To Jennifer and Ryan Cardinal, Katie and Jacob Segrave, and Sarabeth and Jay Accardo. I especially want to thank my husband and best friend, Jay, for his continued support and belief in me. I want to acknowledge my father, Glynn Edward Carter, for unending support and encouragement, especially for my academic endeavors.

-SCD

To Wayne, Kelly, Wayne Jr., Gretchen, and Michael.

-PKL

We dedicate this book to our grandchildren: Camille Anna Cardinal, Caroline Alexa Cardinal, Leah Marie Ladner, Charles Thomas Lee, Michael and Joshua Ladner, and Cooper and Paige Ladner.

You are our future. "G" and "Mimi"

Brief Contents

UNIT 1: Nursing's Perspective: Past, Present, and Future

Chapter 1	Evolution of Nursing and Nursing Education	3
Chapter 2	Nursing Theory	23
Chapter 3	Research and Evidence-Based Practice	41
Chapter 4	Health Care Delivery, Quality, and the Continuum of Care	53

UNIT 2: Nursing Process: The Standard of Care

Chapter 5	Critical Thinking, Decision Making, and the Nursing Process	75
Chapter 6	Assessment	89
Chapter 7	Nursing Diagnosis	109
Chapter 8	Planning and Outcome Identification	125
Chapter 9	Implementation	139
Chapter 10	Evaluation	153

UNIT 3: Professional Accountability

Chapter 11	Leadership, Delegation, and Power	165
Chapter 12	Legal and Ethical Responsibilities	187
Chapter 13	Documentation and Informatics	213

UNIT 4: Promoting Client Health

Chapter 14	Nursing, Healing, and Caring	245
Chapter 15	Communication	261
Chapter 16	Health and Wellness Promotion	281
Chapter 17	Family and Community Health	297
Chapter 18	The Life Cycle	309
Chapter 19	The Older Client	357
Chapter 20	Cultural Diversity	379
Chapter 21	Client Education	401

UNIT 5: Responding to Basic Psychosocial Needs

Chapter 22	Self-Concept	423
Chapter 23	Stress, Anxiety, Adaptation, and Change	439
Chapter 24	Spirituality	463
Chapter 25	Loss and Grief	475

UNIT 6: Responding to Basic Physiological Needs

Chapter 26	Vital Signs	501
Chapter 27	Physical Assessment	539
Chapter 28	Diagnostic Testing	601
Chapter 29	Safety, Infection Control, and Hygiene	653
Chapter 30	Medication Administration	749
Chapter 31	Complementary and Alternative Modalities	833
Chapter 32	Oxygenation	859
Chapter 33	Fluids and Electrolytes	919
Chapter 34	Nutrition	993
Chapter 35	Comfort and Sleep	1043
Chapter 36	Mobility	1087
Chapter 37	Skin Integrity and Wound Healing	1161
Chapter 38	Sensation, Perception, and Cognition	1207
Chapter 39	Elimination	1231
Chapter 40	Nursing Care of the Perioperative Client	1295

TABLE OF CONTENTS

List of Procedures / xix
Contributors / xxiii
Reviewers / xxv
Preface / xxix
How to Use This Text / xxxiii
Acknowledgments / xxxvi
About the Authors / xxxvii

Doctoral Programs	17
Staff Development and Continuing Education	18
Preparing Nurses for Tomorrow's Challenges	18
Differentiated Practice	19
Accelerated Degree Programs	19
Technology Changes in Nursing Education	19
Service Learning	20

UNIT 1

Nursing's Perspective: Past, Present, and Future / 1

CHAPTER 1 EVOLUTION OF NURSING AND NURSING EDUCATION / 3

Evolution of Nursing	4
Origins of Nursing	4
Religious Influences	7
Demands of War	7
Florence Nightingale (1820–1910)	8
Nursing Pioneers and Leaders	9
Nursing in the Twentieth Century	11
Social Forces Affecting Nursing	14
Nursing Education Overview	15
Diploma Education	15
Associate Degree Programs	17
Baccalaureate Programs	17
Master's Programs	17

CHAPTER 2

NURSING THEORY / 23

Components of the Theoretical Foundation	24
What Is a Concept?	24
What Is a Proposition?	24
What Is a Theory?	24
Use of Theories from Other Disciplines	25
Importance of Nursing Theories	25
Scope of Theories	26
Grand Theories	26
Middle-Range Theories	26
Micro-Range Theories	26
Evolution of Nursing Theory	26
Knowledge Development in Nursing	28
Metaparadigm of Nursing	28
Paradigms in Nursing	29
Selected Nursing Theories	30
Florence Nightingale	30
Early Nursing Theories	30
Contemporary Nursing Theories	33
Theories for the New Worldview of Nursing	37
Continuing Evolution of Nursing Theory	38

CHAPTER 3**RESEARCH AND EVIDENCE-BASED PRACTICE / 41**

Research: Substantiating the Science of Nursing	42
Historical Development	42
Framework	43
Research Utilization	47
Nursing Students	47
Evidenced-Based Practice	48
Evidence Reports	49
Trends in Research and Evidence-Based Practice	50

CHAPTER 4**HEALTH CARE DELIVERY, QUALITY, AND THE CONTINUUM OF CARE / 53**

Health Care Delivery: Organizational Frameworks	54
Public Sector	54
Private Sector	55
Health Care Team	55
Nurse: Roles and Functions	55
Advanced Practice Nurse: Roles and Functions	55
Reimbursement Methods	57
Private Insurance	57
Managed Care	57
Government Plans	58
Factors Influencing the Delivery of Health Care	59
Cost	59
Access	60
Quality	60
Nursing Supply and Demand	60
Responses to Health Care Changes	60
Nursing Agenda for Health Care Reform	60
Public versus Private Programs	61
Vulnerable Populations	61
Community Nursing Organizations	61
Continuum of Care	62
Levels of Care	62
Health Care Settings	62
Fragmentation of Care	63
Quality Management in Health Care	65
Defining Quality	65
Factors Influencing Quality in Health Care	66
Quality and Health Care Economics	67
Principles of Quality Improvement	67
Customer Satisfaction	67
Organizational Structure for Quality Management	68
Organizational Culture	68
Process Improvement	70
Nursing's Role in Quality Management	70
Trends in Health Care Delivery	71

UNIT 2**Nursing Process: The Standard of Care / 73****CHAPTER 5****CRITICAL THINKING, DECISION MAKING, AND THE NURSING PROCESS / 75**

Critical Thinking	76
Components of Critical Thinking	76
Development of Critical Thinking Skills	77
Critical Thinking and Creativity	78
Critical Thinking and Problem Solving	78
Critical Thinking and Decision Making	78
The Nursing Process	79
Historical Perspective	79
Overview of the Nursing Process	79
Assessment	79
Diagnosis	81
Outcome Identification and Planning	83
Implementation	84
Evaluation	84
Critical Thinking Applied in Nursing	85

CHAPTER 6**ASSESSMENT / 89**

Purpose of Assessment	90
Types of Assessment	90
Comprehensive Assessment	90
Focused Assessment	90
Ongoing Assessment	91
Data Collection	91
Types of Data	91
Sources of Data	91
Methods of Data Collection	92
Data Verification	96
Data Organization	97
Assessment Models	97
Data Interpretation	98
Data Documentation	98
Types of Assessment Formats	98

CHAPTER 7**NURSING DIAGNOSIS / 109**

What Is a Nursing Diagnosis?	110
Comparison of Nursing and Medical Diagnoses	110
Historical Perspective	111
Research	111
Purposes of Nursing Diagnoses	111
Professionalism	111

Communication	112
Holistic, Individualized Care	112
Nursing Diagnoses and Nursing Informatics	112
Components of a Nursing Diagnosis	114
The Two-Part Statement	115
The Three-Part Statement	115
Categories of Nursing Diagnoses	115
Taxonomy of Nursing Diagnoses	116
Clinical Judgment in Nursing: Developing Nursing Diagnoses	116
Generating Cues	117
Validating Cues	117
Interpreting Cues	117
Clustering Cues	118
Using NANDA-Approved Nursing Diagnoses	118
Writing the Nursing Diagnosis Statement	118
Avoiding Errors in Development and Use of Nursing Diagnoses	118
Assessment Errors	118
Diagnostic Errors	119
Limitations of Nursing Diagnosis	120
Overcoming Barriers and Limitations to Nursing Diagnosis	120

CHAPTER 8

PLANNING AND OUTCOME IDENTIFICATION / 125

Purposes of Planning and Outcome Identification	126
Process of Planning and Outcome Identification	126
Critical Thinking	126
Establishing Priorities	127
Establishing Goals and Expected Outcomes	128
Components of Goals and Expected Outcomes	129
Problems Frequently Encountered in Planning	130
Planning Nursing Interventions	132
Evaluating Care	134
Nursing Outcomes Classification (NOC)	134
Plan of Care	135
Types of Care Plans	135
Strategies for Effective Care Planning	136

CHAPTER 9

IMPLEMENTATION / 139

Purposes of Implementation	140
Requirements for Effective Implementation	140
Cognitive Skills	140
Psychomotor Skills	140
Interpersonal Skills	140
Implementation Activities	140
Ongoing Assessment	140
Establishment of Priorities	141
Allocation of Resources	142

Nursing Interventions	144
Evaluating Interventions	149
Documentation of Interventions	149

CHAPTER 10

EVALUATION / 153

Evaluation of Client Care	154
Components of Evaluation	154
Techniques	154
Sources of Data	155
Goals and Expected Outcomes	155
Methods of Evaluation	155
Establishing Standards	155
Collecting Data	155
Determining Goal Achievement	155
Relating Nursing Actions to Client Status	155
Judging the Value of Nursing Interventions	155
Reassessing the Client's Status	155
Modifying the Plan of Care	155
Critical Thinking and Evaluation	156
Evaluation and Quality of Care	156
Elements in Evaluating the Quality of Care	156
Nursing Audit	158
Peer Evaluation	159
Evaluation and Accountability	159
Multidisciplinary Collaboration in Evaluation	159

UNIT 3

Professional Accountability / 163

CHAPTER 11

LEADERSHIP, DELEGATION, AND POWER / 165

Professional Nursing Practice	166
Criteria of a Profession	166
Professional Accountability	168
Elements of Professional Accountability	168
Legislative Accountability	170
Individual Accountability	171
Student Accountability	172
Advanced Practice Nursing	172
Leadership in Nursing	175
Managerial Functions	175
Leadership Styles	175
Leadership Characteristics	175
Power	180
Mentoring	181
Networking	181
Empowerment	182
Politics of Nursing	182

CHAPTER 12**LEGAL AND ETHICAL
RESPONSIBILITIES / 187**

Legal Foundations of Nursing	188
Sources of Law	188
The Judicial Process	190
Legal Liability in Nursing	190
Legal Responsibilities and Roles	195
Legal Responsibilities of Students	195
Legal Safeguards for Nursing Practice	196
Legislation Affecting Nursing Practice	197
Legal Issues Related to Death and Dying	199
Ethical Foundations of Nursing	200
Concept of Ethics	200
Ethical Theories	201
Ethical Principles	202
Values and Ethics	204
Ethical Codes	204
Clients' Rights	205
Ethical Dilemmas	205
Ethical Roles and Responsibilities of Professional Nurses	207
Ethical Decision Making	208

CHAPTER 13**DOCUMENTATION AND
INFORMATICS / 213**

Informatics	214
Clinical Information Systems	214
Electronic Health Record	215
Nursing Information Systems	215
Documentation as Communication	216
Documentation Defined	216
Purposes of Health Care Documentation	217
Principles of Effective Documentation	223
Elements of Effective Documentation	224
Methods of Documentation	226
Narrative Charting	226
Source-Oriented Charting	226
Problem-Oriented Charting	226
PIE Charting	227
Focus Charting	227
Charting by Exception	227
Computerized Documentation	228
Case Management Process	228
Forms for Recording Data	230
Kardex	230
Flow Sheets	230
Nurses' Progress Notes	230
Discharge Summary	230
Reporting	235
Summary Reports	235
Telephone Reports and Orders	235
Incident Reports	236

Computers in Nursing	237
The Professional Nurse as an Information Consumer and Producer	237
Informatics Competencies for Nurses	237
Applications of Nursing Informatics	238
Telehealth	239
Evidence-Based Practice and Research	239
Criteria for Evaluating Validity of Information	239

UNIT 4**Promoting Client Health / 243****CHAPTER 14****NURSING, HEALING, AND CARING / 245**

Nursing's Therapeutic Value	246
Definition of Nursing	246
Nursing: A Blend of Art and Science	246
Purposes of Nursing	246
Nursing and Healing	247
Theoretical Perspectives of Caring	247
Care in the High-Technology Environment	248
Nurse-Client Relationship	249
Phases of Therapeutic Relationship	249
Therapeutic Use of Self	251
Caring and Communication	252
Characteristics of Therapeutic Relationships	252
Therapeutic Value of the Nursing Process	255
Nursing Roles	256

CHAPTER 15**COMMUNICATION / 261**

The Communication Process	262
Components of the Communication Process	262
Factors Influencing Communication	264
Levels of Communication	265
Modes of Communication	266
Verbal Messages	266
Nonverbal Messages	267
Metacommunication	268
Types of Communication	268
Interdisciplinary Communication	268
Therapeutic Communication	268
Therapeutic Approaches with Clients	269
Barriers to Therapeutic Interaction	273
Language Differences	273
Cultural Differences	273
Gender	273
Health Status	273
Developmental Level	273
Knowledge Differences	273

Emotional Distance	273
Emotions	274
Daydreaming	274
Use of Health Care Jargon	274
Communication Blocks	274
Communication, Critical Thinking, and Nursing Process	274
Assessment	274
Nursing Diagnosis	276
Planning and Outcome Identification	278
Implementation	278
Evaluation	278

CHAPTER 16

HEALTH AND WELLNESS PROMOTION / 281

Health, Illness, and Wellness	282
Models of Health	282
Illness Perspectives	284
Wellness Perspectives	284
Health Behaviors	284
Variables Influencing Health Behaviors	285
Health Promotion	286
Health Promotion Activities	287
Health Protection Activities	287
Disease Prevention Activities	287
Nurse's Role in Health Promotion	288
Health Promotion and Vulnerable Populations	288
The Individual as a Holistic Being	288
Needs and Health	289
Physiological Dimension	289
Psychological Dimension	289
Sociocultural Dimension	289
Intellectual Dimension	290
Spiritual Dimension	290
Promoting Sexual Health	290
Development of Sexuality	290
Gender Identity	290
Sexual Needs	291
Human Sexual Response	291
Sexuality and Health	291
Nursing Process and Sexuality	291

CHAPTER 17

FAMILY AND COMMUNITY HEALTH / 297

Family Health	298
Family Structure	298
Family Roles and Functions	299
Characteristics of Healthy Families	299
Family Development Theories	300
Threats to Family Integrity	300

Community Health	303
Public Health Nursing	304
Disaster Preparedness	304

CHAPTER 18

THE LIFE CYCLE / 309

Fundamental Concepts of Growth and Development

Fundamental Concepts of Growth and Development	310
Principles of Growth and Development	310
Factors Influencing Growth and Development	310

Theoretical Perspectives of Human Development

Theoretical Perspectives of Human Development	312
Physiological Dimension	312
Psychosocial Dimension	312
Cognitive Dimension	315
Moral Dimension	316
Spiritual Dimension	317

Holistic Framework for Nursing

Holistic Framework for Nursing	317
Stages of the Life Cycle	319
Prenatal Period	319
Neonatal Period	322
Infancy	324
Toddler	329
Preschooler	331
School-Age Child	333
Preadolescent	333
Adolescent	335
Young Adult	344
Middle-Aged Adult	344
Older Adult	347

CHAPTER 19

THE OLDER CLIENT / 357

Defining Old Age	358
Theories of Aging	358
Myths and Stereotypes of Aging	359
Quality of Life among Older Adults	360
Changes Associated with Aging	360
Developmental Changes	361
Physiological Changes	361
Psychosocial Changes	365
Medications and the Older Adult	367
Responses to Medication	368
Medication Compliance	368
Mistreatment of the Older Adult	369
Nursing Process and the Older Adult	369
Assessment	370
Nursing Diagnosis	370
Outcome Identification and Planning	370
Implementation	370
Evaluation	375

CHAPTER 20

CULTURAL DIVERSITY / 379

Concepts of Culture 380
 Culture 380
 Ethnicity and Race 381
 Labeling and Stereotyping 381
 Dominant Values in the United States 381
Multiculturalism in the United States 382
 Value of Diversity 382
Organizing Phenomena of Culture 383
 Communication 383
 Space 383
 Orientation to Time 383
 Social Organization 389
 Gender 389
 Lifestyle 390
 Religion 390
Cultural Disparities in Health and Health Care Delivery 390
 Vulnerable Populations 390
 Environmental Control 391
 Folk Medicine 391
 Biological Variations 392
Transcultural Nursing 392
 Cultural Competence 395
Cultural Competence and Nursing Process 395
 Assessment 395
 Nursing Diagnosis 395
 Planning and Outcome Identification 396
 Implementation 396
 Evaluation 397

CHAPTER 21

CLIENT EDUCATION / 401

The Teaching-Learning Process 402
 Purposes of Client Teaching 402
 Facilitators of Learning 403
 Barriers to Learning 404
 Domains of Learning 404
Professional Responsibilities Related to Teaching 405
 Legal Aspects 405
 Documentation 405
Learning Throughout the Life Cycle 405
 Children 405
 Adolescents 409
 Older Adults 409
Teaching-Learning and the Nursing Process 409
 Assessment 409
 Nursing Diagnosis 412
 Planning and Outcome Identification 412
 Implementation 414
 Evaluation 415

UNIT 5

Responding to Basic Psychosocial Needs / 421

CHAPTER 22

SELF-CONCEPT / 423

Components of Self-Concept 424
 Identity 424
 Body Image 424
 Self-Esteem 425
 Role Performance 425
Development of Self-Concept 425
 Childhood 426
 Adolescence 426
 Adulthood 427
Factors Affecting Self-Concept 427
 Altered Health Status 427
 Developmental Transitions 428
 Experience 429
Nursing Process and Self-Concept 429
 Assessment 429
 Diagnosis 430
 Outcome Identification and Planning 430
 Implementation 431
 Evaluation 433

CHAPTER 23

STRESS, ANXIETY, ADAPTATION, AND CHANGE / 439

Stress, Anxiety, and Adaptation 440
 Sources of Stress 440
Responses to Stress 440
 Physiological Response 440
 Manifestations of Stress 441
 Outcomes of Stress 441
Stress and Illness 444
 Impact of Illness and Treatment 445
Stress and Change 446
 Types of Change 447
 Theories of Change 447
 Resistance to Change 448
 Changing Paradigms 448
 Nurse as Change Agent 449
Assessment 449
Nursing Diagnosis 450
Outcome Identification and Planning 450
Implementation 450
 Meeting Basic Needs 450
 Environmental Strategies 450
 Verbalization 450
 Involvement of Family and Significant Others 452
 Stress Management 452
 Crisis Intervention 454

Evaluation 455
Personal Stress Management Approaches for the Nurse 456
 Nursing Burnout 456

CHAPTER 24
SPIRITUALITY / 463

Spirituality Defined 464
Nursing Process and Spirituality 465
 Assessment 465
 Diagnosis 469
 Planning and Outcome Identification 469
 Implementation 470
 Evaluation 471

CHAPTER 25
LOSS AND GRIEF / 475

Loss 476
 Loss as Crisis 476
 Types of Loss 476
Grief 477
 Theories of the Grieving Process 477
 Types of Grief 478
 Factors Affecting Grief 480
 Nursing Care of the Grieving Person 484
Death 487
 Stages of Death and Dying 487
 Ethical Implications 488
 Assessment 488
 Diagnosis 488
 Outcome Identification and Planning 488
 Implementation 488
Care after Death 493
 Care of the Body 493
 Legal Aspects 493
 Care of the Family 495
Nurse’s Self-Care 495

Race 507
 Lifestyle 507
 Environment 507
 Medications 507
 Pain 508
 Other Factors 508
Measuring Vital Signs 509
 Equipment 509
 Measurement of Height and Weight 509
The Nursing Process and Vital Signs 513
 Nursing Process and Thermoregulation 513
 Pulse 517
 Respirations 519
 Blood Pressure 520

CHAPTER 27
PHYSICAL ASSESSMENT / 539

Purposes of Physical Examination 540
 Preparation for Physical Examination 540
 General Survey 542
 Assessment Techniques 544
 Integument 545
 Head and Neck 546
 Thorax and Lungs 567
 Heart and Vascular System 572
 Breasts and Axillae 576
 Abdomen 581
 Musculoskeletal System 584
 Neurologic System 586
Reproductive System 590
 Female Genitalia 590
 Male Genitalia 593
Anus and Rectum 595
 Postassessment Care of the Client 597
 Data Documentation 597

CHAPTER 28
DIAGNOSTIC TESTING / 601

Overview of Noninvasive and Invasive Diagnostic Testing 603
 Nursing Care of the Client 603
Laboratory Tests 608
 Specimen Collection 609
 Hematologic System 613
 Type and Crossmatch 616
 Blood Chemistry 617
 Urine Analysis 624
 Stool Analysis 625
 Culture and Sensitivity Tests 628
 Papanicolaou Test 628
Radiologic Studies 628
 Contrast-Mediated Studies 629
 Plain Films 629
 Risks of Exposure to Radiation 630

UNIT 6

Responding to Basic Physiological Needs / 499

CHAPTER 26
VITAL SIGNS / 501

Vital Signs 502
 Physiological Function 502
Factors Influencing Vital Signs 506
 Age 506
 Gender 507
 Heredity 507

Mammography 630
 Angiography Studies 630
Ultrasonography 630
 Echocardiograms 630
 Doppler Ultrasonography 631
Nonnuclear Scan Studies 631
 Computed Tomography 631
Magnetic Resonance Imaging 632
Radioactive Studies 632
Electrodiagnostic Studies 633
 Electrocardiography 633
 Electroencephalography 633
Endoscopy 634
Aspiration and Biopsy 634
 Amniocentesis 634
 Bone Marrow Aspiration and Biopsy 634
 Paracentesis 636
 Thoracentesis 636
 Cerebrospinal Fluid Aspiration 637

CHAPTER 29
SAFETY, INFECTION CONTROL, AND
HYGIENE / 653

Creating a Culture of Client Safety 654
 Factors Affecting Safety 655
 Types of Accidents 657
 Potential Occupational Hazards 657
Infection Control Principles 658
 Pathogens, Infection, and Colonization 658
 Chain of Infection 659
 Normal Defense Mechanisms 660
 Stages of the Infectious Process 662
 Emerging Infections 662
 Health Care–Associated Infections 663
Hygiene 664
 Factors Influencing Hygienic Practice 664
Assessment 665
 Health History 665
 Physical Examination 666
 Diagnostic and Laboratory Data 667
Nursing Diagnosis 668
 Risk for Injury 668
 Risk for Infection 670
 Self-Care Deficits 670
 Other Nursing Diagnoses 670
Outcome Identification and Planning 671
Implementation 671
 Raise Safety Awareness and Knowledge 671
 Prevent Falls 671
 Prevent Fire 678
 Ensure Safe Operation of Electrical Equipment 678
 Reduce Exposure to Radiation 678
 Prevent Poisoning 679
 Reduce Noise Pollution 679
 Ensure Asepsis 679

Reduce or Eliminate Infectious Agents 681
 Practice Standard and Isolation Precautions 683
 Complementary and Alternative Therapies 687
 Provide for Client Bathing Needs 688
 Provide Clean Bed Linens 689
 Provide Skin Care 689
 Provide Foot and Nail Care 690
 Provide Oral Care 690
 Provide Hair Care 691
 Provide Eye, Ear, and Nose Care 692
Evaluation 694

CHAPTER 30
MEDICATION ADMINISTRATION / 749

Drug Standards and Legislation 750
 Standards 750
 Federal Legislation 751
 State and Local Legislation 751
 Health Care Institution Regulations 751
Pharmacokinetics 751
 Absorption 752
 Distribution 752
 Metabolism 753
 Excretion 753
Drug Nomenclature 753
Drug Action 753
 Pharmacology 753
 Drug Interaction 756
 Side Effects and Adverse Reactions 756
Factors Influencing Drug Action 757
Professional Roles in Medication
Administration 757
 Types of Medication Orders 758
 Parts of the Drug Order 760
Systems of Weights and Measures 760
 Metric System 760
 Apothecary System 760
 Household System 761
Approximate Dose Equivalents 761
 Converting Units of Weight and Volume 761
 Drug Dose Calculations 762
Safe Drug Administration 763
 Guidelines for Medication Administration 763
 Documentation of Drug Administration 765
 Drug Supply and Storage 765
 Drug Abuse 767
Medication Compliance 768
Legal Aspects of Administering
Medications 768
 Medication Errors 768
 Preventing Medication Errors 769
Assessment 770
 Medical History 770
 Drug History 770
 Biographical Data 772

Cultural Diversity 772
 Lifestyle and Beliefs 772
 Sensory and Cognitive Status 772
 Physical Examination 772
 Diagnostic and Laboratory Data 772
Nursing Diagnosis 773
Planning and Outcome Identification 773
Implementation 773
 Medication Administration: Oral 774
 Medication Administration: Enteral 774
 Medication Administration: Parenteral 775
 Medication Administration: Topical 784
Evaluation 788

CHAPTER 31
COMPLEMENTARY AND ALTERNATIVE
MODALITIES / 833

Historical Influences on Contemporary
Practices 834
 From Ancient Tradition to Early Science 834
 Shamanistic Tradition 835
Allopathic Medicine 836
Contemporary Trends 836
 Mind-Body Medicine and Research 837
Holism and Nursing Practice 837
 The Nature of Healing 837
Complementary and Alternative
Interventions 837
 Mind-Body: Self-Regulatory Techniques 837
 Body-Movement: Manipulation Strategies 839
 Energetic-Touch Healing 840
 Spiritual Therapies 845
 Nutritional Therapies 846
 Other CAM Methodologies 848
Nursing and Complementary/Alternative
Approaches 852
 Nurse as Instrument of Healing 852

CHAPTER 32
OXYGENATION / 859

Physiology of Oxygenation 860
 Ventilation 860
 Alveolar Gas Exchange 861
 Oxygen Transport and Delivery 862
 Cellular Respiration 865
Factors Affecting Oxygenation 865
 Age 865
 Environmental and Lifestyle Factors 865
 Disease Processes 865
 Physiological Responses to Reduced
 Oxygenation 869
Assessment 869
 Health History 869

Physical Examination 870
 Diagnostic and Laboratory Data 871
Nursing Diagnosis 872
 Ineffective Airway Clearance 872
 Ineffective Breathing Patterns 872
 Impaired Gas Exchange 873
 Decreased Cardiac Output 874
 Ineffective Tissue Perfusion 875
 Other Nursing Diagnoses 875
Planning and Outcomes 876
 Collaboration 876
Implementation 876
 Interventions to Promote Airway Clearance 876
 Interventions to Improve Breathing Patterns 879
 Interventions to Improve Oxygen Uptake
 and Delivery 880
 Interventions to Increase Cardiac Output and Tissue
 Perfusion 881
 Emergency Interventions 882
 Interventions to Address Associated Nursing
 Diagnoses 883
 Complementary Therapies 884
Evaluation 887

CHAPTER 33
FLUIDS AND ELECTROLYTES / 919

Physiology of Fluid and Acid-Base Balance 920
 Fluid Compartments 920
 Body Water Distribution 921
 Electrolytes 921
 Movement of Body Fluids 921
 Regulators of Fluid Balance 921
 Acid-Base Balance 923
 Regulators of Acid-Base Balance 925
Factors Affecting Fluid and Electrolyte
Balance 926
 Age 926
 Lifestyle 926
Disturbances in Electrolyte and Acid-Base
Balance 926
 Electrolyte Disturbances 926
 Acid-Base Disturbances 934
Assessment 937
 Health History 938
 Physical Examination 938
 Diagnostic and Laboratory Data 939
Nursing Diagnosis 941
 Excess Fluid Volume 941
 Deficient Fluid Volume 941
 Risk for Deficient Fluid Volume 942
 Other Nursing Diagnoses 942
Planning and Outcomes 942
 Collaboration 943
Implementation 943
 Monitor Daily Weight 943
 Measure Vital Signs 943

Measure Intake and Output 943
 Provide Oral Hygiene 944
 Initiate Oral Fluid Therapy 944
 Maintain Tube Feeding 945
 Monitor Intravenous Therapy 945
 Managing IV Therapy 954
Complementary and Alternative Therapy 958
Evaluation 958

CHAPTER 34
NUTRITION / 993

Physiology of Nutrition 994
 Digestion 994
 Absorption 996
 Metabolism 996
 Energy 997
 Excretion 997
Nutrients 997
 Water 997
 Vitamins 997
 Minerals 998
 Carbohydrates 1000
 Proteins 1000
 Lipids 1002
Promoting Proper Nutrition 1003
 Dietary Reference Intakes and Recommended
 Daily Allowances 1003
 The Food Guide Pyramid 1004
 Societal Concerns 1004
 Weight Management 1006
Factors Affecting Nutrition 1006
 Age 1006
 Lifestyle 1007
 Ethnicity, Culture, and Religious Practices 1008
 Other Factors 1009
Assessment 1009
 Nutritional History 1009
 Physical Examination 1009
 Diagnostic and Laboratory Data 1013
Nursing Diagnosis 1014
 Imbalanced Nutrition: Less Than Body
 Requirements 1014
 Imbalanced Nutrition: More Than Body Requirements
 or Risk for Imbalanced Nutrition: More Than Body
 Requirements 1014
 Other Nursing Diagnoses 1015
Planning and Outcome Identification 1015
 Collaboration 1015
Implementation 1016
 Monitoring Weight and Intake 1016
 Initiating Diet Therapy 1016
 Assistance with Feeding 1016
 Providing Nutrition Support 1016
 Enteral Tube Feeding 1018
 Parenteral Nutrition 1021

Administering Medication through
 a Feeding Tube 1023
 Complementary and Alternative Therapy 1023
Evaluation 1026

CHAPTER 35
COMFORT AND SLEEP / 1043

Pain 1044
 Nature of Pain 1044
 Physiology of Pain 1046
 Factors Affecting the Pain Experience 1050
 Assessment 1050
 Nursing Diagnosis 1054
 Planning and Outcomes 1055
 Implementation 1055
 Evaluation 1068
Rest and Sleep 1069
 Physiology of Rest and Sleep 1070
 Biological Clock 1073
 Factors Affecting Rest and Sleep 1074
 Illness or Hospitalization 1075
 Alteration in Sleep Patterns 1075
 Assessment 1076
 Nursing Diagnosis 1076
 Planning and Outcomes 1076
 Implementation 1077
 Evaluation 1080

CHAPTER 36
MOBILITY / 1087

Overview of Mobility 1088
 Body Alignment 1088
 Body Mechanics 1090
Physiology of Mobility 1090
 Musculoskeletal System 1090
 Neurological System 1090
Exercise 1091
 Types of Exercise 1092
 Physical Fitness 1097
Factors Affecting Mobility 1098
 Health Status 1098
 Developmental Stage 1098
 Environment 1099
 Attitudes and Beliefs 1099
 Lifestyle 1099
**Physiological Effects of Mobility
 and Immobility** 1100
 Neurological Effects and Mental Status 1100
 Cardiovascular Effects 1100
 Respiratory Effects 1101
 Musculoskeletal Effects 1101
 Digestive Effects 1101
 Elimination Effects 1102
 Integumentary Effects 1102

Assessment 1102
 Health History 1102
 Physical Examination 1102
 Neurological Assessment 1105
Nursing Diagnosis 1106
Planning and Outcome Identification 1107
 Collaboration 1108
 Bed Rest 1108
 Restorative Nursing Care 1108
 Health Promotion and Fitness 1109
Implementation 1109
 Meeting Psychosocial Needs 1109
 Applying Principles of Body Mechanics 1110
 Maintaining Body Alignment: Positioning 1110
 Performing Range-of-Motion Exercises 1115
 Transfer Techniques 1115
 Assisting with Ambulation 1118
 Wellness Promotion 1124
 Complementary and Alternative Treatment Modalities 1124
Evaluation 1124

CHAPTER 37
SKIN INTEGRITY AND WOUND HEALING / 1161

Wounds 1162
 Physiology of Wound Healing 1162
 Factors Affecting Wound Healing 1164
 Wound Classification 1165
 Assessment 1166
 Nursing Diagnoses 1169
 Planning and Outcomes 1170
 Implementation 1170
 Evaluation 1178
Pressure Ulcers 1178
 Physiology of Pressure Ulcers 1180
 Risk Factors for Pressure Ulcers 1181
 Assessment 1181
 Nursing Diagnoses 1181
 Planning and Outcomes 1181
 Implementation 1184
 Evaluation 1191

CHAPTER 38
SENSATION, PERCEPTION, AND COGNITION / 1207

Physiology of Sensation, Perception, and Cognition 1208
 Components of Sensation and Perception 1211
 Components of Cognition 1211
Factors Affecting Sensation, Perception, and Cognition 1212
 Age 1212

Environment 1213
 Lifestyle 1213
Sensory, Perceptual, and Cognitive Alterations 1213
 Sensory Deficits 1214
 Sensory Deprivation 1214
 Sensory Overload 1215
Assessment 1215
 Health History 1216
 Physical Examination 1216
 Mental Status Assessment 1216
 Functional Abilities 1217
 Environment 1218
Diagnosis 1219
Planning and Outcome Identification 1219
Implementation 1219
 Managing Sensory Deficits 1221
 Managing Sensory Deprivation 1222
 Managing Sensory Overload 1222
 Caring for the Unconscious Client 1223
 Use of Restraints 1224
 Complementary and Alternative Therapies 1224
Evaluation 1224

CHAPTER 39
ELIMINATION / 1231

Physiology of Elimination 1232
 Urinary Elimination 1232
 Bowel Elimination 1234
Factors Affecting Elimination 1235
 Age 1235
 Diet 1235
 Exercise 1236
 Medications 1236
Common Alterations in Elimination 1236
 Urinary Elimination 1236
 Bowel Elimination 1228
Assessment 1240
 Health History 1240
 Physical Examination 1242
 Diagnostic and Laboratory Data 1243
Nursing Diagnosis 1244
 Impaired Urinary Elimination 1244
 Stress Urinary Incontinence 1244
 Reflex Urinary Incontinence 1244
 Urge Urinary Incontinence 1244
 Functional Urinary Incontinence 1245
 Total Urinary Incontinence 1245
 Urinary Retention 1245
 Constipation 1245
 Perceived Constipation 1245
 Diarrhea 1245
 Bowel Incontinence 1245
 Other Diagnoses 1245
Planning and Outcomes 1245

Implementation 1246
 Maintain Elimination Health 1246
 Initiate Exercise Regimen 1248
 Suggest Environmental Modifications 1249
 Initiate Behavioral Interventions 1249
 Monitor Skin Integrity 1250
 Apply a Containment Device 1250
 Initiate Diet and Fluid Therapy 1251
 Administer Medications 1252
 Perform Catheterization 1252
 Administer Enemas 1253
 Initiate Rectal Stimulation 1254
 Monitor Elimination Diversions 1254
 Monitor Surgical Management 1255
 Complementary and Alternative Therapies 1256
Evaluation 1258

CHAPTER 40
NURSING CARE OF THE PERIOPERATIVE
CLIENT / 1295

Surgical Interventions 1296
Setting 1296
Client Safety 1297
Anesthesia 1298
 General Anesthesia 1298
 Regional Anesthesia 1299
 Local Anesthesia 1300

Preoperative Phase 1300
 Assessment 1300
 Diagnosis 1303
 Planning and Outcomes 1305
 Implementation 1307
 Evaluation 1316
Intraoperative Phase 1316
 Surgical Environment 1316
 Assessment 1317
 Nursing Diagnoses 1317
 Planning and Outcomes 1317
 Interventions 1318
 Evaluation 1321
 Transfer to Postanesthesia Care Unit 1321
Postoperative Phase 1321
 Assessment 1321
 Nursing Diagnosis 1323
 Planning and Outcomes 1323
 Interventions 1324
 Evaluation and Discharge from the PACU 1326
 Ongoing Postoperative Care 1326
 Evaluation 1327

Glossary 1337
References 1363
Index 1383

LIST OF PROCEDURES

- Procedure 26-1: Measuring Body Temperature / 524
- Procedure 26-2: Assessing Pulse Rate / 529
- Procedure 26-3: Assessing Respiration / 531
- Procedure 26-4: Assessing Blood Pressure / 533

- Procedure 28-1: Performing Venipuncture / 638
- Procedure 28-2: Performing a Skin Puncture / 641
- Procedure 28-3: Obtaining a Residual Urine Specimen from an Indwelling Catheter / 644
- Procedure 28-4: Collecting a Clean-Catch Midstream Urine Specimen / 645
- Procedure 28-5: Measuring Blood Glucose Levels / 648

- Procedure 29-1: Applying Restraints / 695
- Procedure 29-2: Handwashing: Visibly Soiled Hands / 699
- Procedure 29-3: Applying Sterile Gloves via the Open Method / 701
- Procedure 29-4: Donning and Removing Clean and Contaminated Gloves, Cap, and Mask / 705
- Procedure 29-5: Surgical Hand Antisepsis / 710
- Procedure 29-6: Applying Sterile Gloves and Gown via the Closed Method / 713
- Procedure 29-7: Removing Contaminated Items / 716
- Procedure 29-8: Bathing a Client in Bed / 720
- Procedure 29-9: Changing Linens in an Unoccupied Bed / 724
- Procedure 29-10: Changing Linens in an Occupied Bed / 728
- Procedure 29-11: Perineal and Genital Care / 732
- Procedure 29-12: Oral Care / 735
- Procedure 29-13: Eye Care / 741

- Procedure 30-1: Medication Administration: Oral, Sublingual, and Buccal / 789
- Procedure 30-2: Withdrawing Medication from an Ampule / 793
- Procedure 30-3: Withdrawing Medication from a Vial / 796
- Procedure 30-4: Mixing Medications from Two Vials into One Syringe / 799
- Procedure 30-5: Medication Administration: Intradermal / 802

- Procedure 30-6: Medication Administration: Subcutaneous / 804
- Procedure 30-7: Medication Administration: Intramuscular / 807
- Procedure 30-8: Medication Administration via Secondary Administration Sets (Piggyback) / 809
- Procedure 30-9: Medication Administration: Eye and Ear / 812
- Procedure 30-10: Medication Administration: Nasal / 817
- Procedure 30-11: Medication Administration: Nebulizer / 820
- Procedure 30-12: Medication Administration: Rectal / 823
- Procedure 30-13: Medication Administration: Vaginal / 826
- Procedure 31-1: Administering Therapeutic Massage / 854
- Procedure 32-1: Maintaining and Cleaning the Tracheostomy Tube / 887
- Procedure 32-2: Performing Nasopharyngeal and Oropharyngeal Suctioning / 890
- Procedure 32-3: Suctioning Endotracheal and Tracheal Tubes / 894
- Procedure 32-4: Administering Oxygen Therapy / 897
- Procedure 32-5: Performing the Heimlich Maneuver / 902
- Procedure 32-6: Administering Cardiopulmonary Resuscitation (CPR) / 907
- Procedure 33-1: Measuring Intake and Output / 962
- Procedure 33-2: Preparing an IV Solution / 964
- Procedure 33-3: Preparing the IV Bag and Tubing / 967
- Procedure 33-4: Assessing and Maintaining an IV Insertion Site / 970
- Procedure 33-5: Changing the IV Solution / 971
- Procedure 33-6: Flushing a Central Venous Catheter / 975
- Procedure 33-7: Setting the IV Flow Rate / 976
- Procedure 33-8: Changing the Central Venous Dressing / 980
- Procedure 33-9: Discontinuing the IV and Changing to a Saline or Heparin Lock / 983
- Procedure 33-10: Administering a Blood Transfusion / 986
- Procedure 34-1: Inserting a Nasogastric or Nasointestinal Tube for Suction and Enteral Feedings / 1031
- Procedure 34-2: Administering Enteral Tube Feedings / 1036
- Procedure 35-1: Administering Patient-Controlled Analgesia (PCA) / 1080
- Procedure 36-1: Body Mechanics, Lifting, and Transferring / 1127
- Procedure 36-2: Administering Passive Range-of-Motion (ROM) Exercises / 1129
- Procedure 36-3: Turning and Positioning a Client / 1134
- Procedure 36-4: Moving a Client in Bed / 1138
- Procedure 36-5: Assisting from Bed to Wheelchair, Commode, or Chair / 1140
- Procedure 36-6: Assisting from Bed to Stretcher / 1143
- Procedure 36-7: Using a Hydraulic Lift / 1145
- Procedure 36-8: Assisting with Ambulation and Safe Walking / 1148
- Procedure 36-9: Assisting with Crutches, Cane, or Walker / 1151
- Procedure 37-1: Irrigating a Wound / 1191
- Procedure 37-2: Obtaining a Wound Drainage Specimen for Culturing / 1193
- Procedure 37-3: Applying a Dry Dressing / 1195
- Procedure 37-4: Applying a Wet-to-Damp Dressing (Wet-to-Moist Dressing) / 1198
- Procedure 37-5: Preventing and Managing the Pressure Ulcer / 1201
- Procedure 39-1: Assisting with a Bedpan or Urinal / 1259
- Procedure 39-2: Applying a Condom Catheter / 1261
- Procedure 39-3: Inserting an Indwelling Catheter: Male / 1264

- Procedure 39-4: Inserting an Indwelling Catheter: Female / 1268
- Procedure 39-5: Irrigating an Open Urinary Catheter / 1273
- Procedure 39-6: Irrigating the Bladder Using a Closed-System Catheter / 1276
- Procedure 39-7: Administering an Enema / 1280
- Procedure 39-8: Irrigating and Cleaning a Stoma / 1286
- Procedure 39-9: Changing a Colostomy Pouch / 1289
- Procedure 40-1: Postoperative Exercise Instruction / 1328
- Procedure 40-2: Administering Pulse Oximetry / 1332

CONTRIBUTORS

Sheila L. Allen, BSN, RN, CNOR, CRNFA

Executive Board Member
International Federation of Perioperative Nurses
President
Association of Operating Room Nurses
Nashville, Tennessee

Carma Andrus, MN, RN, CNS

Dauterive Primary Care Clinic
St. Martinville, Louisiana

Billie Barringer, RN, CS, APRN

School of Nursing
Northeast Louisiana University
Monroe, Louisiana

Barbara Bihm, DNS, RN

Associate Professor of Nursing
Loyola University
New Orleans, Louisiana

Barbara Brillhart, PhD, RN, CRRN, FNP-C

College of Nursing
Arizona State University
Tempe, Arizona

Ali Brown, MSN, RN

Assistant Professor
College of Nursing
University of Tennessee
Knoxville, Tennessee

Virginia Burggraf, MSN, RN

Gerontological Nurse Consultant
Kensington, Maryland

Ann H. Cary, PhD, MPH, RN, A-CCC

Director, School of Nursing
Loyola University
New Orleans, Louisiana

Lissa A. Cash, MSN, RN, CCRN, CEN

Sentara Healthcare CU
Norfolk, Virginia

Beth Christensen, MN, RN, CCRN

Touro Infirmary
New Orleans, Louisiana

Jan Corder, DNS, RN

Dean, School of Nursing
Northeast Louisiana University
Monroe, Louisiana

Pain Consultation Service
The Children's Hospital
Denver, Colorado

Mary Ellen Zator Estes, MSN, RN, CCRN

Assistant Professor
School of Nursing
Marymount University
Arlington, Virginia

Mary Frost, MS, RN, HNC, CHTP/I, CHT

Healing Touch Practitioner and Instructor
Covington, Louisiana

Norma Fujise, MS, RN, C

School of Nursing
University of Hawaii
Honolulu, Hawaii

Mikel Gray, PhD, FNP-BC, PNP-BC, CUNP, CCCN, FAANP, FAAN

Clinical Professor
University of Virginia School of Nursing
Charlottesville, Virginia

Janet Kula Harden, MSN, RN

Faculty
Wayne State University College of Nursing
Detroit, Michigan

T. Heather Herdman, PhD, RN

Executive Director
North American Nursing Diagnosis Association International

Lucille Joel, EdD, RN, FAAN

Professor
College of Nursing
Rutgers—State University of New Jersey
Newark, New Jersey

Georgia Johnson, MS, RN, CNAA, CPHQ

Director of Nursing
Southeast Louisiana Hospital
Mandeville, Louisiana

Claire Lincoln, MN, RN, CS

West Jefferson Mental Health Clinic
Marrero, Louisiana

Tina M. Liske, MSN, RN, CCRN, CNS, NP

SCCM, National AACN, Local AACN
Smithfield, Virginia

JoAnna Magee, MN, RN, FNP

Metairie, Louisiana

Judy Martin, MS, JD, RN

Nurse Attorney
Louisiana Department of Health and Hospitals
Health Standards Section
Baton Rouge, Louisiana

Linda McCuiston, PhD, RN

Assistant Professor
School of Nursing
Our Lady of Holy Cross College
New Orleans, Louisiana

Elizabeth “Betty” Hauck Miller, MPH, BSN, RN

Director of Education
Ochsner Hospital, Westbank
Gretna, Louisiana

Mary Anne Modrcin, PhD, RN

Dean and Professor
Caylor School of Nursing
Lincoln Memorial University
Knoxville, Tennessee

Barbara S. Moffett, PhD, RN

Director
School of Nursing
Southeastern Louisiana University
Hammond, Louisiana

Barbara Morvant, MN, RN

Executive Director
Louisiana State Board of Nursing
Baton Rouge, Louisiana

Cathy O’Byrne, MN, RN

PREFACE

We are very excited to share the fourth edition of *Fundamentals of Nursing: Standards and Practice* with you! It is hoped that this text will encourage the student to develop an inquiring stance based on the joy of discovery and a love of learning.

Nursing is facing new challenges in delivering quality care to clients in a variety of settings. The settings for delivery of care are rapidly expanding and challenge nurses to think outside the box in applying best practices based on current research. This edition presents the most current advances in nursing care, nursing education, and research relative to the demands of delivering care across a continuum of settings. Multiple theories of nursing are embraced, and nursing's meta-paradigm elements of theory—human beings, environment, health, and nursing—are threaded throughout this text. The organization of units and chapters is sequential; however, every effort has been made to allow for varying needs of diverse curricula and students. Each chapter may be used independently of the others according to the specific curriculum design.

This comprehensive edition addresses fundamental concepts and skills to help prepare novice graduate nurses to apply an understanding of human behavior to issues encountered in clinical settings. Physiological and psychosocial responses of both client and nurse are addressed in a holistic manner. Integrative modalities are presented in an environment that encourages clients to participate in determining their care.

Up-to-date clinical information is based on sound theoretical concepts and provides a rationale for practice. Scientific evidence is applied to the implementation of nursing interventions.

CONCEPTUAL APPROACH

This edition presents in-depth material in a clear, concise manner using language that is easy to read, by linking related concepts. Nursing knowledge is formulated on the basic

concepts of scientific and discipline-specific theory, health and health promotion, the environment, holism, client teaching, spirituality, research and evidence-based practice, and the continuum of care. Emphasis is placed on cultural diversity, care of the older adult, and ethical and legal principles.

The nursing process provides a consistent approach for presenting information. Assessment tools specific to selected topics are presented to assist students with pertinent data collection. Therapeutic nursing interventions reflect standards of practice and emphasize safety, communication skills, interdisciplinary collaboration, and effective delegation in delivering nursing care. Critical thinking and reflective reasoning skills are integrated throughout the text. The safe and appropriate use of technology has been incorporated throughout the text to reflect contemporary nursing practice.

The conceptual approach used as an organizational framework for the fourth edition falls into four categories:

- **Individuals:** Viewed as holistic beings with multiple needs and strengths and the abilities to meet those needs. Holism implies that individuals are treated as whole entities rather than fragmented parts or problems. Each person is a complex entity who is influenced by cultural values, including spiritual beliefs and practices. Every person has the right to be treated with dignity and respect regardless of race, ethnicity, age, religion, socioeconomic status, or health status.
- **Environment:** A complex interrelationship of internal and external variables. Internal variables include one's self-concept, self-efficacy, cognitive development, and psychological traits. The external environment affects an individual's health status by facilitating or hindering the person's achievement of needs.
- **Health:** Viewed as a dynamic force that occurs on a continuum ranging from wellness to death. An individual's actions and choices affect changes in health status. Individuals who are experiencing illness have strengths that

may improve their health status. On the other hand, individuals who are experiencing a high degree of health generally have areas that can be improved.

- **Nursing:** An active, interpersonal, professional practice that seeks to improve the health status of individuals. Nursing's focus is person-centered and communicates a caring intent. Caring and compassion are demonstrated through nursing interventions. Nursing is a professional practice based on scientific knowledge and delivered in an artful manner.

Other important conceptual threads used to direct the development of this book include the following:

- **Health promotion** encourages individuals to engage in behaviors and lifestyles that facilitate wellness.
- **Standards of practice** are discussed, with information from national and specialty organizations incorporated into each chapter as appropriate.
- **Critical thinking** is an essential skill for blending science with the art of nursing.
- **Evidence-based practice**, which is derived from scientific research, is emphasized across chapters.
- **Cultural diversity** is defined as individual differences among people resulting from racial, ethnic, and cultural variables.
- **Continuum of care** is viewed as a process for providing health care services in order to ensure consistent care across practice settings.
- **Community**, as both an aggregate client and as the setting for delivery of care, is evidenced in Chapter 17 and in the Community Considerations critical thinking boxes threaded throughout the text.
- **Holism** recognizes the bodymind connection and views the client as a whole person rather than fragmented parts.
- **Spirituality**—one's relationship with one's self, a sense of connection with others, and a relationship with a higher power or divine source—is discussed in depth in Chapter 24.
- **Caring**, a universal value that directs nursing practice, is incorporated throughout the text, as well as described in depth in a separate chapter.
- **Alternative and complementary modalities** are treatment approaches that can be used in conjunction with conventional medical therapies. Chapter 31 is dedicated to this integrative approach, and related information featuring integrative concepts is included throughout the text.

ORGANIZATION OF TEXT

This textbook provides student nurses with a bridge that connects theory with clinical practice. The intent of the authors is to help students become proficient critical thinkers who are able to use the nursing process with diverse clients in a variety of settings. Research-based knowledge and clinical skills that reflect contemporary practice are presented in a reader-friendly, practical manner.

Features that challenge students to use critical thinking skills are incorporated into each chapter, and critical thinking questions appear at the end of each chapter. Critical informa-

tion is highlighted throughout the text in a format that is easily accessed and understood. Similar concepts have been grouped together to encourage students to learn through association; this method of presentation also prevents duplication of content.

Fundamentals of Nursing: Standards and Practice, Fourth Edition, presents 40 chapters organized in six units:

- **Unit 1: Nursing's Perspective: Past, Present, and Future** provides a comprehensive discussion of nursing's evolution as a profession and its contributions to health care based on standards of practice. The theoretical frameworks for guiding professional practice and the significance of incorporating research into nursing practice are emphasized. Chapters are reflective of the parallel evolution of nursing and nursing education. Examples showing the incorporation of theory into the nursing process are provided. The concept of evidence-based practice is emphasized along with research utilization. Quality is discussed from the perspective of health care delivery and the continuum of care.
- **Unit 2: Nursing Process: The Standard of Care** discusses standards of care established by the American Nurses Association as well as nursing specialty organizations. Each stage of the nursing process is discussed with an emphasis on critical thinking.
- **Unit 3: Professional Accountability** describes the nurse's responsibilities to the client, the community, and the profession. The legal aspects of delegation are discussed in Chapter 11, and "Delegation Tips" are incorporated into each clinical procedure. Chapter 12 combines legal and ethical aspects of nursing practice to reflect the interfacing of these concepts. An in-depth discussion of informatics has been added to Chapter 13 on documentation.
- **Unit 4: Promoting Client Health** was created to integrate information on health promotion, consumer demand, and client empowerment. Chapter 14 provides nursing theoretical perspectives on caring. Chapter 16 emphasizes the nurse's role in empowering clients to assume more personal accountability for their health-related behaviors. Chapter 17 addresses the health needs of families and communities.
- **Unit 5: Responding to Basic Psychosocial Needs** stresses the importance of the holistic nature of nursing. Spirituality is spotlighted in order to emphasize its impact on individuals' health.
- **Unit 6: Responding to Basic Physiological Needs** discusses aspects of nursing care that are common to every area of nursing practice. Concepts such as safety and infection control, mobility, fluid and electrolyte balance, skin integrity, nutrition, and elimination are described within the nursing process framework.

NEW TO THIS EDITION

- Chapter 13, Documentation and Informatics, has an expanded discussion of the history and impact of technology on nursing practice.

- Free StudyWARE™ CD—with 3-D animations, NCLEX-style chapter quizzes, heart and lung sounds, and a medical terminology audio library—is included.
- NCLEX-style review questions have been added at the end of every chapter. Answers and rationales are located in the instructor's manual.
- Spotlight On is a new feature that focuses attention on issues relating to the caring, compassion, legal, ethical, and professional components of nursing practice.
- Safety First identifies critical health and safety situations and highlights strategies for the appropriate nursing response and management.
- Uncovering the Evidence emphasizes the importance of clinical research by linking theory to practice.
- Respecting Our Differences challenges the student to consider approaches to respectful and appropriate care for clients who may differ in a variety of ways including culture, gender, age, and developmental level.
- Evidence-based practice is highlighted across chapters as appropriate.

EXTENSIVE TEACHING/ LEARNING PACKAGE

The complete supplements package was developed to achieve two goals:

1. To assist students in learning the essential skills and competencies needed to secure a career in the area of nursing
2. To assist instructors in planning and implementing their programs for the most efficient use of time and other resources

ONLINE COMPANION

Delmar offers a series of Online Companions™ through the Delmar Web site: www.delmarlearning.com/companions/index.asp?isbn=1401859186. The DeLaune/Ladner Online Companion enables users of *Fundamentals of Nursing: Standards and Practice*, Fourth Edition, to access a wealth of information designed to enhance the book. Included in the Online Companion are:

- Healthy People 2020 Guidelines
- Appendices, Educational Resources for Caregivers, and Recommended Dietary Allowances
- Concept maps
- HIPAA information

To access the site for *Fundamentals of Nursing: Standards and Practice*, Fourth Edition, simply point your browser to www.delmar.cengage.com. Click on Online Companions, and then select the nursing discipline.

STUDY GUIDE

ISBN 10: 1-4354-8068-6

ISBN 13: 978-1-4354-8068-6

Containing 500 sample questions in an easy-to-use format, this study aid builds on and reinforces the content presented

in the text. Students have an avenue to learn key concepts at a pace that is comfortable for them. Features include:

- Discussion Questions and Critical Thinking Challenges added to every chapter
- Various levels of difficulty
- Questions built upon the key concepts on a chapter-by-chapter basis

SKILLS CHECKLIST

ISBN 10: 1-4354-8069-4

ISBN 13: 978-1-4354-8069-8

This teaching/learning tool contains key steps for every procedure in *Fundamentals of Nursing: Standards and Practice*, Fourth Edition, by Sue C. DeLaune and Patricia K. Ladner. These checklists may be used to help students evaluate their comprehension and execution of the procedures. Key features include:

- Three categories to document performance: able to perform, able to perform with assistance, and unable to perform
- Comments section at each step for constructive feedback
- Easy-to-follow format

INSTRUCTOR RESOURCES

ISBN 10: 1-4354-8070-8

ISBN 13: 978-1-4354-8070-4

Free to all instructors who adopt *Fundamentals of Nursing: Standards and Practice*, Fourth Edition, in their courses, this comprehensive resource includes the following:

Instructor's Guide

- **Instructional Strategies**—Centered around the competencies at the beginning of each chapter, critical thinking questions, followed by a student activity (group and/or individual), are provided to enhance student comprehension and critical thinking skills.
- **Additional Resource Aids**—Additional audiovisual material, computer software, and Web sites are included to increase student awareness of current issues, trends, and skills.
- **Evaluation Strategies**—Discussion questions are provided for each chapter to enhance student writing and thinking skills.

Computerized Test Bank with Electronic Gradebook

- **Test Bank**—Computerized test bank includes over 1200 questions and reflects an NCLEX style of review, including rationales, cognitive level, and text reference.

PowerPoint Presentation

A vital resource for instructors, the slides created in PowerPoint parallel the content found in the book, serving as a foundation on which instructors may customize their own unique presentations.

Image Library

The Image Library is a software tool that includes an organized digital library of more than 700 illustrations and photographs from the text. With the Image Library you can:

- Create additional libraries
- Set up electronic pointers to actual image files or collections
- Sort art by desired categories
- Print selected pieces

WebTutor Advantage

ISBN 10: 1-4354-8071-6

ISBN 13: 978-1-4354-8071-1

This online resource delivered on Blackboard offers value as a standard component to any fundamentals course. Correlated to the text, the WebTutor Advantage includes quizzes and discussion questions, 3-D animations, concept maps, a glossary, and instructor resources.

HOW TO USE THIS TEXT

The following suggests how you can use the features of this text to gain competence and confidence in your assessment and nursing skills.

CHAPTER 29 Safety, Infection Control, and Hygiene 695

PROCEDURE 29-1 Applying Restraints

EQUIPMENT (See Figures 29-14, 29-15, and 26-16)

- Restraints appropriate to the client's condition and type of restraint required
- Cotton batting or foam padding

FIGURE 29-14 Locking Belt Restraint

FIGURE 29-15 Mitts Restraints

FIGURE 29-16 Jacket Restraint

ACTION

CHEST RESTRAINT

1. Wash hands/hand hygiene.
2. Explain that the client will be wearing a jacket at to the bed. Explain that this is for safety.
3. Place the restraint over the client's hospital gown clothing.
4. Place the restraint on the client with the opening front (see Figure 29-15).
5. Overlap the front pieces, threading the ties through slots/loop on the front of the vest.

PROCEDURES

Procedure boxes are step-by-step guides to performing basic clinical nursing skills. This feature will help you gain competence in nursing skills. Use this feature as a study tool to help you understand the rationale behind the nursing interventions, as a guide for mastery of procedures, and as a review aid for future reference.

1024 UNIT 6 Responding to Basic Physiological Needs

NURSING CARE PLAN

Client with Imbalanced Nutrition: More Than Body Requirements

CASE PRESENTATION

Mr. Jones, age 55, was diagnosed 2 years ago with type 2 (non-insulin-dependent) diabetes. She is being seen in the clinic for her 6-month visit. She says, "I hardly have the energy to get up and dress in the morning. I am thirsty all day and awaken several times during the night, having to go to the bathroom." She does not work and hasn't been involved in community activities for the past 5 years since her youngest child graduated from high school. Her daily routine involves cooking for her husband and brother, reading, and watching TV for 6-8 hours. She loves to bake fresh breads and pastry. She has a history of obesity and does not exercise. She says, "I eat because I have nothing else to do."

ASSESSMENT

- Weight, 80.6 kg
- Height, 5'4"
- Triops skinfold, 28 mm
- Elevated blood glucose
- Weight gain, 3.6 kg
- Sedentary lifestyle
- Eats in response to boredom

NURSING DIAGNOSIS: Imbalanced nutrition: more than body requirements related to excess intake of high-calorie foods, eating in response to boredom, and sedentary lifestyle.

NOC: Motivation, weight control

NIC: Weight management

EXPECTED OUTCOMES

The client will:

1. Verbalize factors contributing to excess weight
2. Lose 1-2 lb/week while eating well-balanced meals
3. Engage in 20-30 minutes of exercise 3 times a week
4. Explore outside interests to decrease boredom and increase feelings of self-worth

INTERVENTIONS/RATIONALES

1. Conduct a dietary history, using open-ended statements to assist client in exploring psychological factors that may contribute to eating. Nonjudgmental approach to acquiring information will encourage client trust and honesty.
2. Adapt eating habits to decrease amount of intake (having smaller servings, taking small bites and chewing each bite 12 times, putting the fork on the plate between bites, drinking water with meals, eating only at mealtimes, chewing sugar-free gum when watching TV). Healthy eating habits and tips on recognizing fullness during a meal will help the client eat to satisfy hunger, not boredom.
3. Assess client's motivation to lose weight. Having client's support for care plan will influence success.
4. Discuss risk factors and symptoms (thirst and urination) of diabetes. Client's understanding of her disease may increase motivation to manage it.
5. Instruct client to maintain a daily dietary intake log: time, type, and amount. Helps client recognize her eating patterns and note healthy and unhealthy behaviors.
6. Provide client with dietary materials: Review the food pyramid and diabetic exchange list; plan with client an 1800-kilocalorie diet for a week, taking into consideration food preferences. Ensures client has information necessary to plan healthy meals within recommended guidelines.

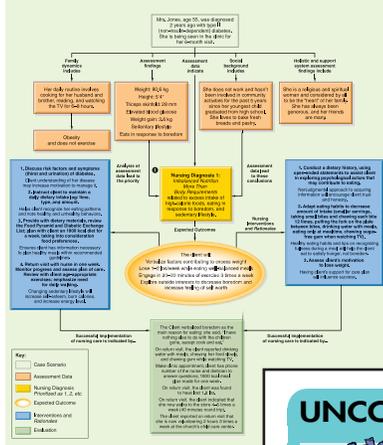

(Continued)

NURSING CARE PLAN

The Nursing Care Plan guides you through the process of planning care, performing interventions, and evaluating the outcomes of your plan of care. These are very helpful in strengthening your understanding of the nursing process in "live" nursing situations, in exercising your critical thinking skills, and for use as a blueprint from which to develop your own complete plans of care.

CONCEPT MAP

THE CLIENT WITH IMBALANCED NUTRITION: MORE THAN BODY REQUIREMENTS

CONCEPT MAPS

Concept maps are used in this edition to visually illustrate five of the nursing care plans included in the text. The mapping process provides the learner with a non-linear option for problem-solving learning.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Patterns of Nursing Intervention Use across 6 Days of Acute Care Hospitalization for Three Older Patient Populations”

AUTHORS

L. L. Shever, M. Titler, J. Dochterman, Q. Fei, and D. M. Picone

PURPOSE

The purpose of this study was twofold: (1) to identify frequently used nursing interventions and (2) to describe patterns of interventions used for each of the three selected groups of clients.

METHODS

This secondary data analysis study used data from a medical center in which the Nursing Interventions Classification (NIC) was used to electronically document nursing care. Statistics were examined to determine the types, frequencies, and patterns of interventions used in providing care to older care recipients.

UNCOVERING THE EVIDENCE BOXES

These boxes emphasize the importance of clinical research in nursing by linking theory to practice. As a learning tool, they focus attention on current issues and trends in nursing.

NURSING CHECKLIST

Critical Thinking

The following questions should be considered by the nurse in the development of a nursing diagnosis:

- Do I have enough data to formulate a nursing diagnosis?
- Are any data missing?
- Is there any information in my database that seems incomplete or uncertain?
- Should I talk to the client and family again?
- What data fit together or have something in common?
- What specific cues from the client made me form this conclusion?
- What elements of this situation, condition, or problem can be enhanced or resolved by therapeutic nursing interventions?
- What elements need to be referred to another discipline (e.g., medicine, social services, dietary)?

NURSING CHECKLIST

Nursing Checklist boxes outline important points for you to consider before, during, and after utilizing the nursing process. Checklists are your reference guide to using critical thinking in nursing and to understanding the steps in the nursing process.

HOW TO USE THIS TEXT (Continued)

SAFETY FIRST

It is absolutely critical to client safety that nursing students verbalize any questions or concerns relative to their assignments before instituting care. Students must ask for directions if unsure of their abilities.

SAFETY FIRST

As a professional, you will need to be able to react immediately in some situations in order to ensure the health and safety of your patients. Pay careful attention to this feature as it will help you to begin to identify and respond to critical situations on your own, both efficiently and effectively.

SPOTLIGHT ON...

Legal

Student Accountability

You are working as a nursing assistant (unlicensed personnel) during your school break. What would be your appropriate response if asked to perform a nursing procedure such as medication administration? Would the fact that you have performed the procedure previously as a nursing student affect your response?

SPOTLIGHT ON

This feature helps you to develop sensitivity to issues about the caring and compassion, legal/ethical, and professional components of nursing practice. You may choose to read through each one and explore the issues before reading the chapter. Then as you read through the chapter, readdress each Spotlight On and reevaluate your original thoughts. If you choose to read them as you go through the chapter, perhaps write your thoughts down, then go back and look at them at a later date.

CLIENT TEACHING CHECKLIST

Actions of Parents to Promote Positive Self-Concept in Children

- Encourage expression of feelings.
- Promote mutual respect and trust by establishing and maintaining open lines of communication
- Demonstrate a willingness to talk about any subject.
- Listen carefully to children, and use words they understand.
- Use examples and anecdotes to promote learning.
- Teach by example. Role-model problem solving and coping skills.
- Encourage children's talents and accept their limitations. Be realistic in your expectations, and avoid comparing one child to another.
- Celebrate children's accomplishments.
- Demonstrate confidence in their abilities.
- Provide children with unconditional love.

CLIENT TEACHING CHECKLIST

As a nurse, you will often be a client's main link to health care. The Client Teaching Checklist is a great resource for ensuring success in teaching exercises and procedures and in relaying critical information to clients.

COMMUNITY CONSIDERATIONS

Belief System

Culturally competent care requires the nurse to work within the client's cultural belief system to resolve health problems. This means that the nurse needs to hear the client and consider the client's world and daily experiences.

COMMUNITY CONSIDERATIONS

Community Considerations spotlight client care in the community environment. Guidelines for care, current trends and issues, and professional protocols are addressed throughout the text.

ACKNOWLEDGMENTS

This textbook is the product of many dedicated, knowledgeable, and conscientious individuals. First, we would like to thank Carol Ren Kneisl for initiating our work on this text. We would like to thank all the contributors who persevered to produce an outstanding contribution to the nursing literature. Your clinical expertise is evident in this final product.

Likewise, we need to thank all the reviewers who critically read and commented on the manuscript. Your clinical and academic expertise provided valuable suggestions that strengthened the text.

Our friends and professional colleagues provided encouragement throughout the development of this manuscript. A special thank you to Paulette Watts, BSN, RN,

CNOR, of Mandeville, Louisiana, who served as a content specialist for Chapter 36, "Mobility." Thank you for sharing so many of your resources and support with us.

Our families deserve recognition for their daily queries relative to the book, which often stimulated humor, easing a sometimes tedious task. Special thanks to the DeLaune family: Jay; Jennifer, Ryan, Camille, and Caroline Cardinal; Katie and Jacob Segrave; and Sarabeth and Jay Accardo. Thanks also to Wayne, Kelly, Wayne Jr., Gretchen, and Michael for demonstrating daily understanding and support when the book had to be given priority.

ABOUT THE AUTHOR

Sue Carter DeLaune earned a bachelor of science in nursing from Northwestern State University, Natchitoches, Louisiana, and a master's degree in nursing from Louisiana State University Medical Center, New Orleans. She has taught nursing in diploma, associate degree, and baccalaureate schools of nursing as well as in RN degree-completion programs. With over 35 years of experience as an educator, clinician, and administrator, Sue has taught fundamentals of nursing, psychiatric-mental health nursing, professionalism, and nursing leadership in a variety of programs. She also presents seminars and workshops across the country that assist nurses to maintain competency in areas of communication, leadership skills, client education, and stress management.

Sue is a member of Sigma Theta Tau, the National League for Nursing, and the American Nurses Association. She has been recognized as one of the “Great 100 Nurses” by the New Orleans District Nurses Association. Sue is a prolific author, having written several professional journal articles and textbook chapters in the areas of nursing education and mental health nursing.

Currently, Sue is an Associate Professor and RN-to-BSN Coordinator at William Carey University School of Nursing, New Orleans. She also is President of SDeLaune Consulting, an independent education consulting business based in Mandeville, Louisiana.

Patricia Ann Kelly Ladner obtained an associate degree in science from Mercy Junior College, St. Louis, Missouri; a bachelor of science in nursing from Marillac College, St. Louis, Missouri; a master of science in counseling and guidance from Troy State University, Troy, Alabama; and a master's degree in nursing from Louisiana State Medical Center, New Orleans, Louisiana.

She has taught at George C. Wallace Junior Community College, Dothan, Alabama; Sampson Technical Institute, Clinton, North Carolina; and Touro Infirmiry School of Nursing and Charity/Delgado School of Nursing in New Orleans, Louisiana. She has also been the Director of Touro Infirmiry School of Nursing and a Director of Nursing at Tulane University Medical Center in New Orleans. With 35 years as a clinician and academician, Ms. Ladner has taught fundamentals of nursing, medical-surgical nursing, and nursing seminars while maintaining clinical competency in various critical care and medical-surgical settings. Her professional career has provided her with the necessary knowledge and skills to be an effective lecturer and community leader.

Ms. Ladner received a governor's appointment to serve on an Advisory Committee of the Louisiana State Board of Medical Examiners, and she also served on an Advisory Committee for Loyola University in New Orleans. She maintains membership in Sigma Theta Tau, the American Nurses Association, and the Louisiana Organization of Nurse Executives. She served for over 10 years on the Louisiana State Nurses Association's Continuing Education Committee. She is the recipient of the New Orleans District Nurses Association Community Service Award and has been recognized as

one of the "Great 100 Nurses" by the New Orleans District Nurses Association.

Ms. Ladner has been listed in *Who's Who in American Nursing*. She is a former Nursing Practice Consultant for the Louisiana State Board of Nursing.

Since Hurricane Katrina in 2004, Ms. Ladner has coordinated the volunteer services for the Catholic Church in DeLisle, Mississippi, and presented in-service education programs on such topics as hygiene, infection control, and grief and loss.

UNIT 1

Nursing's Perspective: Past, Present, and Future

- 1** Evolution of Nursing and Nursing Education / 3
- 2** Nursing Theory / 23
- 3** Research and Evidence-Based Practice / 41
- 4** Health Care Delivery, Quality, and the Continuum of Care / 53

All history is modern history.

—WALLACE STEVENS,
AMERICAN POET AND AUTHOR (1879–1955)

CHAPTER 1

Evolution of Nursing and Nursing Education

COMPETENCIES

1. Define nursing as an art and a science.
2. Identify major historical and social events that have shaped current nursing practice.
3. Describe Florence Nightingale's impact on current nursing practice.
4. Discuss the contributions of early leaders in American nursing.
5. Discuss the impact of selected landmark reports on nursing education and practice.
6. Describe the characteristics of each of the educational programs for entry-level nursing practice.
7. Discuss the Health Care Professionals' Competencies document and the strategies proposed by the Pew Health Professions Commission for nursing education reform.
8. Describe the trends in nursing education that specifically relate to the issues of competency development and delivery of care.

KEY TERMS

autonomy

empowerment

history

nurse

Nursing is an art and a science by which people are assisted in learning to care for themselves whenever possible and cared for by others when they are unable to meet their own needs.

Nursing has evolved from an unstructured method of caring for the ill to a scientific profession. The result has been movement from the mystical beliefs of primitive times to a “high-tech, high-touch” era. Nursing combines art and science. Using scientific knowledge in a humane manner, nursing combines critical thinking skills with caring behaviors.

Nursing requires a delicate balance of promoting clients' independence and dependence. Nursing focuses not on illness but rather on the client's *response* to illness.

Nursing promotes health and helps clients move to a higher level of wellness. This aspect of nursing also includes assisting a client with a terminal illness to maintain comfort and dignity in the final stage of life.

This chapter traces the evolution of nursing by exploring its rich heritage. Social forces that have affected the development of nursing and nursing education are examined. The various educational programs of the United States and Canada are presented in terms of their characteristics and the graduate's nursing role in health care delivery.

To understand the present status of nursing, it is necessary to have a base of historical knowledge about the profession. By studying nursing history, the nurse is better able to understand such issues as **autonomy** (being self-directed), unity within the profession, supply and demand, salary, education, and current practice. **History** is a study of the past that includes events, situations, and individuals (see Figure 1-1). By learning from historical role models, nurses can enhance

their abilities to create positive change in the present and set a course for the future.

The study of nursing history offers another advantage—learning where the profession has been and its advancements. **Empowerment** is the process of enabling others to do for themselves. Only when nurses are empowered are they truly autonomous. Autonomy has historically been difficult for nurses to achieve. Empowerment and autonomy go together and are necessary for nursing to bring about positive changes in health care today (see Figure 1-2).

Learning from the past is the major reason for studying history. Ignoring nursing's history can be detrimental to the future of the profession. By applying the lessons gained from a historical review, nurses will indeed be a vital force in the new millennium.

EVOLUTION OF NURSING

Nursing has evolved with the development of the civilization of mankind. The term **nurse** stems from the Latin word *nutrix* or *nutrio*, which means to nourish. Primitive humans (cave dwellers) demonstrated knowledge regarding the medicinal value of plants and herbs and the therapeutic use of water and heat. Refer to Table 1-1 on page 5 and the following for a discussion of nursing from early civilizations to the present era of advanced nursing practice and health care reform.

ORIGINS OF NURSING

The evolution of nursing dates back to 4000 BC, to primitive societies in which mother-nurses worked with priests.

FIGURE 1-1 Graduating class (1900) of Touro Infirmary Training School for Nurses PHOTO COURTESY OF TOURO INFIRMARY ARCHIVES, NEW ORLEANS, LA

FIGURE 1-2 Through consultation and exchange of information, nurses demonstrate their roles as autonomous professionals. How important are the qualities of autonomy and empowerment to a nurse's career goals? DELMAR/CENGAGE LEARNING

TABLE 1-1 Historical Events Influencing the Evolution of Nursing

DATE	EVENT
4000 BC	Primitive societies
2000 BC	Babylonia and Assyria
800–600 BC	Health religions of India
700 BC	Greece: source of modern medical science
460 BC	Hippocrates
3 BC	Ireland: pre-Christian nursing
AD 390	Fabiola: founded first hospital
390–407	Early Christianity, deaconesses
711	Field hospital with nursing, Spain
1100	Ambulatory clinics, Spain (Moslems)
1440	First Chairs of Medicine, Oxford and Cambridge
1522	Military nursing orders
1600–1752	Deterioration of hospitals and nursing
1633	Founded: Daughters of Charity
1820	Florence Nightingale born
1826	Kaiserwerth deaconesses reestablished
1837	First American college for women, Mount Holyoke
1841	Founded: Nursing Sisters of the Holy Cross
1848	Women's Rights Convention, Seneca Falls, New York
1854–1856	Crimean War
1859	<i>Nightingale's Notes on Nursing</i> published in England
1860	First Nightingale School of Nursing, St. Thomas's Hospital, London
1861–1865	Civil War, United States
1863	Charter granted to the New England Hospital for Women, Boston
1871	New York State Training School for Nurses, Brooklyn Maternity, Brooklyn, New York
1872	New England Hospital for Women: 1-year program for nurses America's first trained nurse, Linda Richards
1873	First three Nightingale schools in United States: Bellevue (New York City), Connecticut, and Massachusetts General
1881	Founded: American Red Cross
1882	Founded: American Association of University Women
1888	Founded: International Council of Women (ICW) Founded: National Council of Women (NCW)
1893	First Nurses' Settlement House, New York City, founded by Lillian Wald and Mary Brewster Founded: first American Nursing Society, American Society of Superintendents of Training Schools for Nurses (Superintendents' Society)
1896	Founded: National Association of Colored Women
1896–1911	Founded: Nurses' Associated Alumnae of the United States and Canada (Associated Alumnae)
1899	Founded: International Council of Nurses (ICN) First postgraduate courses for nurses at Teachers College, Columbia University
1900	<i>American Journal of Nursing (AJN)</i>
1901–1912	Founded: American Federation of Nurses (Federation) Federation joined NCW and ICW

The first nurse to be recorded in history is Deborah. Deborah, referred to as a nurse, accompanied Rebekah when she left home to marry Isaac (Holy Bible, Gen. 24). In 2000 BC, the use of wet nurses is recorded in Babylonia and Assyria.

The ancient Greeks built temples to honor Hygiea, the goddess of health. These temples were more like health spas rather than hospitals in that they were religious institutions governed by priests. Priestesses (who were not nurses) attended to those housed in the temples. The nursing that was done by women was performed in the home.

Around 500 BC, Gautama, later known as Buddha, was born in India. Buddha founded many religious orders that later supported King Asoka in the establishment of homes that provided care. The basic nursing care was provided by male nurses.

The spread of Christianity had a profound influence upon nursing. The followers of Jesus spread Christianity throughout the entire world, and men and women who were committed to love of both the church and the poor and infirm dedicated their lives to caring for the ill.

Hospitals were first established in the Eastern Roman (Byzantine) Empire. St. Jerome was responsible, through one of his disciples, Fabiola, for introducing hospitals in the West. Western hospitals were primarily religious and charitable institutions housed in monasteries and convents. The caregivers had no formal training in therapeutic modalities and volunteered their time to nurse the sick.

The fall of the Roman Empire in 476 AD ushered in the Middle Ages, or medieval period (500–1450 AD), which was characterized by the growth of the Christian church. The Crusaders and religious orders traveled throughout Europe and the Near East with the mission of civilization and conversion. Because of their travels, commercial trade flourished and industries were developed to provide for trade in the world market. Universities were established, and monasteries provided impetus and leadership for the restructuring of the Western world.

Hospitals in large Byzantine cities were staffed primarily by paid male assistants and male nurses. During the medieval era, these hospitals were established primarily as almshouses, with care of the sick being secondary.

Medical practices in Western Europe remained basically unchanged until the eleventh and twelfth centuries, when formal medical education for physicians was required in a university setting. Although there were not enough physicians to care for all the sick, other caregivers were not required to receive any formal training. The dominant caregivers in the Byzantine setting were men; however, this was not true in the rural parts of the Eastern Roman Empire and in the West. In these societies, nursing was viewed as a natural nurturing job for women.

During the Renaissance (1400–1550 AD), interest in the arts and sciences emerged. This was also the time of many geographic explorations by Europeans. As a result, the world literally expanded.

Because of renewed interest in science, universities were established, but no formal nursing schools were founded. Because of social status and customs, women were not

encouraged to leave their homes; they continued to fulfill the traditional role of nurturer and caregiver in the home.

The Industrial Revolution introduced technology that led to a proliferation of factories. Conditions for the factory workers were deplorable. Long hours, grueling work, and unsafe conditions prevailed in the workplace. The health status of laborers received little, if any, attention.

Medical schools were founded, including the Royal College of Surgeons in London in 1800. In France, men who were barbers also functioned as surgeons by performing procedures such as leeching, giving enemas, and extracting teeth.

At the end of the eighteenth century, there were no standards for nurses who worked in hospitals. In the early to mid-1800s, nursing was considered unseemly for women even though some hospitals (almshouses) relied on women to make beds, scrub floors, and bathe the poor. Most nursing care was still performed in the home by female relatives of the ill.

RELIGIOUS INFLUENCES

The strong influence of religions on the development of nursing started in India (800–600 BC) and flourished in Greece and Ireland in 3 BC with male nurse-priests. The Crusades of the medieval era led to the formation of three primary military orders: the Knights of St. John, the Teutonic Knights, and the Knights of Lazarus. These military orders cared for their wounded peers and built hospitals. The Knights of St. John, also called Knights Hospitalers, still have a viable organization in England today; because of their involvement in the International Red Cross, the insignia of their order was adopted for use by the Red Cross. The Teutonic Knights were established in the early twelfth century in a German hospital in Jerusalem; only men could be full members of the order, though women were granted sisterhood. The Knights of Lazarus was founded to care for the lepers in Jerusalem; when leprosy began to abate, the order was taken over by the Knights of St. John.

In 1836, Theodor Fleidner revived the Church Order of Deaconesses to care for those in a hospital he had founded. These deaconesses of Kaiserwerth became famous because they were the only ones formally trained in nursing. Pastor Fleidner had a profound influence on nursing because Florence Nightingale received her nurse's training at the Kaiserwerth Institute.

The Nursing Sisters of the Holy Cross was founded in LeMans, France, by Father Bassil Moreau in 1841. Father Sorin brought four sisters to Notre Dame in South Bend, Indiana, in 1841. In 1844, these sisters established St. Mary's Academy in Bertrand, Michigan. In 1855, the school was moved to Notre Dame and became known as Saint Mary's College, which became influential on the emerging role of women.

DEMANDS OF WAR

Historically, the demand for nurses has increased during wartime. During the Crimean War (1854–1856) orders of nursing sisters provided care to French and Russian soldiers, but there were no organized services to care for the wounded

and sick British soldiers. When the British people learned of their soldiers' poor care, it led to public outcry. The secretary of war, Sir Sidney Herbert, contacted Florence Nightingale for assistance. Nightingale and the recruits were assigned to a barrack hospital in Scutari, Turkey. Using her own private allowance, Nightingale purchased needed supplies, made changes, and within 6 months lowered the death rate from 50%–60% to 2%.

America's need for nurses increased dramatically during the Civil War (1861–1865). The sisters of the Holy Cross were the first to respond to the need for nurses during that war. Answering a request of Indiana's governor, 12 sisters started caring for wounded soldiers. By the end of the war, 80 sisters had cared for soldiers in Illinois, Missouri, Kentucky, and Tennessee.

During the Civil War, nursing care was provided by the Sisters of Mercy, Daughters of Charity, Dominican Sisters, and Franciscan Sisters of the Poor. The sisters were influenced by the roles assigned to women during the nineteenth century. Although they were submissive to authority, they were willing to take risks when human rights were threatened. Women volunteered to care for the soldiers of both the Union and Confederate armies (see Figure 1-3). These women performed various duties, including the implementation of sanitary conditions in field hospitals.

Several individuals are recognized for their nursing contributions during the Civil War: Clara Barton, Dorothea Dix, Harriet Tubman, and Sojourner Truth. Clara Barton, a schoolteacher who volunteered as a nurse during the war, was referred to as the "Angel of the Battlefield" for rendering care in field hospitals. In 1881, Clara Barton established the American Association of the Red Cross and served as its first president. Dorothea Dix (1802–1887), a change agent in government reforms for humane treatment in mental hospitals, volunteered as a nurse when the Civil War began and was appointed the Superintendent of Women Nurses for all military hospitals, the first U.S. Army Nurse Corps.

FIGURE 1-3 During the Civil War, women were instrumental in the effort to minimize the risk of spreading contagious diseases among wounded soldiers. PHOTO COURTESY OF CORBIS-BETTMANN

Harriet Tubman (1820–1913) was known as the "Moses of Her People" for her work with the underground railroad; during the Civil War, she served as a nurse for people of her own race. Sojourner Truth (1797–1883), underground railroad agent, preacher, and women's rights advocate, was a nurse during the Civil War and after the war for the Freedmen's Relief Association.

Following the Civil War, nurse training in the United States and Canada began to use curricula patterned after that of the Nightingale School. The first nursing program in Canada, St. Catherine's in Ontario, was founded in 1874.

Again war entered the picture. The casualties of World War II (1939–1945) created an acute nursing shortage. The Cadet Nurse Corps was established during World War II to provide additional nurses to meet both military and civilian needs. The Corps' training for nurses was shorter than the typical civilian education of 3 years. During this time, auxiliary workers such as licensed practical nurses were created to work under the supervision of registered nurses.

During early wars, nurses often found themselves on the front lines administering physical and spiritual care to wounded soldiers with limited supplies and medicine. The nurse would apply pressure to stop the bleeding, assure the soldier someone would stay at his side, pray with the soldier, or write a letter for the soldier. How would a nurse demonstrate caring in a situation such as September 11?

FLORENCE NIGHTINGALE (1820–1910)

Florence Nightingale is considered the founder of modern nursing. She grew up in a wealthy upper-class family in England during the mid-1800s. Unlike other young women of her era, Nightingale received a thorough education including Greek, Latin, history, mathematics, and philosophy. She had always been interested in relieving suffering and caring for the sick. Social mores of the time made it impossible for her to consider caring for others because she was not a member of a religious order. She became a nurse over the objections of society and her family.

After completing the three-month course of study at Kaiserwerth Institute, Nightingale became active in reforming health care. The advent of Britain's war in the Crimea presented the stage for Nightingale to further develop the public's awareness of the need for educated nurses (see Figure 1-4 on page 9). The implementation of her principles in the areas of nursing practice and environmental modifications resulted in reduced morbidity and mortality rates during the war.

Nightingale forged the future of nursing education as a result of her experiences in training nurses to care for British soldiers. In 1860 she opened the Training School of Nurses at St. Thomas's Hospital in London. This was the first school for nurses that provided both theory-based knowledge and clinical skills. Nightingale revolutionized not only the public's perception of nursing but also the method for educating nurses. Some of her novel beliefs about nursing education were:

- A holistic framework inclusive of illness and health
- The need for a theoretical basis for nursing practice

FIGURE 1-4 Florence Nightingale in the Crimea PHOTO COURTESY OF PFIZER, INC.

- A liberal education as a foundation for nursing practice
- The importance of creating an environment that promotes healing
- The need for a body of nursing knowledge distinct from medical knowledge (Nightingale, 1969)

Nightingale introduced many other concepts that, though unique in her time, are still used today; for example, she advocated (1) having a systematic method of assessing clients, (2) individualizing care on the basis of the client's needs and preferences, and (3) maintaining confidentiality.

Nightingale also recognized the influence of environmental factors on health. She advocated that nurses provide clean surroundings with fresh air and light to improve the quality of care (Nightingale, 1969). Nightingale believed that nurses should be formally educated and should function as client advocates.

NURSING PIONEERS AND LEADERS

In 1848, the Women's Rights Convention in Seneca Falls, New York, signaled the beginnings of social unrest. Women were not considered equal to men, society did not value education for women, and women did not have the right to vote. With suffrage, not only were the rights of women advocated but also the nursing profession itself advanced. By the mid-1900s, more women were being accepted into colleges and universities, even though only limited numbers of university-based nursing programs were available.

Modern nursing was forged by the contributions of many outstanding nurses through the years. The establishment of public health nursing, the provision of rural health care services, and the advancement of nursing education occurred as a result of the works of nurse pioneers, who are discussed in the text that follows. Note that the term *trained nurse* was used historically as the predecessor of *registered nurse*.

Lillian Wald

Lillian Wald spent her life providing nursing care to the indigent population. In 1893, as the first community health nurse, she founded public health nursing with the establishment of the Henry Street Settlement Service (see Figure 1-5) in New York City. Wald was a tireless reformer who:

- Improved housing conditions in tenement districts
- Supported education for the mentally challenged
- Advocated passage of more lenient immigration regulations
- Initiated change of child labor laws and founded the Children's Bureau of the U.S. Department of Labor

In addition to initiating public health nursing, Wald also established a school of nursing.

Isabel Hampton Robb

Isabel Hampton Robb was responsible for founding several nursing organizations, namely, the Superintendents' Society in 1893 and the Nurses' Associated Alumnae of the United States and Canada in 1896. She recognized the necessity of nurses participating in professional organizations to establish unity throughout nursing on positions and issues. She was instrumental in establishing both the American Nurses Association (ANA) and the National League of Nursing Education. Robb was also an early supporter of the rights of

FIGURE 1-5 Nurses at the Henry Street Settlement in New York City PHOTO COURTESY OF VISITING NURSES SERVICE OF NEW YORK

nursing students. She called for shorter working hours and emphasized the role of the nursing student as learner instead of employee.

Jane Delano

During World War I, Jane Delano, a graduate of Bellevue School of Nursing and former ANA president, took one of the first stances that created a division among nursing leaders. In 1912, physicians wanted the Red Cross to put untrained nursing aides at their sides to assist with war casualties. Physicians, not nurses, would train the aides in caring for the sick.

Delano was opposed to the aide education plan because it violated the educational standards already established by nursing. This position pitted Delano against Annie Goodrich and Adelaide Nutting. The Red Cross recognized Delano's leadership abilities and dropped the aide plan. Delano was active in the Army Nurse Corps until she resigned her Army position in 1912 to work full time with the Red Cross. She died during wartime service in Europe.

Annie Goodrich

Annie Goodrich was influential in national and international nursing issues. During World War I, the supply of civilian nurses was greatly depleted because of the army's need for trained nurses. Goodrich pushed for the establishment of an army training school for nurses, which she envisioned as a model for other schools of nursing. She then was appointed dean of the Army School of Nursing. As an advocate of college-based educational nursing programs, Goodrich became the first dean of Yale University School of Nursing.

Adelaide Nutting

Adelaide Nutting was a nursing educator, historian, and scholar. She actively campaigned for nurses being educated in university settings and was the first nurse to be appointed to a university professorship. In 1910, Nutting was appointed to direct the newly established Department of Nursing and Health at Teachers College, Columbia University, in New York City. This department was established to prepare nurses for teaching and supervision in nurse training schools, for administration in hospitals, and for work in preventive and social aspects of nursing.

Lavinia Dock

An influential leader in American nursing education was Lavinia Dock, who graduated from Bellevue Training School for Nurses in 1886. In her early nursing practice, she worked at the Henry Street Settlement House in New York City providing visiting nursing services to the indigent. She wrote one of the first nursing textbooks, *Materia Medica for Nurses*. Dock wrote many other books and was the first editor of the *American Journal of Nursing (AJN)*. Dock was a political activist who in 1914 encouraged nurses to unite when physicians objected to reforming labor laws to include nursing students.

Mary Breckinridge

In 1925, Mary Breckinridge introduced a system for delivering health care to rural America. She created a decentralized system for primary nursing care services in the Kentucky Appalachian Mountains. This system, the Frontier Nursing Service, lowered the childbirth mortality rate in Leslie County, Kentucky, from the highest in the nation to below the national average.

Martha Franklin

Martha Franklin was one of the first people to advocate racial equality in nursing. She was the only African American graduate of her class at Women's Hospital Training School for Nurses in Philadelphia. In 1908, Franklin organized the National Association of Colored Graduate Nurses (NACGN), which advocated that black nurses meet the same standards required of other nurses to prevent a double standard based on race. In 1951, the NACGN merged with the ANA.

Amelia Greenwald

Amelia Greenwald was a pioneer in public health nursing on the international scene. In 1908, she entered the Touro Infirmary Training School for Nurses in New Orleans, Louisiana. After graduation, Greenwald studied psychiatric and public health nursing. She served as chief nurse in several field hospitals during World War I. In 1923, she accepted the challenge of establishing a school of nursing in Poland. She received the Polish Golden Cross of Merit for her contributions to the welfare of the people. Greenwald was a catalyst for international public health nursing.

Mamie Hale

In 1942, Mamie Hale was hired by the Arkansas Health Department to upgrade the educational programs for midwives (see Figure 1-6 on page 11). Hale, a graduate of the Tuskegee School of Nurse-Midwifery, gained the support of granny midwives, public health nurses, and obstetricians. Through education, Hale decreased the superstition and illiteracy of those functioning as midwives. Hale's efforts resulted in improved mortality rates for both mothers and infants.

Mary Mahoney

America's first African American professional nurse, Mary Mahoney, was a noted nursing leader who encouraged a respect for cultural diversity. Today, the ANA bestows the Mary Mahoney Award in recognition of individuals who make significant contributions toward improving relationships among multicultural groups.

Harriet Neuton Phillips

Harriet Neuton Phillips was the first known graduate of the Women's Hospital of Philadelphia. A six-month training course for nurses had been established by Dr. Ann Preston in 1861. Although no formal diplomas were awarded, the graduate nurses worked in the hospital and did private duty

FIGURE 1-6 Mamie Hale PHOTO COURTESY OF HISTORICAL RESEARCH CENTER, UNIVERSITY OF ARKANSAS FOR MEDICAL SCIENCES LIBRARY, LITTLE ROCK

nursing in homes. Thus, Harriet Phillips can claim the title of the first American nurse to receive a training certificate. As a pioneer in community nursing, she worked with Chinese immigrants in San Francisco and with Native Americans in Wisconsin.

Linda Richards

In 1873, the first diploma from an American training school for nurses was awarded to Linda Richards. Richards founded or reorganized 10 hospital-based training schools for nurses. She introduced the practice of keeping nurses' notes and physicians' orders as part of medical records. Also, Richards began the practice of nurses wearing uniforms. As the first superintendent of nurses at Massachusetts General Hospital, she demonstrated that trained nurses gave better care than those without formal nursing education.

Margaret Sanger

In 1912, Margaret Sanger, a nurse living in New York City, became concerned with women who had too many children to support. She coined the phrase "birth control" and began writing about contraceptive measures. Sanger fought to revise legislation that prohibited dissemination of information about contraception.

Sanger was not afraid of controversy and spent 1 month in jail for distributing information on birth control. As a true activist, Sanger made birth control an issue and fought for the rights of poor women. She understood the relationship between poverty, overpopulation, and high infant and maternal mortality rates. Sanger founded the American Birth Control League and was the first president of the International Planned Parenthood Federation.

Adah Belle Thoms

Adah Belle Thoms was a crusader for improved relationships among persons of all races. In the early 1900s, she became acting director of nursing of the Lincoln School for Nurses in New York when African Americans rarely held high-level positions (Chinn, 1994). Thoms was one of the first to recognize public health as a field of nursing. She campaigned for equal rights for black nurses in the American Red Cross and the Army Nurse Corps.

NURSING IN THE TWENTIETH CENTURY

The beginning of the twentieth century brought about changes that have influenced contemporary nursing. Several landmark reports about medical and nursing education, as well as some contemporary reports, are discussed in the following text. The establishment of visiting nurse associations and their use of protocols are discussed.

Flexner Report

With the support of a Carnegie grant in 1910, Abraham Flexner visited the 155 medical schools throughout the United States and Canada to assess the level of accountability in medical education and to bring about necessary reforms. The Flexner report brought about the following changes: closure of inadequate medical schools, consolidation of schools with limited resources, creation of nonprofit status for the remaining schools, and establishment of medical education in university settings based on standards and strong economic resources.

Adelaide Nutting saw the value and impact of the Flexner report on medical education and, in 1911, together with other colleagues of the Superintendents' Society, presented a proposal to the Carnegie Foundation to study nursing education. This foundation never allocated monies to study nursing education, but it supported educational studies in other disciplines such as law, dentistry, and teaching.

Although the efforts of Nutting and other nursing leaders went unheeded, in 1906 Richard Olding Beard successfully established a three-year diploma school of nursing at the University of Minnesota under the College of Medicine.

Early Insurance Plans

At the turn of the twentieth century, there were more than 4,000 hospitals and 1,000 schools of nursing. During this time, the concepts of third-party payments and prepaid health insurance were instituted. Third-party payments refer to situations in which someone other than the recipient of health care (usually an insurance company) pays for the health care

services provided. Prepaid medical plans were started in Pacific Northwest lumber and mining camps, where employers contracted for and paid a monthly fee for medical services. This led to the establishment of the Bureau of Medical Services, where the employer contracted for medical services and the subscriber selected one of the physicians in the bureau.

BLUE CROSS AND BLUE SHIELD. The Depression provided the main impetus for the growth of insurance plans. In addition, the American philosophy of health care for all contributed to the growth of insurance plans. In 1920, American hospitals offered a prepaid hospital plan that led to the “Baylor Plan,” which eventually became the prototype of Blue Cross.

Blue Cross was the result of a joint venture between hospitals, physicians, and the general public. The American Hospital Association (AHA) pioneered the development of an insurance company to provide benefits to subscribers who were hospitalized. Blue Shield was developed by the American Medical Association (AMA) to provide reimbursement for medical services provided to subscribers. In 1933, the AHA endorsed Blue Cross, and in 1938 the AMA endorsed Blue Shield.

The federal government became more involved in health care delivery in 1935 with the passage of the Social Security Act, which provided for (among other things) benefits for the elderly, child welfare, and federal funding for training of health care personnel. During World War II, the U.S. government extended the benefits for military services to include health care for veterans and their dependents.

VISITING NURSES ASSOCIATIONS. In 1901, at the suggestion of Lillian Wald, the Metropolitan Life Insurance Company, which provided visiting nursing services to its policyholders, entered into an agreement with the Henry Street Settlement. Wald worked with Metropolitan to expand the services of the Henry Street Settlement to other cities; thus, one form of managed care began.

Nurses providing care in the home environment experienced greater autonomy of practice than hospital-based nurses (see Figure 1-7). This led to conflicts with some physicians regarding the scope of medical practice versus nursing practice parameters. Some physicians thought nurses were taking over their practice, whereas other physicians encouraged nurses to do whatever was necessary to care for the sick at home.

In 1912, in an effort to provide direction to home health staff nurses, the Chicago Visiting Nurse Association developed a list of standing orders for nurses to follow in providing home care. These orders were to direct the nursing care of clients when the nurse did not have specific orders from a physician. Thus, the groundwork for nursing protocols was established.

Landmark Reports in Nursing Education

During the first half of the twentieth century, a number of reports were issued concerning nursing education and practice. Three of them, the Goldmark, the Brown, and the Institute of Research and Service in Nursing Education reports, are discussed here.

FIGURE 1-7 A baby being weighed by a student nurse and a Junior League volunteer in 1929 PHOTO COURTESY OF TOURO INFIRMARY ARCHIVES, NEW ORLEANS, LA

GOLDMARK REPORT. In 1918, Adelaide Nutting, relentless in her efforts to document the need for nursing education reform, approached the Rockefeller Foundation for support. Funding was provided and, in 1919, the Committee for the Study of Nursing Education was established to investigate the training of public health nurses. E. A. Winslow, professor of public health, Yale University, chaired the committee, composed of 10 physicians, two lay persons, and six nurses: Adelaide Nutting, Mary Beard, Lillian Clay, Annie Goodrich, Lillian Wald, and Helen Wood. Josephine Goldmark, a social worker, served as the secretary to the committee.

As secretary, Goldmark developed the methodology of data collection and analysis for a small sampling of the 1,800 schools of nursing in existence. The study of 23 of the best nursing schools across the nation represented a cross-sample of schools—small and large, public and private.

The Goldmark report, entitled *Nursing and Nursing Education in the United States*, was published in 1923. Goldmark identified the major weakness of the hospital-based training programs as that of putting the needs of the institution (service delivery) before the needs of the student (education). Nursing tradition and the apprenticeship form of education reinforced putting the needs of the client before the learning needs of the student.

Some major inadequacies identified in nursing education by the study were limited resources, low admission standards, lack of supervision, poorly trained instructors, and failure to correlate clinical practice with theory. The report concluded that for nursing to be on equal footing with other disciplines, nursing education should occur in the university setting.

BROWN REPORT. In 1948, Esther Lucille Brown, a social anthropologist, published *Nursing for the Future and Nursing Reconsidered: A Study for Change*. Several recommendations were put forth in this study, including the need for nurses to demonstrate greater professional competence by moving nursing education from the hospital to the university setting.

Although published 20 years after the Goldmark report, the Brown report identified many of the same problems in

diploma education—nursing students were still being used for service by the hospitals, and inadequate resources and authoritarianism in hospitals still prevailed in nursing education.

Brown recognized that nursing education in the university setting would provide the proper intellectual climate for the professional. Visionary nurse educators were securing necessary learning resources: libraries, laboratories, and clinical facilities. Professional endeavors such as research and publication were being implemented by nurse leaders.

INSTITUTE OF RESEARCH AND SERVICE IN NURSING EDUCATION REPORT. During the 1950s, there was a deficit in the supply of nurses as the post–World War II demand for nursing services increased. Some contributing factors to the dearth of nurses were the low esteem of nursing as a profession, long hours with a heavy workload, and low salaries.

The Institute of Research and Service in Nursing Education report resulted in the establishment of practical nursing under Title III of the Health Amendment Act of 1955. There was a proliferation of practical nursing schools in the United States to increase the supply of nurses.

CANADIAN REPORTS. Through the joint efforts of the Canadian Nurses Association and the Canadian Medical Association, a nationwide study of nursing education in Canada was established in 1929. Under the leadership of George M. Weir, MD, the study pointed out serious weaknesses that existed in the hospital schools of nursing. The *Survey of Nursing Education in Canada (1932)*, also known as *The Weir Report*, recommended the following reforms: a higher education standard, increased affiliations between schools, increased employment of graduate nurses, student tuition, and qualified faculty (Donahue, 1985).

In 1936 the National Curriculum Committee of the Canadian Nurses Association published *The Proposed Curriculum for Schools of Nursing in Canada*. “The study and the later *Supplement* became valuable guides to assist with the establishment of a sounder educational foundation for nursing in Canada” (Donahue, 1985, p. 391).

Contemporary Reports

During the 1980s, several important studies were commissioned to examine the areas of nursing education and practice.

NATIONAL COMMISSION ON NURSING. The National Commission on Nursing was created in 1980 by the AHA, the Hospital Research and Education Trust, and the American Hospital Supply Corporation to study nursing education and related issues in hospital management, nursing practice, and nursing education. The commission’s conclusions addressed the need for:

- Adequate clinical education for students
- Baccalaureate education and educational mobility
- Involvement of nurses in collaborative institutional and clinical decision making
- Improved working conditions, specifically, salaries, flexible scheduling, and differentiated practice

As a result of the commission’s study, attention was given to the need for prescribing practitioners and nurses to enter into collaborative practice.

INSTITUTE OF MEDICINE. Concurrent with the National Commission on Nursing study, another study was initiated by Congress in 1979 and conducted by the Institute of Medicine (IOM). The study, *Nursing and Nursing Education: Public Policies and Private Actions*, focused on the need for continued federal funding to nursing education. The findings indicated that there was not a shortage in the general supply of nurses, but there was a serious shortage of nurses in research, teaching, administration, and advanced clinical practice. A significant nursing shortage existed in preventive and primary care for older adults and disadvantaged people in inner cities and rural areas.

