isolation</i>	<p><i>Major</i></p> <ul style="list-style-type: none"> • Expressed feelings of aloneness and/or desire for more social contact <p><i>Minor</i></p> <ul style="list-style-type: none"> • Verbalization that time is passing slowly • Inability to concentrate • Impaired decision making • Expressed feelings of uselessness • Feelings of rejection • Increased irritability • Restlessness • Failure to interact with others nearby • Feelings of hopelessness 	<ul style="list-style-type: none"> • Communicable disease • Psychiatric illness • Death of a significant other • Divorce • Terminal illness • Hospitalization • Institutionalization • Loss of means of transportation • Unemployment
<i>Risk for Injury</i>	<p><i>Major</i></p> <ul style="list-style-type: none"> • Developmental age • Altered mobility • Confusion • Disorientation <p><i>Minor</i></p> <ul style="list-style-type: none"> • Malnutrition 	<ul style="list-style-type: none"> • Sensory dysfunction (decreased sensation, impaired vision, diminished sense of smell)

(From Carpenito, L. J. [1999]. *Handbook of nursing diagnosis: Application to practice* [8th ed., pp. 283–284, 299–300, 304–306]. Philadelphia: Lippincott; North American Nursing Diagnosis Association (2001). *Nursing diagnoses: Definitions and classification. 2001–2002* [pp. 38, 70, 74]. Philadelphia: Author.)

TABLE 36-6
Nursing Interventions to Promote Cognitive Function

Intervention	Examples
Memory retraining	Reality orientation
Social skills therapy	Reinforcing behaviors to be used when interacting with others
Communication therapy	Improving speech patterns or words to complete a thought Minimizing sensory deprivation
Stress management therapy	Identifying and using factors that minimize stress
Reminiscence therapy	Using story telling and memory recall to identify with past experiences
Behavioral therapy	Maintaining consistency and stability to specify expected behaviors Recognizing and controlling environmental stressors Using written schedules and directions to assist with activities
Medication administration	Using pharmacologic agents to manage disruptive behaviors

(From American Psychiatric Association. [1994]. *Diagnostic and statistical manual of mental disorders* [4th ed., rev.]. Washington, DC: Author.)

The American Psychiatric Association (1994) has identified the following as skills to be encouraged in order to promote cognitive functioning: stability, consistency, self-identification, and active participation. Table 36-6 lists nursing interventions that enhance the development of these four essential skills.

IMPLEMENTATION

A major concern of nurses caring for clients with sensory, perceptual, and cognitive alterations is safety. Actions must be taken to ensure that the client's environment is hazard-free and, at the same time, that it provides adequate stimulation. This section describes nursing interventions that promote appropriate sensory, perceptual, and cognitive functioning. Care of clients with visual and hearing impairments is discussed. Also presented is information on communicating with a confused client and a client who is unconscious.

Managing Sensory Deficits

Clients with sensory deficits, including tactile, auditory, and visual impairments, need sensitive nursing care to best adapt to their environments and specific challenges.

Tactile Alterations

The client with impaired tactile sensation is placed at an increased risk for development of skin breakdown. Therefore, it is important to encourage a safe living environment and to educate the individual and significant others in injury prevention measures. For more information on preventing tissue and skin breakdown, refer to

NURSING ALERT

Sensory Alterations and Safety

The client with impaired level of consciousness, weak memory, altered judgment, or confusion is at high risk for injury. It is essential to create a living environment that is safe for people with sensory, perceptual, and cognitive deficits.

Chapter 35. The following Client Teaching Checklist describes therapeutic approaches for maintaining skin integrity of clients with altered touch sensation.

Hearing Deficit/Loss

In addition to safety hazards, individuals with impaired hearing are also at risk for social isolation because of the difficulty in communicating with others. Nurses must ensure that they spend time with hearing-impaired clients, focus on nonverbal communication, and face the client when speaking. Check all assistive devices used by clients to ensure that they are working properly (Figure 36-8). Use an interpreter when one is available for signing; often the client's family can serve as interpreters. If an interpreter is available, the nurse must talk to the *client*, not to the interpreter; see the accompanying display for more information on communicating through an interpreter. Other communication aids include finger spelling, communication boards, and the use of paper and pen for writing messages. Refer to Chapters 12 and 13 for more information on communicating with clients who are hearing impaired.

CLIENT TEACHING CHECKLIST

The Client with a Tactile Deficit

Teach the client and family that burns can occur not only from heat but also from friction, chemicals, or tape. It is important for the client to inspect his skin daily and to avoid the following:

- Sun exposure (use sunblock)
- Hot bath water (use a bath thermometer)
- Hot water bottles, heating pads
- Placing containers of hot food or liquids in lap
- Eating hot foods, such as pizza, or other items that maintain heat for extended periods, without first testing the temperature
- Sitting on objects that may be hot (heaters, concrete, or rocks in sunlight)
- Walking on hot surfaces (pavement or concrete) without shoes
- Contact with items in or on automobile that are hot from exhaust or sunlight (for instance, tailpipe, heater vents directed at feet, seatbelt buckles, steering wheel, or leather or vinyl upholstery)
- Overexposure to very low temperatures (cold weather or ice packs) without proper protection

COMMUNICATING THROUGH AN INTERPRETER

- Use short sentences and questions.
- Avoid the use of ambiguous statements and questions.
- Plan what you intend to say ahead of time; this avoids confusing the interpreter by having to back up, restate, or revise previous statements.
- Avoid the use of technical jargon.

(Data from Kneisl, C. R. [1996]. Therapeutic communication. In H. S. Wilson & C. R. Kneisl [Eds.], *Psychiatric Nursing* [5th ed., p. 129]. Menlo Park, CA: Addison-Wesley.)

Visual Impairment

Clients with visual impairments often have developed the other senses to a high degree. The nurse can, therefore, use a variety of ways to enhance communication with such clients. For example, the nurse should do the following:

- Ask client to explain what is helpful (such as preferred means of communicating, usual routine).
- Look directly at the client while speaking.
- Encourage the client to handle items and objects; use objects that can be identified by other senses.
- Keep furniture and other items in their usual place; orient the client to the environment by using clock

Figure 36-8 The use of hearing aids helps to compensate for hearing loss experienced by some clients.

hours to indicate position of items in relation to the client.

- Use your normal tone, volume, and rate of speaking.
- Inform client when you are entering or leaving the room.
- Ask for permission before touching the client.

See Chapters 12 and 13 for discussion of communicating with visually impaired clients.

Managing Sensory Deprivation

It is important to provide an adequate amount of sensory stimulation to those clients who are understimulated or at risk for developing sensory deprivation. See the accompanying Nursing Process Highlight for guidelines.

Managing Sensory Overload

Caring for clients experiencing sensory overload can be very challenging for nurses, especially in critical care areas (such as the emergency department or intensive care unit). It is important to reduce environmental stimuli as much as possible. The Nursing Checklist provides guidelines for nursing interventions for clients experiencing sensory overload.

Assisting the Confused Client

Nurses need to be extra-supportive when communicating with a client who is confused. Many clients are aware of their cognitive deficit and become frustrated about their inability to process environmental stimuli correctly. The nurse must ask about the client's pre-

Nursing Process Highlight

IMPLEMENTATION: CARING FOR CLIENTS WITH SENSORY DEPRIVATION

Provide multisensory stimuli for 5–10-minute intervals throughout the day. Examples of appropriate stimuli are:

- Taped voices of family or friends
- Music (familiar to clients)
- Television
- Touch (applying lotions, different textures to skin)
- Frequent position changes
- Familiar visual stimuli (pictures, personal items)

Allow rest periods with no stimulation (e.g., 30 minutes to 1 hour uninterrupted sleep every 2–4 hours) to avoid sensory overload.

Reorient clients frequently by talking to them, stating their names, informing them of the day, time, weather outside.

Encourage social stimulation by encouraging visitors as appropriate to clients' health needs.

NURSING CHECKLIST

Care of the Client Experiencing Sensory Overload

- Address the client by name.
- Provide explanations of all procedures prior to implementation.
- Modify environment to reduce excessive multisensory stimulation; reduce distractions, loud noise, excessive light.
- Use a calm, unhurried manner when communicating with the client.
- Provide a private room whenever feasible.
- Plan the delivery of care to allow for rest periods with no stimulation.
- Use soft background music.
- Keep the environment free of strong odors (including perfume or after-shave lotion).
- Limit the number and frequency of visitors.

ferred means of communication, and tailor the interaction accordingly. Sensitive nursing care includes allowing additional time for the client to respond to questions, speaking directly to the client in uncomplicated language, repeating information as needed, and

using visual clues and body language to reinforce verbal messages. It is also important to address only one topic at a time and to give simple directions in sequence. For example, “First, sit up in bed. Then slide your legs over the edge of the bed.” Other interventions that are therapeutic for confused clients include the following:

- Written schedule of activities
- Written checklists for performing ADL
- Written directions for medication self-administration
- Active participation in activities
- Prevent social withdrawal

The following Client Teaching Checklist provides information to share with significant others caring for a confused client.

CLIENT TEACHING CHECKLIST

The Confused Client

- Keep clutter in traffic areas at a minimum; remove small rugs that can cause tripping.
- Make sure bed is low, and that there is proper lighting to help prevent falls.
- Keep dangerous objects from client's reach (including matches, firearms, knives).
- Keep medications out of client's reach.
- Lock doors to areas that could be potentially dangerous if client wanders there.
- Assist in dressing appropriately for the season.
- Do not allow the client to stay alone; have a responsible adult provide supervision.
- Try to keep daily activities as routine as possible.
- Keep activities simple and uncomplicated.
- Provide signs, posters, clocks, and calendars as memory aids.
- Encourage client to be independent while providing assistance as needed.
- Always treat the client with respect and dignity.

Caring for the Unconscious Client

Individuals who are unconscious can often hear what is spoken even though they are unable to respond. Thus, it is important for the nurse to be cautious of what is said in the presence of an unconscious client. Nurses should talk in a normal conversational tone while providing care. Also, remember the value of nonverbal communication, and touch the unconscious client. See the accompanying display for additional guidelines in communicating with a client who is unconscious. See

COMMUNICATING WITH AN UNCONSCIOUS CLIENT

- Orient the client to self, situation, place, and time.
- Address the client by name and explain all procedures prior to implementation.
- Maintain a routine to increase the client's sense of security.
- Use touch deliberately.
- Actively listen to significant others.
- Encourage significant others to talk to and touch the client often.
- Treat the client with the same respect and dignity you display to all clients.

Chapter 12 for additional information on communicating with unconscious clients.

Use of Restraints

Restraints, both physical and chemical, are sometimes used with clients experiencing cognitive and/or sensory perceptual alterations. Cognitively impaired residents of long-term care facilities are the most frequently restrained (Mayhew et al., 1999).

There are many risks associated with the use of restraints, including strangulation, impaired circulation, increased risk of falls, the stigma of being “tied down,” and perception that one is being punished. Minimizing the use of restraints must be done in order to respect client dignity while, at the same time, promoting safety of clients and staff members. See Chapter 31 for a guidelines on the safe use of restraints.

NURSING ALERT

The only therapeutic rationale for the use of restraints is promotion of safety.

Complementary/Alternative Therapies

Natural therapies can play an essential role in maintaining a healthy CNS. This section discusses the use of herbs and aromatherapy as methods for enhancing mental well-being. Refer to Chapter 14 for a complete discussion of complementary/alternative treatment approaches.

Herbals

There are four groups of herbs that especially benefit the nervous system: tonics, sedatives, demulcents, stimulants; see Table 36-7.

RESEARCH FOCUS

Title of Study

“Consequences of Not Recognizing Delirium Superimposed on Dementia in Hospitalized Elderly Individuals”

Authors

Fick, D., & Foreman, M.

Purpose

To describe the recognition and management of delirium in hospitalized clients with and without dementia.

Methods

A descriptive, exploratory design was used with a convenience sample of 20 hospitalized older individuals. The clients were observed using qualitative interviews and observations by hospital staff and family members.

Findings

The prevalence of delirium in this study was 60%. The incidence (new onset) of delirium was 30%. The presence of delirium was associated with lower baseline MMSE scores, depression, incontinence, and weight loss. Delirium superimposed on dementia was less likely to be recognized by nurses and physicians.

Implications

Clients with dementia should be routinely assessed for signs of delirium in order to treat the reversible processes and avoid long-term sequelae. The small sample of 20 clients is a drawback to this study, which should be replicated with larger numbers of participants.

Fick, D., & Foreman, M. (2000). Consequences of not recognizing delirium superimposed on dementia in hospitalized elderly individuals. *Journal of Gerontological Nursing*, 26(1), 30–40.

Aromatherapy

Aromatherapy can be used to relax or stimulate the CNS. Aromatic molecules give off signals that travel to the limbic system (the so-called “emotional switchboard” of the brain). “Because the limbic system is directly connected to those parts of the brain that control heart rate, blood pressure, breathing, memory, stress levels, and hormone balance, scientists have

TABLE 36-7
Herbs for the Nervous System

Classification	Functions	Herbs
Nerve Tonics	<ul style="list-style-type: none"> • Feed, tone, and strengthen the nervous tissues and cells • High in calcium, magnesium, B vitamins, and protein content • To be most effective, should be taken over long period of time. 	Chamomile (<i>Anthemis nobilis</i>) *Ginkgo (<i>Ginkgo biloba</i>) Hops (<i>Humulus lupulus</i>) Skullcap (<i>Scutellaria lactiflora</i>) *NOTE: Ginkgo has vasoconstrictive properties that help improve cerebral blood flow (Tierra, 1998); is licensed in Germany for treatment of cerebral dysfunction (Goldberg, 1999).
Nerve Demulcents	<ul style="list-style-type: none"> • Soothe and heal irritated, inflamed nerve endings. • Gel-like consistency coats and protects nerve endings. 	Barley (<i>Hordeum vulgare</i>) Flax seed Marsh mallow root (<i>Althea officinalis</i>) Oats (<i>Avena sativa</i>) Slippery elm (<i>Ulmus rubra</i>)
Nerve Sedatives	<ul style="list-style-type: none"> • Relax the nervous • Help reduce pain and tension • Promote sleep • Many exert anti-spasmodic effects. 	Catnip (<i>Catnip cataria</i>) Passion flower (<i>Passiflora incarnata</i>) St. John's wort (<i>Hypericum perforatum</i>)
Nerve Stimulants	<ul style="list-style-type: none"> • Activate nerve endings by increasing circulation • Provide nutrients • Revitalize the nervous system 	Cayenne (<i>Capsicum annum</i>) Ginger (<i>Zingiber officinalis</i>) Ginseng (<i>Panax quinquefolius</i> ; <i>Eleutherococcus senticosus</i>) Lemon balm (<i>Melissa officinalis</i>) Peppermint (<i>Mentha piperita</i>) Rosemary (<i>Rosmarinus officinalis</i>) Sage (<i>Salvia officinalis</i>)

ESSENTIAL OILS AND CNS HEALTH

Chamomile (<i>Anthemis nobilis</i>)	Alleviates physical and mental stress
Lavender (<i>Lavandula angustifolia</i>)	Calming, sedative effect
Mandarin (<i>Citrus reticulata</i>)	Relieves anxiety
Peppermint (<i>Mentha piperita</i>)	Stimulant; strengthens adrenal cortex
Yarrow (<i>Achillea millefolium</i>)	Promotes sleep

(Data from Goldberg, B. [1999]. *Alternative medicine: The definitive guide*. Tiburon, CA: Future Medicine Publishing; Tierra, M. [1998]. *The way of herbs*. New York: Pocket Books; Walters, C. [1998]. *Aromatherapy: A basic guide*. New York: Barnes & Noble.)

learned that oil fragrances may be one of the fastest ways to achieve physiological and psychological effects” (Goldberg, 1999, p. 54). The accompanying display lists some essential oils used to promote a healthy CNS.

EVALUATION

Evaluating the care of the client with sensory, perceptual, and cognitive alterations is dependent on the specific expected outcomes for each client. Evaluation of outcome achievement is performed through the nurse's use of observation and communication skills. An important component of evaluation is determination of the client's need for continued assistance in meeting needs. Evaluation of the client's self-care abilities provides information for discharge planning, including follow-up care or placement in a long-term care facility, if necessary.

KEY CONCEPTS

- The well-being of an individual is dependent upon the functions of sensation, perception, and cognition, which are controlled by the central nervous system.

NURSING CARE PLAN**The Client with Impaired Memory****Case Presentation**

Mr. Brown, a 53-year-old contract worker, arrives at the clinic with his son, who had found Mr. Brown wandering aimlessly along a road in his community. The son is worried that his father is becoming “more and more forgetful every day.” This was first noticed one month ago, when Mr. Brown forgot his phone number when completing a job application. Since then, the memory lapses have become more frequent and are now interfering with daily routines (he forgets to take his blood pressure medicine and gets lost returning home). Mr. Brown is currently unemployed and has no health care insurance. He denies that there is any problem and reluctantly agreed to come in today after hearing on the radio about free blood-pressure screenings offered by the clinic.

Assessment

- Impaired memory
- Disorientation (occasionally)
- Impaired judgment
- Impaired problem solving or decision making

Nursing Diagnosis #1

Acute Confusion related to unknown etiology as evidenced by fluctuations in cognition and level of consciousness, and memory disturbances.

Expected Outcome

The client will maintain current level of consciousness with no demonstrated deterioration.

Interventions/Rationales

1. Assess level of consciousness.
Establishes a baseline of data in order to intervene quickly if mental status changes.
2. Tell Mr. Brown your name and why you are meeting with him.
Keeps client oriented to reality.
3. Talk to Mr. Brown while providing care.
Maintains reality orientation.
4. Whenever possible, avoid the use of drugs that may cause drowsiness or sedation.
Increased drowsiness or sedation will make it difficult to determine changes in neurological function.
5. Encourage physical and mental activity, daily exercise, and interaction (e.g., with family or friends, newspaper, TV, etc.)
Improves memory, attention, and orientation.
6. Prepare the client for changes in activity or routines.
Reduces confusion and creates a routine to improve orientation.

Evaluation

Goal partially met. Mr. Brown remained free of injury while at the clinic.

Nursing Diagnosis #2

Risk for Injury related to cognitive deficits.

Expected Outcome

Mr. Brown will remain free of injury.

Interventions/Rationales

1. Assess environment and make alterations to enhance safety if necessary.
Alterations will lessen likelihood of injury.

(continues)

NURSING CARE PLAN**The Client with Impaired Memory (continued)**

2. Provide support to significant others and/or supervision for tasks deemed potentially harmful to client, discouraging tasks as appropriate (e.g., cooking, smoking).
Prevents physical injury to client or danger to others.
3. Provide a list of community resources and cost of services (e.g., day treatment centers, home health agencies) and encourage utilization of resources as appropriate.
A list will promote access to available resources that offer a safe environment through part- or full-time supervised care.

Evaluation

Goal partially met. Mr. Brown remained free of injury while at the clinic. He stated he was not interested in the list of community resources.

Nursing Diagnosis #3

Anxiety related to cognitive deficits and fear of being a burden to family.

Expected Outcomes

1. Mr. Brown will verbalize feelings of anxiety before leaving the clinic.
2. Mr. Brown will demonstrate decreased anxiety as evidenced by decreased irritability and increased cooperation.

Interventions/Rationales

1. Mr. Brown is informed that tests and examination will be performed only with his consent.
Decreases anxiety by reinforcing client's sense of control and shows respect for client.
2. Encourage Mr. Brown to talk about his concerns.
Verbalization of feelings decreases anxiety.
3. Observe for manifestations of anxiety.
Establishes a baseline of data and determines anxiety level.
4. Teach Mr. Brown one simple relaxation technique.
Increases client's control over anxiety-provoking situations.
5. Provide a referral for follow-up appointment.
Allows practitioner to monitor client's mental status.

Evaluation

1. Goal met. Mr. Brown discussed his fears of losing his mind and of being a burden to his son.
2. Goal partially met. Mr. Brown exhibited signs of relaxation; he stated he was not interested in learning relaxation techniques.
3. Goal met. Mr. Brown stated he would see the nurse practitioner as scheduled, and gave the appointment card to his son for "safekeeping."

- Primary components of consciousness include arousal and awareness.
- Cognitive and perceptual functioning is inferred through assessment of the client's behaviors (e.g., consciousness, orientation, speech, thought processes, and perceptions).
- The sensory system is made up of a complex network of afferent fibers within the peripheral nerves, afferent tracts located in the spinal cord and brain stem, and the higher cortex (cerebral lobes).
- Consciousness is a state of awareness of one's self, others, and the surrounding environment, and it affects intellect and emotions.
- Consciousness is controlled by the reticular activating system located within the midbrain and thalamus, as well as connective fibers between these structures and areas within the cerebral cortex.
- The degree of arousal (alertness) is indicated by a person's general response to the environment.
- Orientation refers to awareness of self in relation to the surrounding environment; an individual who is "oriented $\times 4$ " is aware of time, place, person, and situation.
- There are three distinct types of memory: immediate, recent, and remote.
- An individual's affect (mood or feeling tone) can affect thinking ability.

- Judgment is the ability to compare or evaluate alternatives to life situations and arrive at an appropriate course of action.
- There are two types of perceptual distortions, illusions and hallucinations.
- Language is one of the most complex of cognitive functions, involving the ability to speak, read, write, and comprehend.
- A person can become confused as a result of either overstimulation or understimulation.
- Sensory deprivation, a state of reduced sensory input, can occur as a result of illness, trauma, or isolation.
- Sensory overload is a state of excessive and sustained multisensory stimulation manifested by behavior change and perceptual distortion.

CRITICAL THINKING ACTIVITIES

1. What are the nursing implications when caring for someone with impaired judgment?
2. Why might a drug such as morphine sulfate be contraindicated in a client who has an altered level of consciousness?
3. What is the primary objective regarding learning needs for a client with an altered level of consciousness?
4. What is the primary objective regarding learning needs for a client with altered sensory perception?
5. What nursing interventions are therapeutic for a client experiencing sensory deprivation?
6. What nursing interventions are therapeutic for a client experiencing sensory overload?

Chapter 37

Fluid, Electrolyte, and Acid-Base Balance

The most important practical lesson that can be given to nurses is to teach them what to observe—how to observe—what are of importance.

—Nightingale (in Skretkowicz, 1992)

COMPETENCIES

1. Review the physiological processes and core concepts relative to body fluid and acid-base balance and imbalances.
2. Relate the common disturbances in body fluid and acid-base balance to their clinical manifestations and nursing interventions.
3. Identify the key elements for assessing clients with body fluid and acid-base alterations.
4. Describe the nursing data that supports the common nursing diagnosis and goals for clients with body fluid and acid-base disturbances.
5. Describe the common nursing interventions for clients with alterations in body fluid and acid-base balance.
6. Identify the key indicators to evaluate client achievement of expected outcomes to restore and to maintain body fluid and acid-base balance.

KEY
TERMS

acid	homeostasis	implantable port
acid-base balance	hydrostatic pressure	infiltration
acid-base buffer system	hypercalcemia	intracath
acidosis	hyperchloremia	intravenous (IV) therapy
alkalosis	hyperkalemia	isotonic
angiocatheter	hypermagnesemia	osmolality
arterial blood gases (ABGs)	hyponatremia	osmolarity
base	hyperphosphatemia	osmole
butterfly needles	hypertonic	osmosis
colloid	hypervolemia	osmotic pressure
crystalloid	hypocalcemia	permeability
cytomegalovirus (CMV)	hypochloremia	phlebitis
diffusion	hypokalemia	piggybacked
edema	hypomagnesemia	semipermeable
electrochemical gradient	hyponatremia	skin turgor
electrolyte	hypophosphatemia	solute
flashback	hypotonic	solvent
flow rate	hypoxemia	vesicant

The physiological functions and alterations of body fluid and acid-base balance are presented in this chapter. The term *body fluid* is used to denote both water and electrolytes, whereas the term *body water* refers to water alone. **Homeostasis**, or equilibrium of the internal environment, refers to the state of balance of body fluid.

PHYSIOLOGY OF FLUID AND ACID-BASE BALANCE

The body normally maintains a balance between the amount of fluid taken in and the amount excreted. Health promotion requires a maintenance of body fluid and acid-base balance.

Fluid Compartments

The body's fluid is contained within three compartments: cells, blood vessels, and the tissue space (space between the cells and blood vessels). To understand this concept, visualize cars on a freeway. The cars represent cells; the lanes represent the blood vessels, and the space between the cars in the lanes represents the tissue space. The freeway itself is the body.

Just as traffic is ongoing and continuous, fluids move constantly from one compartment to another to accommodate the cell's metabolic needs (Figure 37-1). Specific terms are used in describing compartmentalized body fluid. The prefixes (see the accompanying display) used with the root words for the compartments that contain the body fluid give meaning to the following terms:

- **Intracellular fluid:** *within* the cell
- **Intravascular fluid:** *within* blood vessels
- **Interstitial fluid:** *between* cells; fluid that surrounds cells

PREFIXES

<i>Inter-</i>	Between
<i>Intra-</i>	Within
<i>Extra-</i>	Outside
<i>Hypo-</i>	Under, beneath, deficient
<i>Hyper-</i>	Above, beyond, excessive

There are two types of body fluid: intracellular (ICF) and extracellular (ECF). Because intravascular and interstitial fluid are outside the cells, these fluids are extracellular. Key terms used in explaining the movement of molecules in body fluids are:

- **Solute:** Substance dissolved in a solution
- **Solvent:** Liquid that contains a substance in solution
- **Permeability:** Capability of a substance, molecule, or ion to diffuse through a membrane (covering of tissue over a surface, organ, or separating spaces)
- **Semipermeable:** Selectively permeable (All membranes in the body allow some solutes to pass through the membrane without restriction but will prevent the passage of other solutes.)

Cells have permeable membranes that allow fluid and solutes to pass into and out of the cell. Permeability allows the cell to acquire the nutrients it needs from extracellular fluid to carry on metabolism and to eliminate metabolic waste products.

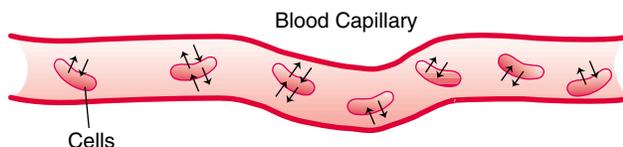

Figure 37-1 The Movement of Fluid Between the Intracellular and Extracellular Compartments

Blood vessels have permeable membranes that bathe and feed the cells. The intravascular fluid of arterioles carries oxygen and nutrients to the cells. The venules take in the waste products from the cells' metabolic activity.

Cells and capillaries form a meshlike structure that creates a tissue space between cells and the vascular system to allow cellular access to the vascular system. Interstitial space promotes access of the cells to the arterioles and venules.

Body Water Distribution

Water is the largest single constituent of the body, representing 45% to 75% of the body's total weight. About two-thirds of the body fluid is intracellular. The remaining one-third is extracellular, with one-fourth of this fluid being intravascular and three-fourths being interstitial fluid. Bones are made up of nearly one-third water, while the muscles and brain cells contain 70% water. Body fat is essentially free of water; therefore, the ratio of water to body weight is greater in leaner people than in obese people.

Water is present in all body tissues and cells, and serves two main functions: to act as a solvent for the essential nutrients, so that they can be used by the body; and to transport nutrients and oxygen from the blood to the cells and to remove waste material and other substance from the cells back to the blood so they can be excreted by the body. Water is also needed by the body to:

- Give shape and form to the cells
- Regulate body temperature
- Act as a lubricant in joints
- Cushion body organs
- Maintain peak physical performance

Water loss has a negative effect on the body's ability to function, because every 2% to 5% of water loss results in a 30% decrease in work performance (Kloss, 1995; Kleiner, 1999).

Electrolytes

An **electrolyte** is a compound that, when dissolved in water or another solvent, forms or dissociates into ions

DISTRIBUTION OF CHLORIDE, BICARBONATE, PHOSPHATE, AND SULFATE IN BODY FLUID

Electrolyte	Extracellular (mEq/L)	Intracellular (mEq/L)
Chloride (Cl ⁻)	98–106	1–4
Bicarbonate (HCO ₃ ⁻)	25–27	10–12
Phosphate (HPO ₄ ⁻)	1.7–4.6	100–104
Sulfate (SO ₄ ⁻)	1	2

(Adapted from Fischbach, F. [2000]. *A manual of laboratory and diagnostic tests* (6th ed.). Philadelphia: Lippincott.)

(electrically charged particles) (Figure 37-2). The electrolytes provide inorganic chemicals for cellular reactions and control mechanisms. Electrolytes have special physiological functions in the body that promote neuromuscular irritability, maintain body fluid osmolarity, regulate acid-base balance, and distribute body fluids between the fluid compartments.

Electrolytes are measured in terms of their electrical combining power, the quantities of cations and anions in a solution, expressed as milliequivalents per liter (mEq/L). Because electrolytes produce either positively charged ions (cations) or negatively charged ions (anions), they are critical regulators in the distribution of body fluid. The main electrolytes in body fluid are: sodium (Na⁺), potassium (K⁺), calcium (Ca²⁺), and magnesium (Mg²⁺).

Table 37-1 discusses the distribution of electrolytes in body fluid, their regulatory functions, and dietary sources. As shown in Table 37-1, the extracellular fluid contains the largest quantities of sodium, chloride, and bicarbonate ions, but only small quantities of potassium, calcium, magnesium, phosphate, sulfate, and organic acid ions. The intracellular fluid contains only small quantities of sodium and chloride ions and almost no calcium ions. Large quantities of potassium and phosphate ions with moderate quantities of magnesium and sulfate ions are contained within intracellular fluid (see the accompanying display).

Movement of Body Fluids

The physiological forces that affect the movement of body fluids through cell walls and capillaries can be perceived as a mass-transportation system that carries traffic between the compartments. These forces transport molecules of water, foods, gases, wastes, and ions to maintain a physiological balance between extracellular and intracellular fluid volumes. These transport processes account for fluid shifts between the compartments (Table 37-2).

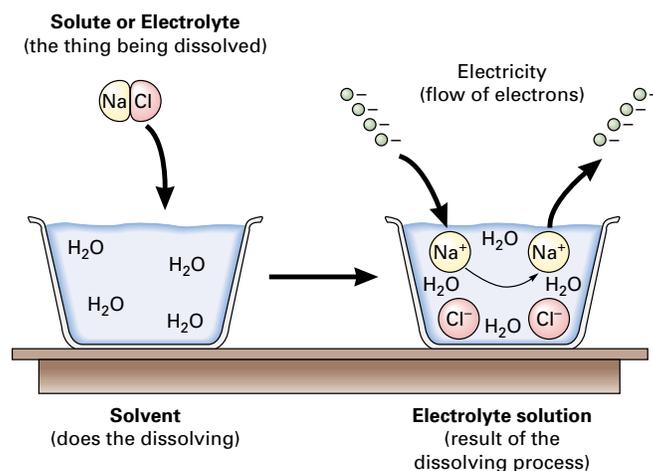

Figure 37-2 Dissolution of Electrolytes

TABLE 37-1
Common Electrolytes

Electrolyte Ion	Distribution in Body Fluid		Basic Functions	Dietary Sources
	Extracellular (mEq/L)	Intracellular (mEq/L)		
Sodium (Na ⁺)	135–154	15–20	<p>Regulates fluid volume within extracellular fluid (ECF) compartment. Increases cell membrane permeability. Regulates vascular osmotic pressure. Controls water distribution between ECF and intracellular fluid (ICF) compartments. Stimulates conduction of nerve impulses. Maintains neuromuscular irritability.</p>	<p>Table salt (NaCl), 40% of which is sodium; cheese, milk, processed meat, poultry, shellfish, fish, eggs, and foods preserved with salt (e.g., ham and bacon)</p>
Potassium (K ⁺)	3.5–5	150–155	<p>Regulates osmolality of ICF. Promotes transmission of nerve impulses. Promotes contraction of skeletal and smooth muscles. Promotes enzymatic action for cellular energy production by transforming carbohydrates into energy and restructuring amino acids into proteins. Regulates acid-base balance by cellular exchange of hydrogen ions.</p>	<p>Fruits, especially bananas, oranges, and dried fruits; vegetables, meats, and nuts</p>
Calcium (Ca ²⁺)	4.5–5.5	1–2	<p>Provides strength and durability to bones and teeth. Establishes thickness and strength of cell membranes. Promotes transmission of nerve impulses. Decreases neuromuscular excitability. Is essential for blood coagulation. Promotes absorption and utilization of vitamin B₁₂. Activates enzyme reactions and hormone secretions.</p>	<p>Dairy products (milk, cheese, and yogurt), sardines, whole grains, and green leafy vegetables</p>
Magnesium (Mg ²⁺)	4.5–5.5	27–29	<p>Activates enzyme systems, mainly those associated with vitamin B metabolism and the utilization of potassium, calcium, and protein. Promotes regulation of serum calcium, phosphorus, and potassium levels. Promotes neuromuscular activity.</p>	<p>Green leafy vegetables, whole grains, fish, and nuts</p>

TABLE 37-2
Movement of Body Fluid

Physiological Force	Process	Related Factors
<p>Diffusion</p> <p>The rate of diffusion (continual movement of molecules in a solution or a gas) is influenced by:</p> <ul style="list-style-type: none"> • The size of the molecule (smaller molecules diffuse faster than larger molecules) • The concentration of the molecules (molecules move from an area of greater concentration to an area of lesser concentration) • The temperature of the solution (higher temperatures increase the rate of diffusion) 	<p>Particles move across a permeable membrane and disperse in all directions through a solution or a gas (Figure 37-3).</p>	<p>The particle's electrical charge can also affect the process of diffusion because ions with opposite charges are pulled toward other ions.</p>
<p>Osmosis</p> <p>The process of osmosis (passage of a solvent from an area of lesser concentration to an area of greater concentration) is influenced by:</p> <ul style="list-style-type: none"> • The net movement of water • The semipermeability of the membrane 	<p>Solvent molecules move across a membrane to an area where there is a higher concentration of solute that cannot pass through the membrane (Figure 37-4).</p>	<p>Osmotic pressure is force created when two solutions of different concentrations are separated by a selectively permeable membrane. An osmole is the unit of measure of osmotic pressure.</p>
<p>Active Transport</p> <p>An electrochemical gradient (sum of all the diffusion forces acting on the membrane, from either a concentration gradient or an electrical or pressure gradient) exists when there is active transport.</p>	<p>Occurs when a cell membrane moves molecules or ions against an electrochemical gradient from an area of lesser concentration to an area of greater concentration.</p>	<p>In order for active transport to occur, there must be a carrier and adenosine triphosphate (ATP) molecules inside the cell membrane (Figure 37-5).</p>
<p>Hydrostatic Pressure</p> <p>Hydrostatic pressure (force a liquid exerts on the sides of the container that holds it) is governed by:</p> <ul style="list-style-type: none"> • The force by which the heart pumps • The rate of blood flow • The arterial blood pressure • The venous blood pressure 	<p>The force of fluid presses outward against the blood vessel wall.</p>	<p>The hydrostatic pressure is twice as great at the arterial end than at the venous end, causing fluid and solutes to go from the arterial end of the capillary into the interstitial space.</p>
<p>Filtration</p> <p>Filtration is governed by the presence of a greater hydrostatic pressure in the arterial end capillaries than in the interstitial spaces.</p>	<p>The movement of fluid through a semipermeable membrane from an area with higher hydrostatic pressure to an area with lower hydrostatic pressure creates an outward gain of fluid in the interstitial spaces.</p>	<p>The body achieves total fluid balance when the excess fluid and solutes remaining in the interstitial spaces are returned to the intravascular compartment by the lymphatic system.</p>
<p>Colloid Osmotic Pressure</p> <p>Created by solutes or colloids (proteins or nondiffusible substances) in the plasma</p>	<p>There is a movement of fluid between the intravascular and interstitial compartments, based on the number of solute particles on the concentrated side and the presence of a semipermeable membrane.</p>	<p>Because the protein content of intravascular fluid is 16 times as great as that of interstitial fluid, the fluids move into the capillary or intravascular compartment when the heart pumps effectively.</p>

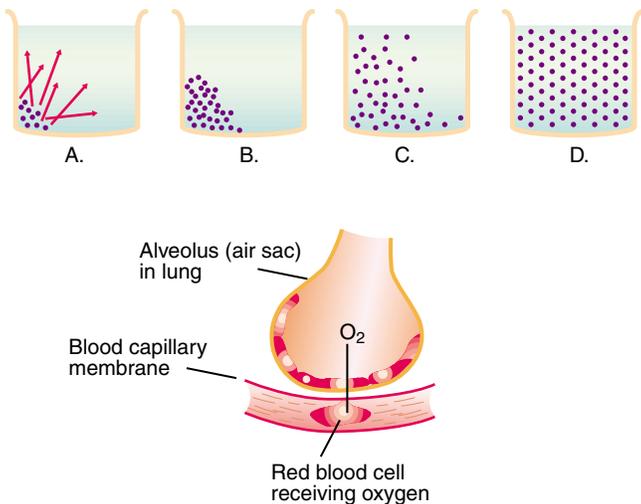

Figure 37-3 The process of diffusion. A. A small lump of sugar is placed in a beaker of water, its molecules dissolve and begin to diffuse outward. B., C. The sugar molecules continue to diffuse through the water from an area of greater concentration to an area of lesser concentration. D. Over a long period of time, the sugar molecules are evenly distributed throughout the water, reaching a state of equilibrium. Example of diffusion in the human body: Oxygen diffuses from an alveolus in a lung, where it is in greater concentration, across the capillary membrane, into a red blood cell, where it is in lesser concentration.

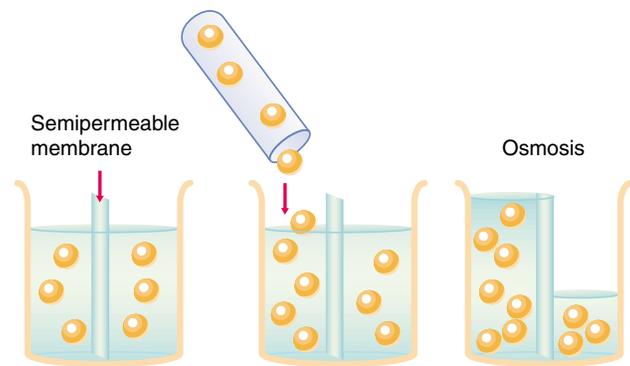

Figure 37-4 The Process of Osmosis

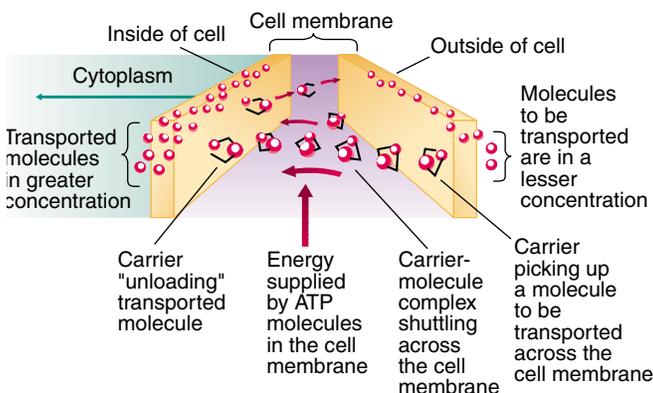

Figure 37-5 The Active Transport of Molecules from an Area of Lesser Concentration to an Area of Greater Concentration

Regulators of Fluid Balance

The body has many regulators that maintain fluid balance, including fluid and food intake, skin, lungs, gastrointestinal tract, and kidneys. When all organs are functioning normally, the body is able to maintain homeostasis.

Fluid and Food Intake and Loss

There are three natural sources by which water enters the body: oral liquids; water in foods; and water formed by oxidation of foods. A normal diet provides the electrolytes required by the body (see the accompanying display for the typical daily amount of body fluid intake for an adult).

Body fluid is replenished by the ingestion of liquids and food products such as meats and vegetables, which contain 65% to 97% water. The third source of body fluid is the metabolism of foods, which yields water of oxidation. The kidneys excrete the largest quantity of fluid; other avenues for water loss are the lungs, skin, and gastrointestinal tract.

NORMAL DAILY BODY FLUID INTAKE FOR AN ADULT

Ingested liquids	1500 ml
Water in foods	700 ml
Water from oxidation	200 ml
TOTAL	2400 ml

Skin

An estimated water loss of 300 to 400 ml per day occurs by diffusion through the skin of an adult. Because the person is not aware of this water loss, it is called *insensible loss*. Water is also lost through the skin by perspiration; however, the total amount of water lost by perspiration can vary from 1.5 to 3.5 L per hour, depending on environmental factors and body temperature.

Lungs

An estimated insensible water loss of 300 to 400 ml per day occurs in an adult through expired air, which is saturated with water vapor. This amount may vary with the rate and depth of respirations.

Gastrointestinal Tract

Although a large amount of fluid—about 8,000 ml per day in the adult—is secreted into the gastrointestinal tract, almost all of this fluid is reabsorbed by the body. In adults, about 200 ml of water is lost per day in feces. Severe diarrhea can cause a fluid and electrolyte deficit because the gastrointestinal fluids contain a large amount of electrolytes.

Kidneys

The kidneys play a major role in maintaining fluid balance by excreting 1,200 to 1,500 ml/day in the adult. The excretion of water by healthy kidneys is proportional to the fluid ingested and the amount of waste or solutes excreted.

When an extracellular fluid volume deficit occurs, hormones play a key role in restoring the extracellular fluid volume. The release of the following hormones into circulation causes the kidneys to conserve water:

- Antidiuretic hormone (ADH) from the posterior pituitary gland acts on the distal tubules of the kidneys to reabsorb water.
- Aldosterone (produced in the adrenal cortex) causes the reabsorption of sodium from the renal tubules. The increased reabsorption of sodium causes water retention in the extracellular fluid, increasing its volume.
- Renin, which is released from the juxtaglomerular cells of the kidneys, promotes vasoconstriction and the release of aldosterone.

The interaction of these hormones with regard to renal functions serves as the body's compensatory mechanism to maintain homeostasis.

Sodium is the main electrolyte that promotes the retention of water. An intravascular water deficit causes the renal tubules to reabsorb more sodium into circulation. Because water molecules go with the sodium ions, the intravascular water deficit is corrected by this action of the renal tubules.

Acid-Base Balance

Acid-base balance refers to the homeostasis of the hydrogen ion concentration in extracellular fluid. The slightest variation in the hydrogen ion concentration causes marked alterations in the rate of cellular chemical reactions. The pH symbol is used to indicate the hydrogen ion concentration of body fluids; 7.35 to 7.45 is the normal pH range of extracellular fluid. Hydrogen ions (H^+), which carry a positive charge, are protons. Depending on the number of hydrogen ions present, a solution can be either acidic, neutral, or alkaline.

As the number of hydrogen ions increases, the fluid becomes acidic. *Acidity of a solution increases as the pH value decreases.* An **acid** is a substance that donates hydrogen ions. For example, hydrochloric acid (HCl) ionizes in water (a solution) to form hydrogen ions and chloride ions. HCl, which is found in gastric juices, has a strong tendency to form ions, discharging hydrogen ions into the solution; carbonic and acetic acids are considered weak acids because in a solution they provide a low concentration of hydrogen ions.

As the number of hydrogen ions decreases, the fluid becomes alkaline. *Alkalinity of a solution increases as the pH value increases.* A **base** is a substance that accepts hydrogen ions (proton acceptor).

A neutral solution has a pH of 7. In such a solution there are equal numbers of hydrogen ions (H^+) and hydroxyl ions (OH^-), which can combine to form water (H_2O). When the number of hydrogen ions is increased, the solution becomes acidic (pH value below 7); a decrease in the number of hydrogen ions causes the solution to become alkaline (pH value above 7). When the number of free hydrogen ions in a solution increases to the point that the pH value becomes less than 7.35, the body is in a state of **acidosis**. The opposite occurs with **alkalosis**, in which a pH value higher than 7.45 results from a low hydrogen ion concentration.

Regulators of Acid-Base Balance

The body has three main control systems that regulate acid-base balance to counter acidosis or alkalosis: the buffer systems; respiration; and renal control of hydrogen ion concentration. These systems vary in their reaction time in regulating and restoring balance to the hydrogen ion concentration of a solution.

Buffer Systems

All body fluids are supplied with an **acid-base buffer system** (a solution containing two or more chemical compounds that prevents marked changes in hydrogen ion concentration when either an acid or a base is added to a solution). The buffer system reacts within a fraction of a second to prevent excessive changes in the hydrogen ion concentration.

There are several *chemical* buffer systems of body fluids, which are activated under different conditions; however, the bicarbonate-carbonic acid system (carbonate system) is the body's primary buffer system. The carbonate system consists of a mixture of carbonic acid (H_2CO_3) and sodium bicarbonate ($NaHCO_3$). The pH of the extracellular fluid can be returned to normal limits by this system because carbonic acid is a weak acid, which ionizes to a limited extent, and bicarbonate is a weak base, which yields the hydroxyl ion.

Bicarbonate helps to stabilize pH by combining reversibly with hydrogen ions. Most of the body's bicarbonate is produced in red blood cells, where the enzyme carbonic anhydrase accelerates the conversion of carbon dioxide to carbonic acid. The production of bicarbonate is illustrated in the following reversible equation:

When the hydrogen ion concentration increases in the extracellular space, the reaction shifts toward the left; a decreased concentration of hydrogen ion drives the reaction to the right.

Respiratory Regulation of Acid-Base Balance

The respiratory buffering system helps to maintain acid-base balance by controlling the content of carbon dioxide

in extracellular fluid. The *rate of metabolism* determines the formation of carbon dioxide. Carbon dioxide is continually being formed in the body by different intracellular metabolic processes. The carbon in foods is oxidized by oxygen to form carbon dioxide.

It takes the respiratory regulatory mechanism several minutes to respond to changes in the carbon dioxide concentration of extracellular fluid. With the increase of carbon dioxide in extracellular fluids, respirations are increased in rate and depth so that more carbon dioxide is exhaled. As the respiratory system removes carbon dioxide, there is less carbon dioxide in the blood to combine with water to form carbonic acid. Likewise, if the blood level of carbon dioxide is low, respirations are depressed to maintain a normal ratio between carbonic acid and basic bicarbonate.

Renal Control of Hydrogen Ion Concentration

The kidneys control extracellular fluid pH by eliminating either hydrogen ions or bicarbonate ions from body fluids. If the bicarbonate concentration in the extracellular fluid is greater than normal, the kidneys excrete more bicarbonate ions, making the urine more alkaline. Conversely, if more hydrogen ions are excreted in the urine, the urine becomes more acidic. The renal mechanism for regulating acid-base balance cannot readjust the pH within seconds, as can the extracellular fluid buffer system, nor within minutes as can the respiratory compensatory mechanism, but it can function over a period of several hours or days to correct an acid-base imbalance.

FACTORS AFFECTING FLUID AND ELECTROLYTE BALANCE

The balance of fluids and electrolytes in the body is dependent on many factors and will vary depending on such elements as age and lifestyle.

Age

Body water distribution is relative to body size. The smaller the body, the larger the fluid content:

- Adult, 60% water
- Child, 60% to 77% water
- Infant, 77% water
- Embryo, 97% water

In the elderly, body water diminishes because of tissue loss; the percentage of total body weight that is fluid may be reduced to 45% to 50% in persons over age 65. Caution must be used when administering diuretics, especially thiazide diuretics, to the elderly to prevent diuretic-induced electrolyte disturbances.

Lifestyle

Loss of body fluids can result from stress, exercise, or a warm or humid environment. Stress leads to increased blood volume and decreased urine production, with a subsequent intensification of antidiuretic hormone levels. Sweating and exercise cause the body to lose water and sodium, thus necessitating electrolyte replacement and intensifying the thirst response. Warm climates can exert a similar effect.

An individual's diet will also determine fluid and electrolyte levels. Adequate intake of fluids, carbohydrates, potassium, calcium, sodium, fats, and protein is essential in helping the body maintain homeostasis and function properly. Dehydration is one of the most common yet most serious fluid imbalances that can occur from poor monitoring of diet. One nursing goal is to ensure that all clients understand the role water plays in health and to see that clients understand how to maintain adequate hydration status.

DISTURBANCES IN ELECTROLYTE AND ACID-BASE BALANCE

The clinical management of clients experiencing disturbances in sodium, potassium, calcium, magnesium, and phosphate is presented using the functional health pattern model. See Table 37-3 for the causes, clinical manifestations, and nursing interventions for these electrolyte disturbances. Because chloride has several characteristics similar to other ions, a brief discussion of chloride imbalance is also presented. Acid-base imbalances caused by a disturbance in the level of either carbonic acid or bicarbonate are also presented using the functional health pattern model.

Electrolyte Disturbances

In health, normal homeostatic mechanisms function to maintain electrolyte and acid-base balance. In illness, one or more of the regulating mechanisms may be affected, or the imbalance may become too great for the body to correct without treatment. Refer to Chapter 28, Table 28-7, for the normal laboratory values of electrolytes.

Sodium

Sodium is the primary determinant of extracellular fluid concentration because of its high concentration and inability to cross the cell membrane easily. As discussed in Table 37-3, alterations in sodium concentration can produce profound central nervous system effects on cognition and sensory perception and on the circulating blood volume. When the kidneys reabsorb sodium ions, chloride and water are reabsorbed with the sodium to maintain the body's fluid volume.

TABLE 37-3
The Clinical Management of Clients Experiencing Common Electrolyte Disturbances

Disturbance/Causes	Clinical Manifestations	Nursing Interventions
<p>Hyponatremia</p> <p>Nutrition and metabolism</p> <ul style="list-style-type: none"> • Low sodium intake • High water intake • Anorexia nervosa • Loss of GI secretions (vomiting, diarrhea, bulimia, suctioning or drainage, tap-water enemas) • Loss of ECF sodium (peritonitis, burns) • Excessive ingestion of water or administration of IV solutions (D₅W) • ECF sodium dilution (congestive heart failure [CHF], cirrhosis, nephrosis) <p>Elimination</p> <ul style="list-style-type: none"> • Advanced renal disorders • Diuretics • Antidiuretic hormone (ADH) • Syndrome of inappropriate antidiuretic hormone (SIADH) 	<ol style="list-style-type: none"> 1. Hyponatremia

Hyponatremia is a deficit in the extracellular level of sodium. With hyponatremia, there is either a sodium deficit or a water excess; a hypo-osmolar state exists because the ratio of water to sodium is too high. The water moves out of the vascular space into the interstitial space and then into the intracellular space, causing edema. The low extracellular serum sodium causes water to enter the cells in the brain, thereby producing cerebral edema as manifested by the cognitive and sensory changes listed in Table 37-3.

Hypertatremia

Hypertatremia is an excess in the extracellular level of sodium. With an excess of sodium or a loss of water, a hyperosmolar state exists because the ratio of sodium to water is too high. This ratio causes an increase in the extracellular osmotic pressure, which pulls fluid out of the cells into the extracellular space. The symptoms of this increase depend on the cause and the location of the edema (see Table 37-3).

Potassium

The normal range of extracellular potassium is narrow (3.5–5.0 mEq/L). The slightest decrease or increase can cause serious or life-threatening effects on physiological functions. A reciprocal relationship exists between sodium and potassium; large sodium intake results in an

increased loss of potassium, and vice versa. When potassium is lost from the cells, sodium enters the cells. Intracellular potassium deficit may coexist with an excess of extracellular potassium. There are two main categories of diuretics that can cause hypokalemia:

- Potassium-wasting diuretics* excrete potassium and other electrolytes, such as sodium and chloride.
- Potassium-sparing diuretics* retain potassium but excrete sodium and chloride.

Hypokalemia

Hypokalemia is a decrease in the extracellular level of potassium. Gastrointestinal-tract disturbances and the use of diuretics can place the client at risk for hypokalemia and an acid-base imbalance (metabolic alkalosis). Potassium-wasting diuretics can cause

NURSING ALERT

Hypokalemia

Hypokalemia can cause a cardiac arrest when:

- The potassium level is less than 2.5 mEq/L.
- The client is taking digitalis (a drug that strengthens the contraction of the myocardium and slows down the rate of the heart). *Hypokalemia enhances the action of the drug, causing toxicity.*

hypokalemia. Besides diuretics, other major drug groups that can cause hypokalemia are laxatives, corticosteroids, and antibiotics.

Hyperkalemia

Hyperkalemia is an increase in the extracellular level of potassium. There are major drug groups that may cause hyperkalemia:

- Potassium-sparing diuretics
- Central nervous system agents
- Oral and intravenous replacement potassium salts

Hyperkalemia can also inhibit the action of digitalis.

NURSING ALERT

Potassium Chloride

Never administer more than 10 mEq of intravenous potassium chloride (KCl) per hour; the normal dose of intravenous KCl is 20–40 mEq/L to infuse over an 8-hour period.

Calcium

Most of the body's calcium (99%) is deposited in bone as phosphate and carbonate. The remaining 1% is in the blood plasma (serum). Normally, 50% of the serum calcium is ionized (physiologically active), with the remaining 50% bound to protein. Free, ionized calcium is needed for cell membrane permeability. The calcium that is bound to plasma protein cannot pass through the capillary wall and therefore cannot leave the intravascular compartment.

NURSING TIP

Serum Calcium

Approximately 50% of the serum calcium level is bound to protein. Correlate the serum calcium level with the serum albumin level when evaluating the laboratory results. *Any change in serum protein will result in a change in the total serum calcium.*

A stable blood level of calcium is maintained by a negative-feedback system controlled by vitamin D, parathyroid hormone, calcitonin (thyrocalcitonin), and the serum concentrations of calcium and phosphate ions. A decreased blood level stimulates the parathyroid gland to secrete parathyroid hormone, which in turn mobilizes the release of calcium from the bone,

increases the renal reabsorption, and increases intestinal absorption in the presence of vitamin D. Likewise, calcitonin, secreted by the thyroid gland, reduces the blood calcium concentration.

Calcium ions are never completely absorbed from the gastrointestinal tract. Dietary calcium absorption and utilization require an adequate amount of protein and vitamin D. Besides being needed by the body for bone and tooth formation, calcium is an important ion in the blood-clotting mechanism and for maintaining the integrity of the neuromuscular system.

Hypocalcemia

Hypocalcemia is a decrease in the extracellular level of calcium. The rapid administration of citrated blood, alkalosis, and elevated levels of serum albumin increase the activity of calcium binders, thereby decreasing the amount of free calcium.

Hypercalcemia

Hypercalcemia is an increase in the extracellular level of calcium. The clinical symptoms result from a decrease in neuromuscular activity, reabsorption of calcium from bone, and the kidney's response to a high serum calcium concentration.

NURSING ALERT

Hypercalcemic Crisis

A rapid increase in the extracellular level of calcium (above 8 to 9 mEq/L) can trigger a hypercalcemic crisis. To prevent a hypercalcemic crisis, provide adequate hydration and administer diuretics or phosphate or both as prescribed by the health care practitioner.

Magnesium

Magnesium plays an important role as a coenzyme in the metabolism of carbohydrates and proteins and as a mediator in neuromuscular activity. Magnesium has the unique characteristic of being the only cation that has a higher concentration in cerebrospinal fluid than in extracellular fluid.

Hypomagnesemia

Hypomagnesemia is a decrease in the extracellular level of magnesium and usually occurs with hypokalemia and hypocalcemia. It is probably the most undiagnosed electrolyte deficit because it is asymptomatic until the serum level approaches 1.0 mEq/L; the normal range is 4.5–5.5 mEq/L (Kee & Paulanka, 2000).

Drugs that may cause hypomagnesemia include: digitalis, potassium-wasting diuretics, cortisone, aminoglycosides, and amphotericin B; the chronic use of laxatives may also cause the condition. Clinical manifestations are related to the neuromuscular, neurologic, or cardiovascular system (see Table 37-3).

NURSING ALERT

Hyperalimentation

The continuous use of total parenteral nutrition (TPN, hyperalimentation) without a magnesium supplement can cause hypomagnesemia.

Hypermagnesemia

Hypermagnesemia refers to an increase in the extracellular level of magnesium. It rarely occurs from excessive dietary ingestion; however, overuse of magnesium-containing drugs (antacids, laxatives, and intravenous magnesium sulfate) can cause hypermagnesemia. The clinical manifestations of hypermagnesemia are non-specific (refer to Table 37-3).

Phosphate

Phosphate is the main intracellular anion; it appears as phosphorus in the serum. Phosphorus is similar to calcium in that vitamin D is needed for its reabsorption from the renal tubules.

THINK ABOUT IT

Intake of Phosphorus

When the dietary intake of calcium from milk is sufficient to meet minimal requirements, phosphorus needs will also be met. How will you educate clients who either cannot or will not consume an adequate daily intake of milk to meet their calcium and phosphorus needs?

Hypophosphatemia

Hypophosphatemia is a decreased extracellular level of phosphorus. An increase in parathyroid hormone causes decreased renal reabsorption and increased excretion of phosphates. The aim of nursing care is to protect the client from injury and to correct the deficit (see Table 37-3).

Hyperphosphatemia

Hyperphosphatemia is an increased extracellular level of phosphorus. Excessive administration (oral or intravenous) of phosphate-containing substances can cause hyperphosphatemia. Other causes of hyperphosphatemia are hypoparathyroidism, renal insufficiency, and laxatives containing phosphate.

Chloride

As previously stated, chloride and water move in the same direction as sodium ions, influencing the osmolality of extracellular fluid. Although chloride losses usually follow sodium losses, the proportion will differ

because a loss of chloride can be compensated for by an increase in bicarbonate. Therefore, signs and symptoms of a chloride imbalance will be similar to those of a metabolic acid-base imbalance, discussed later in this chapter. A deficit of either chloride or potassium will lead to a deficiency of the other electrolyte.

Hypochloremia

Hypochloremia is a decrease in the extracellular level of chloride. Gastrointestinal tract losses may cause a decrease in chloride because of the acid content of gastric juices, mainly hydrogen chloride. Because the bicarbonate ion compensates for the loss of chloride, the client is at risk for developing metabolic alkalosis. The signs and symptoms of hypochloremia are muscle twitching and slow, shallow breathing. With a severe loss of chloride and extracellular fluid volume, there may be a drop in blood pressure.

Hyperchloremia

Hyperchloremia is an increase in the extracellular level of chloride. It usually occurs with dehydration, hyponatremia, and metabolic acidosis. The signs and symptoms of hyperchloremia are muscle weakness, deep, rapid breathing, and lethargy progressing to unconsciousness if untreated.

Acid-Base Disturbances

The common types of acid-base imbalances are respiratory acidosis and alkalosis and metabolic acidosis and alkalosis.

Laboratory Data

The biochemical indicators of acid-base imbalance are assessed by measurement of arterial blood gases (ABGs). **Arterial blood gases** measure the levels of oxygen and carbon dioxide in arterial blood. The levels of blood pH, bicarbonate ion, sodium, potassium, and chloride are also important in the assessment of acid-base imbalance.

In the determination of whether the acid-base imbalance is caused by a respiratory or a metabolic alteration, the key indicators are bicarbonate and carbonic acid levels (Figure 37-6). With respiratory acidosis and alkalosis, the bicarbonate level is normal and carbonic acid is either increased (acidosis) or decreased (alkalosis). With metabolic acidosis and alkalosis, the carbonic acid is normal and the bicarbonate level is either decreased (acidosis) or increased (alkalosis). Refer to Chapter 28 for a complete discussion of arterial blood gas analysis and to Chapter 32, Table 32-4, for normal values for arterial blood gases.

Respiratory Acidosis (Carbonic Acid Excess)

Respiratory acidosis is characterized by an increased hydrogen ion concentration (a blood pH below 7.35), an

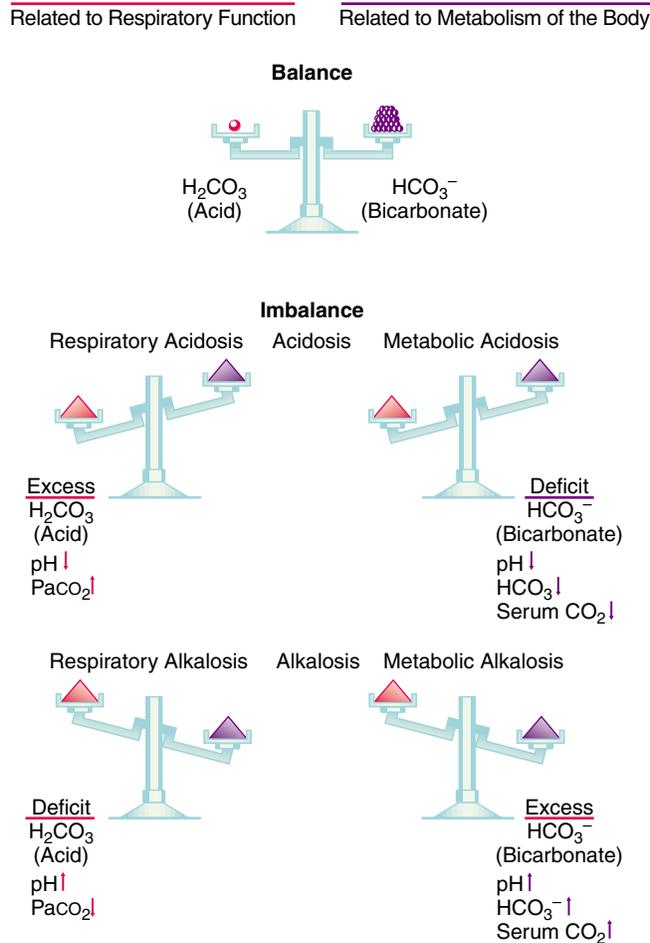

Figure 37-6 Acid-Base Balance and Imbalance

increased arterial carbon dioxide pressure (greater than 45 mm Hg), and an excess of carbonic acid. Respiratory acidosis is caused by hypoventilation or any condition that depresses ventilation (see the accompanying display).

Hypoventilation can begin in the respiratory system, as occurs with respiratory failure, or outside the respiratory system, as occurs with drug overdose. Common drugs that can cause central nervous system depression and place the client at risk for respiratory acidosis are narcotics, barbiturates, and anesthetic agents.

COMMON CAUSES OF ACUTE AND CHRONIC RESPIRATORY ACIDOSIS

Acute

Drug-induced CNS depression
Pneumonia and atelectasis
Pulmonary edema
Respiratory distress syndrome
Pneumothorax
Hypoventilation
Poliomyelitis
Chest trauma
Brain and spinal cord injury

Chronic

Asthma
Cystic fibrosis
Emphysema

Clients with respiratory acidosis experience neurologic changes resulting from the acidity of the cerebrospinal fluid and brain cells. Hypoventilation causes **hypoxemia** (decreased oxygen levels), which causes further neurologic impairments; refer to Chapter 32 for a complete discussion of hypoxemia. Hyperkalemia may accompany acidosis. See Table 37-4 for the clinical manifestations and nursing interventions used to treat respiratory acidosis.

Respiratory Alkalosis (Carbonic Acid Deficit)

Respiratory alkalosis is characterized by a decreased hydrogen ion concentration (a blood pH above 7.45) and a decreased arterial carbon dioxide pressure (less than 35 mm Hg). Respiratory alkalosis is caused by hyperventilation (excessive exhalation of carbon dioxide) resulting in hypocapnia (decreased arterial carbon dioxide concentration). Hyperventilation can be triggered by hypoxia at high altitudes, anxiety, fear, pain, fever, and rapid mechanical ventilation. Other causes of hyperventilation, which involve overstimulation of the respiratory center, include salicylate poisoning, hyperthyroidism, pneumonia, atelectasis, asthma, adult respiratory distress syndrome, congestive heart failure, pulmonary edema and embolus, brain tumors, meningitis, and encephalitis; refer to Table 37-4 for the clinical manifestations and treatment.

Metabolic Acidosis (Bicarbonate Deficit)

Metabolic acidosis is characterized by an increase in hydrogen ion concentration (blood pH below 7.35) or a decrease in bicarbonate concentration. Causes of metabolic acidosis can be divided into two categories: loss of base and gain in metabolic acids. Chronic diarrhea causes an excessive loss of bicarbonate and sodium ions from the small intestines. With the loss of sodium ions, chloride ions are in excess and combine with hydrogen to produce a strong acid (hydrochloric acid).

Clients with certain medical diagnoses are at risk for metabolic acidosis. Such conditions include:

1. **Diabetic ketoacidosis:** The cells are deprived of glucose (decrease or absence of insulin) for metabolism; the liver, in response to the needs of the cells, increases the metabolism of fatty acids, which causes an increase in ketone bodies, making the extracellular fluid more acidic.
2. **Renal failure:** The normal mechanism of the kidneys to conserve sodium and water and excrete hydrogen is compromised.
3. **Anaerobic metabolism:** Cellular catabolism and acid accumulation occur with starvation, severe malnutrition, infection, fever, trauma, shock, and excessive exercise.
4. **Drug overdose:** Acid accumulation results from excessive ingestion of salicylate, paraldehyde, and methanol.

TABLE 37-4
Respiratory and Metabolic Acidosis and Alkalosis

Imbalance/Causes	Clinical Manifestations	Nursing Interventions
Respiratory Acidosis (Retention of Carbon Dioxide)		
<ul style="list-style-type: none"> • CNS disorders • Drug overdose • Pneumonia • Pulmonary edema • Pneumothorax • Restrictive lung disease 	<ol style="list-style-type: none"> 1. (From Hartshorn, J., Sole, M. L., Lamborn, M., & Cullen, B. N. [1997]. *Introduction to critical care nursing* [2nd ed.]. Philadelphia: Saunders; Kee, J. L., & Paulanka, B. J. [2000]. *Fluids and electrolytes with clinical applications* [6th ed.]. Albany, NY: Delmar Thomson Learning)

In response to metabolic acidosis, the respiratory center is stimulated, causing an increase in the rate and depth of respirations (Kussmaul breathing), to lower the acid concentration in extracellular fluid by increasing the exhalation of carbon dioxide. The respiratory compensatory mechanism is usually ineffective in

decreasing acids, especially if the client has chronic obstructive pulmonary disease or is in ketoacidosis. Refer to Chapter 32 for additional information on these diagnoses. The renal compensatory mechanism tries to increase the pH by exchanging sodium ions with hydrogen ions to increase the excretion of hydrogen; refer to Table 37-4 for the clinical manifestations and treatment of metabolic acidosis.

NURSING ALERT

Electrolyte Shift

Metabolic acidosis causes an electrolyte shift: Hydrogen and sodium ions move into the cell, and potassium moves into the extracellular fluid. Hyperkalemia may cause ventricular fibrillation and death.

Metabolic Alkalosis (Bicarbonate Excess)

Metabolic alkalosis is characterized by an increased loss of acid from the body or a gain in base (increased levels of bicarbonate). The blood pH is above 7.45. A gain in base may result from excessive ingestion of antacids. These substances neutralize acids, producing alkalosis

and hypercalcemia. The excessive oral or parenteral administration of sodium bicarbonate or other alkaline salts (e.g., sodium or potassium acetate, lactate, or citrate) increases the amount of base in extracellular fluids.

The following clinical conditions can place clients at risk for metabolic alkalosis:

1. Vomiting and nasogastric suctioning or lavage cause a loss in hydrochloric acid and chloride; with the loss of the hydrogen and chloride ions, bicarbonate ions are absorbed, unneutralized, into the bloodstream and the pH of the extracellular fluid rises (alkalosis).
2. Diarrhea, and steroid or diuretic therapy can cause the excessive loss of potassium, chloride, and other electrolytes; the potassium deficit causes the kidneys to exchange hydrogen ions (instead of potassium ions) for sodium ions, which promotes the loss of hydrogen, thereby increasing bicarbonate level. Hydrochlorothiazide, a thiazide diuretic, blocks the reabsorption of sodium in the cortex in the distal tubule causing sodium to be excreted in greater amounts than water (hyponatremia). Thiazides also cause hypokalemia because of the loss of urinary potassium. The secondary effects of thiazides lead to metabolic alkalosis because of a depletion in volume, chloride, potassium, and hydrogen ions (DeJong, 1998).

The respiratory and renal compensatory mechanisms respond to an increased bicarbonate–carbonic acid ratio. The rate and depth of respirations are decreased in an effort to retain carbon dioxide. The arterial carbon dioxide concentration rises, creating respiratory acidosis, to counter the pH imbalance of metabolic alkalosis.

A normal serum potassium level is a prerequisite to renal compensation. In alkalosis, potassium ions enter the cells in exchange for hydrogen ions, causing hypokalemia. Hypokalemia further potentiates metabolic alkalosis because the kidneys conserve hydrogen ions by excreting potassium ions in exchange for sodium ions. When hypokalemia is present, the kidneys cannot function as a compensatory mechanism; therefore, they continue to excrete hydrogen, and bicarbonate excess continues. Refer to Table 37-4 for the clinical manifestations and treatment of metabolic alkalosis.

ASSESSMENT

Assessment data are used to identify clients who have potential or actual alterations in fluid volume. Clients receiving certain treatments, such as medications and IV therapy, are at risk for developing imbalances. The key nursing assessment indicators that identify imbalances are daily weights, vital signs, intake and output, and the physical findings of the skin, oral cavity, eyes, venous filling, and neuromuscular system.

Health History

The nursing history should elicit data specific to fluids (see the accompanying display for sample topics to direct the interview).

HEALTH HISTORY

- Lifestyle (sociocultural and economic factors, stress, exercise)
- Dietary intake (recent changes in the amount and types of fluid and food, increased thirst)
- Religion (whether illness has had an effect on beliefs or religion; query whether the client would like a visit from his or her religious counselor)
- Weight (sudden gain or loss)
- Fluid output (recent changes in the frequency or amount of urine output)
- Gastrointestinal disturbances (prolonged vomiting, diarrhea, anorexia, ulcers, hemorrhage)
- Fever and diaphoresis
- Draining wounds, burns, trauma
- Disease conditions that could upset homeostasis (renal disease, endocrine disorders, neural malfunction, pulmonary disease)
- Therapeutic programs that can produce imbalances (special diets, medications, chemotherapy, administration of intravenous fluid or total parenteral nutrition, gastric or intestinal suction)

Physical Examination

The nurse performs a complete physical examination and identifies all abnormalities because fluid alterations may affect any body system. The physical assessment of clients with altered fluid status is discussed in this section: refer to Chapter 27 for procedures on weight and vital sign measurement.

Daily Weight

Changes in the body's total fluid volume are indicated by weight; for instance, each kilogram (2.2 lb) of weight gained or lost is equivalent to one liter (1000 ml) of fluid gained or lost. Accurate measurement of daily weight requires the nurse to implement the agency's protocol to control certain variables. For example, the nurse should obtain the measurement at the same time each day, using the same scale.

Vital Signs

Measurement of vital signs provides the nurse with information regarding the client's fluid, electrolyte, and acid-base status and the body's compensatory response for maintaining balance. An elevated temperature places the client at risk for dehydration caused by an increased loss of body fluid.

NURSING TIP

Monitoring Water Balance

The most accurate way to monitor water balance is through daily body weight measurement because water constitutes 45% to 75% of the body's total weight.

Changes in the pulse rate, strength, and rhythm are indicative of fluid alterations. Fluid volume alterations may cause the following pulse changes:

- Fluid volume deficit (FVD): increased pulse rate and weak pulse volume
- Fluid volume excess (FVE): increased pulse volume and third heart sound

Respiratory changes are assessed by inspecting the movement of the chest wall, counting the rate, and auscultating the lungs. Changes in the rate and depth may cause respiratory acid-base imbalances or may be indicative of a compensatory response in metabolic acidosis or alkalosis, as previously discussed in Table 37-4.

Blood pressure measurements can be used to assess the degree of FVD. FVD can lower the blood pressure with or without orthostatic hypotension. A narrow pulse pressure (less than 20 mm Hg) may indicate FVD that occurs with severe hypovolemia.

Intake and Output

Measure and record the client's intake and output for a 24-hour period to assess for an actual or potential imbalance. A minimum intake of 1,500 ml is essential to balance urinary output and the body's insensible water loss. Intake includes all liquids (e.g., ice cream, soup, gelatin, juice, and water) taken by mouth and liquids administered through tube feedings (nasogastric or jejunostomy) and parenterally (IV fluids and blood or its components). Output includes urine, diarrhea, vomitus, and drainage from tubes such as through gastric suction. The recording of intake and output data is usually referred to as the I&O.

Thirst

The most common indicator of FVD is thirst. With a decrease in extracellular fluid volume or an increase in the plasma osmolality, the hypothalamus triggers a thirst response.

Food Intake

The intake of food also contributes to maintaining extracellular fluid volume. One-third of the body's fluid

NURSING ALERT

Dehydration in the Elderly

The elderly are prone to a fluid volume deficit (dehydration), because the thirst mechanism in the medulla becomes less responsive with aging.

needs are met by ingested food. Food also provides the body with necessary electrolytes. See Chapter 38 for a complete discussion of metabolism.

Edema

Edema (the detectable accumulation of increased interstitial fluid) is the main symptom of FVE. Edema may be localized (confined to a specific area) or generalized (occurring throughout the body's tissue). Localized edema is characterized by taut, smooth, shiny, pale skin. The body may retain 5 to 10 pounds of fluid before edema is noticeable (Bulechek & McCloskey, 1999). Inspect the dependent body parts—sacrum, back, and legs—to assess peripheral edema. Pitting edema is rated on a four-point scale:

- +0" no pitting
- +1, 0"–1/4" pitting (mild)
- +2, 1/4"–1/2" pitting (moderate)
- +3, 1/2"–1" pitting (severe)
- +4, greater than 1" pitting (severe)

Skin Turgor

Skin turgor is the normal resiliency of the skin. When the skin is pinched and released, it springs back to a normal position because of the outward pressure exerted by the cells and interstitial fluid. To measure the client's skin turgor, grasp and raise the skin with two fingers as follows:

- Adults: over the sternum, forehead, or inner aspect of the thigh
- Children: over the abdominal area or medial aspect of the thigh

NURSING TIP

Skin Turgor in the Elderly

With aging, there are fewer elastic fibers in the skin, resulting in reduced skin turgor. Assess the tongue for creases or furrows to monitor dehydration in the elderly (Hogstel, 2001).

With dehydration there is a decreased skin turgor, as manifested by lax skin that returns slowly to the normal position. Increased skin turgor, which occurs with edema, is manifested by smooth, taut, shiny skin that cannot be grasped and raised.

Buccal (Oral) Cavity

Inspect the buccal cavity. With FVD, there is a decrease in saliva, which causes sticky, dry mucous membranes and dry cracked lips. The tongue has longitudinal furrows.

Eyes

Inspect the eyes. FVD causes sunken eyes, dry conjunctiva, and decreased or absent tearing. Puffy eyelids (periorbital edema, or papilledema) are characteristic of FVE; the client may also have a history of blurred vision.

Jugular and Hand Veins

Circulatory volume is assessed by measuring venous filling of the jugular and hand veins. Place the client in a low Fowler's position. Then:

1. Palpate the jugular (neck) veins: FVE causes a distention in the jugular veins (Figure 37-7).
2. Place the client's hand below the heart level, and palpate the jugular veins; with FVD there is decreased venous filling (flat neck veins).

Neuromuscular System

Fluid and electrolyte imbalances may cause neuromuscular alterations: The muscles lose their tone and become soft and underdeveloped, and reflexes are diminished. Calcium and magnesium imbalances cause an increase in neuromuscular irritability. To assess for neuromuscular irritability perform the following tests:

1. Chvostek's sign: Tap the facial nerve 2 cm anterior to the earlobe; unilateral twitching of the facial muscles (inclusive of the eyelids and lips) indicates a positive response (Figure 37-8).

Figure 37-7 Positioning the Client to Assess Jugular Vein Distention

Figure 37-8 Assessing for Chvostek's Sign

2. Trousseau's sign: Place a blood pressure cuff on the arm, inflate the cuff slightly above the systolic pressure, leave the cuff inflated 2–3 minutes, and deflate; carpal spasm or tetany indicates a positive response.

A positive Chvostek's sign and Trousseau's sign may occur with hypocalcemia and hypomagnesemia.

Other neurologic signs include inability to concentrate, confusion, and emotional lability, as previously discussed in Tables 37-3 and 37-4.

Diagnostic and Laboratory Data

Biochemical assessment is another essential source of objective data. Laboratory results can be used to detect imbalances before clinical symptoms are assessed in the physical examination. Laboratory tests used in assessing clients with common alterations in extracellular fluid volume are discussed next; refer to Chapter 28 for the normal values presented in this section.

Hemoglobin and Hematocrit Indices

The hematocrit is affected by changes in plasma volume. For instance, with severe dehydration and hypovolemic shock, the hematocrit is increased, whereas overhydration decreases the hematocrit. Hemoglobin levels are decreased with severe hemorrhage.

Osmolality

Osmolality is a measurement of the total concentration of dissolved particles (solutes) per kilogram of water. Osmolality measurements are performed on both serum and urine samples to determine alterations in fluid and electrolyte balance. Osmolality can also be explained in

relation to the specific gravity of body fluids. Specific gravity expresses the weight of the solution when compared with an equal volume of distilled water; the osmolality of a solution can be estimated by the specific gravity.

Serum Osmolality

Serum osmolality is a measurement of the total concentration of dissolved particles per kilogram of water in serum, recorded in milliosmoles per kilogram (mOsm/kg). The particles measured in serum osmolality include electrolyte ions, such as sodium and potassium, and electrically inactive substances dissolved in serum, such as glucose and urea. Water and sodium are the main entities that control the osmolality of body fluids. Serum sodium is responsible for 85% to 90% of the serum osmolality.

The normal serum osmolality is 275 to 295 mOsm/kg (Fischbach, 2000). It can increase with dehydration and loss of body water and decrease with water excess.

In clinical practice, the terms *osmolality* and **osmolarity** (the concentration of solutes per liter of cellular fluid) are often used interchangeably to refer to the concentration of body fluid. However, these terms are actually different, in that osmolality refers to the concentration of solutes in the total body water (solute per kilogram of body weight) rather than in cellular fluid. Figure 37-9 relates osmosis to the osmolality of a solution. The appropriate term to use in intravenous fluid therapy is *osmolarity* (Bulechek & McCloskey, 1999). An osmolaritic solution is described as:

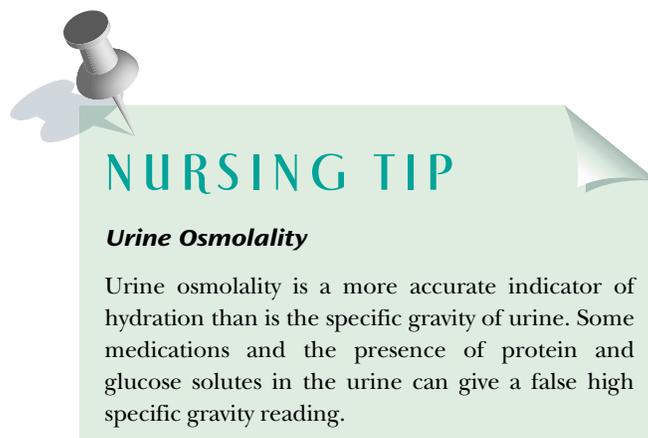

- **Hypotonic** (hypo-osmolar) when there are less solutes in proportion to the volume of water than is the case in the body
- **Isotonic** (iso-osmolar) when body water and solutes (sodium) are in amounts equal to those in the body
- **Hypertonic** (hyperosmolar) when there are more solutes in proportion to the volume of water than is the case in the body

Urine Osmolality

Urine osmolality is a measurement of the total concentration of dissolved particles per kilogram of water in urine, recorded in milliosmoles per kilogram (mOsm/kg). The particles measured in urine osmolality come from nitrogenous waste (creatinine, urea, and uric acid), with urea contributing most. Urine osmolality varies greatly with diet and fluid intake and reflects the ability of the kidney to adjust the concentration of urine in order to maintain fluid balance. With normal kidney function, a dehydrated client will have an elevated urine osmolality, whereas clients with shock, hyperglycemia, hemoconcentration, and acidosis will have elevations in both urine and serum osmolality.

Urine pH

The measurement of the pH of urine reveals the hydrogen ion concentration of the urine to determine its acid or alkaline status. When the kidney buffering system is

NURSING TIP

Urine Osmolality

Urine osmolality is a more accurate indicator of hydration than is the specific gravity of urine. Some medications and the presence of protein and glucose solutes in the urine can give a false high specific gravity reading.

compensating for either metabolic acidosis or alkalosis, the pH of the urine should be within normal range (4.6–8.0). This is considered a sign of normal function. However, when the renal compensatory function fails to respond to the pH of the blood, the urine pH will increase with acidosis and decrease in alkalosis.

Serum Albumin

Albumin is synthesized in the liver from amino acids. Serum albumin plays an important role in fluid and

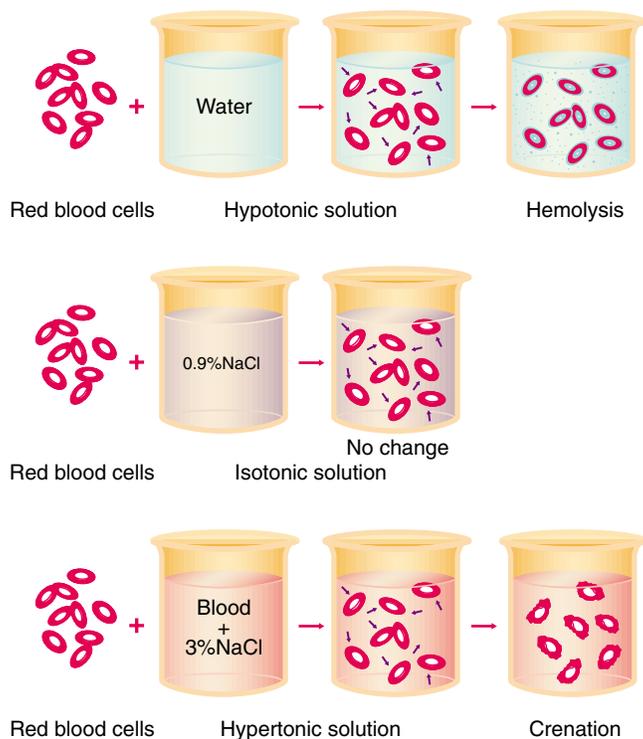

Figure 37-9 Osmosis as it relates to the osmolality of a solution. The movement of water through a membrane from a lower concentration to a higher concentration is called osmosis. In a hypotonic solution, the water moves into the cells, causing them to swell and burst. The cells in the isotonic solution are normal in size and shape because the same amount of water is entering and leaving the cells. Cells in the hypertonic solution are losing water because water moves from a weaker concentration inside the cell to a greater concentration outside the cell membrane.

electrolyte balance by maintaining the colloid osmotic pressure of blood, which prevents the accumulation of fluid (edema) in the tissues. However, serum albumin has a half-life of 21 days and fluctuates according to the level of hydration; therefore, it is not a good indicator of acute alterations in protein depletion. Clinically, this blood test is used to measure prolonged protein depletion, which occurs in chronic malnutrition. Refer to Chapter 38 for a discussion of serum albumin and pre-albumin.

NURSING DIAGNOSIS

In order to make a nursing diagnosis, the nurse must be able to interpret assessment and biochemical data and draw conclusions relative to the client's imbalance. The primary nursing diagnoses for clients with fluid imbalances are presented in the accompanying display.