SECRETARY’S COMMISSION ON NURSING. Although the IOM study indicated that there were sufficient numbers of staff nurses, based on supply and demand, hospitals continued to report severe shortages. As a response to hospitals’ recruitment and retention challenges, Health and Human Services Secretary Otis R. Brown, MD, established the Secretary’s Commission on Nursing, which made the following recommendations related to nursing practice:

- Nurse compensation
- Health care financing
- Nurse decision making
- Development, use, and maintenance of nursing resources

This commission recognized that the federal government alone could not correct the problems facing nursing and health care but rather that the concerted efforts of health care organizations were needed for the implementation of the report’s recommendations.

HEALTHY PEOPLE INITIATIVES. Healthy People initiatives have become the nation’s health agenda. These initiatives began with a report entitled *Healthy People: The Surgeon General’s Report on Health Promotion and Disease Prevention in 1979*. The report described Healthy People as the nation’s health agenda to guide policy on public health initiatives for health promotion and disease prevention activities during the decade 1980–1990. See Chapter 16 for a complete discussion of Healthy People initiatives.

PEW HEALTH PROFESSIONS COMMISSION. The scientific base for nursing practice demands competencies (the ability to function in a particular way) from multiple sources: philosophy and ethics; physical, economic, behavioral, and social sciences; nursing science; and biomedicine. Additional competencies in collaboration, coordination, and the interdisciplinary practice activities of exchanging knowledge and techniques are critical to nursing practice and health care delivery. These competencies raise questions about the single, discipline-specific method of educating the nursing workforce and offer alternative scenarios for nursing education.

The Pew Health Professions Commission (O’Neil, 1993; Pew Health Professions Commission, 1995; Shugars,

HEALTH CARE PROFESSIONALS' COMPETENCIES

- Care for the community's health
- Expand access to effective care
- Provide contemporary clinical care
- Emphasize primary care
- Participate in coordinated care
- Ensure cost-effective, appropriate care
- Practice prevention
- Involve clients and families in the decision-making process
- Promote healthy lifestyles
- Assess and use technology appropriately
- Improve the health care system
- Manage information
- Understand the role of the environment in mitigating the impact of environmental hazards on health
- Provide counseling on ethical issues
- Accommodate expanded accountability
- Participate in a racially and culturally diverse society
- Continue to learn

From Shugars, D. A., O'Neil, E. H., & Bader, J. D. (Eds.). (1991). *Healthy America: Practitioners for 2005: An agenda for action for U.S. health professional schools* (pp. 18–20). Durham, NC: Pew Health Professions Commission.

O'Neil, & Bader, 1991), in its widely referenced and distributed reports, has recommended that academic institutions investigate whether the providers of educational experiences in health care are addressing the needs of clients. See the accompanying display that lists the Pew Health Professions Commission's Health Care Professionals' Competencies.

Nursing leaders have embraced these competencies as consistent with the values and issues raised in *Nursing's Agenda for Health Care Reform* (ANA, 1991). To ensure that the nursing workforce is educated sufficiently to demonstrate these competencies, schools are being challenged to redefine their educational core. To accomplish this goal, schools of nursing, health science centers, and institutions of higher education are refining mission statements, developing strategic plans and implementation activities, and examining curriculum activities, faculty competencies, educational methods and technologies, and sites and populations for clinical experiences.

SOCIAL FORCES AFFECTING NURSING

From the earliest recordings of nursing, 4000 BC through the Christian era, women were allowed to perform the nurse role only in the home. Nursing's links with the church caused nursing to be viewed as a "service," not a profession such as medicine. The Crimean and Civil wars had a significant

impact on nursing's future by focusing on women as nurse providers and on the need for nurse training.

During the twentieth century, the evolution of medical education as an established profession had far advanced that of nursing. The Flexner report carved the destiny for physicians. The Goldmark and Brown reports created havoc for nurses as they debated the issue of nursing education in the university setting.

The Depression and World War II brought social reform and created health and medical insurance that strengthened the organized power base of both physician and hospital. Nursing—almost exclusively a female profession—had little power and, therefore, did not exert much influence on the social forces at play. The greatest advances for nurses were seen in the realm of public health and preventive health care.

As physicians were released from military service after World War II, the era of specialized medicine began. Physicians used their veterans' educational entitlement benefits to take residency training in one or more specialty areas. By 1966, more than 70% of the prescribing practitioners in practice were specialists.

The 1960s was a decade of growth and change. As technological advances increased the scope of practice of medicine and nursing, other social forces were at play: access to health care services enhanced by Medicare and Medicaid, prescribing practitioner and nurse shortages, the feminist movement, the inception of nurse practitioners, and a focus on health maintenance.

The economic recession of the 1970s saw health care costs escalating along with unemployment. Professional autonomy was being debated, nursing theories were being developed, and nursing education was being integrated into the university setting. Nurses were becoming more politically astute in that they were working through professional organizations to affect health care legislation.

During the 1980s, nursing became more specialized and autonomous. The rapid technologic advances in medicine required more specialization in nursing. Nurse practitioners were being more widely accepted by the general public and other health care providers. Expanded roles of nurses were developing in response to greater demands for nursing services. One factor that led to an increased need for nursing was the proliferation of health maintenance organizations in the early 1980s.

During the 1990s, nurses were actively assuming more responsibilities for the delivery of health care. Evolving technology mandated nurses to continue to advance their knowledge base and skills. The aging of the population called for more nursing involvement with the elderly. Nurses, as individuals and as members of professional organizations, were involved in shaping policies for health care reform. Nursing was a stronger advocate for vulnerable populations: older adults, those living in poverty, the homeless, and those with human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS).

In today's society, nurses need to understand how advances in technology, worldwide communication, and globalization and the increasing threat of natural disasters and bioterrorism are constantly evolving and reshaping the practice of nursing. Advancements in technology such as

sophisticated client monitoring equipment and the Internet influence where and how nurses increase their knowledge and provide care. Inherent in these changes are cultural, legal, and ethical issues regarding the health and welfare of the population. For example, as a result of globalization and technology, nurses and other health care providers are practicing across state and national boundaries. Today's health care climate requires the nurse to acquire knowledge, skills, and values and to work collaboratively with other health care professionals when delivering safe, competent client care. Although worldwide communication and globalization make health care accessible to larger populations, there are legal issues regarding licensure that the provider must consider.

Many health care institutions, schools, and communities have educational programs to prepare for natural disasters or nuclear, chemical, or biological attack. Nurses play a critical role in participating in disaster preparedness. These roles may include participation in vaccine research, decontamination in the event of biological attack, triage for natural disaster and mass casualty, or membership in a crisis response unit. In order to meet the challenges of these ongoing changes, nurses must achieve educational competencies such as those addressed by the Pew Commission's strategies for change.

NURSING EDUCATION OVERVIEW

Educational programs that prepare graduates to write a licensing examination must be approved by a state or provincial (Canada) board of nursing. Boards approve entry-level programs to ensure the safe practice of nursing by setting minimum educational requirements and guaranteeing the graduate of the program is an eligible candidate to write a licensing examination. In the United States, candidates must pass the National Council Licensure Examination (NCLEX) to obtain a license to practice nursing. In Canada, the licensure examination is administered by the Canadian Nurses Association Testing Service (CNATS).

Two types of entry-level nursing programs are available in the United States: licensed practical or vocational nurse (LPN or LVN) and registered nurse (RN). An *entry-level educational program* means that the program prepares graduates to write a licensing examination. Graduates of the licensed practical or vocational programs write the NCLEX for practical nurses (NCLEX-PN), and graduates of RN programs write the NCLEX for RNs (NCLEX-RN).

Postgraduate programs prepare nurses to practice in various roles as advanced practice registered nurses (APRNs). Individual states have varying statutory provisions for APRNs. For instance, some states recognize the APRN's credentials to practice, whereas others require licensure.

An LPN or LVN is trained in basic nursing skills to provide client care under the guidance of an RN or other licensed provider, for example, a prescribing practitioner or dentist. In the United States, these programs are 9 to 18 months in length and exist in a variety of settings: high schools, community colleges, vocational schools, hospitals, and other health care agencies. The Canadian equivalent to

the LPN is a registered nurse's assistant (RNA). RNAs usually receive 12 months of education in a community college or hospital setting.

Practical nursing programs provide the graduate with didactic learning and clinical skills to perform selected nursing skills. Once licensed, practical nurses are prepared to work in structured settings, such as hospital and long-term care facilities, under RN supervision.

RN candidates are graduates from programs that are state approved and, in many cases, accredited by national accrediting organizations. In the United States, the National League for Nursing Accrediting Commission (NLNAC) accredits nursing programs; in Canada, the Canadian Association of University Schools of Nursing (CAUSN) accredits baccalaureate programs. The Commission on Collegiate Nursing Education (CCNE) was established in 1996 as an accrediting agency of the American Association of Colleges of Nursing (AACN) to evaluate the quality and integrity of baccalaureate and graduate degree nursing education programs. A variety of nursing education programs are available for entry into professional registered nursing: diploma, associate degree (AD), baccalaureate of science in nursing (BSN), master's degrees, and a few professional doctorate programs for beginning practitioners. Table 1-2 on page 16 provides a summary of educational programs that prepare graduates for entry into professional nursing practice.

Educational preparation for entry into practice has been an ongoing debate in nursing since the 1930s and 1940s, when the Brown and Goldmark reports recommended two levels of educational preparation for nurses. The ANA's 1965 Position Statement identified two entry levels of educational preparation: minimum preparation for professional practice, baccalaureate degree; and minimum preparation for technical practice, AD. Again in 1985, the ANA adopted a resolution regarding titles: professional nurse, a nurse possessing the baccalaureate degree in nursing; and associate nurse, a nurse prepared in an AD program. Although the AACN, CAUSN, and professional nursing organizations in the United States (ANA) and Canada (Canadian Nurses Association) have supported the baccalaureate degree to be the minimum entry level for professional practice, the authority to enforce this requirement rests with the individual states and provinces.

The CAUSN's mission is to promote health and wellness by advancing nursing education and nursing research. Although the CAUSN supports baccalaureate education as the required educational preparation for beginning practitioners, the association established a Task Force for Collaborative Nursing Education Models to foster collaboration between diploma and university schools in Canada (CAUSN Position Statement on Education, November 1998).

DIPLOMA EDUCATION

Florence Nightingale established the first diploma program at St. Thomas's Hospital, London, in 1860. Nightingale's basic principles of nursing education were:

- Placement of the program in an institution supported by public funds and associated with a medical school

TABLE 1-2 Educational Programs That Prepare Graduates to Write the National Council Licensure Examination for Registered Nurses (NCLEX-RN)

	DIPLOMA PROGRAMS	ASSOCIATE DEGREE PROGRAMS	BACCALAUREATE PROGRAMS	MASTER'S PROGRAMS	DOCTORAL PROGRAMS	NURSE DOCTORATE PROGRAMS
Origin	1873 Hospitals	1952 Community colleges and universities	1909 Universities and colleges	1950s Universities and colleges	1960s Universities and colleges	1979 Universities and colleges
Length	2–3 years	2 years	4 years	18–24 months	3–5 years postmaster's	4 years post-baccalaureate
Graduate outcomes	Clinically competent to plan, direct, and implement care for individuals and groups in collaboration with other health care providers in acute care and community-based settings	Technically competent to plan and implement care in hospitals and long-term care settings with other health care providers	Professionally prepared to plan, implement, and coordinate care, health promotion, and illness prevention for individuals, families, and communities in a variety of settings	Advanced practice nurse prepared in a specific area of specialization, such as education, administration, or clinical practice	Leaders for education, administration, clinical practice, and research	Leaders for advanced clinical practice
Articulation or acceleration placement	LPNs or LVNs	LPNs or LVNs	LPNs or LVNs, diploma, and ADN nurses	RNs without degrees, RNs with degrees in other fields, and nonnurse degree graduates	BSNs	Nonnurse degree graduates

Delmar/Cengage Learning

- Affiliation with a teaching hospital but also independent of it
- A program directed by and staffed with professional nurses
- A residency to teach students discipline and character

The nursing curriculum was based on Nightingale's scientific principles of the need for fresh air, medications, quiet, mobility, piped hot water, a call-bell system for patients, cleanliness and comfort in hospitals, as well as education of the public concerning principles of health and disease.

United States

After the Civil War in 1869, the AMA established a committee, headed by Samuel Gross, to study the training of nurses. The outcome of this study had an impact on nurse training that lasted for a century. In opposition to Nightingale's educational principle of an independent school under the direction of nursing leaders, the AMA's committee recom-

mended that all large hospitals have their own nursing schools under the direction of local medical agencies, with the medical staff being responsible for teaching.

Early diploma programs were established based upon the AMA's recommendations, and nurse training was largely of the apprenticeship type. Although there were some formal classes, students learned by doing, and in the process, they provided the majority of the nursing care for the hospitals' clients. The size of the hospital influenced the students' clinical experiences and learning. Standardization of diploma education did not occur until the 1940s following the efforts of the National League for Nursing (NLN), formerly known as the National League for Nursing Education, and the Goldmark report of 1923.

From 1872 until the mid-1960s, the hospital program was the predominant type of nursing program with graduates receiving a diploma in nursing. Refer to Table 1-2 for the general characteristics of diploma programs. By the 1960s,

the majority of diploma programs were associated with colleges or universities where students received college credit for their nonnursing courses. Some of the current diploma programs have evolved into what is called a *single-purpose institution*, having baccalaureate-degree-granting privileges for nursing.

ASSOCIATE DEGREE PROGRAMS

In 1951 Mildred Montag developed the blueprint for AD programs that would produce a nursing technician whose scope of practice was narrower than that of the professional nurse and broader than the PN's scope. Montag envisioned the AD as a terminal degree that prepared nurses to function at the bedside. The AD curriculum focused on preparing graduates to:

- Provide general nursing care under the supervision of baccalaureate nurses
- Assist in the planning of nursing care for clients
- Assist in the evaluation of nursing care

Montag's 5-year research project showed that AD nursing graduates could perform the intended nursing functions to work as technicians under the guidance of professional nurses. In 2000, the *National League for Nursing Educational Competencies for Graduates of Associate Degree Nursing Programs* updated the AD competencies, requiring evidence of professional behaviors, communication and assessment skills, caring interventions, teaching and learning, collaboration, and managing care (Coxwell & Gillerman, 2000). Refer to Table 1-2 for the general characteristics of AD programs.

AD programs have attracted a more diverse group of students to nursing. Traditional diploma nursing students were composed mainly of single, white females, approximately 18 years old, from middle-class families. The AD programs have attracted older, mature, goal-oriented students; minorities; males; and married women. The flexible scheduling patterns of community colleges that allow students to attend classes part-time have attributed to the increased numbers of individuals with baccalaureate and higher degrees in other fields seeking admission to AD programs.

BACCALAUREATE PROGRAMS

The first baccalaureate program in nursing was established at the University of Minnesota in 1909 through the efforts of Dr. Richard Olding Beard. There were only 8 baccalaureate programs by 1919. Colleges and universities were reluctant to establish baccalaureate programs in nursing because of the lack of qualified faculty. Following World War II and the passage of the Nurse Training Act in 1943, baccalaureate nursing programs began to increase slowly. In 1983 there were 420 programs, and by 2000 there were 695 programs. Most graduates of baccalaureate programs receive a bachelor of science degree in nursing (BSN). Refer to Table 1-2 for the general characteristics of baccalaureate programs.

The BSN curricula contain courses in general education, liberal arts, and the sciences related to nursing as well as nursing courses. According to the AACN's essential components

of baccalaureate education, all programs must include a liberal education, professional values, core competencies, core knowledge, and role development (AACN, 1998). Emphasis is placed on developing critical decision-making skills, exercising independent nursing judgment, and acquiring professional values and research skills. Although nursing research, nursing management, and community health are often cited as skills germane to BSN programs, these educational components also may be found in some diploma and AD programs.

MASTER'S PROGRAMS

The first master's education in nursing program began in 1899 at Teachers College in New York; however, it was not until the late 1950s and early 1960s that the number of master's programs began to escalate. The growth in graduate education was first driven by the need to educate qualified faculty for BSN and other types of entry-level programs. The first graduate programs emphasized role preparation. In response to the need for graduates prepared as administrative personnel for management and clinical positions, the content was expanded to include advanced practice components. As the content for advanced nursing became more defined, graduate programs began to prepare the clinical nurse specialist and advanced nurse practitioner in various areas of specialization such as neonatal, pediatric, and adult and family practice. By 1990, there were 231 nursing master's programs in the United States.

Nontraditional Graduate Programs Leading to RN Licensure

Several types of educational programs at the graduate level serve to prepare graduates to write the NCLEX-RN. These nontraditional paths for entry into nursing practice at the graduate level began at Yale University, the University of Texas at Austin, and the University of Tennessee. The impetus for allowing admission of individuals other than BSN graduates came from the significant numbers of degree-prepared nonnurses seeking admission to AD and BSN programs. These nontraditional programs admit nonnurse college graduates and RNs without the baccalaureate degree. The curricula provide for both groups to complete whatever undergraduate or graduate prerequisite courses are needed to acquire the equivalent of a baccalaureate degree in nursing. Following this component, nonnurses are eligible to take the NCLEX-RN examination. See Table 1-2 for the general characteristics of master's programs.

DOCTORAL PROGRAMS

There are various doctoral degrees awarded to nurses: the doctor of philosophy (PhD), doctor of nursing science (DNsc), doctor of science in nursing (DNS), doctor of education (EdD), and doctor of public health (DPH). Graduates of these programs are often prepared as researchers and educators to advance the discipline and profession of nursing. Although there were only 2 programs in 1946, the number of programs increased to 27 in 1983 and 50 in 1990.

Nontraditional Doctoral Programs Leading to RN Licensure

In the 1970s, Schlotfeldt developed the first nontraditional nursing doctorate (ND) program at the Frances Payne Bolton School of Nursing at Case Western Reserve University. Nontraditional programs usually provide curricula containing components of both basic and advanced nursing courses. Upon completion of the program, the graduate is eligible to write the NCLEX-RN examination. See Table 1-2 for the general characteristics of doctoral and nurse doctorate programs.

STAFF DEVELOPMENT AND CONTINUING EDUCATION

Once nurses are in practice, both staff development and continuing education are used to maintain the requisite knowledge and skill needed for contemporary practice in addition to a formal academic degree. Staff development typically occurs in the setting of employment and is described as the delivery of instruction to assist the nurse to achieve the goals of the employer. According to the ANA (1990):

nursing staff development is a process of orientation, in-service education and continuing education for the purpose of promoting the development of personnel within any employment setting, consistent with the goals and responsibilities of the employer. (p. 3)

Orientation is an important organizational tool for recruitment and retention. Orientation sessions typically occur at the initiation of employment and whenever positions and roles change. Content in orientation education unique to the institution of employment includes philosophy, goals, policies and procedures, role expectations, facilities, resources and special services, and assessment and development of competency with equipment and supplies used in the work setting (ANA, 1990).

In-service education is that phase of the staff development process that occurs after orientation and supports the nurse in acquiring, maintaining, and increasing skills to fulfill assigned responsibilities. Challenging learning opportunities in the employment setting include:

- Technology development
- Changing nature of health care and nursing science
- Interdisciplinary practice
- Changing delivery systems
- New equipment and supplies
- Enlarging roles of nursing related to leadership, management, delegation, supervision, and legal and ethical demands on practice

Active orientation and in-service development for nurses is a critical element of a delivery system that holds high standards for quality of care delivery in a cost-effective manner. Staff development is guided by the accreditation standards of the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) and the ANA's (1990) *Standards for Nursing Staff Development*.

Professional nurses are responsible for their own continuing education. Continuing education offers both personal and professional growth to the nurse and may serve as an incentive to pursue an academic degree. Continuing education builds on acquired knowledge, attitudes, and skills and constitutes an essential dimension of lifelong learning.

Although half the boards of nursing require continuing education units (CEUs) as part of the licensure renewal process to document the RN's competency, increasing evidence supports the assertion that "CE [continuing education] requirements do not guarantee continuing competence" (Pew Health Professions Commission, 1995, p. 1).

Lifelong learning is essential to career development and competency achievement in nursing practice. Technology has expanded the delivery and scheduling flexibility of continuing education for nurses in different geographic sites. Accessibility to continuing education will continue to improve the ability of the nurse to be flexible, factual, futuristic, and functional. The nurse of the future will be the professional who knows how to obtain and use evidence-based knowledge to achieve quality outcomes for health care.

PREPARING NURSES FOR TOMORROW'S CHALLENGES

The dynamic changes occurring in society and the health care arena are challenging professional nurses to focus on client outcomes and safety (see Chapter 29). When an aging population that requires more specialized nursing care is coupled with the increasing number of faculty members who are retiring, the reasons for the projected nursing shortage are clearly understood. A new nursing paradigm must be developed and educational programs must be willing to change in order to provide society with an adequate number of safe, competent nurses.

Some educational programs have demonstrated their ability to change, but are these changes sufficient to meet current and future challenges? Diploma education, which evolved with the history of nursing and the creation of hospitals in the United States, produced the nursing workforce for almost a century. The lack of nursing faculty prepared to teach at the baccalaureate level and the cost of a college education contributed to the slow growth of BSN programs. The availability and low cost of AD programs in the community college setting created a more diverse group of students and a phenomenal growth of these programs. This growth, in turn, challenged graduate programs to develop nontraditional programs to capture adult learners from diverse backgrounds by admitting RNs without baccalaureate degrees and degree graduates from nonnursing fields.

Nurse educators are facing real educational challenges. With hospital downsizing and shorter client stays, there are fewer opportunities for clinical learning. When one adds into the picture the aging population of nurse faculty, the decreased enrollment of nurses seeking graduate teaching degrees, and the reduced number of acute-care learning experiences, one has to question the viability of the

traditional education models used to prepare nursing graduates.

The nursing curriculum is the student's first introduction to the process of socialization into the profession. The process of socialization is based on professional values, which are taught by exposing students to learning opportunities that support compassionate, sensitive, empathic care for individuals, groups, and communities.

For the nursing profession to advance, and for nursing education to remain responsive to the changes that occur in society and health care, nursing programs must adjust their methods of teaching to provide for graduate competencies that are responsive to the health care challenges of the twenty-first century. A discussion of some of the most critical challenges follows.

DIFFERENTIATED PRACTICE

One of the major challenges facing professional nursing is the task of describing and differentiating the competencies and the scope of practice of nurses with multiple entry-level nursing programs. As discussed previously, all nurse graduates write the same licensing examination (NCLEX-RN), which is designed to ensure minimum standards of safe practice. One must ask if all graduates are created equal. Yet the curricula and accreditation requirements for graduate competencies differ for each program, and research documents different skill levels based on educational preparation.

Differentiated nursing practice refers to the practice of structuring nursing roles based on the expected competencies of graduates from different kinds of education programs. The Pew Health Professions Commission (1995) recommended that nursing distinguish between the different levels of nursing:

- AD for the entry-level hospital-based setting and nursing home
- BSN for hospital-based care management and community-based practice
- Master's degree preparation for specialty practice in the hospital and independent practice as a primary provider

Several leading organizations support the need for differentiated practice: the National Commission Nursing Implementation Project (NCNIP), the AACN, and the American Organization of Nurse Executives (AONE). Funds from the Robert Wood Johnson Foundation created a demonstration project, the Task Force on Differentiated Competencies for Nursing Practice under the auspices of the AACN and AONE, to develop a value-neutral language to describe differentiated nursing practice and education. This task force is still collecting data. The Council of Associate Degree Programs is working with the NLN to redefine their statement "Educational Outcomes of Associate Degree Nursing Programs: Roles and Competencies." The NCSBN has conducted studies regarding role delineation and job analysis of entry-level nurses.

The final report of the Pew Health Professions Commission identified 21 professional competencies for health care providers for the twenty-first century. These professional

SPOTLIGHT ON...

Professional

With multiple entry-level nursing programs, how would you differentiate the competencies of the graduates of each program?

Should graduates seek employment in settings appropriate to their educational preparation?

If practice settings employed and utilized graduates based on differentiated educational competencies, would this be a strong enough impetus for the NCSBN and state boards of nursing to differentiate licensure?

competencies stress the need for providers to work as a team in providing culturally sensitive care that is evidence-based and incorporates preventive health care.

ACCELERATED DEGREE PROGRAMS

The accelerated degree program for nonnursing students is one innovative educational approach to meet the projected need for a million additional nurses by the year 2010. These programs, at both the baccalaureate and master's degree levels, build on previous learning experiences and transition students with undergraduate degrees in other disciplines into nursing.

Accelerated programs have proliferated over the past 10 years. The growth of these programs can be attributed to their graduates. Employers value the many layers of skill and education these graduates bring to the workplace and are partnering with schools and offering tuition repayment to graduates as a mechanism to recruit highly qualified nurses.

TECHNOLOGY CHANGES IN NURSING EDUCATION

Over the past 10 years, computer technology has been incorporated into all aspects of teaching and learning in nursing programs. Some nursing programs provide distance learning by offering specific courses online, while other programs offer nursing degrees through online courses. Nursing programs have incorporated computer technology into the classroom and learning laboratory, offering a variety of approaches to instruction that appeal to a diverse student population. Computer-assisted instruction (CAI) augments classroom lectures and presentations in the form of interactive and linear video programs, client simulations, and drill and practice routines to promote problem solving, critical thinking, and clinical skills. Electronic mail between faculty members and students provides a mode for reflective learning; faculty members also use handheld computers for student record keeping and evaluation. Other learning management systems, such as Blackboard and WebCT, are an integral part of many nursing programs, whether the programs are online or campus-based.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Video Recording in Clinical Research Mapping the Ethical Terrain”

AUTHOR

L. Broyles

PURPOSE

To determine the ethical issues (informed consent, confidentiality and privacy, and participant burden and safety) of video-recorded clients and clinician research participants.

METHOD

The researcher used the Study of Patient-Nurse Effectiveness With Assisted Communication Strategies to show how these ethical issues can be managed in a clinical trial.

FINDINGS

The ethical issues inherent in video recording in acute care research can be adequately addressed through existing universal human subjects protection strategies when the precise nature of the ethical issues is defined clearly.

IMPLICATIONS

Videography is used often for data collection in clinical research, which requires the securing of institutional review board approval, confidentiality and privacy, safety, and informed consent. It is an effective way to conduct research when the ethical issues are determined and managed during the study.

Broyles, L. (2008). Video recording in clinical research: Mapping the ethical terrain. *Nursing Research*, 57(1), 59–63.

In health care, computers are used in a variety of ways, for example, in voice-activated point-of-care charting, developing nursing care plans, communicating with other health care providers, and regulating the administration of medications. See Chapter 13 for a detailed discussion regarding

nursing informatics such as electronic medical records and order entry.

Other innovations in technology, such as virtual reality (VR), also help to bridge the education gap between knowledge and application by providing students with the opportunity to practice essential nursing skills. With VR, computers and multimedia peripherals (visual display units and speakers) produce a simulated environment that users perceive as comparable to real-world objects and events. With multimedia simulation, students can practice procedures on the computer, assimilate clinical data, and make decisions independently in order to increase their critical thinking skills.

SERVICE LEARNING

Service learning is an educational method that uses community services with explicit learning objectives, preparation, and intentional reflective activities. Service learning is not a new educational method. The early 1900s educators, such as Dewey, recognized the importance of connecting service to educational goals. The need for educators to incorporate service learning into academic coursework is addressed in the following reports: *Healthy People 2010: Understanding and Improving Health*, the Pew Health Professions Commission report, the *National League for Nursing Educational Competencies for Graduates of Associate Degree Nursing Programs*, and the AACN and the NLN BSN competencies. The incorporation of this methodology into the nursing curriculum requires extensive preparation of faculty and collaborative partnership between the nursing program, students, and community agencies. The four critical components of service learning:

- Are experimental in nature
- Allow students to engage in activities that address human and community needs through structured opportunities for learning
- Incorporate reflection
- Embrace the concept of reciprocity between the learner and the person being served

Reflection is the link between the students' performance of service and the learning outcomes of that service.

From *Nightingale's Notes on Nursing*, to the core competencies of graduates as defined by accrediting bodies, to the Pew report and *Nursing's Educational Agenda for the 21st Century*, caring, teaching, research, social justice, service, and community are recurring concepts that link nursing education to a profession that is responsive to societal and individual health care needs.

KEY CONCEPTS

- Nursing is an art and a science in which people are assisted in learning to care for themselves whenever possible and cared for when they are unable to meet their own needs.
- Nurses will understand such issues as autonomy, unity within the profession, supply and demand, salary, education, and current practice and the empowerment of the profession by studying nursing's history.

- Nursing's early history was heavily influenced by religious organizations and the need for nurses to care for soldiers during wartime.
- Florence Nightingale forged the future of nursing practice and education as a result of her experiences in training nurses to care for soldiers.
- Nursing's early American leaders, professional organizations, and landmark reports have influenced the infrastructure of current nursing practice.
- Influential nursing leaders, such as Lillian Wald, Jane Delano, Isabel Hampton Robb, Annie Goodrich, Adelaide Nutting, and Lavinia Dock, were instrumental in the advancement of nursing education and practice.
- Other nursing pioneers, such as Amelia Greenwald, Mary Breckinridge, Mamie Hale, Mary Mahoney, Linda Richards, and Margaret Sanger, made important contributions to both nursing education and the fields of rural, public health, maternity, and multicultural nursing.
- In 1923, the Goldmark report concluded that for nursing to be on equal footing with other disciplines, nursing education should occur in the university setting.
- The Brown report (1948) addressed the need for nurses to demonstrate greater professional competence by moving nursing education to the university setting.
- The Health Maintenance Organization Act of 1973 provided an alternative to the private health insurance industry.
- Contemporary reports issued by the National Commission on Nursing, the IOM, and the Secretary's Commission on Nursing focused on the areas of nursing education, practice, and nursing's role in health care financing policies.
- The three types of programs that currently prepare nurses for entry-level practice are diploma, AD, and baccalaureate degree nursing programs.
- To achieve the competencies established for health care professionals, several strategies for nursing education reform have been proposed in the areas of institutional, governmental, and federal involvement with the nursing profession.
- As the nursing profession continues to evolve and respond to the challenges within the health care system, nurses will remain responsive to societal needs.

REVIEW QUESTIONS

- Which of the following are some of Florence Nightingale's beliefs regarding nursing? Select all that apply:
 - A holistic framework inclusive of illness and health
 - The need for a theoretical basis for nursing practice
 - The importance of creating an environment that promotes healing
 - The need for fresh air and light
 - The need to support the individual's adaptation to stimuli
 - The need to assist persons attain a higher degree of harmony
- During World War I, which nursing leader opposed physician training aides to care for the sick?
 - Isabel Hampton Robb
 - Jane Delano
 - Annie Goodrich
 - Margaret Sanger
- Which educational program prepares the nurse for advanced practice?
 - Associate degree
 - Baccalaureate
 - Master's
 - Licensed practical
- Which social forces have the greatest impact on the supply and demand for nurses?
 - Aging and faculty attrition
 - Economics and technology
 - Faculty attrition and economics
 - Science and technology
- Which is an example of continuing education?
 - Attending an orientation program
 - Meeting with a representative regarding a new piece of monitoring equipment
 - Completing a workshop of legal aspects of nursing
 - Obtaining information regarding a new computer charting system

Visit the DeLaune and Ladner online companion resource at www.delmar.cengage.com for additional content and study aids. Click on Online Companions, then select the Nursing discipline.

Theory is the poetry of Science.

—LEVINE

CHAPTER 2

Nursing Theory

COMPETENCIES

1. Explain the relationships of concepts and propositions to theory.
2. Discuss the purpose of theory.
3. Describe the link between nursing theory and the continuing development of the nursing profession.
4. Explain the interdependent roles of nursing practice, nursing theory, and nursing research.
5. Identify the three categories relating to the scope of theories.
6. Describe the metaparadigm concepts in nursing and how they differ from the metaparadigm concepts in medicine.
7. Discuss the process of paradigm revolution and paradigm shift in nursing and relate it to the current paradigms in nursing.
8. Apply the principles of selected nursing theories, such as the conservation theory, the self-care deficit theory of nursing, the Roy adaptation model, the theory of human caring, the science of unitary human beings, and man-living-health, to nursing practice.

This chapter explores the theoretical foundation on which the knowledge base of the nursing profession has been and is being built. Nursing theory provides a perspective from which to define the *what* of nursing, to describe the *who* of nursing (who is the client) and *when* nursing is needed, and to identify the boundaries and goals of nursing's therapeutic activities. Theory is fundamental to effective nursing practice and research. The professionalization of nursing has been and is being brought about through the development and use of nursing theory.

This chapter first addresses basic ideas about the meaning of nursing theory and its relevance to professional nursing. Issues related to the purpose, use, and diversity of nursing theories are discussed. It then presents a broad overview of selected nursing theories. The major ideas of selected nursing theories are explained, and examples of their use in nursing situations are provided.

COMPONENTS OF THE THEORETICAL FOUNDATION

The basic elements that structure a nursing theory are concepts and propositions. In a theory, propositions represent how concepts affect each other.

WHAT IS A CONCEPT?

A concept is the basic building block of a theory. A **concept** is a vehicle of thought. According to Chinn and Kramer (1999), concepts are complex mental formulations of one's perceptions of the world. A concept labels or names a **phenomenon**, an observable fact that can be perceived through the senses and explained. A concept assists us in formulating a mental image about an object or situation. Concepts help us to name things and occurrences in the world around us and assist us in communicating with each other about the world. Independence, self-care, and caring are just a few examples of concepts frequently encountered in health care. Theories are formulated by linking concepts together. A **conceptual framework** is a structure that links global concepts together and represents the unified whole of a larger reality. The specifics about phenomena within the global whole are better explained by theory.

By its nature, a concept is a socially constructed label that may represent more than a single phenomenon. For example, when you hear the word *chair*, a mental image that probably comes to mind is an item of furniture used for sitting. The word *chair* could represent many different kinds of furniture for sitting, such as a desk chair, a high chair, or an easy chair. Further, the word *chair* could also represent the leader of a committee or the head of a corporation. The meaning of the word *chair* depends on the context in which it is used.

In health care, the concept of *wandering* may be represented by words such as aimless and random movement, disorganized thought processes, and conversation that is difficult to follow. To be useful, the multiple meanings that often underlie a concept must be thoroughly understood and clearly defined within the context in which it is used.

It is important to remember that the same concept may be used differently in various theories. For example, one nursing theory may use the concept of *environment* to mean all that surrounds a human being (the external environment), whereas another theory may use this concept to mean the external environment *and* all the biological and psychological components of the person (the internal environment).

WHAT IS A PROPOSITION?

A **proposition** (another structural element of a theory) is a statement that proposes a relationship between concepts. An example of a nonnursing proposition might be the statement "people seem to be happier in the springtime." This proposition establishes a relationship between the concept of happiness and the time of the year. A nursing propositional statement linking the concept of helplessness and the concept of loss might be stated as "multiple and rapid losses predispose one to feelings of helplessness." Propositional statements in a theory represent the theorist's particular view of which concepts fit together and, in most theories, establish how concepts affect one another.

WHAT IS A THEORY?

A **theory** is a set of concepts and propositions that provide an orderly way to view phenomena. In the scientific literature, *theory* may be defined in many different ways, with subtle nuances specific to the particular author's viewpoint.

These various explanations share a common notion of the purpose of the theory, that being description, explanation, and prediction. “A theory, by traditional definition, is an organized, coherent set of concepts and their relationship to each other that offers descriptions, explanations, and predictions about phenomena” (Parker, 2001, p. 4). A theory not only helps us to organize our thoughts and ideas but also may help direct us in what to do and when and how to do it.

The use of the term *theory* is not restricted to the scientific world, however. It is often used in daily life and conversation. For example, when telling a friend about a mystery novel you are reading, you may have said, “I have a theory about who committed the crime.” Or you may have heard a Little League coach saying to the players, “I have a theory about how to improve our performance.” The way in which this term is used in these statements is a useful way to think about the meaning of theory.

USE OF THEORIES FROM OTHER DISCIPLINES

In addition to using theories specifically constructed to describe, explain, and predict the phenomena of concern to nursing, the nursing profession has long used theories from other disciplines. A **discipline** is a field of study. Theories from biological, physical, and behavioral sciences are commonly used in the practice of nursing. For example, nonnursing theories such as Maslow’s hierarchy of basic human needs, Erikson’s theory of human development, and Selye’s general adaptation syndrome theory have been and continue to be useful in nursing practice.

These nonnursing theories are often incorporated into nursing practice together with specific nursing theories. When used in conjunction with a nursing theory, a nonnursing theory is transformed by the unique approach of the nursing perspective. This perspective provides the specific framework or viewpoint within which to use theories and knowledge from other disciplines.

IMPORTANCE OF NURSING THEORIES

Why do we have nursing theories? In the early part of nursing’s history, knowledge was extremely limited and almost entirely task oriented. The knowledge explosion that occurred in health care in the 1950s produced the need to systematically organize the tremendous volume of new information being generated. From the very beginnings of nursing education, there was a need to categorize knowledge and to analyze client care situations in order to communicate in coherent and meaningful ways. Nursing practice knowledge is generated by theory. According to McEwen and Willis (2007), the integration of theory into practice is the basis for professional nursing.

The literature about the relationship between theory and nursing care yields many interpretations in terms of the

role each component plays in the health care environment. According to Barnum (1994, p. 1), “a theory is a construct that accounts for or organizes some phenomenon.” Chinn and Kramer (1999, p. 71) viewed theory as a “creative and rigorous structuring of ideas that projects a tentative purposeful and systematic view of phenomena.” Meleis (1997, p. 12) stated that a theory is a “conceptualization of some aspect of reality (invented or discovered) that pertains to nursing. The conceptualization is articulated for the purpose of describing, explaining, predicting or prescribing nursing care.” Similarly, Parse (1998, p. 4) defined a theory as a “general term that is a notion or an idea that explains experience, interprets observation, describes relationships, and projects outcomes. Theories are mental powers or constructs created to help understand and find meaning from experience, organize and articulate our knowing, and ask questions leading to new insights.”

Nursing theories provide a framework for thought in which to examine situations. As new situations are encountered, this framework provides a structure for organization, analysis, and decision making. In addition, nursing theories provide a structure for communicating with other nurses and with other members of the health care team. Nursing theories assist the discipline of nursing in clarifying beliefs, values, and goals, and they help to define the unique contribution of nursing in the care of clients. When the focus of nursing’s contribution is clear, then greater professional autonomy and, ultimately, control of certain aspects of practice are achieved.

In the broadest sense, nursing theory is necessary for the continued development and evolution of the discipline of nursing. Because the world of health care changes virtually on a daily basis, nursing needs to continue to expand its knowledge base to proactively respond to changes in societal needs. Knowledge for nursing practice is developed through nursing research that, in turn, is used to either test existing theories or generate new theories. **Nursing research** is the systematic application of formalized methods for generating valid and dependable information about the phenomena of concern to the discipline of nursing (Chinn & Kramer, 1999).

The relationship between nursing practice, theory, and research is depicted in Figure 2-1. These processes are so

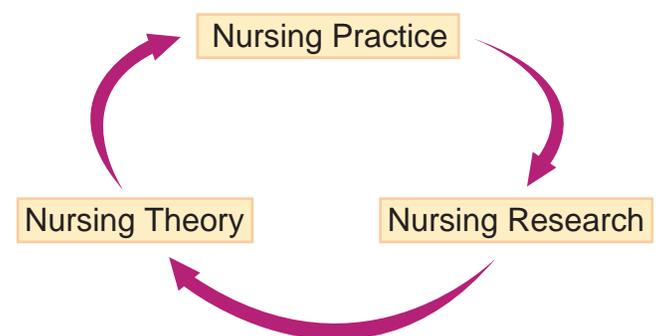

FIGURE 2-1 Process of knowledge development. Nursing practice, theory, and research are interdependent. Nursing theory development and nursing research activities are directed toward developing nursing practice standards. DELMAR/CENGAGE LEARNING

closely related that to consider one aspect without considering the other two aspects would be the same as seeing only a part of the whole. Nursing practice is the focal point of the relationship between practice, theory, and research. It provides the raw material for the ideas that are systematically developed and organized in the form of nursing theory. The ideas proposed by nursing theory must be tested and validated through nursing research. In turn, new knowledge that results from nursing research is used to transform and inform nursing practice. Alternatively, nursing practice generates questions that serve as the basis for nursing research. Nursing research, then, influences the development of nursing theory that, in turn, transforms nursing practice. For example, the Neuman systems model, explained later in this chapter, provides clear direction for the researcher who is interested in describing stressors; explaining the factors that influence reactions to those stressors; and testing the effects of primary, secondary, and tertiary prevention on stressor reactions within the context of a holistic, open system perspective (Fawcett & Gigliotti, 2001).

When nurses explore various nursing theories, they gain new insights into patient care, open new options otherwise hidden, and stimulate innovative interventions (Woodward, 2003). Theoretical thinking enhances and strengthens the nurse's role and helps one to actually *think* nursing. As nurses learn more about specific nursing theories, it may be discovered that they can relate more to one theory than another or that they can appreciate the ideas contained in several different theories. Nurses may use a specific nursing theory to help guide their practice or may choose a more eclectic approach and adopt ideas from several theories. Both of these approaches are valid. Furthermore, nurses may find some theories more appropriate for certain situations. In that case, one theory can be used with a client in a home health care setting, whereas another theory may be more applicable to a client in an acute care environment. Regardless of the approach chosen, nurses will recognize the value and usefulness of nursing theory as a tool for effective nursing practice.

SCOPE OF THEORIES

According to Fawcett (2000), theories address relatively specific and concrete phenomena, but they vary in scope; *scope* refers to the relative level of substantive specificity of a theory and the concreteness of its concepts and propositions. Essentially, three different categories relate to the scope of theories: grand theories, middle-range theories, and micro-range theories. This classification is applicable to both nursing and nonnursing theories.

GRAND THEORIES

A **grand theory** is composed of concepts representing global and extremely complex phenomena. It is the broadest in scope, represents the most abstract level of development, and addresses the broad phenomena of concern within the

discipline. Typically, a grand theory is not intended to provide guidance for the formation of specific nursing interventions, but rather provides an overall framework for structuring broad, abstract ideas (Fawcett, 2005). An example of a grand theory is Orem's self-care deficit theory of nursing.

MIDDLE-RANGE THEORIES

A theory that addresses more concrete and more narrowly defined phenomena than a grand theory is known as a **middle-range theory**. Descriptions, explanations, and predictions put forth in a middle-range theory are intended to answer questions about nursing phenomena, yet they do not cover the full range of phenomena of concern to the discipline. A middle-range theory provides a perspective from which to view complex situations and a direction for interventions (Fawcett, 2005). An example of a middle-range theory is Peplau's theory of interpersonal relations.

MICRO-RANGE THEORIES

A micro-range theory is the most concrete and narrow in scope. A **micro-range theory** explains a specific phenomenon of concern to the discipline (Fawcett, 2005), such as the effect of social supports on grieving, and establishes nursing care guidelines to address the problem.

EVOLUTION OF NURSING THEORY

The work of early nursing theorists in the 1950s focused on the tasks of nursing practice from a somewhat mechanistic viewpoint. Because of this emphasis, much of the art of nursing—the value of caring, the relationship aspects of nursing, and the esthetics of practice—was diminished. During the decades of the 1960s, 1970s, and 1980s, many nursing theorists struggled with making nursing practice, theory, and research fit into the then prevailing view of science. Table 2-1 on page 27 provides a chronological summary of the development of nursing's theory base through the contributions of noted theorists and influential leaders in nursing.

Reflecting changes in global awareness of health care needs, several contemporary nursing theorists have projected a new perspective for nursing that truly unifies the notion of nursing as both an art and a science. Noted nursing theorists such as Leininger, Watson, Rogers, Parse, and Newman have been urging the discipline of nursing to embrace this new emerging view that is seen as more holistic, humanistic, client focused, and grounded in the notion of caring as the core of nursing.

Since the early 1950s, many nursing theories have been systematically developed to help describe, explain, and predict the phenomena of concern to nursing. Each of these established theories provides a unique perspective, and each is distinct and separate from other nursing theories in its particular view of nursing phenomena. An overview of several nursing theories is presented later in the chapter.

KNOWLEDGE DEVELOPMENT IN NURSING

The knowledge in a particular discipline can be arranged in a hierarchical structure that ranges from abstract to concrete. Theories represent the most concrete component of a discipline. Several theories that share a common view of the world can be grouped together to form a paradigm. A **paradigm** is a particular viewpoint or perspective. Each discipline has a defined metaparadigm, which is the most abstract component of knowledge and which can consist of more than one paradigm (Fawcett, 2005). A **metaparadigm** is the unifying force in a discipline that names the phenomena of concern to that discipline.

METAPARADIGM OF NURSING

What is it that distinguishes nursing from any other discipline such as biology, sociology, or psychology? Each of these other disciplines—biology, sociology, and psychology—is concerned with specific aspects of the human being. Every discipline singles out certain phenomena that it will deal with in a unique manner (Fawcett, 2005). The field of biology (the study of living organisms) has defined limits and boundaries that do not extend into psychology. Similarly, psychology (which is concerned with the behavior of individuals) does not extend its concerns into the domain of sociology, which has as its main focus the social behavior of human beings.

The broadly identified concerns of a discipline are defined in its metaparadigm. The metaparadigm concepts provide the boundaries and limitations of a discipline, identify the common viewpoint that all members of a discipline share, and help to focus the activities of the members of that discipline. Disciplines are distinguished from each other by differing metaparadigm concepts. Most metaparadigms consist of several major concepts.

Initial consensus on the metaparadigm concepts in nursing was achieved in 1984. According to Fawcett (2005), the major concepts that provide structure to the domain of nursing are *person, environment, health, and nursing*. These

metaparadigm elements name the overall areas of concern for the nursing discipline. Each nursing theory presents a slightly different view of the metaparadigm concepts. Refer to the section later in this chapter entitled “Selected Nursing Theories” for a discussion of how various theorists address and link the metaparadigm concepts.

Consider for a moment the practice of nursing by a school nurse, an emergency room nurse, and a psychiatric nurse. What is the unifying thread among these various nurses? Although each nurse’s practice is obviously different, they all consider their work as part of the profession of nursing because all share the same major concerns. Regardless of the setting or the type of client involved, each nurse is concerned with person, environment, health, and nursing. Nursing’s metaparadigm is shared by all nurses despite differences in their individual practices.

How is nursing’s metaparadigm different from that of other helping professions? The metaparadigm of medicine focuses on pathophysiology and the curing of disease. Nursing’s metaparadigm is broader and focuses on the person, health, and the environment. Consider a prescribing practitioner’s and a nurse’s view of a client who is newly diagnosed with diabetes. The prescribing practitioner is concerned with reducing the client’s abnormal blood glucose values to normal levels, if possible. The prescribing practitioner prescribes medications, an exercise regime, and nutritional counseling in an effort to control blood sugar levels. In dealing with the same client situation, the nurse is concerned with such issues as the client’s ability to cope with a chronic condition, the effect of the diagnosis on the client’s family, and teaching about the need for changes in the client’s daily living patterns. The nurse is concerned with the impact of the diagnosis on all aspects of the client’s life. Although both health care providers are viewing the same client situation, each has a different perspective or focus. Each discipline’s metaparadigm provides a viewpoint that leads to the development of knowledge as seen within that viewpoint.

Despite the fact that person, health, environment, and nursing are the generally accepted metaparadigm elements in nursing, there is growing discontent with the limitation of these elements. As dialogue continues and as clarity emerges,

the metaparadigm elements will change to reflect contemporary thought and practice.

One example of this evolution in the discipline of nursing is the inclusion of caring as a basic core concept, central to the practice of nursing. Nurse scholars have urged a reconsideration of the identified metaparadigm elements. Watson stated that “care is the essence of nursing and the most central and unifying focus for nursing practice (1985, p. 35). Watson further stated, “I see the value of human caring theory as a foundational ethic and philosophy for any health professional. Though my work comes from nursing, the current momentum for a focus on caring in several health disciplines is congruent with the caring stance that nursing has had across time” (as cited in Fawcett, 2002a, p. 215).

PARADIGMS IN NURSING

The metaparadigm of a discipline identifies common areas of concern. A paradigm is a particular way of viewing the phenomena of concern that have been delineated by the metaparadigm of the discipline. The term *paradigm* stems from the work of Kuhn (1970), who referred to a paradigm as “worldview” about the phenomena of concern in a discipline.

Two individuals with different paradigmatic views can look at precisely the same phenomenon and each will “see” or view the phenomenon differently. For example, consider the viewpoints of a mother and father who are watching their daughter at T-ball practice. The mother looks at her daughter and sees a graceful, yet somewhat shy child who has shown improvement in her ability to make new friends. On the other hand, the father sees a strong runner who needs help with batting drills. Each parent is looking at the same phenomenon (their daughter), but each is seeing the phenomenon from a completely different perspective. Each parent is operating from a different paradigm.

The prevailing paradigm in a discipline represents the dominant viewpoint of particular concepts. This viewpoint is supported by theories and research that for the time being adequately address the concerns of the discipline. By consensus, the community of scholars in a discipline accepts and agrees on a particular viewpoint or worldview. When new theories and research surface that challenge the prevailing paradigm, a new paradigm emerges to compete with the prevailing worldview. The competition between the paradigms results in what Kuhn (1970) refers to as a paradigm revolution. A **paradigm revolution** is the turmoil and conflict that occur in a discipline when a competing paradigm gains acceptance over the dominant paradigm. If the competing paradigm answers more questions and solves more problems for the discipline than the prevailing paradigm, then a paradigm shift occurs. A **paradigm shift** refers to the acceptance of the competing paradigm over the prevailing paradigm or a shifting away from one worldview toward another worldview. Again, by consensus the competing paradigm becomes the dominant paradigm and the process begins again (Kuhn, 1970).

The notion of paradigm revolution can be likened to the revolution that might occur in a country where the ruling government is overthrown by a competing group who

proposed to have more and better solutions to the country’s problems. In this situation, power shifts from one ruling body to another. In another example, a paradigm shift occurred when people began to view the world as round rather than flat. Once it was agreed on by the community of scholars that the world was round (now the prevailing paradigm), all other views about the world also changed. Paradigms can be mutually exclusive. Members of a discipline cannot subscribe to two competing paradigms at the same time. One cannot believe at the same time that the world is flat *and* that the world is round.

Several nursing scholars have proposed that the discipline of nursing is in the midst of a paradigm revolution. The implication is that there are at least two paradigms in competition with each other. Although the scholarly literature in nursing reflects the views of several authors who present and name different paradigms in nursing, the work of Parse is highlighted here. According to Parse (1987), there are currently two paradigms in nursing: the *totality paradigm* and the *simultaneity paradigm* (see Figure 2-2). Each of these paradigms is composed of various nursing theories that are similar in their worldview of the metaparadigm concepts. However, each theory, which is grouped within a particular paradigm, has different definitions of concepts and propositions that state how these concepts are related.

In the **totality paradigm**, the person, who is a combination of biological, psychological, social, and spiritual features, is in constant interaction with the environment to accomplish goals and maintain balance. “The goals of nursing in the totality paradigm focus on health promotion, care

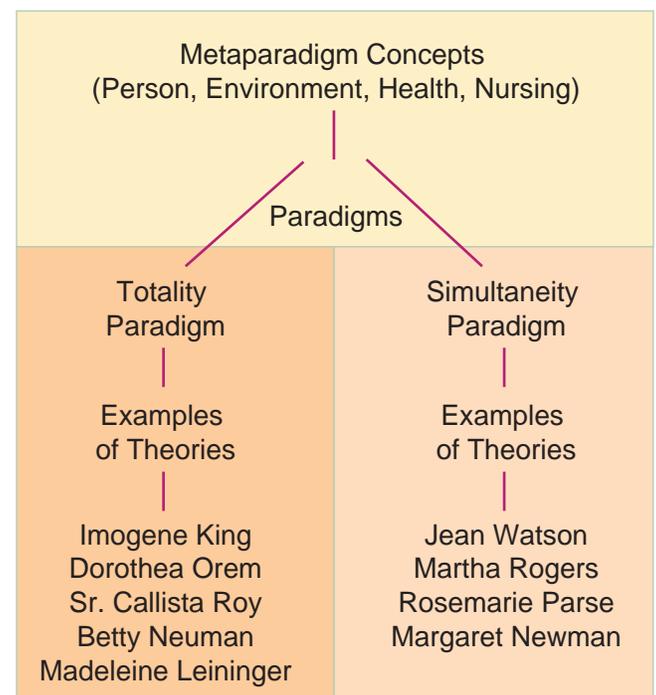

FIGURE 2-2 Hierarchy of knowledge development in nursing. In the hierarchical arrangement of knowledge development in a discipline, the metaparadigm concepts are the most abstract. Theories represent the most concrete level in this hierarchy.

DELMAR/CENGAGE LEARNING

and cure of the sick, and prevention of illness. Those receiving nursing care are persons designated as ill by societal norms” (Parse, 1987, p. 32). Identification with the totality paradigm is understandable because it has been and is the prevailing paradigm in nursing. Many of the nursing theories developed to date have a view of the discipline of nursing that fits the totality paradigm.

In the competing paradigm, the simultaneity paradigm, the person-environment interaction is viewed very differently. In the **simultaneity paradigm**, *whole* means unitary, and the unitary human has characteristics that are different from the parts and cannot be understood by a knowledge of the parts. Moreover, the human cannot be separated from the entirety of the universe, as both change continuously in innovated, unpredictable ways and together create health, a value defined by people for themselves (Parse, 2000). Nursing's goals in the simultaneity paradigm focus on the quality of life from the person's perspective. Designation of illness by societal norms is not a significant factor. The authority and prime decision maker in regard to nursing is the person, not the nurse (Parse, 2000).

Clearly, these two paradigms represent very different viewpoints. These differences give rise to different methods of inquiry and practice and provide sufficient scope to encompass all disciplinary activities.

Debate, dialogue, discussion, theory development, and research continue within the discipline of nursing. Some nursing scholars argue about the structural elements of the discipline; some debate the value of competing paradigms; and some present alternative metaparadigm elements. Yet with all the uncertainty that is created by these questions and alternative ideas, the ongoing dialogue is a healthy sign of the development of the nursing profession.

SELECTED NURSING THEORIES

Although there are many nursing theories, frameworks, and models, this chapter addresses only selected ones (see Table 2-2 on pages 31 and 32). The theories discussed have been selected because they represent the development of nursing's scientific thought. As previously discussed in this chapter, nursing theories serve several essential purposes that enhance nursing's scientific knowledge. Examples are provided throughout the following discussion regarding the contributions of nursing theories to nursing practice, education, and research. Some of the theorists, such as Levine and Roy, demonstrate how their theories complement the nursing process (see Chapters 5–10 for detailed information on the nursing process). While Levine's model relabels and redefines the five phases of the nursing process, Roy designates two steps to assessment, creating a six-step process.

FLORENCE NIGHTINGALE

Nightingale did not develop a theory of nursing as theory is defined today, but she provided the nursing profession with the philosophical basis from which other theories have emerged and developed. Nightingale's ideas about nursing

have guided both theoretical thought and actual nursing practice throughout the history of modern nursing.

Nightingale considered nursing similar to a religious calling to be answered only by women with an all-consuming and passionate response. She considered nursing to be both an art and a science and believed that nurses should be formally educated.

Her writings did not focus on the nature of the person but did stress the importance of caring for the ill person rather than caring for the illness. In Nightingale's view, the person was a passive recipient of care, and nursing's primary focus was on the manipulation of the person's environment to maintain or achieve a state of health.

Despite the fact that she did not believe in the germ theory, her experiences in the Crimean War magnified her interest in the principles of sanitation and the relationship between environment and health. A person's health was the direct result of environmental influences, specifically, cleanliness, light, pure air, pure water, and efficient drainage. Through manipulating the environment, nursing “aims to discover the laws of nature that would assist in putting the patient in the best possible condition so that nature can effect a cure” (Nightingale, 1859/1946, p. 6). Nursing's main focus was health, and health was closely related to nursing. Nursing was concerned with the healthy as well as the sick (Nightingale, 1859/1946).

Nightingale's principles regarding environment-health-nursing were implemented in America at the turn of the twentieth century. With the development of hospital-based schools of nursing, Nightingale's principles of sanitation were used to clean up the rat-infested, dirty hospitals of the day. With the use of Nightingale's ideas, hospitals became a place for people to recover rather than a place to die. When, for a variety of reasons, hospitals did not hire their own nursing graduates, nurses applied Nightingale's principles in the community in the development of public health nursing. The Henry Street Settlement founded by Lillian Wald is an excellent example of Nightingale's theory in practice.

Private duty nursing and public health nursing remained the primary focus of nursing practice until World War II. At this time, there was a tremendous increase in scientific knowledge and technology affecting health care. As the practice of medicine became more scientifically based, more clients were cared for in hospital settings. Nursing practice likewise became centered in the hospital rather than the home. With this development, it became clear that nursing did not have an adequate theory base to organize new knowledge and guide nursing practice. Nursing began to further develop its knowledge base by incorporating the principles of Nightingale into modern nursing theory.

EARLY NURSING THEORIES

By its very nature, the development of nursing's theoretical base has progressed in a methodical and systematic, albeit slow, fashion. Knowledge development is an ongoing process that is often influenced by driving forces outside the discipline of nursing. The early nurse theorists were not attempting to

TABLE 2-2 Summary of Selected Nursing Theorists' Major Concepts

THEORIST AND MODEL	PERSON	ENVIRONMENT	HEALTH	NURSING
Nightingale (1859) Environmental Theory	Physical, intellectual, and spiritual being unable to manipulate the environment to promote health	Physical elements that affect the healing process: cleanliness, light, pure air and water, comfort	State of well-being using one's powers to the fullest extent	To facilitate healing and restore health by manipulating the person's environment
Peplau (1952) Interpersonal Process	Developing organism living in an unstable equilibrium and striving to reduce anxiety	External factors and significant others	Interpersonal processes that facilitate forward movement of the personality	To develop interaction between the nurse and the person
Henderson (1955) Basic Needs	Biological being, oneness of mind and body, who has 14 fundamental needs	The aggregate of all external conditions affecting life and development	Wholeness, the ability to function independently in relation to 14 needs	To assist the person (well and sick) to perform the 14 essential functions
Levine (1969) Conservation Theory	Who the person knows himself or herself to be	Context in which the person lives his or her life	Response of the person to the environment	To use conversation activities aimed at optimizing the person's resources
Rogers (1970) Science of Unitary Beings	A unified irreducible whole; more than the sum of the parts	Pandimensional energy field integral with the human energy field	Patterns of living in harmony with the environment; defined by the culture or individual	Science and art; the art of nursing is the creative use of science for human betterment
King (1971) Goal Attainment Theory	Open system who exhibits characteristics common to others	Internal and external elements involving temporal and spatial reality	Ability to adjust to stressors to achieve maximum potential for daily living	A process of action, reaction, and interaction
Orem (1971) Self-Care Deficit Theory	A unity who functions biologically, symbolically, and socially and whose functioning is linked with the environment	Linked to the individual, forming an integrated system	State in which the individual is structurally and functionally whole	A triad of interrelated action systems
Roy (1976) Adaptation Model	Biopsychosocial being interacting with a dynamic environment	Internal and external conditions that surround and affect individuals	State or process of being or becoming an integrated and whole person through adaptation	To support the individual's adaptation to stimuli
Paterson & Zderad (1976) Humanistic Nursing	Process of becoming in an environment of time and space	Awareness of the individual's uniqueness and commonality with others	State of becoming, well-being, rather than freedom from disease	To respond to human needs and build humanistic nursing science

THEORIST AND MODEL	PERSON	ENVIRONMENT	HEALTH	NURSING
Leininger (1978) Transcultural Caring Theory	Caring, cultural beings	Interrelated, interdependent systems of a society	State of well-being that is culturally defined	To provide care; caring is the central, unifying domain for nursing knowledge and practice
Neuman (1972/1995) Systems Model	Wholistic client, dynamic composite of interrelationships among physiological, psychological, sociocultural, developmental, and spiritual variables	Internal and external factors affecting and affected by the system	Health and wellness is a condition or degree of system stability	To assist client adjustments required for an optimal wellness level through accuracy in the assessment of effects and possible effects of environmental stressors
Watson (1979/1989) Human Caring Theory	Person possesses three spheres: mind, body, and soul; strives to actualize the higher self	Internal and external variables	Unity and harmony within the mind, body, and soul	To assist persons attain a higher degree of harmony by offering caring relationships that clients can use for personal growth and development
Parse (1981/1995) Human Becoming Theory	An open being, coexisting with the environment	Inseparable from the individual; humans and the environment interchange energy, and influence one another's rhythmical patterns of relating	An open process of becoming that encompasses a lived experience, synthesis of values, and rhythmic process of being or becoming	A discipline, the practice of which is a performing art

Delmar/Cengage Learning

address the metaparadigm concepts because initial consensus on these had not yet been achieved. Rather, these theories were attempting to answer the question “What is nursing?”

Hildegard Peplau

Hildegard Peplau, a psychiatric nurse, combined her research and experience in the development of a theory of psychodynamic nursing, published in *Interpersonal Relations in Nursing* (1952). Drawing from her own knowledge and that from other disciplines, Peplau defined the concepts and stages involved in the development of the nurse-client relationship. From that relationship, she identified the roles of the nurse as stranger, resource person, teacher, leader, surrogate, and counselor. Peplau developed a middle-range theory with a focus on both nursing and the person and did not

incorporate all aspects of the metaparadigm into her theory. Although other theories may view the nurse-client relationship differently, the primacy of this relationship in nursing has remained.

Virginia Henderson

Virginia Henderson's definition of nursing, considered to be a classic, first appeared in 1955.

The unique function of the nurse is to assist the individual, sick or well, in the performance of those activities contributing to health or its recovery (or to a peaceful death) that he would perform unaided if he had the necessary strength, will, or knowledge. And to do this in such a way as to help him gain independence as rapidly as possible. (Henderson, 1966, p. 15)

Together with Bertha Harmer, Henderson attempted to identify those basic human needs viewed as the basis of nursing care. These needs include the need to maintain physiologic balance, to adjust to the environment, to communicate and participate in social interaction, and to worship according to one's faith. Henderson's 14 basic needs were published in the *Textbook of the Principles and Practice of Nursing*, one of the first nursing textbooks. Henderson viewed the nursing role as helping the client from dependence to independence. As an early nursing theorist, she did not intend to develop a theory of nursing but rather attempted to define the unique focus of nursing. Henderson's emphasis on basic human needs as the central focus of nursing practice has led to further theory development regarding the needs of the person and how nursing can assist in meeting those needs.

Faye Abdellah

Faye Abdellah, acknowledging the influence of Henderson, expanded Henderson's 14 needs into 21 problems that she believed would serve as a knowledge base for nursing. Throughout her career, she strongly supported the idea that nursing research would be the key factor in helping nursing to emerge as a true profession. The research that was done regarding these common needs or problems has served as a foundation for the development of what we now know as nursing diagnoses.

Joyce Travelbee

Joyce Travelbee, an educator and psychiatric nurse, was influenced by the philosophy of **existentialism**, a movement that is centered on individual existence in an incomprehensible world, the role that free will plays in it, and the search to find meaning in life's experiences. She extensively developed the ideas of sympathy, empathy, and rapport in which the nurse could begin to comprehend and relate to the uniqueness of others. Her work focused on the human-to-human relationship and on finding meaning in experiences such as pain, illness, and distress. Travelbee based most of her theory on her own experiences and readings and first published her work in *Interpersonal Aspects of Nursing* in 1966.

Josephine Paterson and Loretta Zderad

The work of Josephine Paterson and Loretta Zderad was similar to that of Travelbee in that it emphasized the humanistic and existential basis of nursing practice. According to Paterson and Zderad, theory developed from the practice of nursing. Although the models proposed by Travelbee and Paterson and Zderad had some impact at the time of their initial introduction, they did not gain wide popularity and application in nursing. The work of Travelbee and Paterson and Zderad most appropriately fits the simultaneity paradigm. Current theorists—such as Watson, Rogers, Parse, Fitzpatrick, and Newman—who have an existential orientation, are rediscovering the merits of Travelbee and Paterson and Zderad.

CONTEMPORARY NURSING THEORIES

Although early nursing theorists attempted to answer the question “What is nursing?” contemporary theorists have addressed the metaparadigm concepts in more depth, focused more specifically on nursing actions, and tried to answer the question “When is nursing needed?” The work of contemporary theorists such as Levine, Orem, and Roy form the theoretical basis for many interventions in current nursing practice.

Myra Levine

Myra Levine's conservation theory is directly grounded in nursing practice. In her attempt to describe, explain, and predict the phenomena of concern to nursing, Levine published the four conservation principles in 1969 in *Introduction to Clinical Nursing*. Conservation is derived from a Latin word meaning “to keep together.” Levine believed in the wholeness of the human being, and the primary focus of conservation is to maintain that wholeness. Levine viewed nursing as assisting clients with the conservation of their uniqueness by helping clients to adapt appropriately. Conservation principles are universal principles designed to link concepts into a cohesive framework within which nursing practice in different environments can be performed (Levine, 1990).

According to Levine, the four principles of conservation are:

1. *Conservation of energy*: “The individual requires a balance of energy and a constant renewal of energy to maintain life activities” (Levine, 1990, p. 197).
2. *Conservation of structural integrity*: “Structural integrity is concerned with the processes of healing ... to restore wholeness and continuity after injury or illness” (Levine, 1989, p. 333).
3. *Conservation of personal integrity*: “Everyone seeks to defend his or her identity as a self, in both that hidden, intensely private person that dwells within and in the public faces assumed as individuals move through their relationships with others” (Levine, 1989, p. 334).
4. *Conservation of social integrity*: “No diagnosis should be made that does not include the other persons whose lives are entwined with that of the individual” (Levine, 1989, p. 336).

In Levine's view, the *person* is who the person knows himself or herself to be, and the *environment* is the context in which the person lives his or her life. In addition, health is socially defined and the goal of nursing is based on the four conservation principles. Levine did not operationally define and relate the metaparadigm concepts in her theory because her original work was initially intended to be a medical-surgical nursing textbook and not a developed nursing theory. In reevaluating her theory 20 years later, Levine stated that she has “grown in [her] conviction that they [the conservation principles] continue to offer an approach to nursing that is scientific, research oriented, and above all suitable in daily practice in many environments” (Levine, 1989, p. 331). Levine's conservation model is used in a variety of settings

with clients across the life span, such as in the emergency and operating rooms; in critical care, acute care, primary care, and long-term care units; with the homeless; and in the community.

Levine's four conservation principles can also be useful in a home setting in which the family rather than a single individual is the client. The nurse recognizes that energy within the family needs to be maintained to keep the family whole. In caring for the family, the nurse needs to maintain the structural, social, and personal integrity of the family and of each individual while dealing with the illness of a specific family member. Consider, for example, the nurse who makes a home health visit to see a child with cystic fibrosis. In this situation, the nurse's attention needs to be directed toward conservation of energy for the child. To help conserve the child's energy for breathing, exercises must be taught to and done by others. The nurse directs strategies toward conserving the child's structural integrity while recognizing that the child is a unique individual and is a member of a social group, the family. Conservation of social integrity would be accomplished through maintaining interest in and monitoring the family dynamics.

Levine's theory is pragmatic, and the conservation principles can be applied to most nursing situations. Her theory, which is congruent with the characteristics of the totality paradigm, is appropriate for use in situations in which the nurse has had a long-term relationship with the client yet is also useful for short-term relationships.

Dorothea Orem

In attempting to plan a nursing curriculum for licensed practical nurses, Dorothea Orem was searching for a pragmatic framework to organize nursing knowledge. She focused on the questions "What is nursing?" and "When do people need nursing care?" and from this she derived that people need nursing when they are unable to care for themselves. In 1971, she presented the self-care deficit theory of nursing (S-CDTN) in the book *Nursing Concepts of Practice* and has continually revised and updated her theory.

Orem's theory incorporates the medical model rather than rejects it, centers on the individual, is problem oriented, and is easily adaptable in varied clinical situations. As a grand theory, the S-CDTN has three interconnecting theories: theory of self-care, theory of self-care deficit, and theory of nursing systems. Each one is discussed in the following text.

THEORY OF SELF-CARE. According to this theory, **self-care** is a learned behavior and a deliberate action in response to a need. Orem identified three categories of self-care requisites: universal self-care requisites, developmental self-care requisites, and health-deviation self-care requisites. Universal self-care requisites are common to all human beings and include both physiological and social interaction needs. Developmental self-care requisites are the needs that arise as the individual grows and develops. Health-deviation self-care requisites result from the needs produced by disease or illness states. Self-care is performed by mature and maturing

individuals. When someone else must perform a self-care need, it is termed dependent care.

THEORY OF SELF-CARE DEFICIT. This theory purports that nursing care is needed when people are affected by limitations that do not allow them to meet their self-care needs. The relationship between the nurse and the client is established when a self-care deficit is present. Self-care deficits, not medical diagnosis, determine the need for nursing care. According to Orem, the only legitimate need for nursing care is when a self-care deficit exists.

THEORY OF NURSING SYSTEMS. This is the unifying theory that "subsumes the theory of self-care deficit which subsumes the theory of self-care" (Orem, 1991, p. 66). The theory of nursing systems attempts to answer the question "What do nurses do?" This was the original question that prompted the development of Orem's theory.

The nurse determines whether or not there is a legitimate need for nursing care. Is a person able to meet self-care needs? Does a deficit exist? If a deficit exists, then the nurse plans care that identifies what is to be done by whom: the nurse, the client, or other (family or significant other). Collectively, the actions of all these people are called the nursing system. Orem identified three types of nursing systems: wholly compensatory, partly compensatory, and supportive-educative.

In the wholly compensatory nursing system, the nurse supports and protects the client, compensates for the client's inability to care for himself or herself, and attempts to provide care for the client. The nurse would use the wholly compensatory nursing system when caring for a newborn or with a client in a postanesthesia care unit who is recovering from surgery. Both of these clients are completely unable to provide self-care.

In the partly compensatory nursing system, both the nurse and client perform care measures. For example, the nurse can assist the postoperative client to ambulate. The nurse may bring in a meal tray for the client who is able to feed himself or herself. The nurse compensates for what the client cannot do. The client is able to perform selected self-care activities but also accepts care performed by the nurse for needs the client is unable to meet independently.

In the supportive-educative nursing system, the nurse's actions are to help clients develop their own self-care abilities through knowledge, support, and encouragement. Clients must learn and perform their own self-care activities. The supportive-educative nursing system is being used when a nurse guides a new mother to breastfeed her baby. Counseling a psychiatric client on more adaptive coping strategies is another example of the use of the supportive-educative nursing system.

Orem focused primarily on the needs of the person and the action of nursing to meet those needs. Lesser emphasis was given to defining health and the environment. The S-CDTN is useful in determining the kind of nursing assistance needed by the client and, therefore, has merit as a theory that guides nursing practice. Orem's theory is consistent with the characteristics of the totality paradigm.

Betty Neuman

Betty Neuman was motivated to develop a model to respond to the expressed needs of graduate students at the School of Nursing, University of California, Los Angeles, for course content that would present nursing problems prior to content emphasizing nursing problem areas. The Neuman systems model was first published in 1972 as a teaching approach to patient problems. Refinements in the Neuman system model are evident in the three editions of Neuman's book *The Neuman Systems Model* (1982, 1989, and 1995).

The Neuman systems model focuses on the wellness of the client system in relation to environmental stressors and reactions to stressors. Stressors are categorized as follows:

1. *Intrapersonal stressors*: Those that occur within
2. *Interpersonal stressors*: Those that occur between individuals
3. *Extrapersonal stressors*: Those that occur outside the person (Neuman, 1995)

Nursing interventions focus on retaining or maintaining system stability on three preventive levels:

1. *Primary prevention*: Protecting the normal line of defense and strengthening the flexible line of defense
2. *Secondary prevention*: Strengthening internal lines of resistance, reducing the reaction, and increasing resistance factors
3. *Tertiary prevention*: Readapting, stabilizing, and protecting the **reconstitution** (adaptation to a stressor) or return to wellness following treatment

The Neuman systems model is consistent with the characteristics of the totality paradigm.

Madeleine Leininger

Madeleine Leininger first published her theory of cultural care diversity and universality in 1978, *Transcultural Nursing: Concepts, Theories, and Practices*. Leininger credits the development of her early clinical work with mildly disturbed children as the catalyst for her idea of transcultural nursing. The central purpose of the theory of cultural care diversity and universality is “to discover, document, interpret, and explain the phenomenon of cultural care as a synthesized construct” (Leininger, 1996, p. 72). The theory provides for specific nursing interventions to assist people of diverse cultures:

1. *Cultural care preservation or maintenance*: The nurse accepts and complies with the client's cultural beliefs.
2. *Cultural care accommodation or negotiation*: The nurse plans, negotiates, and accommodates the client's culturally specific food preferences, religious practices, kinship needs, child care practices, and treatment practices.
3. *Cultural care repatterning or restructuring*: The nurse is knowledgeable about cultural care and develops ways to repattern or restructure nursing care. (Leininger, 1991, pp. 41–42)

Transcultural nursing is different from the medical model and traditional nursing knowledge and practice, as it is both

Belief System

Culturally competent care requires the nurse to work within the client's cultural belief system to resolve health problems. This means that the nurse needs to hear the client and consider the client's world and daily experiences.

a discipline and practice profession to understand and serve people worldwide (Leininger, as cited in Fawcett, 2002b); see the accompanying Community Considerations display. Also see Chapter 20 for detailed information on cultural diversity.

The publication of the third edition of *Transcultural Nursing* (Leininger & McFarland, 2002) documents use of the theory-based research findings in practice. Leininger (as cited in Fawcett, 2002b, p. 132) states that “transcultural nursing has contributed a large, unique, and distinct growing body of knowledge that is meaningful and beneficial to cultural consumers. Transcultural nursing also has been a breakthrough to nurses, showing that culturally based care contributes to healing (health), well-being, and helping clients face dying or death as the essence of nursing.” Leininger's theory is consistent with the characteristics of the totality paradigm.

Sister Callista Roy

Sister Callista Roy combined general systems theory with adaptation theory to produce the Roy adaptation model. Roy was greatly influenced by her teacher and mentor, Dorothy E. Johnson, a nursing theorist who developed the behavioral systems model. Roy first published her model in the 1970s and has continued to further refine and develop the theory. As a contemporary theorist, Roy worked with the metaparadigm concepts to define and relate these concepts.

Roy defines a person as “an adaptive system ... a whole comprised of parts that function as a unity for some purpose” (Andrews & Roy, 1991, p. 4). The person is a biopsychosocial being in constant interaction with a changing internal and external environment. Nursing attempts to alter the environment when the person is not adapting well or has ineffective coping responses.

“The world around and within (the person as an adaptive system) is called the environment” and “includes all conditions, circumstances, and influences that surround and affect the development and behavior of the person” (Andrews & Roy, 1991, p. 18). The environmental stimuli can be classified as either focal, residual, or contextual. Focal stimuli are those that are immediately present in the person's environment. Focal stimuli are the objects or events that most attract one's attention. Most stimuli never become focal. Residual stimuli are those attitudes that are

TITLE OF STUDY

“Prayer Warriors: A Grounded Theory Study of American Indians Receiving Hemodialysis”

AUTHOR

J. Walton

PURPOSE

The purpose of this classic grounded theory study was to explore what spirituality means to individuals who are American Indians receiving hemodialysis.

METHODS

Twelve women and nine men, ages 24 to 62, volunteered for this study. Informed consent was obtained, and in-depth interviews, field notes, and theoretical memos were completed. The metaphor “Prayer warriors” described the core category of this study.

FINDINGS

The results of this study indicate that spirituality is a way of “being in the world” and involves all aspects of living for individuals who are American Indians, including honoring spirit, resisting hemodialysis, healing old wounds, and connecting with family and community. The concept of spirituality for American Indians blends new ways with old cultural traditions. Praying played a major role in the following categories: (a) suffering, (b) honoring spirit, (c) healing old wounds, and (d) connecting with community. Praying involved hard work, suffering, sweating, hunger, and passion and was a powerful way to cope with the stress of hemodialysis.

IMPLICATIONS

Although the study was limited to individuals who were American Indians receiving hemodialysis in rural northwestern United States, the study demonstrates the complexity of the participants and that a cultural approach may help individuals who are American Indians prepare for dialysis. Future studies in this area are recommended since the goal of grounded theory research is for nurses to use what “fits” in clinical practice, while continuing to build and revise the theory with evidence-based nursing practice.

Walton, J. (2007). Prayer warriors: A grounded theory study of American Indians receiving hemodialysis. *Nephrology Nursing Journal*, 34, 347–356.

that which is a focal stimulus one minute can become a residual stimulus the next.

According to the Roy adaptation model, the person has coping mechanisms that are broadly categorized in either the regulator or cognator subsystem. Adaptation is accomplished through these coping mechanisms that are innate, “genetically determined ... and automatic processes” (Andrews & Roy, 1991, p. 13). The regulator subsystem functions through the autonomic nervous system, which “responds automatically through neural, chemical, and endocrine coping processes” (Andrews & Roy, 1991, p. 14). The cognator subsystem enables the person to respond to stimuli through processing stimuli, learning, judgment, and emotion. All input into the system (the person) is channeled through the regulator and cognator subsystems. If the regulator or cognator subsystem fails, there is ineffective adaptation.

Neither the regulator nor the cognator subsystem can be observed directly. Only the responses that each produces are observable. Roy categorized these responses into four adaptive modes: physiologic, self-concept, role function, and interdependence. The physiologic mode allows individuals to respond physiologically to their environment. The self-concept mode “focuses on psychologic and spiritual aspects of the person” (Andrews & Roy, 1991, p. 16). The basic underlying need of the self-concept mode is psychologic integrity. The role function mode focuses on the need to know who one is. The emphasis of the interdependence mode is affectional adequacy or the feeling of security in nurturing relationships (Andrews & Roy, 1991).

The purposes of adaptation are survival, growth, reproduction, and mastery. Adaptive responses contribute to these goals, whereas ineffective responses may threaten the person’s survival, growth, reproduction, or mastery (Andrews & Roy, 1991). Roy’s new definition of adaptation is “The process and outcome whereby thinking and feeling persons, as individuals or in groups, use conscious awareness and choice to create human and environmental integration” (Roy & Andrews, 1999, p. 30).

The goal of nursing is “the promotion of adaptation in each of the four modes, thereby contributing to the person’s health, quality of life, and dying with dignity” (Andrews & Roy, 1991, p. 20). Nursing care needs to be provided when a person has unusual stressors or when usual coping mechanisms are ineffective. Basically, the nurse attempts to manipulate stimuli in such a way as to allow the client to cope effectively. Roy defines health as “a state and a process of being and becoming an integrated and whole person,” and a “lack of integration represents lack of health” (Andrews & Roy, 1991, p. 419).

In Roy’s view, the nurse must first assess how the client behaves in each adaptive mode and then determine what can be altered in that mode to produce more efficient and effective adaptive responses. The nurse then either alters the environment directly or helps the person to alter the environment for better adaptive responses.

In the physiological mode, problems may arise in areas such as exercise, nutrition, elimination, fluid and electrolytes, temperature regulation, and oxygenation. For example, in

developed during previous experiences in one’s life whose effects on the current situation are unclear. Contextual stimuli are “all the other stimuli present in the situation that contribute to the effect of the focal stimulus” (Andrews & Roy, 1991, p. 9). Because stimuli are constantly changing,

caring for a client with a fever, the nurse helps the client to adapt by administering medications to lower the temperature, administering cool baths, and providing adequate fluids. Through these interventions, the nurse is attempting to alter both the internal and external environments of the person.

In the self-concept mode, the term *self-concept* refers to both the physical and the personal self. The physical self is affected or threatened during invasive procedures such as surgery. Anxiety, guilt, and distress are responses within the personal self to physical or emotional stressors. For example, in caring for an obese person who feels guilty about developing diabetes at an early age, a nurse can help reframe the client's thinking to work through the guilt and anxiety. Through the use of counseling techniques, the nurse can teach the client how to adapt to the present situation and learn how to cope with it in the future.

Within the framework of the role function mode, the nurse would help a woman disabled with arthritis to identify adaptive approaches to maintain the roles of wife and homemaker. Nursing actions might include referral to occupational therapy for needed adaptive devices that could assist the client in maintenance of roles.

In the interdependence mode, problems may include feelings of alienation, disengagement, loneliness, or disenfranchisement that are experienced in various relationships. Examples of clients with problems in interdependence may include a grieving widow or a person with an abusive spouse.

The Roy adaptation model has gained wide acceptance in nursing practice, research, and education and is part of the dominant worldview of nursing. Roy's views of the person and the person-environment interaction clearly represent characteristics of the totality paradigm.

THEORIES FOR THE NEW WORLDVIEW OF NURSING

Theories for the new worldview of nursing describe, explain, and predict the phenomena of concern to nursing from a unique, more holistic perspective. In this new worldview, the client has primacy and the client-environment interaction is of utmost importance. Theories by Jean Watson, Martha Rogers, and Rosemarie Parse exemplify the new worldview.

Jean Watson

In the 1980s, Jean Watson developed the theory of human caring, which focuses on the art and science of human caring. According to Watson (1985, p. 33), "caring is the essence of nursing and the most central and unifying focus of nursing practice." This theory offers a new way of conceptualizing and maximizing human-to-human transactions that occur daily in nursing practice. Watson's theory is influenced by Eastern philosophy and is "based on a metaphysical, spiritual-existential, and phenomenological orientation" (Fawcett, 1993, p. 220). These influences link Watson's theory to the work of early theorists such as Travelbee and Paterson and Zderad.

The theory of human caring evolved from Watson's beliefs, values, and assumptions about caring. In Watson's view (1985), care and love comprise the primal universal psychic energy and are the basis for our humanity. Watson noted that, throughout its history, nursing has been involved in caring and has actually evolved out of caring. Furthermore, she stated that caring will determine nursing's contribution to the humanizing of the world.

Watson's theory is composed of 10 carative factors, which are classified as nursing actions or caring processes. See Chapter 14 for Watson's carative factors. The first three carative factors serve as the philosophical foundation for the science of caring. The remaining seven provide more specific direction for nursing actions.

Watson stated that "health refers to unity and harmony within the mind, body, and soul. Health is also associated with the degree of congruence between the self as perceived and the self as experienced" (Watson, 1985, p. 48). In Watson's (1985, p. 49) view, the goal of nursing "is to help persons gain a higher degree of harmony with the mind, body, and soul." The nurse uses the carative factors to accomplish the goal of nursing. Watson's theory clearly fits within the principles of the simultaneity paradigm.

"Evidence suggests that caring-healing behaviors are the currency that buys patient, family, and coworker satisfaction" (Felgen, 2003, p. 213). The challenge of nursing is to create moments of caring through human-to-human interaction in the fast-paced world of health care.

Martha Rogers

Martha Rogers, a visionary leader and pioneer in the development of nursing's unique knowledge base, developed the highly abstract theory of the science of unitary human beings. According to Rogers, "nursing is a learned profession: a science and an art. A science is an organized body of abstract knowledge. The art involved in nursing is the creative use of science for human betterment" (Rogers, 1990, p. 198). Rogers's contribution to the discipline of nursing was revolutionary and provided new directions for the practice of nursing. Rogers first presented her ideas in the book *An*

SPOTLIGHT ON...

Caring and Nurturance

Recall the last time that you were sick with the flu. Reflect on what it means to you "to be cared about," "to be cared for," and "to be taken care of."

How are these the same? How are these different? As the recipient of care, what kinds of behaviors did you identify as "caring behaviors"? How could these behaviors be different for another person who grew up in a different family? A different culture?

Introduction to the Theoretical Basis of Nursing (1970). Her ideas regarding the person and the environment as energy fields were not considered to be consistent with the dominant paradigm of the 1970s but are more applicable to the principles of the simultaneity paradigm of the late 1980s.

According to Rogers (1990, p. 108), “the uniqueness of nursing is identified in the phenomena of concern. Nursing is the study of unitary, irreducible human beings and their respective environments.” The unitary person is an irreducible pandimensional energy field characterized by a pattern and expressing qualities that are unique to the whole and cannot be foreseen from knowledge of the parts. Environment is defined as “an irreducible pandimensional energy field identified by pattern and integral with a given human field” (Rogers, 1990, p. 109).

Within the viewpoint of the science of unitary human beings, the person is a unified whole and seen as greater than and different from the sum of the parts. The whole person cannot be known by examining any particular aspect or dimension of the person because all aspects together combine to form an entity different from the collection of parts. It is the characterization of the person as a human energy field that unites all aspects of the person into a unified whole. The whole of the person's energy field interacts with the whole of the environmental energy field, which results in the process of life. There is a constant exchange of matter and energy between the person-environment unit, yet the uniqueness of each person is maintained through rhythmic patterns and relationships.

Nursing identifies the patterns and organization of the person-environment unit and aims to repattern the rhythm and organization of these energy fields so that the person's integrity is heightened. Rogers's theory provides for maintenance and promotion of health, prevention of disease, nursing diagnosis, intervention, and rehabilitation to encompass the scope of nursing goals.

Changes have been made in Rogers's conceptual system as it has evolved over the years. “The concepts of the conceptual system currently are labeled energy fields, openness, pattern, and pandimensionality. The principles of hemodynamics now are labeled helicy, resonancy, and integrality” (Fawcett, 2003, p. 44). The changes in the science of unitary human beings reflect Rogers's concern with language and the insights gained over the years from new knowledge. “The development of a science of unitary human beings is a never-ending process. This abstract system first presented some years ago has continued to gain substance. Concomitantly, early errors have undergone correction, definitions have been revised for greater clarity and accuracy, and updating of content is ongoing” (Rogers, 1992, p. 28). Martha Rogers died on March 13, 1994. The Society of Rogerian Scholars continues to refine Rogers's theory.

Rosemarie Parse

Rosemarie Rizzo Parse (1981) began her work to create a theory grounded in the human sciences that would enhance nursing knowledge; the initial result of Parse's effort was the

theory of man-living-health, which was first published in 1982, *Man-Living-Health: A Theory of Nursing*. The theory was renamed the theory of human becoming in 1990. Parse refined her theory to include a school of thought in the second edition of her book (1998) newly titled *The Human Becoming School of Thought: A Perspective for Nurses and Other Health Professionals*. The theory of human becoming and the human becoming school of thought focus on the human-universe-health process. The goal of nursing from the human becoming perspective is quality of life (Parse, 2006). The principles of the theory of human becoming are as follows:

1. Structuring meaning **multidimensionally** (i.e., based on the belief that we live at many realms of the universe all at once) is cocreating reality through the language of valuing and imaging.
2. Cocreating rhythmic patterns of relating is living the paradoxical unity of revealing-concealing and enabling-limiting while connecting-separating.
3. Cotranscending with the possibles is powering unique ways of originating in the process of transforming.

Clearly, Parse's theory is consistent with the principles of the simultaneity paradigm.

Similar to the work of Parse, Joyce Fitzpatrick's life perspective rhythm model (1989) and Margaret Newman's model of health (1986) are current developing theories within the simultaneity paradigm.

CONTINUING EVOLUTION OF NURSING THEORY

The world of health care changes on a daily basis. Client needs and problems often change on a minute-by-minute basis. Knowledge, information, and technology in both health care and nursing are growing at unprecedented rates. In the face of these advances, nursing strives to preserve *the notion of caring* in health care. Theories are needed to organize knowledge and to guide nursing practice and nursing research.

Nurses encounter a variety of clinical situations in which application of nursing theory is needed. The nursing process has been integrated into many nursing frameworks and theories. In these occurrences, nurses may discover that specific theories will be more appropriate for certain clinical situations than others. Knowledge of specific theories should expand as nurses gain experience in nursing practice. In all cases, theories that are selected for application in practice should be congruent with the nurse's own beliefs and values. Parse (1998, p. 74) defines research as “the formal process of seeking knowledge and understanding through use of rigorous methodologies.” Nursing frameworks and theories have provided numerous research instruments to measure constructs operationally defined to provide consistency with the particular framework or theory; such instrumentation is essential to advanced nursing knowledge (Barrett, 2002). Advances have been made in the development of unique research methodologies such as Carboni's Rogerian process of inquiry; Leininger's ethnonursing

research method; Newman's praxis method; and Parse's method of basic research.

Current emphasis has shifted from developing new theories to applying existing theories to practice and expanding existing nursing theories by including such concepts as cultural diversity, spirituality, family, and social change. For example,

Mendyka and Bloom have expanded King's model by adding a cultural perspective. According to Catalano (2006), the theories that are flexible and adaptable to new discoveries while being realistic and usable in practice will continue to thrive and remain the cornerstones of professional nursing; those theories that are too theoretical or rigid will gradually disappear.

KEY CONCEPTS

- Concepts are abstract vehicles of thought and are the building blocks of theory.
- Propositions are relational statements that link concepts together.
- Theories help to show how things fit together. The function of theory is to provide a framework for explaining, predicting, and sometimes controlling situations.
- Nursing uses theories from other disciplines in conjunction with nursing theory.
- The development, use, and testing of nursing theory are necessary for the professionalization of the discipline of nursing.
- The relationship between nursing theory, practice, and research is an interdependent one. As a practice-oriented discipline, nursing theory and research inform and transform nursing practice.
- Theories range in scope from grand theories to middle-range theories to micro-range theories.
- The metaparadigm names the phenomena of concern to a discipline and distinguishes one discipline from another.
- The currently accepted metaparadigm concepts in nursing are person, environment, health, and nursing.
- The metaparadigm may be composed of more than one paradigm. Parse purports that there are two paradigms in nursing: the totality paradigm and the simultaneity paradigm.
- Early nursing theorists were attempting to answer questions related to the "what" and "how" of nursing.
- The theories developed by Levine, Orem, and Roy are useful in guiding nursing practice.
- A new worldview of nursing is emerging in the work of such theorists as Watson, Rogers, and Parse.

REVIEW QUESTIONS

1. Nursing's metaparadigm includes:
 - a. Concepts, theory, health, and environment
 - b. Health, person, environment, and nursing
 - c. Providers, standards, models, and clients
 - d. The person, environment, health, and nursing
2. "An organized, coherent set of concepts and their relationship to each other that is proposed to explain a given phenomenon" best defines which of the following?
 - a. A concept
 - b. A proposition
 - c. A theory
 - d. A discipline
3. Which theories are examples of the totality paradigm? Select all that apply.
 - a. Martha Rogers
 - b. Rosemarie Parse
 - c. Sr. Callista Roy
 - d. Dorothea Orem
 - e. Jean Watson
 - f. Madeleine Leininger
4. A caring, cultural being best defines "person" by which theorist?
 - a. King
 - b. Leininger
 - c. Neuman
 - d. Watson
5. Why are nursing theories needed? Select all that apply.
 - a. To organize knowledge
 - b. To guide nursing practice
 - c. To promote nursing diagnosis
 - d. To guide nursing research
 - e. To develop a language for nurses
 - f. To define professional nursing practice

Visit the DeLaune and Ladner online companion resource at www.delmar.cengage.com for additional content and study aids. Click on Online Companions, then select the Nursing discipline.

By changing nothing, we hang on to what we understand, even if it is the bars of our own jail.

—JOHN LeCARRE

CHAPTER 3

Research and Evidence-Based Practice

COMPETENCIES

1. Explain the basis for research and knowledge development in nursing.
2. Describe the steps in the research process.
3. Explain the responsibilities of the researcher in guarding the rights of research participants and others who assist in the research study.
4. Identify the various applications of nursing research in nursing practice.
5. Describe how evidence-based practice is used to guide clinical decision making.
6. Describe the key elements of evidence reports.

KEY TERMS

abstract	hypothesis	recontextualizing
concepts	independent variable	research
conceptual framework	informed consent	research design
conceptualization	nursing research	secondary source
construct	primary source	theory
dependent variable	qualitative analysis	value
evidence-based practice	qualitative research	variable
full disclosure	quantitative research	

This chapter explores the scientific foundation on which the knowledge base of the profession has been and is being built. **Nursing research** is a “scientific process that validates and refines existing knowledge and generates new knowledge that directly and indirectly influences nursing practice” (Burns & Grove, 2004, p. 4). **Evidence-based practice** (EBP) is using the best evidence available to guide clinical decision making. Research is critical in nursing because the use of research is inherent in the definition of a professional, nurses are accountable for client outcomes, and consumers are demanding evidence-based care (Houser, 2008). The identification of the knowledge base for nursing practice contributes to achieving client outcomes and making nursing practice credible. The emphasis on quality care based on evidence and research is an increasing focus in all areas of health care. The challenge to nurses is to determine the interrelatedness of nursing research to EBP: Does a solid research base exist that will provide evidence of the nursing actions that are effective in promoting positive client outcomes?

RESEARCH: SUBSTANTIATING THE SCIENCE OF NURSING

Nursing is a profession characterized by educational standards, autonomy, socialization, an established knowledge base, licensure, formal entry examinations, a code of ethics, technical expertise, professional standards, altruistic service, and public trust. The main characteristics of a profession are established, specialized training in a body of abstract knowledge and a collectivity of service orientation.

The science of nursing knowledge is established by the same systematic, investigative process used by all science-based disciplines, the research process. **Research** is a systematic method of exploring, describing, explaining, relating, or establishing the existence of a phenomenon, the factors that cause changes in the phenomenon, and how the phenomenon influences other phenomena. Nursing practice activities are substantiated as predicting valid and reliable outcomes for clients (the individual, family, group, or community) only after a body of knowledge has been established and confirmed by numerous research efforts.

HISTORICAL DEVELOPMENT

Nursing research is aligned with the founder of modern nursing, Florence Nightingale. Nightingale “believed that through observation, nurses could best determine care for patients. This early emphasis on systematic observation, as opposed to a trial-and-error approach in providing patient care, planted the seeds for the evolution of nursing science—a unique body of nursing knowledge” (Brockopp & Hastings-Tolsma, 2003, p. 5). The groundwork established by Nightingale for using research to direct client care was not sustained by subsequent nursing leaders because of two forces that had a direct impact on nursing’s future. First, societal norms basically excluded women from becoming scientists; therefore, initiating or participating in scientific discovery (research) was not an option for women. The second force dealt with the “training” as opposed to the “education” of nurses.

In 1923 Teachers College at Columbia University offered the first educational doctoral program for nurses. The first master’s of nursing degree was offered at Yale University in 1929. The placement of nursing education in the university setting is credited to three key studies that addressed educational reform in nursing: the Nutting report, 1912; the Goldmark report, 1923; and the Burgess report, 1926. In 1932 the Association of Collegiate Schools of Nursing (ACSN) was organized to promote the conduct of research to improve education and practice. The ACSN established the first research journal in nursing, *Nursing Research*, in 1952.

Research activities during the 1940s and early 1950s focused on the organization and delivery of nursing services: staffing patterns, nursing personnel and client satisfaction, and client classification systems. Care delivery systems such as comprehensive care, home care, and progressive care were evaluated. Results of these evaluations laid the foundation for the development of self-study manuals that were the precursors of today’s quality assurance manuals.

The American Nurses Association (ANA) contributed to the advancement of nursing research. In 1950 the ANA sponsored a five-year study on nursing functions and activities; the findings were reported in a document entitled *Twenty Thousand Nurses Tell Their Story*. This study benchmarked the development of ANA statements on functions, standards, and qualifications for professional nurses in 1959.

Concurrently, clinical research began expanding as nursing specialty groups developed standards of care.

Nursing research in the late 1950s and early 1960s focused on the effective educational preparation of professional nurses. One outcome was the development of a two-year associate degree nursing program in the junior college setting by Montag. During this era several organizations were established that furthered nursing research by either promoting, expanding, or disseminating study findings: the Institute for Research and Service in Nursing Education at Teachers College, 1952; the American Nurse's Foundation, 1955; the ANA Committee on Research and Studies, 1956; the Department of Nursing Research, Walter Reed Army Hospital, 1957; the Southern Regional Educational Board, 1957; the Western Interstate Commission for Higher Education (WICHE), 1957; and the New England Board of Higher Education, 1957. The *Nursing Research* journal was established in 1952 to communicate nurses' research and scholarly activity.

During the late 1960s and 1970s the nursing profession initiated many scholarly endeavors: the development of conceptual models and theories; clinical studies on quality care, primary client care, and the nursing process; educational studies that evaluated teaching methods and student learning experiences; and the first Nursing Diagnosis Conference in 1973. The ANA established the Commission on Nursing Education in 1970 and the Council of Nurse Researchers in 1972. As enrollments in graduate nursing programs increased at both the master's and doctoral levels, the dissemination of research findings was an issue in the 1970s.

Sigma Theta Tau, the international honor society in nursing, was founded in 1922 and began publishing *Image: Journal of Nursing Scholarship* in 1967 to communicate research findings. The society's purpose is to advance scholarship in nursing by promoting the conduct, communication, and utilization of research in nursing.

The movement of the 1980s and 1990s focused on clinical nursing research as many nurses obtained master's and doctoral degrees, and postdoctoral education was encouraged for nurse researchers. The number of nursing research journals increased during the 1970s and 1980s to include journals such as *Research in Nursing and Health*, *Advances in Nursing Science*, *Applied Nursing Research*, and *Nursing Science Quarterly*.

Federal involvement in nursing research dates back to 1946 with the establishment of the Division of Nursing within the Office of the Surgeon General. In 1955, the first extramural nursing research program was established in the Research Grants and Fellowship Branch of the Division of Nursing Resources, and the National Institutes of Health (NIH) established the Nursing Research Section within the Division of Research Grants to conduct scientific review in the field of nursing. The impetus for establishing the National Institute of Nursing Research (NINR) came from the findings of two federal studies:

1. The 1983 report by the Institute of Medicine recommended that nursing research be included in the mainstream of biomedical and behavioral science.

2. The 1984 NIH Task Force study found nursing research activities to be relevant to the NIH mission.

In 1986 these findings led to legislative action that established the National Center for Nursing Research (NCNR) at the NIH. The NIH Revitalization Act of 1993 was signed into law and changed the NCNR to the NINR. The NINR (2003) supports clinical and basic research to establish a scientific basis for the care of individuals across the life span and may include families within a community context. According to its mandate, the institute seeks to understand and ease the symptoms of acute and chronic illness, to prevent or delay the onset of disease or disability or slow its progression, to find effective approaches to achieving and sustaining good health, and to improve the clinical settings in which care is provided. Research involves clinical care in a variety of settings including the community and home in addition to more traditional health care sites.

The current initiative of the NIH is twofold: the Public Trust Initiative (PTI) and Partners in Research. The purpose of the PTI is to support studies of innovative programs designed to improve public understanding of health care research and promote collaboration between scientists and community organizations to increase public awareness and trust in both the role of the NIH and the importance of new directions of research for advancing the public health. The NIH Partners in Research program is intended to engage a diverse group of scientists, community leaders, members of the public, and client advocacy groups to develop partnerships between scientific or research institutions and community organizations and to evaluate a variety of approaches in a range of target audiences or communities. The goals of the program are to:

- Identify and implement new ways to increase science literacy.
- Communicate the research needs and interests of communities.
- Encourage understanding of biomedical and behavioral research by partnering with community-sanctioned organizations, such as voluntary and professional organizations, health groups, faith-based groups, and housing organizations. (NINR, 2008)

FRAMEWORK

Knowledge gained from both nursing research and practice is necessary to support the predictable outcomes of nursing care. Research used in nursing comes from nursing as well as other disciplines such as psychology, education, sociology, biology, and anthropology. Nursing research explores the many pathways through which scientific and practical knowledge regarding nursing care is established.

Research Process

The person conducting the research is called a *researcher*, *investigator*, or *scientist*. When a researcher poses a problem or answers a question using the *scientific approach*, it is called a

study, an investigation, or a research project. The people who are being studied are called *subjects* or *study participants*.

Scientific research is mainly concerned with vehicles of thought defined as **concepts**. The process of developing and refining concepts is referred to as **conceptualization**. A **construct** is an abstraction or mental representation inferred from situations, events, or behaviors. Constructs are different from concepts in that the constructs are deliberately invented (or constructed) by researchers for a specific scientific purpose. These concepts or constructs are ideas that formulate a **theory**, a set of concepts and propositions that provide an orderly way to view phenomena. "In a theory, concepts (or constructs) are knitted together into an orderly system to explain the way in which our world and the people in it function" (Polit, Beck, & Hungler, 2005, p. 22).

Nurse researchers can use one of two broad approaches to gather and analyze scientific information:

- **Quantitative research:** The systematic collection of numerical information, often under conditions of considerable control, and the analysis of the information using statistical procedures
- **Qualitative research:** The systematic collection and analysis of more subjective narrative materials, using procedures in which there tends to be a minimum of researcher-imposed control. (Polit et al., 2005, p. 26)

See Table 3-1 for a comparison of the major characteristics of quantitative and qualitative research.

The scientific method requires an exact, orderly, and objective approach of acquiring knowledge. Controlled methods are used to study problems and test the **hypothesis**, a statement of an asserted relationship between two or more variables. A **variable** is anything that may differ from

the norm. The two types of variables are independent and dependent.

The **independent variable** (criterion variable) is the variable that is believed to cause or influence the **dependent variable**, which is the outcome variable of interest and is the variable that is hypothesized to depend on or be caused by or predicted by the independent variable (Polit et al., 2005). For example, if the question reads "To what extent does age predict recovery from surgical anesthesia relative to when perioperative instructions were first given?" the independent variable is age and the dependent variable is recovery from surgical anesthesia relative to when perioperative instructions were first given. **Value** is the variation of the variable. The values of the independent variable are actual ages of surgical clients, and the values of the dependent variable are when instructions were first given.

There are multiple ways in which nurses establish the sources and the realm of knowledge about nursing, human responses, diagnoses, and treatments. Burns and Grove (2004) describe how nursing has historically acquired knowledge:

- **Traditions:** basing practice on customs and past trends
- **Authority:** crediting another person as the source of information
- **Borrowing:** using knowledge from other disciplines to guide nursing practice
- **Trial and error:** using unknown outcomes in a situation of uncertainty
- **Personal experience:** gaining knowledge by being personally involved in an event, situation, or circumstance
- **Role modeling and mentorship:** imitating the behaviors of an exemplar

TABLE 3-1 Major Characteristics: Quantitative and Qualitative Research

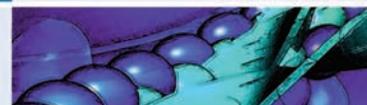

QUANTITATIVE RESEARCH

Purpose: test theory
 Focus: concise and narrow
 Reasoning: deductive
 Design: reductionist
 Data collection: control; instruments
 Basic element of analysis: numbers; statistical analysis
 Reporting of findings: generalization; objective; formal style

QUALITATIVE RESEARCH

Purpose: develop sensitizing concepts, create theory
 Focus: complete and broad
 Reasoning: inductive
 Design: holistic
 Data collection: shared interpretation; communication and observation
 Basic element of analysis: words; individual interpretation
 Reporting of findings: uniqueness; subjective; rich narrative; expressive language

Adapted from Burns, N., & Grove, S. K. (2004). *The practice of nursing research* (5th ed.). Philadelphia: W. B. Saunders.

- *Intuition*: being guided by a feeling or sense that cannot be logically explained
- *Reasoning*: processing and organizing ideas in order to reach conclusions
- *Research*: validating and refining existing knowledge and generating new knowledge

Carper (1978, 1992) describes four fundamental patterns of knowing:

- *Empirical*: using research to explain, describe, and predict
- *Ethical*: extending knowledge of valuing, clarifying, and advocating
- *Personal*: encountering and focusing on self and others
- *Esthetic*: interpreting, engaging, and envisioning clues to knowledge

The research process is based on sequential, interrelated steps; see the accompanying display on the steps in the research process.

Once the researcher has developed the conceptual framework, the research literature is reviewed to provide a foundation on which to base new knowledge. In selecting a research design, the researcher determines the methods to be used to address the research question and test the hypothesis, the specific population to be studied, and how the data will be collected; see the accompanying display on types of research design.

Clearly, the contemporary thought on knowledge generation incorporates a variety of sources of data collection, each with its own strengths and weaknesses. However, knowledge in nursing is developed and used most effectively through the combination of nursing theory, research, and practice.

STEPS IN THE RESEARCH PROCESS

- Formulating a research question or problem
- Defining the purpose of the study
- Reviewing relevant literature
- Developing a **conceptual framework** (structure that links global concepts together to form a unified whole)
- Developing research objectives, questions, and hypotheses
- Defining research variables
- Selecting a **research design** (overall plan used to conduct the research; see the accompanying display for types of research design)
- Defining the population, sample, and setting
- Conducting a pilot study
- Collecting data
- Analyzing data
- Communicating research findings, their implications, and the limitations of the study

TYPES OF RESEARCH DESIGN

- *Historical*: Systematic investigation of a past event using relevant sources to describe or explain the event
- *Exploratory*: Preliminary investigation designed to develop or refine hypotheses or to test the data collection methods
- *Evaluative*: Systematic investigation of how well a program, practice, or policy is working
- *Descriptive*: Investigations that have as their main objective the accurate portrayal of the characteristics of persons, groups, or situations and the frequency with which certain phenomena occur
- *Experimental*: Research studies in which the investigator controls (manipulates) the independent variable and randomly assigns subjects to different conditions
- *Quasi-experimental*: Studies that deviate from the methods of the experimental component in that subjects cannot be randomly assigned to treatment conditions even though the researcher manipulates the independent variable and exercises certain controls to enhance the internal validity of the results

Adapted from Polit, D. F., & Hungler, B. P. (2005). *Nursing research: Principles and methods* (7th ed.). Philadelphia: Lippincott.

Following data collection, the researcher subjects the data to analysis in an orderly fashion so that patterns and relationships can be discerned. **Qualitative analysis** involves “four types of intellectual processes: comprehending, synthesizing, theorizing, and **recontextualizing** (exploration of the developed theory in terms of its applicability to other settings or groups)” (Polit et al., 2005, p. 400), whereas quantitative information is usually analyzed through statistical procedures. If the data support the research hypothesis, the findings are reported in a straightforward fashion; however, if the results fail to support the hypothesis, the researcher must explain the possible reasons for this failure, for example, problems with the research method (use of inappropriate tools for data collection). The research findings can be communicated in various forms such as dissertations and journal articles. Usually, research reports discuss how the findings can be incorporated into the practice of nursing.

Roles

Becoming a nurse researcher requires education and experience in the process of scientific inquiry. That process is then combined with the nurse’s already established clinical experience and expertise. A nurse scientist is a registered nurse with

SPOTLIGHT ON...

Ways of Knowing

Nurses use scientific and “other ways of knowing” to measure the effectiveness of nursing interventions.

Name and describe three other ways of knowing that you use in your personal life to solve problems.

What are the advantages and disadvantages of each method you use?

How can other ways of knowing be used by nurses to measure the client’s situation or the outcome of the nursing activity applied to the situation?

a strong clinical background who has also been educated at the doctoral level to conduct research. However, nurses participate as consumers and critics of research by conducting the important work of translating, applying, and evaluating the new knowledge with clients and systems. Nurses also participate on research teams or with research protocols to plan, apply, collect data, and evaluate the process.

Each of these roles (nurse scientist, principal investigator, research team member, research consumer, and advocate for research clients) offers a substantial contribution to the process of scientific knowledge development in nursing and health care. Interdisciplinary experiences can further enrich the nurse’s understanding of the concept or phenomenon and add to the research team’s perspective of the research project.

Rights

During the research design phase of the process, the researcher must determine how to safeguard the rights of the research participants. An important role of the nurse researcher is that of advocate for the clients’ rights during the process; see the accompanying display regarding the human rights that require protection during research.

Obtaining **informed consent** requires that the researcher provide **full disclosure**, the communication of complete information to potential research subjects regarding the nature of the study, the subject’s right to refuse participation, and the likely risks and benefits that would be incurred (Polit et al., 2005). The nature, seriousness, and likelihood of risks (physical, psychological, social, and legal) are explained to the participants. The researcher must also identify what precautions will be taken to minimize the risks. Protection of subjects requires that the potential benefits outweigh potential risks. To give informed consent in research, persons must be mentally capable of understanding the study, risks, and benefits (Nokes & Nwakeze, 2007).

Nurses have an obligation to collaborate in the research, provided the researcher has followed proper protocols. The researcher must obtain permission from the agency to use its

PROTECTING HUMAN RIGHTS IN RESEARCH

- **Self-determination:** The person has the right to control his or her own destiny.
- **Privacy:** The person has to determine the time, extent, and general circumstances under which private information will be shared with or withheld from others.
- **Anonymity:** Data collected will be kept confidential.
- **Fair treatment:** The person should be treated fairly and should receive what he or she is due or owed.
- **Protection from discomfort and harm:** Based on the principle of beneficence (one should do good and, above all, do no harm), the person should be protected from physical, emotional, social, and economic discomfort and harm.
- **Informed consent:** The person understands the reason for the proposed intervention and its benefits and risks, and he or she agrees to the treatment by signing a consent form.

Adapted from Burns, N., & Grove, S. K. (2004). *The practice of nursing research* (5th ed.). Philadelphia: W. B. Saunders.

facility as part of the research setting. Staff nurses who are expected to participate in the research process must have an adequate understanding of the nature of the study. Likewise, the staff nurse has the right to refuse to participate in the study.

SPOTLIGHT ON...

Legal and Ethical

What should a nurse do when a risk factor has not been fully explained to a client who has agreed to participate in a study?

You are a staff nurse working at a medical center where it is common practice for the nurses to participate in research studies that use investigational drugs. In reading the accompanying literature on the investigational drug being used in this particular study, you discover that the risk for infertility has not been addressed in the informed consent. Although you realize that you do not have to participate in the research, what should you do to protect the client’s rights?

RESEARCH UTILIZATION

Research utilization refers to the use of research findings in practice to improve care. Research utilization occurs at three levels—instrumental, conceptual, and symbolic:

1. *Instrumental* utilization is the direct, explicit application of knowledge gained from research to change practice.
2. *Conceptual* utilization refers to the use of findings to enhance one's understanding of a problem or issue in nursing.
3. *Symbolic* utilization is the use of evidence to change the minds of other people, usually decision makers.

Instrumental research utilization allows the nurse to change nursing practice, for example, by adopting new nursing interventions, procedures, clinical protocols, or guidelines. In conceptual research utilization, the nurse uses the knowledge by thinking about a situation, problem, or phenomenon to provide different alternatives and possibilities in nursing situations. With symbolic research utilization, the nurse uses research findings to influence others to make changes in conditions, policies, or practices relevant to nurses and clients or to the health of clients.

To bridge the gap between nursing research and nursing practice, several research utilization models have been developed to promote quality care. The WICHE Regional Program for Nursing Research Development was the first federally funded research utilization project. The six-year WICHE project studied the feasibility of fostering research activities through regional collaborative activities. There are five components of this model:

1. Definition of nursing care problem
2. Retrieval of relevant research
3. Critical review of the research
4. Development of research-based plan of care
5. Evaluation of the effects of change

The final report from the WICHE project indicated that the project was successful in increasing research utilization; however, there were a limited number of scientifically sound, reliable nursing studies with clearly identified implications for nursing care.

A five-year project, awarded to the Michigan Nurses Association by the Division of Nursing in the 1970s, was the Conduct and Utilization of Research in Nursing (CURN). The purpose of this federally funded project was to develop research-based protocols for clinical practice. The five components of the CURN model include:

1. Identification of research studies and establishment of a research base
2. Transformation of findings into research-based protocols
3. Transformation of protocols into specific nursing interventions
4. Clinical trials in the practice setting
5. Evaluation of the research-based practice

The CURN project concluded that research utilization by practicing nurses is feasible, but only if it is relevant to practice and the results are broadly disseminated.

Over the past decade other utilization projects have been undertaken such as the Iowa model, the Nursing Child Assessment Satellite Training model, the Dracup-Breu model, the Stetler model, and the Horne model. In the 1990s California developed the Orange County Research Utilization in Nursing (OCRUN) project to focus on building organizational capacity as a tool for increasing research utilization. Over a three-year period, nearly 400 nurses participated in continuing education courses that focused on the development of research utilization competency (Rutledge & Donaldson, 1995).

Barriers to Utilizing Nursing Research

Polit and colleagues (2005) identify the following barriers to utilizing nursing research:

- Research itself: inadequate scientific base
- Practicing nurses: educational preparation with limited exposure to research utilization and resistance to change
- Organizational settings: unfavorable organizational climates and resource constraints
- Nursing profession: limited communication and collaboration between practitioners and researchers

Cacchione (2008) addressed another barrier, nurse participation in interprofessional research, citing a nursing intervention study in a long-term care setting that failed because the concerned nurses were not involved in the development of the study.

In 1992, the Agency for Health Care Policy and Research within the U.S. Department of Health and Human Services, renamed the Agency for Healthcare Research and Quality (AHRQ), convened a panel of experts to summarize the state-of-the-art research on certain topics and to develop clinical practice guidelines. Guidelines have been published on such topics as pain management in infants and children, prediction and prevention of pressure sores in adults, and identification and treatment of urinary incontinence. These guidelines, which are based on evidence and provide the consumer with information directly related to the clinical practice guidelines, are available at AHRQ's Web site. The future of nursing research utilization will require commitment and collaboration among researchers, practicing nurses, organizations that train and employ nurses, and the leadership of the nursing profession. See the Uncovering the Evidence box.

NURSING STUDENTS

Accessing nursing research can be a challenge to students. "Nursing students are often intimidated by the research process" (Morse, Oleson, Duffy, Patek, & Sohr, 1996, p. 148). Nursing students are exposed to research in varying degrees as determined by the program's curriculum.

Nursing students need to familiarize themselves with a few general terms before they read and analyze research studies. When an article is written by one or more researchers, it is called a **primary source**. When an author addresses the research of someone else, it is referred to as a **secondary source**.

Research articles usually begin with an **abstract**, a summary statement that identifies the purpose, methodology (inclusive of subject population), findings, and conclusions. Some authors also include implications for further study

within the abstract; see the accompanying display for the major elements in the content of an abstract.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Nurses’ Perceptions of Research Utilization in a Corporate Health Care System”

AUTHOR

D. McCloskey

PURPOSE

To explore selected characteristics of nurses based on educational level, years of experience, and hospital position that might affect perceived availability of research resources, attitude toward research, support, and the use of research in practice.

METHODS

A descriptive nonexperimental mailed survey was sent to nurses in five hospitals within a corporate hospital system using the Research Utilization Questionnaire (RUQ). The RUQ was used to measure nurses’ perception of research utilization regarding four dimensions: perceived use of research, attitude toward research, availability of research resources, and perceived support for research activities.

FINDINGS

Statistically significant differences ($p < .001$) were found regarding perceived use of research, attitude toward research, availability of research resources, and perceived support for research activities based on educational level and organizational position. No significant differences were found for the nurses’ perceptions based on years of experience.

IMPLICATIONS

The results of this study have implications for staff nurses, administrators, advanced practice nurses, hospital educators, and nursing practice. The different nurses’ perceptions that were found based on educational level and hospital position can be positively integrated and used to promote research utilization and evidence-based practice initiatives within the organization system.

McCloskey, D. (2008). Nurses’ perceptions of research utilization in a corporate health care system. *Journal of Nursing Scholarship*, 40(1), 39–45.

ABSTRACT CONTENTS

Title of the Study

Introduction of the Scientific Problem

- Statement of the problem and purpose
- Identification of the framework

Methodology

- Design
- Sample size
- Identification of data analysis methods

Results

- Major findings
- Conclusions
- Implications for nursing
- Recommendations for further research

During the career of a nurse, many clinical and practice questions will be raised that will require research methods to answer confidently. By pursuing and applying research in the area of choice, nurses acquire valid and reliable information that enables them to provide quality care.

EVIDENCED-BASED PRACTICE

The goal of client care is to provide quality nursing services that are effective in promoting health and wellness and

COMMUNITY CONSIDERATIONS

Nursing Research

Research in community health practice is challenging. The variables can be difficult to identify and measure. Consider ways that you might structure your research to answer the following:

How might you measure the “health” or “wellness” of your community?

You have decided to implement a teaching project on stress management to a group of well older adults. What criteria might you use to measure the effectiveness of your nursing interventions?

You are a new occupational health nurse at a local plastics factory. What questions might you ask the employees to better understand their need for and interest in health-promotion topics?

alleviating the discomforts of illness. The need for improved client outcomes, decreased health care costs, and client satisfaction are driving forces for the use of scientific data in the decision-making process of client care (Boswell, 2007). In EBP the nurse integrates research findings with clinical experience, the client's preferences, and available resources in planning and implementing cost-effective, individualized nursing care. Although EBP has been emphasized in medicine for years, nursing is in the initial stages of developing an EBP. "However, for the goals of evidence-based practice to be met, a culture of practice must be developed in which all clinicians from every discipline are expected to justify their practices from the best evidence currently available" (Burns & Grove, 2004, p. 296). Nurses must rely on the best evidence available to justify their practice until a solid scientific knowledge base evolves into EBP. Nursing as a profession has always recognized the importance of research as an essential basis for its development. The identification of the knowledge base for nursing practice contributes to achieving client outcomes and making nursing practice credible.

Although the terms *best practices* and *evidence-based practice* are often used interchangeably, these terms have different meanings. EBP can be a best practice, but a best practice is not necessarily evidence-based; best practices are simply ideas and strategies that work, such as programs, services, or interventions that produce positive client outcomes or reduce costs. Nurses need to base their clinical practice on empirical evidence to optimize client outcomes, to provide cost-effective safe practice, and to enhance the credibility of nursing care.

Nurses draw from their experience by selecting specific nursing interventions that influence client outcomes; however, there is little scientific evidence to support nurses' clinical decision making and expected outcomes. Early efforts to study client outcomes arose from quality assurance or quality improvement studies with nurse involvement in the development of interdisciplinary care plans such as critical pathways and care maps. However, critical pathways and care maps are not necessarily EBPs. According to Burns and Grove, "Outcomes research methods will be an important means to document the effect that nursing practice has on patient outcomes and to build the scientific base for evidence-based practice in nursing" (2004, p. 297). Outcomes studies will allow nurses the opportunity to explain the impact of their care through measures of outcomes of client care that reflect nursing practice. Although nurses are well placed to contribute toward more clinically effective and cost-effective client care, nurses need skills and resources to appraise, synthesize, and implement the best evidence in practice.

Benefield (2002) defines EBP as using the best evidence available to guide clinical decision making. This definition shifts the provision of health care away from opinion, past practice, and precedent toward a more scientific basis. "To use research-based interventions, nurses need to learn how to evaluate research reports, describe the level of evidence that exists on a particular topic, and identify the strength of the association for the research evidence that does exist" (Brockopp & Hastings-Tolsma, 2003, p. 40). Health care

providers use evidence reports that have been developed and disseminated by government programs, such as the AHRQ's National Guideline Clearinghouse that serves as a public resource for evidence-based clinical practice guidelines, or private entities like the Cochrane Collaboration.

EVIDENCE REPORTS

"Evidence reports include knowledge synthesis, review, and documentation of how evidence-based practices are used in the clinical area, and can include discussion of the clinical relevance and utility of such practices" (Benefield, 2002, p. 803). The evidence report usually contains four distinct parts: statement, analysis, evidence, and recommendations (see Figure 3-1). Once the nurse becomes aware of the need for information, EBP requires the development of the *question* or problem statement that best defines the need. Once the question is defined, the nurse systematically reviews what research has been done on the particular topic. Systematic reviews differ from literature reviews. Systematic reviews use all relevant literature from multiple sources, published and unpublished, and there is a more rigorous and systematic appraisal and evaluation.

Following the review and analysis of the systemic data, the nurse must determine what the research demonstrates and decide the level of evidence in order to make recommendations to promote EBP. A structured research summary statement succinctly describes what the evidence reports. The analysis of the scientific data describes a review of the various published and unpublished research, the details of the analysis, target populations that were studied, the type of clinical interventions that were investigated, and the strength of individual and collective study results (Benefield, 2002). The level of evidence ranks the strength and quality of the study results. Research findings should be evaluated within the context of actual or potential usefulness in practice; if the evidence deems it appropriate, the end product is a recommendation in the form of a practice-focused guideline or clinical intervention. EBP promotes quality care that has been demonstrated to be effective; see the accompanying display on page 50 on determining evidence-based nursing practice

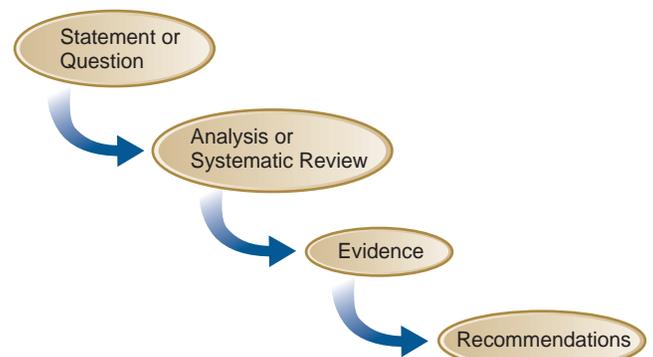

FIGURE 3-1 Evidence reports identify the need for information, analysis of scientific data, level of evidence, and recommendations for practice. DELMAR/CENGAGE LEARNING

for an example of how nurses may utilize research findings to make recommendations to promote EBP. If practice guidelines do not exist for a specific problem, the nurse needs to search for relevant evidence in studies, integrate reviews and analyses, and assess the quality of the evidence.

TRENDS IN RESEARCH AND EVIDENCE-BASED PRACTICE

The following trends in health care will have a definite impact on future nursing research and EBP:

1. Heightened focus on EBP: Nurses will be encouraged to engage in EBP; therefore, improvements are needed in both the quality of nursing studies and in nurses' skills in understanding, critiquing, and utilizing study results.
2. Stronger scientific knowledge base: Nurses should deliberately replicate, or repeat, studies with different populations, settings, and times to ensure that findings are solid.
3. Greater stress on integrative reviews of nursing knowledge: Nurses should amass comprehensive research information on the topic, weigh pieces of evidence, and integrate information to draw conclusions about the state of knowledge.
4. Increased emphases on multidisciplinary collaboration: Collaboration of nurses with researchers in related fields should lead nurses to a more prominent role in creating national and international health care policies.
5. Expanded dissemination of findings: The Internet and other modes of electronic communication, such as the *Online Journal of Knowledge Synthesis for Nursing* and the *Online Journal of Clinical Innovation*, will assist in promoting EBP.
6. Increased interest in outcomes research: Nurses will assess and document the effectiveness of health care

DETERMINING EVIDENCE-BASED NURSING PRACTICE

A nurse working on an oncology unit is interested in the relationship of oral contraceptives and the development of ovarian cancer.

- Step 1. Review and critique research reports related to oral contraceptives and the development of ovarian cancer.
- Step 2. Based on the critique of the literature on oral contraceptives and the development of ovarian cancer, identify the level and strength of the evidence: good, fair, or insufficient to support or reject a cause-and-effect interpretation of the association.
- Step 3. Make specific recommendations regarding the use of oral contraceptives and the development of ovarian cancer based on the critiqued research and the level and strength of the evidence found in the research.

Adapted from Brockopp, D., & Hastings-Tolsma, M. (2003). *Fundamentals of nursing research* (3rd ed.). Sudbury, MA: Jones & Bartlett.

services that are both cost-effective and still achieve outcomes without compromising care (Polit & Beck, 2006).

By identifying clear, significant priorities for study, striving for excellence in the evolving knowledge base, and confirming study findings, nursing researchers are providing a creditable scientific position from which to address societal health care issues and guide nursing practice.

KEY CONCEPTS

- The science of nursing is established by the same systematic, investigative process used by all science-based disciplines, the research process.
- Knowledge and nursing science are predicated on many ways of knowing, such as tradition, systematic inquiry, esthetics, and empiricism, and are influenced by gender perspectives.
- The five steps of the research process are statement of the research problem, delineation of a conceptual framework and review of the literature, selection of a research design, analysis and interpretation of the findings, and communication of the results of the research study.
- Research, education, and practice constitute the required integrated approach to the daily practice of all nurses.
- Obtaining informed consent for clients participating in the research process requires that the researcher provide full disclosure of the nature of the study, the subject's right to refuse participation, and the likely risks and benefits that would be incurred by the study.
- The various applications of nursing research to education and practice can significantly influence the quality and delivery of nursing care.
- The importance of nursing research will increase as the result of trends occurring in educational programs, interdisciplinary collaboration, interrelationships between nursing practice and research, and nurse-client involvement in research activities.
- To bridge the gap between nursing research and nursing practice, several research utilization models

- have been developed to promote quality care (e.g., the WICHE, CURN, and OCRUN models).
- EBP promotes quality care that has been demonstrated to be effective.
 - Researchers, educators, and practitioners need to work collaboratively to ensure that nursing establishes an evidence base for nursing practice.

REVIEW QUESTIONS

1. Which of the following best describes the foundation of research?
 - a. Evidence
 - b. Experience
 - c. Critical thinking
 - d. Scientific method
2. “The systematic collection of numerical information, often under conditions of considerable control, and the analysis of the information using statistical procedures” best defines:
 - a. Quantitative research
 - b. Qualitative research
 - c. Experimental research
 - d. Evidence-based practice
3. Informed consent requires that the researcher communicate which of the following to the participant? Select all that apply.
 - a. The nature of the study
 - b. The subject’s right to refuse participation
 - c. That the data will be shared with all health care providers
 - d. The expected outcomes, risks and benefits, of the study
 - e. That the family and the prescribing practitioner determine the client’s rights to participate
 - f. That the agency has the right to use the data freely
4. Which of the following are obstacles to moving research rapidly into client care?
 - a. Inadequate scientific base
 - b. Unfavorable organizational climates
 - c. Lack of access to a health care library
 - d. Limited communication and collaboration between researchers and practitioners
5. Number the following steps of evidence-based reports in the appropriate order.
 - a. Level of evidence
 - b. Ask the clinical question
 - c. Analysis of scientific data
 - d. Recommendations for practice

CHAPTER 4

Health Care Delivery, Quality, and the Continuum of Care

COMPETENCIES

1. Describe the current status of the U.S. health care delivery system.
2. Discuss the various health care settings through which health care services are delivered.
3. Identify the members of the health care team and respective roles.
4. Explain factors influencing health care delivery.
5. Explore the challenges that exist within the health care system.
6. Discuss nursing's role in meeting the challenges within the health care system.
7. Describe the emerging trends and issues for the health care delivery system.
8. Define the continuum of care concept.
9. Identify the levels of preventive care.
10. Discuss the phases of health care delivery that promote continuity of care.
11. Discuss methods for improving quality of health care delivery.
12. Explain the relationship between consumer satisfaction and quality.

KEY TERMS

- capitated rates
- comorbidity
- continuous quality improvement
- cross-functional team
- customer
- exclusive provider organizations
- fee-for-service
- functional team
- health care delivery system
- health maintenance organizations
- managed care
- organizational culture
- performance improvement
- preferred provider organizations
- primary care provider
- primary health care
- process improvement
- quality
- quality assurance
- single-payer system
- single point of entry
- team
- total quality management

Nursing is a major component of the U.S. **health care delivery system**. Consequently, nurses must understand the changes occurring within this system as well as their role in shaping the changes. This chapter discusses the types of health care services available, various settings in which these services are provided, and the members of the health care team. The economics of health care and the challenges within the health care delivery system are also discussed. Nursing's role in meeting these challenges is described. In addition, this chapter discusses quality improvement in health care as well as continuity of care.

HEALTH CARE DELIVERY: ORGANIZATIONAL FRAMEWORKS

The U.S. health care delivery system is complex, involving myriad providers, consumers, and settings. Health care services in the United States are delivered by both the public (including official and voluntary) and private sectors. No single agency or group controls the entire health care system.

PUBLIC SECTOR

Public agencies are financed with tax monies; thus, these agencies are accountable to the public. The public sector includes official (or governmental) agencies, voluntary agencies, and nonprofit agencies. Figure 4-1 shows the hierarchy of the public sector of health care delivery.

At the local level, services provided include immunizations, maternal-child care, and activities directed at control of chronic diseases. Each state varies in the provision of public health services. Generally, a state department of health coordinates the activities of local health units.

At the national level, the U.S. Department of Health and Human Services (DHHS) is administratively responsible for health care services delivered to the public. The surgeon general is the chief officer of the U.S. Public Health Service (USPHS), the major agency that oversees the actual delivery of care services. Table 4-1 on page 55 lists the USPHS agencies and their purposes.

An important part of the public sector of the health care delivery system is voluntary agencies. These not-for-profit

agencies exert significant legislative influence (e.g., the American Nurses Association [ANA] and the American Medical Association). Other voluntary agencies, such as the American Cancer Society and the American Heart Association, provide educational resources to the general public and to health care providers. Voluntary agencies are funded in a variety of ways, including individual contributions, corporate philanthropy, and membership dues.

Protecting public health is a shared responsibility among the federal, state, and local governments. Some local governments provide funding for indigent care through operating public hospitals and clinics. "Even as demands on the public health infrastructure have increased, support for public health has languished in recent decades". There is recognition of an increased need for local public health

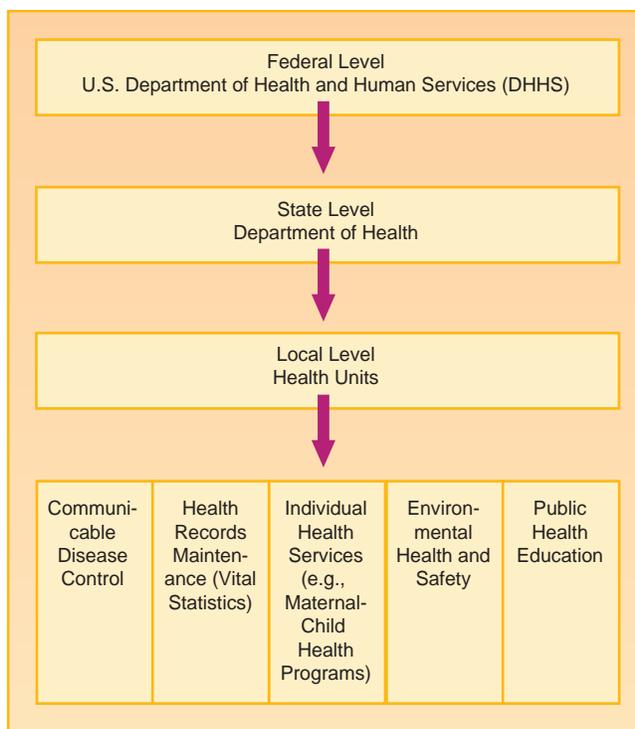

FIGURE 4-1 The Public Sector of Health Care Delivery DELMAR/ CENGAGE LEARNING

TABLE 4-1 Agencies of the U.S. Public Health Service

AGENCY	PURPOSE
Health Resources and Services Administration (HRSA)	Provide health-related information Administer programs concerned with health care for the homeless, people with human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS), organ transplants, rural health care, and employee occupational health
Food and Drug Administration (FDA)	Protect the public from unsafe drugs, food, and cosmetics
Centers for Disease Control and Prevention (CDC)	Prevent the transmission of communicable diseases
National Institutes of Health (NIH)	Conduct research and education related to specific illnesses
Substance Abuse and Mental Health Services Administration (SAMHSA)	Improve quality and availability of substance abuse prevention, alcohol and drug addiction treatment, and mental health services
Agency for Toxic Substances and Disease Registry (ATSDR)	Maintain registry of certain diseases Provide information on toxic agents Conduct mortality and morbidity studies on defined population groups
Indian Health Service (IHS)	Provide health care services to Native Americans, including health promotion, disease prevention, alcoholism prevention, substance abuse prevention, suicide prevention, nutrition, and maternal-child health care
Agency for Healthcare Research and Quality (AHRQ)	Primary source of federal support for research related to quality and safety of health care delivery

Delmar/Cengage Learning

agencies to provide primary prevention services. Sanitation, immunization, and health surveillance are only some of the services provided at the local level. The threat of bioterrorism and natural disasters reinforces the need to have health resources available at the local level.

PRIVATE SECTOR

The private component of the health care system consists of all nongovernmental sources. It comprises the largest segment of the health care system because most health care facilities in the United States are run by private for-profit or nonprofit corporations. Also included in the private system are the health insurance industry, pharmaceutical companies, and suppliers of health care technology and equipment (Pulcini, Neary, & Mahoney, 2007). The variety of settings in which health care is delivered and the roles of nurses in these settings are directly influenced by social and economic factors.

HEALTH CARE TEAM

Health care services are delivered by a multidisciplinary team. Table 4-2 on page 56 provides a list of health care

providers. Because nurses work with other care providers on an ongoing basis, it is necessary to understand the role of each provider. Nurses coordinate the care provided by the multidisciplinary team.

NURSE: ROLES AND FUNCTIONS

Nurses fulfill a variety of roles while assisting clients to meet their needs. Table 4-3 on page 57 defines the most common roles of nurses. Nurses work to promote, maintain, or restore health. A major aspect of nursing is to help individuals cope with the outcomes of illness or injury. Nurses are advocates and educators for individuals, families, and communities. Nursing roles are affected by changes in the health care environment. Nurses function in dependent, independent, and interdependent roles. The degree of autonomy nurses experience is related to client needs, expertise of the nurse, and practice setting.

ADVANCED PRACTICE NURSE: ROLES AND FUNCTIONS

The advanced practice of nursing has evolved as the profession has become more complex and specialized. Since the

TABLE 4-2 Health Care Providers

PROFESSIONAL	FUNCTION/ROLE
Nurse (RN)	Provides care to individuals who are unable to care for themselves; with a holistic approach, nurses assist clients to cope with illness or disability Addresses the needs of the client (individual, family, community) Emphasizes health promotion
Advanced practice registered nurse (APRN)	Diagnoses primary health care problems Prescribes therapeutic modalities Promotes continuity of care May specialize in a variety of areas (e.g., family practice, geriatrics, pediatrics)
Physician (MD)	Makes medical diagnoses and prescribes therapeutic modalities Performs medical procedures (e.g., surgery) May specialize in a variety of areas (e.g., gynecology/obstetrics, oncology, surgery)
Physician assistant (PA)	Provides medical services under the supervision of a physician
Pharmacist (RPh)	Prepares and dispenses drugs for therapeutic use Is often involved in client education
Dentist (DDS)	Diagnoses and treats conditions affecting mouth, teeth, and gums Performs preventive measures to promote dental health
Dietitian (RD)	Plans diets to meet special needs of clients Promotes health and prevents disease through education and counseling May supervise preparation of meals
Social worker (SW)	Assists clients with psychosocial problems (e.g., financial, marital) Conducts discharge planning Makes referrals for placement
Respiratory therapist (RT)	Administers pulmonary function tests Performs therapeutic measures to assist with respiration (e.g., oxygen administration, ventilators)
Physical therapist (PT)	Works with clients experiencing musculoskeletal problems Assesses person's strength and mobility Performs therapeutic measures (e.g., range of motion, massage, application of heat and cold) Teaches new skills (e.g., walking with crutches)
Occupational therapist (OT)	Works with clients with functional impairment to learn skills for activities of daily living
Chaplain	Assists in helping clients meet spiritual needs Provides individual counseling Provides support to families Conducts religious services
Unlicensed assistive personnel (UAP)	Assists in provision of client care activities under the direction of the RN May include certified nurses aide, personal care assistant, nursing assistant, orderly, and certified phlebotomist

Delmar/Cengage Learning

late 1960s, nurse practitioners (NPs), clinical nurse specialists (CNSs), certified nurse midwives (CNMs), and other advanced practice registered nurses (APRNs) have provided health care services to individuals, many of whom would have had inadequate or no access to services. APRNs possess

advanced skills and in-depth knowledge in specific areas of practice. Even though there are differences in various advanced practice roles, all APRNs are experts who work with clients to prevent disease and to promote health (see Chapter 11).

TABLE 4-3 Nursing Roles

ROLE	DESCRIPTION
Caregiver	Traditional and most essential role Functions as nurturer Provides direct care Is supportive Demonstrates clinical proficiency Promotes comfort of client
Teacher	Provides information Serves as counselor Seeks to empower clients for self-care Encourages compliance with prescribed therapy Promotes healthy lifestyles Interprets information
Advocate	Protects the client Provides explanations in client's language Acts as change agent Supports client's decisions
Manager	Makes decisions Coordinates activities of others Allocates resources Evaluates care and personnel Serves as a leader Takes initiative
Expert	Advanced practice clinician Conducts research Teaches in schools of nursing Develops theory Contributes to professional literature Provides testimony at governmental hearings and in courts
Case manager	Tracks client's progress through the health care system Coordinates care to ensure continuity
Team member	Collaborates with others Possesses highly skilled communication methods Performs therapeutic measures to assist with respiration (e.g., oxygen administration, ventilators)

Delmar/Cengage Learning

APRNs must meet higher educational standards and higher clinical practice requirements than those of the basic nursing education and licensure required for all nurses. Many APRNs promote quality of health care by providing services to populations often underserved by other health care providers. They provide primary health care services by diagnosing and treating common acute illnesses and injuries. APRNs prescribe medications according to regulations that vary from state to state.

REIMBURSEMENT METHODS

Efforts to reform the health care system have been motivated primarily by health care costs. Control of costs has shifted from the health care providers to the insurers and, as a result, there are constraints on reimbursement. Historically, the predominant method of covering health care costs was the **fee-for-service** method, in which the recipient directly pays the provider for health care services when they are performed.

The U.S. health care system has a diverse financial base, comprising both private and public funding. As a result, administrative costs for health care reimbursement are higher in the United States than in countries with a **single-payer system**, a model in which the government is the only entity to reimburse health care costs (e.g., Canada). Despite the enormous expenditures of public funds, the United States does not provide adequate health care coverage for all citizens.

PRIVATE INSURANCE

A major source of financing health care services in the United States is private insurance. One of the largest sectors of the health care system is private insurance companies. Payment rates to health care providers vary among insurance companies. Insured individuals or their employers are paying substantial monthly premiums and deductibles for health care services. The cost of the premiums limits access for many Americans. Insurers will no longer pay for services that they deem unnecessary or, in many cases, have not been pre-approved by the insurer. The quality of care provided is being monitored by providers, third-party payers, regulatory bodies, legislators, and consumers.

MANAGED CARE

Managed care is a system of providing and monitoring care in which access, cost, and quality are controlled before or during delivery of services. The goal of managed care is the delivery of services in the most cost-efficient manner possible. Managed care seeks to control costs by monitoring delivery of services and restricting access to expensive procedures and providers. Managed care plans assume a significant portion of the risk of providing health care and, consequently, encourage both prudent use by consumers and prescription by providers.

The rationale for managed care is to give consumers preventive health services delivered by a **primary care provider** (PCP; a health care provider whom a client sees first for health care), which in turn results in less expensive interventions. PCPs are usually physicians or NPs.

The Health Maintenance Organization Act passed in 1973 provided federal grants and loans that were made available to **health maintenance organizations** (HMOs), prepaid health plans that provide primary health care services for a preset fee and focus on cost-effective treatment measures. The HMOs were mandated to comply with strict federal regulations as opposed to the less restrictive state requirements.

Managed care refers to an organizational structure. One type of managed care is represented by HMOs, which are both providers and insurers. Other variations are represented by **preferred provider organizations** (PPOs), a type of managed care model in which member choice is limited to providers within the system, and **exclusive provider organizations** (EPOs), organizations in which care must be delivered by providers in the plan for clients to receive reimbursement. The latter creates a network of providers (such as physicians and hospitals) and offers the incentive of consumer services with little or no copayment if these providers are used exclusively. Table 4-4 provides an overview of independent practice and managed care organizational structures.

The impact of managed care is that caregivers and institutions must change from providing as many services as possible to providing fewer services so as to protect their financial interests.

Health Maintenance Organizations

HMOs often maintain primary health care sites and commonly employ health care professionals. They use **capitated rates** (a preset flat fee that is based on membership in, not services provided by, the HMO), assume the risk of clients who are heavy users, and exert control on the use of services. HMOs have been noted for their use of APRNs as PCPs, precertification programs to limit unnecessary hospitalization, and an emphasis on client education for health promotion and self-care.

Another common feature of HMOs is the practice of **single point of entry** (entry into the health care system is required through a point designated by the plan) through which primary care is delivered. **Primary health care** is the client’s point of entry into the health care system and includes assessment, diagnosis, treatment, coordination of care, education, preventive services, and surveillance. It consists of the spectrum of services provided by a family practitioner (nurse or physician) in an ambulatory setting. PCPs serve as “gatekeepers” to the health care system in that they determine which, if any, referrals to specialists are needed by the client. To reduce costs, direct access to specialists is limited.

Preferred Provider Organizations

The most common type of managed care system is the PPO. A PPO is a contractual relationship between hospitals, providers, employers, and third-party payers to form a network in which providers deliver health services at a predetermined price. Currently, managed care is emerging as the preferred model for delivery of services.

GOVERNMENT PLANS

The federal government became a third-party payer for health care services with the advent of Medicare in 1965. The Centers for Medicare and Medicaid Services (CMS), formerly known as the Health Care Financing Administration, is a federal agency that regulates Medicare and Medicaid expenditures. Medicare was established to help retired older people pay for their health care expenses. Currently, three federal programs for reimbursing health care—Medicare, Medicaid, and the State Children’s Health Insurance Program (SCHIP)—are administered by the CMS. Medicare is the federally funded program that provides health care coverage for older adults and people with disabilities. Medicaid is a program jointly administered between the federal and state governments to provide health care coverage for the economically disadvantaged.

The federal government created diagnosis-related groups (DRGs) to curtail spending for hospitalized Medicare recipients and to ensure that health care dollars would get to those who most need them. Through this system, an inclusive rate is established for each episode of hospitalization

TABLE 4-4 Independent Practice and Managed Care Options

TYPE	DESCRIPTION
Independent practice	Fee-for-service Consumer choice of provider Disease-oriented philosophy
Health maintenance organizations (HMOs)	Fee is preset and prepaid Provide services to a group of enrolled persons Service provision is limited
Preferred provider organizations (PPOs)	Fees are preset and prepaid Networks of providers that give discounts to sponsoring organization Members are not mandated to select a specific primary care provider but must use a provider in the network
Exclusive provider organizations (EPOs)	Plan pays no benefit if member is treated outside the network Usually regulated by state insurance laws

Delmar/Cengage Learning

based on the client's age, principal diagnosis, and the presence or absence of surgery and **comorbidity** (existence of simultaneous disease processes within an individual). Hospitals are reimbursed only for services that are determined to be medically necessary by the CMS. An accelerating trend for the federal government is to give recipients of public monies the personal right to choose, through the use of vouchers, a managed care program in the private sector.

Another trend is that the CMS will no longer pay for certain incidents called "never events." The Medicare Modernization Act and Deficit Reduction Act of 2005 permit the CMS to reduce or refuse reimbursement to hospitals for certain medical events. The new rules went into effect in 2008. A never event is a serious, preventable adverse event that is a hospital-acquired condition (HAC). Examples of some of the HAC never events are surgical site infections, severe pressure ulcers, and falls. Other HAC events will experience reduced CMS reimbursement in the future.

Medicare

When Medicare was established in 1965, it was intended to protect individuals over the age of 65 from exorbitant costs of health care by providing public funds to cover the majority of health care services. Medicare does not pay for all health care expenses incurred by older adults. Some of the expenses not fully reimbursed include prescription drugs, preventive services (e.g., annual physical exams), dental care, and vision and hearing services. A major need of older adults not addressed by Medicare is reimbursement for long-term care and catastrophic illness. Also, Medicare does not provide adequate reimbursement to older people for the expense of medications. This imposes a great financial hardship since many older individuals take multiple expensive medications. In 1972, Medicare was modified to include individuals with permanent disabilities and those with end-stage renal disease.

Medicaid

Medicaid is a shared venture between the federal and state governments. Each state has latitude in determining who is "medically indigent" and thus eligible for public monies. Minimal services covered by Medicaid are defined by the federal government and include inpatient and outpatient hospital services, physician services, laboratory services (including x-rays), and rural health clinic services. States may elect to cover other services, such as dental, vision, and prescription drugs. Medicaid reimburses NPs and CNMs if state regulations have authorized the APRN to provide the services specified by the CMS.

State Children's Health Insurance Program

The Balanced Budget Act of 1997 established the SCHIP. This public health insurance program, administered at the state level, is like all other federal insurance plans in that it is funded from general taxes. Nurses play an essential advocacy role by helping

parents of economically disadvantaged children to enroll in the SCHIP with their respective state health agencies.

In addition to Medicaid and SCHIP funds, states also administer the federally funded Title V Maternal-Child Block Grant Program. The objective of this program is to improve maternal, infant, and adolescent health. Also covered under this block grant are services for children at risk of chronic, disabling conditions.

States have a great deal of influence on health care reimbursement in that each state regulates insurance companies. Each state makes decisions about Medicaid financing and is, therefore, concerned about escalating health care costs. Several states offer some form of managed care to Medicaid participants in an attempt to control rising costs.

FACTORS INFLUENCING THE DELIVERY OF HEALTH CARE

Numerous social, political, and cultural factors influence the delivery of health care. Despite cost-containment efforts (such as DRGs established by the federal government and managed care by the insurers), the U.S. health care system still has problems with issues of cost, access, and quality. Other factors that influence health care delivery include regulatory mandates, the shortage of registered nurses, technological advances, increasing consumerism, and vulnerable population groups.

COST

Cost has been a driving force for change in the health care system as evidenced by the strength and numbers of managed care plans, increased use of outpatient treatment, and shortened hospital stays. The market force to maximize profits by minimizing costs is dominating the current changes in the health care system.

The United States spends more per person on health care than any other country. In 2007, the per capita health care expenses were \$7,600 per person, with total health care spending representing 16% of the gross national product (National Coalition on Health Care [NCHC], 2008). Even though the United States has the most expensive health care system in the world, it ranks behind most other industrialized nations in the health of its citizens (Hunt, 2009). Every dollar that the government spends on health care is a dollar subtracted from other programs (e.g., education and housing) that affect citizens' well-being. Following are some of the factors that contribute to the escalation of health care costs:

- The aging population
- Technological advances
- A surplus of hospital beds
- Increased number of people with chronic illnesses

The cost of health care services is prohibitive to many people; thus, it is a major barrier to access to services. Another factor that contributes to the high cost of health care is the increase in health-related lawsuits that has resulted in the unnecessary use of services.

ACCESS

In addition to the issue of cost, access to health care services has a serious impact on the functioning of the health care system. As a result of the cost, health care for many people is crisis-oriented and fragmented. A large number of Americans are unable to gain access to health care services owing to low income or lack of insurance; therefore, their illnesses progress to an acute stage before intervention is sought. Services used by individuals during acute illnesses are typically those provided by emergency departments. Emergency room and acute care services are expensive when compared with early intervention and preventive measures. Poverty often adversely affects an individual's access to health care services. For example, limited transportation (lack of an automobile or funding for public transit) interferes with the ability to travel to health care facilities.

Approximately 47 million Americans are uninsured, which severely limits access to care (NCHC, 2008). Only a small portion of the medically indigent is covered by Medicare. In addition, many individuals are underinsured. These people are neither poor nor old, but middle-class unemployed Americans or those in jobs without adequate health care benefits.

In addition to poverty and unemployment, the following factors impede a person's ability to access available health care services:

- No provision for insurance by an employer due to prohibitive costs
- Inability to obtain individual insurance due to high costs
- Difficulty for people with certain medical problems (pre-existing conditions) to obtain insurance
- Cultural barriers
- Shortages of health care providers in some geographic areas (especially rural or inner-city areas)
- Limited access to ancillary services (e.g., child care, transportation)

QUALITY

Many unnecessary diagnostic and medical procedures are performed in order to decrease the possibility of being sued for professional malpractice. This inappropriate use of resources can be traced to several causative factors, including:

- The litigious environment that creates the tendency toward defensive practice
- Resource consumption, which is highly influenced by the widely held American belief that more is better
- Lack of access to and continuity of services with subsequent misuse of acute care services

In an attempt to provide universal access to services in a cost-effective manner, quality does not have to be sacrificed. However, safety and quality are frequently compromised by inappropriate substitution of unlicensed personnel for registered nurses in direct care of clients. Sufficient numbers of registered nurses may decrease the occurrence of adverse events (Gordon, Buchanan, & Bretherton, 2008; Kane, Shamliyan, Mueller, Duval, & Wilt, 2007; Mark & Harless, 2007; Thungjaroenkul, Cummings, & Embleton, 2007).

Health care consumers and legislators, as well as the nursing profession, are concerned about the effects of fewer nurses in the workplace. Some states are instituting legislation that mandates the ratio of nursing staff to clients.

In an attempt to be cost-effective, some hospitals have decreased the number of registered nurses. Any movement toward reform must focus on providing quality nursing care to all consumers. According to Thungjaroenkul and colleagues (2007, p. 264), "Patient costs were reduced with greater RN staffing as RNs have higher knowledge and skill levels to provide more effective nursing care."

NURSING SUPPLY AND DEMAND

Currently an imbalance exists between the number of registered nurses and the demand for nursing services. The shortage of registered nurses in the United States could reach 500,000 by the year 2025 (Buerhaus, Staiger, & Aeburach, 2009). Following is a list of some of the many factors that are increasing the gap between the demand for and supply of registered nurses:

- A declining number of nursing faculty
- Technological advances that result in treatment of more medical problems
- Increasing emphasis on preventive care
- Growing number of older adults who are more likely to need nursing care
- Declining numbers of enrollees in nursing schools

RESPONSES TO HEALTH CARE CHANGES

As the United States continues to look for ways to address the issue of health care reform, the implications for nursing will continue to increase. Some nurses feel threatened by impending changes, whereas others are excited about the possibility of transforming the health care system into something better. Advocating for clients, educating public policy makers, and continuing to provide direct quality care are only a few of the actions that nurses implement to ensure delivery of care in a safe, therapeutic manner.

NURSING AGENDA FOR HEALTH CARE REFORM

In response to the problems of high cost, limited access, and eroding quality that were affecting the U.S. health care system, the nursing community created a public policy agenda that is currently endorsed by more than 70 organizations. *Nursing's Agenda for Health Care Reform* (ANA, 2005) provides a valid framework for change in health care policy. A cornerstone of this policy statement is the delivery of health care services in environments that are easily accessible, familiar, and consumer-friendly. Another essential part of *Nursing's Agenda* is the empowerment of consumers for self-care. This goal has enormous implications for nurses as health educators and for the use of incentives for increasing personal accountability for

one's own health status. Some elements of the ANA's Health Care Agenda 2005 are as follows:

- A nationally defined standard package of basic health care services available to all U.S. residents
- A phase-in of essential services that address vulnerable populations with limited access to health care
- Plans to decrease the costs of health care
- Activities that address long-term care needs with emphasis on consumer responsibility (ANA, 2005)

PUBLIC VERSUS PRIVATE PROGRAMS

The nursing profession supports an integration of public and private sector programs and resources for health care delivery. The competition between the two types of settings has encouraged quality and progress. Each setting provides benefits as well as drawbacks to health care recipients.

Public dollars are required to help the poor and those who do not receive health care benefits through the workplace. Actual services should be available through a variety of public and private sources. To safeguard the health care system from becoming a two-tiered process based on personal resources, both the poor and nonpoor and the privileged and nonprivileged need to be enrolled in the same programs: see Spotlight On: Caring and Compassion.

Finally, the basic required package of services must be defined in the same way in each state and required as the minimum for both public and private sector programs. The movement toward establishing national standards must be tempered with a respect for local needs and differences. In other words, set minimal national standards, but promote local planning and implementation. National standards are needed to promote equitable use of federal resources in the provision of health care services.

VULNERABLE POPULATIONS

Meeting the health care needs of underserved populations is especially challenging. Groups that may be unable to gain access to health care services include children, older adults, the homeless, and people living in poverty. Health is strongly related to socioeconomic status, with those in lower income brackets having poor health outcomes (Edelman & Mandle, 2006). See the accompanying Nursing Checklist for information about working with vulnerable individuals.

Our current health care system neglects the overall needs of children. Children are more likely than adults to be uninsured. As the federal and state governments continue to curb expenditures for health care, more children will be declared ineligible for Medicaid. Children who are covered by health insurance have a greater degree of well-being. Public health insurance provides significant benefits for children's access and use of health care services (Duderstadt, Hughes, Soobader, & Newacheck, 2006).

Many preschool children in the United States are not immunized. Preventive health care should be available to children of all ages, with an emphasis on early immunization. In addition, maternal-child health among some ethnic and racial minorities in certain geographic areas of the United States is poorer than that in developing countries. The ANA

Working with Members of Vulnerable Population Groups

- Establish an environment that is comfortable and nonthreatening
- Understand the verbal and nonverbal communication
- Learn about specific cultural practices that affect health care practices
- Collaborate with other care providers
- Make referrals to community agencies as necessary

and a coalition of allied nursing associations are working together in an attempt to immunize all children in the United States. The Centers for Disease Control and Prevention stated that in 2006, more than 77% of U.S. infants and toddlers received all the recommended immunizations. However, that number is below the 90% rate recommended by the Healthy People 2010 initiative.

Traditionally, rural areas have had few health care providers and facilities that were easily accessible. A large number of older people live in rural areas. Because people in rural areas tend to work for small businesses or are self-employed, many of them have no health insurance. Also, many hospitals in rural areas have been closed due to economic pressures.

Generally, adults in the United States who receive little assistance in health promotion maintain unhealthy lifestyles, which lead to the development of chronic illnesses. Older adults who have accumulated problems that could have been prevented are admitted to nursing homes, which are very costly (McCallion, 2007).

It is in the best interests of society to see that those who cannot afford the basic health services are not denied such services. The entire society's health is threatened when some sectors are denied basic care. As a group, nurses are concerned with the availability of health care services to everyone, regardless of their ability to pay (Hicks & Boles, 2008).

COMMUNITY NURSING ORGANIZATIONS

Community nursing organizations (CNOs) were established to help meet the needs of people in the community. The goal of CNOs is to provide quality health care services in a cost-effective manner. In CNOs, nurses are the PCPs. One

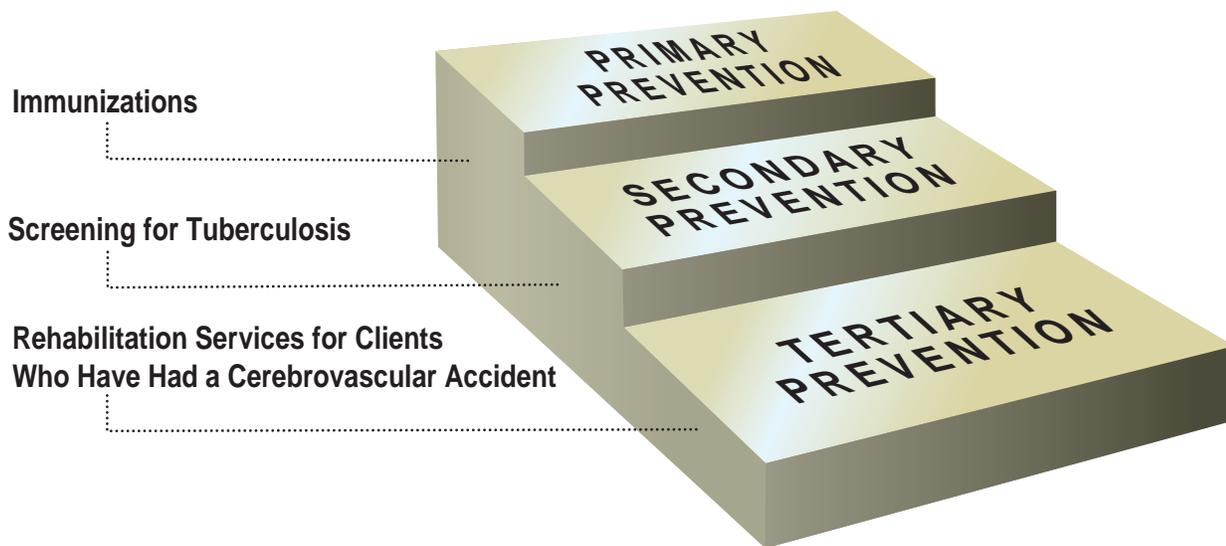

FIGURE 4-2 Three Levels of Prevention and Examples DELMAR/CENGAGE LEARNING

example of a CNO is Columbia Advanced Practice Nurse Associates (CAPNA), which was established in 1998. CAPNA is affiliated with the Columbia University School of Nursing and provides primary care to the community at large.

CONTINUUM OF CARE

Acute care provided in hospitals constitutes only a small portion of health care services provided to the U.S. population. Clients need to have services provided over a broad spectrum of settings and time frames. Most large medical centers and hospitals provide a full range of services, including preadmission, outpatient, acute inpatient, long-term inpatient, hospitalization, and aftercare, which may consist of home health, hospice, subacute, or long-term care (e.g., nursing homes) Table 4-6 later in this chapter describes the settings in which health care services are provided.

LEVELS OF CARE

Basically, health care services can be categorized into three levels: primary, secondary, and tertiary (see Figure 4-2). The complexity of care varies according to the individual's need, provider's expertise, and delivery setting. Table 4-5 on page 63 provides an overview of the types of care.

Primary: Health Promotion and Illness Prevention

The major purposes of health care are to promote wellness and prevent illness or disability. Traditionally, the U.S. health care system has focused on disease prevention rather than health promotion. However, within the past decade, society has begun to engage in health-promoting behaviors. Illness prevention activities are directed at the individual, the family, and the community.

Secondary: Diagnosis and Treatment

Most health care services are the secondary type of health care interventions. Acute treatment centers (hospitals) are

still the predominant site of delivery of health care services. There is a growing movement to have diagnostic and therapeutic services provided in locations that are more easily accessed by individuals.

Tertiary: Rehabilitation

Restoring an individual to the state that existed before the development of an illness is the purpose of rehabilitative (or restorative) care. In situations in which the person is unable to regain previous functional abilities, the goal of rehabilitation is to help the client reach the optimal level of self-care. Restorative care is holistic, in that the entire person is cared for—physiological, psychological, social, and spiritual dimensions.

HEALTH CARE SETTINGS

Health care services are delivered in a variety of settings; see Table 4-6 on page 63. Even though the majority of RNs currently are employed by hospitals, the fastest-growing employment opportunity for nurses in the near future is expected to be outpatient settings, i.e., clinics and home health care agencies (Bureau of Labor Statistics, 2007).

Technological advances have allowed many health care services to be delivered in outpatient settings. Such technology and increased medical specialization have resulted in improved health outcomes for many individuals. However, specialization has also led to a major problem, fragmentation of care.

Are there programs in your community in which nurses are delivering health services to vulnerable populations? What is the need for such services, taking into consideration populations such as children, older adults, the indigent, and the homeless?

TABLE 4-5 Types of Health Care Services

TYPE OF CARE	DESCRIPTION	EXAMPLES
Primary	<ul style="list-style-type: none"> • <i>Goal:</i> To decrease the risk to a client (individual, family, or community) for disease or dysfunction • <i>Explanation:</i> General health promotion Protection against specific illnesses 	<ul style="list-style-type: none"> • Teaching • Lifestyle modification for health (e.g., smoking cessation, nutritional counseling) • Referrals • Immunization • Promotion of a safe environment (e.g., sanitation, protection from toxic agents)
Secondary	<ul style="list-style-type: none"> • <i>Goal:</i> Early intervention to alleviate disease and prevent further disability • <i>Explanation:</i> Early detection and intervention 	<ul style="list-style-type: none"> • Screenings • Diagnosis • Acute care • Surgery

Delmar/Cengage Learning

FRAGMENTATION OF CARE

Health care often becomes fragmented when a person sees more than one health care provider and receives care at more than one facility. As a result of the fragmentation, clients may

be misdiagnosed, receive unnecessary care, and be viewed as a “case” rather than a whole person. For example, a client who is being treated for hypertension by the PCP is referred to a gynecologist for an annual Pap smear, who then refers

the client to an oncologist for treatment of cervical cancer. The client is then treated by a hematologist, radiologist, and endocrinologist. Each specialty-care physician treats a certain problem instead of the entire person.

Fragmented care may also occur as the client progresses through various treatment settings. For example, the client may be seen in an outpatient clinic by one set of health care providers, then admitted to the hospital, and then discharged to home health care. Due to the variety of settings and care providers, the person's individuality may be overlooked. Many health care providers and organizations (such as HMOs) are implementing the concept of seamless service to overcome the delivery of fragmented services. Seamless service means that an organization provides preadmission, acute inpatient, and aftercare services to a client. Such a delivery system helps prevent a client from being lost in the system with resulting unmet needs.

SPOTLIGHT ON...

Professionalism

Before focusing on the problems within the current health care delivery system, stop and think!

The American health care system is first in technologic advances, biomedical research, and state-of-the-art clinical equipment and facilities. Yet even with these advantages, many consider that this system is in crisis. From your perspective, is the U.S. health care system in a position of strength or weakness? Explain why.

QUALITY MANAGEMENT IN HEALTH CARE

Quality of care, cost, and access are dominant themes in health care delivery. Health care services must be delivered in a manner that increases the occurrence of expected health outcomes. Nurses, as well as all other health care providers, are accountable for quality care. The challenge for nursing has never been greater as political, economic, and regulatory requirements increase and the demand for quality care intensifies.

DEFINING QUALITY

Health care has struggled for many years to define and measure quality. **Quality** is defined as meeting or exceeding requirements of the customer or client. A **customer** is anyone who uses the products, services, or processes of an organization. Quality is measured in terms of customer perspective with emphasis on the following:

- Accessibility and availability of service
- Timely and safe delivery of service
- Coordination and continuity of care between services
- Effectiveness of services (i.e., the delivery and outcome of care)

A health care organization must be concerned with *doing the right things* (efficacy, appropriateness) and *doing the right things well* (availability, timeliness, effectiveness, continuity, safety, efficiency, and respect and caring). **Performance improvement** consists of those activities and behaviors that each individual does to meet customers' expectations. It is doing the right thing well and continually striving to do better (Joint Commission, 2008).

Quality measurement consists of evaluating three interrelated components: structure, process, and outcome. Each

of these components is interrelated. The ANA's *Nursing: Scope and Standards of Practice* (2004) uses these three components of care to guide nursing practice within the framework of the nursing process.

Quality management has its own array of terminology. Despite the similarities, there are differences in the concepts, as outlined here:

- **Quality assurance (QA)** is the traditional approach to quality management in which monitoring and evaluation focus on individual performance, deviation from standards, and problem solving.
- **Continuous quality improvement (CQI)** is the approach to quality management in which scientific, data-driven approaches are used to study work processes that lead to long-term system improvements. This concept has evolved into systems such as process improvement or performance improvement.
- **Total quality management (TQM)** is the method of management and system operation used to achieve CQI. TQM promotes an organizational culture that supports customer need, empowers employees to work as teams, emphasizes self-development, and requires a new leadership style in which employees are viewed as resources.

TQM is a system of operation, whereas CQI is the desired outcome of a quality management program. It is difficult to achieve performance improvement without a TQM culture. The goal of a quality management program is to focus on process improvement, which will ultimately improve the quality of care.

FACTORS INFLUENCING QUALITY IN HEALTH CARE

Today there are many consumers of health care in addition to clients and their families. One major consumer of health care is third-party payers, such as insurance companies, managed care organizations, and federal and state governments. The diversity of needs represented by these consumers requires improvement in health care delivery systems. The major factors that have influenced the development of the quality movement in health care are consumer demands, financial viability, professional accountability, regulatory requirements, progress in quality improvement techniques, and changes in health care delivery.

Consumer Demands

Health care consumers are sophisticated, knowledgeable, and selective. Clients no longer place blind trust in health care providers; they realize that variables in practice and results occur. Today's consumers negotiate services and compare health care costs among providers.

Financial Viability

Health care has entered an era of increased competitiveness for services, staff, and customers. There is a demand to reduce spending and contain costs. Budgetary constraints

continue to increase in both the private and public health sectors. Health care organizations must strive to reduce professional liability, increase reimbursement eligibility, and promote cost-effectiveness through increased efficiency.

Professional Accountability

Emphasis on clinician accountability and adherence to codes of ethical practice is increasing. Health care professionals must be dedicated to reducing practice variances in order to protect the public.

Regulatory Requirements

The CMS standards, Joint Commission standards, and numerous laws require quality improvement programs. The CMS is a subsidiary of the DHHS and is the federal agency responsible for administering the Medicare and Medicaid programs. The regulations established by these organizations for accreditation and reimbursement have facilitated the quality initiative in health care. Such externally mandated regulations have promoted the development of internal monitoring and evaluation systems within health care organizations.

Progress in Quality Improvement Techniques

During the past decade, health care providers have spent valuable resources on defining and measuring quality. As a result, evaluation methodologies have improved considerably. Information systems are available through which national and regional norms for comparative data can be obtained. Measurability methods have been upgraded and include a variety of process improvement models. **Process improvement** examines the flow of client care between departments to ensure that the processes work effectively and that acceptable levels of performance are achieved. Overall quality improvement methodologies enhance performance and work processes.

Changes in Health Care Delivery

Significant changes in health care delivery have occurred, and unprecedented change is anticipated in the future. Clients being admitted to hospitals today are more acutely ill yet are being discharged more quickly than in the past. Alternative care options such as home health care, in-home intravenous therapy, and intermediate care facilities have proliferated, resulting in an even greater need to coordinate a continuum of services.

Factors that have influenced the quality movement in health care have also protected those populations most vulnerable to inadequate health care (e.g., the uninsured, older adults, and low-income families). The quality movement has promoted access to care, standards of care, cost-effective service, and a continuum of care. Thus, the quality movement in health care has served as an advocate for consumers.

Legal Implications of Quality Improvement

Nurses, as well as other health care providers, must understand the roles that laws and regulations play in the quality movement. These aspects define professional practice. Laws define legal practice, while regulations define guidelines for delivery of care.

Legal considerations have an impact on quality management in several ways:

- Laws and regulations create the external structure for quality management.
- Failure to provide quality health care can result in lawsuits.
- Institutions can face liability for action taken against a practitioner if objective measures are not applied to performance and due process is not provided.

Quality management programs must protect against substandard care and ultimately reduce litigation. Organizations must have clearly defined processes for professional review. These responsibilities are based on federal regulations.

Federal Regulations

A number of federal agencies regulate health care standards, for example, the CMS, the Food and Drug Administration, and the Occupational Safety and Health Administration (OSHA). OSHA requires employers to protect employees from work-related injuries and illnesses (e.g., exposure to infectious materials). There are also federal laws that prohibit substandard care, promote health care provider peer review, and mandate the reporting of serious injury or death of clients resulting from unsafe use of medical devices.

Failure to adhere to the guidelines in these legislative acts can result in sanctions for violation of standards. Federal funding and payment for services can be denied for failure to provide quality care.

QUALITY AND HEALTH CARE ECONOMICS

Health care costs have skyrocketed in the past decades. The primary source of health insurance in the United States is employer coverage. Payers are becoming increasingly concerned about health care costs, and the issue of health care expenditures is being intensely debated.

Delivery of poor quality care has a negative financial impact on health care organizations. Management in some organizations argues that the quality improvement initiative is costly because of staff time involved in such activities. However, one must consider the cost of poor quality, which results in the following problems:

- Duplicated work between departments
- Loss of time due to inefficient task performance
- Loss of staff due to job dissatisfaction
- Recruitment and training of new employees

- Expenditure of energy and time in investigation of complaints and allegations
- Litigation and malpractice settlements
- Expenses related to overutilization of diagnostic tests to avoid malpractice

Originally, the perception of quality was that of doing more, that is, the performance of more tasks, which resulted in intensive intervention. Today, it is believed that efficiency can be improved without compromising quality.

Health care leaders must now look at the individual and collective effectiveness of organizational management. Organizations must also begin to examine the cumulative cost associated with a less-than-optimal ability to plan, delegate, communicate, and listen. The prevailing philosophy is to do more with less. Such an approach to health care management has resulted in downsizing, cross-training, and reduction of middle-management staff.

PRINCIPLES OF QUALITY IMPROVEMENT

Because CQI examines ways in which the entire organization can improve, the involvement of everyone, especially administration, is required. CQI is based on the following principles:

- Quality is a central theme to the organization. It is part of the organization's mission and the core of daily activities.
- Leadership is committed to and involved in creating an **organizational culture** (commonly held beliefs, values, norms, and expectations that drive the workforce) for quality improvement.
- All staff members are personally responsible for quality; therefore, decision making is done by the people doing the work.
- Education and training must be continual to improve skills and promote self-development.
- Processes and system operation, in addition to individual performance, are monitored.
- A scientific approach based on analysis of data is used.
- Accurate information is available and must be used in decision making. Individuals and institutions can no longer use opinion and intuition; they must manage by facts.

CUSTOMER SATISFACTION

Promoting customer satisfaction requires an organizational commitment from every employee to be sensitive to the needs, wants, and expectations of customers. This commitment requires putting the customer first. Customers include those internal and external to the organization, such as clients, suppliers, third-party payers, families, visitors, coworkers, and the community. Managers must meet employee needs and service delivery demands. The direct care provider must meet client needs, coworkers' needs, and organizational needs.

SPOTLIGHT ON...

Legal/Ethical

You are working in a skilled nursing facility. Regulations require that unlicensed personnel complete training and testing for certification as nursing assistants. You discover that there has been a recent turnover in staff and many newly employed nursing assistants are not yet certified.

What are the legal and ethical ramifications of this situation? What should you do?

Health care agencies do not have unlimited resources allocated solely to keeping customers happy. Therefore, the organization and each employee must understand the implications of customer dissatisfaction from a financial perspective. The loss of one admission is relatively insignificant to a multimillion dollar budget; however, multiple losses can have a substantial effect on a health care facility's financial well-being.

There is additional potential revenue loss from related ancillary services following hospitalization, such as home health care, laboratory procedures, pharmaceutical supplies, and office follow-up. A customer's dissatisfaction with one facet of service can be generalized to all related delivery systems.

Another effect of customer dissatisfaction is a tarnished community image. There is a multiplier (or ripple) effect in which one bad encounter can affect the attitude and opinion of many. An unhappy client may inform the immediate family, extended family, neighbors, friends, and coworkers. Seemingly simple acts, such as the following, can result in client dissatisfaction despite a positive health outcome:

- A cold food tray
- Failure to respond to a call light in a timely manner
- Waiting for tests
- Late treatment
- Unemptied bedpan
- Delayed pain medication
- Failure of health care provider to introduce himself or herself

Satisfaction is a subjective perception; therefore, health care providers must listen to the customer constantly to determine satisfaction and dissatisfaction. Then, improvements can be initiated.

ORGANIZATIONAL STRUCTURE FOR QUALITY MANAGEMENT

Because quality has become a central issue in health care delivery, nurses must consider the impact of organizational

structure on the quality of care provided. Nurses are key in establishing a culture for excellence in most health care organizations.

Several factors within an organization affect quality management, including organizational culture, workforce diversity, empowerment, leadership, and teamwork. To improve the quality of care, the organization should be viewed as a system that is comprised of governance, management, clinical, and support devices. Many processes within the system involve more than one group. Therefore, a framework must be established to promote collaboration.

ORGANIZATIONAL CULTURE

Organizations have both formal and informal cultures. Incongruence between the formal operational style espoused by management and the style demonstrated by staff members may be evident. This can result in an ineffectual organization in which achieving continual improvement is difficult. Thus, the culture of an organization can affect the quality of care. A positive culture promotes trust, information sharing, collaboration, and risk taking, whereas a negative culture produces divisiveness, resistance, and a desire to maintain the status quo. In a negative culture, inertia develops and employees lack creativity and self-direction. Table 4-7 on page 69 compares characteristics of organizational culture within traditional and high-performance organizations.

Leadership

Organizational leadership contributes to the creation of the culture based on CQI beliefs and practice. Leadership must create a people-oriented culture. In today's fast-paced, high-tech, cost-driven health care environment, the human factor is frequently overlooked. Although staffing incurs the greatest expense and is a primary target for cost reduction, it is the people in the health care organization who are the greatest asset. Therefore, management must focus on ensuring a return on this important resource.

Teamwork

Improving quality requires team effort. Authoritarian, hierarchical, and traditional ways of management are no longer effective; therefore, health care organizations are turning to team-based strategies for organizing labor.

A **team** is a group of individuals who work together to achieve a common goal. The dynamics of team interaction are important. Teams must demonstrate commitment, cooperation, and communication. The way the team communicates and solves problems has a significant impact on outcome and delivery of service. For quality care to occur, work groups must function as teams.

To promote quality improvement, teams are used to study processes. There are two types of process improvement teams: functional and cross-functional. A **functional team** is a departmental or unit-specific group whose scope is limited to departmental or work area processes. A **cross-functional team** is an interdepartmental, multidisciplinary group that is assigned to study an organization-wide process

TABLE 4-7 Organizational Culture

DIMENSION	TRADITIONAL ORGANIZATION	HIGH-PERFORMANCE ORGANIZATION
Structure	<ul style="list-style-type: none"> • Authoritarian, hierarchical 	<ul style="list-style-type: none"> • Team focused
Decision making	<ul style="list-style-type: none"> • Limited input, based on politics and alliances, dissonance 	<ul style="list-style-type: none"> • By consensus, based on resources, commitment to action

FIGURE 4-3 Members of a cross-functional health care team. How is the quality of health care improved by the involvement of more than one discipline? DELMAR/CENGAGE LEARNING

(see Figure 4-3). An effective team demonstrates mutual respect and trust, displays open communication, builds on skills of members, and seeks consensus.

The use of teams to restructure and improve work processes has many advantages, such as:

- Increased involvement and understanding
- More opportunities to share ideas
- Assistance in building relationships
- Involvement of staff in problem solving

The team approach is effective for coordinating and integrating interdepartmental work processes.

PROCESS IMPROVEMENT

For years, the focus of health care quality has been on performance improvement. No single individual's performance really stands alone. Each person's action in an organization is actually a performance step that is connected to the actions of others. This series of interconnected steps is known as a process; processes interconnect to form a system.

Tools for Measuring Quality

A variety of tools are used to collect and analyze data so that decisions can be made about organizational performance. Some mechanisms frequently used to obtain and measure data are:

- **Audit:** Reviewing client records for compliance to predetermined criteria that measure process and outcome of care
- **Peer review:** Evaluating care based on the judgment of a colleague with equal education and experience
- **Benchmarking:** Measuring service or practice against the competition
- **Clinical pathways:** Measuring the performance of care according to critical outcomes and key incidents that must occur within given time frames

In addition, comparative data can be obtained from the literature, practice guidelines, and external reference databases.

NURSING'S ROLE IN QUALITY MANAGEMENT

The primary purpose of nursing is to provide quality care to clients. Providing quality care means always seeking to improve the care delivered. Nurses function as clinicians, team members, and managers. Each of these roles has specific responsibilities for quality performance and requires certain skills to achieve the expected level of performance (see Table 4-8).

Whether functioning as a clinician, team member, or manager, nurses continually strive for excellence in everything they do. See the Uncovering the Evidence feature. By using a CQI approach, which examines structure and process instead of individual performance, nurses can move forward in the provision of quality care. Quality improvement identifies situations when nursing teams are more productive and functioning at a higher quality level.

TABLE 4-8 Nursing Roles and Responsibilities: Quality Improvement

ROLE	RESPONSIBILITIES
Clinician	<ul style="list-style-type: none"> • Maintain ethical standards of practice • Seek self-development via continuing education • Be self-directed • Serve as change agent • Practice efficient time management • Achieve customer satisfaction • Be committed to reducing cost and improving performance
Team member	<ul style="list-style-type: none"> • Be knowledgeable about group dynamics • Support colleagues • Promote mutual trust and respect • Build rapport with other disciplines • Practice active listening • Praise coworkers
Manager	<ul style="list-style-type: none"> • Develop leadership skills • Be knowledgeable about statistical analysis • Provide clear and direct communication • Delegate to and empower staff • Lead by example

UNCOVERING THE

Evidence

TITLE OF STUDY

“Quality Improvement: The Divergent Views of Managers and Clinicians”

AUTHORS

M. Price, L. Fitzgerald, and L. Kinsman

PURPOSE

Identify and explore nurse managers’ and nurse clinicians’ perceptions of quality improvement.

METHODS

This descriptive qualitative research study collected data via semistructured interviews. The data were analyzed using constant comparative analysis.

FINDINGS

The concept of quality improvement and how it applies to nursing practice varied between the two groups. Each group identified the importance of quality in delivery of care. However, managers and clinicians stated it was the other group that was responsible for decreased quality care delivery.

IMPLICATIONS

Nurse managers and clinicians provided divergent views of the deficiencies in the way quality improvement is implemented. In order to be successful, a quality improvement program must include the views of both managers and clinical nurses.

Price, M., Fitzgerald, L., & Kinsman, L. (2007). Quality improvement: The divergent views of managers and clinicians. *Journal of Nursing Management*, 15(1), 43–50.

TRENDS IN HEALTH CARE DELIVERY

As current trends continue, the delivery of health care services will continue to change. “Today the terms *change* and *chaos* are used interchangeably to describe the current state of the U.S. health care system. No one seems to have a clear vision of how health care services will be organized and delivered in the future” (Heinrich & Thompson, 2007, p. 208). Some factors that will continue to shape reform of the health care delivery system are:

- The aging of the U.S. population
- Increasing diversity in the U.S. population
- Increased number of single-parent families, with more children living in poverty
- Continued growth in outpatient settings with a greater demand for PCPs
- Advances in technology with a resultant ability to perform more services in outpatient settings (including the home)
- Emphasis on disease prevention and health promotion at the workplace
- Expectations of third-party payers and providers for clients to assume more personal responsibility for care

The states and private sector will lead the way through a process to a product suited to the American character. The nursing profession has reached a point in time where there are few questions about the direction or process of health care reform. “What is clear today is that economic incentives and concerns will continue to drive future health system changes, and that business and corporate Americans will increasingly have more of a say in how the future health care delivery system will be organized” (Heinrich & Thompson, 2007, pp. 211–212). The challenge is to improve the nation’s delivery of health care services by positioning nursing to preserve its integrity and guarantee its preferred future. Nurses must continue to be in the forefront of change.

KEY CONCEPTS

- The three levels of health care services can be categorized as primary, secondary, and tertiary levels.
- Health care services are delivered by both the public (official, voluntary, and nonprofit agencies) and private (hospitals, extended care facilities, home health agencies, hospices, outpatient settings, schools, industrial clinics, managed care organizations, community nursing centers, and rural hospitals) sectors.
- The health care team is composed of nurses, APRNs, physicians, physician assistants, pharmacists, dentists, dietitians, social workers, therapists, and chaplains.
- Health care in the United States is financed through a combination of both private and public funding.
- Managed care organizations seek to control health care costs by monitoring the delivery of services and restricting access to costly procedures and providers.
- Managed care plans include HMOs, PPOs, and EPOs.
- The primary federal government insurance plans are Medicare, the program that provides health care coverage for older adults and people with disabilities, and Medicaid, the jointly administered program that provides health care services for the poor.

- Health care reform must address the three critical issues of cost, access, and quality of health care services to achieve equity for all Americans.
- *Nursing's Agenda for Health Care Reform*, written by the ANA and endorsed by over 70 professional organizations, outlines nursing's proposals for easing the current problems in health care delivery.
- The AHRQ aims to identify therapeutic standards for which the health care community can be held accountable.
- A primary goal of the nursing profession within the areas of public health, community health, and long-term care is to provide health care services that emphasize prevention and primary health care to clients in these settings and thus help reduce the cost and increase the quality of health care.
- The quality movement was initiated by consumer demands, financial viability, professional accountability, regulatory requirements, progress made in quality improvement techniques, and changes in health care delivery.
- Federal regulations establish guidelines for quality management.
- Continuous quality improvement focuses on studying work processes that promote system improvements.
- Total quality management is a method of organizational operation that establishes a work environment to achieve continuous improvement.
- A customer is anyone who uses the products, services, or processes within an organization. Clients, families, visitors, employees, suppliers, and the community are all considered customers within the health care system.
- Customer dissatisfaction can have significant financial implications for health care organizations.
- Quality management requires positive organizational culture, leadership, and teamwork.
- A variety of tools (e.g., audits, peer reviews, and benchmarking) are available through which data about variations in process improvement can be collected and analyzed.
- The nurse is responsible for quality improvement as a clinician, team member, and manager.

REVIEW QUESTIONS

1. A client asks the nurse, "Exactly what is an HMO?" The nurse's response should include which of the following information? Select all that apply.
 - a. HMOs are groups of federally financed insurance companies.
 - b. Many HMOs provide a continuum of care to individuals and families.
 - c. HMOs were established to control the costs of health care delivery.
 - d. An HMO provides unlimited services to its members.
 - e. The HMO was developed as a type of fee-for-service reimbursement system.
 - f. HMOs were intended to emphasize prevention rather than treatment of chronic conditions.
2. The largest insurer of health care services in the United States is the _____.
3. When working with a person from a vulnerable population, it is important for the nurse to do which of the following?
 - a. Perform the nursing assessment as quickly as possible so the individual can return to the community.
 - b. Learn about the person's specific cultural practices.
 - c. Focus only on the client's verbal communication.
 - d. Refer the client to another nurse who is from the same cultural group as the client.
4. The nurse who is working in a rehabilitation facility is providing which level of care?
 - a. Primary
 - b. Secondary
 - c. Tertiary
 - d. Palliative
5. Which of the following nursing actions will adversely affect customer satisfaction of hospitalized clients?
 - a. Introducing self to client and family
 - b. Assessing pain level
 - c. Implementing a routine schedule for every client
 - d. Documenting all care provided in a timely manner

CHAPTER 5

Critical Thinking, Decision Making, and the Nursing Process

COMPETENCIES

1. Identify the components of critical thinking.
2. Describe the relationship between critical thinking, problem solving, and decision making.
3. Compare critical thinking and creative thinking.
4. Relate critical thinking to the nursing process.
5. Describe the assessment step of the nursing process.
6. Describe the process of nursing diagnoses.
7. List the tasks involved in the outcome identification and planning step of the nursing process.
8. Discuss the nursing implementation phase of the nursing process.
9. Discuss the evaluation process.

KEY TERMS

wellness nursing diagnosis

Due to the constantly changing health care environment, critical thinking is a requisite skill in order for nurses to make complex decisions. Critical thinking is the process through which nurses analyze and make sense of situations in order to make sound clinical decisions. This chapter presents information about the relationship between problem solving, decision making, and the nursing process. Critical thinkers are people who know how to think. They possess intellectual autonomy, in that they refuse to accept conclusions without evaluating the evidence (facts and reasons) for themselves. Critical thinkers have the ability to think beyond the obvious and make connections between ideas. **Critical thinking** is the process that allows nurses to see the big picture (envision the overall perspective) instead of focusing only on details.

CRITICAL THINKING

There are many definitions of critical thinking, including Ennis's (1987) classic description, "reasonable reflective thinking that is focused on deciding what to believe or do" (p. 10). Critical thinking is a "skilled process that conceptualizes and applies information from observation, experience, reflection, inference, and communication" (Shin, Lee, Ha, & Kim, 2006, p. 182). Following is a brief summary of various definitions of critical thinking:

- The rational examination of ideas, assumptions, principles, conclusions, beliefs, and actions (Bandman & Bandman, 1995)
- Reasonable reflective thinking that focuses on decisions about actions and beliefs (Ennis, 1989)
- Purposeful, autonomous judgments that lead to interpretation, analysis, inference, evaluation, and explanation (Facione, 1990)
- Self-directed rational thinking that validates what we know and identifies what we do not know (Paul, 1992)
- A set of requisite abilities necessary for defining problems, recognizing assumptions, developing hypotheses, drawing conclusions, and validating inferences (Watson & Glaser, 1964)

Critical thinking is identified by the National League for Nursing (1997) as an essential nursing competency and an

accreditation criterion; thus, nursing students and graduates must demonstrate competency in critical thinking skills.

COMPONENTS OF CRITICAL THINKING

Critical thinking has several components, including mental operations, knowledge, and attitudes.

Mental Operations

Mental operations include activities such as decision making and reasoning that are used to find or create meaning. Nurses engage in such activities whenever they search for solutions based on rationale and develop outcomes accordingly. The result of these mental operations is creative, appropriate problem solving. Critical thinking enables nurses to make sound clinical judgments by analyzing information and applying knowledge.

Knowledge

Critical thinking calls for a knowledge base that includes **declarative knowledge**, which is specific facts or information, and **operative knowledge**, which is an understanding of the nature of that knowledge. Nursing curricula assist the student in learning specific facts about nursing and the delivery of quality care. Students are also taught how to examine beliefs underlying facts in order to analyze and interpret those facts. In other words, students are not expected to merely repeat facts that have been memorized (learned by rote) but instead to understand the reasoning behind the knowledge. Finding meaning in what one is learning is the core of critical thinking.

In order to think critically, to solve problems, and to make decisions, nurses must develop a broad base of knowledge. Nurses' intuitive knowledge is essential for delivery of care. "Intuition is a rich source of nursing knowledge and ... integral to the practice of nursing" (Billay, Myrick, Luhanga, & Yonge, 2007, p. 155). Nurses acquire a broad knowledge base that includes information from other disciplines such as physical science (anatomy, physiology, biology), psychology, and philosophy (logic). Nurses apply this knowledge to specific client situations through the use of critical thinking.

Cultural

You are working in the emergency department when a client is admitted for treatment of gunshot wounds. Consider how you would feel when caring for this client if you knew his injuries were:

- Suffered during a robbery
- Inflicted by his wife during a domestic disturbance
- Caused by his homosexual lover in a fit of rage
- Self-inflicted
- The result of a gang-related revenge shooting
- Experienced when he was selling drugs

Attitudes

Certain attitudes enhance a person's ability to think critically. One of the most important attitudes needed by a critical thinker is a sense of curiosity that allows the person to question assumptions upon which decisions are based. Analysis of basic assumptions allows the person to plan and act in a rational manner rather than out of habit or routine. Some attitudes demonstrated by critical thinkers are:

- Tolerance, open-mindedness, nonjudgmental mind-set
- Curiosity
- Persistence, intellectual courage
- Respect for others' perspectives
- Comfort dealing with ambiguity, uncertainty
- Intellectual humility (knowing that one does not have all the answers)
- Self-confidence (belief in own ability to think things through and make appropriate decisions)
- Flexibility
- Organization (Alfaro-LeFevre, 2008; Forehand, 2005)

The attitude of open-mindedness helps the nurse better care for clients whose lifestyle choices and values differ from those of the nurse; see the Respecting Our Differences box on reflective thinking and value systems. Critical thinkers question their assumptions and the effect of those assumptions on their actions.

DEVELOPMENT OF CRITICAL THINKING SKILLS

The development of critical thinking skills is a gradual process related to the individual's maturity, in that maturity enhances the ability to suspend judgment until the data have been collected. Perry (1970) developed a four-stage model describing cognitive development; see Table 5-1. It is important to note that every person does not function at the highest level of cognitive thinking. Also, the level of a person's cognitive function may vary according to the situation and professional experience. As people gain maturity and experience, their ability to think critically usually increases. The development of critical thinking is the aim of nursing educational programs. One longitudinal study (Standing, 2007) of newly graduated students showed that "as Registered Nurses they found having to 'think on your feet' without the 'comfort blanket' of student status both a stressful and formative learning experience" (p. 269). Thinking on one's feet mandates the use of the critical thinking process. The development of critical thinking occurs over time.

Following are some specific strategies that promote the development and application of critical thinking:

- Identify goals
- Determine what knowledge is required
- Assess the margin for error
- Determine the amount of time available for decision making
- Identify available resources
- Recognize factors (i.e., biases, fatigue) that may influence decision making (Alfaro-LeFevre, 2008)

Table 5-2 on page 78 lists skills necessary for critical thinking to occur.

TABLE 5-1 Stages of Cognitive Development

STAGE	DESCRIPTION
Stage 1: Dualism	View the world in dichotomous (polarized) terms Look to authority figures for the right answers
Stage 2: Multiplicity	Acknowledge that uncertainty or different perspectives exist Believe differences are in effect only until the right answer is discovered by the experts
Stage 3: Relativism	Ability to form opinions and values based on weighing information in situations
Stage 4: Commitment	Able to develop own truth after evaluating information from several sources and integrating this with what is already known Validity of right answers depends on situation and context

Data from Perry, W. G. (1970). *Forms of intellectual and ethical development in the college years*. New York: Holt, Rinehart, & Winston.

TABLE 5-2 Critical Thinking Skills

Interpretation	Categorize, decode sentences, clarify meanings
Analysis	Examine ideas, identify and analyze arguments
Influence	Query evidence, conjecture alternatives, draw conclusions
Explanation	State results, justify procedures, present arguments
Evaluation	Assess claims, assess arguments
Self-regulation	Self-examination, self-correction (if necessary)

Data from Pesut, D. J., & Herman, J. (1999). *Clinical reasoning: The art and science of critical and creative thinking*. Clifton Park, NY: Thomson Delmar Learning.

CRITICAL THINKING AND CREATIVITY

Critical thinkers are also creative thinkers. Critical and creative thinkers are those who question the status quo and search for innovative, yet practical, strategies for improvement. Those who think critically and creatively are the ones most likely to carry out research and apply the results of research studies. Creative nurses think in new ways when searching for solutions to problems. The process of creative problem solving is goal-directed thinking that leads to achievement by using new ideas or methods. The challenges presented by the current health care environment demand that nurses be creative thinkers. Critical thinking helps nurses make a smooth transition from the old to the new by facilitating analysis and planning.

Creative thinking is the foundation for individualizing client care, in that the nurse identifies the unique needs of each client and develops interventions specific to those needs. Without creative thinking, nursing care would become routine, that is, the same for every client.

There is a strong link between critical and creative thinking. In order to develop creative solutions to problems, the nurse needs to use critical intellect. Critical and creative thinkers engage in the following behaviors:

- Recognize the existence of a problem (stimulus for change)
- Consider new ways of problem solving
- Establish criteria for assessing the effectiveness of an action
- Learn from one's mistakes
- Transfer learning from one situation to another
- Create innovative solutions to complex problems

Habitual thinking patterns often interfere with creative thinking. Some common barriers to creative thinking include:

- Habit
- Comfort with the status quo

- Fear of making mistakes
- Tradition
- Use of meaningless routines and rituals
- Rigid mind-set

Groupthink, going along with the majority opinion while personally having another viewpoint, is also a major block to creativity. It takes intellectual courage to think something new and different from one's peers and then to act on those thoughts.

CRITICAL THINKING AND PROBLEM SOLVING

Critical thinking includes problem-solving and decision-making processes. With the problem-solving method, problems are identified, information is gathered, a specific problem is named, a plan for solving the problem is developed, the plan is put into action, and results of the plan are evaluated. However, this kind of problem solving is frequently based on incomplete data, and plans are sometimes based on guesses.

A formalized problem-solving approach, the nursing process, enables nurses to identify client needs and develop strategies for addressing those needs. It is a systematic and scientifically based process that requires the use of many cognitive and psychomotor skills. The following actions interfere with effective problem solving:

- Jumping too quickly to a conclusion before exploring all the aspects of a problem
- Failing to obtain critical facts, about either the problem or proposed change
- Selecting problems or changes that are too general, too complex, or poorly defined
- Failing to articulate a rational solution to the problem or proposed change
- Failing to implement and evaluate the proposal appropriately

Critical thinkers avoid such pitfalls by clearly defining the problem, analyzing the data, understanding the causes, and creating new ideas that will lead to problem resolution.

CRITICAL THINKING AND DECISION MAKING

With the rapid changes in health care and the influx of new technology, nurses must be able to use critical thinking. Decisions that provide optimal client care are the result of careful and deliberate use of critical thinking.

When making a clinical decision, the nurse determines actions that will help move the client toward achievement of the expected outcomes. Thus, **decision making** is defined as considering and selecting interventions from a repertoire of actions that facilitate the achievement of a desired outcome. Professional nurses use critical thinking to develop and support sound clinical decisions. Safe, effective nursing interventions are implemented only after reflection and reasoning, two aspects of critical thinking. A nurse who makes sound clinical judgments knows "what to look for, ... draws valid conclusions about what the signs mean, ... and knows what to do about it" (Chitty, 2007, p. 381).

Nurses exercise clinical judgment by making sound decisions; clinical judgment can be viewed as the application of critical thinking. Nursing judgments are formed after collecting assessment data, examining the relationships among those data in order to identify patterns, and taking appropriate action to address the problem(s).

Nurses make decisions every day. It is important that those decisions be the best decisions possible, that they be based on reliable information, and that they be made with as much critical thought as possible. Through a process of problem solving, one arrives at the point at which decisions can be made. The nursing process is the specific problem-solving method used by nurses to arrive at the point at which decisions about client care can be made.

THE NURSING PROCESS

The **nursing process** is the framework for providing professional, quality nursing care. It directs nursing activities for health promotion, health protection, and disease prevention and is used by nurses in every practice setting and specialty.

HISTORICAL PERSPECTIVE

Lydia Hall first referred to nursing as a “process” in a 1955 journal article, yet the term was not widely used until the late 1960s (Edelman & Mandle, 2006). Referring to the “nursing process” as a series of steps, Johnson (1959), Orlando (1961), and Wiedenbach (1963) further developed this description of nursing. Initially, the nursing process involved only three steps: assessment, planning, and evaluation. In their 1967 book *The Nursing Process*, Yura and Walsh identified four steps in the nursing process:

- Assessing
- Planning
- Implementing
- Evaluating

The *Standards of Practice*, first published in 1973 by the American Nurses Association (ANA), included eight standards. These standards identified each of the steps, including nursing diagnosis, that are now included in the nursing process.

Fry (1953) first used the term **nursing diagnosis**, but it was not until 1974, after the first meeting of the group now called the North American Nursing Diagnosis Association (NANDA), that nursing diagnosis was added as a separate and distinct step in the nursing process. Prior to this, nursing diagnosis had been included as a natural conclusion to the first step, assessment.

Following publication of the ANA standards, the nurse practice acts of many states were revised to include the steps of the nursing process specifically. The ANA made revisions to the standards in 1991 to include outcome identification as a specific part of the planning phase. Currently, the steps in the nursing process are:

- Assessment
- Diagnosis

- Outcome identification and planning
- Implementation
- Evaluation

The ANA (2004) practice standards address each step of the nursing process.

OVERVIEW OF THE NURSING PROCESS

A **process** is a series of steps or acts that leads to the accomplishment of some goal or purpose. The purpose of the nursing process is to provide care for clients that is individualized, holistic, effective, and efficient. The nursing process is not linear but involves overlapping steps that build on each other (see Figure 5-1). The steps are explained one after the other for ease of understanding. In actual practice, there may not be a definite beginning or end to each step. Work in one step may begin before work in the preceding step is completed.

The nursing process is dynamic and requires creativity for its application. The steps remain the same, but the application and results will be different in each client situation. The nursing process is designed to be used with clients throughout the life span and in any setting in which a nurse provides care. It is also a basic organizing system for the National Council Licensure Examination for Registered Nurses (NCLEX-RN).

ASSESSMENT

Assessment is the first step in the nursing process and includes collection, verification, organization, interpretation, and documentation of data. The completeness and correctness of the information obtained during assessment are directly related to the accuracy of the steps that follow. Assessment involves several steps:

- Collecting data from a variety of sources
- Validating the data
- Organizing data

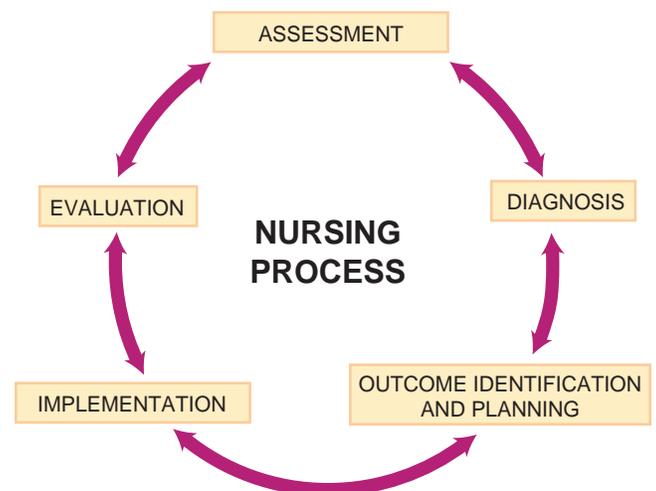

FIGURE 5-1 Components of the Nursing Process DELMAR/CENGAGE LEARNING

Cultural Influences

You are collecting data from a 35-year-old Asian American woman while her parents and older brother are in the room. Family is very important to this client, whose parents consistently interrupt her while she is answering your questions. If you ask the family to leave the room while you complete the interview, you risk offending the client and her family and creating barriers to your communication process. If you allow the family to remain in the room, the parents may influence the client's responses so that you are unable to perform an accurate assessment. How do you respect family dynamics while ensuring that the client receives the most appropriate care?

- Categorizing or identifying patterns in the data
- Making initial inferences or impressions
- Recording or reporting data

Data are collected from a variety of sources; however, the client should be considered the **primary source** of data (the major provider of information about self). As much information as possible should be gathered from the client, using both interview techniques and physical examination skills. Sources of data other than the client are considered **secondary sources** and include family members, other health care providers, and medical records. See the Respecting Our Differences feature about cultural influences.

Assessment provides information that will form the client database. Two types of information are collected through the assessment component: subjective and objective.

Subjective data are gathered by interacting with the client and include the client's feelings, perceptions, and concerns. The method of collecting subjective information is primarily the interview. Using therapeutic interviewing techniques, the nurse collects data that will be used to establish the client database. Examples of subjective information include such statements as:

- "I drink only coffee for breakfast."
- "I have had pains in my legs for three days now."

NURSING PROCESS HIGHLIGHT

Assessment

Think of all the ways you can use your senses when assessing clients. What type of information can you gather through vision, hearing, smell, and touch?

- "I go to sleep easily each night, but I wake up about two hours later and cannot go back to sleep until it is time to get up in the morning."

Objective data are observable and measurable and are obtained through physical examination and diagnostic tests. See the Nursing Process Highlight. The primary method of collecting objective information is the physical examination, which provides information about the function of body systems (see Figure 5-2). Examples of objective information include:

- T 98.6°F, P 100, R 12, BP 130/76
- Bowel sounds auscultated in all four quadrants
- Gait slow, shuffling, and unsteady

This objective information may add to or validate subjective information. Validation is a critical step in data collection to avoid omissions, prevent misunderstandings, and avoid incorrect inferences and conclusions.

Data that are collected must be organized in order to be useful to the health care professional collecting the data as well as others involved with the client's care. Clustering similar pieces of information assists the nurse in constructing a picture of the client's problems and strengths. There are a number of organizing frameworks for collection of data—for example, Gordon's functional health patterns. Many health care agencies use an admission assessment format, which assists the nurse in collecting data in specific categories of functioning.

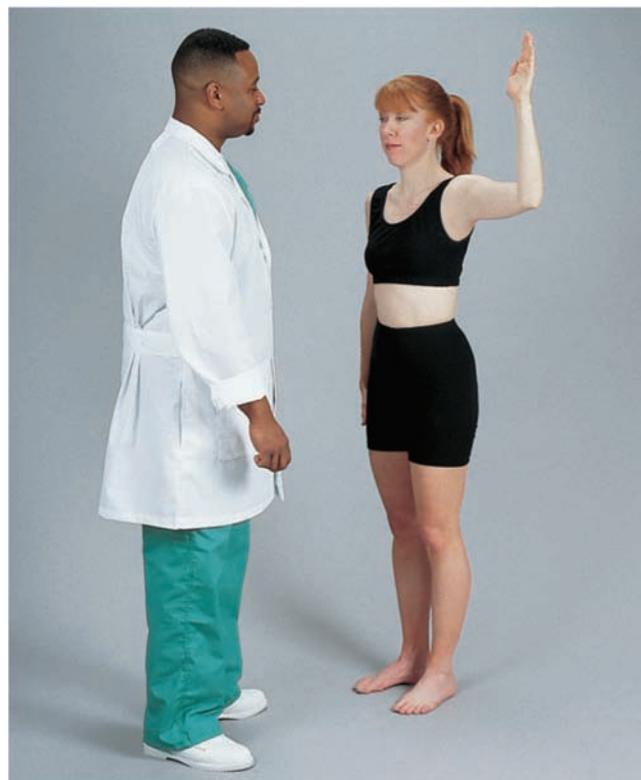

FIGURE 5-2 This nurse is gathering objective data through assessment of the client's ability to perform range-of-motion (ROM) activity DELMAR/CENGAGE LEARNING

Critical thinking is used in determining the significance of data collected. Once data are organized into categories, the data are clustered into groups of related pieces. Placing data into clusters helps the nurse to recognize patterns of response or behavior. When data are placed into clusters, the nurse can:

- Distinguish between relevant and irrelevant data
- Determine if and where there are gaps in the data
- Identify patterns of cause and effect

With this information, the nurse—through critical thinking—can begin to develop impressions or inferences about what the data mean.

Assessment data must be recorded and reported. The nurse makes a judgment about which data are to be reported immediately and which data need only to be recorded at that time. Data that reflect a significant deviation from the normal (e.g., rapid heart rate with irregular rhythm, severe difficulty in breathing, or high levels of anxiety) would need to be reported as well as recorded. Examples of data that need only to be recorded at the time include a report that prescribed medication has relieved a headache and a determination that an abdominal dressing is dry and intact.

Assessment does not end with the initial interview and physical examination. Assessment is dynamic and continues with each nurse-client interaction.

DIAGNOSIS

The second step in the nursing process involves further **analysis** (breaking the whole down into parts that can be examined) and **synthesis** (putting data together in a new way) of the data that have been collected. Formulation of the list of nursing diagnoses is the outcome of this process. A nursing diagnosis focuses on an individual, family, or community response to actual or potential health problems. The nursing diagnoses developed during this phase of the nursing process provide the basis for client care delivered through the remaining steps. Clients receive both medical and nursing diagnoses. Table 5-3 compares the two categories of diagnoses.

The nurse uses critical thinking and decision-making skills in developing nursing diagnoses. This process is facilitated by asking questions such as:

- Are there problems here?
- If so, what are the specific problems?
- What are some possible causes for the problems?
- Is there a situation involving risk factors?
- What are the risk factors?
- Is there a situation in which a problem can develop if preventive measures are not taken?
- Has the client indicated a desire for a higher level of wellness in a particular area of function?
- What are the client's strengths?
- What data are available to answer these questions?
- Are more data needed to answer the questions?
- If so, what are some possible sources of the data that are needed?

See the accompanying Nursing Process Highlight for a clinical example of applying critical thinking when determining nursing diagnoses.

Types of Nursing Diagnoses

Analysis of the collected data leads the nurse to make a diagnosis in one of the following categories:

- Actual problems
- Potential problems (including those where risk factors exist and there are possible problems)
- Wellness conditions
- Collaborative problems

See Table 5-4 on page 82 for examples of the various types of diagnoses.

An **actual nursing diagnosis** indicates that a problem exists and is composed of the diagnostic label, related factors, and signs and symptoms. An example of an actual diagnosis is *impaired skin integrity* related to prolonged pressure on bony prominence as manifested by (AMB) stage II pressure ulcer over coccyx, 3 cm in diameter.