NURSING DIAGNOSES FOR FLUID ALTERATIONS

Excess Fluid Volume related to:

- Excessive fluid intake secondary to excess sodium intake
- Compromised regulatory mechanism (renal and cardiac dysfunction)
- Inaccurate intravenous infusion rate

Deficient Fluid Volume related to:

- Excessive fluid loss secondary to vomiting, blood loss, surgical drains and tubes, diarrhea, and diuretics

Risk for Deficient Fluid Volume related to:

- Extremes of age (very young or old) and weight
- NPO and fluid restrictions
- Increased fluid output from normal routes: vomiting, diarrhea, urine
- Increased fluid losses from drainage or suction routes: wounds, drains, indwelling tubes (e.g., urine catheter, nasogastric suction)
- Loss of plasma associated with severe trauma and burns
- Disorders that impair fluid intake or absorption (immobility, unconsciousness)
- Chronic disorders: congestive heart failure, pulmonary edema, chronic obstructive lung disease, renal failure, diabetes, cancer, transplant candidates
- Deficient knowledge related to factors influencing fluid requirements (hypermetabolic states, hyperthermia, and dry, hot environment)
- Medications (e.g., diuretics)

Excess Fluid Volume

Excess fluid volume (EFV) exists when the client has increased interstitial and intravascular fluid retention and edema. EFV is related to the excess fluid either in tissues of the extremities (peripheral edema) or in lung tissues (pulmonary edema). Factors that put the client at risk for EFV are:

- Excessive intake of fluids (e.g., intravenous therapy, sodium)
- Increased loss or decreased intake of protein (chronic diarrhea, burns, kidney disease, malnutrition)
- Compromised regulatory mechanisms (kidney failure)
- Decreased intravascular movement (impaired myocardial contractility)
- Lymphatic obstruction (cancer, surgical removal of lymph nodes, obesity)
- Medications (steroid excess)
- Allergic reaction

Assessment findings in the client with FVE include acute weight gain; decreased serum osmolality (less than 275 mOsm/kg), protein and albumin, BUN, Hgb, Hct; increased central venous pressure (greater than 12–15 cm H₂O); and signs and symptoms of edema. The clinical manifestations of edema are relative to the area of involvement, either pulmonary or peripheral (see the accompanying display).

CLINICAL MANIFESTATIONS OF EDEMA

Pulmonary Edema

Constant cough
Dyspnea
Engorged neck and hand veins
Moist crackles in lungs
Bounding pulse

Peripheral Edema

Pitting edema in extremities
Edematous area: tight, smooth, shiny, pale, cool skin
Puffy eyelids
Weight gain

Deficient Fluid Volume

Deficient fluid volume (DFV) exists when the client experiences vascular, interstitial, or intracellular dehydration. The degree of dehydration is classified as mild, marked, severe, or fatal on the basis of the percentage of body weight lost.

There are three types of dehydration based on the proportion of fluid and particles in the intracellular and extracellular spaces (see the accompanying display).

Kleiner (1999) reports that a portion of the general population may be chronically mildly dehydrated based on the Nationwide Food Consumption Surveys. According to Sansevero (1997), approximately 1 million elderly people a year are admitted to hospitals with iso-

TYPES OF DEHYDRATION

Isotonic dehydration (hypovolemia) refers to the loss of both fluid and particles in the vascular space that occurs with vomiting, diarrhea, and bleeding; it is the most common form of dehydration, especially in infants and children.

Hypertonic dehydration refers to a greater loss of fluid than particles in the vascular space when the body tries to maintain a normalized isotonic state by pulling fluids from the intracellular space into the vascular space; it occurs in diabetic ketoacidosis, renal insufficiency, and with the administration of hypertonic solutions.

Hypotonic dehydration refers to a greater loss of particles than fluid in the vascular space when the body tries to maintain a normal isotonic state by pushing fluids from the vascular space into the intracellular space, causing the cells to swell; it occurs in chronic disease states and with the administration of hypotonic solutions.

Adapted from Woods, A. (1998). Understanding types of dehydration. *The Nurse Practitioner*, 23(12), 62.

tonic dehydration, and 19% of emergency room admissions were prompted by dehydration, frequent falling, or failure to care for self. Mild dehydration, as little as 2% loss of body weight, results in impaired physiological and performance responses, and may be misinterpreted as a sign of aging and not hydration status (Kleiner, 1999).

Assessment findings in the client with DFV include thirst and weight loss, with the amount varying with the degree of dehydration. With marked dehydration, the mucous membranes and skin are dry. There is poor skin turgor; low-grade temperature elevation; tachycardia; respirations 28 or greater; a decrease (10–15 mm Hg) in systolic blood pressure; slowing in venous filling; a decrease in urine (less than 25 ml per hour); concentrated urine; elevated Hct, Hgb, BUN, and an acid blood pH (less than 7.4).

Severe dehydration is characterized by the symptoms of marked dehydration. Also, the skin becomes flushed. The systolic blood pressure continues to drop (60 mm Hg or below). There are behavioral changes (restlessness, irritability, disorientation, and delirium). The signs of fatal dehydration are anuria and coma that leads to death.

Risk for Deficient Fluid Volume

Risk for fluid volume deficit exists when the client is at high risk of developing vascular, interstitial, or intracellular dehydration resulting from active or regulatory losses of body water in excess of needs. The multiple factors that can place the client at risk for FVD are listed in the preceding accompanying display.

NURSING ALERT

Loss of Gastric Juices

Clients who lose excessive amounts of gastric juices, either through vomiting or suctioning, are prone to develop not only DFV but also metabolic alkalosis, hypokalemia, and hyponatremia; gastric juices contain hydrochloric acid, pepsinogen, potassium, and sodium.

Other Nursing Diagnoses

The relationship between the primary nursing diagnoses just discussed and the secondary diagnoses in clients with fluid imbalances are reciprocal: The primary diagnoses influence and are influenced by the secondary diagnoses. Holistic nursing requires that all diagnoses relative to clients be considered when developing their plan of care.

Impaired Gas Exchange

Impaired gas exchange related to a ventilation perfusion imbalance occurs when clients experience a decreased passage of oxygen or carbon dioxide between the alveoli of the lungs and the vascular system. This alteration is assessed by measuring the oxygen and carbon dioxide content through arterial blood gas analysis or pulse oximetry or both. Refer to Chapter 32 for further discussion of oxygenation.

Decreased Cardiac Output

Decreased cardiac output occurs when the blood pumped by a client's heart is reduced so much that it is inadequate to meet the needs of the body's tissue. This alteration may be caused by heart failure and various types of shock. Assessment findings may include low blood pressure; cool, clammy skin; weak, thready pulses; decreased urinary output; and a diminished level of consciousness.

Risk for Infection

Many disorders may place the client at risk for invasion by pathogenic organisms. Clients receiving IV therapy are at risk for an infection because their primary defense, the skin, is broken at the puncture site. Assessment findings indicative of IV site infection are client complaints of soreness around site, erythema, swelling at site, and foul-smelling discharge.

Impaired Oral Mucous Membrane

Altered oral mucous membrane occurs when a client experiences disruption in the tissue layers of the oral cavity. It is frequently related to dehydration. Assessment findings may include: oral pain or discomfort; stomatitis; and decreased salivation.

Deficient Knowledge

A knowledge deficit may exist to varying degrees in clients with fluid imbalances. Information obtained from a client's health history may indicate the client's level of understanding and perception of these alterations and direct teaching. Clients need to participate actively in their plan of care.

PLANNING AND OUTCOME IDENTIFICATION

Holistic nursing care for clients experiencing fluid imbalances requires that the nurse, in collaboration with each client, identify specific goals for the nursing diagnosis. These goals should be individualized to reflect the client's capabilities and limitations and should be appropriate to the diagnosis as determined by the assessment data.

During the planning phase, the nurse also selects and prioritizes nursing interventions to support the client's achievement of expected outcomes based on the goals. For example, if vomiting and diarrhea, with a weight loss of 5% and dry mucous membranes, led to a diagnosis of *Deficient Fluid Volume*, then goals might include relief from vomiting and diarrhea and achievement of the proper fluid balance of intake and output.

Expected outcomes for clients with fluid imbalances are not only specific to their primary diagnosis but also require inclusion of outcomes relative to interventions. An expected outcome for clients receiving IV therapy might read: *IV site remains free from erythema, edema, and purulent drainage, because these clients are at risk for infection.* Achievement of the goals and the client's expected outcomes indicates resolution of the problem.

IMPLEMENTATION

Nurses have the responsibility to collaborate with and advocate for clients to assure that they receive care that is appropriate, ethical, and based on practice standards. Nurses rely heavily on the data obtained from the history in formulating expected outcomes and selecting appropriate nursing interventions to support the clients' natural patterns as revealed in their history.

The rationale for interventions related to alterations in either body fluid or electrolytes is based on the goal of maintaining homeostasis and regulating and maintaining essential fluids and nutrients. The nurse capitalizes on the clients' adaptive capabilities by selecting interventions based on the clients' perception of their support, strengths, and options.

Bulechek and McCloskey (1999) address the importance of the nursing interventions relative to fluid therapy by identifying the nurse's responsibilities to:

- Understand the client's metabolic needs and to make judgments concerning the outcomes of therapy
- Perform frequent assessment and monitoring to recognize the adverse effects of fluid and electrolyte therapy and prevent complications
- Prevent the rapid depletion of the body's protein and energy reserves

The nursing activities relative to assessment and implementation often require the same measurements: for example, weight and vital signs. Common interventions that promote attainment of expected outcomes to restore and maintain homeostasis are discussed next.

Monitor Daily Weight

Daily weight is one of the main indicators of water and electrolyte balance. The nurse is responsible for the accurate measurement and recording of daily weights; the health care practitioner uses these data with other clinical findings in determining the client's fluid therapy.

Measure Vital Signs

The frequency of measuring the vital signs is dependent upon the client's acuity level and clinical situation. For example, the vital signs of the typical postoperative client might be taken every 15 minutes until stable, whereas a client experiencing shock or hemorrhage should have vital signs monitored continuously. Vital sign measurements and other clinical data are used to determine the type and amount of fluid therapy.

Measure Intake and Output

Intake and output measurements are initiated to monitor the client's fluid status over a 24-hour period (see Procedure 37-1 for information on how to measure the I&O). Agency policy relative to I&O may vary with regard to:

- The time frames for charting (e.g., every 8 hours versus every 12 hours)
- The time at which the 24-hour totals are calculated
- The definition of "strict" I&O

"Strict" I&O measurement usually involves accounting for incontinent urine, emesis, and diaphoresis and might require weighing soiled bed linens. *Don gloves before handling soiled linen.*

The nurse reviews the client's 24-hour I&O calculations to evaluate fluid status. Intake should exceed the output by 500 ml to account for insensible body losses. I&O and daily weights are critical components of intervention because these measurements are also used to evaluate the effectiveness of diuretic or rehydration therapy.

PROCEDURE 37-1

Measuring Intake and Output

Equipment

- | | |
|----------------------------------|--------------------------------------|
| ■ I&O form at bedside | ■ I&O graphic record in chart |
| ■ Glass or cup | ■ Bedpan, urinal, or bedside commode |
| ■ Graduated container for output | ■ Nonsterile gloves |

Action

1. Wash hands.
2. Explain purpose of keeping I&O record to client. Explain that:
 - All fluids taken orally must be recorded.
 - Form for recording must be used.
 - Client must void into bedpan or urinal, not into toilet.
 - Toilet tissue should be disposed of in plastic-lined container, not in bedpan.

Oral Intake

3. Measure all oral fluids in accord with agency policy (e.g., cup = 150 ml, glass = 240 ml).
4. Record time and amount of all fluid intake in the designated space on bedside form (oral, tube feedings, IV fluids).
5. Transfer 8-hour total fluid intake from bedside I&O record to graphic sheet or 24-hour I&O record on client's chart.
6. Record all forms of intake, except blood and blood products, in the appropriate column of the 24-hour record.
7. Complete 24-hour intake record by adding all 8-hour totals.

Output

8. Don nonsterile gloves.
9. Empty urinal, bedpan, or indwelling catheter drainage bag into graduated container or commode "hat."
10. Remove gloves, and wash hands.
11. Record time and amount of output (urine, drainage from nasogastric tube, drainage tube) on bedside I&O record.
12. Transfer 8-hour output totals to graphic sheet or 24-hour I&O record on the client's chart.
13. Complete 24-hour output record by totaling all 8-hour totals.

Rationale

1. Reduces potential for transmission of pathogens.
2. Elicits client support.
3. Provides for consistency of measurement.
4. Documents fluids.
5. Provides for data analysis of client's fluid status.
6. Documents intake by type and amount.
7. Provides consistent data for analysis of client's fluid status over a 24-hour period.
8. Reduces potential for transmission of pathogens.
9. Provides accurate measurement of urine.
10. Prevents cross-contamination.
11. Documents output.
12. Provides for data analysis of client's fluid status.
13. Provides consistent data for analysis of client's fluid status over a 24-hour period.

Securing an accurate I&O requires the full support of the client and his or her family. The client and family members should be taught how to measure and record the intake (see the accompanying display for special home health care considerations).

APPLICATION: HOME CARE

Considerations for Measuring I&O

- Elicit client and family member input when selecting household items to be used for intake measurement.
- Provide containers for measuring output; adapt the urinary container to home facilities, and include teaching relative to proper washing and storage.
- Teach handwashing technique.
- Provide written instructions on what is to be measured.
- Provide sufficient I&O forms to last between the nurse's visits.
- Identify the parameters for evaluating a discrepancy between the intake and output and for notifying the nurse or health care practitioner.

NURSING ALERT

Remove Gloves before Charting

Remove gloves and wash hands before recording the amount of drainage on the I&O form, to prevent the transfer of microorganisms when the form is removed from the client's room.

Provide Oral Hygiene

The nurse is responsible for providing oral hygiene to promote client comfort and integrity of the buccal cavity. Refer to Chapter 31 for the procedure on oral hygiene. The frequency of oral hygiene depends on the condition of the client's buccal cavity and the type of

THINK ABOUT IT

Oral Hygiene

When you wake up in the morning, do you drink or eat anything before brushing your teeth? If you were sick, hospitalized, without family or significant other support, would you want to drink or eat if your mouth tasted sour? Many of your clients will feel the same way and will need supportive nursing care to maintain oral hygiene. Muscular weakness and difficulty swallowing are other problems that could compound the client's dependency on you for oral hygiene.

fluid imbalance. A client who is dehydrated or NPO for more than 24 hours may have decreased or absent salivation, coated tongue, and furrows on the tongue. These clients are at risk for developing oral diseases such as stomatitis, oral lesions or ulcers, and gingivitis.

NURSING TIP

Mouthwashes

Avoid the use of alcohol and glycerin mouthwashes and glycerin swabs. These ingredients may feel refreshing, but they have a drying effect on the mucous membranes.

Initiate Oral Fluid Therapy

Oral fluids may be totally restricted—a situation commonly referred to as *nothing by mouth* (NPO, which is from the Latin *non per os*)—or they may be restricted or forced, depending on the client's clinical situation. For example, oral replacement therapy is often used for clients with mild dehydration. According to Hugger, Harkless, and Rentschler (1998), oral rehydration therapy has a very high success rate in the treatment of childhood diarrhea with mild to moderate dehydration, and it has fewer complications when compared to intravenous replacement therapy. Severe dehydration in children is a medical emergency and must be treated with intravenous replacement therapy.

Nothing by Mouth

Clients are placed NPO status as prescribed by the health care practitioner. On the basis of agency policy and clarification with the health care practitioner, the client may be allowed small amounts of ice chips or medications with a sip of water when NPO. Common clinical situations that may require NPO status include the need to:

- Avoid aspiration in unconscious, perioperative, and preprocedural clients who will receive anesthesia or conscious sedation
- Rest and heal the gastrointestinal (GI) tract in clients with severe vomiting or diarrhea or when the client has a GI disorder (inflammation or obstruction)
- Prevent the further loss of gastric juices in clients with nasogastric suctioning

NPO clients should receive oral hygiene every 1 to 2 hours or as needed for comfort and to prevent alterations of the mucous membranes.

Restricted Fluids

Intake may be restricted to 200 ml over a 24-hour period; intake is commonly restricted in the treatment of EFV related to heart and renal failure. Client and family teaching and collaboration are the main nursing interventions in implementing this measure.

How the nurse limits the fluids should be determined in collaboration with the client. For example:

- Fifty percent of the allowed fluids might be taken at breakfast and lunch.
- The remaining 50% might be taken with the evening meal, before bedtime, unless the client has to be awakened during the night for a medication.

Forced Fluids

Forcing or encouraging the intake of oral fluids, mainly water, may be done when treating elderly clients who are at risk for dehydration and clients with renal and urinary problems, for example, kidney stones. Compliance is obtained by client education and preference relative to timing and the type of liquids.

A client might, for example, be requested to consume 2,000 ml over a 24-hour time period. If the client is intimidated on hearing this amount, which may sound very large, explain that the number of glasses to which this volume equates is only eight. Follow a similar time frame as set forth for restricted fluids, with the largest quantity of fluids administered with meals. Ice, gelatin, and ice cream count as liquid intake.

Maintain Tube Feeding

When the client cannot ingest oral fluids and has a normal GI tract, fluids and nutrients can be administered through a feeding tube as prescribed by a health care practitioner. Refer to Chapter 38 for a complete discussion of feeding tubes.

Monitor Intravenous Therapy

When fluid losses are severe or the client cannot tolerate oral or tube feedings, fluid volume is replaced parenterally through the intravenous route. **Intravenous (IV) therapy** is the administration of fluids, electrolytes, nutrients, or medications by the venous route. The health care practitioner prescribes IV therapy to treat or prevent fluid and electrolyte or nutritional imbalances. The nurse has specific responsibilities relative to IV therapy (see the accompanying Nursing Process Highlight).

The Intravenous Nurses Society (INS) is the professional organization that establishes standards of practice to promote excellence in intravenous nursing to ensure the highest quality, cost-effective care for all individuals requiring infusion therapies (INS, 2000). INS standards of practice direct the development of agency policy/pro-

Nursing Process Highlight

Implementation of IV Therapy

- Know why the therapy is prescribed.
- Document client understanding.
- Select the appropriate equipment in accordance to agency policy.
- Obtain the correct solution as prescribed.
- Assess the client for allergies: tape, iodine, ointment, or antibiotic preparations to be used for skin preparation of the venipuncture site.
- Administer the fluid at the prescribed rate.
- Observe for signs of **infiltration** (the seepage of substances into the interstitial tissue that occurs as the results of accidental dislodgement of the needle from the vein) and other complications that are fluid-specific.
- Document implementation of prescribed IV therapy in the client's medical record.

ocols in accordance with state and federal regulations and should complement the manufacturer's direction for usage. The nurse should review the agency's protocols before gathering the equipment. IV therapy requires parenteral fluids (solutions) and special equipment: administration set, IV pole, filter, regulators to control IV flow rate, and an established venous route.

Parenteral Fluids

The nurse confirms the type and amount of IV solution by reading the health care practitioner's prescription in the medical record. IV solutions are sterile and packaged in plastic bags or glass containers. Solutions that are incompatible with plastic are dispensed in glass containers.

Plastic IV solution bags collapse under atmospheric pressure to allow the solution to enter the infusion set. Plastic solution bags are packaged with an outer plastic bag, which should remain intact until the nurse prepares the solution for administration. When the plastic solution bag is removed from its outer wrapper, the solution bag should be dry. If the solution bag is wet, the nurse should not use the solution. The moisture on the bag indicates that the integrity of the bag has been compromised and that the solution cannot be considered sterile. The bag should be returned to the dispensing department that issued the solution. Glass containers are discussed in the section on equipment.

IV solutions are usually packaged in quantities ranging from 50 to 1,000 ml. The nurse should select a container that has the prescribed amount of solution or select several containers that together contain the prescribed volume. *At no time should the nurse select a container*

whose volume is greater than that prescribed. For example, if the client is to receive 600 ml of normal (0.9%) saline, the nurse must not select a 1000 ml container, but rather two containers, 100 ml and 500 ml (containers are not prepared in volumes of 600 ml). **Crystalloids** (electrolyte solutions with the potential to form crystals) are used to replace concurrent losses of water, carbohydrates, and electrolytes. Sodium chloride and Ringer's lactate are commonly used crystalloid solutions.

There are three types of parenteral fluids that are classified in accord with the tonicity of the fluid relative to normal blood plasma. As previously discussed, an osmolar solution can be hypotonic, isotonic, or hypertonic. The type of solution is prescribed on the basis of the client's diagnosis and the goal of therapy. The normal osmolarity of blood is between 280 and 295 mOsm/L, so the desired effect of the tonicity of the fluid is determined as follows:

1. Hypotonic fluid (hypo-osmolar, less than 290 mOsm/L) lowers the osmotic pressure and causes fluid to move into the cells; if fluid is infused beyond the client's tolerance, water intoxication may result.
2. Isotonic fluid (iso-osmolar, 290 mOsm/L) increases extracellular fluid volume; if fluid is infused beyond the client's tolerance, cardiac overload may result.
3. Hypertonic fluid (hyperosmolar, greater than 290 mOsm/L) increases the osmotic pressure of the blood plasma, drawing fluid from the cells; if fluid is infused beyond the client's tolerance, cellular dehydration may result (Bulechek & McCloskey, 1999).

Table 37-5 discusses the common types of intravenous solutions in terms of their tonicity, contents, and clinical usage.

Crystalloid solutions can be isotonic (equal to the sodium chloride concentration of blood, 0.9%); hypotonic (less than the sodium chloride concentration of blood); and hypertonic (greater than the sodium chloride concentration of blood) (Kee & Paulanka, 2000).

Colloids (nondiffusible substances) function like plasma proteins in blood by exerting a colloidal pressure to replace intravascular volume only. Examples of colloidal solutions are albumin, dextran, Plasmanate, and hetastarch (artificial blood substitute). During the admin-

TABLE 37-5
Common Intravenous Solutions

Tonicity	Solution	Contents (MEq/L)	Clinical Implications
Hypotonic	Sodium chloride 0.45%	77 Na ⁺ , 77 Cl ⁻	Daily maintenance of body fluid and establishment of renal function.
Isotonic	Dextrose 2.5% in 0.45% saline	77 Na ⁺ , 77 Cl ⁻	Promotes renal function and urine output.
	Dextrose 5% in 0.2% saline	38 Na ⁺ , 38 Cl ⁻	Daily maintenance of body fluids when less Na ⁺ and Cl ⁻ are required.
	Dextrose 5% in water (D ₅ W)		Promotes rehydration and elimination; may cause urinary Na ⁺ loss; good vehicle for K ⁺ .
	Ringer's lactate	130 Na ⁺ , 4 K ⁺ , Ca ²⁺ , 109 Cl ⁻ , 28 lactate	Resembles the normal composition of blood serum and plasma; K ⁺ level below body's daily requirement.
	Normal saline (NS), 0.9%	154 Na ⁺ , 154 Cl ⁻	Restores sodium chloride deficit and extracellular fluid volume.
	Dextran 40 10% in NS (0.9%) or D ₅ W		A colloidal solution used to increase plasma volume of clients in early shock; <i>it should not be given to severely dehydrated clients and clients with renal disease, thrombocytopenia, or active hemorrhaging.</i>
Dextran 70% in NS		A long-lived (20 hours) plasma volume expander; used to treat shock or impending shock due to hemorrhage, surgery, or burns. <i>It can prolong bleeding and coats the RBCs (draw type and crossmatch prior to administering).</i>	

(continues)

TABLE 37-5 (continued)
Common Intravenous Solutions

Tonicity	Solution	Contents (MEq/L)	Clinical Implications
Hypertonic	Dextrose 5% in 0.45% saline	77 Na ⁺ , 77 Cl ⁻	Daily maintenance of body fluid and nutrition; treatment of FVD.
	Dextrose 5% in saline 0.9%	154 Na ⁺ , 154 Cl ⁻	Fluid replacement of sodium, chloride, and calories (170).
	Dextrose 10% in saline 0.9%	154 Na ⁺ , 154 Cl ⁻	Fluid replacement of sodium, chloride, and calories (340).
	Dextrose 5% in lactated Ringer's	130 Na ⁺ , 4 K ⁺ , 3 Ca ²⁺ , 109 Cl ⁻ , 28 lactate	Resembles the normal composition of blood serum and plasma; K ⁺ level below body's daily requirement; caloric value 180.
	Hyperosmolar saline 3% and 5% NaCl	856 Na ⁺ , 865 Cl ⁻	Treatment of hyponatremia; raises the Na ⁺ osmolarity of the blood, and reduces intracellular fluid excess.
	Ionosol B with dextrose 5%	57 Na ⁺ , 25 K ⁺ , 49 Cl ⁻ , 25 lact., 5 Mg ²⁺ , 7 PO ₄ ⁻	Treatment of polyionic parenteral replacement caused by vomiting-induced alkalosis, diabetic acidosis, fluid loss from burns, and postoperative FVD.
	Ionosol D-CM with dextrose 5%	138 Na ⁺ , 12 K ⁺ , 5 Ca ²⁺ , 108 Cl ⁻ , 50 lactate, 3 Mg ²⁺	Treatment of electrolyte losses of duodenal fluids caused by intestinal suction or biliary or pancreatic drainage; treatment of mild acidosis.
	Aminosyn RF 5.2%	5.4 K ⁺	Restores fluid and protein and promotes wound healing.
	Aminosyn II 3.5%	18 Na ⁺	Treatment of malnourished elderly clients and hypoproteinemia; <i>it is not to be given to clients with severe liver damage.</i>

(From Kee, J. L., & Paulanka, B. J. [2000]. *Fluids and electrolytes with clinical applications* [6th ed.]. Albany, NY: Delmar Publishers)

istration of these solutions, the nurse should monitor the client for hypotension and allergic reactions (Bulechek & McCloskey, 1999; Kee & Paulanka, 2000). Blood transfusions are discussed later in this chapter.

Equipment

IV equipment is sterile, disposable, and prepackaged with user instructions. The user instructions are usually placed on the outside of the package, with a schematic that labels the parts, allowing the user to read the package prior to opening. The following discussion regarding intravenous equipment, inclusive of the frequency when to change disposal intravenous therapy equipment, is based on the revised *2000 Infusion Nursing Standards of Practice* developed by INS. All intravenous equipment must be inspected by the nurse to determine the integrity of the IV product before, during, and after

use. Product integrity refers to the sterility of the equipment. Products are assessed for integrity by visual examination of the product and checking the expiration date on the equipment. All products identified with a defect must be returned to the appropriate department within the agency with a written report identifying the defect.

Since intravenous therapy provides a direct access into the vascular system, the nurse must understand the basic epidemiology principles and common organisms that may cause an infection and implement infection control measures to minimize the potential for infectious complications. The nurse uses aseptic technique and standard precautions when assembling and changing intravenous equipment. To decrease the risk of pathogen transmission, handwashing is required before and immediately after all IV procedures and upon removal of gloves. The frequency of changing sterile intravenous equipment not only reflects the national standards of practice but the

agency's established infection control policies. Infection control data may allow the agency to increase the time interval beyond the recommended standard provided the data verifies low infection rates. INS (2000) recommends that an organization that exhibits an increased rate of catheter-related bloodstream infection with the practice of 72-hour administration set changes should return to a 48-hour administration set change interval.

Administration Set

The administration set (infusion set) refers to the plastic disposal tubing that provides for the infusion of a solution. There are several types of infusion sets to accommodate the solution and the mode of administration: primary continuous; secondary; primary intermittent; and special tubing for certain solutions such as blood/blood components. There are several add-on devices, such as extension sets, filters, stopcocks, PRN adaptor, and needleless devices that are used in conjunction with the administration set and changed whenever the set is changed. Administration sets are changed at established time intervals and immediately upon suspected contamination or when the integrity of the set has been compromised. The administration set contains an insertion spike with a protective cap, a drip chamber, tubing with a slide clamp and regulating (roller) clamp, a rubber injection port, and a protective cap over the needle adapter (Figure 37-10). The protective caps keep both ends of the infusion set sterile and are removed only just before usage. The insertion spike is inserted into the port of the IV solution container.

Infusion sets can be vented or nonvented. The nonvented type is used with plastic bags of IV solutions and vented bottles. The vented set is used for glass containers that are not vented (Figure 37-11).

Glass containers require an air vent so that air can displace fluid from the container into the IV tubing.

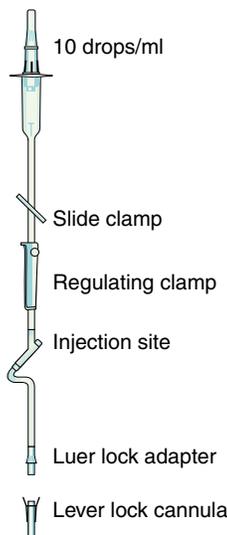

Figure 37-10 Basic Administration Set (Courtesy of Baxter, IV Systems Division)

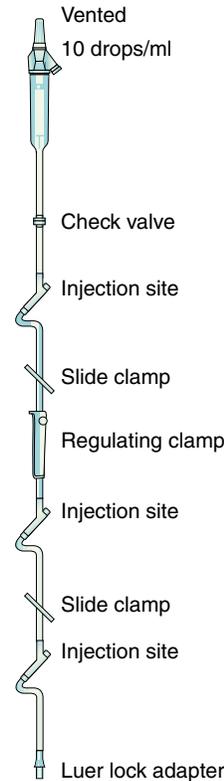

Figure 37-11 Vented Administration Set (Courtesy of Baxter, IV Systems Division)

Some glass bottles are vented with an inside tube that exits the bottle into a rubber stopper in the neck of the bottle; if the bottle is not vented, then the nurse needs to select a vented infusion set.

The drip chamber is calibrated to allow a predictable amount of fluid to be delivered. There are two types of drip chambers: a macrodrip, which delivers 10 to 20 drops per milliliter of solution, and a microdrip, which delivers 60 drops per milliliter. The drip rate varies with the manufacturer as indicated on the package.

The administration set has a manual flow-control device such as a slide clamp (Figure 37-10), a roller clamp, or a screw to regulate a prescribed infusion rate. Follow the manufacturer's guidelines when using the manual flow-control device to regulate the prescribed infusion rate. The end of the IV tubing contains a needle adapter that attaches to the sterile device inserted in the client's vein. Extension tubing may be used to lengthen the primary tubing. A primary continuous administration set is used to administer routine solutions prescribed to infuse continuously over a 24 hour period. The primary administration set, inclusive of the add-on devices, is changed every 48 to 72 hours in conjunction with the peripheral cannula change. A bag of intravenous solution should not hang longer than 24 hours. Secondary administration sets are often referred to as "piggyback" administration sets. The secondary tubing is connected into the primary tubing at an injection site (see Figure 37-11) and allows for the administration of a second solution such as medication.

Secondary administration sets are also changed every 48 to 72 hours.

Primary intermittent administration sets are used to deliver medications at prescribed intervals through an injection/access port and are changed every 48 to 72 hours; all add-on devices such as extension sets, filters, PRN adaptors, and stopcocks are changed with the intermittent administration set. A sterile needle/needleless device should be aseptically attached to the intermittent administration set prior to administering the medication and removed immediately after each use.

Health Hazard

A *Health Alert* from Health Care Without Harm (HCWH) (1999) cautioned the public about the potential risks of exposure to diethylhexyl phthalates (DEHP) from medical products such as IV bags and tubing. More than 500 million IV bags are used in the United States every year to deliver blood, medication, and other essential solutions to clients (HCWH, 1999). Eighty percent of the IV bags are made with polyvinyl chloride (PVC), which requires a plasticizer to make the bags soft and flexible. DEHP is the softener used in PVC products. DEHP has been shown to leach from IV bags into the solutions they contain and directly into the client's bloodstream.

The Environmental Protection Agency has classified DEHP as a probable human carcinogen and HCWH claims that studies have shown that DEHP can damage the heart, liver, testes, and kidneys and interfere with sperm production. Certain drugs such as Taxol (used to treat breast cancer) and Taxotere (used to treat ovarian and breast cancer and AIDS-related Kaposi's sarcoma) have been shown to increase the leaching of DEHP from PVC plastics into the solution (Stewart, 1999); see the accompanying display for additional drugs that can increase leaching of DEHP from PVC IV products. Although one leading producer of intravenous vinyl IV bags containing DEHP plans to develop an alternative to polyvinyl chloride or PVC for their products, no time frames were given to totally remove these products from the market.

DRUGS THAT INCREASE LEACHING OF DEHP FROM PVC PLASTICS

- Chemotherapeutic agents: Etoposide (VePesid) and Teniposide (Vumon)
- Antianxiety agents: Chlordiazepoxide HCl (Librium)
- Antifungal agents: Miconazole (Monistat IV)
- Immunosuppressive agents: Cyclosporine (Sandimmune) and Tacrolimus (Prograf)
- Nutritional solutions: Fat emulsions and vitamin A

Adapted from Stewart, M. (1999). IV bags pose patient risk. *The American Nurse*, March/April, 12.

A second health hazard is inherent in the use of DEHP. The disposal of medical products containing DEHP releases highly toxic and endocrine-disrupting dioxins. According to the ANA (1999), PVC is the only plastic linked both to phthalate chemical leaching and to the production of dioxin.

NURSING TIP

Age Considerations for Choosing IVs and Equipment

Neonates, infants, and children are at risk for *Altered Fluid Balance: Overload, related to rehydration*. IV tubing with a microdrip and special volume control chambers is used to regulate the amount of fluid to be administered over a specific time interval. Armboards and soft restraints are used to stabilize peripheral infusions by immobilizing the extremity to prevent accidental removal of infusion devices.

Intravenous Filters

Intravenous filters prevent the passage of undesirable substances such as particulate matter and air from entering the vascular system. Particulate matter filters are utilized when preparing infusion medications for administration to prevent obstruction in the vascular/pulmonary systems, irritation and **phlebitis** (inflammation of a vein). Air-eliminating filters are used for the delivery of infusion therapy to decrease the potential of air emboli; the filter should be located as close as possible to the cannula site. IV filters come in various sizes; the finer the filter, the greater is the degree of solution filtration. Although studies have shown that IV filters reduce the risk of bacteremia and phlebitis as much as 40%, some agencies do not use IV filters because of cost. Many IV catheters contain an in-line filter; if the catheter has an in-line filter, it is not necessary to add a filter to the tubing.

Needles and Venous Peripheral-Short Catheters

Needles and peripheral-short catheters provide access to the venous system. A variety of devices are available in different sizes to complement the age of the client, the type and duration of the therapy, and to protect the user from injury (Figure 37-12).

As with any gauge needle, the larger the number, the smaller the lumen. The nurse considers the client's age, body size, and the type of solution to be administered when selecting the gauge of the needle or catheter:

- Infants and small children, 24 gauge
- Preschool through preteen, 24 or 22 gauge

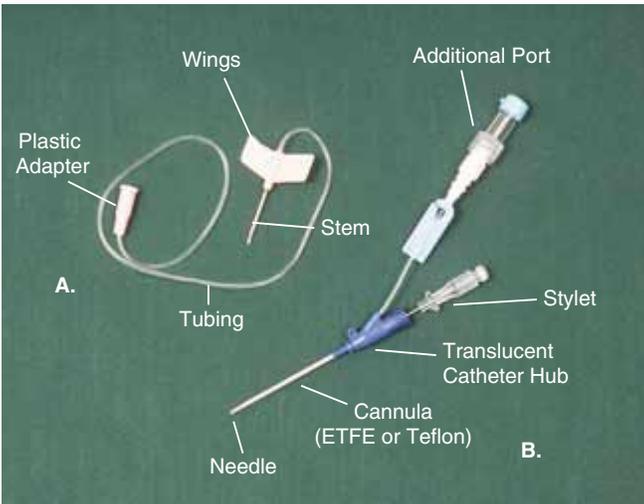

Figure 37-12 Peripheral IV Devices: A. Butterfly; B. Angiocatheter

- Teenagers and adults, 22 or 20 gauge
- Geriatric, 22 or 24 gauge

Butterfly (scalp vein or wing-tipped) **needles** are short, beveled needles with plastic flaps attached to the shaft. The flaps (which are flexible) are held tightly together to facilitate ease of insertion and then flattened against the skin to prevent dislodgement during infusion. These needles are commonly used for short-term or intermittent therapy and for infants and children.

There are several types of short catheters used to access peripheral veins. Short peripheral venous catheters vary in length from $\frac{3}{4}$ to $1\frac{1}{4}$ inches. During insertion, some of these catheters are threaded over a needle, and others are threaded inside a needle. **Intracath** is a term used to refer to a plastic tube inserted into a vein. An **angiocatheter** is a type of intracath with a metal stylet to pierce the skin and vein, after which the plastic catheter is threaded into the vein and the metal stylet is removed, leaving only the plastic catheter in the vein. Short venous catheters can have safety devices to reduce the risk of accidental needlesticks. These devices are designed to allow for easy insertion of the catheter while providing a built-in safety feature for the user. As the catheter is threaded over the needle and advanced into the vein, the built-in needle guard advances forward toward the tip of the needle; when the catheter hub is removed from the device, the entire needle is encased within the needle guard.

Peripheral Intravenous (PI) and Heparin Locks

Peripheral intravenous (PI) and heparin locks are devices that establish a venous route as a precautionary measure for clients whose condition may change rapidly or who may require intermittent infusion therapy. A butterfly needle or peripheral catheter is inserted into a vein and the hub is capped with a lock port, also called a Luer lock (Figure 37-13).

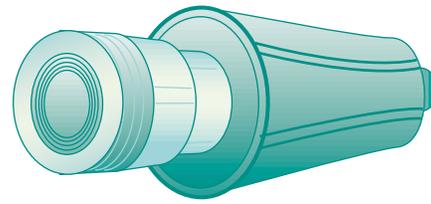

Figure 37-13 Luer Lock Injection Site

Needle-Free System

Safety is a concern associated with IV therapy; refer to Chapter 31. Accidental needle-stick injuries and puncture wounds with contaminated devices increase the employee's risk for infectious diseases such as AIDS, hepatitis (B and C), and other viral, rickettsial, bacterial, fungal, and parasitic infections. Most health care agencies now use totally needle-free IV systems (Figure 37-14) to decrease the risk of employee injuries.

Vascular Access Devices

Vascular access devices (VAD) include various catheters, cannulas, and infusion ports that allow for long-term IV therapy or repeated access to the central venous system. The kind of VAD used depends on the client's diagnosis and the type and length of treatment (see Table 37-6). Site selection and insertion of central catheters, other than peripherally inserted central catheters, is a medical act performed by a practitioner. Although there are many types of catheter materials, insertion techniques and kinds of central catheters, *all central catheters must be radiopaque to allow for radiographic verification of placement of the catheter and its tip prior to the administration of any solution.*

Central catheters are usually inserted into the internal jugular and subclavian veins with the distal tip located in the superior vena cava to minimize vessel irritation and sclerosis. The femoral vein can be used for central venous access when there is thrombosis of the internal jugular or subclavian veins; correct tip location should be in the inferior vena cava. Insertion of a central catheter can be performed either percutaneously or surgically. Surgically, a central catheter is either placed

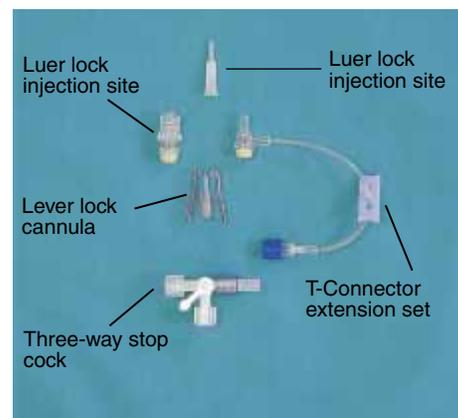

Figure 37-14 Needle-free System

NURSING ALERT

Inserting a CVC

When assisting with the insertion of a long-line central catheter, observe the client for symptoms of a pneumothorax: sudden shortness of breath or sharp chest pain; increased anxiety; a weak, rapid pulse; hypotension; pallor or cyanosis. These symptoms indicate accidental puncture of the pleural membrane.

entirely under the skin (implanted), or the catheter partially exits the skin (tunneled).

A tunneled catheter is inserted through the subcutaneous tissue, usually between the nipple and clavicle, with the catheter tip inserted through the cephalic or external jugular vein and threaded to the right atrium.

An **implantable port** is a device made of a radiopaque silicone catheter and a plastic or stainless steel injection port with a self-sealing silicone-rubber septum. The health care practitioner inserts the device into a subcutaneous pocket, usually over the third or fourth rib, lateral to the sternum. The distal tip of the catheter is surgically tunneled in the cephalic or external jugular vein, with the proximal end of the catheter tunneled through the subcutaneous tissue into the injection port of the device.

Implanted ports and pumps are vascular access devices that provide for the delivery of prescribed parenteral therapies. Accessing these devices requires the use of aseptic technique. Noncoring needles such as a Huber needle are used to access an implanted port/pump and should be changed at least every 7 days. The smallest gauge noncoring needle that can deliver the prescribed therapy should be used when accessing the port/pump. Nurses caring for clients with

implanted ports/pumps must have a thorough knowledge of the design features of the device, as explained in the manufacturer's guidelines, to ensure correct access and administration techniques, maintenance, and potential complications.

Implanted pumps have a reservoir designed to continuously infuse a specific volume of solution over a pre-set period of time; the pump must be routinely emptied and refilled at established intervals. Some pumps have an additional feature, a side port designed for administration of intermittent medication. The flow rate of some pumps is sensitive to changes in atmospheric pressure, body temperature, blood pressure and the viscosity of the medications. Clients are instructed to report changes in their lifestyle and physical condition that may affect the pump's flow rate. *Only nurses who have been specially trained are allowed to access an implanted port/pump because of the risk of infiltration into the tissue if needle placement is incorrect.*

A peripherally inserted central catheter (PICC) is the generic name for 11 different devices. A PICC is a silicone or polyurethane catheter inserted into one of the major veins in the antecubital fossa. Although the length of the catheter varies, on an average a PICC is 52 cm long, and its tip resides in the lower-third section of the superior vena cava. A PICC can be trimmed at the time of insertion to a specific length that is determined by the approximate distance between the insertion site and the superior vena cava. The majority of state boards of registered nurses allow specially trained nurses to insert the PICC. Placement of the catheter's tip is confirmed by x-ray prior to the administration of any solution. The registered nurse that inserts the PICC must document the type of PICC inserted and the total length of the inserted catheter, and record if the length of the catheter was trimmed prior to insertion.

TABLE 37-6
Vascular Access Devices

Type	Brand Name	Use
Nontunneled central venous catheter (triple-lumen)	Hohn, Deseret	Short-term fluid or blood administration, obtaining blood specimens, and administering medications
Tunneled central venous catheter (single or double lumen)	Hickman, Broviac, Groshong	Long-term (months to years) fluid replacement therapy, medication administration, nutritional supplement, and blood specimen withdrawal
Implanted infusion port	Chemo-Port, Infuse-a-Port, Mediport, Port-a-Cath	Long-term (months to years) fluid replacement therapy, medication administration (especially chemotherapy), blood or blood product administration, and blood specimen withdrawal
Peripherally inserted central catheter (PICC)	C-PICC, Groshong PICC, SoloPICC	Long-term fluid replacement therapy, medication administration (chemotherapy, antibiotics, controlled narcotics), blood or blood product administration, and blood specimen withdrawal

Preparing an Intravenous Solution

To prepare an IV solution, read the agency's protocol and gather the necessary equipment. Because IV equipment and solutions are sterile, check the expiration date on the package prior to usage. The solution can be prepared at the nurses' work area or in the client's room (Procedure 37-2).

The nurse prepares and applies a time strip to the IV solution bag to facilitate monitoring of the infusion rate as prescribed by the health care practitioner (Figure 37-19). The IV tubing is tagged with the date and time to indicate when the tubing replacement is necessary. IV tubing is changed every 48 to 72 hours in accord with the agency's protocol. The nurse initials the time strip and IV tubing tag.

PROCEDURE 37-2

Preparing an Intravenous Solution

Equipment

- | | |
|-------------------------------|--|
| ■ IV solution (bag or bottle) | ■ Administration set (vented or nonvented) |
| ■ Extension set | ■ IV pole |
| ■ IV line filter | |

Action

1. Wash hands before preparing IV equipment.
2. Check the health care practitioner's order for the type and amount of solution.
3. Check integrity of the IV solution and equipment.
4. Select IV tubing in accord with agency policy.
5. Prepare IV solution label with client's name, date, time, additives, and your initials.

Plastic Bag

6. Prepare the IV solution bag for administration
 - Remove outer wrapper around IV bag of solution.
 - Inspect bag for tears or leaks by noting any moisture on the protective covering.
 - Apply gentle pressure and observe for leakage.
 - Examine solution for discoloration, cloudiness, or particulate matter by holding the bag against a dark and light background; if there is any evidence of contamination, do not use, and return bag to agency's dispensing department.
7. Hang IV bag on the IV pole.
8. Remove administration set from the package and close the roller clamp on the IV tubing (Figure 37-15).
9. Remove the protective cap from the nonvented IV tubing spike and maintain the sterility of the spike.

Rationale

1. Decreases the transmission of microorganisms.
2. Ensures the correct type and amount of fluid.
3. Ensures the sterility of the solution and items.
4. Agency protocols reflect which items of equipment are to be used with specific IV solutions and to complement volume control devices.
5. Provides information to other health care workers relative to when the solution was hung and what additives are infusing in the solution.
6. Ensures that solution is free of contamination; contaminated solutions are returned to central supply or pharmacy for manufacturer notification.
7. Provides easy access to container.
8. Prevents solution from escaping into the tubing until the drip chamber on the tubing has been primed.
9. Prepares the sterile spike for insertion into the IV container; IV bags have a vented port.

(continues)

PROCEDURE 37-2

Preparing an Intravenous Solution (continued)

Action

Figure 37-15 Remove tubing from the package, leaving the protective caps on both ends intact.

10. Grasp the port of the IV bag with your nondominant hand. With your dominant hand, remove the plastic tab covering the port (Figure 37-16) and insert the full length of the spike into the bag's port (Figure 37-17).

Figure 37-16 Open the IV plastic bag and pull down the plastic tab covering the port with one hand while pinching the port with the other hand.

Figure 37-17 Remove the cap from the spike and spike the IV port.

11. Squeeze and quickly release pressure on the drip chamber of the IV tubing until the chamber is one-third to one-half full.

Rationale

10. Prevents contamination of both the port and the spike.

11. Primes the chamber by displacing air with IV solution, allowing half the chamber to remain free of solution. *(continues)*

PROCEDURE 37-2

Preparing an Intravenous Solution (continued)

Action

12. Connect IV filter to tubing.
 - Remove cap from filter.
 - Fit tubing's male adapter into filter's female connector, and twist to ensure tight connection.
 - Hold filter so connector joint is pointed down.
 - Hold tubing's end tip higher than the tubing's dependent loop to displace the air.
 - Open roller clamp on IV tubing to prime the tubing and filter (Figure 37-18).
 - Tap the filter as the IV solution runs through.
 - Close the roller clamp on the IV tubing.

A.

Rationale

12. Reduces the risk for bacteremia and the incidence of infusion phlebitis; tapping the filter as the solution runs through it eliminates any air bubbles trapped in the filter's membrane.

B.

Figure 37-18 A. Priming the IV Tubing. B. Open the roller clamp on the tubing to allow the fluid to enter the tube and expel the air.

13. Replace the cap on the IV tubing's free end.
 - 13. Maintains the sterility of the system.
14. Attach a Dial-a-Flo fluid regulator at the end of the IV tubing if fluids are to be administered with this device. With the cap off the end of the tubing, turn the Dial-a-Flo to the open position, open all the tubing regulator clamps, and clear the tubing of air; close the regulator clamp and replace the cap on the end of the tubing.
 - 14. Controls the rate of infusion.
15. Tag tubing with date and time and your own initials.
 - 15. Indicates when tubing replacement is due (every 24 to 48 hours, in accord with agency protocol).
16. Explain to the client what you are doing before taking the IV equipment into the client's room.
 - 16. Elicits client cooperation.

(continues)

PROCEDURE 37-2

Preparing an Intravenous Solution (continued)

<i>Action</i>	<i>Rationale</i>
Glass Bottle	
<p>17. Repeat steps 1–5.</p> <ul style="list-style-type: none"> • Vented tubing is used for glass bottles that are not vented. 	
<p>18. Prepare the IV solution for administration.</p> <ul style="list-style-type: none"> • Check bottle for cracks or leaks. • Remove metal cap, metal disk, and rubber diaphragm from top of glass bottle, or remove protective additive cap if pharmacy has added medications to the IV bottle. • Listen for the escape of air when the rubber diaphragm is removed. 	<p>18. Ensures that solution is free of contamination; contaminated solutions are returned to central supply or pharmacy for manufacturer notification. Escape of air indicates the breaking of the vacuum inside the bottle, which will allow the fluid to flow into the tubing.</p>
<p>19. Close the roller clamp on the IV tubing.</p>	<p>19. Stops flow of fluid.</p>
<p>20. Remove the protective cap from the IV tubing spike and maintain the sterility of the spike.</p>	<p>20. Prevents contamination.</p>
<p>21. Place the glass bottle on a firm surface, and, using firm downward pressure, insert the spike through designated port on the bottle cap.</p>	<p>21. Pressure is required to puncture the rubber stopper in the neck of the IV bottle.</p>
<p>22. Invert IV bottle (if the bottle is vented, the fluid inside the vent tube will escape), and hang the bottle on an IV pole.</p>	<p>22. Allows gravity to displace the air in the IV tubing when the roller clamp is opened.</p>
<p>23. Continue steps 11–16.</p>	

Figure 37-19 Apply time strip to the IV container.

Initiating IV Therapy

When initiating IV therapy, the nurse should assess for a venipuncture site. Figure 37-20 presents the common peripheral sites for starting IV therapy in pediatric, adult, and geriatric clients (see Chapter 28, Procedure 28-1, Venipuncture).

When assessing clients for potential sites, consider their age, body size, clinical status and impairments, and the skin condition (see the accompanying display for contraindications when selecting a site). Lower-extremity veins are used for IV therapy only when so prescribed by the health care practitioner; circulating

NURSING ALERT

Marking an IV Bag

Do not use a felt-tip pen to mark an IV bag; the ink from the pen can leak through the plastic and contaminate the solution. Do not label bag with time strip made of adhesive/silk/paper tape, as the adhesive will leach into the bag. Use only labels appropriate for IV bags.

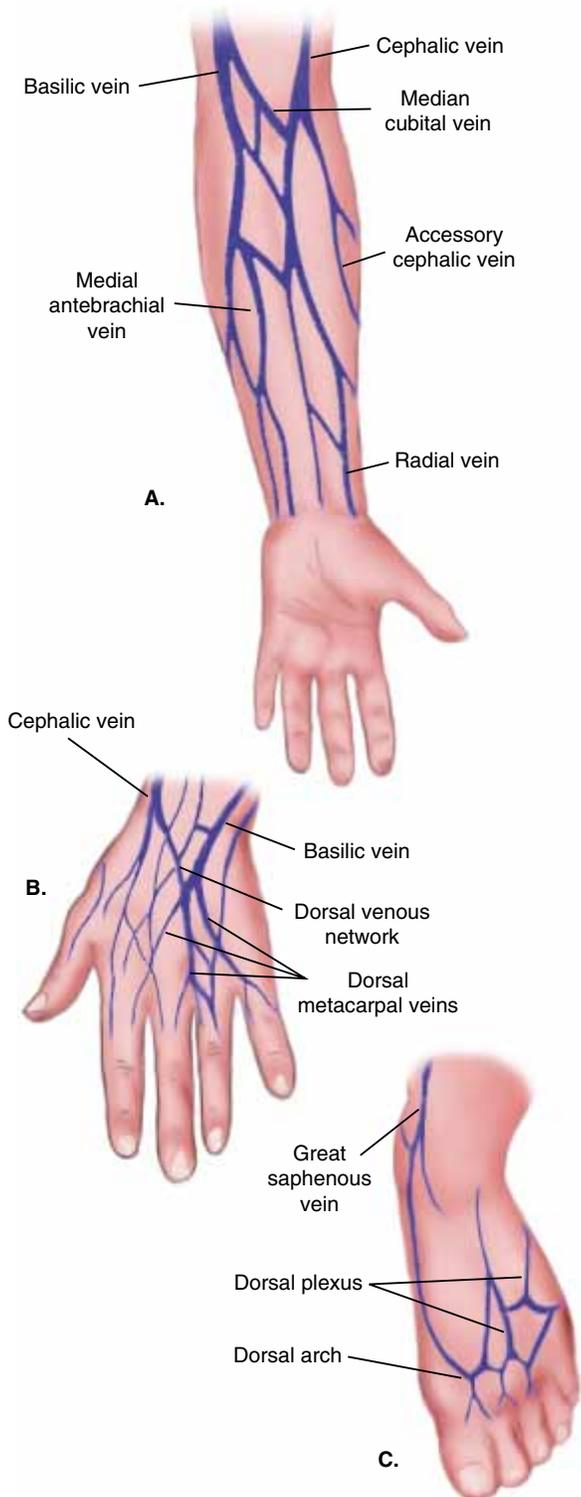

Figure 37-20 Peripheral Veins Used in Intravenous Therapy. A. Arm and Forearm; B. Dorsum of the Hand; C. Dorsal Plexus of the Foot

blood in the lower extremities is likely to pool and clot, which may result in an embolism. Because contact with blood is likely, venipuncture requires the implementation of Standard Precautions. Refer to Chapter 31 for a complete discussion of Standard Precautions.

Select a vein for puncture at its most distal end to maintain the integrity of the vein, because venous blood

VENIPUNCTURE SITE CONTRAINDICATIONS

- Signs of infection, infiltration, or thrombosis
- Affected arm of a postmastectomy client
- Arm with a functioning arteriovenous fistula
- Affected arm of a paralyzed client
- Any arm that has circulatory or neurologic impairments

NURSING ALERT

Prepping Skin for Venipuncture

When prepping the client's skin for a venipuncture, cleanse the skin with betadine and wait for it to dry. Do not apply alcohol after the skin has been prepped with betadine. If these substances are combined, they form a toxic material that may be absorbed through the skin.

flows with an upward movement toward the heart. When a vein is punctured with an instrument, such as a needle, fluids can infiltrate (leak from the vein into the tissue at the site of puncture). If IV therapy has to be discontinued for any reason, such as infiltration, it can be restarted above the initial puncture site only.

Vein Finder

A vein finder is a device used to locate hard-to-find veins. It is helpful, for example, in working with obese clients whose superficial veins are difficult to locate. A Venoscope (Figure 37-21) is a type of vein finder with adjustable fiberoptic arms that reveal veins. The room is dimmed, and the disposable skirts are placed flush against the skin. The nurse slowly moves the Venoscope along the extremity until a dark, shadowy line is seen between the fiberoptic arms.

Once the vein is identified, it can also be checked to determine whether it is sclerotic. To assess for sclerotic veins, apply a downward pressure over the fiberoptic arms and observe the vein when pressure is applied then released. A nonsclerotic vein will disappear with pressure and reappear when pressure is released.

Administering IV Therapy

Once the solution is prepared for administration, the nurse calculates the rate and explains the procedure to the client (see Procedure 37-3 for the administration of IV therapy). There are three ways to administer solutions:

1. Initiate the infusion by performing a venipuncture.
2. Use an existing IV system: catheter, heparin or PI lock, central line, or implanted port.
3. Add a solution to a continuous-infusion line.

Figure 37-21 Venoscope (Courtesy of Applied Biotech Products, Inc., P.O. Box 52703, Lafayette, LA 70505-2703, 800-284-7655)

NURSING TIP

Age Considerations for Initiating IV Therapy

The aging process causes physiological changes in the skin, muscles, and veins. The skin loses its durability, making it prone to tears and abrasions. Decrease in muscle mass may cause the vein to roll during puncture. The veins themselves are also more fragile in the elderly. When first infusing fluid into the vein, administer it slowly and observe carefully for any sign of infiltration.

Fluid administration can be continuous, ongoing over a 24-hour period, or intermittent, 1000 ml ordered once in a 24-hour period. Although fluids may be continuous, the type of fluids can alternate over a 24-hour period; for example, an order might be *add 40 mEq of KCl to first bag of 1000 ml of normal saline*.

IV medications may be **piggybacked**, added to an existing intravenous solution to infuse concurrently. IV solutions and medications that have been refrigerated should

PROCEDURE 37-3

Administering an IV Solution

Equipment

Adding Solution to a Continuous Infusion Line

- Prepared IV solution and medication

Adding a Secondary Line, Additive Bag (IV Piggyback)

- Prepared and labeled medication solution bag from pharmacy
- Alcohol swab

Adding a Solution to an Existing Heparin or PI Lock

- Prepared IV solution system with needleless locking cannula
- Alcohol or iodophor swab

- Secondary administration set
- Needleless locking cannula

- Needleless injection cap (if one is not in place)
- 2 prefilled syringes of 2 ml each of normal saline
- Nonsterile gloves

Action

- Gather prepared equipment (solution labeled with the client's name, and time-taped for fluids to infuse per hour). Check the prescriber's order for the type and amount of solution.
- Wash hands, and don gloves if you have to perform a venipuncture or connect the tubing to an existing PI. *Gloves are not necessary if you are adding fluids to an existing infusion line.*

Rationale

- Ensures correct fluids to be administered to the right client at the prescribed infusion rate.
- Decreases risk of transmission of microorganisms.

(continues)

PROCEDURE 37-3

Administering an IV Solution (continued)*Action**Rationale*

3. Check the client's armband.
4. Explain the procedure to the client.
5. Assess the puncture site.
 - Observe for redness and puffiness.
 - Palpate for tenderness.
6. Check patency of infusion site.
 - Verify that fluid is infusing.
 - Remove IV container from the pole and lower the container below the level of infusion site.
 - Observe for backflow of blood into the hub of the venous access device.
 - Replace container on IV pole.

3. Ensures correct client.
4. Elicits client support and decreases anxiety.
5. Indicates signs of infiltration or infection.
6. Verifies patency of IV system with venous access device in the client's vein.

Adding Solution to a Continuous Infusion Line

7. Check the date on the tubing tag; if the tubing needs changing, refer to Procedure 37-2.
8. Hang the new bag of fluids on the IV pole and remove the cover from the port.
9. Remove the current infusion bag of fluids from the IV pole.
10. While maintaining aseptic technique, remove the tubing spike from the port of the infusing bag of fluids and reinsert the tubing spike into the port on the new bag of fluids; push the full length of the spike into the port.
11. Set the infusion rate.

7. Indicates when tubing replacement is due.
8. Provides easy access to the fluids.
9. Makes room for new bag.
10. Maintains the sterility of the IV system.
11. Produces correct drip rate.

Manual Rate Regulation

- Open regulator clamp; close slowly while observing the drip chamber until the fluid is dripping at a slow, steady pace.
- Count the number of drops for a 15-second interval and multiply by 4; for example, if the drop factor of tubing is 10 drops/ml then the drop rate should be 21 drops/minute to infuse 1000 ml/8 hours (Figure 37-22).
- Open the regulator clamp slowly to increase the drip flow rate; close the regulator clamp to decrease the drip rate to achieve 21 drops/minute.
- Recount the drop rate after 5 and 15 minutes.
- Proceed to steps 12–19.

- Determines patency of venous access device.
- Determines number of drops falling per minute.
- Controls drip rate with regular clamp.
- Detects changes in rate due to expansion and contraction of tubing.

(continues)

PROCEDURE 37-3

Administering an IV Solution (continued)

Action

Figure 37-22 Manual Rate Regulation: Counting the Number of Drops for a 15-Second Interval

Rationale

Dial-a-Flo Regulation

- Turn Dial-a-Flo regulator until arrow is aligned with desired volume of fluid to infuse over 1 hour.
- Check drip rate over 15 seconds, and multiply by 4.
- Adjust height of IV pole if necessary.
- Recount drip rate after 5 minutes and again after 15 minutes.
- Proceed to steps 12–19.

Infusion Controller or Pump Regulation

- Insert tubing into infusion controller or pump in accord with manufacturer's instruction (Figure 37-23).
- Close door to controller or pump and open all tubing clamps and regulators.
- Set volume dials to regulate the volume to infuse per hour or drops per minute in accord with the type of machine.
- If the controller or pump has an electronic eye, clamp it over the upper portion of the drip chamber that does not contain fluid.
- Push the *start* or *on* bottom.
- If desired, set the volume infusion alarm.
- Proceed to steps 12–19.

- Regulates infusion of fluid at the desired rate.
- Verifies calculated drip rate with infusion rate.
- Facilitates flow by gravity; the higher the pole, the greater is the infusion rate.
- Detects changes in rate due to expansion and contraction of tubing.
- Ensures proper functioning of the device.
- Allows controller or pump to regulate the infusion rate.
- Determines amount of fluid the device will deliver.
- Allows controller or pump to monitor drip rate.
- Initiates the device's regulation of the fluid flow.
- Sounds when the set volume has been infused.

(continues)

PROCEDURE 37-3

Administering an IV Solution (continued)

Action

Figure 37-23 IV Tubing Threaded into an Infusion Pump with Controls Set

*Rationale***Volume Control Chamber (Buretrol) Regulation**

- Close regulators both above and below the chamber.
- If adding a new Buretrol, open regulator above the chamber and fill the chamber with 10 ml of fluid, close the top regulator, and slowly open the regulator below the chamber to remove air from the tubing. Close the bottom regulator (Figure 37-24).
- Allows for precise release of fluids into the chamber.
- Facilitates priming the drip chamber and clearing the tubing below the chamber of air.

Figure 37-24 Volume Control Set

(continues)

PROCEDURE 37-3

Administering an IV Solution (continued)

<i>Action</i>	<i>Rationale</i>
<ul style="list-style-type: none"> • Open the top regulator and fill the chamber with the volume of fluid to infuse in 1 hour or 2 hours if the volume is small. • Close top regulator and ensure that air vent is open. • Open bottom regulator and regulate drops to calculated drip rate in accord with the drop factor. • Count drip rate over 15 seconds and multiply by 4. • Time-tape the chamber if a controller or pump is not used. • Check chamber every 1 to 2 hours depending on the volume placed in the chamber. • Proceed with steps 12–19. 	<ul style="list-style-type: none"> • Facilitates close monitoring of fluid volume. • Allows fluid to escape from the chamber. • Determines volume to infuse over an hour. • Verifies rate of infusion. • Facilitates easy check of fluid infusion and shows when to add fluid to the chamber. • Maintains fluid infusion and prevents air from entering the chamber and tubing if all fluid is infused.
<p>12. On the time tape, write the time the fluids were initiated and your initials.</p>	<p>12. Facilitates easy check of fluid infusion progress as prescribed.</p>
<p>13. Monitor the volume delivered every 1 to 2 hours and compare with the time tape.</p>	<p>13. Ensures the actual volume being delivered.</p>
<p>14. If fluids are not infusing at the prescribed rate as indicated by time tape:</p> <ul style="list-style-type: none"> • Check setting on controller or pump or Dial-a-Flo and adjust as indicated. • Increase height of IV pole. • Assess puncture site, reposition the venous access device, lower the IV fluid container below the puncture site and observe for a backflow of blood. Replace container on pole. 	<p>14. Ensures that prescribed amount of fluid is delivered.</p> <ul style="list-style-type: none"> • Allows gravity to facilitate the drip rate. • Ensures that venous access device is still in the vein.
<p>15. Instruct client to limit movement of puncture site and to notify a nurse of any problems or discomfort.</p>	<p>15. Facilitates early detection of problems.</p>
<p>16. Apply an armboard, if indicated (Figure 37-25).</p>	<p>16. Immobilizes the extremity receiving the infusion.</p>

Figure 37-25 Positioning of Client with an IV Armboard

(continues)

PROCEDURE 37-3

Administering an IV Solution (continued)

<i>Action</i>	<i>Rationale</i>
17. Position the client for comfort and place the call light in easy reach.	17. Promotes client comfort and safety.
18. Wash hands and dispose of used supplies.	18. Decreases transmission of microorganisms.
19. Document on the client's medical record: <ul style="list-style-type: none"> • Time of initiation of fluid infusion • Type and volume of fluid infusing • Infusion device used, if applicable • Status of the venous access insertion site • Problems encountered: for example, if venous access device is repositioned • Client's tolerance to the fluid infusion • Client teaching and learning 	19. Provides a record of the nursing intervention and the client's response.
Adding a Secondary Line, Additive Bag (IV Piggyback)	
Refer to Chapter 29, Procedure 29-7.	
Adding a Solution to an Existing Heparin or PI Lock	
20. Repeat steps 1–5.	
21. Hang IV solution on IV pole.	21. Provides easy access to system.
22. Don nonsterile gloves and cleanse needleless injection port with alcohol or iodophor swab. Allow to dry.	22. Reduces risk of transmission of microorganisms.
23. Insert saline syringe into port, slowly aspirate, and observe for blood; flush system and observe for swelling at puncture site.	23. Indicates a patent system and, with the presence of blood and lack of swelling, that the needle is probably in the vein.
24. Connect needleless locking cannula into injection port, open tubing clamp, and adjust rate as indicated in step 11.	24. Ensures administration of solution at the correct drip rate.
25. Dispose of equipment and gloves in proper receptacle and wash hands.	25. Reduces risk of transmission of pathogens.
26. When secondary bag and drip chamber are empty, don gloves, close the clamp, and disconnect the needleless locking cannula from the port's lock.	26. Indicates infusion of the solution.
27. Flush port with second saline syringe and place sterile needleless injection cap on the port.	27. Clears the line and reduces the risk of contaminating the port.
28. Dispose of equipment and gloves in proper receptacle and wash hands.	28. Reduces risk of transmission of pathogens.
29. Record fluid administration on MAR and client response in nurses' notes.	29. Documents nursing intervention and any client adverse reactions.

Nursing Process Highlight

Implementation

Instead of setting the total volume to be infused (e.g., 1000 ml), set the volume slightly lower (e.g., at 950 ml) so that the alarm will go off before the fluids are absorbed completely. This method will give you time to have the next bag of fluids ready when all 1000 ml has been absorbed. This is especially helpful when dealing with refrigerated fluids that must be warmed to room temperature before administering. If you will be off duty when the volume will be absorbed and you have set the alarm to go off early, tell the oncoming nurse during report.

be warmed to room temperature before administration (usually 30 minutes) to increase client's comfort.

Flushing

Flushing refers to the instillation of a solution into an intravenous cannula. Flushing is performed to assess and maintain cannula patency and prevent the mixing of incompatible medications and/or solutions, following the conversion of continuous IV therapy to intermittent IV therapy, and to maintain intermittent cannula patency following IV medication administration and blood sampling.

The type of solution and frequency of flushing an intermittent intravenous cannula is determined by the agency's policy/protocol. According to the INS (2000), flushing a cannula at established intervals with saline (0.9% sodium chloride injection) is the accepted solution to ensure and maintain patency of an intermittent PI cannula, while a heparin flush solution is the accepted solution to maintain patency of an intermittent central venous devices. The volume of flush is equal to the volume capacity of the cannula and add-on devices times two (INS, 2000). Consideration is also given to the volume and frequency of heparin flush in order to prevent an alteration in the client's clotting factors.

When flushing a cannula positive pressure within the lumen of the catheter must be maintained to prevent the reflex of blood into the cannula lumen. Use the manufacturer recommended maximum pressure limits (pounds per square inch) when selecting the size of the syringe to use for flushing since the smaller the syringe the greater the pressure generated; excessive internal pressures in the device increase the potential for cannula damage and/or progressive internal cannula weakening over the life of the device (INS, 2000). If resistance is met when flushing a cannula, do not exert pressure in an attempt to restore patency of an occluded cannula since

Title of Study

"The Use of Heparin and Normal Saline Flushes in Neonatal Intravenous Catheters"

Authors

Paisley, M. K., Stamper, M., Brown, J., Brown, N., & Ganong, L. H.

Purpose

To compare the use of heparin versus normal saline flush solutions on maintaining the patency of peripheral IV catheters in neonates.

Methods

This quasi-experimental study compared the outcomes in 87 infants with 159 IV starts who were 32 weeks or older gestation at birth; 32 received heparin, and 54 received normal saline.

Findings

There were no statistically significant differences in the duration of patency between the groups receiving heparin and normal saline; however, the duration of patency was significantly longer for term than pre-term infants and for insertion in the scalp, arm, or hand veins rather than the leg or foot veins.

Implications

Although this study found no difference in the duration of patency relative to the type of flush solution, two other variables were identified for duration of patency for IV catheters: gestational age and site of insertion. Results of this study also demonstrated the cost-saving benefit to the agency when using saline as a flush solution rather than heparin.

Paisley, M. K., Stamper, M., Brown, J., Brown, N., & Ganong, L. H. (1997). The use of heparin and normal saline flushes in neonatal intravenous catheters. *Pediatric Nursing*, 23(5), 521–524, 527.

this action may result in the dislodgement of a clot into the vascular system and/or rupture of the catheter.

Regulating IV Solution Flow Rates

Infusion sets with macrodrip chambers are often used for adult clients, whereas microdrip chambers are used for volume-sensitive clients, such as geriatric or pediatric clients. Pediatric and geriatric clients usually require some type of device to regulate the fluids as a safety factor to prevent overload. Devices such as

controllers and pumps are commonly used to regulate the rate of infusion.

Calculation of Flow Rate

The **flow rate** is the volume of fluid to infuse over a set period of time as prescribed by the health care practitioner. The health care practitioner will identify either the amount to infuse per hour (such as 125 ml per hour or 1000 ml over an 8-hour period). Calculate the hourly infusion rate as follows:

$$\frac{\text{Total volume}}{\text{Number of hours to infuse}} = \text{ml/hour infusion rate}$$

For example, if 1000 ml is to infuse over 8 hours:

$$\frac{1000}{8} = 125 \text{ ml/hour}$$

Calculate the actual infusion rate (drops per minute) as follows:

$$\frac{\text{Total fluid volume}}{\text{Total time (minutes)}} \times \text{drop factor} = \text{drops per minute}$$

For example, if 1000 ml is to infuse over 8 hours with a tubing drop factor of 10 drops per milliliter:

$$\frac{1000 \text{ ml}}{8(60) \text{ min}} \times 10 \text{ drops/ml} = \frac{10,000 \text{ drops}}{480 \text{ min}} = 20.8 \text{ or } 21 \text{ drops/min}$$

Another way to calculate the actual infusion rate is to use the hourly infusion rate; for the example just given:

$$\frac{125 \text{ ml} \times 10 \text{ drops/ml}}{60 \text{ min}} = 20.8 \text{ or } 21 \text{ drops/min}$$

Flow-Control Devices

Flow-control devices are used to regulate the infusion at the prescribed administration rate. Safety factors such as the client's age and condition, prescribed therapy, and setting are considered when selecting a flow-control device. There are two basic types of flow-control devices: manual flow-control devices and electronic infusion devices. Manual flow-control devices include roller, screw, and slide clamps and may include volume control devices such as Buretrol. These devices are used routinely to regulate the accurate delivery of most prescribed IV therapy.

Electronic infusion devices are operated either by electricity or battery and are used to administer IV fluids and medications and should be considered on all central access devices (INS, 2000). Electronic infusion pumps have audible alarms that sound when the solution has infused, the infusion tubing contains air or is kinked, or the cannula is clotted. There are two types of electronic infusion devices: controllers and pumps. Controller infusion devices generate flow by gravity and are capable of maintaining a constant preset flow rate either by drop counting or volumetric delivery. The nurse sets the flow rate, and the specific gravity of the solution and the height of the bag determine the maxi-

um delivery pressure. Fluids with low-viscosity are usually infused by electronic controllers.

Infusion pumps maintain the flow rate under positive pressure. Pumps counter the effects of resistance in the delivery system and pressure fluctuations at the infusion site (McConnell, 1999). Positive pressure infusion devices are classified as either volumetric or syringe pumps, and are used to deliver viscous fluids or large volumes of fluids. Volumetric pumps use either a peristaltic pumping action or a pumping cassette or chamber to delivery a fixed volume over a specified period of time. Syringe infusion pumps rely on a syringe or cartridge to deliver the fluid at a specific set rate.

Managing IV Therapy

IV therapy requires frequent client monitoring by the nurse to ensure an accurate flow rate and other critical nursing actions; refer to Procedure 37-4. These other actions include ensuring client comfort and positioning; checking IV solution for correct solution, amount, and timing; monitoring expiration dates of the IV system (tubing, venipuncture site, dressing) and changing as necessary; and being aware of safety factors.

NURSING ALERT

Catheter Sepsis

If client complains of chills and fever, check length of time that this IV solution has been hanging and the needle or catheter has been in place; assess client's vital signs, and assess for other symptoms of pyrogenic reactions, such as backache, headache, malaise, nausea, and vomiting. Unexplained fever may be related to catheter sepsis. Pulse rate increases and temperature is usually above 100°F if IV-related sepsis occurs. Stop infusion, notify health care practitioner, and obtain blood specimens if prescribed.

Coordinate client care with the maintenance of IV lines. Clients with IV therapy usually require assistance with hygienic measures, such as changing a gown (see Procedure 37-4). Change IV tubing when doing site care to decrease the number of times the access device is manipulated, thereby decreasing the risk for infiltration and phlebitis. PI devices are changed every 72 hours as directed by the Centers for Disease Control and Prevention (CDC) guidelines.

Hypervolemia

Hypervolemia (increased circulating fluid volume) may result from rapid IV infusion of solutions. This causes cardiac overload, which may lead to pulmonary edema and cardiac failure. Monitor the infusion rate hourly and refer to the Nursing Care Plan, Client with Fluid Volume Excess, for the assessment and interventions for a client experiencing fluid volume excess.

PROCEDURE 37-4

Managing IV Therapy and Dressing Change

Equipment

Assessing and Changing IV Tubing

- Nonsterile gloves (use with contact with bodily fluids)

Troubleshooting an IV System

- Nonsterile gloves
- Sterile needle and 5-cc syringe with 1 ml normal saline
- Armboard

Changing a Gown

- Clean gown

Converting to a Heparin or PI Lock

- Nonsterile gloves
- Protective pad
- Needleless injection cap

Changing a Peripheral IV Dressing

- Protective pad
- Tape (check for client allergy to tape)
- 70% isopropyl alcohol or povidone-iodine swab (check for client allergy to iodine)
- Receptacle for contaminated items

Discontinuing an IV Line

- Sterile 2 × 2 gauze
- Nonsterile gloves

- Administration sets (as determined by tubing to be replaced)

- 70% isopropyl alcohol or povidone-iodine swab (check for client allergy to iodine)

- Sterile needle and 3-cc syringe with 1–3 ml of normal saline; if heparin lock, second sterile needle and syringe with heparin, in accord with agency protocol

- Sterile IV dressing tray or sterile 2 × 2 gauze dressing; or sterile adhesive, or transparent semipermeable membrane (TSM) dressing; and sterile gloves

- Band-Aid

Action

1. Gather equipment, check integrity of the equipment, and wash hands.
2. Explain procedure to client.
3. Place bed at comfortable working height and lower side rails as necessary.

Managing IV Site

4. Don gloves; assess IV site, in accord with agency protocol and CDC guidelines, at least every 4 hours for signs and symptoms of complications (phlebitis, infiltration, infection at site, allergic reaction).
5. Assess dressing.
 - Determine when dressing was applied by checking date and time written on dressing itself.
 - Observe dressing for moisture.

Rationale

1. Promotes efficiency; ensures the sterility of the item; prevents transmission of microorganisms.
2. Decreases anxiety and elicits client cooperation.
3. Promotes proper body mechanics and provides access to area.
4. Decreases risk of contact with bloodborne pathogens; provides early detection of symptoms of complications and appropriate intervention.
5. Allows for assessment without disrupting an intact IV dressing.
 - Monitors medium for bacterial growth that would render sterile dressing contaminated.

(continues)

PROCEDURE 37-4

Managing IV Therapy and Dressing Change (continued)

*Action**Rationale*

- | | |
|---|--|
| <ul style="list-style-type: none"> • Observe that dressing is intact. • Gently palpate over the intact dressing. • If client complains of tenderness or pain, remove dressing and inspect site. <ol style="list-style-type: none"> 6. Change dressing immediately if it becomes wet, soiled, or loose. 7. Change TSM dressings routinely every 48 hours in accord with agency IV protocol. 8. Observe patency of IV line and needle. <ul style="list-style-type: none"> • Open roller clamp and observe for rapid flow of fluid into drip chamber; close roller clamp and set drip rate to prescribed flow rate. • If fluid does not flow, remove IV container from pole, place below level of infusion site, and observe for blood return. 9. Peripheral-short cannulas are removed and changed to a new site every 72 hours. 10. Change administration sets. <ul style="list-style-type: none"> • Use IV sets for blood, blood products, or lipids only once. • Every 24 hours, change IV tubing used for hyperalimentation. • Every 24 hours, change IV tubing used for piggyback solutions and when adding a new container to a continuous IV line. <p>Troubleshooting an IV system</p> <ol style="list-style-type: none"> 11. Overfilled drip chamber: <ul style="list-style-type: none"> • Close drip chamber. • Remove container from IV pole and turn it upside down. • Squeeze drip chamber until it is one-third to one-half full. 12. Air in tubing: <ul style="list-style-type: none"> • Observe fluid level in drip chamber. • Check tubing connections. • Disinfect injection port distal to air. | <ul style="list-style-type: none"> • Decreases risk of bacterial contamination to venipuncture site from nonadhering dressing. • Detects IV site swelling and edema around venipuncture site. • Detects early signs of phlebitis. <ol style="list-style-type: none"> 6. Decreases risk of bacterial infection. 7. Decreases risk of complications. 8. Ensures proper infusion rate; IV line and needle must be free of kinks, knots, and clots. <ul style="list-style-type: none"> • Denotes patency of IV line and prevents fluid overload. • Determines patency of needle or cannula and placement of the device in the vein; venous pressure should be greater than IV tubing pressure. 9. Supports CDC recommendations for changing peripheral cannulas to a new site every 48–72 hours to decrease the risk of complications. 10. Promotes compliance with CDC guidelines to prevent infection. <ol style="list-style-type: none"> 11. Maintains air in chamber to allow for flow-rate calculation. 12. Prevents infusion of air into the bloodstream. |

PROCEDURE 37-4

Managing IV Therapy and Dressing Change (continued)

<i>Action</i>	<i>Rationale</i>
<ul style="list-style-type: none"> • Insert sterile needle and syringe into injection port, and aspirate. 	
<p>13. Blood is backing up IV tubing:</p> <ul style="list-style-type: none"> • Check that IV container is above the level of the site and heart. • Check security of tubing connections. • Check fluid level in tubing chamber and IV container. 	<p>13. Prevents clot formation at the needle or cannula tip inside the vein.</p>
<p>14. IV is positional:</p> <ul style="list-style-type: none"> • Reposition hand or arm. • If IV infuses freely in new position, stabilize with armboard. 	<p>14. Maintains bevel of needle or tip of cannula away from the inner lumen of the vein.</p>
<p>15. Infusion controller or pump alarms:</p> <ul style="list-style-type: none"> • Check drip chamber for excess or inadequate fluid level. • Remove tubing from controller or pump and open all roller clamps. Check that air vent is open (if applicable) and that tubing is free of kinks. • Check patency of IV site, disinfect injection port closest to site, and insert needle and syringe with 5 ml of saline. Gently flush with saline and aspirate for blood; if unsuccessful, discontinue IV and change to a new site. • Place tubing in controller or pump and reset alarm. 	<p>15. Indicates flow problem.</p>
<p>Changing a Gown, Continuous IV Infusion in Hand or Arm</p>	
<p>16. Untie back or side of gown.</p>	<p>16. Allows gown to slip freely from arms.</p>
<p>17. Remove gown's sleeve from arm and hand without IV.</p>	<p>17. Frees the gown for removal from the involved arm.</p>
<p>18. Adjust the tubing to extend over IV hand, then slip the sleeve down arm; avoid tugging on tubing.</p>	<p>18. Prevents pressure on the tubing, which could disturb the venipuncture site or dislodge the IV.</p>
<p>19. Place clean gown over client's chest and abdomen.</p>	<p>19. Prevents unnecessary exposure and maintains client warmth.</p>
<p>20. Remove IV container from pole and slip sleeve over container, keeping container above client's arm.</p>	<p>20. Prevents backflow of blood into tubing.</p>
<p>21. Place your hand up through distal end of clean gown sleeve and grasp container; pull container and tubing out through clean gown sleeve.</p>	<p>21. Maintains integrity of the IV system.</p>

(continues)

PROCEDURE 37-4

Managing IV Therapy and Dressing Change (continued)

<i>Action</i>	<i>Rationale</i>
22. Hang container on pole and check flow rate.	22. Ensures that solution is infusing at prescribed rate.
23. Slip sleeve over client's IV arm and then on other arm; tie gown at back.	23. Maintains client's warmth and comfort.
Converting to a Heparin or PI Lock	
24. Perform steps 1–3.	
25. Check health care practitioner's order.	25. Verifies action to establish a lock.
26. Don clean gloves and close roller clamps on tubing.	26. Decreases risk of contact with bloodborne pathogens; prevents escape of solution from tubing.
27. Place protective pad under arm or hand with venipuncture site.	27. Prevents soiling of bed linen.
28. Open sterile package containing needleless injection cap and place in easy reach near venipuncture site.	28. Provides easy access.
29. With your nondominant hand, grasp hub of needle or cannula. With your dominant hand, disconnect IV tubing and attach needleless injection cap to hub.	29. Prevents dislodgement of needle or cannula.
30. While stabilizing hub with nondominant hand, inject needleless injection cap port with 1 ml of normal saline; if heparin lock, instill heparin.	30. Maintains patency of lock.
31. Discard old tubing and used supplies in receptacle.	31. Promotes a clean environment.
Changing a Peripheral IV Dressing	
32. Perform steps 1–3.	
33. Place protective pad under IV site; don gloves.	33. Prevents soiling of bed linen; reduces risk of contact with bloodborne pathogens.
34. Remove transparent or gauze dressing in direction that client's hair grows; keep pressure over IV site and leave in place tape that secures IV needle or cannula (Figure 37-26).	34. Decreases client's discomfort when removing tape; prevents dislodgement of needle or cannula.
35. Discard dressing and gloves in receptacle; wash hands.	35. Reduces risk for transmission of microorganisms.
36. Don gloves; inspect IV site for erythema, edema, infiltration.	36. Reduces risk of contact with bloodborne pathogens; denotes complications—for example, phlebitis, infiltration—that would necessitate changing IV site.
37. Cleanse IV site with alcohol or povidone-iodine. Using a circular motion, start at the puncture site and move outward peripherally; allow to dry (1 minute).	37. Reduces skin surface bacteria and prevents cross-contamination from skin bacteria near venipuncture site.

(continues)

PROCEDURE 37-4

Managing IV Therapy and Dressing Change (continued)

Action

Figure 37-26 Removing Tape from a Peripheral-Short Catheter. Remove tape with one hand while stabilizing the catheter's hub with the other hand.

38. Replace tape:

Butterfly

- Place smallest pieces of tape across wings of butterfly.
- Place another piece of tape across middle to form an H; or
- Place small piece of tape under wings (Figure 37-27).

Figure 37-27 Retaping a Butterfly Needle via the Crisscross Method

Rationale

38. Allows for stabilization of needle or catheter without tape's covering the insertion site, and eliminates positional flow of IV solution.

(continues)

PROCEDURE 37-4

Managing IV Therapy and Dressing Change (continued)

Action

- Tape over to form a V.
- Then place piece of tape across V.
- Avoid placing tape over insertion site.

Peripheral-short Catheters

- With tape edges sticking to your thumb and fingertip, slide small piece of tape under catheter hub, with adhesive side up.
- Cross tape over hub to form a U (Figure 37-28).
- Place another small piece of tape across catheter hub.
- Avoid placing tape over insertion site.

Figure 37-28 Retaping a Peripheral-Short Catheter via the U Method

39. Using aseptic technique, apply transparent or gauze dressing over IV insertion site; avoid wrinkling transparent dressing.
40. The catheter–skin junction site should be visible.
41. Place date, time, and your initials directly on dressing.
42. Discard soiled items and gloves in receptacle; wash hands.
43. Reassess patency of IV system, flow rate, and client's response to dressing change.
44. Record in nurses' notes: time and type of dressing change, nature of venipuncture site, patency and IV flow rate.

Rationale

39. Provides protective barrier against bacteria.
40. Allows for visual inspection palpation for tenderness through the intact dressing.
41. Documents dressing change.
42. Reduces risk of transmission of microorganisms.
43. Validates patency of IV system and infusion of solution at prescribed flow rate.
44. Documents actions taken and condition of IV site and system.