A **risk nursing diagnosis** (potential problem) indicates that a problem does not yet exist, but special risk factors are present. A risk diagnosis is composed of the diagnostic label preceded by the phrase “risk for,” with the specific risk factors listed. An example of a risk diagnosis is *risk for impaired skin integrity* related to inability to turn self from side to side in bed.

TABLE 5-3 Comparison of Medical Diagnoses and Nursing Diagnoses

MEDICAL DIAGNOSIS	NURSING DIAGNOSIS
Focuses on the illness, injury, or disease process	Focuses on the responses to actual or potential health problems or life processes
Remains constant until a cure is effected	Changes as the client's response or the health problem changes
Identifies conditions the physician is licensed and qualified to treat	Identifies situations in which the nurse is licensed and qualified to intervene

Delmar/Cengage Learning

TABLE 5-4 Types of Nursing Diagnoses

NURSING DIAGNOSIS	EXAMPLE
Actual diagnosis	<i>Deficient fluid volume</i> related to nausea and vomiting as manifested by dry skin and mucous membranes and decreased oral intake of fluids
Risk diagnosis	<i>Risk for infection</i> related to presence of invasive lines (intravenous line and indwelling bladder catheter)
Possible diagnosis	<i>Possible imbalanced nutrition</i> : less than body requirements related to insufficient oral intake
Wellness diagnosis	<i>Readiness for enhanced spiritual well-being</i>
Collaborative problem	<i>Potential complication (PC)</i> : increased intracranial pressure

Delmar/Cengage Learning

A **possible nursing diagnosis** indicates a situation in which a problem could arise unless preventive action is taken. In addition, a possible diagnosis may state a “hunch” or intuition by the nurse that cannot be confirmed or elimi-

nated until more data have been collected. A possible diagnosis is composed of the diagnostic label and related factors. An example of a possible diagnosis is *possible situational low self-esteem* related to recent retirement and relocation. The nurse may not yet have enough data to confirm this diagnosis or a more specific one. However, this diagnosis will alert other nurses to collect data that will either confirm this or another diagnosis, verify a risk diagnosis, or rule out the existence of a problem.

A **wellness nursing diagnosis** indicates the client’s expression of a desire to attain a higher level of wellness in some area of function. It is composed of the diagnostic label preceded by the phrase “readiness for enhanced.” For example, a client who is neither overweight nor underweight tells the nurse that she knows she could improve her diet in some ways. She states that she eats only a small number of vegetables and fruits and thinks that the fat content of her diet is probably high. She expresses a desire to know more about how to improve her diet. The nurse would make a wellness diagnosis of *readiness for enhanced nutrition*.

Carpenito (2007) introduced the bifocal clinical practice model that includes nursing diagnoses and collaborative problems. **Collaborative problems** are defined as physiologic complications monitored by nurses to assess changes in client status. Collaborative problems are managed through the use of interventions prescribed by other prescribing practitioners and nurses (Carpenito, 2007). Collaborative problems include those conditions in which the nurse seeks medical input for treatment of potential medical problems. Usually, collaborative problems involve alterations in organ or system function or structure (e.g., myocardial infarction, duodenal ulcer). Collaborative problems begin with the label *potential complication (PC)* followed by the situation—for example, *potential complication: hemorrhage*.

Analysis of the data also assists the nurse in identifying strengths of the client. For example, a client’s supportive family would be identified as a strength. Client strengths will be reinforced and used as a basis for planning care for those areas in which functioning is less than optimal.

NURSING PROCESS HIGHLIGHT

Diagnosis

Example

Mr. Jona is a client on your unit. He is a 70-year-old widower, admitted 2 days ago with a broken left hip. While bowling with his church bowling league, Mr. Jona tripped, fell, fractured his hip, and sprained his right wrist. He has recently retired from an administrative position with a large company and moved to Florida from his home in Iowa. He has two children, who both live about 500 miles away. Mr. Jona lives alone in a one-bedroom apartment about 10 blocks from the hospital. In 2 days, Mr. Jona will be discharged and referred to the home health division for follow-up care.

Questions

1. Is he right-handed?
2. What tasks can he perform with his left hand?
3. Will there be anyone to stay with him when he gets home?
4. Who will shop for and prepare food?
5. Does he live in an upstairs apartment? If yes, is there an elevator?
6. Is there someone in his church who could help with errands and food?
7. Can his children stay with him for awhile?
8. Did you identify any other questions about Mr. Jona’s situation?

After it is formulated, the list of diagnoses is presented to the client for confirmation if possible. If that is not possible, family members may be able to confirm the diagnoses. Finally, the list of nursing diagnoses is recorded in the client's record. Once this list is developed and recorded, the remainder of the client's plan of care can be completed. The list of nursing diagnoses is not static; rather, it is dynamic, changing as more data are collected, as client goals change, and as client responses to interventions are evaluated.

OUTCOME IDENTIFICATION AND PLANNING

Planning (the third step of the nursing process) involves developing a proposed course of action in regard to the client's health status. Once the nursing diagnoses have been established and client strengths have been identified, planning can begin. The planning phase involves several tasks:

- Prioritizing the list of nursing diagnoses
- Identifying and writing client-centered long- and short-term goals and outcomes
- Developing specific interventions
- Recording the plan of care

Once the list of nursing diagnoses has been developed from the data, decisions must be made about priority. Critical thinking enables the nurse to make decisions about which diagnoses are the most important and need attention first. A number of frameworks are used to prioritize nursing diagnoses; however, those diagnoses involving life-threatening situations are given the highest priority. For example, the following nursing diagnoses would be stated in this order of priority:

- *Ineffective airway clearance* related to excessive and thick secretions and pain secondary to surgery and inability to cough effectively; respirations: 25, shallow, wheezing
- *Risk for injury* (falls) related to unsteady gait
- *Imbalanced nutrition: less than body requirements* related to nausea and vomiting

Often, the words *goals* and *outcomes* are both used to describe expectations of what is to be achieved as a result of nursing actions. Goals and outcomes are measures for determining client progress.

Client-centered goals are established in collaboration with the client whenever possible. A **goal** is an aim, intent, or end. Goals are broad statements that describe the intended or desired change in the client's behavior. Goal statements refer to the diagnostic label (or problem statement) of the nursing diagnosis. If the client or significant others are unable to participate in goal development, the nurse assumes that responsibility until the client is able to participate. Client-centered goals assure that nursing care is individualized and focused on the client.

Expected outcomes are specific objectives related to the goals and are used to evaluate the nursing interventions. They must be measurable, have a time limit, and be realistic. Once goals and expected outcomes have been established,

nursing interventions are planned that enable the client to reach the goals.

Nursing Outcomes Classification (NOC) is a systematic process for organizing and evaluating expected results from nursing interventions. According to Moorhead, Johnson, Maas, and Swanson (2007), the NOC research has three aims:

- To identify and classify nursing-sensitive client outcomes
- To validate the classification system
- To use clinical data in order to measure the outcomes

Client outcomes are important in that they are the criteria for measuring the client's progress in response to nursing interventions. Because client outcomes are dynamic, the nurse uses critical thinking to reflect on status changes and to develop new interventions as necessary. There is a close relationship between nursing diagnoses and nursing outcomes; see Table 5-5.

A **nursing intervention** is the activity that the nurse will perform to promote accomplishment of the goals. Nursing interventions refer directly to the related factors in the actual nursing diagnoses and the risk factors in risk nursing diagnoses. If the nursing interventions can remove or reduce the related factors and the risk factors, the problem can be resolved or prevented. Nursing interventions also refer to the diagnostic label for possible diagnoses and focus on data needed to confirm or eliminate the diagnosis.

For each nursing diagnosis, there may be a number of nursing interventions. Nursing interventions are individualized and are stated in specific terms. Examples of nursing interventions are:

- Turn, cough, and deep breathe twice an hour beginning at 0800, 2/10.
- Teach "nipple care when breastfeeding" at 1000, 2/11.
- Weigh client at each visit.

TABLE 5-5 NOC: Nursing Diagnoses and Nursing Outcomes, a Comparison

NANDA DIAGNOSIS	NOC OUTCOME
Constipation	Bowel continence
Diarrhea	Bowel elimination
Family Processes, Interrupted	Family functioning Family coping
Hopelessness	Hope
Deficient Knowledge	Knowledge: disease process Knowledge: medication

Delmar/Cengage Learning

Once the interventions have been determined for each diagnosis, the interventions are recorded on the client's plan of care. As is true with other steps in the nursing process, the list of interventions is not static. Interventions may change as the nurse interacts with the client, assesses responses to interventions, and evaluates those responses. Critical thinking is essential in every step of the nursing process, especially in developing client outcomes and relevant intervention strategies.

IMPLEMENTATION

The fourth step in the nursing process is implementation. **Implementation** involves the execution of the nursing plan of care derived during the planning phase. It consists of performing nursing activities that have been planned to meet client outcomes. Nurses may delegate some of the nursing interventions to other persons assigned to care for the client—for example, licensed practical nurses and unlicensed assistive personnel.

In 1996, the Iowa Intervention Project team developed the Nursing Interventions Classification (NIC), which is a system for organizing nursing actions using standardized language. Priority interventions are identified for selected nursing outcomes. These priority interventions “are the most obvious interventions to effect problem resolution, but this does not mean that they are the only interventions to be used. A variety of interventions should always be considered” (Wilkinson, 2006, p. xvii). Critical thinking enables the nurse to decide which interventions are most appropriate and therefore individualize client care.

Implementation involves many skills. The nurse must continue to assess the client's condition before, during, and after the interventions. Assessment prior to the intervention provides the nurse with baseline data. Assessment during and after the intervention allows the nurse to detect positive or negative client responses. If negative responses occur during the procedure, the nurse must take appropriate action. If positive responses occur, the nurse adds this information to the database for use in evaluating the efficacy of the intervention. See the Uncovering the Evidence box for an example.

The nurse must also possess psychomotor skills, interpersonal skills, and critical thinking skills in order to perform the nursing interventions that have been planned. The nurse uses psychomotor skills when performing procedures such as giving injections, changing dressings, and helping the client perform range-of-motion (ROM) exercises. Interpersonal skills are necessary as the nurse interacts with the client and the family to collect data, provide information in teaching sessions, and offer support in times of anxiety. Critical thinking skills enable the nurse to think through the situation, ask the appropriate questions, and make decisions about what needs to be done.

The implementation step also involves reporting and documentation. Data to be recorded include the client condition prior to the intervention, the specific intervention

UNCOVERING THE

Evidence

TITLE OF STUDY

“Nurses’ Reported Thinking during Medication Administration”

AUTHORS

L. A. Eisenhauer, A. C. Hurley, and N. Dolan

PURPOSE

To document nurses’ self-reported thinking processes during medication administration.

METHODS

Semistructured interviews and tape recordings were used to document the types of thinking processes used by nurses practicing in inpatient units.

FINDINGS

Content analysis led to identification of 10 types of thinking used by nurses. Situations requiring judgment about dosage, timing, or selection of specific medications gave the most definitive data about nurses’ use of critical thinking and clinical judgment. A major theme identified was nurses’ vigilance to ensure that appropriate medications were administered.

IMPLICATIONS

Nurses’ thinking extended beyond mere considerations of policies, rules, and regulations. The thinking processes were based on professional knowledge and consideration of client data. Identification of thinking processes can help nurses explain the complex expertise required for safe medication administration.

Eisenhauer, L. A., Hurley, A. C., & Dolan, N. (2007). Nurses’ reported thinking during medication administration. *Journal of Nursing Scholarship*, 39(1), 83–87.

performed, the client response to the intervention, and client outcomes. Critical thinking is essential for complete, accurate documentation to occur. Nurses must reflect on the care that was planned, consider the interventions performed, and evaluate the client's response to those interventions. Thorough documentation shows client progress in response to nursing interventions.

EVALUATION

Evaluation, the fifth step in the nursing process, involves determining whether client goals have been met, partially met, or not met. If the goal has been met, the nurse must

Priorities and Referrals

Mrs. Mendosa delivered a baby with congenital defects yesterday and is being discharged later today. You are responsible for her discharge planning, which includes the need for education about how to feed her infant. The baby is expected to be discharged in approximately 2 to 3 weeks. Think of the priority needs of Mrs. Mendosa. What follow-up care will be necessary for her and the infant? Which community agencies are available to provide support for both mother and child?

then decide whether nursing activities will cease or continue in order for the client's status to be maintained.

If the goal has been partially met or not been met, the nurse must reassess the situation. Data are collected to determine why the goal has not been achieved and what modifications to the plan of care are necessary. There are a number of possible reasons that goals are not met or are only partially met, including:

- The initial assessment data were incomplete.
- The goals and expected outcomes were unrealistic.
- The time frame was too optimistic.
- The goals and nursing interventions planned were not appropriate for the specific client.

Evaluation is an ongoing process. Nurses continually evaluate data in order to make informed decisions during other phases of the nursing process. Critical thinking promotes evaluation by helping nurses look at the overall picture in order to determine client status. Evaluation is an essential component of discharge planning that allows the nurse to work with clients and families in deciding whether further health care is needed and then providing necessary referrals; see the accompanying Community Considerations display.

CRITICAL THINKING APPLIED IN NURSING

Critical thinking is a skill that can be learned just as other skills are learned. The skill of critical thinking is important and useful in all aspects of a person's life. However, it is a vital tool for the nurse. Critical thinkers develop a questioning attitude and delve into situations in order to seek possible explanations for what is happening. See the Nursing

NURSING CHECKLIST

Examples of Critical Thinking Questions for Use with the Nursing Process

• ASSESSMENT

Are the data complete? What other data do I need? What are some possible sources of those data? What assumptions or biases do I have in this situation? What is the client's point of view? Are there other points of view?

• DIAGNOSIS

What do these data mean? What else could be happening? Are there any gaps in the data? How are these data similar and how are they different? What assumptions or biases do I have in this situation? Have my assumptions affected my interpretation of the data? If so, in what way?

• OUTCOME IDENTIFICATION AND PLANNING

What are the goals for this client? What do I want to accomplish? How are my goals related to what the client wants to accomplish? What are the expected outcomes for this client? What interventions are to be used? Who is the best-qualified person to perform these interventions? How much involvement can the client and family or significant others have at this time? How much involvement does the client wish to have at this time?

• IMPLEMENTATION

What is the client's current status? What are the most critical steps in this intervention? How must I alter the intervention to best meet this client's needs and maintain principles of safety? What is the client's response during and after the intervention? Is there a need to alter the intervention in any way? If so, why and how?

• EVALUATION

Were the interventions successful in assisting the client to achieve the desired goals? How could things have been done differently? What data do I need to make new decisions? Where will I get the data? Were there assumptions, biases, or points of view that I missed that affected the outcomes? What can be done about these assumptions, biases, or points of view?

Checklist for examples of questions the nurse as a critical thinker might ask at each step in the nursing process. Table 5-6 on page 86 provides examples of how critical thinking is used in each phase of the nursing process.

Delmar/Cengage Learning

KEY CONCEPTS

- Critical thinking, problem-solving, and decision-making skills are essential in nursing.
- Critical thinkers ask questions, evaluate evidence, identify assumptions, examine alternatives, and seek to understand various points of view.
- The nursing process is an organized method of planning and delivering nursing care.
- The nursing process is composed of five steps: assessment, diagnosis, outcome identification and planning, implementation, and evaluation.
- Assessment is the first step in the nursing process and involves collecting, validating, organizing, categorizing, and recording data.
- The second step in the nursing process involves further analysis and synthesis of the data and results in a list of nursing diagnoses.
- Planning, the third step in the nursing process, involves prioritizing nursing diagnoses, identifying and writing goals and client outcomes, developing nursing interventions, and recording the plan of care in the client's record.
- Implementation, the fourth step in the nursing process, involves performing or delegating nursing activities.
- Evaluation, the fifth step in the nursing process, involves deciding whether the client goals have been met, been partially met, or not been met.

REVIEW QUESTIONS

1. When reviewing a client's lab results, the nurse must have a knowledge base that includes which of the following types of knowledge in order to think critically?
 - a. Affective
 - b. Declarative
 - c. Nonjudgmental
 - d. Psychomotor
2. Which of the following phrases accurately describes the nursing process? Select all that apply.
 - a. Applicable to every setting
 - b. Can be implemented by unlicensed personnel
 - c. Framework for licensure examination
 - d. Is a linear process
 - e. Organized care delivery framework
 - f. Used with adults only

3. The nurse uses creative thinking in order to
 - a. Express his or her own artistic tendencies
 - b. Individualize care
 - c. Liven up the work environment
 - d. Please clients and families
4. Which of the following is an example of objective client data?
 - a. 500 mL of amber-colored urine in collection bag
 - b. Client complaint of nausea
 - c. Client states pain is 9 on a scale of 1–10
 - d. Self-report of insomnia
5. A client in the intensive care unit (ICU) has several health problems. Which of the following nursing diagnoses should be of priority concern to the nurse?
 - a. Imbalanced nutrition: less than body requirements
 - b. Impaired skin integrity
 - c. Ineffective airway clearance
 - d. Risk for injury (falls)
6. When referring to a client's medical record for information, the nurse is using which data source?
 - a. Analytical
 - b. Primary
 - c. Secondary
 - d. Tertiary

CHAPTER 6

Assessment

COMPETENCIES

1. Identify major purposes of data collection.
2. Describe three types of assessment.
3. Differentiate subjective and objective data.
4. Identify examples of nursing and nonnursing models used in collecting and organizing data.
5. Describe five methods involved in data collection.
6. Explain the stages of the assessment interview.
7. Outline the elements of the health history and their importance.
8. Describe the purposes of the physical assessment.
9. Discuss assessment techniques used in the physical examination.
10. Discuss the use of data clustering in organizing the information obtained about the client.
11. Identify four types of assessment formats.

KEY TERMS

assessment
 assessment model
 auscultation
 closed questions
 comprehensive assessment
 data clustering
 data interpretation

data verification
 focused assessment
 health history
 inspection
 interview
 objective data
 observation

ongoing assessment
 open-ended questions
 palpation
 percussion
 review of systems
 subjective data

Assessment is the first step in the nursing process and includes systematic collection, verification, organization, interpretation, and documentation of data for use by health care professionals. Effective planning of client care depends on a complete database and accurate interpretation of information. Incomplete or inadequate assessment may result in inaccurate conclusions and incorrect nursing interventions. Proper collection of assessment data guides the decision-making activities of professional nurses.

Assessment is the collection and analysis of data that are used in formulating nursing diagnoses, identifying outcomes and planning care, and developing nursing interventions. This chapter discusses the purpose of assessment, types of assessment, and the use of data in the assessment process.

PURPOSE OF ASSESSMENT

The purpose of assessment is to establish a database concerning a client's physical, psychosocial, and emotional health in order to identify health-promoting behaviors as well as actual and potential health problems. Through assessment, the nurse determines the client's functional abilities and the absence or presence of dysfunction. The client's normal routine for activities of daily living and lifestyle patterns are also assessed. Identification of the client's strengths provides the nurse and other members of the treatment team with information about the skills, abilities, and behaviors the client has available to promote the treatment and recovery process. Some examples of client strengths are family support, intelligence, spiritual beliefs, and coping skills (how previous problems have been solved). The assessment phase also offers an opportunity for the nurse to form a therapeutic interpersonal relationship with the client. During assessment, the client is provided an opportunity to discuss health care concerns and goals with the nurse. The essential elements of the assessment process are:

- Data collection
- Data verification
- Data organization
- Data interpretation
- Data documentation

Assessment, like all other phases of the nursing process, is client-centered.

TYPES OF ASSESSMENT

The type and scope of information needed for assessment are usually determined by the health care setting and needs of the client (see Figure 6-1). Three types of assessment are comprehensive, focused, and ongoing. Although a comprehensive assessment is most desirable in initially determining a client's need for nursing care, time limitations or special circumstances may dictate the need for abbreviated data collection, as represented by the focused assessment. The assessment database can then be expanded after the initial focused assessment, and data should be updated through the ongoing assessment process.

COMPREHENSIVE ASSESSMENT

A **comprehensive assessment** is usually performed upon admission to a health care agency and includes a complete health history to determine current needs of the client. This database provides a baseline against which changes in the client's health status can be measured and should include assessment of physical and psychosocial aspects of the client's health, the client's perception of health, the presence of health risk factors, and the client's coping patterns.

FOCUSED ASSESSMENT

A **focused assessment** is an assessment that is limited in scope in order to focus on a particular need or health care

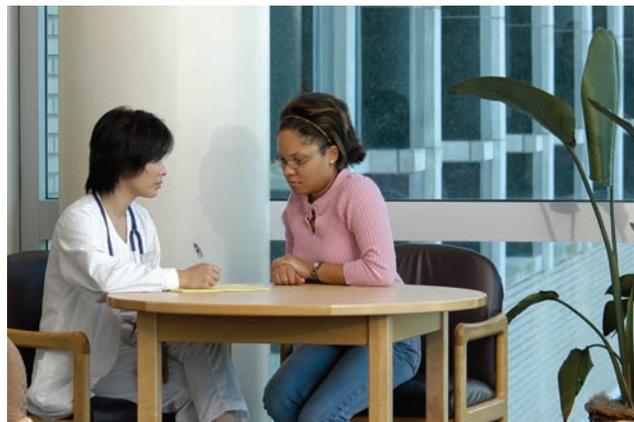

FIGURE 6-1 In this focused assessment, the nurse is collecting data about the client prior to elective surgery DELMAR/CENGAGE LEARNING

problem or potential health care risks. Focused assessments are not as detailed as comprehensive assessments and are often used in health care agencies in which short stays are anticipated (e.g., outpatient surgery centers and emergency departments), in specialty areas such as labor and delivery, and in mental health settings or for purposes of screening for specific problems or risk factors (e.g., well-child clinics). For example, the following is a list of sample questions used to assess a client experiencing labor:

- When did your contractions begin?
- How far apart are the contractions?
- Are they getting stronger?
- When did your water break?

ONGOING ASSESSMENT

Systematic follow-up is required when problems are identified during a comprehensive or focused assessment. An **ongoing assessment** is an assessment that includes systematic monitoring and observation related to specific problems. This type of assessment allows the nurse to broaden the database or to confirm the validity of the data obtained during the initial assessment. Ongoing assessment is particularly important when problems have been identified and a plan of care has been implemented to address these problems. Systematic monitoring and observation allow the nurse to determine client response to nursing interventions and to identify any emerging problems.

The nurse delivering care to a client at home uses ongoing assessment. Use of specific questions will be most helpful in eliciting specific information; see the accompanying Community Considerations box.

DATA COLLECTION

The nurse must possess strong critical thinking, interpersonal, and technical skills in order to elicit appropriate information and make relevant observations during the data collection process. This process often begins prior to initial contact

between the nurse and the client, primarily through the nurse's review of biographical data and medical records. Upon meeting the client, the nurse continues data collection through interview, observation, and examination. A variety of sources and methods are used in compiling a comprehensive database.

TYPES OF DATA

Client data include information that clients communicate about perceptions of their own health status as well as specific observations made by the nurse. These two types of information are referred to as subjective and objective data. **Subjective data** are data from the client's point of view and include feelings, perceptions, and concerns. These data (also referred to as symptoms) are obtained through interviews with the client. They are called subjective because they rely on the feelings or opinions of the person experiencing them and cannot be readily observed by another.

Objective data are measurable data that are obtained through observation, standard assessment techniques performed during the physical examination, and laboratory and diagnostic testing. These data (also called signs) can be seen, heard, or felt by someone other than the person experiencing them. Assessments that are comprehensive and accurate include both subjective and objective data. See Table 6-1 on page 92 for examples of both types of data.

SOURCES OF DATA

A comprehensive database should consist of data from every possible source, including:

- Client
- Family and significant other
- Other health care professionals
- Medical records
- Interdisciplinary conferences, rounds, and consultations
- Results of diagnostic tests
- Relevant literature

The client should always be considered the primary source of information; however, other sources should not be overlooked. The client's family and significant others can also provide useful information, especially if the client is unable to verbalize information. In addition, other health care professionals who have cared for the client may contribute valuable information. Medical records, including the medical history and physical examination, should also be reviewed; results of laboratory and diagnostic tests and various health care professionals should also be consulted.

Pertinent literature should be investigated in order to pursue relevant information and plan appropriate nursing interventions. Written standards are valuable sources of data for comparison, for example, a standard table of infant growth to determine whether an infant's weight and height are within the normal growth range. Another valuable source of data is knowledge about the client's normal parameters of functioning. The nurse's knowledge based on experience is another important source of data.

Assessing Clients at Home

- What led up to your most recent hospitalization?
- What medications were prescribed for you during that time?
- What kind of diet were you on?
- What type of activities did you do while you were in the hospital?
- While in the hospital, what did you learn about ... ?
- What adaptations for your comfort and care have you and your family made since your return home?

TABLE 6-1 Sample Application: Types of Data

DATA	TYPE OF DATA
Charlene Rhodes, age 47, has come to the clinic after “passing out” twice in the last 2 days. She tells the nurse that she becomes “lightheaded” after almost any type of activity. She has experienced some nausea since yesterday and vomited after eating breakfast this morning. She also tells the nurse that she is very nervous about these occurrences because she remembers her mother having similar symptoms when the mother suffered from a brain disorder. The nurse observes that the client’s gait is unsteady and her skin is pale. The client also has large bruises on her right arm and the right side of her face, which she states occurred when she fell.	<p>Subjective</p> <ul style="list-style-type: none"> Report of fainting Complaint of dizziness Nausea Verbalization of anxiety Self-reported fall <p>Objective</p> <ul style="list-style-type: none"> Vomiting Unsteady gait Pale skin Bruises on right side of face and right arm

Delmar/Cengage Learning

METHODS OF DATA COLLECTION

The nurse collects information through the following methods: observation, interview, health history, symptom analysis, physical examination, and laboratory and diagnostic data. These approaches require systematic use of the assessment skills discussed in the following text.

Observation

The nurse uses the skill of **observation** to carefully and attentively note the general appearance and behavior of the client. These observations occur whenever there is contact with the client and include factors such as client mood, interactions with others, physical and emotional responses, and any safety considerations. Observation helps the nurse determine the client’s status, both physical and mental. By carefully watching the client, the nurse can detect nonverbal cues that indicate a variety of feelings, including presence of pain, anxiety, and anger. Observational skills are essential in detecting the early warning signs of physical changes (e.g., pallor and sweating).

NURSING PROCESS HIGHLIGHT

Assessment

Sources of Data

Mrs. Palmer, age 76, was admitted to the hospital following a stroke. She is responsive but unable to speak or move extremities on the right side. Her daughter, who lives next door, is present at the bedside. What would be the best source of data in this situation?

Interview

An **interview** is a therapeutic interaction that has a specific purpose. The nurse interviews for a variety of reasons throughout the nurse-client relationship, including data collection, teaching, exploration of the client’s feelings or concerns, and provision of support. Effective interviewing depends on the nurse’s knowledge and ability to skillfully elicit information from the client using appropriate techniques of communication. Observation of nonverbal behavior during the interview is also essential to effective data collection.

INTERVIEW PREPARATION The interview is more productive if the nurse has an opportunity to prepare for the interaction. Such preparation includes review of the client’s medical records, conversations with other health care team members (e.g., personnel in emergency departments or long-term care facilities), and research of the presenting medical diagnosis. This information can be useful in obtaining the client’s relevant history and formulating a current needs assessment.

INTERVIEW STAGES Since the assessment interview often occurs at the beginning of a nurse-client relationship, it is helpful to begin the process with an orientation phase. During this period introductions are made, rapport is established, and roles are defined. The first few minutes of the nurse-client meeting may give an indication of the type of interviewing needed, so it is important that the nurse employ active listening skills. There are three phases to an interview: introduction, working, and closure.

Introduction Stage. The introduction stage of the interview establishes the goals for the interaction. The primary goal of the assessment interview is the collection of data about the client. In this phase of the interview, the purpose and use of the data collection should be discussed. For example, the nurse might state, “I need to talk to you for a few

minutes about your health so that we can better plan your care.” Adequate time and privacy should be allowed for the interview so that the client feels free to share any information that may be relevant. The parameters of confidentiality must be clearly explained to the client; see Chapter 12 for more information on confidentiality. The nurse should also inform the client about the approximate duration of the interview.

The client is more likely to respond freely if the interview environment provides comfort and privacy and if rapport exists between the client and the nurse. The nurse should sit (if possible), establish eye contact with the client, and listen attentively. It is the nurse’s responsibility to note nonverbal messages that may indicate that the client is uncomfortable, tired, or preoccupied with other matters. If any of these situations occur, it might be necessary to complete the interview at a later time. For example, if the client is guarding an incision and verbalizing discomfort or is extremely anxious about an impending procedure, only essential data are collected and the comprehensive interview is postponed until immediate needs have been met.

Working Stage. The working stage of the interview focuses on the details of data collection. The scope of the assessment interview depends on the type of assessment to be conducted (e.g., comprehensive or focused). The interview may be structured and formal (used in situations when a large amount of information needs to be obtained) or unstructured and informal (used in interactions that focus on a specific area of concern to the client). The nurse should be familiar with the specific assessment format used by the health care agency so that attention can be focused toward the client rather than the form itself.

The interview generally begins with questions about biographical and other nonthreatening information. The client’s reason for seeking health care is also addressed early in the working phase. Information is usually gathered from the general to the specific, with details about intimate or potentially embarrassing topics reserved until later in the interview. The Nursing Checklist provides guidelines for interview preparation.

Techniques used during the interview will be determined by the setting and purpose of the interview. A comprehensive interview that seeks to identify problems and

concerns is facilitated by open-ended questions, while an interview that focuses on specific details about a presenting problem will be facilitated by direct, closed questions. For example, an emergency setting would likely employ more direct, closed questions, while admission to a long-term care facility might require greater use of open-ended questions.

Closed questions are questions that can be answered briefly or with one-word responses. For example, the question “Have you been in the hospital before?” is a closed question that can easily be answered by a one-word response. Questions about the dates of and reasons for the hospitalizations are also closed questions that require brief answers.

Open-ended questions are questions that encourage the client to elaborate about a particular concern or problem. For example, the question “What led to your coming here today?” is open-ended and allows the client flexibility in response. Both closed and open-ended questions can be effective in collecting information; see the accompanying Nursing Process Highlight.

Closure Stage. Closure is established in the introduction phase when approximate time parameters are set. As the interview session is concluding, the nurse should indicate this fact by stating that almost all the information needed has been obtained or that the time for the interview is almost over. This action allows the client an opportunity to present any other relevant information, and it avoids surprises when the interview terminates. During the closure phase, the nurse summarizes what was covered or accomplished during the interview and requests validation of perceptions with the client. If the nurse or the client feels that additional time is needed for further exploration of specific points discussed during this session, plans can be made for future interviews.

Health History

A primary focus of the data collection interview is the health history. The **health history** is a review of the client’s functional health patterns prior to the current contact with a health care agency. While the medical history concentrates on symptoms and the progression of disease, the nursing health history focuses on the client’s functional health patterns, responses to changes in health status, and alterations in lifestyle. The health history is also used in developing the

NURSINGCHECKLIST

Preparing the Interview Environment

- Ensure adequate lighting.
- Maintain a comfortable room temperature.
- Select an environment that is as free of noise and distractions as possible.
- Maintain client privacy.
- Make sure that the interview is timed appropriately.
- Promote client comfort.

NURSING PROCESS HIGHLIGHT

Assessment

Interview Techniques: Questioning

Which questions—closed or open-ended—do you think will extract the most useful and complete information from the client? Under which circumstances would each type of question be best used?

plan of care and formulating nursing interventions. Following are elements of the health history:

- Demographic information
- Reason for seeking health care
- Client perception of health status
- Previous illnesses, hospitalizations, surgeries
- Client and family medical history
- Immunizations and exposure to communicable disease
- Allergies
- Current medications
- Developmental level
- Psychosocial history
- Sociocultural history
- Activities of daily living
- Review of systems

DEMOGRAPHIC INFORMATION Personal data include name, address, date of birth, gender, religion, race and ethnic origin, and occupation. This information may be useful in helping to foster understanding of a client's perspective.

REASON FOR SEEKING HEALTH CARE The client's reason for seeking health care should be described in the client's own words. For example, the statement "fell off four-foot ladder and landed on right shoulder; unable to move right arm" is the client's actual report of the event that precipitated the need for health care. The client's perspective is important because it explains what is significant about the event from the client's point of view. It is also important to determine the time of the onset of symptoms as well as a complete symptom analysis.

CLIENT PERCEPTION OF HEALTH STATUS Perception of health status refers to clients' opinions of their general health. It may be useful to ask clients to rate their health on a scale of 1 to 10 (with 10 being ideal and 1 being poor), together with the clients' rationales for their rating scores. For example, the nurse may record a statement such as the following to represent the client's perception of health: "Rates health a 7 on a scale of 1 (poor) to 10 (ideal) because he must take medication regularly in order to maintain mobility, but the medication sometimes upsets his stomach."

PREVIOUS ILLNESSES, HOSPITALIZATIONS, AND SURGERIES The history and timing of any previous experiences with illness, surgery, or hospitalization are helpful in order to assess recurrent conditions. It is also helpful to anticipate responses to illness, since prior experiences often have an impact on current responses.

CLIENT AND FAMILY MEDICAL HISTORY The nurse needs to determine any family history of acute and chronic illnesses that tend to be familial. Health history forms will frequently include checklists of various illnesses that can be used as the basis of the questions about this aspect. The client should be instructed that family history refers to blood relatives. It is also helpful to indicate *who* the relative is in relation to the client (e.g., mother, father, sister).

IMMUNIZATIONS AND EXPOSURE TO COMMUNICABLE DISEASE Any history of childhood or other communicable diseases should be noted. In addition, a record of current immunizations should be obtained. This is particularly important with children; however, records of immunizations for tetanus, influenza, and hepatitis B can also be important for adults. If the client has traveled out of the country, the time frame should be indicated in order to determine incubation periods for relevant diseases. The client should also be asked about potential exposure to communicable diseases, such as tuberculosis.

ALLERGIES Any drug, food, or environmental allergies should be noted in the health history. In addition to the name of the allergen, the type of reaction to the substance should be noted. For example, a client may report developing a rash or becoming short of breath. This reaction should be recorded. Clients may report an "allergy" to a medication because they developed nausea after ingesting it, which the nurse will recognize as a side effect that would not necessarily preclude administration of the drug in the future. A client's sensitivity to a drug can also change over time. Severe reactions may occur even though the client has successfully taken the drug or experienced only mild reactions to the drug in the past.

CURRENT MEDICATIONS All medications currently taken, both prescription and over the counter, are to be recorded by name, frequency, and dosage. Remind clients that this information should include medications such as birth control pills, laxatives, and nonprescription pain relief medications. Ask which, if any, herbal preparations the client uses. Patterns related to caffeine and alcohol intake and use of tobacco or recreational drugs should also be explored. Use of alternative or complementary treatment methods, including herbals, is often not shared by health care consumers. Some clients fear rejection or ridicule when divulging such information to health care providers. The nurse uses a sensitive, non-judgmental approach when assessing the client's use of all healing practices.

DEVELOPMENTAL LEVEL Knowledge of developmental level is essential for considering appropriate norms of behavior and for appraising the achievement of relevant developmental tasks. Any recognized theory of growth and development can

▼ SAFETY FIRST ▼

ASSESSMENT FOR ALLERGIES

It is essential that the nurse explore possible allergies prior to administering any medications. Allergic reactions can be life threatening and can occur even with very low dosages of medications.

be applied in order to determine whether clients are functioning within the parameters expected for their age group. For example, if the nurse uses Erikson's stages of psychosocial development, evaluation of an adult client attaining the developmental task of generativity versus stagnation can be validated by a nurse's statement such as "client prefers to spend time with his family; very involved in children's school activities."

PSYCHOSOCIAL HISTORY Psychosocial history refers to assessment of dimensions such as self-concept and self-esteem as well as usual sources of stress and the client's ability to cope (see Chapter 23). Sources of support for clients in crisis (such as family, significant others, religion, or support groups) should be explored.

SOCIOCULTURAL HISTORY In exploring the client's sociocultural history, it is important to inquire about the home environment, family situation, and client's role in the family. For example, the client could be the parent of three children and the sole provider in a single-parent family. The responsibilities of the client are important data by which the nurse can determine the impact of changes in health status and thus plan the most beneficial care for the client.

ACTIVITIES OF DAILY LIVING The activities of daily living are a description of the client's lifestyle and capacity for self-care. This information is useful both as baseline information and as a source of insight into usual health behaviors. This database should include the following areas:

- **Nutrition:** Includes type of diet, foods eaten, and fluids consumed regularly; food preparation; the size of portions; and the number of meals per day. Food preferences and dislikes, as well as the client's need for assistance in food preparation or eating, should also be determined.
- **Elimination:** Includes both urinary and bowel elimination frequency and patterns. Any recent changes or problems in these patterns should be noted.
- **Rest and sleep:** Includes the usual number of hours of sleep, number of hours of sleep needed to feel rested, sleep aids used, and the time within the day or night when sleep usually occurs. Any bedtime rituals (especially with children) should also be noted.
- **Activity and exercise:** Includes types and patterns of exercise in a typical day or week. If assistance is needed with activities such as walking, standing, or meeting hygienic needs, this information should be noted.

REVIEW OF SYSTEMS The **review of systems** (ROS) is a brief account from the client of recent signs or symptoms associated with any of the body systems. This allows the client an opportunity to communicate any deviations from normal that have not been otherwise identified. The ROS relies on subjective information provided by the client rather than data from the physical examination. When a symptom is encountered, either while eliciting the health history or during the physical examination, the nurse should obtain as much information as possible about the symptom. Relevant data include:

- **Location:** The area of the body in which the symptom (such as pain) can either be pointed to or described in detail.
- **Character:** The quality of the feeling or sensation (e.g., sharp, dull, stabbing).
- **Intensity:** The severity or quantity of the feeling or sensation and its interference with functional abilities. The sensation can be rated on a scale of 1 (very little) to 10 (very intense).
- **Timing:** The onset, duration, frequency, and precipitating factors of the symptom.
- **Aggravating and alleviating factors:** The activities or actions that make the symptom worse or better.

Physical Examination

The purpose of the physical examination is to make direct observations of any deviations from normal and to validate subjective data gathered through the interview. Baseline measurements are obtained, and physical examination techniques are used to gather objective data.

BASELINE DATA Baseline data collection is the systematic organization of observations obtained during the physical examination. The baseline becomes the basis for comparison and evaluation to establish the status of a client at a given point in time. Measurement of height, weight, and vital signs (temperature, pulse, respirations, and blood pressure) is important for comparison with future measurements in order to judge the significance of any changes (progress or regression) over time.

ASSESSMENT TECHNIQUES The physical examination incorporates the use of visual, auditory, tactile, and olfactory senses and the use of systematic assessment techniques. The use of visual, auditory, and tactile senses will be described with each of the specific assessment techniques. In addition, olfaction (sense of smell) is helpful in detecting characteristic odors as well as those associated with altered health states. For example, presence of infection is sometimes first detected by a change in the characteristic odor of body fluids or drainage. The four assessment techniques used in physical examination are inspection, palpation, percussion, and auscultation.

Inspection. **Inspection** involves careful visual observation. The client is observed first from a general point of view and then with specific attention to detail. For example, the nurse first observes for patterns of skin lesions and then focuses on the specific characteristics of individual lesions. Instruments such as a penlight and otoscope are often used to enhance visualization. Effective inspection requires adequate lighting and exposure of the body parts being observed. Beginning nurses often feel self-conscious or embarrassed using the technique of inspection; however, most become comfortable with the technique over time. Nurses must also be sensitive to the client's feelings of embarrassment with the use of inspection and respond to

this situation by discussing the technique with the client and using measures, such as draping for privacy, in order to increase the client's comfort level.

Palpation. **Palpation** uses the sense of touch to assess texture, temperature, moisture, organ location and size, vibrations and pulsations, edema, masses, and tenderness. Palpation requires a calm, gentle approach and is used systematically, with light palpation preceding deep palpation and palpation of tender areas performed last.

The technique of palpation uses the hands and fingers in different ways for assessment of:

- *Temperature:* Best detected using the dorsal (back) surface of the hand
- *Texture, pulses, and edema:* Best detected using fingertips
- *Vibration:* Best detected with the base of the fingers
- *Shape and consistency of organs or masses:* Best detected by grasping organ or mass between fingertips

SAFETY FIRST

PALPATION

Deep palpation is a technique requiring expertise and should not be employed by beginning nursing students without supervision.

Percussion. **Percussion** uses short, tapping strokes on the surface of the skin to create vibrations of underlying organs. It is used for assessing the density of structures or determining the location and the size of organs in the body. Structures with relatively more air (such as the lungs) produce louder, deeper, and longer sounds with percussion than more dense, solid structures (such as the liver), which produce softer, higher, and shorter sounds.

Auscultation. **Auscultation** involves listening to sounds in the body that are created by movement of air or fluid. Areas most often auscultated include the lungs, heart, abdomen, and blood vessels. Although direct auscultation is sometimes possible, a stethoscope is usually employed in order to amplify the sound.

Laboratory and Diagnostic Data

Results of laboratory and diagnostic tests can be useful objective data as these values often serve as defining characteristics for various altered health states; these can also be helpful in ruling out certain suspected problems. For example, diabetic clients who are poorly controlled on diet or medication will usually have an elevated blood glucose level. The pattern of these types of variations is useful in determining a plan of care. In addition, the effectiveness of nursing and medical interventions and progress toward health restoration are often monitored through laboratory and diagnostic test data.

DATA VERIFICATION

Data verification is the process through which data are validated as being complete and accurate. Once the nurse completes the initial data collection, the data are reviewed for inconsistencies or omissions. This process is particularly important if data sources are considered unreliable. For example, if a client is confused or unable to communicate, or if two sources provide conflicting data, it is necessary for the nurse to seek further information or clarification. Data verification is done by examining the congruence between subjective and objective data. For example, a client might exhibit nonverbal expressions of pain (e.g., guarding a part of the body, facial grimacing) but verbally deny feeling pain. The nurse would need to consider possible reasons for this discrepancy in findings and collect more information before formulating conclusions or planning care. Findings should also be compared with norms. Any grossly abnormal findings should be rechecked and confirmed. See the Uncovering the Evidence display.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Passing the Audition—The Appraisal of Client Credibility and Assessment by Nurses at Triage”

AUTHORS

S. Edwards and D. Sines

PURPOSE

To build a grounded theory of the process of initial assessment at triage by nurses in emergency departments.

METHODS

A grounded theory and symbolic interactionist methodology were used in this study in which 38 recordings were made of live triage interactions between nurses and clients in an emergency department. The recording was stopped and the nurse was asked to describe his or her thoughts about each comment.

FINDINGS

The findings suggest that client manifestation of clinical problems was interpreted according to the nurse's perceptions of the problems. Triage is a process in which nurses judge clinical assessment data.

IMPLICATIONS

Nursing practice and research need to consider the client's input during triage decision making.

Edwards, B., & Sines, D. (2008). Passing the audition—The appraisal of client credibility and assessment by nurses at triage. *Journal of Clinical Nursing, 17*(18), 2444–2451.

DATA ORGANIZATION

After data collection is completed and information is validated, the nurse organizes, or clusters, the information together in order to identify areas of strengths and weaknesses. This process is known as **data clustering**. How data are organized depends on the assessment model used.

ASSESSMENT MODELS

An **assessment model** is a framework that provides a systematic method for organizing data. The use of a model helps to ensure comprehensive and organized data collection. A guiding framework also provides direction for decision making about nursing diagnoses. A number of nursing and nonnursing models are used to assist with organization of data. This section describes only a few of the many assessment models available to nurses.

Nursing Models

Nursing models have been developed to focus on a wide range of human responses to alterations in health status. These models typically include psychosocial, sociocultural, and behavioral data as well as biophysical data. Nursing models may offer the advantage of organizing information in a mode that more easily allows transition from data collection to nursing diagnoses.

FUNCTIONAL HEALTH PATTERNS Gordon's (2002) human functional health patterns model provides a systematic framework for data collection that focuses on 11 functional health patterns. Following is a list of the functional patterns that can be used in assessment of individuals, families, and communities:

- Health perception–health management pattern: Describes client's perceived pattern of health and well-being and how health is managed
- Nutritional-metabolic pattern: Describes pattern of food and fluid consumption relative to metabolic need and pattern indicators of local nutrient supply
- Elimination pattern: Describes patterns of excretory function (bowel, bladder, and skin)
- Activity-exercise pattern: Describes pattern of exercise, activity, leisure, and recreation
- Cognitive-perceptual pattern: Describes sensory-perceptual and cognitive pattern
- Sleep-rest pattern: Describes pattern of sleep, rest, and relaxation
- Self-perception–self-concept pattern: Describes self-concept pattern and perceptions of self
- Role-relationship pattern: Describes pattern of role engagements and relationships
- Sexuality-reproductive pattern: Describes patterns of satisfaction or dissatisfaction with sexuality; describes reproductive patterns
- Coping–stress-tolerance pattern: Describes coping pattern and its effectiveness in stress tolerance

- Value-belief pattern: Describes goals and value and belief patterns that underlie decision making (Gordon, 2002)

These functional health pattern areas allow gathering and clustering of information about a client's usual patterns and any recent changes in order to determine if the client's response is functional or dysfunctional. For example, if the activity-exercise pattern was assessed for a client who recently experienced a stroke, data collection would be focused on mobility and exercise patterns prior to the stroke, current muscle strength and joint mobility, and the effect of any changes on the client's lifestyle and functional ability.

HUMAN RESPONSE PATTERNS The North American Nursing Diagnosis Association (NANDA), in an effort to standardize terminology related to client problems, has developed a taxonomy of nursing diagnoses (NANDA, 2009). The first taxonomy was completed in 1973 and consisted of 31 diagnostic categories. This taxonomy has developed into over 100 diagnostic categories arranged in a hierarchical structure organized according to nine human response patterns (see Chapter 7). This framework suggests that a person's health status is evidenced by observable phenomena that can be classified into one of these response patterns. These human response patterns can then be used as a model for organizing data collection.

THEORY OF SELF-CARE The theory of self-care, developed by Orem (2001), is based on a client's ability to perform self-care activities. Self-care is a learned behavior and a deliberate action in response to a need. It includes activities that an individual performs to maintain health. A major focus of this theory is the appraisal of the client's ability to meet self-care needs and the identification of existing self-care deficits (see Chapter 2). Since this theory focuses on deficits in care, it primarily addresses illness states.

ROY ADAPTATION MODEL The Roy adaptation model is organized around adaptive behaviors (Andrews & Roy, 2008). The individual is considered a product of biological, psychological, and sociological influences and is in constant interaction with the environment. The ability of the person to cope with internal and external stressors determines the health status of the individual (see Chapter 2). Assessment is focused toward an individual's response to stimuli in the environment in the areas of physiological status, self-concept, role function, and interdependence.

Nonnursing Models

Nursing neither exists nor functions in a vacuum. Nurses use related health concepts from other disciplines, some of which are discussed in the following text.

BODY SYSTEMS MODEL Approaching data collection by examining body systems is sometimes referred to as the "medical model," since it is frequently used by physicians to investigate presence or absence of disease. This method

organizes data collection according to the organ and tissue function in various body systems (e.g., cardiovascular, respiratory, gastrointestinal). Although nurses often use this method as well, the body systems model does not facilitate the formulation of nursing diagnoses. In addition, psychosocial aspects of the client's status are often neglected, with resultant fragmentation of care.

HIERARCHY OF NEEDS Maslow's hierarchy of needs model (1971) proposes that an individual's basic physiological needs must be met before progressing to higher-level needs. Maslow's framework can be used to prioritize client needs. Use of a hierarchy of needs model requires initial assessment of all physiological needs, followed by assessment of higher-level needs. Using Maslow's theory, a person's needs should be addressed in the following order:

- First: Physiologic needs—the basic survival needs, such as food, water, and oxygen
- Second: Safety and security needs—both physical (e.g., protection from bodily harm) and psychological (e.g., security and stability)
- Third: Need for love and belonging—humans have an innate need to be a part of a group and to feel accepted by others
- Fourth: Self-esteem needs—individuals need to feel they are valued and worthwhile
- Fifth: Self-actualization needs—the need to function at one's optimal level and to be personally fulfilled

DATA INTERPRETATION

Data clustering facilitates recognition of patterns and determination of further data that are needed. **Data interpretation** is necessary for identification of nursing diagnoses. Through data interpretation, the nurse examines all the information collected and seeks to make it meaningful in order to correctly determine pertinent client problems.

DATA DOCUMENTATION

Accurate and complete recording of assessment data are essential for communicating information to other health care team members. In addition, documentation is the basis for determining quality of care and should include appropriate data to support identified problems and diagnoses.

TYPES OF ASSESSMENT FORMATS

Health care agencies may choose from a variety of assessment forms for documentation depending on the type of agency, the population served by the facility, and the primary reasons for documentation. For example, clients seeking health care in a clinic or prescribing practitioner's office might be asked to complete a brief self-questionnaire, while a client admitted to an acute care facility for labor and delivery might be asked to provide only information directly related to pregnancy and child care needs. Four types of documentation

formats include open-ended, checklist, combination, and specialty. See Figure 6-2 on page 99 for an example of a form used in occupational nursing.

Open-Ended Formats

The open-ended format for documentation allows the nurse to write a narrative description of observations (see Figure 6-3 on page 100). This format is more time-consuming for the nurse but allows flexibility in recording findings.

Checklist Formats

Formats that include checklists facilitate documentation by summarizing findings in an abbreviated form (see Figure 6-4 on pages 101–104). They also provide more consistency in the recording of information and reduce the likelihood of omitting relevant information. However, checklists may discourage nurses from obtaining elaboration about observations from clients that require further explanation. For example, if a checklist indicates that mobility is impaired, further explanation is required in order to determine the extent of the impairment and thus plan the necessary interventions.

Combination Formats

Combination formats often allow the convenience of a checklist together with space to document a complete narrative description of any significant or abnormal findings (see Figure 6-5 on page 105). Some agencies provide cues on the form to alert personnel when further information is needed. This format provides for some consistency in recording data while allowing flexibility for documenting specific information.

Specialty Formats

Specialty areas such as outpatient surgery, labor and delivery, and psychiatric facilities may use abbreviated formats focused directly on assessment needs for the particular service provided. In addition, specialty assessment forms may be included together with comprehensive assessment forms for clients at particular risk for various conditions (e.g., falls, impaired skin integrity).

Documentation of assessment data is essential as a means of communication among health care team members to ensure accurate problem identification, determination of appropriate client outcomes, and continuity of care.

The Minimum Data Set

The Minimum Data Set (MDS) was developed by the Centers for Medicare and Medicaid Services (CMS) to promote the development of a comprehensive care plan for every resident of Medicare- or Medicaid-certified nursing homes. As such, the MDS is a standardized assessment instrument used in all long-term care facilities that are funded by CMS. The MDS is a comprehensive assessment tool designed to collect data about client needs.

HEALTH HISTORY

Name _____ Date _____ Time _____

Demographic Data: Date of birth _____ Gender _____ Marital status _____

Reason for Seeking Health Care: _____

Perception of Health Status: _____

Previous Illness/Hospitalization/Surgeries: _____

QUALITY OF LIFE CONCERNS/NEEDS

Is patient within appropriate developmental stage as defined by age-specific policy/tool? No Yes
 If "no," state specific delay and intervention necessary in addressing delay: _____

All areas identified will be addressed before discharge:

- Nutrition:**
- Current diet:** _____
- Nausea/vomiting x 3 days or greater**
- 10 lbs +/- weight change in 6 months**
- Dysphagia (Speech Therapy)**
- Chewing problems**
- Lives Alone (if greater than 75 yrs. old)
- 3 or greater complex/chronic diagnosis
- Symptoms of depression (frequent crying spells, sleep disturbance, change in appetite, feelings of helplessness/hopelessness, fatigue, etc.)
- History of substance abuse
- Possible abuse or neglect
- Homeless/crime victim
- Suicide attempt/ideations
- Unable to perform ADL's, dress, bathe self and no support system in place
- Transient
- Fetal demise/miscarriage
- Infant under care of neonatologist
- Adoption arrangements made/requested
- Non-compliant with taking medication
- Explain: _____
- Other: _____

Are there any customs or religious beliefs that may affect your plan of care? No Yes

If "yes," explain: _____

Pastoral follow-up requested by patient/family? No Yes
 If "yes," did family request a specific pastor/priest? No Yes
 If "yes," name of pastor/priest: _____
 If "yes" to pastoral follow-up but no specific clergy member requested, was Volunteer Services notified? No Yes

VACCINATION STATUS

Screening Tool Implemented

SAFETY

- Yes
- Over 75 yrs. old
 - History of falls
 - + Visual impairment, not corrected
 - Disability with physical impairment
 - + Walker, crutches, cane, _____
 - + Confusion
 - Agitation
 - Impaired memory/judgment
 - Hard of hearing
 - + Altered level of consciousness
 - Drugs that produce sedation
 - Drugs that promote diuresis, affect GI mobility, alter thought processes, lower blood pressure
 - Weakness
 - + • Paresis
 - History of seizures or new onset seizures
 - Seizure precautions initiated

Comments: _____

NOTE: If patient meets 3 or more criteria above or one criteria designated by a cross (+), Fall Prevention should be instituted.

- Yes
- Fall Prevention Instituted
 - If "yes," is it entered into HBOC?
 - Is a sign placed at bedside?
 - Family/patient instructed on FPP?

FUNCTIONAL SCREENING

MAY REQUIRE REHAB

- Ability to accomplish:
- Communication ability (Speech Therapy)
 - Bed mobility skills (Physical Therapy/Occupational Therapy)
 - Transfer skills (Physical Therapy/Occupational Therapy)
 - Balance (Physical Therapy)
 - Ambulation with or without assistive devices (Physical Therapy)
 - Feeding skills (Speech Therapy/Occupational Therapy)
 - Personal hygiene (Occupational Therapy)
 - Bathing (Occupational Therapy)
 - Dressing/fasteners (Occupational Therapy)
 - Toileting (Occupational Therapy)
 - Body position awareness (Physical Therapy/Occupational Therapy)
 - Ability to understand or follow instructions (Speech Therapy/Occupational Therapy)
 - Deficit does not require rehab (e.g., old CVA).

FIGURE 6-4 Continued

DATE: ___/___/_____

Explanation Given Regarding:

- Bed Mechanics
- Call Bell
- Telephone
- Activity Allowed

BRADEN SCALE

If Braden score is 17 - 23, pressure ulcer prevention precautions will be implemented.
 If Braden score is 12 - 16, moderate pressure ulcer prevention precautions will be implemented.
 If Braden score is 0 - 11, strict pressure ulcer prevention precautions will be implemented.

Clinical Condition Parameters

1. Sensory Perception: Response to Pressure-Related Discomfort

Completely Limited (unresponsive, quad, coma)	1
Very Limited (Responds only to painful stimuli, paraplegic, semicoma)	2
Slightly Limited (Responds with some sensory impairment CVA)	3
No Impairment (No limiting sensory deficit)	4

2. Moisture: Degree To Which Skin Is Exposed To Moisture

Constantly Moist (Always incontinent, 2 or more linen changes every 8 hours)	1
Moist (Often incontinent, linen change every 8 hours)	2
Occasionally Moist (Seldom incontinent, linen changes 2 every 24 hours)	3
Rarely Moist (Skin is dry, routine linen change)	4

3. Activity: Degree Of Physical Activity

Bed rest (Confined to bed)	1
Chairfast (Minimum weight bearing, ambulatory w/assist)	2
Walks Occasionally (Ambulatory short distance, sits mostly)	3
Walks Frequently (Ambulatory outside room, BID)	4

4. Mobility: Ability To Control, Change Body Position

Completely Immobile (Cannot move self)	1
Very Limited (Makes insignificant movements)	2
Slightly Limited (Makes slight changes independently)	3
No Limitations (Makes major, independent changes)	4

5. Nutrition: Usual Food Intake Pattern

Very Poor (NPO, IV greater than 5 days, less than 1/3 meals)	1
Problem Inadequate (Needs assistance, less than 1/2 meals)	2
Adequate (TPN, enteral needs met, greater than 1/2 meals)	3
Excellent (No supplement, eats most meals)	4

6. Friction and Shear: Ability To Maintain Body Position

Problem (Requires complete assist., slides down in bed/chair)	1
Potential Problem (Requires maximum assist., sometimes slides down in bed/chair)	2
No Apparent Problem (Moves independently, maintains good position in bed/chair)	3

Score _____

- Braden Score entered into HBOC
- Prevention Protocol Initiated

SKIN ASSESSMENT

- No abnormalities noted.
- Abnormalities present. See "Skin Injury/Wound Assessment Flowsheet."

Note: Abnormalities include, but are not limited to, skin tears, surgical incisions (does not include healed scars), lacerations, decubitus ulcers, rashes, bruises and hematomas.

KEY CONCEPTS

- Assessment includes collection, verification, organization, interpretation, and documentation of data.
- The nurse uses the process of assessment to establish a database about the client, to form an interpersonal relationship with the client, and to provide the client with an opportunity to discuss health care concerns.
- Assessment can be comprehensive, focused, or ongoing, depending on the health care setting and needs of the client.
- The two types of data collected during the assessment process are subjective (data from the client's point of view) and objective (observable and measurable data that are obtained through both the physical examination and laboratory and diagnostic tests).
- Although a variety of sources should be used in data collection, the client is the primary source of information.
- Assessment models such as Gordon's functional health patterns, NANDA's human response patterns, Orem's theory of self-care model, Roy's adaptation model, the body systems model, and Maslow's hierarchy of needs model ensure comprehensive data collection and organization.
- Data are collected through the interview, health history, symptom analysis, physical examination, and laboratory and diagnostic tests.
- The three stages of assessment interview are the introduction, working, and closure phases.
- A comprehensive health history is useful in determining the client's functional health patterns, responses to changes in health status, and alterations in lifestyle.
- The elements of the health history are demographic information; reason for seeking health care; perception of health status; previous illnesses, hospitalizations, and surgeries; client and family medical history; immunizations and exposure to communicable disease; allergies; current medications; developmental level; psychosocial history; sociocultural history; activities of daily living; and review of systems.
- The purposes of the physical examination are to gather baseline data, confirm data obtained in the interview and health history, and evaluate progress toward established goals.
- The physical examination includes the techniques of inspection, palpation, percussion, and auscultation.
- Accurate and complete documentation of assessment findings is essential for communication to other health care team members.
- Data may be recorded on a variety of tools, such as open-ended, checklist, combination, and specialty formats.

REVIEW QUESTIONS

- Which of the following nursing responses is an example of an open-ended statement?
 - "Are you feeling better?"
 - "Do you have any pain now?"
 - "Tell me about your health."
 - "Tell me how many children you have."
- The process of assessment includes which of the following activities? Select all that apply.
 - Collecting
 - Documenting
 - Interpreting
 - Organizing
 - Planning
 - Verifying
- A 72-year-old client comes to the emergency department for treatment of difficult, painful urination. What type of assessment is most appropriate for this client?
 - Comprehensive
 - Focused
 - Ongoing
 - Subjective
- The nurse is performing an admission assessment. Which of the following are examples of objective data? Select all that apply.
 - 10 cc of emesis in basin
 - Cool, clammy skin
 - Client says, "My feet are swollen."
 - Complaint of nausea by client
 - Oral temperature 103°F
 - Rapid, thready pulse
- When performing an assessment, which of the following would the nurse use as a primary source of data?
 - All health care personnel
 - Client
 - Client family and/or friends
 - Client medical records
- Which of the following statements accurately describes the review of systems (ROS)?
 - It is performed by the nurse at the earliest possible time.

- b. It is the client's statement about perceived health status.
 - c. ROS should be performed only by advanced nurse practitioners.
 - d. The nurse does a head-to-toe physical examination of the client.
7. A newly admitted client states that she has a severe headache. What is the nurse's first action?
- a. Administer pain medication as ordered in the client's medical record.
 - b. Check the client's vital signs.
 - c. Have the client sign consent forms for treatment and diagnostic procedures.
 - d. Orient the client to the unit and explain safety guidelines.

CHAPTER 7

Nursing Diagnosis

COMPETENCIES

1. Describe nursing diagnosis as a critical step in clinical judgment.
2. Explain the purposes of nursing diagnoses.
3. List the types of nursing diagnoses and the components of each type.
4. Explore characteristics of the nursing diagnosis taxonomy.
5. Describe the process of developing a nursing diagnosis.
6. Identify common errors in developing a nursing diagnosis.
7. Discuss limitations of nursing diagnoses.
8. Explore barriers that can affect the use of a nursing diagnosis.
9. Describe strategies to overcome limitations of and barriers to using nursing diagnoses.
10. Describe how a nursing diagnosis enables the delivery of holistic, comprehensive nursing care.
11. Explain how a nursing diagnosis enhances accountability and empowerment in the nursing profession.

KEY TERMS

- cluster
- cues
- defining characteristics
- definition
- diagnosis
- diagnostic label
- etiology
- medical diagnosis
- nursing diagnosis
- nursing informatics
- related factors
- risk factors
- taxonomy of nursing diagnoses

The **nursing diagnosis** is the second step in the nursing process and includes clinical judgments made about wellness states, illness states and syndromes, and the readiness to enhance current states of wellness experienced by individuals, families, and aggregate populations (communities). Diagnosing is based on a critical analysis of the assessment data. The purpose of a nursing diagnosis is to effectively communicate client needs among members of the health care team. Society tends to interpret nursing through the use of nursing language. When a nursing diagnosis is a part of the client’s plan of care, the nurse is able to communicate the client’s needs to other professionals involved in that care. These needs encompass physiologic, role function, self-concept, interdependence, and spiritual dimensions. To determine individualized therapeutic nursing interventions, the nurse must develop appropriate nursing diagnoses that are based on organized assessment data.

This chapter describes the nature of a nursing diagnosis, the purpose and types of nursing diagnoses, and the components of a nursing diagnostic statement. Development of nursing diagnoses and methods for avoiding diagnostic errors in the formulation of nursing diagnoses are also presented. Strategies for overcoming barriers to the use of nursing diagnoses are discussed.

WHAT IS A NURSING DIAGNOSIS?

Diagnosis is the science and art of identifying problems or conditions. Although this process has been linked primarily with physicians, it is also used by members of other professions, such as nurses, lawyers, social workers, mechanics, psychologists, and teachers. Though the term *nursing diagnosis* may convey multiple meanings, “in effect, nursing diagnosis defines nursing practice” (Ralph & Taylor, 2008, p. xxi).

Many definitions of nursing diagnosis have evolved over the past decades. The North American Nursing Diagnosis Association International (NANDA-I) defines nursing diagnosis as:

A clinical judgment about individual, family or community responses to actual and potential health problems or life processes. Nursing diagnoses provide the basis for selection of nursing interventions to achieve outcomes for which the nurse is accountable. (NANDA-I, 2009, p. 8)

Additional definitions of nursing diagnosis abound in the nursing literature. It is clear that although all definitions

are not exactly alike, there are similar attributes among them, such as a focus on client-centered problems; the promotion of nursing accountability; an awareness of the human response to health problems; the formation of clinical judgments about individuals, families, or communities; and the development of nursing interventions that a nurse is licensed to implement.

COMPARISON OF NURSING AND MEDICAL DIAGNOSES

It is important to differentiate a nursing diagnosis from a medical diagnosis (see Table 7-1). Clarification of this point is necessary to distinguish between the nursing and medical professions and the potential legal ramifications.

Delineation of “What is the nature of nursing?” versus “What is the nature of medicine?” is critical. In order to practice nursing, nurses need to know what it is that they do. Nursing diagnoses assist nurses in defining their scope of practice just as medical diagnoses assist physicians in defining their scope of practice. In addition, the use of diagnoses in nursing and medicine enables clarification of the legal boundaries for practice.

TABLE 7-1 Comparison of Selected Nursing and Medical Diagnoses

NURSING (HUMAN RESPONSES)	MEDICINE (DISEASE STATES)
<i>Ineffective breathing pattern</i>	Chronic obstructive pulmonary disease
<i>Activity intolerance</i>	Cerebrovascular accident
<i>Acute pain</i>	Appendectomy
<i>Disturbed body image</i>	Amputation
<i>Risk for imbalanced body temperature</i>	Strep throat
Delmar/Cengage Learning	

Medicine uses the term *medical diagnosis* and nursing uses the term *nursing diagnosis* to identify problems relating to a client's health status:

- **Medical diagnosis** is the terminology used for a clinical judgment by the physician that identifies or determines a specific disease, condition, or pathologic state.
- **Nursing diagnosis** is the terminology used for a clinical judgment by the professional nurse that identifies the client's or aggregate's actual, risk, wellness, or syndrome responses to a health state, problem, or condition.

There are both similarities and differences between medical and nursing diagnoses. The similarities include (1) using the diagnostic process, with "process" implying purpose, organization, and creativity (Bevis, 1978); (2) using cognitive, interpersonal, and psychomotor skills; (3) collecting and critically analyzing assessment data; (4) evaluating outcomes to ascertain continuation, resolution, or change of identified diagnosis; and (5) performing within legal dimensions and standards of the respective profession. An example of these similarities can be illustrated by considering a client who has a medical diagnosis of asthma. The physician and nurse would both collect assessment data on respiratory status. The physician would use this information to treat the disease of asthma and the nurse would use this information to focus on the client's response to the disease, which would result in a nursing diagnosis of *ineffective breathing pattern*.

Nursing diagnoses are different from medical diagnoses in (1) purpose, (2) goals, and (3) therapeutic interventions. The *purpose* of a nursing diagnosis is to focus on the human response or responses of the individual, family, or community to identified problems or conditions. Medical diagnoses center on the disease state or pathological condition. For example, if the medical diagnosis for a client is breast cancer, appropriate nursing diagnoses may include *fear*, *deficient knowledge* related to treatment measures, *grieving*, *disturbed body image*, *powerlessness*, and *ineffective coping*. In addition, the goals (aims, intent, or ends) that accompany these nursing diagnoses differ, as do the specific, individualized therapeutic nursing interventions (nursing actions to promote or restore health and enhance general well-being).

HISTORICAL PERSPECTIVE

The term *nursing diagnosis* has been in the literature since the early 1950s. Fry (1953) identified that nursing diagnosis is integral to the plan of nursing care and is an important tool for individualizing client care. However, these ideas were slow to gain momentum despite the interests of several nurse theorists and the focus on client-centered problems in the 1960s and the 1970s. In 1973, the First National Conference for the Classification of Nursing Diagnoses met to identify, develop, and classify nursing diagnoses. In 1982, at the fifth national conference, the organization was renamed the North American Nursing Diagnosis Association (NANDA).

Additional endorsement for nursing diagnosis came from the American Nurses Association (ANA) in 1973. Ongoing discussions occurred in the nursing literature, with increasing

support evident by the 1980s for nursing diagnosis and the diagnostic process. The ANA continues to support nursing diagnosis as the second step of the nursing process. Key elements of the ANA standards for diagnosis state that diagnoses are:

- Based on data collected during assessment of client
- Validated with client, significant others, and health care providers
- Documented so that they can be used in further development of expected outcomes and plan of care (ANA, 2004)

Following the biennial conference in April 1994, the Taxonomy Committee identified the need to revise the structure of Taxonomy I. During the 14th biennial conference in April 2000, NANDA adopted Taxonomy II, which was designed to improve the flexibility of the nomenclature (NANDA-I, 2009). As NANDA's work continued to grow, countries outside the United States began to incorporate the nursing diagnosis taxonomy, translating it and contributing in turn to the organization. In 2002, at the 14th national conference, the organization was renamed NANDA-I to represent the many countries that participate in the work of the organization.

In 2003, the ANA (2004) revised nursing's social policy statement to include the essential features of professional nursing. Among these features is the processes of diagnosis through the use of critical thinking. NANDA-I officially began collaboration with the Center for Nursing Classification and Clinical Effectiveness (University of Iowa) to sponsor joint biennial conference meetings through the NNN (NANDA-NIC-NOC) Alliance to promote the development, dissemination, and utilization of standardized nursing languages.

RESEARCH

Since the inception of the first conference on nursing diagnoses in 1973, NANDA-I has supported research on the development of a nursing diagnosis classification system. The initial research conducted was identification studies, in which clinicians repeatedly observed a condition in order to label a nursing diagnosis.

PURPOSES OF NURSING DIAGNOSES

Nursing diagnosis is unique in that it focuses on a client's *response* to a health problem, rather than on the problem itself, and it provides the structure through which nursing care can be delivered. Although these characteristics have always been in existence within nursing, they were unidentified prior to the mid-twentieth century.

PROFESSIONALISM

One of the requisites of a profession is a unique body of knowledge. Clearer conceptualization of knowledge unique to nursing increases both professional accountability and autonomy (Carpenito-Moyet, 2007). Therefore, nursing diagnosis contributes to the professional status of the discipline. The diagnostic process includes data collection, interpretation,

clustering of data (cues), and naming that cluster of cues. Nurses must be able to identify the phenomena of concern, determine appropriate outcomes, and then intervene to make those outcomes attainable.

COMMUNICATION

Nursing diagnosis also provides a means for effective communication. It is generally agreed among nurses, prescribing practitioners, and other health care professionals that there is a need for a common language within the health care sector. A mutual vocabulary that can be used for describing practice, research, and education benefits both the profession and the consumer. In addition, communication about nursing diagnoses is possible through computer-based searches.

HOLISTIC, INDIVIDUALIZED CARE

Holistic client care is facilitated with the use of nursing diagnosis. The list of NANDA-I–approved nursing diagnoses (NANDA-I, 2009) for clinical use provides assistance for the nurse in individualizing care and developing comprehensive therapeutic nursing interventions. See Table 7-2 for a listing of NANDA-I–approved diagnoses. “The interpretation of human responses is a complex nursing task that serves as the basis for selecting nursing interventions” (da Cruz, de Matos Pimenta, & Lunney, 2006, p. 229). Quality care and continuity of care are enhanced with identified nursing diagnoses as part of the client’s plan of nursing care. See the accompanying Community Considerations box, which illustrates the value of applying nursing diagnosis to a client receiving home health care.

Home Health Care Setting

Individualizing care of the home health client is an important function of nursing diagnosis. For example, the following questions can be used as a guide in developing nursing interventions as a response to the nursing diagnosis of *compromised family coping* related to a caregiver appearing to be unable to assist a client with management of a health problem:

- Has the caregiver expressed concern or anxiety about performing certain functions for the client?
- Does the care performed by the caregiver for the client yield satisfactory results in terms of alleviation of symptoms?
- What changes have occurred within the family situation that have altered the dynamics between the client and caregiver?

NURSING DIAGNOSES AND NURSING INFORMATICS

Nursing informatics is a specialty within nursing that assists organizations, clients, and clinicians through its focus on the methods and tools needed for dealing with information within nursing practice (see Chapter 13). Standards of

Text not available due to copyright restrictions

Text not available due to copyright restrictions

Text not available due to copyright restrictions

practice for nursing informatics, developed in 1995, address such topics as identifying, naming, organizing, grouping, collecting, processing, analyzing, storing, retrieving, communicating, transforming, and managing data or information (ANA, 2008). Certification is also available in nursing informatics. This specialty is absolutely critical to the implementation of NANDA and other nursing terminology systems within the clinical environment.

The advent of the electronic medical record has moved standardized nursing languages forward—perhaps faster than any other movement within health care. As more and more health care organizations computerize documentation, it becomes necessary for nursing to be able to efficiently and completely document both nursing care delivery and the clinical judgments (nursing diagnoses) that drive that care. The health care climate of recent years has been one of increasing mergers and partnerships between health care organizations that were formerly competitors. The task then is to be able to bring divergent computer systems together to meet the needs of the clients and the clinicians in these new

alliances. Use of a standardized nursing language allows for ease in sharing and interpreting nursing care.

Nursing informatics has the ability to demonstrate nursing's value to clients and to improve client safety and quality of client care. Evidence-based nursing care, and the strong push toward measuring the quality of that care, has led organizations to harvest information out of all the data that are collected daily within their systems as a way of proving nursing's value. Point-of-care computing and clinical decision support are two of the many ways that informatics are improving the safety of client care, while at the same time making documentation of that care more efficient for nurses (see Chapter 13).

COMPONENTS OF A NURSING DIAGNOSIS

There are five components of a nursing diagnosis that should be understood by the student and practicing clinician alike. The **diagnostic label** (or concept) consists of one or more

nouns (and may also include an adjective) that name the diagnosis and can be a word or a phrase that describes the pattern of related cues. The **definition** provides a clear description and differentiates one diagnosis from other similar diagnoses. The **defining characteristics** are observable manifestations of a specific diagnosis (NANDA-I, 2009). **Risk factors** are those elements that increase the chances of an individual, family, or community being susceptible to a disease state or life event that will have an impact on health. Finally, **related factors** can precede, be associated with, contribute to, or be related to nursing diagnoses in some type of patterned relationship (NANDA-I, 2009).

Several formats have been used to structure nursing diagnosis statements. Two formats that are frequently seen in the nursing literature are the two- and three-part statements. The two-part statement is NANDA-approved and is used by most nurses, in large part because of its brief and precise format. The three-part statement is preferred by those nurses desiring to strengthen the diagnostic statement by including specific manifestations, an attribute that is not possible through the use of the two-part format.

THE TWO-PART STATEMENT

The components of a nursing diagnosis typically consist of two parts. The first component is a problem statement or diagnostic label that describes the client’s response to an actual, a possible, a risk for a health problem, or a wellness condition.

The second component of a two-part nursing diagnosis is the etiology. The **etiology** is the related contributing factor of the problem. The diagnostic label and etiology are linked by the term *related to* (RT). Examples of nursing diagnoses are *disturbed body image* RT loss of left lower extremity and *activity intolerance* RT decreased oxygen-carrying capacity of cells. Descriptive words or modifiers may be added to clarify specific nursing diagnoses. These modifiers, which limit or specify the meaning of a nursing diagnosis, are called judgments. NANDA-I (2009) recognizes the following: *anticipatory, compromised, decreased, defensive, deficient, delayed, disabled, disorganized, disproportionate, disturbed, dysfunctional, effective, enhanced, excessive, imbalanced, impaired, ineffective, interrupted, low, organized, perceived, readiness for, and situational*. These terms are placed before the problem statement.

The population for which a diagnosis is being used can also be named. The populations identified by NANDA-I

(2009) include *individual, family, group, and community*. If a population is not specified within the diagnostic label, such as with *readiness for enhanced family processes*, it becomes the individual by default.

THE THREE-PART STATEMENT

The nursing diagnosis can also be expressed as a three-part statement. As in the two-part statement, the first two components are the diagnostic label and the etiology. The third component consists of defining characteristics (collected data that are also known as signs and symptoms, subjective and objective data, or clinical manifestations). In the three-part nursing diagnosis format, the third part is joined to the first two components with the connecting phrase “as evidenced by” (AEB). Defining characteristics list the relevant clinical manifestations, such as signs or symptoms for the identified client problem and the related etiology. Defining characteristics are identified for each NANDA-approved diagnosis. These characteristics continue to evolve as they are reviewed and updated. Defining characteristics may assist the nurse in identifying client goals, measurable client outcome criteria, and relevant nursing interventions.

Some nurses believe that the three-part statement strengthens the diagnostic process. However, other nurses prefer the two-part statement and refer to the defining characteristics as part of the original database. Table 7-3 depicts the components and relationship of the one-, two-, and three-part statements. Although the most commonly used format is the two-part statement, it is beneficial for the nurse to be knowledgeable about the use of the three-part statement for development of a nursing diagnosis. See Table 7-4 on page 116 for a comparison of selected NANDA-approved diagnoses in the two- and three-part statements.

CATEGORIES OF NURSING DIAGNOSES

Nursing diagnoses may be classified into four categories of health status: actual, risk, health promotion, and wellness. Health status indicates the place along the continuum from wellness to illness at which the nursing diagnosis is being made. The most common nursing diagnoses used are actual and risk diagnoses.

TABLE 7-3 Comparison of One-, Two-, and Three-Part Nursing Diagnosis Statements

ONE-PART STATEMENT	TWO-PART STATEMENT	THREE-PART STATEMENT
Part 1: Wellness condition or state to be enhanced (no related to, no etiology, and no defining characteristics)	Part 1: Problem related to Part 2: Etiology (no defining characteristics)	Part 1: Problem related to Part 2: Etiology Part 3: Defining characteristics

Delmar/Cengage Learning

NURSING DIAGNOSIS	TWO-PART STATEMENT	THREE-PART STATEMENT
<i>Feeding self-care deficit</i>	<i>Feeding self-care deficit</i> RT decreased strength and endurance	<i>Feeding self-care deficit</i> RT decreased strength and endurance AEB inability to maintain fork in hand from plate to mouth
<i>Ineffective airway clearance</i>	<i>Ineffective airway clearance</i> RT fatigue	<i>Ineffective airway clearance</i> RT fatigue AEB dyspnea at rest
<i>Anxiety</i>	<i>Anxiety</i> RT change in role functioning	<i>Anxiety</i> RT change in role functioning AEB insomnia, poor eye contact, and quivering voice
<i>Deficient knowledge</i>	<i>Deficient knowledge</i> RT misinterpretation of information	<i>Deficient knowledge</i> RT misinterpretation of information AEB inaccurate return demonstration of self-injection
<i>Spiritual distress</i>	<i>Spiritual distress</i> RT separation from religious ties	<i>Spiritual distress</i> RT separation from religious ties AEB crying and withdrawal

Data from American Nurses Association. (2004). *Nursing: Scope and standards of practice*. Washington, DC: Author.

- *Actual diagnoses* are those problems that are already in existence. Examples of actual diagnoses include *excess fluid volume* RT intravenous infusion therapy overload and *anxiety* RT unknown results of breast biopsy.
- *Risk diagnoses* are identified when there is a recognized vulnerability for the client to exhibit a problem, but that response has not yet manifested itself. Examples of risk diagnoses include *risk for poisoning* RT increased mobility of infant and failure to have house childproofed and *risk for deficient fluid volume* RT excessive number of stools.
- *Health promotion diagnoses* identify behaviors that indicate a desire to increase well-being.
- *Wellness diagnoses* identify the client condition or state of being healthy that may be enhanced by deliberate health-promoting activities. These consist of a one-part statement (no “related to” phrase) that uses the label “readiness for enhanced” followed by the state to be enhanced. Examples of wellness diagnoses include *readiness for enhanced community coping* and *readiness for enhanced spiritual well-being*.

TAXONOMY OF NURSING DIAGNOSES

The **taxonomy of nursing diagnoses** classifies diagnostic labels based on which human responses the client is demonstrating in response to the actual or perceived stressor. Rather than consult the alphabetical listing of NANDA diagnoses, some nurses might find it more helpful to review the NANDA listing by pattern of human responses. This listing is called the NANDA Taxonomy II and organizes the NANDA-approved nursing diagnoses under the corresponding human

response category. NANDA Taxonomy II is composed of three levels: domains, classes, and diagnostic statements (nursing diagnoses). The 13 domains under which nursing diagnoses are placed are:

- Health promotion
- Nutrition
- Elimination/exchange
- Activity/rest
- Perception/cognition
- Self-perception
- Role relationship
- Sexuality
- Coping/stress tolerance
- Life principles
- Safety/protection
- Comfort
- Growth/development (NANDA-I, 2009, pp. 266–267)

CLINICAL JUDGMENT IN NURSING: DEVELOPING NURSING DIAGNOSES

Clinical judgment in nursing requires a firm foundation in the study of the humanities and life sciences in order to properly assess for cues related to diagnoses. The ability to cluster cues obtained during assessment, and the interpretation of assessment data to form hypotheses (potential nursing diagnoses), then drives additional assessment to validate or refute those hypotheses. The development of a nursing diagnosis is a systematic process in which certain activities

NURSING CHECKLIST

DEVELOPING NURSING DIAGNOSES

- Collect data cues by comprehensive, accurate assessment activities.
- Validate data cues.
- Determine the meaning of data cues through application of critical thinking.
- Group data into clusters.
- Review the NANDA-approved list of diagnoses and related defining characteristics.
- Write the first part of the diagnostic statement.
- Identify and record the *related to* (RT) variables.
- Combine the last two steps into a two-part diagnostic statement.

need to be executed; see the Nursing Checklist for steps in developing nursing diagnoses.

GENERATING CUES

In the assessment phase, the nurse collects data cues from the client. **Cues** are small amounts of data that are applied to the decision-making process. Nurses should be attentive to the cues gathered from the interview, health history, symptom analysis, physical examination, and laboratory and diagnostic data since they increase the index of suspicion and stimulate further observation of additional sets of cues. Examples of cues might be poor skin turgor, parched lips, dry skin, decreased urine output, and complaint of thirst. The expert nurse immediately processes these cues and together with the client determines a nursing diagnosis, plans client outcomes, and implements therapeutic nursing interventions. The novice nurse must proceed more cautiously and use additional time to process these data cues. See the accompanying Spotlight On display on identifying data cues.

VALIDATING CUES

After reviewing the data cues, the nurse validates that information and examines it carefully to determine if the information is accurate and complete (see Figure 7-1). This process involves verifying subjective and objective data. Verification can be done by interviewing the client again and reassessing data cues.

INTERPRETING CUES

Through interpretation of data cues and use of critical thinking strategies, the nurse assigns a meaning to the data cues. In order to interpret subjective and objective data cues, the nurse should ask the following questions that stimulate critical thinking:

- What is this information telling me?
- Is there a pattern?

SPOTLIGHT ON...

Professionalism

Identifying Data Cues

What are the relevant data cues that can be gathered from the following assessment data for Peter Zachary, age 44?

Subjective Data

"I am the father of two boys."

"I paint houses for a living."

"I go to church every Sunday."

"I always seem to be hungry, and I eat five or six times a day."

"I've gained twelve pounds this year."

Objective Data

Client is 5 feet 10 inches and weighs 204 pounds.
Protruding abdomen over belt and waist of pants.
Double chin.

Fleshy, loose upper arms.

Dimpling of buttocks.

One bowel movement every other day.

Vital signs: P 92; BP 130/80; R 17; T 98.9°F.

Red scaly patches on skin.

Nonproductive cough.

Birthmark right upper hip.

- Can this information be put together?
- Is the information falling into a logical arrangement?
- Is the information forming natural groupings?

Interpreting data cues is one example of critical thinking that the nurse must do on a daily basis. Specifically, the synthesis of information that takes place when interpreting data

FIGURE 7-1 This nurse is validating the cues collected from this client during the assessment phase DELMAR/CENGAGE LEARNING

NURSING CHECKLIST

Critical Thinking

The following questions should be considered by the nurse in the development of a nursing diagnosis:

- Do I have enough data to formulate a nursing diagnosis?
- Are any data missing?
- Is there any information in my database that seems incomplete or uncertain?
- Should I talk to the client and family again?
- What data fit together or have something in common?
- What specific cues from the client made me form this conclusion?
- What elements of this situation, condition, or problem can be enhanced or resolved by therapeutic nursing interventions?
- What elements need to be referred to another discipline (e.g., medicine, social services, dietary)?

cues demonstrates how essential it is for the nurse to think critically. Interpreting cues is pivotal for correctly diagnosing actual or potential problems or wellness states. The accompanying Nursing Checklist provides questions that are helpful in developing appropriate diagnoses.

CLUSTERING CUES

Once the cues have been collected, validated, and interpreted, the data are then grouped into clusters. A **cluster** is a set of data cues in which relationships between and among cues are established to identify a specific health state or condition. Related pieces of information about the client are grouped together. Conclusions are drawn from the data cues. One piece of information by itself can be misleading. This idea is analogous to the assembly of a jigsaw puzzle. One puzzle piece by itself does not give an accurate idea of the picture. In the same way, one data cue (or piece of assessment data) does not have much relevance by itself. When more pieces of the puzzle are assembled or when more data assessment cues are put together, the nurse may have a beginning idea of what the puzzle picture or the client's health looks like.

USING NANDA-APPROVED NURSING DIAGNOSES

After the data have been organized into clusters, the nurse needs to consult the NANDA-approved diagnoses, carefully reviewing the definitions, defining characteristics, and risk or related factors. This allows the nurse to ascertain similarities and differences between the clusters and NANDA diagnoses. The clustered data are then matched with a particular

NANDA diagnosis. It is important that the nurse review the actual definitions and defining characteristics to ensure that the diagnosis being made is accurate; reliance on only the diagnostic statement can lead to inaccuracies in diagnosis.

WRITING THE NURSING DIAGNOSIS STATEMENT

The nursing diagnosis selected from NANDA-approved diagnoses becomes the diagnostic label, the first part of the diagnosis statement. Etiologies can be identified using the related factors listed with each nursing diagnosis. The appropriate etiology is selected and joined to the first part of the statement with the "related to" phrase. Because the NANDA list of nursing diagnoses is constantly evolving, there may be times when no etiology is provided. In such cases, the nurse should attempt to describe likely contributing factors to the client's condition. In a two-part statement, the nursing diagnosis for an overweight client would be *imbalanced nutrition: more than body requirements* RT excessive food intake. The three-part statement would be *imbalanced nutrition: more than body requirements* RT excessive food intake AEB weight gain, increased appetite, excess adipose tissue, and increased abdominal girth.

AVOIDING ERRORS IN DEVELOPMENT AND USE OF NURSING DIAGNOSES

Following is a discussion of common errors that may occur in the process of developing nursing diagnoses. Being aware of possible errors helps decrease the likelihood of their occurrence.

ASSESSMENT ERRORS

There is an underlying assumption that nurses have adequate assessment skills and are knowledgeable about what data need to be collected. However, this is not always the case. The novice nurse may have only rudimentary assessment skills and limited clinical experience. Experienced nurses are challenged to keep current and sometimes are ill equipped to collect appropriate assessment data. Errors may be made when writing a nursing diagnosis due to an incomplete database or inappropriately collected assessment data. When assessment data are missing, regardless of the cause, the end result is either an omission of nursing diagnoses, inaccurate diagnoses, or incorrect qualifying statements about the diagnoses.

Incomplete Assessment Data

Incomplete collection can occur when the nurse has neither had nor taken the time to appropriately address all subjective and objective data. For example, during admission of a new client to a health care facility, a nurse is interrupted during

the data collection and fails to return to finish the admission process.

Restricted data collection occurs when a client is unable or unwilling to provide the necessary data. An example would be a newly admitted client with a cerebrovascular accident who has impaired speech and can provide only limited assessment data.

Validation Errors

Failure to validate occurs when the nurse does not confirm previously collected data. An example would be failure by the nurse to recheck an admission blood pressure that was elevated. A follow-up blood pressure may have revealed a transient elevation due to the stress of the admission process.

Misinterpreting Data

Misinterpretation can occur when the meaning attached to the data is incorrect. An example would be a client who comes to the ambulatory care clinic and presents with several signs and symptoms, including a reported 4-pound weight gain that month. Further investigation indicates this finding is not related to increased adipose tissue but, rather, is associated with fluid retention that accompanies an edematous state. See the accompanying Respecting Our Differences display.

DIAGNOSTIC ERRORS

Errors can also occur in the nursing diagnostic process during the clustering, interpretation, and statement of the diagnosis. Critical thinking skills and the use of standardized nursing language, such as NANDA diagnoses, help ensure accuracy in the diagnostic statement.

Inappropriate Data Clustering

Inappropriate data clustering may occur when the nurse lacks sufficient theoretical knowledge and clinical expertise in order to appropriately cluster data cues. An example would be the client who visits an industrial clinic with complaints of flulike symptoms, stomach cramps, and vomiting. The nurse attributes the vomiting to the influenza, but further analysis indicates that this client is actually manifesting symptoms of a toxic reaction to a prescribed drug that is causing the vomiting.

Incorrect Writing of the Nursing Diagnosis Statement

Incorrect writing of the statement can occur when the nurse does not follow the guidelines for formulating a two- or three-part statement. An example would be in the two-part statement *imbalanced nutrition: less than body requirements* RT renal disease. Renal disease is a medical diagnosis, and, according to the guidelines, the etiology must be a human response that the nurse is licensed and competent to treat. This diagnosis would be better stated as *imbalanced nutrition: less than body requirements* RT inadequate intake of an appropriate renal diet.

RESPECTING OUR DIFFERENCES

Errors in Data Interpretation

Your client, a 35-year-old married man with two children, has been discharged home following open-heart surgery. During your first two visits to assess the client's progress, you notice that the client seems reluctant to leave his bed and expresses minimal interest in topics other than the television programs he has been watching. When you inquire about his attempts to participate in leisure activities with his wife and children, he shrugs his shoulders and appears bored with the discussion. On the basis of this assessment, you formulate a nursing diagnosis of *deficient diversional activity* RT client's lack of engagement in recreational activities. If you were to determine on your third visit that the client has refrained from these kinds of activities because of his fear of reopening the incision, how would you reconcile the discrepancy between the assessment data gathered and the nursing diagnosis that was developed? Do you think that your values relating to this client's conduct may have played a role in the misinterpretation of the data and the resulting nursing diagnosis?

Values play an important role in interpretation of data, clustering of data, and ultimately the development of the diagnosis. Nurses must be cognizant of personal biases, being careful not to impose their value systems on clients. Personal prejudices should be avoided in the diagnostic statement. The Nursing Checklist provides selected questions that nurses

NURSING CHECKLIST

Avoiding Common Diagnostic Errors

When nurses are in the process of developing nursing diagnoses, the following questions should be considered:

- Am I saying the same thing twice?
- Am I using the medical diagnosis in my nursing diagnosis?
- Am I implying negligence or blaming anyone in my diagnosis?
- Have I stated the diagnosis with a client response or a client need?
- Am I making any value judgments about the client?

can ask themselves in order to avoid making mistakes when developing nursing diagnoses.

Nurses must also remember to focus on the client when developing a nursing diagnosis. The problem statement is client centered, not nurse centered. The nursing diagnosis directs nursing actions by providing the focus for evaluating outcomes.

LIMITATIONS OF NURSING DIAGNOSIS

A number of limitations and professional concerns are associated with nursing diagnosis. The primary concern is directed toward the lack of consensus among nurses regarding the NANDA-approved nursing diagnosis list. Criticisms about the list include disagreement over specific labels in the classification system and the perception that the list is confining, incomplete, illness and disease oriented, and confusing. Many nurses are not familiar with the NANDA list and do not know how to use it or feel “it doesn’t have the diagnosis” they need. It should be noted that this list is not meant to be inclusive. Development and refinement of diagnoses continue to be a focus of NANDA conferences. In addition, nurses may disagree with or refuse to use diagnoses such as noncompliance or knowledge deficit (Carpenito-Moyet, 2007). In these instances, the nurse then has the choice and the right to not use these specific diagnoses.

Novice nurses need to know nursing diagnosis and nursing process in order to understand how the discipline of nursing intersects with the other health care providers. NANDA-I (2009) recognizes that health care continues to move toward an interdisciplinary, client-focused care environment that requires standardization of languages across disciplines. Many acute care facilities use an interdisciplinary care plan such as care maps or critical pathways to monitor client outcomes. All health care providers use the same care plan to document the client’s response to specific interventions. Common “client problems” listed on a critical pathway are written as nursing diagnoses such as *risk for infection* or *risk for injury*.

Legal considerations concerning the use of nursing diagnoses also exist. Nurses are accountable for their actions and must document their interventions. If a nursing diagnosis is inappropriate or a nursing diagnosis list is incomplete and, as a result, the interventions are inappropriate or lacking, the nurse is liable for these errors in clinical judgment. These errors can be avoided by collecting comprehensive assessment data and by critically analyzing these data.

OVERCOMING BARRIERS AND LIMITATIONS TO NURSING DIAGNOSIS

NANDA’s language is relatively new compared to medical language that has existed for several hundred years. Some

nurses would rather wait until the NANDA listing is complete before they use it. However, it is unrealistic to think that a system such as NANDA should not be used until it is completed. Indeed, as nursing science continues to evolve, nursing diagnoses will be added, removed, or refined; there will never be a “completed” list of nursing or medical diagnoses for this very reason. The ever-changing health care scene dictates that nurses participate in evolving methods to communicate within the health care industry.

Another barrier to the use of nursing diagnoses is the numerous approaches for application that are found in the nursing literature. Due to these various methods, it may be difficult for nurses to choose one method with which they feel comfortable. Nurses may also be unable and unwilling to use nursing diagnoses because of incomplete knowledge about the process and disagreements about wording.

After identifying the existence of barriers to the use of nursing diagnoses, it is possible to design strategies to overcome them. One strategy is to develop a common nursing language that is globally used throughout the profession. Nursing diagnostic terminology serves this purpose. Familiarity with this language empowers the nurse to communicate more effectively with other nurses and health care team members. Effective communication, in turn, improves the accuracy in nursing diagnoses. Ultimately, the quality of care should improve, and the costs associated with that care should decrease. Due to the fact that many health care facilities are asking nurses to do more with fewer resources, nurses are challenged to learn more efficient ways of performing their duties. Nurses’ time is spent more efficiently if less time is spent deciphering meanings of words.

The move toward electronic health records is making it more important than ever to have standardized nursing languages. As health care settings are required to communicate with other organizations to improve client management, it will be important to have standardized languages within those electronic systems so that different information systems are able to “talk to” one another by sending and receiving data that diverse systems can readily understand. The current method of “free text charting” will become a thing of the past, and standardized nursing languages representing nursing diagnoses, interventions, and outcomes will be critical to the success of these information systems. See the Nursing Process Highlight on page 121 in order to practice developing a diagnostic statement. The accompanying Uncovering the Evidence display on page 121 describes how education can improve the use and documentation of nursing diagnoses.

When a nurse encounters client situations that do not readily fit the nursing diagnosis language, every attempt should be made to describe the phenomena. The nurse may be on the threshold of documenting the need for a new, as-yet-undiscovered nursing diagnosis. Indeed, the work of NANDA is done by nurses working in client care areas, education, and research. Potential diagnoses are submitted to NANDA for approval based on research in the area of concern. Nurses are strongly encouraged to share their needs for nursing diagnosis language with NANDA so that the language will grow, become more inclusive, and become more usable for nurses in practice.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Improved Quality of Nursing Documentation: Results of a Nursing Diagnoses, Interventions, and Outcomes Implementation Study”

AUTHORS

M. Muller-Staub, I. Needham, M. Odenbreit, M. A. Lavin, and T. van Achterberg

PURPOSE

To evaluate the impact of the quality of nursing diagnoses, interventions, and outcomes in an acute care setting after implementation of an educational program.

METHODS

This experimental design study utilized pre- and post-tests on nurses who participated in two educational sessions about the use of nursing diagnoses, interventions, and outcomes. Nursing records were randomly selected for analysis before and after the implementation of the educational strategy.

FINDINGS

Significant improvements in the quality of documented nursing diagnoses, interventions, and outcomes were found following the implementation of the educational program.

IMPLICATIONS

Education can be a viable strategy for improving documentation of nursing diagnoses, interventions, and outcomes.

Muller-Staub, M., Needham, I., Odenbreit, M., Lavin, M. A., & van Achterberg, T. (2007). Improved quality of nursing documentation: Results of a nursing diagnoses, interventions, and outcomes implementation study. *International Journal of Nursing Terminologies & Classifications: The Official Journal of NANDA International*, 18(1), 1–2.

As nurses collaborate on the refinement of nursing diagnoses, it may be possible to agree on certain aspects of the language. The achievement of this goal will end the use of multiple approaches and will make choices less complicated. Enhanced communication among nurses in everyday settings and among professionals who convene nationally and internationally to exchange ideas about nursing diagnoses is essential.

Most nursing educational programs now offer standardized content related to nursing diagnoses. In addition, experienced nurses need opportunities to review principles of nursing diagnoses. See the Nursing Checklist for a list of strategies that are helpful for overcoming barriers to the use of nursing diagnoses.

NURSING CHECKLIST

Strategies for Optimizing the Use of Nursing Diagnoses

Nurses should implement the following strategies when working with nursing diagnoses:

- Agree on a common language.
- Acknowledge and embrace the fluid nature of the language of nursing diagnosis.
- Discuss the purpose and value of nursing diagnosis with administrators and medical staff.
- Support colleagues when they use nursing diagnosis language.
- Adopt a positive attitude toward the principles and taxonomy of nursing diagnosis.
- Be willing to add to the existing body of knowledge by describing unusual nursing phenomena.
- Participate in conferences, workshops, and other educational activities that advance and promote nursing diagnosis.
- Continue communicating with other nurses about nursing diagnosis.

NURSING PROCESS HIGHLIGHT

Diagnosis

Example

Mr. Lowder is a 62-year-old male who was admitted last night through the emergency room because of difficulty breathing. He was also experiencing some difficulty voiding. His lower extremities are very swollen. History reveals he smokes one pack of cigarettes a day and has done this for the past 45 years. His vital signs are P 112; R 30; BP 172/96; T 101.1°F. He has an eighth-grade education, attends church every week, is estranged from his daughter, and says, “I hate hospitals because my mother died in one.”

Questions

1. From the data cues in this case study, group data into clusters.
2. Look at the NANDA list of diagnoses and see which diagnoses “fit” best with your data clusters.
3. Write the first part of the NANDA diagnosis for each cluster.
4. Attempt to identify etiological (related to) factors for the list you started in Step 3.
5. Write two-part nursing diagnosis statements by combining Steps 3 and 4.
6. Identify whether the nursing diagnoses on your list are actual, possible, risk, or wellness-oriented nursing diagnosis statements.
7. Prioritize the nursing diagnoses.

KEY CONCEPTS

- Nursing diagnosis is the second step in the nursing process and is the clinical judgment about individual, family, or community (aggregate) responses to actual or risk problems, wellness states, or syndromes.
- Through the efforts of NANDA and the ANA, the identification and validation of nursing diagnosis as the second step of the nursing process has been substantiated and forms the basis for professional accountability.
- Nursing diagnosis contributes to a clearer understanding of knowledge unique to nursing, improves communication among nurses and other health care professionals, promotes individualized client care, and supports theory development and nursing research.
- Nursing diagnoses can be written as either two-part statements (diagnostic label and etiology) or three-part statements (diagnostic label, etiology, and defining characteristics).
- The NANDA nursing diagnosis taxonomy is composed of 13 domains: health promotion, elimination/exchange, perception/cognition, role relationship, coping/stress tolerance, safety/protection, growth/development, nutrition, activity/rest, self-perception, sexuality, life principles, and comfort.
- The process of developing a nursing diagnosis includes analysis of assessment cues, validation of cues, interpretation of cues, clustering of data, consulting NANDA's list of approved nursing diagnoses, and writing the nursing diagnosis statement.
- The nurse who is knowledgeable about the components of the nursing diagnosis process and is equipped to develop the diagnostic statement is able to make appropriate decisions regarding therapeutic nursing interventions.
- To avoid committing errors in the nursing diagnostic process, nurses should ensure that the data collection is complete, that the interpretation of the data is accurate and based upon the nursing and not the medical diagnosis, and that the client's response to a health problem is amenable to therapeutic nursing interventions.
- The barriers that have been identified as preventing the use of nursing diagnosis are the constraints on the time nurses can devote to client care, the continuing organization of health care according to medical diagnosis, the inapplicability of the list of nursing diagnoses to every client situation, the constantly evolving refinement of the nursing diagnosis language, and the availability of numerous approaches for formulation and application of nursing diagnoses.
- Although barriers to the use of nursing diagnosis may be present, they may be overcome by employing specific strategies such as agreeing on a common language, supporting colleagues' use of nursing diagnoses, adopting a nonjudgmental attitude, contributing to the development of nursing diagnosis language through submission of new diagnoses or revising existing diagnoses in the NANDA taxonomy, and continuing to communicate with other nurses at national and international levels.

REVIEW QUESTIONS

1. A nurse reads the following list of nursing diagnoses on a client's plan of care. Which of these statements is written correctly as a nursing diagnosis?
 - a. Acute pain RT pain in right foot
 - b. Impaired skin integrity RT infrequent repositioning by staff
 - c. Impaired swallowing RT stasis of food in oral cavity after chewing
 - d. Chronic confusion RT Alzheimer's disease
2. A client limps into the clinic with pain in the right foot. The physical examination shows that the client is 5 feet 6 inches tall, weighs 275 pounds, and has edema in the right lower extremity. Which of the following statements would be an accurate nursing diagnosis for this client?
 - a. Acute pain RT pain in right foot
 - b. Imbalanced nutrition: more than body requirements
 - c. Impaired mobility RT pain
 - d. Risk for injury RT obesity
3. A client who underwent hip replacement surgery has a nursing diagnosis of impaired physical mobility RT pain. Which of the following nursing interventions would be a priority for a client with this diagnosis?
 - a. Elevating the client's foot
 - b. Administering the prn analgesic medication as ordered
 - c. Providing a walker for ambulation
 - d. Teaching the client techniques for safely transferring from the bed to a wheelchair
4. An elderly client with thin, dry skin has a nursing diagnosis of impaired skin integrity. Which of the following nursing interventions should be implemented? Select all that apply.
 - a. Repositioning the client every 2 hours

- b. Keeping the bed linens dry
 - c. Reducing the client's fluid intake
 - d. Encouraging the client to consume a high-fiber diet
 - e. Making sure that the bed linens are wrinkle-free
 - f. Instructing the client to take deep breaths and cough
5. The nurse makes a nursing diagnosis of risk for impaired physical mobility RT pain. Which of the following is the risk factor for this client?
- a. Immobility
 - b. Impaired skin integrity
 - c. Malnutrition
 - d. Pain

CHAPTER 8

Planning and Outcome Identification

COMPETENCIES

1. Explain the purposes of outcome identification and planning.
2. Describe four elements of the planning component.
3. Describe characteristics of goals and expected outcomes.
4. Discuss the five components in the construction of goals and expected outcomes.
5. Describe problems frequently encountered in planning nursing care.
6. Explain strategies to improve the planning of nursing care.
7. Differentiate dependent, independent, and interdependent nursing interventions.