(continues)

PROCEDURE 37-4

Managing IV Therapy and Dressing Change (continued)

<i>Action</i>	<i>Rationale</i>
Discontinuing an IV Line	
45. Perform steps 1–3. Don nonsterile gloves.	
46. Assess device in place before discontinuing.	46. Allows for verification of complete removal of device.
47. Close roller clamp on IV tubing. If infusing, note amount of solution left in IV container.	47. Prevents spillage of solution when needle or catheter is removed; provides accurate amount of solution infused.
48. Stabilize needle or cannula with nondominant hand and remove tape in direction of hair growth.	48. Prevents unnecessary movement that could injure the vein; decreases discomfort when tape is removed.
49. Place sterile 2 × 2 gauze over puncture site and, while applying pressure, quickly and smoothly remove needle or catheter. Avoid pressing down on top of needle point while it is still in the vein.	49. Decreases bleeding and prevents injury to the vein.
50. Discard needle or catheter in receptacle.	50. Reduces risk of transmission of microorganisms.
51. Apply pressure over puncture site with sterile 2 × 2 gauze until bleeding stops. Apply Band-Aid; discard 2 × 2 gauze and gloves in receptacle and wash hands.	51. Promotes clot formation; keeps puncture site clean.
52. Inspect site for redness, swelling, or hematoma formation.	52. Determines whether bleeding is occurring in the tissue.
53. Check site again in 15 to 30 minutes.	53. Monitors for complications.
54. Record in nurses' notes: time and amount of IV solution left in container when discontinued and nature of puncture site.	54. Documents actions taken; promotes accurate intake recording, and documents condition of puncture site.

If a solution infuses at a rate greater than prescribed, decrease the rate to *keep vein open* (KVO) and immediately notify the health care practitioner. Report the amount and type of solution that infused over the exact time period and the client's response.

Infiltration

Infiltration may be caused by inserting the wrong type of device, using the wrong-gauge needle, or dislodgement of the device from the vein. When a drug or solution is administered under high pressure by a pump, it may also cause infiltration or vein irritation.

Infiltration results in the leaking of fluids or medications into the surrounding tissue. The client usually

complains of discomfort at the IV site. Inspect the site by palpating for swelling, and feel the temperature of the skin (coolness and paleness of skin are indications of infiltration).

The nurse confirms that the needle is still in the vein by pinching the IV tubing; this action should cause a **flashback** (blood should rush into the tubing if the needle is still in the vein). If a flashback does not occur, aspirate the injection port nearest the device as explained in Procedure 37-4. Discontinue the needle or catheter if it cannot be aspirated and apply a sterile dressing to the puncture site.

After the IV has been removed, the puncture site may ooze or bleed (especially in clients receiving anticoagulants).

NURSING ALERT

IVs and the Critically Ill

Never remove a functioning intravenous device from a critically ill client until another successful venipuncture has been performed; an established intravenous route may be needed for the administration of solutions, medications, or blood components.

If oozing or bleeding occurs, apply pressure and reapply a sterile dressing until it stops. Accurately assess and document the degree of edema.

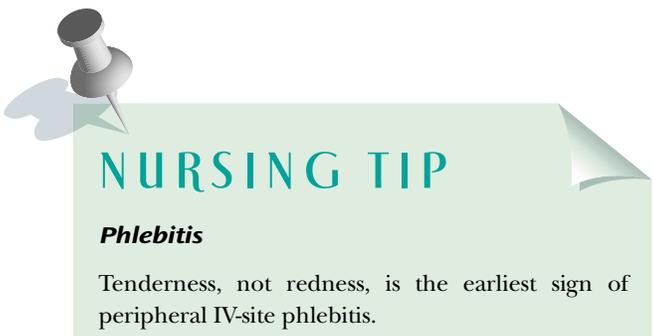

Clients may be injured by infiltration. If the IV site becomes grossly infiltrated, the edema in the soft tissue may cause a nerve compression injury with permanent loss of function to the extremity. If a **vesicant** (medication that causes blistering and tissue injury when it escapes into surrounding tissue) infiltrates, it may cause significant tissue loss with permanent disfigurement and loss of function.

Phlebitis

Phlebitis may result from either mechanical or chemical trauma. Mechanical trauma may be caused by inserting a device with too large a gauge, using a vein that is too small or fragile, or leaving the device in place for too long. Chemical trauma may result from infusing too rapidly, or from an acidic solution, hypertonic solution, a solution that contains electrolytes (especially potassium and magnesium), or other medications.

Phlebitis may be a precursor of sepsis. Listen for client complaints of tenderness, the first indication of an inflammation. Inspect the IV site for changes in skin color and temperature (a reddened area or pink or red stripe along the vein, warmth, and swelling are indications of phlebitis).

If phlebitis is present, discontinue the IV infusion. Before removing and discarding the venous device, check the agency's protocol to see whether the tip of the device needs to be cultured and sent to the laboratory for a culture and sensitivity. After removing the device, apply a sterile dressing to the site and wet warm compresses to the affected area. Document in the nurses' notes the time, symptoms, and nursing interventions.

NURSING TIP

Phlebitis

Tenderness, not redness, is the earliest sign of peripheral IV-site phlebitis.

Hypertonic solutions may cause irritation necessitating frequent IV site changes. Observe site for symptoms of postinfusion phlebitis following IV removal. This may occur in response to either chemical or mechanical factors of the preexisting IV. Postinfusion phlebitis is treated with hot compresses to the site and elevation of the extremity.

Intravenous Dressing Change

IV dressing changes require the use of Standard Precautions and aseptic technique; refer to Procedure 37-4. Institutional protocol and the type of intravenous access device and dressing determine the frequency of care:

1. Nontransparent (gauze) dressing may be used for a PI. It is changed every 24 hours.
2. Transparent dressings (Bioclusive, OpSite, Tegaderm) allow visualization of the IV site; these dressings are changed every 48 hours.

Persistent drainage at the IV site may require dressing changes more frequently or necessitate changing the IV site.

Discontinuation of Intravenous Therapy

Intravenous therapy is discontinued on health care practitioner order as determined by the client's need or response to therapy. The removal of a short peripheral catheter is a nursing intervention to minimize the complication risks related to infusion therapy or to implement the health care practitioner's order. Peripheral catheters are removed every 48 hours and immediately upon suspected contamination or complications. Pressure and a dry sterile dressing are applied to the site upon removal of the catheter; refer to Procedure 37-4. The integrity of the catheter and insertion site should be assessed with observations and actions documented to the client's medical record.

The removal of a PICC is usually a simple procedure; however, research suggests that, in 7% to 12% of PICC removals, difficulties can arise (Macklin, 2000). Only nurses who have been trained in the insertion of a PICC line should remove the catheter. Since the catheter is completely inserted in the vascular system and invisible, the nurse must feel for resistance during removal. If resistance is felt, the nurse stops and assesses for certain complicating factors: venous spasm, vagal reaction, phlebitis, thrombosis, and knotting of the catheter. Prior to removal, the nurse must verify in the client's medical record the type and the specific length of the inserted PICC.

Blood Transfusion

The purpose of a blood transfusion is to replace blood loss (deficit) with whole blood or blood components. On the basis of the client's unique needs, the health care practitioner determines the type of transfusion to

administer, either whole blood or a component of whole blood, such as packed red blood cells.

Whole Blood and Blood Products

Clients with a demonstrated deficiency in either whole blood or a specific component of blood are given a blood transfusion. Whole blood contains red blood cells (RBCs) and plasma components of blood. It is used when the client needs all the components of blood to restore blood volume after severe hemorrhage and to restore the capacity of the blood to carry oxygen. Various types of blood components are used in the clinical setting (Table 37-7). Packed RBCs are more commonly prescribed than whole blood.

Plasma or fresh frozen plasma is separated and frozen within 8 hours after blood collection. Albumin (protein colloid) is a volume expander that maintains the colloid osmotic pressure of the blood. Albumin, hetastarch, and dextran (nonprotein colloids) are agents that increase intravascular volume in order to maintain hemodynamic stability and to provide adequate tissue perfusion. Cryoprecipitate is the most expensive of all blood components because it is constituted from many units of whole blood.

When the health care practitioner prescribes the administration of whole blood or a blood product, the client's blood is typed and crossmatched; refer to Chapter 28 for a complete discussion of blood groups and Rhesus (Rh) factor. Check with the family for donors if time and the client's condition permit. The blood is stored in the blood bank after typing and crossmatching until the nurse is ready to administer.

Although whole blood has a refrigerated shelf life of 35 days, platelets must be administered within 3 days after they have been extracted from whole blood. If the

RBCs and plasma are frozen, their shelf life can be extended up to 3 years (Kee & Paulanka, 2000).

Initial Assessment and Preparation

The nurse must perform an initial assessment before administering blood (see the accompanying display). The viscosity of whole blood usually requires the use of an 18- or 19-gauge needle or catheter to prevent damage to the red cells.

BLOOD TRANSFUSION, INITIAL ASSESSMENT

- Verify that client has signed a blood administration consent form and that this consent matches what the health care practitioner has prescribed.
- Verify whether the client has an 18- or 19-gauge needle or catheter in the vein; if the blood is to be infused quickly, a 14- or 15-gauge device must be used. Pediatric and elderly clients may require a 23-gauge device because of smaller or thin-walled veins.
- Ensure patency of the existing IV site.
- Establish baseline data for vital signs, especially temperature, and assess skin for eruptions or rashes.
- Check client's blood type against the label on the whole blood or blood component prior to administration, to ensure compatibility.
- Assess client's age. If the client is at risk for circulatory overload (pediatric, elderly, or malnourished clients), notify the blood bank to divide the 500-ml bag of blood into two 250-ml bags or discuss with the health care practitioner other alternatives, such as packed RBCs rather than whole blood.

TABLE 37-7
Blood-Component Therapy

Type	Use	Special Considerations
Fresh or frozen plasma	Replaces deficient coagulation factors. Increases intravascular compartment.	Use within six hours with any straight-line administration set. Client is at risk for hepatitis.
Platelet	Corrects bleeding disorders (e.g., thrombocytopenia). Replaces platelets.	Infuse at rate of 10 minutes a unit with special platelet administration set.
Albumin	Restores intravascular volume. Treats shock and hypoproteinemia.	Available in 5% and 25% solution. Infuse slowly with special tubing that accompanies solution.
Granulocyte (white blood cell)	Restores the leukocyte count, usually depressed in clients receiving radiation or chemotherapy.	Infuse slowly, over 2- to 4-hour interval with Y-type blood filters, and prime with normal saline.
Cryoprecipitate	Restores factor VIII and fibrinogen in treating hemophilia A.	Infuse with a straight-line administration set. Observe for febrile reactions.

NURSING ALERT

Transfusion Reaction

The severity of a transfusion reaction is relative to its onset. Severe reactions may occur shortly after the blood starts to infuse. At the first sign of a reaction, stop the blood infusion immediately.

Scheduled IV medications should be infused before blood administration. This sequence prevents a reaction to a medication while blood is infusing; if a reaction were to occur, the nurse would not be able to discern which infusate was causing the reaction.

Administering Whole Blood or a Blood Component

The agency's blood protocol may require that a licensed person sign a form to release the blood from the blood bank and that a blood product be checked by two licensed personnel prior to infusion. The following information must be on the blood bag label and verified for accuracy: the client's name and identification number, ABO group and Rh factor, donor number, type of product ordered by the practitioner, and the expiration date.

Observe the blood bag for any signs of puncture, gas bubbles, color, and consistency (RBCs clumping). When the information has been verified, both licensed person-

nel sign the appropriate form. If any of the information does not match exactly or if the product has expired, return the product immediately to the blood bank.

Blood should be administered within 30 minutes after it has been received from the bank, to maintain RBC integrity and to decrease the chance of infection. Whole blood should not go unrefrigerated for more than 4 hours. Room temperature will cause RBC lysis, releasing potassium and causing hyperkalemia (Procedure 37-5).

Safety Measures

As discussed in Procedure 37-5, the client should be observed for the initial 15 minutes for a transfusion reaction. Vital signs are usually taken every 15 minutes for the first hour, then every hour while the blood is transfusing.

To prevent blood contamination, change the blood tubing and filter every 4 hours or after each unit of blood. Transfuse each unit of blood over a 2- to 4-hour interval.

NURSING ALERT

Blood Transfusion Incompatibility

Use only normal saline with a blood product. Blood transfusions are incompatible with dextrose and with Ringer's solution. Together, they cause hemolysis, clumping of RBCs.

PROCEDURE 37-5

Administering a Blood Transfusion

Equipment

- Y-administration set tubing with in-line filter
- 2 bags of 250 to 500 ml of normal saline
- 18 or 19-gauge needle or 18- or 19-gauge catheter; if blood is to be administered rapidly, 14-gauge needle
- Alcohol swabs and tape
- Needleless injection cap
- Regular administration set
- Blood unit as prescribed by health care practitioner
- Venipuncture supplies, if client does not have an IV in place
- Nonsterile gloves

Action

1. Check prescriber's orders for number of units and client's signed consent form.
2. Check with the blood laboratory or blood bank that type and crossmatch have been completed and that blood is ready.
3. Gather equipment and check integrity of the equipment.
4. Check client's arm for an identaband (special band that contains essential data, blood group and type).

Rationale

1. Verifies health care practitioner prescription for blood transfusion and client's consent.
2. Ensures that blood is ready for administration.
3. Promotes efficiency. Blood must be started within 30 minutes from the time it is removed from refrigeration. Ensures the sterility of the items.
4. Verifies client. Blood can not be administered without an identaband.

(continues)

PROCEDURE 37-5

Administering a Blood Transfusion (continued)

<i>Action</i>	<i>Rationale</i>
<ol style="list-style-type: none"> 5. Explain procedure to client, and answer questions. 6. Assess IV site for patency, gauge size of needle or catheter and verify that IV is in place. 7. Check vital signs. 8. Obtain whole blood unit or packed cells from the blood laboratory or blood bank. <ul style="list-style-type: none"> • Check requisition form with laboratory personnel. • Check blood label against blood unit for client's name and identaband number, blood group (ABO) and type (Rh), blood unit number, and expiration date of blood unit. 9. Check requisition form and blood label with another RN and sign form with another RN in accord with agency protocol (Figure 37-29). 	<ol style="list-style-type: none"> 5. Decreases client anxiety and elicits cooperation. 6. Ensures patent IV with the correct needle gauge to prevent hemolysis of RBCs. 7. Provides baseline data. 8. Ensures correct blood unit to decrease the risk of a transfusion reaction. 9. Provides for a double-check to decrease the risk of error.
	
<p>Figure 37-29 Blood Transfusion Verification</p>	
<ol style="list-style-type: none"> 10. Check blood unit for bubbles, cloudiness, dark color, or sediment; if any of these signs is present, return blood unit to laboratory and process a written report of actions in accord with agency protocol. 11. Check label on blood unit against client's identaband: name, identification number, blood group, blood type, and blood unit number. 12. Hang one bag of normal saline on IV pole, pull back tab, and spike with regular administration set; prime tubing, replace protective cap on distal end of tubing. 13. Prepare Y-set tubing with in-line filter: <ul style="list-style-type: none"> • Hang second bag of normal saline and blood bag on pole. 	<ol style="list-style-type: none"> 10. Indicates bacterial contamination of blood. 11. Decreases risk of error; ensures correct ABO group and Rh factor. 12. Establishes a secondary bag of normal saline to infuse in the event of a transfusion reaction when Y-set with blood and normal saline is discontinued. 13. Allows for normal saline infusion to flush existing needle or catheter. <ul style="list-style-type: none"> • Isotonic saline prevents hemolysis.

(continues)

PROCEDURE 37-5

Administering a Blood Transfusion (continued)

Action

- Remove Y-tubing from package and close roller clamp. Note red and white caps of tubing spikes.
 - Remove tab from normal saline port.
 - Remove white cap from Y-tubing spike, insert into port of normal saline bag, and hang on IV pole.
14. Prime Y-set with normal saline.
- Open clamp to saline bag.
 - Squeeze sides of drip chamber until filter is half covered and drip chamber is full (Figure 37-30).

Figure 37-30 Closing Roller Clamp on Administration Set and Priming Drip Chamber

- Open main clamp, remove protective cap from distal end of tubing, and prime tubing.
 - Close main clamp when tubing is primed, and replace protective cap.
15. Don nonsterile gloves.
16. Gently rotate blood bag.
17. Continue preparing Y-set.
- Remove tab from blood bag to expose port.
 - Remove red cap from tubing spike; insert spike into port of blood bag.
18. Cleanse injection port with alcohol swab.
19. Affix large-gauge needle to end of Y-tubing and prime needle.

Rationale

14. Clears air bubbles from tubing.

15. Reduces risk of contact with blood-borne pathogens.
16. Mixes blood with plasma.
17. Prepares blood bag for infusion.
18. Decreases transfer of microorganisms.
19. Prevents damage to RBCs.

(continues)

PROCEDURE 37-5

Administering a Blood Transfusion (continued)

Action

20. Insert needle into injection port, and tape.
21. Open roller clamp to saline bag, and open main clamp on Y-set; infuse slowly to clear the lock.
22. Clamp off saline bag, and open clamp to blood bag (Figure 37-31); if administering packed RBCs, allow saline to infuse simultaneously with RBCs.

Figure 37-31 Closing the Saline Roller Clamp and Opening the Blood Roller Clamp

Rationale

- | | |
|--|--|
| <ol style="list-style-type: none"> 23. Squeeze sides of Y-set drip chamber to allow blood to cover entire filter. 24. Regulate drip rate with main clamp to deliver 20 gtts per minute for the first 15 minutes. 25. Take vital signs, and observe closely for reactions: chilling, skin rash, backache, headache, nausea or vomiting, tachycardia, tachypnea, fever, or hypotension; if reaction occurs, stop transfusion. 26. Adjust flow rate as prescribed. If no adverse reactions, complete blood transfusion in less than 4 hours. 27. Instruct client to call a nurse if there are any unusual symptoms; test call light, and place within easy reach. 28. Monitor client throughout transfusion in accord with protocol; observe IV site for formation of a hematoma. If this occurs, stop transfusion and discontinue IV site. | <ol style="list-style-type: none"> 20. Decreases manipulation of needle, and preserves integrity of vein. 21. Allows saline to flush the lock, preventing mixing of blood with incompatible solutions. 22. Prevents saline from infusing into blood bag when roller clamp is opened; saline is needed to decrease the viscosity of packed cells; otherwise tubing or needle will clog. 23. Fills chamber with blood. 24. Allows time to observe for adverse reactions. Most reactions occur within the first 15 minutes of infusion. 25. Assesses client for adverse transfusion reactions. 26. Prevents rapid deterioration of blood that occurs after 2-hour exposure to room temperature. 27. Elicits client support in monitoring for a transfusion reaction or circulatory overload. 28. Reveals signs of infiltration, needle dislodgement from vein. |
|--|--|

(continues)

PROCEDURE 37-5

Administering a Blood Transfusion (continued)

<i>Action</i>	<i>Rationale</i>
29. Initiate transfusion record.	29. Documents onset of blood administration and baseline data.
30. Discontinue Yset when transfusion is complete. <ul style="list-style-type: none"> • Close blood roller clamp. • Open saline roller clamp, and allow all blood in tubing to infuse. • Don nonsterile gloves. • Close main clamp. • Disconnect tubing from injection port. If other fluids are to follow, connect or reestablish the lock. 	30. Ensures that client receives the full bag of blood. Infuses blood in the tubing, and flushes IV needle or catheter with saline.
31. Discard Yset tubing and blood bag in a biohazard bag and follow protocol regarding disposition.	31. Provides for proper disposal of contaminated equipment. Many protocols require return of blood bag and tubing to blood bank.
32. Remove gloves, wash hands.	32. Decreases spread of microorganisms.
33. Obtain postinfusion vital signs.	33. Monitors client response to transfusion, and detects signs of circulatory overload.
34. Document to transfusion record: <ul style="list-style-type: none"> • Date and time of starting and completing the transfusion • Type of blood transfused • Vital signs • Absence or presence of any reaction or complications • Status of the IV site • Disposition of the blood bag and tubing 	34. Provides a recording of significant data.

As a precaution against a blood transfusion reaction, prepare a bag of normal saline, as directed by protocol. The normal saline is prepared as a secondary infusion system; it should not be connected to the Yset tubing that is transfusing blood. If the client has a reaction, and the blood is discontinued, the secondary bag of normal saline should be connected and infused. This action prevents the client from receiving all the blood that is in the Yset tubing, approximately 20 to 30 ml. Even though the procedure for infusing packed cells, and sometimes whole blood, requires a Yset for coadministering normal saline, the secondary bag of normal saline is a precautionary measure for transfusion reactions.

There are three basic types of transfusion reactions: allergic, febrile, and hemolytic. Other complications include sepsis, hypervolemia, and hypothermia. An allergic reaction may be mild or severe, depending on the cause. Hemolytic reactions may be immediate or

delayed up to 96 hours, depending on the cause of the reaction. The classic symptoms of a reaction and sepsis are fever and chills.

The immediate nursing actions for all types of reactions and complications are: stop the transfusion, keep the vein open with normal saline, and notify the health care practitioner. Other measures include sending the IV tubing and bag of blood back to the blood bank; obtaining a blood and urine specimen; labeling the specimen “Blood Transfusion Reaction”; processing a transfusion reaction report; monitoring vital signs every 15 minutes for 4 hours or until stable; and monitoring the intake and output.

A delayed hemolytic reaction results when the donor and client’s anti-A or anti-B agglutinins are mismatched or when there has been improper storage of the blood unit. This reaction causes the cells to clump and form plugs in small blood vessels. Within a few hours or days, the phagocytic WBCs and the reticuloendothelial sys-

tem destroy agglutinated cells, releasing hemoglobin into the plasma. The client is monitored for jaundice, persistent anemia or fever, oliguria, flank pain, and abnormal bleeding.

An immediate hemolytic reaction is a rare occurrence. It results from a mismatch of donor and client's blood, causing immediate hemolysis of RBCs. The antibodies cause lysis of RBCs, which release proteolytic enzymes that rupture the cell membranes. The clinical manifestations are headache, dyspnea, cyanosis, chest pain, and tachycardia.

Febrile reactions are common and result from the client's sensitivity to WBCs, platelets, or plasma proteins. Warm, flushed skin, headache, muscle pain, and anxiety are the symptoms of a febrile reaction. It is treated with antipyretic medication.

To help prevent a febrile reaction, keep the client warm during the transfusion. Make sure that the tubing has a leukocyte-reduction filter. The leukocyte-reduction filters also reduces the risk of transmitting **cytomegalovirus (CMV)** (a DNA virus that causes intranuclear and intracytoplasmic changes in infected cells). Approximately 10% of seropositive donors are capable of transmitting CMV infection.

Mild allergic reactions are common, resulting from a sensitivity to infusing plasma proteins. Allergic reactions cause a rash, itching, hives (urticaria), and wheezing. Clients with these symptoms should be monitored for anaphylactic shock. Antihistamines may be prescribed to counter the allergic response.

Severe allergic reaction results from an antibody-antigen response as demonstrated by shortness of breath and chest pain; if untreated, it may cause circulatory collapse and cardiac arrest. If this occurs, initiate CPR after the blood has been discontinued.

Sepsis results from the administration of contaminated blood (containing gram-negative bacteria). It is a serious complication. Clinical manifestations include chills and fever, vomiting, abdominal cramping, diarrhea, shock, and renal failure. It is treated with broad-spectrum antibiotics and steroids. Nursing measures are directed toward maintaining hydration and monitoring intake and output to evaluate renal function.

Hypervolemia from fluid overload is a preventable complication. Clients at risk for FVE are placed in a sitting position. The blood is transfused at a reduced flow rate; request the blood laboratory to divide the unit into 2 containers of blood so that none of it is unrefrigerated for more than 2 hours during transfusion. Clinical manifestations of hypervolemia are similar to those of FVE (dyspnea, cough and rales, distended neck veins, hypertension, tachycardia, and pulmonary edema). Administer oxygen and IV diuretics as prescribed to treat circulatory overload.

Clients needing rapid transfusions are at risk for transfusion-induced hypothermia. Such clients may include neonates needing exchange-transfusions and trauma victims who require large volumes of whole

blood. A blood-warming device may be prescribed to prevent transfusion-induced hypothermia. The symptoms of transfusion-induced hypothermia result from the rapid transfusion of large amounts of cold blood. If the infusing blood temperature is below 30°C (86°F), the myocardial temperature decreases, causing hypotension and myocardial irritability that may progress to ventricular fibrillation and cardiac arrest. Nursing interventions are directed toward warming the client with temperature-regulating blankets after the transfusion has been stopped. Obtain an ECG to assess for cardiac arrhythmias.

Complementary Therapy

Herbs and certain foods are used to maintain health and prevent the onset of chronic debilitating diseases such as diabetes mellitus and renal failure. Naturopathic health care practitioners (NDs) use herbs as medicine, and although herbs are the main ingredient of some of the drugs used in conventional medicine, NDs use herbs differently than MDs. MDs prescribe drugs to treat symptoms. For example, in hypertension, the prescribed drug controls the blood pressure but does not correct the reason why the body has increased the pressure in the first place; an ND uses herbs to correct the underlying problem (Morton & Morton, 1996). The following discussion will explain how herbs and foods can be used to treat certain conditions that create disturbances in body fluids and pH.

Traditional Chinese medicine relies on nutrition and dietetic principles to treat certain illnesses and/or imbalances. Foods are recommended based on their energetic properties such as toxifying, dispersing, heating, cooling, moistening, and drying, and by eating in tune with seasonal changes. Cooling foods such as watermelon, celery, and cucumber are recommended during the warmer months of spring and summer because they contain a higher percent of water than warming foods such as meats, garlic, and spices, which are eaten during the cooler months of autumn and winter (Kloss, 1995).

Many plants have a hypoglycemic action; they lower blood sugar levels. Such plants include dandelion root, garlic, ginseng, and nettles. Other plants have also been identified as possessing hypoglycemic action such as allspice, artichoke, banana, barley, bugleweed, lettuce, oats, onion, and spinach, to name a few. When herbs and diet are used in a tailor-made combination for the individual, the amount of glucose entering the blood is kept at a constant level (Hoffmann, 1998). Tierra (1998) recommends dandelion root in combination with other tonic herbs such as ginseng and a little ginger for maximum benefit, along with a balanced diet for hypoglycemia.

Herbs such as dandelion and cleavers, which aid the kidneys, are not only useful for renal problems but may aid the cleansing mechanism in treating the whole

body, no matter what the problem (Hoffmann, 1998). The main benefits of dandelion are exerted upon the functions of the liver by clearing obstructions and stimulating and aiding the liver to eliminate toxins from the blood. Dandelion root is helpful in treating hypertension, thus aiding the action of the heart. Dandelion (root and leaf) acts as a diuretic and can be taken for fluid retention, cystitis and nephritis. Dandelion also contains a high percentage of potassium and actually increases the potassium level, thereby avoiding the loss of potassium caused by synthetic diuretics.

Caution should be used when taking licorice since this herb contains a variety of active ingredients. Glycyrrhizin, an active ingredient of licorice, can produce effects similar to aldosterone. Due to the aldosterone-like effects, whole licorice can cause fluid retention, high blood pressure, and potassium loss in doses that exceed 3 g daily for more than 6 weeks. Clients who take digitalis or a thiazide diuretic or who

have hypertension, heart disease, diabetes, or kidney disease should avoid the use of licorice.

EVALUATION

Evaluation is an ongoing process for clients with fluid, electrolyte, and acid-base imbalances. Focus on the client's responses when evaluating whether the time frames and expected outcomes are realistic (such as whether the intake and output are within 200 to 300 ml of each other). The client's vital signs should be within normal limits. The IV infusion rate is accurately calculated and reassessed throughout therapy to maintain the client's hydration. The IV site should remain free from erythema, edema, and purulent drainage. The nursing care plan is modified as necessary to support the client's expected outcomes.

NURSING CARE PLAN

The Client with Deficient Fluid Volume

Case Presentation

Mrs. Gray is a 75-year-old woman with diabetes who has been experiencing flu-like symptoms of vomiting and diarrhea for 5 days. She lives alone and does not like to cook. When she got up this morning, she felt weak and dizzy; she called 911 to take her to the clinic. The EMS providers called the practitioner en route, and Mrs. Gray was taken directly to the infusion center.

Assessment

- Marked thirst
- Temperature 37.2°C
- BP 94/74
- Wt 157 lb (5% loss from 165)
- Dry mucous membranes
- Respirations 30
- Apical pulse 108/min
- ↑ Hct, ↑ Hbg, ↑ BUN

Nursing Diagnosis #1

Deficient Fluid Volume related to vomiting and diarrhea.

Expected Outcomes

1. The client will
 - Experience relief from vomiting and diarrhea in 2–4 hours.
 - Demonstrate clinical signs of adequate hydration prior to discharge.
 - Understand the reasons for the deficient fluid and the amounts and types of foods and fluids to consume to prevent a recurrence.
2. The client's fluid intake and output will be balanced in 12–24 hours.
3. The client's weight will be stable and lab values will be within normal limits prior to discharge.

Interventions/Rationales

1. Assess and document amount, color, and characteristics of vomitus and diarrhea. *Determines fluid replacement.*

(continues)

NURSING CARE PLAN**The Client with Deficient Fluid Volume (continued)**

2. Maintain NPO status. *Allows the GI tract to heal.*
3. Measure vital signs qh. *Monitors client status.*
4. Assess skin turgor. *Indicates hydration status.*
5. Administer antiemetics and antidiarrheals. *Prevents further fluid loss.*
6. Measure and document qh. *Assesses fluid balance.*
7. Report and document O ↓ 30 ml/h. *Alerts to severe fluid imbalance.*
8. Administer PO fluids as tolerated 2 hours postvomiting/diarrhea. *Gradually reintroduces oral intake.*
9. Administer IV lactated Ringer's solution with flow rate as prescribed. *Prevents overhydration.*
10. Assess and document skin and mucous membrane moisture, skin color and hydration, urine for sugar or acetone, and mental status. *Indicates hydration status.*
11. Weigh the client on same scale, in the same clothes, after voiding. Monitor serum glucose, osmolality, Hct, Hgb, BUN. *Monitors weight changes and fluid and electrolyte status.*
12. Assess the client's knowledge level; provide information about causes and why interventions are being performed, and explain actions to take to prevent a recurrence. *Educates client as to causes and remedies for fluid volume deficit.*

Evaluation

Client free from vomiting 2 hours postadmission; diarrhea stopped within 5 hours after being placed NPO. Hourly urinary output >30 ml/h; tolerated 4 oz of Gatorade 6 hr postadmission, progressed to clear liquid diet; I&O balanced 20 hrs post-admission.

Mucous membranes moist; good skin turgor and color; absence of thirst; urine was free from sugar and acetone; alert client prior to discharge.

Client's weight and lab values were within normal limits prior to discharge.

Client verbalizes knowledge of causes and methods of monitoring fluid status

NURSING CARE PLAN**The Client with Excess Fluid Volume****Case Presentation**

Mr. Hill, a 68-year-old widower, was taken to the emergency department by his granddaughter and stated, "I can't breathe." He has a history of hypertension and heart disease. He is obese. The practitioner ordered a stat chest x-ray, CBC, electrolytes.

Assessment

- Shortness of breath, rales
- Constant cough
- Wt 161.8 lb
- Pitting edema, ankles
- 36.4°C; 186/114; 98; 30 and labored
- Engorged neck veins
- Pulmonary congestion (x-ray)
- ↓ Hct; ↓ Hgb

Nursing Diagnosis #1

Excess Fluid Volume related to body fluid overload secondary to heart dysfunction.

Expected Outcomes

1. The client will
 - Have a balanced fluid intake and output (est. 2,500 ml/day) for 2 days.

(continues)

NURSING CARE PLAN

The Client with Excess Fluid Volume (continued)

- Identify a specific amount of weight to lose over the next 6 months.
 - Manifest normal hydration status prior to discharge.
 - Demonstrate understanding of the causes of excess fluid and the role of heart medications, foods, and exercise to assist with weight reduction.
2. The client's skin integrity will be maintained over the edematous areas.

Interventions/Rationales

1. Measure and document hourly I&O; restrict fluids as ordered. *Monitors fluid status.*
2. Administer diuretics as ordered, document the response. *Increases excretion of electrolytes.*
3. Weigh daily at the same time with the same clothing. *Monitors overall client status.*
4. Measure and document vital signs qh until shortness of breath (SOB) subsides, then q2h. Hourly assessments: auscultate for third heart sound, breath sounds; assess rate, rhythm, depth of respirations, and the position the client takes to relieve SOB; report changes in respiratory pattern. *Monitors client response to therapy and diuretics, gives information to modify plan of care.*
5. Inspect and palpate areas of edema. *Determines whether edema is localized or generalized and reveals extent.*
6. Institute preventive skin measures: elevate extremities on pillows to ↓ pressure and promote venous circulation; avoid rubbing the skin, apply lotion, pat dry; avoid soap on the area; inspect for redness or blanching. *Maintains skin integrity, promotes circulation, and promotes client comfort.*
7. Assess client's knowledge of hypertension, decreased cardiac output; digitalis; the effects of a large abdominal girth on breathing; foods low in sodium, fats, and carbohydrates. *Educating client about causes, aggravating and alleviating factors, and effects of fluid excess is the first step in encouraging client in proper self-care.*

Evaluation

Output for the first 2 hr 2020 mls; day 2, I&O measurements indicative of fluid balance.

Client identified need to lose 30 lb over the next 6 months.

The client's hemodynamic status is within normal levels as demonstrated by Hct, Hgb, BP 156/92; the absence of SOB, abnormal breath sounds, jugular engorgement; peripheral edema.

The client's skin integrity was maintained.

The client was unable to verbalize knowledge of how his weight, high-sodium diet, failure to take his heart medications, and chronic alterations caused the fluid excess. Was referred to home health for client teaching.

Nursing Process Highlight**Implementation**

Fluid replacement is based on weight loss. A 2.2-pound (1 kg) loss is equivalent to 1 liter (1000 ml) of fluid loss. First, convert Mrs. Gray's weight from pounds to kilograms. Then determine the fluid intake replacement needed on the basis of the weight loss: Include the IV lactated Ringer's solution and PO Gatorade in milliliters. On the basis of the intake, what should have been her output prior to discharge?

Nursing Process Highlight**Nursing Diagnosis**

The nursing diagnosis *EFV: Edema* usually has many accompanying secondary nursing diagnoses: *Breathing Patterns: Ineffective*, related to increased capillary permeability causing fluid overload in the lung tissue (pulmonary edema); *Skin Integrity: Impaired*, related to edematous tissues (peripheral edema); *Ineffective Tissue Perfusion*, related to hypervolemia as manifested by peripheral (tissue) edema; *Deficient Knowledge: EFV*, related to chronic alterations.

KEY CONCEPTS

- Health promotion requires a maintenance of body fluid and acid-base balance.
- There are two types of body fluid: intracellular and extracellular. Because intravascular and interstitial fluid are outside the cells, these fluids are called extracellular fluids.
- Water is the largest single constituent of the body, representing 45% to 75% of the body's total weight.
- Electrolytes have special physiological functions in the body that: promote neuromuscular irritability; maintain body fluid osmolarity; regulate acid-base balance; and distribute body fluids between the fluid compartments. The body has many regulators that maintain fluid balance: fluid and food intake, skin, lungs, gastrointestinal tract, and kidneys.
- When an extracellular fluid volume deficit occurs, hormones play a key role in restoring the extracellular fluid volume.
- Sodium is the main electrolyte that promotes the retention of water.
- Acid-base balance refers to the homeostasis of the hydrogen ion concentration in body fluids.
- When the number of free hydrogen ions in a solution increases to lower the pH value below 7.35, the body is in a state of acidosis. The opposite occurs with alkalosis; a pH value higher than 7.45 results from a low hydrogen ion concentration.
- The body has three main control systems to regulate acid-base balance: buffer systems, respiratory regulation; and renal control of hydrogen ion concentration.
- In health, normal homeostatic mechanisms function to maintain electrolyte and acid-base balance; in illness, one or more of the regulating mechanisms may be affected, or the imbalance may become too great for the body to correct without treatment.
- Disturbances in one of the body's electrolytes usually cause changes in other electrolytes and can alter the pH of the blood.
- The slightest decrease or increase in extracellular potassium can cause serious, adverse, or life-threatening effects on physiological functions.
- The client's health history, physical assessment, and biochemical data are used by the nurse in formulating nursing goals, expected outcomes, diagnoses, and interventions.
- Nursing interventions that promote the resolution of alterations in fluid balance are based on the principles of client safety and standards of care.
- Following institutional protocol and established procedures for IV therapy helps ensure client safety.
- Hospitalized clients, especially the elderly, are at risk for developing dehydration.
- Clients receiving intravenous therapy and blood transfusions require constant monitoring for complications.

- Evaluation of the achievement of client expected outcomes requires the interrelational analysis of weight, intake and output, vital signs, and biochemical results.

CRITICAL THINKING ACTIVITIES

1. What are the three sources of body water replacement?
2. Which electrolyte regulates the osmotic pressure of extracellular fluid?
3. Which electrolyte deficit are clients with draining wounds prone to develop?
4. Given that half of serum calcium is bound to another solute in the blood, which other serum level do you have to evaluate when monitoring the serum level of calcium?
5. What is the most common indication of a fluid volume deficit?
6. What effect does an acid-base imbalance have on the body's cells?
7. Jennifer has been vomiting for 3 days and is unable to keep any food or water in her stomach. Besides having a fluid volume deficit, what other alterations would you expect from the excessive loss of gastric juices?
8. All of the following are clinical manifestations of FVE, except:
 - a. Edema
 - b. Weight gain
 - c. Increased serum osmolality
 - d. Decreased serum osmolality
9. Besides potassium-wasting diuretics, what other drugs can cause hypokalemia?
10. What effect does potassium have on digitalis?
11. What is the maximum amount of intravenous potassium chloride (KCl) that can be infused per hour?
12. What is the first sign of phlebitis?
13. Why is a peripheral intravenous (PI) or heparin lock established?
14. Which type of intravenous solution is sodium chloride (0.45%)?
 - a. Hypotonic
 - b. Isotonic
 - c. Hypertonic
15. Which type of intravenous solution is dextrose 5% in water (D₅W)?
 - a. Hypotonic
 - b. Isotonic
 - c. Hypertonic
16. Gloria is receiving a blood transfusion. The nurse is about to take the first set of 15-minute vital signs. Gloria states, "I am cold. I think I am having chills, and my chest hurts." What should the nurse do?

Nutrition

“The human body is a complex organism with the ability to heal itself—if only you listen to it and respond with proper nourishment and care.”

—Balch and Balch (1997)

COMPETENCIES

1. Identify the physiological value of nutrients.
2. Describe the processes of digestion, absorption, and metabolism.
3. Describe how diet guidelines and menu planning promote nutrition and health.
4. Explain how culture influences food preferences and eating habits.
5. Explain the impact of age-related changes on nutritional status.
6. Describe the process of assessing a client’s nutritional status.
7. Identify common knowledge deficits related to nutrition.
8. Describe the expected outcomes of nursing interventions that promote optimum nutritional status.
9. Identify common nursing interventions for clients experiencing nutritional deficits.
10. Describe the role of nutritional support teams in managing the care of clients with nutritional deficits.

KEY
TERMS

absorption	fatty acids	monosaturated fatty acids
aerobic metabolism	free radicals	negative nitrogen balance
anabolism	free radical scavenger	nitrogen balance
anaerobic metabolism	gluconeogenesis	nonessential amino acids
anorexia nervosa	glycolysis	nutrition
anthropometric	high-biological-value	obligatory loss of proteins
measurements	proteins (complete	parenteral nutrition
antioxidants	proteins)	peristalsis
appetite	hyperglycemia	phospholipids
atherosclerosis	hyperthyroidism	polysaccharides
basal metabolic rate	hypoglycemia	polyunsaturated fatty acids
body mass index	hypothyroidism	positive nitrogen balance
bulimia nervosa	insulin	pre-albumin
calorie	ketogenesis	proteins
carbohydrate	ketones	recommended dietary
catabolism	kilocalorie	allowances
cholesterol	lipids	saccharides
chylomicrons	low-biological-value proteins	satiety
deamination	(incomplete proteins)	saturated fatty acids
deglutition	malnutrition	skinfold measurement
diabetes mellitus	mastication	total parenteral nutrition
dietary fiber	metabolic rate	transferrin
digestion	metabolism	triglycerides
disaccharides	mid-upper-arm	unsaturated fatty acids
enteral nutrition	circumference	vitamins
essential amino acids	minerals	water-soluble vitamins
fat-soluble vitamins	monosaccharides	

The body requires the consumption of nutrients to support physiological activities of digestion, absorption, and metabolism to maintain homeostasis. The metabolism of nutrients (carbohydrates, proteins, fats, vitamins, and minerals) plays an essential role in providing the body with the necessary substances to maintain internal homeostasis.

PHYSIOLOGY OF NUTRITION

Nutrition is the process by which the body metabolizes and utilizes nutrients. Nutrients are classified as energy nutrients, organic nutrients, and inorganic nutrients; see the accompanying display. Energy nutrients release energy for maintenance of homeostasis. Organic nutrients build and maintain body tissues and regulate body processes. Inorganic nutrients provide a medium for chemical reactions, transport materials, maintain body temperature, promote bone formation, and conduct nerve impulses.

In the body, essentially all carbohydrates are converted into glucose before they reach the cells, proteins are converted into amino acids, and fats are converted into fatty acids. These nutrients are digested, absorbed by the blood or lymphatic system, and transported to the body's cells. Inside the cells' mitochondria, the nutrients react chemically with oxygen and various enzymes to produce energy.

CLASSES OF NUTRIENTS

<i>Description</i>	<i>Classes</i>
Energy nutrients	Carbohydrates Proteins Fats
Organic nutrients	Carbohydrates Proteins Fats Vitamins
Inorganic nutrients	Water Minerals

Digestion

Digestion refers to the mechanical and chemical processes that convert nutrients into a physically absorbable state. Figure 38-1 shows the anatomical structures of the gastrointestinal (GI) tract (digestive tract). Figure 38-2 explains the physiological mechanisms that support the digestive process in each anatomical structure.

The mouth prepares foodstuffs for digestion by **mastication** (chewing, tearing, or grinding of food by the teeth into fine particles and the mixing with enzymes in saliva). The salivary glands release lubricating secretions that bind with food particles to facilitate swallowing.

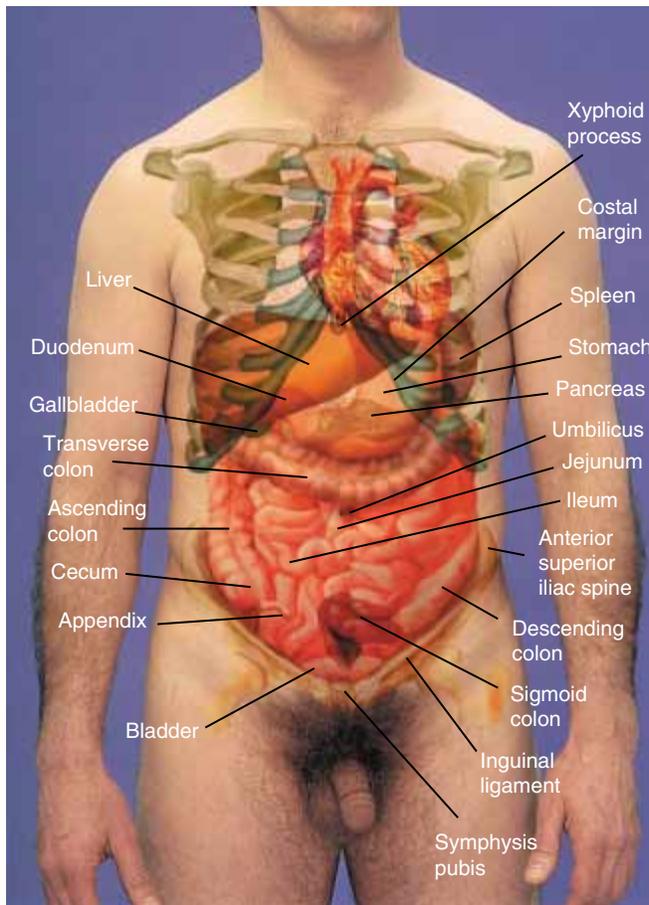

Figure 38-1 Gastrointestinal Tract

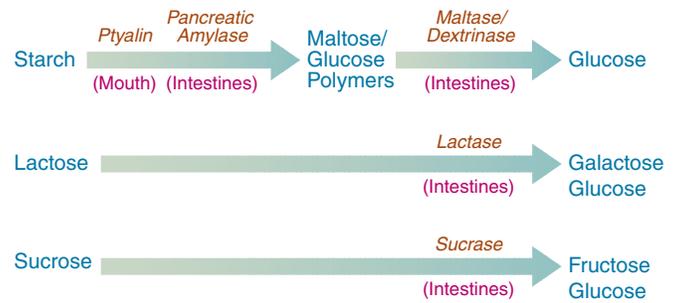

Deglutition (swallowing of food) begins in the mouth and continues in the pharynx and esophagus. Peristaltic waves and mucous secretions move food down the esophagus. Relaxation of the lower esophageal sphincter (gastroesophageal constrictor muscle) allows food to enter the stomach; contraction of this sphincter muscle prevents regurgitation (reflux) of stomach contents.

Digestion begins in the stomach and is completed in the small intestines. This is accomplished by specific substances entering the duodenum: pancreatic enzymes through the pancreatic duct, bile through the common bile duct, and intestinal enzymes produced in the jejunum. **Peristalsis** (coordinated, rhythmic, serial contraction of the smooth muscle lining of the intestines) forces chyme (an acidic, semifluid paste) through the small intestines to the large intestines and promotes the absorption of vitamins, minerals, and water. Only carbohydrates, proteins, and fats require chemical digestion by enzymatic activity for absorption.

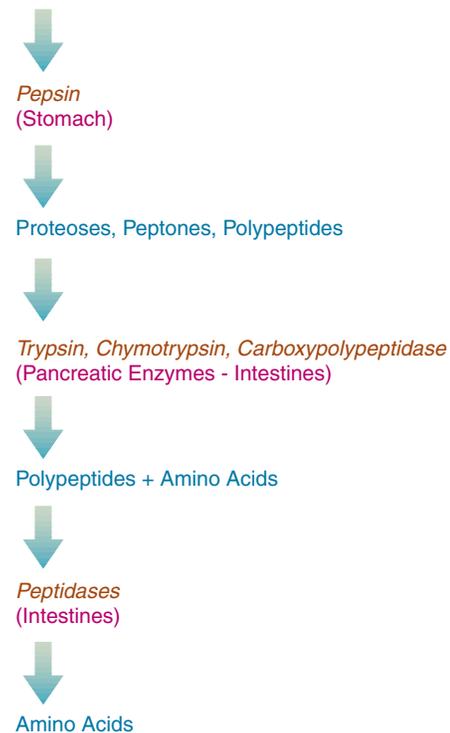

Absorption

Absorption is the process by which the end products of digestion—**monosaccharides** (simple sugars), amino acids, glycerol, fatty acid chains, vitamins, minerals, and water—pass through the epithelial membranes in the

A. Carbohydrates

B. Proteins

C. Fats

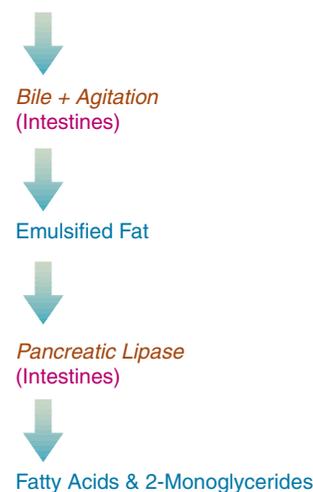

Figure 38-2 Digestion of Proteins, Carbohydrates, and Fats

small and large intestines into the blood or lymph systems. Most absorption occurs in the small intestines through the processes of osmosis, diffusion, and active transport; refer to Figure 38-3. Water absorption occurs throughout the digestive tract.

The main functions of the large intestines are to absorb water and collect food residue (dietary fiber). **Dietary fiber** is the part of food that body enzymes cannot digest and absorb, such as outer hulls of corn kernels, grains of wheat, celery strings, and apple skins. Dietary fiber absorbs water in the large intestine, promoting the formation of a soft, bulky stool that moves quickly through the large intestine; some fiber is believed to bind cholesterol in the colon, thus reducing the risk of heart attack (Townsend & Roth, 1999). In healthy individuals, most of the end products of digestion are absorbed (99% of carbohydrates, 95% of fat, and 92% of protein) and used by the body (Townsend & Roth, 1999).

Metabolism

Metabolism is the aggregate of all chemical reactions and processes in every body cell, such as growth, generation of energy, elimination of wastes, and other bodily functions as they relate to the distribution of nutrients in the blood after digestion.

The liver prepares nutrients for their role in energy production. The liver converts all monosaccharides to glucose and excess amino acids to urea, carbohydrates, or fats. Excess fats are converted in the liver to glycerol and fatty acids, then to acetyl coenzyme A (acetyl-CoA).

Glycolysis refers to the breakdown of glucose by enzymes located inside the cell's cytoplasm. This process produces adenosine triphosphate (ATP) and pyruvate, which provide the cell with energy. Pyruvate may be used

in two different metabolic functions. In **aerobic metabolism**, pyruvate enters the cell's mitochondria and in the presence of oxygen is converted to acetyl-CoA. In **anaerobic metabolism** (metabolism without the presence of oxygen) lactate is produced in the cytoplasm by an enzyme (lactate dehydrogenase); this type of metabolism takes place when the oxygen supply is limited, as in the muscles and red blood cells, which lack mitochondria.

When pyruvic acid is formed by glycolysis, it is then converted into acetyl-CoA. This conversion begins a cyclic metabolic pathway called the Krebs cycle (citric acid cycle or tricarboxylic acid cycle). The Krebs cycle extracts energy through oxidation of acetyl-CoA within the mitochondria of body cells. The Krebs cycle is a pathway common to all energy nutrients because acetyl-CoA may be formed from carbohydrates, proteins, and fats; refer to Figure 38-4.

Built into the inner mitochondrial membrane is a series of molecules that assist in electron transport during aerobic metabolism. The electron transport system converts energy released from the Krebs cycle into ATP for use by cells in anabolism and catabolism. **Anabolism** refers to the constructive phase of metabolism, in which smaller molecules, such as amino acids, are converted to larger molecules, such as proteins. **Catabolism** is the destructive phase in which larger molecules, such as glycogen, are converted to smaller molecules, such as pyruvic acid.

The rate of metabolism is governed primarily by the hormones triiodothyronine (T_3) and thyroxine (T_4) secreted by the thyroid gland. **Hyperthyroidism** refers to the increased secretion of these thyroid hormones, which increases the rate of metabolism. With **hypothyroidism**, a decrease in the secretion of thyroid hormones, the metabolic rate is decreased.

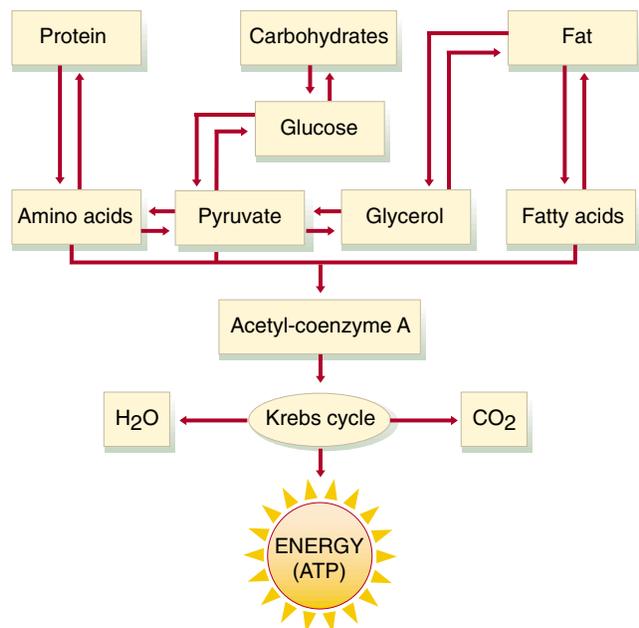

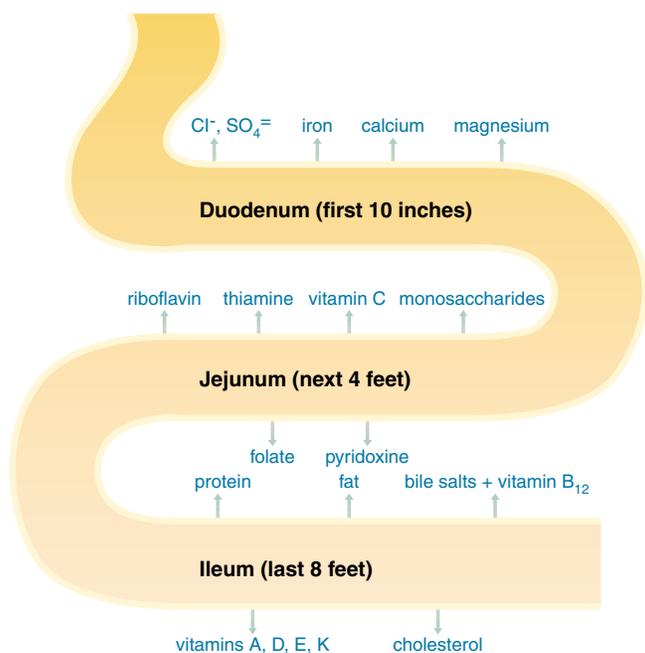

Figure 38-3 Nutrient Absorption in the Small Intestines

Figure 38-4 Energy Nutrients and the Krebs Cycle

Energy

Metabolic rate refers to the rate of heat liberation during chemical reactions; it is expressed in units called calories. A **calorie** is the quantity of heat required to raise the temperature of 1 gram of water 1°C; it is used to express the quantity of energy released from the different foods or expended by the different functional processes of the body. Because a large quantity of energy is released during metabolism, the energy is expressed in terms of **kilocalories** (kcal), each of which is equivalent to 1000 calories. The **basal metabolic rate (BMR)** refers to the energy needed to maintain essential physiological functions, such as respiration, circulation, and muscle tone, when a person is at complete rest both physically and mentally.

Excretion

Digestive and metabolic waste products are excreted through the intestines and rectum. Other excretory organs are the kidneys, sweat glands, skin, and lungs; refer to Chapter 39 for a complete discussion of elimination. The skin and sweat glands remove water, toxins, salts, and nitrogen wastes; the lungs remove carbon dioxide and water.

NUTRIENTS

Understanding the role of basic nutrients provides the foundation for selecting foods that promote health. There are six categories of nutrients: water, vitamins, minerals, carbohydrates, proteins, and lipids (fats). Selecting the healthiest forms of each of these nutrients and eating them in proper balance enables the body to function at its optimal level of health. Nutrients work synergistically; for example, there is a cooperative action between certain vitamins and minerals, that work as catalysts, promoting the absorption and assimilation of other vitamins and minerals.

Water

Water is the most abundant nutrient in the body and accounts for 60% to 70% of an adult's total body weight and 77% of an infant's weight. It is a major component of body fluids, secretions, and excretions. Body water decreases as body fat increases and with aging.

Water and electrolytes are substances that must be acquired from the diet. In the United States, much of water consumption is in the form of beverages (milk, coffee, tea, and soft drinks). The estimated water requirement for infants, children, and adults is 1.5 ml/kcal of energy expenditure. The water and electrolyte requirements for infants correspond to the water-to-energy ratio and the electrolyte composition in human milk and common formulas. Although pregnancy and lactation increase bodily demands for water and electrolytes, these demands are usually met with

normal ingested amounts; the one exception is in a lactating woman, who requires, on average, an additional 750 ml/day of water during the first 6 months to match the amount of milk secreted.

Normally, the body maintains a balance between the amount of fluid taken in and the amount excreted. The requirements for body water are met through the consumption of liquids and foods and the oxidation of food. Solid foods, especially fruits and vegetables, contain 85% to 95% water. The normal daily turnover of water is 4% of an adult's total body weight and 15% of an infant's total body weight; refer to Chapter 37 for a complete discussion of water's role in maintaining homeostasis.

Vitamins

Vitamins are organic compounds that regulate cellular metabolism, assisting the biochemical processes that release energy from digested food. Vitamins are called micronutrients because they are needed in small quantities when compared with other nutrients (water, carbohydrates, proteins, and fats). Vitamin requirements are dependent on many factors, such as body size, amount of exercise, rate of growth, and pregnancy; refer to Appendix B for the recommended dietary allowances (RDAs) of vitamins.

Of the major vitamins, some are classified as either fat-soluble or water-soluble. **Fat-soluble vitamins** (vitamins A, D, E, and K) require the presence of fats for their absorption from the GI tract and for cellular metabolism and can be stored for longer periods of time in the body's fatty tissue and the liver. **Water-soluble vitamins** (vitamin C and B-complex vitamins) require daily ingestion in normal quantities because these vitamins are not stored in the body.

Certain vitamins, mineral, and enzymes are classified as **antioxidants**, a substance that blocks or inhibits destructive oxidation reactions, such as vitamins C and E, the minerals selenium and germanium, and the enzymes catalase and superoxide dismutase, coenzyme Q₁₀, and some amino acids. Antioxidants help to protect the body from the formation of **free radicals**, atoms or groups of atoms that can cause damage to cells. Free radicals can impair the immune system and lead to infections and certain degenerative diseases such as heart disease and cancer. Free radicals are normally controlled by **free radical scavengers**, substances that remove or neutralize free radicals. Certain enzymes (superoxide dismutase, methionine reductase, catalase,

NURSING ALERT

Vitamin Toxicity

Megadoses of both types of vitamins (fat- and water-soluble) can cause toxicity. Once the catalytic demands have been met by these vitamins, the remaining vitamins act as free chemicals that may be toxic to the body.

and glutathione peroxidase) are free radical scavengers that are produced by the body. Besides vitamins C, E, A, and beta-carotene, certain herbs also act as antioxidants, such as bilberry, ginkgo, grape seed extract, green tea, and flavonoids. Sprouted grains and fresh fruits and vegetables contain antioxidants; however, in

order to provide the body with a sufficient quantity of antioxidants, supplements are often needed by the body to control the free radicals (Fontaine, 2000). The functions, clinical significance, and dietary sources of fat-soluble and water-soluble vitamins are presented in Table 38-1.

TABLE 38-1
Fat-Soluble and Water-Soluble Vitamins

Vitamin	Functions	Clinical Significance	Dietary Sources
Fat-Soluble			
Vitamin A (retinol, retinal, retinoic acid)	Epithelial tissue proliferation	Scaly skin, dry mucous membranes	Whole milk and products, eggs, fruits and vegetables (green leafy and yellow), fish, animal liver, fish liver oil <i>Caution:</i> Do not exceed a daily dose of over 10,000 international units if pregnant or history of liver disease
	Retinal pigmentation	Night blindness	
	Immune system (antigen recognition)	Increased risk for infections	
	Antioxidant	Cancer and other diseases	
Vitamin D (cholecalciferol, ergosterol)	Bone and tooth development	Children: rickets and delayed dentition	Fortified milk, margarine, eggs, fish, cod liver oil, oatmeal, sweet potatoes, vegetable oils
	Enhances immunity	Adults: osteomalacia	
Vitamin E (tocopherol)	Synthesis of heme	Premature infants: macrocytic anemia and hemolysis of RBCs	Cold-pressed vegetable oils, dark green leafy vegetables, milk, eggs, meats, legumes, nuts, seeds, whole grains
	Antioxidant, prevents oxidation of polyunsaturated fatty acids and of Vitamins A and C	Damage to red blood cells, destruction to nerves	
Vitamin K	Formation of prothrombin, blood clotting	Newborn: hemorrhagic disease	Dark green leafy vegetables, asparagus, broccoli, Brussels sprouts, cabbage, cauliflower, egg yolks, liver, oatmeal, oats, rye, safflower oil, soy beans, wheat
	Bone formation and repair	Adults: prolonged clotting times	
	Synthesis of osteocalcin	Osteoporosis	
Water-Soluble			
Vitamin C (ascorbic acid)	Formation of RBCs	Bleeding gums, bruising	Citrus fruits, strawberries, cantaloupe, fresh vegetables: potatoes, cabbage, tomatoes, broccoli, green peppers
	Production of collagen (capillary wall integrity) enzyme	Poor wound healing, retardation of bone growth, fragile blood vessel walls, gum lesions (referred to as scurvy)	
	Metabolism of amino acids		
	Prevention of oxidation of vitamins

TABLE 38-1 (continued)
Fat-Soluble and Water-Soluble Vitamins

Vitamin	Functions	Clinical Significance	Dietary Sources
B Complex Vitamin B ₁ (thiamine)	Metabolism of carbohydrates and some amino acids (energy), production of hydrochloric acid, enhances circulation and assists in blood formation	Degeneration of myelin sheath in CNS (paralysis) and in peripheral nerves (polyneuritis) Weakness of cardiac muscle: heart failure, peripheral vasodilatation and edema GI: indigestion, severe constipation, anorexia, gastric atony, hypochlorhydria (referred to as beriberi—all above systems involved)	Pork, fish, eggs, poultry, dried beans, whole grains, wheat germ, oatmeal, bread, pasta, brown rice, legumes, rice bran, peanuts
Niacin (nicotinic acid)	Coenzyme in energy metabolism	Muscular weakness, CNS lesions, dementia Skin: cracked, pigmented scaliness Irritation and inflammation of the mucous membranes of GI tract, producing GI hemorrhage (referred to as pellagra)	Meats, dairy products, whole grains, cereals, tuna, broccoli, carrots, cheese, corn flour
Vitamin B ₂ (riboflavin)	Oxidation and reduction of carbohydrates, fats, protein Red blood cell formation, antibody production	Digestive disturbances, burning sensations in eyes and skin, headaches, mental depression, forgetfulness (frequently occurs with thiamine or niacin deficiency), skin lesions, eye disorders (cataracts)	Milk, whole grains, green vegetables, liver, cheese, egg yolks, fish, legumes, meat, poultry, yogurt
Vitamin B ₁₂ (cobalamin compounds)	Metabolic functions as a coenzyme: hydrogen acceptor and replication of genes	Demyelination of large spinal cord nerves: loss of peripheral sensation and paralysis (usually the result of intrinsic factor deficiency)	Milk, eggs, cheese, meat, fish, poultry, brewer's yeast
Folic acid (pteroylglutamic acid)	Synthesis of purines and thymine (DNA formation) Maturation of RBCs Functions as coenzyme in DNA and RNA synthesis	Retarded growth Sore red tongue Macrocytic anemia	Liver, green leafy vegetables, meat, fish, poultry, whole grains, barley, bran, brewer's yeast, brown rice
Vitamin B ₆ (pyridoxine)	Functions as coenzyme to protein and amino acid metabolism, absorption of fats and protein	Convulsions, dermatitis, nausea, and vomiting, anemia, flaky skin	Whole grains, liver, fish, poultry, green beans, meats, nuts, potatoes, eggs, brewer's yeast

(continues)

TABLE 38-1 (continued)
Fat-Soluble and Water-Soluble Vitamins

Vitamin	Functions	Clinical Significance	Dietary Sources
Pantothenic acid	Metabolism of carbohydrates and fats	None known	Meats, whole grain cereals, legumes
Biotin	Synthesis of fatty acids	Infants: seborrheic dermatitis (cradle cap)	Liver, kidneys, dark green vegetables, egg yolk, green beans, brewer's yeast, milk, poultry, saltwater fish, whole grains
	Protein metabolism	Adults: rare	
	Utilization of glucose		

Minerals

Minerals (inorganic elements) serve as catalysts in biochemical reactions. Minerals are classified according to their daily requirement: macrominerals (quantities of 100 mg or greater) and microminerals (trace elements, quantities less than 100 mg). The major macrominerals required by the body are calcium, phosphorus, and magnesium; refer to Chapter 37 for a complete discussion of these minerals (electrolytes).

Microminerals such as copper, fluoride, iodine, iron, selenium, and zinc play an essential role in metabolism. For example:

- Copper and iron are needed for hemoglobin formation.
- Copper is needed for the synthesis of phospholipids and prostaglandin and for the formation of some enzymes.
- Iron is needed for the synthesis of vitamins, purines, and antibodies.
- Fluoride is required for teeth formation and the prevention of dental caries.
- Iodine is the basic component of thyroid hormones.
- Selenium enhances vitamin E absorption and stimulates antibody response to infection.
- Zinc plays a major role in wound healing, maintains connective tissue integrity, assists with the formation of enzymes and insulin, and boosts the immune response and maintains normal blood concentrations of vitamin E. Zinc also aids in the absorption of vitamin A, has antioxidant properties, and is a constituent of the antioxidant enzyme superoxide dismutase.

Other microminerals are arsenic, cadmium, nickel, silicon, tin, and vanadium; however, the specific roles that these microminerals play in metabolism have not been identified. Refer to Appendix B for the RDAs of minerals.

Carbohydrates

Carbohydrates are organic compounds composed of carbon, hydrogen, and oxygen. They play a significant role in providing cells with energy and supporting the normal functioning of the body. Table 38-2 identifies the functions of carbohydrates and the problems that result from insufficient intake.

Carbohydrates are classified according to the number of **saccharides** (sugar units):

- **Monosaccharides** (simple sugars) include glucose, galactose, and fructose.
- **Disaccharides** (double sugars) include sucrose, lactose, and maltose.
- **Polysaccharides** (complex sugars) include glycogen, cellulose (fiber), and starch.

Glucose supplies the major source of energy needed for cellular activity, such as muscle contractions and nerve impulse transmission. When metabolized, every gram of glucose yields 4 kcal. Glucose is also needed for the synthesis of fatty acids and amino acids.

Carbohydrates have a protein-sparing action, based on a minimum daily ingestion of 50 to 100 grams (200–400 kcal) to spare the metabolism of protein. When dietary intake is below minimum requirement, **triglycerides** (lipid compounds consisting of three fatty acids and a glycerol molecule) and proteins are metabolized to produce energy.

The three major sources of dietary carbohydrates are starches (nonanimal foods, primarily grains), lactose (milk), and sucrose (cane sugar). The ordinary diet contains far more starches than either lactose or sucrose. Refer to Figure 38-2A for information on the digestion of these sugars.

Cells are unable to store large quantities of carbohydrates. The liver converts excess galactose and fructose into glucose and stores it in the form of glycogen. **Insulin** (pancreatic hormone) aids in the diffusion of

TABLE 38-2
Normal Function and Deficiencies of Selected Nutrients

Nutrient	Functions	Deficiencies
Proteins	Growth and replacement: clotting factor production, collagen synthesis, epithelial cell proliferation, fibroblast proliferation	Increased risk of bruising and hemorrhage Muscular wasting Depigmentation of hair and skin Poor wound healing
	Immunity: antibodies, white blood cell production and migration, cell-mediated phagocytosis	Decreased enzyme production Lymphopenia Impaired cellular immunity
	Fluid balance: intracellular osmotic pressure, albumin, maintenance of blood volume	Edema Hypoalbuminemia
	Sodium and potassium balance	Impaired nerve impulse transmission and muscle function
	Buffer action	pH imbalances
	Energy source	Negative nitrogen balance
Carbohydrates	Primary source of energy	Impaired brain functions
	Sparing of protein	Increased ketone bodies, producing acidosis Poor wound healing
Fats	Source of concentrated energy and essential fatty acids	Inhibited tissue repair Irritated and reddened skin
	Cell membrane integrity	Deficit in fat-soluble vitamins
	Promotes absorption of fat-soluble vitamins	Impaired fat digestion
	Maintains body temperature	
	Synthesis of bile salts, steroid hormones, and Vitamin D	Electrolyte depletion
Vitamin A	Collagen synthesis	Poor wound healing
	Epithelialization	Dry, scaly skin
Vitamin C	Collagen synthesis	Poor wound healing
	Maintains capillary integrity	Increased risk of bruising and hemorrhage
Vitamin K	Coagulation	Increased risk of bruising and hemorrhage
Pyridoxine, riboflavin, and thiamine	Cofactors in cellular development	Irritated and reddened skin
	Red blood cell formation	Nerve and muscular weakness
	Immunity: antibodies and white blood cell formation	Anemia Increased risk of infection

TABLE 38-2 (continued)
Normal Function and Deficiencies of Selected Nutrients

Nutrient	Functions	Deficiencies
Copper	Red blood cell and connective tissue formation	Decreased collagen synthesis Poor wound healing from local tissue ischemia (anemia)
Iron	Collagen synthesis Enhancement of leukocytic activity Hemoglobin synthesis	Impaired collagen cross-linkage Increased risk of infection Anemia
Zinc	Cell proliferation Cofactor in enzymes	Poor wound healing Increased risk of infection Alteration in taste

Adapted From: Townsend, C. E. & Roth, R. A. (1999). *Nutrition and Diet Therapy* (7th ed.). Albany, N.Y.: Delmar Thomson Learning.

glucose into the liver and muscle cells and in the synthesis of glycogen. Glucose metabolism is dependent on the availability of insulin, as shown in Figure 38-5.

An increase in blood glucose levels can cause **hyperglycemia** (a blood glucose level greater than 110 mg/dl). This occurs in **diabetes mellitus** (a disease in which the pancreas fails to secrete adequate levels of insulin to accommodate blood glucose levels). When hyperglycemia occurs, **ketones** (the end product of incomplete fat metabolism) build up in the bloodstream, causing metabolic acidosis.

In **hypoglycemia**, the blood glucose level is below normal (less than 80 mg/dl) because the supply of insulin is so high that most of the glucose moves from the blood into the cells. Because brain tissue requires a constant source of glucose for energy, hypoglycemia can alter the normal functions of the brain.

Glucose (dextrose) is a common substance in intravenous therapy (dextrose-5%-water) because it is readily absorbed into the body's cells. This solution provides

170 kcal/L; refer to Chapter 37 for a complete discussion of intravenous replacement therapy.

Proteins

Proteins are organic compounds that contain carbon, hydrogen, oxygen, and nitrogen atoms; some proteins also contain sulfur.

After water, proteins are the most abundant intracellular substance. Proteins are essential for almost every bodily function, beginning with the genetic control of protein synthesis, cell function, and cell reproduction; see Table 38-2. The end products of protein digestion are amino acids.

The normal blood concentration of amino acids is between 35 and 65 mg/dl. There are 20 identified amino acids, which are categorized as either essential or nonessential:

- **Nonessential amino acids** can be synthesized (manufactured) in the cells; see the accompanying display.
- **Essential amino acids** must be ingested in the diet because they cannot be synthesized in the body; see the accompanying display.

Proteins are also classified as complete or incomplete. **High-biological-value proteins (complete proteins)** contain all of the essential amino acids. Complete proteins are primarily animal proteins, such as those in meats, poultry, fish, dairy products, and eggs.

Low-biological-value proteins (incomplete proteins) lack one or more of the essential amino acids, usually lysine, methionine, and tryptophan. Most vegetables are incomplete proteins. By properly mixing complementary proteins in the diet, such as corn and beans, one can produce a complete protein.

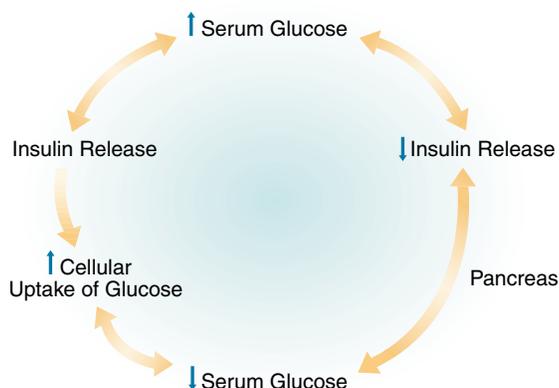

Figure 38-5 Serum Glucose–Insulin Feedback System

AMINO ACIDS

Nonessential Amino Acids

glycine	cysteine	glutamine
alanine	aspartic acid	tyrosine
serine	glutamic acid	proline
asparagine		

Essential Amino Acids

threonine	methionine	valine
leucine	isoleucine	lysine
arginine	phenylalanine	tryptophan
histidine		

All essential amino acids are needed by cells for anabolism and repair. The surplus amino acids are sent back to the liver, where they are degraded (nitrogen is split from the amino acid); the remaining parts are used for energy or converted to carbohydrate or fat and stored as glycogen or adipose tissue. Carbon dioxide, water, and nitrogen are the end products of amino acid metabolism.

The degradation of amino acids begins the process of **deamination**, the removal of the amino groups from the amino acids. During protein deamination, several other physiological processes of clinical significance occur:

1. **Gluconeogenesis**, the conversion of amino acids into glucose or glycogen
2. **Ketogenesis**, the conversion of amino acids into keto acids or fatty acids
3. **Nitrogen balance**, the net result of intake and loss of nitrogen that measures protein anabolism and catabolism
4. **Positive nitrogen balance**, the condition that exists when nitrogen intake exceeds output (protein anabolism exceeds catabolism)
5. **Negative nitrogen balance**, the condition that exists when nitrogen output exceeds intake (protein catabolism exceeds anabolism)
6. **Obligatory loss of proteins**, the degrading of the body's own proteins into amino acids, which are then deaminated and oxidized (occurs when a person fails to ingest adequate amounts of proteins)

Nitrogen balance measures protein equilibrium and is used to evaluate the client's nutritional status. Clients on bed rest or with a fever are in a catabolic state that produces a negative nitrogen balance. The muscle wasting that occurs with immobility causes negative nitrogen balance. Massive trauma and burns are other common examples of catabolic states that produce a negative nitrogen balance initially upon injury. Diet therapy is directed toward providing adequate amounts of proteins and kilocalories so that the body does not use its own protein as an energy source.

NURSING ALERT

Protein Ingestion

A person must ingest a minimum of 20 to 30 grams of protein each day to prevent a net loss of body proteins.

NURSING TIP

Electrolytes

Potassium and magnesium enhance the utilization of protein by the body. These electrolytes assist with the transport of amino acids into the cells.

Lipids

Lipids (fats) are organic compounds that are insoluble in water but soluble in organic solvents such as ether and alcohol. Lipids are composed of the same elements as carbohydrates (carbon, hydrogen, and oxygen) but have a higher hydrogen concentration. Refer to Table 38-2 for a discussion of the normal functions of fats and the problems that arise from insufficient intake.

Fatty acids are basic structural units of most lipids. They contain carbon chains and hydrogen. **Saturated fatty acids** form fats, glycerol esters of organic acids whose carbon atoms are joined by single bonds (all the carbon atoms are saturated with hydrogen). Diets high in saturated fats are associated with a high incidence of coronary heart disease. Foods high in such fats are animal meats (especially beef), whole-milk products, butter, most cheeses, and some plant fats, such as chocolate, coconut, and palm oils.

Unsaturated fatty acids form glycerol esters of organic acids whose carbon atoms are joined by double or triple bonds (at least two carbon atoms in the fatty acid chains in the esters are unattached to hydrogen atoms). **Monounsaturated fatty acids** are fatty acids that form esters with one double or triple bond; foods in this category are nuts, fowl, and olive oil. **Polyunsaturated fatty acids** form esters that have many carbons unbonded to hydrogen atoms. Foods such as fish, corn, sunflower seeds, soybeans, cottonseeds, and safflower oil contain such esters.

The most important lipids follow:

- **Triglycerides** are lipid compounds composed of three fatty acid molecules attached to a glycerol molecule.
- **Phospholipids** are composed of one or more fatty acid molecules and one phosphoric acid radical, and usually contain a nitrogenous base.

- **Cholesterol** (a lipid that is produced by the body and used in the synthesis of steroid hormones and excreted in bile), is considered a fat and is found in whole milk and egg yolk.

NURSING TIP

Blood Cholesterol

To decrease the blood cholesterol level, the client needs a diet low in saturated fat; a diet high in saturated fat increases the blood cholesterol level by 15% to 25%.

Phospholipids and cholesterol lipids constitute 2% of the total cell mass; they are basically insoluble in water and are used to form membranous barriers that separate the different intracellular compartments. The cell membrane is composed almost entirely of proteins and lipids (phospholipids and cholesterol).

Besides phospholipids and cholesterol, some cells contain triglycerides, which account for 95% of the fat cell mass. Triglycerides are the body's main storehouse of energy-giving nutrients; when dissolved, they can be used for energy as needed.

Most dietary fats are triglycerides, found primarily in animal food. Most plant foods contain trace elements of triglycerides. Other than butter fat, which is digested by gastric lipase (tributyrase), essentially all fat digestion occurs in the small intestines in the presence of pancreatic juices, as shown in Figure 38-2C.

When free fatty acids, monoglycerides, free cholesterol, and phospholipids are absorbed by the blood and lymph system, they are resynthesized into minute molecules called **chylomicrons** (lipoproteins, synthesized in the intestines, that transport triglycerides to the liver).

Low-density lipoproteins are responsible for the formation of **atherosclerosis** (a disease of the arteries in which fatty lesions called atheromatous plaques develop inside the wall of the arteries). A diet high in saturated fats and cholesterol causes the formation of atherosclerosis.

Almost half the deaths in the United States and Europe are attributed to atherosclerosis. These deaths are usually the result of coronary artery thrombosis.

PROMOTING PROPER NUTRITION

Hunger means a craving for food and is a subjective sensation. For example, when a person has not eaten for hours, the stomach undergoes intense rhythmic contractions called hunger contractions. These contractions sometimes cause pain, in the form of *hunger pangs*. Hunger is not only a physiological response; it also involves psychological sensations. For instance, with a total gastrectomy (surgical removal of the stomach) clients still report a *craving for food*.

Appetite means the desire for specific types of food instead of food in general. A person's appetite determines the type of foods he or she eats. **Satiety** means a feeling of fulfillment from food. It is the opposite of hunger and occurs when the person's nutritional stores have been replenished and psychological cravings have been met.

THINK ABOUT IT

Satiety

How does a person know when she has eaten enough food? What role do the *oral factors* of chewing, salivation, swallowing, and tasting play in satiety? How true is the saying that healthy eating habits require three meals a day and that each of those meals should be filling? How are lifelong eating habits developed in early childhood?

Daily food guides have been developed by various organizations to establish standards that promote nutrition and health. These guides assist healthy persons in meal planning; however, the guides do not take into account the nutritional needs arising from metabolic and other medical disorders. Besides the American food guides, there are guidelines developed by other countries—for instance, Canada's *Food Guide to Healthy Eating*—and by the World Health Organization.

THINK ABOUT IT

A Fatty Meal

What impact would it have on a person, especially a teenager, if he or she could see a blood sample drawn 30 minutes after eating a large quantity of fast foods? Do you think seeing the blood turn turbid or yellowish after a fatty meal would alter the person's eating habits?

Dietary Reference Intakes and Recommended Daily Allowances

The **recommended dietary allowances** (RDAs) are recommended allowances of essential nutrients (protein, fat-soluble and water-soluble vitamins, and minerals) by age category, inclusive of weight and height. RDAs are established by the National Nutrition Board of the National Academy of Sciences–National Research Council. See

Appendix B. RDAs represent the normal nutritional needs of 97% to 98% of the people in each specific category; the RDAs do not take into consideration an individual's specific needs or physiological disorders.

Although RDAs have been in existence for the past 20 years as a nutritional guide to support healthy persons, the Food and Nutrition Board, in partnership with Health Canada, has initiated an effort to define new nutrient reference values. The Dietary Reference Intake (DRI) is a generic term that refers to at least three types of reference values: Estimated Average Requirement (EAR), RDA, and Tolerable Upper Intake Level (UL). EAR is the intake value that is estimated to meet the requirement defined by a specific indicator of adequacy in 50% of an age-specific and gender-specific group. UL is the maximum level of daily nutrient intake that is unlikely to pose risks of adverse health effects to almost all of the individuals in the group for whom it is designed. The goal of DRI is to set nutrient reference values for all the nutrients; see the accompanying display for the first seven nutrient groups studied.

EVALUATION OF DIETARY REFERENCE INTAKES

The seven nutrient groups are as follows:

1. Calcium, vitamin D, phosphorus, magnesium, and fluoride
2. Folate and other B vitamins
3. Antioxidants (e.g., vitamins C and E, and selenium)
4. Macronutrients (e.g., protein, fat, carbohydrates)
5. Trace elements (e.g., iron, zinc)
6. Electrolytes and water
7. Other food components (e.g., fiber, phytoestrogens)

The Food Guide Pyramid

The food guide pyramid outlines in graphic presentation six groups of food and the number of servings based on the dietary guidelines and the basic four food groups, as shown in Figure 38-6. The pyramid suggests a variety of foods with the right amount of calories and nutrients to maintain a healthy weight. Canada's *Food Guide to Healthy Eating* offers a similar routine for a daily diet (Figure 38-7).

Societal Concerns

The Leading Health Indicators for Healthy People 2010 report recognizes that one-third of the U.S. population is considered overweight, while undernutrition is a specific problem for the elderly and for people with eating disorders. Although "weight" is one of the 10 indicators in the Health Determinants and Health Outcome Set (refer to Chapter 17 for a complete discussion of this

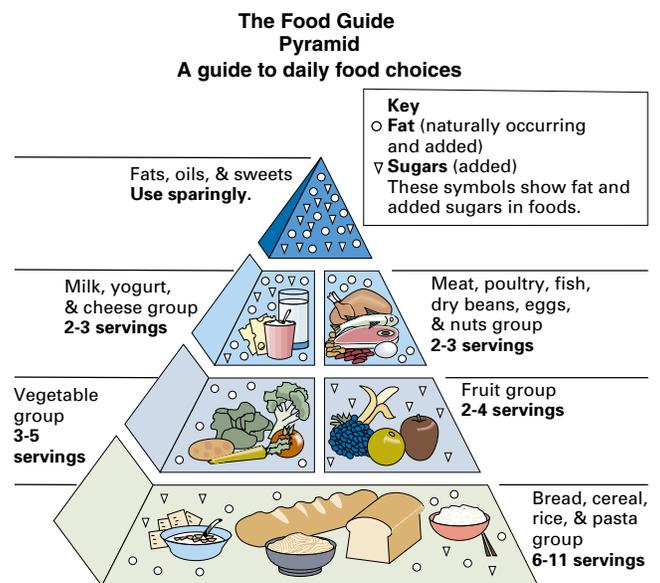

Figure 38-6 Food Guide Pyramid (Courtesy of the U.S. Departments of Agriculture and Health and Human Services, revised 1996)

indicator), diet and nutrition were excluded from the proposed set of indicators because of measurement challenges inherent in this indicator. The committee based this decision on the fact "that the state-of-art of dietary measurement has not yet achieved a level that would provide regular, timely, valid and reliable measurement for each indicator, for diverse population groups, and at multiple jurisdictional levels" (Leading Health Indicators for Healthy People 2010, Final Report, pp. 47–48).

Modern society has turned from a diet of whole grains, fruits, and vegetables to a diet of processed foods, fast foods, additives, preservatives, and hydrogenated oils that can have a damaging effect on a person's health. Processed foods usually contain excessive amounts of sodium that can cause fluid retention and lead to hypertension, aggravating many medical disorders such as congested heart failure, certain forms of kidney disorders and premenstrual syndrome (PMS). Additives are placed in foods for one or more of the following reasons: to lengthen shelf life; to make a food more appealing by enhancing color, texture, or flavor; to facilitate food preparation; or to otherwise make the product more marketable. Some additives are derived from natural sources such as sugar, while other additives are made synthetically like aspartame (NutraSweet). Although additives are usually identified on the "ingredient label" of a product, they are initially used without health warnings. For example, monosodium glutamate (MSG), and artificial sweeteners cyclamate, saccharin, and aspartame are used without warning, but have been known to cause headaches, diarrhea, confusion, memory loss, and seizures.