KEY TERMS

collaboration	independent nursing	nursing order
consultation	interventions	ongoing planning
criteria	initial planning	planning
dependent nursing interventions	interdependent nursing	plan of care
discharge planning	interventions	rationale
expected outcome	long-term goal	short-term goal
goal	nursing intervention	

Planning, the third step of the nursing process, includes the formulation of guidelines used to establish the client's plan of care. Preceding this step is the collection of assessment data and the formulation of nursing diagnoses. After a nurse thoroughly assesses a client and determines the client's unique nursing diagnoses (or problems), a plan of action is developed with specific goals to resolve the nursing diagnoses or health problems. Following the planning component, the nursing process continues with implementation of nursing interventions and evaluation of the client's response to the plan of care.

This chapter explains the planning component of the nursing process. The planning concept is illustrated with theory and examples. Strategies for effective planning of quality nursing care are described together with problems frequently encountered in this stage of the nursing process. The role of critical thinking in planning and outcome identification is emphasized.

PURPOSES OF PLANNING AND OUTCOME IDENTIFICATION

The American Nurses Association (2004) identifies outcome identification and planning as essential principles for ensuring the delivery of competent nursing care and outlines these components in terms of their significance within the nursing process. Although the overall purpose of a client's plan of care should be to maintain or improve health at an optimal level, planning is a framework on which to base scientific nursing practice. Therefore, planning is done in order to provide quality nursing care. Planning also improves staff communication and provides continuity in the delivery of individualized, quality nursing care to all clients. The four critical elements of planning include:

- Establishing priorities
- Setting goals and developing expected outcomes (outcome identification)
- Planning nursing interventions (with collaboration and consultation as needed)
- Documenting

PROCESS OF PLANNING AND OUTCOME IDENTIFICATION

The five steps of the nursing process are at the very core of using scientific reasoning for the delivery of individualized, quality nursing care in any setting (Doenges, Moorhouse, & Geissler, 2006). The ability to make appropriate decisions based on a strong knowledge base and problem-solving strategies is an expected behavior of the professional nurse.

CRITICAL THINKING

Nurses must think critically in order to make intelligent decisions. By applying the critical thinking skills inherent in the nursing process to the client's identified nursing diagnoses, the nurse can focus on resolving the client's problems with greater proficiency.

Planning is sequential, dynamic, and future oriented. Planning includes establishing priorities, identifying goals and expected outcomes, developing nursing interventions, and documenting the client's plan of care. Appropriate guidelines are used to prioritize urgent needs. The client's nursing diagnoses are determined and then ranked by mutual agreement between the nurse and client or significant others. The planning component continues with thorough examination of this prioritized list of nursing diagnoses and determination of the client's goals and desired expected outcomes. After a clear picture is obtained regarding the diagnoses and goals, the nursing interventions can be planned to achieve the desired outcomes.

The planning of nursing care occurs in three phases: initial, ongoing, and discharge. Each type of planning contributes to the coordination of the client's comprehensive plan of care. **Initial planning** involves the development of the beginning of care by the nurse who performs the admission assessment and gathers the comprehensive admission assessment data. Because of progressively shorter lengths of hospitalization, initial planning is important in addressing each prioritized problem, identifying appropriate client goals, and correlating nursing care to hasten resolution of the client's problems. **Ongoing planning** entails continuous updating of the client's plan of care. Every nurse who cares for the client is involved in ongoing planning. As new information

about the client is gathered and evaluated, revisions may be formulated and the initial plan of care becomes further individualized to the client. **Discharge planning** involves critical anticipation and planning for the client's needs after discharge. Discharge planning is a multidisciplinary team effort that focuses on providing a seamless transition across the continuum of care.

Establishing long-term goals is important in successful discharge planning. Goal setting assists in coordinating all health care team members to accomplish the same overall purpose, that is, client discharge. Coordination promotes continuity of care into settings such as restorative care or home health and requires the establishment of priority needs (see the accompanying Nursing Process Highlight display).

In the planning phase, the nurse uses organized (critical) thinking in order to make sound clinical decisions. To think critically is to examine an issue purposefully from a goal-directed perspective. Critical thinking is based on scientific principles and methodologies (Alfaro-LeFevre, 2008). Therefore, critical thinking is necessary for the development of objectives and in the formulation of a blueprint to achieve those objectives. The formulation of objectives is accomplished by using valid and reliable data previously gathered during the assessment phase of the nursing process.

ESTABLISHING PRIORITIES

When an individual client has more than one diagnosis, the nurse and client need to establish priorities to identify which nursing diagnosis will be addressed initially in the plan of care (Carpenito-Moyet, 2007). By communicating this decision-making process to other members of the health care team, the nurse encourages an orderly approach to the achievement of optimal health for each client.

The establishment of priorities is the first element of planning. When establishing priorities, the nurse examines the client's nursing diagnoses and ranks them in order of

physiological or psychological importance. This method organizes a client's nursing diagnoses into a systematic framework for the planning of nursing care. The diagnoses should be mutually ranked by the nurse and client. Involving the client in shared decision-making power helps motivate the client and gives the client a feeling of control, which inspires successful achievement of each goal (Doenges et al., 2006).

Various guidelines are used in determining which nursing diagnosis will be addressed initially. The client's safety, basic needs, and desires, as well as anticipation of future diagnoses, must be considered. One of the most common methods of setting priorities is the consideration of Maslow's hierarchy of needs, which requires that a life-threatening diagnosis be given more urgency than a non-life-threatening diagnosis. Once the basic physiological needs (e.g., respiration, nutrition, hydration, elimination) are met to some degree, the nurse may consider needs on the next level of the hierarchy (e.g., safe environment, stable living condition) and progress up the hierarchy until all the client's nursing diagnoses have been prioritized.

A useful guide for the beginning nursing student would be to examine each nursing diagnosis, determine its level of need, and rank the need in order of priority. Table 8-1 illustrates this process.

Another consideration in the designation of priorities is client preferences. If at all possible, the client should be involved in the decision-making process of establishing priorities. The client must participate in the identification of priorities so that the nature of the problem as well as the client's values are reflected in the selected course of action. If the priorities are not mutually determined, the client's problems will likely remain unresolved. See the accompanying Nursing Process Highlight display on setting mutual priorities.

An additional point regarding the establishment of priorities is the anticipation of future diagnoses. Nursing diagnoses of low and moderate priorities often involve the prevention of anticipated potential or risk diagnoses. Although potential

NURSING PROCESS HIGHLIGHT

Planning

Prioritizing Nursing Diagnoses

Mr. Clyde Morrison, an elderly homeless client, was admitted to the hospital with a medical diagnosis of malnutrition. Identified nursing diagnoses include imbalanced nutrition, less than body requirements related to inability to procure appropriate food; constipation related to inadequate fluid intake; and disturbed body image related to feelings of inadequacy and inability to live up to identified standards. What should the priority ranking of this client's nursing diagnoses be?

TABLE 8-1 Ranking Nursing Diagnoses

NURSING DIAGNOSIS	MASLOW'S HIERARCHY OF NEEDS	RANK
<i>Anxiety</i> related to hospitalization	Safety and security	Moderate
<i>Ineffective coping</i>	Self-esteem	Low
<i>Ineffective airway clearance</i> related to excessive secretions	Physiological	High

Delmar/Cengage Learning

nursing diagnoses may not be a current threat to the client, their seriousness may require that the nurse consider the development of nursing interventions directed toward prevention of the problems. For example, a client in the postanesthesia care unit may have a high-priority nursing diagnosis of *ineffective breathing pattern* related to the anesthesia and sedative drugs. Despite the fact that the client currently has no problem in this area, this diagnosis is indeed the basis for the Postanesthesia Care Unit protocol of monitoring the client closely.

Establishing priorities does not mean that one diagnosis must be totally resolved before giving attention to another diagnosis. Nursing interventions for several diagnoses may be carried out simultaneously. However, at times, it is crucial that the nurse and client correctly identify the order of priority of the client's nursing diagnoses so that maximum effort can be directed toward resolution of the most urgent diagnosis; see Table 8-2.

ESTABLISHING GOALS AND EXPECTED OUTCOMES

After assessing the client, formulating nursing diagnoses, and establishing priorities, the nurse sets goals and identifies and establishes expected outcomes for each nursing diagnosis. The purposes of setting goals and expected outcomes are to provide guidelines for individualized nursing interventions and to establish evaluation criteria for measuring the effectiveness of the nursing care plan.

NURSING PROCESS HIGHLIGHT

Diagnosis

Setting Mutual Priorities

Mr. Jules Gordon has been admitted with third-degree burns of approximately 80% of his body. He is particularly concerned with the nursing diagnosis of *body image disturbance* related to scarring and disfigurement, whereas the nurse's major concern is with the nursing diagnosis of *deficient fluid volume* related to fluid shifts because it is far more life threatening. In this situation, the nurse's and client's priorities are not set mutually because they have separate primary goals. This situation may lead to conflict and interfere with goal accomplishment. What are some ways that this situation can be approached so that both nursing diagnoses may be resolved?

A **goal** is an aim, an intent, or an end. A goal is a broad or globally written statement describing the intended or desired change in the client's behavior, response, or outcome. An **expected outcome** is a detailed, specific statement that describes the methods through which the goal will be achieved. Expected outcomes are addressed through direct nursing care activities, such as client teaching.

Goals

Written goals need to be constructed clearly in order to improve the chances that goals will be achieved. When goals are clearly written, their establishment provides direction for the nursing plan of care and for determination of effectiveness in the evaluation of nursing interventions. A guideline is provided for the desired change in the client, and the client has a clear idea of the direction to be taken for achieving resolution of each nursing diagnosis. Goals establish appropriate evaluation criteria to measure the effectiveness of planned nursing interventions that are directed at resolving the client's individual nursing diagnoses.

Goals should be established to meet the immediate, as well as long-term prevention and rehabilitation, needs of the client. A **short-term goal** is a statement written in objective format demonstrating an expectation to be achieved in resolution of the nursing diagnosis in a short period of time, usually in a few hours or days. A **long-term goal** is a statement written in objective format demonstrating an expectation to be achieved in resolution of the nursing diagnosis over a longer period of time, usually over weeks or months (Alfaro-LeFevre, 2008). See Table 8-3 on page 129 for examples of short-term and long-term goals.

Another consideration is the accuracy in identifying the etiology of the problem. If the etiology of the problem is incorrectly identified, the client may meet the short-term

TABLE 8-2 Prioritizing Nursing Diagnoses with Accompanying Nursing Implications

PRIORITY	DIAGNOSIS	NURSING IMPLICATIONS
High	Ineffective breathing pattern	<ul style="list-style-type: none"> Assess breath sounds. Auscultate lungs. Monitor vital signs. Reposition client.
Moderate	Risk for impaired skin integrity	<ul style="list-style-type: none"> Perform comprehensive skin assessment. Keep skin clean and dry. Provide turning schedule.
Low	Ineffective coping	<ul style="list-style-type: none"> Assist to identify problem. Encourage keeping daily journal. Teach client strategies for expressing feelings.

NURSING DIAGNOSIS	GOALS	EXPECTED OUTCOMES
Sleep deprivation	Client will sleep uninterrupted for 6 hours.	Client will request back massage for relaxation. Client will set limits on family visitation.
Ineffective tissue perfusion: peripheral	Client will have palpable peripheral pulses within 1 week.	Client will identify three factors to improve peripheral circulation. Client's feet will be warm to touch.

Delmar/Cengage Learning

goal but the problem will not be resolved. Thus, it is important to correctly identify the etiology of the problem.

Expected Outcomes

After the goal is established, the expected outcomes can be identified based on the goal. Given the client's unique situation and resources, expected outcomes are constructed to be:

- Realistic
- Mutually desired by the client and nurse
- Attainable within a defined time period

These desired outcomes are the measurable steps toward achieving the previously established goals (Doenges et al., 2006). An expected outcome depicts measurable behavioral change or evidence of change in the client when the goal has been met. Several expected outcomes may be required for each goal. Expected outcomes are used in the evaluation process by providing a standard for comparison to determine if the client successfully accomplished the goal. Because nursing care is based on a holistic approach, expected outcomes may be written in the spiritual, emotional, physiological, developmental, and social dimensions.

When goals and outcomes are written clearly, the nurse can select nursing interventions to ensure that the client's baseline data are thoroughly assessed, individual client needs are identified, and appropriate approaches are used to address needs.

Usually, each nursing diagnosis has one global goal and several expected outcomes. In writing the goal statement, the nurse considers the nursing diagnosis for the formulation of a suitable client behavior that illustrates reduction or alleviation of the nursing diagnosis. These concepts are demonstrated in Table 8-4. In the construction of both goals and expected outcome objectives, essential components include the subject, task statement, criteria, conditions (if necessary), and time frame (Doenges et al., 2006).

See the Uncovering the Evidence on page 130 display for more on goal setting.

COMPONENTS OF GOALS AND EXPECTED OUTCOMES

There are five components of well-constructed goals and expected outcomes: subject, task statement, criteria, conditions, and time frame. An in-depth discussion of each component of an appropriately written goal follows. For clarity of each concept, examples are provided. The examples are designed with the intent of developing skills in goal construction.

Subject

The component to be considered initially in writing a goal is the subject. The subject identifies the person who will perform the desired behavior or meet the goal. In a client-centered plan of nursing care, the client is the person who needs to achieve a desired change in behavior. See the accompanying Nursing Process Highlight for an application of the subject component.

Task Statement

The next component in writing goals is the task statement or the action verb. This component describes what the client will do to achieve the expected change in behavior. The task statement enables the evaluator to determine achievement of the observable behavior. When the actual behavior is stated as a task statement that can be clearly and directly measured, the nurse can determine whether the client is demonstrating achievement of the goal.

Only one task statement should be used for each goal. It is clearer to write separate goals than to try to accurately

UNCOVERING THE

Evidence

TITLE OF STUDY

“Healthcare Professional versus Patient Goal Setting in Intermittent Allergic Rhinitis”

AUTHORS

J. O’Conner, C. Seeto, B. Saini, S. Bosnic-Anticevich, I. Krass, C. Armour, and L. Smith

PURPOSE

To compare the effect of goal setting by a health care professional with client goal setting for the self-management of intermittent allergic rhinitis on severity of symptoms and quality of life.

METHODS

A 6-week parallel group study in which Group A participants designated relevant goals and strategies for responding to allergic rhinitis. Group B participants had their goals and strategies established by a health care professional. The main outcome measures were client-perceived symptom severity and quality of life.

FINDINGS

Both groups demonstrated significant improvements in quality of life and reduction of symptom severity. Group B symptom severity scores improved more. Group B set a greater number of goals that had more specific strategies for improvement.

IMPLICATIONS

Self-management goals established by a health care provider that are tailored to client symptoms lead to better outcomes than goals that are established solely by the client.

O’Conner, J., Seeto, C., Saini, B., Bosnic-Anticevich, B. S., Krass, I., Armour, C., et al. (2008). Healthcare professional versus patient goal setting in intermittent allergic rhinitis. *Patient Education and Counseling*, 70(1), 111–117.

measure a combination of tasks. See the accompanying Nursing Process Highlight for examples of task statements.

Criteria

The next essential component is the criteria of a goal. **Criteria** are standards used to evaluate whether the behavior demonstrated indicates accomplishment of the goal. Criteria may be written in a variety of ways and may include:

- A time limit
- Amount of activity
- Characteristics of accurate performance
- Description of the performance to be followed

NURSING PROCESS HIGHLIGHT

Planning

Subject of Goal

1. By Saturday, the client will ambulate the entire length of the hallway three times a day.
2. The client will demonstrate the technique for self-administration of insulin by Friday.
3. The client will take own radial pulse and obtain the same results as the nurse by Saturday.
4. By Friday, the client will plan a low-salt diet for 24 hours in accordance with the diet plan left by the dietitian.

Question

Who is to achieve the desired behavior in each of the preceding examples?

Because the plan of nursing care is based on the client, the subject is the client.

The nurse should specify the precise performance to be considered acceptable in accomplishment of the goal.

It is not always possible to specify a criterion with as much detail as one would like; however, the nurse should continue to communicate precise criteria as explicitly as possible. To provide better direction to the client, the nurse considers how well the client, family member, or significant other should perform the task. See the accompanying Nursing Process Highlight for examples of criteria.

Conditions

The next component to be included in writing effective goals is the conditions under which the client should perform or demonstrate mastery of the task. Although this component is optional in terms of writing goals, conditions may provide clarity and assist the client to demonstrate the expected behavior. The conditions may include the experiences that the client is expected to have before performing the task. See the accompanying Nursing Process Highlight for examples of conditions.

Time Frame

The last component to be included in writing goals appropriately is the time frame in which the client should perform or demonstrate mastery of the task. A written time frame serves as a parameter for evaluating goal achievement.

PROBLEMS FREQUENTLY ENCOUNTERED IN PLANNING

Planning care is a complex process. Nursing students, as beginners in the use of the nursing process, often fall into some common pitfalls when applying the process to practice.

NURSING PROCESS HIGHLIGHT

Planning

Task Statement

1. By Saturday, the client will ambulate the entire length of the hallway three times a day.
2. The client will demonstrate the technique for self-administration of insulin by Friday.
3. The client will take own radial pulse and obtain the same results as the nurse by Saturday.
4. By Friday, the client will plan a low-salt diet for 24 hours in accordance with the diet plan left by the dietitian.

Question

What is the action that the client is expected to do in each of the preceding examples?

The examples demonstrate exactly what the client is to perform (“will ambulate”; “will demonstrate”; “will take”; and “will plan”).

These pitfalls are described with the intent of providing a clear direction for the use of this process and proposing suggestions for avoiding common errors.

In regard to writing goals, errors frequently observed in this component involve improper format. Format errors include goals that are nurse centered instead of client centered, unrealistic, negative rather than positive, generically copied from a reference and not individualized to the client, unmeasurable, nonspecific, nonbehavioral, vague, wordy, and lacking a time frame.

Another challenge in the development of goals and expected outcomes is the establishment of appropriate time frames for accomplishment of the intended results. Although this component may be difficult at first to master, nursing students should practice writing goals that are realistic and include appropriate time frames using available literature and resources to gain expertise. It is preferable for a goal to include an excessively short, rather than an excessively long, time frame because the goal is brought to attention in the evaluation process more frequently. By inserting the time frame “daily” for specific goals, the expected outcome will be brought up frequently for evaluation. Through a process of building on continued professional growth and experience, students and novice nurses will become more adept and realistic in applying the nursing process to client situations.

Finally, novices as well as experienced nurses tend to make decisions for clients in a paternalistic fashion by deciding what is best for the client without input from the client. To correct this problem, the nurse must establish a trusting nurse-client relationship that promotes mutual understanding and caring. The nurse should encourage clients to make their own decisions regarding health care and respect those decisions.

NURSING PROCESS HIGHLIGHT

Planning

Criteria

1. By Saturday, the client will ambulate the entire length of the hallway three times a day.
2. The client will demonstrate the technique for self-administration of insulin with aseptic technique.
3. The client will take own radial pulse and obtain the same results as the nurse by Saturday.
4. By Friday, the client will plan a low-salt diet for 24 hours in accordance with the diet plan left by the dietitian.

Question

What are the standards that will be used to evaluate the client’s achievement of the objective in each of the preceding examples?

The examples indicate the standards used to evaluate whether the behavior demonstrated by the client indicates that the goal has been reached. The first example includes a time limit and the amount of activity.

Example 2 demonstrates important characteristics of performance accuracy by stating “with aseptic technique.”

Example 3 sets standards of performance accuracy and includes a time limit.

Example 4 includes a time limit and a sample plan to be followed.

NURSING PROCESS HIGHLIGHT

Planning

Conditions

1. By Saturday, the client will ambulate the entire length of the hallway three times a day with the use of a walker.
2. By Friday, the client will plan a low-salt diet for 24 hours in accordance with the diet plan left by the dietitian.

Question

What are the conditions under which the activity must be performed in each of the preceding examples?

Example 1 states the condition with which the activity must be performed (“with the use of a walker”). Example 2 cites the condition by which the activity must be performed (“in accordance with the diet plan left by the dietitian”).

PLANNING NURSING INTERVENTIONS

Once the goals have been mutually agreed on by the nurse and client, the nurse should use a decision-making process to select appropriate nursing interventions. A **nursing intervention** is an action performed by a nurse that helps the client to achieve the results specified in the goals and expected outcomes. These actions are based on scientific principles and knowledge from nursing, behavioral, and physical sciences. Usually, several nursing interventions are developed for each of the goals identified for the client (Ralph & Taylor, 2008). It is important to identify as many nursing interventions as possible so that if one proves to be unsuitable, others are readily available. The interventions are prioritized according to the order in which they will be implemented.

The delivery of quality, individualized nursing care is greatly enhanced by combining critical thinking and the scientific problem-solving approach. Through critical thinking, sound conclusions are reached in the selection of nursing interventions to prevent, reduce, or eliminate the nursing diagnoses or problems.

Several factors can assist the nurse in selecting nursing interventions. Just as the client's goals can be derived from the nursing diagnosis, the nursing interventions can be developed from the etiology of each nursing diagnosis. The effective nurse plans interventions that are directed toward the causative factors of the client's nursing diagnosis or problem. For example, for a client with angina who may have the nursing diagnosis of *pain* related to myocardial ischemia, an appropriate nursing intervention would be to help the client conserve energy (i.e., bed rest).

The nurse may use various guidelines in selecting appropriate nursing interventions. These guidelines include nurse practice acts, state boards of nursing regulations, and professional standards for nursing care. In addition to legal and professional guidelines, other factors affect the selection of appropriate nursing interventions. The Nursing Checklist provides a list of questions that are helpful in selecting interventions.

When determining which nursing interventions to use, the nurse should critically consider the consequences and the risks of each intervention. After considering these factors, the nurse selects interventions that are most likely to be effective with the minimum of risk. Table 8-5 applies the guidelines for selection of appropriate nursing interventions related to a specific nursing diagnosis.

After setting the goals and planning the appropriate nursing interventions, the nurse writes nursing orders to communicate the exact nursing interventions that are to be implemented for the client. A **nursing order** is a statement written by the nurse that is within the realm of nursing practice to plan and initiate. These statements specify direction and individualize the client's plan of care. For example, a prescribing practitioner's order to force fluids must be specified in the nursing order as the number of milliliters per hour or per shift (e.g., 100 mL/h on Day shift = 800 mL; Evening shift = 800 mL; Night shift = 400 mL).

NURSING CHECKLIST

SELECTING APPROPRIATE NURSING INTERVENTIONS

- Is the action realistic in terms of client ability?
- Can the intervention be performed safely and accurately by the nurse?
- Are the necessary resources available?
- Is the intervention compatible with the client's value system?
- Can the intervention be safely carried out with the other planned therapies?

TABLE 8-5 Nursing Interventions: Selection Guidelines

Nursing diagnosis	Acute pain related to myocardial ischemia
Goal	Client will resume normal activities of daily living.
Expected outcome	Client will verbalize relief of pain.
Etiology	Myocardial ischemia
Nursing interventions	<p>Assess pain characteristics such as location, quality, severity, duration, onset, relief.</p> <p>At first signs of pain, instruct client to relax and discontinue activity.</p> <p>Instruct client to take sublingual nitroglycerin as ordered.</p> <p>If pain continues after repeating doses every 5 minutes for a total of three pills, notify the prescribing practitioner.</p> <p>Administer oxygen as prescribed.</p> <p>Note time interval between episodes of pain.</p> <p>Maintain bed rest and quiet environment to decrease oxygen demands.</p> <p>Give analgesic medications as prescribed.</p> <p>Offer assurance and emotional support by explaining all treatments and procedures and by encouraging questions.</p>

Delmar/Cengage Learning

Ensuring that nursing orders are well written requires several essential elements. These elements include the nursing order date, action verb, detailed description, time frame, and signature (Wilkinson, 2006). See Table 8-6 for a summary of the elements of a nursing order.

The type of nursing order written is determined by the client problem. The nurse is responsible for writing nursing orders that involve health promotion, observation, prevention, and treatment (Wilkinson, 2006). Table 8-7 gives examples of types of nursing orders.

Categories of Nursing Interventions

Nursing interventions are classified according to three categories: independent, interdependent, and dependent. **Independent nursing interventions** are nursing actions initiated by the nurse that do not require an order from another health care professional. These interventions are sanctioned by professional nurse practice acts derived from licensure laws. In many states, the nurse practice acts allow independent nursing interventions regarding activities of daily living, health education, health promotion, and counseling. An example of an independent nursing intervention is the nurse's action to elevate a client's edematous extremity.

Interdependent nursing interventions are those actions that are implemented in a collaborative manner by the nurse with other health care professionals. **Collaboration** is a partnership in which all parties are valued for their contribution. Collaboration is used to gather data, plan, implement, evaluate, and gain objectivity by examining another's viewpoint. Interdependent nursing interventions allow the client's nursing diagnoses to be resolved on the basis of recommendations by an interdisciplinary health care team. For example, a

TABLE 8-6 Elements of Nursing Orders

Date	Date on which the order is written Is updated to reflect review and revision
Action verb	Directs nursing activities Example: explain, demonstrate, auscultate
Detailed description	Precise clarification of the action Explains what, where, when, by whom, and how
Time frame	Specifies frequency and duration that action is to be performed
Signature	Indicates person who writes the order Implies legal accountability

Delmar/Cengage Learning

TABLE 8-7 Types of Nursing Orders

TYPE	DESCRIPTION	EXAMPLE
Health promotion	Nursing orders that encourage behaviors leading to a higher level of wellness	Teach the importance of a daily exercise regimen.
Observation	Nursing orders that include observations regarding potential complications as well as observations of client's current responses	Auscultate lungs q4h.
Prevention	Nursing orders that direct nursing care in the reduction of risk factors or the prevention of complications	Turn, cough, and deep breathe q2h.
Treatment	Nursing orders that include teaching, referrals, or physical care necessary in the treatment of an existing problem	Refer client to occupational therapist for assistance with skills for activities of daily living.

Delmar/Cengage Learning

client care conference or a discharge planning committee uses an interdisciplinary approach that includes health care members such as a nursing supervisor, a home health care nurse, a dietitian, a social worker, and a physical therapist. The nurse assumes the responsibility of being both the primary coordinator of the client's plan of nursing care and the intermediary of interdepartmental collaboration (Doenges et al., 2006).

In addition to collaboration, the planning of interdependent nursing interventions may also include consultation. **Consultation** is a method of soliciting help from a specialist in order to resolve nursing diagnoses. The need for consultation arises when individual nurses identify a problem that cannot be solved using their own knowledge, skills, or resources. In the management of the client's plan of care, nurses may consult with other health care personnel such as clinical nurse specialists, nutritionists, physical therapists, and social workers. Nurses frequently consult to verify assessment data or to obtain clinical advice, for example, discussing the effects of chemotherapy on a client's self-esteem with an oncology clinical nurse specialist. Consultation can be informal or formal. An informal consultation may simply involve asking another practitioner for ideas regarding a nursing problem. Some agencies have a formal protocol for the consultation of a health professional and may require that certain

forms be completed. Steps in formal consultation reflect a logical sequence and include:

- Identifying the problem
- Collecting all relevant data
- Selecting a suitable consultant
- Communicating unbiased data regarding the problem
- Discussing recommendations with the consultant
- Incorporating the recommendations into the client's plan of care

The consultation process often generates new approaches to the client's individualized plan of care. Acquiring supplementary knowledge may help in ensuring that the best conceivable plan of care is being developed. In addition, nurses who have sought the help of a consultant are presented with an opportunity to learn knowledge and/or skills that can be applied to future situations.

Dependent nursing interventions are those actions that require an order from another health care professional. An example of a dependent intervention is administration of a medication. Although this intervention requires specific nursing knowledge and responsibilities, in many states it is not within the realm of legal nursing practice to prescribe medications. The nurse may not order medications but, when administering them, the nurse is responsible for knowing the classification, the pharmacologic action, normal dosage, side effects, adverse effects, contraindications, and nursing implications of the drugs. Dependent nursing interventions must always be guided by appropriate knowledge and judgment. Many state nurse practice acts sanction advanced practice registered nurses to prescribe medications. In those states, prescriptive authority is an independent intervention for advanced practice nurses. Figure 8-1 illustrates the three categories of nursing interventions.

All nursing interventions require critical thinking in making appropriate nursing judgments. Alfaro-LeFevre (2008) states that the development of critical reasoning skills by nurses is a progressive process that requires a dedication to examine common health problems, participate in diverse clinical experiences, and prepare for delivery of care in clinical settings. Given the emphasis on critical thinking in the planning step of the nursing process, the nurse does not automatically carry out a prescribing practitioner's order without due

SAFETY FIRST

NURSING JUDGMENT

All nursing interventions must be guided by appropriate knowledge and judgment. An in-depth knowledge base is necessary to recognize an error and take corrective action.

consideration. All requested orders are given consideration for their appropriateness. See the Safety First display. The use of rationales helps the nurse practice decision making and substantiate judgments. The rationales should accompany the nursing intervention or nursing order statement on the written plan of nursing care. A **rationale** is an explanation based on theories and scientific principles of natural and behavioral sciences and the humanities.

EVALUATING CARE

Evaluating care involves determining the client's progress toward achievement of expected outcomes. Effective planning is essential if evaluation is to be effective. In other words, the planned outcomes are the yardsticks by which effectiveness of therapies is evaluated. If there is no stated expectation of care (i.e., client outcome), there is nothing against which to measure progress.

NURSING OUTCOMES CLASSIFICATION (NOC)

Recently, there has been increased emphasis by the nursing profession on evaluating outcomes. Nurse researchers (Moorhead, Johnson, Maas, & Swanson, 2007) at the University of Iowa have developed classifications of client outcomes, the Nursing Outcomes Classification (NOC). The NOC provides a standardized language that can be used to measure the effects of nursing practice on client outcomes. The NOC

B.

C.

FIGURE 8-1 Examples of types of nursing interventions: (A) Independent—assisting with hygiene needs; (B) Interdependent—multidisciplinary team meeting; (C) Dependent—performing a wound culture DELMAR/CENGAGE LEARNING

FIGURE 8-2 Relationship between Nursing Classification Systems DELMAR/CENGAGE LEARNING

outcomes, which are used in the United States and other countries, are constantly undergoing research to validate application to clinical practice. Figure 8-2 illustrates the relationship between the nursing classification systems. Just as the North American Nursing Diagnosis Association International (NANDA-I) and the Nursing Interventions Classifications (NIC) are continuing to develop standardized nursing language relative to diagnosis and intervention, the NOC is striving toward a similar goal of standardized language for classifying nursing outcomes. The NOC system can be used to enhance decision making in clinical practice and research.

Linking nursing interventions to improved client outcomes through scientific research is important. Nurse researchers who are observing, measuring, and studying client outcomes believe that outcomes indicate the quality or effectiveness of the nursing interventions provided. The use of classification systems in nursing promotes nurses' descriptions of their contributions and helps validate the value of nursing activities. The accompanying Community Considerations display lists some selected outcomes relevant to safety maintenance for an elderly client being cared for in the home. Strengthening the links between nursing interventions and client outcomes will benefit not only clients, but nursing as well. Having solid research evidence that documents the effectiveness of nursing care on client outcomes will influence political and financial decisions relative to nursing.

The NOC taxonomy focuses on function, physiology, psychosocial aspects, health knowledge and behavior, and perceived self-health and family health. The NOC system, which defines over 330 client outcomes that are sensitive to nursing interventions, allows nurses to evaluate client status over time.

PLAN OF CARE

The **plan of care** is a written guide that organizes data about a client's care into a formal statement that will be used to help the client achieve optimal health. Nursing care plans usually include components such as assessment, nursing diagnoses, goals and expected outcomes, nursing interventions, and evaluations. The nurse begins the nursing care plan on the day of admission and continually updates and individualizes the client's plan of care until discharge.

The plan of care directs the efforts of the entire health care team regarding each client. This plan promotes the health care team's delivery of holistic, individualized, and goal-oriented care to the client. Attention to a comprehensive assessment of the entire person allows for a holistic approach. Individualization is enhanced by continuous reviewing and

Nursing Outcomes Classification (NOC)

Knowledge of Personal Safety for a Home Health Client

- Description of fall prevention measures
- Description of risk reduction measures
- Description of home safety measures
- Description of emergency procedures
- Description of community safety risks

updating of the plan of care. A carefully formulated written plan of care prioritizes problems and addresses short- and long-term needs of the client. The written plan of care authenticates activities of assessment by maintaining written records and providing evidence of nursing interventions, the client's response to nursing interventions, and changes in the client's condition.

Although plans of care differ in various institutions from handwritten to computerized forms, they all have the same basic elements in common. The plan of care is realistically designed and customized to each individual client's health status and is the final result of the planning component of the nursing process. The nursing plan of care documents health care needs, coordinates nursing care, promotes continuity of care, encourages communication within the health care team, and promotes quality nursing care.

TYPES OF CARE PLANS

There are several types of care plans. These different types include student-oriented, standardized, institutional, and computerized care plans.

Student-Oriented Care Plan

The student-oriented care plan promotes learning of problem-solving skills, the nursing process, verbal and written communication skills, and organizational skills. This comprehensive care plan focuses on teaching the process of planning care. Therefore, care plans developed by student nurses in educational settings are generally more detailed than the plans used by nurses in daily practice. Educational programs vary, but usually the student-oriented care plan begins with assessment and proceeds in a sequential manner, concluding with the plan for evaluation.

Standardized Care Plan

The standardized care plan is a preplanned, preprinted guide for the nursing care of client groups with common needs.

This type of care plan generally follows the nursing process format (i.e., problem, goals, nursing orders, and evaluation). The nurse may use standardized care plans when a client has predictable, commonly occurring problems. Individualization may be accomplished by the inclusion of additional handwritten notes on unusual problems or circumstances unique to the client.

Institutional Care Plan

Institutional nursing care plans are concise documents that become a part of the client's medical record after discharge. The Kardex nursing care plan is an example of this type of care plan. The institutional nursing care plan may simply include the problem, goal, and nursing action. In addition, the Kardex nursing care plan may be expanded to include assessment, nursing diagnosis, goal, implementation, and evaluation.

Computerized Care Plan

Computers are used for creating and storing nursing care plans and can generate both standardized and individualized nursing care plans. The nurse selects appropriate diagnoses from a menu of possible goals and nursing interventions. The nurse has the option of reading the client's plan of care from the computer screen or printing out an updated working copy.

STRATEGIES FOR EFFECTIVE CARE PLANNING

In planning quality nursing care for each client, the nurse assumes responsibility for the coordination of total nursing care. The nurse coordinates the participation of various health care team members to incorporate their recommendations into the delivery of quality nursing care. Critical thinking assists the nurse in establishing collaborative relationships with other members of the health care team and managing complex nursing systems; see the Spotlight On: Caring display that discusses coordination of care.

An important strategy for effective planning is clear communication of the client's plan of care to other health care personnel. The nurse must always communicate the plan of

SPOTLIGHT ON...

Caring

Coordination of Care

Mr. Eduardo Rodriguez has been admitted with arthritis. His left knee is extremely edematous, and the prescribing practitioner has ordered heat application of 100°F to the left knee four times a day for 2 hours. In considering the appropriateness of this order, the nurse detects an error regarding the time frame because heat produces maximum vasodilation in 20 to 30 minutes to dissipate the edema; further application of heat may lead to a rebound phenomenon of tissue congestion and vessel constriction, as well as potential burns. At this point, the nurse needs to seek clarification of the order from the prescribing practitioner. What would be appropriate methods of handling this situation?

care in clear, precise terms, avoiding vague terminology such as *improved*, *adequate*, and *normal*.

Another strategy for effective planning is to establish a realistic nursing plan of care because this will avoid setting a goal that is too difficult or impossible to achieve. If a goal is too ambitious or is unattainable, the client and nurse may become discouraged or apathetic about the resolution of nursing diagnoses. In addition, goals should be measurable. Quantitative terms assist in the determination of measurement. Finally, the goals should be future oriented. Because a goal is an aim or a desired achievement, goals should be written in future tense format.

Once appropriate nursing diagnoses are individualized to the client, the plan of care has a stable framework on which an optimum level of wellness for the client can be based. Although some clients may not achieve complete resolution of all nursing diagnoses, the nursing plan of care that is individualized can improve health to the client's optimal level.

KEY CONCEPTS

- The outcome identification and planning component of the nursing process is a sequential, orderly method of using problem-solving skills and critical thinking to formulate a nursing plan of care to resolve nursing diagnoses.
- The planning component of the nursing process includes establishing priorities, setting goals, developing expected outcomes, selecting nursing interventions, and documenting the plan of care.
- The purposes of outcome identification and planning are to provide direction for nursing care, to improve staff communication, and to provide continuity of nursing care.
- The establishment of priorities may be guided by such factors as endangerment of well-being, Maslow's hierarchy of needs, client preferences, and anticipation of future diagnoses.

- Setting goals and expected outcomes provides guidelines for directing nursing interventions and establishes evaluation criteria by deciding on goals that illustrate a desired change in the client's behavior.
- Goals and expected outcome objectives include the components of subject, task statement, criteria, conditions, and time frame.
- Two common problems frequently encountered in planning goals are improper format and unrealistic, nonmeasurable qualities.
- In planning nursing care, the nurse uses an expansive scientific knowledge base and critical thinking to select independent, interdependent, and dependent nursing interventions guided by local and federal standards of care.
- The plan of care documents health care needs, coordinates nursing care, promotes continuity of care, encourages communication within the health care team, and promotes quality nursing care.
- Strategies for effective care planning include communication of the client's plan of care within the health care team, establishment of a realistic plan of care, and formulation of measurable and future-oriented goals.

REVIEW QUESTIONS

- Which of the following best describes the plan of nursing care?
 - Client assessment data, medical treatment regime and rationales, and diagnostic test results and significance
 - Prescribing practitioner's orders, demographic data, and medication administration and rationales
 - Collected documentation of all team members providing care for the client
 - Assessment data, nursing diagnoses, goals and expected outcomes, and nursing interventions
- What is the main purpose of the expected outcome?
 - To describe the education plans to be taught to the client
 - To describe the behavior the client is expected to achieve as a result of nursing interventions
 - To provide a standard for evaluating the quality of health care delivered to the client during the hospital stay
 - To make sure that the client's treatment does not extend beyond the time allowed under the diagnosis-related group system
- Which of the following are the essential components of an expected outcome?
 - Nursing diagnosis, interventions, and expected client behavior
 - Target date, nursing action, measurement criteria, and desired client behavior
 - Nursing action, client behavior, target date, and conditions under which the behavior occurs
 - Client behavior, measurement criteria, conditions under which the behavior occurs, and target date
- When planning care, which of the following should the nurse use as a guideline?
 - Choose actions that a nurse can perform without leaving the unit or consulting with medical staff.
 - Make intervention statements specific to ensure continuity of care.
 - Write interventions in general terms to allow maximum flexibility and creativity in delivering nursing care.
 - Make sure that nursing care activities receive priority over other aspects of the treatment regime.
- Which of the following statements is correctly stated as a client expected outcome?
 - Client will ambulate on fourth postoperative day.
 - Client will ambulate safely.
 - Client will be able to safely walk down the hallway.
 - Client will safely walk unassisted to the end of the hallway within 4 days.

Knowing is not enough; we must apply. Willing is not enough; we must do.

—GOETHE

CHAPTER 9

Implementation

COMPETENCIES

1. Describe the purposes of the implementation step of the nursing process.
2. Explore the types of skills required for effective implementation.
3. Discuss various implementation activities that nurses execute as directed by the nursing plan of care.
4. Explain the nurse's roles and responsibilities in the delegation of care to assistive personnel and their impact on implementation.
5. Identify the specific types of nursing interventions that are implemented by the nurse and the characteristics of each type.
6. Discuss the Nursing Interventions Classification (NIC) system.
7. Discuss the importance of documentation in the implementation process.

KEY TERMS

case management
delegation
functional nursing
implementation

modular nursing
nursing intervention
primary nursing
protocol

rationale
standing order
team nursing
total client care

Implementation, the fourth step in the nursing process, involves the execution of the nursing plan of care that was developed during the planning phase. It involves completion of nursing activities to accomplish predetermined goals and to make progress toward achievement of specific outcomes. The implementation phase of the nursing process, as with the other phases of the process, requires a broad base of clinical knowledge, careful planning, critical thinking and analysis, and judgment on the part of the nurse.

This chapter discusses the purposes of implementation, the specific skills associated with effectively implementing the nursing plan of care, and the activities involved in this process. Although identified as the fourth step of the nursing process, the implementation phase begins with assessment and continually interacts with the other steps of the process to reflect the changing needs of the client and the response of the nurse to those needs.

PURPOSES OF IMPLEMENTATION

Implementation is directed toward a fulfillment of client needs that results in health promotion, prevention of illness, illness management, or health restoration in a variety of settings including acute care, home health care, ambulatory clinics, or extended care facilities. Implementation also involves delegation of tasks and documentation of nursing interventions.

The American Nurses Association (2004) describes the standards applicable to implementation in terms of both a standard of care and standards of professional performance. Adherence to these standards requires that the nurse have a current knowledge base, be proficient with technical and communication skills, and use sound judgment in determining safe and efficient use of personnel and materials.

REQUIREMENTS FOR EFFECTIVE IMPLEMENTATION

The implementation phase of the nursing process requires cognitive (intellectual), psychomotor (technical), and interpersonal communication skills. These skills serve as vehicles with which effective nursing care can be delivered and are used either in conjunction with each other or individually as required by the client and the specific needs of the situation.

COGNITIVE SKILLS

Cognitive skills enable nurses to make appropriate observations, understand the rationale for the activities performed, and appreciate how differences among individuals influence nursing care. Critical thinking is an important element within the cognitive domain because it helps nurses to analyze data, organize observations, and apply prior knowledge and experiences to current client situations.

PSYCHOMOTOR SKILLS

Proficiency with psychomotor skills is necessary to safely and effectively perform nursing activities. Nurses must be able to handle medical equipment with a high degree of competency and to perform skills such as administering medications and assisting clients with mobility needs (e.g., positioning and ambulating).

INTERPERSONAL SKILLS

The use of interpersonal skills involves communication with clients and families as well as with other health care professionals. The nurse-client relationship is established through the use of therapeutic communication that helps ensure a beneficial outcome for the client's health status. Interaction between members of the health care team promotes collaboration and enhances holistic care of the client. Communication is also the mechanism by which nurses teach clients, families, and other community groups.

IMPLEMENTATION ACTIVITIES

Nurses perform a variety of activities that are designed to assist clients in meeting needs. Nursing implementation activities include:

- Ongoing assessment
- Establishment of priorities
- Allocation of resources
- Initiation of nursing interventions
- Documentation of interventions and client responses

These activities are interactive, and each is discussed in further detail.

ONGOING ASSESSMENT

The nursing plan of care is based on the initial assessment data collected by the nurse and the nursing diagnoses derived

from those data. Because a client's condition can change rapidly, or new data may become available, ongoing assessment is necessary to validate the relevance of proposed interventions. Goals, expected outcomes, and interventions may need to be altered as new data are collected or progress toward outcome achievement is evaluated. Although a focused assessment should be completed during the initial interaction with the client, continuous observations during the implementation process allow for adaptations to be made to better individualize care. See the accompanying Nursing Process Highlight display.

It is not unusual for nursing diagnoses to change or to be resolved in a short period of time. For example, the nursing care plan for a preoperative client might include an intervention to teach her about the use of a patient-controlled analgesia (PCA) pump. As the use of this equipment is being demonstrated, the nurse observes that the client is unable to depress the button easily with the fingers of her right hand. The client informs the nurse that she forgot to mention that her joints swell occasionally and she has very little strength in her hand during these times. This information is essential for both developing a nursing diagnosis concerning the client's impaired physical mobility and determining appropriate teaching methods for use of the PCA pump.

Ongoing assessment demands attention to verbal and non-verbal cues from the client and requires knowledge of expected responses to specific interventions. If nurses observe that responses are different from those expected, this assessment data can lead to changes in expected outcomes and accompanying interventions.

Ongoing assessment is especially important in home health care or extended care settings when contact with skilled health care providers might occur less frequently and the length of time that the care is required varies (see the accom-

panying Community Considerations display). The nurse's assessment and clinical judgment often determine whether the client needs continued care or referral to other health care providers.

ESTABLISHMENT OF PRIORITIES

Following ongoing assessment and review of the problem list, priorities are determined for implementation of care. Priorities are based on:

- Which problems are deemed most important by the nurse, client, family, or significant others
- Activities previously scheduled by other departments (e.g., surgery, diagnostic testing)
- Available resources

The change-of-shift report can also be a valuable tool in determining priorities. A client's condition can change quickly and frequently—especially in acute care settings—requiring that the nurse exercise strong clinical judgment and maintain flexibility in organizing care. For example, the nursing care plan for a client who had hip replacement surgery might reflect a priority nursing diagnosis of *impaired physical mobility* with interventions focused toward learning to ambulate. When the nurse listens to the client's breath sounds on a particular morning, it is noted that breathing is more labored and crackles can be auscultated in the lung bases. This assessment is noted on the change-of-shift report, and the priorities of interventions change to focus on this new development.

Time management is important whether the nurse is caring for one client or a group of clients. It is helpful to

NURSING PROCESS HIGHLIGHT

Implementation

Relationship between Assessment and Implementation

Mrs. James, who has been diagnosed with diabetes, will be discharged from the hospital within a few days. The expected outcome in the nursing plan of care is that Mrs. James will correctly and accurately withdraw the prescribed amount of insulin and inject her own insulin. While implementing this teaching intervention, you observe that Mrs. James is unable to visualize the correct amount of insulin to withdraw in the syringe because of her impaired vision. How does the assessment of her response affect your interventions related to the teaching strategies that need to be implemented with the client?

COMMUNITY CONSIDERATIONS

Care in the Home

An important element in the ongoing assessment of clients in the home is the appraisal for the risk of falls. The following questions can help the nurse determine the seriousness of this risk.

- Which medications are currently prescribed for the client, and what are their effects on the central nervous system?
- Are elimination problems such as incontinence being experienced?
- Has the mental status of the client recently changed in terms of orientation to time and place?
- Does the client's level of mobility require ambulatory assistance devices such as a cane, walker, or wheelchair?
- If the client has previously experienced a fall, what were the conditions under which it occurred?

make a list of tasks that need to be accomplished throughout the day and to create a worksheet outlining a target time for these activities. Those activities with specified times for completion should be scheduled first. For example, medications usually allow a narrow time frame for administration and must be scheduled at specific times on the worksheet. An example of a worksheet that outlines a plan for activities is shown in Table 9-1. The time allotted for activities depends on the complexity of the task and the amount of assistance required by the client. See Table 9-2 on page 143 for an example of a worksheet for a group of clients.

ALLOCATION OF RESOURCES

Before implementing the nursing plan of care, the nurse reviews proposed interventions to determine the level of knowledge and the types of skills required for safe and effective implementation. The assessment provides data for determining

if an activity can be performed independently by the client, can be completed with assistance from family, or requires assistance of health care personnel.

Delegation of Tasks

Whereas some interventions are complex and require the knowledge and skills of a registered nurse, other interventions are relatively simple and can be delegated to assistive personnel. **Delegation** is the process of transferring a selected nursing task in a situation to an individual who is competent to perform that specific task. It must be remembered that although some activities can be assigned to other health care personnel, the registered nurse remains accountable for appropriate delegation and supervision of care provided by these individuals. See the accompanying Safety First display. See Chapters 11 and 12 for more information on delegation.

Types of Nursing Management Systems

Wise use of resources dictates that tasks be assigned to the most cost-effective level of personnel who can safely and proficiently perform the activity. The nursing management system often determines the numbers and types of personnel available. Changes in health care delivery in recent years have resulted in an increasing emphasis on cost containment and have subsequently created several unique management models. The redesign of the workplace in many health care agencies has included cross-training of employees, with nurses frequently assuming responsibilities formerly assigned to other health care providers. For example, nurses might draw blood for laboratory tests, perform electrocardiograms, or administer respiratory treatments, as care is focused around the client rather than the various departments in the agency. Nurses in community health settings have traditionally exercised a variety of roles in their practice. As health care delivery continues to evolve in this country, a variety of innovative approaches will emerge to better meet the needs of clients. The most common management systems currently used include functional nursing, team nursing, primary nursing, total client care, modular nursing, and case management.

FUNCTIONAL NURSING The **functional nursing** approach divides care into tasks to be completed and uses various levels of personnel depending on the complexity of the

TABLE 9-1 Sample Worksheet of Nursing Activities (One Client)

TIME	ACTIVITY
6:45 AM	Listen to change-of-shift report.
7:00	Perform head-to-toe assessment of client, including vital signs.
7:10	Check routine medication times.
7:30	Chart assessment findings.
8:00	Serve breakfast. While client eats breakfast, review chart for new laboratory test data.
8:30	Record I and O after breakfast; remove breakfast tray.
8:40	Gather supplies for hygiene. Assist with AM care.
9:00	Administer medications.
9:15	Assist up to chair. Show films about diabetic skin care.
10:00	Document interventions and observations on chart.
10:15	Review care plan for any needed revisions.
10:30	Report status of client to charge nurse. Attend inservice on IV care.
11:45	Take and record vital signs.

Delmar/Cengage Learning

SAFETY FIRST

LEGAL RESPONSIBILITY AND DELEGATION

The registered nurse is legally responsible for all nursing care given. Even though a task may be delegated, the nurse is accountable for safe performance of that task.

TABLE 9-2 Sample Worksheet of Nursing Activities (Group of Clients)

	7 AM	8 AM	9 AM	10 AM	11 AM	NOON
351 Hughes	V/S assess		Meds	Assist to chair	V/S Meds	Meds
352 Parsons	V/S assess	Feed	To PT	D/C plan	V/S	Telem. strip
353 Crowson	V/S assess	Ck. PTT results	Meds; Amb. in hall	Show video	BP sit/stand Meds	Telem. strip

Delmar/Cengage Learning

assignment. Members of the staff perform their assigned tasks for each client. For example, one nurse may assess each client and document findings and another may give all medications and treatments. Another nurse may be assigned to complete client teaching or discharge planning (process that enables the client to resume self-care activities before leaving the health care environment). One nursing assistant might serve all trays and collect intake and output records for each client while another is responsible for giving baths or making beds.

The advantage of this system is that a large number of clients can be cared for by a relatively small number of personnel. In addition, it allows the use of less skilled (and less expensive) personnel for some tasks and allows personnel to be used in areas for which they have special knowledge or skill. However, this system can also result in fragmented and depersonalized care and may invite omissions in care because no *one* person is responsible for the total care of the client.

TEAM NURSING The **team nursing** approach uses a variety of personnel (professional, technical, and unlicensed) in

the delivery of nursing care. The registered nurse is the leader of the team and is responsible for supervision of the team members as well as planning and evaluating the results of caregiving activities. This management system uses professional nurses for skilled observations and interventions and provision of direct care to acutely ill clients, while licensed practical nurses care for less acutely ill clients and nursing assistants are responsible for serving trays, making beds, and assisting the nurses with other tasks. This management system is frequently used because it is cost-effective and provides more individualized care than the functional approach.

PRIMARY NURSING In the **primary nursing** management system, the professional nurse assumes full responsibility for total client care for a small number of clients. Although care may be delegated to nurse associates for shifts when the primary nurse is not in attendance, the primary nurse maintains responsibility for total client care 24 hours a day (see Figure 9-1). The primary nurse sets health care goals with the client and plans care to meet those goals. The principal advantage of this approach is the continuity of care inherent

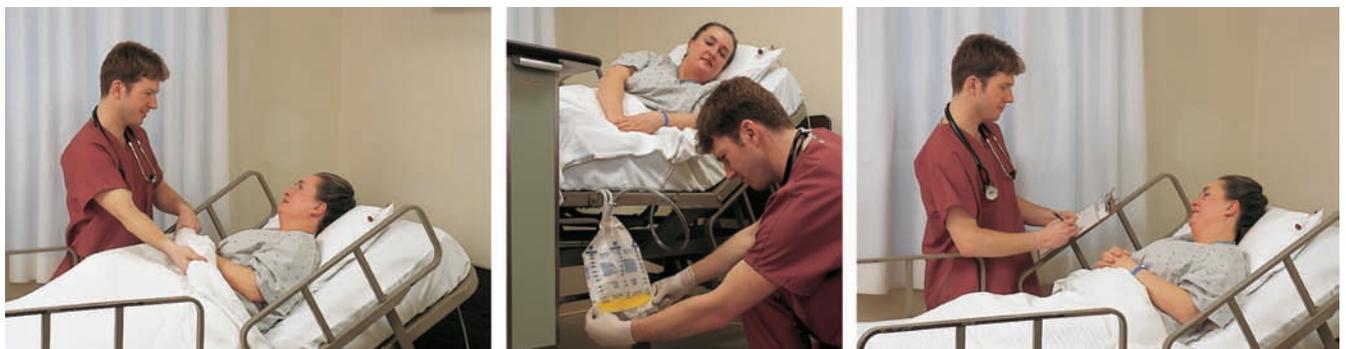

FIGURE 9-1 Delivery of care via the primary nursing management system. This primary nurse is responsible for meeting the total health care needs of this client. DELMAR/CENGAGE LEARNING

in the system. Primary nursing is most effective with a total staff of registered nurses, which makes this system expensive to maintain. Due to the expense and the current limited supply of registered nurses, the primary nursing model is rarely used except in critical care areas.

TOTAL CLIENT CARE AND MODULAR NURSING Total client care and modular nursing are variations of primary nursing. Although these systems imply that one nurse is responsible for all the care administered to a client, responsibility for the client actually changes from shift to shift with the assigned caregiver. These systems use both registered nurses and licensed practical nurses; the registered nurses are assigned to more complex client situations. A unit manager or charge nurse typically coordinates activities on the unit. Modular nursing attempts to assign caregivers to a small segment or “module” of a nursing unit, ensuring that clients are cared for by the same personnel on a regular basis.

CASE MANAGEMENT In the case management system, the nurse assumes responsibility for planning, implementing, coordinating, and evaluating care for a given client, regardless of the client’s location at any given time. This approach is often used when care is complex and a number of health care team members are involved in providing care. Generally, a case management plan, or critical pathway, is developed based on the norm or typical course of the condition. The nurse evaluates the progress of the client in relation to what is expected, investigating and following up on any variance in the time required or the amount of improvement noted. Although the case load for the individual nurse might be smaller (thus making this approach expensive), continuity of care and collaboration are enhanced.

A case manager oversees client care across the continuum of practice settings to ensure comprehensive, less fragmented delivery of care. The goal of case management is to help the client maintain optimal health with the least amount of intervention from health care providers. Critical pathways and care maps are tools used by case managers to measure the client’s progress according to predetermined time frames for achievement of expected objectives. The case manager seeks to improve the quality of health care by evaluating client outcomes, cost-effectiveness, and agency efficacy (Chitty & Black, 2007). See the accompanying Community Considerations display.

COMMUNITY CONSIDERATIONS

Factors Influencing a Case Manager’s Decision for Home Care

- Assessment of home environment
- Learning needs of client and family
- Need for skilled nursing care
- Need for long-term care

NURSING INTERVENTIONS

After reviewing the client’s current condition, verifying priorities, and examining resources, the nurse should be ready to initiate nursing interventions. A **nursing intervention** is an action performed by the nurse that helps the client to achieve the results specified by the goals and expected outcomes. All interventions must conform to professional standards of care. Nurses should understand the reason for any intervention, the expected effect, and any potential problems that may result. Understanding the reason for a nursing intervention is the hallmark of a professional nurse, in that the nurse is using logic and scientific reasoning as the basis of practice. It is important for novice nurses to identify the **rationale** (the fundamental principle) of all interventions in order to implement theory-based practice. Nursing interventions are a blend of science (rational acts) and art (intuitive actions).

Interventions are determined by and directed toward the cause of the problem, or factors contributing to the nursing diagnosis, and may vary for clients with similar nursing diagnoses depending on realistic expected outcomes for the individual. Prior to implementation, it is necessary to determine exactly:

- What is to be done
- How it is to be done
- When it should be done
- Who will do it
- How long it should be done

Consideration should be given to client preferences, the developmental level of the client, and availability of resources. In addition, the prescribing practitioner’s orders often have an impact on nursing interventions by imposing restrictions on factors such as diet or activity.

Types of Nursing Interventions

Nursing interventions are written as orders in the care plan and may be nurse initiated, prescribing practitioner initiated, or derived from collaboration with other health care professionals. These interventions can also be categorized as independent, dependent, or interdependent, depending on the authority required for initiation of the activity; see Chapter 8 for more details.

Interventions can be implemented on the basis of standing orders or protocols. A **standing order** is a standardized intervention written, approved, and signed by a prescribing practitioner that is kept on file within health care agencies to be used in predictable situations or in circumstances requiring immediate attention. Nurses can implement standing orders in these situations after they have assessed the client and identified the primary or emerging problem. For example, nurses in an ambulatory clinic or home health care agency may have standing orders for administering certain medications or ordering laboratory tests when indicated, or a prescribing practitioner may establish standing orders on an inpatient unit that specify certain medications that can be administered for common complaints, such as headache.

Table 9-3 provides an example of standing orders used for client preparation for a barium enema.

A **protocol** is a series of standing orders or procedures that should be followed under certain specific conditions. They define what interventions are permissible and under what circumstances the nurse is to implement the measures. Health care agencies or individual prescribing practitioners frequently have standing orders or protocols for client preparation for diagnostic tests and for immediate interventions in life-threatening circumstances. These protocols prevent needless duplication of writing the same orders repeatedly for different clients and often save valuable time in critical situations.

Nursing Interventions Classification

In 1993, the Iowa Intervention Project developed a taxonomy of nursing interventions that includes both direct and indirect activities directed toward health promotion and illness management. This taxonomy, the Nursing Interventions Classification (NIC), is a standardized language system that describes nursing interventions performed in all practice settings. The NIC is a method for linking nursing interventions to diagnoses and client outcomes (Bulechek, Dochterman, & Butcher, 2007).

The format for each intervention is as follows: label name, definition, a list of activities that a nurse performs to carry out the intervention, and a list of background readings (Bulechek et al., 2007). See Table 9-4 on page 146. The NIC offers standardized language for research on nursing interventions and is a promising tool for determining reimbursement for nursing services in a variety of practice settings.

TABLE 9-3 Example of Standing Orders

DATE	PRESCRIBING PRACTITIONER'S ORDERS
8/1	Standing orders for barium enema
	<i>Prior to test:</i>
	Clear liquid supper evening prior to test
	16 oz citrate of magnesia 6 PM
	Ducolax tabs iii at 8 PM
	NPO after midnight
	Enemas until clear AM of test
	<i>Following test:</i>
	Milk of magnesia 30 mL PO
Delmar/Cengage Learning	

Nursing Intervention Activities

Implementing nursing interventions requires that consideration be given to client rights, nursing ethics, and the legal implications associated with providing care. Nursing interventions include:

- Assisting with activities of daily living (ADL)
- Delivering skilled therapeutic interventions
- Monitoring and surveillance of response to care
- Teaching
- Discharge planning
- Supervising and coordinating nursing personnel

Clients have the right to refuse any intervention. However, the nurse must explain the rationale for the intervention and possible consequences associated with refusing treatment. If the intervention refused was prescribed by another health care professional, that person should be informed of the refusal of care. Ethical standards require that clients be afforded privacy and confidentiality. Matters related to a client's condition and care should be discussed only with individuals directly involved with the client's care, and any discussion should be held in a location where information cannot be overheard by visitors or bystanders. From a legal standpoint, the nurse must ensure that the authority for prescribing any intervention has been satisfied and that applicable standards of care are maintained during implementation of all nursing interventions. See the accompanying Safety First display.

ACTIVITIES OF DAILY LIVING Clients frequently need assistance with ADL such as bathing, grooming, ambulating, eating, and eliminating. The goal for most clients is to return to self-care or to regain as much autonomy as possible. The nurse's role is to determine the extent of assistance needed and to provide support for ADL while at the same time fostering independence. Ongoing assessment is important for determining the appropriate balance between ensuring safety and promoting independence. For example, maintaining personal grooming is important for purposes of hygiene and comfort as well as for promoting self-esteem. The nurse must always provide privacy when assisting clients with personal hygiene. If these tasks are assigned to other personnel, adequate supervision is imperative to ensure compliance with these principles.

THERAPEUTIC INTERVENTIONS Therapeutic nursing interventions are those measures directed toward resolution of a

SAFETY FIRST

MAINTAINING STANDARDS OF CARE

If nurses have never performed a specific procedure or feel unsure about their ability to safely perform the skill, they must always secure assistance before implementation.

current problem and include activities such as administration of medications and treatments, performing skilled procedures, and providing physical and psychological comfort. Written orders must be verified before implementing interventions requiring prescriptive authority. Reassessment of the client is also needed to determine whether the intervention remains appropriate. In addition, a nurse must also understand the rationale, expected effects, and possible complications that could result from any intervention.

MONITORING AND SURVEILLANCE Observation of the client's response to treatment is an integral part of the implementation of any intervention. Monitoring and surveillance

of the client's progress or lack of progress are essential in determining the effectiveness of the plan of care and detecting potential complications. Specific interventions require specific monitoring activities; however, typical monitoring activities include observations such as vital signs measurement, cardiac monitoring, and recording of intake and output. See the Uncovering the Evidence display.

TEACHING A major intervention in health promotion and illness management is educating clients in order to help them modify their behaviors in response to potential health risks and actual health alterations. As part of this teaching process, nurses must also discuss the rationales for the interventions in the nursing plan of care.

Numerous opportunities arise every day for informal teaching related to client care. For example, teaching clients about the medications they are taking and possible side effects should occur routinely as medications are administered. Similarly, as nurses perform assessment activities, the sharing of observations with the client can be informative in terms of what characteristics are desirable and what observations are sources of concern. This knowledge can be valuable to a client for self-monitoring.

Effective teaching requires insight into the client's knowledge base and readiness to learn. Realistic teaching goals and learning outcomes should be set on the basis of these factors. It is also desirable to include the family or significant others in teaching plans. A suitable learning environment should be created that is nonthreatening and allows active participation by the client.

Nurses should be careful to use terminology easily understood by the client. It is important that learning outcomes are validated to be sure that clients can safely and effectively care for themselves after discharge. See Chapter 21 for information about client education.

DISCHARGE PLANNING Preparation for discharge begins at the time of admission to a health care agency. As the average length of stay in acute care settings continues to decrease, early discharge planning becomes imperative. Expected outcomes dictate the type of planning required and the interventions necessary to attain the desired outcomes. Interventions directed toward discharge planning include activities such as teaching and consultation with other agencies (e.g., home health, rehabilitation facilities, nursing homes) concerning follow-up care. Teaching related to any changes in diet, medications, or lifestyle must be implemented; any barriers or problems in the home environment must be resolved before discharge from an acute or extended care facility. Some agencies employ personnel with the primary responsibility of teaching or discharge planning for groups of clients; however, the nurse who is caring for the individual client is also responsible for ensuring that all appropriate interventions have been implemented before discharge.

SUPERVISION AND COORDINATION OF PERSONNEL The management style and type of facility, as well as the needs of the client, determine the scope of interventions

UNCOVERING THE

Evidence

TITLE OF STUDY

"Patterns of Nursing Intervention Use across 6 Days of Acute Care Hospitalization for Three Older Patient Populations"

AUTHORS

L. L. Shever, M. Titler, J. Dochterman, Q. Fei, and D. M. Picone

PURPOSE

The purpose of this study was twofold: (1) to identify frequently used nursing interventions and (2) to describe patterns of interventions used for each of the three selected groups of clients.

METHODS

This secondary data analysis study used data from a medical center in which the Nursing Interventions Classification (NIC) was used to electronically document nursing care. Statistics were examined to determine the types, frequencies, and patterns of interventions used in providing care to older care recipients.

FINDINGS

Three interventions (surveillance, IV therapy, and diet staging) were used for all three groups of clients. There were some NIC treatment approaches that were unique to each client population.

IMPLICATIONS

The use of standardized nursing language (i.e., NIC) in electronic medical records enhances the collection and analysis of data. These data serve as guides for nurse managers in making decisions about staffing, resource allocation, and education.

Shever, L. L., Titler, M., Dochterman, J., Fei, Q., & Picone, D. M. (2007). Patterns of nursing intervention use across 6 days of acute care hospitalization for three older patient populations. *International Journal of Nursing Terminologies and Classifications*, 18(1), 18–29.

associated with supervision and coordination of client care. In a health care facility in which nurses are assigned clients within a total client care management system, responsibilities for supervision might be minimal, whereas facilities that use a variety of ancillary personnel for certain client activities might require a large percentage of time devoted to supervision of care. In home health care, for example, the primary role of the professional nurse might be supervision of personnel who provide assistance with ADL. Although a nurse might delegate certain tasks to other personnel, it is still the nurse's responsibility to ensure that the task was completed according to standards of care and to note the response of the client in order to evaluate progress toward expected outcomes.

Regardless of management style or type of facility, coordination of client activities among various health care providers remains the nurse's responsibility. For example, in acute care settings, the nurse needs to coordinate client activities around the schedule of diagnostic tests or physical therapy. Scheduling procedures, therapy, treatments, and medications for a number of clients often requires considerable organizational skills, creativity, and resourcefulness.

EVALUATING INTERVENTIONS

An important step to ensure the delivery of quality care is evaluation of nursing interventions. One approach to determining the efficacy of nursing interventions is by evaluating clients' achievement of expected outcomes. The NIC, previously described in this chapter, provides a systematic method for linking nursing activities to client outcomes. When treatment can be shown to directly improve client outcomes, both nursing and health care consumers benefit. Another taxonomy, the Nursing Outcomes Classification (NOC), has been specifically designed to measure client responses to nursing interventions.

DOCUMENTATION OF INTERVENTIONS

Communication concerning implementation of interventions must be provided through written documentation and should also be verbally conveyed when responsibility of the client's care is transferred to another nurse. The nurse is legally required to record all interventions and observations related to the client's response to treatment. This not only provides a legal record but also allows valuable communication with other health care team members for continuity of care and for evaluating progress toward expected outcomes. In addition, written documentation provides data necessary

for reimbursement for services and tracking of indicators for quality improvement.

The recording of information can be in the form of either checklists, flow sheets, or narrative summaries. A complete description must be provided if there are any deviations from the norm or if any changes have occurred (see Chapter 13).

Verbal interaction among health care providers is also essential for communicating current information about clients. When delegating the tasks to unlicensed assistive personnel (UAP), the nurse must elicit feedback from the UAP about the activity performed and the client's response. In addition, assistive personnel should be alerted as to what additional data are meaningful, and these data should be conveyed to the nurse responsible for the client's care. For example, if a nursing assistant observes that a client hospitalized with a deep vein thrombosis of the left leg is having difficulty swallowing and has eaten very little, this information should be reported to the nurse. This is especially important if the behavior is a new occurrence and not a part of the established problem list, because the nurse might not otherwise seek this information.

Communication between nurses generally occurs at the change of shift, when the responsibility for care is transferred from one nurse to another. Nursing students must communicate relevant information to the nurse responsible for their clients when they leave the unit. Information that should be shared in the verbal report includes:

- Activities completed and those remaining to be completed
- Status of current relevant problems
- Any abnormalities or changes in client status
- Results of treatments (i.e., client response)
- Diagnostic tests scheduled or completed (and results)

All communication—whether written, verbal, or both—must be objective, descriptive, and complete. The communication includes observations rather than opinions and is stated or written so that an accurate picture of the client is conveyed. For example, if it is noted that a client is less alert today than yesterday, the *behavior* that led to that conclusion should be documented. This observation can be objectively and descriptively communicated by the statement “Does not respond unless firmly touched; quickly returns to sleep.” This description results in a more complete picture of the client than simply stating, “Less alert today.” Thorough and detailed communication of implementation activities is fundamental to ensuring that client care and progress toward goals can be adequately evaluated.

KEY CONCEPTS

- The implementation step of the nursing process is directed toward meeting client needs and results in health promotion, prevention of illness, illness management, or health restoration.
- Implementation involves delegation of nursing care activities to assistive personnel.
- Implementation requires application of cognitive, psychomotor, and intellectual skills to accomplish goals and make progress toward expected outcomes.
- Implementation activities include ongoing assessment, establishment of priorities, allocation of

resources, initiation of specific nursing interventions, and documentation of interventions and client responses.

- Ongoing assessment is necessary for determining effectiveness of interventions and for detecting new problems.
 - Changing variables in clients and the environment demand clinical judgment and flexibility in organizing care.
 - Time management skills are essential in implementing client care.
 - The nurse maintains responsibility for care delegated to other health care personnel.
 - The most common management systems currently used include functional nursing, team nursing, primary nursing, total client care, modular nursing, and case management.
- Interventions can be nurse initiated, prescribing practitioner initiated, or collaborative in origin and thus are considered dependent, independent, or interdependent.
 - NIC is a system for sorting, labeling, and describing nursing interventions.
 - Nursing interventions include assisting with ADL, skilled therapeutic interventions, monitoring and surveillance of client response to care, teaching, discharge planning, and supervision and coordination of nursing personnel.
 - Communication concerning interventions should be provided verbally and in writing.

REVIEW QUESTIONS

1. Which of the following best describes the purpose of ongoing evaluation when implementing nursing activities?
 - a. To be sure the activities performed are independent activities
 - b. To determine client progress toward expected outcomes
 - c. To ensure compliance with agency protocols
 - d. To establish a nursing diagnosis
2. Establishing priority among several nursing interventions depends on which of the following? Select all that apply.
 - a. Availability of resources
 - b. Client perception
 - c. Client's willingness to comply
 - d. Education level of nurse
 - e. Length of time necessary for the intervention
 - f. Nurse determination of importance
3. Which of the following is an example of the functional nursing approach to care delivery?
 - a. Team member has an assigned task to perform for the client.
 - b. Full responsibility for total client care rests upon the registered nurse.
 - c. The registered nurse coordinates care for the client across the entire care continuum.
 - d. The registered nurse works with licensed practical/vocational nurses and unlicensed assistive personnel to deliver care.
4. Briefly answer the following question by filling in the blank:
The nursing management system in which a group of care providers (RN, LPN, and UAP) coordinates activities to deliver care is defined as the _____ nursing approach.
5. Which of the following should nurses do initially when performing a procedure they have never done before?
 - a. Double-check the prescribing order.
 - b. Seek help from another nurse who is proficient in performing the procedure.
 - c. Inform the nursing supervisor that they are unwilling to do the procedure because it is a new skill for them.
 - d. Try to remember all the steps of the procedure they learned in nursing school.
6. Which of the following statements made by a new nurse indicates a need for further guidance when giving a change-of-shift report?
 - a. "The client had a good night."
 - b. "The client is scheduled to have a CT scan this morning."
 - c. "The client slept 5 uninterrupted hours after receiving Demerol."
 - d. "We did not get all the blood glucose levels drawn this morning."

CHAPTER 10

Evaluation

COMPETENCIES

1. Explain the purposes of evaluation in professional nursing practice.
2. Describe the components of comprehensive evaluation in nursing.
3. Describe the steps through which evaluation is conducted.
4. Describe the three types of evaluation.
5. Discuss the relationship between evaluation and accountability.
6. Explain the significance of multidisciplinary collaboration in evaluating client care.

KEY TERMS

evaluation
nursing audit

outcome evaluation
peer evaluation

process evaluation
structure evaluation

Evaluation is the fifth step in the nursing process and involves determining whether the client goals have been met, have been partially met, or have not been met. Even though it is the final phase of the nursing process, evaluation is an ongoing part of daily nursing activities. The major purpose of evaluation is to determine the effectiveness of those activities in helping clients achieve expected outcomes. Evaluation is not only a part of the nursing process but also an integral process in determining the quality of health care delivered. This chapter discusses the purposes, components, and methods of evaluation. The relationship between evaluation and quality of care is described.

EVALUATION OF CLIENT CARE

Evaluation is the measurement of the degree to which objectives are achieved. Therefore, evaluating the care provided to clients is an essential part of professional nursing. The American Nurses Association (2004) designates evaluation as a fundamental component of the nursing process. The purposes of evaluation include:

- To determine the client's progress or lack of progress toward achievement of expected outcomes
- To determine the effectiveness of nursing care in helping clients achieve the expected outcomes
- To determine the overall quality of care provided
- To promote nursing accountability

Evaluation is done primarily to determine whether a client is progressing—that is, experiencing an improvement in health status. Evaluation is not an end to the nursing process, but rather an ongoing mechanism that ensures quality interventions. Effective evaluation is done periodically, not just prior to termination of care. Evaluation is closely related to each of the other stages of the nursing process. The plan of care may be modified during any phase of the nursing process when the need to do so is determined through evaluation. Client goals and expected outcomes provide the criteria for evaluation of care. The Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC) taxonomies are methods useful in evaluating clients' achievement of outcomes and the efficacy of nursing interventions.

COMPONENTS OF EVALUATION

Evaluation is a fluid process that depends on all the other components of the nursing process. As shown in Figure 10-1, evaluation affects, and is affected by, assessment, diagnosis, outcome identification and planning, and implementation of

nursing care. Ongoing evaluation is essential if the nursing process is to be implemented appropriately. As Alfaro-LeFevre (2008) states:

When we evaluate early, checking whether our information is accurate, complete, and up-to-date, we're able to make corrections *early*. We avoid making decisions based on outdated, inaccurate, or incomplete information. Early evaluation enhances our ability to act safely and effectively. It improves our *efficiency* by helping us stay focused on priorities and avoid wasting time continuing useless actions. (p. 20)

Specific criteria are to be used in the process of evaluation. The evaluation criteria must be planned, goal directed, objective, verifiable, and specific; that is, strengths, weaknesses, achievements, and deficits must be considered.

TECHNIQUES

Effective evaluation results primarily from the nurse's accurate use of communication and observation skills. Both verbal and nonverbal communication between the nurse and the client can yield important information about the accuracy of the goals, expected planned outcomes, and nursing interventions that have been executed for resolution of the client's problems. The nurse needs to be sensitive to clients' willingness or hesitation to discuss their responses to nursing actions and must use therapeutic communication techniques to collect all necessary data.

Effective nurses are aware of changes in the client's physiological condition, emotional status, and behavior. Because these changes are often subtle, they require astute observational skills on the part of the nurse. Observation occurs through use of the senses. In other words, what the nurse sees, hears, smells, and feels when touching the client all provide clues to the client's current health status.

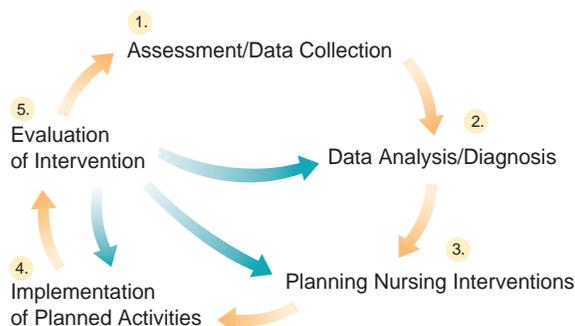

FIGURE 10-1 Relationship of Evaluation to Nursing Process
DELMAR/CENGAGE LEARNING

SOURCES OF DATA

Evaluation is a mutual process occurring among the nurse, client, family, and other health care providers. Both subjective and objective data are used in evaluating the client's status. Asking clients to describe how they feel results in subjective data. Objective data consist of observable facts, such as laboratory values and the client's behavior.

When a nurse communicates an assessment of a client's response to an actual or potential health problem, clients and families are empowered to discuss their concerns and questions. When feedback is given, the nurse must avoid being defensive because that attitude may cause clients or families to avoid being open and honest. As a result, clients may say only what they think the nurse wants to hear or they may refuse to participate in the evaluation process. The nurse's verbal and nonverbal communication establishes the atmosphere in which clients and families freely share their comments, both positive and negative.

GOALS AND EXPECTED OUTCOMES

The effectiveness of nursing interventions is evaluated by examination of goals and expected outcomes. Goals provide direction for the plan of care and serve as measurements for the client's progress, or lack of progress, toward resolution of a problem.

Realistic goals are necessary for effective evaluation. These goals must take into consideration the client's strengths, limitations, resources, and the time frame for achieving the objectives. Examples of client strengths are educational background, family support, and financial resources (e.g., money to purchase medications and foods that support the prescribed interventions). Examples of client limitations are delayed developmental level, poverty, and unwillingness to change (lack of motivation).

METHODS OF EVALUATION

The nurse who successfully evaluates nursing care uses a systematic approach that ensures thorough, comprehensive collection of data. Evaluation is an orderly process consisting of seven steps, which are explained here.

ESTABLISHING STANDARDS

Specific criteria are used to determine whether the demonstrated behavior indicates goal achievement. Standards are established before nursing action is implemented. Evaluation of criteria examines the presence of any changes, direction of change (positive or negative), and whether the changes were expected or unexpected.

COLLECTING DATA

Assessment skills are used to gather data pertinent to goals and expected outcomes. The nurse must be proficient in

assessment skills in order for effective, comprehensive evaluation to occur. Evaluation data are collected to answer the following question: Were the treatment goals and expected outcomes achieved?

DETERMINING GOAL ACHIEVEMENT

Data are analyzed to determine whether client behaviors indicate goal achievement. This process is validated through analysis of the client's response to the specific nursing interventions that are developed in the plan of care. For example, these data can take the form of either physiological responses (such as the client's being able to cough productively in order to promote effective breathing patterns) or psychosocial responses (such as the client's being able to verbalize concerns about an impending surgical procedure in order to alleviate anxiety).

RELATING NURSING ACTIONS TO CLIENT STATUS

Nursing interventions are examined to determine their relevance to the client's needs and nursing diagnoses. Effective nursing actions are those that address pertinent client needs and help clients appropriately resolve actual or potential problems.

JUDGING THE VALUE OF NURSING INTERVENTIONS

Critical thinking skills are employed to determine whether nursing actions have contributed to the client's improved status. These skills enable the nurse to analyze the client's responses to the nursing interventions. Evaluating the benefits of nursing actions helps identify additional opportunities for changes in the plan of care.

REASSESSING THE CLIENT'S STATUS

The client's health status is reevaluated through use of assessment and observation skills. Evaluation focuses on the client's current health status and compares it with baseline data collected during the initial assessment. Omissions or incomplete data within the database are identified so that an accurate picture of the client's health status is obtained.

MODIFYING THE PLAN OF CARE

If the evaluation data indicate a lack of progress toward goal achievement, the plan of care is revised. These revisions are developed through the following process: reassessment of the client, formulation of more appropriate nursing diagnoses, development of new or revised goals and expected outcomes, and implementation of different nursing actions or repetition of specific actions to maximize their effectiveness (e.g., client teaching). See the Nursing Checklist for guidelines for evaluating effective application of the nursing process to client care.

NURSING CHECKLIST

EVALUATING NURSING CARE

Following are guidelines useful in analyzing the application of the nursing process:

- Assessment is thorough and accurate.
- Nursing diagnoses are relevant.
- Client and family participate in goal setting.
- Goals are specific, measurable, and realistic.
- Nursing actions address client's problems.
- Client and family participate in evaluation.
- Evaluation is ongoing and results in a revised plan of care according to the client's status changes.
- Plan of care is revised according to the client's needs.
- Documentation reflects the client's status, including responses to nursing interventions.

Evaluation is performed by every nurse in all practice settings for each client. For example, the home health nurse evaluates the care provided regularly throughout the client's relationship with the agency. Evaluation of the home care client is carried out in order to determine whether the care was delivered in an effective and efficient manner, to modify the plan of care as needed, and to decide when the client is ready for discontinuation of home care services. The accompanying Community Considerations display provides an example of evaluation performed by the home health care nurse.

CRITICAL THINKING AND EVALUATION

Evaluation is a critical thinking activity. It is a deliberate mechanism used to analyze and make judgments. Evaluation

COMMUNITY CONSIDERATIONS

Evaluation in the Home Health Care Setting

When evaluating the effectiveness of care, the home health care nurse can use the following questions to examine client achievement of expected outcomes:

- Were the goals realistic in terms of client abilities and time frame?
- Were there external variables (e.g., housing problems, impaired family dynamics) that prevented goal achievement?
- Did the family have the resources (e.g., transportation) to assist in meeting the goals?
- Was the care coordinated with other providers to facilitate efficient delivery of care?

involves analysis and is much more complex than merely answering questions. Nurses need to remain objective when evaluating client care in order to modify care based on reason rather than emotion. Nurses use critical thinking throughout evaluative activities by comparing client responses to expected behaviors. They make conclusions about whether expected outcomes have been met. In order to make such conclusions, assessment data are needed to determine client progress toward achievement of objectives.

EVALUATION AND QUALITY OF CARE

Evaluation is performed at the individual and institutional levels. For example, individual evaluation focuses on the client's achievement of goals and also on the individual nurse's delivery of care. Quality and evaluation are closely related. This section examines the role of evaluation in ensuring the delivery of quality health care. Because it is the mechanism used by nurses in determining the need for improvement, evaluation assists in the provision of quality care. The aspects that need to be evaluated to determine the quality of health care are:

- Appropriateness (the care provided adhered to standards and resulted in achievement of goals)
- Clinical outcomes
- Client satisfaction
- Cost-effectiveness
- Access to care
- Availability of resources

Quality management involves constant, ongoing evaluation (monitoring of activities).

ELEMENTS IN EVALUATING THE QUALITY OF CARE

Organizational evaluation examines the agency's overall ability to deliver quality care. Evaluation can be classified according to what is being evaluated: the structure, the process, or the outcome. Figure 10-2 on page 157 illustrates the variables to be assessed in each type of evaluation.

Structure Evaluation

Structure evaluation is a determination of the health care agency's ability to provide the services offered to its client population. Structure evaluation examines the physical facilities, resources, equipment, staffing patterns, organizational patterns, and the agency's qualifications for staff. The majority of problems with providing effective health care stem from problems in the structural area. The purpose of structure evaluation is to identify any system errors that can be corrected.

Structure evaluation involves determining whether client care meets legal and professional standards. A frequently used method to evaluate whether the agency provides care within legal parameters is a review of policy and procedure

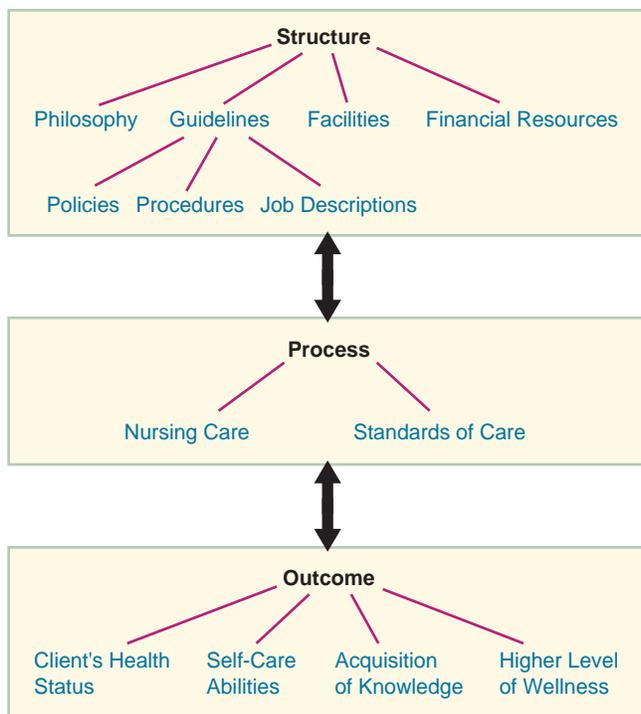

FIGURE 10-2 Elements within Each Type of Evaluation DELMAR/ CENGAGE LEARNING

manuals to check for compliance with regulations. Table 10-1 describes ways to perform structure evaluation, which measures the adequacy of an agency to meet client needs.

Process Evaluation

Process evaluation is the measurement of nursing actions by examining each phase of the nursing process. This type of evaluation is done to determine whether nursing care was adequate, appropriate, effective, and efficient. Nursing interventions are judged to be effective when use of the action results in the desired outcome. See the Uncovering the Evidence display. Process evaluation determines the nurse’s ability to establish an environment that promotes the client’s health. See the Nursing Process Highlight for recommendations

TABLE 10-1 Structure Evaluation

EVALUATION QUESTIONS	DATA SOURCES
<ul style="list-style-type: none"> • Are nursing policies readily available to staff? • Do orientation programs provide information necessary for job performance? • Do staffing patterns show ability to meet client needs? 	<ul style="list-style-type: none"> • Orientation programs • Policy manuals • Procedure manuals • Staffing patterns

Delmar/Cengage Learning

for client evaluation. Note that these recommendations are applicable to all practice settings.

Outcome Evaluation

Outcome evaluation is the process of comparing the client’s current status with the expected outcomes. This type of evaluation examines all direct care activities that affect the client’s health status. Outcome evaluation focuses on changes in the client’s health status. A basic question to ask when evaluating the outcome is “Has the expected change occurred?”

UNCOVERING THE

Evidence

TITLE OF STUDY

“Evaluating the Effectiveness of Preoperative Interventions: The Appropriateness of Using the Children’s Emotional Manifestation Scale”

AUTHOR

H. C. Li

PURPOSE

This study had two purposes: (1) to compare the effectiveness of two preoperative nursing interventions and (2) to examine the appropriateness of using the Children’s Emotional Manifestation Scale for evaluating the efficacy of preoperative interventions.

METHODS

This was a randomized controlled trial in which children admitted for elective same-day surgery were assigned to one of two groups: the experimental group that received therapeutic play intervention and the control group that received routine preoperative information.

FINDINGS

Children receiving preoperative therapeutic play intervention reported significantly lower anxiety levels and fewer negative emotions and experienced lower heart rates and mean arterial blood pressures than children who received the routine preoperative preparation.

IMPLICATIONS

This study demonstrates the appropriateness of using the Children’s Emotional Manifestation Scale to evaluate the effectiveness of preoperative nursing interventions. It also presents clear evidence that supports the efficacy of therapeutic play in preparing children for surgery.

Li, H. C. (2007). Evaluating the effectiveness of preoperative interventions: The appropriateness of using the Children’s Emotional Manifestation Scale. *Journal of Clinical Nursing, 16*(10), 1919–1926.

NURSING PROCESS HIGHLIGHT

Evaluation

Client Evaluation

- Upon admission, each client is assessed by a registered nurse.
- Each client has an individualized plan of care.
- Nursing interventions are specified in the plan of care.
- Client responses to interventions are documented.

Another variable assessed during outcome evaluation is the client’s self-care ability. Has the client demonstrated an improved ability to care for himself or herself? Does the client verbalize knowledge related to self-care needs? See the Nursing Checklist for suggested approaches to performing outcome evaluation. The accompanying Nursing Process Highlight shows the application of the North American Nursing Diagnosis Association (NANDA), NOC, and NIC systems with a client experiencing problems in feeding himself or herself.

NURSING AUDIT

A **nursing audit** is the process of collecting and analyzing data to evaluate the effectiveness of nursing interventions. A nursing audit can focus on implementation of the nursing process, client outcomes, or both in order to evaluate the quality of care provided. Nursing audits examine data related to:

- Safety measures
- Treatment interventions and client responses

NURSING CHECKLIST

OUTCOME EVALUATION

- The client demonstrates new knowledge or skills.
- There is documented evidence of client status relative to expected outcomes.
- There is documentation of client coping abilities.
- There is a discharge plan that specifies follow-up activities for client and family.

- Preestablished outcomes used as basis for interventions
- Client teaching
- Discharge planning
- Adequacy of staffing patterns

Audits are based on components such as institutional policies; federal, state, and local regulations; accreditation standards; and professional standards (see Figure 10-3). Audits assist in identifying strengths and weaknesses that, in turn, provide direction for areas needing revision. Corrective

FIGURE 10-3 Influences Affecting Nursing Audit DELMAR/CENGAGE LEARNING

(2007). *Nursing outcomes classification (NOC)* (4th ed.). St. Louis, MO: Elsevier; North American Nursing Diagnosis Association. (2009). *Nursing diagnosis—Definitions and classification 2009–2011*. Philadelphia: John Wiley & Sons, Inc; Wilkinson, J. M. (2008). *Nursing diagnosis handbook* (9th ed.). Upper Saddle River, NJ: Prentice-Hall.

action plans are developed in accordance with the audit results.

PEER EVALUATION

Another method of evaluating quality of care is **peer evaluation** (also referred to as *peer review*), the process by which professionals provide to their peers critical performance appraisal and feedback that are geared toward corrective action. Peer evaluation, when performed appropriately, improves the quality of care by addressing specific behavior of the nurse being evaluated. It can be verbal or written depending on agency policy. Peer evaluation may be done formally or informally, with information being provided in a timely manner.

By evaluating itself, nursing is demonstrating an essential criterion by which professions are recognized. Peer evaluation promotes both professional and individual accountability. The quality of nursing care is strongly evident to coworkers and nurses who are expected to assess the work of their peers.

Such judgment may result in one of the following outcomes:

- Destructive: Complaints and attacks that undermine morale and cohesiveness
- Constructive: Positive feedback that improves the quality of care

Peer evaluation can be destructive if the parties involved begin to personalize the process, misunderstand the purpose, or deliver feedback in an unfeeling and nonobjective manner. Peer evaluation can be threatening when guidelines have not been established for the process and when the assessment focuses on emotions and personalities instead of on behaviors. Conversely, peer evaluation is constructive when the focus remains on quality improvement and encourages the

continued growth and learning of all the parties involved. See the Spotlight On display.

EVALUATION AND ACCOUNTABILITY

Accountability means assuming responsibility for one's actions. Evaluation enhances nursing accountability by providing a mechanism for assisting the nurse to define, explain, and measure the results of nursing actions. Accountability is increased by ongoing evaluation; nurses are continually checking their own progress against predetermined standards.

Accountability is an integral part of professional nursing practice and is an important method through which commitment to quality client care can be demonstrated. Nurses are accountable for their judgments, decisions, and actions to:

- Clients, families, and significant others
- Colleagues
- Employers
- The general public (society)
- The nursing profession
- Themselves

Nurses demonstrate their commitment to accountability in a variety of ways, including maintaining expertise in skills and participating in continuing education programs. Other ways of demonstrating accountability are achieving and maintaining certification and participating in peer evaluation.

MULTIDISCIPLINARY COLLABORATION IN EVALUATION

Evaluating the quality of care provided is a responsibility shared among members of the health care team. In addition to those directly involved (the health care providers, clients, and families), others interested in the outcomes of evaluation include the community and third-party payers (both public and private reimbursement organizations).

An ongoing monitoring process is implemented to evaluate quality of care. Ideally, every discipline monitors its own quality efforts. No single discipline is responsible for all-inclusive evaluation of client care. However, in most health care agencies, nurses are actively involved in monitoring evaluation activities. Many agencies have nurses on staff who function either as quality management coordinators, utilization review evaluators, or both.

When health care providers from all the relevant disciplines are involved in evaluation, the result is decreased fragmentation of care. The team approach mandates active involvement of all care providers in the evaluation of quality care. Multidisciplinary evaluation helps promote a continuum of care for the client, from the preadmission phase to discharge planning and follow-up care.

SPOTLIGHT ON...

Professionalism

Peer Evaluation and Friendship

Your coworker is also a close friend. You are assigned to perform a peer evaluation with her. Before the process begins, she asks you to be especially lenient when evaluating her performance. When collecting information about the quality of her work, you discover that she is often hurried and unorganized, a practice that results in her providing only mediocre care. You know that if the evaluation is not above average, your friend will likely experience disciplinary action from her supervisor. In view of your friendship, what do you do in this situation?

NURSING CARE PLAN

The Client Experiencing Self-Care Deficits and Risk for Injury

CASE PRESENTATION

Mr. Magee was admitted yesterday with right-sided weakness. His medical diagnosis is cerebral vascular accident (CVA). He is 68 years of age and resides alone in the house on his farm where he and his wife lived for 40 years. She died last year. He reports that he is right-handed and has difficulty holding a fork.

ASSESSMENT

- “I can’t handle this milk carton with only one hand.”
- “I do not like to use that walker. It gets in my way.”
- Gait unsteady and shuffling
- Asymmetrical strength in arms and legs
- Unable to hold fork in right hand

NURSING DIAGNOSIS 1: *Feeding self-care deficit* related to weakness in right hand AEB inability to hold fork.

NOC: Client will be able to feed self independently.

NIC: Serve finger foods to promote independence.

EXPECTED OUTCOMES

The client will:

1. Attend a teaching session on feeding himself with his left hand at 1000 on 2/12.
2. Practice using adaptive spoon at 1400 on 2/12.
3. Use adaptive spoon for meals beginning with breakfast on 2/13.

INTERVENTIONS/RATIONALES

1. Present a teaching session “Feeding oneself with the nondominant hand” at 1000 on 2/12. For clients recovering from illness and/or injury, information about adapting to limitations fosters independence.
2. Provide the client with four foods of differing textures, adaptive spoons, and apron for a practice session at 1400 on 2/12. Providing practice time reinforces skills learned and fosters an improved confidence level in the learner.
3. Notify the dietary department to include a left-hand adaptive spoon with breakfast tray on 2/13. Using adaptive devices provides safety and promotes independence.
4. Encourage client to feed self independently at each meal, beginning 2/13. Recognizing and commending success promotes positive self-esteem.
5. Assist client with food preparation and feeding as needed at each meal, beginning 2/12. Assistance preserves strength, avoids tiring the client, promotes safety, and decreases frustration as the client strives for independence.

EVALUATION

1. Goal met. Mr. Magee attended teaching session on 2/12, asked questions, and participated in the practice session.
2. Goal partially met. Mr. Magee practiced using a spoon in his left hand to feed himself oatmeal, soup, ice cream, and canned peaches on 2/12. Successful self-feeding with all foods except soup. Continue practice, reevaluate 2/19.
3. Goal partially met. On 2/13, fed self 75% of each meal, using adaptive spoon. Continue. Reevaluate on 2/15.

NURSING DIAGNOSIS 2: *Risk for injury: falls* related to unsteady, shuffling gait.

NOC: Risk for fall will be decreased by environmental modifications.

NIC: Instruct client in fall prevention measures (e.g., handrails, grab bars, and shower mats).

(Continues)

NURSING CARE PLAN (Continued)

EXPECTED OUTCOMES

The client will:

1. Participate in physical therapy evaluation of mobility strengths and weaknesses on 2/11 at 1100.
2. Attend a muscle-strengthening class on 2/12 at 1600.
3. Perform all strengthening exercises prescribed BID at 1000 and 1600, beginning 2/13.

INTERVENTIONS/RATIONALES

1. Request physical therapy consultation for appropriate assistive devices, strengthening exercises, and gait training on 2/11. Collaboration with other health care providers provides the best care for the client.
2. Escort client to muscle-strengthening class on 2/12 at 1600. Provides safety and support as the client begins to learn new skills.
3. Assigned caregiver will record each exercise, number of repetitions, and client response BID. Documenting client progress toward the achievement of goals aids in outcome attainment and evaluation of care.

EVALUATION

1. Goal not met. Appointment not kept on 2/11. Dental emergency. Continue. Reevaluate 2/15.
2. Goal not met. Unable to evaluate on 2/12. Continue. Reevaluate on 2/15.
3. 2/15: Goal met. Client attended muscle-strengthening class and has performed exercises as prescribed two times each day.

KEY CONCEPTS

- Evaluation, the fifth step in the nursing process, involves determining whether client goals have been met, have been partially met, or have not been met.
- The purposes of evaluation are to determine the client's progress or lack of progress toward achievement of client objectives, to judge the efficiency of nursing actions in helping clients to achieve objectives, to determine the health care agency's overall ability to deliver care in an effective and efficient manner, and to promote nursing accountability.
- Evaluation is based primarily on the skills of communication and observation.
- Evaluation is a mutual, ongoing process occurring among the nurse, client, family, and other health care providers.
- The effectiveness of nursing interventions is evaluated by examination of goals and expected outcomes that provide direction for the plan of care and serve as standards by which the client's progress is measured.
- Evaluation is an orderly process consisting of seven steps: establishing standards, collecting data related to the goals and expected outcomes, determining goal achievement, relating nursing actions to client status, judging the value of nursing interventions in assisting clients to achieve goals and objectives, reassessing the client's status, and modifying the plan of care if necessary.
- There is a relationship between quality management and evaluation. Evaluation is necessary in the provision of quality care because it is the mechanism used by nurses in determining how to improve care.
- Structure evaluation judges a health care agency's ability to provide the services offered to its client population.
- Process evaluation measures nursing actions by examining each phase of the nursing process to determine the effectiveness of the actions in helping clients meet expected outcomes and goals.
- Outcome evaluation compares the client's current status with the expected outcomes and examines all direct care activities that affect the client's status.
- A nursing audit can focus on implementation of the nursing process, client outcomes, or both in order to evaluate the quality of care provided.
- Peer evaluation (peer review) is the process by which professionals provide to their peers performance appraisal feedback geared toward corrective action.

- Evaluation enhances professional nursing accountability by providing a mechanism for assisting the nurse to define, explain, and measure the results of nursing actions.
- Evaluating the quality of care is a shared responsibility among members of the health care team.

REVIEW QUESTIONS

- Which of the following accurately describes the purposes of evaluation? Select all that apply.
 - Determine client progress toward achievement of expected outcomes.
 - Determine effectiveness of nursing care.
 - Establish client expected outcomes.
 - Establish priorities for nursing interventions.
 - Promote nursing accountability.
 - Write the plan of care, including specific measurable goals.
- Which of the following client statements are indicators of client strengths? Select all that apply.
 - “I don’t think that I’ll be able to stop smoking.”
 - “I dropped out of school in the eighth grade to go to work.”
 - “I have no relatives to bother me.”
 - “My company pays for my health insurance.”
 - “My family is willing to change their eating habits since I’m on a diet.”
 - “My wife and I are both employed as school teachers.”
- In which of the following situations is the nurse performing evaluation?
 - Determining a client’s baseline temperature
 - Developing expected client outcomes
 - Asking a client if pain is relieved after administration of analgesics
 - Writing an individualized plan of care for a client
- Which of the following statements best describes the evaluation of quality care?
 - Carried out to determine whether the client feels better
 - Determined after the project is completed
 - Performed only by nursing
 - Shared responsibility of multidisciplinary team
- Which of the following mechanisms is based on honest confrontation and open communication?
 - Establishing standards
 - Outcome evaluation
 - Peer review
 - Structure evaluation
- A nurse helps reposition a client who has difficulty breathing. Which of the following nursing actions, when performed after the intervention, demonstrates evaluation?
 - Arranging pillows behind the client’s back
 - Changing the rate of flow for oxygen delivery
 - Checking the client’s respiratory status
 - Instructing the client on the importance of mobility

 scope of practice
 situational leadership
 synergy

As nursing continues to evolve, many questions arise: Is nursing truly a profession? Are nurses really autonomous? Autonomy is related to accountability. As autonomy increases, so does the need to be accountable. To whom are nurses accountable?

This chapter addresses these issues and emphasizes the need to be involved in activities that advance the nursing profession. In addition, nursing leadership, power, and the politics of nursing are discussed in terms of their contributions to professional nursing practice.

PROFESSIONAL NURSING PRACTICE

Isabel Hampton Robb, the first president of the American Nurses Association (ANA), stated in the late nineteenth century that nursing lacked two elements of a profession—organization and legislation (ANA, 1976). Believing nurses were not capable of managing their own affairs, hospital authorities opposed any efforts of nurses to organize. Moreover, the lack of accepted standards for nursing education caused graduates of one nursing school to question the credentials of graduates of other nursing schools. The result of these

negative responses to the autonomy of the nursing profession was the belief held by nurses that it was neither possible nor desirable to work collectively (ANA, 1976).

However, in the early twentieth century, nursing did organize. The primary goal was to establish legislation that would legitimize nursing practice and gain recognition of nursing as a profession. Even though nursing is often referred to as a profession, there is debate about whether nursing is a *true* profession when appraised against the criteria of a profession.

CRITERIA OF A PROFESSION

A **profession** is a group (vocational or occupational) that requires specialized education and intellectual knowledge. There has been much debate about whether nursing is a profession or an occupation. Registered nurses consider nursing to be a profession similar to other professions (e.g., accounting, engineering, pharmacy, law, and medicine). However, for nursing to be recognized as a profession by the society it serves, nursing must demonstrate on an ongoing basis that it meets the criteria of a profession (Table 11-1 on page 167). See the accompanying Spotlight On display.

Nursing has accomplished much in the way of establishing its body of knowledge, scope of practice, research base, and code of ethics. However, nursing continues to struggle with maintaining authority over its own practice. As political forces affect the health care delivery system, the challenge to maintain control over nursing practice will become even greater. If nursing is to maintain professional autonomy, it must have a strong political base that seeks to inform public policy makers about the role and scope of professional nursing.

A profession is only as good as its individual members. Every member of the profession must practice as a professional and contribute to nursing as a profession. Beginning nursing students should understand the significance of ascribing to professional attitudes and values and how their behavior can influence the public's view of the nursing profession.

As professionals, nurses are accountable for providing quality care. **Accountability** is the process in which individuals are answerable for their actions and have an obligation

SPOTLIGHT ON...

Professionalism

Indicators of Professionalism

Observe registered nurses in various practice settings. How do the nurses interact with one another? How do the nurses demonstrate professional commitment? Are they involved in professional activities, such as continuing education and professional association activities? How do these nurses contribute to the public's perception of the nursing profession?

TABLE 11-1 Comparison of Nursing to Criteria of a Profession

CRITERIA OF A PROFESSION	NURSING ACHIEVEMENTS
The work is intellectual and distinguished by a substantial body of knowledge.	<ul style="list-style-type: none"> Professional nursing requires knowledge, judgment, and skills based on biological, sociological, psychological, and nursing sciences.
Provision of a unique service to society.	<ul style="list-style-type: none"> Since the early twentieth century, the public has granted nursing the right and responsibility for self-regulation through state licensure laws. Historically, the public has been concerned about having an adequate number of registered nurses to provide service.
An expanding body of knowledge.	<ul style="list-style-type: none"> Nursing, by its nature, is expanding its knowledge base to meet the demands of health care delivery (i.e., increased technology, changing reimbursement systems, new practice settings). Nurse theorists and nurse researchers contribute to the knowledge base.
Personal responsibility to the public for services provided.	<ul style="list-style-type: none"> Professional registered nurses are held individually accountable to the public through such mechanisms as legal regulations and licensure.
A long period of education, including both theory and practice.	<ul style="list-style-type: none"> Professional nursing is based on a broad knowledge base, requiring specialized knowledge, skills, and abilities. Nursing education is both theory and practice based. Nursing has successfully established its educational base away from the apprentice approach and moved into higher education.
Autonomy and the ability to develop policy about the discipline and control of the activity of one's members.	<ul style="list-style-type: none"> Nurse practice acts generally grant authority for regulating the profession to an agency or board comprised of a majority of nurses. Nurse administrators have achieved positions at levels comparable with other hospital administrators.
Members share a common identity, values, and attitudes.	<ul style="list-style-type: none"> Registered nurses generally adhere to their dedication to care and identify their role as client advocates in the health care system. Professional organizations share common values.
Career choice of its members is motivated by altruism and reflects a long-term commitment to the public.	<ul style="list-style-type: none"> Historically, people entered the field of nursing to care for those in need; however, few individuals (predominantly female) anticipated long-term employment. Today, more men and minorities are entering nursing. Further, more registered nurses are employed full time in nursing than ever before and anticipate continuing this practice.
A code of ethics to which its members adhere.	<ul style="list-style-type: none"> The ANA has a long-standing published code of ethics. Many of the values identified within this code have been incorporated into nurse practice acts, thus establishing them as legal requirements. Violations of legal standards are grounds for disciplinary action against one's license. Traditionally, registered nurses have ascribed to and supported the professional organization's responsibility to develop a code of ethics. Registered nurses have demonstrated support of boards of nursing in enforcing professional practice and have participated by reporting violations.

Data from Chitty, K. K., & Black, B. P. (2007). *Professional nursing: Concepts and challenges* (5th ed.). St. Louis: Elsevier; Kelly, P. (2008). *Nursing leadership & management* (2nd ed.). Clifton Park, NY: Cengage Delmar.

(or duty) to act. Accountability is demonstrated by nurses in several ways. For example, the accountable nurse is one who demonstrates caring and compassion to clients and families. By providing client-centered holistic care, the nurse is meeting the expectations of society.

PROFESSIONAL ACCOUNTABILITY

Accountability is a term often used in nursing. How does a nurse demonstrate accountability? The nursing profession is accountable for establishing and maintaining standards that promote safe, effective care. Accountability involves responsibility—that is, being able and willing to respond. Nurses are accountable to many: themselves, clients and their families, the nursing profession, employers, and the general public for provision of safe, effective care established by the profession.

Accountability is one of the distinguishing characteristics of a profession. The professional nurse is accountable in several domains: professional, legal, and ethical. See Chapter 12 for complete discussion of legal and ethical accountability.

ELEMENTS OF PROFESSIONAL ACCOUNTABILITY

To appreciate one's accountability as a professional, it is important to first understand the social context of nursing. Professions arise from an identified public need for specialized knowledge and skills. The more specialized the knowledge and skills, the greater the risk to the public from an incompetent professional. Therefore, the public entrusts the profession to regulate itself on behalf of the public's best interests.

The public holds nursing accountable for safe nursing care and proper judgment in the provision of nursing services. The profession is held accountable by the public to

ensure that only qualified individuals are granted the right to practice and that those who fail to uphold the professional standards are denied the future right to practice. See the accompanying Spotlight On display.

Professional accountability within nursing is fostered through the mechanisms by which nurses obtain the right to practice. These mechanisms include rights and responsibilities, organizational accountability, legislative regulations, individual accountability, and student accountability.

Rights and Responsibilities

The nurse has responsibility to the client to be competent, to render nursing services in accordance with standards of nursing practice, and to adhere to the profession's ethical code. The public trusts that an individual titled registered nurse will have appropriate knowledge and skills to render the services offered. This translates to accountability of nurses to accept assignments for which they are competent and to maintain the necessary knowledge and skills to perform such services.

When the registered nurse chooses a specific area of practice (e.g., emergency or home health nursing) additional knowledge, skills, and abilities will be required as the nurse evolves from novice to expert. The registered nurse is accountable for acquiring and maintaining these abilities. Furthermore, the nurse is accountable for adhering to the standards of care for that specialty. This process may be accomplished through various methods such as orientation, in-service education, peer review, continuing education, journal articles, professional association activities, and formalized advanced education. Although employers may provide some continuing education opportunities to the registered nurse, the ultimate accountability to gain and maintain competency rests with every nurse.

Organizational Accountability

Organization is the means by which members of a profession, such as nursing, join together to promote and protect the profession. **Professional regulation** is the process by which nursing ensures that its members act in the public interest by providing a unique service that society has entrusted to them (ANA, 2008). Professional regulation is the responsibility of professional organizations. The accompanying Spotlight On display on self-regulation lists ways in which the nursing profession regulates itself.

The basis of professional regulation in nursing is the scope of nursing practice. Professional standards evolve from the scope of nursing practice and provide the framework for the development of competency statements. **Professional standards** are authoritative statements developed by the profession by which the quality of practice, service, and education can be judged (ANA, 2004). Professional standards form the basis of educational outcomes and criteria for organized nursing services (ANA, 2008). In addition, professional standards provide the framework for accreditation and certification.

SPOTLIGHT ON...

Professionalism

Accountability

Think of the following actions as ways to demonstrate professional accountability:

- Assuming only those responsibilities that are within one's scope of practice
- Not assuming responsibility for activities in which competency has not yet been mastered
- Evaluating the outcomes of one's own actions
- Admitting mistakes rather than blaming others
- Documenting nursing interventions
- Select one day of your clinical experience and identify ways in which you demonstrated accountability.

SPOTLIGHT ON...

Professionalism

Self-Regulation of the Nursing Profession

- Defining its practice base
- Providing for research and development of that practice base
- Establishing a system for nursing education
- Establishing the structures through which nursing services will be delivered
- Providing quality review mechanisms such as a code of ethics, standards of practice, structures for peer review, and a system of credentialing

Data from American Nurses Association (ANA). (2004). *Nursing: Scope and standards of practice*. Washington, DC: Author.

Accreditation

Accreditation is the process by which a nongovernmental agency appraises and grants status to institutions that meet predetermined criteria. The Joint Commission is one example of an accrediting body that promotes quality of health care by evaluating agencies' achievement of performance standards. Another type of accreditation is performed by the American Nurses Credentialing Center, which develops criteria for continuing nursing education agencies and evaluates those agencies in terms of meeting the criteria.

Accreditation and certification are mechanisms for promoting nursing accountability. The National League for Nursing (NLN) establishes educational standards and surveys educational programs to ensure that these standards are achieved by each accredited school of nursing. The ANA promotes the accountability of individual nurses through its certification process.

Certification

Certification is the process by which a nongovernmental agency certifies that an individual licensed to practice a profession has met predetermined standards specified for practice (ANA, 2008). Certification is an indicator that the nurse has obtained specialized knowledge and skills. Certification is one avenue for demonstrating and maintaining competence. It is a voluntary process through which nurses demonstrate their belief in the importance of ongoing education and excellence in clinical practice. Certification signifies a higher level of competence than is expected at the time of initial licensure.

The American Nurses Credentialing Center, a subsidiary of the ANA, develops and administers the certification examinations. It also requires a specified amount of continuing education in each specialty area for those nurses who choose to be certified.

Standards of Nursing Practice

Professional nursing is responsible for determining standards of nursing practice. Every nurse is accountable for providing quality care by adhering to professional standards.

The ANA revised its standards of clinical nursing practice in 2004. As the professional organization representing all registered nurses, the ANA's focus was to develop a set of standards applicable to all nurses engaged in clinical practice. The ANA, as well as many specialty nursing associations, has developed standards of practice for specific areas of practice, for example, medical-surgical nursing, gerontology nursing, and perioperative nursing.

Nursing must be able to articulate the core of practice for which practitioners are accountable to the public regardless of clinical setting or specialty. The *Scope and Standards of Nursing Practice* (ANA, 2004) reflect both the caring and professional expectations of nursing (see Table 11-2).

In Canada, the Canadian Nurses Association (CNA) is the professional organization entrusted with the responsibility of developing professional standards. For nurses in Canada,

TABLE 11-2 Standards of Nursing Practice

STANDARDS OF CARE

- I. Assessment: Collects data
- II. Diagnosis: Analyzes data
- III. Outcome Identification: Individualizes expected outcomes for client
- IV. Planning: Develops plan of care
- V. Implementation: Implements interventions in plan of care
- VI. Evaluation: Determines client progress toward outcome achievement

STANDARDS OF PROFESSIONAL PERFORMANCE

- I. Quality of Care: Evaluates quality and efficacy of nursing practice systematically
- II. Performance Appraisal: Compares one's own nursing practice to professional standards of care
- III. Education: Maintains current knowledge/skills
- IV. Collegiality: Contributes to professional development of others
- V. Ethics: Delivers care in an ethical manner
- VI. Collaboration: Works with others to provide client care
- VII. Research: Applies current research findings to practice
- VIII. Resource Utilization: Considers safety, efficacy, and cost in care delivery

American Nurses Association. (2004). *Nursing: Scope and standards of practice*. Washington, DC: Author.

the guiding principles of practice are listed in the CNA ethical code (2008).

LEGISLATIVE ACCOUNTABILITY

For nurses to be recognized as professionals, nursing must have legislation that clearly defines the role and scope of nursing practice. **Scope of practice** refers to the legal boundaries of practice for health care providers as defined in state statutes. Legislation defines the legal rights granted to the profession by the public. It is essential to public well-being that nursing regulate its practice to ensure that only those individuals qualified to practice are allowed to do so.

Legal regulation is the process by which the state attests to the public that the individual licensed to practice is at least minimally competent to do so (ANA, 2008). The **nurse practice act**, the laws governing the practice of nursing, defines the legal scope of practice within a state or territory. Such laws generally authorize state boards of nursing to interpret the legal boundaries of safe nursing practice (ANA, 2008). Other laws may also have an impact on the scope of nursing practice, for example, licensure laws of other health care providers.

Although specific duties of boards of nursing vary among states or territories, the primary purpose is to protect the public from unqualified or incompetent practitioners. Boards of nursing are authorized to:

- Establish legal standards of practice
- Approve educational programs that prepare individuals for licensure
- Grant licensure to individuals who meet minimum qualifications
- Renew licensure for competent practitioners
- Discipline licensees as necessary to protect the public

Boards of nursing are authorized to adopt rules and regulations that establish legal standards for nursing education, practice, and licensure within the context of the nurse practice acts. Nurses are accountable for complying with the provisions of the nurse practice act and the related rules and regulations established by the board of nursing in their respective states. Regulating bodies for nursing have the legal authority to set practice standards for the protection of the general public. In the United States, boards of nursing in each state serve as the regulatory bodies, whereas in Canada the authority for governing nursing lies within the board in each province or territory. There is no national board of nursing in either the United States or Canada.

Licensure

Licensure is the method by which a state holds the nurse accountable for safe practice to citizens of that state. Licensure grants the nurse legal authority to perform certain acts, to use a specific title that reflects one's practice rights, and to offer one's services and receive compensation for those services in the state that issues the license. Licensure is granted based on evidence that the individual has attained the minimum degree of **competency** (the ability, qualities, and

capacity to function in a particular way) to ensure that one is a safe practitioner.

Mandatory licensure laws prohibit any individual from practicing as a registered nurse without a current license. Licensure laws receive authority from the U.S. Constitution that defines the protection from harm as a constitutional right of every citizen. The Constitution entrusts the individual states with the inherent power to police human activities and to protect citizens in the human needs for safety, general welfare, and health. Laws enacted under the "police power" of the state are designed to protect society from ignorance, incapacity, deception, and fraud and must benefit the public primarily, *not* the members of the profession.

Licensure Process

There are two methods by which one may become initially licensed as a registered nurse in a particular state:

- **Licensure by examination** is the process by which an individual who has completed an approved nursing program seeks initial licensure by successfully passing a standardized competency examination.
- **Licensure by endorsement** is the process by which an individual who is duly licensed as a registered nurse under the laws of one state or country has those credentials accepted and approved by another state or country. Individuals are licensed to practice only in the state in which they initially took the licensing examination. Endorsement allows registered nurses to practice in states other than the one of initial licensure.

Nurse Licensure Compact

Nurses today are mobile and often travel to other states in which they practice temporarily. Also, electronic nursing means that nurses who are licensed in one state may be assessing, counseling, teaching, or otherwise caring for clients who are in another state. *Multistate licensure*, *interstate practice*, and *mutual recognition* are terms that refer to the practice of allowing a nurse to obtain one state licensure that grants privilege to practice across state lines. The Nurse Licensure Compact (NLC), which was first recognized by the National Council of State Boards of Nursing (NCSBN) in 1997, refers to a legal agreement between states to recognize the privilege of nurses to practice across state lines without having to apply for a license in each state (NCSBN, 2004). The nurse, however, is responsible for knowing and complying with the nursing licensure laws of each state in which the nurse practices. Each state must enact legislation that endorses the NLC and must adopt legal rules and regulations for implementing the compact. The NCSBN (2004) lists the following as some benefits of the NLC:

- Improved mobility for nurses
- Improved access to nursing care
- Clarification of the authority to practice for nurses working in interstate practice or telenursing
- Improved access to nurses during times of great need (i.e., a disaster)

The mutual recognition licensure system is based on states entering into an agreement, known as an interstate compact, to authorize practice by individuals licensed in one state to practice in the other state. The interstate compact defines such issues as jurisdiction, discipline, and information exchange between party states. Currently, 23 states are partners in NLC licensure (NCSBN, 2008).

The state boards of nursing have the authority and responsibility to determine that only qualified individuals are granted licensure. The boards of nursing may deny licensure based on information that indicates one to be “unfit” for such licensure. Examples of such activities are:

- A criminal history (especially a criminal act that affects one’s ability to render safe nursing care)
- Chemical addiction
- Practicing without a current, proper license
- Aiding someone else who is unlicensed to pose as a nurse

State boards of nursing are required to report adverse actions taken against licensees to national data banks.

National Data Banks

Two national clearinghouses collect data about incompetent and fraudulent health care providers. The National Practitioner Data Bank was established by Congress and is administered by the U.S. Department of Health and Human Services. The Healthcare Integrity and Protection Data Bank is a national data collection program for information about adverse actions taken against health care providers. Both data banks are designed to improve the quality of health care by restricting the practice of health care providers who are incompetent. The need for creating such data banks was highlighted by incompetent and fraudulent practitioners who would move from one state to another to avoid restrictions on their professional practice.

The Data Banks’ Proactive Disclosure Service Prototype (PDS) went online May 1, 2007. The PDS provides an opportunity for health care agencies (e.g., hospitals, HMOs) to continuously check up on their practitioners (U.S. Department of Health & Human Services, Health Resources & Services Administration, 2008). Types of adverse actions that must be reported to the data banks include:

- Health care–related civil judgments
- Health care–related criminal convictions
- Adverse actions taken by federal or state agencies responsible for licensing and certification
- Exclusions of prescribing practitioners, providers, and suppliers from participation in federal or state health care programs
- Actions taken by boards of nursing against licensees who violate state licensure laws

Licensure Examination

Each state is responsible for determining the licensing requirements for an individual to practice in that state.

Boards of nursing are entrusted to determine the appropriate examination to measure minimum competency for practice as a registered nurse. In the United States, through the NCSBN, the same examination is given nationally to qualified candidates. Known as the NCLEX-RN (National Council Licensure Examination for Registered Nurses), this examination has been adopted as the standard licensure examination by all 50 states and the U.S. territories.

A separate test (National Council Licensure Examination for Practical Nurses, NCLEX-PN) is administered to practical and vocational nurses. Use of a national licensure examination ensures uniformity in testing and facilitates endorsement of licensure in other states.

The examination is designed to distinguish qualified candidates from those who do not possess the necessary competencies for safe practice. The NCLEX-RN measures the competencies expected of a nursing graduate at the generalist level. The NCLEX-RN reflects the belief that nursing requires knowledge of:

- Safe and effective care environment
- Health promotion and maintenance
- Psychosocial integrity
- Physiological integrity (NCSBN, 2007)

The NCLEX-RN is not an examination for which one prepares in the last few weeks before graduation. Nursing students successfully complete this examination through careful study and achievement of nursing courses. Activities offered during the academic experience prepare students for registered nurse practice. Clinical experiences through which students learn the practice of nursing contribute to the ability to pass the licensure examination.

INDIVIDUAL ACCOUNTABILITY

Professional nurses must understand the method by which the board of nursing adopts rules and regulations in their state of licensure so that they can be active participants in the development of such regulations. Nurses can use a variety of ways to demonstrate individual accountability; two methods are continued competency and professional development.

Continued Competency

A registered nurse has the professional responsibility to attain and maintain competency. There has been much debate within the profession and consumer advocacy groups about the roles and responsibilities of health profession licensing boards to ensure that their members maintain minimum competency requirements for safe practice.

Once licensed, it is the responsibility of the registered nurse to maintain a current active license to practice in accordance with state requirements. Registered nurses must renew their licenses on an annual or biannual cycle before the expiration date and meet other requirements for license renewal as required by the individual state board of nursing.

The nursing profession has traditionally used three methods of ensuring accountability to the public—licensure examination, continuing education, and certification. These three methods are currently being scrutinized by the ANA in an attempt to ensure that nurses demonstrate competency. A variety of mechanisms are being considered as measures to improve accountability. Development of a professional portfolio is one avenue for demonstrating continued competence.

Professional Development

Active involvement in student organizations at the school, state, and national levels enables nursing students to develop critical professional skills and participate in events that may have an impact on their careers. Table 11-3 lists some professional organizations in which nurses can participate. In addition to these professional organizations, there are professional associations organized around specialty practice areas, including:

- American Academy of Nurse Practitioners
- American Association of Critical-Care Nurses
- American Association of Legal Nurse Consultants
- American Forensic Nurses
- American Holistic Nurses Association
- American Nursing Informatics Association
- American Psychiatric Nurses Association
- American Society of Pain Management Nurses
- Emergency Nurses Association
- Home Healthcare Nurses Association

Involvement with district and state nurses' associations is also encouraged. Nursing students can participate in these groups through continuing education, legislative activity, or political action. In addition, students have the opportunity of making contacts with registered nurses within these associations who will eventually be their colleagues. Such contacts are helpful when seeking guidance in employment opportunities and can develop into valuable mentoring relationships.

STUDENT ACCOUNTABILITY

Nursing students' accountability is directly related to their legal authority to practice. Nursing students function legally as an *exception* to the state licensure requirements *while enrolled in a nursing program* that is approved by the state board of nursing. Such exception is granted only when the student is engaged in learning activities structured within the program of studies. Performing nursing activities (other than those assigned to unlicensed individuals) outside the formalized clinical practicum of the nursing curriculum constitutes the illegal practice of nursing; see the accompanying Spotlight On display. Accountability for nursing care is shared by the student, faculty, educational institution in which the student is practicing, and clinical agency. The various responsibilities of each of these parties are determined by the respective state boards of nursing.

For nursing students, accountability for competency begins the first clinical day and continues throughout their careers. Therefore, students have the responsibility to:

- Be prepared for clinical practice
- Engage only in those skills for which they have gained competence
- Seek instruction as necessary

Students must not engage in client care activities without proper preparation, prior validation of competency by their instructor, and appropriate supervision (see Figure 11-1 on page 175). Nursing students have a responsibility to request clear information regarding the instructor's expectations and to seek direct supervision when uncertain of their own competency. See the accompanying Safety First display.

ADVANCED PRACTICE NURSING

Advanced practice nursing is the practice of nursing at a level requiring an expanded knowledge base and clinical expertise in a specialty area. Advanced practice registered nurses (APRNs) have an increased level of accountability to the public, the profession, and themselves. The autonomy that is experienced by nurses in advanced practice roles increases the sense of responsibility for personal decisions and actions. The general public also expects a higher level of ability and skills from APRNs just as it does from specialists in other professions. As APRNs assume leadership roles in

SAFETY FIRST

It is absolutely critical to client safety that nursing students verbalize any questions or concerns relative to their assignments before instituting care. Students must ask for directions if unsure of their abilities.

the nursing profession, they will promote increased accountability as a standard for the entire profession.

A changing health care environment has brought new attention to and demand for nursing's advanced practice roles. However, a lack of uniformity in the educational base for entry into advanced practice nursing and the method by which states regulate this area has led to confusion.

Advanced practice nursing, which represents new opportunities for registered nurses, requires specialized knowledge and clinical proficiency (ANA, 2008). Advanced practice nursing is differentiated from specialty practice in that specialization involves concentrating one's practice in a particular field of nursing and advancement involves expanded

practice roles (ANA, 2008). Preparation for advanced practice has evolved from hospital-based certificate programs to university coursework. Although APRNs are prepared primarily in graduate programs, some individuals in current practice have been prepared in postbasic programs. Currently identified roles of APRNs are (ANA, 2008):

- Clinical nurse specialist (CNS)
- Nurse practitioner (NP)
- Certified nurse midwife (CNM)
- Certified registered nurse anesthetist (CRNA)

Table 11-4 on page 176 provides a description of the advanced practice nursing roles.

FIGURE 11-1 This nursing student is being taught to measure the client's blood pressure. If the instructor were temporarily called away from the bedside and the client asked the student about the measurement and its significance, what do you think the student should do? DELMAR/CENGAGE LEARNING

LEADERSHIP IN NURSING

Leadership is a method of modeling accountable behavior to others. Nursing has numerous leaders who demonstrate and encourage accountability. *Leadership* and *management* are terms often used interchangeably; however, some significant differences exist. **Management** is the accomplishment of tasks either by oneself or by directing others. **Leadership** is the interpersonal process that involves motivating and guiding others to achieve goals. Managers tend to be task oriented, whereas leaders focus on people. Every nurse, regardless of title or position, is a manager; each has the potential to be a leader.

MANAGERIAL FUNCTIONS

Essential functions that are performed by effective managers include:

- **Planning:** Determining objectives and identifying methods that lead to achievement of those objectives

- **Organizing:** Using resources (human and material) to achieve predetermined outcomes
- **Directing:** Guiding and motivating others to meet the expected objectives
- **Controlling:** Using performance standards as criteria for measuring success and taking corrective action, if necessary, to see that others comply with performance standards
- **Decision making:** Identifying a problem and deciding which alternatives can best achieve the objectives

These five functions are used daily by managers to accomplish the goal of providing quality care.

LEADERSHIP STYLES

Effective leaders accomplish goals by motivating and inspiring other people. In other words, they use the concept of **synergy** (the combined power of many) rather than attempting to achieve success alone.

The leader's behavior greatly determines the behavior of the group. There are basically three styles of leadership: autocratic, democratic, and laissez-faire (see Table 11-5 on page 177).

The **autocratic leadership style** is leader focused; that is, the leader maintains strong control, makes all decisions, and solves all problems. The leader dominates the group by issuing commands rather than making suggestions or seeking input.

The **democratic leadership style** (also called participative leadership) is based on the belief that every group member should have input into development of goals and problem solving. The democratic leader acts primarily as a facilitator and resource person. Concern for each member of the group as a unique individual is demonstrated by the leader.

In the **laissez-faire leadership style**, the leader assumes a passive, nondirective, and inactive approach. Leadership responsibilities are either assumed by the members of the group or completely abdicated. All decision making is left to the group, with the leader giving little, if any, guidance, support, or feedback. Almost any behavior by the group is permissible due to the leader's lack of limit setting and stated expectations. The tasks are unmet, and the relationship needs of group members are ignored.

No single style is superior to the other. Each leadership approach has its advantages and disadvantages (see Table 11-5). The effective leader will use **situational leadership**, which is a blending of styles based on current circumstances and events. The leader knows that behavior does not occur in a vacuum; thus, leadership styles are assumed according to the needs of the group and tasks to be achieved.

LEADERSHIP CHARACTERISTICS

There is debate about the development of effective leaders: Is leadership innate, or is it acquired through experience?

TABLE 11-4 Advanced Practice Registered Nursing (APRN) Roles

ADVANCED PRACTICE ROLE	EDUCATIONAL PREPARATION	MAJOR RESPONSIBILITIES
Clinical Nurse Specialist (CNS)	Graduate degree in a recognized nursing specialty	Authorized to provide direct nursing care to a select population Plans, guides, and directs care provided by other nursing personnel
Nurse Practitioner (NP)	Advanced preparation in a specific area of care	Authorized to provide primary care to individuals, families, and other groups in a variety of settings, including but not limited to homes, institutions, offices, industry, schools, and community agencies Conducts physical examinations Takes medical histories Orders and interprets laboratory and other diagnostic tests Diagnoses Treats minor illnesses (acute or chronic) or injuries Counsels and educates clients
Certified Nurse Midwife (CNM)	Advanced preparation in nursing and midwifery	Authorized to manage the care of women during all phases of pregnancy and newborns
Certified Registered Nurse Anesthetist (CRNA)	A registered nurse who is prepared in the science of anesthesiology	Authorized to select and administer anesthetics and ancillary services to clients

Delmar/Cengage Learning

The characteristics of effective leaders are discussed in the following sections.

Communication

Effective leadership relies on the individual's ability to communicate. Just as the effective nurse uses communication skills with clients, the effective manager uses communication as a tool for motivating others to be successful. Active listening is the major technique that managers use in order to understand others' needs and goals. Active listening is also the mechanism that allows the manager to instruct, to provide and receive feedback, and to keep the team moving forward. An effective nurse leader will:

- Listen actively to others
- Articulate thoughts in an intelligent, persuasive manner
- Differentiate aggressive, passive, and assertive behavior in order to communicate appropriately in a given situation

Aggressive behavior occurs when an individual meets one's needs regardless of the impact on others. *Passive behav-*

ior is giving up one's rights and not having one's needs met. *Assertive behavior* occurs when an individual seeks to meet one's needs while respecting the rights of other people. Effective leaders communicate in an assertive manner; that is, they speak directly and honestly to others.

Credibility

A leader motivates others by demonstrating enthusiasm and exerting influence. To be influential, the leader must be credible. Credibility, the quality or power of inspiring beliefs, is based on competence. From competence comes confidence. Individuals who know what they are doing and perform well are those who can influence others.

Delegation

The nurse leader must be able to delegate effectively to coordinate the delivery of care. **Delegation** is the process of transferring a selected task in a situation to an individual who is competent to perform that specific task. Delegation is a

TABLE 11-5 Leadership Stages

STYLE	DESCRIPTION	LEADER BEHAVIORS	POTENTIAL IMPACT ON GROUP MEMBERS	ADVANTAGES	DISADVANTAGES
Autocratic	<ul style="list-style-type: none"> Basic premise: Leader knows best. Communication flows downward. 	<ul style="list-style-type: none"> Controlling Directive Makes all decisions and solves all problems Issues commands 	<ul style="list-style-type: none"> Hostility Rebellion 	<ul style="list-style-type: none"> Task oriented, high productivity Facilitates a quick response Often necessary in crisis situation 	<ul style="list-style-type: none"> Inhibits creativity and autonomy of members Promotes mistrust and fear among followers Members may become hostile or passive
Democratic (“participative leadership”)	<ul style="list-style-type: none"> Basic premise: Every member should have input. Communication is open and mutual. 	<ul style="list-style-type: none"> Acts as a facilitator Serves as resource person Encourages members’ active participation 	<ul style="list-style-type: none"> Improved productivity More opportunity for personal growth Increased cooperation and teamwork 	<ul style="list-style-type: none"> Promotes empowerment of team members Facilitates communication Increased creativity and autonomy 	<ul style="list-style-type: none"> Time-consuming May be less efficient (in quantifiable terms) Disagreements may happen as members express their viewpoints
Laissez-faire	<ul style="list-style-type: none"> Basic premise: Leadership responsibilities are assumed by group. Almost any behavior by the group is permissible due to the leader’s lack of limit setting and stated expectations. 	<ul style="list-style-type: none"> Passive, nondirective approach Provides little, if any, support, guidance, or feedback Sets no limits 	<ul style="list-style-type: none"> Unmet tasks Relationship needs of group members ignored Apathy 	<ul style="list-style-type: none"> Promotes autonomy and creativity in some members 	<ul style="list-style-type: none"> May evoke passivity in team members Aimless behavior often occurs Chaos common Inefficiency and low productivity

Delmar/Cengage Learning

multifaceted process involving communication, conflict resolution, feedback and evaluation, and knowledge of the person to whom a task is delegated (Hansten & Jackson, 2008).

Delegation is a helpful tool for nurse leaders in that it encourages team members to develop skills. Prior to delegating, the nurse manager must first assess the delegatee’s ability to perform the specific task. Delegation is, therefore, a mechanism for encouraging staff members’ growth as the effective manager will be available to teach and assist when necessary. The “five rights” of delegation must be followed to assure that the assignment is the *right task* delegated under the *right circumstances* to the *right person* with the *right directions and communication* and with the *right supervision and evaluation*

(NCSBN, 2006). The nurse uses professional judgment when determining which activities to delegate. Any activity that requires nursing judgment or independent nursing action cannot be legally delegated. See the Nursing Process Highlight.

In general, registered nurses are authorized by law to both provide nursing care to clients directly and supervise and instruct others to deliver this care. Further, the registered nurse is empowered to delegate selected tasks to either licensed or unlicensed nursing personnel (see Figure 11-2 on page 178). Decisions about delegation are guided by the needs of the client, the number and type of available personnel, and the nursing management system of the unit or agency.

NURSING PROCESS HIGHLIGHT

Planning

Delegation of the Nursing Process

Which steps of the nursing process may be legally and safely delegated?

Assessment: No. Input from other health care providers may be solicited (e.g., vital signs of client with noncomplex problem).

Diagnosis: No. Only registered nurses can establish nursing diagnoses.

Planning: No. Input is solicited from other members of the health care team.

Implementation: Yes. Certain tasks (e.g., hygiene, feeding, ambulating) can be delegated to other members of the care delivery team.

Evaluation: No. Input from others may be sought.

Data from American Nurses Association. (2005). *Principles for delegation*. Retrieved December 2, 2008, from <http://www.safestaffingsaveslives.org/WhatIsSafeStaffingPrinciples/PrinciplesforDelegation.html.aspx>.

The first consideration in determining the most appropriate nursing personnel to administer care is client safety. For example, administration of blood or blood products is not an act that can be legally delegated to licensed practical nurses or unlicensed assistive personnel in most states. Other activities, such as assisting clients with activities of daily living (ADL, those activities performed by a person usually on a daily basis), ordering supplies, or transcribing orders, can often be safely delegated to other personnel.

If delegation of a particular activity is legally allowed, the nurse should validate the knowledge and skill level of personnel

before delegation. If uncertain about the level of competence of an individual to perform an activity, the nurse should not delegate the task.

The nurse practice act defines which aspects of care can be delegated and which must be performed by the registered nurse. Because nurse practice acts vary among the states and provinces, it is imperative that the nurse stay current with the rules and regulations promulgated by the respective state (or provincial) board of nursing regarding the delegation of nursing tasks. See Figure 11-3 on page 179 for elements to consider when delegating.

Even though a task may be delegated, the nurse who delegates maintains accountability for the overall nursing care of the client. Only the task, not the ultimate accountability, may be delegated to another. See the accompanying Spotlight On display.

Critical Thinking

Critical thinking is another characteristic of an effective leader. According to Alfaro-LeFevre (2008), “Critical thinking is the key to resolving problems. Nurses who don’t think critically become *part* of the problem” (p. 13). The critical thinker has an open-minded, questioning attitude that facilitates problem solving (Figure 11-4 on page 179). This underlying curiosity leads the individual to search for answers based on rationales. The ineffective leader is one who falls into routine ways of thinking without even being aware of what is happening. See Chapter 5 for more information on critical thinking.

**SPOTLIGHT ON...****Legal/Ethical****Delegation**

Your employer, a large acute care hospital, has hired consultants to examine the cost of care expended in the facility and recommend a more cost-effective system. These consultants recommend decreasing the number of both registered nurses and licensed vocational nurses and increasing the responsibilities of unlicensed assistive personnel. As a registered nurse in charge of the care of medical-surgical clients, what questions would you ask regarding this proposal? In what ways do you think your responsibilities would increase because of this situation? Do you think your responsibilities would decrease significantly? What impact would this proposal have on the ethical delivery of care to clients, specifically the nurse’s need to cause no harm and promote good? What are the legal implications of this recommendation?

FIGURE 11-2 The registered nurse is responsible for delegating nursing tasks to other members of the health care team.

DELMAR/CENGAGE LEARNING

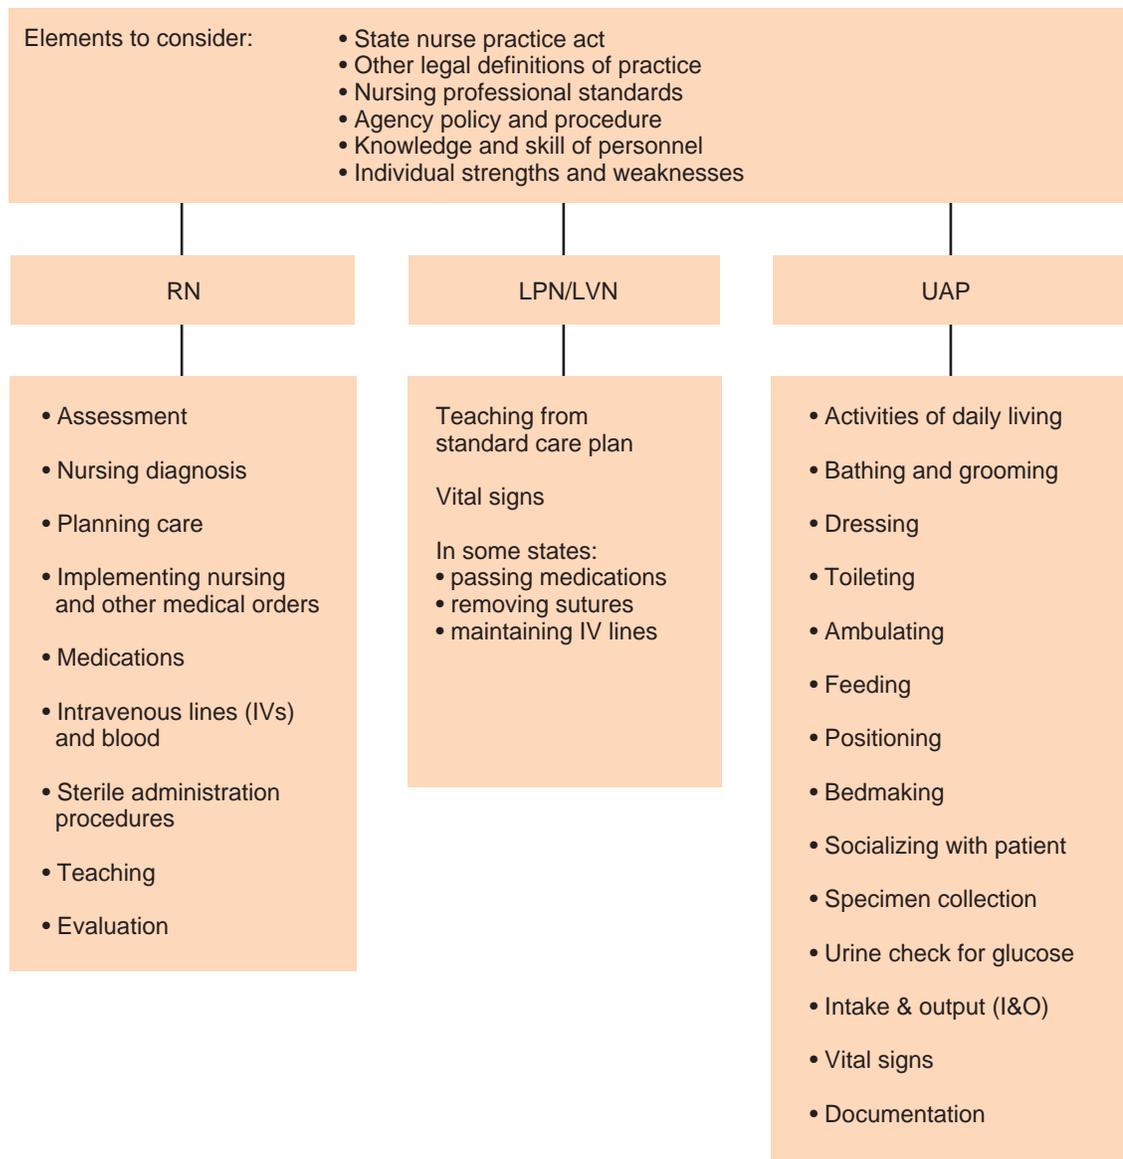

FIGURE 11-3 Considerations in Delegation POLIFKO-HARRIS, K. (2004). *CASE APPLICATIONS IN NURSING LEADERSHIP & MANAGEMENT*. CLIFTON PARK, NH: THOMSON DELMAR LEARNING.

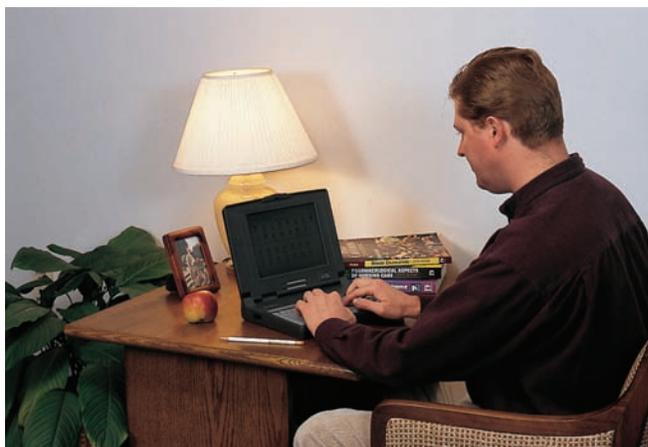

FIGURE 11-4 Critical thinking skills are integral to the analysis of problems and the development of leadership skills. How does critical thinking contribute to professional accountability? DELMAR/ CENGAGE LEARNING

Initiating Action

In addition to thinking critically, a leader initiates action. Only by putting ideas into action does a person become a leader. A leader does not adopt a wait-and-see attitude with problems; instead, a leader initiates measures to solve problems. When taking action, the effective leader demonstrates flexibility. If one behavior is ineffective, the leader is not hesitant to try another approach. By initiating action, the proactive leader role-models successful behaviors and encourages others to strive for quality.

Risk Taking

Taking action to solve problems (i.e., to initiate change) involves taking a risk. People who take risks are those who are not satisfied with the status quo and strive continually for improvement. Effective risk takers are not reckless or haphazard; instead, their risk-taking activities are goal directed.

**SPOTLIGHT ON...****Professionalism****Risk Taking**

It is not always comfortable to assume the role of change initiator. However, whether you choose to act or not to act, you have made a choice. The question that must be answered is “Can I accept the consequences of my choice(s)?”

People engage in risk taking every day, often with no awareness of this behavior. Some common examples of risk-taking behaviors are:

- Volunteering to be in charge of a project
- Giving constructive criticism to others
- Expressing opinions even when they are unpopular

Effective leaders understand that the benefits of risk taking far outweigh the potential negative consequences and, therefore, act accordingly. See the accompanying Spotlight On display.

Persuasiveness and Influence

An effective leader uses influence to motivate and inspire others to achieve goals. A leader understands how to use power effectively, not to dominate but, rather, to motivate others. In order to motivate others, the leader must be able to inspire confidence. Ellis and Hartley (2007) have identified the following as behaviors of inspirational leaders:

- Being predictable and dependable
- Exercising good judgment
- Being knowledgeable and competent
- Demonstrating patience
- Recognizing efforts of others

Persuasiveness is a tool that managers can use to create enthusiasm for a project, encourage collaboration, and increase cohesiveness among team members. The persuasive leader is one who communicates effectively and demonstrates personal power. Persuasive people demonstrate enthusiasm for the task at hand and, therefore, are able to inspire others to work with them to accomplish goals. Because persuasive people exhibit enthusiasm, they are able to energize those around them. The accompanying Nursing Checklist provides some hints for increasing persuasiveness and influence. Also, see the accompanying Spotlight On display.

POWER

A leader is a powerful person. **Power** is the ability to do or act and results in the achievement of desired results. Power causes things to happen. Powerful people are able to modify behavior and influence others to change, even when others are

**SPOTLIGHT ON...****Professionalism****Leadership Characteristics**

How can you, in the preprofessional role, function as a leader? Think of all the situations in which you will attempt to motivate others to change, for example:

- Encouraging clients and families
- Interacting with team members
- Collaborating with classmates and instructors

resistant to change. Every person uses power to some degree to meet individual goals. Effective nurse leaders use power to improve the delivery of care and to enhance the profession.

Effective power is shared and enables all to work toward their potential. Power involves using force, which is derived from a variety of sources, including physical strength, ability to reward and punish, financial incentives, legal actions, position within an organization, and expertise.

Types of Power

The type of power used depends on various power sources or bases. Table 11-6 on page 181 provides an overview of types of power according to their sources. Personal power can be developed by building trust and gaining the confidence of coworkers. Another way to develop power is to focus on solving problems rather than complaining about them. Creating outcomes is powerful!

Principles of Power

Nurse leaders must recognize certain guiding principles when obtaining and using power. Effective nurse leaders understand that power is an expendable resource, so they are careful to renew their sources of power in order to maintain an adequate power base. Power requires the leader to be committed to organizational goals; a leader who loses sight of the objectives also loses the power to influence others. The leader who uses power effectively will use only as much power as necessary to achieve the expected goal.

**NURSING CHECKLIST****WAYS TO INCREASE PERSUASIVENESS AND INFLUENCE**

- Role-model expected behaviors.
- Use effective problem-solving skills.
- Communicate expectations clearly.
- Give praise for accomplishments.
- Maintain one's own competency.
- Encourage others to participate in decision making.

TABLE 11-6 Types and Sources of Power

TYPE	SOURCE	EXAMPLE
Coercive power	Ability to punish	A head nurse assigns a staff nurse who has been “insolent” to an undesirable shift.
Expert power	An excellent knowledge base and skill level; the person has expertise in an area not held by those who are to be influenced by the leader	The instructor exerts power with students.
Informational power (“positional”)	Based on the types and amount of information that an individual can access	A staff nurse has just learned through her experience a new way to teach a client. She tells her coworkers about the approach. Knowledge is shared and power increases.
Legitimate power	Based on one’s position within a hierarchy	The nurse executive has legitimate power over a staff nurse within the same agency or institution.
Personal power	Derives from a high degree of self-confidence that is based on positive self-esteem	A nurse with a take-charge attitude is powerful during a crisis.
Referent power	Charisma; others wanting to associate with one	A unit manager is powerful because he is popular with both his superiors and subordinates.
Reward power	Ability to provide incentives	A nurse manager can decide when to schedule vacation time for staff nurses.

Delmar/Cengage Learning

Developing a Power Base

Power can be a positive element in nursing. For example, a nurse manager can use personal power to promote cohesiveness and teamwork with subordinates. The power of a work group can be harnessed by a leader who is skilled in communication and time management techniques. Power is a force used by nursing leaders to accomplish goals. However, many nurses do not want to be labeled as powerful because of a perceived negative connotation of the word. In the past, many nurses have tended to abdicate their power by negating their own contributions and expertise. Power is abdicated by:

- Focusing on the negative
- Failing to seize power and use it
- The way one dresses
- Body language (hesitant voice tone, slouched posture)
- Always playing it safe rather than taking risks

Expanded practice roles have increased nursing’s power. For example, NPs are empowered legally through licensure to use advanced knowledge and skills. Expansion of the scope of nursing practice results in greater accountability to one’s self, the profession, and the public. Competence of

APRNs increases their power to exert a positive influence on the health care delivery system.

In addition to advanced practice nursing, another way for nurses to achieve power is affiliation. There are a variety of ways to build affiliations, including mentorship and networking.

MENTORING

A mentor is an experienced person who serves as a guide to a novice. Mentors help novices develop skills. When seeking out a mentor, it is wise for nursing students or graduate nurses to look for a person who communicates directly and focuses on the positive. In selecting a mentor, the novice nurse should choose a person who can provide criticism in a supportive, constructive manner through teaching and role modeling (Zerwekh & Claborn, 2008).

NETWORKING

Networking, the process of building connections with others, is essential for the success of nurses because it is a way to increase power. Networking helps nurses to become

NURSING CHECKLIST

NETWORKING STRATEGIES

- Seek opportunities to help others develop.
- Role-model successful behaviors.
- Share “secrets” for success.
- Encourage others to take professional risks.
- Provide support.
- Teach those who are less experienced.
- Express pride in others’ achievements.
- Respect colleagues’ judgment and work.
- Consult with colleagues and respect their input.
- Introduce others to contacts.
- Acknowledge all help received from contacts.
- Make frequent contact with network members.

more influential because it encourages sharing of information and creates a synergistic effect for all those involved. Establishing and maintaining connections with others can be accomplished in a variety of ways (including mentoring and preceptorship), some of which are shown on the accompanying Nursing Checklist.

EMPOWERMENT

Empowerment, the process of enabling others to do for themselves, is an interpersonal process. Empowerment occurs when individuals are able to influence what happens to them.

Many elements are necessary for creating an atmosphere conducive to empowerment. Open communication built on trusting relationships is of utmost importance; the environment must be supportive and caring. Nurses who work in a nurturing environment are more likely to be empowered than those working in settings that do not attend to employee needs. Another element for establishing empowerment is mutual goal setting and decision making; personal power increases as these become shared responsibilities. Nurses who are empowered are the ones who are motivated to become active problem solvers. They become more confident and competent as a result of empowerment.

Empowerment of Clients

Client teaching is a major tool used by nurses to empower clients. By teaching clients how to better meet their needs, nurses are promoting client independence and power. For clients to be truly empowered (i.e., enabled to care for themselves), many health care providers need to shift their thinking away from the paternalistic belief that is based on the need for control. Paternalism is the process of treating adults like children by telling them what to do. Some health care providers still use a paternalistic approach to clients (e.g., telling a client to do something “for your own good”). Nurses who empower others treat clients as partners in

CLIENT TEACHING CHECKLIST

CLIENT EMPOWERMENT

- Determine client’s learning needs, focusing on the client’s perception of importance.
- Speak in terms easily understood by the client and family.
- Demonstrate the skill and ask client to perform a repeat demonstration.
- Provide feedback immediately to reinforce the learning.
- Ask clients to state in their own words what has been learned about the topic.

health care. An example of client empowerment is a nurse teaching a client how to self-administer insulin injections. The accompanying Client Teaching Checklist offers suggestions for empowering clients.

Another mechanism for nurses to empower clients is advocacy. Acting as client advocates, nurses can work through the political and legislative processes to bring about positive changes for vulnerable populations. For example, nurses exert influence with policy makers regarding health care needs of the elderly, children, those who are economically impoverished, and homeless individuals.

Empowerment of Nurses

Empowerment is not something that is given to nurses. It is encouraged by enlightened leaders who value the work of their colleagues. Nurses will continue to create environments that promote the process of empowerment. Some ways to promote nurse empowerment include:

- Sharing power and resources (including knowledge) with others
- Admitting when a mistake is made (demonstrates trustworthiness and honesty)
- Avoiding power struggles
- Using persuasion
- Using accurate information in decision making

An example of nurse empowerment is self-governance (the process of having nurses work together to develop their own schedule for unit staffing coverage).

POLITICS OF NURSING

Politics is often used to refer to governmental and legislative issues. However, politics is a much broader concept in that it refers to how things are done within an organization. **Politics** is the way in which people try to influence decision making, especially decisions about the use of resources. See the

UNCOVERING THE

Evidence

TITLE OF STUDY

“Nursing Leadership: Championing Quality and Patient Safety in the Boardroom”

AUTHORS

M. F. Mastal, M. Joshi, and K. Schulke

PURPOSE

Identify the extent to which hospital boards of trustees, CEOs, and CNOs (chief nursing officers) are engaged in quality and safety at the leadership and governance level.

METHODS

A total of 73 telephone interviews were conducted with hospital board chairs, CEOs, and CNOs from a convenience sample of 36 hospitals in the United States. The telephone interviews were followed up by a focus group consisting of nurse executives.

FINDINGS

There were significant differences in the perceptions of CNOs versus those of board chairs and CEOs. CNOs reported greater increases in understanding quality and client safety than did board chairs. Board chairs and CEOs have limited comprehension of inherent nursing quality issues, including client safety.

IMPLICATIONS

Nurse executives have a critical role in championing client safety and quality improvement issues among the power brokers of health care.

Mastal, M. R., Joshi, M., & Schulke, K. (2007). Nursing leadership: Championing quality and patient safety in the boardroom. *Nursing Economics, 25*(6), 323–330.

Uncovering the Evidence display. Organizational politics determine the following:

- Who has the power

NURSING CHECKLIST

BUILDING POLITICAL POWER WITHIN AN ORGANIZATION

- Call attention to oneself by volunteering to serve on committees.
- Know what the organization values, both the written and the unwritten rules of expected conduct.
- Prepare oneself by earning the credentials needed for the particular position that is being sought.
- Communicate ideas, both verbally and in writing.
- Develop an extensive network by getting to know people who work in other areas of the organization.
- Become involved in professional associations.
- Seek out a mentor (membership in professional organizations facilitates this goal).
- Project a positive image, not only in dress and posture, but also in one's behavior.

- Who controls the resources
- Who is rewarded
- Who makes the decisions

Every nurse is affected by organizational politics. It is up to the individual nurse to decide whether to join the political “game” or whether to let others make decisions.

Nurses who are able to advance their careers have determined where the opportunities lie and have taken advantage of these opportunities. Some specific ways that nurses can increase their political power within an organization are listed in the Nursing Checklist.

Nurses need to be involved not only in organizational politics but also in politics that affect society at large. Because nurses provide essential services, they possess much potential power. However, nurses need better organization to fully actualize that potential. When that potential is realized, nursing will become even more powerful and, therefore, better able to influence the delivery of health care.

KEY CONCEPTS

- The criteria for professional nursing practice include intellectual work, provision of a unique service, an expanding body of knowledge, personal responsibility to the public, an extended period of education that includes theory and practice, autonomy, a common identity shared by members, a sense of altruism and commitment to the public, and a code of ethics upheld by its members.
- Accountability is a process that requires individuals to be answerable for their actions. Being accountable means having an obligation (or duty) to act.
- As a profession, nursing is accountable for establishing and maintaining standards that promote safe, effective care.
- Professional accountability within nursing is fostered through mechanisms by which nurses obtain the

right to practice and is the basis for understanding the responsibility nurses have to the public.

- Professional standards provide the framework for the development of competency statements.
- Nurse practice acts, which vary from state to state, clearly define the role and scope of nursing practice.
- Licensure gives an individual the right to offer one's services and receive compensation as a registered nurse.
- An individual can be granted the right to practice nursing within a state or territory by licensure through examination or licensure through endorsement.
- The registered nurse has the professional responsibility to attain and maintain competency.
- Nursing students have the responsibility to be prepared for clinical practice, to perform those skills for which competency has been achieved, and to seek instruction as necessary.
- Advanced practice nursing requires specialized knowledge and clinical proficiency. Advanced practice nursing roles include clinical nurse specialist, nurse practitioner, certified nurse midwife, and certified registered nurse anesthetist.
- Leadership involves motivating and guiding others to achieve goals.
- Managerial functions can be categorized into five major areas: planning, organizing, directing, controlling, and decision making.
- Characteristics of effective leaders include communication, credibility, delegation, critical thinking ability, initiating action, risk taking, and persuasiveness and influence.
- Types of power (rewarding, coercive, referent, expert, legitimate, personal, and informational) are derived from sources such as ability to provide incentives, ability to punish, charisma, expertise, position within an organization, self-confidence, and information.
- Through empowerment, both nurses and clients can achieve their professional and personal goals.
- Nurses influence the delivery of health care services through participation in organizational politics.

REVIEW QUESTIONS

1. Which of the following is the primary legal guide for professional nursing practice?
 - a. Agency-specific job description
 - b. American Nurses Association *Ethical Code for Nurses*
 - c. Federal nurse practice act
 - d. State nurse practice acts
2. Which of the following is an ineffective leader behavior?
 - a. Clarifying a misunderstanding
 - b. Confronting a supervisor
 - c. Yelling at a coworker
 - d. Yielding on an unimportant issue
3. A nurse manager understands that the autocratic leadership style is most appropriate:
 - a. during crisis situations.
 - b. when a manager prefers a "telling" style.
 - c. when followers cannot agree on a course of action.
 - d. when problems are routine.
4. A nurse is licensed through a multistate compact to practice in Tennessee, Kentucky, and North Carolina. The nurse, who was originally licensed to practice in Tennessee, is providing diabetic education to a client residing in North Carolina. Which of the following correctly describes this situation?
 - a. Only the Tennessee State Board of Nursing has regulatory authority over this nurse's actions.
 - b. The client must go to Tennessee in order to be treated by this nurse legally.
 - c. The nurse is guilty of professional malpractice due to practicing without a license.
 - d. The nurse's practice must be in compliance with rules and regulations of the North Carolina State Board of Nursing.
5. Which of the following statements correctly describes a state's nurse practice act?
 - a. Legislative act that defines nursing practice and sets standards for the profession in that state
 - b. Means of regulating health care institutions under a voluntary standard of accreditation
 - c. Professional credential that is granted by a professional nursing organization to demonstrate excellence in practice
 - d. Reference to a nurse's legal responsibilities for harm caused to a client by inappropriate nursing action
6. The nurse manager calls a meeting of the nursing staff to discuss cost-cutting strategies. Staff members are encouraged to share their ideas and comments. The manager is demonstrating the importance of using which type of leadership style?
 - a. Autocratic
 - b. Democratic
 - c. Laissez-faire
 - d. Social trait

7. In planning care for a group of clients, which assignment planned by the registered nurse would be most appropriate?
 - a. Asking a nursing assistant to explain to the client how to empty a urine collection bag
 - b. Assigning the nursing assistant to orient a new graduate practical nurse to the unit
 - c. Delegating the administration of all medications to the practical nurse
 - d. Delegating the administration of an intermittent tube feeding to the practical nurse
8. When the nurse is preparing to assign duties to the unit staff, which element must be present to ensure effective delegation?
 - a. A solid information base
 - b. Adequate supplies and equipment
 - c. Experienced staff members
 - d. Informed clients and families

Action indeed is the sole medium of expression for ethics.

—JANE ADDAMS

CHAPTER 12

Legal and Ethical Responsibilities

COMPETENCIES

1. Explain the relationship between ethics and law.
2. Identify the sources of public law and their implications for nursing practice.
3. Describe the sources of civil law and their impact on the nursing profession.
4. Explain the actions that constitute unintentional and intentional torts.
5. List the legal responsibilities of nurses in delivering client care.
6. Discuss actions that nurses can implement to avoid potential liability.
7. Explain the role of the nurse in the informed consent process.
8. Define the three types of advance directives.
9. Describe the legal and ethical considerations for nurses involved in client care situations involving abortion, pronouncement of death, do not resuscitate orders, euthanasia, care of the deceased, wills, organ donation, autopsies, and refusal of treatment.
10. Discuss the ethical theories of teleology and deontology.
11. Describe the major ethical principles that affect health care.
12. Explain the link between ethics and values.
13. Identify the rights of the client as established by the American Hospital Association.
14. Discuss the roles of the nurse as client advocate and whistle-blower in the delivery of ethical nursing care.
15. Apply the steps identified in the ethical decision-making framework to selected dilemmas.

KEY TERMS

active euthanasia	ethical reasoning	material principle of justice
administrative law	ethics	misdemeanor
advance care medical directive	euthanasia	morality
assault	expert witness	negligence
assisted suicide	expressed contract	nonmaleficence
autonomy	false imprisonment	passive euthanasia
battery	felony	paternalism
beneficence	fidelity	plaintiff
bioethics	formal contract	public law
categorical imperative	fraud	statutory law
civil law	Good Samaritan acts	teleology
client advocate	impaired nurse	testimony
contract law	implied contract	tort
criminal law	informed consent	tort law
defamation	invasive	unprofessional conduct
defendant	jurisprudence	utility
deontology	justice	values
durable power of attorney	law	values clarification
duty	liability	veracity
ethical dilemma	living will	whistle-blowing
ethical principles	malpractice	

Law, like nursing, is responsive to changing needs, roles, and relationships in society. As the nursing profession has continued to evolve, the scope of applicable law has enlarged considerably. This chapter discusses laws affecting nursing practice and the legal responsibilities of nurses. In addition to legal standards, nurses must also practice according to ethical guidelines. Therefore, this chapter also explores the concept of ethics, ethical theories and principles, ethical codes, and the application of ethical decision-making guidelines in nursing practice.

LEGAL FOUNDATIONS OF NURSING

The word **law** is derived from an Anglo-Saxon term meaning *that which is laid down or fixed*. The two types of law are **public law**, which deals with an individual's relationship to the state, and **civil law**, which deals with relations between individuals.

SOURCES OF LAW

The three sources of public law at the federal and state levels are constitutional, administrative, and criminal. The three sources of civil law at the federal and state levels are contracts, torts, and protective and reporting laws.

Public Law

As shown in Table 12-1 page 189, public law governs the legal aspects of constitutional, administrative, and criminal law. The law of the United States is set forth in the Constitution. Laws enacted by legislative bodies are referred to as **statutory law**. State boards and professional practice acts, such as nurse practice acts, are created and governed under statutory laws.

Administrative law (regulatory law) is developed by groups who are appointed to governmental administrative agencies and who are entrusted with enforcing the statutory laws passed by the legislature. Under administrative law, state boards of nursing are given the power to further delineate the rules and regulations governing nursing as set forth in nurse practice acts. In these administrative rules, boards identify specific processes such as:

- Licensure
- Grounds for disciplinary proceedings
- Establishment of fees for the services
- Penalties rendered by the board

The most common example of public law is **criminal law**, which refers to acts or offenses against the welfare or safety of the public. In criminal law there are two types of crimes, felonies and misdemeanors. A **felony** is a crime of a serious nature, usually punishable by imprisonment in a state penitentiary at hard labor or by death, or a crime in violation of federal statute in which punishment is more than 1 year

TABLE 12-1 Types of Public Law

CONSTITUTIONAL LAW		ADMINISTRATIVE LAW		CRIMINAL LAW	
FEDERAL	STATE	FEDERAL	STATE	FEDERAL	STATE
<ul style="list-style-type: none"> • U.S. Constitution • Civil Rights Act 	<ul style="list-style-type: none"> • State constitutions 	<ul style="list-style-type: none"> • Food, Drug, and Cosmetic Act • Social Security Act • National Labor Relations Act 	<ul style="list-style-type: none"> • Practice acts (e.g., nurse, medical, pharmacy) • Workers' compensation laws • State Labor Relations Act • Employment Security Act 	<ul style="list-style-type: none"> • Controlled Substances Act • Kidnapping 	<ul style="list-style-type: none"> • Criminal codes (define murder, manslaughter, criminal negligence, rape, fraud, illegal possession of drugs, theft, assault, and battery)

Data from Aiken, T. D. (2008). *Legal and ethical issues in health occupations* (2nd ed.). St. Louis, MO: Elsevier.

incarceration. A **misdemeanor** is an offense that is less serious than a felony and may be punished by a fine or sentence to a local prison for less than 1 year.

Civil Law

Civil law deals with crimes against a person or persons in such legal matters as contracts, torts, and protective/reporting law (see Table 12-2). Malpractice, also referred to as professional liability, is a violation of civil law (Aiken, 2008).

CONTRACT LAW. **Contract law** is the enforcement of agreements among private individuals. A legal contract has three essential elements:

1. Promise(s) between two or more legally competent individuals stating what each individual must do or not do
2. Mutual understanding of the terms and obligations that the contract imposes on each individual
3. Compensation for lawful actions performed

Contracts are recognized at the state level as shown in Table 12-2.

TABLE 12-2 Types of Civil Law

Data from Aiken, T. D. (2008). *Legal and ethical issues in health occupations* (2nd ed.). St. Louis, MO: Elsevier.

The terms of a contract may be agreed on orally or in writing; however, a written contract (**formal contract**) cannot be changed legally by an oral agreement. With an **expressed contract**, the conditions and terms of the contract are usually given in writing by the concerned parties. An **implied contract** recognizes a relationship between parties for services.

In accord with U.S. and Canadian contract law, the nurse, as an employee, is legally required to:

1. Adhere to the employer's policies and standards unless they are in conflict with federal or state law
2. Fulfill the terms of contracted service with the employer
3. Respect the rights and responsibilities of other health care providers, especially in areas that promote the continuity of client care

Accompanying these legal responsibilities are the nurse's rights to:

1. Expect adequate and qualified assistance in providing care
2. Receive reasonable and prudent conduct from the client
3. Expect from the employer compensation for services and provision of a safe environment with the necessary resources to perform the services
4. Be treated with prudent, reasonable behaviors by other health care providers

TORT LAW. **Tort law** is the enforcement of duties and rights among individuals independent of contractual agreements. **Tort** is an act that harms a person. Tort liability can be classified as unintentional (negligence and malpractice) and intentional (assault and battery, false imprisonment, invasion of privacy, defamation, and fraud). Intentional torts must prove that the defendant intended to commit the act. Examples of tort law are listed in Table 12-2.

THE JUDICIAL PROCESS

Courts interpret a state's laws as they apply to everyday events. Once a court in the same jurisdiction, such as a state or city, interprets a law in a certain manner, other courts tend to follow the same interpretation. This is referred to as setting a precedent.

Additionally, lower courts in the same jurisdiction must adhere to the interpretations of higher courts in the same region. Thus, all of a state's lower courts must adhere to the interpretations and procedures specified by that state's supreme or highest court, and all courts in the United States must follow the rules established by the U.S. Supreme Court. This body of judge-made law is referred to as **jurisprudence**. A well-known and controversial example of jurisprudence is the constitutional right to an abortion recognized by the Supreme Court.

LEGAL LIABILITY IN NURSING

When the nurse fails to meet the legal expectations of care, the client can initiate action if harm or injury is incurred by the client.

Negligence and Malpractice

Liability is an obligation one has incurred or might incur through any act or failure to act. The term **malpractice** refers to a professional person's wrongful conduct, improper discharge of professional duties, or failure to meet the standards of acceptable care that results in harm to another person (Zerwekh & Claborn, 2008). **Negligence** (breach of duty) is the failure of an individual to provide care that a reasonable person would ordinarily use in a similar circumstance. In other words, action that is contrary to the conduct of a reasonable person and results in harm is considered to be negligent behavior. When a nurse commits a negligent act that results in injury, it is known as malpractice.

Proof of liability depends on four elements:

1. **Duty** is an obligation created either by law or contract or by any voluntary action. It is the first element that must be proved for malpractice.
2. Breach of duty occurs when a nurse fails to act in accord with the standard of care. An act of commission or omission of the nurse may constitute a breach of the standard of care.
3. Injury (physical, financial, or emotional harm) must be demonstrated by the person making the claim to prove negligence.
4. Causation is the breach of duty that must be proved to have legally caused the injury. A cause-and-effect relationship must be clearly established.

To succeed in a malpractice suit, the **plaintiff** (the party who initiates a lawsuit that seeks damages or other relief) must first show that the **defendant** (the person being sued) owed him or her a duty. The plaintiff must then show that the defendant did not meet the duty and that this breach of duty caused harm, requiring compensation. Once the plaintiff files charges, the defendant must either refute the charges by demonstrating that if a duty was owed, the duty was fulfilled or that if a duty was breached, the breach was not the cause of the plaintiff's complaint of injury.

A person typically has no difficulty showing that a nurse owed a duty. All that needs to be demonstrated is that the nurse was working on the day of the injury and was responsible for the person's care as verified by the staffing schedules and assignment sheets. It is more difficult to prove that the duty owed was breached.

Courts usually apply the *reasonable person standard*, which asks, "What would a reasonable nurse do in a similar situation?" To answer this question, courts look to the institution's policies and procedures to determine how client care is to be performed in that facility. When determining a breach of a duty, the actions of the nurse are also compared against the professional standards of nursing care. This is done by using published nursing standards developed by specialty nursing groups or by having another nurse testify as an expert witness. An **expert witness** is a person called upon by parties in a malpractice suit who is a member of the same profession as the party being sued and who is qualified to testify about the expected behaviors

performed by members of the profession in a similar situation.

When a nurse is called to testify in a malpractice lawsuit, either as the defendant or as an expert witness, the **testimony** (written or verbal evidence given by a qualified expert in an area) must be based on facts. The jury and the court must form an opinion on their own; they are interested in the facts, not the witness's opinions, on the matter in dispute.

Nurses are expected to administer client care based on both institutional policy and procedure and the professional standards of care. The nurse defendant would use the same methods to prove that a breach of duty did not occur: showing that the facility's policies and procedures were followed and that the actions followed professional nursing standards. An expert witness is often asked to describe the relevant standards of care that will demonstrate that the client had the right to receive a *duty owed* from the nurse.

It is not sufficient to imply that the nurse breached a duty. The claimant must also show that this breach caused harm. A person cannot be compensated for a breach that caused no harm. Frequently, complaints against nurses are in one of the following categories: client falls, medication errors, failure to monitor a client in restraints, improper technique in giving treatment, failure to follow hospital procedures, and failure to supervise nonlicensed employees.

Informed Consent

Laws regarding informed consent protect the client's right to self-determination. A client is able to make an informed decision about consenting to or refusing a treatment regime only if adequate information has been presented.

The law requires that clients, or their representatives, be given sufficient information regarding various treatment modalities so that the consent is an informed process. A consent is a voluntary act by which a person agrees to allow someone else to do something. **Informed consent** means that the client understands the reason for the proposed intervention, and its benefits and risks, and agrees to the treatment by signing a consent form (see Figure 12-1). Consent forms must be obtained for all **invasive** (accessing body tissues, organs, or cavities through some type of instrumentation) procedures.

The client must be mentally competent to give consent for medical procedures. Obtaining the informed consent requires client teaching by the health care provider since clients must understand procedures and consequences of treatment and nontreatment.

The health care provider may not coerce the client to sign the consent. The client has the right to refuse the information, waive the informed consent, and undergo treatment. The client's refusal must be documented in the client's medical record. The signing of an informed consent can also be waived for urgent medical and surgical intervention as long as institutional policy so indicates. Obtaining the client's informed consent is the responsibility of the health care provider who is to perform the therapeutic activity; see the

FIGURE 12-1 This nurse is witnessing the signing of a consent form after the prescribing practitioner has fully informed the client about the proposed treatment. How does the nurse's compliance with the policy of informed consent decrease the nurse's liability in terms of this client's care? DELMAR/CENGAGE LEARNING

Safety First display. When nurses sign a consent form as a witness, in actuality they are validating that they have seen the client sign the consent form. See Figure 12-2 on page 192 for an example of a consent to treatment form.

Parental or guardian consent should be obtained before treatment is initiated on a minor. There are three exceptions to this ruling: an emergency; situations where the consent of the minor is sufficient, such as treatment of a sexually transmitted disease; and situations where a court order or other legal authorization has been obtained. If a client is a minor and the parents or legal guardian deny the lifesaving treatment, the court may overrule the decision. Under the laws of most states and Canadian provinces, an emancipated minor (one who is married, pregnant, a parent, or financially independent) can give a valid consent to treatment.

Assault and Battery

Assault is a stated intent to touch a person in an offensive, insulting, or physically intimidating manner. **Battery** is the touching of another person without the person's consent. The legal issues arising from assault and battery are usually based on whether the client consented to the touching that occurred.

▼ **SAFETY FIRST** ▼

It is the legal responsibility of the health care provider performing the procedure to obtain the client's informed consent.

TULANE MEDICAL CENTER Hospital and Clinic 1415 Tulane Avenue New Orleans, Louisiana 70112	
Consent for medical procedure and acknowledgement of receipt of information	
<p style="text-align: right;">Date _____</p> <p>In keeping with the Louisiana State Law, you are being asked to sign a confirmation that we have discussed your contemplated operation or medical procedure. We have already discussed with you the common problems or risks. We wish to inform you as completely as possible. Please read the form carefully. Ask about anything that you do not understand and we will be pleased to explain it.</p> <p>1.] I hereby authorize and direct Dr. _____, with associates or assistants of his choice, to perform upon _____, the following surgical, diagnostic, or medical procedure</p> <p>_____</p> <p>_____</p> <p>including any necessary or advisable anesthesia.</p> <p>2.] In general terms, the nature and purpose of this operation or medical procedure is:</p> <p>_____</p> <p>_____</p> <p>_____</p> <p>3.] This procedure has been explained to me. Alternate methods have also been explained to me, as have the advantages and disadvantages. I am advised that though good results are expected, the possibility and nature of complications cannot be accurately anticipated and that, therefore, there can be no guarantee as expressed or implied either as to the result of surgery or as to cure. The possible risks include death, brain damage, quadriplegia, paraplegia, loss of organ, loss of an arm or leg, or disfiguring scars.</p> <p>4.] I authorize the administration of a blood transfusion and such additional transfusion as may be deemed advisable in judgement of the attending physician, or his associates or assistants. It has been fully explained that blood transfusions are not always successful in producing a desirable result and that there is a possibility of ill effects, such as the transmission of infectious hepatitis or other diseases or blood impairments. Also, it has been explained that emergencies may arise when it may not be possible to make adequate cross-matching tests, and that immediate need may make it necessary to use existing stocks of blood which may not include compatible blood types.</p> <p>5.] I further authorize the doctors to perform any other procedure that in their judgement is advisable for my well being. I hereby authorize and direct the above named physician and associates or assistants to provide such additional services as they may deem reasonable and necessary including, but not limited to, the administration of any anesthetic agent, or the services of the X-ray department or laboratories, and I hereby consent thereto.</p> <p>6.] I hereby state that I have read and understand this consent, all questions about the procedure or procedures have been answered in a satisfactory manner, and that all blanks were filled in prior to my signature.</p> <p>Witness _____ Signature _____ (patient or person authorized to consent)</p> <p>Witness _____ Relationship _____ (required only for telephone consent or consents signed with an X)</p> <p>I certify that all blanks in this form were filled in prior to signature and that I explained them to the patient or his representative before requesting the patient or his representative to sign it.</p> <p style="text-align: right;">Signature _____ (above named physician to sign)</p>	

**CONSENT FOR MEDICAL PROCEDURE AND ACKNOWLEDGEMENT
OF RECEIPT OF INFORMATION**

- Order by priority when consenting to medical/surgical procedure (except for care and treatment of mentally ill)**
- | | |
|---|---|
| 1. Any competent adult, age 18 or older, for himself.
2. Any parent, whether an adult or minor, for his minor child.
3. Any married person, whether an adult or minor, for his/her spouse if spouse is unable to consent.
4. Any person temporarily standing in place of a parent whether formally served or not for the minor under his care and any guardian for his ward. | 5. Any female regardless of age or marital status, for herself when given in connection with pregnancy or childbirth.
6. In the absence of a parent, any adult, for his minor brother or sister.
7. In the absence of a parent, any grandparent for his minor grandchild. |

FIGURE 12-2 Example of a Consent Form COURTESY OF TULANE UNIVERSITY HOSPITAL AND CLINIC, NEW ORLEANS, LA

Because assault and battery both deal with *acts of touching*, the client's cultural values, beliefs, and practices must be respected by the nurse. If the nurse fails to recognize cultural differences, undesired outcomes may occur in the nurse-client relationship.

False Imprisonment

False imprisonment occurs when clients are led to believe they cannot leave a place. The most common example of this tort is telling a client not to leave the hospital until the bill is paid (Zerwekh & Claborn, 2008). Another example of false imprisonment is the misuse of physical or chemical restraints; see the Safety First display.

RESTRAINTS AND SECLUSION. The Omnibus Budget Reconciliation Act (OBRA) of 1987 outlines the rights of the client and the responsibilities of health care providers regarding the use of both physical and chemical restraints. The nurse is to use safety measures, such as keeping the client's bed in a low position and frequently assessing the client, in an effort to avoid the use of restraints. Chemical restraints, primarily psychotropic medications (e.g., sedatives, hypnotics, antianxiety agents, and neuroleptics), are used to control hyperactive behavior of agitated clients.

If a competent client refuses to follow orders and the nurse uses restraints, the nurse can be charged with false imprisonment, assault and battery, or both. In an emergency situation when a client becomes violent and is in imminent danger of harming himself or herself or others, the nurse may apply restraints and then immediately obtain an order from the prescribing practitioner. The law mandates that the use of restraints or seclusion must have a prescribing practitioner order. The nurse is legally accountable for the client in restraints or seclusion. Care of clients in restraints requires documentation according to specific agency policies.

Privacy and Confidentiality

An essential component of nursing practice is protecting the client's confidentiality and privacy. The American Nurses Association (ANA) *Guide to the Code of Ethics for Nurses* (2008a) identifies privacy and confidentiality as key elements in maintaining the integrity of the nursing profession. Nurses are accountable for respecting the client's right to privacy. State laws that respect privilege doctrine guarantee that no one will reveal confidential information without the client's

permission. Nurses must obtain the client's permission before disclosing any information regarding the client, going through the client's personal belongings, performing procedures, and photographing the client.

The Canadian Nurses Association (CNA) has developed its own code of ethics. The CNA's *Code of Ethics for Nursing* (2008) has involved nurses in all provinces and territories in Canada. Within the CNA's *Code of Ethics*, the value that applies to confidentiality states that the nurse is responsible to hold confidential all information about a client learned in health care settings. The nurse-client relationship is based on trust. Any violation of the client's privacy or breach of confidentiality may interfere with trust.

Nurses must ensure that clients understand their privacy rights, including withholding information, such as their diagnoses, from the family. For example, clients with sexually transmitted diseases or who are positive for the human immunodeficiency virus (HIV) may choose to withhold this information from their family.

Privacy involves more than protecting confidential communication. Nursing care should be delivered with a caring attitude that provides for privacy, such as keeping the door to the client's room closed, knocking before entering the client's room, closing the curtains around the bed before exposing the client, and draping the client appropriately for procedures.

A rapidly increasing problem that threatens privacy and confidentiality is access to electronic data. The technological proliferation of cellular phones, facsimile machines, and electronic health records (EHRs) may jeopardize the privacy of information. In 2004, a presidential executive order called for the adoption of EHRs by 2014 (Westra, Delaney, Konicek, & Kennan, 2008). As the use of EHRs expands, there will be more issues about protecting the privacy of shared health information.

In 1996, Congress enacted the Health Insurance Portability and Accountability Act (HIPAA) to ensure the privacy of individual health care information. HIPAA rules require written confirmation that clients have been informed about their privacy rights (U.S. Department of Health and Human Services, 2002). As a result of the HIPAA, the following changes have been implemented in health care settings:

- Posting a client's name near the room door is prohibited.
- Charts containing clients' names cannot be within public view.
- Calling out clients' names (e.g., in clinic waiting rooms) is prohibited.
- Medical records must be stored in secure areas.
- Clients' health care information must be discussed in private areas.

Defamation

Defamation occurs when information is communicated to a third party that causes damage to someone else's reputation either in writing (libel) or verbally (slander). The most common examples of this tort are giving out inaccurate or inappropriate information from the medical record; discussing

SAFETY FIRST

Restraints are legal only if they are necessary to protect the client or others from harm. The rationale for use of restraints must be documented in the client's health care record.

clients, families, or visitors in public areas; and speaking negatively about coworkers (Zerwekh & Claborn, 2008).

Fraud

Fraud results from a deliberate deception intended to produce unlawful gain. Fraudulent billing practices include overcharging for services and billing for services that were not provided. Other examples of fraud in health care include obtaining and using false credentials and falsifying medical records. Nursing activities to deter fraud include the following:

- Documenting facts accurately
- Reporting illegal activities
- Educating peers and the public as to what constitutes fraud

Unprofessional Conduct

Conduct of a health care provider that could adversely affect the health and welfare of the public constitutes **unprofessional conduct**. The following actions or omissions constitute unprofessional conduct:

- Breach in client confidentiality
- Failure to use sufficient knowledge, skills, or nursing judgment when practicing nursing
- Physically or verbally abusing a client
- Assuming duties without sufficient preparation
- Knowingly delegating nursing tasks to unlicensed personnel that places the client at risk for injury
- Failure to accurately maintain a record for each client or falsifying a client's record
- Leaving a nursing assignment without properly notifying appropriate personnel

Use of Controlled Substances

The improper use of controlled substances may lead to criminal penalties under laws governing the distribution and use of controlled substances (narcotics, depressants, stimulants, and hallucinogens). Agencies that distribute controlled substances must follow federal and state regulations regarding the security and access to these drugs. Title II of the Comprehensive Drug Abuse Prevention and Control Act of 1970 (Controlled Substances Act) requires accurate documentation of narcotic administration.

THE IMPAIRED NURSE. If a nurse suspects a coworker is abusing chemicals, the nurse has a duty to report the individual to nursing administration in a confidential manner with the goal of treatment being the priority issue. Nursing administration should then notify the board of nursing regarding the nurse's behavior.

Nurses must safeguard the client and the public by reporting the incompetent, unethical, or illegal practice of any person. Some boards of nursing will discipline a nurse for failing to report a fellow nurse who is abusing drugs. An **impaired nurse** is habitually intemperate or is addicted to

the use of alcohol or habit-forming drugs. Some indicators of substance abuse in nurses are:

- Social isolation (e.g., requesting to work the night shift)
- Changes in personal appearance and mood
- Excessive work-related tardiness, absences, and accidents
- Excuses for being unavailable while on duty
- Resistance to change
- Defensive when questioned about client complaints and discrepancies in the narcotic control sheet
- Failure to meet schedules and deadlines
- Inaccurate and sloppy documentation

With the formation of the Task Force on Addiction and Psychological Disturbance by the ANA in 1981, many states have initiated programs to identify, treat, and assist impaired nurses. Intervention programs allow the nurse to seek and comply with a treatment regimen as an alternative to disciplinary action, such as suspension of nursing license.

Safety

The promotion of physical safety is one of the most important responsibilities of the nurse. There are four areas regarding client safety in which nurses are at legal risk: (1) failure to monitor client status, (2) medication errors, (3) falls, and (4) use of restraints.

Failure to monitor means that the nurse must be aware of the client's condition at all times. This calls for frequent assessment of all clients and adherence to policy guidelines regarding assessment of clients with special needs, such as those who are immobile, critically ill, or unconscious.

A major safety issue in health care is the prevention of medication errors. Medication errors not only jeopardize client safety but are also expensive. "Besides harming patients, they can lead to expensive follow-up care, litigation, and monetary awards for damages" (Austin, 2008, p. 36). Some of the most common types of medication errors are improper dosing, administration of the wrong drug, and omitting to administer a medication. Nurses play a major role in the prevention of adverse drug events by careful drug administration and client assessment. See Chapter 30 for information on safe administration of medication.

Another major area for potential liability is client falls. Elderly clients are especially at risk for fall-related injuries. The most important measures for preventing lawsuits related to falls are assessing for fall potential and taking action to prevent falls (Aiken, 2008).

Another potential problem is the use of medical equipment. Whenever nurses are confronted with unfamiliar medical equipment, they are expected to seek out information and training on use of the machinery. Nurses must always use equipment according to the manufacturer's instructions. Nurses must also report malfunctioning or broken equipment according to the employing agency's policies. Austin suggests, "Never try guessing how to use equipment" (2008, p. 39).

Understaffing

Understaffing refers to the failure of a facility to provide a sufficient number of professional staff to meet client needs.

Health care providers must have written staffing guidelines for each client population and setting to comply with the standards of the Joint Commission. Usually staffing policies are in place to direct the decision making regarding increasing or downsizing staff numbers.

REASSIGNMENT. Questions are often raised by nurses in hospitals regarding the liabilities of “floating” (reassignment to work on an unfamiliar unit). This is an acceptable, legal practice used by hospitals to solve their understaffing problems. Legally, a nurse cannot refuse to float unless a union contract guarantees that nurses work only in a specified area or the nurse can prove the lack of knowledge for the performance of assigned tasks.

When reassignment occurs, nurses should set priorities and identify potential areas of harm to the client. The nurse is legally mandated to be competent before performing procedures; inexperience is no legal excuse for errors. Nurses who are required to float should receive orientation prior to reassignment.

Executing Prescribed Orders

Medical practice acts of states and provinces usually define medicine as any act of diagnosis, prescription, surgery, or treatment of illness. This definition allows for the initiation of written or verbal prescribing practitioner orders. In accord with nurse practice acts, nurses are obligated to follow the orders of a licensed prescribing practitioner *unless the orders would result in client harm*.

The nurse has a legal responsibility to the client to ensure that the order is clear and appropriate to the client’s treatment. When the nurse questions an order, the prescribing practitioner should be contacted to provide clarification. If, after prescribing practitioner clarification, the nurse still questions the order, the nurse should institute agency policy (e.g., notify the supervisor). Following the agency’s policy in this matter protects the nurse from employer disciplinary action. See the Safety First display.

LEGAL RESPONSIBILITIES AND ROLES

Nurses are legally responsible to practice nursing as defined by nurse practice acts and professional standards of care. There are several roles performed by nurses related specifically to legal accountability.

▼ SAFETY FIRST ▼

The nurse remains liable for incorrectly administering a medication even if it is ordered incorrectly by the prescribing practitioner. Sound nursing judgment is required for every medication that is administered.

Provider of Care

The nurse is legally responsible to ensure that the client receives competent, safe, and holistic care. Nurses are expected to:

- Render care based on their education, experience, and circumstances (standard of “reasonable, prudent person”)
- Discuss with the client the associated risks and outcomes inherent in the plan of care
- Supervise and evaluate aspects of care that have been delegated to licensed and unlicensed caregivers
- Document the care the client receives and other significant events affecting the client
- Maintain clinical competency

The nurse is also responsible for the client’s physical safety as discussed in this chapter’s section on safety.

Expert Witness

To qualify as an expert witness, the nurse’s education and experience are presented to the court to prove the nurse is knowledgeable about current standards and practice. The credentials of an expert witness have to match or exceed a defendant’s qualifications. During the trial, the plaintiff’s and the defendant’s attorneys have the right to use the testimony of the expert witness for their respective cases.

Forensic Specialist

Another role for nurses is that of forensic nurse. The ANA’s *Scope and Standards of Forensic Nursing Practice* (2008b) describes some of the responsibilities of forensic nurses as treating incarcerated clients, investigating trauma cases, and serving as expert witnesses in court. As violence continues to escalate in the United States, there will be an increased demand for forensic nurses.

Client Educator

Safe nursing care requires that the client has a thorough understanding of the treatment plan. Although the prescribing practitioner has specific responsibilities regarding client education, the nurse must also provide client teaching and document the degree of learning. See Chapter 21 for a complete discussion of the nurse’s responsibilities for client education.

Reporting Responsibilities

Nurses should know which situations have to be reported because reporting statutes vary among the states and provinces; refer to Table 12-2 for protective and reporting laws. Criminal acts of rape and sexual assault must also be reported in most states and provinces.

LEGAL RESPONSIBILITIES OF STUDENTS

Nursing students must act as reasonably prudent persons, equivalent with education and experience, when performing nursing duties. When employed as caregivers, nursing students

must perform only tasks that they are competent to perform; see the Spotlight On display.

LEGAL SAFEGUARDS FOR NURSING PRACTICE

There is a common set of actions a nurse can take to protect against litigation. Although each client encountered presents a unique situation that can place the nurse at legal risk, certain general nursing care activities decrease this risk (see the Nursing Checklist). Implementing the guidelines in the checklist should help protect nurses from lawsuits as well as provide defense in the event of a suit.

Institutional Policies

All health care facilities have policies for delivering safe, effective care. Nursing students and registered nurses are obligated to know the policies and follow the procedures and protocols that flow from policy. Although policies are not laws, courts generally rule against nurses who violate policies.

Professional Liability Insurance

Nurses should purchase their own liability insurance for protection against malpractice lawsuits. When securing liability insurance, the nurse should validate the company's reputation. Most professional nursing organizations offer group liability insurance.

Nurses may erroneously assume that they are protected by their employer's professional liability policies. Usually when a nurse is sued, the employer is also sued for the nurse's actions or inaction. Even though this is the norm, nurses are encouraged to have their own malpractice insurance. Having one's own insurance also provides the nurse protection as an individual and allows the nurse to have an attorney who has only the nurse's interests in mind.

As Willson (2007, p. 11) states:

In Canada, most nurses are covered by their employer's liability insurance and therefore have representation by a lawyer appointed by the employer's insurer. This means that the lawyer acting on behalf of the hospital is also acting on behalf of you as an employee. An exception to this is if your alleged

SPOTLIGHT ON...

Legal

Legal Implications for Nursing Students

When agency policy conflicts with the nurse practice act, what should you do? Remember that the state legislature empowers the board of nursing to define and monitor practice. If, as a nursing student, you willfully violate the state board's ruling, what future implication(s) could this have on your ability to apply for licensure?

NURSING CHECKLIST

Actions to Decrease the Risk of Liability

- Communicate with clients by keeping them informed and listening to what they say.
- Acknowledge unfortunate incidents and express concern about these events without either taking the blame, blaming others, or reacting defensively.
- Chart and time observations immediately while facts are still fresh in mind.
- Take appropriate actions to meet the client's nursing needs.
- Follow the facility's policies and procedures for administering care and reporting incidents.
- Acknowledge and document the reason for any omission or deviation from agency policy, procedure, or standard.
- Maintain clinical competency and acknowledge one's own limitations. Nurses who do not know how to do something should ask for help.
- Promptly report any concern regarding the quality of care, including the lack of resources with which to provide care, to a nursing administration representative.
- Implement appropriate standards of care.
- Time and document changes in conditions requiring notification of the prescribing practitioner and include the prescribing practitioner's response.
- Delegate client care based on the documented skills of licensed and unlicensed personnel.
- Treat all clients and their families with kindness and respect.

conduct fell outside the scope of your employment or if it was criminal in intent, in which case you may not be eligible for legal representation through your employer.

Risk Management Programs

Risk management is a method of identifying, evaluating, and decreasing the agency's risk of financial loss. Most health care facilities are required to have formal risk management programs in place by agencies such as the Department of Health and Human Services, accrediting bodies, and liability insurance carriers. These programs are based on systematic reporting of incidents or unusual occurrences (e.g., client falls).

INCIDENT REPORTS. In accord with the agency's policies, nurses are required to file incident reports when a situation arises that could or did cause client harm. When filing an incident report, the nurse should state only the *facts* surrounding the incident. The nurse's opinions or conclusions about the incident are not to be documented. Also, the

client's medical record should not contain any reference to the filing of an incident report. See Chapter 13 for more information on incident reports.

LEGISLATION AFFECTING NURSING PRACTICE

There are legal, as well as ethical, implications inherent in nursing practice that require nurses to know and comply with the specific existing health care laws and regulations in their state of licensure. Following is a discussion of some laws that impact nursing.

Patient Self-Determination Act

The Patient Self-Determination Act (PSDA) of 1990 requires that on admission to any health care service, clients are to be given the opportunity to determine what type of life-prolonging or lifesaving actions they want performed. The PSDA applies to all health care settings, including hospitals, home health agencies, and long-term care centers. Often, the nurse is the person designated to educate the client on care options. Ideally, health care decisions would be made before an emergency arises. Ellis and Hartley (2007, p. 297) state:

One suggestion has been that these matters first be discussed in the health care provider's office, before admission. When this is possible, it allows for more time to consider alternatives and consult significant others. The final decision is then made away from the pressure of the health care environment.

The three types of documents that comply with the PSDA include the following:

1. A **living will** is a document prepared by a competent adult that provides direction regarding medical care in the event that the person becomes unable to make decisions personally.
2. **Durable power of attorney** (health care proxy) is an authorization that enables any competent individual to name someone to exercise decision-making authority, under specific circumstances, on the individual's behalf.
3. An **advance care medical directive** is a document in which an individual, in consultation with the prescribing practitioner, relatives, or other personal advisors, provides precise instructions for the type of care the client wants or does not want in a number of scenarios.

The living will is the most widely available instrument for recording future health care–related decisions. Figure 12-3 on page 198 presents a sample document of a living will. All states provide for a general durable power of attorney.

Roe v. Wade

The 1973 Supreme Court decision of *Roe v. Wade* increased the safety and availability of abortions in the United States.

Health care agencies and practitioners in various states may be required to report abortions performed as well as other information about the client, the procedure, and any resulting complications. Some states require the reporting of abortions only for minors.

Nurses may need to explore their own feelings or beliefs about abortion before assisting with these procedures. The nurse should also be aware of the client's feelings before the abortion so that appropriate referral can be made for post-procedure care if necessary.

The Americans with Disabilities Act

Passed by the U.S. Congress in 1990, the Americans with Disabilities Act (ADA) prohibits discrimination on the basis of disability in employment, public services, and public accommodations. The ADA defines a person with a disability as having a physical or mental impairment that substantially limits one or more of the major life activities. See the Respecting Our Differences display.

Good Samaritan Acts

Good Samaritan acts are laws that provide protection to health care providers by ensuring immunity from civil liability when assistance is provided at the scene of an emergency when the caregiver does not intentionally or recklessly cause client injury. The caregiver will be evaluated by how a reasonable and prudent caregiver would have responded in a similar situation. Good Samaritan acts are examples of common and statutory laws as determined by the individual states. Although all 50 states and the District of Columbia have Good Samaritan acts, some of the Canadian provinces (e.g., Ontario and Quebec) do not have such acts.

Good Samaritan acts vary in coverage from state to state, and it is the responsibility of caregivers to know the law for their own jurisdictions. Keep in mind that some states cover only nurses licensed in that state and that these acts are amended periodically by legislation. Good Samaritan acts do not provide immunity to the nurse who is providing care as an employee (Zerwekh & Claborn, 2008). See the accompanying Spotlight on page 198 On display.

RESPECTING OUR DIFFERENCES

Hearing Impaired Coworker

How would you feel about a nurse coworker who is hearing impaired and cannot hear heart, lung, and bowel sounds? What are your responsibilities in such a situation?

Declaration

Declaration made this _____ day of _____ (month, year).

I, _____, being of sound mind, willfully and voluntarily make known my desire that my dying shall not be artificially prolonged under the circumstances set forth below and do hereby declare:

If at any time I should either have a terminal and irreversible incurable injury, disease, or illness or be in continual profound comatose state with no reasonable chance of recovery, certified by two physicians who have personally examined me, one of whom shall be my attending physician, and the physicians have determined that my death will occur whether or not life-sustaining procedures are utilized and where the application of life-sustaining procedures would serve only to prolong artificially the dying process, I direct that such procedures be withheld or withdrawn and that I be permitted to die naturally with only the administration of medication or the performance of any medical procedure deemed necessary to provide me with comfort care.

In the absence of my ability to give directions regarding the use of such life-sustaining procedures, it is my intention that this declaration shall be honored by my family and physician(s) as the final expression of my legal right to refuse medical or surgical treatment and accept the consequences from such refusal.

I understand the full import of this declaration and I am emotionally and mentally competent to make this declaration.

Signed: _____

City, Parish, and State of Residence _____

The declarant has been personally known to me and I believe him or her to be of sound mind.

Witness: _____

Witness: _____

Legal

Good Samaritan Acts

If, as a nurse, you charge or accept a fee for the services rendered during an emergency situation, will you still be protected by a Good Samaritan act? What are the legal implications for accepting compensation for your professional services?

their unsafe practice. The major goal of this legislation was to deter incompetent practitioners from moving to a new state without having to report on problematic care delivery in previous states. This legislation established the National Practitioner Data Bank to serve as a clearinghouse for information on unsafe practitioners and to provide immunity to those who report incompetent peers.

Occupational Safety & Health Administration

In 1970, the Occupational Safety & Health Administration (OSHA) was established to ensure safe work environments for Americans. The intent of the act was to decrease work-related injuries. The act was expanded in 1991 to develop standards for safety of those who may experience work-related exposure to bloodborne contaminants. OSHA also provides

Health Care Quality Improvement Act

The Health Care Quality Improvement Act was enacted in 1986 to identify unsafe health care providers and restrict

guidelines for health care workers' potential exposure to drugs and chemicals, biological agents (e.g., influenza virus), radioactivity, and threats to respiratory health. Ergonomic hazards from lifting and repetitive movements are also addressed by OSHA (2008). Employers are fined if they violate OSHA rules and regulations.

LEGAL ISSUES RELATED TO DEATH AND DYING

Nurses encounter numerous legal and ethical challenges when caring for clients who are dying. The following section discusses do not resuscitate orders, wills, pronouncement of death, care of the deceased, autopsies, and organ donation.

Do Not Resuscitate Orders

Cardiac arrest requires the initiation of cardiopulmonary resuscitation (CPR) by competent persons. In health care settings, caregivers (often nurses) perform CPR and other lifesaving measures according to agency policy unless the primary prescribing practitioner has written a *do not resuscitate* (DNR) order in the client's medical record. The prescribing practitioner's DNR order provides an exception to the universal standing order to resuscitate.

Health care agencies are required to have policies in place that provide a mechanism for reaching a DNR decision as well as for resolving conflicts in decision making. The principles of informed consent must be respected by the prescribing practitioner who writes a DNR order. When the client is either comatose or near death, there should be knowledgeable concurrence by the prescribing practitioner and the client's family or guardian about actions to prolong the client's life. It is the responsibility of the nurse to know and follow the client's wishes relative to resuscitation and the application of life-support systems. This information must be documented in the client's medical record.

Wills

The United States and Canada have laws regarding the legal requirements for written and oral wills. Nurses are usually required to notify the prescribing practitioner and nurse supervisor before acting as a witness and signing a will. Nurses should refrain from assisting the client with the wording of the will, as this should be done with legal advice from an attorney. When serving as a witness, a nurse is verifying that it is indeed the client who is actually signing the documents.

Pronouncement of Death

Medicine has yet to agree on one acceptable definition of death. The various definitions are as follows: the absence of awareness of external stimuli, lack of movement or spontaneous breathing, absent reflexes, a flat brain wave repeated twice in 24 hours, and the Uniform Definition of Brain Death, which requires irreversible cessation of all functioning of the brain (Zerwekh & Claborn, 2008). See the accompanying Spotlight On display.

State regulatory boards have initiated laws to protect the public when dealing with issues of death. It is usually within the scope of practice of medicine to pronounce a client dead. However, some boards of nursing allow the nurse, in certain circumstances and with thorough documentation, to make a determination and pronouncement of death. Because state laws vary concerning this issue, it is important for registered nurses to know the laws in their own state or province of licensure.

Care of the Deceased

When a client dies, the nurse is obligated to treat the deceased with respect and dignity. The nurse should prepare the body for removal to the morgue in accordance with agency policies. The nurse is responsible for properly identifying the body. Wrongful identification of the body could result in severe distress for the family of the deceased as well as negative legal ramifications for both the health care agency and the nurse.

Autopsies

An autopsy is performed to determine the cause of death. Autopsy results are used in cases of suspicious death or the presence of communicable disease. The cause of death also has implications regarding payment from insurance policies and workers' compensation.

Some states require consent for an autopsy in writing, whereas other states accept telegrams or documented telephone conversations. Regardless of how consent is obtained, the prescribing practitioner must document that consent was obtained and identify in the client's record who authorized the autopsy. In some states, consent for an autopsy is not required in unwitnessed deaths because this situation requires a mandatory autopsy. The nurse is responsible for ensuring that all documentation is in place before releasing a body for autopsy.

Organ Donation

All 50 states have adopted the Uniform Anatomical Gift Act for cadaver organ donation. In the United States and Canada, any person aged 18 or older may become an organ donor by

SPOTLIGHT ON...

Legal

What Constitutes Death?

Considering the various definitions of death, is it absolutely clear when the moment of death occurs? Based on these definitions, when can the life-supporting machines be turned off? Although the right of the client to refuse treatment, which may lead to death, has been established, can you identify clinical circumstances where the client might be deprived of the right to die?

written consent. In the absence of appropriate documentation, a family member or legal guardian may authorize donation of the organs. Nurses and other caregivers are expected to approach families for organ donation in the absence of documentation of the client's wishes. Consent for an organ donation requires the collaborative efforts of the nurse with prescribing practitioners, social workers, and clergy to ensure timely removal of the organs.

ETHICAL FOUNDATIONS OF NURSING

Every day, nurses encounter situations in which they must make decisions based on the determination of right and wrong. How do they make such decisions? Which values determine the rightness of an action?

The delivery of ethical health care is becoming an increasingly difficult and confusing issue in contemporary society. Nurses are committed to maintaining clients' rights related to health care. This desire to maintain clients' rights, however, often conflicts with professional duties and institutional policies. It is essential to balance these two perspectives so that the primary objective, delivery of quality care, is achieved. See the Uncovering the Evidence display.

It is also necessary to realize that there are no absolute right answers. Dealing with the gray areas (ambiguities) causes discomfort for some nurses. Unlike mathematics and other empirical sciences, there are no apparent absolute rules governing ethics. Scientists can say for certain that two plus two always equals four—regardless of the time factors, circumstances, feelings, or beliefs of those involved in the calculations. Ethical guidelines are less clear and more open to interpretation. In other words, ethical decisions may vary according to each individual and each situation. Because clients and nurses are humans, no two situations can ever be exactly alike.

CONCEPT OF ETHICS

Ethics is the branch of philosophy that examines the differences between right and wrong. Simply put, ethics is the study of the rightness of conduct. Ethics deals with one's responsibilities (duties and obligations) as defined by logical argument. Ethics looks at human behavior—what people do under what type of circumstances. But ethics is not merely a philosophical discussion; ethical persons put their beliefs into action.

Often the term *morals* is mistakenly used when ethics is meant. **Morality** is behavior in accordance with custom or tradition and usually reflects personal or religious beliefs. An example of a moral belief is a person's desire to maintain his or her right to die. Ethics is the free, rational, and publicly stated assessment of alternative actions in relation to theories, principles, and rules. Ethics is rooted in the legal system and reflects the political values of our society. An example of an ethical belief is the practice of parents' teaching their children the importance of telling the truth.

TITLE OF STUDY

“Ethical Dilemmas among Nurses as They Transition to Hospital Case Management: Implications for Organizational Ethics, Part II”

AUTHOR

L. T. O'Donnell

PURPOSE

To describe the ethical concerns experienced by clinical nurses as they moved into their new role of hospital case management.

METHODS

An interpretive phenomenological approach was used to identify themes in ethical concerns and relate them to the role of hospital nurse case management. Interviews were conducted to explore participants' resolution of ethical dilemmas.

FINDINGS

As nurses are promoted to the expanded role of case manager, they face situations that require ethical decision making and clinical judgment.

IMPLICATIONS

(1) Nurse case managers are confronted daily with ethical dilemmas. (2) There is a need for continued education of the case manager role.

O'Donnell, L. T. (2007). Ethical dilemmas among nurses as they transition to hospital case management: Implications for organizational ethics, Part II. *Professional Case Management*, 12(4), 219–231.

Relationship between Legal and Ethical Concepts

There is a connection between acts that are legal and acts that are ethical. Sometimes, it is difficult to separate legalities from ethics. Some legal acts are considered to be unethical and vice versa. According to Burkhardt and Nathaniel (2007), the following contribute to the occasional discrepancies between law and ethics:

- Ethical opinions reflect individual differences.
- Human behavior and motivation are too complex to be accurately reflected in law.
- The legal system judges action rather than intention.
- Laws change according to social and political influences.

Professional nursing actions are both legal and ethical. See the accompanying Spotlight On display on page 201.

Bioethics

The application of general ethical principles to health care is referred to as **bioethics**. Ethics affects every area of health

care, including direct care of clients, allocation of finances, and utilization of staff. Ethics does not provide easy answers but can help provide structure by raising questions that ultimately lead to answers.

Ethics is exerting an ever-increasing influence on health care today. Several factors contribute to an increased need to provide health care in an ethical manner. Some of these factors are:

1. An increasingly technological society. The nature of advanced technology creates situations that involve complicated issues that never had to be considered before. As a result of technological advances:
 - Many newborns are surviving at earlier gestational ages, and many of them have serious health problems.
 - People are living much longer than ever before.
 - Organ transplants and the use of bionic body parts are becoming more common.
2. The changing fabric of our society. Family structure is moving from extended families to nuclear families, single-parent families, and nonrelated individuals living together as families.
3. Clients are becoming more knowledgeable about their health and health-related interventions. As consumer demand for information increases, health care providers must adapt quickly. The result is a focus on a consumer-driven system.

Nurses face situations in which they must make decisions that transcend technical and professional concerns. These situations may or may not involve life-or-death issues. Such situations raise complex problems that cannot be answered completely with technical knowledge and professional expertise. Technological advances have created unprecedented choices, not only for society at large, but specifically for clients and nurses.

There is emphasis on ethical issues involving life-or-death situations. However, nurses daily encounter challenges about what *ought* to be done, even in the most ordinary circumstances. The accompanying Spotlight On display lists

ethical dilemmas that frequently occur in nursing practice. The way in which nurses relate to clients, families, and other health care providers is the true demonstration of ethical behavior.