Genetically altering of the world's food has caused many persons to question the essential ingredients of nutrients and the role of the U.S. Food and Drug Administration (FDA) in regulating safe, healthy food

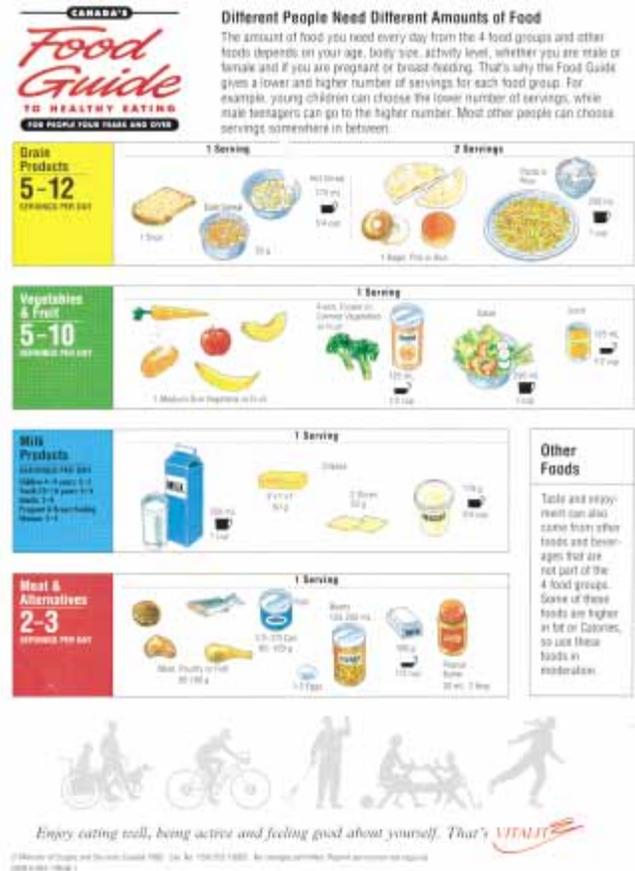

Figure 38-7 Canada's Food Guide (From *Canada's Food Guide to Healthy Eating*, Health, Canada, 1992, ©Minister of Public Works and Government Services Canada, 2001)

products. Although the FDA in 1993 approved the use of rBGH, a genetically engineered bovine growth hormone that makes dairy cows produce 100% more milk than normal, Canadian health officials rejected a major U.S. corporation's request for approval of rBGH because the product label acknowledges that it can cause udder infections, painful, debilitating foot disorders, and reduced life span in treated cows. Humans who drink the milk from cows treated with rBGH can develop breast or prostate cancer, as well as other reproductive disorders and diseases.

The European Union's Scientific Committee on Veterinary Measures reported that 17 beta-oestradiol, one of the six growth hormones that are used in 90% of all nonorganic beef raised in the United States, is "a complete carcinogen." American beef is banned in Europe because these hormones "may cause a variety of health problems, including cancer, developmental problems, harm to the immune system and brain disease" (Campaign for Food Safety News, 1999).

In 1995, no genetically modified crops were grown for commercial sale; however, these statistics have changed rapidly in the past three years: by 1998, 73 million acres of genetically modified crops were grown worldwide, more than 50 million acres of them in the United States; in 1999 an estimated 30,000 genetically modified products were in U.S. grocery stores; and in 2000, 100% of a major U.S. corporation's soybeans (60

million acres) were genetically modified (Rachel's Environment & Health Weekly, 1999). The FDA's position is that genetically modified foods do not need to be labeled; therefore, the consumer is deprived the opportunity to make an informed choice in the grocery store.

"Consumers are increasingly choosing organic products out of concern for the purity of their food and the health of the environment" (Long, p. 44, 1999). In 2000, new organic certification rules were passed in the United States. These new regulations prohibit organic farmers from using toxic synthetic pesticides and fertilizers, genetically engineered seeds or other materials, irradiation and sewage sludge. Organic farmers must adhere to strict standards regarding the use of fresh manure, animal confinement and antibiotics and hormones. For a product to be labeled "certified organic" on the front of the package, 95% or more of the ingredients must be organically grown. To indicate on the label "made with organic ingredients," the product must contain at least 50% organic ingredients.

Weight Management

Maintaining homeostasis requires a balance between intake of nutrients and energy expenditure. Average weight is relative to energy balance, the situation in which energy intake equals energy output.

Overweight

Overweight is an energy imbalance in which more food is consumed than is needed, causing a storage of fat. Overweight indicates a positive energy balance and is defined as weight 10% to 20% above average; obesity refers to weight 20% above average. Overweight may result from one or more factors: genetic, psychological, social, cultural, economic, or physiological. Genetically linked factors, such as a low BMR, excess fat distribution, and obese parents, place the person at risk for obesity. Some people overeat in response to emotional stress or whenever food is available rather than in response to hunger. Sociocultural norms influence eating habits; some cultures place a high value on excess weight. Hormonal imbalances, such as decreased thyroxin levels, can lower the BMR, causing weight gain if food intake remains constant.

THINK ABOUT IT

Vulnerability to Obesity

Cultural practices may encourage a calorie-dense diet. Some ethnic groups consider overweight and obesity acceptable or even desirable. An individual's emotional status affects eating. What implications do these factors have in teaching clients about weight in relation to health?

Underweight

An underweight person expends more calories than are consumed. Underweight, a negative energy balance, is weight at least 10% to 15% below average. Being underweight decreases the individual's resistance to infection and increases susceptibility to fatigue and sensitivity to cold environments.

Family dynamics and a fear of fatness are psychological conditions that can contribute to eating disorders. **Anorexia nervosa** (self-starvation) disrupts metabolism because of inadequate calorie intake and results in hair loss, low blood pressure, weakness, amenorrhea, brain damage, and even death (Townsend & Roth, 1999). **Bulimia nervosa** refers to food-gorging binges followed by purging of food, usually through self-induced vomiting or laxative abuse.

Underweight can also be caused by long-term conditions that deplete the body's resources, such as fever, infection, and cancer, or that prevent nutrient absorption, as occurs with diarrhea, metabolic or GI disorders, and laxative abuse. Other causes of underweight are hyperthyroidism and poverty.

FACTORS AFFECTING NUTRITION

Understanding the factors that may influence nutrition is essential in eliciting client and family cooperation in providing optimal nutritional care.

CLIENT TEACHING CHECKLIST

Tips to Reduce Dietary Fat

- Read the nutritional labels for fat content on products before buying.
- Substitute plant proteins for meat, and avoid chocolate.
- Use low fat dairy products, such as skim milk, instead of whole milk and low fat yogurt instead of sour cream.
- Use 1/4 cup of egg substitute or two egg whites for one whole egg.
- Substitute margarine that is low in saturated fat for butter on breads and use low-fat dressings for salads.
- Trim fats from meats and skin from poultry before cooking, and drain fat from meat after cooking.
- Include more fish and less red meat in your diet.
- Use herbs and spices instead of margarine, oil, and salt when cooking, to bring out the flavor in foods.
- Cook foods by baking, broiling, boiling, roasting, stewing, or microwaving to avoid additional fat from frying.
- Avoid adding flour, bread crumbs, and coating mixes when preparing foods.
- Use vegetable oils and sprays instead of shortening, lard, or butter when cooking and baking.
- Eat fresh fruits and vegetables instead of desserts high in fat.

Age

Infants and children vary in weight and energy requirements; refer to RDA, Appendix B. The infant's physiological development has implications for fluid, electrolyte, and food intake that can predispose this age group to various imbalances. These factors are directly related to the infant's total body surface area, immature physiologic development, and the rate of growth and development during the first year of life; refer to Chapter 17 for a complete discussion on growth and development.

From ages 1 to 6 years, nutritional intake varies in relation to growth rate, making the child's eating habits erratic. The child will usually select foods based on developmental nutritional needs in accord with:

- High kilocalorie intake to maintain energy requirements
- Adequate levels of protein, vitamin D, calcium, and phosphate to complement teeth eruption and an increase in muscle mass and bone density

School-age children can eat larger meals less frequently because of the digestive system's maturation

and the presence of permanent teeth. A diet that supplies the RDAs will promote optimal development and health and at the same time avoid weight gains during the preadolescent period.

Adolescence, a period of rapid growth and sexual maturation, requires guidance in dietary choices. Hormonal changes associated with menstruation make girls prone to fluid imbalance. Teenagers eat many of their meals away from home—for example, in fast-food restaurants.

Peer groups influence a teenager's choices, such as what, when, and where to eat; refer to Figure 38-8. At the same time, body image is of critical importance for teenagers. The social pressures and other emotional stressors of adolescence may have a negative effect on eating habits, leading to obesity, use of fad diets, and eating disorders such as anorexia nervosa and bulimia. See the accompanying display for some points about food related behaviors.

During adulthood, growth stops and metabolism declines, thereby decreasing the need for kilocalorie intake. With pregnancy and lactation, the nutritional needs once again increase. During pregnancy, changes occur that may result in fluid retention (dependent edema); for example, hormonal changes, pressure of the fetus on the inferior vena cava, vascular congestion, and increased capillary filtration pressure.

The aging process brings about structural and functional changes that may put older adults at risk. The older population cannot be classified as a homogeneous group, because people do not age physically at the same rate as they do chronologically (Hogstel, 2001); refer to the Client Teaching Checklist for dietary guidelines for the elderly.

Figure 38-8 Adolescents are vulnerable to peer influence.

Socioeconomic factors, access to a grocery store, and lifestyle may affect the nutritional status of older adults. Having to prepare their own food and eat alone are other challenges the elderly face. Refer to Chapter 18 for additional information on the elderly.

Lifestyle

Eating is a social activity in most cultures. A person's lifestyle may have a major impact on food-related behaviors. Families with both parents working or with children involved in sports and other activities might find it difficult to sit down at the dinner table together for a home-cooked meal. When meals are eaten on the run, they tend to be high in fat and carbohydrate content, and the family misses the opportunity to be together and share important events of the day.

Food preferences are usually developed in childhood and modified throughout the life span. Lifestyle nutritional behaviors often come from traditional family practices. These practices affect not only food-related behaviors but also the individual's beliefs regarding health and wellness. If a person gets sufficient rest, has the self-awareness to recognize stress, exercises regularly, and avoids addictive behaviors, such as smoking and alcohol, he or she will usually make healthy nutritional decisions.

Ethnicity, Culture, and Religious Practices

Dietary customs reflect the socialization and cultural patterns of ethnic groups (Figure 38-9). Culture is evidenced by patterns of values and behaviors that are characteristics of a particular group. Religious beliefs often dictate what types of foods may be eaten and how they should be prepared.

Although it is not possible to learn the nutritional behaviors for all ethnic groups, recognize the need to comply with the client's routine patterns (see the accompanying display for nutritional behaviors of some

NURSING TIP

Preventing Eating Disorders

- Encourage healthy dietary habits and adequate exercise.
- Emphasize a healthy lifestyle over physical appearance and weight loss.
- Encourage increased self-esteem and stress a positive self-worth.
- Avoid pressuring children to achieve perfection or to perform beyond their abilities.
- Recognize signs and symptoms of eating disorders, and seek professional help when suspected.

(From Estes, M. E. [2002]. *Health assessment and physical examination*. Albany, NY: Delmar Publishers.)

CLIENT TEACHING CHECKLIST

Special Dietary Considerations for the Elderly

- Special attention must be given to water needs, regardless of physical activity, because the thirst mechanism is less responsive than in younger people.
- Decrease the kilocaloric requirements in relation to activity: 10% for ages 51–75 and 20% to 25% for ages 75 and older. Bedridden and immobilized persons need a further reduction in kilocalories. Limit the quantities of empty kilocalorie foods (sugars, sweets, fats, oils, and alcohol).
- Maintain protein requirements, with 12% to 14% of the kilocalories being derived from protein food (meat, fish, eggs, poultry, milk, and cheese).
- Ensure adequate consumption of fats, especially unsaturated fats, to provide a source of energy, provide the essential amino acids, utilize the fat-soluble vitamins, and serve as a lubricating agent.
- Select carbohydrates as follows: limit concentrated sweets; use moderate amounts of simple sugars (candy, sugar, jams, jellies, preserves, and syrups); the main source should be complex carbohydrates (fruits, vegetables, cereals, and breads).
- Ensure adequate amounts of vitamin D, calcium, and phosphorus to maintain bone integrity (fortified milk is a good source).
- Ensure high-fiber foods (dried fruits, whole grain cereals, nuts, fresh fruit, and vegetables) to increase satiety and maintain intestinal mobility to avoid constipation.
- Ensure a safe, adequate intake of sodium, avoiding canned foods and salted or cured meats high in sodium content for those with cardiac problems and hypertension.
- Include foods from the food guide pyramid in the amounts that meet the RDAs for age 51 and older.

ethnic groups). Refer to Chapter 16 for additional cultural factors that are evidenced in food behaviors.

Other Factors

There are other factors that influence the types of foods selected and their nutritional value. Economics exert a major influence on food selection; fresh fruits and vegetables and lean meats are expensive and are often sub-

THINK ABOUT IT

Food-Related Behaviors

How are food *fads* developed? What lasting impact do these fads have on health? What role does the media play in forming an individual's food beliefs? Is the statement "Yogurt and vitamin E retard aging" related to a fad or a misconception, or is it a fact based on research? To answer this last question, refer to Table 38-1.

NUTRITIONAL BEHAVIORS OF SELECTED ETHNIC GROUPS

- Asians' main food types are rice, green tea, vegetables, and fish. A rice-and-water soup is often fed to the sick.
- The Islamic (Muslim) law does not permit the consumption of pork or alcohol or of meat that has not been slaughtered according to the Islamic code. The main meal is at midday.
- Orthodox Jews are not allowed to eat pig, rabbit, and shellfish; milk and meat are not taken at the same meal. A vegetarian diet is acceptable when kosher meat is not available. Strict guidelines dictate food preparation.

stituted with products that tend to be low in protein and high in starch.

Food preferences are an expression of an individual's likes and dislikes. They may be related to the texture of food, how it is prepared, or what was served to the individual during childhood. However, preferences can also be an expression of the person's economic, ecological, ethical, or religious beliefs. Vegetarians, for example, follow a diet of plant foods and may include eggs or milk, depending on preference. A vegetarian diet is healthy when it includes a wide variety of foods that supply adequate amounts of protein, vitamins, and minerals.

Figure 38-9 Family and cultural values often affect diet.

Gender may play a role in food selection, owing mainly to stereotyping (for example, the idea that males eat meat and potatoes and females eat salads). Peer pressures often dictate what teenagers eat. Stress, depression, and alcohol abuse alter the appetite. Medications can alter food absorption and excretion and affect the taste of food. GI disorders can cause anorexia, nausea, vomiting, diarrhea, constipation, discomfort, and pain, all of which may alter eating habits and food preferences.

ASSESSMENT

The goals of a nursing assessment are to collect subjective and objective data regarding the client's nutritional status and to determine what type of nutritional support is needed. Nurses are in a unique position to recognize **malnutrition**, or alterations related to inadequate intake, disorders of digestion or absorption, and overeating. Assessment must be performed in a logical fashion and should include three basic components: nutritional history, physical examination with anthropometric measurements, and diagnostic and laboratory data.

Nutritional History

The nutritional history of clients experiencing alterations in nutrition and metabolism is of critical importance in the development of the plan of care. Several methods can be used in collecting these subjective data: 24-hour recall, food frequency questionnaire, food record, and diet history; refer to Table 38-3 for an example of a nutritional history. Begin the history with a thorough exploration of the client's presenting problems as they relate to onset, duration, nature, pattern, severity, associated symptoms, and efforts taken to relieve the symptoms.

24-Hour Recall

The 24-hour recall requires client identification of everything consumed in the previous 24 hours. It is performed easily and quickly by asking pertinent questions. However, clients may be unable to recall their intake accurately or anything atypical for their diet. Family members can often assist with these data, if necessary.

THINK ABOUT IT

Personal Biases

Performing a nutritional history requires a questioning, nonjudgmental attitude. Examine your biases so that you can treat the viewpoints of all clients equally. To gain a sincere understanding of clients' perspectives, develop an open mind and listen with empathy.

Food-Frequency Questionnaire

The food-frequency method gathers data relative to the number of times per day, week, or month the client eats particular foods. The nurse can tailor the questions to particular nutrients, such as cholesterol and saturated fat. This method helps to validate the accuracy of the 24-hour recall and provides a more complete picture of foods consumed.

Food Record

The food record provides quantitative information regarding all foods consumed, with portions weighed and measured for three consecutive days. This method requires full client or family member cooperation.

Diet History

The diet history elicits detailed information regarding the client's nutritional status, general health pattern, socioeconomic status, and cultural factors, as presented in Table 38-3. This method incorporates information similar to that collected by the 24-hour recall and food-frequency questionnaire. Inform the client that the history might require more than one interview because of the amount of data to be collected.

Although the history data may indicate adequate nutrition, clients must be reassessed periodically to prevent nutritional problems from occurring. Fear, anxiety, or depression before or during hospitalization may lead to poor food intake, which is the leading cause of malnutrition.

Physical Examination

A physical assessment requires decision making, problem solving, and organization; refer to Chapter 27 for a complete discussion of physical assessment. This section presents the physical assessment findings that suggest nutrient imbalance. "The nurse should be aware of rapidly proliferating tissues such as hair, skin, eyes, lips, and tongue that usually show nutrient deficiencies sooner than other tissues" (Hammond, 1999, p. 355). Refer to Table 38-4. Essential components of anthropometric measurements (height, weight, and skinfolds) are also discussed.

Intake and Output (I&O)

Intake and output measurements and daily weights are critical components of a nutritional assessment; refer to Chapter 37, Procedure 37-1, intake and output measurements, and Chapter 27 for a complete discussion on weight measurement.

Anthropometric Measurements

Anthropometric measurements (measurement of the size, weight, and proportions of the body) evaluate the

TABLE 38-3
Health History Related to Nutrition and Metabolism

Environment and Lifestyle	Possible Findings
Employment	Exposure to heat, toxic chemicals Extent of physical exertion Degree of stress
Home environment	Central air/heat; lives alone or with other family members; ability to shop/cook
Tobacco use	Use of smokeless tobacco; cigarettes: number of years; packs per day; if quit, how long
Nutritional status	Weight changes: loss or gain Fluid consumption for 24 hours: number of glasses of water, cups of coffee or tea, soft drinks; amount of alcohol consumed Food preferences and restrictions Dietary restrictions (sodium) Use of supplements: vitamins, minerals, commercial liquids, herbs
Presenting Problem	Possible Findings
Weight loss	Onset: sudden or gradual, duration Pattern: decreased intake, increased activity Severity: how much, specific time frame Associated symptoms: anorexia, nausea, vomiting, diarrhea, dysphagia (difficulty in swallowing), odynophagia (pain in swallowing), polyuria (passage of excessive urine), fatigue, dyspnea, depression, cognitive impairment, motor weakness or paralysis Efforts to relieve weight loss: increased intake, decreased activity
Anorexia	Onset: sudden, gradual, duration Pattern: continuous, occasional, related to food intake—specific foods, time of day, activity, drugs, radiation or chemotherapy Severity: intake for 24 hours Associated symptoms: weight loss, nausea, vomiting, diarrhea, dysgeusia (distortion of sense of taste), fatigue, depression Efforts to relieve anorexia: dietary changes—types of foods and preparation, time of day, eating with others or alone
Nausea and vomiting	Onset: sudden, gradual, duration Nature of emesis: color, consistency, amount Pattern: continuous, occasional, related to food intake—specific foods, time of day, position or activity Severity: specific amount in a 24-hour period Associated symptoms: weight loss, anorexia, dysphagia, diarrhea, fatigue, motor weakness, pain Efforts to relieve nausea and vomiting: eliminating odors, certain foods, medications, changing position or activity after meals
Diarrhea	Onset: sudden or gradual, duration Nature of feces: color, consistency, amount Pattern: frequency, related to food intake Severity: number of times in 24 hours Associated symptoms: nausea, vomiting, pain, fatigue, motor weakness, weight loss Efforts to relieve: decrease fluid intake with meals, identify foods, medications, and other stressors that trigger diarrhea
Past Health History	Possible Findings
Previous or chronic illnesses	Allergies, anorexia, malnutrition, gastroenteritis, cancer, diabetes mellitus History of: heart disease, hypertension, renal disease, pulmonary disease History of trauma: head or crushing injuries
Medications and therapies	Diuretics, steroids, antacids, antihypertensives, digoxin IV therapy, total parenteral nutrition, chemotherapy

(continues)

TABLE 38-3 (continued)
Health History Related to Nutrition and Metabolism

Family History	Possible Findings
Illnesses in family members	Allergies, cancer, anorexia, diabetes mellitus, cardiovascular disease
Knowledge Level	Possible Findings
Client's knowledge of disease process	Ability to name illness Ability to identify current treatments (e.g., medications)
Coping Ability	Possible Findings
Client and family coping strategies	Client's and family's perception of impact of illness on lifestyle Presence of social support systems

client's calorie-energy expenditure balance, muscle mass, body fat, and protein reserves based on height, weight, skinfolds, and limb and girth circumferences. Chapter 27 discusses the assessment of height and weight; refer to Chapter 37 for additional nursing measures relative to daily weights.

The **body mass index (BMI)** determines whether a person's weight is appropriate for height and is calculated using a simple formula: $BMI = \frac{\text{weight (kg)}}{[\text{height (m)}]^2}$

For example, a person who weighs 65 kg and is 1.6 m tall would have a BMI of $\frac{65 \text{ kg}}{(1.6 \text{ m})^2}$, or 25.4. A BMI of 27

or greater indicates obesity. Height and weight tables are available in most health care settings; see Table 38-5.

Skinfold Measurements

Skinfold measurement indicates the amount of body fat. This information is beneficial in promoting health and determining risks and treatment modalities associated with chronic illness and surgery. This assessment is usually performed in an outpatient setting when the nurse develops a client's profile.

A special caliper is used to measure skinfolds. The caliper should grasp only the subcutaneous tissue, not the underlying muscle. Measurements can be taken of the triceps, subscapular, biceps, and suprailiac skinfolds.

1. To measure the triceps fold, locate the midpoint of the upper arm. Grasping the skin on the back of the upper arm, place the calipers 1 cm below your fingers (Figure 38-10), and measure the thickness to the nearest millimeter.
2. For a subscapular skinfold measurement, grasp the skin below the scapula with three fingers, angle the fold about 45° laterally to the scapula (Figure 38-11), place the caliper 1 cm above your fingers, and read the measurement.

It is essential to document the skinfold sites, the type of caliper used, and the measurement in millimeters.

Mid-Upper-Arm Circumference

The measurement of **mid-upper-arm circumference (MAC)** serves as an index for skeletal muscle mass and protein reserve. Instruct the client to relax and flex the forearm; with a measuring tape, measure the circumference at the midpoint of the upper arm (Figure 38-12).

Abdominal-Girth Measurement

When made repeatedly over a span of time, an abdominal girth measurement serves as an index as to whether abdominal distention is increasing, decreasing, or remaining the same. With an indelible pen, place an X on the client's abdomen at the point of greatest distention. Using a measuring tape, measure the abdomen's circumference. This measurement should be performed at the same time each day and consistently recorded in either inches or centimeters.

Diagnostic and Laboratory Data

Biochemical data assessment is another essential source of objective data. Trends revealed in laboratory results can be used to detect alterations in nutrition and metabolism before clinical symptoms are assessed in the examination. Refer to Chapter 28 for a detailed discussion of laboratory testing. No single laboratory test is diagnostic of malnutrition.

Protein Indices

Several tests that reflect protein synthesis can also reflect nutritional status. Serum levels of albumin and transferrin are used to identify protein-calorie malnutrition.

Serum Albumin

Albumin is synthesized in the liver from amino acids. Serum albumin plays an important role in fluid and electrolyte balance and the transport of nutrients, hormones, and drugs. However, serum albumin has a half-life of 21 days and fluctuates according to the level of hydration; therefore, it is not a good indicator of acute alterations in protein status. Clinically, this blood test is used to measure prolonged protein depletion that

TABLE 38-4
Adult Physical Assessment Findings: Nutrient Imbalance

Assessment Findings	Nutrient Deficiencies and Excesses	Assessment Findings	Nutrient Deficiencies and Excesses
Hair: Dull, dry, brittle Hair loss	Protein deficiency Protein, zinc, and biotin deficiency or vit A excess	Nails: Koilonychia (spoon-shaped nails) Brittle, fragile	Iron deficiency Protein deficiency
Loss of pigment in strips around hair line	Protein and copper deficiency	Heart: Tachycardia Hypertension	Vit B ₁ deficiency Calcium and potassium deficiency or sodium excess
Head and neck: Headache Epistaxis (nosebleed) Thyroid enlargement	Vit A and D excess Vit K deficiency Iodine deficiency	Abdomen: Ascites	Protein deficiency
Eyes: Pale conjunctiva Blue sclerae Conjunctival and corneal dryness Corneal vascularization	Iron deficiency Iron deficiency Vit A deficiency Vit B ₂ deficiency	Musculoskeletal: Muscle wasting Edema Calf tenderness Bone tenderness	Protein and vit B ₁ deficiency Vit B ₁ and C, biotin, selenium deficiency Vit D, calcium, and phosphorus deficiency or vit A excess
Mouth: Lesions at corners of mouth Glossitis (red, sore tongue) Gingivitis (inflamed gums) Hypogeusia (poor sense of taste) Dysgeusia (bad taste) Dental caries Mottling of teeth Atrophy of papillae on tongue	Vit B ₂ deficiency Niacin, folate, vit B ₁₂ , and other vit B deficiencies Vit C deficiency Zinc deficiency Zinc deficiency Fluoride deficiency Fluoride excess Iron and vit B deficiency	Knock knees, bowed legs, and fragile bones	Vit D, calcium, phosphorus, and copper deficiency
Skin: Dry, scaly Eczematous lesions Petechiae and ecchymoses Darkening and peeling of sun-exposed areas Poor wound healing	Vit A, zinc, and essential fatty acids deficiency or vit A excess Zinc deficiency Vit C and vit K deficiency Niacin deficiency Protein, zinc, and vit C deficiency	Neurologic: Paresthesia Weakness Ataxia Tremor Decreased tendon reflexes Disorientation Drowsiness, lethargy Depression	Vit B ₁ , B ₆ , B ₁₂ , and biotin deficiency Vit C, B ₁ , B ₆ , and B ₁₂ deficiency Vit B ₁ and B ₁₂ deficiency Magnesium deficiency Vit B ₁ deficiency Vit B ₁ deficiency or vit A and D excess Vit B ₁ and biotin deficiency

occurs in chronic malnutrition, liver disease, and nephrosis. Albumin levels below 3.5 g/dl may indicate some degree of malnutrition.

Pre-Albumin

Research has provided a newer, more accurate test to evaluate protein status. **Pre-albumin** (a precursor of

albumin) has a half-life of 2–3 days; it is used to determine protein depletion in acute conditions, such as trauma and inflammation, and serves as a guide for nutritional therapy. Pre-albumin levels between 15 mg/dl to 5 mg/dl reflect mild to moderate protein depletion while levels below 5 mg/dl indicate severe protein depletion.

TABLE 38-5

*Values in this table are for height without shoes and weight without clothes. To convert inches to centimeters, multiply by 2.54; to convert pounds to kilograms, multiply by 0.455

**The weight range is the lower weight for small frame and the upper weight for large frame.

(Reproduced courtesy of Metropolitan Life Insurance Company *Statistics Bulletin*.)

Serum Transferrin

Transferrin (nonheme iron) is a blood protein in combination with iron; it is used to transport iron throughout the body to all cells. It is responsive to iron stores, increasing when iron stores are low and decreasing when iron stores are high. This test is considered a sensitive indicator of protein deficiency because it responds promptly to changes in protein intake. Levels below 200 mg/dl may indicate mild to moderate protein depletion and below 100 mg/dl may indicate severe depletion.

Hemoglobin Level

The hemoglobin test measures the oxygen- and iron-carrying capacity of the blood; the normal level is 12 to 15 g/100 ml. A decreased hemoglobin may indicate some form of anemia, such as microcytic iron deficiency anemia, or blood loss.

Total Lymphocyte Count

Another test that may be used to measure protein depletion is total lymphocyte count. Protein deficiency may cause a depression in the immune system, with a resultant

Figure 38-10 Measuring Triceps Skinfold, at Midpoint of the Upper Arm

Figure 38-11 Measuring the Subscapular Skinfold

Figure 38-12 Measuring the Mid-Upper-Arm Circumference

decrease in the total lymphocyte count; this can occur with severe debilitating diseases, such as cancer or renal disease.

Nitrogen Balance

Nitrogen balance studies indicate the degree to which protein is being depleted or replaced in the body. The *blood urea nitrogen (BUN)* is increased with severe dehydration, malnutrition, starvation, excessive protein intake, and most commonly in kidney disease (the kidneys fail to excrete urea). A decreased BUN results from a diet low in protein-rich foods.

Urine Creatinine Excretion

During skeletal muscle metabolism, creatinine is released at a rate in proportion to the total body mass. A 24-hour urine test is done to measure the total amount of creatinine excreted by the kidneys. In mal-

nutrition, the creatinine level is decreased as a result of muscle atrophy.

NURSING DIAGNOSIS

In order to make a nursing diagnosis, the nurse must interpret the subjective and objective data and draw conclusions from the client's assessment data obtained during a comprehensive health history and physical examination. The approved nursing diagnoses are discussed to assist with appropriate selection of primary and secondary nursing diagnoses for clients with nutritional alterations.

Imbalanced Nutrition: Less Than Body Requirements

An estimated 30% to 50% of hospitalized clients are at risk for malnutrition; increased morbidity and mortality rates are associated with malnutrition (McCloskey & Bulechek, 1999). The diagnosis *Imbalanced Nutrition: Less Than Body Requirements* exists when the client fails to ingest or digest food or absorb nutrients. The Nursing Process Highlight lists some possible causes of this nursing diagnosis.

Such clients may experience a weight loss of 20% or more from their ideal weight. The dietary history may reveal: inadequate food intake based on the RDAs; a lack of interest in or an aversion to eating; perceived inability to ingest food; and a reduced energy level. Clients have poor muscle tone, with skinfolds less than

Nursing Process Highlight

Nursing Diagnosis

Multiple factors can cause *Imbalanced Nutrition: Less Than Body Requirements*:

- **Biological:** Buccal cavity discomfort, pain; difficulty in swallowing; stomach strictures, ulcers; inflammation, obstruction of the biliary or intestinal system; chronic diarrhea; pulmonary disorders; postoperative status; transplantation candidate, pre- and post-surgery; cancer and radiation therapy; immunosuppression
- **Psychological:** Anorexia nervosa; bulimia; severe stress, anxiety, fatigue, or depression; prolonged grieving; lack of knowledge; extreme food fad and dieting practices.
- **Economic:** Inadequate finances to purchase protein-rich foods

NURSING TIP

Creatinine Excretion

Record the client's height and sex on the laboratory request for a creatinine excretion test because the normal values are standardized on the basis of these variables.

60% of standard measurement, and may experience difficulty in swallowing or masticating food, because of muscular weakness. The conjunctive and mucous membranes are usually pale, and the buccal cavity is sore and inflamed.

Imbalanced Nutrition: More Than Body Requirements or Risk for More Than Body Requirements

Imbalanced Nutrition: More Than Body Requirements exists when clients experience or are at risk for an intake of nutrients that exceeds metabolic needs. Clients may be at risk because of one or more of the following factors: hereditary predisposition or obesity in one or both parents; dysfunctional psychological conditioning in relationship to food, such as using food as a reward or comfort measure; and age-related factors, most notably early infancy, adolescence, and aging.

Clients with more than body requirements experience a weight gain of 10% to 20% over the ideal for height and frame and triceps skinfolds greater than 15 mm in men and 23 mm in women. The client's dietary history may reveal a sedentary activity level and one or more dysfunctional eating patterns: pairing food with other activities, such as watching TV; concentrating the intake of food at night; eating in response to internal cues (anxiety) or external cues (such as a social event) instead of in response to hunger.

Other Nursing Diagnoses

The client who is protein-depleted may also experience deficiencies in vitamins (especially A and C) and minerals (especially zinc, magnesium, and iron). Refer to the accompanying display for a listing of common secondary nursing diagnoses related to nutritional and metabolic problems. Because the secondary diagnosis is related to the nutritional/metabolic problem, it is written in terms of the etiology of the primary diagnosis, for example, *High Risk for Impaired Skin Integrity: related to inadequate intake of proteins, vitamins, and minerals*.

OUTCOME IDENTIFICATION AND PLANNING

The nurse relies heavily on the data obtained from the nutritional history and collaborates with the client and other health team members in formulating goals and expected outcomes to promote optimal nutritional care. Nursing diagnoses of life-threatening conditions, such as *Impaired Swallowing related to decreased or absent gag reflex*, are given first priority. Other diagnoses that are actual problems take priority over high-risk problems.

SECONDARY NURSING DIAGNOSES FOR CLIENTS WITH NUTRITIONAL PROBLEMS

Activity Intolerance: related to insufficient energy from protein depletion

Acute Pain: related to lactose intolerance

Ineffective Health Maintenance: related to excessive intake of nutrients

Impaired Oral Mucous Membrane: related to dehydration

Ineffective Breathing Pattern: related to decreased energy and fatigue from protein depletion

Constipation: related to inadequate dietary intake and fiber

Ineffective Health Maintenance: related to inadequate financial resources to purchase nutritious foods

Risk for Infection: related to nutrient replacement therapy

Deficient Knowledge: related to information of normal nutrition

Ineffective Therapeutic Regimen Management (individual): related to cultural influences on the client's food preferences

Impaired Swallowing: related to decreased strength of muscles involved in mastication

Chronic Low Self-Esteem: related to obesity

Risk for Impaired Skin Integrity: related to inadequate intake of proteins, vitamins, and minerals

(From NANDA [2001]. *Nursing diagnosis: Definitions & Classifications [2001–2002]*. Philadelphia: Author.)

In the planning phase, the nurse identifies and explains to the client the need for and basis of the therapy. The nurse takes into consideration the client's dietary habits, likes, dislikes, needs, and nutritional assessment data in defining goals and developing outcomes in collaboration with the client. Refer to the accompanying display for a sample list of expected outcomes for clients with imbalanced nutrition and the Research Focus, which concluded that obese binge-eating women had no weight loss with diet or non-diet therapies.

EXPECTED OUTCOMES FOR CLIENTS WITH IMBALANCED NUTRITION

- Client maintains intake and output balance.
- Client consumes the proper amounts of foods from the four food groups, as evidenced by the food-frequency record.
- Client complies with diet therapy, avoiding saturated fats.
- Client tolerates tube feeding without experiencing any vomiting and diarrhea.
- Client remains infection-free while receiving parenteral nutrition.

The nurse selects appropriate nursing interventions to match the client's routine patterns, as obtained in the health history, and to support achievement of the goals and outcomes. Proceeding in this fashion facilitates the client's adaptive capabilities through skillful interventions.

IMPLEMENTATION

The nurse is responsible for understanding the client's nutritional needs and for making clinical judgments relative to outcomes of therapy. This responsibility includes intervening to prevent the rapid depletion of the body's protein and energy reserves. Performance of nursing interventions to accomplish goals and outcomes includes monitoring the client's weight and intake, diet therapy, and feeding. Client teaching occurs with each intervention to maximize the effectiveness of nutritional therapy.

Monitoring Weight and Intake

Weight and intake measurements are used to assess the client's nutritional status and to monitor the effectiveness of therapy. Refer to Chapters 27 and 37 for nursing actions relative to daily weights and intake and output considerations.

Initiating Diet Therapy

Nutritional problems often require dietary modification. Therapeutic nutrition requires consideration of the client's total needs: cultural, socioeconomic, psychological, and physiological. Modified diets should promote effective nutrition within the client's lifestyle; this often requires client teaching regarding the avoidance of certain foods or adding food items to the diet, given the client's sociocultural context, economic restraints, and religious beliefs.

Nothing by Mouth

Placing the client on NPO (nothing by mouth) status is a type of diet modification as well as a fluid restriction; refer to Chapter 37 for a complete discussion of fluid restrictions. This intervention is prescribed prior to surgery and certain diagnostic procedures, to rest the GI tract (and prevent diarrhea or vomiting), or when the client's nutritional problem has not been identified.

Clear-Liquid Diet

Dairy products are not allowed on a clear-liquid diet. The client is allowed to ingest only liquids that keep the GI tract empty (no residue), such as water, apple juice, and gelatin. A clear-liquid diet is prescribed primarily for surgical clients.

Liquid Diet

A liquid (or full liquid diet) consisting of various types of liquids is prescribed mainly for postoperative clients because of calorie and nutrient considerations. If the client tolerates a liquid diet without nausea or vomiting and has normal bowel sounds, the diet is progressed to *as tolerated* (client eats whatever foods that cause no problems).

Soft Diet

A soft diet promotes the mechanical digestion of foods. It is prescribed for clients experiencing difficulty in chewing and swallowing. A soft diet is also therapeutic for clients with impaired digestion and/or absorption, due to conditions such as ulcerative colitis and Crohn's disease. Foods to be avoided on this diet include nuts, seeds (tomatoes and berries with seeds), raw fruits and vegetables, fried foods, and whole grains.

Mechanical Soft Diet

A mechanical soft diet is similar to a soft diet; however, it allows clients variation, permitting foods with different tastes, such as chili beans. It is prescribed for clients experiencing difficulty chewing or who are unable to chew food thoroughly, as may occur with poorly fitted dentures.

Pureed Diet

A pureed diet provides food that has been blenderized to a smooth consistency. It is prescribed for clients with dysphagia, or difficulty in swallowing. Special consideration needs to be given to meal preparation; when food has the same consistency, it is difficult to distinguish the taste of different foods.

Low-Residue Diet

A low-residue diet has reduced fiber and cellulose. It is prescribed to decrease GI mucosal irritation in clients with diverticulitis, ulcerative colitis, and Crohn's disease. Foods to be avoided are raw fruits (except bananas), vegetables, seeds, plant fiber, and whole grains. Dairy products are limited to two servings a day.

High-Fiber Diet

High-fiber-diet foods are the opposite of low-residue foods. A high-fiber diet is an integral part of the treatment regimen for diverticulosis because it increases the forward motion of the indigestible wastes through the colon. See the accompanying Research Focus for additional information.

Liberal Bland Diet

A liberal bland diet eliminates chemical and mechanical food irritants, such as fried foods, alcohol, and caffeine.

RESEARCH FOCUS

Title of Study

“Nondietering Versus Dietering Treatment for Overweight Binge-Eating Women”

Authors

Goodrick, G., Poston II, W. S. C., & Kimball, K. T.

Purpose

Randomized controlled trial of women who are overweight and binge-eat to measure the effectiveness of a nondieting intervention with a behavioral dieting intervention.

Methods

A total of 219 women who responded to media advertisement with the following characteristics were included in the study: 25–50 years of age; 14–41 kg overweight; scored 0.20 on the Binge Eating Scale; had no history of diabetes, cardiovascular or gastrointestinal diseases; had no purging behaviors within the previous 6 months; were not pregnant or breast feeding; had physician clearance for a walking regimen; were not enrolled in another weight loss program; and did not smoke. Participants were placed in a dieting treatment or nondieting treatment group or to a waiting list control group (WLC). Weight, eating dyscontrol, and physical activity were assessed in all groups after 6 months of treatment and in the two intervention groups at 18 months.

Findings

There was no weight loss in the two intervention groups at 6 months when compared with the WLC group; both interventions reduced binge eating. The two treatment groups at 18 months had similar weight gains and decreases in binge eating scores, and both maintained modest increases in exercise.

Implications

Professional nurses in ambulatory settings need to recognize the complexity of issues surrounding weight management.

Goodrick, G., Poston II, W. S. C., & Kimball, K. T. (1998). Nondietering versus treatment for overweight binge-eating women. *Journal of Consulting Clinical Psychology, 66*(4), 363–368.

Fat-Controlled Diet

Fat-controlled diets reduce the total fat ingested by replacing saturated fats with monounsaturated and polyunsaturated fats and restricting cholesterol. They are prescribed for clients with atherosclerosis, heart disease, and obesity. Saturated foods to be avoided include animal fats, gravies, sauces, chocolate, and whole-milk products.

Sodium-Restricted Diet

Sodium intake may be restricted as follows: mild, 2 to 3 g; moderate, 1000 mg; strict, 500 mg; severe, 250 mg. A sodium-restricted diet is prescribed for clients with excess fluid volume, hypertension, heart failure, myocardial infarction, and renal failure.

Lactose Intolerance Diet

A lactose intolerance diet eliminates milk and all dairy products except yogurt. **Lactose** is a sugar found in milk and aids the body absorption of calcium. Lactose intolerance is caused by a lack or deficiency of lactase, an enzyme normally made in the small intestines that splits lactose into glucose and galactose. Incomplete digestion of lactose results in diarrhea, gas, and abdominal cramps between 30 minutes and 2 hours after consumption of dairy foods.

Candidiasis Diet

The candidiasis diet is free of fruits, sugar, yeast, and fermented foods. *Candida albicans* is a normal parasitic yeast-like fungus that lives in healthy balance with other bacteria and yeasts in the body. In response to certain conditions or therapies such as antibiotics or chemotherapy, this fungus may multiply, weakening the immune system and causing an infection known as candidiasis. Candidiasis can infect any bodily structure that contains mucous membranes, the most common being the mouth, ears, nose, gastrointestinal tract, and vagina. Candidiasis may be characterized by many symptoms ranging from diarrhea, acne, muscle and joint pain to impotence, PMS, fatigue, vaginitis, kidney and bladder infections, arthritis, depression, and even diabetes (Balch & Balch, 1997).

Assistance with Feeding

Assessment data provide direction regarding how to assist the client with eating. Clients with difficulty in self-feeding, chewing, or swallowing will require assistance to promote safety and adequate intake of nutrients; see the Nursing Process Highlight.

Because eating is a social activity (Figure 38-13), it is important to encourage a family member or friend to be present at meals. If this is not possible, assess the avail-

This diet is prescribed for clients with gastritis and ulcers because it reduces GI irritation.

Nursing Process Highlight

IMPLEMENTATION

Nursing Measures That Promote Client Feeding

- Before bringing the meal tray into the room, ask whether the client needs to void or have a bowel movement.
- Provide hygiene measures before serving the meal tray.
- Position the client in a comfortable position, preferably in a chair, if not contraindicated.
- Ask about the client's eating habits, and as to the foods he or she prefers to eat first. Ask what help is needed. For instance, elderly people may want scrambled eggs placed in a sandwich to make them easier to handle.
- Make sure the foods are being served at the correct temperature.
- Provide assistance if the client is unable to handle eating utensils or open containers and packages.
- Provide adequate time for the client who has difficulty in chewing or swallowing. Make sure that someone is in the room while the client is eating.
- Document the type and amount of food taken at each meal.
- Remove the tray after the meal and provide hygiene measures.

ability of other resources to provide social stimulation during meals, such as watching TV, listening to music, or having a staff member remain with the client.

Providing Nutrition Support

Proper nutrition in hospitalized clients is necessary for wound healing, recovery, reduction in morbidity, and consequent reductions in length of stay and mortality.

Figure 38-13 Eating is a social activity.

NURSING TIP

Facilitating Feeding for the Client with Impaired Vision

Clients with impaired vision need established routines that facilitate feeding. For example, foods are usually placed on the plate in a clockwise order: bread at the 12 o'clock position, meat at 3 o'clock, starches at 6 o'clock, and vegetable at 9 o'clock. The plate should have a raised edge so that the food can be scooped to the outside of the plate. Serving liquids in either a glass or a cup with a plastic lid and straw may be helpful to avoid spills.

The most common nutritional deficiency in hospitalized clients is protein-energy malnutrition. This type of malnutrition depletes body cell mass and impairs tissue and organ function. When protein-energy malnutrition is left untreated, the following client negative outcomes may occur:

- Weakness
- Compromised immunity
- Decreased wound healing
- Increased risk for complications

Nutrition support is prescribed for those clients at risk for protein-energy malnutrition.

There are two routes for delivery of nutrition support (NS) in adult clients: enteral nutrition (EN) and parenteral nutrition (PN). **Enteral nutrition** includes both the ingestion of food orally and the delivery of nutrients through a gastrointestinal tube. **Parenteral nutrition** refers to nutrients bypassing the small intestine and entering the blood directly. EN is preferred over PN because of decreased bacterial translocation and reduced expense, and is usually delivered through a feeding tube (Figure 38-14).

Critical indicators for determining the feeding route and nutrition support formula include GI function, expected duration of therapy, aspiration risk, and the potential for or the actual development of organ dysfunction. For example, the decision to initiate PN or EN support is based on evidence that the client is unable to meet his or her own nutritional needs by oral intake and will therefore experience malnutrition. Refer to Figure 38-15 for a clinical-decision algorithm that outlines the selection process for choosing the route of nutritional support in adult clients. The client's nutrition support may be determined by a nutrition support team (NST) in accord with the American Society for Parenteral and Enteral Nutrition (ASPEN) guidelines.

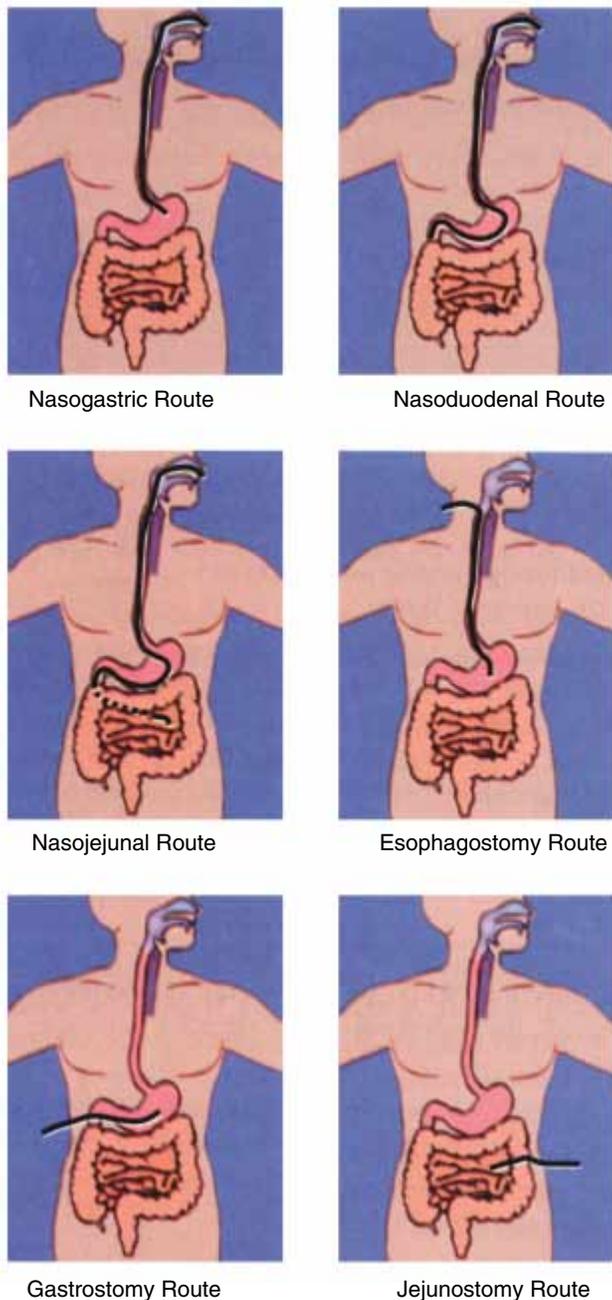

Figure 38-14 Enteral Feeding Routes

Nutrition Support Teams

Since the early 1980s, nutrition support teams (NSTs) were established to reduce the complications of PN. To achieve the expertise required for a consulting service, the teams have become multidisciplinary.

The nurse is seen as the vital link between the client and other team members to include a physician, nurse, pharmacist, and dietitian; see the accompanying display for the functions of NSTs. The nurse's role is critical, both for the implementation of nutritional support and for ongoing assessment, because the nurse administers and monitors nutritional therapies.

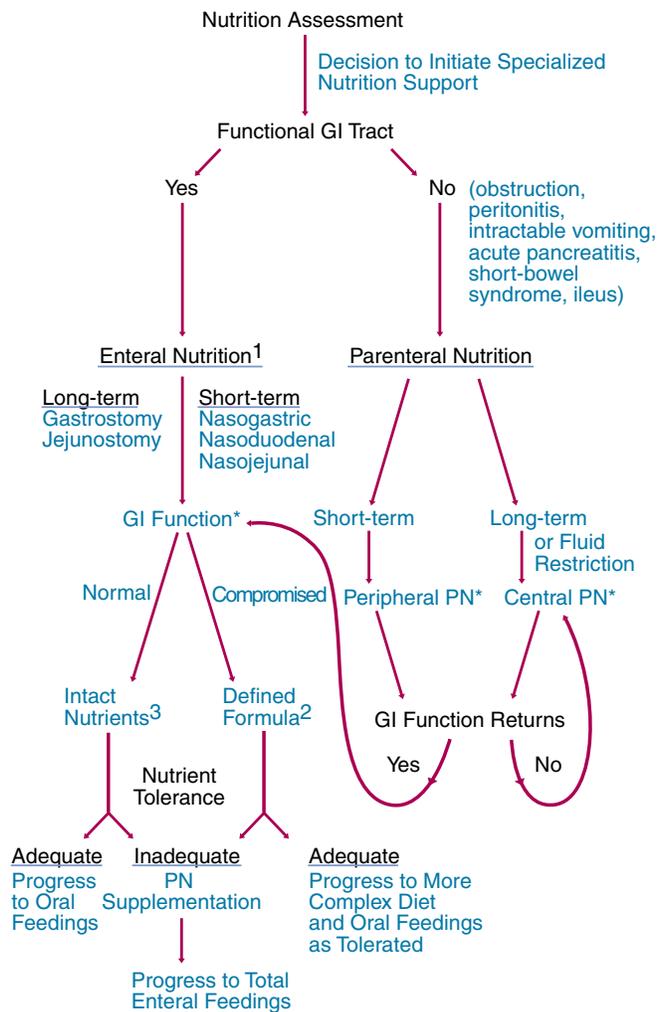

Figure 38-15 Clinical Decision Algorithm (Reprinted from the American Society for Parenteral and Enteral Nutrition [ASPEN], [1993]. Guidelines for the use of parenteral and enteral nutrition in adult and pediatric patients. *Journal of Parenteral and Enteral Nutrition*, 17, 15A–52SA. ASPEN does not endorse this material in any form other than its entirety. For information on ordering a complete set of guidelines, contact ASPEN, 8630 Fenton Street, Silver Spring, MD 20910, [301] 587-6315.)

CLINICAL FUNCTIONS OF NUTRITION SUPPORT TEAMS

- Identification of clients who are nutrition-impaired or at risk for malnutrition
- Performance of a nutritional assessment to guide nutritional therapy
- Provision of nutritional support that is safe and effective

The nurse is also responsible for eliciting the client's or family's continued consent and collaboration with the therapy. The physician obtains the client's informed consent for starting the therapy. The nurse teaches the

client and family about the nutritional support to restore a sense of independence and self-esteem. Many staff nurses are board-certified in nutrition support by ASPEN.

Providing Enteral Nutrition

Candidates for enteral tube feeding are clients who have a functional GI tract and will not, should not, or cannot eat. Therefore, tube feedings are used for clients who are (or may become) malnourished and in whom oral feedings are insufficient to maintain adequate nutritional status.

Enteral tube feedings maintain the structural and functional integrity of the GI tract, enhance the utilization of nutrients, and provide a safe and economical method of feeding. Enteral tube feedings are contraindicated in clients with the following:

- Diffused peritonitis
- Intestinal obstruction that prohibits normal bowel functioning
- Intractable vomiting; paralytic ileus
- Severe diarrhea

NURSING ALERT

Tube Feedings

An enteral tube feeding is used with caution in clients with severe pancreatitis, enterocutaneous fistulae, and GI ischemia. These feedings are not recommended during the early stages of short-bowel syndrome or in the presence of severe malabsorption.

Feeding Tubes

Most feeding tubes are made of silicone or polyurethane, which are durable and biocompatible with formulas. They vary in diameter (8 to 12 French) and length in accord with the route and formula. The physician selects the route (Figure 38-14) and type of feeding tube on the basis of the anticipated duration of feeding, the condition of the GI tract, and the potential for aspiration.

Insertion of Enteral Feeding Tubes

Nasoenteral insertion of a gastric feeding tube is the simplest and most often used method of tube feeding. It is used as a temporary measure for clients who are expected to resume oral feeding. Nasogastric intubation refers to insertion of a tube through the nostril into the stomach; refer to Procedure 38-1. Nasoduodenal or nasojejunal intubation allows nasal access to the duodenum and jejunum; it is done with a longer tube and

NURSING ALERT

Small-Bore Feeding Tube

When inserting a small-bore feeding tube with the guidewire or stylet, never attempt to reinsert the guidewire or stylet while the tube is in the client. The guidewire or stylet may perforate the GI mucosa, especially the esophagus, and injure the client.

decreases the client's risk of vomiting and aspiration. Radiographic visualization is used to confirm tube placement prior to feeding.

Enterostomy is the surgical creation of an artificial fistula (gastrostomy, jejunostomy) in the intestines by incision through the abdominal wall. Tube enterostomies can be placed at various points along the GI tract and are performed when long-term tube feeding is anticipated or when obstruction makes nasal intubation impossible.

Percutaneous endoscopic gastrostomy (PEG) tube placement is usually performed by the physician at the bedside or in the endoscopy room; *insertion of a PEG tube does not require surgery*. Endoscopy nurses are often trained to assist with PEG placement. PEG has become an accepted technique to provide enteral access for both children and adults (Wilson, 2000).

Enteral Formulas

Nutrients administered through tubes are liquefied so they can be easily digested and absorbed. Commercially prepared formulas are available and used in most health care settings. There are three basic types of formulas, which differ in osmolality, digestibility, kilocalories, lactose content, viscosity, and fat content; see the accompanying display.

Administration of Enteral Feedings

Once the feeding tube's position has been radiographically verified, the formula can be administered as prescribed; refer to Procedure 38-2. Most clients with a small-bore tube receive continuous feeding with a formula pump to regulate the rate. One of the advantages of continuous feeding is that it keeps gastric volume small, minimizing residual volume and reducing the risk of aspiration pneumonia; the client is less likely to experience bloating, nausea, abdominal distention, and diarrhea.

NURSING ALERT

Allergies

Before administering a tube feeding, determine whether the client has any food allergies. Clients may be lactose-intolerant or have an allergy to the formula.

PROCEDURE 38-1

Inserting a Nasogastric or Nasojejunal Tube for Suction and Enteral Feedings

Equipment

- Nonsterile gloves
- Cup of ice or water and straw
- Towel and tissues
- Flashlight or penlight
- Hypoallergenic tape, rubber band, safety pin
- 20-ml syringe or asepto syringe, 30 ml or larger with small bore tube
- Disposable irrigation set (optional)
- Wall mount or portable suction equipment as available
- Ice chips in an emesis basin
- Water-soluble lubricant
- Tongue blade
- pH chemstrip
- Number 6, 8, 12 French tube for gastric suction (Levine, Salem sump, or Anderson) or a small-bore feeding tube, 8 or 12 French tube (Keofeed, Dobbhoff, Moss)
- Administration set with pump or controller for feeding tube

Action

1. Review client's medical record.

Nasogastric Tube Insertion

2. Gather equipment. Wash hands.
3. Check client's armband; explain procedure, showing items.
4. Place client in Fowler's position, at least a 45° angle or higher, with a pillow behind client's shoulders; provide for privacy. *Place comatose clients in semi-Fowler's position.*
5. Place towel over chest, put tissues in reach. Don gloves.
6. Examine nostrils and assess as client breathes through each nostril.
7. Measure length of tubing needed by using tube as a tape measure:
 - Measure from bridge of client's nose to earlobe to xiphoid process of sternum (Figure 38-16A).
 - If tube is to go below stomach (nasoduodenal or nasojejunal), add an additional 15 to 20 cm (Figure 38-16B).
 - Place a small piece of tape on tube to mark length.

Figure 38-16A Measuring the Length of Nasogastric Tubing.

Rationale

1. Confirms physician's prescription for inserting a nasogastric tube; history of nasal or sinus problems.
2. Promotes efficiency. Reduces transfer of microorganisms.
3. Verifies correct client; reduces anxiety and increases client cooperation.
4. Facilitates passage of the tube into the esophagus and swallowing.
5. Prevents soiling of gown and bedding and protects nurse from contamination with bodily fluids; lacrimation can occur during insertion through nasal passages.
6. Determines the most patent nostril to facilitate insertion.
7. Approximates length of tube needed to reach stomach.

(continues)

Figure 38-16B Measuring Length of Nasoduodenal or Nasojejunal Tubing.

PROCEDURE 38-1

Inserting a Nasogastric or Nasointestinal Tube for Suction and Enteral Feedings (continued)

<i>Action</i>	<i>Rationale</i>
8. Have client blow nose and encourage swallowing of water if level of consciousness and treatment plan permit.	8. Clears nasal passage without pushing microorganisms into inner ear; facilitates passage of tube.
9. Lubricate first 4 inches of tube with water-soluble lubricant.	9. Facilitates passage into the nares.
10. Insert tube as follows: <ul style="list-style-type: none"> • Gently pass tube into nostril to back of throat (client may gag); aim tube toward back of throat and down. • When client feels tube in back of throat, use flashlight or penlight to locate tip of tube. • Instruct client to flex head toward chest. • Instruct client to swallow, offer ice chips or water, and advance tube as client swallows. • If resistance is met, rotate tube slowly with downward advancement toward client's closest ear; do not force tube. 	10. Promotes passage of tube with minimal trauma to mucosa. <ul style="list-style-type: none"> • Ensures tip's placement. • Opens esophagus and assists in tube insertion after tube has passed through nasopharynx and reduces risk of tube entering trachea. • Assists in pushing tube past oropharynx. • Tube may be coiled or kinked or in the oropharynx or trachea.
11. Withdraw tube immediately if changes occur in respiratory status.	11. Indicates placement of tube in the bronchus or lung.
12. Advance tube, giving client sips of water, until taped mark is reached.	12. Assists with tube insertion.
13. Check placement of tube: <ul style="list-style-type: none"> • Attach syringe to free end of tube and aspirate sample of gastric contents and measure with chemstrip pH (Figure 38-17). 	13. Ensures proper placement in the stomach; pH below 3, tube is in stomach; a pH range of 6 to 7 indicates intestinal sites.

Figure 38-17 For Measuring the pH of Aspirate

- Leave syringe attached to free end of tube.
 - If prescribed, obtain x-ray; keep client on right side until x-ray is taken.
14. Secure tube with tape as shown in Figure 38-18 or use a commercially prepared tube holder.
- Prevents leakage of gastric contents.
 - Confirms correct placement; if nasoduodenal or nasojejunal feedings are required, passage through pylorus may require several days.
14. Prevents tube from becoming dislodged.

(continues)

PROCEDURE 38-1

Inserting a Nasogastric or Nasointestinal Tube for Suction and Enteral Feedings (continued)

Action

Rationale

Figure 38-18 Securing Tube to the Client's Nose with Tape

- Split a 4-inch piece of tape to a length of 2 inches and secure tube with tape by placing the intact end of the tape over the bridge of the nose. Wrap split ends around the tube as it exits the nose.
 - Place a rubber band, using a slip knot, around the exposed tube (12–18 inches from nose toward chest); after x-ray, pin rubber band to client's gown.
15. Instruct client about movements that can dislodge the tube.
 16. Gastric decompression:
 - Remove syringe from free end of tube and connect tube to suction tubing; set machine on type of suction and pressure as prescribed.
 - Levine tubes are connected to intermittent low pressure.
 - Salem sump or Anderson's tube is connected to continuous low suction.
 - Observe nature and amount of gastric tube drainage.
 - Assess client for nausea, vomiting, and abdominal distention.
 17. Provide oral hygiene and cleanse nares with a tissue.
 18. Remove gloves, dispose of contaminated materials in proper container, and wash hands.
- Prevents trauma to nasal mucosa by reducing pressure on nares.
 - Allows client movement without causing friction on nares; metal devices are removed for x-rays to prevent artifacts.
15. Reduces anxiety and teaches client how to prevent tugging on tube with head movement.
 16. Provides for decompression as prescribed by physician; intermittent or continuous suctioning is determined by type of tube inserted.
- Provides information about patency of tube and gastric contents.
 - Indicates effectiveness of intervention.
17. Promotes comfort.
 18. Reduces transmission of microorganisms; protects other workers from coming into contact with objects contaminated with body fluids.

(continues)

PROCEDURE 38-1

Inserting a Nasogastric or Nasointestinal Tube for Suction and Enteral Feedings (continued)

<i>Action</i>	<i>Rationale</i>
19. Position client for comfort, and place call light in easy reach.	19. Promotes comfort and safety.
20. Document: <ul style="list-style-type: none"> • The reason for the tube insertion • The type of tube inserted • The type (intermittent or continuous) of suctioning and pressure setting • The nature and amount of aspirate and drainage • The client's tolerance of the procedure • The effectiveness of the intervention, such as nausea relieved 	20. Promotes continuity of care and shows implementation of intervention.
Insertion of a Small-Bore Feeding Tube	
21. Repeat steps 1 through 8 as stated earlier.	21. See steps 1 through 8.
22. Open adapter cap on tube, snap off end of water vial, and inject water into feeding tube adapter.	22. Activates Keolube lubricant in tube's lumen.
23. Close adapter cap.	23. Ensures a tight fit so water does not leak from adapter site.
24. Check that stylet does not protrude through holes in feeding tube; adjust as necessary.	24. Prevents mucosa trauma.
25. Repeat steps 9 through 12 as stated earlier.	25. See steps 9 through 12.
26. Check placement of tube: <ul style="list-style-type: none"> • Aspirate gastric contents with Luerlock syringe; see Figure 38-19. • Measure pH of aspirate with chemstrip pH. 	26. Assures correct placement has been achieved; provides measurement of pH of secretions, as explained in step 13. <i>Note:</i> May not be able to aspirate contents from small bore tubes.

Figure 38-19 Aspirating Gastric Contents with Luerlock Syringe with Stylet in Place

(continues)

PROCEDURE 38-1

Inserting a Nasogastric or Nasointestinal Tube for Suction and Enteral Feedings (continued)

Action

27. Leave stylet in place until x-ray confirms that placement in case tube needs to be advanced into the duodenum or jejunum.
28. Obtain x-ray. Remove stylet from feeding tube after x-ray, and plug open end of tube until feeding.
29. Repeat steps 17 through 20.
30. Replace small-bore tube every 3 to 4 weeks.

Rationale

27. Provides a safety measure. See the Nursing Alert on small-bore feeding tubes on p. 1165.
28. Confirms placement of tube prior to instilling formula; prevents gastric juices from seeping out of the tube.
29. See steps 17 through 20.
30. Prevents obstruction and sepsis of small-bore tubes.

PROCEDURE 38-2

Administering Enteral Tube Feedings

Equipment

- | | |
|--|------------------------------------|
| ■ Asepto syringe or 20- to 50-ml syringe | ■ Emesis basin |
| ■ Clean towel | ■ Disposable gavage bag and tubing |
| ■ Formula | ■ Infusion pump for feeding tube |
| ■ Water to follow feeding | ■ Nonsterile gloves |

Action

1. Review client's medical record.
2. Gather equipment.
3. Check client's armband.
4. Explain procedure to client.
5. Assemble equipment. If using a bag, fill with prescribed amount of formula.

Rationale

1. Verifies physician's prescription for appropriate formula and amount.
2. Promotes efficiency during procedure.
3. Verifies correct client.
4. Reduces anxiety and increases client cooperation.
5. Ensures efficiency when initiating feeding.

Figure 38-20 Preparing Formula

(continues)

PROCEDURE 38-2

Administering Enteral Tube Feedings (continued)

<i>Action</i>	<i>Rationale</i>
<ol style="list-style-type: none"> 6. Place client on right side in high Fowler's position. 7. Wash hands and don nonsterile gloves. 8. Provide for privacy. 9. Observe for abdominal distention; auscultate for bowel sounds. 10. Check feeding tube: Insert syringe into adapter port, aspirate stomach contents, and determine amount of gastric residual. <ul style="list-style-type: none"> • If residual is greater than 50 to 100 ml (or in accordance with agency protocol), hold feeding until residual diminishes. • Instill aspirated contents back into feeding tube. 11. Administer tube feeding: 	<ol style="list-style-type: none"> 6. Reduces risk of pulmonary aspiration in event client vomits or regurgitates formula. 7. Reduces transmission of pathogens from gastric contents. 8. Places client at ease. 9. Assesses for delayed gastric emptying; indicates presence of peristalsis and ability of GI tract to digest nutrients. 10. Indicates whether gastric emptying is delayed. <ul style="list-style-type: none"> • Reduces risk of regurgitation and pulmonary aspiration related to gastric distention. • Prevents electrolyte imbalance. 11. Provides nutrients as prescribed.
Intermittent—Bolus	
<ul style="list-style-type: none"> • Pinch the tubing. • Remove plunger from barrel of syringe and attach to adapter. • Fill syringe with formula; see Figure 38-21. • Allow formula to infuse slowly; continue adding formula to syringe until prescribed amount has been administered. • Flush tubing with 30 to 60 ml or prescribed amount of water. 	<ul style="list-style-type: none"> • Prevents air from entering tubing. • Provides system to delivery feeding. • Allows gravity to control flow rate, reducing risk of diarrhea from bolus feeding. • Prevents air from entering stomach and reduces risk for gas accumulation. • Maintains patency of feeding tube.

Figure 38-21 Adding Formula to Nasogastric Tube

(continues)

PROCEDURE 38-2

Administering Enteral Tube Feedings (continued)

<i>Action</i>	<i>Rationale</i>
Intermittent—Gavage Feeding	
<ul style="list-style-type: none"> • Hang bag on IV pole so that it is 18 inches above the client's head. • Remove air from bag's tubing. • Attach distal end of tubing to feeding tube adapter and adjust drip to infuse over prescribed time. • When bag empties of formula, add 30 to 60 ml or prescribed amount of water; close clamp. • Change gavage bag every 24 hours or wash reusable gavage bag with soap and hot water every 24 hours. 	<ul style="list-style-type: none"> • Allows gravity to promote infusion of formula. • Prevents air from entering stomach. • Decreases risk of diarrhea. • Ensures that remaining formula in tubing is administered and maintains patency of tube; prevents air from entering the stomach. • Decreases risk of multiplication of microorganisms in bag and tubing.
Continuous Gavage	
<ul style="list-style-type: none"> • Check tube placement at least every 4 hours. • Check residual at least every 8 hours. • If residual is above 100 ml, stop feeding. • Add prescribed amount of formula to bag for a 4-hour period; dilute with water if prescribed. • Hang gavage bag on IV pole. • Prime tubing. • Thread tubing through feeding pump and attach distal end of tubing to feeding tube adapter; keep tubing straight between bag and pump. • Adjust drip rate. • Monitor infusion rate and signs of respiratory distress or diarrhea. • Flush tube with water every 4 hours as prescribed or following administration of medications. • Replace disposable feeding bag at least every 24 hours, in accord with agency's protocol. • Turn client every 2 hours. • Provide oral hygiene every 2 to 4 hours. 	<ul style="list-style-type: none"> • Ensures that feeding tube remains in stomach. • Indicates ability of GI tract to digest and absorb nutrients. • Reduces risk of regurgitation and pulmonary aspiration related to gastric distention. • Provides client with prescribed nutrients and prevents bacterial growth (formula is easily contaminated). • Removes air from tubing. • Provides for controlled flow rate; prevents loops in tubing. • Infuses formula over prescribed time. • Prevents complications associated with continuous gavage. • Maintains patency of tube. • Decreases risks of microorganisms. • Promotes digestion and reduces skin breakdown. • Provides comfort and maintains the integrity of buccal cavity.

(continues)

PROCEDURE 38-2

Administering Enteral Tube Feedings (continued)

Action	Rationale
12. Administer water as prescribed with and between feedings.	12. Ensures adequate hydration.
13. Clamp proximal end of feeding tube after formula has been administered.	13. Prevents air from entering the tube.
14. Remove gloves and wash hands.	14. Reduces risk of transmission of microorganisms.
15. Record total amount of formula and water administered on I&O form and client's response to feeding.	15. Documents administration of feeding and achievement of expected outcome; for example, client tolerates feeding and weight is maintained or increased.

BASIC TYPES OF FORMULAS

- *Isotonic formula* contains proteins, fats, and carbohydrates with a high molecular weight and an osmolality equal to that of the body (300 mOsm). Isocal and Osmolite are isotonic formulas that supply 1 kcal/ml and are lactose-free.
- *Elemental (monomeric) formula* contains monosaccharides and amino acids with minimal triglyceride content in hypertonic concentrations. Vivonex and Vivonex HN are elemental formulas that supply 1 kcal/ml; they are started at half strength or less and gradually increased to full strength due to their hypertonic concentration.
- *Fluid restriction formula* contains a highly concentrated source of kilocalories (2 kcal/ml). Magnacal is a fluid restriction formula that is started at half strength or less and gradually increased to full strength due to the hypertonic concentration.

Safety Considerations

Clients receiving EN through a feeding tube are at risk for aspiration. The prevalence of tube placement errors, as reported in the literature, varies from 1.3% to 50% in adults (Cirgin & Marsha, 1997). Tube feeding aspiration can result from several factors: displacement of the tube into the esophagus, large amounts of gastric residual, and lowered intestinal motility and delayed gastric emptying, which may occur in clients who are on bed rest or receiving narcotics for pain relief (Pratt & Tolbert, 1996). Auscultate for bowel sounds to determine gastric motility. If the bowel sounds are hypoactive or absent, stop or withhold additional feeding and notify the physician.

Always assess placement of the feeding tube before administering any liquids. Clients who are receiving continuous gastric feeding should be assessed every 4 hours for tube placement and residual gastric contents. Aspirate gastric contents with a syringe. This is done

more easily with a large-bore tube than a small-bore tube. The lumen of a small-bore tube collapses easily, making aspiration difficult and sometimes impossible. Observe and check the pH of the aspirate as explained in Procedure 38-1; refer to the Research Focus. Replace stomach contents after checking the residual to prevent fluid and electrolyte imbalance.

Another way of determining tube placement is to visually examine the aspirate; refer to the accompanying display. If the pleural aspirates contain blood, they will fail to show their normal characteristics.

Client safety and comfort require daily cleansing of the feeding tube's exit site. Cleanse the skin with a clean washcloth, soap, and water. Nasal feeding tubes require daily removal of the tape from the nose, cleansing, and inspection of the skin for irritation, inflammation, and infection and the nares for erosions, ulcers, or abscesses.

CHARACTERISTICS OF ASPIRATES

Gastric Aspirates

Cloudy and green, tan or off-white, or bloody or brown (fresh or old blood)

Intestinal Aspirates

Basically clear and yellow to bile-colored

Pleural Aspirates

Tan or off-white mucus, may be pale yellow and serous (indicating blood)

NURSING ALERT

Gastric Resection

Never insert, manipulate, or remove a nasogastric tube on gastric resection clients; *the suture line could easily be interrupted, causing hemorrhage.*

RESEARCH FOCUS

Title of Study

“pH and Concentration of Bilirubin in Feeding Tube Aspirates as Predictors of Tube Placement”

Authors

Metheny, N. A., Stewart, B. J., Smith, L., Yan, H., Diebold, M., & Clouse, R. E.

Purpose

This is a descriptive study to correctly predict feeding tube placement based on pH and the concentration of bilirubin in feeding tube aspirates.

Methods

Over a 3-year period, a total of 587 samples were collected and analyzed for concurrent pH and bilirubin from adult clients in a variety of acute care settings. A total of 437 gastrointestinal samples were obtained for pH and bilirubin testing from newly inserted small-bore feeding tubes; 125 tracheobronchial secretions were obtained by suctioning clients with artificial airways, and 24 pleural fluid samples were obtained at the time of thoracenteses to provide additional respiratory samples. Certain clients were excluded from the study based on previous gastric surgery or trauma, oral or tube-administered medications prior to sample collection, and samples that were grossly bloody. Data from the pH and bilirubin tests were compared with tube location as determined by radiography.

Findings

Samples from concurrent pH and bilirubin testing could significantly decrease the number of x-rays needed to exclude respiratory placement and to distinguish between gastric and intestinal placement.

Implications

The professional nurse needs quantifiable methods at the bedside to determine placement of feeding tubes. Although the pH is measurable at the bedside, research needs to address a clinical laboratory testing product for measuring bilirubin content in gastrointestinal and respiratory aspirates at the bedside.

Metheny, N. A., Stewart, B. J., Smith, L., Yan, H., Diebold, M., & Clouse, R. E. (1999). pH and concentration of bilirubin in feeding tube aspirates as predictors of tube placement. *Nursing Research*, 48(4), 189–197.

Enterostomy tubes require surgical asepsis of the exit site until the incision heals; rotate the tubes within the stoma to promote healing. Report any observations of redness, irritation, or gastric leakage at the site. Once the stoma has healed, the tube can be removed and reinserted for each feeding. Between feedings, a prosthetic device may be used to cover the ostomy opening.

PEG tubes require daily rotation to relieve pressure on the skin. Notify the physician if you are unable to rotate the PEG; it may be an indication of internal embedding of the tube into the gastric wall. When the tube is internally embedded, it can cause gastric acid reflux, which results in skin breakdown, sepsis, and cellulitis. Care must be taken to avoid dislodgment of the tube. Keep it secured to the client’s abdomen with tape, being careful not to use excessive tension. PEG tubes require frequent flushing to prevent clogging. These tubes have small lumens. If a tube becomes clogged, flush it with 60 ml of lukewarm tap water.

APPLICATION: HOME CARE

Clients with feeding tubes may be discharged to the home. The NST evaluates these clients to determine:

- Ability to meet nutrient requirements orally
- Clinical status relative to home discharge
- Tolerance of prescribed nutritional therapy
- Willingness and ability to perform the necessary tasks of tube feeding
- Benefits of continuing therapy at home

The NST works with the client and caregiver to secure the necessary supplies prior to discharge from the hospital. Clients on home feedings require monitoring by nurses and nutritional support specialists who are familiar with the procedure and complications of enteral tube feeding.

Potential Complications

Clients receiving EN need to be monitored closely to prevent complications. The nurse should perform the following actions:

1. Assess the client for signs of gastric retention: nausea, vomiting, and cramping. Palpate the abdomen for distention; auscultate for bowel sounds with a stethoscope; and aspirate the gastric contents every 4 hours. If the aspirate exceeds 100 ml in a 4-hour period or if bowel sounds are absent (indicating an ileus), discontinue the feeding and notify the physician. *Do not remove the feeding tube.*
2. Monitor the feeding tube placement every 4 hours by checking for any coils or kinks in the back of the throat and measuring the length of tubing outside the body.
3. Assess the client for pulmonary aspiration by checking the gag reflex. If the reflex is absent, suction the client.

Discontinue the feeding and remove the tube if signs of respiratory distress are present and notify the physician.

4. Keep the client in a high Fowler's position to prevent aspiration if vomiting should occur. If vomiting does occur, suction client immediately and assess the formula amount and rate at which it was given.
5. Dilute feedings to half strength and slow the feeding time to prevent diarrhea.
6. To maintain or achieve patency of gastric and/or jejunostomy feeding tubes, a medical device called a DeClogger may be used as prescribed by the client's physician to maintain the patency of these tubes.

Teach the client and caregiver how to monitor for complications prior to discharge for home treatment. The client and caregiver should be given the opportunity to practice these assessment measures and demonstrate competency in performing the actual procedures.

NURSING CHECKLIST

Use of a DeClogger

1. Gather equipment: towel, receptacle for used items, nonsterile gloves, appropriate size DeClogger that corresponds to the size of the feeding tube as prescribed by the physician.
2. Verify the health care practitioner's prescription.
3. Review the agency's policy.
4. Check the client's armband, and explain the procedure.
5. Provide for privacy.
6. Wash hands.
7. Turn the enteral feeding pump to the PAUSE mode; if feeding to gravity, clamp the tubing.
8. Don nonsterile gloves.
9. Place the clean towel under the tube to protect the bed linens.
10. Disconnect tubing, and place cap on delivery tube to prevent contamination.
11. Attempt to flush tube with 30–60 cc of water.
12. Gently insert the appropriate size DeClogger into the opening of the tube.
13. Slowly rotate the DeClogger in a clockwise fashion until the stop disc meets the opening of the tube.
14. To remove, slowly rotate the DeClogger in a counter-clockwise fashion as you pull back on the device.
15. Flush the feeding tube with 30–60 cc of water.
16. Reconnect the delivery tube, and restart enteral feedings.
17. Discard the DeClogger into the receptacle, remove gloves, place in receptacle, and dispose of receptacle in accord with agency policy.
18. Wash hands, and document procedure in the client's medical record.

NURSING CHECKLIST

Removal of a Nasogastric Tube

1. Gather equipment: tube plug or clamp, towel, washcloth, paper towel, receptacle for contaminated items, and nonsterile gloves.
2. Verify the physician's prescription.
3. Check the client's armband and explain the procedure.
4. Provide for privacy.
5. Wash hands and don gloves.
6. Place the client in a high Fowler's position and adjust the height of the bed to a comfortable working position.
7. Place the towel across the client's chest.
8. Clamp or plug the tube and unpin the tube from client's gown.
9. Remove the tape securing the tube from the client's nose.
10. Hold the paper towel open in your nondominant hand under the client's chin; with your dominant hand, grasp and pinch the tube near the nostril, and remove the tube with a steady, continuous pull, allowing the tube to fall into the paper towel.
11. Dispose of the tube and paper towel in the receptacle.
12. Clean the client's nares and provide oral hygiene.
13. Position the client comfortably, place call light in easy reach, and return bed to a low position.
14. Remove gloves, place in receptacle, and dispose of receptacle in accord with agency policy.
15. Wash hands and document procedure in the client's medical record.

Removal of a Nasogastric Tube

When the physician determines that the client's nutritional status no longer warrants EN therapy or the need to provide decompression of the gastric contents, the nasogastric tube is removed; refer to the nursing checklist. If the client is connected to suction for decompression, the physician may prescribe clamping the tubing for several hours prior to removal, to ensure a functioning GI tract.

Providing Parenteral Nutrition

Parenteral nutrition is the infusion of a solution directly into a vein to meet the client's daily nutritional requirements. Formerly called hyperalimentation, it is frequently referred to as **total parenteral nutrition (TPN)**, the intravenous infusion of a solution containing

Nursing Process Highlight

IMPLEMENTATION

Malnourished clients are prone to infections because their immune systems have been compromised. EN and PN provide a positive medium for potential growth of microorganisms. To decrease the risk of infection, institute the following nursing measures:

1. Verify placement of feeding line prior to administration of liquids.
2. Administer nutrients in accordance with the prescribed time interval.
3. Add small quantities of enteral formula to the bag.
4. Wash reusable EN feeding bag with warm water and soap after each use, at least every 24 hours.
5. Keep PN refrigerated; remove from refrigerator 30 minutes prior to administration.
6. Change EN and PN tubing every 24 hours.

dextrose, amino acids, fats, essential fatty acids, vitamins, and minerals. Other terms used interchangeably with *TPN* are *3 in 1* (dextrose, amino acids, and fats) and *total nutrient admixtures* (TNA).

PN is used to treat malnourished clients or clients who have the potential for becoming malnourished and who are not candidates for enteral support. PN can be prescribed for either short-term or long-term use, as previously discussed in the decision algorithm (Figure 38-15).

The type of device used for the PN therapy is determined by the duration of the therapy and the osmolality of the solution. Peripheral parenteral nutrition (PPN) is used for short-term treatment to deliver isotonic or mildly hypertonic solutions into a peripheral vein; the volume is usually limited to between 2,000 and 3,000 ml/day, providing a caloric value of about 2,000 kcal/day.

Central parenteral nutrition (CPN) is used for long-term therapy to infuse highly hypertonic solutions directly into the superior vena cava. The delivery of highly hypertonic solutions into peripheral veins can cause sclerosis, phlebitis, or swelling; refer to Chapter 37 for a complete discussion of intravenous therapy complications. Specific client populations that benefit from PPN or TPN are described in the accompanying display.

Components of Parenteral Nutrition

PN solutions are predigested or chemically prepared nutrients that can be administered singly or as admixtures. The basic components of PN are:

1. Carbohydrates, primarily in the form of monohydrous glucose, ranging from 5% solution for PPN to 50% to 70% hypertonic solution for CPN; provides the client with 60% to 70% of caloric (energy) needs.
2. Amino acids, in the form of synthetic crystalline amino acid solutions; provides 5% to 15% of the total calories (CPN solutions contain sufficient amino acids for tissue synthesis).
3. Lipid (fat emulsions), prepared from safflower and soybean oil with egg phospholipids; supply up to 30% of the client's caloric (energy) intake; additional lipid emulsions and glucose or amino acids provide for a TNA isotonic solution.

Other ingredients, called admixtures, provide for the client's biochemical needs (electrolytes, vitamins, and trace elements such as zinc, selenium, chromium, magnesium, iodine, copper, iron, and molybdenum).

Medications, such as heparin, may also be added to the TPN solution. Heparin is commonly added to reduce the buildup of a fibrinous clot at the catheter's tip. When the TPN catheter is the only available venous access, TPN may be used to deliver antibiotics. The TPN solution should be prepared only by a pharmacist using sterile technique and a laminar flow hood to reduce the risk of contamination.

CANDIDATES FOR PPN OR CPN THERAPY

Short-Term (up to 2 weeks) PPN

1. Preoperative for severely depleted clients
2. Postoperative for abdominal surgery clients who have been NPO for several days because of an ileus
3. Inflamed or ulcerated bowel needing 1 or more weeks of rest: acute exacerbations of Crohn's disease and colitis, radiation enteritis, acute or necrotizing pancreatitis, or an enterocutaneous or high-output fistula
4. Congenital anomalies before surgical repair: intestinal obstruction, tracheo-esophageal fistula, midgut malrotation, volvulus, and omphacele
5. Short-bowel syndrome: small-bowel resection of 75% or more to control diarrhea and prevent dehydration and malnutrition
6. Cancer clients receiving chemotherapy or radiation therapy

Long-Term (greater than 2 weeks) CPN

1. Hyperemesis gravidarum
2. Low-birthweight neonates
3. Failure to thrive
4. Intractable diarrhea
5. Severely burned clients

**NURSING CHECKLIST****Interventions for Client Receiving TPN**

1. Monitor weight: baseline and daily weight for 1 week and twice a week thereafter. The ideal weight gain for a client is 1 pound per week. Rapid weight gain may be indicative of fluid overload; monitor such a client for peripheral and pulmonary edema.
2. Monitor I&O: record daily intake and output and compare these data with the client's weight. Closely monitor the infusion rate with an infusion pump (preferably a volumetric pump for the greatest accuracy).
3. Monitor biochemical lab values:
 - Electrolytes, especially magnesium and calcium, if these have been added to the PN solution, day 1 and once a week thereafter while on PN. With severely malnourished clients, observe for "refeeding syndrome" (a rapid drop in potassium, magnesium, and phosphate serum levels). Initiate feeding slowly to avoid cardiac overload.
 - Pre-albumin serum levels: check on day 1 and once a week while on PN. In clients who are severely dehydrated, the albumin levels may drop initially as treatment restores hydration.
 - Glucose (capillary): check every 6 hours for the first week, then once daily while on PN. Monitor for signs of hyperglycemia (thirst and oliguria) and confirm weekly blood glucose meter levels with laboratory tests.
 - Bleeding indices (PT) on day 1 and once a week while on PN, indicated for clients receiving heparin therapy.
 - Liver function tests, especially enzymes, bilirubin, triglycerides, and cholesterol on day 1 and once a week for clients on PN with lipids; abnormal values may indicate an intolerance to or an excess in lipid emulsions or problems with the metabolism with glucose and protein.
 - Renal function tests, especially blood urea nitrogen and creatinine and a 24-hour urinary urea nitrogen, days 2–5; abnormal values indicate an excess of amino acids.
 - Transferrin should be measured on day one and every 2 weeks thereafter.
4. Administer solution with an IV tubing filter to remove crystals from the solution, vent air, and trap microorganisms.
5. Change IV tubing, using aseptic technique, as indicated by the agency's protocol; most infection control guidelines recommend changing the tubing every 24 hours.
6. Use a volumetric pump to ensure accurate infusion rates.

**NURSING CHECKLIST****Interventions for Client Receiving TPN (continued)**

7. Monitor for common complications of PN therapy:
 - Phlebitis or thrombosis at the IV site, as indicated by tenderness and redness
 - Catheter tip sepsis, as indicated by fever and other signs and symptoms of sepsis
 - Liver, renal, and metabolic complications (as discussed in monitoring the biochemical laboratory values)
8. Wean the client from PN, documenting the dietary intake of total calories and protein.
9. Teach the client and the caregiver about the management of PN therapy and arrange for a home health care consult; if possible, have the home health nurse consult with the client while the client is still in the hospital, to promote continuity of care.

THINK ABOUT IT**Withholding NS**

The obligation to promote the good of the patient is basic to being a health care provider and is part of each professional's duty to the patient. This obligation underlies the requirement to evaluate the benefits and burdens of a treatment from the patient's perspective.

When and by whom should a decision be made to withhold or withdraw nutritional support in the absence of an advance directive? Consider the benefits to the clients and the burdens nutritional support places on the client, family, and caregiver.

NURSING ALERT**Egg Allergy**

Clients with a known egg allergy should not receive TPN with lipid emulsions.

NURSING ALERT**Quality Controls**

It is the responsibility of the nurse to perform daily equipment quality controls to ensure that the volume is being delivered as indicated by the setting on the infusion pump. *If the pump fails and delivers the wrong amount of fluid, the nurse is responsible.*

Administering Medication through a Feeding Tube

Refer to agency protocol regarding medication administration and contraindications. Feeding tubes with a double lumen have two separate ports; read the manufacturer's instructions to determine which port to use to administer the medication. Administering medications through the wrong port may cause the tube to clog.

Check for tube placement, clear the tubing of formula, and check the patency of the tube by flushing it with water before administering the medication. It is advisable to use the liquid form of any medications when possible. After administering each medication, flush the port to prevent clogging. Measure the aspirates removed, all liquids instilled into the tube, and the water used for flushing and medications, and record them on the client's intake and output record. Refer to Chapter 29 for additional information on administering medication through a feeding tube.

Complementary Therapy

Holistic nursing recognizes wellness as a state of harmony among mind, body, and spirit. To nourish means to provide that which is necessary for life, health, and growth; to nourish also means to cherish, to strengthen, and to promote (Jackson, 2000). Nourishment encourages expansion and growth, supporting each being as unique, whole, and individual. The following discussion provides a broad perspective regarding the use of nutrients in complementary therapies and how herbal medicine incorporates certain plants for their specific properties in order to treat digestive symptoms/diseases.

APPLICATION: HOME CARE

Client assessment for home parenteral nutrition (HPN) should consider the physical, psychosocial, and financial resources of the client and the caregiver. Maintaining a client on HPN is challenging because of the expense, technology, and required changes in lifestyle. When the PN is prescribed daily, it is usually administered overnight to minimize disruption to the client's lifestyle. Home health nurses should visit the client daily until the client and caregiver demonstrate proficiency in handling the equipment and maintaining aseptic technique.

Clients receiving PN in the home environment require close monitoring to prevent catheter sepsis and cardiac overload. The PN solution should be administered with a volumetric infusion pump. If the home does not have air conditioning to maintain the proper temperature of the solution during infusion, the solution can be divided into two bags. The second bag can be refrigerated while the first bag is infusing. The same schedule is followed for monitoring the biochemical effectiveness of PN, as discussed above for the hospitalized client.

Although there are numerous types of complementary therapies, they all integrate, to some degree, nutrition as part of their therapeutic regimen. Diet and nutrition are used by many alternative modalities for the prevention and treatment of chronic diseases:

1. *Ayurvedic Medicine*, India's ancient system of healing, treats the whole person with diet, nutrition, and lifestyle recommendations to promote health and spiritual development.
2. *Traditional Chinese Medicine*, one of the oldest systems of healing, incorporates acupuncture, Chinese herbs, massage, food therapy, exercise, and lifestyle changes into prevention and treatment.
3. *Chiropractic Medicine*, an American heritage, relies on a sound nutritional program as adjunct therapy to support the body's inherent ability to heal itself by reestablishing an unobstructed flow of nerve impulses between the brain and the rest of the body.
4. *Naturopathic Medicine*, an ancient form of healing that was formalized in America into a system of preventive and restorative treatments around the early 1900s, uses clinical nutrition as a main cornerstone of therapy to achieve and maintain health.
5. *Osteopathic Medicine*, founded by Dr. Andrew Taylor Still, a medical surgeon for the Union Army during the Civil War, integrates into conventional medicine nutritional recommendations for prevention. For example, to prevent coronary heart disease, a diet low in saturated fats is combined with antioxidants (vitamins C, A, and E) to help prevent free radical formation, thus preventing tissue breakdown as well as the accumulation of plaque in the arteries.
6. *Herbal Medicine* recognizes food as medicine, ensuring that the unique healing properties of specific herbs have a direct effect upon tissue. The healing effect is through direct contact with the tissue and the effects caused by the metabolism and absorption of the chemicals present in the various plants. Based on a holistic context, herbal medicine recognizes that true healing must involve all dimensions of the person to change whatever dietary indiscretions exist as well as to make other adjustments in one's lifestyle.

Many herbal products are available in various forms such as teas, extracts, capsules, and tablets to provide nutrients that nourish our bodies and relieve digestive symptoms. The following discussion addresses the digestive and nondigestive actions of certain herbs: bitters, chamomile, dandelion, peppermint, rosemary, and slippery elm.

Bitters is a term used to describe a group of herbs that have a bitter taste. The taste of bitterness on the tongue sends a message to the brain through the nervous system to stimulate the secretion and activity of the esophagus, and the secretions of the stomach, duodenum, and gallbladder, and to stimulate the production of insulin by the pancreas. The bitterness promotes appetite and in a complex way aids digestion. Bitter

NURSING CARE PLAN**Client with Imbalanced Nutrition:
More Than Body Requirements****Case Presentation**

Mrs. Jones, age 55, was diagnosed 2 years ago with type II (non-insulin-dependent) diabetes. She is being seen in the clinic for her 6-month visit. She says, “I hardly have the energy to get up and dress in the morning. I am thirsty all day and awaken several times during the night, having to go to the bathroom.” She does not work and hasn’t been involved in community activities for the past 5 years since her youngest child graduated from high school. Her daily routine involves cooking for her husband and brother, reading, and watching the TV for 6–8 hours. She loves to bake fresh breads and pastry. She has a history of obesity and does not exercise. She says, “I eat because I have nothing else to do.”

Assessment

- Weight, 80.6 kg
- Height, 5’4”
- Triceps skinfold, 28 mm
- Elevated blood glucose
- Weight gain, 3.6 kg
- Sedentary lifestyle
- Eats in response to boredom

Nursing Diagnosis

Imbalanced Nutrition: More Than Body Requirements, related to excess intake of high-calorie foods, eating in response to boredom, and sedentary lifestyle.

Expected Outcomes

The client will

1. Verbalize factors contributing to excess weight
2. Lose 1–2 lbs/week while eating well-balanced meals
3. Engage in 20–30 minutes of exercise 3 times a week
4. Explore outside interests to decrease boredom and increase feeling of self-worth

Interventions/Rationales

1. Conduct a dietary history, using open-ended statements to assist client in exploring psychological factors that may contribute to eating.
Nonjudgmental approach to acquiring information will encourage client trust and honesty.
2. Adapt eating habits to decrease amount of intake (smaller servings, taking small bites and chewing each bite 12 times, putting the fork on the plate between bites, drinking water with meals, eating only at mealtime, chewing sugar-free gum when watching TV).
Healthy eating habits and tips on recognizing fullness during a meal will help the client eat to satisfy hunger, not boredom.
3. Assess client’s motivation to lose weight.
Having client’s support for care plan will influence success.
4. Discuss risk factors and symptoms (thirst and urination) of diabetes.
Client understanding of her disease may increase motivation to manage it.
5. Instruct client to maintain a daily dietary intake log: time, type, and amount.
Helps client recognize her eating patterns and note healthy and unhealthy behaviors.
6. Provide with dietary materials, review the Food Pyramid and Diabetic Exchange List; plan with client an 1800-kilocalorie diet for a week, taking into consideration food preferences.
Ensures client has information necessary to plan healthy meals within recommended guidelines.
7. Return visit with nurse in one week. Monitor progress and assess plan of care. Review with client age-appropriate exercises; emphasize need for daily walking.
Changing sedentary lifestyle will increase self-esteem, burn calories, and increase energy level.
8. Review with client community and church interests outside the home, unrelated to cooking and eating.
Helps client focus on activities not involving food to decrease boredom and to increase self-esteem. (continues)

NURSING CARE PLAN**Client with Imbalanced Nutrition:
More Than Body Requirements (continued)****Evaluation**

The client verbalized boredom as the main reason for eating; she said, “I have nothing else to do with the children gone, except cook and eat.”

On return visit, the client reported drinking water with meals, chewing her food slowly, and chewing gum while watching TV.

Make clinic appointment; client has phone number of the nurse and dietitian to answer questions;

1800-kilocalorie meal plan made for one week.

On return visit, the client was found to have lost 1.8 lbs.

On return visit, the client indicated that she now walks to the store 4–5 times a week (40 minutes round trip).

The client reported on return visit that she is now volunteering 2 hours 3 times a week at the church’s child care center.

Nursing Process Highlight**IMPLEMENTATION**

Planning interventions to assist clients with their nutritional problems requires consideration of the specific contributing factors, food preferences and beliefs, and chronic conditions related to the problem. Changing eating patterns requires client motivation and desire to change. No one can make another person change his or her behavior, but nurses can assist their clients with the “why” and “how” regarding change. Reinforce all positive changes.

herbs are considered digestive stimulants because they stimulate various parts of the digestive system to increase or improve digestive activity. The most valuable bitter herbs are barberry, centaury, gentian root, golden seal, mugwort, white horehound, and wormwood (Hoffmann, 1998).

Chamomile contains calcium, essential oils, iron, magnesium, manganese, potassium, tannic acid, vitamin A, apigenin (a sedative compound), and other nutritive ingredients. Chamomile possesses the following actions: anti-inflammatory, appetite stimulant, digestive aid, diuretic, nerve tonic, and sleep aid. Traditionally, Chamomile is used for stress and anxiety, indigestion, and insomnia, and it is often used to treat colitis, diverticulosis, fever, headaches, and pain. It is effective as a gargle or mouthwash for treating gingivitis. *Caution:* This herb should not be taken over long periods of time, as it may lead to a ragweed allergy; it should not be used by those who are allergic to ragweed (Balch & Balch, 1997).

Dandelion leaves and roots are high in iron, manganese, phosphorus, protein, aluminum, and vitamin A with trace amounts of calcium, chromium, niacin, riboflavin, silicon, zinc, and vitamin C. It is a potent digestive tonic that may be used in conditions that affect the gastrointestinal tract such as heartburn, gas, gastroesophageal reflux, and constipation. Dandelion has a toning effect on the liver, gallbladder, and pancreas, providing relief from gallstones or gallbladder attacks, as well as diabetes and hypoglycemia. Dandelion is considered safe and may be taken as often as needed. *Caution:* Due to its laxative effects, large sudden intake may result in diarrhea; start with smaller doses and gradually increase over time.

Peppermint contains essential oils, tannic acid, vitamin C, and other ingredients. It is one of the best carminative agents (stimulates and soothes the digestive system, removes gas), and it enhances digestion by increasing stomach acidity. It is often recommended for chills, colic, diarrhea, headache, heart trouble, indigestion, nausea, poor appetite, rheumatism, and spasms. *Caution:* This herb may interfere with iron absorption.

Rosemary is often used as a natural food preservative because of its chemical and nutritive content. It is considered a circulatory and digestive bitter; it fights bacteria, relaxes the stomach and acts as a decongestant; it also helps prevent liver toxicity, and has anticancer and antitumor properties. It relieves intestinal colic, flatulent dyspepsia, headaches, high and low blood pressure, circulatory problems, and menstrual cramps, and it is used to treat ulcerative colitis, Crohn’s disease, and fevers, especially colds and influenza (Hoffmann, 1998; Balch & Balch, 1998).

Slippery elm bark contains calcium, phosphorus, polysaccharides, starch, tannins, and vitamin K. It soothes inflamed mucous membranes of the stomach, bowels, and urinary tract. It may be used to treat gastritis, gastric or duodenal ulcer, enteritis, colitis, diarrhea, and colds, flu, and sore throat.

NURSING CARE PLAN**Client with Imbalanced Nutrition:
Less Than Body Requirements****Case Presentation**

Jim, age 28, has been HIV-positive for 4.5 years. He went to the clinic complaining of diarrhea and cramping for 3 weeks and a burn wound on his right forearm that would not heal. He stated, “I do not have the energy to eat or get dressed.” The past month, he has eaten mainly bread, cereal, milk, and potatoes.

Assessment

- Weight loss
- Dry, scaly skin
- Pale conjunctiva
- Decreased Hbg, Hct, MCV
- Triceps skinfold, 7.2 mm
- Gingivitis
- Decreased Na, K, Fe, zinc
- Decreased serum albumin, pre-albumin, transferrin, nitrogen balance, zinc, and TLC; urine creatinine excretion

Nursing Diagnosis

Imbalanced Nutrition: Less Than Body Requirements, related to inability to absorb nutrients because of HIV enteropathy.

Expected Outcomes

The client will

1. Receive adequate nutrients to meet metabolic needs
2. Stabilize weight within 24–48 hr after initiation of TPN
3. Gain 0.25–0.5 kg/wk
4. Select a diet high in calcium, iron, protein, and calories

Interventions/Rationales

1. Weigh daily; record hourly I & O; Monitor q h BP, P, R rate, breath sounds, edema.
Monitors overall health status for changes, balance of fluid intake and output, and signs of deterioration.
2. NPO until diarrhea subsides; record frequency and consistency of stools (weight and measure).
As prescribed, monitors progression of diarrhea.
3. Administer TPN as ordered, implement TPN protocol.
Maintains calorie intake needs safely.
4. Monitor daily laboratory data: glucose, vitamins, minerals, trace elements, electrolytes; monitor pre-albumin and BUN every other day.
Assesses nutritional effect of TPN.
5. Mouth care every 2–4 hours to keep mucous membranes moist.
Provides for client comfort.
6. Collaborate with the nutritional support team for a progressive diet postdiarrhea, taking into consideration client’s food preferences.
Outlines appropriate diet; client is most likely to eat foods he prefers.
7. Offer small, frequent feedings.
Facilitates digestion and maintains constant energy levels.
8. Provide oral hygiene before and after meals.
Enhances taste sensation.
9. Assist the client with meals as needed. Provide rest periods 1 hour before and after meals.
Surrounds eating with quiet time to focus; improves digestion.

(continues)

NURSING CARE PLAN**Client with Imbalanced Nutrition:
Less Than Body Requirements (continued)**

10. Gradually wean the client off TPN as ordered.
Begin return to oral nutrition intake.
11. Monitor daily calorie count for 3 days and stool counts daily.
Gives indication of amount eaten versus amount excreted; monitors diarrhea.
12. Allow client to select food high in protein and calories.
Client involvement in diet planning increases compliance.
13. Administer drugs between meals.
Helps avoid nausea at mealtime.
14. Provide positive reinforcement for increased food intake and weight gain.
Helps client acknowledge progress; shows support for plan of care.
15. Assess the client's knowledge of the RDAs.
Current knowledge levels will determine learning needs.
16. Instruct the client on dietary planning based on the Food Guide Pyramid, as directed by the nutritional support team.
Client involvement in dietary planning increases likelihood of success.

Evaluation

Fluid intake and output balanced; diarrhea subsided in 24 hours; afebrile.

Laboratory values with normal limits 48 hours postadmission.

Weight stabilized in 48 hours, with the client tolerating clear liquids.

The client is unable to independently select foods to increase body weight; no nausea reported for routine scheduled medications.

The client was able to select food items as prescribed by the nutritional support team and gained 0.45 kg in 8 days.

THINK ABOUT IT**Assumptions and the Provision of Care**

Did you make any assumptions when you read the case presentation and nursing diagnosis? Did you assume that Jim was a homosexual? Were any data presented to substantiate that assumption? Jim's sexual preference would not have made any difference in how his care was planned, but could it have made a difference in how the nursing care was administered?

EVALUATION

Evaluation of nutritional therapy is ongoing. The nurse uses current data to measure the achievement of goals and outcomes; once they are achieved, the plan of care is revised accordingly. If goals are not met, the nurse should determine whether the nursing diagnosis was accurate or whether the nursing interventions were appropriate and the outcomes achievable.

The plan of care should be modified to maximize the client's response to therapy. For example, if the home health client states compliance with diet therapy to

maintain the HDL, LDL, and cholesterol levels within normal limits, but the values are not within normal limits, institute a food record to monitor cholesterol and fat intake for three consecutive days. Visit the client on the fourth day and review the record. Provide teaching as necessary to assist the client in changing eating patterns.

KEY CONCEPTS

- The metabolism of nutrients (carbohydrates, proteins, fats, vitamins, and minerals) plays an essential role in providing the body with the substances necessary for maintaining homeostasis.
- Most nutrients are absorbed in the small intestines through the processes of osmosis, diffusion, and active transport.
- The intracellular productions of energy from carbohydrates, proteins, and fats are interrelated and depend on other physiological processes, such as conversions that take place in the liver, glycolysis, Krebs cycle, and electron transport system.
- A calorie is the quantity of heat required to raise the temperature of 1 gram of water 1°C.
- There are six categories of nutrients: water, carbohydrates, proteins, fats, vitamins, and minerals.

- Carbohydrates have a protein-sparing action, based on a minimum daily ingestion of 50 to 100 grams (200–400 kcal).
- Proteins are essential for almost every bodily function, beginning with the genetic control of protein synthesis, cell function, and cell reproduction.
- Diets high in saturated fats are associated with an increased incidence of coronary heart disease.
- Low-density lipoproteins are responsible for the formation of atherosclerosis, which develops from a high blood plasma level of cholesterol and usually results from a diet high in saturated fats.
- Daily food guides assist healthy persons in meal planning.
- The recommended dietary allowance represents the dietary intake of essential nutrients by age category, inclusive of weight and height.
- The Food Guide Pyramid outlines the number of servings in each of the six food groups needed to maintain a healthy weight.
- Peer-group influence, social pressures, and other emotional stressors of adolescence may have a negative effect on eating habits, leading to obesity, fad diets, anorexia nervosa, and bulimia.
- Food preferences are usually developed in childhood, are modified throughout the life span, and are an expression of an individual's likes and dislikes.
- Malnutrition refers to alterations relative to inadequate intake, disorders of digestion or absorption, and overeating.
- Assessment includes three basic components: nutritional history, physical examination with anthropometric measurements, and diagnostic and laboratory data.
- Anthropometric measurements evaluate the client's calorie-energy expenditure balance, muscle mass, body fat, and protein reserves, based on height, weight, skinfold, and limb and girth circumferences.
- The blood urea nitrogen (BUN) is increased with severe dehydration, malnutrition, starvation, excessive protein intake, and, most commonly, in kidney disease.
- The nurse is responsible for understanding the client's metabolic needs and for making clinical judgments relative to nutritional outcomes.
- Therapeutic nutrition requires consideration of the client's total needs: cultural, socioeconomic, psychological, and physiological.
- Protein-energy malnutrition is the most common nutritional deficiency in hospitalized clients.
- Enteral and parenteral nutrition are two methods of delivering nutrition support in adult clients.
- Clients receiving PN in the home environment require close monitoring to prevent catheter sepsis and cardiac overload.

CRITICAL THINKING ACTIVITIES

1. Which mineral is important in the formation of collagen?
 - a. Calcium
 - b. Iron
 - c. Phosphorus
 - d. Zinc
2. Why does the body need dietary fiber?
3. Atherosclerosis may result from an excessive ingestion of which nutrient?
4. Which of the following produces a negative nitrogen balance?
 - (1) Fever
 - (2) Immobility
 - (3) Reducing diets
 - (4) Moderate exercise
 - a. 1 and 2
 - b. 1, 2, and 3
 - c. 1, 2, and 4
 - d. 4 only
5. Which of the following provides the best approach for assisting a client to change eating behaviors?
 - a. Explaining the functions of each of the nutrients
 - b. Relating the changes to the client's culture and lifestyle
 - c. Identifying those conditions that result from poor nutrition
 - d. Curtailing the kind and amount of food served at meals
6. What is the most accurate test to determine whether a person is overweight or obese?
 - a. Weight in relation to height
 - b. Body composition
 - c. Triceps skinfold measurement in millimeters
 - d. Waist size in centimeters
7. How frequently should you assess a client who is receiving a continuous tube feeding? What nursing measures are included in such an assessment?
8. Which of the following expected outcomes is most appropriate for a client receiving a nasogastric tube feeding?
 - a. Intake and output balance is maintained.
 - b. Insertion site remains free of infection.
 - c. Minimal residual is obtained from aspiration of stomach contents.
 - d. Nutritional needs are met for client who is unable to digest nutrients.
9. Which nursing actions should be instituted when a client with a continuous-feed nasogastric tube vomits?
10. What is the main advantage of CPN over PPN?

Elimination

There are so many things we do, from treatments and antibiotics to laughter, prayer, and collaboration. Our purpose is to facilitate healing.

—Winslow (In Gray, Rayome, & Anson, 1995)

COMPETENCIES

1. Describe the normal urinary elimination process.
2. Explain age-related changes that affect elimination.
3. Assess the critical elements of urinary structures.
4. Relate the principles of asepsis to urinary catheterization.
5. Discuss normal bowel elimination.
6. Assess the critical elements of bowel function.
7. Describe the expected outcomes of nursing interventions that promote normal elimination.
8. Discuss nursing interventions for selected alterations in bowel function.

KEY
TERMS

bacteriuria	functional incontinence	stoma
constipation	hematuria	stool
defecation	hemorrhoids	stress urinary incontinence
detrusor muscle	impaction	urge urinary incontinence
diarrhea	instability incontinence	urinalysis
dysuria	nocturia	urinary incontinence
extraurethral incontinence	peristalsis	urinary retention
fecal incontinence	pyuria	voiding
flatulence	specific gravity	

Elimination patterns are essential to maintain health. The urinary and gastrointestinal systems together provide for the elimination of body wastes. The urinary system filters and excretes urine from the body, thereby maintaining fluid, electrolyte, and acid-base balance. Normal bowel function provides for the regular elimination of solid wastes.

During periods of stress and illness, clients experience alterations in elimination patterns. Nurses assess for changes, identify problems, and intervene to assist clients with maintaining proper elimination patterns. The nurse's role encompasses teaching clients self-care activities to promote independence and health.

PHYSIOLOGY OF ELIMINATION

The urinary system is composed of the kidneys, ureters, bladder, and urethra. The kidneys form the urine, the ureters carry urine to the bladder, the bladder acts as a reservoir for the urine, and the urethra is the passage-way for the urine to exit the body.

The gastrointestinal tract is composed of the stomach, small intestine, large intestine, and rectum. The small intestine absorbs nutrients, the large intestine absorbs fluids and the remaining nutrients, and the distal portion of the large intestine collects and stores the remaining solid waste until elimination occurs.

Urinary Elimination

The physiological mechanisms that govern urinary elimination are complex and not yet completely understood. Continence in the adult requires anatomic integrity of the urinary system, nervous control of the detrusor muscle, and a competent sphincter mechanism. **Urinary incontinence** occurs when abnormalities of one or more of these factors causes an uncontrolled loss of urine that produces social, physiological, or hygienic difficulties for the client.

Structures of the Urinary Tract

The urinary system is typically divided into upper and lower tracts. The upper urinary tract includes the kid-

neys, renal pelves, and ureters; the lower urinary tract includes the urinary bladder, urethra, and pelvic muscles (Figure 39-1).

Upper Urinary Tract

The kidneys are a pair of reddish brown, bean-shaped organs located in the retroperitoneal space, adjacent to vertebral bones T-12 to L-2. The right kidney lies slightly lower than the left because of the presence of the liver. The periphery of the kidney contains approximately 1 million nephrons; collectively this aspect of the organ is called the parenchyma. The hilus of the kidney (its convex surface) contains the renal pelvis and the ureters, which connect the kidneys and the bladder. The primary function of the kidney is to maintain internal homeostasis through filtration of the blood and production of urine. In addition, the kidney is an endocrine organ (producing erythropoietin, a hormone that aids in the production of red blood cells), and it plays a role in vitamin D synthesis.

After production within the nephron, urine passes through the calyceal system of the kidneys into the renal pelvis. The renal pelvis is shaped like a funnel, holds approximately 15 ml of urine, and serves as a temporary storage area for urine before transport to the lower urinary tract. The ureter is a long tube, shaped like an inverted S, that begins at the renal pelvis, passes under the psoas muscle of the back, and enters the pelvis near the sacroiliac junction. When entering the pelvis, the ureters curve medially to end in the base of the bladder. The union between bladder and ureter is called the ureterovesical junction.

Both the renal pelvis and ureters consist primarily of smooth muscle, and they move urine from the upper to the lower urinary tract by muscular contraction. This process is called **peristalsis**, and it is similar to the peristaltic waves of the gastrointestinal system used to digest food and produce fecal waste. The process of peristalsis occurs during the prolonged phases of bladder filling and storage, but it is temporarily interrupted during micturition.

Lower Urinary Tract

The bladder is a hollow, muscular organ located in the pelvis. It has a fixed base and a distensible upper portion composed of multiple bundles of smooth muscle. Collectively, the smooth muscle bundles are called the detrusor muscle.

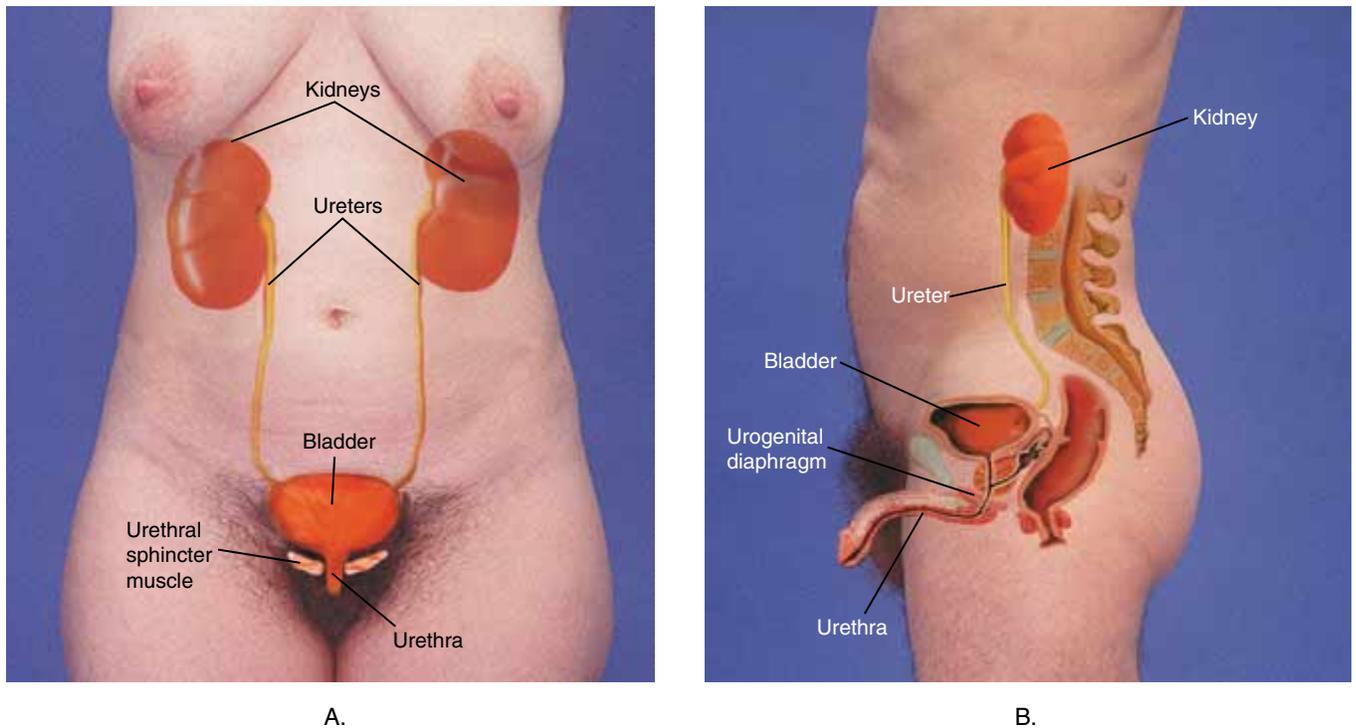

Figure 39-1 Urinary tract: A. Female, B. Male

The urethra is a tube that is a conduit for urinary elimination. The urethra differs significantly in women and men. In women, the urethra exits the bladder base and travels at a 16° angle to the external meatus located at the vestibule. The female urethra is approximately 3.5 to 5.5 cm long, and the distal third is histologically fused with the vaginal wall (Figure 39-1). The entire length of the urethra forms a sphincter mechanism with elements of compression and elements of tension.

In men, the urethra is approximately 23 cm long. It begins at the bladder base, pierces the anterior portion of the prostate, and turns to exit the body through the penis. The proximal third of the male urethra forms a sphincter mechanism comparable to the female urethra. The distal two-thirds is a conduit for the expulsion of urine or semen.

The pelvic muscles connect the anterior and posterior aspects of the bony pelvis, support the organs of the true pelvis, and contribute to the urethral sphincter mechanism in both women and men. The pelvic muscles contain primarily slow-twitch fibers that are physiologically suited for prolonged periods of tone. In addition, fast-twitch fibers within the pelvic muscles respond rapidly to sudden increases in abdominal pressure, although they soon fatigue. Fibers from the pelvic muscles surround the membranous urethra of the male and the proximal two-thirds of the female urethra. In both sexes, the urethra pierces the muscular diaphragm of the pelvic muscles.

Nervous Control of the Detrusor Muscle

The **detrusor muscle**, the smooth muscle of the bladder, is under indirect voluntary control, allowing the continent adult to postpone urination until a “socially appro-

priate” time and location for bladder evacuation is identified. Specific areas of the brain, spinal cord, and peripheral nervous system modulate the reflex activity of the detrusor muscle.

Central nervous control of the bladder begins in several modulatory centers in the brain. A neurologic lesion affecting one or more of these areas causes hyperactive detrusor contractions and a loss of bladder control. The primary areas in the brain that modulate the detrusor muscle are located in the frontal lobes, the thalamus, hypothalamus, basal ganglia, and cerebellum. The limbic system, which controls many aspects of autonomic nervous function, also influences continence.

A micturition center, located near the base of the brain, has two groups of neurons that mark the origin of the urination (micturition), the evacuation of urine from the bladder. In the infant, urinary elimination is controlled entirely by the micturition center, which evacuates the bladder when a specific “threshold” volume is reached or when the bladder is stimulated in another way. In the adult, however, the micturition center is controlled by the multiple centers of the brain, and urination usually occurs when the individual wishes to empty the bladder.

Reticulospinal tracts in the spinal cord transmit messages from the brain and brain stem to the peripheral nerves of the bladder. Bladder filling and urinary storage are promoted by excitation of the sympathetic nervous system via efferent, sympathetic spinal nuclei at spinal segments T-10 to L-2. Excitation of these neurons relaxes the detrusor muscle and contracts the muscular elements of the sphincter mechanism. Urinary evacuation is accomplished through the parasympathetic nervous system. Excitation of neurons located at segments

S-2 to S-4 causes **voiding** (urination) by contraction of the detrusor muscle and relaxation of muscular elements of the sphincter mechanism.

Two peripheral nerves transmit messages from the central nervous system to the detrusor muscle. The pelvic plexus transmits parasympathetic impulses to the smooth muscle of the detrusor. Nervous excitation of the parasympathetic nerves causes release of a neurotransmitter, acetylcholine, which produces contraction of detrusor muscle cells. Other substances also affect contraction of the detrusor muscle, but all act under the influence of the central nervous system.

The inferior hypogastric nerves provide the majority of sympathetic tone to the bladder wall and sphincter mechanism. In the detrusor muscle, excitation of β -adrenergic receptors causes release of norepinephrine, which inhibits detrusor muscle contraction. In addition, stimulation of α -adrenergic (excitatory) receptors at the bladder neck, proximal urethra, and in the prostatic urethra in men causes contraction of muscular components of the sphincter mechanism, promoting urethral closure and continence.

Urethral Sphincter Mechanism

The urethral sphincter is traditionally divided into two muscles, an internal (smooth muscle) and external (striated) sphincter. Unfortunately, this schema leads to more confusion than it addresses, and it should be discarded for a conceptualization of the sphincter as a single mechanism, comprising elements of compression and elements of tone, with essential supportive structures.

Urethral compression relies on three components: urethral mucosa softness, mucous secretions, and a vascular cushion. During bladder filling and urinary storage, the epithelium must fill in the gaps of the collapsed (closed) urethral lumen, creating a watertight seal through which no urine can escape. Coaptation requires a pliable, soft, and nonscarred urethra, with adequate mucous secretions to reduce surface tension and to fill in the microscopic gaps left by the epithelium. These elements of compression are supplemented by a rich network of vascular connections in the submucosal space. This vascular network promotes urethral closure by nourishing the epithelium and mucous production cells and by serving as a cushion for the transmission of force exerted by the muscular elements of the sphincter mechanism. In women, all the elements of compression are directly influenced by the presence of estrogens.

Elements of urethral tension protect the individual from urinary leakage during physical exercise or exertion. Smooth muscle bundles at the bladder neck and proximal urethra (and prostatic urethra of the male) close the urethra during bladder filling and urinary storage. The urethral wall also contains a set of highly specialized, triple-innervated striated muscle fibers that form a rhabdosphincter. It is crucial for maintaining continence during normal exertion. Striated muscle fibers from the pelvic muscle surround the urethra and

contribute to the sphincter. These muscles are particularly needed when abdominal pressure changes from sneezing, coughing, or lifting a heavy object.

The muscular elements of the urethra rely on supportive structures to provide an optimal configuration allowing them to contract and relax efficiently. Loss of support interferes with efficient urethral sphincter function.

Bowel Elimination

The process of normal fecal elimination is not completely understood. Continence primarily relies on the consistency of the **stool** (fecal material), intestinal motility, compliance and contractility of the rectum, and competence of the anal sphincters.

Structures of the Gastrointestinal Tract

The gastrointestinal system (alimentary canal) begins at the mouth and ends at the anus. The small intestine in the adult is approximately 22 feet long. The small intestine is primarily responsible for the digestion and absorption of nutrients, vitamins, minerals, fluids, and electrolytes. The digestive chyme (mixture of partially digested food and secretions) travels through the small bowel by a combination of segmental contractions and peristaltic waves. Substances that are well tolerated move through the bowel relatively slowly; foods or drugs that are toxic or irritable to the small bowel are evacuated rapidly. The small intestine joins the large bowel (colon) at the ileocecal valve. This valve works in conjunction with the ileocecal sphincter to control emptying of contents from the small intestine into the colon and to prevent regurgitation of digestive chyme from the large to small bowel (Figure 39-2).

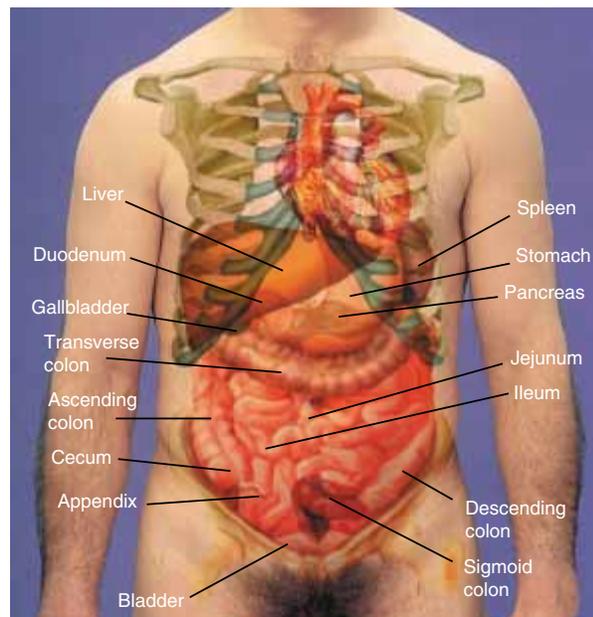

Figure 39-2 Gastrointestinal Tract

The colon is approximately 5 to 6 feet long in adults. It is divided into six segments: the cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and anal canal. The primary functions of the colon are to collect, concentrate, transport, and eliminate waste materials (feces). The anal sphincter consists of smooth and skeletal muscles that line the distal portion of the anal canal. It works with the anus to store and to eliminate feces under voluntary control.

Intestinal Motility and Rectal Accommodation

Fecal continence relies on regular delivery of small boluses of stool that are stored in the rectum before elimination. The transit time from ingestion of food to passage of stool from the bowels varies. Typically, at least 80% of intake that is not absorbed by the body is excreted from the bowel within 5 days following ingestion. Transit time is significantly affected by the type of foods ingested, subsequent dietary intake, exercise, and stress-related factors.

Filling of the rectum causes a growing awareness of the presence of stool, which is stored until an appropriate opportunity for **defecation** (evacuation of stool from the rectum) is identified. In the continent individual, an initial awareness of stool in the rectum is identified at 150 ml. The desire to defecate is typically transient, diminishing as the rectum accommodates larger volumes of stool. When 400 ml or more of stool is collected in the rectum, this urge becomes strong, and the call to defecate becomes more persistent. Failure to heed the call to defecate may lead to overdistension of the rectum with hardening of the stool and subsequent constipation.

Anal Sphincter Mechanism

The anal sphincter is divided into two mechanisms, called the internal and external sphincters (Figure 39-3). An internal anal sphincter is primarily made up of smooth muscle bundles that are connected to the smooth muscle of the rectum. It begins in the distal portion of the rectum and extends approximately 3 cm into the anal canal. The internal sphincter mechanism is primarily innervated by sympathetic nerves that promote smooth muscle contraction and by parasympathetic nerves that cause sphincter relaxation.

The external sphincter is composed of striated muscle fibers that are divided into deep and superficial components. The deep portion of the external anal sphincter comprises muscle fibers that encircle the proximal aspect of the anal canal and attach to the symphysis pubis, forming a U shape. The superficial portion of the anal sphincter also encircles the anal canal, forming a U shape; however, it attaches to the coccyx and postanal plate rather than to the anterior aspect of the pelvis. Like the periurethral muscles, the striated com-

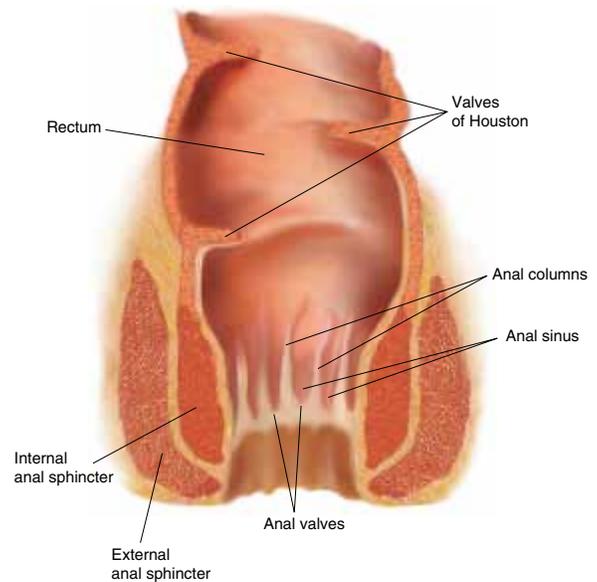

Figure 39-3 Anal Sphincter

ponent of the external anal sphincter contains both fast- and slow-twitch fibers that allow sustained tone over a period of time before voluntary defecation.

Sensory receptors located at the proximal anal canal affect anal function. These specialized sensory receptors are able to “sample” fecal contents, allowing the individual to differentiate among solid stool, liquid stool, and gas.

Distension of the rectum causes a reflex inhibition of the internal anal sphincter and contraction of the external sphincter. The proximal anal sphincter then samples the contents of the rectum, and the individual perceives the desire to defecate. If the person postpones defecation, rectal accommodation occurs and the desire to defecate is postponed. If the desire to defecate is heeded, the person voluntarily relaxes the external anal sphincter and evacuates the bowel of feces.

The significance of rectal contractions during defecation remains unclear. Many persons strain to defecate, and abdominal force is readily transmitted to the rectum, creating an effective expulsive force. The continent individual is able to simultaneously increase abdominal pressure by straining and maintain external anal sphincter relaxation, allowing effective evacuation of feces from the bowel.

FACTORS AFFECTING ELIMINATION

Age

A client’s age or developmental level will affect control over urinary and bowel patterns. Infants initially lack a pattern to their elimination. Control over bladder and bowel movements can begin as early as 18 months of age

but is typically not mastered until age 4. Nighttime control usually takes longer to achieve, and boys typically take longer to develop control over elimination than girls.

Control of elimination is generally constant throughout the adult years, with the exception of illness and pregnancy stages, when temporary loss of control, urgency, and retention may develop. With increasing age comes loss of muscle tone and therefore bladder control; this is usually accompanied by the urge to void more frequently.

Diet

Adequate fluid and fiber intake are critical factors to a client's urinary and bowel health. Inadequate fluid intake is a primary cause of constipation, as is ingestion of constipating foods such as certain dairy products. Diarrhea and **flatulence** (discharge of gas from the rectum) are a direct result of foods ingested, and clients need to be educated as to which foods and fluids promote healthy elimination and which foods may inhibit it.

Exercise

Exercise enhances muscle tone, which leads to better bladder and sphincter control. Peristalsis is also aided by activity, thus promoting healthy bowel elimination patterns.

Medications

Medications can have an impact on a client's elimination health and patterns and should be assessed during the health history interview. Cardiac clients, for instance, are commonly prescribed diuretics, which increase urine production. Antidepressants and antihypertensives may lead to urinary retention. Some over-the-counter (OTC) cold remedies, especially antihistamines, may also result in urinary retention. Other OTC medications are designed specifically to promote bowel elimination or to

soften stools; the nurse needs to inquire about all medications being taken in order to provide proper care for a client experiencing alterations in elimination patterns.

COMMON ALTERATIONS IN ELIMINATION

Urinary Elimination

Urinary incontinence and urinary retention are the most common causes of altered urinary elimination patterns. Urinary incontinence is the uncontrolled loss of urine that constitutes a social or hygienic problem. **Urinary retention** is the inability to completely evacuate urine from the bladder during micturition. There are two primary types of urinary incontinence, acute and chronic. In addition, chronic urinary incontinence can be subdivided into several distinctive types. Because each has its own etiology and management, it is important to determine the type of incontinence before subjecting the client to the expense, potential risks, and rigors of a treatment program.

Acute Urinary Incontinence

Acute urinary incontinence is a transient and reversible loss of urine. It may occur during an acute illness or after an injury. Common causes of acute urinary incontinence include urinary tract infection, atrophic vaginitis, polyuria related to diabetes, acute confusion, immobility, and sedation. Medications that increase or decrease bladder or urethral sphincter tone also may contribute to acute incontinence.

Chronic Urinary Incontinence

Acute incontinence is distinguished from established or chronic incontinence. There are four predominant types of chronic urine loss: stress urinary incontinence, instability incontinence, functional incontinence, and extraurethral incontinence.

Stress Urinary Incontinence

Stress urinary incontinence (SUI) is the uncontrolled loss of urine caused by physical exertion in the absence of a detrusor muscle contraction. SUI is associated with urethral hypermobility or with intrinsic sphincter deficiency.

Urethral hypermobility is the abnormal movement of the bladder base and urethra during physical exertion. The relationship between urethral hypermobility and SUI is not entirely understood, although several mechanisms have been proposed. Descent of the urethra into the lower portion of the pelvis may cause a loss of abdominal pressure transmission when compared with forces that affect the bladder. In addition, muscular contraction is compromised in the hypermobile urethra.

THINK ABOUT IT

Sensitivity During the Genital Exam

Assessment of the genital area can produce feelings of anxiety and embarrassment in both clients and nurses. Before beginning the genital examination, consider your client's cultural background and what beliefs or attitudes he or she may have about having the examination. Does the client's culture prohibit a female nurse from examining a male client? Does the client's culture prohibit a male nurse from examining a male client? Remember that you are assessing a person, not just a body part.

Loss of the normal anatomical relationships between the urethral sphincter and related structures also may contribute to SUI by reducing the efficiency of the muscular elements of the sphincter. The contribution of estrogen deficiency, which compromises the elements of urethral coaptation in the woman, remains unclear. Table 39-1 identifies common factors that contribute to SUI.

Intrinsic sphincter deficiency is a disorder of the muscular components of the urethral sphincter. Sphincter closure is compromised, and urinary leakage is often severe. Severe urine loss caused by intrinsic sphincter deficiency is defined as *Total Incontinence* by the North American Nursing Diagnosis Association (NANDA) system. Unlike urethral hypermobility, which is a women's health concern, intrinsic sphincter deficiency occurs in both genders and is related primarily to iatrogenic or neuropathic causes. Table 39-1 identifies common causes of intrinsic sphincter deficiency. It is important to note that intrinsic sphincter deficiency and urethral hypermobility frequently coexist in women.

Instability Incontinence

Instability incontinence is the loss of urine caused by a premature or hyperactive contraction of the detrusor. In the person with normal sensations of the lower urinary tract, these unstable detrusor contractions initially cause a precipitous desire to urinate, followed by urinary leakage unless the opportunity to toilet is immediately available. In those without sensations of bladder filling and impending urination, the contraction is followed by urinary incontinence that is often described as unpredictable. The NANDA classification schema divides this type of incontinence into two forms: *Urge Incontinence* and *Reflex Incontinence*. This distinction is clinically relevant because reflex incontinence is commonly associated with detrusor sphincter dyssynergia, an uncontrolled

contraction of striated muscle of the sphincter mechanism during micturition. Dyssynergia, or a loss of coordination between the bladder and sphincter mechanism, causes a functional obstruction of the bladder outlet and urinary retention. Table 39-2 outlines common causes of instability incontinence of urine.

Functional Incontinence

Functional incontinence is the loss of urine caused by altered mobility, dexterity, access to the toilet, or changes in mentation. Altered mobility and dexterity produce incontinence when the individual is unable to reach the toilet within a reasonable time after the onset of the urge to urinate. These conditions are worsened in an unfamiliar environment, such as a hospital, where side rails are raised on beds and sedatives are used to enhance sleep. Difficulty in reaching the toilet due to environmental factors, such as stairs, poor lighting, toilet height, narrow doors that are impassable to wheelchairs or walkers, or other conditions also produce

functional incontinence when they render the person unable to enter the bathroom with reasonable ease. Acute confusion or dementia causes urinary incontinence when the signals to toilet become unclear. Functional incontinence exists as a separate entity from stress or instability urinary leakage. Nonetheless, it is important to remember that functional limitations also exacerbate these forms of urine loss.

Functional incontinence related to dementia may be managed by a prompted voiding technique. Prompted voiding is a technique of providing the opportunity to toilet on the basis of an individualized urge response toileting program (PURT) or using a routine schedule. A PURT program is based on knowledge of the individual's typical voiding pattern. The client's voiding pattern is assessed by the use of a specially designed device to monitor urinary elimination patterns or by routine assessment of containment devices for wetness. The client is then placed on a prompted voiding schedule requiring the nurse or other caregiver to approach the client, offer the opportunity to urinate, and assist with toileting. Voiding is praised, as is dryness during the period before voiding. PURT is limited to clients with adequate cognitive awareness to respond to the prompted voiding and to those with caregivers willing to comply with the demands of this ongoing program. Prompted voiding programs also may be instituted using a more arbitrary schedule for toileting, usually every 2 to 3 hours.

Extraurethral Incontinence

Extraurethral incontinence is the uncontrolled loss of urine that exists when the sphincter mechanism has been bypassed. According to the NANDA classification system, extraurethral leakage is termed *Total Incontinence*, although that term is also applied to severe SUI. The three causes of extraurethral incontinence are ectopia (a congenital defect in which leaks occur from a source outside the urethra), a fistula (acquired passage allowing urinary leakage), or a surgical bypass of the urinary bladder (such as the ileal conduit). The severity of extraurethral incontinence varies from a dribbling leakage superimposed on an otherwise normal voiding pattern to a continuous urine loss that replaces any recognizable voiding pattern.

Urinary Retention

Urinary retention is caused by two conditions: bladder outlet obstruction and deficient detrusor muscle contraction strength. Bladder outlet obstruction causes incomplete bladder evacuation by blocking the outflow of urine through the sphincter mechanism or the urethra. Deficient detrusor muscle contraction strength occurs when contractions are insufficient to maintain urethral opening long enough for complete emptying of the bladder's contents. Because the management of each condition is different, it is important to differentiate between these disorders during evaluation. Table 39-3 describes common causes of urinary retention.

TABLE 39-3
Common Causes of Urinary Retention

Bladder outlet obstruction	Prostatic enlargement <ul style="list-style-type: none"> • Benign prostatic hyperplasia • Prostate cancer • Prostatitis Bladder neck dyssynergia (dyssynergia of the smooth muscle of the sphincter mechanism) Detrusor sphincter dyssynergia (typically indicates dyssynergia between detrusor and striated muscle of sphincter) Urethral stricture Urethral tumor (rare)
Deficient detrusor contraction strength	Transient conditions <ul style="list-style-type: none"> • Fecal impaction • Acute immobility • Side effects of drugs including anticholinergics, tricyclic antidepressants • Side effect of recreational drugs including hallucinogens • Herpes zoster of sacral dermatomes Established conditions <ul style="list-style-type: none"> • Lesions of sacral spine • Cauda equina syndrome • Diabetes mellitus (late stages) • Tabes dorsalis • Poliomyelitis

Bowel Elimination

Many diseases and conditions affect bowel function. Although many alterations in bowel elimination patterns may be observed, this discussion is limited to three common alterations: constipation, diarrhea, and fecal incontinence.

Constipation

Colonic **constipation** is the infrequent and difficult passage of hardened stool. (Perceived constipation, influenced by psychological and emotional stress, is not included in this discussion.)

Dietary factors may contribute to constipation. Dehydration causes drying of the stool as the body increases the reabsorption of water and sodium from the bowel. Inadequate dietary bulk also dehydrates the stool. Diverticular disease, a common problem in the elderly, also reduces colonic transit, further increasing the risk of constipation.

Neuropathic conditions promote constipation by diminishing the efficiency of gastric motility. They also weaken the abdominal muscles, reducing the efficiency of straining and rectal evacuation. Lesions of the brain, such as cerebrovascular accident, and spinal disorders, disc problems, or spinal stenosis contribute to constipation by reducing mobility, weakening the abdominal muscles, and diminishing the motility of the smooth muscle of the colon and rectum. Functional limitations, particularly impaired mobility, predispose elderly clients to constipation; they perceive a diminished desire to defecate and have prolonged colonic transit time. Multiple medications, particularly narcotics, sedatives, anticholinergics, antidepressants, antiparkinsonian drugs, and iron, also contribute to constipation.

In women, mechanical factors may exacerbate constipation. A rectocele is the herniation of the rectum and surrounding tissues into the potential space of the vagina (Figure 39-4). A significant rectocele causes a mechanical obstruction to defecation and subsequent constipation. Both women and men may experience constipation because of incomplete control of the anal sphincter. In this case, failure of complete relaxation of the anal sphincter causes fecal retention, drying of stool, and constipation.

In severe cases, the hardened stool may consolidate into an **impaction**. This bolus of stool serves as a nidus for bacterial overgrowth and produces an obstruction that further slows colonic transit time and the passage of further fecal contents.

Diarrhea

Diarrhea is the passage of liquefied stool that, because of its increased frequency and consistency, represents a change in the person's bowel habits. The primary causes of diarrhea include infectious agents, malabsorption disorders, inflammatory bowel disease, short bowel syndrome, side effects of drugs, and laxative or enema misuse.

Infectious diarrhea occurs when overgrowth of a pathogen produces osmotic diarrhea via toxins or reduced absorptive ability due to mucosal damage. Common pathogens include *Clostridium difficile*, entero-

toxigenic *Escherichia coli*, *Salmonella*, *Shigella*, *Entamoeba histolytica*, and *Giardia*.

Malabsorption syndromes produce diarrhea when nonabsorbed substances in the diet create an osmotic imbalance and liquefaction of the stool. Lactose intolerance, sorbitol intolerance, and celiac sprue syndrome are examples of common malabsorption syndromes that predispose clients to diarrhea. Persons with inflammatory bowel disease or short bowel syndrome are predisposed toward diarrhea because of a reduced surface area for reabsorption.

Specific drugs may cause diarrhea as a side effect. Administration of multiple antimicrobial agents may indirectly predispose the client to diarrhea by promoting an overgrowth of *C. difficile* in the bowel. Cholinergic drugs increase motility and reduce reabsorption of water and electrolytes from the stool. Other drugs produce osmotic diarrhea, primarily because of the vehicle for delivery, which frequently contains sorbitol and a high osmolality.

Enteral feedings contain a relatively high osmolality that frequently predisposes the client to diarrhea. These formulas may contain lactose, which causes intolerance in some people. The risk of diarrhea is further enhanced in the critically ill who have highly catabolic states and decreased absorptive ability and among those receiving bolus administration of intravenous fluids.

The misuse of laxatives and enemas is frequently associated with diarrhea among clients living at home. Overuse of saline cathartics may produce osmotic diarrhea, and the chronic misuse of laxatives may alter motility patterns and cause an osmotic shift in the bowel.

Secretory diarrhea occurs when the normal mechanisms that produce intestinal fluid are hyperactivated, causing excessive production and movement of food through the intestinal system. Zollinger-Ellison syndrome, pancreatic cholera, carcinoid syndrome, and villous adenoma may produce severe, chronic diarrhea.

Fecal Incontinence

Fecal incontinence is the involuntary loss of stool of sufficient magnitude to create a social or hygienic problem. The primary mechanisms that predispose the adult to incontinence of stool are dysfunction of the anal sphincter, disorders of the delivery of stool to the rectum, disorders of rectal storage, and anatomic defects.

A disorder of stool volume and consistency is typically not enough to produce fecal incontinence in the otherwise normal individual. Instead, the person is likely to perceive a precipitous urgency to defecate, an impulse that is heeded rapidly. However, if the volume of stool is sufficient and the storage capacity of the rectum is compromised, or sphincter function is suboptimal, fecal incontinence may result. When severe constipation leads to an impaction of stool, bacteria in the rectum overgrow, producing a liquefied medium. The toxins

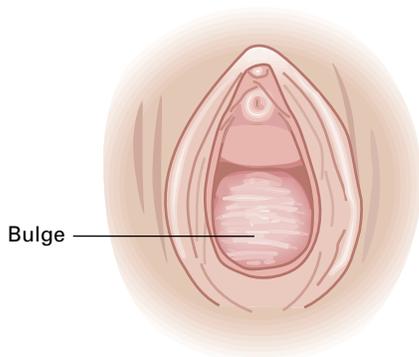

Figure 39-4 Rectocele

produced by this liquefied stool are likely to stimulate the bowel and may produce transient seepage of stool in the normally continent client.

Low compliance of the rectum also predisposes the client to fecal incontinence. In the normal individual, the rectum is able to accommodate 400 ml of feces at low pressure. However, clients with radiation proctitis, rectal wall fibrosis due to inflammatory disorders, infectious proctitis, chronic obstruction, or malignancies store lower volumes of stool at higher pressures. Low rectal compliance diminishes storage capacity and causes greater than normal urgency to defecate when

stool enters the rectum. When a large volume of stool enters the rectum rapidly, the urgency to defecate is likely to be overwhelming, and the risk of incontinence is significant.

Anal sphincter dysfunction is likely to cause incontinence when both the internal and external mechanisms are compromised. Neurologic lesions are the most common cause of anal sphincter dysfunction. Typically, the client is able to compensate for sphincter weakness, provided the rectum is presented with a normal delivery of solid stool. However, in the presence of diarrhea, significant fecal incontinence may occur.

Sensory disorders also predispose the client to fecal incontinence. Loss of the sensitive epithelium in the proximal anal canal interferes with the client's ability to differentiate gas and solid and liquid contents in the rectum. In addition, loss of proprioception in the rectum disturbs the client's ability to detect rectal fullness. These individuals are particularly prone to incontinence when a large bolus of stool enters the rectum rapidly or when an impaction occurs.

Anatomic disorders also may compromise sphincter function and predispose the individual to fecal incontinence. Among women, the most common risk factor is obstetric trauma. Vaginal deliveries, particularly those requiring the use of forceps and those complicated by third-degree tearing, are likely to damage the anal sphincter mechanism.

RESEARCH FOCUS

Title of Study

"Fecal Incontinence in Hospitalized Patients Who Are Acutely Ill"

Authors

Bliss, D. Z., Johnson, S., Savik, K., Clabots, C. R., & Gerding, D. N.

Purpose

To determine the incidence of fecal incontinence in acutely ill hospitalized patients, and to ascertain the relationship between fecal incontinence and stool consistency, and between diarrhea and two well-known nosocomial or iatrogenic etiologies of diarrhea: *Clostridium difficile* and tube feeding.

Methods

Rectal swabs and stool specimens were obtained weekly from 152 patients on acute or critical care units; information regarding tube feeding and medications, severity of illness, and nutritional data were prospectively recorded on each patient.

Findings

A total of 33% of the patients had fecal incontinence. Although a greater percentage of patients with diarrhea had fecal incontinence than patients without diarrhea, the condition was not associated with any specific cause of diarrhea.

Implications

Even though treatments may be beneficial in managing fecal incontinence, treatments that slow intestinal transit should be avoided in patients with *Clostridium difficile*-associated diarrhea.

Bliss, D. Z., Johnson, S., Savik, K., Clabots, C. R., & Gerding, D. N. (2000). Fecal incontinence in hospitalized patients who are acutely ill. *Nursing Research*, 49(2), 101.

ASSESSMENT

The nursing assessment of elimination is based on a client interview, evaluation of an objective log or record of urinary or fecal elimination patterns, focused physical examination, and review of diagnostic laboratory

THINK ABOUT IT

Assessment of Elimination Patterns

Consider your feelings about urinary and fecal incontinence. Many people, including health care professionals, consider incontinence to be a hygienic rather than a health concern. Parents may view incontinence in children to be a form of misbehavior. Some adults consider incontinence to be a form of childlike or infantile behavior, or they may believe that urinary or fecal leakage is an inevitable consequence of aging. Consider your feelings if you lost control of your bowels or your bladder. Would you not wish your health care providers to consider this a significant problem worthy of aggressive treatment? Would you feel embarrassed about bringing up this problem to a nurse or physician? Would you be relieved when a nurse or physician asked you about this problem? Would you desire privacy when discussing this health care issue?

NURSING ALERT

Spotting Sexual Abuse

Suspect abuse if you note any of the following during inspection of a client's genital area: bruises, cuts, tears, or bleeding, especially around the genitals, anus, buttocks, hips, and thighs. Emotional signs such as refusing a rectal examination, lack of eye contact during the examination, or extreme anxiety or guarding of body parts during the assessment may all be indicators of abuse. Document all signs of suspected abuse, and know your state's and institution's policies regarding reporting abuse. Remember that no client, regardless of age or gender, should be excluded from evaluation for sexual abuse.

data. When altered patterns of elimination indicate a significant health problem, additional diagnostic information is used to formulate a plan of care.

Health History

Because issues of elimination may produce feelings of anxiety, guilt, or shame among clients, the interview must be instigated by the nurse and conducted in a setting that provides adequate privacy. Clients are asked to describe their usual elimination habits. Table 39-4 presents the typical questions asked when assessing urinary and fecal elimination patterns.

When screening questions concerning altered patterns of elimination reveal significant findings, the interview should be expanded to include specific questions about the nature of the elimination disorder. These questions explore the type of incontinence, complicating factors, and bladder (Table 39-5) and bowel management strategies currently used by the client.

Physical Examination

The physical examination for elimination patterns focuses on functional issues associated with urinary or fecal incontinence and assesses the perineal and perianal areas. Functional evaluation begins with the interview and continues throughout the physical examination. Mental status can be evaluated by listening to the client's responses to questions and by observing interactions with others. When mental assessment reveals changes from normal or expected function, a more specific tool, such as the Mini-Mental Status Examination may be administered (see Chapter 36 for a complete discussion of the Mini-Mental Status Examination).

Mobility and dexterity are evaluated by observation or by asking the client to perform simple tasks. Mobility may be evaluated by observing the client undress or move onto a table, chair, or bed. Dexterity is assessed by observing the client remove clothing; particular attention is paid to the manipulation of zippers, buttons, shoestrings, and snaps.

TABLE 39-4
Health History Questions for Clients with Altered Elimination

Area of Inquiry	Sample Question	Significant Findings
Determine duration of problem	How long have you been bothered with problems controlling your bladder or bowel?	Association of onset of urinary or fecal incontinence with injury; disorder of central nervous system, brain, or spine; pelvic trauma; vaginal delivery; onset of climacteric.
Determine type of urinary incontinence	What activities make you leak? Do you leak when you cough, sneeze, laugh, exercise, walk? Do you leak with a strong urge to urinate? Do you leak with no sensation or warning? How much do you typically leak? Is it enough to dampen your underclothing? Is it enough to saturate your underclothing, dress, or pants? Is it enough to run down your legs and require a change of clothing?	Leakage with physical exertion is related to SUI. Leakage associated with a sudden urge to urinate is related to detrusor hyperactivity (urge incontinence). Leakage associated with no sensation or warning is generally associated with bypassing of sphincter (extraurethral incontinence). SUI is typically associated with smaller volumes of leakage with each episode. Urge incontinence often produces larger-volume leakage.

(continues)

TABLE 39-4 (continued)
Health History Questions for Clients with Altered Elimination

Area of Inquiry	Sample Question	Significant Findings
Determine type of fecal incontinence	Do you have trouble controlling gas or liquid stool?	Fecal incontinence associated with motility disorders (dietary intolerance), low compliance of the rectal vault, or rectal urgency is associated with diarrhea. Intermittent fecal incontinence associated with mild anal sphincter intolerance may cause loss of control only when coping with liquid stool or gas. Regular loss of solid stool is typically associated with central nervous system disorders or significant dysfunction of the anal sphincter mechanism.
Identify complicating factors of urinary incontinence	Do you ever experience bladder (urine or urinary tract) infections? Do you feel you completely empty your bladder? Do you ever lose control of your bowels? Do you ever seep stool?	Urinary tract infections are commonly associated with incontinence complicated by obstruction or urinary retention. Combined fecal and urinary incontinence typically implies neurologic disorders, including altered mentation.
Identify complicating factors of fecal incontinence	Are there any foods that routinely cause you to experience nausea, vomiting, or diarrhea? Do you experience constipation? Do you pass hardened stool? How frequently do you move your bowels?	Intolerance of specific dietary elements (such as lactose) increases small bowel motility and the subsequent risk of incontinence. The infrequent, difficult passage of hardened stool (constipation) increases the bacterial load within the rectum, creating a liquid stool around the hardened stool. This bacteria-laden, liquefied stool increases both rectal urgency and the risk of fecal incontinence.
Identify bladder management program	How do you manage your leakage?	Clients often experience complications of urinary incontinence, including altered skin integrity, shame, and humiliation. These can be prevented by using better containment devices.
Identify the bowel management program	How do you evacuate (move) your bowels? Do you regularly use laxatives, suppositories or other stool softeners, or an enema to assist with a bowel movement?	The normal individual may move the bowels as frequently as once each day or as little as once every 2 to 3 days. Clients with perceived or organic constipation frequently use laxatives, stool softeners, or enemas to assist with bowel movements. Clients with paralyzing neurologic lesions often must use a digital stimulation, an enema, or a suppository to stimulate a bowel movement.

The perineum is initially inspected for skin integrity. Among clients with severe urinary leakage, the characteristic odor of urine may be present, and the skin may show signs of a monilial rash (maculopapular, red rash with satellite lesions) or an ammonia contact dermatitis (papular rash with saturated, macerated skin). Among patients with severe fecal incontinence, the skin is fre-

quently denuded, red, and painful to touch, particularly if it has been exposed to liquid stool. The integrity of the skin typically remains intact with mild to moderate fecal or urinary incontinence, although a monilial rash may be present. This monilial rash may involve the inner aspect of the thighs, and it frequently extends throughout the skin surface covered by a containment device.

TABLE 39-5
Questions for Clients with Altered Patterns of Urinary Elimination

Area of Inquiry	Sample Question	Significant Findings
Diurnal voiding habits	How long can you postpone urination? Can you postpone urination for 2 hours?	Diurnal frequency greater than every 2 h
Nocturia (awakening from sleep to urinate)	How many times do you wake up at night and urinate? Does the urge to urinate interrupt your sleep?	Nocturia greater than once per night in adults less than 65 years old Nocturia greater than twice per night in older adults
Urinary incontinence	Do you leak urine or lose bladder control? Does this leakage cause any problems for you?	Any leakage sufficient to be defined as a problem by the client or significant others
Urinary retention	Do you feel you completely empty your bladder? Have you ever been unable to urinate at all?	Any episode of acute urinary retention; suspicion of chronic retention (incomplete emptying) significant when complicated by urinary tract infections or incontinence

The vaginal vault of the woman is inspected for signs of atrophic vaginitis and for bladder and urethral support. The atrophic vagina has a dry, thin, friable mucosa with a loss of rugae (regular folds of tissue observed in the normal vagina). It is tender to touch, pale, and cracks or bleeds easily. The vaginal introitus and vault may be quite small, and the client may be intolerant of even gentle efforts to distend the vagina for examination. Atrophic vaginal changes are important to assess because they are associated with SUI, irritative voiding symptoms, and urge incontinence.

Pelvic support is assessed in the woman because it is associated with pelvic muscle weakness. Loss of pelvic muscle tone is associated with pelvic descent, increasing the risk of urethral hypermobility or intrinsic sphincter deficiency. Both can lead to SUI or defects of the anal sphincter or rectocele, causing chronic constipation and incomplete evacuation of stool with defecation. Paravaginal support is assessed using a gloved hand or speculum. The posterior vaginal wall is supported using either a Sims' speculum or a gloved finger gently inserted into the vagina. The woman is asked to cough or strain down, and movement of the posterior vaginal wall is evaluated. Bulging of the anterior wall indicates a cystocele or loss of support of the bladder base. This maneuver is repeated, and the posterior vaginal wall is evaluated for the presence of a rectocele. Uterine prolapse is noted when the uterus or cervix migrates toward the vaginal introitus in response to physical exertion.

The sensations of the perineal area are assessed, using a small needle to evaluate sharp versus dull stimuli and using two probes to determine one- versus two-point discrimination. The bulbocavernosus reflex (BCR) is evaluated by gently tapping on the clitoris while observing the anal sphincter. A positive reflex will produce an anal "wink" or contraction of the perianal

muscle. A weaker response is assessed by placing a gloved finger at the anus or by pelvic muscle electromyogram using patch or needle electrodes. Loss of sensations or absence of the BCR indicates neurologic damage associated with urinary incontinence or retention.

Careful inspection of the perianal area and a digital rectal examination are particularly important for men and women. The cheeks of the buttocks should be pulled apart and the anus and surrounding area visually inspected. The client may be asked to bear down and the anus inspected for prolapse or for gaping, indicating significant weakness of the anal sphincter. In both genders, the anal sphincter is assessed for tone and symmetry. The gloved, lubricated finger is gently inserted into the anal sphincter. The finger is rotated 360° and the tone of the external sphincter is assessed. In addition, the rectum is palpated for evidence of stool or the hardened, large mass of feces characteristic of fecal impaction. **Hemorrhoids** (perianal varicosities of the hemorrhoidal veins) may also be identified. The prostate is examined for size, consistency, and induration when urinary retention is suspected. Benign prostatic hyperplasia, a common cause of urinary retention in older men, produces a uniform enlargement of the prostate. In contrast, prostate cancer causes asymmetric enlargement or discrete, hard nodules.

When altered patterns of urinary or fecal elimination are suspected from the health history, a log or diary should be completed. The simple bladder log is kept over a long period of time to determine patterns of urinary elimination and patterns of incontinence. A more detailed log allows the nurse to evaluate fluid intake, client responses to prompted toileting, functional bladder capacity, and the estimated volume of an incontinent episode.

THINK ABOUT IT

Professionalism During the Rectal Assessment

The rectal examination may cause the client to feel uncomfortable or embarrassed. How would you handle the following situations if they were to occur during the rectal assessment?

- The client has an erection during the examination.
- The client loses bowel control.
- The client passes flatus during the examination.

Diagnostic and Laboratory Data

When significant urinary or fecal elimination problems are observed, further testing is needed to evaluate the underlying cause of the condition and to determine treatment options. When urinary incontinence exists, a dipstick **urinalysis** is obtained and evaluated for nitrites, leukocytes, hemoglobin, glucose, and specific gravity. When nitrites or leukocytes are present, a microscopic analysis is completed to determine the presence of white blood cells in the urine (**pyuria**) and bacteria in the urine (**bacteriuria**). Urine culture and sensitivity testing are completed and the client is treated for a urinary tract infection. If glucose is noted in the urine, the patient may undergo further evaluation for diabetes mellitus, or methods of glucose control may be reviewed and adjusted in the client with known diabetes. If the **specific gravity** (weight of urine compared with weight of distilled water) of the urine is abnormally low (below 1.010), the volume of fluid consumed by the client over a 24-hour period is evaluated further. **Hematuria** (blood in the urine) may be noted.

More detailed diagnostic testing of lower urinary tract function may be obtained in cases of complex urinary retention or incontinence. Urodynamics is a set of tests that measure bladder and surrounding abdominal pressures. Pressure data are combined with electromyography of the pelvic muscles and urinary flow rate to determine lower urinary tract function during bladder filling and micturition.

Laboratory tests also may be obtained for select cases of fecal incontinence. A stool culture may be analyzed for ova and parasites, electrolytes, or culture when dietary intolerance or a gastrointestinal infection is thought to be causing diarrhea and related incontinence. When anal sphincter weakness is suspected as a cause of fecal incontinence, anorectal manometry may be completed to further evaluate anal sphincter and rectal vault function. When pelvic muscle weakness and descent are thought to cause fecal incontinence, defecography (x-ray images of the rectal vault and anal sphincter obtained during defecation) or anorectal ultrasonography may be completed.

NURSING DIAGNOSIS

The following nursing diagnoses are frequently encountered in clients experiencing changes in urinary and bowel habits.

Impaired Urinary Elimination

Impaired Urinary Elimination is the state in which the individual experiences a disturbance in urine elimination. Defining characteristics include **dysuria** (painful urination), frequency, hesitancy, incontinence, nocturia, retention, and urgency. Altered urinary elimination patterns can result from multiple causes, including anatomic obstruction, sensory motor impairment, and urinary tract infection.

Stress Urinary Incontinence

Stress urinary incontinence is the state in which an individual experiences a loss of urine less than 50 ml occurring with increased abdominal pressure. Major characteristics include reported or observed dribbling with increased abdominal pressure. Minor characteristics may include urinary urgency and urinary frequency (more often than every 2 hours). The client may also be experiencing related factors such as degenerative changes in pelvic muscles and structural supports associated with increased age, high intra-abdominal pressure (e.g., obesity, gravid uterus), incompetent bladder outlet, overdistension between voidings, or weak pelvic muscles and structural supports.

Reflex Urinary Incontinence

The state in which an individual experiences an involuntary loss of urine, occurring at somewhat predictable intervals when a specific bladder volume is reached, is known as *Reflex Urinary Incontinence*. Major characteristics include no awareness of bladder filling, no urge to void or feelings of bladder fullness, and uninhibited bladder contraction or spasm at regular intervals. Related factors include a neurologic impairment (e.g., spinal cord lesion that interferes with conduction of cerebral messages above the level of the reflex arc).

Urge Urinary Incontinence

Urge Urinary Incontinence is the state in which an individual experiences involuntary passage of urine occurring soon after a strong sense of urgency to void. Major characteristics include urinary urgency, frequency (voiding more often than every 2 hours), and bladder contraction or spasm. Minor characteristics include nocturia (more than two times per night), voiding small amounts (less than 100 ml) or large amounts (more than 550

ml), and inability to reach the toilet in time. Urge incontinence may be related to decreased bladder capacity (e.g., history of pelvic inflammatory disease, abdominal surgeries, indwelling urinary catheter), irritation of bladder stretch receptors causing spasm (e.g., bladder infection), alcohol, caffeine, increased fluids, increased urine concentration, or overdistension of the bladder.

Functional Urinary Incontinence

The state in which an individual experiences an involuntary, unpredictable passage of urine is called *Functional Urinary Incontinence*. Major characteristics include urge to void or bladder contractions sufficiently strong to result in loss of urine before reaching an appropriate receptacle. Altered environment, sensory, cognitive, or mobility deficits may contribute to functional incontinence.

Total Urinary Incontinence

Total Urinary Incontinence is the state in which an individual experiences a continuous and unpredictable loss of urine. Major characteristics include constant flow of urine occurring at unpredictable times without distension, uninhibited bladder contractions or spasms, unsuccessful incontinence refractory treatments, and nocturia. Related factors include neuropathy that prevents transmission of the reflex that indicates bladder fullness, neurologic dysfunction causing triggering of micturition at unpredictable times, independent contraction of the detrusor reflex owing to surgery, trauma, or disease that affects spinal cord nerves, or anatomy (fistula).

Urinary Retention

The state in which the individual experiences incomplete emptying of the bladder is known as *Urinary Retention*. Major characteristics for urinary retention include bladder distension and small, frequent voiding or absence of urine output. Minor characteristics include sensation of bladder fullness, dribbling, residual urine, dysuria, and overflow incontinence. High urethral pressure caused by weak detrusor, inhibition of reflex arc, strong sphincter, and blockage are related factors for urinary retention.

Constipation

A state in which an individual experiences a change in normal bowel habits characterized by a decrease in frequency or passage of hard, dry stools is called *Constipation*. Defining characteristics include decreased activity level, frequency less than usual pattern, hard-formed stools, palpable mass, reported feeling of pres-

sure and fullness in rectum, and straining at stool. Other possible characteristics include abdominal pain, appetite impairment, back pain, headache, interference with daily living, and use of laxatives. Related factors for constipation are still under development by NANDA; some possible considerations may be change in daily routine and less than adequate fluid and dietary intake.

Perceived Constipation

Perceived Constipation is the state in which an individual makes a self-diagnosis of constipation and ensures a daily bowel movement through abuse of laxatives, enemas, and suppositories. Major characteristics include expectation of daily bowel movement, with the resulting overuse of laxatives, enemas, and suppositories, and expected passage of stool at the same time every day. Related factors may include cultural or family health beliefs, faulty appraisal, or impaired thought processes.

Diarrhea

Diarrhea is the state in which an individual experiences a change in normal bowel habits characterized by the frequent passage of loose, fluid, unformed stools. Defining characteristics include abdominal pain, cramping, increased frequency, increased frequency of bowel sounds, loose or liquid stools, and urgency. Other possible characteristics include change in color of stools. Gastrointestinal, metabolic, nutritional, or endocrine disorders; infectious processes; tube feedings; fecal impaction; change in dietary intake; adverse effects of medications; and high stress levels may all contribute to diarrhea.

Bowel Incontinence

A state in which an individual experiences a change in normal bowel habits characterized by involuntary passage of stool is called *Bowel Incontinence*. Related factors may include gastrointestinal and neuromuscular disorders, colostomy, loss of rectal sphincter control, and impaired cognition.

Other Diagnoses

Other nursing diagnoses that may be important for clients experiencing alterations in elimination patterns include *Situational Low Self-Esteem*, *Deficient Knowledge*, *Risk for Infection*, *Risk for Impaired Skin Integrity*, and *Toileting Self-Care Deficit*. Nursing diagnoses and the resulting plan of care need to be developed to ensure delivery of thoughtful nursing care for both the physical and psychosocial aspects of altered elimination patterns that may affect a client's well-being.

OUTCOME IDENTIFICATION AND PLANNING

The targeted outcomes for clients with alterations in elimination patterns center around restoring and maintaining regular elimination habits and preventing potential associated complications such as infections and altered skin integrity. Interventions to respond to the client's physical needs relating to maintaining skin health and fluid volume balance need to be developed, as well as strategies to address the client's psychosocial needs, such as countering deficient knowledge, enhancing self-esteem, and reducing or controlling anxiety.

Client teaching is also a critical factor in planning care for clients with urinary and fecal complications. The nurse's role in educating clients concerning proper diet and exercise regimens to maintain urinary and fecal health is also an important aspect of planning care. When ostomies are involved, clients and their families will need instruction and demonstration on proper care and the warning signs of infection.

IMPLEMENTATION

Maintain Elimination Health

The nursing management of altered patterns of urinary and bowel elimination begins with an understanding of the principles for general bladder and bowel health and by primary prevention of problems whenever feasible. All clients should be taught basic principles of fluid intake and urinary output, regular bowel evacuation, stool consistency, and altered patterns of elimination. The Client Teaching Checklists offer suggestions for maintaining urinary and bowel elimination patterns.

Fluid Intake

Clients should be taught to drink an adequate volume of fluid each day. The recommended daily allowance (RDA) for fluids is 30 ml/kg body weight, or roughly 1/2 oz/lb body weight. In the average-sized adult, this equals 1500 to 2000 ml/d, although obese and thin individuals will vary from this range. Manipulation of the volume of fluid intake showed only a weak correlation with voluntary or incontinent episodes in the classical research regarding elderly women (Wyman, Elswick, Ory, Wilson, & Fantl, 1991). A person who experiences altered patterns of urinary elimination, particularly incontinence, is likely to reduce fluid intake in an attempt to manage the problem. Many clients reason that curtailing fluid intake will reduce urinary output and the risk of incontinence. Unfortunately, it will not. Systematic dehydration may increase rather than diminish the risk of urinary incontinence by promoting bacteriuria and by concentrating the urine, thereby enhancing its irritative properties

CLIENT TEACHING CHECKLIST

Managing Altered Urinary Elimination

- Ensure adequate daily fluid intake (15 ml/lb body weight).
- Reduce or avoid bladder irritants.
- Reduce alcohol consumption.
- Stop smoking.
- Teach pelvic muscle exercises to women (Kegel exercises).

CLIENT TEACHING CHECKLIST

Managing Altered Fecal Elimination

- Understand the relationship between dietary and fluid intake and stool consistency.
- Understand the relationship between altered stool consistency and altered patterns of bowel elimination, including incontinence.
- Ensure adequate daily fluid intake (15 ml/lb body weight).
- Ensure adequate intake of dietary fiber.
- Establish regular schedule of defecation.
- Heed the urge to defecate.

when stored in the bladder. Dehydration also causes the body to compensate for a shortage of available fluids by reabsorbing fluids and sodium from the bowel, causing drying of the stool and constipation.

Diet

Persons with urinary incontinence or frequent urination associated with urgency should be taught to recognize potential bladder irritants. Specific foods and beverages irritate the bladder and produce frequent urination and bladder discomfort in certain persons, while exerting relatively little effect among others. Foods or substances that may irritate the bladder are:

- Caffeinated beverages, carbonated drinks, and acidic fluids (including coffee and tea)
- Aspartame, particularly when added to a caffeinated or carbonated beverage
- Citrus fruits or juices
- Foods containing tomatoes or tomato-based sauces
- Chocolate
- Greasy or spicy foods

Dietary fiber may prevent constipation and increase the desire to defecate. The client is advised to increase

the amount of fiber-rich foods in the diet, including grains, fruits, and vegetables (Table 39-6). Remind the client that dietary fiber should be increased gradually; a sudden increase in fiber may produce bloating and abdominal discomfort.

Lifestyle and Prevention

For many clients, lifestyle and habits affect normal elimination patterns. Individual, social, family, and cultural variables play an important role in elimination. Proper nutrition, adequate rest and sleep, and regular exercise help maintain healthy elimination patterns. Clients with elimination problems can take measures to correct or alter the problem by modifying their lifestyle.

Alcohol and Tobacco Use

Consumption of alcohol exerts significant effects on the bladder. Alcohol suppresses antidiuretic hormone (ADH) excretion by the hypothalamus, causing polyuria and increasing the risk of urinary leakage. In addition, the sedative effects of alcohol increase the risk of urinary incontinence, both while awake and during sleep. Alcohol irritates the intestines and bowels, causing inflammation. The irritant effect causes increased elimination of fluid in the stool, resulting in diarrhea. With chronic use of alcohol, inflammation results, causing enteritis or colitis.

Cigarette smoking also may irritate the bladder. Cigarette smoke may increase the risk of SUI because of

its association with a chronic cough, and smoking is a significant risk factor for the development of bladder cancer. Smoking stimulates the bowel through the action of nicotine, present in tobacco, causing increased bowel tone and motility. The result is diarrhea.

Stress Management

Managing stress promotes healthy bowel and urinary elimination patterns. Acute and chronic stress affect both elimination systems. The bowel responds by increasing activity when the parasympathetic nervous system is stimulated. However, the longer lasting effect of norepinephrine causes slowing of the gastrointestinal tract. In response to the effect of ADH, the kidneys retain fluid. The effect of ADH in combination with the effect of norepinephrine and epinephrine elevates the blood pressure. Using education and support, nurses can help clients manage stress. See Chapter 20.

Elimination Habits

The client is urged to establish a regular schedule of bowel elimination and to answer the desire to defecate. In the normal individual, the desire to move the bowel is transient and lost when avoided or ignored. Although occasional avoidance of the urge to defecate is a useful tool for continence, routine avoidance may predispose the client to constipation and reduce the efficiency of bowel evacuation. The urge to defecate is typically greatest after a meal, and it may be enhanced by dietary stimulants such as fiber or a caffeinated beverage or by light exercise. In an unfamiliar setting, such as the hospital, it is important to provide adequate privacy so that the client can heed the urge to defecate without undue interruption or embarrassment.

Encourage the client to establish a regular elimination pattern to prevent urinary incontinence. This can be successfully accomplished by using techniques such as relaxation and timing. The client, with the assistance of the nurse, establishes a voiding schedule. Once the client has met the goal of staying continent for the established time period, the interval between voidings can be lengthened. Within the interval between urinations, the client can use relaxation exercises to help manage the feelings of urgency.

Positioning

Positioning of the client plays an important role in elimination. Sitting is the usual position for both men and women for bowel elimination. Sitting is also the usual position for women to urinate; standing is the position preferred by some men. Clients unable to use the toilet require assistance in accomplishing elimination. Devices such as the bedpan, commode, or urinal can be substituted (Figures 39-5 and 39-6).

Clients who use a bedpan need as comfortable a setting as possible, therefore, after placement of the

TABLE 39-6
Common Dietary Fiber Sources

Whole grains	Wheat, rye, oat, millet, buckwheat All bran cereal Shredded wheat cereal Popcorn Brown rice
Fruits	Apple Blackberries Raspberries Strawberries Peach Pear Bananas Apricot
Vegetables	Beans Asparagus Carrots Garlic Broccoli Brussels sprouts Acorn squash Zucchini squash

Figure 39-5 Types of Bedpans: A. Fracture, B. Regular

Figure 39-6 Male Urinal

bedpan the head of the bed should be elevated to a 45° angle, unless contraindicated. The nurse may need to assist the client to cross the legs in order to create somewhat of a sitting position. Male clients who are unable to stand should have the head of the bed elevated to a 45° angle, unless contraindicated, while using the urinal. Procedure 39-1 outlines the steps in positioning and removing a bedpan.

Clients who are able to get out of bed but are unable to ambulate to the toilet can use a bedside commode, which resembles a toilet but is portable. Typically, the client is assisted to stand and pivot to the commode from the bed.