ETHICAL THEORIES

Ethical theories were debated by ancient philosophers such as Plato and Aristotle, and the debate continues today. No theory in and of itself can provide the “correct” answer to any single ethical conflict. However, ethical theories can be used as a way to analyze ethical problems.

Teleology

Teleology is the ethical theory stating that the value of a situation is determined by its consequences. Thus, the outcome of an action—not the action itself—is the criterion for determining the goodness of that action. This theory (also called the consequentialist theory) was advocated by the philosopher John Stuart Mill. The principle of **utility** is a basic concept of teleology; utility states that an act must result in the greatest amount of good for the greatest number of people involved in a situation. “Good” refers to positive benefit. Any act can be ethical if it delivers “good” results. Every alternative is assessed for its potential outcomes, both positive and negative. The selected action is the one that results in the most benefits and the least amount of harm for all those involved.

Deontology

Deontology is the ethical theory that considers the intrinsic significance of the act itself as the criterion for determination of good. That is, in determining the ethics of a situation, a person must consider the motives of the actor, not the consequences of the act.

This theory (also called formalism) was postulated by the philosopher Immanuel Kant. Kant established the concept of the categorical imperative, which states that one should act only if the action is based on a principle that is universal (everyone would act in the same way in a similar situation). The **categorical imperative** also mandates that a person

Legal/Ethical

Legal and Ethical Concepts

Which of the following behaviors are ethical and illegal? Legal and unethical? Illegal and unethical? Legal and ethical?

- Working in a clinic that performs abortions
- Honoring a terminally ill client’s request to have “no heroic” actions taken
- Discontinuing a comatose client’s life support at the request of the family
- Diverting medications from a client for your own use

SPOTLIGHT ON...

Ethics

Frequently Occurring Ethical Dilemmas

- Informed consent
- Refusal of treatment
- Use of scarce resources
- Cost-containment initiatives that negatively affect client well-being
- Incompetent health care providers

should never be treated as a means to an end. Adherence to this concept may pose an ethical concern to health care researchers, who sometimes may risk the well-being of a person participating in an experimental procedure for the sake of finding a drug that will save many from suffering.

ETHICAL PRINCIPLES

Ethical principles are tenets that direct or govern actions. They are widely accepted and generally are based on the humane aspects of society. Ethical decisions are principled; that is, they reflect what is best for the client and society. Table 12-3 summarizes the major ethical principles. Each principle is discussed in detail in the following paragraphs.

By applying ethical principles, nurses become more systematic in solving ethical conflicts. Ethical principles can be used as guidelines in analyzing dilemmas; they can also serve as a justification (rationale) for the resolution of ethical problems. Remember that these principles are not absolute; there can be exceptions to each principle in any given situation.

Autonomy

The principle of **autonomy** refers to the individual's right to choose and the ability to act on that choice. The individuality of each person is respected when autonomy is maintained. This respect for personal liberty is a dominant value of mainstream American society.

Nurses must respect clients' right to decide and protect those clients who are unable to decide for themselves. The ethical principle of autonomy reflects the belief that every competent person has the right to determine his or her own course of action. The right to free choice rests on the client's competency to decide.

Informed consent is based on clients' right to decide for themselves. Upholding autonomy means that the nurse accepts the client's choices, even when those choices are not in the client's best interests. Following are examples of clients' autonomous behavior that can impair recovery or treatment:

- Smoking after a diagnosis of emphysema or lung cancer
- Refusing to take medication

- Continuing to drink alcohol when one has cirrhosis
- Refusing to receive a blood transfusion because of religious beliefs

The PSDA of 1990 was legislated to ensure that clients have the right to make their own health care decisions. Based on the principle of autonomy, this act requires that every person admitted to a health care facility be informed of the right to self-determination.

Nonmaleficence

Nonmaleficence is the duty to cause no harm to others. Harm can take many forms: physiological, psychological, social, or spiritual. Nonmaleficence refers to both actual harm and the risk of harm. The principle of nonmaleficence helps guide decisions about treatment approaches; the relevant question is "Will this treatment modality cause more harm or more good to the client?" Determining whether technology is harmful to the client is not always a clear-cut decision. Factors to consider include the following:

- The treatment must offer a reasonable prospect of benefit.
- It must not involve excessive expense, pain, or other inconvenience.

Nonmaleficence requires that the nurse act thoughtfully and carefully, weighing the potential risks and benefits of research or treatment. Sometimes it is easier to weigh the risk than to measure the benefit. It is possible to violate this principle without acting maliciously and without ever being aware of the harm.

Nonmaleficence is considered a fundamental duty of health care providers. Both nursing's Nightingale Pledge and medicine's Hippocratic Oath state that providers are to cause no harm to clients. Some clinical examples of nonmaleficence are:

- Preventing medication errors (including drug interactions)
- Being aware of potential risks of treatment modalities
- Removing hazards (e.g., obstructions that might cause a fall)

See the accompanying Spotlight On display on page 203.

When upholding the principle of nonmaleficence, the nurse practices according to professional and legal standards

TABLE 12-3 Overview of Ethical Principles

PRINCIPLE	EXPLANATION
Autonomy	Respect for an individual's right to self-determination; respect for individual liberty
Nonmaleficence	Obligation to do or cause no harm to another
Beneficence	Duty to do good to others and to maintain a balance between benefits and harms
Justice	Equitable distribution of potential benefits and risks
Veracity	Obligation to tell the truth
Fidelity	Duty to do what one has promised

Delmar/Cengage Learning

**SPOTLIGHT ON...****Ethics****Nonmaleficence**

Weighing the potential benefit and harm of treatment approaches is value laden. At what point does pain, inconvenience, or expense become excessive? Who determines excessiveness? Is the result of a therapy that will prolong the client's life a benefit or a burden? Who determines what is an acceptable and what is an unacceptable quality of life?

of care. The question most frequently asked in court of a nurse is "Did you cause any harm?"

Beneficence

Beneficence is the ethical principle that means the duty to promote good and to prevent harm. There are two elements of beneficence:

1. Providing benefit
2. Balancing benefits and harms

One undesirable outcome of beneficence is **paternalism**, an occurrence in which health care providers decide what is "best" for clients and then attempt to coerce (or "encourage") them to act against their own choices. Paternalistic health care providers treat competent adults as if they are children who need protection.

Paternalism is usually not considered an ethical approach. However, in some situations paternalism may be advisable. For example, when prevention of harm overrides the loss of individual freedom and when an individual's ability to choose is limited by incompetency, paternalism may be justified. See the accompanying Spotlight On display.

Justice

The principle of **justice** is based on the concept of fairness. The major health-related issues of justice involve fair treatment of individuals and allocation of resource distribution. Justice considers action from the point of view of the least fortunate in society. As a result of equal and similar treatment of people, benefits and burdens are distributed equally.

The ethical principle of justice requires that all people be treated equally unless there is a justification for unequal treatment. The **material principle of justice** is the rationale for determining when unequal allocation of scarce resources is appropriate. This concept specifies that resources should be allocated:

- Equally
- According to need
- According to individual effort
- According to the individual's merit (ability)
- According to the individual's contribution to society

**SPOTLIGHT ON...****Ethics****Paternalism**

Listen to the messages communicated to clients by health care professionals. What comments can you think of that would be considered paternalistic? Would you consider the following comments to be paternalistic? Why or why not?

- "Just follow the doctor's orders and everything will be OK."
- "We know what's best for you; trust us."
- "This is for your own good."

An application of the material principle of justice is the Department of Veteran Affairs (VA). Individuals who gave to their country by serving in the military are eligible to receive health care through the VA in ambulatory, acute care, and psychiatric facilities.

According to the ANA (2008a), three types of actions are considered to be unjust:

- Discrimination or arbitrary unequal treatment in enforcing policies and rules
- Exploiting (taking unfair advantage of) another
- Making unfair (false or derogatory) remarks about others

In health care institutions, the principle of justice is being strenuously tested on the issue of allocation of one important resource: nursing personnel. Many institutions and agencies are downsizing their professional staff as a cost-containment measure. As a result, some health care facilities are so poorly staffed or have such a high ratio of underqualified personnel providing care that quality care is being sacrificed.

The principles of justice and beneficence often conflict. For example, should federal funds be spent on a costly transplant that will benefit only one Medicaid recipient, or should the funds be spent on less expensive measures that would prevent disease in many (e.g., immunizations)?

Veracity

Veracity means truthfulness, neither lying nor deceiving others. Deception can take many forms: intentional lying, nondisclosure of information, or partial disclosure of information. Veracity often is difficult to achieve. It may not be difficult to tell the truth, but it is not always easy to decide how much truth to tell. See the accompanying Spotlight On display on page 204.

Fidelity

The concept of **fidelity**, which is the ethical foundation of nurse-client relationships, means faithfulness and keeping promises. Clients have an ethical right to expect nurses to act in their best interests. As nurses function in the role of

**SPOTLIGHT ON...****Ethics****Veracity**

- Is honesty always the best policy?
- Is withholding information the same as lying?
- Can you ethically justify withholding information?
- Can you ethically justify telling white lies?

client advocate (a person who speaks up for or acts on behalf of the client), they are upholding the principle of fidelity. Fidelity is demonstrated when nurses:

- Represent the client's viewpoint to other members of the health care team
 - Avoid letting their own personal values influence their advocacy for clients
 - Support the client's decision even when it conflicts with the nurse's preferences or choices
- See the accompanying Spotlight On display.

VALUES AND ETHICS

The close relationship between ethics and values both illuminates and complicates the nurse's approach toward balancing the principles of health care delivery with those of the client. Nurses need to examine their own value systems in order to determine the best approach in managing the care of clients whose values differ. In order to practice ethically, nurses must understand the impact of their own values. **Values** influence the development of beliefs and attitudes and thus affect behaviors indirectly. Almost nothing in life is value free, even though individuals often fail to consider the impact of values on decisions and resultant behaviors. Values are similar to breathing; one does not think about them until there is a problem.

Nurses often care for clients whose value systems conflict with theirs. Determining what is meaningful to the client is based on an understanding of the client's value system. The nurse's values can become problematic when they conflict with the values of clients.

Values Clarification

Through values clarification, a nurse can increase self-awareness and become better able to care for people with different values. **Values clarification** is the process of analyzing one's own values to better understand what is truly important. In their classic work *Values and Teaching*, Raths, Harmin, and Simon (1978, p. 47) formulated a theory of values clarification and proposed a three-step process of valuing, as follows:

1. **Choosing:** Beliefs are selected freely (that is, without coercion) from among alternatives. The choosing step involves analysis of the consequences of various alternatives.

**SPOTLIGHT ON...****Legal/Ethical****Client Advocate**

A 15-year-old girl visits a family planning clinic because she suspects she is pregnant. Her suspicion is confirmed after an examination. She informs the nurse practitioner that she wants an abortion, and she refuses to tell her parents about the situation. In considering this dilemma, keep in mind that the client is a minor. What are the ethical obligations of the nurse practitioner? Do the ethical obligations coincide or conflict with the legal responsibilities? How would you resolve this conflict?

2. **Prizing:** The beliefs that are selected are cherished (prized).
3. **Acting:** The selected beliefs are demonstrated consistently through behavior.

Nurses must understand that values are individual rather than universal; therefore, nurses should not impose their own values on clients. The provision of ethical nursing care is directly related to one's values. For example, the nurse who strongly values the sanctity of life may experience an ethical conflict when caring for a terminally ill client who refuses treatment that may extend life for a short period of time.

ETHICAL CODES

One hallmark of a profession is the determination of ethical behavior for its members. Several nursing organizations have developed codes as guidelines for ethical conduct. The International Council of Nurses (ICN) first developed its ethical code in 1953 and revised it in 2006. The *ICN Code for Nurses* (ICN, 2006) emphasizes nursing's respect for human rights, including the right to life, the right to dignity, and the right to be treated with respect. The ICN code promotes an environment that respects the values, customs, and spiritual beliefs of the individual.

The ANA (2008a) code for ethical conduct spells out the nurse's obligations to clients and society at large. Some of those obligations include maintaining clients' privacy and safety, improving the standards of nursing care, and assuming responsibility for one's nursing actions. The ethical code, which provides broad principles for determining and evaluating nursing care, is not legally binding for registered nurses. In most states, however, the board of nursing has authority to reprimand nurses for unprofessional conduct that results from violation of the ethical code.

The CNA developed a code of ethics in 1980 and revised it in 2008 (CNA, 2008). The CNA code serves as a guide for professional nurses to assist in working through ethical dilemmas encountered in all practice settings.

CLIENTS' RIGHTS

The concept of rights is often misused, overused, and abused. Society tends to take rights for granted; rights and obligations are culturally defined. The dominant American society has an ethnocentric perspective in believing that its rights and values are shared globally.

Clients have certain rights including, but not limited to, the right to

- Make decisions regarding their care
- Be actively involved in the treatment process
- Be treated with dignity and respect

These rights apply to all clients regardless of the setting for delivery of care. For example, during the initial assessment, the home health nurse discusses these rights with the client. When clients are admitted to short-term acute care agencies or extended care facilities, they are also entitled to certain rights. In 1972, the American Hospital Association (AHA) established A Patient's Bill of Rights, which includes the rights and responsibilities of clients receiving care in hospitals. This document was revised and renamed in 2003 (see Box on next page). The *Patient Care Partnership* (AHA, 2003) increases health care providers' awareness of the need to treat clients in an ethical manner and encourages all health care providers to protect the rights of clients.

ETHICAL DILEMMAS

An **ethical dilemma** occurs when there is a conflict between two or more ethical principles. Ethical dilemmas are situations of conflicting requirements for which there is no right or wrong option. The most beneficial decision depends on the circumstances. Ethical analysis is not an exact science. When an ethical dilemma occurs, the nurse must make a choice between two alternatives that are equally unsatisfactory. In some cases, even after a dilemma seems to have been resolved, questions remain. This ambiguity makes it emotionally painful for the persons involved. The emotional discomfort is often a result of the nurse's trying to second-guess the decision and may lead to such self-messages as "If only I had done this" or "Maybe I should have...." See the accompanying Spotlight On display.

Euthanasia

Most people hope to experience a peaceful gentle death when their "time comes." The word **euthanasia** comes from the Greek word *euthanatos*, which literally means "good, or gentle, death." In current times, euthanasia refers to mercy killing (deliberate ending of life as a humane action). See the accompanying Spotlight On display.

Active euthanasia refers to taking deliberate action that will hasten the client's death. In contrast, **passive euthanasia** means cooperating with the client's dying process. Passive euthanasia is the omission of an action that would prolong life.

Assisted suicide is a form of active euthanasia in which health care professionals provide clients with the means to end their own lives. Recently, physician-assisted suicide has been

SPOTLIGHT ON...

Ethics

Ethical Conflicts

As a nurse, you will often be caught in a dilemma involving what you ought to do (on the basis of one ethical principle) and what you ought not to do (on the basis of another principle). For example, should you tell a client who has been diagnosed as having breast cancer the complete truth about the diagnosis, or should you soft-pedal the bad news because it might result in loss of hope? The dilemma is a conflict between the principles of veracity and nonmaleficence. Also, the principle of autonomy is involved. Not telling violates autonomy by denying the client the right to make an informed choice.

the topic of much controversy. In 1997, the U.S. Supreme Court decided that there was no constitutionally protected right to physician-assisted suicide for clients who are terminally ill.

Nurses have differing opinions regarding assisted suicide. Some view it as a violation of the ethical principles upon which the practice of nursing is based: autonomy, nonmaleficence, beneficence, justice, veracity, and fidelity. Other nurses view assisted suicide as a humane act. Regardless of a nurse's personal viewpoint, assisted suicide is still illegal except in Oregon, the only state that has designated assisted suicide as a legal action. Other nurses may see assisted suicide as an ethical dilemma; they agree that it violates some ethical principles but question whether it violates others. For example, does assisted suicide violate the principle of autonomy? From one standpoint, it is *refusal* to assist a suicide that violates a client's autonomy. In its *Position Statement: Active Euthanasia*, the ANA (1994) states that participation in active euthanasia violates nursing's ethical code.

Ethics

Ethical Debate: Euthanasia

What does the phrase "good death" mean to you? For some people, it means:

- Dying with dignity
- Being pain-free
- Dying in the company of loved ones and friends

To others, dying a good death means:

- Being at home
- Determining when death will occur (maintaining control)

Refusal of Treatment

The client's right to refuse treatment is based on the principle of autonomy. In fairness, the client can refuse only after the treatment methods and their consequences have been explained. A client's right to refuse treatment and the right to die challenge the values of most health care providers.

Consider the use of ventilators. Medical technology makes it possible for clients to continue breathing as long as they are connected to a machine; without the machine, these clients would die. But what are the costs—emotional, physical, psychological, and fiscal? And what is the quality of a life prolonged by technology?

Use of Scarce Resources

With the current emphasis on containing health care costs, the use of expensive services is being examined closely. The use of specialists, organ transplants, and distribution of services is being influenced by social and political forces. For example, the length of stay in a hospital and the number of office visits allowable for individual clients are already predetermined by many third-party payers. In addition to economics, the availability of goods (such as organs) is contributing to a scarcity of resources. In many situations, clients experience extended waiting periods before receiving a donated organ. The allocation of scarce resources is emerging as a major ethical dilemma in today's health care environment.

As a result of technological advances and the aging of the population, there is an increased demand for health care services. There is a critical need for decisions regarding the fair and equitable use of health care services in the United States. See the accompanying Spotlight On display.

ETHICAL ROLES AND RESPONSIBILITIES OF PROFESSIONAL NURSES

As professionals, nurses are accountable for protecting the rights and interests of the client. Consequently, sound nursing practice involves making ethical decisions. Ethics affects

SPOTLIGHT ON...

Ethics

Allocation of Scarce Resources

The following two people are in desperate need of a liver transplant:

A 62-year-old alcoholic who is destitute and has no family

A 24-year-old mother of three young children

One liver is available. In your opinion, who should get the liver? What influenced your decision?

nurses in every health care setting, and each practice setting presents the nurse with its own set of ethical concerns. For example, consider home health nursing. With the increased acuity level of clients cared for in the home setting, home health nurses face ever-increasing ethical challenges of continuing to provide quality care under federally mandated cost-containment initiatives.

Whatever the setting, nurses need to balance their ethical responsibilities to each client with their professional obligations. Often there is an inherent conflict. The Nursing Checklist provides guidelines for promoting ethical care.

Ethics Committees

The provision of ethical health care requires self-examination of the care provider and the opportunity for dialogue with other health care providers. Many health care agencies now recognize the need for a systematic approach for discussing ethical concerns. Formation of multidisciplinary committees, referred to as institutional ethics committees, is one approach for facilitating dialogue regarding ethical dilemmas. In addition to serving as a forum where ethical issues are discussed, ethics committees can lead to the establishment of policies and procedures for prevention and resolution of dilemmas.

Client Advocacy

When acting as a client advocate, the nurse's first step is to develop a meaningful relationship with the client. The primary ethical responsibility is to protect clients' rights to make their own decisions. The nurse who functions as a client advocate is adhering to the ANA code of ethics. Specific examples of advocacy behaviors include empowerment of clients through education, providing support, actively listening to clients' concerns, and acting as a liaison between clients and other health care providers.

Whistle-Blowing

The term **whistle-blowing** refers to calling attention to unethical, illegal, or incompetent actions of others. This behavior is based on the ethical principles of veracity and nonmaleficence. Even though nurses are expected to "blow the whistle" on incompetent health care providers, many are reluctant to do so. Why? Because there are inherent risks in whistle-blowing behavior.

Federal law and state laws (to varying degrees) provide protection to whistle-blowers. The federal government encourages whistle-blowers to report Medicare and Medicaid fraud (Centers for Medicare and Medicaid Services, 2003). Unfortunately, however, the inclination to protect one's co-workers and fear of reprisal may deter a nurse from fulfilling the ethical obligation to report substandard behaviors. See the accompanying Spotlight On display on page 209.

ETHICAL DECISION MAKING

Nurses must understand the rationale for their decisions. **Ethical reasoning** is the process of thinking through what one

ought to do in an orderly, systematic manner to provide justification of actions based on principles. Ethical decisions cannot be based entirely on intuition or emotions. Ethical decision making is used in situations in which the right decision is not clear or in which there are conflicts of rights and duties. A framework for resolving ethical dilemmas follows.

Framework for Ethical Decision Making

Once an ethical dilemma is identified, the nurse must determine the relevant parts of the conflict in order to resolve it. When making an ethical decision, the nurse must consider the following relevant parts:

- Which theories are involved?
- Which principles are involved?
- Who will be affected?
- What will be the consequences of the alternatives (ethical options)?

To resolve ethical dilemmas, the nurse must be able to make decisions in a systematic fashion. Figure 12-4 illustrates a method for making ethical judgments that uses steps similar to those of the nursing process.

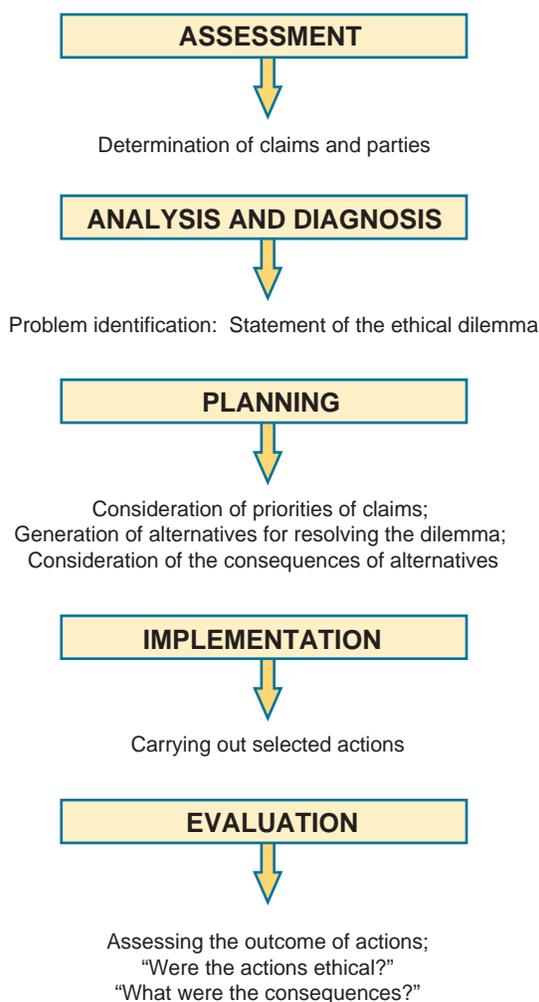

FIGURE 12-4 Ethical Decision-Making Model DELMAR/CENGAGE LEARNING

NURSINGCHECKLIST

Providing Ethical Care

- Initiate dialogue concerning the client's wishes. Do more listening than talking. (For example, the following is a question you might ask to help determine the client's wishes: "If your heart stopped, would you want us to try to start it again?")
- Assess the client's understanding of the illness and available treatment options.
- Allow time for the client to explore values and to communicate.
- Facilitate communication of the client's desires to family and other health care providers.

The first step of ethical analysis is to gather relevant data in order to identify the problem. Determine what type of ethical problem exists: Do principles conflict with principles? Do actions conflict with actions? Do actions conflict with principles?

SPOTLIGHT ON...

Ethics

Whistle-Blowing

A coworker often takes Tylenol from a client's medication drawer. When you confront her about the behavior, she states: "It's only Tylenol. Besides, the client's not taking it anymore anyway." Should you blow the whistle? Why or why not? Would your response be different if your coworker were taking narcotics from the client?

Next, consider all the people involved. What are their rights, responsibilities, duties, and decision-making abilities? Who is the most appropriate person to make the decision? It is important to identify several possible alternatives and predict the outcome of each. Then, and only then, select a course of action that ends in resolution of the problem. The final step of ethical decision making is evaluation of the resolution process.

KEY CONCEPTS

- Laws define and limit relationships among individuals and the government.
- The three sources of public law at the federal and state levels are constitutional law, administrative law, and criminal law.
- Administrative law empowers state boards of nursing to protect the public by regulating the scope of nursing practice.
- The three sources of civil law at the federal and state levels are contract law, tort law, and protective and reporting laws.
- A nurse employed by a health care facility is legally responsible for the terms of an implied contract.
- The two types of tort law at the state level are unintentional torts, which include negligence and malpractice, and intentional torts, which include assault and battery, false imprisonment, invasion of privacy, defamation, and fraud.
- Protective and reporting laws, such as the ADA and Good Samaritan acts, protect a designated group of individuals.
- The legal responsibilities of the nurse, defined in practice acts and standards of care, include elements such as providing services to clients and acting as expert witnesses in malpractice suits.
- Incident reports are filed by the nurse when a situation arises that might or did cause client harm.
- To prevent incurring liability due to the policy of floating, nurses should set priorities, identify potential areas of harm to the client, and receive orientation and cross-training before reassignment.
- Legal instruments such as informed consent and advance directives uphold the right of all people to control decisions relating to their own health care.
- Nurses may witness the signing of a consent form by a client as permitted by institutional policies; however, if the nurse discovers circumstances that render a signed consent form invalid, the nurse should notify the prescribing practitioner and, if necessary, the nurse manager.
- In terms of specific client care issues such as abortion, pronouncement of death, DNR orders, euthanasia, care of the deceased, wills, organ donation, and autopsies, nurses must know and comply with the existing laws and regulations that pertain to these areas in their individual states and provinces of licensure.
- Ethics is the study of the rightness of conduct.
- Ethics examines human behavior—what people do under what circumstances.

- Morality is not the same as ethics. Morality is behavior in accordance with custom or tradition and usually reflects personal or religious beliefs.
- There is a connection between acts that are legal and acts that are ethical. Professional nursing actions are both legal and ethical.
- Teleology is an ethical theory that states that the moral nature of a situation is determined by its consequences.
- Deontology is an ethical theory that considers the intrinsic moral significance of the act itself as the criterion for determination of good.
- Ethical decisions are based on the principles of autonomy, nonmaleficence, beneficence, justice, veracity, and fidelity.
- Nurses need to explore their own values in order to acknowledge the sometimes different value systems of clients.
- Values clarification is a process through which nurses can gain knowledge of their values and apply that understanding to the care of clients.
- Ethical codes that have been developed by nursing organizations such as the ICN, the ANA, and the CNA establish guidelines for the ethical conduct of nurses.
- The AHA's *Patient Care Partnership* is designed to guarantee ethical care of clients in terms of health care decision making.
- Nurses must apply the process of ethical reasoning to resolve ethical dilemmas in which conflict exists between principles and duties.
- The framework for ethical decision making consists of five steps: assessment, analysis and diagnosis, planning, implementation, and evaluation.
- The roles of client advocate and whistle-blower enable nurses to protect their clients' rights and ensure the ethical and competent actions of their peers within the nursing profession.

REVIEW QUESTIONS

1. Which of the following is based on the teleological theory of ethics?
 - a. Dialysis for clients with end-stage renal disease (ESRD)
 - b. Immunizations for all preschool children
 - c. Parenting classes in outpatient prenatal clinics
 - d. Protection of health care workers
2. A nurse tells a client, "You must take the medication. If you don't swallow it, I'll have to give you an injection." Which of the following best describes this nurse's illegal act?
 - a. Assault
 - b. Battery
 - c. False imprisonment
 - d. HIPAA violation
3. Which of the following statements best describes professional liability insurance for a registered nurse?
 - a. Advanced practice registered nurses are the only nurses who need to purchase professional liability insurance.
 - b. Each nurse should purchase professional liability insurance.
 - c. Nurses are protected by their employer's insurance.
 - d. Nurses will be represented by the employer's attorney.
4. A nurse is preparing a client for a surgical procedure. Which of the following should the nurse do if there is no surgical consent form signed by the client?
 - a. Explain the procedure and its risks to the client and have the client sign the consent form.
 - b. Notify the surgeon of the client's need for informed consent.
 - c. Send the client to surgery with a notation that the consent form is unsigned.
 - d. Tell the client that the form must be signed prior to surgery.
5. A nurse who usually works on a medical-surgical unit with adult clients is reassigned ("floated") to the pediatric unit. Which of the following accurately describes the nurse's legal obligations?
 - a. File a grievance against the hospital for changing the assignment.
 - b. Participate in orientation to the new unit.
 - c. Refuse to work in another specialty area.
 - d. Work on the newly assigned unit and follow the actions of the other nurses there.
6. A nurse thinks that too much medication has been ordered for a client due to the client's weight. Which of the following actions should the nurse take?
 - a. Administer a smaller dose of medication to the client.
 - b. Ask the nursing supervisor what should be done.
 - c. Contact the prescriber and clarify the order.
 - d. Give the medication as ordered by the prescriber.
7. Which of the following nursing actions is based on the ethical principle of autonomy?

- a. Removing a throw rug from the client's bedside
 - b. Respecting a client's refusal of treatment
 - c. Telling a client the truth about a negative diagnosis
 - d. Using a paternalistic approach when answering client questions
8. The allocation of scarce resources involves which of the following ethical principles?
 - a. Autonomy
 - b. Beneficence
 - c. Fidelity
 - d. Justice

CHAPTER 13

Documentation and Informatics

COMPETENCIES

1. Describe the role of information in nursing.
2. Discuss the use of information technology in promoting client safety.
3. Explain the purposes of documentation in health care.
4. Identify the HIPAA requirements related to security and privacy.
5. Discuss the principles of effective documentation.
6. Describe various methods of documentation.
7. Describe various types of documentation records.
8. Explain how to verify verbal orders.
9. Identify the entry-level informatics competencies for a nurse.
10. Describe the ways that computers and informatics support evidence-based practice and the research process.

Throughout the development of modern nursing, a variety of documentation systems have emerged in response to changes inherent in health care delivery. Changes in consumer and legal expectations, federal and state regulations, accreditation standards, and research findings direct provider accountability for the documentation of services. Systems of recording and reporting data pertinent to the care of clients have evolved primarily in response to the demand for health care practitioners to be held accountable to societal norms, professional standards of practice, legal and regulatory standards, and institutional policies and standards.

As with all facets of health care, advanced technology has affected the expectations for documentation. Benchmarking activities in quality improvement and cost containment have also increased the demands on prescribing practitioners to create efficient documentation systems. Efficiency is measured in terms of time, thoroughness, and the quality of the observations being recorded. The documentation systems in use today reflect the specific needs and preferences of the numerous health care agencies.

Since client safety is the major standard that directs nursing care, the ability to communicate information clearly, accurately, and promptly is vital to providing the safest care possible. In the changing world of health care and economics, the profession of nursing, like all other disciplines, is being challenged to decrease waste and reduce cost. Within the infrastructure of nursing informatics is an emerging system that fosters improvement in efficiency, safety, and quality client care.

INFORMATICS

In order to understand one method of documentation, computerized documentation, nurses need to be familiar with informatics. **Informatics** is a science of turning data into information. According to Hebda and Czar (2009), the broad definition of **nursing informatics** (NI) is the use of information and computer technology to support all aspects of nursing practice, including direct delivery of care, administration, education, and research.

The American Nurses Association (ANA) first defined the role of the informatics nurse specialist in 1992. The ANA

revised its definition in 1994, 2001, and 2007 to define the evolving scope of practice:

Nursing informatics is a specialty that integrates nursing science, computer science, and information science to manage and communicate data, information, knowledge and wisdom into nursing practice. Nursing informatics facilitates the integration of data, information, knowledge and wisdom to support patients, nurses, and other providers in their decision making in all roles and settings. This support is accomplished through the use of information structures, information processes, and information technology. (ANA 2007, p. 1)

Computer literacy refers to a familiarity with the use of personal computers, including the use of software tools such as word processing, spreadsheets, databases, presentation graphics, and e-mail (Hebda & Czar, 2009). **Information literacy** is the ability to recognize when information is needed as well as the skills to find, evaluate, and use needed information effectively (Association of College and Research Libraries, 2008). **Information technology** (IT) refers to the management and processing of information with the assistance of computers (Hebda & Czar, 2009). This technology has allowed organizations to develop management information systems such as a hospital information system (HIS) that focus on the types of data needed to manage client activities. An information system refers to the use of computer hardware and software to process data into information to solve a problem.

There are two basic types of HISs: clinical information systems (CISs) and administrative information systems. CISs are large computerized database management systems with subsystems such as order entry, admission, result retrieval admissions (e.g., laboratory, pharmacy, and radiology), and documentation that support and enhance health care. Administrative information systems manage financial and demographic information and provide reporting capabilities to support client care.

CLINICAL INFORMATION SYSTEMS

The main purpose of CISs is to allow health care providers and researchers to gain quick and safe access to information,

order appropriate medications and treatments, and implement cost-effective, evidence-based care without duplicating services. For example, the nurse documents client allergies in the initial assessment; these data are then accessible to all health care providers, such as the prescribing practitioner and the pharmacist. The tools or subsystems of this clinical system include electronic health records, clinical decision support systems, and bedside medication administration using positive client identification, computerized prescribing practitioner order entry, client surveillance, and clinical data warehouses (Hebda & Czar, 2009).

Computerized physician (provider or prescriber) order entry (CPOE) is the process by which the prescribing practitioner directly enters orders for client care into an HIS. Information is drawn from several systems, such as pharmacy and laboratory systems, with drug databases to warn the prescriber of potential problems with dosages, drug interactions, allergies, and contraindications.

E-prescribing refers to the electronic transmission of drug prescriptions to a pharmacy from a hospital-based inpatient ordering system (CPOE), personal digital assistants, wireless computers, or other handheld devices. This system reduces error regarding illegible handwriting; it also incorporates lists of client allergies and other medications the client is taking.

Positive client identification is accomplished through the use of barcodes or radio frequency identification (RFID). Barcodes are the dominant technology in use to reduce identification errors. In 2004 the Food and Drug Administration required barcodes on most prescription and some over-the-counter medications to decrease medication errors. The barcode system requires scanning of the nurse's identification, the client's identification bracelet, and all prescription medications during the medication administration process. Once scanned into the computer, the information is processed and confirms the right client, drug, and dosage. RFID technology produces data when stimulated by radio frequency energy; it is a costly system and is not as widely used as barcoding.

Decision-support software (DSS) refers to a computer application that analyzes data, such as laboratory values or standards of care, and presents it in a fashion that facilitates decision making. For example, DSS guides the triage nurse through a series of observations, questions, interventions, and safety alerts when a client presents with a specific complaint.

ELECTRONIC HEALTH RECORD

Client safety, accessibility to health information, and economics are the driving forces of the government, professional organizations, and accrediting bodies toward the development and implementation of the electronic health record (EHR). The Bush administration called for the adoption of the EHR by 2014 to help transform health care in the United States. The traditional paper medical record is episode oriented, with a separate record for each client visit to a health care agency (Hebda & Czar, 2009). Critical information, such as client allergies, may be lost from one episode of care to the next, jeopardizing client safety.

The EHR is a longitudinal electronic record of client health information generated by one or more encounters in any health care setting (Healthcare Information and Management Systems Society [HIMSS], 2008). Because the EHR system stores the complete record of every clinical encounter, health care providers can access clinical data to identify quality issues, link interventions with positive outcomes, and make evidence-based decisions. The EHR also provides interactive client access and allows the client to append information.

The HIMSS (2008) developed a definitional model for EHR with these attributes:

- Provides secure, reliable, real-time access to client health record information where and when it is needed to support care
- Records and manages episodic and longitudinal EHR information
- Functions as clinicians' primary information resource during the provision of client care
- Assists with the work of planning and delivery of evidence-based care to individuals and groups of clients
- Captures data used for continuous quality improvement, utilization review, risk management, resource planning, and performance management
- Captures the client health-related information needed for medical records and reimbursement
- Provides longitudinal, appropriately masked information to support clinical research, public health reporting, and population health initiatives
- Supports clinical trials and evidence-based research

The development of the EHR relies on an operational electronic medical record and a national health information network. The Department of Health and Human Services formed the EHR collaborative with professional organizations in 2003 to facilitate rapid input from the health care community to support the adoption of standards for the EHR. Hebda and Czar (2009) cite the benefits of the EHR for nursing: It facilitates comparison of data from different health care encounters, maintains an ongoing record of a client's education and learning in all encounters, eliminates the need for repetitive demographic data, ensures administration and documentation of medications and treatments, facilitates research, automates critical and clinical pathways, and allows recognition of nursing work in measurable units when used with a common unified structure for nursing language. During the last decade, the use of EHRs has become more widespread, from large academic medical centers to community-based acute care and outpatient facilities (Kosman & Scheidenhelm, 2008).

NURSING INFORMATION SYSTEMS

A nursing information system is a subsystem of CISs, supports the use and documentation of nursing processes and interventions, and provides tools for managing the delivery of nursing care. The system should provide access to the information nurses need: client medical records, test results, progress notes, hospital policy and procedures, and tools for

online literature searches such as the Cumulative Index of Nursing and Allied Health Literature (CINAHL), Medline, and automated drug information.

Nursing information systems have two basic approaches to nursing care and documentation: the nursing process and critical pathways or protocols. The traditional nursing process approach uses established formats such as admission and postoperative assessments, problem lists, care plans, discharge planning instructions, and intervention lists. A more organized version incorporates standardized nursing languages such as the North American Nursing Diagnoses Association (NANDA), Nursing Interventions Classification (NIC), and Nursing Outcomes Classification (NOC).

The nursing process approach uses traditional paper forms for automated documentation. The documentation of nursing and admission assessment and discharge instructions relies on a menu-driven approach to obtain essential information. A menu list with related commands directs the nurse through assessment, such as a client's past medical history, advance directives, psychosocial history, and review of systems. Once the assessment data are entered into a computer, a program will offer menu lists for the nurse to select appropriate nursing diagnoses and interventions for an individualized care plan and discharge instructions. The program will generate printed copies of discharge instructions, medication information, and follow-up appointments for nurses to review with clients on discharge.

The nursing process approach also includes system formats for the following:

- Generating a nursing work list that directs routine scheduled activities related to client care
- Documenting discrete data or activities such as vital signs, weight, and intake and output measurements
- Documenting routine client care activities such as bathing, positioning, blood glucose measurement, dietary intake, and/or wound care in a flow sheet format
- Documenting nursing care in progress notes using one of the following charting formats: narrative, charting by exception, or flow sheet
- Documenting medication administration

These systems require acceptance of the nursing process by each nurse and sufficient technical equipment to provide for nurse documentation.

The second design is based on evidenced-based clinical protocols or critical pathways, often used in a multidisciplinary manner, with many types of care providers accessing the system for information and to document care. This system allows for the selection of one or more appropriate critical pathways for a client. Standard prescribing practitioner order sets can be included with each critical pathway and may be automatically processed by the system. The system identifies variances of the anticipated outcomes when charted and provides aggregate variance data for analysis by the care provider.

Hakes and Whittington (2008) measured nurse documentation time before and after the implementation of an electronic medical record and found that there was no difference in documentation time between the preelectronic medical

record and the postelectronic medical record. Although there are an insufficient number of studies that show the impact of computerized record systems on nursing practice and client outcomes, there is an increase of computers in health care settings. Anecdotal reports and descriptive studies suggest that computerized documentation enhances the systematic approach to client care through standardized protocols, teaching documents, data management, and communication.

DOCUMENTATION AS COMMUNICATION

Communication is a dynamic, continuous, and multidimensional process for sharing information as determined by standards or policies. Reporting and recording are the major communication techniques used by health care providers to direct client-based decision making and continuity of care. The medical record serves as a legal document for recording all client activities assessed and initiated by health care practitioners.

DOCUMENTATION DEFINED

Documentation is defined as written (paper and pen or electronic) evidence of:

1. The interactions between and among health professionals, clients, their families, and health care organizations
2. The administration of tests, procedures, treatments, and client education
3. The results or client response to these diagnostic tests and interventions

Documentation provides written records that reflect client care provided on the basis of assessment data and the client's response to interventions.

Nurses rely on documentation tools, including computerized systems, that support the implementation of the nursing process. These tools are the charting records and systems that facilitate a logical sequencing of events. All the tools used by nurses to record their nursing care should form a system. Systematic documentation is critical because it presents the care administered by nurses in a logical fashion, as follows:

1. Assessment data (obtained by interviewing, observing, and inspecting) identify the client's specific alterations and provide the foundation of the nursing care plan.
2. The risk factors and the identified alteration in the functional health pattern direct the formulation of a nursing diagnosis.
3. Identifying the nursing diagnosis promotes the development of the client's short-term goals, long-term goals, and expected outcomes and also triggers the nursing interventions. These activities occur during the planning and implementation phases of the nursing process.

4. The plan of care identifies the nursing interventions necessary to resolve the nursing diagnosis.
5. Implementation is evidenced by actions the nurse performed to assist the client in achieving the expected outcomes.

The effectiveness of the nursing interventions in achieving the client's expected outcomes becomes the criterion for evaluation that determines the need for subsequent reassessment and revision of the plan of care.

The system becomes a vehicle for expressing each phase of the nursing process. Nurses rely on systems that provide thorough, accurate charting reflective of the nurse's decision-making ability and the client's plan of care. The nurse's critical thinking skills, judgments, and evaluation must be clearly communicated through proper documentation.

PURPOSES OF HEALTH CARE DOCUMENTATION

Professional responsibility, accountability, and client safety are the primary reasons why practitioners document. Other reasons to document include communication, education, research, meeting legal and practice standards, and reimbursement. Documentation provides written evidence of the nurse's accountability to the client, the institution, the profession, and society. See the accompanying Nursing Checklist display.

Communication

Recording is a method of communication that validates the care provided to the client. It should clearly communicate all important information regarding the client. Thorough documentation provides:

- Accurate data needed to plan the client's care in order to ensure the continuity of care
- A method of communication among the health care team members responsible for the client's care
- Written evidence of what was done for the client, the client's response, and any revisions made in the plan of care
- Compliance with professional practice standards (e.g., the ANA)
- Compliance with accreditation criteria (e.g., the Joint Commission)
- Compliance with the Health Insurance Portability and Accountability Act (HIPAA)
- A resource for review, audit, reimbursement, education, and research
- A written legal record to protect the client, institution, and practitioner

The client's medical record contains documents for record keeping. The type of document that constitutes the medical record is determined by the health care institution. References will be made to the various types of medical record documents throughout this chapter; refer to Table 13-1 on page 218 for an explanation of these documents. These medical record documents are either on paper or contained within a computerized system.

Education

The documentation contained within the client's medical record can be used for the purpose of education. Health care students use the medical record as a tool to learn about disease processes, complications, medical and nursing diagnoses, and interventions. The results of physical examination and laboratory and diagnostic testing provide valuable information regarding specific diagnoses and interventions.

Nursing students can enhance their critical thinking skills by examining the records in chronological order, analyzing the results, and following the health care team's plan of care (e.g., how it was developed, implemented, and evaluated). Students and all health care professionals need to be aware of confidentiality issues before reading any client's chart; these are discussed later in the chapter.

Clinical rounds and case conferences, which rely heavily on information contained in the medical record, have also proved to be effective teaching tools. These learning experiences usually involve several disciplines that contribute to the review and discussion of client outcomes.

Student nurses need to learn the "flow" of documenting clinical data according to institutional policy in a legible, descriptive, and time-sequenced fashion. A good way to learn this flow is to review the client's condition as presented in the chart before hearing the report. The data obtained from chart review should direct the assessment of signs and symptoms on rounds.

Research

Researchers rely heavily on clients' medical records as a clinical data source to determine if clients meet the research criteria of a study. Researchers use computers to expedite collection and

NURSING CHECKLIST

REVIEWING A CHART

- Can the assessment data that triggered the nursing diagnosis be identified?
- When the defining characteristics of a specific nursing diagnosis are compared to the client's presenting signs and symptoms, is there supporting evidence?
- Were critical questions asked during the client interview?
- Did the nurse use the data obtained from both the interview and physical assessment in establishing the diagnoses?
- Can any assumptions that might have misled the nurse's judgment be identified?
- Are the nursing data correlated with the results of the physical examination and findings from diagnostic tests?
- Are the expected outcomes realistic?

TABLE 13-1 Medical Record Documents

DOCUMENT	INFORMATION
Face sheet	Biographical data: name, date of birth, address, phone number, Social Security number, marital status, employment, race, gender, religion, closest relative; insurance coverage; allergies; attending prescribing practitioner; admitting medical diagnosis; assigned diagnosis-related group; statement of whether the client has an advance directive.
Consent form	<i>Admit:</i> Gives the institution and prescribing practitioner the right to treat. <i>Surgery:</i> Explains the reason for the operation in lay terms, the risks for complications, and the client's level of understanding. <i>Blood transfusion:</i> Permission to administer blood or blood products.
Medical history and physical examination	Results of the client's initial history and physical assessment as performed by the health care provider.
Prescriber order sheet	Medical orders to admit and the treatment plan.
Progress notes	Evaluation of the client's response to treatment; may contain the progress recording of interdisciplinary practitioners (e.g., dietary or social services).
Consultation sheet	Initiated by the prescribing practitioner to request the evaluation or services of other practitioners.
Diagnostic results	The results from laboratory and diagnostic tests (e.g., x-ray, hematology).
Nursing admit assessment	Recording of data obtained from the interview and physical assessment conducted by the RN.
Nursing plan of care	Contains the treatment plan (e.g., nursing diagnosis or a problem list, initiation of standards of care, or protocols).
Graphic sheet	Data recording regarding vital signs and weight.
Flow sheet	Contains all routine interventions that can be noted with a check mark or other simple code; allows for a quick comparison of measurement.
Nurses' progress notes	Additional data that do not duplicate information on the flow sheet (e.g., client's achievement of expected outcome or revision of the plan of care).
Medication administration record (MAR)	Contains all medication information for routine and prn drugs: date, time, dose, route, site (for injections).
Client education record	Recording of nurses' teaching of clients, families, and other caregivers and the learners' responses.
Health care team record	Treatment and progress record for nonmedical and nonnursing practitioners, when the prescribing practitioner's progress notes are not used by other practitioners (e.g., respiratory, physical therapy, dietary).
Clinical pathway	A multidisciplinary form for each day of anticipated hospitalization that identifies the interventions and achievement of client outcomes; the practitioner's initial implementation and variances from the norm are explained in the progress notes.
Discharge plan and summary	A multidisciplinary form used before discharge from a health care facility containing a brief summary of care rendered and discharge instructions (e.g., food-drug interactions, referrals, follow-up appointments).
Advance directive or living will	Federal law requires that health care providers discuss with clients the use of advance directives (e.g., the living will and the durable power of attorney). Most states recognize the living will as a legal document. If the client has advance directives, they are reviewed at the time of admission and placed in the medical record.

Delmar/Cengage Learning

analysis of data. Mobile devices such as notebook computers at the study site can transmit data to another computer for compilation and analysis. Documentation also can validate the need for research. For example, if documentation

demonstrates an increased infection rate with intravenous catheters, researchers can identify and study the nursing intervention variables that may be associated with the increased infection rate.

Legal and Practice Standards

The client's medical record is a legal document, and in the case of a lawsuit, the record serves as the description of exactly what happened to a client. The legal issues of documentation require:

- Legible and neat writing for paper records
- Proper use of spelling and grammar
- Use of authorized abbreviations
- Factual and time-sequenced descriptive notations

These elements of effective documentation are discussed later in this chapter.

Nurses are responsible for the care the client receives and can be held liable if appropriate interventions are not implemented in a timely manner when information is available that would dictate otherwise. The nurse is responsible for documenting on the chart when a “prescribing practitioner was notified” along with what significant information was orally communicated. If the nurse does not get a response from the prescribing practitioner that recognizes the urgency of the information, the nurse must document the prescribing practitioner's response and notify the supervisor of the situation.

DeMilliano (2009) and the Nurses Service Organization, which is a medical malpractice, professional liability, and risk management company, identified common charting errors that can result in malpractice:

- Failing to record pertinent health or drug information
- Failing to record nursing actions
- Failing to record that medications have been given
- Recording on the wrong chart
- Failing to record drug reactions or changes in the client's condition
- Transcribing orders improperly or transcribing improper orders
- Writing illegible or incomplete records
- Failing to document a discontinued medication

In addition to these omissions, nurses should chart only their own actions; never chart for someone else unless the caregiver has left the unit and calls with additional information that needs to be documented. Follow agency policy when documenting a late entry, as discussed later in this chapter.

HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT (HIPAA) The HIPAA of 1996 was the first federal legislation to protect automated client records. This act called for the establishment of electronic record systems and privacy rules to legally protect personal health information (PHI). PHI is any information contained in automated records that is transmitted or maintained in any form or medium, including verbal discussions, electronic communications regarding clients, and written communications (Hebda & Czar, 2009). Examples of PHI include name, address, birth date, Social Security number, allergies, claims data, laboratory results and other diagnostic history, prescription history, past visits to a prescribing practitioner, emergency rooms and

other health care encounters, vaccination records, and prior in- and outpatient procedures.

The HIPAA privacy rule mandates how an organization must address administrative and technical procedures to protect privacy (Hebda & Czar, 2009). Examples of administrative procedures include information access controls; formal mechanisms for processing records; security incident procedures, training, and management processes; and termination procedures. Technical measures require audit controls, authorization controls, data authentication, communication and network controls, encryption, and other types of authentication such as event reporting and message integrity.

In 2003 HIPAA published the security rule that mandates safeguards for the physical storage, maintenance, transmission, and access to PHI to ensure its confidentiality, data integrity, and availability when required for treatment (Hebda & Czar, 2009). The HIPAA law provides for penalties of non-compliance with either the privacy rule or the security rule.

HIPAA allows for student access but demands individual accountability for viewing PHI (Milo & Carlton, 2008). Using IT and learning to perform clinical documentation is an important facet in the education of student nurses and needs to be integrated into all clinical courses (Milo & Carlton, 2008; Thede, 2008).

Hospital and nursing information systems must ensure rapid access to accurate and complete client information to legitimate users, while safeguarding client privacy and confidentiality (Hebda & Czar, 2009). HIPAA requires health care organizations to demonstrate measures that protect client information and comply with accreditation criteria.

In IT language, privacy refers to the client's right to determine what information is collected, how it is used, and the ability to access collected information to review its security and accuracy. HIPAA requires that all clients be given clear written explanations of how facilities and providers may use and disclose client health data. Nurses are held legally accountable by the ANA *Code of Ethics* and state practice laws to protect client privacy.

Confidentiality is necessary for the accurate assessment, diagnosis, and treatment of health problems, and it refers to a situation in which a relationship has been established and private information is shared. The ethical duty of confidentiality requires that information shared during the course of a professional relationship is kept secure and secret from others. Appropriate security mechanisms must address the storage and transmission of private information; ensure that the equipment used for storage and transmission is secure; and prevent the interception of e-mail, instant messages, faxes, and other correspondence containing private information. Fax numbers should be confirmed prior to sending confidential information. All printed information, such as faxes and e-mails, that contains confidential information must be destroyed. Most agencies have shredders or locked receptacles for shredding and later incineration of client record information.

Information privacy requires informed consent for the release of specific information. Information security is the protection of information against threats to its integrity,

inadvertent disclosure, or availability. Consent is when an individual authorizes health care providers to release information based on an informed understanding of how this information will be used. As with all consents, the individual must be made aware of any risks that may exist to privacy as well as the security measures taken to protect privacy.

Security mechanisms use a combination of two basic protection measures: logical and physical restrictions such as firewalls and the installation of antivirus and spyware detection software. Automatic sign-off is an example of logical restriction; this mechanism logs off a user from the system after a specific period of inactivity on the computer.

Identification management deals with identifying individuals in a system and controlling access to resources within that system by associating user right and restriction with the established identity. Identity must be authenticated to determine whether someone is who he or she professes to be. Some examples of authentication are passwords, digital certificates, and public or private keys used for encryption and biometric measures.

Access codes and passwords are collections of alphanumeric characters that users type into the computer. The password is usually required after the entry and acceptance of the access code, often called the *user name*. The password should not be known to anyone but the user. A strong password should contain letters, numbers, and symbols to ensure a high level of security. The user should log off when leaving the computer unattended.

A firewall is a barrier between systems to protect those systems from unauthorized access. A firewall screens traffic, allowing only approved transactions to pass through them, and restricts access to other systems or sensitive areas such as client information, payroll, or personal data (Hebda & Czar, 2009).

Antivirus software refers to a set of computer programs that can locate and eradicate viruses and other malicious programs from scanned memory sticks, storage devices, individual computers, and networks. These systems require updating to combat the constant creation of new viruses. Users can install and activate antivirus software to automatically run a virus check on a personal computer or server on a scheduled basis in addition to performing random checks. Network computers automatically perform a virus scan of new files and update antivirus files; administrators can also set privileges to prohibit unauthorized file downloads.

Another security concern is spyware. Spyware is a self-installing data collection mechanism that is installed without the user's permission. This may happen when the user is browsing the Web or downloading software. Spyware often includes cookies that track Web use as well as applications that capture credit card, bank, and PIN numbers or other PHI stored on that computer for illicit purposes by an authorized person (Hebda & Czar, 2009). Indicators of a computer spyware infection are the presence of pop-up ads, keys that do not work, random error messaging, and poor system performance. Spyware detection software should be installed on computers because of this security threat.

COMPONENTS OF A POLICY TO PROTECT AND SECURE PHI IN COMPUTERIZED RECORDS

- Computer access is governed by user passwords that should not be shared with anyone.
- Once the user is logged into the computer, the computer screen should not be left unattended or accessible for public viewing.
- All unnecessary computer-generated paper must be shredded.
- Users must know how to correct an entry error.
- Users must know how to chart client-sensitive material, such as a diagnosis of AIDS.
- A firewall protects the server from unauthorized access.

Most health care agencies allow student and graduate health professionals access to client records for the purpose of education and research. Client records are used to support learning such as conferences, rounds, and nursing care plans. Students must comply with ethical codes and legal and agency regulations such as HIPAA to hold all client information in confidence. The student is responsible for protecting the client's privacy by not using a name or any statements in the notations that would identify the client (Hebda & Czar, 2009). Health care agencies, in compliance with HIPAA mandates, specifically the Security Rule of 2005, have policies and procedures to ensure the privacy and confidentiality of PHI stored in computers; see Box above for a sample policy that protects the privacy and security of computerized records.

SPOTLIGHT ON...

Legal/Ethical

Is this just a cliché: "If it wasn't charted, it wasn't done"? Since the purpose of the medical record is to document the care administered to the client, how can a practitioner convince a jury that care was administered if it is not documented in the medical record? Consider the following. A nurse, by habit, always administers an intramuscular injection in the ventrogluteal site, although both the ventrogluteal and dorsogluteal sites are within the accepted guidelines of care. The nurse, however, fails to chart the site on the medication administration record (MAR). The client files a suit for sciatic nerve damage. Knowing that there is an identified greater risk factor for sciatic nerve injury with the dorsogluteal site, do you think it would be difficult to defend care given in this case?

SAFETY FIRST

THE IMPORTANCE OF COMMUNICATION

Important information obtained from an assessment that warrants immediate intervention should not only be documented in the medical record but also communicated orally to the other practitioners. The element of time must direct decision making when critical information is obtained.

INFORMED CONSENT **Informed consent** means that the client understands the reason for and the risks of the proposed intervention and agrees to the treatment by signing a consent form. Legally, the client must be mentally competent, and the prescribing practitioner who is to perform the procedure is responsible for obtaining the client's informed consent (refer to Chapter 12). Failure to provide educational opportunities for a client to participate in decision making could open the door to litigation.

In order to assist the prescribing practitioner with proper documentation of teaching, many facilities have pre-printed informed consent documents that explain procedures in lay terms and identify the risk factors and possible complications. These documents are usually duplicate copies: The original goes in the medical record, and the copy is given to the client. This procedure provides the client with a written copy of the information that can be reviewed at a later time in a more relaxed environment.

Nurses are responsible for ensuring that the client understands the procedure or intervention and has signed the informed consent. The best way to assess client knowledge of an intervention is to ask clients to explain, in their own words, what is going to be done and the common risks and possible complications. If the informed consent has not been signed or if the nurse assesses a lack of understanding on the client's part, the prescribing practitioner should be notified and the client should not be allowed to undergo the procedure. If the intervention is a surgical procedure, the nurse should notify the operating room at the time the surgeon is notified.

Although most informed consents deal with medical interventions, nurses are sometimes responsible for implementing the interventions: For example, administering blood or blood products requires informed consent. It is also the responsibility of the nurse to obtain oral consent for certain nursing interventions, such as initiating intravenous therapy or inserting a nasogastric tube or urinary catheter. Remember that consents require client education with an explanation of outcomes and documentation of the client's understanding of the procedure.

Once the client has been educated by the prescribing practitioner and nurse about the intervention, the informed consent needs to be signed by the client and witnessed. Witnessing the signing of the consent confirms that the person who signs the consent is in fact the client and *is competent*,

SAFETY FIRST

CONSENT FROM SEDATED CLIENTS

Sedated clients should never be requested or allowed to sign an informed consent; they may not be capable of understanding the nature of and risks associated with the procedure, so the consent will be invalid, and the nurse and institution will be at legal risk. Wait instead for the client to be competent and free of sedation, or have a legally acceptable family member brought into the decision.

alert, and aware of all actions at that point in time. Refer to Chapter 12 for further discussion of informed consent.

ADVANCE DIRECTIVES An **advance directive** is a statement made by clients that defines care they deem acceptable if they become incapacitated. It effectively allows clients, while competent, to participate in end-of-life decisions and to choose the types of life-sustaining procedures they will permit if they become unable to make their own decisions at a later time. A **durable power of attorney** allows the client to appoint a person to make health-related decisions when the client is incapable of making them. The Patient Self-Determination Act of 1990 requires health care facilities (hospitals, skilled-nursing facilities, and home health agencies) to inform adult clients of their rights regarding advance directives and to document in the medical record whether the client has such a directive. The implementation of advance directives is discussed in Chapter 12.

AMERICAN NURSES ASSOCIATION STANDARDS OF CARE Standards of documentation are established by professional organizations. The ANA's Standards of Clinical Nursing Practice serve as guidelines for determining safe, quality nursing care and practice. The nursing process gives structure to the standards of care, with specific measurement criteria for each phase in the process. For each of the six standards (assessment, diagnosis, outcome identification, planning, implementation, and evaluation), there is a measurement criterion that states "are documented." ANA standards make explicit the role of data collection and documentation in nursing practice. They specify that data collection be systematic and continuous and that data be accessible, communicated, and recorded (ANA, 1997).

STATE NURSE PRACTICE ACTS In an attempt to recognize and control the practice of nursing, nurse practice acts, on a state-by-state basis, have established guidelines to ensure safe practice and to demonstrate accountability to society. The standards of care, as set forth in the practice acts, are based on the phases of the nursing process and require evidence of compliance by documentation. Nurses should be familiar with the practice acts and rules of the state in which they work.

THE JOINT COMMISSION The Joint Commission surveys health care facilities to measure compliance with its standards for safe health care provision. Although facilities voluntarily submit to this accreditation process, reimbursement eligibility for Medicare, Medicaid, and private funding is dependent upon Joint Commission accreditation.

The Joint Commission recommends the use of an HIS and requires that reports be submitted using computerized formats. The Joint Commission's National Patient Safety Goal for 2008 requires organizations to develop technology that will assist with the process of positive client identification. National initiatives are focused on reducing identification errors for procedures and nursing interventions such as medication administration, bedside glucose checks, and the administration of intravenous fluids and blood transfusion.

In 1994 the Joint Commission issued information management standards for health care organizations. The standards addressed these areas:

- Measures to protect information confidentiality, security, and integrity
- Uniform definitions and methods for data capture as a means to facilitate data comparison within and among health care agencies
- Education on the information management principles and training for system use
- Accurate and timely transmission of information
- Integration of clinical systems such as pharmacy, nursing, laboratory, and radiology and nonclinical systems such as medical records and admissions
- Client-specific data and information related to outcomes that facilitate care, provide financial and legal records, aid research, and support decision making
- Aggregate data and information records that support operations and research and improve performance and care
- Knowledge-based information capable of providing literature in print or electronic form
- Data that facilitate comparison of one institution with other agencies

The Joint Commission revised these standards in 2006 to provide for business continuity and disaster recovery planning, data and information retention, decision support, and specific documentation areas and formats (Hebda & Czar, 2009).

The Joint Commission no longer requires that health care organizations have traditional nursing care plans, but documentation of an individualized plan of care must be evident for each client. The Joint Commission's standards require:

- The involvement of the client or family in the development of the plan, which must be documented in the medical record
- Interdisciplinary planning and implementation of all aspects of care

The use of interdisciplinary tools has proven to be an effective approach to documenting client and family education for agencies not yet using critical pathways (discussed later in the chapter) or care mapping.

During the accreditation survey, the reviewer looks for evidence of an organized and systematic method of monitoring and evaluating client care that is reflected through documentation in the medical record. Documenting the steps of the nursing process ensures compliance with the Joint Commission's plan of care requirements.

Reimbursement

Peer review organizations (PROs), consisting of prescribing practitioners and nurses, are required by the federal government to monitor and evaluate the quality and appropriateness of care given. Medical record documentation is the mechanism for the PRO review, which evaluates the intensity of services and the severity of illness on the basis of a comparison of sample medical records from different facilities against specific screening criteria.

The federal enactment of the diagnosis-related group (DRG) classification system changed the health care provider reimbursement process from a cost-per-case formula to a prospective payment system (PPS). With PPS, the medical record must provide documentation that supports the DRG and the appropriateness of care. Nursing documentation must also show evidence of client and family education and discharge planning.

From a hospital's perspective, when information in the medical record demonstrates compliance with Medicare and Medicaid standards, the reimbursement is maximized. If nurses fail to document the equipment or procedures used daily (e.g., feeding pump; daily weight, intake and output; intravenous therapy; drug additives), reimbursement to the facility can be denied.

Another federal law, the Comprehensive Omnibus Budget Reconciliation Act (COBRA), allows employees to temporarily carry their employer-provided health insurance benefits for 90 days after termination, reduction in the work hours, or retirement. The law requires that for any COBRA client receiving care in an emergency room, the client's condition must be stabilized before the client can be transferred to another facility. If the client's condition is not stable, then the institution cannot initiate a transfer.

Facilities in violation of COBRA laws are fined and stand to lose their eligibility to Medicare and Medicaid funding. Compliance with this law is evaluated through medical record review. The documentation concerning client transfers must include:

- Chronology of the event
- Measures taken or treatment implemented
- Client's response to treatment
- Results of measures taken to prevent the client's condition from deteriorating

SPOTLIGHT ON...

Legal/Ethical

Why would an emergency room want to transfer a COBRA client who has insurance? Do you think these clients are considered high risk? Suppose a pregnant client in the seventh month of gestation comes to the emergency room in labor. The client is assessed by the prescribing practitioner and nurse. Labor is in progress, but delivery is not imminent, and the client's blood pressure is 210/124. Treatment is initiated; however, the blood pressure remains high (190/110). Can this client be transferred? If not, why not? Why would this health care provider want to stabilize and transfer the client before delivery?

PRINCIPLES OF EFFECTIVE DOCUMENTATION

Documentation requirements will differ depending on the health care facility (hospital, nursing home, home health agency) and the setting within the facility (e.g., emergency room, perioperative, medical-surgical unit) and with specific client populations (e.g., obstetrics, pediatrics, geriatrics). Regardless of what client care is administered, the documentation of that care must reflect the nursing process. General documentation guidelines for paper records and computerized charting are listed in the accompanying display.

Nursing notes must be logical, focused, and relevant to care and must represent each phase in the nursing process. Nursing documentation based on the nursing process facilitates effective care because client needs can be traced from assessment, through the identification of the problems, to the care plan, implementation, and evaluation. A brief reminder of the elements of the nursing process follows:

- **Assessment:** Summarize, without duplication, assessment data that are related to an actual or potential health care need. With reassessment, highlight any new findings or any changes in the client's condition (e.g., increased pain). The accompanying display outlines some assessment-specific documentation guidelines.
- **Diagnosis:** Identify the client's problem or need using NANDA terminology.
- **Outcome identification and planning:** Discuss with the client and communicate to members of the multidisciplinary team the expected outcomes or goals of client care.
- **Implementation:** After the intervention has been performed, document observations, treatments, teaching, and related clinical judgments. Client teaching should include learning needs, teaching plan content, methods of teaching, who was taught, and the learners' responses.

GENERAL DOCUMENTATION GUIDELINES

- Ensure that you have the correct client record or chart and that the client's name and identifying information are on every page of the record.
 - Document as soon as the client encounter is concluded to ensure accurate recall of data (follow institutional guidelines on frequency of charting).
 - Date and time each entry.
 - Sign each entry with your full legal name and with your professional credentials, or per your institutional policy.
 - Do not leave space between entries.
 - If an error is made while documenting, use a single line to cross out the error, then date, time, and sign the correction (check institutional policy); avoid erasing, crossing out, or using correction fluid.
 - Never change another person's entry, even if it is incorrect.
 - Use quotation marks to indicate direct client responses (e.g., "I feel lousy").
 - Document in chronological order (if chronological order is not used, state why).
 - Write legibly.
 - Use a permanent-ink pen (black is usually preferable because of its ability to photocopy well).
 - Document in a complete but concise manner by using phrases and abbreviations as appropriate.
 - Document all telephone calls that you make or receive that are related to a client's case.
 - Keep computer passwords confidential.
 - Once logged on to the computer, do not leave the computer screen unattended or accessible to public viewing.
- **Evaluation:** Evaluate and document the effectiveness of the interventions in terms of the expected outcomes: progress toward goals; client response to tests, treatments, and nursing interventions; client and family response to teaching and significant events; and questions, statements, or complaints voiced by the client or family.
 - **Revisions of planned care:** Document the reasons for the revisions with the supporting evidence and client and family agreement.
- Charting in accordance with the nursing process ensures thorough documentation in compliance with the ANA's standards of care, practice acts, and reimbursement and accreditation criteria.

Home Health Care

Home health agencies also keep documents: prescribing practitioner orders, history and physical forms, home care team records, and nursing records (initial assessment form, plan of care, problem list for daily progress notes, client teaching activities, and discharge summary). Home health care providers are required to comply with state and federal regulations that affect health care, documentation, and reimbursement.

ELEMENTS OF EFFECTIVE DOCUMENTATION

Effective documentation requires:

- Use of a common vocabulary
- Legibility and neatness
- Use of only authorized abbreviations and symbols
- Factual and time-sequenced organization
- Accurately including any errors that occurred

The following discussion of effective charting refers to all nursing documents, such as flow sheets, progress notes, and so on. Add to the nursing documents when:

- A change occurs in the client's condition
- Measuring the client's response to an intervention or expected outcome
- The client or family voices a complaint

Use of Common Vocabulary

The use of a common vocabulary in nursing is considered critical by many nurse leaders in order for nurses to define the practice of nursing. A common vocabulary allows nurses to provide continuity of care as well as researchers to collect and compare data among large groups of clients, facilitating the development of evidence-based practice (EBP). When nurses use multiple terms for describing nursing assessment, diagnoses, interventions, and client outcomes, it is difficult to conduct comparisons of nursing care.

With the formulation of nursing diagnoses by the NANDA as well as the NIC and NOC, nursing is moving toward a coordinated set of clinical languages. This system should provide nursing care with decision support and a standardized language to describe nursing activities.

In the early 2000s, nursing leaders in the United States began meeting with international groups to determine acceptable nursing terminologies to be computable and semantically interoperable with one another. In 2003 the international summit members adopted the first model of standards, and by 2008 the group shifted from developing standards to reviewing, revising, and implementing standards

ASSESSMENT-SPECIFIC DOCUMENTATION GUIDELINES

- Record all data that contribute directly to the assessment (e.g., positive assessment findings and pertinent negatives).
- Document any parts of the assessment that are omitted or refused by the client.
- Avoid using judgmental language such as "good," "poor," "bad," "normal," "abnormal," "decreased," "appears to be," and "seems."
- Avoid evaluative statements (e.g., "client is uncooperative," "client is lazy"); cite instead specific statements or actions that you observe (e.g., "client said 'I hate this place' and kicked trash can").
- State time intervals precisely (e.g., "every 4 hours," "b.i.d.," instead of "seldom," "occasionally").
- Do not make relative statements about findings (e.g., "mass the size of an egg"); use specific measurements (e.g., "mass 3 cm × 5 cm").
- Draw pictures when appropriate (e.g., location of scar, masses, skin lesion, decubitus, deep tendon reflex).
- Refer to findings using anatomical landmarks (e.g., left upper quadrant [of abdomen], left lower lobe [of lung], midclavicular line).
- Use the face of the clock to describe findings that are in a circular pattern (e.g., breast, tympanic membrane, rectum, vagina).
- Document any change in the client's condition during a visit or from previous visits.
- Describe what you observed, not what you did.

(Ozbolt & Saba, 2008). By 2008 the basic groundwork was laid with the data and terminology tools for computability and semantic interoperability.

Legibility

Whatever is charted must be easily readable, without any chance of error. If your handwriting is not readable, print. If you make a mistake, do not erase or obliterate it; draw one line through the erroneous entry and state the reason for the error, then sign and date the correction.

Abbreviations and Symbols

Facilities usually have a list of acceptable abbreviations and symbols, approved by the Medical Records Committee, to be used when documenting information in the client's record. The National Coordinating Council for Medication Error Reporting and Prevention and the Joint Commission

have both issued dangerous abbreviations to be avoided by all health care providers. These dangerous abbreviations (e.g., “U,” “IU,” and the use of “zero” with a decimal point) are not to be used in any clinical documentation; see the accompanying display and Chapter 30 on dangerous abbreviations and use of the decimal point. The use of trailing zeros is banned because the overlooked decimal point can lead to a tenfold overdose. However, the “zero” before a decimal point should always be used when prescribing and recording.

Always refer to the facility’s approved listing (see Symbols and Abbreviations on the inside back cover of this book). Avoid abbreviations that can be misunderstood; see Chapter 30 for a list of dangerous abbreviations. For example, when qd (every day) is not written legibly, it may be read as q.i.d. (four times a day).

Organization

Start every entry with the date and time. Chart in a chronological order—assessment data, observation, intervention, and evaluation. Comply with the time frame indicated in the facility’s guidelines for documentation (e.g., the frequency of charting observations for a client with restraints or the time frame within which the admit assessment must be completed).

Chart in a timely fashion to avoid the omission of pertinent data; it is not a good practice to wait until the end of the shift to chart on all the clients. Chart medications immediately after administration to avoid errors. Sign your name after each entry.

When the nurse forgets to document significant data, it is appropriate and advisable to include these data at a later date. There are several reasons why a late entry might have to be made:

- The chart was not available (e.g., the chart was with the client in a special procedures lab).
- Entries had to be added after notes were completed.
- Information was documented on the wrong record.

As with other aspects of documentation, follow the facility’s policy for charting a late entry. Common practice is to enter the date and time and label “Late entry” to indicate that it is out of sequence. Then record the date and time it should have been made in the body of the entry.

Accuracy

Accurate and objective data are crucial if the documentation is to be useful either clinically or for research. Use factual, descriptive terms to chart exactly what was observed or done. See the accompanying display for incorrect and correct examples.

Use correct spelling and grammar, and write complete sentences. Differentiate who does what; for example, “Dr. Smith inserted a triple-lumen, 20-gauge catheter into the right subclavian vein.” Read the notes recorded by nurses on previous shifts and make further comments on their findings to maintain the continuity of care.

Documenting a Medication Error

Facilities require nurses to report medication errors on incident reports (discussed later in this chapter and Chapter 12).

This information should also appear on the MAR with a notation in the nurses’ progress notes. Remember, the purpose of the medical record is to report any care or treatment the client receives.

When a medication error occurs, the following should be charted:

1. Chart the medication on the MAR to prevent other caregivers from giving the client additional doses of the drug, similar drugs, or drugs that may be contraindicated.
2. Document the error in the nurses’ notes as follows: name and dosage of the medication, time it was given, client’s response to the medication, name of the prescribing practitioner who was notified of the error, time of the notification, nursing interventions or medical treatment to counteract the error, and client’s response to treatment.

Confidentiality

Nurses are bound by ethical codes and laws to treat all client information in a confidential and professional manner; this includes the client’s record. The written documentation contained in the client’s chart is a legal record of care, and it should be available only to members of that client’s health care team. The client’s significant others, insurance companies, and other parties not directly involved in the care provided by the health care team may not have access to clients’ records; it is the nurse’s responsibility to protect the privacy and confidentiality of client interactions, assessments, and care. Even clients themselves must submit a written request to have their information released, and then they must specify exactly what information is to be released and to whom. In many institutions, particularly teaching hospitals, client records may be used for educational or research purposes. Members of these educational and research teams are held to the same standards of privacy protection and may not

DANGEROUS ABBREVIATIONS AND USE OF THE DECIMAL POINT

Incorrect	Correct
25 U of regular insulin	25 units of regular insulin
.9 mg	0.9 mg

FACTUAL DESCRIPTIVE TERMS

Incorrect	Correct
“Wound appears the same.”	“Wound is 2.5 cm by 1.0 cm.”
“Large amount of drainage.”	“Foul-smelling, yellowish drainage completely saturated two 4 × 4s.”

legitimately use client information for any purposes other than education or research or in any manner that would identify specific clients in any way.

METHODS OF DOCUMENTATION

Documentation must reflect the complexity of care, and it must embody accuracy, completeness, and evidence of professional practice with efficient and cost-effective systems. The clinical standards (structure, outcome, process, and evaluation) are used to develop a system that complies with legal, accreditation, and professional practice requirements of documentation.

Many methods are used for documentation, including:

- Narrative charting
- Source-oriented (SO) charting
- Problem-oriented charting
- PIE charting
- Focus charting
- Charting by exception (CBE)
- Computerized documentation
- Case management with critical paths

NARRATIVE CHARTING

Narrative charting, the traditional method of nursing documentation, is a story format that describes the client's status, interventions and treatments, and the client's response to treatments. Before the advent of flow sheets, this was the only method for documenting care.

Narrative documentation is easy to use in emergency situations, in which a simple, chronological order is needed. However, in this type of documentation it is often difficult to avoid being subjective, and there is normally a lack of analysis and critical decision making on the part of the nurse. Narrative charting is now being replaced by other formats because:

- The flow of care is disorganized. It is difficult to show a relationship between data and critical thinking skills. Each nurse writes with a unique style, making continuity of care difficult to identify.
- It fails to reflect the nursing process. The focus is on tasks without emphasis on assessment data or progress toward achievement of outcomes.
- It is time-consuming. The paragraphs are free-flowing, so it takes more time to record accurate data and for others to read it.
- The information is difficult to retrieve. The same problems may not be addressed from shift to shift, so it is difficult to track the client's progress. Auditors often disallow charges for equipment and supplies because consistent usage cannot be identified.

In a nursing information system, narrative charting is accomplished using free text entry or menu selections.

SOURCE-ORIENTED CHARTING

Source-oriented (SO) charting is described as a narrative recording by each member (source) of the health care team

on separate records. Because each discipline has a separate record, care is often fragmented and communication between disciplines becomes time-consuming. SO charting has similar advantages and disadvantages to narrative charting since nurses use an unstructured approach to documenting in the progress notes.

PROBLEM-ORIENTED CHARTING

The **problem-oriented medical record (POMR)** was introduced in 1969 by Lawrence Weed, a physician at Case Western Reserve University. The focus of POMR documentation is on the client's problem, with a structured, logical format to narrative charting called **SOAP**:

- S: subjective data (what the client or family states)
- O: objective data (what is observed/inspected)
- A: assessment (conclusion reached on the basis of data formulated as client problems or nursing diagnoses)
- P: plan (actions to be taken to relieve client's problem)

SOAPIE and SOAPIER refer to formats that add:

- I: intervention (measures to achieve an expected outcome)
- E: evaluation (effectiveness of interventions)
- R: revision (changes from the original plan of care)

See the accompanying display for a sample of SOAPIE charting. As you chart according to these systems, think about which piece of information corresponds with each letter in the SOAP, SOAPIE, or SOAPIER entry.

The POMR system was modified by nonmedical caregivers and is referred to as the problem-oriented record (POR). The system is used by hospitals, nursing homes, and home care agencies.

There are four critical components of POMR/POR:

- Database: Assessment data, representative of all disciplines (history, physical, nursing admit assessment, laboratory findings, educational and discharge needs), which become the basis for a problem list evaluation of the client's condition.
- Problem list: Derived from the database: a listing of the client's problems as identified, with each problem numbered and labeled as acute, chronic, active, or inactive. Nurses use NANDA terminology in writing client problems as nursing diagnoses; the list is revised as new problems arise and others are resolved.
- Initial plan: Based on problem identification; the starting point for care plan development with client participation in setting goals, expected outcomes, and learning needs.
- Progress notes: Charting based on the SOAP, SOAPIE, or SOAPIER format.

The POR system uses flow sheets to record routine care and a discharge summary that addresses each problem on the list and notes whether it was resolved. SOAP entries are usually made every 24 hours on any unresolved problem or whenever the client's condition changes.

SOAPIE CHARTING—PROBLEM 2 KETOACIDOSIS

Date/Time	<p>S: Client states, “I feel sick all over.” Client claims difficulty in breathing, abdominal pain, and nausea.</p> <p>O: Lungs clear, R 28/min, labored. Abdomen distended, bowel sounds underactive all four quadrants, 5+ abdominal pain.</p> <p>A: Alteration in nutrition and comfort R/T ketoacidosis. Blood sugar 458 mg/dL. Ketones strongly positive, pH < 7.3.</p> <p>P: Maintain IV infusion of 0.9% NS with regular insulin as ordered. NPO. Oral hygiene hrly. Maintain accurate I & O. Assess for rales, hypotension, cardiac dysrhythmias. Monitor blood glucose & electrolytes. (Signature)</p>
Date/Time	<p>I: Called Dr. Smith, blood sugar 458 mg/dL, IV bolus regular insulin given as ordered, 1000 mL 0.9% NS infusing @ 1 L/H central line 1 via infusion pump. 50 units regular insulin in 500 mL NS infusing @ 50 mL/H central line 2 via infusion pump. EKG taken, placed on telemetry. (Signature)</p>
Date/Time	<p>E: Lungs clear, R 24/min, nonlabored, NSR, 3+ abdominal pain. Urinary output 750 mL/hr. Blood glucose 360 mg/dL. (Signature)</p>

PIE CHARTING

After SOAP charting gained in popularity, the **problem, intervention, evaluation (PIE)** system was instituted at Craven Regional Medical Center in 1984 to streamline documentation. Whereas SOAP was developed on a medical model, PIE charting has a nursing origin. PIE is an acronym for problem, intervention, and evaluation of nursing care. The key components of this system are assessment flow sheets and nurses’ progress notes with an integrated plan of care that eliminates the need for a separate care plan. Each client problem is labeled and numbered for easy reference. When interventions are implemented to manage the client’s problem, the problem number is identified; see the accompanying display on PIE charting. This system eliminates the traditional care plan by incorporating an ongoing plan of care into the daily documentation.

FOCUS CHARTING

Focus charting is a method of identifying and organizing the narrative documentation of client concerns to include data, action, and response. This method is not limited to client “problems” but allows for the identification of all “concerns” such as a significant event (e.g., results of a diagnostic test). Focus charting was created in 1981 at Eitel Hospital in Minneapolis, when the results from a SOAP audit revealed weaknesses in writing care plans and charting the client’s response to care. Focus charting uses a columnar format within the progress notes to distinguish the entry from other recordings in the narrative notes, as shown in the accompanying display on focus charting on page 230.

CHARTING BY EXCEPTION

Charting by exception (CBE) is a charting method that requires the nurse to document only deviations from preestablished norms. CBE was instituted in 1983 by St. Luke Medical Center in Milwaukee to overcome the recurring problem of lengthy, repetitive notes and to enable the identification of trends in client status. The CBE system has three key components:

1. **Flow sheets:** Highlight significant findings and define assessment parameters and findings.
2. **Reference documentation:** Is related to the standards of nursing practice. (All standards are met unless otherwise documented.)
3. **Bedside accessibility:** Is related to the documentation forms. CBE requires the nurse to document significant findings and exceptions to predefined norms.

PIE CHARTING—IMBALANCED NUTRITION R/T KETOACIDOSIS

- Date/Time **P4:** Imbalanced nutrition R/T ketoacidosis. Blood glucose 458 mg/dL, ketones strongly positive, pH 7.2.
- I4:** Called Dr. Smith, blood sugar 458 mg/dL. IV bolus regular insulin given as ordered. 1000 mL 0.9% NS infusing @ 1 L/H central line 1 via infusion pump. 50 units regular insulin infusing @ 50 mL/H central line 2 via infusion pump. EKG taken, placed on telemetry.
- Date/Time **E4:** Lungs clear, R 24/min, nonlabored. 3+ abdominal pain. Urinary output 750 mL/H (0730–0830). Blood sugar 360 mg/dL. (Signature)

COMPUTERIZED DOCUMENTATION

Computerized clinical records systems allow nurses to use computers to store client data. These systems allow nurses to record client assessment, medication administration (see Figure 13-1), client teaching, progress notes, care plan updating, client acuity, and charges into either a bedside computer terminal or a small, portable handheld terminal. Figure 13-2 on page 229 provides an example of a computer-generated vital sign graphic record that allows nurses to see at a glance trends in the client's vital signs.

To document nursing interventions and client responses, the nurse chooses from standardized lists of terms or enters narrative information into the computer. Automated documentation should provide all normal standards and allow the nurse to document any exception by menu selection or free text entry. Flow sheet charting should provide for

routine aspects of care to be documented in tabular form; a pointing device such as a mouse is used to make menu selections or text entries. The automated MAR is one form of flow sheet charting.

CASE MANAGEMENT PROCESS

Case management is defined as a methodology for organizing client care through an episode of illness so that specific clinical and financial outcomes are achieved within an allotted time frame. The outcome of this process is a DRG-specific case management plan that contains daily assessment documentation, care plan, outcome-oriented multidisciplinary interventions, teaching, and discharge planning.

At admission, the nurse case manager and the admitting practitioner individualize the case management plan (called a

critical pathway) to meet the client’s specific needs. A **critical pathway** (or critical path) is an abbreviated summary of key elements from the case management plan. The pathway is used by all health care providers as a monitoring and documentation tool to ensure that interventions are performed on time and that client outcomes are achieved on time. See Chapters 32 and 36 for sample critical pathways.

Variations, sometimes referred to as a variance, are goals not met or interventions not performed within the time

frame. The nurse documents on the back of the critical pathway the unexpected event (e.g., hospital-acquired decubiti), actions taken in response to the event, and appropriate discharge planning.

The advantages of case management are that it makes efficient use of time and increases the quality of care, with the expected outcomes identified on the plan. It also promotes collaboration, communication, and teamwork, which work to the advantage of the client and the facility, with

discharge occurring in a timely manner. Case management also has several limitations; mainly, it is useful for clients with only one or two diagnoses. When clients have more than two diagnoses or variations, documentation becomes complicated because of limited space. This situation requires additional documentation forms to complement the pathway, such as intervention flow sheets and nurses' notes.

FORMS FOR RECORDING DATA

Several types of forms are used in record keeping: Kardex, flow sheets, nurses' progress notes, and discharge summaries. All these forms are designed to facilitate record keeping, reduce duplicate activity, and ensure quick and easy access to information.

KARDEX

A **Kardex** (client profile and client summary sheets) is a summary worksheet reference of basic client care information that traditionally is not part of the medical record. The Kardex, a concise client data source, is used as a reference throughout the shift and during change-of-shift reports. Kardexes come in various sizes, shapes, and types (and they may also be computer generated). The Kardex is designed to complement the care delivery setting. For example, a home health Kardex would contain information related to family contacts, prescribing practitioners, other services, and emergency referrals. The Kardex usually contains the following information:

- Client data: Name, age, marital status, religious preference
- Medical diagnoses: Listed by priority
- Nursing diagnoses: Listed by priority
- Medical orders: Diet, medications, IV therapy, treatments, diagnostic tests and procedures (inclusive of dates and results), and consultations
- Activities permitted: Functional limitations, assistance needed in activities of daily living, and safety precautions

FLOW SHEETS

Flow sheets have vertical or horizontal columns for recording dates and times to show assessment and interventions, making it easy to track changes in the client's condition. Client teaching, use of special equipment, and IV therapy are other aspects of the flow sheet. Because the flow sheets have small spaces for recording, these forms usually contain legends that identify the approved abbreviations to chart data (see Figures 13-3 on page 231 and, on page 233, 13-4). It is important to fill out flow sheets completely because blank spaces imply that an intervention was not completed, attempted, or recognized.

The information on the flow sheet can be formatted to meet the specific needs of client populations (special needs, activity, and measurement and intervention). For example, recording assessment data may be different in pediatric clinics and pediatric hospital units than in facilities for adults. Flow sheets in critical care settings are more comprehensive than are those on a medical-surgical unit. Flow sheets can also complement other types of records of specific interventions (e.g., MAR, IV therapy).

Flow sheets are used as supplements to most documentation systems because they decrease the redundancy of charting in the nurses' progress notes. But they do not replace the progress notes. Nurses still need to document observations, client responses and teaching, detailed interventions, and other significant data in the progress notes.

NURSES' PROGRESS NOTES

The nurses' progress notes are used to document the client's condition, problems, and complaints; interventions; response to interventions; and achievement of outcomes. Progress notes include the following forms: nurses' notes, MARs, personal care flow sheets, teaching records, intake and output forms, vital sign records, and specialty forms (e.g., diabetic flow sheet and neurologic assessment form). The progress notes can be completely narrative or incorporated into a standardized flow sheet to complement SOAP(IE), PIE, focus charting, and other documentation systems.

DISCHARGE SUMMARY

Discharge summaries highlight the client's illness and course of care. When a narrative discharge summary is entered into the progress notes, it includes:

- The client's status at admission and discharge
- A brief summary of the client's care
- Intervention and education outcomes

FIGURE 13-4 Surgical Intensive Care Unit (SICU) Flow Sheet REPRINTED WITH PERMISSION BY TULANE UNIVERSITY HOSPITAL & CLINIC, NEW ORLEANS, LA

- Resolved problems and continuing care needs for unresolved problems, inclusive of referrals
- Client instructions regarding medications, diet, food-drug interactions, activity, treatments, follow-up instructions, and other special needs

Many facilities have a documentation form that itemizes discharge and client instructions. The form has a duplicate copy for the client; the original goes in the medical record. Figure 13-5 on page 234 shows the common elements of this tool.

REPORTING

Reporting is the verbal communication of data regarding the client's health status, needs, treatments, outcomes, and responses. When a report is given, it needs to summarize the current critical information that facilitates clinical decision making and continuity of care. As with recording, reporting is based on the nursing process, standards of care, and legal and ethical principles. The nursing process provides structure for an organized report, a challenge inherent in verbal communications. In order to verbally communicate an efficient and well-organized report, the nurse must consider:

- What needs to be said
- Why it needs to be said
- How to say it
- What the expected outcomes are

Considering these aspects of reporting before the communication will provide for a concise, organized report.

Another critical element in reporting is listening (see Chapter 15). Reports require participation from everyone present. When receiving a report, the nurse focuses behaviors to enhance listening skills: The nurse eliminates distractions, puts thoughts and concerns aside, concentrates on what is being said, and does not anticipate what the presenter will say next. The reporting process is an integral component of developing effective interpersonal and intrapersonal relationships that promote continuity of client care. Regardless of the type of communication, planned presentation of client data is a key to accurate, concise, effective reporting. Summary reports, walking rounds, telephone reports and orders, and incident reports are all types of reporting.

SUMMARY REPORTS

Summary reports summarize pertinent client information that focuses on the client's needs as identified by the nursing process for the new caregiver. Summary reports commonly occur at the change of shift and when the client is transferred to another area.

A summary, or end-of-shift, report should be presented as follows:

- Background data obtained from client interactions and assessment of the functional health patterns
- Primary medical and nursing diagnoses and priority problems

SPOTLIGHT ON...

Professionalism

Can nurses give a detailed enough shift report by telephone? If you give a report by telephone, can you then skip the face-to-face update with the oncoming nurse? Does the telephone shift report really save time, or does it double the time of giving a report?

- Identification of client risk problems
- Recent changes in condition or in treatments (e.g., new medications, elevated temperature)
- Effective interventions or treatments of priority problems, inclusive of laboratory and diagnostic results (e.g., client's response to pain medication)
- Progress toward expected outcomes: priority problems, teaching or discharge planning
- Adjustments in the plan of care
- Client or family complaints

This format will provide structure and organization to the data that are both logical and time sequenced since the format follows the nursing process. The new caregiver needs to receive an accurate, concise report about what has happened during the previous shift in order to provide continuity of care. Client and family complaints should be addressed last for each client because these situations usually generate questions and discussion.

TELEPHONE REPORTS AND ORDERS

Telephone communications are another way nurses report transfers, communicate referrals, obtain client data, solve problems, and inform the prescribing practitioner and the client's family members regarding a change in the client's condition. Nurses are expected to demonstrate phone courtesy and professionalism when initiating and receiving telephone reports and orders.

When initiating a phone call, organize the information to be reported or received. For example:

1. Make sure all lab results are back; if they are not, identify in advance which ones are missing and phone the lab or check the computer to determine if other results are available. Write down which tests have been performed and the results. Spell the client's name and provide the client's medical record number to avoid error in getting the results on the wrong client.
2. Review your notes and have your assessment data readily available, especially any significant client data related to the call. If you have not assessed the client, do an assessment before telephoning the practitioner; otherwise, the practitioner might ask you questions that you will not be able to answer.
3. Let the charge nurse or someone else at the nurses' station know that you are placing the call so that you will not be interrupted while on the phone.

When you place the call, state the reason you are calling: For example, "I am calling Dr. Smith regarding the blood sugar results for Mrs. White." Be brief and listen carefully. Repeat the test results and any orders the prescribing practitioner gives over the phone.

Record accurately in the medical record the date and time the phone call was placed, the client data you reported on the phone, the name of the person you spoke with, and whether an order was obtained. Do not chart "prescribing practitioner notified, no orders obtained." Rather, chart "Dr. Smith notified by phone, blood sugar 260 mg (drawn by the

lab at 1300), orders received and recorded on the prescribing practitioner order sheet.” Charting telephone orders and documentation in the nurses’ progress notes should be done as soon as possible after the phone call to prevent an entry by another caregiver before you chart the telephone report. The Joint Commission (2008) revised communication goals regarding orders and critical test results delivered verbally, whether in person or by telephone, require the receiver of the information to write it down or enter it into the computer, and then read it back. This new requirement is applicable to all spoken orders, not just medication orders. The only exception to writing down the verbal order prior to repeating the order is during surgery or a code when the spoken order can be just repeated.

A telephone order should be documented as follows on the prescribing practitioner’s order sheet: Date and time the entry; record the order as given by the prescribing practitioner; then sign the order beginning with *t.o.* (telephone order), write the prescribing practitioner’s name, and sign your name. If another nurse witnesses the phone order, that nurse’s signature should go after yours.

The prescribing practitioner needs to countersign the order within a time frame as specified by the facility’s policy. Fax machines have decreased the need for lengthy or complicated telephone orders, both saving time and avoiding error. To confirm the prescribing practitioner’s identity as the initiator of the fax orders, telephone the prescribing practitioner. The prescribing practitioner needs to countersign the fax orders according to agency policy.

INCIDENT REPORTS

Incident reports, or occurrence reports, are used to document any unusual occurrence or accident in the delivery of client care, such as falls or medication errors. The *Code for Nurses* (ANA, 1985) states that nurses are expected “to protect the client when safety is affected.” Ethical practice requires that nurses file an incident report to protect the client, not to punish the caregiver.

The filing of incident reports is not only an internal device for the facility but also a requirement by federal, national, and state accrediting agencies. Nurses are often

advised not to document the filing of an incident report in the nurses’ notes for legal reasons, but as previously discussed, documenting medication errors requires an incident report and documentation in the nurses’ notes to ensure that the client receives safe care.

The incident report serves two functions:

1. It informs the facility’s administration of the incident, so risk management personnel can consider changes that might prevent similar occurrences in the future.
2. It alerts the facility’s insurance company to a potential claim and the need for further investigation.

Litigation can be avoided if the facility takes prompt action by investigating an occurrence. The incident report is not part of the medical record, but it may be used later in litigation.

Each person with firsthand knowledge of the occurrence should fill out and sign a separate report. Although the incident report format varies from one facility to another, key elements must be addressed when filing a report:

- Record the date, exact time, and place you discovered the occurrence.
- Identify the person(s) involved in the occurrence, including witnesses.
- Document accurately and objectively the exact occurrences that you witnessed or first saw after the incident:

NURSING PROCESS HIGHLIGHT

Implementation

Documentation of Client Fall

Assessment

- Check for bruises, lacerations, or abrasions.
- Check blood pressure, pulse, respirations.
- Perform a neurologic assessment (slurred speech, weakness, mental status).
- Check for incontinency (urinary or fecal).
- Note any pain or deformity in the extremities (arm, lumbar spine, hip, or leg).

Interview the Client

- Were there any symptoms prior to the fall (lightheadedness, impaired vision, dizziness, weakness, palpitations, shortness of breath, chest pain)?
- What were your actions prior to the fall (movements, muscle jerks, breathing pattern)?
- How did the fall occur (getting out of bed, while walking in the room)?
- Did anyone witness the fall?

Be sure to chart what you observe (“Client prone on floor”), not what you conclude (“Client fell out of bed”). Document all data in the nurses’ progress notes and on the incident report.

SAFETY FIRST

DOCUMENTATION ERRORS

Charting procedures or medications before they are completed constitutes a documentation error; the error can cause a client to miss a dose of medication or a treatment and can confuse, misrepresent, or mask a client’s real condition. Likewise, errors are committed when nurses fail to document observations of the client such as deterioration, pain, or agitation or particular signs of complications related to the illness or therapies.

For example, record, “Found the client sitting on the floor. Client stated that ...” rather than “Client fell.”

- Record the exact details, in time sequence, of what happened, and the consequences for the persons involved.
- Record your actions to provide care and results of your assessment for injuries and client complaints.
- Notify the supervisor on duty and record the time and name of the prescribing practitioner notified; if telephone orders were received from the prescribing practitioner, document as previously discussed and implement the orders.
- Do not record your opinions, judgments, conclusions, or assumptions about what occurred; point blame; or suggest how to prevent occurrence of a similar incident.
- Forward the incident report to the designated person as defined in the facility’s policy.

As an additional safeguard, the nurse can write a brief, accurate description of the incident and keep it at home. In the description, include the details of the incident and the names of the people who were involved, especially if they can substantiate the information. Lawsuits may take several years from the time of an incident until the case goes to court; personal notes will help with accurate recall of the incident. Use the same elements described earlier in filing an incident report because your personal notes may be read by the plaintiff’s attorney.

Special attention should be given to documenting falls; client falls are the main reason nurses are sued. (See Chapter 29 for information on how to prevent client falls and their legal ramifications.) The Nursing Process Highlight identifies the required nursing documentation when a client falls.

COMPUTERS IN NURSING

Documentation is not the only reason registered nurses must have a basic level of computer literacy. Nurses are involved in many activities that require computer technology: administrative nursing functions such as staffing and quality assurance, educating nurses and clients, communicating with health care providers and clients, and accessing EBP and conducting research.

THE PROFESSIONAL NURSE AS AN INFORMATION CONSUMER AND PRODUCER

“Healthcare delivery systems are knowledge-intensive settings with nurses as the largest group of knowledge workers within those systems” (Hebda & Czar, 2009, p. 7). According to the Institute of Medicine (2007), there is a failure on the part of the present health care delivery system to consistently translate new knowledge into practice and apply new technologies safely, appropriately, and expeditiously. When nurses learn and use IT such as research-driven evidence-based care or online drug databases, this new knowledge can have a positive outcome on client care. IT tools can assist nurses in

expanding decision-making skills and client monitoring. Hebda and Czar (2009, pp. 9–10) provide these examples:

- Data gatherer: The nurse collects clinical data such as vital signs.
- Information user: The nurse interprets and structures clinical data, such as a client’s pain, into information that can be used to assist clinical decision making and client monitoring.
- Knowledge user: The nurse takes individual client data and compares them with existing nursing knowledge.
- Knowledge builder: The nurse aggregates clinical data and shows patterns across clients that serve to create new knowledge or can be interpreted within the context of existing nursing knowledge.

Data collected and documented by nurses using automated systems can benefit other health care professionals such as aggregate critical pathways and laboratory and pharmacy information systems. The interface of these systems eliminates redundant data collection such as client allergies, current medications, demographic data, and diagnoses.

INFORMATICS COMPETENCIES FOR NURSES

The 1998 Pew Health Professions Commission recommended 21 competencies for health care professionals in the twenty-first century (see Chapter 1). One of the Pew competencies addresses the need to use communication and IT effectively and appropriately. The American Association of Colleges in Nursing (AACN) endorsed a new set of competency standards that will enhance the ability of baccalaureate-prepared nurses to provide safe, high-quality client care. Of the 9 essential competencies identified by AACN, 1 addresses the need for professional nursing practice to be grounded in the analysis and application of evidence for practice. Informatics competencies are deemed necessary to facilitate the delivery of safer, more efficient care; to add to the knowledge base for the profession; and to transition toward EBP. “The federal mandate that all Americans have an electronic medical record by 2014 makes informatics competencies necessary for all healthcare professionals” (Hebda & Czar, 2009, p. 15).

The competencies for the beginning nurse focus primarily on the ability to retrieve and enter data in an electronic format that supports client care, analyze and interpret information in planning care, use informatics applications designed for nursing practice, and implement policies relevant to informatics. The ANA (2007) has identified the following informatics competencies for the beginning nurse:

- The ability to demonstrate basic computer literacy, inclusive of basic desktop applications and electronic communications
- The ability to use IT to support clinical and administrative processes such as information literacy to support EBP
- The ability to access data and perform documentation with computerized records
- The ability to support safety initiatives through the use of IT
- The ability to define the role of informatics in nursing

The ANA has also identified competencies for the experienced nurse and the informatics nurse.

NI competencies are also available on the TIGER (Technology Informatics Guiding Educational Reform) Web site and the Quality and Safety Education for Nurses (QSEN) site. The TIGER competencies are organized into four domains: basic computer, information literacy, information management and informatics, and attitude and awareness. The QSEN site was developed as part of a Robert Wood Johnson–funded project designed to facilitate reform in nursing education in the areas of quality and safety.

As communications and technology continue to evolve, competencies will need to be frequently reviewed and updated in contexts such as education, practice, and administration (Hebda & Czar, 2009). Educators must ensure that students have the knowledge, skills, and attitudes to fully engage in the technology of nursing practice. Nurses in practice must develop an attitude of continuous learning while nurse administrators must strive to assess and evaluate staff competencies, offer continuing education in core competencies, and continuously advocate for improvement in IT (Androwick, Kraft, & Haas, 2008).

APPLICATIONS OF NURSING INFORMATICS

“Nursing is a function of healthcare, which is, increasingly, a business that reflects and responds to the society in which it operates” (Simpson, 2008, p. 253). IT has to be part of health care change to support the work of health care professionals and consumers. Hebda and Czar (2009, pp. 35–36) cite the following examples of how informatics and computers support various areas of nursing and consumer health. Nursing education:

- Online course registration and scheduling and completion of mandatory education requirements
- Course delivery and support for Web-based education
- Computerized student tracking, testing, grade management, and communications with students
- Access to remote library and Internet resources
- Capability for podcasts, Webcasts, teleconferencing, and presentation of prepared slides and handouts

Nurse educators are challenged to transform curricula and teaching methods to integrate information resources into the cognitive, psychomotor, and organizational processes of professional practice (see Uncovering the Evidence).

Nursing practice:

- Staff reminders of planned nursing interventions and documentation prompts to ensure comprehensive charting
- Computer-generated nursing care plans, critical pathways, and client documentation such as discharge instructions and medication information
- Monitoring devices for vital signs and other measurements directly into the client’s record
- Automatic billing for supplies or procedures with documentation

UNCOVERING THE

Evidence

TITLE OF STUDY

“One Strategy to Reduce Medication Errors: The Effect of an Online Continuing Education Module on Nurses’ Use of the Lexi-Comp Feature of the Pyxis MedStation 2000”

AUTHOR

M. Straight

PURPOSE

To evaluate the impact of an online self-learning module on nurse knowledge and use of the Lexi-Comp feature of the Pyxis MedStation Rx 2000 system, a point-of-care medication delivery system.

METHODS

Data were collected among nurse-users at a community-based health care organization (N = 41). Pre- and posttraining surveys were used to evaluate training effects.

FINDINGS

Posttraining, completion of the tutorial and knowledge and use of the Lexi-Comp feature increased by 23% and 53%, respectively. One month posttraining, a drop in medication error on administration was observed.

IMPLICATIONS

These findings suggest that evaluative and instructional tools improve integration of technology and clinical practice and improve client outcomes in medication error reduction.

Straight, M. (2008). One strategy to reduce medication errors: The effect of an online continuing education module on nurses’ use of the Lexi-Comp feature of the Pyxis MedStation 2000. *CIN: Computers, Informatics, Nursing*, 26(1), 23–30.

- Access to computer-archived client data from previous encounters
- Online drug information

Nursing research:

- Computerized literature searching
- Standardized language related to nursing terms
- Internet access for obtaining data collection tools and conducting research
- Collaboration with other researchers

IT applications regarding consumer health may include communications with health care providers through e-mail and instant messaging, online scheduling of tests or procedures, support groups, and remote monitoring and other telehealth services. Information access has fostered consumerism that will make all of health care more accountable (Simpson, 2008).

TELEHEALTH SERVICES

Consult with colleagues
 Assess and monitor clients
 View diagnostic images
 Review slides and laboratory reports
 Decrease health care costs
 Provide health education
 Improve the coordination of care
 Improve the equity of access to services
 Improve the quality of client care

Hebda, T., & Czar, P. (2009). *Handbook of informatics for nurses & healthcare professionals*. Upper Saddle River, NJ: Pearson Prentice Hall.