Initiate Exercise Regimen

Regular exercise leads to good muscle tone and body metabolism. Exercise also stimulates the bowels to move regularly and leads to good urine production. Poor muscle tone can lead to impaired bladder muscle contraction and poor urination control. Pelvic muscle exercises are taught to manage SUI, and a strength training program is begun using principles of exercise physiology. Clients are taught to identify, isolate, and contract the pelvic muscles and to avoid contraction of distant

PROCEDURE 39-1

Positioning and Removing a Bedpan

Equipment

- Bedpan (regular or fracture)
- Disposable gloves
- Bedpan cover
- Toilet paper
- Washcloth and towel

Action

Rationale

Positioning a Bedpan

- | | |
|--|--|
| <ol style="list-style-type: none"> 1. Close curtain or door. 2. Wash hands, apply gloves. 3. Lower head of bed so client is in supine position. 4. Assist client to side-lying position using side rail. 5. Warm bedpan under warm water if needed, powder if necessary. 6. Place bedpan under buttocks, with lower end near the lower back region (Figure 39-7). 7. While holding the bedpan with one hand, help the client to roll onto her back (Figure 39-8). 8. Check placement of bedpan by looking between client's legs. | <ol style="list-style-type: none"> 1. Provides for privacy. 2. Prevents transmission of microorganisms. 3. The supine position will increase ability of client to move to side-lying position. 4. Provides for best position for proper placement of bedpan. 5. For comfort, prevents bedpan from sticking to the skin. 6. Ensures proper placement of the bedpan before client rolls on top of bedpan. 7. Prevents dislocation or alignment of bedpan. 8. May prevent spillage due to misalignment of bedpan. |
|--|--|

(continues)

PROCEDURE 39-1

Positioning and Removing a Bedpan (continued)

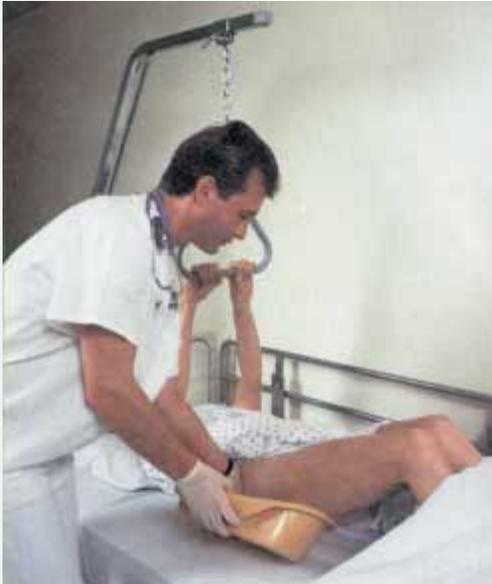

Action

Figure 39-7 Slip the bedpan under the client's buttocks while client lifts herself with the trapeze.

9. If indicated, elevate head of bed to 45° angle.
10. Place call light within reach of patient; place side rails in upright position and allow for privacy.

Removing a Bedpan

11. Wash hands, don gloves.
12. Lower head of bed to supine position.
13. While holding bedpan with one hand, roll client to side.
14. Assist with cleaning or wiping; always wipe with a front to back motion.
15. Empty bedpan, clean it, and store it in proper place; if bedpan is to be emptied outside client's room, cover it during transport.
16. Remove gloves and wash hands.
17. Allow client to wash hands.
18. Place call light within reach; recheck that side rails are in the upright position.

Rationale

Figure 39-8 Place the bedpan against the client's buttocks while rolling client to side.

9. Check physician order; bed remains flat if patient has a spinal cord injury or spinal surgery. Elevating the head of bed creates a more normal elimination position.
10. Privacy allows for a more comfortable elimination environment; elevated side rails provide for safety.
11. Prevents transmission of microorganisms.
12. Increases patient's ability to move to side-lying position.
13. Prevents possible spillage of bedpan contents.
14. Client may not be able to clean herself; wiping from front to back decreases chances of cross-contamination from anus to urethra.
15. Promotes privacy and decreases the chance of spilling contents.
16. Prevents transmission of microorganisms.
17. Provides for physical hygiene and comfort.
18. Ensures client safety and comfort.

NURSING TIP

Assisting with Elimination

Elimination is normally a private function done without assistance. However, during periods of immobility and illness, assistance is needed. The main focus of the nurse is to provide maximum comfort and privacy to lessen the client's embarrassment.

muscles groups such as the thigh or abdominal muscles. Because clients frequently have difficulty isolating the pelvic muscles, biofeedback may be helpful. The nurse teaches the client to perform a single exercise that combines maximal strength and endurance. The client is asked to perform a maximal strength contraction of the muscles “surrounding the urethra and vagina or rectum” for a count of 10, or approximately 6 seconds, followed by a rest period of equal length. The program begins with few contractions (typically 10 or fewer), and the number of repetitions is increased to a maximum of 35 to 50. The exercise regimen must be integrated into activities of daily living for maximal effectiveness. Pelvic muscle exercises, particularly when combined with biofeedback techniques, are typically taught by a specialty practice or advanced practice nurse with specific education in the management of the client with SUI.

Other management techniques are administered by the advanced practice or specialty practice nurse. These include transvaginal or transrectal electrical stimulation and placement of a vaginal pessary (a supportive device).

Inadequate tone in the abdominal muscles, diaphragm, and the perineal muscles can cause difficulty in defecating. If a client is suffering from constipation, a regimen of walking or light recreational exercise should be recommended to promote peristalsis and defecation.

Suggest Environmental Modifications

Functional incontinence is managed by removing the barriers to toileting. The environment is manipulated to maximize opportunities for toileting, to minimize the impact of poor mobility, and to remove any environmental barriers. Clothing is carefully evaluated, and buttons, zippers, and multiple layers of clothing are exchanged for items that are simpler to remove. Mobility is maximized by selection of shoes with nonskid soles, and Velcro straps are preferred over strings when dexterity is compromised. The accompanying display

APPLICATION: HOME CARE

Mr. M is a 79-year-old with Parkinson's disease and altered cognition. His home health care nurse was consulted for management of his incontinence. A recent medical evaluation had shown mild sensory urgency but failed to demonstrate significant urge or SUI. He is cared for primarily by Mrs. M, his 70-year-old wife. She reports using paper towels and baby diapers to contain his urinary leakage. She notes that he is wet every 2 to 3 hours and that he awakens her at night to urinate, but he is unable to postpone voiding long enough to reach the toilet.

On the basis of this health history, his home health care nurse diagnosed functional incontinence. She inspected the home and found that the bathroom was 35 steps from the couch and 15 steps from the bed. Mr. M walks with some difficulty, requiring a walker for assistance. He usually wears slick-soled shoes and trousers with two buttons and a zipper. The home health nurse recommended alterations in clothing and the addition of a hand-held urinal for rapid urination. Mr. M has begun to wear stretchband trousers that can be easily lowered for urination. A hand-held urinal was offered when the urge to urinate was perceived, thereby dramatically reducing the number of incontinent episodes. Because of these interventions, no containment device was required for urination, and his incontinent episodes were reduced from 2 to 3 per day to fewer than one per week.

describes the effectiveness of environmental modifications in managing functional incontinence.

The nursing management of fecal incontinence begins with measures to normalize stool consistency because constipation and diarrhea increase the risk of incontinent episodes. The environment is also manipulated to minimize functional limitations to bowel elimination. Mobility is enhanced by assistive devices (canes, walkers) as needed, and by altering seating and toilets to a height that allows optimal ease when transferring. Clothing is altered to minimize the time required for removal in preparation for defecation. Environmental barriers including poor lighting, narrow doorways, and slippery flooring are removed, or portable toileting facilities are made available.

Initiate Behavioral Interventions

A scheduled defecation program is used for clients with either a diminished ability to sense rectal distension or altered cognition who are unable to adequately respond to the presence of a bolus of stool in the rectum. The colon is cleansed of any excess stool, using an oral laxative or enema. The diet is altered to enhance the formation of a soft, solid stool, and supplemental bulk is added if indicated. Patterns of bowel elimination are evaluated,

and the client is encouraged to defecate on this schedule if feasible. Otherwise, bowel elimination is scheduled after either a meal or another stimulant, such as a caffeinated beverage or a pharmacologic agent. The importance of heeding the urge to defecate is emphasized, and the client with altered cognition is prompted to defecate.

Clients with significant sensory and motor deficits of the rectum and anus typically require a scheduled defecation program combined with vigorous stimulation of defecation. Persons with a paralyzing neurologic disorder have significant loss of anal sphincter control, poor abdominal muscle control, and altered colonic mobility. As a result, defecation must be scheduled and vigorously stimulated to avoid impaction and fecal incontinence. The colon is cleansed and stool consistency is normalized at the outset of the program. A timetable for bowel elimination is identified. Because of the need for an extensive process for effective defecation, this program must consider the schedule of the client and significant others, as well as premorbid defecation patterns. The bowel is stimulated by a pharmacologic device, such as bisacodyl or a mini-enema.

Behavioral interventions play a primary role in the management of urge incontinence. Methods of biofeedback are used to teach the client to perform either a “quick flick” maneuver or a sustained contraction in response to an episode of precipitous urgency. The quick flick is a rapid, maximal contraction of the pelvic muscles held for 3 to 4 seconds, and a sustained contraction is held for 6 to 10 seconds. The client is instructed to stop, rather than rush to the bathroom, thus decreasing the risk of falling. Several quick flicks or a sustained contraction are then performed until the precipitous urge is controlled. At this point, the client is instructed to proceed to the bathroom at a normal pace, but without further delays.

Other techniques, including electrical stimulation and more extensive biofeedback training, also may be used for urge incontinence. These treatment programs are typically managed by the advanced practice or specialty practice continence nurse.

The management of urinary retention is influenced by the underlying cause and the severity of the symptom. Mild urinary retention caused by poor detrusor contractility or obstruction may be managed by timed voiding or by double voiding. Timed voiding is a strategy to reduce overdistension and loss of muscle tone in clients with diminished sensations of urinary urgency. The client is taught to urinate at specific intervals, typically every 3 to 4 hours. Double voiding is an attempt to increase the efficiency of urine evacuation by contracting the detrusor twice during micturition. The client is taught to void, rest on the toilet for 2 to 5 minutes, and void again.

Intermittent catheterization is used for moderate to severe urinary retention, when the residual urine volume is 50% or more of the total bladder capacity. Intermittent self-catheterization is taught using a clean

technique. The client is taught to wash his hands and to locate and catheterize the urethra using a water-based soluble lubricant. Catheters may be cleaned and reused, and the client or significant other may catheterize without applying sterile gloves.

Monitor Skin Integrity

Because problems with urinary functioning may result in disturbances in hydration and excretion of body wastes, the skin should be carefully assessed for color, texture, turgor, and the excretion of any wastes. The integrity of the skin in the perineal area also should be assessed. Problems with incontinence may result in severe excoriation.

The risk of altered skin integrity is significant. The client is taught to regularly clean and thoroughly dry the skin. Clients with fragile skin are advised to use a skin cleanser; otherwise, use of soap and water is adequate. After cleansing, the skin should be dried thoroughly. A hair dryer set on the low (cool) setting may be recommended.

When monitoring a client with diarrhea, the nurse should assess the perineal skin for altered integrity. After each defecation, the skin is routinely cleansed with tap water or a gentle cleanser specifically designed for incontinence. Soap and water and abrasive cleaning techniques are avoided because they increase discomfort and the risk of altered skin integrity. The skin is then protected by application of a sealant or moisture barrier. Denuded skin is first treated with a pectin-based powder, followed by a skin sealant or moisture barrier.

Apply a Containment Device

Condom Catheter

The condom catheter is a device that resembles a condom with a large-caliber connector at its distal end (Figure 39-9). This is connected to a drainage bag via a leg bag or bedside container for urinary containment. Procedure 39-2 discusses the application of a condom catheter. Several types of condom catheters are available. The ideal device adheres to the penile skin without

Figure 39-9 Condom Catheter

producing irritation and has sufficient elasticity to maintain its watertight seal whether the penis is in an erect or a flaccid state. Because of the potential for altered skin integrity, the condom catheter is reserved for severe SUI.

Men without adequate upper extremity dexterity may manage urine containment using a condom catheter. The bladder outlet resistance caused by detrusor sphincter dyssynergia must be managed by pharmacotherapy or by transurethral or laser sphincterotomy. A special device, the Urolume, also may be inserted. This device consists of a wire mesh that is inserted into the urethra via a special cystoscopic device and expanded at the membranous urethra. The wire mesh of the Urolume gently holds the sphincter open, promoting urine evacuation and preventing the deleterious effects of sphincter dyssynergia.

Incontinent and Dribble Pads

Many women attempt to contain urine with feminine hygiene pads. Although these pads effectively contain menstrual flow, they are not designed for urine loss. As a result, they must be changed frequently, and the risk of odor and soiling outer clothing is enhanced. Women with mild SUI typically benefit from a small incontinent pad that adheres to the undergarments. Unlike the feminine hygiene pad, the ideal incontinent pad contains Superabsorbents[®] that increase the product's absorptive ability. Women with more severe SUI also may use a device that adheres to the undergarments. However, larger pads that are capable of absorbing up to 500 ml are recommended (Figure 39-10). Only women with very severe leakage are advised to use an incontinent brief. It is important to remember that containment devices are considered temporary, and the ultimate goal is reduction or ablation of urinary leakage so that pads are not needed.

Men with mild SUI may use a “dribble pad,” a device that adheres to the undergarments and holds the penis in a specially designed pouch. More absorptive pads or incontinent briefs are reserved for severe cases. Two additional devices, the penile clamp and condom

Figure 39-10 Incontinent Pads

Nursing Process Highlight

IMPLEMENTATION

Teach the client and significant others to remove and reapply the condom. Teach skin inspection and care during routine changes for the hospitalized client. Advise the client to seek care if erosions, rashes, or other lesions are noted on the penis.

catheter, are also used for men with SUI. The penile clamp is a constrictive device that mechanically closes the pendulous urethra. The device is worn for a brief period and removed to prevent ischemia to local tissues. Because of the risk of necrosis and discomfort associated with the clamp, its use is limited.

Rectal Pouch and Rectal Tube

Severe diarrhea may justify the use of a rectal pouch or rectal tube to contain leakage and to protect the surrounding skin. The rectal pouch is a drainable pouch attached to an adhesive skin barrier that conforms to the perianal region. The pouch is attached to the perianal area and any exposed skin surfaces are carefully protected with a skin sealant. Attachment to intact skin is relatively straightforward; however, application to denuded skin is difficult, and consultation with an enterostomal therapist or incontinence nurse specialist is recommended.

The rectal tube is an alternative to the rectal pouch. A larger catheter (30 French) is passed into the rectum and attached to a large bedside drainage bag. Although the rectal tube is effective for short-term use, its safety when used over longer periods of time is uncertain.

Initiate Diet and Fluid Therapy

It is important to remember that foods and beverages affect each client differently and that a very restrictive diet, designed to remove all potential irritants, is not reasonable for most clients. Therefore, nurses can teach the client to eliminate potential irritants one at a time and to judge the effects on patterns of voiding and urinary leakage.

Dietary fiber and fluid intake can be increased to promote the passage of soft, hydrated stool. The client who is unable or unwilling to obtain adequate fiber from the diet may be given a bulk laxative (such as Metamucil) or a bran mixture as a specific dietary supplement. The nurse should present options for taking this supplement, honoring the client's preferences whenever feasible. Initially, 3 to 6 grams of the supplement is

PROCEDURE 39-2

Applying a Condom Catheter

Equipment

- Bedpan (regular or fracture)
- Disposable gloves
- Bedpan cover

- Toilet paper
- Washcloth and towel

Action

1. Wash hands and apply gloves.
2. Select an appropriate condom catheter.
3. Cleanse the penile shaft.
4. Inspect the penile shaft for excessive hair.
5. Inspect the penis for altered skin integrity.
6. Stretch the shaft of the penis and unroll the condom to the base of the penis (Figure 39-11). Follow product directions for the application of the sealant (Figure 39-12).
7. Attach the condom to the drainage apparatus, either a leg bag or bedside drainage bag.
8. Remove gloves and wash hands.
9. Remove and reapply the condom catheter every 24 to 48 hours, or when leakage occurs.

Rationale

1. Reduces risk of contamination.
2. The condom catheter must be sized correctly (refer to manufacturer's recommendations), contain a distal tip that resists twisting and occlusion, and contain an adhesive that prevents leakage; latex condom catheters are avoided in men who are allergic to latex and in boys with myelodysplasia.
3. Reduces surface dirt and pathogens.
4. Excessive penile hair is shaved to provide a watertight seal when the condom is applied.
5. Small lesions may be protected by the use of a skin sealant; significant erosions or rashes require consultation with the enterostomal nurse specialist or a dermatologist.
6. The condom is applied over the entire penile shaft to maximize a watertight seal; the adhesive may be built into the wall of the condom, or a dual-sided sealant strip may be used to prevent leakage.
7. Ensures adequate urine containment.
8. Reduces the risks of contamination.
9. Regular reapplication allows routine inspection of the penile skin and avoids bacterial overgrowth and altered skin integrity under the condom.

Figure 39-11 Unroll condom catheter to the base of the penis.

Figure 39-12 Secure the condom catheter with a strap.

administered, and the dosage is gradually increased until a soft, well-formed stool is obtained.

The initial management of diarrhea involves the removal of factors that predispose the individual to the condition and the maintenance of adequate fluid and electrolyte balance. The nurse collaborates with the client, physician, and dietitian to determine foods that contribute to diarrhea by malabsorption or inflammation of the gastrointestinal tract. These foods are then eliminated from the diet or given with a substance (such as Lactaid) that renders them tolerable to the client. Persons with infectious diarrhea are given antimicrobials to destroy the pathogens that produce diarrhea. Anti-inflammatory drugs are administered as directed for diarrhea caused by inflammatory disorders of the bowel (see the accompanying Nursing Checklist).

Bulking agents may be used for clients with watery diarrhea. These agents absorb water in the stool and improve the consistency of feces. Antidiarrheal drugs, including diphenoxylate and loperamide, may be administered to reduce intestinal motility and increase absorption of water from the stool. However, these drugs are contraindicated in patients with infectious diarrhea because the diminished motility would enhance overgrowth of pathogens in the gastrointestinal tract.

Clients who have significant diarrhea may experience mild to severe dehydration and electrolyte imbalances. Oral fluids are given as tolerated; beverages containing glucose and electrolytes are encouraged. In contrast, beverages that contain caffeine are avoided because they stimulate colonic motility. Individuals with severe fluid volume deficits and large-volume diarrhea may require intravenous fluid and electrolyte support until the diarrhea subsides.

NURSING CHECKLIST

Managing Diarrhea

- Eliminate from the diet foods and beverages that contain malabsorbed substances.
- Administer antimicrobials for infectious diarrhea.
- Administer anti-inflammatory agents for irritative disorders of the bowel.
- Administer bulking agents for watery stools.
- Provide oral fluids as tolerated; offer fluids rich in electrolytes.
- Administer intravenous fluids and electrolytes as directed for clients unable to tolerate oral fluids.
- Monitor perianal skin for integrity.
- Apply skin barriers for altered integrity.
- Apply a rectal pouch or insert a rectal tube for severe, large-volume diarrhea.

Administer Medications

Constipation is initially managed by assisting the individual to pass hardened stool or by removing any impacted feces (see the accompanying Nursing Checklist). Bowel evacuation is encouraged by an oral laxative, such as psyllium, a bulk-forming agent. Constipation resulting in an impaction requires mechanical disruption and removal, followed by a cleansing enema or an oral laxative. As an alternative, a pulsed irrigation enhanced evacuation (PIEE) system can be used to remove severe impaction. The PIEE uses gravity to deliver intermittent pulses of warmed saline to break up and remove hardened and impacting fecal material.

The medical management of SUI includes both OTC and prescription drugs. OTC medications such as Dexatrim without caffeine and Sudafed contain the α -adrenergic agonists phenylpropanolamine and pseudoephedrine, respectively, which increase urethral sphincter tone and relieve urinary leakage. Nurses teach the client the specific purpose of these medications, and they advise clients to ignore the dosage and scheduling recommendations on the medication container. Instead, the client is taught to take the medication only during waking hours rather than around the clock to reduce the risk of associated insomnia. Potential side effects associated with these medications, such as restlessness and hypertension, are discussed with the client, and blood pressure is monitored regularly.

Stress urinary incontinence also may be managed by prescription medications including imipramine (Tofranil) and topical estrogens, often administered in combination. The client is taught the dosage and administration of each of these agents. Because imipramine has anticholinergic as well as α -adrenergic

NURSING CHECKLIST

Managing Constipation

- Remove hardened or impacted stool by mechanical means, cleansing enema, stimulant or laxative, or pulsed irrigation enhanced evacuation (PIEE).
- Increase dietary fiber and fluid until soft, formed stool is obtained.
- Administer supplemental bulk laxative for client intolerant of dietary fiber.
- Encourage light exercise to stimulate defecation.
- Encourage regular pattern of defecation.
- Teach client to stimulate defecation by mini-enema, oral laxative or stimulant, or digital stimulation as needed.

effects, clients are advised of additional side effects including dry mouth, the potential for constipation, and mydriasis. Women who are placed on topical or systemic estrogens are advised to seek ongoing care from their gynecologist, including routine vaginal examinations and Papanicolaou (Pap) smears.

Medications are often prescribed for urge urinary incontinence. Anticholinergics or antispasmodics relax detrusor muscle contractions by blocking the action of acetylcholine, by a local anesthetic effect, or by a direct effect on the detrusor muscle. Common agents, their actions, and potential side effects are described in Table 39-7. None of these agents will be effective unless the client is taught to adhere to a timed voiding schedule and to identify and limit the intake of bladder irritants.

Several pharmacologic agents may be used in the management of urinary retention. Finasteride, a 5- α -reductase inhibitor, is used to reduce prostatic size and related urinary retention. Men who take finasteride are taught the dosage and administration of the drug and its potential side effects, including impotence and loss of libido. Caregivers are cautioned to refrain from handling the drug without gloves because transdermal absorption and irritation of the skin have been reported.

Alpha-adrenergic blocking agents also may be used to manage urinary retention caused by prostatic hyperplasia, bladder neck dyssynergia, or detrusor striated sphincter dyssynergia. Because of the risk of postural hypotension when the medication reaches a peak

plasma level, the client is taught to take these drugs before bedtime. Clients are also taught to monitor for medication side effects, including postural dizziness during waking hours, fatigue, and headache. The significance of titrating the dosage of an α -blocking agent is emphasized, and the client is reminded that the dosage must be retitrated if the medication is inadvertently stopped for a period of more than 72 hours.

Perform Catheterization

Occasionally, an indwelling urethral or suprapubic catheter may be used to provide continuous drainage for reflex incontinence (Figure 39-13). An indwelling catheter may be inserted for an acute episode of urinary retention or when other strategies to manage retention are ineffective. A catheter is chosen that minimizes urethral irritation and maximizes drainage from the bladder. A silicone or other inert-material catheter is preferred over a Silastic catheter coated with Teflon. A Lubricious-coated catheter (Bard Urological, Covington, Georgia) also may be used because of its hydrophilic nature and its low friction coefficient. The client is provided with a drainage bag with adequate storage capacity for overnight use (typically 2000 ml) and a leg bag with non-latex straps when indicated.

The use of a coudé catheter is indicated when intermittent catheterization is needed. The coudé catheter works much like the other catheters; however, a

TABLE 39-7
Common Anticholinergic/Antispasmodic Medications

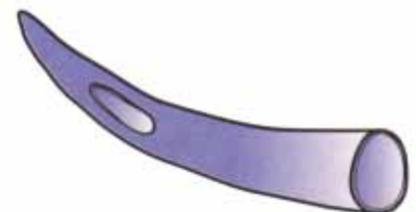

Agent	Effect	Common Side Effects
Oxybutynin (Ditropan)	Relaxation of unstable detrusor contractions Reduces urgency Maximal therapeutic response requires 5 to 7 days	Dry mouth Slightly blurred vision Constipation Nightmares, confusion may occur in elderly client
Propantheline (Pro-Banthine)	Relaxation of unstable detrusor contractions Maximal therapeutic response requires 3 to 5 days	Similar to oxybutynin effects
Hyoscyamine (Levsin)	Relaxation of unstable detrusor	Similar to oxybutynin effects, but dry mouth less pronounced

A.

B.

C.

Figure 39-13 Types of Catheters: A. Foley Catheter; B. Three-Way Foley Catheter with Balloon Inflated; C. Coudé Catheter

distinguishing feature is that the tip of the catheter is more pointed and curved. The coude catheter does not have a balloon; therefore it cannot be used for a procedure requiring an indwelling catheter. Procedures 39-3 and 39-4 discuss catheterization. Procedures 39-5 and 39-6 discuss irrigation of catheters.

Intermittent Self-Catheterization

Women with reflex incontinence have more-limited options for management because no effective condom device has been designed for women. Intermittent self-catheterization is chosen whenever feasible. This option

PROCEDURE 39-3

Performing Urinary Catheterization: Male Client

Equipment

- | | |
|---|---|
| <ul style="list-style-type: none"> ■ Indwelling catheter with drainage system ■ Adequate lighting source ■ Blanket or drape ■ Warm water ■ Forceps | <ul style="list-style-type: none"> ■ Sterile catheterization kit ■ Disposable gloves ■ Soap and washcloth ■ Towel |
|---|---|

Action

1. Provide for privacy and explain procedure to client.
2. Set the bed to a comfortable height to work, and raise the side rail on the side opposite you.
3. Assist the client to a supine position with legs slightly spread.
4. Drape the client's abdomen and thighs, and place the penis over the thighs.
5. Ensure adequate lighting of the penis.
6. Wash hands, don disposable gloves, and wash perineal area.
7. Remove gloves and wash hands.
8. Prepare a sterile field, apply sterile gloves, and connect the catheter and drainage system (if necessary).
9. Gently retract the foreskin (if present) and, using forceps, cleanse the glans penis with a povidone-iodine solution or other antimicrobial cleanser (see Figure 39-14).
10. Inject 10 ml water-soluble lubricant (use a 2% xylocaine lubricant whenever feasible) into the urethra *before* catheter insertion; generously coat the distal portion of the catheter with water-soluble, sterile lubricant.
11. Hold the penis perpendicular to the body and pull up gently.
12. Steadily insert the catheter about 8 inches, until urine is noted. Continue inserting until the hub of the catheter (bifurcation between drainage port and retention balloon arm) is met.

Rationale

1. Promotes cooperation and client dignity.
2. Promotes proper body mechanics and assures client safety.
3. Relaxes muscles to facilitate insertion of the catheter.
4. Promotes client comfort and warmth.
5. Facilitates proper execution of technique.
6. Reduces transfer of microorganisms.
7. Reduces transfer of microorganisms.
8. The catheter and drainage system may be pre-connected; otherwise it is connected before catheterization to avoid exposing the client to ascending infection from an open-ended catheter.
9. Removes dirt and minimizes the risk of urinary tract infection by removing surface pathogens.
10. Avoids urethral trauma and discomfort during catheter insertion and facilitates insertion.
11. Facilitates catheter insertion by straightening urethra.
12. Ensures adequate catheter insertion before retention balloon is inflated.

(continues)

PROCEDURE 39-3

Performing Urinary Catheterization: Male Client (continued)

Action

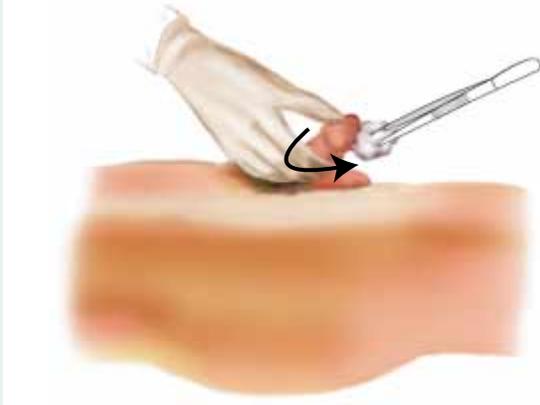

Figure 39-14 Cleanse the glans penis with a cotton ball held with forceps.

13. Inflate the retention balloon using manufacturer's recommendations or according to physician orders.
14. Instruct the client to immediately report discomfort or pressure during balloon inflation; if pain occurs, discontinue the procedure, deflate the balloon, and insert the catheter farther into the bladder.
15. Gently pull the catheter until the retention balloon is snugged against the bladder neck (resistance will be met) (Figure 39-15).

Figure 39-15 Correct Catheter Placement: Male Client

16. Secure the catheter to the abdomen or thigh.
17. Place the drainage bag below the level of the bladder.
18. Remove gloves, dispose of equipment, and wash hands.
19. Help client adjust position.
20. Assess and document the amount, color, odor, and quality of urine.

Rationale

13. Ensures retention of the balloon; up to twice the recommended volume of fluid may be inserted safely into the retention balloon if needed.
14. Pain or pressure indicates inflation of the balloon in the urethra; further insertion will prevent misplacement and further pain or bleeding.
15. Maximizes continuous bladder drainage.

16. Prevents excessive traction from the balloon rubbing against the bladder neck, inadvertent catheter removal, or urethral erosion.
17. Maximizes continuous drainage of urine from the bladder (drainage is prevented when the drainage bag is placed above the abdomen).
18. Prevents transfer of microorganisms.
19. Promotes client comfort.
20. Monitors urinary status.

NURSING TIP

Catheterization Procedure

1. Prepare the client for catheterization by reviewing the procedure. Reassure the client that catheterization will not produce a sharp pain; instead, inform the client that catheterization will produce sensations of intense urgency to urinate and pressure centered on the urethral and suprapubic area.
2. Documentation of the amount of water used to inflate the retention balloon assists when removing the indwelling catheter.
3. A Silastic catheter with Teflon is used only for short-term catheterization. Otherwise the catheter should be constructed of silicone or a Lubricious coating to minimize urethral trauma and irritation.
4. Clients with myelodysplasia should be routinely catheterized with nonlatex products.

is typically used in combination with pharmacotherapy for detrusor hyperreflexia. Indwelling catheterization is used only when other means of bladder management are not feasible.

Of the bladder management programs available for the client with a spinal injury or multiple sclerosis and reflex incontinence, intermittent self-catheterization is preferred when feasible. The nurse teaches the client with adequate upper extremity dexterity to perform self-catheterization, and the skill is also taught to significant others. Pharmacotherapy, consisting of an anticholinergic agent, imipramine, or (rarely) a calcium channel blocker, is frequently required to control hyperreflexic detrusor contractions.

Administer Enemas

Enema administration is a procedure used to introduce fluid into the lower bowel. The purpose of an enema is to cleanse the lower bowel, to assist in the evacuation of stool or flatus, or to instill medication. Table 39-8 outlines four types of enemas, along with the solutions and the indications for use of each.

Enemas can be large or small depending on their purpose. Large-volume enemas, which typically contain 500 to 1000 ml fluid, are administered to cleanse the

PROCEDURE 39-4

Performing Urinary Catheterization: Female Client

Equipment

See Procedure 39-3

Action	Rationale
1. See Procedure 39-3, steps 1 and 2.	
2. Assist the client to a supine position with legs spread and feet together or to a side-lying position with upper leg flexed.	2. Facilitates visualization of area and promotes client comfort.
3. Drape client's abdomen and thighs.	3. Promotes client comfort and warmth.
4. Ensure adequate lighting of the perineum.	4. Facilitates proper execution of technique.
5. Refer to Procedure 39-3, steps 6, 7, and 8.	
6. Separate the perineum and, using forceps, cleanse the periurethral mucosa with a povidone-iodine or other antimicrobial cleanser (Figure 39-16).	6. Removes dirt and minimizes the risk of urinary tract infection by removing surface pathogens.
7. Generously coat the distal portion of the catheter with water-soluble, sterile lubricant.	7. Avoids urethral trauma and discomfort during catheter insertion.
8. Gently insert the catheter into meatus until urine is noted. Continue inserting for 1 to 3 additional inches.	8. Ensures adequate catheter insertion before retention balloon is inflated.

(continues)

PROCEDURE 39-4

Performing Urinary Catheterization: Female Client (continued)

Action

Figure 39-16 Cleanse the labia minora with a cotton ball held with forceps.

9. Inflate the retention balloon using manufacturer's recommendations or according to physician orders.
10. Instruct the client to immediately report discomfort or pressure during balloon inflation; if pain occurs, discontinue the procedure, deflate the balloon, and insert the catheter further into the bladder.
11. Gently pull the catheter until the retention balloon is snugged against the bladder neck (resistance will be met) (Figure 39-17).
12. Secure the catheter to the abdomen or thigh.
13. Place the drainage bag below the level of the bladder.
14. See Procedure 39-3, steps 18–20.

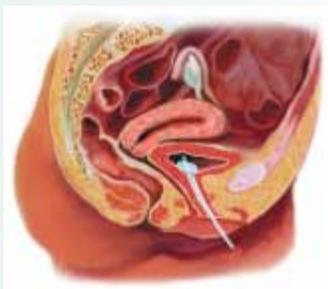

Figure 39-17 Correct Catheter Placement: Female Client

Rationale

9. Ensures retention of the balloon; up to twice the recommended volume of fluid may be inserted safely into the retention balloon if needed.
10. Pain or pressure indicates inflation of the balloon in the urethra; further insertion will prevent misplacement and further pain or bleeding.
11. Maximizes continuous bladder drainage.
12. Prevents excessive traction from the balloon rubbing against the bladder neck, inadvertent catheter removal, or urethral erosion.
13. Maximizes continuous drainage of urine from the bladder (drainage is prevented when the drainage bag is placed above the abdomen).

PROCEDURE 39-5

Irrigating an Open Catheter

Equipment

- | | |
|--|--|
| <ul style="list-style-type: none"> ■ Catheter tip irrigation syringe ■ Sterile gloves ■ Sterile basin | <ul style="list-style-type: none"> ■ Solution in amount ordered by physician ■ Sterile drape ■ 5–10 alcohol wipes |
|--|--|

Action

Rationale

- | Action | Rationale |
|---|---|
| 1. Introduce yourself, explain procedure. | 1. Awareness of procedure and what to expect may relax client. |
| 2. Wash hands. | 2. Decreases chance of contamination. |
| 3. Open sterile drape and form a sterile field. | 3. Promotes sterile environment. |
| 4. Using sterile technique, open and place basin on sterile field. | 4. Using sterile technique decreases the chances of bacteria being introduced into the bladder. |
| 5. Pour solution into sterile basin. | 5. Solution should be no warmer than 99° to 102°F. |
| 6. Open syringe, remove tip and fill with solution, then place at opposite end of sterile field away from basin and solution. | 6. Maintains sterile environment. |
| 7. Open alcohol wipes exposing only half a wipe. | 7. Facilitates handling of wipe. |
| 8. Don sterile gloves. | 8. Prevents or inhibits contamination. |
| 9. Clean junction between catheter and drainage tube with alcohol wipes. | 9. Prevents contamination when juncture is disconnected. |
| 10. Simultaneously twist and pull catheter and drainage tube apart. | 10. Twisting and pulling makes disconnections easy. |
| 11. Hold both drainage tube and catheter in non-dominant hand; with dominant hand take catheter tip syringe and place into catheter opening. Depending on the amount, syringe may need to be refilled and procedure repeated. | 11. Holding both drainage and catheter tubing decreases the chances of falling and cross-contamination. |
| 12. Gently squeeze solution into the catheter using plunger. | 12. Rapid infusion may cause bladder spasms. |
| 13. Clean both tips with alcohol and reconnect. | 13. Avoids reintroducing bacteria into catheter system. |
| 14. Drain solution via gravity. | 14. Pulling back solution through syringe may cause damage to bladder. |
| 15. Clean work area and dispose of contaminated supplies properly. | 15. Maintains safe, clean work environment. |
| 16. Remove gloves and wash hands. | 16. Prevents spread of bacteria. |
| 17. Document amount of solution given; amount, color, and clarity of return; and client's response. | 17. Provides record of procedure and client's status. |

PROCEDURE 39-6

Irrigating a Closed Catheter

Equipment

- Three-way indwelling catheter
- Sturdy IV pole
- Gloves

- Irrigation solution
- Large drainage bag
- Wipes

Action

1. Explain procedure and provide for privacy.
2. Obtain irrigation solution from pharmacy as prescribed by the physician.
3. Hang solution (1–3 L) from a sturdy IV pole (depending on anticipated rate of irrigation) using one-, two-, or three-port irrigation tubing.
4. Connect the irrigation infusion tubing to the third irrigation port of the three-way catheter; refer to the product for instructions and identification of the irrigation port (Figure 39-18).

Figure 39-18 Connect the irrigation tubing to the irrigation port of the catheter.

5. Consult the physician concerning the rate of irrigation; *never* slow the irrigation rate because “pink urine” has been observed unless directed by the physician or urologic nurse specialist.
6. Regularly check the drainage container; empty the bag when filled two-thirds or more.

Rationale

1. Promotes cooperation and client dignity.
2. Irrigation solutions are selected for their antimicrobial properties or to remove clots and debris; a hypotonic or hypertonic solution may be absorbed through resected tissue causing fluid and electrolyte imbalances.
3. Relatively rapid irrigation may be used to remove debris or clots from the bladder; slower irrigations are used to treat local infection.
4. Ensures proper irrigation and simultaneous drainage from the bladder.
5. Clotting and catheter obstruction following transurethral resection of the prostate or transurethral sphincterotomy frequently occur because the nurse has prematurely slowed the irrigation; a pink solution is expected when an adequate irrigation is being performed; this finding does not mean that all bleeding has stopped.
6. Filling of the drainage bag occurs rapidly and can obstruct the irrigation.

TABLE 39-8
Types of Enemas

Type	Solution	Indication
Cleansing	Tap water Soap suds Normal saline	Evacuate lower bowel before diagnostic studies or surgery
Retention (should be retained for at least 30 min)	Emollient (oil)	Soften and lubricate stool for easy evacuation
Carminative (return flow)	Tap water Normal saline	Relief of distension due to flatus
Medication	Normal saline Sterile water mixed with prescribed medication	Will depend on what medication is introduced

bowel. Small-volume enemas are used for the purpose of evacuating stool or instilling medications in the lower bowel. These are usually found as prepackaged solutions, which contain 150 to 240 ml fluid. Refer to Procedures 39-7 and 39-8 for guidelines on enema administration.

Caution should be used when administering large-volume enemas, because fluid and electrolyte imbalance can occur. This is related to the volume, frequency, and type of solution used. Table 39-9 lists the types of enema solutions and their effects.

NURSING ALERT

Enema Administration

If “enema till clear” is ordered, no more than 3 L fluid should be administered in any one series of enemas. Repeated enemas produce irritation of bowel mucosa and perianal area, as well as electrolyte loss and exhaustion. If returns are not clear, consult physician for further instructions.

NURSING ALERT

Effects of Enemas

Large-volume enemas disrupt the normal flora of the bowel, predisposing the client to diarrhea as the bowels recover from this traumatic event. Provide yogurt with active cultures or buttermilk to help the client restore normal flora. Antibiotic enemas may disrupt vitamin K synthesis by intestinal flora. Supplemental vitamin K may be required until normal intestinal flora is restored.

NURSING TIP

Small and Mini-Enemas

Small enemas come premixed and in their own receptacle containing about 150 to 240 ml solution. Mini-enemas usually contain 4 to 10 ml liquid. Clients should be instructed to call for assistance immediately if light-headedness, dizziness, or faint feeling occur.

TABLE 39-9
Solutions Used for Enemas

Solution	Action	Class
Tap water	Stimulates, dilates bowel	Hypotonic
Soap suds	Dilates, stimulates, and irritates bowel	Hypotonic
Normal saline	Dilates, simulates, irritates bowel	0.9% (isotonic) <0.9% (hypotonic) >0.9% (hypertonic)
Oil	Lubricates, softens	
Sodium polystyrene sulfonate (Kayexalate)	Medication reduces serum potassium	Hypertonic
Antibiotic	Cleansing	Antibacterial, may be hypertonic or hypotonic

Initiate Rectal Stimulation

As an alternative to a scheduled defecation program, digital rectal stimulation may be used to regulate fecal elimination patterns. This process requires circular palpation of the anal sphincter and distal anus for 2 to 3 minutes. This process is repeated in 20 minutes if defecation does not occur. Deep breathing is encouraged during defecation because it drops the diaphragm and partially compensates for the client's inability to effectively strain.

Persons with chronic fecal incontinence due to anal sphincter incompetence may be managed with biofeedback techniques. These techniques are typically taught by a specialty or advanced practice nurse with specific

PROCEDURE 39-7

Administering a Large Enema

Equipment

- Enema bag (disposable comes with rectal tip catheter; reusable may need to have rectal tip catheter checked for damage and rectal tip may need to be replaced)
- Towel and washcloth
- Solution per physician's order
- Water-soluble lubricant
- Clean gloves
- Bedpan, commode, or toilet

Action

1. Introduce yourself and explain procedure.
2. Prepare the solution, assure temperature within range of 99° to 102°F by using a thermometer or placing a few drops on your wrist.
3. Wash hands and don gloves.
4. Assist patient to left side-lying position, with right knee bent.
5. Hang bag of enema solution 12 to 18 inches above anus.
6. Lubricate 4 to 5 inches of catheter tip.
7. Place bedpan, commode, robe and slippers within easy reach.
8. Separate buttocks, insert catheter tip into anal opening, slowly advance catheter approximately 4 inches.
9. Slowly infuse solution via gravity flow; bag height may be increased but not to exceed 18 inches above anal opening (Figure 39-19).

Rationale

1. Client may be more relaxed if prepared for procedure and told what to expect.
2. Avoids harming the intestinal mucosa.
3. Protects from contamination.
4. Lying flat on left side allows fluid to flow through to colon with contour of bowel.
5. This height allows for steady flow of fluid into the patient by gravity; a bag placed at a height greater than 18 inches allows for too rapid an infusion rate and could result in cramping or discomfort for the client.
6. Eases catheter tip insertion.
7. Urgent evacuation of bowels or inability to retain fluid may occur.
8. Further catheter advancement could cause damage to bowel.
9. Rapid infusion caused by bag height over 18 inches may cause cramping and discomfort. Bowel perforation is also a risk.

Figure 39-19 Raise the height of the enema container to allow infusion of the solution.

PROCEDURE 39-7

Administering a Large Enema (continued)*Action**Rationale*

- | | |
|--|---|
| <p>10. If client complains of increased pain or cramping, or if fluid is not being retained, stop procedure, wait a few minutes, then restart.</p> <p>11. Clamp tubing when fluid finishes infusing; remove catheter tip.</p> <p>12. Assist client to bedpan, commode, or toilet; refer to Procedure 39-1 for giving and removing bedpan.</p> <p>13. Discard equipment in proper place. If equipment is reusable, properly clean and store it.</p> <p>14. Remove gloves and wash hands.</p> <p>15. Instruct client to call for assistance when finished eliminating, or if untoward feeling occurs, such as lightheadedness or dizziness.</p> <p>16. Assist client with washing if needed.</p> | <p>10. Discomfort may cause poor retention of fluid.</p> <p>11. Stops flow of fluid.</p> <p>12. If bedpan is used, place client in sitting position. Clients should be instructed to retain fluid for as long as possible.</p> <p>13. Prevents spread of microorganisms.</p> <p>14. Reduces spread of microorganisms.</p> <p>15. Provides assistance and avoids potential harm to client.</p> <p>16. Promotes client comfort.</p> |
|--|---|

PROCEDURE 39-8

Administering a Small (Mini-)Enema*Equipment*

- | | |
|---|--|
| <ul style="list-style-type: none"> ■ Enema—small and mini-enemas come premixed ■ Disposable gloves ■ Washcloth and towel | <ul style="list-style-type: none"> ■ Lubricant ■ Bedpan, commode, toilet |
|---|--|

*Action**Rationale*

- | | |
|---|--|
| <p>1. Introduce yourself, explain procedure, close door or curtain.</p> <p>2. Place commode next to bed; have robe and slippers available.</p> <p>3. Wash hands and don gloves.</p> <p>4. Lower head of bed to flat position.</p> <p>5. Assist client to roll to left side-lying position with right knee slightly bent.</p> <p>6. Place bedpan slightly under buttocks.</p> <p>7. Remove catheter tip guard; gently squeeze bottle until fluid drips (for mini-enemas tip needs to be punctured with needle or pin).</p> | <p>1. Client may be more relaxed with privacy and knowing what to expect.</p> <p>2. If client is able to use commode, easy access is necessary due to urgency after enema administration.</p> <p>3. Prevents cross-contamination of bacteria.</p> <p>4. Easier for client to roll to left side.</p> <p>5. Lying on left side helps solution flow with the contour of the bowel.</p> <p>6. Have bedpan ready if client is unable to retain fluid.</p> <p>7. Most prepared enemas have perforated tips; a gentle squeeze will ensure this.</p> |
|---|--|

(continues)

PROCEDURE 39-8

Administering a Small (Mini-)Enema (continued)

<i>Action</i>	<i>Rationale</i>
8. Lubricate catheter tip.	8. Most premixed solutions are prelubricated; however, additional lubrication may be needed.
9. Separate buttocks and insert enema tip into anal opening; gently squeeze contents into rectum.	9. Gentle insertion and infusion lessens risk of undue discomfort and damage to colon.
10. Remove tip and assist to bedpan, commode, or toilet. Ask client to retain fluid for as long as possible, at least 30 minutes.	10. Assistance ensures safe transfer for client. Better results occur when enema has been retained for longer period of time.
11. Dispose of contaminated material in proper receptacles.	11. Prevents contamination.
12. Remove gloves and wash hands.	12. Reduces risk of contamination.
13. Assist client with cleaning if needed.	13. Illness or fatigue may cause some clients to require assistance for cleaning.

training in the field of gastrointestinal disorders and biofeedback techniques.

Monitor Elimination Diversions

Urinary Diversions

Surgically created extraurethral incontinence is managed by a pouch. The ileal conduit is, by design, an incontinent stoma constructed from a 10-cm segment of ileum. The ileum is isolated from the fecal stream and connected to the ureters using a refluxing end-to-end anastomosis. A small incision is made in the abdominal wall, and a stoma is constructed from the distal portion of the ileal segment. An enterostomal nurse is consulted to advise the surgeon on stoma site selection and to assist the client to adapt to and learn to manage the stoma.

The continent urinary diversion is an alternative to the ileal conduit. It contains a reservoir for urinary storage and gains continence from various mechanisms. The urinary reservoir may be created from small or large bowel. The Kock Indiana and Florida pouches are types of pouches created from intestinal material. Continence is obtained by forming an abdominal reservoir. Continence also may be preserved by the Mitrofanoff technique, which uses a segment of appendix or ureter to create a continent stoma. Evacuation of urine from the reservoir relies on intermittent catheterization of these continent mechanisms. Orthotopic urinary diversions have been described in which the bladder is attached to the urethra, and its sphincter mechanism is relied on for continence. Urine may be evacuated from the urinary reservoir by catheterization of the urethra or by strain voiding.

Bowel Diversions

The fecal stream is diverted when tissue damage from trauma or inflammation necessitates the temporary bypassing of a segment of bowel or when permanent resection of malignant or irreversibly damaged tissue is necessary. Several techniques are used to create a fecal diversion; some require a pouch to contain fecal contents, whereas others maintain continence. Continent diversions rely on catheterization of an abdominal stoma or evacuation of stool from a pouch reservoir reattached to the anal sphincter.

Virtually any portion of the large and small intestine can be diverted or used to form a fecal reservoir. Some diversions rely on a **stoma** (surgically created opening) for the evacuation of fecal contents. Stomas are primarily constructed in three ways. An *end stoma* is created by dividing the bowel and bringing the proximal segment to the abdominal wall. The end is rolled and attached to the skin of the abdomen, creating a red rosette of intestinal mucosa. A *double-barrel stoma* is constructed by dividing the bowel and bringing both the proximal and distal ends to the abdominal wall. The proximal end is used to evacuate stool. The distal stoma is typically referred to as a mucous fistula. The double-barrel stoma is designed for temporary diversion of the fecal stream. A *loop stoma* is created by opening the anterior aspect of the bowel either longitudinally or transversely. The resulting stoma has both proximal and distal openings that are separated by the posterior wall of the bowel loop. It is designed for temporary fecal diversion.

The fecal stream is diverted at the most distal point possible to maximize the absorption of food, fluid, and electrolytes and to preserve continence. The *ileostomy* (diversion of the bowel at the level of the ileum) is more

uncommon than it was during earlier decades. A permanent ileostomy is typically reserved for clients with severe Crohn's colitis, familial adenomatous polyposis, or chronic ulcerative colitis. A loop (temporary) ileostomy may be created as one stage in an ileoanal reservoir procedure or as a staged procedure for the relief of obstruction of the ascending colon.

The colostomy is created as a permanent or temporary fecal diversion (Figure 39-20). Among adults, it may be created in cases of severe diverticulitis or trauma. The most common indication for a permanent colostomy among adults is an abdominoperineal resection for lower rectal cancer. A temporary colostomy may be created from the transverse colon or (rarely) from the cecum. The descending or sigmoid colon may be temporarily diverted because of radiation proctitis or low rectal carcinoma. Procedure 39-9 outlines steps for changing a colostomy pouch.

Continent diversions of the bowel may incorporate the anus and sphincter or may be constructed with an abdom-

Figure 39-20 Colostomy. What are some major nursing implications when caring for this client?

inal stoma. The ileoanal reservoir is created in a staged approach. In the first stage an abdominal colectomy is completed, followed by a rectal mucosectomy, creation of a J- or S-shaped pouch comprising anus and ileum, and a temporary end or loop ileostomy. In the second stage the

PROCEDURE 39-9

Changing a Colostomy Pouch

Equipment

- Appropriate pouch
- Skin barrier (Figure 39-21)
- Pouch clip or rubber band
- Skin paste
- Disposable gloves
- Soap and washcloth
- Warm water

A.

B.

Figure 39-21 Equipment for Application of a Colostomy Pouch: A. Colostomy Pouch; B. Skin Barrier

Action

1. Explain the procedure to client and provide for privacy. Include caregivers in instruction if indicated.
2. Assist client to a standing (preferable) or sitting position.
3. Wash hands and don gloves.
4. Remove the soiled pouch by gently pressing on the skin while pulling the pouch.
5. Dispose of the pouch in a plastic bag after removing the clip used to seal the pouch.
6. Cleanse the skin with soap and water.

Rationale

1. Promotes cooperation and boosts caregiver confidence in ability to perform procedure.
2. Facilitates application of pouch by reducing wrinkles.
3. Reduces risk of contamination.
4. Avoids trauma to the peristomal skin.
5. Minimizes odor associated with the pouch change.
6. Removes fecal material and pathogens and prepares the skin for pouch reapplication.

(continues)

PROCEDURE 39-9

Changing a Colostomy Pouch (continued)

Action

7. Inspect the peristomal skin for redness, altered skin integrity, or rashes; consult the enterostomal nurse if lesions of the peristomal skin are observed.
8. Remove excessive hair with a safety razor or electric razor.
9. Inspect the pouch opening and ensure that it fits the stoma; use a pouch pattern to customize the fit if indicated (Figure 39-22).
10. Apply a skin sealant or skin paste if indicated; apply skin barrier (Figure 39-23).
11. Gently apply the pouch and press into place (Figure 39-24). Seal the inferior opening with the clip or a rubber band.
12. Remove gloves and discard; wash hands.
13. Note type and size of pouch; condition of stoma (drainage amount and odor; surrounding skin); and client response.

Figure 39-22 Measure the stoma for the colostomy pouch.

Rationale

7. Peristomal skin conditions cause morbidity and problems with pouch application unless managed promptly.
8. Excessive hair is removed to promote the seal between pouch adhesive and peristomal skin.
9. Ensures appropriate-sized pouch and protects the peristomal skin.
10. Promotes an effective seal and protects the peristomal skin.
11. Prevents leakage of effluent from the pouch.
12. Reduces risk of transfer of microorganisms.
13. Documents client status and condition of stoma.

Figure 39-23 Apply the skin barrier to the stoma.

Figure 39-24 Press the pouch into place.

temporary ileostomy is taken down and the ileoanal reservoir is reattached to the rectal stream.

The Kock continent ileostomy is performed as a single procedure. A colectomy and proctectomy are performed, and the distal 45 cm of the ileum is used to form the reservoir for the ileostomy and the abdominal stoma. The abdominal stoma is rendered continent by intussusception of the bowel that is stabilized to the abdominal wall by stapling or suturing the nipple valve. A polyglycolic acid mesh may be incorporated to provide further support if necessary. Effluent gathered in the reservoir is evacuated by catheterization through the abdominal stoma.

Monitor Surgical Management

The surgical management for SUI differs for urethral hypermobility as compared with intrinsic sphincter deficiency. Urethral hypermobility is managed by a bladder suspension designed to prevent descent of the bladder base and urine loss during physical exertion. The selection of the procedure depends on the severity of the incontinence and client and surgeon preference.

Clients with adequate urethral support and intrinsic sphincter deficiency may be managed with a urethral bulking agent, such as Contigen (Bard Urological, Covington, Georgia). This product is a glutaraldehyde cross-linked collagen that improves continence by enhancing compressive elements of the urethral sphincter mechanism. It is injected transurethrally, and local anesthesia with systemic sedation is often used in preference to general anesthesia. Women with a combination of urethral hypermobility and intrinsic sphincter deficiency may undergo a suburethral sling procedure, in which the proximal third of the urethra is supported with fascia or a synthetic material.

An artificial urinary sphincter device also may be used to manage intrinsic sphincter deficiency. This mechanical device allows the client to mechanically inflate and deflate a cuff that compresses underlying urethral tissues. Each of these procedures requires specific nursing care and instruction. See a urologic nursing text for a detailed discussion of the nursing care for urologic surgery.

Surgery plays only a limited role in the management of urge incontinence. Surgical procedures designed to denervate the bladder (sever nerves needed for contraction of the detrusor muscle) have had little success because of significant complications, including fecal incontinence and impotence among men. A surgically implanted device designed to deliver electrical stimulation to the lower urinary tract has been approved for use in the United States. Refer to a urologic nursing text for management of these clients.

The management of reflex incontinence is complicated by the combination of urine leakage and urinary retention caused by detrusor sphincter dyssynergia. A bladder management program is chosen that both protects the upper urinary tracts from serious damage and maximizes continence.

Surgical reconstruction is sometimes used in the long-term management of reflex incontinence. An augmentation enterocystoplasty enlarges bladder capacity and alleviates reflex incontinence by converting the hyperreflexic bladder into a large, atonic bladder with improved storage ability. Unfortunately, the augmented bladder rarely empties efficiently, and clients are advised that lifelong intermittent self-catheterization will be necessary after augmentation surgery. A continent or incontinent urinary diversion is occasionally used to manage urine elimination in the patient with reflex incontinence. However, urinary diversion is completed only when bladder function threatens the normal function of the upper urinary tracts.

Fistulae and ectopia are managed by surgical closure whenever possible. When surgery is not feasible, a fistula may be treated by careful application of a sclerosing agent, such as tetracycline or doxycycline in suspension. The solution is applied monthly, and a skin barrier is used on the area surrounding the fistula to prevent scarring. The fistula that cannot be closed surgically or by sclerosing therapy must be managed by application of a urinary containment device and a preventive skin program.

Surgery or endoscopic procedures alleviate urinary retention caused by bladder outlet obstruction. Transurethral resection of the prostate, open prostatectomy, VaporTrode, visual ablation of the prostate, and other procedures are used to alleviate obstruction caused by benign prostatic hyperplasia. Transurethral incision of the bladder neck or transurethral sphincterotomy may be used for bladder neck or striated sphincter dyssynergia. Refer to a textbook of urologic nursing for the care following these specialized procedures.

Complementary Therapies

“One of the largest health problems in the western world is in the area of elimination” (Barney, 1996, p. 57). When the body fails to eliminate waste that is full of toxic substances, other systems are compromised and the person becomes prone to illness. Herbalists view the role of the kidneys and the intestines in a holistic manner. The proper function of any part of the body is dependent on the effective elimination of waste products and toxins.

“Considering the importance of the kidneys, it is not surprising that nature is abundant in herbs that can aid their functions” (Hoffmann, 1998, p. 109). Herbs that aid the functions of the urinary system are:

- *Diuretics*: Dandelion root and leaf (refer to Chapter 38 for a full discussion of this herb) and cleavers
- *Antiseptics*: bearberry, birch, boldo, buchu, celery seed, couchgrass, juniper, and yarrow
- *Antimicrobials*: Echinacea root (refer to Chapter 31 for a full discussion of this herb) and wild indigo root
- *Demulcents*: corn silk, couchgrass, and marshmallow leaf

NURSING CARE PLAN**The Client Experiencing Constipation****Case Presentation**

Mrs. M is a 30-year-old woman who sustained a complete spinal cord injury of the seventh cervical vertebra 2 years before this hospital admission. She currently manages her bowels by enemas every 5 to 7 days when she notes pressure and distension of her abdomen. She has frequent episodes of fecal incontinence, described as passage of moderate amounts of black, watery stool. She manages these episodes by administering one or two enemas, followed by passage of a large volume of odorous, dark feces. Before her spinal injury she denied problems with her bowel control. She states that she moved her bowels every other day, typically after breakfast. Currently, she reports fluid intake of 3 to 4 glasses per day. She eats primarily meats, white breads, some pastas, and one portion of vegetables per day. She does not routinely eat cereals or fruits or supplement her diet with bulk laxatives.

Assessment

- Inadequate fluid intake
- Inadequate fiber intake
- Presence of large impaction in the rectum

Nursing Diagnosis #1

Constipation, related to spinal cord injury and neurogenic bowel.

Nursing Diagnosis #2

Bowel Incontinence related to fecal impaction, altered stool consistency, and neurogenic bowel.

Expected Outcome

The rectum will be cleansed of impaction.

Intervention/Rationale

1. Administer PIEE until impaction is disrupted.
Bowel is clear of impacted stool as assessed by digital examination.

Expected Outcome

Stool will be soft and formed.

Interventions/Rationales

1. Encourage dietary intake of fiber-rich foods, including one serving of cereal per day, one serving of fruit, and two servings of vegetables.
2. Increase fluid intake to 15 ml/lb body weight; encourage water intake to equal at least 50% of fluids.
3. Administer supplemental bulk laxatives (Metamucil) if client is unable to alter diet to meet needs for fiber.
Stool will be soft, formed feces, without impacted or dry, hardened material.

Expected Outcome

A regular routine for bowel elimination will be established.

Interventions/Rationales

1. Begin a bowel program every other day.
2. Determine time for evacuation with client; encourage defecation after breakfast, based on premorbid bowel elimination pattern.
3. Encourage bowel evacuation program after meal if premorbid schedule is not feasible with current activities.
Bowel evacuation will occur every other day after a meal, based on client's activities of daily living, preferences, and premorbid bowel elimination patterns.

(continues)

NURSING CARE PLAN**The Client Experiencing Constipation (continued)****Expected Outcome**

Bowel management program will cause completed elimination of feces from rectum.

Interventions/Rationales

1. Begin stimulated, scheduled bowel evacuation program using oral laxative, mini-enema, digital stimulation program.
2. Discuss program with client, significant others, giving description of each stimulation program, time required, cost implications, and advantages and disadvantages.
Client will completely evacuate the bowel using a stimulation or timed management program.

Expected Outcome

Fecal incontinent episodes will be alleviated.

Interventions/Rationales

1. Teach client relationship among stool consistency, regularity of evacuation, fecal impaction, and fecal continence.
2. Advise client to consult nurse specialist or gastroenterologist if fecal incontinent episodes persist despite regulation of bowel management program.
3. Warn client that occurrence of diarrhea may predispose to acute transient fecal incontinence.
Fecal incontinent episodes will be reduced by greater than 50%.

Herbs that possess other properties may also be used, such as urinary astringents (beth root, horsetail, and plantain tormentil), to treat blood in the urine caused by minor problems, and to aid the healing of lesions, and antilithics (gravel root, hydrangea, and stone root), to prevent the formation of or aid in the removal of calculi (stones or gravel) in the urinary system.

Both urinary and fecal elimination are reliant upon sufficient amounts of fiber and fluids in the diet. Poor nutrition is the most common cause of chronic constipation (Barney, 1996). The following herbs are helpful in relieving constipation: *Cascara sagrada* bark, senna, ginger root, butternut root bark, burdock root. Also, milk thistle, a cholagogue, may be used to aid liver function and to enhance bile flow to soften stools.

Cascara sagrada bark is an old Indian remedy to encourage peristalsis and tone relaxed muscles of the digestive tract. Senna is the most widely used stimulant laxative when compared to synthetic drugs (Barney, 1996). *Cascara* and senna should be combined with aromatics and carminatives such as licorice and ginger root to increase palatability and reduce gripping. Ginger root aids in digestion and enhances bile flow from the liver. Burdock root is a mild laxative and an effective diuretic; its cleansing effect goes beyond its diuretic and laxative properties as it promotes perspiration and strengthens the liver.

Psyllium seed and flaxseed are also helpful for constipation. Psyllium seed must be taken with a full glass of water. Mineral oil should not be taken on a regular basis because, if inhaled, it can damage the lungs, and it reduces the absorption of fat-soluble vitamins (Balch & Balch, 1997).

EVALUATION

Evaluating the effectiveness of the nursing interventions is an ongoing process. The client's level of maintenance or restoration of elimination patterns and return to an appropriate level of independence are indicators of success. When evaluating these aspects, it is important for the nurse to reassess how realistic the original identified outcomes were, especially for goals that were not met, and to modify the target outcomes accordingly. Prevention of skin breakdown and infection can also be used to determine the appropriateness of the plan of care. Client understanding of procedures and self-care should be evaluated to determine the effectiveness of teaching plans, and modifications should be made to address deficiencies and ongoing learning needs. If support persons were included in the teaching process, their understanding of skills and competence with procedures should also be measured. If additional care or teaching is deemed necessary, clients should be given referrals for community and other resources to support their continuing learning needs.

KEY CONCEPTS

- Normal urination requires anatomic integrity of the lower urinary tract, nervous control of the detrusor muscle, and competence of the urethral sphincter mechanism.

- Normal bowel evacuation relies on motility factors, the storage abilities of the rectum, and competence of the internal and external sphincter mechanisms.
 - Common alterations in urinary elimination include SUI, instability incontinence (urge and reflex incontinence), functional urinary incontinence, extrarethral incontinence, and urinary retention.
 - Constipation and diarrhea are common alterations in stool consistency that cause changes in fecal elimination patterns and predispose clients to bowel incontinence.
 - Clients with altered patterns of urinary and bowel elimination are evaluated with a detailed historical interview, focused physical examination, record of bladder and bowel elimination patterns, and review of laboratory values.
 - Multiple options, including behavioral management strategies, pharmacotherapy, and surgical interventions are used to manage clients with altered patterns of elimination.
 - Altered stool consistency is prevented or alleviated by managing malabsorption syndromes, maintaining a regular pattern of elimination, ensuring dietary intake of adequate fluid and fiber, and heeding the urge to defecate.
 - Bowel incontinence is managed by normalization of stool consistency, maximization of rectal storage abilities, and management of anal sphincter incompetence.
8. What is the primary behavioral intervention for urge incontinence? Teach yourself to perform a quick flick contraction of the pelvic muscles.
 9. Identify at least six strategies to reduce environmental barriers to toileting. Develop a checklist when assessing the client with urinary incontinence.
 10. What are the two elements of the anal sphincter?
 11. What are the primary causes of diarrhea? Differentiate the treatment of secretory, malabsorptive, and inflammatory diarrhea. Determine which forms of diarrhea are likely to respond to antidiarrheal agents. Determine which forms of diarrhea are likely to be exacerbated by antidiarrheal agents.
 12. What are the indications for consultation with the enterostomal technician for a client experiencing diarrhea? Identify and introduce yourself to the enterostomal nurses in your health care facility.
 13. What is the purpose of regulating fluid and fiber intake when managing constipation? Determine your daily intake of fluids using a record. Determine the servings of fiber-rich foods in your diet and observe the consistency (and pattern) of your bowel elimination. Slowly add fluids and fiber to your diet and note changes in your bowel elimination patterns.
 14. Why does diarrhea or constipation increase the risk of bowel incontinence?
 15. What are the indications for referral for a client with bowel elimination problems?

CRITICAL THINKING ACTIVITIES

1. Which central nervous system structures regulate detrusor muscle contractions?
2. How do urethral support mechanisms help prevent stress urinary incontinence?
3. What are the causes of stress urinary incontinence?
4. How do urge and reflex incontinence differ? Why are clients with reflex incontinence at greater risk for urinary retention than those with urge incontinence?
5. What are the primary causes of functional incontinence?
6. What are the general principles of bladder health? What is the RDA for fluid intake in an adult? Calculate the RDA for fluids for yourself, for a 110-lb client, for a 379-lb client.
7. What is the primary behavioral intervention for the management of stress urinary incontinence? Teach yourself to perform a pelvic muscle contraction. Test yourself by performing 10, 20, or 35 repetitions. Can you detect fatigue of the muscles as you exercise? Do you find yourself using distant muscle groups, such as the abdominal or thigh muscles?

^a The allowances, expressed as average daily intakes over time, are intended to provide for individual variations among most normal persons as they live in the United States under usual environmental stresses. Diets should be based on a variety of common foods to provide other nutrients for which human requirements have been less well defined.

^b Weights and heights of Reference Adults are actual medians for the U.S. population of the designated age.

^c Retinol equivalents. 1 RE = 1 μg retinol or 6 μg β-carotene.

^d As cholecalciferol. 10 mg cholecalciferol = 400 U of vitamin D.

^e Tocopherol equivalents. 1 mg d-α-tocopherol = 1 α-TE.

^f Ne Niacin equivalent = 1 mg of niacin or 60 mg of dietary tryptophan.

(From Food and Nutrition Board, National Academy of Sciences—National Research Council: *Recommended dietary allowances*, ed. 10, Washington, DC, 1989, The Council.)

Educational Resources for Caregivers

The following groups provide information about specific disorders. Instruct the caller to request any written materials that are available.

Acquired Immunodeficiency Syndrome (AIDS)

National AIDS Hotline—(800) 342-AIDS
National Association of People with AIDS—
(202) 898-0414

Alcoholism

Alcoholics Anonymous—(212) 647-1680
Al-Anon Family Group Headquarters—(757) 563-1600

Alzheimer's

Alzheimer's Disease and Related Disorders
Association—(800) 621-0379

Arthritis

The Arthritis Foundation—(404) 872-7100

Blindness or Visual Impairment

American Council for the Blind—(800) 424-8666
National Federation of the Blind—(301) 588-6545

Breast Cancer

American Cancer Society—(800) 227-2345
YME Breast Cancer Support—(800) 221-2141

Breastfeeding

La Leche League International—(800) 525-3243
(800 LaLeche)

Cancer

American Cancer Society—(800) 227-2345
Candlelighters Childhood Cancer Foundation—
(800) 366-2223
Leukemia Society of America—(800) 955-4LSA

Cerebral Palsy

United Cerebral Palsy—(800) 872-5827

Chronic Pain

American Chronic Pain Association—(301) 652-4948

Cystic Fibrosis

Cystic Fibrosis Foundation—(800) FIGHT-CF or
(301) 951-4422

Deafness/Hearing Impairment

National Association for Hearing and Speech Action
Line—(800) 638-8255
American Society for Deaf Children—(800) 942-2732
National Information Center on Deafness—
(202) 651-5051

Diabetes

American Diabetes Association—(800) 342-2383
Juvenile Diabetes Foundation International—
(800) 223-1138

Drug Abuse

Cocaine Hot-Line—(800) COCAINE
Narcotics Anonymous—(919) 755-5391

Epilepsy

Epilepsy Information Line—(800) 332-1000

Genetic Diseases

Alliance of Genetic Support Groups—(301) 652-5553
National Foundation for Jewish Genetic Diseases—
(212) 682-5550 or (212) 371-1030

Head Injury

National Head Injury Foundation—(800) 444-6443

Heart Disease or Surgery

American Heart Association—(214) 750-5300

Hemophilia

National Hemophilia Foundation—(212) 219-8180

Herpes

Herpes Resource Center—(800) 230-6039

Huntington's Disease

Huntington's Disease Society of America—
(800) 345-HDSA

Hypertension

High Blood Pressure Information Center—
(800) 444-6472

Incontinence

The Simon Foundation—(800) 23SIMON

Kidney Disease

National Kidney Foundation—(212) 889-2210
The Kidney Transplant/Dialysis Association—
(703) 549-1500

Laryngectomy

International Association of Laryngectomies—
(800) 231-2300

Lung Conditions

American Lung Association—(212) 315-8700
The Lung Line Information Service—(800) 222-LUNG

Lupus Erythematosus

The American Lupus Society—(800) 331-1802
The Lupus Foundation of America—(800) 558-0121

Mental Illness

The National Alliance for the Mentally Ill—
(800) 950-NAMI
National Mental Health Association—(703) 684-7722

Multiple Sclerosis

National Multiple Sclerosis Society—(212) 986-3240

Muscular Dystrophy

Muscular Dystrophy Association—(212) 689-9040

Osteoporosis

National Osteoporosis Foundation—(202) 223-2226

Parkinson's Disease

American Parkinson's Disease Association—
(800) 223-APDA
National Parkinson's Foundation—(800) 327-4545
Parkinson's Education Program—(800) 344-7872

Psoriasis

National Psoriasis Foundation—(503) 297-1545

Reye's Syndrome

National Reye's Syndrome Foundation—(800) 233-7393

Scleroderma

United Scleroderma Foundation, Inc.—(800) 722-
HOPE

Scoliosis

The National Scoliosis Foundation—(617) 341-6333

Sickle Cell Disease

National Association for Sickle Cell Disease—
(800) 421-8453

Spina Bifida

Spina Bifida Association of America—(800) 621-3141

Spinal Cord Injuries

National Spinal Cord Injury Association—
(800) 962-9629
Spinal Injury Hotline—(800) 526-3456
Neurological Recovery Foundation—(800) 624-1698

Stroke

National Stroke Association—(303) 762-9922

Tay-Sachs Disease

National Tay-Sachs and Allied Diseases Association—
(212) 371-1030

Tourette Syndrome

Tourette Syndrome Association—(800) 237-0717

E

LEARN WHEN TO USE—NOT ABUSE—A GOOD THING

Do you use gloves when you turn a patient? How about when changing I.V. bags? If you answered yes, take a moment to reevaluate your use of this form of barrier protection. The Centers for Disease Control and Prevention's new standard precautions recommend using gloves when handling any body fluids or items contaminated with body fluids. But overusing gloves—as in the two situations just mentioned—can lead to problems as well: latex allergies, hospital environmental contamination, and increased glove disposal, to name a few. To make sure you're using gloves correctly, follow the chart below. You should also review your hospital policy to make sure it's up-to-date. Wear gloves whenever soilage of hands with body fluids is likely. Wear *clean, nonsterile* gloves when handling body fluids and contaminated items. Wear *sterile* gloves for all invasive procedures, such as inserting urinary catheters.

	When to use gloves	When NOT to use gloves
Bathing and turning	<ul style="list-style-type: none"> • Bathing a patient's genitalia; bathing patient when contact with body fluids is possible • Cleaning patient after bowel movement 	<ul style="list-style-type: none"> • Routine bathing or turning of patient (when not in contact with genitalia) • Washing patient's hair
Bowel and bladder	<ul style="list-style-type: none"> • Turning incontinent patient • Handling such items as urinary drainage bags, bedpans, and urinals. Change gloves between patients when collecting urine output at end of shift. • Cleaning incontinent patient • Inserting rectal probes and tubes • Inserting, caring for, or removing external urinary catheters 	<ul style="list-style-type: none"> • Assisting patient to bathroom or bedside commode • Ambulating patient with an indwelling urinary catheter
Cleaning	<ul style="list-style-type: none"> • Routine environmental cleaning with disinfectants 	<ul style="list-style-type: none"> • Confining spill (for example, with towel) until housekeeping removes it
Environment	<ul style="list-style-type: none"> • Removing body-fluid spills • Working with patient who has antibiotic-resistant organisms and handling anything in patient's environment 	<ul style="list-style-type: none"> • Handling items or surfaces for patient not colonized with antibiotic-resistant organisms, such as bed, stretcher, or chair, as long as no body fluids are present

(continues)

Fluids and skin	<ul style="list-style-type: none"> • Handling or touching any patient's body fluids or mucous membranes • Handling items or surfaces soiled by body fluids • Handling soiled sanitary napkins 	<ul style="list-style-type: none"> • Touching intact skin • Taking blood pressure, pulse, or respirations where there is no obvious soiling by body fluids
I.V. lines and sharps	<ul style="list-style-type: none"> • Procedures involving inserting needles or catheters into patient (such as starting I.V. lines) • I.V. dressing changes • Discontinuing I.V. line or applying pressure to vascular access site • Performing finger sticks for blood studies 	<ul style="list-style-type: none"> • Changing I. V. fluid bags • Connecting secondary I.V. sets to primary tubing
Linen and supplies	<ul style="list-style-type: none"> • Changing linen grossly contaminated with body fluids • Handling soiled supplies such as instruments 	<ul style="list-style-type: none"> • Routine changing of linen without gross spillage • Removing hamper to place in laundry chute (unless fluid leakage is visible) • Handling clean supplies
Oral care, suctioning, and feeding	<ul style="list-style-type: none"> • Routine oral care and suctioning • Tracheal, nasopharyngeal, and mouth suctioning 	<ul style="list-style-type: none"> • Handling used suction container, as long as no drainage is outside the container • Feeding patient • Taking body to morgue
Postmortem care	<ul style="list-style-type: none"> • Routine postmortem care 	<ul style="list-style-type: none"> • Handling clean plastic bags with specimen containers confined inside
Specimens	<ul style="list-style-type: none"> • Obtaining specimens from patients • Emptying specimens into other containers 	<ul style="list-style-type: none"> • Assessing axillary and tympanic membrane temperatures
Temperatures	<ul style="list-style-type: none"> • Assessing rectal temperature • Assessing oral temperature when herpetic lesions are present 	<ul style="list-style-type: none"> • Transporting patients when no body fluids are obvious
Transportation	<ul style="list-style-type: none"> • Transporting patients when body fluids can't be confined or contained 	<ul style="list-style-type: none"> • Routine enteral feedings
Tubes, drains, and catheters	<ul style="list-style-type: none"> • Inserting or removing enteral or endotracheal tubes, urinary catheters, and surgical drains 	
Wound care and dressing changes	<ul style="list-style-type: none"> • All wound care and dressing changes 	<ul style="list-style-type: none"> • Care of Stage I pressure ulcer (intact skin)

(Reprinted with permission of Sue Crow RN, CIC, MSN.)

STANDARD PRECAUTIONS

FOR INFECTION CONTROL

Wash Hands (Plain soap)

Wash after touching **blood, body fluids, secretions, excretions**, and **contaminated items**. Wash immediately **after gloves are removed** and **between patient contacts**. Avoid transfer of microorganisms to other patients or environments.

Wear Gloves

Wear when touching **blood, body fluids, secretions, excretions**, and **contaminated items**. Put on **clean gloves just before touching mucous membranes** and **nonintact skin**. Change gloves between tasks and procedures on the same patient after contact with material that may contain high concentrations of microorganisms. Remove gloves promptly after use, before touching noncontaminated items and environmental surfaces, and before going to another patient, and wash hands immediately to avoid transfer of microorganisms to other patients or environments.

Wear Mask and Eye Protection or Face Shield

Protect mucous membranes of the eyes, nose and mouth during procedures and patient-care activities that are likely to generate **splashes** or **sprays** of **blood, body fluids, secretions**, or **excretions**.

Wear Gown

Protect skin and prevent soiling of clothing during procedures that are likely to generate **splashes** or **sprays** of **blood, body fluids, secretions**, or **excretions**. Remove a soiled gown as promptly as possible and wash hands to avoid transfer of microorganisms to other patients or environments.

Patient-Care Equipment

Handle used patient-care equipment soiled with **blood, body fluids, secretions**, or **excretions** in a manner that prevents skin and mucous membrane exposures, contamination of clothing, and transfer of microorganisms to other patients and environments. Ensure that reusable equipment is not used for the care of another patient until it has been appropriately cleaned and reprocessed and single use items are properly discarded.

Environmental Control

Follow hospital procedures for routine care, cleaning, and disinfection of environmental surfaces, beds, bedrails, bedside equipment and other frequently touched surfaces.

Linen

Handle, transport, and process used linen soiled with **blood, body fluids, secretions**, or **excretions** in a manner that prevents exposures and contamination of clothing, and avoids transfer of microorganisms to other patients and environments.

Occupational Health and Bloodborne Pathogens

Prevent injuries when using needles, scalpels, and other sharp instruments or devices; when handling sharp instruments after procedures; when cleaning used instruments; and when disposing of used needles.

Never recap used needles using both hands or any other technique that involves directing the point of a needle toward any part of the body; rather, use either a one-handed "scoop" technique or a mechanical device designed for holding the needle sheath.

Do not remove used needles from disposable syringes by hand, and do not bend, break, or otherwise manipulate used needles by hand. Place used disposable syringes and needles, scalpel blades, and other sharp items in puncture-resistant sharps containers located as close as practical to the area in which the items were used, and place reusable syringes and needles in a puncture-resistant container for transport to the reprocessing area.

Use **resuscitation devices** as an alternative to mouth-to-mouth resuscitation.

Patient Placement

Use a **private room** for a patient who contaminates the environment or who does not (or cannot be expected to) assist in maintaining appropriate hygiene or environmental control. Consult Infection Control if a private room is not available.

The information on this sign is abbreviated from the HCIC/NC Recommendations for Isolation Precautions in Hospitals.

Appendix

G

Clinical pathways are designed to be used when providing care for clients with specific health problems. The form may vary among institutions. This pathway is an example of a hospital setting and a client with congestive heart failure (CHF) in the acute phase, emergency department and the first day, in the improving phase and discharge phase. Courtesy of St. Francis Hospital, Wilmington, Delaware.

Answers to Review Questions

Chapter 1

1. “Using their own history” means to learn from the past, to avoid repeating mistakes, and to learn new solutions for problems. Some major lessons nurses can learn from history are to promote higher education, actively participate in politics (from having ongoing dialogue with legislators to campaigning for office), and function as client advocates.
2. The answer will vary according to the history of each nursing program.
3. Contemporary nursing leaders and their contributions include Ruth Gordon, development of functional health patterns; Delores Kreiger, Therapeutic Touch as nursing intervention; Hildegard Peplau, interpersonal theory of nursing; Jean Watson, theory of caring; Martha Rogers, nursing theory (exchange of energetic fields); Helen Yura, pioneer work in nursing process.
4. c.
5. The Health Maintenance Organization Act, 1973; Nurse Training Act, 1964; Rural Health Clinic Service Act, 1977; Omnibus Reconciliation Act, 1980.

Chapter 2

1. Concepts are the basic elements of theories; concepts are vehicles of thought that help us to label and name phenomena. Propositions, another structural element of theories, are statements that propose a relationship between two or more concepts.
2. A theory is a set of concepts and propositions that provides an orderly way to view phenomena. The purpose of theory in a scientific discipline such as nursing is to describe, explain, predict, and control phenomena of concern to the discipline.
3. Nursing practice is central to the relationship between practice, theory, and research. Nursing practice provides the raw material for the ideas that are systematically developed and organized into nursing theories. Theories are tested and validated through nursing research. Further, new knowledge that results from nursing research is used to transform and inform nursing practice. Alternatively, nursing practice generates research questions. Nursing research influences the development of nursing theory which, in turn, illuminates nursing practice.
4. A metaparadigm is the unifying force in a discipline that names the phenomena of concern to that discipline. Metaparadigm concepts provide the boundaries and limitations of a discipline, identify the common viewpoint that all members of a discipline share, and help to focus the activities of the members of that discipline. By consensus, the metaparadigm elements in nursing are person, environment, health, and nursing. The metaparadigm of medicine focuses on pathophysiology and the curing of disease. Nursing’s metaparadigm is a broader one and focuses on caring for people, their health, and their environment.
5. A paradigm is a particular way of viewing the phenomena of concern that have been delineated by the metaparadigm of the discipline. A paradigm provides a worldview, or a lens, through which to view and explore phenomena.
6. The two paradigms in nursing identified by Parse are the Totality Paradigm and the Simultaneity Paradigm. In the Totality Paradigm, the person is viewed as a bio-psycho-social-spiritual being who is in constant interaction with the environment in order to accomplish goals and maintain balance. In this paradigm, the goals of nursing are health promotion, care and cure of the sick, and prevention of illness. Recipients of nursing care are those individuals designated by society as ill. In the Simultaneity Paradigm, the person is viewed as mutually and simultaneously changing with the environment. A freely choosing being, the person is considered to be more than and different from

the sum of the parts. Nursing focuses on quality of life as viewed from the person's perspective. The primary decision maker in the nurse-person relationship is the person.

7. Nightingale provided the nursing profession with the philosophical basis from which other theories have emerged and developed.
8. False. The early nursing theorists working in the 1950s were not attempting to address the meta-paradigm concepts; initial consensus on these was not achieved until 1984.
9. Levine developed the conservation theory. Levine believed in the wholeness of the human being and that the primary focus of conservation is to maintain that wholeness. Nursing is viewed as assisting clients with the conservation of their uniqueness by helping clients to adapt appropriately. Levine's four principles of conservation provide structure for the theory.

In Roy's view, the person is a bio-psycho-social being in constant interaction with a changing internal and external environment. Nursing attempts to alter the environment when the person is not adapting well or has ineffective coping responses. Stimuli are classified as either focal, contextual, or residual. Adaptation to these stimuli is accomplished through coping mechanisms which are broadly categorized as either the cognator or the regulator subsystem. The person responds to stimuli in the environment in four ways, or modes: physiological, self-concept, role function, and interdependence. Nursing care needs to be provided when a person has unusual stressors or when usual coping mechanisms are ineffective.

Orem's self-care deficit theory of nursing comprises three interconnecting theories: theory of self-care; theory of self-care deficit; and theory of nursing systems. According to the theory of self-care, self-care requisites can be classified as either universal, developmental, or health-deviation self-care requisites. According to the theory of self-care deficit, nursing care is needed when a self-care deficit exists. The theory of nursing systems unifies the two other theories. According to the theory of nursing systems, if a deficit exists, then the nurse plans care (what is to be done and by whom) using three types of actions or nursing systems: wholly compensatory, partly compensatory, and supportive-educative.

Watson developed the theory of human caring, which focuses on the art and science of human caring. Watson's theory is composed of 10 carative factors, which are nursing actions or caring processes. According to Watson, the goal of nursing is to help persons improve and enhance harmony between mind, body, and spirit.

Rogers developed the science of unitary human beings. According to Rogers, both the person and the environment are viewed as energy fields. The whole of the person's energy field interacts with the whole of the environmental energy field, which results in the process of life. There is a constant exchange of matter and energy between the person and the environment. Nursing identifies the patterns and organization of the person-environment unit and aims to repattern the rhythm and organization of these energy fields so that the person's integrity is heightened.

10. Answers will vary.

Chapter 3

1. **a.** By having one licensure examination that is administered to associate, baccalaureate, and diploma graduates, the nursing profession is stating that there are no differences in the educational preparation, clinical expectations, and utilization of nurses. "A nurse is a nurse is a nurse" is the message.
 b. Regardless of the entry into practice issue, educational preparation is different among the three entry-level programs as documented by curricula comparison. Nursing has always had greater role expectations of the BSN nurse relative to nursing theory and research as scientific bases of decision making and leadership skills. However, job descriptions fail to differentiate practice on the basis of education. The challenge to change rests with licensure and accreditation bodies in collaboration with educational programs.
2. Nursing education will use nontraditional methods to promote student mastery of technical skills so that time with clients focuses on implementation of the nursing process. It will use cost-effective care settings for learning experiences; for example, transitional services between acute care and home settings or transitional services provided in the home setting. It will collaborate with other health care disciplines for multicompetency education. Curriculum content about client and family teaching will be increased to produce graduates who are effective in this realm of practice. Students will be able to choose tracks such as informatist, primary care, health promotion, and genetic or ethical counseling in their senior year.
3. Example: Why are nursing students required to spend laboratory time learning how to make a bed and bathe a client in bed (these are basic skills performed daily by most people)? Design an experimental research study and randomly assign half the students to the experimental group, which will only read the reasons why bed baths and clean, tightly fitted bed linen are important. The control

group will be exposed to the normal rigors of learning how to bathe a client and make a bed according to procedure. Outcome data will be collected by observing both groups performing these skills and outcomes will be measured on the basis of the critical elements of the skill.

4. c.
5. Ensures that the client understands what to expect regarding the proposed interventions and possible risk factors.
6. The focus of research is on preventive medicine.

Chapter 4

1. Rapidly escalating costs; limited access for many Americans; quality that is being threatened by cost-containment measures; oversupply of hospital beds; inability of many Americans to obtain health care insurance.
2. Canada

<ul style="list-style-type: none"> • Universal access • Single-payer system 	United States <ul style="list-style-type: none"> • Limited access • Dual-payment system (public and private payers) • No provision for catastrophic events • Managed care is predominant method of reimbursement
---	--
3. Answers will vary. Some suggestions are: advanced practice nurses provide quality care in a cost-effective manner; APNs must be reimbursed directly by third-party payers; prescriptive authority for APNs will enhance accessibility to care for many Americans; cost-containment measures must not affect the quality of health care services provided.
4. *Nursing's Agenda for Health Care Reform:*
 - Universal access to care: Provide a package of essential health care services to all.
 - Wellness and health as priorities: There would be incentives for employees and insurers to participate in health-promoting behaviors.
 - Empowerment of consumers: Nurses will educate consumers about self-care activities for health promotion.
5. Ways in which nurses can address the challenge of shorter length of hospital stays: involvement in home health care; provision of preventive health care services such as client teaching; promotion of healthy lifestyles such as smoking cessation programs; establishment of nurse-managed clinics to care for clients with chronic health care problems such as diabetes mellitus and hypertension; expanded use of nurse practitioners; delivery of services in outpatient settings.

Chapter 5

1. Examples of information collected by each of the senses follow. There are many others. *Vision:* Inspecting the skin; evaluating a wound; reading a thermometer; identifying body language. *Hearing:* Listening to the client tell current and past problems; evaluating heart sounds, bowel sounds, and blood pressure. *Smell:* Identifying breath odor; evaluating wound and urine odor. *Touch:* Evaluating skin temperature, texture, contour, moisture; measuring size and assessing mobility of masses; identifying pulsations, vibrations.
2. Subjective data are given by the client. Objective data are collected by the health care professional using the senses of vision, hearing, smell, and touch.

O Temperature 102°F	O Pulse 98, irregular
S "My head hurts."	O Red maculopapular rash
S Nausea	S Vomiting for 3 days
O Grimaces when blinds open	S Skin flushed, hot
3. Answers to the matching:

1. b	6. d
2. c	7. a
3. a	8. e
4. a	9. b
5. c	10. c
4. d.

Chapter 6

1. O Temp 103.2 S Right upper quadrant pain
S Nausea O Swelling in ankles
O Hematocrit 33% S Itching
2. a. Tell me how you manage your care at home.
b. Describe your cough.
c. How do you feel about your health?
d. Describe your chest pain.
3. Previous illnesses, hospitalizations, and surgeries; client and family medical history; immunizations; allergies; home medications; developmental level; psychosocial history; sociocultural history; activities of daily living.
4. *Inspection:* General appearance; examination of skin color or lesions; facial expressions; movement.
Palpation: Skin temperature; texture; pulses; swelling; to determine size, shape, and consistency of masses.
Percussion: To determine location of organs; assess relative amount of air in a cavity. *Auscultation:* Breath sounds; heart sounds; bowel sounds.
5. "Mr. Robbins, although you state that you have taken your blood pressure medicine as prescribed, your wife does not remember having your prescription refilled. Can you help to clarify this?"
6. Focused assessment (with focus on elimination).

Chapter 7

1.
 - a. Correct
 - b. Blaming
 - c. Blaming
 - d. Medical Diagnosis
 - e. Circular
2. Initial nursing diagnoses based on the data may include *Activity Intolerance*, *Risk for Pain*, *Acute*; *Altered Nutrition: More Than Body Requirements*; *Impaired Physical Mobility*.
3. Possible sources of errors may include (a) Incomplete collection of assessment data. This error may be avoided by Nurse Smythe continuing the initial assessment started by Nurse Jones. (b) Failure to validate data. This error may be avoided by Nurse Smythe confirming previously collected data. (c) Faulty writing of the diagnosis statement. This error may be avoided by following guidelines for writing the statement and being sure that the medical diagnosis is not listed as an etiology.
4. Etiologies may include: related to decreased strength and endurance; related to edema; related to fatigue; related to pain; related to motivation. An example of a two-part diagnostic statement would be: *Impaired Physical Mobility* RT decreased strength and endurance.
5. One strategy to overcome barriers to using nursing diagnoses might include using the NANDA approved list to ensure a common language. This could be done by duplicating a copy of the NANDA list for each nurse or nursing student on the assigned clinical unit and having a reference book available that would list and describe how to use the specific diagnosis.
6. Nursing diagnoses are the logical conclusion to data that have been collected. Using nursing diagnoses provides the profession with a common language, which may enhance communication among nurses.
7. Nursing diagnoses assist in clarifying what the nurse is doing for the client; clarification could support reimbursement just as reimbursement for a medical diagnosis is based on DRGs. Once it is known what the nurses do, personal and professional power can coexist within the discipline of nursing.

Chapter 8

1. Number 3 is the only client-centered goal, because it clearly describes that the client will perform the action of describing the purposes of a low-fat diet. Number 1 is nursing assistant-centered, because the nursing assistant is the subject who will perform the action. Numbers 2 and 4 have omitted a subject, but the nurse is the implied subject.

2. Number 3 is the only objective stated correctly with an action verb. Numbers 1, 2, and 4 do not contain action verbs; “will know,” “will be able to,” and “will understand” are vague and not measurable. How can one measure what one knows, understands, or what one is able to do? However, one can identify, state, explain, demonstrate, or list. These verbs are more specific and clearly identify what individual skills are necessary to perform the assignment and reach the goal.
3. Number 1 is the only one with criteria. The standards include a time frame (“by Friday”).
4. None of the above. Not every goal will necessitate a condition.
5. Number 1 has a time frame (“by Friday”). The other numbers do not have a time frame.
6. d.
7. b.
8. b.
9. d.
10. b.

Chapter 9

1.
 - a. dep.
 - b. dep.
 - c. ind.
 - d. ind.
 - e. ind.
 - f. int.
 - g. int.
 - h. dep.
2. Examples are numerous and will vary by respondent. *Ongoing assessment*: A nurse gives a medication for pain and returns in 20 minutes to assess the effectiveness of the medication. *Setting priorities*: A nurse has been assigned five patients for the day (7–3). One of the patients is to go to surgery at 7:30 AM. The nurse’s first priority might be to assess the patient going to surgery in order to determine if all needed preparations have been made. *Allocation of resources*: In reviewing a list of activities, the nurse finds that two patients need discharge instructions and teaching, one needs a catheter inserted, one needs pain medication, and one needs to be turned and positioned. The nurse delegates the pain medication and catheter insertion to the LPN, turning and positioning to the nursing assistant, and does patient teaching and discharge herself. *Nursing interventions*: Monitoring of client progress; skilled interventions (medications, IVs, and so on). *Documentation of interventions*: At the beginning of each shift, the nurse documents a head-to-toe assessment.
3. Communication, legal record, research, reimbursement.
4. (a) Teach proper use and storage of nitroglycerin tablets. (b) Monitor (and teach Ms. Long to

monitor) type and frequency of chest pain. (c) Discuss purpose and procedures related to prescribed diagnostic tests. (d) Arrange consultation with dietitian concerning weight reduction and low-fat diet. (e) Assist Ms. Long in developing long-term plan to incorporate exercise into daily activities.

5. Answers will be individualized, but should incorporate the following guidelines: (a) List all activities to be completed; (b) Determine priorities (what must be done in what time period); (c) Determine if any activities can be delegated and, if so, to whom.
6. Answers will vary, but should incorporate brief, concise, complete, and accurate descriptions.
7. Answers will vary with each student.
8. Answers will vary with each state.
9. 8:00 Assist with breakfast
8:30 Assist with bed bath
8:55 Give routine medications
9:00 Up in chair and observe response to strengthening exercises with physical therapist; change linen
9:50 Prepare for transport for CT
12:00 Assist with lunch
1:00 Give routine medications
2:00 Up in chair at bedside

Chapter 10

1. Evaluation is an ongoing process performed at every stage of the nursing process.
2. *Structure evaluation:* Examines the agency's ability to provide the services offered to its client population. Evaluates the physical facilities, resources, equipment, staffing patterns, organizational patterns, and staff qualifications. *Process evaluation:* Examines each phase of the nursing process to judge the quality of nursing care in terms of adequacy, appropriateness, effectiveness, and efficiency. *Outcome evaluation:* Compares the client's current status with the expected outcomes to determine whether expected changes have occurred.
3. Evaluation provides a mechanism for comparing one's actions with standards.
4. Ask the client about his or her health status. Observe the client for behavior change (e.g., increased self-care ability, decreased anxiety). Monitor for physiological signs of improvement (e.g., stabilized vital signs, improved cardiovascular functioning).
5. Promotes professional growth. Improves quality of care.
6. Policy and procedure manuals and client's chart reflect evidence of the following: (1) Side rails up if client is confused or has received medication such as narcotics; (2) Call light is easily accessed

by the client; (3) Floors and passageways are kept free of obstacles; (4) Clients are educated on the safe and effective use of medication and equipment.

Chapter 11

1. Answers will vary according to nurses interviewed. Some ways of demonstrating caring are active listening, offering self (presence), use of touch, empathy, meeting basic needs (such as safety and comfort), spending time with clients and families answering their questions, serving as client advocate, educating clients and families.
2. Students' philosophies will vary. Some beliefs about healing and caring may include concepts related to the interwoven nature of bodymind (effect of physical and emotional health on one another), the holistic nature of individuals, healers seeking to help individuals tap into their inner healing reserves, caring and curing being different.
3. Answers will vary according to individual interviewed.
4. a. Attending behaviors include maintenance of appropriate eye contact, sitting in a position facing the client, nodding your head.
b. Other actions that indicate active listening include stating "Uh huh...", asking relevant questions, restating, reflecting.
c. Ways to demonstrate therapeutic use of self include spending time with the client, being available to listen and answer questions, being sensitive to nonverbal messages.

Chapter 12

1. Communication requires active involvement of all participants. It is difficult to undo a previously sent message. Communication is ongoing, always occurring. For example, even when people remain silent, they are still sending out messages through nonverbal cues.
2. Sender, receiver, message, channel.
3. Nonverbal cues speak louder than words and therefore convey the most accurate meaning of the intended message.
4. Active listening, observation of behavior.
5. Communication that is directed toward helping a client with needs, concerns, or problems.
6. Plan to interview at an appropriate time; ensure privacy; establish guidelines for the therapeutic interaction; provide for comfort during the interaction; accept the client exactly as is; encourage spontaneity; focus on the client and on the leads and cues presented; encourage the expression of feelings; be aware of your own feelings during the interaction.

7. Judging, blaming, belittling, rejecting, disapproving, probing.
8. Reflection, restating, focusing, directing, observing.

Chapter 13

1. *Cognitive*: Client states the name and purpose of prescribed medications. *Affective*: Client accepts limitations imposed by an injury (evidenced by stating, "I'll just have to learn to use those crutches."). *Psychomotor*: Client self-administers insulin injection.
2. Barriers to learning include *Physiological*—pain, fatigue, sensory deprivation, oxygen deprivation; *Environmental*—interruptions, lack of privacy, multiple stimuli; *Psychological*—anxiety, fear, anger, depression; *Sociocultural*—language, value system, educational background.
3. To promote learning by accessing a variety of learning styles (auditory, visual, kinesthetic); to reinforce learning by repeating information via the different learning styles.
4. Answers will vary: some key concepts that should be included are: Learning is a lifelong process; learning is a mutual process; individuals learn in a variety of ways and at their own pace; learning is an effective way to promote wellness.
5. Answers will vary.
6. Examples of answers, which will vary: Nurses in hospitals focus on immediate needs such as treatment modalities (including medications and procedures), diagnosis-specific information, and improving self-care abilities. Nurses in extended care facilities focus on self-care abilities and skills for coping with stressors, including relaxation and problem-solving skills. The focus of nurses in clinics depends on the type of clinic; for example, in a prenatal clinic, topics will include preparation for labor, signs and symptoms of impending labor, caring for a newborn, and nutritional guidelines. Information taught by nurses in schools will depend on the specific health-related and age-related needs. For example, a high school nurse will provide information on substance abuse, sexual health issues, suicide prevention, and self-esteem issues. Industrial nurses focus on prevention of exposure to toxins (including noise pollution), safety information (accident prevention), and wellness promotion (exercise, stress management). In the home environment, nurses focus on follow-up to promote self-care activities such as medication information, nutritional guidelines, and lifestyle modifications. Nurses in health maintenance organizations focus on recommended schedule for screening examinations, recommended schedule for immunizations, disease

prevention and health promotion activities, lifestyle modifications (e.g., diet, exercise), and stress management. *Note*: Regardless of practice setting, nurses teach families and significant others, as well as clients.

7. Answer will vary according to client needs and type of setting (see number 6 for some suggested content areas).
8. Answer will vary according to client needs. The nursing actions must be relevant to the client's identified learning needs.

Chapter 14

1. *Physical dimension*: hypnosis, imagery, biofeedback, meditation, relaxation, chiropractic, yoga, tai chi, therapeutic touch, healing touch, massage, acupuncture, acupressure, reflexology. *Emotional dimension*: hypnosis, imagery, meditation, relaxation, yoga, tai chi, therapeutic touch, healing touch, massage, faith healing, prayer, humor, pet therapy, music, aromatherapy. *Social dimension*: all may lead to improved social health. *Spiritual dimension*: faith healing, prayer, laying on of hands, shamanistic practices.
2. Answers will vary according to the community.
3. Balloons, bubble gum, bubble solution, comic books, Nerf squeeze balls, Koosh balls, crayons and markers, paper for drawing, smiley face stickers, cartoon books, joke books, jacks, marbles, kaleidoscope, spinning top, clay. These are only suggestions; use your imagination and creativity when answering this question.
4. Answer will vary with each individual and the individual's experience with the imagery exercise.
5. Appropriate therapies include music, massage, therapeutic touch, healing touch, pet therapy, humor (especially nonverbal expressions). A physician's order is not required as these are independent nursing interventions.

Chapter 15

1. Assist clients to meet lower-level (more basic) needs first. Provision of food, water, oxygen, shelter, and comfort must be attended to before addressing self-esteem and belonging needs.
2. Individual answers will vary but may include topics such as legislative proposals to cut health care financing; controversy over establishing a new landfill in the community; detection of toxins in the water supply; the unhealthy smog index reported in air quality reports; the closure of a community hospital.
3. Answers will vary depending upon the interviewee. In general, individuals do experience a

positive correlation between emotional and physical health.

4. Answers will vary depending upon the interviewee. Common determinants of health are ability to do what one needs or wants to do; absence of painful or debilitating symptoms; ability to care for self.
5. Answers will vary. Common motivators are to be free of pain; to remain independent; a desire to stay healthy throughout one's life; decreased health insurance premiums for health-promoting behaviors (e.g., no cigarette smoking, consistent use of seat belts); ability to work without missing any time.
6. Important issues that affect the health of Americans are lack of cost-effective, easily accessible basic health care services; the current health care delivery system, which is driven primarily by economics; the AIDS epidemic; increasing number of adolescent pregnancies; resurgence of communicable diseases, such as tuberculosis; high incidence of alcohol and drug abuse; cigarette smoking; violence.
7. Answers will vary. Some examples may include Meals on Wheels for the elderly; Women, Infants, and Children (WIC) food program; shelters for the homeless; public health clinics.

Chapter 16

1. Answers will vary depending on the person interviewed. Ideally, the discussion will provide information about cultural beliefs relative to definition of health and illness, folk remedies, folk healers used (if any), beliefs and rituals related to birth and death.
2. Stereotypes can affect nursing care by influencing perceptions formed during assessment; affecting the types of nursing diagnoses formulated; determining the behavioral responses of nurses to clients from varying cultural backgrounds.
3. Services for the homeless population vary greatly from community to community. Some examples of such services may include shelters, soup kitchens, indigent clinics, mobile clinics (medically equipped vans). These may be funded by the local governing agencies, private endowments, volunteers, or churches.
4. The answers for this question are highly personal in nature and therefore will vary. It is most important to think about the last question, which focuses on your assumptions and attitudes about people of other racial and ethnic groups because such assumptions and attitudes affect behavior.
5. Even though the answers will vary with each student, some things for all to consider include:
 - What lessons were learned from the most important book read?

- Is there congruence between your values and your behavior? For example, if you value your health over your appearance yet spend more time every day on improving your appearance than on your health, incongruence exists.
- How many qualities of a "good nurse" do you possess? What can you do to develop others?

Chapter 17

1. Because growth can occur at any time in the life span, recognize that every client, regardless of age, has the ability to learn and to change. Nurses can intervene to help clients successfully master developmental conflicts at any stage.
2. Some ways in which nurses demonstrate their faith are: respecting the dignity of each client; treating clients as equals; spending time with each client; providing information; honoring the client's decisions; involving the client in the care provided.
3. Storybooks, puzzles (10–25 pieces), large crayons, finger painting materials, clay, balls, simple computer games, sandbox, toy telephones.
4. STD education should include basic information about the disease, type of treatment and consequences, notification of sexual partners.
5. Answer will vary depending on each student's value system.

Chapter 18

1. Old age can be viewed as a result of physical changes, psychosocial development, or a combination of the two. No one theory is successful at explaining all the changes of the aging process; a holistic approach that considers all the client's characteristics, including values, self-concept, cultural background, and family status, will give a more complete picture of the aging adult.
2. The section on physiological changes outlines the many changes the older adult will experience; specific tips on helping the client manage these are given in the related boxes.
3. An older adult's reaction to the psychosocial changes of aging will mirror the development of his or her psychosocial health over the years. Individuals who have a positive outlook on the aging process and who are mentally and financially prepared for old age are likely to have fewer health alterations and needs than those individuals who resist the aging process and view it only in terms of the negative changes and limitations it introduces.
4. Polypharmacy refers to the concurrent use of several medications; because the elderly in general take multiple medications, the nurse must be aware of side effects, contraindications, and other

medication alerts to protect the health of the elderly client.

5. Elder abuse can manifest in both physical and psychological symptoms; refer to the displays outlining these signs.
6. Home environment evaluations focus on removing safety hazards such as poor lighting, loose throw rugs, and the like; see the chapter displays for complete outlines of safety hazards.
7. Remember that older adults are persons of dignity and value who deserve your respect and thoughtful nursing care. Teaching guidelines should be clear, concise, and targeted to the client's level of understanding and functioning. Visual and auditory aids will help enhance comprehension and retention of material.
8. It is important to describe the purpose of the class. In order to prepare, get to know the social history of each client who will be in the group. This involves establishing a therapeutic relationship, reviewing the social history on the medical record, and interviewing the family/significant others if available. The agenda for the class should include the class purpose and a simple explanation of life review. The group norms would also be explained. Evaluation of the class efficacy should focus on behavioral changes of the clients; for example, smiling and verbalizing pleasant memories.

Chapter 19

1. Self-concept is determined in large part by familial and cultural influences, so these may help determine if one factor is more important than another. Also, because self-concept changes with developmental level, the strength of one component over another may increase or decrease over time. For instance, body image may predominate in the formulation of self-concept for the teenager, whereas role performance or identity may be more important to the new parent.
2. *Childhood:* Family experiences, interactions with parents and siblings, degree to which needs are met, development of new skills, sense of autonomy, development of language, awareness of emotions and empathy, interactions with peers and teachers at school. *Adolescence:* Body image and appearance, physical changes, impressions of childhood, interactions with peers and friends, association with role models, social status. *Adulthood:* Physical changes, changes in energy levels, changing roles, changes in skill competencies, professional status, life review.
3. Provide privacy, encourage client to relate stories and personal anecdotes, encourage client to keep personal items at bedside, involve client in care decisions to promote independence and feeling of

self-worth, fully explain all procedures, involve family members or significant others in care.

4. Additional assessments could include: loss of former role of income provider; loss of professional status; anxiety over meeting financial goals given change in income status; changes in self-esteem based on new roles; need to find and accept a modified identity based on new life situation. Nursing care would be directed at helping the client identify these additional concerns; working together to find means to manage them in a way that would help the client boost self-confidence; assisting the client in seeing the changes as positive challenges; helping the client to emphasize not just the differences but the similarities between his former roles and his new roles.

Chapter 20

1. Answers will vary.
2. Answers will vary.
3. The “fight-or-flight” response occurs during the resistance stage of GAS; is a physiological response to stress in which the autonomic nervous system and endocrine system are aroused to prepare the body for defense against a stressor by either fighting or fleeing.
4. People who experience chronic, prolonged periods of stress have impaired immune systems as a result of the stress response. Clients are *not* responsible for causing the illness; however, they can help the recovery process by learning to deal with stress effectively.
5. Answers will vary.
6. Possible answers: by being active in student government association; by questioning; by being assertive, not aggressive or passive.
7. Possible answers: By continuously adding to your knowledge base; by increasing your skill level; by asking questions; by encouraging clients to speak up for themselves.
8. Answers will vary.
9. Answers will vary.
10. Answers will vary.
11. c.

Chapter 21

1. Interventions for the client focus on providing physical comfort, meeting psychosocial needs, and assisting with fulfillment of spiritual needs. Interventions for the family focus on providing support and education. One of the most important nursing roles in caring for the dying client and family is to provide support.
2. Keep the client clean and dry; provide a safe, nonthreatening environment; demonstrate a

- respectful, caring attitude; teach the client relaxation techniques (deep breathing, imagery, progressive muscle relaxation); touch; massage; music.
3. The stages of grief are met in varying degrees by each individual. Not every person will progress through each stage of grief.
 4. Intense preoccupation with the deceased; treasuring the deceased's possessions; inability to resume normal activities.
 5. Answers will vary.
 6. Subjective: Client verbalizes the presence of pain. Objective: Tense muscles, guarding a certain part of the body, facial grimacing, frowning, elevated pulse, diaphoresis, increased respiratory rate.
 7. Answers will vary.

Chapter 22

1. Answers will vary according to program availability. Programs sponsored by state nurses associations, district or provincial nursing associations, and nursing schools are all aimed at promoting the integrity of the nursing profession.
 2. Qualifications, member selection, and duties of the board of nursing vary from state to state.
 3. Answers will vary depending upon the association officers interviewed.
 4. The definition of nursing varies slightly from state to state. The authority for APRNs also varies according to state regulations.
 5. Ways to gain competency after graduation include participating in continuing education programs; attending employee-sponsored in-service and orientation programs; reading current journal articles related to your area of practice and about the profession of nursing in general; enrolling in postgraduate courses; networking with colleagues to discuss the latest advances; continuing to practice as a licensed professional.
 6. Answers will vary depending upon the identified leaders; however, some qualities of leaders are communication skills, credibility, delegation skills, critical-thinking ability, ability to initiate action, effective risk-taking skills, and ability to use persuasiveness and influence appropriately.
 7. Ways to increase personal power include maintain competence and knowledge base to build credibility, associate with powerful people, develop the skill of persuasion, share power with others, share information with others, encourage peers to develop, demonstrate self-confidence.
- individuals stating what each individual must do or not do; mutual understanding of the terms and obligations the contract imposes on each individual; and compensation for lawful actions performed.
4. Types of intentional torts are assault and battery, defamation, fraud, invasion of privacy, and false imprisonment.
 5. Proof of liability depends on four elements: duty, breach of duty, injury, and causation.
 6. A reasonable nurse is obligated by the courts to follow the institution's policies and procedures for how client care is to be performed in that facility and to notify the physician of changes in the client's condition. In addition, in the determination of a breach of a duty, the actions of the nurse are compared against the professional standards of nursing care.
 7. Complaints against nurses are in one of the following categories: client falls, medication errors, failure to monitor a client in restraints, improper technique in giving treatment, failure to follow hospital procedures, and failure to supervise non-licensed employees.
 8. Actions or omissions by the nurse that constitute unprofessional conduct are: breach in client confidentiality; failure to use sufficient knowledge, skills, or nursing judgment when practicing nursing; physically or verbally abusing a client; assuming duties without sufficient preparation; knowingly delegating nursing care to unlicensed personnel, which places the client at risk for injury; failure to accurately maintain a record for each client or falsifying a client's record; and leaving a nursing assignment without properly notifying appropriate personnel.
 9. Nursing students, when employed as caregivers, must act as reasonably prudent persons, equivalent with education and experiences, and assume only those duties that they are competent to perform, as stated in their job description.
 10. The nurse administered the enema without the client's consent, which constitutes battery. The client proved that the enema was offensive, insulting, or physically intimidating and that the client did not agree to the touching that occurred. The client had a heart attack and injury was incurred.

Chapter 24

Chapter 23

1. a.
2. b.
3. A legal contract has three essential elements: promise(s) between two or more legally competent

1. See Table H-1 for some suggested answers.
2. *Assessment* (Determination of claims and parties): Mary Washington, the newborn, health care providers.
Analysis and diagnosis (Problem identification: statement of the ethical dilemma): Length of life versus quality of life; parents' right to refuse treatment for their child. Ethical principles: Mother's

TABLE H-1
Answers for question 1, Chapter 24

Tenet	Actualizing Behaviors	Ethical Principle
1. Respect every client's human dignity and uniqueness.	<ul style="list-style-type: none"> a. Call each client by name. b. Be sensitive to client's cultural background. c. Establish a trusting relationship with client. d. Recognize and honor each client's individuality. e. Develop an individualized plan of care based on each client's unique situation. 	Autonomy
2. Safeguard client's right to privacy.	<ul style="list-style-type: none"> a. Share client information only with members of the health care team involved in that client's care. b. Do not discuss clients or families in public areas (e.g., hallways, cafeterias, elevators). 	Nonmaleficence and fidelity
3. Protect clients and the public from incompetent, unethical, or illegal practice of any person.	<ul style="list-style-type: none"> a. Report incompetent, unethical, or illegal practice by health care providers. b. Know the criteria of your state or provincial nurse practice act as it relates to whistleblowing. c. Adhere to facility policy for whistleblowing. 	Nonmaleficence, fidelity, and veracity
4. Be responsible and accountable for your own nursing judgments and actions.	<ul style="list-style-type: none"> a. Demonstrate accountability by admitting mistakes instead of blaming others or "the system." b. Make decisions through use of critical-thinking skills, as opposed to rash impulsive decisions. 	Beneficence, nonmaleficence, and fidelity
5. Maintain competence in nursing.	<ul style="list-style-type: none"> a. Maintain current knowledge base and expertise by participating in educational activities. b. Achieve certification in area of practice. 	Beneficence and nonmaleficence
6. Exercise informed judgment and use individual competence and qualifications as criteria in seeking consultation, accepting responsibilities, and delegating nursing activities to others.	<ul style="list-style-type: none"> a. Use critical-thinking skills when making decisions about delegation. b. Determine the qualifications of a delegatee prior to making assignments. c. Ask questions as needed. d. Demonstrate competency for assigned tasks. 	Nonmaleficence and beneficence
7. Participate in activities that contribute to the development of nursing's body of knowledge.	<ul style="list-style-type: none"> a. Conduct research studies. b. Assist in research studies. c. Use research findings in practice. 	Beneficence and fidelity
8. Participate in the profession's efforts to implement and improve standards of nursing.	<ul style="list-style-type: none"> a. Be active in professional associations. b. Communicate with legislators about nursing and health care issues. 	Beneficence
9. Participate in the profession's efforts to establish and maintain conditions of employment conducive to high-quality nursing care.	<ul style="list-style-type: none"> a. Adhere to agency's policies on staffing. b. Communicate to nursing management when low staff:client ratio interferes with delivery of quality care. c. Communicate with legislators and other policy makers about the relationship between work environment and client safety. 	Nonmaleficence, beneficence, fidelity, and justice
10. Protect the public from misinformation and misrepresentation; maintain the integrity of nursing.	<ul style="list-style-type: none"> a. Provide client and family with factual information. b. Maintain membership in professional association. 	Nonmaleficence, fidelity, and veracity
11. Collaborate with members of the health professions and other citizens to promote health of the public.	<ul style="list-style-type: none"> a. Maintain open lines of communication with other health care providers. b. Teach clients and families health-promoting activities. 	Nonmaleficence, beneficence, fidelity, and justice

autonomy, nonmaleficence; infant's right to non-maleficence, beneficence.

Planning (Consideration of priorities of claims; generation of alternatives for resolving the dilemma; consideration of the consequences of alternatives): Whose claim should take precedence? Alternatives: Withhold treatment, which would result in newborn's death; Provide extraordinary treatment and send the child home with the mother; Provide extraordinary treatment and have the child become a ward of the state if the mother abandons the child or gives up parental rights.

Implementation (Carrying out selected moral actions): Select one of the alternatives and perform it.

Evaluation (Assessing the outcome of moral actions. "Were the actions ethical? What were the consequences?"): Answers will vary.

Assessment (Determination of claims and parties): the 80-year-old client, her family, health care providers.

Analysis and diagnosis (Problem identification: statement of the ethical dilemma): Length of life versus quality of life; client's right to refuse treatment versus family's desire for extraordinary treatment. Ethical principles: Client's autonomy, nonmaleficence, fidelity. Family's right to nonmaleficence, beneficence.

Planning (Consideration of priorities of claims; generation of alternatives for resolving the dilemma; consideration of the consequences of alternatives): Whose claim should take precedence? Alternatives: Withhold treatment, which would result in client's death; Provide extraordinary treatment.

Implementation (Carrying out selected moral actions): Select one of the alternatives and perform it.

Evaluation (Assessing the outcome of moral actions; "Were the actions ethical? What were the consequences?"): Answers will vary.

3. The answer regarding values will vary with each student. Some of the ethical implications for each situation follow.
 1. Autonomy, nonmaleficence, beneficence
 2. Autonomy, nonmaleficence
 3. Nonmaleficence
 4. Autonomy and nonmaleficence
4. Answers will vary to question 1. In the situation of the young sexually active female who is diagnosed as HIV-positive, the client's right to privacy conflicts with the public's right to safety. Laws concerning confidentiality vary from state to state. Generally, the need to inform the public overrides the client's right to privacy in cases of STDs. This is based on the ethical theory of teleology in which utility states that an act must result in the greatest

amount of good for the greatest amount of people.

5.
 - Answers will vary based on individual opinion.
 - Examples of support for a client's right to refuse treatment: fully explaining the consequences of no treatment, complete discussion of all treatment options, acting as an advocate for the client who refuses.
 - Responses to a client's decision to continue self-harmful practices: recognize that the client who is an adult and competent has the right to engage in practices as long as they are within legal parameters. For example, the client who is diagnosed with emphysema and continues to smoke must be treated as an individual worthy of respect.
6. Answers will vary based on individual belief systems.
7. Each of the situations will evoke a variety of emotional responses. However, as a professional nurse, it is imperative to provide respectful, compassionate care to all clients.

Chapter 25

1.
 - a. Lab personnel, courier, physician, unit secretary.
 - b. Send a copy to physician for initialing and immediately file original on chart. Have physician go to lab to sign results. Fax results to physician, who initials and then forwards report to unit.
2.
 - a. The following processes can be analyzed: orientation for new staff regarding medication administration; the process for documenting medication errors; the process for reporting medication errors; the way in which medication is administered; the mechanism for providing coverage during vacation time.
 - b. Possible solutions for each variation: increased orientation about medication administration and documentation for newly hired staff; ongoing education with all staff about medication administration; provide more staff for vacation coverage.
3. The phrase "doing the right thing" refers to efficacy and appropriateness. The phrase "doing the right things well" involves the dimensions of availability, timeliness, effectiveness, continuity, safety, efficiency, and respect and caring.
4. Quality assurance is an older term, retrospective, focused on individual performance. Quality improvement is a newer concept that is more encompassing; is focused on present and future; emphasizes process, not individual performance.
5. Nurses improve quality of care by maintaining competence (through ongoing educational activities); listening to clients; focusing on client's perceived needs; looking for one thing every day to do better.

Chapter 26

1. All the documentation tools should form a system that reflects the nursing process. The assessment data should identify the client's specific alteration, which leads to the formulation of a nursing diagnosis. The nursing diagnosis then triggers the client's plan of care with expected outcomes and the specific nursing interventions to assist the client in achieving those outcomes, as well as the criteria for evaluation, which determines the need for subsequent reassessment and revision of the plan of care. The system itself becomes a vehicle for expressing each phase of the nursing process without duplication of information.
2. The client's medical record contains documents for record keeping that provide written evidence of what was done for the client and the client's response to the interventions.
3. The critical elements of assessment should be reviewed to determine the client's condition as presented in the chart. This information should identify what specifically helped the client in each particular situation.
4. Mrs. White's medical record must provide documentation that supports her medical diagnosis of diabetic ketoacidosis and the appropriateness of care to maximize reimbursement. Documentation on the flowsheet should reflect routine interventions such as the frequency of vital sign measurements, telemetry, daily weight and intake and output measurement, hourly specific gravity results, and blood glucose levels. Nursing documentation must also show evidence of client and family education and discharge planning.
5. Mrs. White is an insulin-dependent diabetic admitted on 10/14/97 with diabetic ketoacidosis. On admission she was hyperventilating, vomiting, and hypotensive. The results of her laboratory tests indicated that she was hyperglycemic, hypokalemic, and dehydrated. Interventions were directed toward restoring a normal blood glucose level and correcting the hyperglycemia, hypokalemia, and dehydration. As a safety measure, fall precautions were instituted. Client teaching focused on diet, activity and exercise, and insulin. Her husband was present for the teaching sessions. She was referred to home health to monitor the effectiveness of teaching and her ability to manage her diabetes.
6. 10/15/97, 1500: Mrs. White, room 402, 56 years old, admitted on 10/14 by Dr. Smith with an admit diagnosis of diabetic ketoacidosis. She has a history of diabetes mellitus, insulin-dependent. Her husband has been with her all day and has a dinner tray ordered for this evening; their daughter will bring him home after dinner.

Mrs. White is on bed rest and hourly vital signs, which have stabilized (T 98.6°F; P 88/min and regular; R 18/min, and BP 146/84). She is on telemetry, normal sinus rhythm. Hourly output, ranging from 80 to 100 ml/h per Foley catheter, total for this shift, 750 ml/8 h. The hourly specific gravity was discontinued last evening at 2100. The urinalysis report is on the chart, results were called to Dr. Smith at 1035.

Daily weights at 0600; she weighed 61 kg this morning. She was NPO until this morning; started on a 1600-calorie diet at breakfast. She ate 60% of her breakfast and 80% of lunch; she refuses to drink the skim milk. Dietary has been contacted and the calories will be adjusted to allow for 2% low-fat milk as requested by the client. No complaints of nausea. Hourly blood glucose, ranging from 350 to 320 mg, 1400 glucose was 322 mg. Notify Dr. Smith if the blood glucose is less than 300 mg.

She has a triple lumen catheter in the right subclavian, IV fluids are infusing as prescribed. Line 1: 1000 ml of 0.9% normal saline at 125 ml/h per pump, a new bag was hung at 1100, claim 625 ml for your shift; Line 2: 500 ml of 0.9% normal saline with 50 U of regular insulin at 7 ml/h per pump, a new bag was hung at 1400, claim 500 ml. Her total intake for this shift was 1230 ml/8 h. IV tubing was changed when new bags of fluids were hung. Sterile dressing was changed this morning, it is dry and intact. The third port is flushed with heparin every 8 h, it is patent.

Oral hygiene has been done hourly, mucous membranes moist, without lesions. Fall precautions implemented since admission.

7. The nurse should document in the progress notes changes that occur in the client's condition, the client's response to an intervention or the expected outcome, and all client or family members' complaints.
8. O, A, S, P.
9. Focus charting uses a columnar format within the progress notes to distinguish the entry from other recordings in the narrative notes; it is a method of identifying and organizing the narrative documentation of client concerns that includes data, action, and response.
10. The advantages of computerized charting are: saves documentation time; increases legibility and accuracy; provides clear, decisive, and concise key words; enhances implementation of the nursing process; enhances decision making; supports multidisciplinary networking. The disadvantages of computerized charting are: cost of installation, which limits the number of terminals at nursing stations; too slow at peak usage times; downtime (time for routine servicing or sudden unexpected failure); nurses' resistance, not wanting to change

long-practiced documentation behaviors; risk of loss of client confidentiality of information contained in the medical record and personnel sharing of access codes (passwords); need to determine who should have access to and how the clinical database should be used.

Chapter 27

1. Respirations and blood pressure are above the normal limits for Ms. Reynolds' age.
2. You would expect to find an elevated temperature. Mr. Warren has the fan on because he feels warm. Convection, the use of the fan, increases the amount of heat loss by air currents.
3. Do not measure the blood pressure in Mrs. Gray's right arm.
4. Reduced hemoglobin content in the blood causes a bluish discoloration (cyanosis) of the lips and nail beds.
5. Resonant sound is normally heard over the posterior apices on percussion.
6. Auscultation of bronchial breath sounds is normal over the trachea. Vesicular sounds are normally heard in the lung periphery. The auscultation of bronchial sounds in the lung periphery usually indicates emphysema.
7. A bimanual technique is used when palpating large breasts.
8. Fine crackle: Dry, high-pitched crackling, popping sound of short duration
Coarse crackle: Moist, low-pitched crackling, gurgling sound of long duration
Sonorous wheeze: Low-pitched snoring sound
Sibilant wheeze: High-pitched musical sound
Pleural friction rub: Creaking, grating sound
Stridor: Crowing sound

Chapter 28

1. The nurse practitioner identified during the history that for the past 2 months, Mr. Simon has had repeated colds with fever, fatigue, weakness, and a 20-pound weight loss; during the physical examination, the nurse found multiple bruises on his extremities and trunk and bone and joint pain on movement. These symptoms prompted the nurse practitioner to order a white blood cell differential. Although the repeated colds, fever, and weakness may indicate an infection, the cause of the weight loss, bruising, and pain has to be determined. Changes occur in the white blood cells (leukocytes) in inflammatory and immune responses. The WBC count provides an overview of the client's immune status, and the differential identifies the proportions of each WBC type. Table 28-5 identifies the common disorders associated

with changes in the WBC type. Based on Mr. Simon's symptoms, the nurse was trying to identify changes in the WBC types that would indicate a malignancy, such as an increase in segmented neutrophils and lymphocytes or a decrease in lymphocytes. The WBC count and differential only partially reflect the client's condition; however, when put into the context of the client's clinical manifestations, they provide a key to assessing the client's defenses and allow for appropriate interventions.

2. Whenever the skin is broken, as occurs with a puncture, the body's first line of defense against infection is compromised. Within 48 to 72 hours clinical manifestations of an infection may be present and the WBC count and segmented neutrophils and bands will be greater than normal. With an acute infection, this increase can occur within 4 to 24 hours post-puncture as the body speeds neutrophil production to destroy bacteria.
3. Correct client positioning and selection and preparation of equipment and vein provide for a safe and efficient venipuncture to prevent hemoconcentration, which can be caused by prolonged standing or a prolonged time of application of a tourniquet during venipuncture; hemolysis, which results from the rapid flow of blood through small-bore needles and exposure to large negative pressures; and the variability that occurs when a blood specimen is drawn from a site above an intravenous infusion.
4. The normal prothrombin time for adults is 12 to 14 seconds. This time interval represents the time it takes the body to convert prothrombin, an inactive precursor in the coagulation process, to thrombin to form a clot. If the control time is 12 seconds, the therapeutic range will be 24 to 30 seconds (2 to 2.5 times the control time).
5. When an offspring has a blood type of AB positive, the possible parental blood types are AB + A or AB + AB. Blood type O is the universal donor because the red blood cells have no agglutinogens and therefore do not react with either anti-A or anti-B serum. Blood type AB has both A and B agglutinogens and agglutinates with both types of serum.
6. Acetylcholine is a chemical substance that functions as a synaptic transmitter. The enzyme cholinesterase causes the rapid split of acetylcholine to acetate and choline, which allows for the transmission of nerve impulses. When the cholinesterase level is low and the client is scheduled to receive succinylcholine, the practitioner should be notified because succinylcholine further depresses the action of cholinesterase, which can cause prolonged periods of dyspnea and general muscle relaxation, resulting in respiratory distress.
7. Mrs. Smith is considered at high risk for coronary heart disease because her HDL is less than 35 mg/dl.

8. The nurse should review the radiological reports and the practitioner's progress notes to determine the potential risk factors for Maria Rodriguez.
9. Before the arteriography is performed, the nurse ensures that the client is not allergic to the dye and that the client knows what to expect during the procedure: The client will be placed on his back and connected to a cardiac monitor; the practitioner will insert a catheter through a peripheral artery such as in the groin; the catheter's tip will be threaded into the area being studied; and then a radiopaque dye will be injected into the catheter. Postprocedure teaching should include informing the client that the involved extremity will have to be maintained in a straight and immobile position. The client will be instructed to notify the nurse if he or she experiences any warm, trickling sensations at the puncture site that would indicate bleeding.
10. After a cardiac catheterization, the nurse should:
 - Place the client on telemetry.
 - Apply manual pressure (for 30 minutes or longer) when the catheter sheath is removed, then apply a pressure dressing.
 - Keep the client on bedrest, with the involved extremity straight and immobile.
 - Monitor and record vital signs, including the presence, quality, and character of peripheral pulses and the color, temperature, and tactile sensation of the involved extremity.
 - Encourage oral fluids and record intake and output.
 - Instruct the client to report any warm, trickling sensations at the puncture site that would indicate bleeding.
 - Monitor for procedural complications such as bleeding or hematoma formation at the site; allergic reactions; and cardiovascular, pulmonary, and neurological changes.

Chapter 29

1. Consult with the physician to consider prescribing another form of oral sulfamethoxazole because Mrs. Adams' arthritis may prevent her from vigorously shaking the bottle. If a suspension is not mixed properly, it may prevent the prescribed dosage of the medication from being poured from the bottle.

Mrs. Adams' teaching should include the drug's action, adverse effects, scheduling, and specific considerations for each drug prescribed.

Sulfamethoxazole: She should continue taking the drug until the full prescription has been taken. She should drink a large glass of water with each dose, plus four to six additional glasses of water to prevent crystalluria. Mrs. Adams should be cautioned to avoid sunlight and notify the physician

at the first signs of a sore throat or fever. The nurse should stress the importance of Mrs. Adams' returning to the physician's office for a urine culture, urinalysis, and CBC as directed by the physician 5 days after discharge. *Granisetron:* Instruct Mrs. Adams to notify the physician immediately of any adverse reactions such as headache, somnolence, diarrhea, constipation, nausea, vomiting, or decreased appetite. Stress the importance of taking the medication every 12 hours to achieve maximum effectiveness from the drug's actions even though she is not experiencing nausea. Inform Mrs. Adams that, although morphine is a narcotic, she will not become addicted to the drug when taken as prescribed for pain. Caution her to be careful when ambulating and to avoid driving and other potentially hazardous activities that require mental alertness until the drug's adverse effects are known.

2. Group B.
3. Use the household system, one tumblerful (glass) equals 240 ml. There are 1000 milliliters in a liter; 2 liters are equivalent to 2000 milliliters. By dividing 2000 ml by 240 ml, you get 8.3 glasses. Instruct the client that the physician has written the order for 8 glasses of liquid over a 24-hour period. Refer to Chapter 37 for how to schedule liquids over a 24-hour time period.
4. 2 tablets.
5. 57 mg.

Chapter 30

1. Emergency surgery requires immediate intervention in order to sustain life. The nurse should collaborate with the physician and the anesthetist in planning the client's essential care to ensure that the hospital stay is as short as possible after surgery. The nurse should meet with Mrs. G.'s family to discuss and plan the discharge teaching, assessing what resources are available in the home. The nurse should begin discharge teaching in the immediate postoperative phase in collaboration with the surgeon and a home health nurse. The accounting office should be notified that all efforts are being made to provide for a safe and speedy recovery. The family should be assured that Mrs. G. will receive safe, effective care and that arrangements will be made for the family to pay for the hospitalization.
2. As the client's age and developmental stage can influence the ability to cope with surgery, the nurse should listen to the child's concerns and explain the surgical experience using terms the child can understand. An 11-year-old boy may be hesitant to express his fears. The nurse, in the presence of the parent, should encourage the child to talk about what he is feeling. Before

discharge, the nurse should ensure that the parent demonstrates competency in changing a sterile dressing and proper disposal of soiled dressings and equipment.

The nurse should consider the specific age-related factors when doing discharge teaching. The client will have limitations in his activity, and the nurse should help the parent plan how these can be handled in the home environment with two younger siblings. For example, the 5-year-old could help his brother to the bathroom and the 3-year-old could bring pillows and other safely carried items to help with the care. Meals should be eaten at the table, and regular bedtimes should be maintained. The nurse should help the parent see how establishing routines in the 11-year-old's care will foster a sense of participation for the whole family unit.

3. The nurse should honor Mr. S.'s request and have a priest minister the sacrament of Anointing of the Sick. This sacrament is often used for its power of healing. The nurse should allow the client to prepare for surgery in accordance with his personal and religious beliefs. As with all interventions, after the Anointing, the nurse should document it in the nurse's notes.
4. The nurse has many actions to perform when preparing the client for surgery. These actions promote client safety and facilitate a smooth transition from one perioperative phase to another. Timing is a critical factor in planning perioperative care. All tests and their results should be on the chart before surgery. Preoperatively, the client should be prepared for discharge. Client teaching is a major factor in preventing complications such as infection that may place the client at risk and increase hospital costs.
5. The nurse's first action should be to assess for hypoxemia. The nurse should remain with the client and use the call light to have another staff member bring a portable pulse oximeter to the bedside to measure the client's blood oxygen saturation level. If the reading is below the normal range (95% to 100%), initiate oxygen via nasal cannula at 4 L/min and notify the physician. Oxygen is a drug and requires an order from a practitioner except in emergency situations. Clients with chronic obstructive lung disease should receive only low doses of oxygen 2 L/min, so that the hypoxic respiratory drive remains intact.

The physician may order arterial blood gases (ABGs) and a chest x-ray to rule out atelectasis and pulmonary infection. Postoperative clients may develop respiratory complications caused by general anesthesia such as atelectasis, which may lead to hypoxemia. Pain can also reduce ventilatory effort and function, and result in hypoxemia. The client's symptoms may be caused by the morphine, an opi-

ate analgesia that can cause respiratory depression, especially after the initial dose and after an increase in dosage. Although respiratory depression rarely occurs when the client receives the same continuous dose, the nurse should frequently monitor clients on a PCA pump for changes in respiratory status and signs of hypoxemia.

Early signs of hypoxemia are changes in mental status such as restlessness, confusion, agitation, and altered levels of consciousness. Pulse oximetry changes alert the nurse to changes in the blood oxygen level within seconds; whereas cyanosis is a late sign of hypoxemia. The nurse should monitor the client's blood pressure, urine output, pulses, and capillary refill for signs of diminished cardiac output and the client's respiratory status for signs of respiratory distress such as retractions, nasal flaring, unequal chest expansion on inspiration, and use of accessory muscles.

6. Mrs. Broussard's discharge plan of care:
 - Nursing diagnosis: *Impaired Physical Mobility* related to musculoskeletal impairment
 - Expected outcomes: Client will self-medicate to control pain; client will remain free from infection; client will perform exercises to keep the joint mobile; client will avoid activities that increase the risk of dislocating the prosthesis.
 - Interventions: Teach client about patient-controlled analgesia. Home health nurse to change dressing daily using aseptic technique, and monitor for signs of infection, such as redness, drainage from incision, and fever. Ensure that the client is taking prophylactic antibiotics. Observe the client performing range of motion (ROM) and continuous passive motion (CPM). Instruct client to keep hips abducted and avoid crossing legs when sitting; avoid bending hips more than 90° when getting up out of bed or chair, and avoid hip flexion greater than 60° at all other times; sit in high-back chairs with firm seats; notify the physician immediately if a sudden increase in pain is felt.
 - Evaluation: Pain controlled with analgesia. Incision site free from infection. Hip healed in 6 weeks. Client instructed to start frequent walks, swim, and use a high rocking chair to exercise hip.

Chapter 31

1. The typical hospital room has one or two beds in a well-lighted room. If two beds are present, a curtain is present between the beds. The beds can be lowered or raised mechanically, and the head and foot of the bed can also be raised or lowered mechanically. The beds have side rails on both sides for patient safety. A small dressing table with several drawers is present near the side of the bed. A bedside table is present to assist with eating and

grooming activities. Near the head of the bed is wall-mounted equipment such as oxygen outlet, vacuum outlet, blood pressure cuff, intercom system, outlet for call button, and an emergency button. Near the side of the bed, usually stored under the bed, is a stepping stool used to enter the bed. The room usually has a closet for storage space. A television is mounted on the wall. A bathroom is in the hospital room. It is equipped with a toilet, sink, shower and/or tub, grab rails near toilet and in the shower or tub, and an emergency call light.

Safety nursing interventions include: keeping the room well lighted; keeping the floors free of equipment; assessing the functioning of the bed and all equipment; keeping the foot stool stored under bed; keeping the bed in the lowest position; and keeping the bathroom clean.

2. A safety protocol for a client who is 65 years of age, is confused, and has severe arthritic contractures of the hand would minimally include:

- *Assessment:* Assess client's functional ability, especially use of hands. Assess visual acuity and hearing ability. Assess for previous falls. Assess medications.
- *Report to Physician:* Client's physical limitations and assistive devices needed. Client's history of falling.
- *Client Teaching:* Orient client to environmental surroundings as often as necessary. Instruct client on safety measures. Instruct client to call for assistance. Post reminders in obvious places.
- *Environmental Interventions:* Keep bed in lowest position, brakes locked, and side rails raised. Keep room lighted. Keep frequently used objects near bed or chair. Keep floor clean and clutter-free. Provide with assistive devices such as spoons and forks with large handles that facilitate grip. Place client in room nearest the nurse's station. Frequently check on client. Encourage family members to remain with client during the client's most active period of the day. Side rails and hand rails should have special grip handles to accommodate client's limited grip.
- *Direct Nursing Care:* Respond promptly to calls. Anticipate client's needs. Assist with ADLs. Provide proper assistive equipment for ambulation and other needs. Provide protective devices as necessary.
- *Evaluation:* Evaluate client's functional ability with the use of assistive equipment, client's orientation and knowledge of safety measures, and the effectiveness of client teaching and direct nursing care.
- *Documentation:* Document client's risk appraisal, safety plan of care, all safety nursing interventions implemented and client's response, and client education.

3. The patient should be placed on Standard Precautions for infection control. To break the

transmission of methicillin-resistant *Staphylococcus aureus* (MRSA), the most critical isolation precaution is handwashing before and after each patient contact. Some hospital infection control policies for MRSA may add Contact Precautions.

4. Factors known to affect a client's personal hygiene practices are body image; social and cultural habits and practices; personal preferences in regard to time, type of soap, and manner of bath; socioeconomic status; and knowledge. People who take pride in their appearance will usually engage in daily hygienic practices during their illness. Clients will request hygienic practices to be performed in accordance with their cultural beliefs and values. For example, some women may not be permitted to bathe during menstruation. Some cultures forbid a male nurse to bathe a female client. A client's personal preferences will determine the type of soap and shampoo used; the type of bath—full, partial, tub, shower, or bed bath; and the time of day that hygienic practices are desired. Some clients perform hygienic practices before going to bed; others upon wakening. Some clients may not be accustomed to a daily bath because of socioeconomic circumstances. Some clients may use only soap and water for hygienic practices and not use perfumes and deodorants because of their expense. A client's knowledge about his or her illness and ability to practice normal hygiene during this illness will influence his or her hygiene practices in the hospital. In addition, do not assume that clients are knowledgeable about the relationship between normal hygiene and health. Bathing is an excellent time to educate a client on the relationship between hygiene and health.

Chapter 32

1. Hemoglobin saturation (SaO_2) accounts for the vast majority of the total oxygen content of arterial blood.
2. Elevation of the head of the bed or assuming a sitting position may improve breathing efficiency by increasing diaphragmatic excursion and elevating the clavicles. In extreme examples (such as severe COPD), the client may lean forward with the arms resting on a table or ledge.
3. Anaerobic metabolism produces less energy (in the form of adenosine triphosphate, or ATP) than does aerobic metabolism; anaerobic metabolism produces lactic acid, which is cytotoxic, as a by-product.
4. IPPB forces air into the lungs under positive pressure; incentive spirometry relies on spontaneous (negative pressure) deep breathing.
5. Oxygen toxicity, resulting in alveolar collapse (atelectasis) and alveolar damage, results when

high concentrations of oxygen are administered for extended time periods. Clients with COPD may lose their drive to breathe when given excessive supplemental oxygen. Finally, oxygen increases the risk of fire in the immediate area.

6. The upper airway structures (nasal cavities, mucosal surfaces, cilia) serve to warm, humidify, and filter inspired air. When these structures are bypassed, air must be artificially warmed and humidified, and places the client is at increased risk for infection.
7. Heart failure produces increased pressure in the venous circuits—systemic veins and pulmonary veins. This increased pressure is transmitted backward to the venules and capillary beds, where increased hydrostatic (fluid) pressure forces water from the vascular space into the interstitial space.
8. Placing the extremity below heart level utilizes gravity to improve arterial blood flow; placing the extremity above heart level would force blood to flow against gravity, decreasing perfusion and thus increasing pain.

Chapter 33

1. *Somatic pain*: Nonlocalized; originates in support structures such as tendons, ligaments, and nerves. *Cutaneous pain*: Caused by stimulation of the cutaneous nerve endings in the skin; is described as well-localized “burning” or “pricking” sensations. *Visceral pain*: Pain felt in the internal organs; transmission is slower than cutaneous pain messages; poorly localized dull aching or throbbing sensation. *Referred pain*: Pain that originates in one area and is felt in another. For example, the pain associated with a myocardial infarction may be experienced as pain in the jaw. *Ischemic pain*: Occurs when the blood supply of an area is restricted or cut off completely, leading to inadequate oxygenation and inadequate removal of waste products. *Acute pain*: Characterized by a sudden onset and relatively short duration, mild to severe intensity, and a steady decrease in intensity over a period of days to weeks. *Chronic pain*: Pain that is long-term (lasting 6 months or longer), persistent, nearly constant, or recurrent.
2. Nonpharmacologic interventions appropriate for a 50-year-old woman with arthritis: Establishment of rapport, touch, imagery, progressive muscle relaxation, heat application, massage, exercise (unless symptoms are exacerbated), client teaching. For a 9-year-old oncology client: Establishment of rapport; touch; imagery; distraction (e.g., play, video games, music, reading); massage; teaching child and family. For a couple experiencing childbirth: Establishment of rapport; touch; imagery; distraction (e.g., use of a focal point, deep breathing techniques); massage; reframing; client teaching.
3. Perform a complete assessment to determine: (1) type, duration, intensity, and location of pain; (2) any allergies to medications; (3) previous success with medications in pain relief; (4) all medications currently used. Use adjuvant medications to: (1) enhance the analgesic efficacy of opioids; (2) treat concurrent symptoms that exacerbate pain; (3) provide independent analgesia for specific types of pain. Do not abandon the client experiencing severe pain if the present interventions are not effective. Combining analgesics, titrating dosages, using adjuvant medications for neuropathic pain or clients with severe anxiety, and optimal use of nonpharmacologic interventions may be required.
4. *NREM stage 1*: Usually lasts only 10 minutes or so; characterized by a high degree of muscle tension, rapid eye movements, and fast EEG patterns. *NREM stage 2*: Fifty percent of normal adult sleep may be spent in stage 2; characterized by fairly light sleep, with a further slowing of brain wave (EEG) patterns and loss of slow rolling eye movements. *NREM stages 3 and 4*: Most stage 3 to 4 sleep occurs early in the sleep period, with the initial amount in adults being 60 minutes or so. All cortical brain cells appear to be firing at the same time, resulting in large slow waves on the EEG. It is believed that stages 3 and 4 sleep have restorative value, necessary for physical recovery. *REM sleep*: After the initial 90 minutes or so of NREM sleep, adults experience rapid eye movement (REM) sleep. An adult typically has 4 to 6 REM sleep periods through the night, accounting for 20% to 25% of sleep. REM sleep makes up 50% of sleep in the newborn, then gradually declines to 20% to 25% of sleep by early childhood and remains fairly constant throughout the remainder of the life span.
5. *Neonates*: Generally sleep in 3- to 4-hour intervals for a total of about 16 to 20 hours per day; are usually very passive, with little activity during sleep. *Infants*: Average about 12 to 16 hours of sleep per day. As infants age, the amount of sleep decreases. At approximately 2 months of age, many infants begin to sleep throughout the night. *Toddlers*: Daily average amount of sleep is 12 to 14 hours. Bedtime rituals often develop and assume great importance in providing nighttime security. *Elderly*: Sleep requirements usually decrease to 5 to 7 hours per day. Many elderly people misinterpret this decreased need as insomnia.
6. Outcomes of sleep deprivation: “REM rebound,” or increased REM sleep the next night; mild to moderate REM sleep deprivation can cause irritability; if sleep deprivation lasts for an extended period, the person may exhibit psychosis.
7. Nursing interventions that promote comfort, rest, and sleep: therapeutic nurse-client relationship; touch; distraction; reframing; relaxation techniques (e.g., imagery and progressive muscle relaxation); biofeed-

back; cold applications; heat applications; massage; transcutaneous electrical nerve stimulation (TENS); acupuncture/acupressure; exercise; client education; psychotherapy; medication administration.

Chapter 34

1. *Factors that facilitate:* Client's degree of motivation, readiness; instruction on proper use of walker; education about the importance of ambulation. *Factors that hinder:* Pain; anxiety; fear; being connected to tubing and machinery; presence of a splint or cast.
2. *Newborns:* Usually very little activity when sleeping. *Infants:* Rapid increase in motor ability, from raising head and neck, to rolling over, to pushing up, to crawling, to standing, to learning to walk. *Toddlers:* Usually very active, especially as their motor skill abilities increase. *Preschoolers:* Remain physically very active. *School-aged children:* Usually very active in school and play activities (sports). *Adolescents:* Have alternating periods of intense activity and sleep. *Adults:* Many tend to develop sedentary lifestyles with limited physical activity or exercise. *Elderly:* Prone to falls; females at risk for osteoporosis.
3. See answers for number 2.
4. Answers will vary.
5. Answers will vary. Some examples include: back support belts; Hoyer lifts; dress and safety codes that require proper shoes (low heel, rubber treads).

Chapter 35

1. Wounds may occur as a result of trauma or surgery, whereas pressure ulcers can occur whenever the skin is exposed to such factors as prolonged pressure, constant irritation, and immobility. Wound management requires that the nurse understands the physiology of the healing process and provides care that promotes healing and prevents complications such as infection.

Pressure ulcers are caused by compression of underlying blood vessels, which decreases blood flow, oxygen, and nutrients to the compressed area. Prevention is the primary goal of nursing care. The nurse should provide hygiene and skin care, positioning, and the use of support surface therapy.

Clients who have a wound or are at risk for a pressure ulcer require individualized outcomes that reflect the client's health status. Client teaching is an integral part of care.

2. The defensive (inflammatory) phase occurs immediately in response to injury and lasts 3 to 4 days postinjury. It is characterized by vasoconstriction of damaged large blood vessels, aggregation of platelets that forms a plug, and the formation of a fibrin mesh that initially closes the wound, preventing excessive loss of blood and body fluids and

wound contamination. The inflammatory reaction is characterized by vascular and cellular responses: vasoactive substances such as histamine, serotonin, complement, and kinins cause vasodilation that results in an increased blood supply to the injured tissue. During this process, leukocytes are transported to the area for phagocytosis, causing a red, edematous, warm-to-touch exudate area, beginning the cellular response. Phagocytosis is initiated by the neutrophils that die and are replaced by macrophages. Macrophages secrete substances such as FAF and AGF that promote wound healing by stimulating formation of new blood vessels, which ends the first phase of healing.

The second phase, reconstructive (proliferative), starts with the fibroblasts, which synthesize and secrete collagen needed for tissue repair, and angiogenesis, which supplies nutrients and oxygen for healing. Granulation (epithelialization) begins around the wound's edges and serves as a net to catch migrating cells, which differentiate into various cells that form the various layers of the epidermis. The edges of the wound are drawn together by the action of the myofibroblasts that cause contraction of the new tissue and wound closure. This phase takes approximately 2 to 3 weeks. The wounds takes on a red, translucent, granular appearance as scar tissue develops.

Maturation, the last stage of healing, begins around day 21 and can continue up to 2 or more years depending on the depth and size of the wound. The scar tissue is remodeled and continues to gain strength as the capillaries gradually disappear, producing a whitish (avascular) scar.

3. Depending on the extent of tissue loss, healing can occur in three ways: Primary intention healing occurs in noncomplicated wounds with minimal tissue loss, well-approximated edges, and minimal granulation and tissue scarring. Secondary intention healing occurs in wounds with extensive tissue loss, poorly approximated edges that heal through granulation and scarring, placing the client at risk for complications that can further delay healing. Tertiary intention healing results from poor circulation or infection of the wound, which causes a delayed closure. The wound cannot be sutured until the circulation is increased and the infection is resolved.
4. The various types of exudate are characterized by the primary substance contained therein: Serous exudate (composed mainly of serum) results from a mild inflammatory response (minimal capillary permeability and protein loss), which gives a watery appearance such as a blister from a burn. Purulent exudate (composed of leukocytes, liquefied dead tissue debris, and dead and living bacteria) results from a severe inflammatory response that produces pus that varies in color (yellow, green, or brown) as determined by the causative

organism. Hemorrhagic exudate (composed primarily of RBCs) occurs with a severe inflammatory response resulting from the degree of bleeding into the wound that is bright red (fresh blood) or dark red (old blood). Mixed types of exudates, such as serosanguineous, which is clear and tinged with RBCs, contain one or more substances.

5. Wound healing is promoted by providing adequate blood circulation to transport oxygen and nutrients needed by the body. The nurse should recognize those factors that can have a negative outcome on healing, such as the client's age, nutritional status, lifestyle, chronic conditions such as diabetes mellitus, and medications. Client teaching is a critical element of nursing care. Exercise promotes circulation and increases oxygen to tissue, which aids in healing, whereas smoking and obesity decrease oxygenation to tissues. The client should be taught the value of a balanced diet with adequate amounts of protein, carbohydrates, fats, vitamins (A, C, K, pyridoxine, riboflavin, and thiamine), and minerals, especially copper, iron, and zinc.

Healing is also promoted by preventing complications such as hemorrhage, infection, and evisceration. The nurse should monitor the dressing for drainage, inspect the wound for signs of infection, and use sterile technique when caring for the wound and changing the dressing. The client should be taught how to prevent disruption of healing or splitting of the area around the wound by avoiding pressure on the wound's edges or incision line when coughing and the avoidance of straining that may occur when lifting heavy objects.

6. Heat causes vasodilation and increases blood flow to the affected area; cold causes vasoconstriction, which reduces blood flow to the affected area. Heat and cold can be applied in dry or moist forms depending on the type and location of the wound or injury and the presence of drainage or inflammation. Moist heat is used for an open wound to improve circulation, relieve edema, and hasten the suppurative process and healing. Dry heat (e.g., a heating pad) is used in treating muscle sprains to decrease inflammation or edema. Cold packs or compresses are used initially to treat an injury such as a sprained ankle to decrease or prevent bleeding and to reduce swelling.
7. The comatose client is at high risk for developing pressure ulcers. The nurse should assess the skin daily, cleanse the skin with warm water and mild cleansing agents whenever soiling occurs, apply moisturizing lotions to dry skin, turn and reposition the client at least every 2 hours (avoid shearing and friction when repositioning), and use pressure-reducing devices.

Chapter 36

1. Nursing interventions should focus on ensuring client's safety and alleviating risks associated with impaired judgment, which leads to impulsive behavior and inappropriate decisions, and decreased problem-solving ability.
2. Morphine decreases respiratory rate; a client with impaired LOC is already at high risk for respiratory depression.
3. Safety.
4. Safety, self-care.
5. To increase sensory stimulation, use taped voices of family or friends, music (familiar to client), television, touch (applying lotions, different textures to skin), frequent position changes, and familiar visual stimuli (pictures, personal items), and allow rest periods with no stimulation.
6. Goal: To modify the environment to reduce excessive multisensory stimulation, reduce distractions, loud noise, and excessive light; use a calm, unhurried manner; provide a private room; plan the delivery of care to allow for rest periods; address the client by name; provide explanations of all procedures; use soft background music; keep the environment free of strong odors; and limit the number and frequency of visitors.

Chapter 37

1. The three sources of body water replacement are liquids; food products such as meats and vegetables, which contain 65% to 97% water; and the metabolism of foods, which yields water of oxidation.
2. Sodium is the primary determinant of extracellular fluid concentration because of its high concentration and inability to cross the cell membrane easily.
3. Calcium.
4. The serum albumin level.
5. Thirst.
6. It changes the rate of cellular chemical reactions.
7. Sodium imbalance, hypokalemia, hypernatremia, hypomagnesemia, and metabolic alkalosis.
8. c.
9. Laxatives, corticosteroids, and antibiotics.
10. It enhances the action of the drug, causing toxicity.
11. 10 mEq per hour.
12. Tenderness.
13. To establish a venous route as a precautionary measure for clients whose condition may change rapidly or who may require intermittent infusion therapy.
14. a.
15. b.
16. Stop the blood transfusion, infuse the normal saline, and notify the physician.

Chapter 38

1. d.
2. Dietary fiber promotes the formation of a soft, bulky stool that moves quickly through the large intestine; some fiber is believed to bind cholesterol, thus reducing the risk of heart attack.
3. Dietary cholesterol. The blood cholesterol level is related most directly to the risk of developing atherosclerosis.
4. b.
5. b.
6. c.
7. Clients who are receiving continuous gastric feeding should be assessed every 4 hours for tube placement and residual gastric contents.
8. c.
9. Place the client in a high Fowler's position, suction client immediately to prevent aspiration, and assess the amount and rate at which the formula was given.
10. Allows for the infusion of hypertonic solutions without damaging the vein, such as sclerosis, phlebitis, or swelling.

Chapter 39

1. The primary areas in the brain that modulate the detrusor muscle reflex are located in the frontal lobes, the thalamus, hypothalamus, basal ganglia, and cerebellum. The limbic system also influences continence. A micturition center, located near the base of the brain, has two groups of neurons that mark the origin of urination (micturition). In the adult, the micturition center is controlled by multiple centers of the brain. Reticulospinal tracts in the spinal cord transmit messages from the brain and brain stem to the peripheral nerves of the bladder. Bladder filling and urinary storage are accomplished through excitation of the sympathetic nervous system via efferent, sympathetic spinal nuclei at spinal segments T-10 to L-2. Excitation of these neurons relaxes the detrusor muscle and contracts muscular elements of the sphincter mechanism. Urinary evacuation is accomplished through the parasympathetic nervous system. Excitation of neurons located at segments S-2 to S-4 causes voiding by contraction of the detrusor muscle and relaxation of muscular elements of the sphincter mechanism. Two peripheral nerves transmit messages from the central nervous system to the detrusor muscle. The pelvic plexus transmits parasympathetic impulses to smooth muscle of the detrusor. Nervous excitation of the parasympathetic nerves causes release of a neurotransmitter, acetylcholine, which produces contraction of detrusor muscle cells. Other substances influence the detrusor reflex, but all act under the influence of the central nervous system.
2. The pelvic muscles connect the anterior and posterior aspects of the bony pelvis, support the organs of the true pelvis, and contribute to the urethral sphincter mechanism in both women and men. The pelvic muscles contain primarily slow-twitch fibers that are physiologically suited for prolonged periods of tone. Fibers from the pelvic muscles surround the membranous urethra of the male and the proximal two-thirds of the female urethra, and the urethra pierces the muscular diaphragm in both genders.
3. Stress urinary incontinence is associated with urethral hypermobility, with intrinsic sphincter deficiency (damage to the muscular components of the sphincter mechanism), or a combination of these factors.
4. With urge incontinence, the person experiences normal sensations of the lower urinary tract, whereas reflex incontinence is commonly associated with detrusor sphincter dyssynergia. Clients with reflex incontinence are at a greater risk for urinary retention than are those with urge incontinence because reflex incontinence causes a functional obstruction of the bladder outlet and urinary retention.
5. The primary causes of functional incontinence are altered mobility, dexterity, access to the toilet, or changes in mentation such as acute confusion or dementia.
6. The general principle of bladder health is the relationship between fluid intake and urinary output. The Recommended Daily Allowance (RDA) for fluids is 30 ml/kg of body weight, or roughly 1/2 ounce per pound of body weight for the average sized adult; this translates to 1500 to 2000 ml/day.
7. The primary behavioral intervention for the management of stress urinary incontinence is to teach the client pelvic muscle exercises. A strength training program is begun using principles of exercise physiology. Clients are taught to identify, isolate, and contract the pelvic muscles, and to avoid contraction of distant muscle groups such as the thigh or abdominal muscles. Because they frequently have difficulty isolating the pelvic muscles, biofeedback is recommended. The client is taught to perform a single exercise that combines maximal strength and endurance. The client is asked to perform a maximal strength contraction of the muscles surrounding the urethra and vagina or rectum for a count of 10 or approximately 6 seconds, followed by a rest period of equal length. The program begins with a few contractions (typically 10 or fewer), and the number of repetitions is increased to a maximum of 35 to 50. The exercise regimen must be integrated into activities of daily living for maximal effectiveness.
8. The primary behavioral intervention for urge incontinence uses biofeedback to teach the client

to perform either a quick flick maneuver or a sustained contraction in response to an episode of precipitous urgency. The quick flick is a rapid, maximal contraction of the pelvic muscles held for 3 to 4 seconds; a sustained contraction is held for 6 to 10 seconds. The client is instructed to stop, rather than rush to the bathroom, thus decreasing the risk of falling. Several quick flicks or sustained contractions are then performed until the precipitous urge is controlled. At this point, the client is instructed to proceed to the bathroom at a normal pace but without further delays.

9. The following strategies can be used to reduce environmental barriers to toileting: Modify clothing to facilitate ease of removal (e.g., stretch-band pants, one or two buttons or Velcro versus a zipper, or non-skid soles on shoes to increase mobility); the use of a hand-held urinal or bedside commode.
10. The anal sphincter has two basic mechanisms: (1) An internal anal sphincter that is primarily composed of smooth muscle bundles that are connected to the smooth muscle of the rectum. It is primarily innervated by sympathetic nerves that promote smooth muscle contraction and parasympathetic nerves that cause sphincter relaxation. (2) An external sphincter that is composed of striated muscle fibers that are divided into deep and superficial components. The deep portion comprises muscle fibers that encircle the proximal aspect of the anal canal and attach to the symphysis pubis, forming a U shape. The superficial portion of the anal sphincter also encircles the anal canal forming a U shape; however, it attaches to the coccyx and postanal plate rather than to the anterior aspect of the pelvis. The striated component of the external anal sphincter contains both fast- and slow-twitch fibers, allowing sustained tone over a period of time before voluntary defecation.
11. The primary causes of diarrhea are malabsorption disorders, infectious agents, inflammatory bowel disease, short bowel syndrome, side effects of drugs, and laxative or enema misuse. The treatment of diarrhea is to remove the predisposing factors and maintain adequate fluid and electrolyte balance. Foods and beverages that contain malabsorbed substances are removed from the diet. Infectious diarrhea is treated with antimicrobials; anti-inflammatory drugs are used to treat irritative disorders of the bowel. Antidiarrheal agents may be used to reduce intestinal motility and increase absorption of water from the stool; these drugs are contraindicated in clients with infectious diarrhea.
12. The enterostomal nurse should be consulted for clients with denuded skin in the perianal area that requires a rectal pouch.
13. The purpose of regulating dietary fiber and fluid intake is to promote the passage of soft, hydrated stools.
14. Constipation and diarrhea are common alterations in stool consistency that cause changes in fecal elimination patterns and predispose clients to bowel incontinence.
15. Clients with bowel elimination alterations are given referrals when additional care or teaching is deemed necessary.

Glossary

A

Abduction To move a body part away from the midline.

Absorption Process by which the end products of digestion pass through the epithelial membranes in the small and large intestines into the blood or lymph system; passage of a drug from the site of administration into the bloodstream.

Abstract Summary statement of a research article that identifies the purpose, methodology, findings, and conclusions.

Accommodation Component of cognitive development that allows for readjustment of the cognitive structure (mindset) in order to take in new information.

Accountability Process that mandates that individuals are answerable for their actions and have an obligation (or duty) to act.

Accreditation Process by which a voluntary, nongovernmental agency or organization appraises and grants accredited status to institutions and/or programs or services that meet predetermined structure, process, and outcome criteria.

Acculturation Process that consists of learning norms, beliefs, and behavioral expectations of a group through which people of a subculture assume the characteristics of the dominant culture.

Acid A molecule or an ion that can function as a hydrogen ion donor.

Acid-Base Balance Regulation of hydrogen ion concentration.

Acid-Base Buffer System A solution containing two or more chemical compounds that prevents marked changes in the hydrogen ion concentration when either an acid or a base is added to a solution.

Acidosis A condition that occurs when there is an excessive number of hydrogen ions in a solution.

Acquired Immunity Formation of antibodies (memory B cells) to protect against future invasions of an already experienced antigen.

Active Euthanasia Process of taking deliberate action that will hasten the client's death.

Active Listening Listening that focuses on the feelings of the individual who is speaking.

Active-Assistive Range-of-Motion Range-of-motion exercises performed by the client with the assistance of the nurse.

Active Range-of-Motion Range-of-motion exercises performed independently by the client.

Actual Nursing Diagnosis Nursing diagnosis that indicates that a problem exists; composed of the diagnostic label, related factors, and signs and symptoms.

Acupressure The use of finger pressure applied to specific points (energy pathways) on the body to promote healing.

Acupuncture The use of needles inserted at specific points on the body (energy pathways) to promote healing.

Acute Illness Disruption (usually reversible) in functional ability characterized by a rapid onset, intense manifestations, and a relatively short duration.

Acute Pain Discomfort identified by sudden onset and relatively short duration, mild to severe intensity, and a steady decrease in intensity over several days or weeks.

Adaptation Component of cognitive development that refers to the changes that occur as a result of assimilation and accommodation; ongoing process by which an individual adjusts to stressors in order to achieve homeostasis.

Addiction Physiological and/or psychological dependence upon a substance.

Adduction To move a body part toward the midline.

Adjuvant Medication Drugs used to enhance the analgesic efficacy of opioids, treat concurrent symptoms that exacerbate pain, and provide independent analgesia for specific types of pain.

Administrative Law Laws developed by groups who are appointed to governmental administrative agencies and who are entrusted with enforcing the statutory laws passed by the legislature.

Adolescence Developmental stage from the ages of 12 to 20 years that begins with the appearance of the secondary sex characteristics (puberty).

Advance Care Medical Directive Document in which an individual, in consultation with the physician, relatives, or other personal advisers, provides precise instructions for the type of health care the client wants or does not want in a number of scenarios (e.g., end-of-life decisions).

Advance Directive Written instruction for health care that is recognized under state law and is related to the provision of such care when the individual is incapacitated.

Advanced Practice Nursing Practice of nursing at a level requiring an expanded knowledge base and clinical expertise in a specialty area.

Adventitious Breath Sounds Super-imposed sounds on the normal vesicular, bronchovesicular, and bronchial breath sounds.

Adverse Reaction Any drug effect other than what is therapeutically intended.

Aerobic Metabolism Metabolism of nutrients in the presence of oxygen; a metabolic pathway that uses oxygen to convert glucose into cellular energy.

Affect Mood or feeling.

Affective Domain Area of learning that involves attitudes, beliefs, and emotions.

Afferent Nerve Pathway Ascending pathways that transmit sensory impulses to the brain.

Afferent Pain Pathway Ascending spinal cord.

Ageism Imposition of age stereotypes and discrimination.

Agent Entity capable of causing disease.

Agglutination Clumping together of red blood cells.

Agglutinin A specific kind of antibody whose interaction with antigens is manifested as agglutination.

Agglutinogen Any antigenic substance that causes agglutination by the production of agglutinin.

Airborne Transmission Mode of transfer of disease through contact with droplet, nuclei, or dust particles suspended in the air.

Algor Mortis Lack of skin elasticity as a result of death.

Alkalosis Excessive removal of hydrogen ions from a solution.

Allen Test Assessment procedure that measures the collateral circulation to the radial artery.

Allodynia Pain caused by a stimulus that does not normally evoke pain.

Allopathic That which is recognized by a specific culture as being traditional, conventional, or mainstream (e.g. Western medicine).

Alternative Therapies Treatment approaches that are not accepted by mainstream medical practice.

Ambulation Assisted or unassisted walking.

Amniocentesis Withdrawal of amniotic fluid to obtain a sample for specimen examination.

Anabolism Constructive phase of metabolism.

Anaerobic Metabolism Metabolism of nutrients in the absence of oxygen; a metabolic pathway that converts glucose into energy in the absence of oxygen.

Analysis Breaking the whole down into parts that can be examined.

Analyte A substance dissolved in a solution; also called solute.

Anemia Reduction in the amount of hemoglobin in the blood, thus decreasing the oxygen-carrying capacity of the blood.

Anesthesia Absence of pain.

Aneurysm Localized (aortic) abnormal dilation or weakness of a wall of a blood vessel.

Angina Pain in the chest, neck, and/or arm resulting from myocardial ischemia.

Angina Pectoris Pain caused by tissue ischemia in the heart.

Angiocatheter An intracatheter with a metal stylet.

Angiogenesis Formation of new blood vessels.

Angiography Visualization of the vascular structures through the use of fluoroscopy with contrast medium.

Anions Ions with a negative charge.

Anorexia Nervosa Self-imposed starvation that results in a 15 percent or more loss of body weight.

Anthropogenic Descriptor for transmission of microorganisms resulting from changes in the relationship between humans and the environment.

Anthropometric Measurements Measurement of the size, weight, and proportions of the body.

Antibody An immunoglobulin produced by the body in response to bacteria, viruses, or other antigenic substances; counteracts and neutralizes the effects of antigens, and destroys bacteria and other cells. Agglutinin is one type of antibody.

Anticipatory Grief Occurrence of grief work before an expected loss.

Antigens A substance, usually a protein, that causes the formation of an antibody and reacts specifically with that antibody (e.g., agglutininogen).

Anxiety Subjective response that occurs when a person experiences a threat to well-being; it is a diverse feeling of dread or apprehension.

Aphasia Impairment or absence of language function that can result from an injury to the cortex.

Apnea Monitor Machine with chest leads that monitors the movement of the chest.

Appetite Desire for specific foods instead of food in general (hunger); involves a psychological desire or craving.

Aromatherapy Therapeutic use of concentrated essences or essential oils that have been extracted from plants and flowers.

Arousal A component linked closely to the appearance of wakefulness and alertness.

Arterial Blood Gases (ABGs) Measurement of levels of oxygen and carbon dioxide, as well as pH and bicarbonate ion in arterial blood.

Arteriography Radiographic study of the vascular system following the injection of a radiopaque dye through a catheter.

Arthritis An inflammation of the joints that causes pain and swelling.

Arthroplasty Total hip replacement.

Artifact Specific type of nonverbal message that includes items in the client's environment, grooming, or use of clothing and jewelry.

Ascites Accumulation of fluid in the abdomen.

Asepsis Absence of microorganisms.

Aseptic Technique Infection control practice used to prevent the transmission of pathogens.

Aspiration Procedure performed to withdraw fluid that has abnormally collected or to obtain a specimen.

Assault Intentional and unlawful offer to touch a person in an offensive, insulting, or physically intimidating manner.

Assessment First step in the nursing process; includes collection, verification, organization, interpretation, and documentation of data.

Assessment Model Framework that provides a systematic method for organizing data.

Assimilation Component of cognitive development that involves taking in new experiences or information.

Assisted Suicide Situation in which a health care professional provides a client with the means to end his or her own life.

Atelectasis Collapsed alveoli.

Atherosclerosis Disease characterized by narrowing and eventual occlusion of the lumen (opening of the arteries) by deposits of lipids, fibrin, and calcium on the interior walls of the arteries.

Atherosclerotic plaque A thick, hard deposit on the walls of the inner arteries that can clog the arteries in the heart and the brain.

Atrophy Reduction in muscle size and shape, resulting in thin, flabby muscles.

Attending Behaviors A set of nonverbal listening skills that conveys interest in what the other person is saying.

Auditory Channel Transmission of messages through spoken words and by cues.

Auditory Learner Style of learning in which an individual learns by hearing.

Auscultation Physical examination technique that involves listening to sounds in the body that are created by movement of air or fluid.

Auscultatory Gap The temporary disappearance of sounds at the end of Korotkoff phase I and beginning of phase II.

Autocratic Leadership Style Style of leadership in which the leader maintains strong control, makes the decisions, and solves all the problems.

Autoimmune Disorder Condition in which the specific immune defense inappropriately reacts to the host's own tissue.

Autonomy Being self-directed, taking initiative instead of waiting for direction from others; ethical principle that refers to the individual's right to choose for oneself and the ability to act on that choice.

Autopsy Postmortem examination to determine the cause of death.

Autoregulation Redistribution of blood flow to areas of greatest need.

Awareness The capacity to perceive sensory impressions and react appropriately through thoughts and actions.

Ayurveda A healing system based on Hindu philosophy and Indian philosophy, that embraces the concept of an energy force in the body that seeks to maintain balance or harmony.

B

Bacteremia Bacteria in the blood.

Bacteriuria Bacteria in the urine.

Barium Chalky-white contrast medium.

Barium Enema Rectal infusion of barium sulfate used to visualize the colon.

Barium Swallow Fluoroscopic visualization of the esophagus following the ingestion of barium sulfate.

Basal Metabolic Rate (BMR) Energy needed to maintain essential physiological functions when a person is at complete rest both physically and mentally.

Base A molecule or an ion that will combine with hydrogen ions.

Base of Support Foundation on which a person or object rests.

Baseline Values Establish the norm against which subsequent vital sign measurements can be compared.

Basic Human Need Need that must be met for survival.

Battery Touching another person without consent.

Behavior Observable response of an individual to external stimuli.

Benchmarking Process that evaluates products, services, and priorities against the performance of others.

Beneficence Ethical principle regarding the duty to promote good and prevent harm.

Bereavement Period of grieving following the death of a loved one.

Bioavailability Readiness to produce a drug effect.

Bioethics Application of general ethical principles to health care.

Biofeedback Measurement of physiological responses that yields information about the relationship between the mind and body and helps clients learn how to manipulate these responses through mental activity.

Biological Agent Living organism that invades a host, causing disease.

Biological Clock Endogenous mechanism capable of measuring time in a living organism.

Biopsy Excision of a small amount of tissue.

Bisexuality Having an equal or almost equal preference for sexual partners of either gender.

Black Wound Wound containing necrotic tissue.

Blanching White color of the skin when pressure is applied.

Blood Pressure Measurement of pressure pulsations exerted against the blood vessel walls during systole and diastole.

Body Alignment Position of body parts in relation to each other.

Body Image Individual's perception of physical self, including appearance, function, and ability.

Body Mass Index (BMI) Determines whether a person's weight is appropriate for height by dividing the weight in kilograms by the height in meters squared.

Body Mechanics Purposeful and coordinated use of body parts and positions during activity.

Bodymind Inseparable connection and operation of thoughts, feelings, and physiological functions.

Bonding Formation of attachment between parent and child.

Bradycardia A heart rate less than 60 beats per minute in an adult.

Bradypnea Respiratory rate of 10 or fewer breaths per minute.

Bronchial Sounds Loud and high-pitched sounds with a hollow quality heard longer on expiration than inspiration from air moving through the trachea.

Bronchography Radiographic study of the trachea and bronchi following the injection of a contrast agent through a catheter.

Bronchovesicular Sounds Medium-pitched and blowing sounds heard equally on inspiration and expiration from air moving through the large airways, posteriorly between the scapula and anteriorly over bronchioles lateral to the sternum and second intercostal spaces.

Bruits Blowing sounds that are heard when the blood flow becomes turbulent as it rushes past an obstruction.

Bruxism Teeth grinding during sleep.

Buccal Pertaining to the inside cheek.

Bulimia Insatiable appetite.

Bulimia Nervosa An eating disorder characterized by episodic binge eating followed by purging.

Burnout State of physical and emotional exhaustion that occurs when caregivers deplete their adaptive energy; characterized by fatigue, depersonalization, and decreased feelings of personal accomplishment.

Butterfly Needles Winged-tipped needle.

C

Cachexia Weight loss marked by weakness and emaciation that usually occurs with a chronic illness such as tuberculosis or cancer.

Calorie Quantity of heat required to raise the temperature of 1 gram of water 1°C.

Capitated Rate Preset fees based on membership, not services provided; payment system used in managed care.

Carbohydrate Organic compound composed of carbon, hydrogen, and oxygen.

Cardiac Catheterization Radiographic study with the use of a contrast medium injected into a vascular catheter that is threaded into the heart, coronary, and/or pulmonary vessels.

Cardiac Conduction System Specialized cells in the heart that generate and conduct electrical impulses; consists of the sinoatrial node, internodal pathways, atrioventricular node, bundle of His, right and left bundle branches, and Purkinje fibers.

Cardiac Cycle Series of electrical and mechanical events resulting in a cycle of atrial and ventricular contraction and relaxation.

Cardiac Output Measurement of blood pumped by the heart in one minute; measured by multiplying the heart rate by the ventricle's stroke volume.

Cardiopulmonary Resuscitation (CPR) Technique of applying respiration and chest compressions to support oxygenation in the event of cardiac and respiratory arrest.

Case Management Methodology for organizing client care through an episode of illnesses so that specific clinical and financial outcomes are achieved within an allotted time frame.

Catabolism Destructive phase of metabolism.

Categorical Imperative Concept that states that one should act only if the action is based on a principle that is universal.

Catharsis Process of talking out one's feelings; "getting things off the chest" through verbalization.

Cations Ions with a positive charge.

Causation Breach of duty that must be legally proved to have caused an injury.

Cavities Dental caries.

Ceiling Effect Phenomenon in which increasing doses of a medication above a certain level does not result in increased analgesic effect.

Centering Process of bringing oneself to an inward focus of serenity that is done before beginning an energetic touch therapy treatment.

Central Line Venous catheter inserted into the superior vena cava through the subclavian, internal, or external jugular vein.

Certification Process by which a nongovernmental agency or association certifies that an individual licensed to practice a profession has met predetermined standards specified by that profession for specialty practice.

Certified Nurse Midwife Advanced practice nurse who is prepared in nursing and midwifery.

Certified Registered Nurse Anesthetist Advanced practice nurse who is prepared in the science of anesthesiology.

Chakra A concentrated area of energy that influences the physical body, emotions, mental patterns, and spiritual awareness.

Chain of Infection Phenomena of developing an infectious process.

Change Dynamic process in which an individual's response to a stressor leads to an alteration in behavior.

Change Agent Individual who intentionally creates and implements change.

Channel Medium through which a message is transmitted.

Charting by Exception (CBE) Charting method that requires the nurse to document only deviations from preestablished norms.

Chemical Agent Substance that interacts with a host, causing disease.

Chemical Restraints Medications used to control the client's behavior.

Chest Physiotherapy Technique of percussing or vibrating the chest wall in an effort to mobilize pulmonary secretions; usually accompanies postural drainage.

Chiropractic Promotion of healing through manipulation of the spinal column.

Cholangiography Roentgenographic visualization of the integrity of the biliary system by a radiopaque contrast medium.

Cholesterol Lipid that is produced by the body and used in the synthesis of steroid hormones. Cholesterol is excreted in bile.

Cholinesterase Enzyme manufactured in the liver that is responsible for the breakdown of acetylcholine and other choline esters.

Chronemics Study of the effects of time on the communication process.

Chronic Acute Pain Discomfort that occurs almost daily over a long period (months or years) and that has a high probability of ending; also known as progressive pain.

Chronic Illness Disruption in functional ability usually characterized by a gradual, insidious onset with lifelong changes that are usually irreversible.

Chronic Nonmalignant Pain Discomfort that occurs almost daily, has been present for at least 6 months, and ranges in intensity from mild to severe; also known as chronic benign pain.

Chronic Obstructive Pulmonary Disease (COPD) Category of alterations in ventilation including emphysema, asthma, and chronic bronchitis.

Chronic Pain Discomfort that is persistent, nearly constant, and long-lasting (6 months or longer); or recurrent pain that produces significant negative changes in a person's life.

- Chronobiology** Science of studying biorhythms.
- Chronological Age** Exact age of a person from birth.
- Chylomicrons** Lipoproteins synthesized in the intestines that transport triglycerides to the liver.
- Circadian Rhythm** Biorhythm that cycles on a daily basis.
- Civil Law** Law that deals with relations between individuals.
- Clean-Contaminated Wound** Intentional wound created by entry into the alimentary, respiratory, or genitourinary tract under controlled conditions.
- Clean Object** Object on which there are microorganisms that are not usually pathogenic.
- Cleansing** Removal of soil or organic material from instruments and equipment used in providing client care.
- Clean Wound** Intentional wound in which no inflammation was encountered and the respiratory, alimentary, and oropharyngeal tracts were not entered.
- Client Advocate** Person who speaks up or acts on behalf of the client.
- Client Behavior Accidents** Mishaps that occur when the client's behavior or actions precipitate the incident.
- Clinical Nurse Specialist** Advanced practice nurse educated in a recognized nursing specialty area who is authorized to provide direct nursing care to a select population.
- Closed Question** Interviewing technique that consists of questions that can be answered briefly with one-word responses.
- Closed Suction Drainage System** Drain with a reservoir that, when compressed, creates negative pressure, or a vacuum, which draws exudate away from a wound.
- Cluster** Set of data cues in which relationships between and among cues are established to identify a specific health state or condition.
- Cognition** The intellectual ability to think.
- Cognitive Domain** Area of learning that involves intellectual understanding.
- Cognitive Reframing** Stress management technique in which the individual changes his or her own negative perception of a situation or event to a more positive, less threatening perspective.
- Colic** Acute abdominal pain.
- Collaboration** A partnership in which all parties are valued for their contribution.
- Collaborative Problems** Certain physiological complications that nurses monitor to detect onset of changes in status.
- Collagen** Protein responsible for tissue repair.
- Colloid** Nondiffusible substances.
- Colonization** Multiplication of microorganisms on or within a host that does not result in cellular injury.
- Communicable Agent** Infectious agent transmitted to a client by direct or indirect contact, vehicle or vector, or airborne route.
- Communicable Disease** Disease caused by a communicable agent.
- Communication** Dynamic, continuous, and multidimensional process for sharing information as determined by standards or policies.
- Co-morbidity** Existence of simultaneous disease processes within an individual.
- Competency** Ability, qualities, and capacity to function in a particular way.
- Complementary Therapies** Treatment approaches that can be used in conjunction with conventional medical therapies.
- Complicated Grief** Associated with traumatic death such as death by homicide, suicide, or an accident.
- Comprehensive Assessment** Type of assessment that provides baseline client data, including a complete health history and current needs assessment.
- Compromised Host** Person whose normal defense mechanisms are impaired.
- Computed Tomography** Radiological scanning of the body with x-ray beams and radiation detectors that transmit data to a computer that transcribes the data into quantitative measurement and multidimensional images of the internal structures.
- Concept** Vehicle of thought.
- Conceptual Framework** Structure that links global concepts together to form a unified whole.
- Conceptualization** Process of developing and refining abstract ideas.
- Conduction** Loss of heat to an object in contact with the body.
- Conscious Sedation** Minimally depressed level of consciousness during which the client retains the ability to maintain a continuously patent airway and to respond appropriately to physical stimulation or verbal commands.
- Consciousness** State of awareness of self, others, and the surrounding environment.
- Consent** Voluntary act by which a person agrees to allow someone else to do something.
- Constipation** Infrequent and difficult passage of hard stool.
- Constitution** Set of basic laws that defines and limits the powers of government.
- Construct** Abstraction or mental representation inferred from situations, events, or behaviors.

Consultation Method of soliciting help from a specialist in order to resolve diagnoses.

Contact Transmission Mode of transfer of disease through direct contact.

Contaminated Wound Open, traumatic wound or intentional wound with acute nonpurulent inflammation.

Continuous Passive Motion Device (CPM) Device that increases range of motion and stimulates healing of the articular cartilage by decreasing swelling and the formation of adhesions.

Continuous Quality Improvement Approach to quality management in which scientific, data-driven approaches are used to study work processes that lead to long-term system improvements.

Contract Law Enforcement of agreements among private individuals.

Contrast Medium Radiopaque substance that facilitates roentgen imaging of the body's internal structures.

Convalescent Stage Period of time in which acute symptoms of an infection begin to disappear until the client returns to the previous state of health.

Convection Movement of heat away from the body's surface.

Costal (Thoracic) Breathing Occurs when the external intercostal muscles are used to move the chest upward and outward.

Counterstimulation Technique used to achieve relaxation by activating the endogenous opioid and monoamine analgesia systems.

Crackle An audible breath sound heard on inspiration over the base of the lungs. May be either a dry, high-pitched popping of short duration or a moist, low-pitched gurgling of long duration.

Creative Problem Solving Goal-directed thinking that leads to achievement by using a new idea or method.

Crepitus Grating or crackling sensation caused by two rough surfaces rubbing together, as in subcutaneous emphysema.

Criminal Law Acts or offenses against the welfare or safety of the public.

Crisis Acute state of disorganization that occurs when the individual's usual coping mechanisms are no longer effective.

Crisis Intervention Specific technique used to assist clients in regaining equilibrium.

Criteria Standards that are used to evaluate whether the behavior demonstrated indicates accomplishment of the goal

Critical Pathway Abbreviated summary of key elements from the case management plan.

Critical Period Time of the most rapid growth or development in a particular stage of the life cycle in which an individual is most vulnerable to stressors of any type.

Critical Thinking Disciplined, deliberate method of thinking used to search for meaning; employs strategies such as asking questions, evaluating evidence, identifying assumptions, examining alternatives, and seeking to understand various points of view.

Cross-Functional Team Interdepartmental, multidisciplinary group that is assigned to study an organization-wide process.

Crystallized Intelligence The application of life experiences and learned skills to solve problems.

Crystalloid Electrolyte solution with the potential to form crystals.

Cues Small amounts of data that are applied to the decision-making process.

Cullen's Sign Bluish discoloration around the umbilicus in postoperative clients; can indicate intra-abdominal or perineal bleeding.

Cultural Assimilation Process by which individuals from a minority group are absorbed by the dominant culture and take on the characteristics of the dominant culture.

Cultural Competence Process through which the nurse provides care that is appropriate to the client's cultural context.

Cultural Diversity Individual differences among people that result from racial, ethnic, and cultural variables.

Culture Dynamic and integrated structures of knowledge, beliefs, behaviors, ideas, attitudes, values, habits, customs, languages, symbols, rituals, ceremonies, and practices that are unique to a particular group of people; growing microorganisms to identify a pathogen.

Customer Anyone who uses the products, services, or processes provided by an organization.

Cutaneous Pain Discomfort caused by stimulation of the cutaneous nerve endings in the skin.

Cyanosis Blue or gray discoloration of the skin, resulting from reduced oxygen levels in the arterial blood.

Cystocele Bladder hernia that protrudes through the vagina.

Cystography Radiographic study used to visualize the excretory function by instilling an aqueous iodine contrast agent into the bladder through a urinary catheter.

Cytology Study of cells.

Cytomegalovirus (CMV) DNA virus that causes intranuclear and intracytoplasmic changes in infected cells.

D

Data Clustering Process of grouping significant cues together according to a specific assessment model to establish a nursing diagnosis.

Data Interpretation Recognition of patterns in data to determine nursing diagnoses.

Data Verification Process through which data are validated as being complete and accurate.

Deadspace Condition in which lung tissue is well ventilated but poorly perfused.

Deamination Removal of the amino groups from the amino acids.

Decision making The consideration and selection of interventions that facilitate the achievement of a desired outcome.

Declarative Knowledge Specific facts or information and an understanding of the nature of that knowledge.

Defamation Act that occurs when information that damages an individual's reputation is communicated to a third party either in writing (libel) or verbally (slander).

Defecation Evacuation of feces from the rectum.

Defendant Person being sued in a lawsuit.

Defense Mechanisms Unconscious operations that protect the mind from anxiety.

Defining Characteristics Collected data that are also known as signs and symptoms, subjective and objective data, or clinical manifestations.

Deglutition Swallowing of food.

Degrees Units which measure the heat of the body.

Dehiscence Partial or complete separation of the wound edges and the layers below the skin.

Delegation Process of transferring a selected nursing task in a situation to an individual who is competent to perform that task.

Democratic Leadership Style Style of leadership (also called participative leadership) that is based on the belief that every group member should have input into the development of goals and problem solving.

Deontology Ethical theory that considers the intrinsic moral significance of an act itself as the criterion for determination of good.

Dependence Reliance on or need to take a drug.

Dependent Nursing Intervention Nursing action that requires an order from a physician or other health care professional.

Dependent Variable Outcome variable of interest.

Depersonalization Treating an individual as an object rather than as a person.

Dermatome Map Cutaneous area whose sensory receptors and axons feed into a single dorsal root of the spinal cord.

Detrusor Muscle Smooth muscle of the bladder wall.

Development Behavioral changes in functional abilities and skills.

Developmental Tasks Certain goals that must be achieved during each developmental stage of the life cycle.

Diabetes Mellitus A disease in which the pancreas fails to secrete adequate levels of insulin to accommodate blood glucose levels.

Diagnosis Science and art of identifying problems or conditions.

Diaphoresis Profuse perspiration.

Diaphragmatic (Abdominal) Breathing Occurs when the diaphragm contracts and relaxes as observed by the movement of the abdomen.

Diarrhea Passage of liquified stool (increased frequency and consistency of stool sufficient to represent a change in bowel habits).

Diastole Process of cardiac chamber filling.

Dietary Fiber The part of food that body enzymes cannot digest and absorb.

Diffusion Movement of molecules in a solution or a gas from an area of high concentration to one of low concentration.

Diffusion Defect Decrease in efficiency of gas diffusion from the alveolar space into the pulmonary capillary blood.

Digestion Mechanical and chemical processes that convert nutrients into a physically absorbable state.

Digital Subtraction Angiography Computerized imaging of the vasculature with visualization on a monitor screen following the intravenous injection of iodine through a catheter.

Dirty and Infected Wound Traumatic wound with retained dead tissue, or intentional wound created when purulent drainage was present.

Dirty Object Object on which there is a high number of microorganisms, including some that are potentially pathogenic.

Disaccharide Double sugar.

Disseminated Intravascular Coagulation (DIC) An acquired hemorrhagic syndrome characterized by uncontrollable formation and deposition of thrombi.

Dissolution Rate at which a drug becomes a solution.

Discharge Planning Planning that involves critical anticipation and planning for the client's needs after discharge; the client begins to resume self-care activities before leaving the health care environment.

Discipline Field of study.

Disinfectant Chemical solution used to clean inanimate objects.

Disinfection Elimination of pathogens, with the exception of spores, from inanimate objects.

Disorientation A mentally confused state in which the person's awareness of time, place, self, and/or situation is impaired.

Distraction Technique of focusing attention on stimuli other than pain.

Distress Experienced when stressors evoke an ineffective response.

Distribution Movement of drugs from the blood into various body fluids and tissues.

Documentation Written evidence of the interactions between and among health care professionals, clients and their families, and health care organizations; the administration of tests, procedures, treatments, and client education; the result or client's response to these diagnostic tests and interventions.

Dominant Culture Group whose values prevail within a society.

Doppler Hand-held transducer.

Drug Allergy Hypersensitivity to a drug.

Drug Incompatibility Undesired chemical or physical reaction between a drug and a solution, between two drugs, or between a drug and the container or tubing.

Drug Tolerance Reaction that occurs when the body becomes accustomed to a specific drug and requires larger doses of the drug to produce the desired therapeutic effect.

Dullness A high-pitched sound of short duration.

Durable Power of Attorney Document or legal status that enables any competent individual to name someone to exercise health-related decision-making authority, under specific circumstances, on the individual's behalf when the client is incapable of making decisions for self.

Duty Obligation created either by law or contract, or by any voluntary action.

Dysfunctional Grief Failure to progress through the stages of overwhelming emotions associated with grief; or failure to demonstrate any behaviors commonly associated with grief.

Dyspnea Difficulty in breathing as observed by labored or forced respirations through the use of accessory muscles in the chest and neck to breathe.

Dysrhythmia Irregular heartbeat.

Dysuria Painful urination.

E

Echocardiogram Ultrasonic procedure used to reveal abnormal structure or motion of the heart wall and thrombi.

Edema Detectable accumulation of increased interstitial fluid.

Efferent Nerve Pathway Descending pathways that send sensory impulses from the brain.

Efferent Pain Pathway Descending spinal cord.

Effleurage Massage technique consisting of long, smooth strokes used at the beginning and end of treatment and between other movements.

Electrocardiogram Graphic recording of the heart's electrical activity.

Electrochemical Gradient Sum of all the diffusion forces acting on the membrane.

Electroencephalogram Graphic recording of the brain's electrical activity.

Electrolyte Element or compound that, when dissolved in water or another solvent, dissociates (separates) into ions (electrically charged particles) and provides for cellular reactions.

Embryonic Stage Developmental stage that occurs during the first 2–8 weeks after fertilization of a human egg.

Empathy Understanding another person's perception of a situation.

Empowerment Process of enabling others to do for themselves.

Encoding Use of language and other specific signs and symbols for sending messages.

Endorphins Group of opiate-like substances produced naturally by the brain; these substances raise the pain threshold, produce sedation and euphoria, and promote a sense of well-being.

Endoscopy Visualization of a body organ or cavity through a scope.

Energetic Touch Therapies Techniques in which the hands are used to direct or redirect the flow of the body's energy fields to enhance balance within the fields.

Enteral Instillation Administration of drugs through a gastrointestinal tube.

Enteral Nutrition The nonvolitional delivery of nutrients through a gastrointestinal tube.

Enzyme Protein produced in the body that catalyzes chemical reactions in organic matter.

Epithelialization Growth of epithelial tissue.

Equipment Accidents Accidents resulting from the malfunction or improper use of medical equipment.

Equity Process that acts in accordance with the spirit, not the letter, of the law.

Erythema Increased blood flow to an inflamed area.

Erythrocytes Red blood cells.

Essential Amino Acids Amino acids that are required for growth and development and must be obtained from food.

Ethical Dilemma Situation that occurs when there is a conflict between two or more ethical principles.

Ethical Principles Tenets that direct or govern actions.

Ethical Reasoning Process of thinking through what one ought to do in an orderly, systematic manner in order to provide justification of actions based on principles.

Ethics Branch of philosophy concerned with determining right from wrong on the basis of a body of knowledge.

Ethnicity Cultural group's perception of themselves (group identity) and others' perception of them.

Ethnocentrism Assumption of cultural superiority and an inability to accept other cultures' ways of organizing reality.

Etiology Related cause of or contributor to a problem.

Eupnea Easy respirations with a normal breath rate of breaths per minute that are age specific.

Eustress Type of stress that results in positive outcomes.

Euthanasia Intentional action or lack of action causing the merciful death of someone suffering from a terminal illness or incurable condition; derived from the Greek word *euthanatos*, which literally means "good or gentle death."

Evaluation Fifth step in the nursing process; involves determining whether client goals have been met, partially met, or not met.

Evaporation Continuous insensible heat loss from the skin and lungs when water is converted from a liquid to a gas.

Evidenced-Based Practice The application of the best available empirical evidence, including recent research findings to clinical practice in order to aid clinical decision-making.

Evisceration Protrusion of the internal viscera through a disrupted wound.

Exclusive Provider Organization Organization in which care must be delivered by the plan in order for clients to receive reimbursement for health care services.

Excretion Elimination of drugs from the body.

Existentialism Movement that is centered on individual existence in an incomprehensible world and the role that free will plays in it.

Expected Outcome Detailed, specific statement that describes the methods through which a goal will be achieved and includes aspects such as direct nursing care, client teaching, and continuity of care.

Expert Witness Person called by parties in a malpractice suit who is a member of the same profession as the party being sued and who is qualified to testify to the expected behaviors usually employed by members of the profession when in a similar situation.

Expiration (Exhalation) Movement of gases from the lungs to the atmosphere.

Expressed Contract Conditions and terms of a contract given in writing by the concerned parties.

Extension To straighten a joint.

External Respiration See Oxygen Uptake.

Extinction Ability to discriminate the points of distance when two body parts are simultaneously touched.

Extraurethral Incontinence Uncontrolled loss of urine caused when the sphincter mechanism has been bypassed.

Extubation Removal of an endotracheal tube.

Exudate Material and cells discharged from blood vessels.

F

False Imprisonment Situation that occurs when clients are made to wrongfully believe they cannot leave a place.

Fat-Soluble Vitamins Vitamins that require the presence of fats for their absorption from the gastrointestinal tract and for cellular metabolism.

Fatty Acids Basic structural units of most lipids that contain carbon chains and hydrogen.

Fecal Incontinence Involuntary loss of stool of sufficient duration and volume to create a social or hygienic problem.

Feedback Information the sender receives about the receiver's reaction to a message.

Fee-for-Service Health care recipient directly pays the provider for services as they are provided.

Felony Crime of a serious nature usually punishable by imprisonment in a state penitentiary or by death.

Fetal Alcohol Syndrome Condition in which fetal development is impaired by maternal consumption of alcohol.

Fetal Stage Intrauterine developmental period from 8 weeks to birth.

Fidelity Ethical concept that means faithfulness and keeping promises.

Fight-or-Flight Response State in which the body becomes physiologically ready to respond to a stressor by either fighting or running away from the danger (which may be actual or perceived).

Fixation Inadequate mastery or failure to achieve a developmental task that inhibits healthy progression through subsequent stages.

FlashBack Rush of blood back into intravenous tubing when a negative pressure is created on the tubing.

Flatulence Discharge of gas from the rectum.

Flexion To bend a joint.

Flora Vegetation of microorganisms on the human body.

Flow Rate Volume of fluid to infuse over a set period of time.

Fluency Ability to talk in a steady manner.

Fluid Intelligence Ability to acquire new concepts and adapt to unfamiliar situations; mental activities based on organizing information.

Fluoroscopy Immediate, serial images of the body's structure or function.

Focused Assessment Type of assessment that is limited in scope in order to focus on a particular need or health care problem or potential health care risks.

Focus Charting Documentation method using a columnar format to chart data, action, and response.

Formal Contract Written contract that cannot be changed legally by an oral agreement.

Fraud Wrong that results from a deliberate deception intended to produce unlawful gain.

Friction Force of two surfaces moving against one another; massage technique whereby the heels of the hands or the thumb pads are used to apply deep penetrating pressure on knotted muscles.

Full Disclosure Communication of complete information to potential research subjects regarding the nature of the study, the subject's right to refuse participation, and the likely risks and benefits that will be incurred.

Full-Thickness Wound Wound involving the entire epidermis and dermis.

Functional Assessment Assessment of the client's ability to perform activities of daily living.

Functional Incontinence Loss of urine caused by altered mobility or dexterity, access to the toilet, or changes in mentation.

Functional Team Departmental or unit-specific group whose scope is limited to departmental or work area processes.

G

Gait or Transfer Belt Two-inch wide webbed belt worn by the client for the purpose of stabilization during transfers and ambulation.

Gallop Extra heart sounds.

Gate Control Pain Theory Theory that proposes that the cognitive, sensory, emotional, and physiological components of the body can act together to block an individual's perception of pain.

Gender Identity View of one's self as male or female in relationship to others.

General Adaptation Syndrome Physiological response that occurs when a person experiences a stressor.

General Anesthesia Anesthesia that causes the client to lose all sensation and consciousness; used for major surgical procedures.

Germicide Chemical that can be applied to both animate and inanimate objects to kill pathogens.

Germinal Stage Developmental stage that begins with conception and lasts approximately 10 to 14 days.

Gingivitis Inflammation of the gums.

Glasgow Coma Scale (GCS) An international scale used in grading neurologic responses to determine the client's level of consciousness.

Gluconeogenesis Conversion of amino acids into glucose or glycogen.

Glycolysis Breakdown of glucose by enzymes located inside the cell's cytoplasm.

Goal Aim, intent, or end.

Goniometer A protractor with two movable arms used to measure the angles of skeletal joint during range of motion.

Good Samaritan Acts Laws that provide protection to health care providers by assuring immunity from civil liability when the caregiver provides assistance at the scene of an emergency and does not intentionally or recklessly cause the client injury.

Grand Theory Theory composed of concepts representing global and complex phenomena.

Graphesthesia Ability to identify numbers, letters, or shapes when drawn on the skin.

Grief Series of intense physical and psychological responses that occur following a loss.

Grief Work Phrase coined from Lindemann, it describes the process experienced by the bereaved. It consists of: freedom from attachment to the deceased, becoming reoriented to the environment in which the deceased is no longer present, and establishing new relationships.

Group Communication A complex level of communication that occurs when three or more people meet in face-to-face encounters or through another communication medium, such as a conference call.

Group Dynamics Study of the events that take place during small-group interaction and the development of subgroups.

Groupthink Going along with the majority opinion while personally having another viewpoint.

Growth Quantitative (measurable) changes in the physical size of the body and its parts.

Guided Imagery A process in which the person uses all the senses to experience the sensation of relaxation.

H

Half-Life Time it takes the body to eliminate half of the blood concentration level of the original drug dose.

Halitosis Bad breath.

Hallucination A sensory perception that occurs in the absence of external stimuli and is not based on reality.

Handwashing Rubbing together of all surfaces and crevices of the hands using a soap or chemical and water.

Healing Process of recovery from illness, accident, or disability.

Healing Touch Energy-based therapeutic modality that alters the energy fields through the use of touch, thereby affecting physical, mental, emotional, and spiritual health.

Health Process through which the person seeks to maintain an equilibrium that promotes stability and comfort; includes physiological, psychological, sociocultural, intellectual, and spiritual well-being.

Health Care Delivery System Mechanism for providing services that meet the health-related needs of individuals.

Health History Review of the client's functional health patterns prior to the current contact with a health care agency.

Health Maintenance Organization Prepaid health plan that provides primary health care services for a preset fee and focuses on cost-effective treatment methods.

Health-Promoting Behaviors Actions that increase well-being or quality of life.

Health Promotion Process undertaken to increase levels of wellness in individuals, families, and communities.

Health-Seeking Behaviors Activities that are directed toward attaining and maintaining a state of well-being.

Heart Failure Inability of the heart to pump enough blood to meet the metabolic needs of the body; often accompanied by a backup of blood in the venous circuits (congestive heart failure).

Heaves Lifting of the cardiac area secondary to an increased workload and force of left ventricular contraction.

Heimlich Maneuver Application of sharp, upward thrusts to the abdomen in order to remove an airway obstruction.

Hematoma Localized collection of blood underneath the tissue.

Hematuria Blood in the urine; *microscopic hematuria* is the presence of blood noted on microscopic examination of the urine; *gross hematuria* is the presence of blood visible to the naked eye.

Hemoconcentration Reduced volume of plasma water and the increased concentration of blood cells, plasma proteins, and protein-bound constituents; occurs with increased capillary hydrostatic pressure, which causes water to shift from the intravascular into the interstitial space.

Hemodynamic Regulation Physiological function of blood circulating to maintain an appropriate environment in tissue fluids.

Hemoglobin Electrophoresis A laboratory test that uses an electromagnetic field to identify various types of hemolytic anemia.

Hemolysis A breakdown of red cells and the release of hemoglobin.

Hemorrhage Persistent bleeding.

Hemorrhagic Exudate Discharge with a large component of red blood cells; present with severe inflammation.

Hemorrhoids Perianal varicosity of the hemorrhoidal veins.

Hemostasis Cessation of bleeding.

Heterosexuality Sexual activity between a man and a woman.

High-Biological-Value Proteins (Complete Proteins) Proteins that contain all of the essential amino acids.

High-Level Wellness State in which individuals function at their maximum health potential while remaining in balance with the environment.

History Study of the past, including events, situations, and individuals.

Homeostasis Equilibrium (balance) between physiological, psychological, sociocultural, intellectual, and spiritual needs.

Homosexuality Sexual activity between two members of the same sex.

Hospice Type of care for the terminally ill founded on the concept of allowing individuals to die with dignity and surrounded by those who love them.

Host Simple or complex organism that can be affected by an agent.

Humoral Immunity Stimulation of B cells and antibody production.

Hydrostatic Pressure Pressure that a liquid exerts on the sides of the container that holds it; also called filtration force.

Hygiene Science of health.

Hyperalgesia Extreme sensitivity to pain.

Hypercalcemia Excess in the extracellular level of calcium.

Hypercapnia Elevation of carbon dioxide levels in the blood indicating inadequate alveolar ventilation.

Hyperchloremia Excess in the extracellular level of chloride.

Hyperglycemia Condition characterized by a blood glucose level greater than 110 mg/dl.

Hyperkalemia Excess in the extracellular level of potassium.

Hypermagnesemia Excess in the extracellular level of magnesium.

Hypernatremia Excess in the extracellular level of sodium.

Hyperphosphatemia Excess in the extracellular level of phosphorus.

Hypersomnia Alteration in sleep pattern characterized by excessive sleep, especially in the daytime.

Hypertension Refers to a persistent systolic pressure greater than 135 to 140 mm Hg and a diastolic pressure greater than 90 mm Hg.

Hyperthyroidism Increased secretion of thyroid hormones, which increases the rate of metabolism.

Hypertonic Solution with more solutes in proportion to the volume of body water; also called a hyperosmolar solution.

Hypertonicity Increased muscle tone.

Hypertrophy Refers to an increase in muscle size and shape due to an increase in muscle fiber.

Hyperventilation Characterized by deep, rapid ventilations.

Hypervolemia Increased circulating fluid volume.

Hypnosis State of heightened awareness and focused concentration.

Hypocalcemia Deficit in the extracellular level of calcium.

Hypochloremia Deficit in the extracellular level of chloride.

Hypoglycemia Condition characterized by a blood glucose level less than 80 mg/dl.

Hypokalemia Deficit in the extracellular level of potassium.

Hypomagnesemia Deficit in the extracellular level of magnesium.

Hypонатremia Deficit in the extracellular level of sodium.

Hypophosphatemia Deficit in the extracellular level of phosphorus.

Hypotension A systolic blood pressure less than 90 mm Hg or 20 to 30 mm Hg below the client's normal blood pressure.

Hypothesis Statement of an asserted relationship between dependent variables.

Hypothyroidism Decreased secretion of thyroid hormones, which decreases the metabolic rate.

Hypotonic Solution with less solute in proportion to the volume of water; also called a hypo-osmolar solution.

Hypotonicity A flabby muscle with poor tone.

Hypoventilation Characterized by shallow respirations.

Hypoxemia Decreased oxygen level in the blood.

Hypoxia Oxygen deprivation of the body's cells.

I

Identity What sets one person apart as a unique individual. It may include a person's name, gender, ethnic identity, family status, occupation, and various roles.

Idiosyncratic Reaction Reaction of overresponse, underresponse, or an atypical response.

Illness Inability of an individual's adaptive responses to maintain physical and emotional balance that subsequently results in an impairment in functional abilities.

Illness Stage Time interval when client is presenting or manifesting specific signs and symptoms of an infectious agent.

Illusion An inaccurate perception or misinterpretation of sensory stimuli.

Imagery Relaxation technique in which the individual uses the imagination to visualize a pleasant, soothing image.

Immediate Memory The retention of information for a specified and usually short period of time.

Impaction Hard bolus of stool that obstructs the fecal stream.

Impaired Nurse Nurse who is habitually intemperate or is addicted to the use of alcohol or habit-forming drugs.

Implantable Port Device with a radiopaque silicone catheter and a plastic or stainless steel injection port with a self-sealing silicone-rubber septum.

Implementation Fourth step in the nursing process; involves the execution of the nursing plan of care formulated during the planning phase of the nursing process.

Implied Contract Contract that recognizes a relationship between parties for services.

Incentive Spirometers Breathing devices that measure the client's ventilatory volumes.

Incidence Refers to the prevalence of a disease in a population or community. The predictive value of the same test can be different when applied to people of differing ages, genders and geographic locations.

Incident Report Documentation of an unusual occurrence or an accident in delivery of client care.

Incontinence Loss of the ability to initiate, control, or inhibit elimination.

Incubation Period Time interval between the entry of an infectious agent in the host and the onset of symptoms.

Independent Nursing Intervention Nursing action initiated by the nurse that does not require direction or an order from another health care professional.

Independent Variable Variable that is believed to cause or influence the dependent variable.

Infancy Developmental stage from the first month to the first year of life.

Infarction Death (necrosis) of an area of tissue caused by oxygen deprivation.

Infection Actual invasion and multiplication of microorganisms in body tissue with cellular injury.

Infectious Agent Microorganism that causes infections.

Infiltration Seepage of foreign substances into the interstitial tissue.

Inflammation Nonspecific cellular response to tissue injury or infection; involves increased blood flow in the affected area.

Informed Consent Client understands the reason for the proposed intervention, its benefits and risks, and agrees to the treatment by signing a consent form.

Initial Planning Planning that involves development of an initial plan of care by the nurse who performs the admission assessment and gathers the comprehensive admission assessment data.

Injury Physical, financial, or emotional harm.

Insensible Heat Loss Heat that is lost through the continuous, unnoticed water loss that occurs with vaporation.

Insomnia Chronic inability to sleep, or inadequate quality of sleep.

Inspection Physical examination technique that involves careful visual observation.

Inspiration (Inhalation) Intake of air into the lungs.

Instability Incontinence Loss of urine caused by a premature or hyperactive contraction of the detrusor.

Insulin Pancreatic hormone that aids in the diffusion of glucose into the liver and muscle cells and the synthesis of glycogen.

Integrative therapy A clinical approach that combines Western technological medicine with techniques from Eastern medicine.

Integumentary System (Skin, hair, scalp, and nails) provides the body with external protection, regulates temperature, and is a sensory organ for pain, temperature, and touch.

Intentional Wound Wound acquired during treatment (such as surgery) or therapy (such as venipuncture).

Interdependent Nursing Intervention Nursing action that is implemented in a collaborative manner with other health care professionals.

Intermittent Claudication Ischemia to the extremities usually brought on by activity and relieved by rest.

Internal Respiration Process of gas exchange between capillary blood and the body's cells, in which the cells receive oxygen and carbon dioxide is removed.

Interpersonal Communication Process that occurs between two people in face-to-face encounters, over the telephone, or through other communication media.

Interview Therapeutic interaction that has a specific purpose.

Intracath Plastic tube for insertion into a vein.

Intradermal (ID) Injection into the dermis.

Intramuscular (IM) Injection into the muscle.

Intraoperative (during surgery) Phase that begins when the client is transferred to the operating room and ends when the client is transferred to a postanesthesia care unit.

Intrapersonal Communication Messages one sends to oneself, including "self-talk," or communication with oneself.

Intrapsychic Theory Theory that focuses on an individual's unconscious processes. Feelings, needs, conflicts, and drives are considered to be motivators of behavior.

Intravenous Pyelogram A series of x-rays of the kidneys, ureters, and bladder following the administration of an intravenous iodine preparation.

Intravenous (IV) Injection into a vein.

Intravenous (IV) Therapy Administration of nutrients, fluids, electrolytes, or medications by the venous route.

Intubation Insertion of an endotracheal tube into the bronchus through the nose or mouth to ensure an airway.

Invasive Accessing the body tissues, organs, or cavities through some type of instrumentation procedure.

Ischemia Oxygen deprivation, usually caused by poor perfusion, that is usually temporary and localized.

Ischemic Pain Discomfort resulting when the blood supply of an area is restricted or obstructed.

Isotonic Solution with body water and solutes (sodium) in equal amounts; also called an isosmolar solution.

J

Judgment The ability to compare or evaluate alternatives to life situations and arrive at an appropriate course of action.

Jurisprudence Body of judge-made law.

Justice Ethical principle based on the concept of fairness that is extended to each individual.

K

Kardex Summary worksheet reference of basic client care information.

Ketogenesis Conversion of amino acids into keto acids or fatty acids.

Ketones Products of incomplete fat metabolism.

Ketonuria Abnormally high concentration of ketones in the urine.

Kilocalorie Equivalent to 1,000 calories.

Kinesthetic Channel Transmission of messages through sensation of touch.

Kinesthetic Learner Learning style in which a person processes information by experiencing the information or by touching and feeling.

L

Laissez-Faire Leadership Style Style of leadership in which the leader assumes a passive, nondirective, and inactive style.

Lancinating Type of pain that is typically described as piercing or stabbing.

Late Potentials Electrical activity that occurs after normal depolarization of the ventricles.

Law That which is laid down or fixed.

Leadership Interpersonal process that involves motivating and guiding others to achieve goals.

Learning Process of assimilating information with a resultant change in behavior.

Learning Plateau Peak in effectiveness of teaching and depth of learning.

Learning Style Way in which an individual incorporates new information.

Legal Regulation Process by which the state attests to the public that the individual licensed to practice is competent to do so.

Lentigo Senilis Benign brown pigmented areas on the face, hands, and arms of older people.

Leukocytes White blood cells.

Liability Obligation one has incurred or might incur through any act or failure to act.

Licensure Method by which a state holds the nurse accountable for safe practice to citizens of that state.

Licensure by Endorsement Process by which an individual who is duly licensed as a registered nurse under the laws of one state or country has his or her credentials accepted and approved by another state or country.

Licensure by Examination Process by which an individual who has completed an approved program of studies leading to registered nurse licensure seeks initial licensure by successfully passing a standardized competency examination.

Line of Gravity Vertical line passing through the center of gravity.

Lipids Organic compounds that are insoluble in water but soluble in organic solvents such as ether and alcohol; also known as fats.

Lipoproteins Blood lipids bound to protein.

Liver Mortis Bluish purple discoloration that is a by-product of red blood cell destruction.

Living Will Document prepared by a competent adult that provides direction regarding medical care should the person become incapacitated or otherwise unable to make decisions personally.

Local Adaptation Syndrome Physiological response to a stressor (e.g., trauma, illness) affecting a specific part of the body.

Local Anesthesia Anesthesia that causes the client to lose sensation to a localized body part (e.g., spraying the back of the throat with lidocaine decreases the gag reflex).

Localized Infection Infection limited to a defined area or single organ.

Lock-Out Interval Minimum time allowed between doses for the client to self-medicate; feature found in infusion pumps used for patient-controlled analgesia.

Locus of Control A person's perception of the source of control over events and situations affecting the person's life.

Logrolling A technique for moving a client whose body must remain in straight alignment.

Long-Term Goal Statement written in objective format demonstrating an expectation to be achieved in resolution of the nursing diagnosis over a long period of time, usually over weeks or months.

Loss Any situation in which a valued object is changed or is no longer accessible to an individual.

Low-Biological-Value Proteins (Incomplete Proteins) Proteins lacking in one or more of the essential amino acids.

Lumbar Puncture Aspiration of cerebrospinal fluid from the subarachnoid space.

Lymphangiography Radiographic study of the lymphatic system following a catheter injection of an oil-based dye.

Lymphokine Mediator substance released by lymphocytes.

M

Magnetic Resonance Imaging An imaging technique that uses radiowaves and a strong magnetic field to make continuous cross-sectional images of the body.

Maladaptation Process of ineffective coping with stressors.

Malignant Hyperthermia (MH) A potentially lethal syndrome caused by a hypermetabolic state that is precipitated by the administration of certain anesthetic agents.

Malnutrition Nutritional alterations related to inadequate intake, disorders of digestion or absorption, or overeating.

Malpractice Professional person's wrongful conduct, improper discharge of professional duties, or failure to meet the standards of acceptable care that results in harm to another person.

Mammography A low-dose radiographic study of the breast tissue.

Managed Care System of providing and monitoring care in which access, cost, and quality are controlled before or during delivery of services. These networks "manage" or control costs in many ways (for example, by limiting referrals to costly specialists). HMOs are a common form of managed care.

Management Accomplishment of tasks either by oneself or by directing others.

Mandatory Licensure Laws Legislation that prohibits any individual from practicing as a registered nurse without a current license.

Mastication Chewing into fine particles and then mixing the food with enzymes in saliva.

Material Principles of Justice Rationale for determining when there can be unequal allocation of scarce resources.

Maturation Process of becoming fully grown and developed; involves physiological and behavioral aspects.

Maturation Loss Adolescent that loses the younger child's freedom from responsibility.

Medical Asepsis Practices that reduce the number, growth, and spread of microorganisms.

Medical Diagnosis Clinical judgment by the physician that identifies or determines a specific disease, condition, or pathological state.

Medical Model Traditional approach to health care in which the focus is on treatment and cure of disease.

Meditation Quieting the mind by focusing one's attention.

Menarche Onset of the first menstrual period.

Message Stimulus produced by a sender and responded to by a receiver.

Metabolic Rate Rate of heat liberated during chemical reactions.

Metabolism Aggregate of all chemical reactions in every body cell.

Metacommunication Relationship aspect of communication, which refers to the message about the message.

Metaparadigm Unifying force in a discipline that names the phenomena of concern to that discipline.

Micro-Range Theory Theory that explains a specific phenomenon of concern to a discipline.

Middle Adulthood Developmental stage from the ages of 40 to 65 years.

Middle-Range Theory Theory that addresses more concrete and more narrowly defined phenomena than a grand theory but does not cover the full range of phenomena of concern to a discipline.

Mid-Upper-Arm Circumference Measures skeletal muscle mass and serves as an indicator of protein reserve.

Minerals Inorganic elements.

Minority Group Group of people who constitute less than a numerical majority of the population and who, because of their cultural or physical characteristics, are labeled and treated differently from others in the society.

Misdemeanor Offense less serious than a felony that may be punished by a fine or sentence to a local prison for less than one year.

Mixed Agonist-Antagonist Compound that blocks opioid effects on one receptor type while producing opioid effects on a second receptor type.

Mobility Ability to engage in activity and free movement.

Mode of Transmission Process that bridges the gap between the portal of exit of the biological agent from the reservoir and the portal of entry of the susceptible “new” host.

Monosaccharides Simple sugars.

Monounsaturated Fatty Acids Fatty acids with one double or triple bond.

Morality Behavior in accordance with custom or tradition that usually reflects personal or religious beliefs.

Moral Maturity Ability to decide for oneself what is “right.”

Mourning Period of time during which the grief is expressed and resolution and integration of the loss occur.

Moxibustion Type of acupuncture that involves the application of heat from certain burning substances, such as herbs, at acupuncture points on the body.

Murmur Swishing or blowing sounds of long duration heard during the systolic and diastolic phases, created by turbulent blood flow through a valve.

Muscle Tone Normal state of balanced tension present in the body that allows muscles to respond quickly to stimuli.

Music-Thanatology Holistic and palliative method for use of music with dying clients; solely concerned with dissipating any obstacle to a peaceful passage.

Myelography Study of the spinal cord and its surrounding subarachnoid spaces through the use of radiography and pantopaque, a contrast agent.

Myocardial Infarction Necrosis of the heart muscle.

Myoneuronal Junction Point at which nerve endings come in contact with muscle cells.

Myofascial Pain Syndromes Group of muscle disorders characterized by pain, muscle spasm, tenderness, stiffness, and limited motion.

N

Narcolepsy Sleep alteration characterized by sudden uncontrollable urges to fall asleep.

Narrative Charting A story format of documentation that describes the client’s status, interventions and treatments, and the response to treatments.

Necrosis Tissue death as the result of disease or injury.

Need Anything that is absolutely essential for existence.

Negative Nitrogen Balance Condition that exists when nitrogen output exceeds intake, protein catabolism exceeds anabolism.

Negligence Failure of an individual to provide the care in a situation that a reasonable person would ordinarily provide in a similar circumstance.

Neonatal Period First 28 days of life following birth.

Networking Process of building connections with others.

Neuralgia Paroxysmal pain that extends along the course of one or more nerves.

Neuropathic Pain Discomfort from damage to portions of the peripheral or central nervous system.

Neuropeptides Amino acids produced in the brain and other sites in the body that act as chemical communicators.

Neurotransmitters Chemical substances produced by the body that facilitate nerve impulse transmission.

Nitrogen Balance Net result of intake and loss of nitrogen that measures protein anabolism and catabolism.

Nociception Process by which an individual becomes aware of pain.

Nociceptor Receptive neuron for painful sensations.

Nocturia Awakening from sleep to urinate.

Nonessential Amino Acids Amino acids that can be synthesized in the adult body.

Noninvasive Body is *not* entered with any type of instrument.

Nonmaleficence Ethical principle that means the duty to cause no harm to others.

Nonverbal Message Message communicated without words.

Nosocomial Infection Infection acquired in the hospital that was not present or incubating at the time of the client’s admission.

Nurse-Client Relationship One-to-one interactive process between client and nurse that is directed at improving the client’s health status or assisting in problem solving.

Nurse Practice Act Law determined by each state governing the practice of nursing.

Nurse Practitioner Advanced practice nurse educated in a specified area of care who is authorized to provide primary care to individuals, families, and other groups in a variety of settings.

Nursing An art and a science that assists individuals to learn to care for themselves whenever possible; it also involves caring for others when they are unable to meet their own needs.

Nursing Audit Process of collecting and analyzing data to evaluate the effectiveness of nursing interventions.

Nursing Diagnosis Second step in the nursing process; a clinical judgment about individual, family, or community (aggregate) responses to actual, possible, or risk (potential) health problems, wellness states, or syndromes.

Nursing Intervention Action performed by a nurse that helps the client achieve the results specified by the goals and expected outcomes.

Nursing Intervention Classification (NIC) Standardized language for nursing interventions.

Nursing Minimum Data Set (NMDS) Elements contained in clinical records and abstracted for studies on the effectiveness and costs of nursing care.

Nursing Order Statement written by the nurse that is within the scope of nursing practice to plan and initiate.

Nursing Process Systematic method of providing care to clients; consists of five steps: assessment, diagnosis, outcome identification and planning, implementation, and evaluation.

Nursing Research Systematic application of formalized methods for generating valid and dependable information about the phenomena of concern to the discipline of nursing.

Nutraceuticals Natural substances found in plant or animal foods that act as protective or healing agents.

Nutrition Process by which the body metabolizes and utilizes nutrients.

Nystagmus Involuntary, rhythmical oscillation of the eyes.

O

Obesity Weight that is 20 percent or more above the ideal body weight.

Objective Data Observable and measurable data that are obtained through both standard assessment techniques performed during the physical examination and laboratory and diagnostic tests.

Obligatory Loss of Proteins Degradation of the body's own proteins into amino acids in response to inadequate protein intake.

Observation Skill of watching carefully and attentively.

Obstructive Pulmonary Disease Category of lung diseases characterized by obstruction of the airways and trapping of air distal to the obstruction.

Occult Blood in the stool that can be detected only through a microscope or by chemical means.

Older Adulthood Developmental stage occurring from the age of 65 and beyond.

Oliguria Diminished production of urine (typically less than 400 ml/24 hours).

Ongoing Assessment Type of assessment that includes systematic monitoring and observation related to specific problems.

Ongoing Planning Planning that entails continuous updating of the client's plan of care.

Onset of Action Time it takes the body to respond to a drug after administration.

Open-Ended Questions Interview technique that encourages the client to elaborate about a particular concern or problem.

Operative Knowledge An understanding of the nature of knowledge (knowing the "how" or "why").

Opposition One body part being across from another part at nearly 180°.

Oppression Condition in which the rules, modes, and ideals of one group are imposed on another group.

Oral Cholecystography Visualization of the gallbladder and presence of stones through the administration of radiopaque iodine tablets.

Organization Means by which members of a profession join together to promote and protect the profession as a valuable service to society.

Organizational Culture Commonly held beliefs, values, norms, and expectations that drive the work force.

Orientation Perception of self in relation to the surrounding environment.

Orientation Phase First stage of the therapeutic relationship in which the nurse and client become acquainted, establish trust, and determine the expectations of each other.

Orthostatic Hypotension (Postural Hypotension) Refers to a sudden drop in 25 mm Hg in systolic pressure and 10 mm Hg in diastolic pressure when the client moves from a lying to a sitting or a sitting to a standing position.

Osmolality Measurement of the total concentration of dissolved particles (solutes) per kilogram of water.

Osmolarity Concentration of solutes per liter of cellular fluid.

Osmole Unit of measure of osmotic pressure.

Osmosis Process caused by a concentration difference of water.

Osmotic Pressure Force that develops when two solutions of different strengths are separated by a selectively permeable membrane.

Osteoarthritis The most common type of degenerative arthritis in which the joints become stiff and tender to touch.

Osteoporosis Process in which reabsorption exceeds accretion of bone.

Outcome Evaluation Process of comparing the client's current status with the expected outcomes.

Oximeter Machine that measures the oxygen saturation of the blood through a probe clipped to the fingernail or earlobe.

Oxygen Uptake Process of oxygen diffusing from the alveolar space into the pulmonary capillary blood; also called external respiration.

Oxyhemoglobin Dissociation Curve Graphic representation of the relationship between partial pressure of oxygen and oxygen saturation.

P

Pain State in which an individual experiences and reports the presence of physical discomfort; may range in intensity from uncomfortable sensation to severe discomfort.

Pain Threshold Level of intensity at which pain becomes appreciable or perceptible.

Pain Tolerance Level of intensity or duration of pain that a person is willing to endure.

Palliative Care Control of the symptoms rather than cure.

Palpation Physical examination technique that uses the sense of touch to assess texture, temperature, moisture, organ location and size, vibrations and pulsations, swelling, masses, and tenderness.

Papanicolaou Test Smear method of examining stained exfoliative cells.

Paracentesis Aspiration of fluid from the abdominal cavity.

Paradigm Pattern, model, or mindset that strongly influences one's decisions and behaviors.

Paradigm Revolution Turmoil experienced by a discipline when a competing paradigm gains acceptance over the dominant, prevailing paradigm.

Paradigm Shift Acceptance of a competing paradigm over the prevailing paradigm.

Parasomnia Sleep alteration resulting from activation of physiological systems at inappropriate times during the sleep-wake cycle.

Paraverbal communication The way in which a person speaks, including voice tone, pitch, and inflection.

Paraverbal cues Verbal messages accompanied by cues, such as tone and pitch of voice, speed, inflection, volume, and other non-language vocalizations.

Parenteral Nutrition Nutrients bypass the small intestine and enter the blood directly.

Paresthesia Abnormal sensation such as burning, prickling, or tingling.

Paroxysmal Nocturnal Dyspnea Episode of sudden shortness of breath occurring during sleep.

Partial Thickness Wound Wound involving the epidermis and part of the dermis.

Passive Euthanasia Process of cooperating with the client's dying process.

Passive Range-of-Motion Range of motion exercises performed by the nurse for the dependent client.

Patency Openness of tube lock or bodily passageway.

Paternalism Practice by which health care providers decide what is "best" for clients and then attempt to coerce clients to act against their own choices.

Pathogen Microorganism that causes disease.

Pathogenicity Ability of a microorganism to cause disease.

Patient-Controlled Analgesia Device that allows the client to control the delivery of intravenous or subcutaneous pain medication in a safe, effective manner through a programmable pump.

Patient-Focused Care Specific approach to care delivery that involves the decentralization of services, physical redesign of units, and cross-training of employees to bring client care and services to the client in order to minimize contacts with large numbers of staff and to increase overall client satisfaction.

Peak Plasma Level Achievement of the highest blood concentration of a single drug dose until the elimination rate equals the rate of absorption.

Peer Evaluation Process by which professionals provide critical performance appraisal and feedback that is geared toward corrective action.

Penrose Drain Flexible drain that functions by gravity.

Perception Person's sense and understanding of the world.

Percussion Physical examination technique that uses short, tapping strokes on the surface of the skin to create vibrations of underlying organs.

Performance Improvement Activities and behaviors that each individual does to meet customers' expectations.

Perineal Care Cleansing of the external genitalia, perineum, and surrounding area.

Perioperative Refers to the management and treatment of the surgical client during the three phases of surgery: preoperative, intraoperative, and postoperative.

Peristalsis Coordinated, rhythmic, serial contraction of the smooth muscles of the gastrointestinal tract.

Permeability Capability of a substance, molecule, or ion to diffuse through a membrane.

Petrissage Massage technique using squeezing, kneading, and rolling movements to release muscle tension and stimulate circulation.

Phagocytosis Process by which certain cells engulf and dispose of foreign bodies.

Phantom Limb Pain Neuropathic pain in which pain sensations are referred to an area from which an extremity has been amputated.

Pharmacokinetics Study of the absorption, distribution, metabolism, and excretion of drugs.

Phenomenon Observable fact or event that can be perceived through the senses and is susceptible to description and explanation.

Phenylketonuria Genetic disorder that can lead to impaired intellectual functioning if untreated.

Philosophy Statement of beliefs that is the foundation for one's thoughts and actions.

Phlebitis Inflammation of a vein.

Phlebotomist Individual who performs venipuncture.

Phospholipids Composed of one or more fatty acid molecules and one phosphoric acid radical, and usually contain a nitrogenous base.

Physical Agent Factor in the environment capable of causing disease in a host.

Physical Dependence Reaction of the body to abrupt discontinuation of a medication; also known as withdrawal syndrome.

Physical Restraints Manual methods or physical equipment attached to the client to reduce the client's movement.

Phytonutrients Chemical found in plants.

PIE Charting Documentation method using problem, intervention, evaluation (PIE) format.

Piggybacked Addition of an intravenous solution to infuse concurrently with another infusion.

Piloerection Hairs standing on end as a result of the body's decrease in body temperature.

Plaintiff Party who initiates a lawsuit that seeks damages or other relief.

Plan of Care Written guide that organizes data about a client's care into a formal statement of the strategies that will be implemented to help the client achieve optimal health.

Planning Third step of the nursing process; includes the formulation of guidelines that establish the proposed course of nursing action in the resolution of nursing diagnoses and the development of the client's plan of care.

Plateau Level at which a drug's blood concentration is maintained.

Pleura Lining of the chest cavity.

Pleural Friction Rub Heard on either inspiration or expiration over anterior lateral lungs as a continuous creaking, grating sound.

Pneumatic Compression Device Device that provides intermittent compression cycles to the veins of the extremities to promote circulation.

Pneumothorax Collection of air or gas in the pleural space causing the lungs to collapse.

Point-of-Care Charting Documentation system that allows health care providers to gain immediate access to client information at the bedside.

Poison Any substance that causes an alteration such as injury or death in the client's health when inhaled, injected, ingested, or absorbed by the body.

Politics Way in which people try to influence decision making, especially decisions about the use of resources.

Polyp A small, abnormal growth of tissue.

Polypharmacy Concurrent use of several different medications.

Polysaccharide Complex sugar.

Polyunsaturated Fatty Acids Fatty acids that have many carbons unbonded to hydrogen atoms.

Port-a-Cath A port that has been implanted under the skin with a catheter inserted into the superior vena cava or right atrium through the subclavian or internal jugular vein.

Positive Nitrogen Balance Condition that exists when nitrogen intake exceeds output, protein anabolism exceeds catabolism.

Possible Nursing Diagnosis Nursing diagnosis that indicates a situation exists in which a problem could arise unless preventive action is taken, or a "hunch" or intuition by the nurse that cannot be confirmed or eliminated until more data have been collected. It is composed of the diagnostic label and related factors.

Postoperative (after surgery) Begins when the client leaves the operating room and is taken to a postanesthesia care unit; this phase continues until the client is discharged from the care of the surgeon.

Postural Drainage A technique of positioning that promotes gravity drainage of specific lung lobes.

Power Ability to do or act, resulting in the achievement of desired results.

Preadolescence Developmental stage from the ages of approximately 10 to 12 years.

Pre-Albumin Precursor of albumin.

Precapillary Sphincters Smooth muscles surrounding the smallest arterioles that control blood flow through the capillary beds.

Predictive Value The ability of screening test results to correctly identify the disease state, such as a true-positive correctly identifies persons who actually have the disease, whereas a true-negative correctly identifies persons who do not actually have the disease (Fischbach, 2000).

Preferred Provider Organization Type of managed care model in which member choice is limited to providers within the system.

Prenatal Period Developmental stage beginning with conception and ending with birth.

Preoperative (before surgery) Refers to the time interval that begins when the decision is made for surgery until the client is transferred to the operating room.

Presbycusis Hearing loss associated with old age.

Preschool Stage Developmental stage from the ages of 3 to 6 years.

Presence The process of “just being” with another; a therapeutic nursing intervention

Prescriptive Authority Legal recognition of the ability to prescribe medications.

Pressure Ulcer Localized area of tissue necrosis that develops when soft tissue is compressed between a bony prominence and an external surface for a prolonged period of time; also known as bedsore or decubitus ulcer.

Primary Care Provider Health care provider who a client sees first for health care; typically, a family practitioner (physician/nurse), internist, or pediatrician.

Primary Health Care Client’s point of entry into the health care system; includes assessment, diagnosis, treatment, coordination of care, education, preventive services, and surveillance.

Primary Intention Healing Healing process of a wound with minimal tissue loss and well-approximated edges; occurs with minimal granulation tissue and scarring.

Primary Source Major provider of information about client; research article written by one or more researchers.

Proactive Initiating change rather than responding to change imposed by others.

Problem-Oriented Medical Record (POMR) Documentation focused on the client’s problem with a structured, logical format to narrative charting called SOAP (subjective and objective data, assessment, plan).

Process Series of steps or acts that lead to accomplishment of a goal or purpose.

Process Evaluation Measurement of nursing actions by examination of each phase of the nursing process.

Process Improvement Process that examines the flow of client care between departments in order to ensure that the processes work as they were designed and that acceptable levels of performance are achieved.

Prodromal Stage Time interval from the onset of nonspecific symptoms until specific symptoms of the infectious agent begin to manifest themselves.

Profession Group (vocational or occupational) that requires specialized education and intellectual knowledge.

Professional Regulation Process by which nursing ensures that its members act in the public interest by providing a unique service that society has entrusted to them.

Professional Standards Authoritative statements developed by the profession by which quality of practice, service, and/or education can be judged.

Progressive Muscle Relaxation Stress management technique involving tensing and relaxing muscles.

Proposition Statement that proposes a relationship between concepts.

Proprioception Awareness of posture, movement, and changes in equilibrium and the knowledge of position, weight, and resistance of objects in relation to the body.

Prosody Melody of speech that conveys meaning through changes in the tempo, rhythm, and intonation.

Proteins Organic compounds of amino acid polymers connected by peptide bonds that contain carbon, hydrogen, oxygen, and nitrogen.

Protocol Series of standing orders or procedures that should be followed under certain specific conditions.

Proxemics Study of the distance between people and objects.

Psychomotor Domain Area of learning that involves performance of motor skills.

Psychoneuroimmunology Study of the complex relationship between the cognitive, affective, and physical aspects of humans.

Puberty Appearance of secondary sex characteristics that signals the beginning of adolescence.

Public Law Law that deals with an individual’s relationship to the state.

Pulse Bounding of blood flow in an artery that is palpable at various points on the body.

Pulse Deficit Condition in which the apical pulse rate is greater than the radial pulse rate.

Pulse Oximeter Sensor device used to measure the oxygen saturation level of the blood.

Pulse Pressure Measurement of the ratio of stroke volume to compliance (total distensibility) of the arterial system.

Pulse Quality Refers to the “feel” of the pulse, its rhythm and forcefulness.

Pulse Rate Indirect measurement of cardiac output obtained by counting the number of apical or peripheral pulse waves over a pulse point.

Pulse Rhythm Regularity of the heartbeat.

Pulse Volume Measurement of the strength or amplitude of the force exerted by the ejected blood against the arterial wall with each contraction.

Purulent Exudate Thick discharge composed of leukocytes, liquefied dead tissue debris, and dead and living bacteria; also known as pus.

Pyogenic Bacteria Bacteria that produce pus.

Pyorrhea Periodontal disease.

Pyrexia When heat production exceeds heat loss and body temperature rises above the normal range.

Pyrogens Bacteria, viruses, fungi, and some antigens.

Pyuria Pus (white blood cells) in the urine.

Q

Qualitative Analysis Integration and synthesis of narrative, nonnumerical data.

Qualitative Research Systematic collection and analysis of subjective narrative materials, using procedures for which there tends to be a minimum of research-imposed control.

Quality Meeting or exceeding requirements of the client.

Quality Assurance Traditional approach to quality management in which monitoring and evaluation focus on individual performance, deviation from standards, and problem solving.

Quantitative Research Systematic collection of numerical information, often under conditions of considerable control.

R

Race Grouping of people based on biological similarities such as physical characteristics.

Racism Discrimination directed toward individuals who are misperceived to be inferior because of biological factors.

Radiation Loss of heat in the form of infrared rays.

Radiofrequency ablation The delivery of low-voltage, high-frequency alternating electrical current to cauterize the abnormal myocardial tissue.

Radiography Study of x-rays or gamma ray-exposed film through the action of ionizing radiation.

Range-of-Motion Extent to which a joint can move.

Rapport Bond or connection between two people that is based on mutual trust.

Rationale Explanation based on the theories and scientific principles of natural and behavioral sciences and the humanities.

Readiness for Learning Evidence of willingness to learn.

Receiver Person who intercepts the sender’s message.

Recent Memory The result of events that have occurred over the past 24 hours.

Recommended Dietary Allowances (RDA) Recommended allowances of essential nutrients established by the Food and Nutritional Academy of Sciences–National Research Council.

Recurrent Acute Pain Discomfort marked by cycles of repetitive pain episodes that alternate with pain-free intervals; this pain may recur over a prolonged period or throughout a person’s lifetime.

Red Cell Indices Laboratory measurement of the size and hemoglobin content of the red cells.

Red Wound Wound in the proliferative phase of repair.

Referred Pain Discomfort from the internal organs that is felt in another area of the body.

Reframing Technique of monitoring negative thoughts and replacing them with positive ones.

Regional Anesthesia Anesthesia that causes the client to lose sensation in a particular area of the body (e.g., laparoscope for a tubal sterilization).

Regurgitation Backward flow of blood through a diseased heart valve, also known as insufficiency.

Relaxation Response State of increased arousal of the parasympathetic nervous system which leads to a relaxed physiological state.

Relaxation Techniques Methods used to decrease anxiety and muscle tension.

Remote memory The retention of experiences that occurred during earlier periods of life.

Research Systematic method of exploring, describing, explaining, relating, or establishing the existence of a phenomenon, the factors that cause changes in the phenomenon, and how the phenomenon influences other phenomena.

Research Design Overall plan used to conduct research.

Resident Flora Microorganisms that are always present, usually without altering the client’s health.

Respiration The act of breathing.

Rest State of relaxation and calmness, both mental and physical.

Restorative Nursing Care Nursing care provided to clients who have residual impairment as a result of disease or injury; seeks to increase the client's independence and ability to perform self-care.

Restraints Protective devices used to limit the physical activity of a client or to immobilize a client or extremity.

Restrictive Pulmonary Disease A category of lung diseases characterized by impaired mobility or elasticity of the lungs or chest wall.

Review of Systems A brief account of any recent signs or symptoms related to any body system.

Rhonchi Heard predominantly on expiration over the trachea and bronchi as a continuous, low-pitched musical sound.

Rigor Mortis Stiffening of the body after death caused by contraction of the skeletal and smooth muscles.

Risk for Infection State in which an individual is at increased risk for being invaded by pathogenic organisms.

Risk Nursing Diagnosis Nursing diagnosis that indicates that a problem does not yet exist but specific risk factors are present; composed of the diagnostic label preceded by the phrase "Risk for" with the specific risk factors listed.

Role Set of expected behaviors associated with a person's status or position.

Role Conflict When the expectations of one role compete with the expectations of other roles.

Rounds Reporting method; care team members walk to clients' rooms and discuss care and progress with each other and with the clients.

S

Saccharides Sugar units.

Satiety Feeling of fulfillment from food.

Saturated Fatty Acids Glycerol esters of organic acids whose atoms are joined by a single-valence bond.

School-Age Period Developmental stage from the ages of 6 to 12 years.

Scope of Practice Legal boundaries of practice for health care providers as defined in state statutes.

Sebum Substance produced by the skin to kill bacteria.

Secondary Gain Outcomes of the sick role other than alleviation of anxiety (primary gain); examples include gaining attention and sympathy, avoiding responsibilities, and receiving financial compensation or reward.

Secondary Intention Healing Healing process of a wound that has extensive tissue loss and poorly approximated edges; occurs with gradual tissue replacement and scarring.

Secondary Source Source of data other than the client, family members, other health care providers, or medical records; article in which an author addresses the research of someone else.

Self-Care Learned behavior and a deliberate action in response to a need.

Self-Care Deficit State in which an individual is not able to perform one or more activities of daily living.

Self-Concept Individual's perception of self; includes self-esteem, body image, and ideal self.

Self-Efficacy Belief in one's ability to succeed; according to social cognitive theory of learning, serves as an internal motivator for change.

Self-Esteem Individual's perception of self-worth; includes judgments about one's self and one's capabilities.

Semipermeable Selective permeability of membranes.

Sender Person who generates a message.

Sensation The ability to receive and process stimuli received through the sensory organs.

Sensitivity Determines the susceptibility of a pathogen to an antibiotic; the ability of a test to correctly identify those individuals who have the disease.

Sensory Deficit A change in the perception of sensory stimuli.

Sensory Deprivation A state of reduced sensory input from the internal or external environment, manifested by alterations in sensory perceptions.

Sensory Overload Increased perception of the intensity of auditory and visual stimuli.

Sensory Perception The ability to receive sensory impressions and, through cortical association, relate the stimuli to past experiences to form an impression of the nature of the stimulus.

Serous Exudate Watery discharge composed primarily of serum, with a low protein count.

Sex Roles Culturally determined patterns associated with being male or female.

Sexuality Human characteristic that refers not just to gender but to all the aspects of being male or female, including feelings, attitudes, beliefs, and behavior.

Sexual Orientation Individual's preference for ways of expressing sexual feelings.

Shaman Folk healer-priest who uses natural and supernatural forces to help others.

Shamanism Practice of entering altered states of consciousness with the intent of helping others.

Shearing Force exerted against the skin by movement or repositioning.

Short-Term Goal Statement written in objective format demonstrating an expectation to be achieved in resolution of the nursing diagnosis in a short period of time, usually a few hours or days.

Shunting Condition in which alveolar regions are well-perfused but not adequately ventilated.

Side Effects Mild non-therapeutic drug effect.

Signal-Averaged ECG Surface ECG that amplifies late potentials.

Simultaneity Paradigm Nursing viewpoint that focuses on the quality of life from the client's perspective and conceptualizes the interaction between person and environment as mutual and simultaneous.

Single-Payer System Health care delivery model in which the government is the only entity to reimburse.

Single Point of Entry Entry into the health care system is required through a point designated by the plan.

Situational Leadership Style of leadership in which there is a blending of styles based on current circumstances and events.

Situational Loss Occurs in response to external events, usually beyond the individual's control (such as the death of a significant other).

Skinfold Measurement Measures the amount of body fat.

Skin Shear Result of dragging skin across a hard surface.

Skin Turgor Normal resiliency of the skin.

Sleep State of altered consciousness during which an individual experiences fluctuations in level of consciousness, minimal physical activity, and a general slowdown of the body's physiological processes.

Sleep Apnea A syndrome in which breathing periodically ceases during sleep, often associated with heavy snoring.

Sleep Cycle Sequence of sleep that begins with the four stages of no rapid eye movement (NREM) sleep, with a return to stages 3 then 2, then passage into the first rapid eye movement (REM) stage.

Sleep Deprivation Prolonged inadequate quality and quantity of sleep.

Small-Group Ecology Study of proxemics in small-group situations.

Snellen Chart A chart of graduating black letters which test visual acuity.

SOAP Charting Documentation method using subjective data, objective data, assessment, and plan.

Solute A substance dissolved in a solution; also called analyte.

Solvent A liquid with a substance in solution.

Somatic Pain Nonlocalized discomfort originating in tendons, ligaments, and nerves.

Somnambulism Sleepwalking.

Source-Oriented (SO) Charting Narrative recording by each member (source) of the health care team on a separate record.

Spasticity Increase in muscle tension

Specific Gravity Weight of urine compared with weight of distilled water; a specific gravity greater than 1.000 indicates solutes in the urine.

Specificity The ability of a test to correctly identify those individuals who do not have the disease.

Spherocytes Small, thick red cells.

Spiritual Distress The client's perception that their belief system, or their place within it, is threatened.

Spirituality Relationship with one's self, a sense of connection with others, and a relationship with a higher power or divine source.

Spores Single-celled microorganisms or microorganisms in the resting or inactive stage.

Standing Order Standardized intervention written, approved, and signed by a physician that is kept on file within health care agencies to be used in predictable situations or in circumstances requiring immediate attention.

Stat Orders An order for a single dose of medication to be given immediately.

Statutory Law Laws enacted by legislative bodies.

Stenosis Narrowing or constriction of a blood vessel or valve.

Stereognosis Ability to identify objects by manipulation and touch.

Stereotyping Belief that all people within the same racial, ethnic, or cultural group act alike and share the same beliefs and attitudes.

Sterilization Total elimination of all microorganisms including spores.

Stock Supply Medications dispensed and labeled in large quantities for storage in the medication room or nursing unit.

Stoma Surgically created opening.

Stomatitis Inflammation of the oral mucosa.

Stool Fecal material.

Stress Body's reaction to any stimulus.

Stressor Any stimulus encountered by an individual; leads to the need to adapt.

Stress Test Measures the client's cardiovascular response to exercise tolerance.

Stress Urinary Incontinence Uncontrolled loss of urine caused by physical exertion in the absence of a bladder contraction.

Striae Red or silver-white streaks over the breasts or axillae.

Stridor Heard predominantly on inspiration as a continuous crowing sound.

Stroke Volume Measurement of blood that enters the aorta with each ventricular contraction.

Structure Evaluation Determination of the health care agency's ability to provide the services offered to its client population.

Subacute care Short-term aggressive care that emphasizes restorative interventions before the client's reentry into the community

Subculture Group of people with characteristic patterns of behavior that distinguish it from the larger culture or society.

Subcutaneous (SC/SQ) Injection into the subcutaneous tissue.

Subjective Data Data from the client's point of view, including feelings, perceptions, and concerns.

Sublingual Under the tongue.

Superficial Wound Wound confined to the epidermis layer.

Supination Turning a body part upward.

Suppository A substance specifically designed to insert into a bodily orifice other than the mouth (anus, vagina, urethra). The suppository is typically composed of a vehicle containing a medication.

Suppression Conscious defense mechanism whereby a person decides to avoid dealing with a stressor at the present time.

Suppuration Formation of pus, or purulent exudate.

Surfactant Phospholipid secreted by Type II alveolar cells that reduces the alveolar surface tension and thus helps prevent alveolar collapse.

Surgical Asepsis Practices that eliminate all microorganisms from an object or area.

Susceptible Host Person who lacks resistance to an agent and is therefore vulnerable to disease.

Suture Surgical means of closing a wound by sewing, wiring, or stapling.

Synergy Combined power of many people.

Synthesis Putting data together in a new way.

Systemic Infection Infection that affects the entire body with involvement of multiple organs.

Systole Process of cardiac chamber emptying or ejecting blood.

T

Tachycardia A heart rate in excess of 100 beats per minute in an adult.

Tachypnea Respiratory rate greater than 24 breaths per minute.

Tactile Fremitus Vibrations created by sound waves.

Tapotement Massage technique using a light tapping of the fingers that stimulates movement in tired muscles.

Taxonomy of Nursing Diagnoses Type of classification under which the diagnostic label is grouped according to which human response the client is demonstrating to the actual or perceived stressor.

Teaching Active process in which one individual shares information with another as a means to facilitate behavioral changes.

Teaching-Learning Process Planned interaction that promotes a behavioral change that is not a result of maturation or coincidence.

Teaching Strategies Techniques employed by the teacher to promote learning.

Team Group of individuals who work together to achieve a common goal.

Teleology Ethical theory that states that the moral value of a situation is determined by its consequences.

Teratogenic Substance Substance that can cross the placental barrier and impair normal growth and development.

Termination Phase Third and final stage of the therapeutic relationship; focuses on evaluation of goal achievement and effectiveness of treatment.

Tertiary Intention Healing Healing process of a wound in which primary closure of a wound is undesirable; occurs when circulation is poor or when infection is present.

Testimony Written or verbal evidence given by a qualified expert in an area.

Thallium Radionuclide that is the physiological analogue of potassium.

Theory Set of concepts and propositions that provide an orderly way to view phenomena.

Therapeutic Describes actions that are beneficial to the client.

Therapeutic Communication Use of communication for the purpose of creating a beneficial outcome for the client.

Therapeutic Massage Application of pressure and motion by the hands with the intent of improving the recipient's well-being.

Therapeutic Procedure Accidents Accidents that occur during the delivery of medical or nursing interventions.

Therapeutic Range Achievement of a constant therapeutic blood level of a medication within a safe range.

Therapeutic Relationship Relationship that benefits the client's health status.

Therapeutic Touch Holistic technique that consists of assessing alterations in a person's energy fields and using the hands to direct energy to achieve a balanced state.

Therapeutic Use of Self Process in which nurses deliberately plan their actions and approach the relationship with a specific goal in mind before interacting with the client.

Thermoregulation Body's physiological function of heat regulation to maintain a constant internal body temperature.

Thoracentesis The aspiration of fluids from the pleural cavity.

Thrills Vibrations that feel similar to a purring cat.

Thrombus Blood clot.

Toddler Developmental stage beginning at approximately 12 to 18 months of age, when a child begins to walk, and ending at approximately age 3.

Tolerance Phenomenon of requiring larger and larger doses of an analgesic to achieve the same level of pain relief.

Tort Civil wrong committed upon a person or property stemming from a direct invasion of some legal right of the person, the infraction of some public duty, or the violation of some private obligation by which damages accrue to the person.

Tort Law Enforcement of duties and rights among individuals independent of contractual agreements.

Totality Paradigm Nursing viewpoint that conceptualizes the interaction between person and environment as constant in order to accomplish goals and maintain balance.

Total Parenteral Nutrition Intravenous infusion of a solution containing dextrose, amino acids, fats, essential fatty acids, vitamins, and minerals.

Total Quality Management Method of management and system operation that is used to achieve continuous quality improvement.

Touch Means of perceiving or experiencing through tactile sensation.

Toxic Effect Reaction that occurs when the body cannot metabolize a drug, causing the drug to accumulate in the blood.

Tracheotomy A surgical procedure in which an opening (stoma) is made through the anterior neck into the trachea; an artificial airway (tracheostomy tube) is placed into the stoma.

Transcultural Nursing Formal area of study and practice focused on comparative analysis of different cultures and subcultures with respect to cultural care, health and illness beliefs, values and practices, with the goal of providing health care within the context of the client's culture.

Transcutaneous Electrical Nerve Stimulation (TENS) Method of applying minute amounts of electrical stimulation to large-diameter nerve fibers via electrodes placed on the skin to block the passage of pain to the dorsal spinal root.

Transducer Instrument that converts electrical energy to sound waves.

Transferrin (nonheme iron) Combination of a blood protein and iron.

Transient Flora Microorganisms that attach to the skin for a brief period of time but do not continuously live on the skin.

Transsexuality Belief that one is psychologically of the sex opposite his or her anatomic gender.

Trigger Point Hypersensitive point in a muscle, ligament, fascia, or joint capsule that, when stimulated, causes a local twitch or jump response.

Triglycerides Lipid compounds consisting of three fatty acids and a glycerol molecule.

Trocar Large-bored abdominal paracentesis needle.

T-Tube Artificial drain placed in the common bile duct during surgery.

Tympany A low-pitched sound of long duration.

Type and Cross-Match Laboratory test that identifies the client's blood type (e.g., A or B) and determines the compatibility of the blood between potential donor and recipient.

U

Ultrasound Use of high-frequency sound waves instead of x-ray film to visualize deep body structures; also called an echogram.

Uncomplicated Grief A fairly predictable grief reaction following a significant loss, ending with the relinquishing of the lost object and resumption of the previous life.

Understaffing Failure of a facility to provide a sufficient number of professional staff to meet the needs of their clients.

Unintentional Wound Wound resulting from trauma or accident.

Unit Dose Form System of packaging and labeling each dose of medication, usually for a 24-hour period.

Unprofessional Conduct Conduct that could adversely affect the health and welfare of the public.

Unsaturated Fatty Acids Glycerol esters of organic acids whose atoms are joined by double or triple valence bonds.

Urgency Timely intervention of surgery.

Urge Urinary Incontinence Uncontrolled discharge of urine caused by hyperactive (unstable) contractions of the detrusor muscle.

Urinalysis Laboratory analysis of the urine.

Urinary Incontinence Uncontrolled loss of urine of sufficient duration and volume to create a social or hygienic problem.

Urinary Retention Inability to completely evacuate the bladder.

Urobilinogen Derived from the normal bacterial action of intestinal flora on bilirubin.

Utility Ethical principle that states that an act must result in the greatest amount of good for the greatest number of people involved in a situation.

V

Vaccination Inoculation with a vaccine to produce immunity against specific diseases.

Value Variation of the variable.

Values Principles that influence the development of beliefs and attitudes.

Values Clarification Process of analyzing one's own values to better understand what is truly important to oneself.

Variable Anything that may differ from the norm.

Variations Goals not met or interventions not performed according to the time frame; also called variance.

Vasoconstriction The narrowing of the vessels, usually leading to reduced blood flow.

Vasodilation The widening of the vessels, usually leads to increased blood flow.

Vector-Borne Transmission Mode of transmission of disease through animate objects.

Vehicle Transmission Mode of transmission of disease through inanimate objects.

Venipuncture Puncturing of a vein with a needle to aspirate blood.

Venography Radiographic study of the venous system of the lower extremities following the injection of an iodine contrast agent.

Ventilation Movement of air into and out of the lungs for the purpose of delivering fresh air to the alveoli.

Ventilation–Perfusion (V/Q) Mismatching Condition in which perfusion and ventilation of the lung areas are not adequately balanced.

Veracity Ethical principle that means that one should be truthful, neither lying nor deceiving others.

Verbal Message Message communicated through words or language, both spoken and written.

Vesicant Medication that causes blisters and tissue injury when it escapes into surrounding tissue.

Vesicular Sounds Soft, breezy, and low-pitched sounds heard longer on inspiration than expiration that result from air moving through the smaller airways over the lung's periphery, with the exception of the scapular area.

Vibration Massage technique using rapid movements that stimulate or relax muscles.

Virulence Degree of pathogenicity of an infectious microorganism (pathogen).

Visceral Pain Discomfort felt in the internal organs.

Visual Channel Transmission of messages through sight, observation, and perception.

Visual Learner Style of learning in which people learn by processing information by seeing.

Vital Capacity Amount of air exhaled from the lungs after a minimal full inspiration.

Vital Signs Measurement of the client's body temperature (T), pulse (P) and respiratory (R) rates, and blood pressure (BP).

Vitamins Organic compounds.

Voiding Process of urine evacuation.

W

Walking Rounds Reporting method used when the members of the care team walk to each client's room and discuss care and progress with each other and the client.

Water-Soluble Vitamins Vitamins that require daily ingestion in normal quantities because they are not stored in the body.

Wellness Condition in which an individual functions at optimal levels.

Wellness Nursing Diagnosis Nursing diagnosis that indicates the client's expression of a desire to obtain a higher level of wellness in some area of function. It is composed of the diagnostic label preceded by the phrase "potential for enhanced."

Wheezes Heard predominantly on expiration all over the lungs as a continuous sonorous wheeze or sibilant wheeze.

Whistle-blowing Calling attention to the unethical, illegal, or incompetent actions of others.

Withdrawal Syndrome State in which symptoms occur after abrupt discontinuation of a narcotic.

Work of Breathing Amount of muscular energy (work) required to accomplish ventilation.

Working Phase Second stage of the therapeutic relationship in which problems are identified, goals are established, and problem-solving methods are selected.

Wound Disruption in the integrity of a body tissue.

Y

Yellow Wound Wound with fibrinous slough or purulent exudate from bacteria.

Young Adulthood Developmental stage from the ages of 21 to approximately 40 years.

Z

Z-Track Injection Method of IM injection to seal the medication in the muscle, preventing the drug from irritating the subcutaneous tissue.

4. Follow the installation prompts from there.

(Note: Sound card and speaker are ONLY required for products that include sound.)

License Agreement for Delmar, a division of Thomson Learning Educational Software/Data

You the customer, and Delmar, a division of Thomson Learning incur certain benefits, rights, and obligations to each other when you open this package and use the software/data it contains. BE SURE YOU READ THE LICENSE AGREEMENT CAREFULLY, SINCE BY USING THE SOFTWARE/DATA YOU INDICATE YOU HAVE READ, UNDERSTOOD, AND ACCEPTED THE TERMS OF THIS AGREEMENT.

Your rights:

1. You enjoy a non-exclusive license to use the software/data on a single microcomputer in consideration for payment of the required license fee, (which may be included in the purchase price of an accompanying print component), or receipt of this software/data, and your acceptance of the terms and conditions of this agreement.
2. You acknowledge that you do not own the aforesaid software/data. You also acknowledge that the software/data is furnished "as is," and contains copyrighted and/or proprietary and confidential information of Delmar, a division of Thomson Learning or its licensors.

There are limitations on your rights:

1. You may not copy or print the software/data for any reason whatsoever, except to install it on a hard drive on a single microcomputer and to make one archival copy, unless copying or printing is expressly permitted in writing or statements recorded on the diskette(s).
2. You may not revise, translate, convert, disassemble or otherwise reverse engineer the software/data except that you may add to or rearrange any data recorded on the media as part of the normal use of the software/data.
3. You may not sell, license, lease, rent, loan, or otherwise distribute or network the software/data except that you may give the software/data to a student or and instructor for use at school or, temporarily at home.

Should you fail to abide by the Copyright Law of the United States as it applies to this software/data your license to use it will become invalid. You agree to erase or otherwise destroy the software/data immediately after receiving note of Delmar, a division of Thomson Learning termination of this agreement for violation of its provisions.

Delmar, a division of Thomson Learning gives you a LIMITED WARRANTY covering the enclosed software/data. The LIMITED WARRANTY follows this License.

This license is the entire agreement between you and Delmar, a division of Thomson Learning interpreted and enforced under New York law.

This warranty does not extend to the software or information recorded on the media. The software and information are provided "AS IS." Any statements made about the utility of the software or information are not to be considered as express or implied warranties. Delmar, a division of Thomson Learning will not be liable for incidental or consequential damages of any kind incurred by you, the consumer, or any other user.

Some states do not allow the exclusion or limitation of incidental or consequential damages, or limitations on the duration of implied warranties, so the above limitation or exclusion may not apply to you. This warranty gives you specific legal rights, and you may also have other rights which vary from state to state. Address all correspondence to: Delmar, a division of Thomson Learning, 5 Maxwell Drive, P.O. Box 8007, Clifton Park, NY 12065 Attention: Technology Department

LIMITED WARRANTY

Delmar, a division of Thomson Learning warrants to the original licensee/purchaser of this copy of microcomputer software/data and the media on which it is recorded that the media will be free from defects in material and workmanship for ninety (90) days from the date of original purchase. All implied warranties are limited in duration to this ninety (90) day period. THEREAFTER, ANY IMPLIED WARRANTIES, INCLUDING IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE, ARE EXCLUDED. THIS WARRANTY IS IN LIEU OF ALL OTHER WARRANTIES, WHETHER ORAL OR WRITTEN, EXPRESS OR IMPLIED.

If you believe the media is defective please return it during the ninety day period to the address shown below. Defective media will be replaced without charge provided that it has not been subjected to misuse or damage.

This warranty does not extend to the software or information recorded on the media. The software and information are provided "AS IS." Any statements made about the utility of the software or information are not to be considered as express or implied warranties.

Limitation of liability: Our liability to you for any losses shall be limited to direct damages, and shall not exceed the amount you paid for the software. In no event will we be liable to you for any indirect, special, incidental, or consequential damages (including loss of profits) even if we have been advised of the possibility of such damages.

Some states do not allow the exclusion or limitation of incidental or consequential damages, or limitations on the duration of implied warranties, so the above limitation or exclusion may not apply to you. This warranty gives you specific legal rights, and you may also have other rights which vary from state to state. Address all correspondence to: Delmar, a division of Thomson Learning, Box 15015, Albany, NY 12212 Attention: Technology Department