Nursing administration has a set of applications to assist with staff scheduling and online bidding for unfilled shifts, electronic mail, cost analysis and budget trends, quality assurance and outcomes analysis, and client tracking and placement of case management (Hebda & Czar, 2009). One of the greatest challenges to chief nurse executives is to select and implement IT enabling tools that allow nurses to learn continuously while never losing sight of nursing's caring mission (Simpson, 2008).

TELEHEALTH

One of the goals of Healthy People 2010 includes eliminating health disparities among populations and improving quality of life and life expectancy. Telehealth is seen as a venue for improving health care access in vulnerable populations through the use of electronic devices in the clients' homes that monitor and assess for early complications (Prinz, Cramer, & Englund, 2008).

Telehealth refers to the use of telecommunication technologies and computers to exchange health care information and to provide services to clients at another location such as health promotion, disease prevention, diagnosis, consultation, education, and therapy. Telehealth nursing refers to the utilization of the nursing process via telecommunications devices with individual clients or defined client populations (Prinz et al., 2008). Telehealth devices allow the nurse to monitor pulse oximetry, heart rate, blood pressure, and weight. Some of the tools used to support these services are voice only (regular telephone), video images (digital pictures), data exchange (keyboard and mouse operations), and virtual contact (videoconferencing); see the Box on the following page regarding some of the professional services provided by telehealth.

EVIDENCE-BASED PRACTICE AND RESEARCH

Client safety is the dominant principle on which all nursing care is based; nursing has an ethical obligation to the client to use all the resources at its disposal to ensure client safety

(Straight, 2008). Although technologies such as electronic medical records and barcoding allow nurses to make treatment decisions and ensure proper medications are being administered, none of the technologies address the need for instant access to human knowledge and expertise through timely communications. In health care, the ability to communicate information clearly, accurately, and promptly is vital to providing the best possible care for clients and ensuring that no critical matters involving a client's well-being are overlooked or left unattended (Kuruzovich, Angst, Faraj, & Agarwal, 2008).

EBP is an approach to providing care that integrates nursing experience and intuition with valid and current clinical research to achieve best client outcomes (Salmond, 2007). Although there is agreement that EBP is imperative for ensuring quality, cost-effective, safe care and more predictable outcomes for health care consumers, the initial expectations have not been fully realized, and there is little evidence showing how use in practice brings the intended value. There are issues with standardized nursing terminologies—the NANDA, NOC, and NIC versus the languages recognized by the ANA's Committee on Nursing Practice Information Infrastructure—for incorporation into the EHR. Nurses and administrators need education to appreciate the importance and power of standardized language so that nursing records can be integrated with other records to support communication and retrieval of critical information.

EBP requires the application of current research. To apply research to practice, the nurse must be knowledgeable about the research process; specifically, the nurse must be able to perform a research synthesis (systematic review). A research synthesis is a review of a clearly formulated question that uses systematic and explicit methods to identify, select, and critically appraise relevant research and to collect and analyze data from the studies (Newhouse, 2008). Stevens (2008) recommends the steps outlined in the *Cochrane Handbook* for conducting a systematic review: Evidence should be reviewed by two people, the approach should be explicit, evidence should be rated and graded, and both reviewers should produce recommendations for practice. The Cochrane Collaboration and *Worldviews on Evidence-Based Nursing* are reliable sources for systematic reviews in nursing. EBP is possible only as a result of IT's ability to collect, aggregate, and present client and practice data whenever and wherever nurses need it in the provision of care (Simpson, 2008).

CRITERIA FOR EVALUATING VALIDITY OF INFORMATION

Professional accountability requires all health care providers to critically evaluate the quality of online information and assist consumers to judge all retrieved materials. According to Hebda and Czar (2009), the following criteria should be used to evaluate online resources:

1. Credentials of the source: Large professional associations such as hospitals, universities, government, and official health organizations tend to have the most reliable Web sites.

2. Ability to validate information: When facts and studies are cited, the original source should be retrieved for review, allowing the user to draw conclusions.
 3. Accuracy: Internet content should identify contact persons or cite references that may be checked to allow evaluation of posted information.
 4. Comprehensiveness of information: If the site is comprehensive, it should have all relevant information on that site; for example, if the site deals with medications, it should discuss indications, contraindications, protocols, and dosage.
 5. Date of issue or revision: All valid Web sites should indicate when material was written, revised, or reviewed so that the user can determine if the information is current or outdated.
 6. Bias or sponsorship: The content should be well organized, with hyperlinks to current Web pages, and load easily.
 7. Intended purpose and audience: Terminology and reading level should be appropriate for the intended audience.
 8. Disclaimers: Sites that allow for individual opinions should contain a statement to that effect to help users distinguish between fact and opinion.
 9. Site of accreditation: To ensure the quality of information found on health-related Web sites, some sites display a “seal” that indicates that the site has voluntarily met a set of predetermined standards for the quality of information posted.
 10. Privacy policies: Sites that collect personal information need to identify how that information may be used so the user can determine whether to disclose the information.
- Material found on the Internet and Web should be credited to the authors, just like any other media; failure to cite sources is copyright infringement.

KEY CONCEPTS

- Informatics is the application of computer and statistical techniques to the management of information.
- Nursing informatics is the use of information and computer technology as a tool to process information to support all areas of nursing.
- A health care information system consists of clinical and administrative systems.
- A nursing information system using the nursing process approach should support the use and documentation of nursing processes and provide tools for managing nursing care activities.
- Critical pathways or protocol approaches to nursing information systems provide a multidisciplinary format for planning and documenting client care.
- Documentation provides a system of written records that reflect client care provided on the basis of assessment data and the client’s response to interventions.
- The medical record can be used by health care students as a teaching tool and is a main source of data for clinical research.
- Nurses are responsible for assessing and documenting that the client has an understanding of the treatment prior to the intervention.
- Competent adult clients have the right, through an advance directive, to make decisions regarding life-sustaining interventions when they become incapacitated or terminally ill.
- Standards of care, as set forth by state boards of nursing and the ANA, require nurses to use the nursing process in their documentation.
- Accreditation and reimbursement agencies require accurate and thorough documentation of the nursing care rendered and the client’s response to interventions.
- Effective documentation requires clear, concise, accurate recording of all client care and other significant events in an organized and chronological fashion, representative of each phase of the nursing process.
- Client safety requires appropriate reporting and recording of medication errors and other occurrences in compliance with the facility’s policy, as well as the avoidance of dangerous abbreviations and inappropriate use of the decimal point.
- Narrative charting requires an organized presentation of the client’s problems and response to interventions in chronological order.
- Problem-oriented charting provides structure when documenting the client’s problems and responses in the nurses’ progress notes.
- Computerized documentation saves time, increases legibility and accuracy, provides standardized nursing terminology, enhances the nursing process and decision-making skills, and supports continuity of care.
- Technology advances are providing systems that promote client safety such as the electronic administration system.
- Managed care incorporates client participation in planning the care while focusing on the quality of care provided in a timely fashion.
- Critical pathways document the key interventions of managed-care plans.

- Flow sheets are used to document assessment findings, activity, measurements, treatments, and equipment.
- The discharge summary is used to highlight the client's illness, course of care, and aftercare instructions.
- Incident reports are used to document any unusual occurrence in the delivery of client care.
- The competencies for the beginning nurse focus mainly on developing and using skills that rely on the ability to retrieve and enter data in an electronic format that is relevant to client care.
- An example of the application of NI is computer-generated client documentation that includes discharge instructions and medication information.
- As technology advances, it ensures that telehealth can emerge as a viable solution to providing accessible, quality health care.
- Nurses need to use critical thinking skills to evaluate information found on the Internet.

REVIEW QUESTIONS

- Which best describes the client's medical record?
 - It serves as a legal document for recording all client activities assessed and initiated by prescribing practitioners.
 - It provides a written record for nurses to document all phases of the nursing process.
 - It is a systematic documentation of critical elements of care performed by nurses.
 - It contains the client's medical record that can be used for educational purposes.
- A client tells the nurse, "I have a headache and feel nauseous." This is an example of what type of data?
 - Assessment
 - Historical
 - Subjective
 - Objective
- Which of the following charting entries is written in the most accurate way?
 - Client up, out of bed, walked to the bathroom with assistance, tolerated well.
 - Client up, out of bed, walked 40 feet to the bathroom and back to bed, tolerated well.
 - Client up, out of bed, walked 40 feet to the bathroom and back to bed with assistance from the nurse.
 - Client up, out of bed, walked 40 feet to the bathroom and back to bed with assistance from the nurse, heart rate 84 and regular before exercise, 92 and regular after exercise.
- The case manager nurse should be assigned to provide services to which of the following clients?
 - A mother experiencing her first pregnancy
 - A client with newly diagnosed diabetes mellitus
 - A client with a broken arm following a bicycle accident
 - A group of teenagers who are members of SADD (Students against Drunk Driving)
- The nurse has to document the assessment findings of a surgical incision with staples and retention sutures; however, the pop-up screen on the computer provides for only staples. How should the nurse document the findings regarding the retention sutures?
 - Document the assessment of the staples on the computer screen, and click to go to the next screen with no mention of the retention sutures.
 - Document the retention sutures assessment on the paper chart.
 - Document assessment of the retention sutures as free text in summary notes attached to the appropriate nursing documentation computer page.
 - Call the surgeon, give an oral report of the assessment findings, and document the phone call in the computerized nursing progress notes.
- Which of the following actions by the nurse would make her or him more vulnerable to legal action?
 - Documenting all pertinent client information
 - Following agency documentation policies
 - Discussing a client's case with a peer in the elevator
 - Assisting a client to find appropriate Web sites
- The major concern in implementing an electronic health record is:
 - Cost
 - Utilization
 - Privacy
 - Accuracy

CHAPTER 14

Nursing, Healing, and Caring

COMPETENCIES

1. Describe the influence of caring and compassion on the practice of professional nursing.
2. Explore the value of nursing care in today's technologically advanced health care system.
3. Compare selected perspectives on the relationship between caring and nursing.
4. Explain the primary nursing functions in each phase of the nurse-client relationship.
5. Discuss the impact of communication on the delivery of compassionate care.
6. Describe the characteristics of a therapeutic relationship.
7. Explain nursing roles that are important in demonstrating care and compassion.

KEY TERMS

active listening
attending behaviors
catharsis
client advocate
depersonalization
empathy
empowerment
healing

nurse-client relationship
orientation (or introductory)
phase
paraverbal communication
presence
rapport
role

termination (or concluding)
phase
therapeutic
therapeutic relationship
therapeutic use of self
transcultural nursing
working (or exploitative) phase

This chapter presents information about caring—the fundamental value in nursing. The relationship between caring and nursing is explored and nursing’s impact on healing is examined. The nurse-client relationship is discussed, and the stages of this relationship are described with attendant nursing goals and the behaviors usually exhibited by clients in each stage.

NURSING’S THERAPEUTIC VALUE

Nursing is both an art and a science that leads to therapeutic outcomes in clients. The term **therapeutic** refers to activities that are beneficial to the client. When therapeutic interventions are performed in a caring compassionate manner, an environment that promotes healing is established.

DEFINITION OF NURSING

According to the American Nurses Association (2004), nursing is defined as “the protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations” (p. 7). This definition places nursing’s focus on the individual experiencing a health problem rather than on the problem (or disease) itself—that is, on caring for clients as they deal with health issues fundamental to the practice of professional nursing.

The Canadian Nurses Association (1986), similarly, describes nursing as a caring relationship that helps the client achieve and maintain an optimal level of health.

NURSING: A BLEND OF ART AND SCIENCE

Nursing creates therapeutic change through the application of scientific principles. As the science of nursing has rapidly progressed over the past decade, nurse theorists have formulated various frameworks by which to organize nursing’s unique body of knowledge. While continuing to expand its theoretical base, nursing must remain firmly rooted in its essence—caring. In other words, nursing does not rely on

science alone. The application of knowledge and skills enables the nurse to value the uniqueness of each client (Warelow, Edward, & Vinek, 2008).

Caring is a universal value that directs nursing practice. Leininger and McFarland (2002, p. 21) define caring in the nurse-client relationship as “the direct (or indirect) nurturant and skillful activities, processes, and decisions related to assisting people to achieve or maintain health.” Even though clients cannot always be cured, caring is ongoing within the nurse-client relationship.

A prerequisite for the nursing art is the nurse’s commitment to helping the client; this trait is also referred to as intentionality. Intention occurs when we consciously focus on someone in order to learn something about and to help that person (Dossey, Keegan, & Guzzetta, 2008). Caring is more than an intuitive process; it can be learned both intellectually and interpersonally. One learns caring by interacting with others who demonstrate caring. When nurses exhibit caring behaviors, they are serving as role models—to students, colleagues, clients, and families.

PURPOSES OF NURSING

A **therapeutic relationship** is one that benefits the client’s health status. The therapeutic relationship is based on the belief that a person has a natural drive toward optimal health. Caring—being willing and able to nurture others—is an attribute of the effective nurse. Caring rids the client of the disease or disability; caring nurtures the person even if the disorder is incurable. When it is understood that complete, or perhaps even partial, recovery is not possible, nursing goals focus on facilitating comfort by alleviating pain and promoting as much client autonomy as possible.

Nursing promotes healthy lifestyle behaviors, prevents the development of illness and injury, and restores individuals to their optimal level of functioning. Another purpose of nursing is to improve client satisfaction with the delivery of health care services.

Consumer satisfaction greatly influences where services are provided. Nurses who demonstrate caring behaviors enhance the quality of care provided; thus, clients are more satisfied with care delivered in a caring, compassionate manner.

NURSING AND HEALING

Nursing is a humanistic discipline that provides care from a holistic framework. Seeing and responding to the client as a whole person instead of a disease, disorder, or case lead to complete care of the total person. **Healing** is the process of recovery from illness, accident, or disability. This return to an optimum level of functioning may occur rapidly or gradually. Healing encompasses the physical, emotional, and spiritual domains of individuals. Nursing and caring are essential components in the healing process. See Chapter 31 for further discussion of nurses as healers.

THEORETICAL PERSPECTIVES OF CARING

There are numerous theoretical concepts relative to caring in nursing. Some major ideas related to caring have been postulated in Watson's theory of human caring, Leininger and McFarland's theory of transcultural caring, and Benner's novice to expert model; see Table 14-1.

The theory of human caring evolved from Watson's beliefs, values, and assumptions about caring. In Watson's view (2007), care and love comprise the primal, universal psychic energy and are the basis for our humanity.

Watson's theory is composed of 10 carative factors, which are classified as nursing actions or caring processes. Watson's carative factors are:

1. Formation of a humanistic-altruistic system of values
2. Nurturing of faith-hope

3. Cultivation of sensitivity to one's self and to others
4. Developing a helping-trusting, human caring relationship
5. Promotion and acceptance of the expression of positive and negative feelings
6. Use of creative problem-solving method processes
7. Promotion of transpersonal teaching and learning
8. Provision for a supportive, protective, or corrective mental, physical, sociocultural, and spiritual environment
9. Assistance with gratification of human needs
10. Allowance for existential-phenomenological forces (Watson, 2007)

The first 3 carative factors serve as the philosophical foundation for the science of caring. The remaining 7 provide more specific direction for nursing actions.

Transcultural nursing focuses on the study and analysis of different cultures and subcultures with respect to cultural care, health beliefs, and health practices, with the goal of providing health care within the context of the client's culture (Leininger & McFarland, 2002). A basic assumption of transcultural nursing is that when health care providers see problems from the client's cultural viewpoint, they are more open to understanding, appreciating, and working effectively with those clients. Other assumptions of transcultural nursing theory are:

- Every culture has some kind of system for health care that is based on values and behaviors.
- Cultures have certain methods for providing health care. These methods of care are often unknown by nurses from other cultures (Leininger & McFarland, 2002).

TABLE 14-1 Perspectives of Caring in Nursing

THEORIST	THEORY	MAJOR CONCEPTS
Watson	Theory of human caring	<ul style="list-style-type: none"> • Caring is central to nursing practice. • Emphasis is on the dignity and worth of individuals. • Each person's response to illness is unique. • Caring is demonstrated interpersonally. • Caring involves a commitment to care and is based on knowledge.
Leininger and McFarland	Transcultural care theory	<ul style="list-style-type: none"> • Caring is the essence of nursing. • Caring is universal, occurring in all cultures. • Caring behaviors are determined by and occur within a cultural context.
Benner	Novice to expert	<ul style="list-style-type: none"> • Caring is central to all helping professions. • Caring is the foundation of being. • People and interpersonal concerns are important. • Caring is communicated through actions. • Problem solving is a major component of caring. • Advocacy is caring.

RESPECTING OUR DIFFERENCES

Caring Behaviors That Occur in Different Cultures

Attention	Presence
Comfort	Protection
Compassion	Restoration
Empathy	Support
Instruction	Surveillance
Love	Tenderness
Nurturance	Touch
Personalized help	Trust

Data modified from Leininger, M., & McFarland, M. R. (2002). *Trans-cultural nursing: Concepts, theories, research, and practice* (3rd ed.). New York: McGraw-Hill.

FIGURE 14-1 Clasping the client's hand is one way to communicate caring through touch. DELMAR/CENGAGE LEARNING

Leininger and McFarland identify several behaviors as caring and state that these behaviors occur in various cultures; see the accompanying display on caring behaviors.

Benner (2001, p. 49) describes the caring nurse as one who has “courage to be with the patient, offering whatever comfort the situation allows.” Caring occurs within the context of a relationship that consists of several steps. First, hope is mobilized for both the client and nurse. Second, the relationship focuses on discovering the meaning of the illness, pain, or emotion. Finally, the client is aided in using social and spiritual support (Benner, 2001).

Caring—being willing and able to nurture others—is a hallmark of the effective nurse. It occurs when a nurse acts in a genuine, authentic manner with the client. Caring is a process and an art that requires commitment and knowledge; it is a combination of behaviors and attitudes. The way in which nursing actions are implemented expresses caring. Specific behaviors that indicate caring are provision of information, relief of pain, spending time with clients and families, and promoting client autonomy. Treating each client in a dignified, courteous manner is the true expression of caring.

Touch is an effective method for communicating a sense of caring (see Figure 14-1). Touch is a powerful nonverbal medium for communication that can be used to soothe, comfort, and establish rapport. It can communicate a sense of caring—as it does when a nurse holds a person's hand during

a painful procedure—or it can be perceived as intrusive or hostile. Touch, no matter how well intended, may sometimes be misinterpreted by a client; see the Safety First display.

CARE IN THE HIGH-TECHNOLOGY ENVIRONMENT

Caring is the soul of nursing. Nurses demonstrate caring in various ways, such as anticipating client requests and providing information. Clients feel supported and more comfortable in the presence of a nurse who, through caring, helps alleviate fears and anxieties. Although technological advances have resulted in many possibilities in health care, the major risk of reliance on technology is that clients may be perceived as objects. The focus of attention becomes the disease, instead of the individual experiencing the illness. The compassionate nurse treats each client with respect and dignity.

Depersonalization is the process in which individuals are treated as objects instead of people. Some examples of dehumanizing actions are checking on the equipment and not the person, failing to respond to the client, and communicating a lack of interest in what the client says. When the machinery becomes the focus of the nurse's activities, depersonalization of the client is likely to occur. Critical care nursing, with its multiple technological activities, presents a challenge to the development of a therapeutic nurse-client relationship (O'Connell, 2008). Spending time with the client is one way to counteract depersonalization; see Figure 14-2.

Nursing care counteracts depersonalization by emphasizing a client's individuality. It is through caring that the nurse humanizes the client. The reason people are admitted to acute care facilities is to receive nursing care. Caring is what clients want and need most from nurses. While receiving care, people want to be treated with compassion. The nontechnical element of care makes clients feel cared for as individuals; the use of high-touch activities communicates

SAFETY FIRST

Avoid touching clients who are suspicious, hostile, or very confused as the nurse's intent may be misinterpreted.

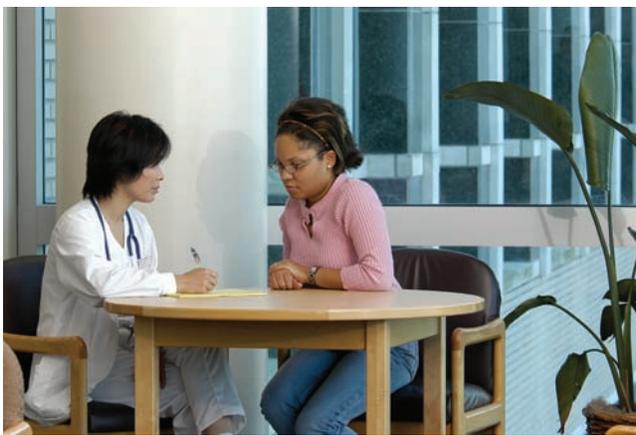

FIGURE 14-2 Nursing is caring. It is showing concern for and interest in the client. Identify behaviors of the nurse that demonstrate caring. DELMAR/CENGAGE LEARNING

UNCOVERING THE

Evidence

TITLE OF STUDY

“The Challenges of Caring in a Technological Environment: Critical Care Nurses’ Experiences”

AUTHOR

M. McGrath

PURPOSE

To examine the behaviors and feelings of experienced critical care nurses in a technological setting.

METHODS

Data, which were collected from unstructured interviews with 10 critical care nurses, were analyzed according to the Walters data analysis system.

FINDINGS

The use of technology may create an “alien environment” by increasing distance between the nurse and client. However, this study demonstrates that experienced critical care nurses can use technology to increase the bond between nurses and clients and families.

IMPLICATIONS

Experienced critical care nurses can transcend the barrier created by technology. However, nursing education should place more emphasis on the use of technology in order to help novice nurses bridge the chasm sometimes created by technology.

McGrath, M. (2008). The challenges of caring in a technological environment: Critical care nurses’ experiences. *Journal of Clinical Nursing*, 17(8), 1096–1104.

caring. As society continues to place a high value on technology, caring is often undervalued. Nurses make a crucial contribution by valuing both care *and* technology.

Although the concept of caring is being de-emphasized in today’s health care environment because of exploding technology and cost-containment strategies, nursing must persevere in delivering compassionate care to clients. The challenge of nursing is to create moments of caring through human-to-human interaction in the face of the fast-paced world of health care. “Caring professionals need to balance state-of-the-art technology with integrated and comprehensive care” (Almerud, Alpack, Fridlund, & Ekebergh, 2008, p. 136).

NURSE-CLIENT RELATIONSHIP

Caring is communicated interpersonally; thus, the vehicle for communicating a caring intent is the nurse-client relationship. The **nurse-client relationship** is the one-to-one interactive process between client and nurse that is directed at improving the client’s health status or assisting in problem solving. The primary goal of the relationship is the client’s achievement of therapeutic outcomes. The nurse-client relationship is a planned process that focuses on meeting the needs of the client. There are many differences between the therapeutic nurse-client relationship and a social relationship; see Table 14-2 on page 250.

The interactive process between client and nurse greatly influences the client’s progress in healing. Peplau (1952), the first nurse theorist to define nursing as an interpersonal process, viewed the nurse-client relationship as the basis of nursing. Interpersonal skills are the foundation for establishing the therapeutic relationship. Only through interacting does the nurse have the ability to adequately assess the client’s needs, teach methods for best meeting those needs, empower the client to achieve goals, and evaluate the outcome of nursing interventions.

PHASES OF THERAPEUTIC RELATIONSHIP

The three phases of the nurse-client relationship are orientation, working, and termination. These phases overlap and influence each other. Each phase is characterized by specific client behaviors and nursing goals. Figure 14-3 on page 250 illustrates the phases of the interactive relationship.

Orientation Phase

The **orientation (or introductory) phase** is the first stage of the therapeutic relationship, in which the nurse and client become acquainted with each other, establish trust, and determine the expectations of the other. Usually, the only knowledge the client and nurse have of each other is preconceived ideas. The nurse gets to know the client as an individual by giving up biases and judgmental thoughts. The orientation stage is especially important because it is the time in which the foundation for the relationship is established.

TABLE 14-2 Comparison of Social and Therapeutic Relationships

SOCIAL

- Is spontaneous, just happens.
- Is mutually beneficial.
- Often has no planned agenda.
- Is based on mutual interests.
- Each participant expects to be liked by the other.
- Problems are shared.
- Communication is spontaneous.

THERAPEUTIC

- Is planned and goal directed.
- Seeks to meet clients' needs.
- Is based on theory.
- Privileged information is available to health care provider.
- Clients are emotionally vulnerable.
- Clients must be accepted as they are.
- Communication is planned.
- Has clear-cut boundaries.

Delmar/Cengage Learning

CLIENT BEHAVIORS The usual response of the client in the orientation stage is anxiety, which can result from several factors including:

- Fear of the unknown
- Pain or distress
- Unfamiliar environment
- Undergoing unfamiliar, often painful, procedures
- Loss of freedom and control

As a result of the client's insecurity, anxiety escalates. Because anxiety is communicated interpersonally, the nurse should project a calm, relaxed attitude during every interaction with the client to decrease anxiety.

Another behavior frequently exhibited by the client during the orientation stage is testing. The client attempts to determine the degree of the nurse's trustworthiness. Through behavior, the client is asking:

- Is the nurse truly willing to help?
- Is the nurse competent to help?
- Is the nurse reliable and trustworthy?

The nurse answers such questions through consistent, reliable behavior that promotes the development of trust.

NURSE BEHAVIORS The most important nursing actions during the orientation phase are assessment and creating a climate conducive to rapport. The nurse must determine the client's needs, knowledge base, strengths and limitations, coping mechanisms, and support system. Often clients do

not express their needs directly; behavior is the only clue to their needs. The nurse's goal is to determine the real meaning of the behavior and to assess the client's perception of the most crucial needs and problems.

To reduce a client's anxiety and promote trust, the nurse provides some specific information. Information the client should receive during the orientation phase includes:

- Nurse's name
- Nurse's role
- Reasons the nurse must ask questions
- Confidentiality and its parameters

See the Spotlight On display, which addresses confidentiality.

Working Phase

The **working (or exploitative) phase** is the second stage of the therapeutic relationship, in which problems are identified,

SPOTLIGHT ON...

Legal/Ethical

Confidentiality in the Therapeutic Relationship

Nurses have ethical and legal responsibilities to protect client confidentiality. Consider what you would do in each of the following situations:

You are assisting Ms. Adams with her AM care when she says, "Isn't it just terrible about Mr. Denton across the hall? I heard his tests came back negative. What are his chances of making it?"

Your neighbor asks you if a mutual friend is being treated for AIDS.

In a crowded elevator at work, you overhear two coworkers discussing a client's condition.

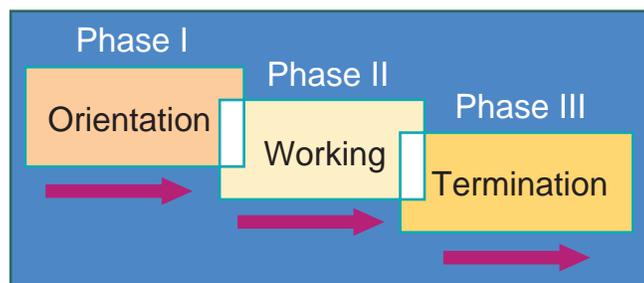

FIGURE 14-3 Phases of the Nurse-Client Relationship DELMAR/CENGAGE LEARNING

goals are established, and problem-solving methods are selected. Attainable goals play an important part in the client's perception of control (Reb, 2007). Actions are chosen after carefully considering both the consequences of actions and the client's values. It is necessary to consider the client's value system when determining problem-solving methods. Client participation increases when consideration of values is incorporated into care planning. It is important that nurses consider clients' feelings of personal control and intervene to increase perceptions of control, especially for clients treated in inpatient facilities (Williams, Dawson, & Kristjanson, 2008).

CLIENT BEHAVIORS The client engages with the nurse in active problem solving to achieve mutually developed outcomes. Behaviors that indicate the client is in the working phase are:

- Asking questions about his or her own problems
- Seeking clarification from the nurse
- Being attentive to instructions
- Asking for more information about his or her own role in recovery

NURSE BEHAVIORS The nurse seeks to maximize the client's success in problem solving. Nursing goals to be achieved during the working phase are to:

- Reevaluate goals and related activities as new information arises
- Support realistic problem-solving activities of the client

Termination Phase

The **termination (or concluding) phase**, the third and final stage of the therapeutic relationship, focuses on the evaluation of goal achievement and effectiveness of treatment. It is important that the client has been prepared for the final stage of the relationship by encouraging discussion of feelings.

CLIENT BEHAVIORS Some clients welcome this final phase, whereas other clients who have become overly dependent on their nurse will be more resistant to saying goodbye. Planning for termination is actually initiated during the beginning of the relationship. A relationship that ends abruptly is likely to place the client at risk for difficulties such as increased:

- Anxiety levels
- Frustration
- Suspiciousness
- Unwillingness to engage in future relationships with health care providers

NURSE BEHAVIORS Evaluation is the primary goal for the client and nurse in the third stage of the nurse-client relationship. Questions to be answered include:

- Were the goals meaningful?
- Were the goals realistic?
- Were the client and family actively involved?

See the Nursing Checklist, which can be used to evaluate skills in establishing a therapeutic nurse-client relationship.

THERAPEUTIC USE OF SELF

The interpersonal process between nurse and client is a therapeutic process because interventions are planned and implemented to benefit the client. The nurse's most effective tool for helping the client is the **therapeutic use of self**, a process in which nurses deliberately plan their actions and approach the relationship with a specific goal in mind before interacting with the client. The nurse's most effective tool for demonstrating caring is not some technologically sophisticated machine but rather one's self. Figure 14-4 illustrates therapeutic use of self. Therapeutic use of self provides an opportunity for the nurse and client to make a person-to-person connection. The term **presence** refers to the process of "just being with" another. Presence requires the nurse to demonstrate patience in a caring manner.

Therapeutic use of self involves verbal and nonverbal communication. Just as important as what one says is *how* one says it. With a deliberate, planned approach, the nurse communicates a sense of caring and willingness to help: The nurse is committed to helping clients find ways to help themselves. The nurse's true expression of humanistic concern for a client is shown by taking the time to simply be with the client.

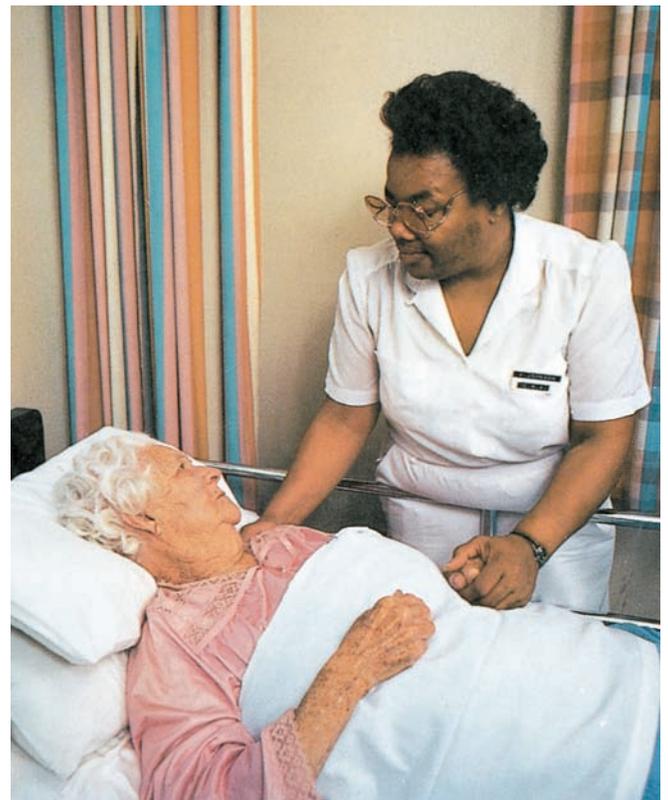

FIGURE 14-4 In this situation, what factors indicate that rapport has been established between nurse and client? DELMAR/CENGAGE LEARNING

**NURSING CHECKLIST****ESTABLISHING THERAPEUTIC RELATIONSHIPS**

- Introduce self on initial contact
- Explain own role
- Develop groundwork for trust
- Establish therapeutic boundaries
- Determine client's perception of problem(s)
- Understand client's expectations of care
- Communicate at client's level of comprehension
- Involve client in evaluating treatment

CARING AND COMMUNICATION

Communication is the mechanism for demonstrating compassion and caring. Therapeutic communication is deliberately planned by the nurse to result in positive client outcomes.

Therapeutic communication:

- Is purposeful and goal-directed
- Has well-defined boundaries
- Is client-focused
- Is nonjudgmental
- Uses well-planned, selected techniques

There are numerous techniques that are helpful in promoting therapeutic communication; see Chapter 15 for an explanation of these techniques.

CHARACTERISTICS OF THERAPEUTIC RELATIONSHIPS

Compassionate delivery of care is based on the establishment of a therapeutic relationship between client and nurse. In order to establish therapeutic relationships, the nurse must possess certain interpersonal skills. Some characteristics of therapeutic nurses are:

- Warmth
- Hope
- Rapport
- Trust
- Empathy
- Acceptance
- Humor
- Compassion
- Self-awareness
- Flexibility
- Risk taking
- Active listening
- Nonjudgmental approach

Catharsis, which refers to the relief experienced from verbalizing one's problems, is often referred to as "getting things off one's chest." It is a universal experience that is therapeutic for individuals experiencing stress.

Nurses use interpersonal skills to help clients express their feelings and meet their needs. A discussion of each characteristic follows.

Warmth

Warmth is the demonstration of positive behaviors toward the client. Respect, genuine interest, caring—all are expressions of warmth. The nurse who demonstrates warmth is approachable and available rather than aloof. Warmth means projecting an interested attitude without overwhelming the client. The nurse demonstrating warmth responds to the client as one human being to another. The therapeutic nurse is approachable and available yet maintains objective boundaries.

Hope

Hope means anticipating the future by helping clients look realistically at their potential. Hope is strengthened by relationships with others; social isolation reinforces a sense of despair. Many clients, especially those with great losses, experience distress, despair, and hopelessness. The reemergence of hope may be a gradual process. Hope is not to be confused with false reassurance, which is countertherapeutic; see the accompanying Spotlight On display.

Providing opportunities for clients to socialize and making resources available are two ways in which nurses can help instill hope in clients. Hope is necessary for coping with severe stressors, such as illness. Nurses must determine the client's source of hope, which may include the following:

- Relationships with others
- Positive emotions
- Anticipating the future
- Availability of resources

The instillation of hope helps clients meet their spiritual needs. Since spirituality is closely related to hope, nurses can also assess clients' spiritual needs to determine which interventions are most appropriate; see Chapter 24.

**SPOTLIGHT ON...****Caring and Compassion****Hope Versus False Reassurance**

Consider the following example of false reassurance. Mrs. Ngyuen is awaiting results of diagnostic testing that will confirm or deny the suspected diagnosis of cancer. She says to her nurse, "I think it's taking a long time to get the results. Something must be wrong." The nurse replies, "Oh, don't worry, everything's going to be just fine!"

What do you suppose motivated the nurse's response?

What will be the impact of the nurse's behavior on Mrs. Ngyuen?

Rapport

Rapport is a bond between two people that is based on mutual trust. This connection does not just happen spontaneously; it is planned by the nurse who purposefully implements behaviors that promote trust. When seeking to establish trust, the nurse recognizes the client as a unique individual and reinforces that individuality. In other words, actions that humanize the client are therapeutic. To establish rapport, the nurse's actions show that the client is considered important. Actions are implemented to boost the level of the client's self-esteem. Nonverbal interventions are of utmost importance in helping establish rapport.

Interacting with family and significant others is also helpful in establishing rapport with the client (see Figure 14-5). Recognizing the importance of the family's influence on the healing process allows the nurse to bond with those who will encourage and support the client. "The nurse must know when to move aside and allow family members a greater role in the care of the patient and when to relieve the family member" (Benner, 2001, p. 66).

Trust

Trust must be present for help to be given and received. A therapeutic relationship is firmly rooted in trust. The nurse sets the tone of the relationship by creating an atmosphere in which the client feels free to express feelings. How does the nurse promote a trusting relationship? Three major activities will facilitate the development of trust: *consistency*, *respect*, and *honesty*. Table 14-3 lists actions that facilitate the development of trust. The basis of trust is a caring relationship that is essential for most nursing interventions. Being consistently trustworthy is an expression of the nurse's personal integrity and builds the foundation for a therapeutic relationship.

Empathy

Empathy—understanding another person's perception of the situation—is a key element in the therapeutic relationship. The phrase "Walk a mile in my shoes" describes empathy

FIGURE 14-5 Through interaction with the client's family, how can the nurse help the client obtain optimal health? DELMAR/CENGAGE LEARNING

TABLE 14-3 Trust: Essential Behaviors

CONSISTENCY	RESPECT	HONESTY
<ul style="list-style-type: none"> Follow through on plans. Adhere to schedule. Seek out client for extra time to interact. Be straightforward; no hidden motives. 	<ul style="list-style-type: none"> Call client by name. Provide clear explanations. Recognize own strengths and limitations. Listen to client. 	<ul style="list-style-type: none"> Ask client about personal preferences. Keep any promises. Maintain confidentiality. Be flexible in responding to requests.

Delmar/Cengage Learning

well. The empathic nurse understands that the client's perception of the situation is real to the client. By perceiving clients' understanding of their own needs, the nurse is better able to assist clients in determining which actions are most appropriate. Empathy enables the nurse to assist the client to become a fully participating partner in treatment rather than a passive recipient of care.

Through empathy, the nurse validates the experiences of the client. The challenge for the nurse is to see the world from the client's perspective with as much understanding as possible. This involves understanding the client's perspective and communicating that understanding to the client. According to Kirk (2007), empathy is built on intentionality. Empathy is not the same as sympathy. Sympathy is rarely therapeutic; in fact, a barrier occurs when the nurse sympathizes and becomes paralyzed by the expression of pity. For example, empathic listening allows the nurse to encourage clients to find meaning in their experiences and move on to problem solving.

Acceptance

Accepting the client as a person worthy of dignity and respect is basic to providing nursing care. Acceptance means compassionately working with clients, even those who demonstrate negative behaviors. It is extremely important for the nurse to show acceptance of the client while setting limits on unhealthy or undesirable behavior. The accepting nurse conveys the message that the client does not have to put on a front. The client knows it is safe to be genuine because of the nurse's acceptance; see the accompanying Spotlight On display.

Active Listening

Active listening (listening that focuses on the speaker) is the basic skill for interpersonal effectiveness. Active listening is facilitated by **attending behaviors**, a set of nonverbal listening skills that conveys interest in what the other person is

SPOTLIGHT ON...

Caring and Compassion

Acceptance of Clients

Think of some client behaviors that you may not approve of, such as smoking, using alcohol, refusing to comply with treatment, or aborting a fetus. Even when clients engage in behavior that nurses think is wrong, bad, or immoral, those clients still have a legal and ethical right to quality nursing care. How will you respond when caring for someone whose behavior opposes your basic values?

saying. These behaviors allow the nurse to show caring, concern, and acceptance. Behaviors such as sitting down, facing the client, maintaining eye contact, and head nodding are indicators of active listening. Active listening requires the nurse to turn down inner dialogue because total attention must be focused on what the client is saying.

Also, it is important for the nurse to avoid looking rushed or distracted. The primary message that is communicated through active listening is the nurse's concern and intent to assist in problem solving. Active listening is required in every nurse-client relationship.

The active listener is cognizant of all three elements of communication: the *verbal*, *paraverbal*, and *nonverbal*. The verbal message is *what* is said. **Paraverbal communication** is the way in which a person speaks, including voice tone, pitch, and inflection, and the nonverbal message is body language. The active listener pays attention to all three aspects in order to hear the true intent of the communicator.

Active listening means that the nurse focuses on the feelings behind the words, *not* just the words themselves. It is important for the nurse to note any incongruities between the client's verbal and nonverbal messages. For example, if the client says, "Oh, I'm just fine!" and is slumped over with head hanging down, there is an incongruity—the behavior and the words do not match.

The client's expression of feelings demonstrates trust in the nurse. This expression of trust must be recognized and respected. By listening carefully to the client, the nurse is able to learn what the client perceives as the most crucial problem. *Listening is the first step in personalizing care for each client.* Listening can improve client outcomes by letting clients know their input is essential and increasing their sense of control. "For clients, being able to control one's own life is a source of power" (Oudshoorn, Ward-Griffin, & McWilliam, 2007, p. 1443). Some outcomes of active listening are:

- Establishment of rapport
- Expression of genuine concern
- Communication of intent to assist in problem solving
- Promotion of comfort level
- Decreased level of anxiety

- Client empowerment for self-care
- Facilitation of learning

Humor

Humor is another characteristic of therapeutic nurses. The use of humor as a therapeutic intervention is not a new concept for nurses. Nightingale (1969) recognized the influence of the mind on the body and acknowledged humor as an important nursing intervention.

As shown in Figure 14-6, humor can assist in establishing a relationship because it helps break the ice, decreases fear, and promotes trust. Humor is a medium for sharing; thus, it can be used to strengthen the therapeutic relationship. Humor also stimulates creative thinking, which is helpful for both clients and nurses in problem solving.

Humor is influenced by one's cultural background, so it is imperative that the nurse be sensitive to the client's interpretation and use of humor. A humor assessment can be conducted by noting:

- What makes the client smile or laugh
- The use of jokes by clients
- Type of humor expressed by the client

FIGURE 14-6 Note the exchange of laughter between client and nurse. What are some therapeutic outcomes facilitated by the nurse's deliberate use of humor? DELMAR/CENGAGE LEARNING

Humor is a powerful tool for coping. Humor helps individuals to alleviate stress and to express anger in a socially acceptable manner.

Nurses use humor to defuse the negative effects of stress. Although humor can relieve tension and stabilize high-stress situations, it must be used with caution since it can be destructive if used carelessly. For example, when using humor as a therapeutic intervention, the nurse must differentiate between *laughing at* and *laughing with* another.

Compassion

Compassion is truly caring about what happens to another person. Kindness and genuine concern are demonstrated through compassionate acts. Some behaviors that communicate the nurse's compassion include:

- Acting on the belief that everyone is equally deserving of care
- Treating individuals with dignity
- Respecting a client's privacy—which includes simple acts such as keeping the client covered and knocking on the door before entering the room

Other examples of compassion are a nurse caring for the homeless in a shelter or holding the hand of a person with acquired immunodeficiency syndrome (AIDS).

Self-Awareness

Being aware of one's feelings is the first step in developing therapeutic behavior. Knowledge of one's assets is necessary in that effective nurses are able to identify their own skills and abilities. Conversely, only after identifying deficits in knowledge and skills can the nurse initiate necessary improvements. This process of analyzing one's strengths and limitations is an ongoing part of learning. The therapeutic nurse knows learning is a lifelong process that contributes to growth—personally and professionally. Self-awareness allows the nurse to remain objective, that is, separate enough to distinguish one's own feelings and needs from those of the client.

Nonjudgmental Approach

Nonjudgmental behavior must be used if nursing interventions are to be therapeutic. Nonjudgmental means acting without biases, preconceptions, or stereotypes. Nonjudgmental nurses do not evaluate the client's moral values nor tell the client what to do; these nurses accept people as they are. Nonjudgmental nurses do not stereotype people nor expect others to behave in certain ways because they belong to a certain group.

Judgment influences perceptions because people tend to see what they expect to see. Judgmental behavior interferes with the therapeutic value of nursing interventions. It is non-therapeutic for nurses to allow biased views that stem from personal values to influence their actions. The initial assessment of clients is often influenced by preconceived ideas. See the Respecting Our Differences display.

RESPECTING OUR DIFFERENCES

Getting to know people with diverse cultural backgrounds expands the knowledge base and helps one become more tolerant and open-minded.

Becoming nonjudgmental is an ongoing process consisting of the following steps:

- The first step is the most difficult—recognizing that one's thoughts are biased and prejudicial.
- Second, in order to change, nurses must accept their own feelings.
- The third step consists of identifying the source of the negative feelings—not to blame but to gain an understanding of the origins.

Flexibility

Flexibility is another trait necessary for creating a therapeutic relationship. A flexible nurse is one who is ready for the unexpected—knowing that every day is filled with unplanned events and situations. The flexible nurse is able to adapt by taking things in stride and making necessary adjustments. Some of the unexpected events require immediate actions. The flexible nurse is able to establish priorities by determining which needs are urgent and which can be tended to later. Staying calm during a crisis is characteristic of the flexible nurse.

Risk Taker

A risk taker is a person who takes steps to find innovative solutions in problem solving. To become effective risk takers, nurses must give themselves permission to try something new, to step outside their comfort zones, and to not be bound by tradition or fear. The result of risk taking is creative solutions to problems. Successful risk takers give themselves credit for trying something new regardless of the outcome. Smart risk takers learn from those risk-taking ventures that are less than successful. They do not allow themselves to become complacent, that is, content to stay at a comfortable plateau.

THERAPEUTIC VALUE OF THE NURSING PROCESS

The nursing process provides a framework for the delivery of compassionate care. It gives direction by organizing the nurse's actions: assessing, diagnosing, planning, implementing, and evaluating.

The nursing process itself is therapeutic because it focuses on the client's response to illness, disease, or disability rather than just on the problem. By focusing on the caring

aspects, the nursing process helps nursing define its practice. Professional accountability is reinforced by the use of this process, which is client centered. When functioning within the parameters of the nursing process, the nurse assumes a variety of roles, including:

- Caregiver
- Counselor
- Teacher
- Client advocate
- Change agent
- Team member
- Resource person

NURSING ROLES

A **role** is a set of expected behaviors associated with an individual's status or position. A role includes behaviors, rights, and responsibilities. Nurses function in a variety of roles every day. Often roles overlap, which may lead to a conflict in expectations or responsibilities. A discussion of some predominant nursing roles follows.

Caregiver

The caregiver is the role most commonly associated with nursing by the general public. In the role of caregiver, the nurse provides direct care when clients are unable to meet their own needs. Specific activities characteristic of the caregiver role include feeding, bathing, and administering medications. When individuals are ill, they are more likely to be dependent upon others for assistance in meeting their basic needs, referred to as activities of daily living (ADL). Such dependency may result in the person experiencing a perceived loss of control and feelings of helplessness. Effective nurses understand the importance of helping clients maintain control as much as possible. To promote healing, nurses must help clients regain or maintain a sense of control. "Many patients feel alienated from their recovery and treatment; frequently it is the nurse who assists the patient in regaining a sense of participation and control" (Benner, 2001, p. 61).

Counselor

When acting as a counselor, the nurse assists clients with problem identification and resolution. The counselor facilitates client action by helping clients to make their own decisions. Counseling is done to help clients increase their coping skills. Effective counseling is holistic, in that it addresses the individual's emotional, psychological, spiritual, and cognitive dimensions. The counselor role is most often fulfilled by the nurse who intervenes with clients experiencing chronic conditions and those who are grieving.

Teacher

Teaching is an intrinsic part of nursing. The nurse views *each* interaction as an opportunity for education; both client and nurse can learn something from every encounter with each

other (see Figure 14-7). Client education focuses on client **empowerment**, that is, enabling clients to do as much as possible for themselves. Compassionate nurses provide information that is easily understood by clients and that will assist them in problem solving.

Client Advocate

A **client advocate** is a person who speaks up for or acts on behalf of the client. Advocacy empowers clients to be partners in the therapeutic process rather than passive recipients of care. The relationship that encourages client empowerment is one of mutual participation by client and nurse. Clients and families are actively involved in establishing goals.

Frequently, clients and families do not communicate their concerns to prescribing practitioners but will do so to the nurse with whom a bond has been established. Nurses function as client advocates by listening and communicating the expressed concerns to other health care providers and including those concerns in care planning.

Change Agent

Nurses who function in the role of change agent recognize that change is a complex process. The change agent is proactive (takes the initiative to make things happen) rather than reactive (responding to things after they have happened). Change should not be done in a random manner. It should be planned carefully and implemented in a deliberate way to facilitate the client's progress.

The compassionate nurse understands that the decision to change rests with the client. For example, consider the client who is instructed to lose weight in order to lower cholesterol levels. The nurse provides the necessary information but knows that the client has ultimate control in determining whether to make the necessary lifestyle modifications recommended by the health care providers. In other words, caring nurses do not attempt to force people to change.

FIGURE 14-7 In this situation, the nurse is providing prenatal instructions to the clients. DELMAR/CENGAGE LEARNING

Referrals

The nurse must have a broad understanding of community resources in order to connect clients with support services that are accessible. For example, an emergency room nurse may need to refer a woman to a battered women's shelter. Or a nurse who works in an obstetric clinic may need to refer a client to a local health unit in order to receive information about the supplemental nutrition program for women, infants, and children (WIC).

Team Member

A vital role of the nurse is that of team member. The nurse does not function in isolation but rather works with other members of the health care team. Collaboration requires the nurse to use effective interpersonal skills and promotes continuity of care. See Chapter 15 for a discussion on promoting healthy relationships with clients and colleagues.

Resource Person

The nurse functions as a resource person by providing skilled intervention and information. Identifying resources and making referrals as needed also fall under the auspices of this role (see Community Considerations accompanying display). Nurses must consider clients' strengths as well as availability of resources, including physical, intellectual, economic, social, and environmental factors.

KEY CONCEPTS

- Caring is the fundamental value in nursing.
- Today's high-tech environment requires that nurses provide humanistic caring.
- The therapeutic nurse-client relationship is the one-to-one interactive process between client and nurse that is directed at improving the client's health status or assisting in problem solving.
- Therapeutic relationships differ from social relationships in that they are deliberately planned, focus on client problems, and communicate acceptance of the client.
- Nursing is an interpersonal process between someone who needs help in meeting needs and someone who is competent to assist in meeting those needs.
- The three interwoven phases of the nurse-client relationship are orientation, working, and termination.
- Therapeutic use of self is a process in which nurses deliberately plan their actions and approach the relationship with a specific goal in mind before interacting with the client.
- Several interpersonal characteristics and skills can be developed to increase the therapeutic value of a nurse's interventions. These include warmth, hope, rapport, trust, empathy, acceptance, active listening, humor, compassion, awareness, nonjudgmental attitude, flexibility, and risk taking.
- The nursing process is the framework for providing compassionate care.
- Nurses function in a variety of roles when working with clients. The roles overlap and have specific responsibilities.

REVIEW QUESTIONS

1. The nurse is assigned a new client. Which of the following nursing actions will facilitate the development of a therapeutic relationship? Select all that apply.
 - a. Clarifying client's expectations for care
 - b. Determining the nurse's perception of problems
 - c. Discussing the nurse's problems
 - d. Establishing boundaries
 - e. Explaining the guidelines for confidentiality
 - f. Setting the groundwork for trust
2. Which of the following client behaviors is indicative of the working phase of the nurse-client relationship?
 - a. Asking questions about treatment methods
 - b. Changing the topic frequently
 - c. Demonstrating elevated anxiety
 - d. Testing the nurse's reliability
3. When planning care for a client, the nurse will decide to use touch if the client demonstrates:
 - a. Confusion
 - b. Cooperativeness
 - c. Hostility
 - d. Suspiciousness
4. A nurse manager observes a newly hired staff nurse providing care to a client. Which of the following staff nurse behaviors indicates that depersonalization has occurred?
 - a. Calling the client by name
 - b. Checking the client's vital signs without speaking

- c. Knocking on the client's door before entering the room
 - d. Talking to the client
5. The nurse is talking with a client scheduled for surgery the next day. The client expresses much anxiety about the procedure. Which of the following nursing responses is an example of empathy?
- a. "Everyone feels like this before surgery."
 - b. "I'm sure everything will work out fine."
 - c. "Things always look worse before they get better."
 - d. "You sound very anxious about the surgery."
6. Which of the following nursing actions demonstrates that the nurse is acting as a client advocate?
- a. Administering medications according to the prescribing practitioner's orders
 - b. Discussing the client's concerns at a treatment team meeting
 - c. Insisting that the client make all health care decisions without family input
 - d. Urging the client to consent to a treatment procedure that the client is refusing
7. During the nurse-client interaction, when the nurse tries to gain an understanding of the client's viewpoint, the nurse is exhibiting the use of _____.

verbal messages
visual channel

Communication is the fundamental element of the nurse-client relationship, client teaching, case management, staff development, and all the activities performed by nurses. In order to be an effective communicator, the nurse must be aware of the different levels on which communication is conducted between nurses and clients and among members of the health care team.

This chapter discusses the communication process, modes of communication, types of communication, and barriers to therapeutic interaction. Knowledge of these aspects of communication helps the nurse establish a therapeutic relationship with the client and deliver quality nursing care.

THE COMMUNICATION PROCESS

Communication, the process of transmitting thoughts, feelings, facts, and other information, includes verbal and nonverbal behavior. Kneisl (2009) describes communication as every aspect of behavior and, therefore, more than simply transmitting or imparting facts. Meaning must be assigned to those facts for communication to occur. All people engage in the dynamic process of communication. In fact, people cannot *not* communicate.

In nursing, communication is the vehicle for establishing a therapeutic relationship with a client. There would be a void if the nurse did not relate to clients—if there were no fondness, no closeness, no bonding. In fact, communication is the relationship between nurse and client (Kneisl, 2009). The quality of the relationship between nurse and client is directly associated with the quality of their communication.

COMPONENTS OF THE COMMUNICATION PROCESS

The five major components of the communication process are sender, message, channel, receiver, and feedback. See Figure 15-1, which provides a framework for understanding the process of communication.

The Sender

The communication process begins when a person, known as the **sender**, generates a message. Messages stem from a person's need to relate to others, to create meanings, and to understand various situations. Messages are generated by external stimuli, such as what the sender sees, hears, touches, tastes, or smells. However, the sender also perceives internal stimuli that generate messages. Examples of internal stimuli that affect communication include hunger, fatigue, or the mental activities of fantasizing and thinking (i.e., self-talk). The source (or encoder) is the stimulus, such as the idea, event, or situation. **Encoding** involves the use of language and other specific signs and symbols for sending messages.

The Message

The **message** is a stimulus produced by a sender and responded to by a receiver. Messages may be verbal, nonverbal, written materials, and artistic. Verbal and nonverbal

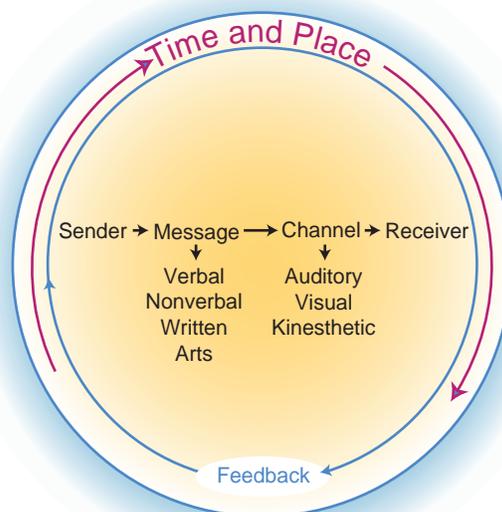

FIGURE 15-1 A Communication Model DELMAR/CENGAGE LEARNING

transmissions of messages are discussed at length later in this chapter.

The Channel

The **channel** is the medium through which a message is transmitted. There are three major communication channels: visual, auditory, and kinesthetic. The **visual channel** consists of sight and observation. The **auditory channel** consists of spoken words and cues. The **kinesthetic channel** refers to experiencing sensations. See Table 15-1. Each person has a dominant channel that influences communication. See the Respecting Our Differences display.

The Receiver

The **receiver** is the person who intercepts the sender’s message. Receiving is influenced by complex physiological, psychological, and cognitive processes.

The physiological component involves the process of hearing. An intact, healthy auditory system, including those areas of the brain involved in the hearing process, enables the receiver to hear messages. Good eyesight allows for the reception of messages via the visual channel. Likewise, homeostasis in those bodily structures where touch is applied allows for reception of tactile stimuli.

The psychological process refers to mental mechanisms that affect human behavior. This component may enhance or impede the receiving process. For example, anxiety may restrict the perceptual field, causing the client to hear, see, or feel less accurately. However, during mild and moderate levels of anxiety, the perceptual field broadens, causing the client to be more alert, with increased perception.

The cognitive aspect is the “thinking” part of receiving and involves interpretation of stimuli, thus converting them into meaning. The receiver assigns meaning through his or her own method of perceiving and “self-talk,” or communication with oneself. Engaging in too much self-talk may cause

RESPECTING OUR DIFFERENCES

Your Dominant Channel

Culture influences the way a person processes information. To determine which channel—visual, auditory, or kinesthetic—is your dominant mode, ask yourself these questions. How do I learn best: by seeing, hearing, or doing? When people speak, what do I pay most attention to: their appearance, their words, or their actions?

the receiver to do a poor job of listening. Controlling this self-talk requires continuous focusing and validating of the sender’s message. Through cognitive processing, the receiver decodes messages, interprets them, and then provides feedback to the sender.

Feedback

Feedback is the information the sender receives about the receiver’s reaction to the message. The function of feedback is to provide the sender with information about the receiver’s perception of a situation. Having this information, the sender can then adjust the delivery of the message to communicate more effectively.

Communication is reciprocal in that both the sender and receiver must be involved; the sender must transmit the message, and the receiver must provide feedback for a communication transaction to be complete. Characteristics of effective feedback include:

- Specific rather than general
- Descriptive

TABLE 15-1 Communication Channels

CHANNEL	MODE OF TRANSMISSION	CONGRUENT WORDS
Visual	Sight	• “I see what you mean.”
	Observation	• “It looks perfectly clear that . . .”
Auditory	Hearing	• “I hear you.” • “Tell me what you mean.”
	Listening	• “Sounds like you’re saying . . .” • “Tell me what you mean.”
Kinesthetic	Procedural touch	• “How does that feel?”
	Caring touch	• “That is so touching.”

Delmar/Cengage Learning

- Supportive and nonthreatening
- Timely delivery (as soon as possible after the behavior or the message)
- Clear and unambiguous
- Direct and honest

FACTORS INFLUENCING COMMUNICATION

In addition to channels, there are many other variables that influence communication. The primary influential factors are discussed in the following text.

Perception

Perception is a person's sensing and understanding of the world. Perception of an event or situation is unique in that it varies from person to person. Perceptions help a person determine the meaning of the words and the content of the messages being communicated. It is important for listeners to confirm what they think they have heard because interpre-

tation of the message depends upon the hearer's perception of the message.

Cultural Context

Because behavior is learned, nonverbal communication varies from culture to culture. For example, the messages communicated by touch and eye contact depend to a great extent on one's cultural context. See the accompanying *Respecting Our Differences* display on page 265 and Chapter 20 for a complete discussion of cultural variations related to communication.

Space and Distance

Proxemics is the study of the distance between people and objects. Each person has an invisible boundary, buffer zone, or personal space. Table 15-2 describes the types of personal space. Culturally defined boundaries alert a person as to how close another can comfortably approach. Invasion of personal space produces discomfort, anxiety, and the fight-or-flight response; see Chapter 23. The nurse respects the client's personal space in several ways, such as not touching or moving the client's possessions unless necessary.

TABLE 15-2 Types of Personal Space

TYPE	DESCRIPTION	NURSING IMPLICATIONS
Intimate distance (0 to 18 inches around the person's body)	<ul style="list-style-type: none"> • Reserved for people with whom one has a relationship • Vision is affected in that it is restricted to one portion of the other's body; may be distorted • Tone of voice may seem louder • Body smells noticeable • Increased sensation of body heat 	<ul style="list-style-type: none"> • Nurses often must intrude on this space to provide care • Explain intention to client • Respect client's space as much as possible • May be used for comforting and protecting • Therapeutic examples: <ul style="list-style-type: none"> — Rocking a toddler — Administering a massage — Checking vital signs (temperature, pulse, respiratory rate, and blood pressure)
Personal distance (zone extends 1.5 to 4 feet around person's body)	<ul style="list-style-type: none"> • Usually maintained with friends • Vision is clear since more of the other person is visible • Tone of voice is moderate • Sensations of body smells and heat are lessened 	<ul style="list-style-type: none"> • Better able to read nonverbal communication at this distance • Therapeutic examples: <ul style="list-style-type: none"> — Conversation between client and nurse usually occurs in this zone — One-to-one teaching — Counseling
Social or public distance (zone extends from 4 feet and beyond)	<ul style="list-style-type: none"> • Generally used when conducting impersonal business • Communication is more formal and less intense • Sensory involvement is less intense • Increased eye contact 	<ul style="list-style-type: none"> • Therapeutic examples: <ul style="list-style-type: none"> — Making rounds — Leading a group — Teaching a class

Data from Kneisl, C. R. (2009). Therapeutic communication. In C. R. Kneisl & E. Trigoboff, *Contemporary psychiatric mental health nursing* (2nd ed.). Upper Saddle River, NJ: Prentice-Hall; Spector, R. E. (2008). *Cultural diversity in health and illness* (7th ed.). Upper Saddle River, NJ: Pearson.

RESPECTING OUR DIFFERENCES

When talking with clients from diverse cultures, it is especially important to attend to nonverbal messages. Eye contact, voice volume and tone, facial expression, and gestures can be used to enhance communication with individuals of every cultural background. When communicating with people who do not understand English, what do you do to promote effective communication?

Time

The study of the effects of time on the communication process is referred to as **chronemics**. The entire communication process is influenced by time. For example, the same message received at 3:00 AM will be perceived and responded to differently at 3:00 PM. The amount of time spent in communicating depends on the client's needs. Some clients will require more of the nurse's time than others. The client who is seriously ill or nontrusting may respond better to brief, frequent contact than to prolonged, infrequent contact. If the nurse is hurried during the interaction with the client, a nonverbal message of impatience may be transmitted. Keeping clients waiting conveys a message that they are unimportant. On the other hand, the nurse who is prompt and who allows time for the client to talk communicates nonverbally, "You are important to me" and "I value you as a person."

LEVELS OF COMMUNICATION

Communication occurs at different levels, with each level influencing the others. The following text discusses the intrapersonal, the interpersonal, and group levels of communication.

Intrapersonal Level

Intrapersonal communication consists of the messages one sends to oneself, including self-talk, or communication with oneself. A person receiving internal or external messages organizes, interprets, and assigns meaning to the messages. Figure 15-2 illustrates the process of self-talk. The result of this process is the individual's unique way of perceiving. The message of the speaker may differ from that heard by the receiver because of the intrapersonal communication of each. Also, self-talk can interfere with attention to others and cause much to be missed during interpersonal exchanges.

Interpersonal Level

Interpersonal communication is the process that occurs between two people either in face-to-face encounters, over the telephone, or through other communication media. Interpersonal communication builds on the intrapersonal level in that each person communicating must communicate with the

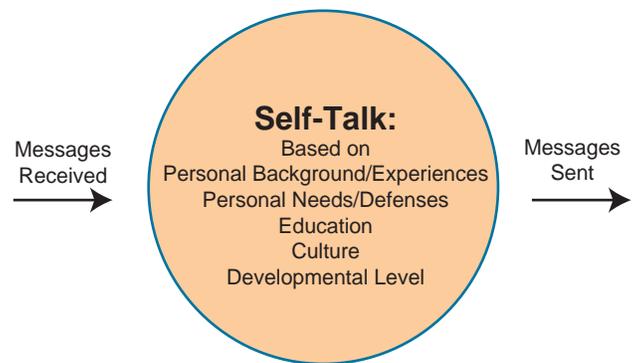

FIGURE 15-2 Intrapersonal Communication DELMAR/CENGAGE LEARNING

self in order to communicate with others. An important outcome of interpersonal communication is the development of an interpersonal relationship (see Figure 15-3). Interpersonal skills are essential competencies for nurses.

Group Level

Group communication occurs when three or more people meet in face-to-face encounters or through another communication medium, such as a conference call or webinar. This level of communication is complex because of the number of people communicating intrapersonally and interpersonally and the combinations of the people involved.

The study of the events that take place during group interaction is called **group dynamics**. The dynamics of any group influence the productivity of the group. Nurses deal with groups as they interact with families of clients, treatment teams, therapy groups, and committees within their health care settings (see Figure 15-4 on page 266). Table 15-3 on page 266 highlights some of the differences between one-to-one and small group interactions.

In dealing with groups, the nurse should be aware of the various nonverbal messages derived from the spatial arrangement of group members. For example, the leader tends to sit at the end or head of the table. Timid or uninterested

FIGURE 15-3 A Nurse Communicating with a Client on the Interpersonal Level DELMAR/CENGAGE LEARNING

FIGURE 15-4 Team Conference: What factors could improve communication in this situation? DELMAR/CENGAGE LEARNING

participants tend to sit at the back of the room. Seat clients in a circle rather than in rows to promote interaction and cohesion. The study of proxemics in small group situations is called **small group ecology** and provides a potent source of nonverbal messages about participants.

A group is formed around a common purpose or goal; this common goal is the factor that leads to **cohesiveness** (bonding among group members). Several types of groups exist; see Table 15-4 on page 267 for a listing of groups in which nurses usually participate. Nurses' participation in groups depends upon educational level. According to the American Nurses Association (2004), nurse generalists (those prepared at the baccalaureate level or below) may lead and colead all types of groups except psychotherapy groups. Only nurse specialists (those with graduate degrees) are to lead psychotherapeutic groups.

Since groups are interventions to improve a client's health status, it is important for nurses to refer clients to groups when necessary. Following are three mechanisms used by nurses to connect clients with health-promoting groups:

1. Communication—The nurse actively listens to the client to determine needs.
2. Critical thinking—The nurse uses cognitive processes to decide which groups are congruent with the client's needs.
3. Collaboration—The nurse works with multidisciplinary team members (i.e., social workers, physicians, clergy) to start the referral process.

MODES OF COMMUNICATION

Communication occurs in a variety of ways: through words, actions, or a combination of words and actions. When there is congruence (“a match”) between one's words and actions, communication is enhanced.

VERBAL MESSAGES

Verbal messages are messages communicated through words and language, either spoken or written. Verbal messages are accompanied by **paraverbal (or paralinguistic) cues**: tone and pitch of voice; speed, inflection, and volume; and grunts and other nonlanguage vocalizations. Paraverbal cues embellish a verbal message, thus adding to its meaning. Paraverbal communication often influences the listener more than the actual words do. Even when the words themselves are not understood, the power of the paraverbal cues can lead to understanding. For example, when a person speaking a foreign language is angry, the paraverbal cues of yelling,

TABLE 15-3 Differences between One-to-One and Group Communication

ONE-TO-ONE INTERACTIONS

- One sender and one receiver, each with his or her own unique perceptions.
- Influenced by dynamics of creating, maintaining, and terminating a therapeutic nurse-client relationship.
- Requires understanding of nurse-client relationship theory, communication theory, and an overall theoretical approach (e.g., Rogers, Peplau, Reusch).
- Problem identification and problem solving are done by the client, with input from the nurse.
- The nurse is the major support for the client during the interaction.
- The logical outcome of one-to-one communication is the development of the nurse-client relationship.

GROUP INTERACTIONS

- Numerous senders and receivers, each with unique perceptions.
- Influenced by group dynamics.
- Requires understanding of underlying modalities as well as a theoretical framework to guide both interventions and interpretations (e.g., psychoanalytic, behavioral, or interpersonal model).
- Problem identification and problem solving are done by the group, with assistance from the leader.
- The group is the major support for the client during the interaction.
- The logical outcomes are group cohesiveness and group productivity.

Delmar/Cengage Learning

TABLE 15-4 Types of Groups

TYPE	DESCRIPTION	EXAMPLES
Task group	<ul style="list-style-type: none"> • Focuses on achievement of a specific goal • Emphasizes problem solving and decision making 	<ul style="list-style-type: none"> • Diabetes education group • Committee to study staffing issues • Student Nurses Association
Therapeutic group	<ul style="list-style-type: none"> • Increases members' coping abilities • Offers support • Provides education and information 	<ul style="list-style-type: none"> • Stress management class • Bereavement and grieving group • Exercise group (i.e., mall-walkers club)
Therapy group	<ul style="list-style-type: none"> • Helps members learn about and change problematic behaviors • Focuses on emotional and behavioral disorders 	<ul style="list-style-type: none"> • Cognitive-behavioral group • Psychotherapy group
Self-help group	<ul style="list-style-type: none"> • Focuses on a common experience of all members • Often led by nonprofessionals 	<ul style="list-style-type: none"> • Weight Watchers • Reach for Recovery (a group for women who have had mastectomies) • Alcoholics Anonymous

Delmar/Cengage Learning

shouting, grunting, or hissing through clenched teeth convey the message across language barriers.

NONVERBAL MESSAGES

Nonverbal messages are messages communicated without words, that is, through body language. Much of the communication between people is nonverbal. Unspoken messages often carry more weight than verbal and paraverbal ones, and they can be more reliable. Nurses must pay attention to nonverbal communication in order to determine the meaning of changes in client behavior. See the accompanying Spotlight On display. Major nonverbal aspects of communication are discussed in the following text.

The nurse must never assume the meaning of a person's body language. Nonverbal messages can have several interpretations. Consider a client who crosses his or her arms when listening to the nurse. What does the client's nonverbal communication mean? It could be a signal that the client is shutting out the nurse's words, is trying to get warm, or is repositioning for comfort. It is essential that the nurse validate the intended meaning of the message with the client.

Facial Expression

The face is the greatest conveyor of nonverbal messages. Facial expressions give clues that support, contradict, or disguise the verbal message. Many types of feelings and reactions are reflected in a person's face. Facial expressions serve as clues to emotionally charged topics and often communicate the client's needs.

The eyes often belie facial expressions because there is little voluntary control over the eyes. For example, a frightened client might say, "I am fine," and voluntarily control the muscles of the face to portray inner calm. However, the pupils of the eyes dilate widely in fear, thus alerting the receiver to the real message. Eyes, together with the use of the eyebrows and eyelashes, give numerous signals to others. They show interest, concern, sadness, dishonesty, or honesty. The eyes may also indicate shock, shyness, pleasure, displeasure, excitement, and flirtation. They exemplify all feelings: anger, happiness, sadness, and fear.

The lips also communicate several messages, such as:

- Warmth and friendliness when they smile
- Malevolence when they snarl

SPOTLIGHT ON...

Professionalism

Elements of Communication

Nonverbal behavior is a more accurate indicator of the individual's intended message than words. Why do you think the adage "Actions speak louder than words" is true? A client yells, "I am NOT angry!" while pounding his fist on the bedside table. Which message—the verbal or the nonverbal—do you heed? Why?

- Anger when they pout
- Fear when they quiver

People who do not wish to share their feelings might clamp their jaws shut or purse their lips. Anxious people often chew their bottom lips. The nurse can use such clues to understand the client's messages.

Posture

Much about an individual may be learned by observing and interpreting posture. Posture indicates anxiety, relaxation, and negative or positive self-image. Leaning forward usually indicates interest; leaning backward may communicate aversion or rejection. Standing straight and tall with chest forward generally shows confidence, whereas individuals who are depressed, tired, or bored often slump.

Gestures

Gestures refer to the movement of body parts. Shrugging the shoulders, waving the hands, tapping the feet—all add a distinct dimension to verbal communication. The nurse communicates openness and a willingness to listen by facing the client in a relaxed position, with hands resting palms up on the lap. Crossed arms pulled closely against the body may indicate nonacceptance and a lack of desire to hear the client.

Touch

Touch is a powerful nonverbal medium for communication. It can be used to soothe, comfort, and establish rapport. Touch can communicate a sense of caring—as it does when a nurse holds a person's hand during a painful procedure—or it can be perceived as intrusive or hostile. Touch should be used cautiously with clients who are:

- *Confused*: They may misinterpret the intent of the touch.
- *Aggressive*: They may see the touch as a threat and lash out.
- *Suspicious*: They may think the touch is harmful.
- *Victims of abuse*: They may be frightened by touch.

The nurse must understand various cultural perceptions of touch in order to prevent problems. See the Respecting Our Differences display, and see Chapter 20 for discussion of the cultural significance of touch.

Physical Appearance and Artifacts

Physical appearance and **artifacts** (specific types of nonverbal messages that include items in the client's environment, grooming, or use of clothing and jewelry) convey nonverbal messages that enhance or detract from the spoken words. For example, uniforms often send nonverbal messages that stifle interpersonal exchange by setting up a boundary of superiority. For this reason, nursing uniforms are not worn in certain areas, such as pediatrics, psychiatry, and some home health settings. If worn, a uniform that is clean and pressed, along with shoes that are polished, can help inspire confidence in the caregiver.

Interpreting Nonverbal Behavior

Never assume that a nonverbal behavior has the same meaning for everyone. Interpretation of various nonverbal aspects of communication varies among people because of developmental, cultural, and experiential factors.

METACOMMUNICATION

Metacommunication is the relationship aspect of communication. It refers to the message about the message. For example, a person who is silent is still sending out messages through nonverbal communication. Metacommunication refers to all the factors that influence how messages are received. It involves focusing on the communication process rather than only on the content. The “reading between the lines” that occurs in metacommunication allows the receiver to better understand the sender's true message (Edelman & Mandle, 2006).

TYPES OF COMMUNICATION

There are several types of communication: social, therapeutic, and formal. Formal communication, which consists of written messages and the arts, may include lectures, reports, charting in the client's record, and public speaking. Usually, with formal communication, there is one sender transmitting messages to several others.

INTERDISCIPLINARY COMMUNICATION

The health care team consists of the client and all medical personnel involved in providing care. All members of the team perform important, though different, roles in the health care delivery system. See Chapter 4 for a complete discussion of the roles of health care team members. It is important that all health care team members communicate with each other regarding assessment, intervention outcomes, and client status. The interdependent nature of teams requires thoughtful and effective communication. Breakdown of communication between different team members can interfere with the client's treatment.

THERAPEUTIC COMMUNICATION

Therapeutic communication is the use of communication for the purpose of creating a beneficial outcome for the client. Therapeutic communication:

- Is purposeful and goal-directed
- Has well-defined boundaries
- Is client-focused

- Is nonjudgmental
- Uses well-planned, selected techniques

Ruesch (1961), who originated the term *therapeutic communication*, stated that the purpose is to improve the client's ability to function. Furthermore, therapeutic communication facilitates the establishment of the nurse-client relationship and fulfills the purposes of nursing (Kneisl, 2009). Therapeutic communication forms a connection between client and nurse. Technological advances cannot replace the need for communication between client and nurse. The "high-tech" environment demands the presence of "high-touch" nursing care. Table 15-5 on page 270 presents the essential elements of therapeutic communication: empathy, trust, honesty, validation, caring, and use of active listening.

Principles of Therapeutic Interaction

Regardless of the type of interaction, principles and guidelines of therapeutic communication are used to direct the nurse when relating with clients. A discussion of basic principles for guiding therapeutic communication follows.

Plan to interview at an appropriate time. The time frame within which an interaction occurs influences the outcome. For example, it is unwise to plan to talk with a client during visiting hours, during change of shift, or when the client is distracted by environmental stimuli (e.g., the homebound client is watching a favorite television show). In such situations, the nurse may be rushed or the client may be preoccupied. Neither situation would be conducive to effective interaction.

Ensure privacy. Clients are entitled to confidentiality. It is both a legal mandate and an ethical obligation that nurses respect the client's confidence; this includes spoken words and medical records. No one wants to discuss private matters when or where other people are listening. Privacy can be arranged by screening the client's bed, closing the door to the room, or finding a quiet secluded place in which to talk. See the accompanying Community Considerations display.

Establish guidelines for the therapeutic interaction. During the initial contact with the client, the nurse should share certain information such as the nurse's name and affiliation, purpose of the interaction, the expected length of the contact with the client, and the assurance of confidentiality. The client needs to have this basic information, and it serves as an introduction to the development of the therapeutic nurse-client relationship.

Ensuring Privacy in the Home Setting

In the home setting, it may be necessary to ask family members or visitors for time and space to promote confidentiality. Federal laws protect the confidentiality of every client in every health care setting, including those treated in community settings.

NURSING CHECKLIST

Meeting the Client's Comfort Needs

- Regulate the temperature of the environment.
- Sit in comfortable chairs or help position client comfortably on bed or stretcher.
- Provide adequate room ventilation.
- Implement measures to decrease pain.
- Institute actions to protect privacy.

Provide for comfort during the interaction. Discomfort can be distracting. Pain interferes with a person's ability to concentrate; thus, communication becomes impaired. See the Nursing Checklist, which provides guidelines for promoting a client's comfort in order to improve communication.

Accept the client exactly as is. Being judgmental blocks communication. Nurses who put aside personal prejudices, curiosities, feelings, and values are more receptive to the feelings and behaviors of the client, regardless of content stated by the client. Nonjudgmental nurses are less encumbered by their own personal needs.

Encourage spontaneity. The nurse gathers more data when the client is talking freely. Also, the client experiences relief and freedom from worries by talking without inhibition.

Focus on the leads and cues presented by the client. Asking questions just for the sake of talking or for the satisfaction of one's own curiosity does not contribute to effective interviewing. Therapeutic interaction involves discussing the client's problems, needs, or concerns. Therefore, allow the client to initiate the topic to be discussed; then, use techniques to focus on that topic. Pay attention to the verbal, paraverbal, and nonverbal cues and signals of the client, and focus on them when they occur.

Encourage the expression of feelings. Simply allowing the client to talk is not interviewing. Therapeutic interaction occurs when the client is permitted to voice feelings about troublesome events or interpersonal situations. Doing so requires the nurse to identify those areas that are emotionally charged and to focus on them.

Be aware of one's own feelings during the interaction. The nurse's feelings influence the interaction. For example, the nurse who becomes anxious may change the subject or make comments that finalize the session. The nurse must make a conscious effort to prevent personal feelings from getting in the way of the client's progress. Identifying one's own feelings and behavior and recognizing the way they affect the client lead to better communications.

THERAPEUTIC APPROACHES WITH CLIENTS

In addition to using the interviewing principles discussed previously, there are numerous techniques that help promote therapeutic communication. It is important to use the communication techniques as tools for building relationships with clients. See Table 15-6 on page 271 for an analysis of these techniques.

TABLE 15-5 The Elements of Therapeutic Communication

DEFINITION	BEHAVIORS OF THE NURSE	OUTCOMES
Empathy: An emotional linkage between two or more people through which feelings are communicated; involves trying to imagine what it must be like to be in another person's situation	<p><i>Verbal comments:</i></p> <ul style="list-style-type: none"> • “This must make you feel sad.” <p><i>Nonverbal actions:</i></p> <ul style="list-style-type: none"> • Nodding the head to indicate understanding 	<ul style="list-style-type: none"> • Promotes understanding of the client's feelings and condition • Provides the client with cues that the nurse is following and understanding what is being said
Trust: The client's belief that the nurse will behave predictably and competently while responding to the client's needs	<ul style="list-style-type: none"> • Ensuring confidentiality • Being consistent • Doing exactly what you say you will do for the client • Being consistently open and honest 	<ul style="list-style-type: none"> • Establishes the foundation of the therapeutic relationship • Provides the basis for progress during future encounters • Makes the client feel comfortable with the nurse, rather than guarded or afraid
Honesty: The ability to be truthful, frank, and sincere	<ul style="list-style-type: none"> • Providing realistic reassurance • Avoiding false reassurance • Developing insight into the way your feelings and reactions affect the client • Accepting yourself 	<ul style="list-style-type: none"> • Promotes the development of trust • Enables the nurse to gain personal insight and modify behavior as needed
Validation: Listening to the client and responding congruently in order to be sure that the nurse and client have the same understanding of a problem or issue	<p><i>Verbal comments:</i></p> <ul style="list-style-type: none"> • “So you are saying that . . .” • “Tell me what you understand about what I just said.” 	<ul style="list-style-type: none"> • Clarifies communication • Helps the client to feel accepted, respected, and understood
Caring: The level of emotional involvement between the nurse and the client	<p><i>Nonverbal actions:</i></p> <ul style="list-style-type: none"> • Spending quality time with the client • Paying attention to the client's needs • Using tactile messages, such as a pat on the back, to show support 	<ul style="list-style-type: none"> • Helps the client feel accepted • Provides the client with the knowledge that the nurse is willing to help
Active listening: Hearing and interpreting language, noticing nonverbal and paraverbal enhancements, and identifying underlying feelings	<ul style="list-style-type: none"> • Taking time to listen • Giving the client your undivided attention • Making eye contact • Responding to verbal and nonverbal leads, cues, and signals from the client • Suspending judgment • Noticing discrepancies between facts and feelings • Noticing things omitted such as topics that the client should be discussing but avoids • Using communication principles and techniques to be a sounding board 	<ul style="list-style-type: none"> • Promotes understanding of the client • Allows the client to express himself or herself more freely • Helps the client gain a better understanding of the problem(s) • Promotes problem solving by the client • Enhances the client's self-esteem

TABLE 15-6 Therapeutic Communication Techniques

TYPE	DESCRIPTION	EXAMPLES
TECHNIQUES THAT ALLOW THE CLIENT TO SET THE PACE		
Offering self	<ul style="list-style-type: none"> Nurse is available, physically and emotionally Indicates nurse's willingness and intent to help Nurse's presence is reassuring; may prompt client to continue Indicates nurse's attention and interest 	<ul style="list-style-type: none"> "I'll sit with you awhile." "Go on." "Uh-huh." Head nodding
Broad openings	<ul style="list-style-type: none"> Encourage client to choose topic for discussion Demonstrate respect for client's thoughts Emphasize importance of client's needs 	<ul style="list-style-type: none"> "What do you want to talk about?" "Can you tell me more about that?" "How have things been going?"
Silence	<ul style="list-style-type: none"> Gives client time to reflect Encourages client to express self Indicates interest in what client has to say Increases nurse's understanding of client's message Helps to structure and pace the interaction Conveys respect and acceptance 	<ul style="list-style-type: none"> Sit quietly and observe client's behavior Use appropriate eye contact Employ attending behaviors Control own discomfort during quiet periods or conversation lulls
TECHNIQUES THAT ENCOURAGE SPONTANEITY		
Open-ended comments	<ul style="list-style-type: none"> Unfinished sentences that prompt client to continue Questions that require more than a one-word answer Allow client to decide what content is relevant 	<ul style="list-style-type: none"> "Tell me about your pain" instead of "Are you in pain?" "Tell me about your family" rather than "How many children do you have?"
Reflection	<ul style="list-style-type: none"> Focuses on content of client's message and feelings Repeating client's words in order to prompt further expression Lets client know the nurse is actively listening Communicates nurse's interest 	<p><i>Client:</i> "Do you think I should tell the doctor I stopped taking my medication?"</p> <p><i>Nurse:</i> "What do you think about that?"</p> <p><i>Client:</i> "I probably should. But the medicine makes me so tearful and agitated."</p> <p><i>Nurse:</i> "You sound a bit agitated now."</p>
Restating	<p>Repeating or paraphrasing client's main idea</p> <p>Indicates nurse is listening to client</p> <p>Encourages further dialogue</p> <p>Gives client an opportunity to explain or elaborate</p>	<p><i>Client:</i> "I told the doctor that I had problems with this medicine, but he just didn't listen to me!"</p> <p><i>Nurse:</i> "Sounds like you're angry at him."</p> <p><i>Client:</i> "I don't sleep well anymore."</p> <p><i>Nurse:</i> "You're having problems sleeping?"</p>
TECHNIQUES THAT FOCUS ON THE CLIENT BY RESPONDING TO VERBAL, PARAVERBAL, AND NONVERBAL CUES		
Exploring	<ul style="list-style-type: none"> Attempts to develop in more detail a specific area of concern to client Identifies patterns or themes 	<ul style="list-style-type: none"> "Tell me more about how you feel when you do not take your medication." "Could you tell me about one of those times when you felt so upset?"
Recognition	<ul style="list-style-type: none"> Nurse points out observed cues to client 	<ul style="list-style-type: none"> "I notice that you became embarrassed when ..." "I see that you have some pictures of the new baby."

(Continues)

TABLE 15-6 (Continued)

TECHNIQUES THAT FOCUS ON THE CLIENT BY RESPONDING TO VERBAL, PARAVERBAL, AND NONVERBAL CUES

Focusing	<ul style="list-style-type: none"> • Questions or statements that help client develop or expand an idea • Directs conversation toward key topics 	<ul style="list-style-type: none"> • “You mentioned that you are having a problem with . . .” • “You say you feel nauseous a lot.”
Directing	<ul style="list-style-type: none"> • Comments that elicit specific information from the client • Is used to collect assessment data, not to satisfy nurse’s curiosity 	<p><i>Client:</i> “They told me I needed to see a specialist.”</p> <p><i>Nurse:</i> “What made them say that to you?” or “When were you told this?” or “How do you feel about seeing another doctor?”</p>

TECHNIQUES THAT ENCOURAGE EXPRESSION OF FEELINGS

Verbalizing the implied	<ul style="list-style-type: none"> • An attempt to detect the true meaning of verbal messages 	<p><i>Client:</i> “How much is this x-ray going to cost?”</p> <p><i>Nurse:</i> “You’re worried about your medical bills?”</p>
Making observations	<ul style="list-style-type: none"> • Nurse calls attention to behavior indicative of feelings 	<ul style="list-style-type: none"> • “You seem sad today.” • “You’re limping as if your leg hurts.”
Clarifying	<ul style="list-style-type: none"> • Makes the meaning of client’s message clear • Prevents nurse from making assumptions about client’s message 	<p><i>Client:</i> “Whenever I talk to my doctor, I feel upset.”</p> <p><i>Nurse:</i> “Tell me what you mean by upset.”</p> <p><i>Client:</i> “They said I could be discharged tomorrow.”</p> <p><i>Nurse:</i> “Who told you this?”</p>

TECHNIQUES THAT ENCOURAGE THE CLIENT TO MAKE SOME CHANGES

Confronting	<ul style="list-style-type: none"> • Nurse’s verbal response to incongruence between client’s words and actions • Encourages client to recognize potential areas for change 	<p><i>Client:</i> “I am so angry at her” (stated while smiling).</p> <p><i>Nurse:</i> “You say you’re angry, yet you’re smiling.”</p> <p><i>Client:</i> “I never know which of my symptoms to pay attention to. I think maybe I’m just a hypochondriac.”</p> <p><i>Nurse:</i> “You say you’re not sure which symptoms are important, yet you knew when to come to the clinic for help.”</p>
Limit setting	<ul style="list-style-type: none"> • Stating expectations for appropriate behavior • Establishing behavioral parameters 	<p><i>Nurse:</i> “It seems that you are feeling unsure of how to behave right now.”</p> <p><i>Client:</i> “What do you mean?”</p> <p><i>Nurse:</i> “Well, you’re asking me a lot of personal questions. The reason you’re here is because you have some health problems. How can I help you tell me more clearly what brought you here to the clinic?”</p>

Laraia (Eds.), *Principles and practice of psychiatric nursing* (8th ed.). St. Louis, MO: Elsevier.

BARRIERS TO THERAPEUTIC INTERACTION

Communication barriers present real challenges to the nurse, but need not stop communication. Rather, barriers pose hurdles that the nurse is able to scale by using creative and different approaches with the client. The nurse develops strategies for overcoming barriers by use of critical thinking skills. Common communication barriers are discussed in the text that follows.

LANGUAGE DIFFERENCES

When English is the clients' second language, they may have problems navigating through the health care system. An inability to communicate effectively with health care providers adversely affects clients' responses to interventions. The impact of this barrier can be lessened by learning the client's language (or parts of it), or by using interpreters, pictures and symbols, and foreign language dictionaries. Other ways of ameliorating language problems are discussed later in this chapter.

Communication problems can also occur even when everyone speaks the same language. For example, complex sentence structure and the different meanings of words may lead to communication difficulties. The use of value-laden terms also blocks the exchange of information, ideas, and feelings.

CULTURAL DIFFERENCES

Various cultures and subcultures use language differently. People's communication patterns reflect their culture. In some cultures, expression of thoughts and feelings is spontaneous and exuberant, whereas people of other cultural groups may be reserved and stoic in their verbalizations. Some of the communication variables that are culture specific include eye contact, proximity to others, direct versus indirect questioning, and the role of social small talk. See Chapter 20 for a discussion of the influence of culture on communication.

GENDER

Sending, receiving, and interpreting messages can vary between men and women. The effect and use of nonverbal cues are often gender dependent. For example, women tend to be better decoders of nonverbal cues, and men prefer more personal distance between themselves and others than do women (Boggs, 2006). See the Respecting Our Differences display on gender roles and expectations.

HEALTH STATUS

One's health status affects communication. For example, the client who is oriented will communicate more reliably than a client who is delirious, confused, or disoriented. Communi-

RESPECTING OUR DIFFERENCES

Gender Roles and Expectations

Traditional sex-role beliefs support the idea that women bear the primary responsibility for family well-being. How might the gender-biased expectations of both nurse and client affect the messages communicated? What are your gender-biased expectations of women as either clients or care providers? What approaches could you take to make your communication more gender conscious?

cation is affected by sensory perceptual alterations, such as loss of vision or hearing.

DEVELOPMENTAL LEVEL

Failure to communicate at the client's developmental level can be a roadblock. For example, communicating with children requires the use of different words and approaches than those used with adults because a child cannot think in abstract concepts. Relating at the client's developmental level is necessary for understanding. A discussion of communicating with children is presented later in this chapter.

KNOWLEDGE DIFFERENCES

All people need to be understood. Nurses consistently assess the knowledge levels of clients in order to determine the best way to correct knowledge deficits. When assessing knowledge level, the nurse should:

- Take note of the client's vocabulary
- Observe the numbers and kinds of facts verbalized by the client
- Determine the client's educational background

With this information, the nurse is able to assess the teaching needs of the client and determine the most appropriate method of instruction.

EMOTIONAL DISTANCE

Satisfying encounters are described by words such as *rapport* and *empathy*, and they occur when both parties are willing to be "present" as persons. Emotional distance, on the other hand, involves treating the client as a curiosity, a problem, or a disease, thus preventing satisfying interaction and possibly causing hostility. For instance, a client who is on strict isolation for an infectious disease, or someone who is confused and disoriented, is at risk for experiencing emotional isolation. By maintaining rapport with clients regardless of their status, nurses are able to decrease emotional distance.

EMOTIONS

When the nurse or the client is anxious, communication may change, stop, or take a nonproductive course. Nurses should be aware of their own feelings and try to control them in order to ensure progress in the interview. It is important that the nurse present a calm manner in order to ease the client's apprehension and, thus, improve the quality of communication.

DAYDREAMING

People can hear words faster than they can speak. Therefore, the listener's mind may wander, and the point of a message may be missed. Mind-wandering can also happen because the listener is bored or preoccupied with worrisome thoughts. Nurses can keep themselves from daydreaming by constantly attending to what the client has to say, by staying alert, and by controlling their own thoughts.

USE OF HEALTH CARE JARGON

The use of health care jargon can provoke anxiety in the client. Nurses and other health care providers have a language unique to their subculture. Nurses who use health care jargon with clients are likely contributing to blocked communication. Terms or phrases such as "CBC," "prn," "intake," "BP," and "take your vitals" are often misinterpreted by clients and families. It is important that nurses use language that is easily understood and explain medical terminology so that it is clear to clients and families.

COMMUNICATION BLOCKS

Certain responses (e.g., giving advice and agreeing) that would be acceptable during social conversation are not useful during therapeutic interaction. Unhelpful techniques are those that halt the progress of the interview and may result in the client's experiencing feelings of inadequacy, intimidation, or confusion. Table 15-7 on page 275 describes several communication roadblocks that are to be avoided. Nurses must constantly be aware of potential barriers to effective communication between themselves, their clients, and members of the health care team, and they must develop strategies to maximize their therapeutic interactions with clients.

COMMUNICATION, CRITICAL THINKING, AND NURSING PROCESS

Critical thinking is an important part of effective communication. Critical thinking involves analysis to determine why a certain conclusion has been reached. In other words, nurses

carefully formulate questions and propose answers by thinking critically. Interpersonal skills (as evidenced by effective communication) and critical thinking are competencies upon which nursing practice is based; see the accompanying Nursing Process Highlight for examples of the use of communication throughout the nursing process.

ASSESSMENT

Therapeutic communication is the vehicle for establishing a partnership between client and nurse. Peplau (1960) stated, "To encourage the patient to participate in identifying and assessing his problem is to engage him as an active partner—an enterprise of great concern to him" (p. 47). When performing the admission assessment, the nurse seeks to understand the client's entire message by focusing on both verbal and nonverbal communication. For example, note what a client is doing when stating, "I have a terrible headache." What nonverbal cues support the words?

NURSING PROCESS HIGHLIGHT

Relationship between Communication and Nursing Process

Assessment

- Asking questions to elicit key information
- Observing nonverbal behavior
- Reading medical records

Diagnosis

- Posing questions to help analyze and cluster data into meaningful patterns
- Talking with client and family or significant others to determine perception of needs and problems

Planning/Outcome Identification

- Talking with clients to mutually determine areas of concern and to formulate goals and objectives
- Staff meetings with coworkers to develop plans of care
- Writing and reading plans of care

Implementation

Determination of most appropriate intervention or method of responding; calls for input from client, significant others, and health care team members

Evaluation

Critiquing the client's response to interventions; requires direct communication with client and significant others

TABLE 15-7 Communication Roadblocks

ROADBLOCK	DEFINITION	EXAMPLES
Reassuring	Comments that indicate to the client that concerns or fears are unwarranted	<ul style="list-style-type: none"> • “Everything will be fine.” • “You will feel better soon.”
Agreeing	Comments that indicate that the nurse’s views are those of the client	<ul style="list-style-type: none"> • “I agree.” • “I think you are right.”
Approving	Comments that indicate that the client’s views, actions, needs, or wishes are “good” rather than “bad”	<ul style="list-style-type: none"> • “That’s good.” • “I think you did the right thing.”
Defending	Comments that are aimed at protecting the nurse, someone else, or something from verbal attack	<ul style="list-style-type: none"> • “I did not say that.” • “Doctor Jones is a good physician.” • “I am sure your father meant nothing by that comment.”
Using closed questions	Questions or comments that can be answered by the client with one word	<ul style="list-style-type: none"> • “Are you tired?” • “Could we talk now?” • “Did you sleep well?”
Using stereotyped comments	“Pat” answers or clichés that indicate that the client’s concerns are unimportant or insignificant	<ul style="list-style-type: none"> • “C’est la vie.” • “That’s the way the ball bounces.” • “It will all come out in the wash.”
Changing focus	Switching to a topic that is more comfortable to discuss	<p><i>Client:</i> “I wish I were dead.”</p> <p><i>Nurse:</i> “Did your wife visit today?”</p>
Judging	Comments or actions by the nurse that indicate pleasure or displeasure with what the client says	<ul style="list-style-type: none"> • A stern look • Rolling the eyes • “I like that.” • “I do not like that.”
Blaming	Accusing the client of misconduct; undermining the client’s need to be loved and accepted	<ul style="list-style-type: none"> • “You should know better than to talk like that.” • “If you had not moved, I would have been able to complete this venipuncture.”
Belittling the client’s feelings	Indicating to the client that feelings expressed are unwarranted or unimportant	<ul style="list-style-type: none"> • “Don’t feel that way.” • “Be a big boy and stop crying.”
Advising	Giving the client opinion or direction about solving a problem	<ul style="list-style-type: none"> • “If I were you, I would talk to your husband about this.” • “I think you should do something for yourself for a change.”
Rejecting	Indicating to the client that certain topics are not open to discussion	<ul style="list-style-type: none"> • “Let’s not talk about that right now.”
Disapproving	Indicating displeasure about comments or behaviors or placing a value on them	<ul style="list-style-type: none"> • “That’s bad.”
Probing	Pressuring the client to discuss something before he or she is ready	<ul style="list-style-type: none"> • “Why do you feel this way?” • “Why did you come to the hospital?” • “Why are you angry with your son?”

Data from Antai-Otong, D., & Wasserman, F. (2007). Therapeutic communication. In D. Antai-Otong & P. Hawkins (Eds.), *Psychiatric nursing: Biological and behavioral concepts* (2nd ed.). Clifton Park, NY: Delmar Learning; Kneisl, C. R. (2009). Therapeutic communication. In C. R. Kneisl & E. Trigoboff, *Contemporary psychiatric mental health nursing* (2nd ed.). Upper Saddle River, NJ: Pearson; Stuart, G. W., & Laraia, M. T. (2004). Therapeutic nurse-patient relationship. In G. W. Stuart & M. T. Laraia (Eds.), *Principles and practice of psychiatric nursing* (8th ed.). St. Louis, MO: Elsevier.

TABLE 15-8 Classification of Aphasias

Broca's aphasia	Slow hesitant speech
	Difficulty selecting and organizing words
	Naming, word, and phrase repetition
	Writing impaired
Wernicke's aphasia	Slight comprehension defects
	Auditory comprehension impaired
	Impaired speech content
Anomic aphasia	Client unaware of deficits
	Unable to name objects or places
Conduction aphasia	Comprehension and repetition of words and phrases intact
	Difficulty repeating words; substitutes incorrect sounds for another
Global aphasia	Severe impairment of oral and written comprehension
	Impaired naming and repetition of words
	Impaired writing ability

Delmar/Cengage Learning

Or is there an incongruity between the words and behavior? Assessing the client's communication ability involves collecting data relevant to the presence of physical and psychological barriers. Assessment of the client's ability to communicate must be ongoing. The presence of **aphasia** (impairment or absence of language function) should not be misinterpreted as confusion. Table 15-8 describes the types of aphasia.

NURSING DIAGNOSIS

Accurate diagnosis of client problems can be achieved by establishing a therapeutic relationship with the client. By paying meticulous attention to the client's communication, nurses are able to determine pertinent needs and, thus, develop accurate diagnostic judgments. Through effective communication, the nurse develops an atmosphere in which the client feels safe to express all relevant concerns.

The North American Nursing Diagnosis Association International (2009) defines communication as the ability to receive and transmit a system of symbols. Whenever a client is unable to send, receive, or interpret messages accurately, the diagnosis *Impaired verbal communication* is applicable; see the Nursing Process Highlight.

NURSING PROCESS HIGHLIGHT

Diagnosis

Nursing Diagnosis: Impaired Verbal Communication

Definition: State in which a person experiences a decreased, delayed, or absent ability to process, receive, or transmit meaning

Defining Characteristics

- Disorientation
- Inability or unwillingness to speak
- Difficulty speaking
- Difficulty expressing thoughts verbally
- Partial or total visual defect
- Stuttering or slurring of words
- Willful refusal to speak
- Unable to speak dominant language

Related Factors

- Cultural differences
- Decreased cerebral blood flow
- Physical barrier (e.g., tracheostomy)
- Anatomical defect (e.g., cleft palate)
- Developmental differences

Data from North American Nursing Diagnosis Association International. (2009). *Nursing diagnoses—Definitions and classification 2009–2011*. Philadelphia: John Wiley & Sons, Inc.

Other diagnoses that may be relevant for the person experiencing communication difficulties include the following:

- Social isolation related to impaired verbal communication
- Anxiety related to impaired verbal communication

NURSING CHECKLIST

Overcoming Language Barriers

- Speak slowly and distinctly in a normal tone of voice.
- Use gestures or pictures to emphasize meaning of words.
- Avoid cliches, medical jargon, or value-laden terms.
- Avoid defensive or challenging body language.
- Provide reading material written in the appropriate language.
- Use an interpreter who is fluent in health care terminology.
- Speak to the client rather than to the interpreter.
- Use the same interpreter for every interaction if feasible.

TABLE 15-9 Communicating with Vulnerable Populations

Clients who are hearing impaired	Determine if the client reads lips. If so, face the client and reduce background noise to a minimum.
	If client is using a hearing aid, check to see that it is in working order.
	Always face the client.
	Speak at a normal pace in a normal tone of voice.
	Focus on nonverbal cues from the client.
	Use gestures and facial expressions to reinforce verbal messages.
Clients who are visually impaired	Provide pen and paper to facilitate communication if client is literate.
	When speaking to visually impaired clients, always face them as if they were sighted.
	Follow the cues of the clients in order to allow as much independence as possible.
	Look directly at the client.
	Speak in a normal tone of voice; it is demeaning to yell.
Clients who are aphasic	Ask for permission before touching the client.
	Orient the client to the immediate environment.
	Assess the client's usual method of communication; adapt the interaction to accommodate the client's abilities.
	Use a written interview format, letter boards, or yes/no cards.
	Allow additional time for client's responses.
	Do not answer for the client.
	Use closed (one-word response) questions when possible.
Repeat or rephrase the comment if client does not understand.	
Unconscious clients	Speak directly to the client, not to the intermediary.
	To reinforce verbal messages, use facial expressions, gestures, and voice tone.
	Assume the client can hear.
	Talk to the client in a normal tone of voice.
	Engage in normal conversational topics as with any client.
Confused clients	Speak to the client before touching.
	Use touch to communicate a sense of presence.
	Maintain appropriate eye contact.
	Keep background noises to a minimum.
	Use simple, concrete words and sentences.
Angry clients	Use pictures and symbols.
	Use closed rather than open-ended questions.
	Give the client time to respond.
Use caution when communicating with a client who has a history of violent behavior or poor impulse control.	

(Continues)

TABLE 15-9 (Continued)

Do not turn your back on the client. Arrange the setting so that the client is not between you and the door to the room.
Focus on the client's body language.
Be alert for physical indicators of impending aggression: narrowed eyes, clenched jaw, clenched fist, or a loud tone of voice.
Model the expected behavior by lowering your tone of voice.
Stay within the client's line of vision.
Do not use touch.

Delmar/Cengage Learning

UNCOVERING THE

Evidence

TITLE OF STUDY

“Impact of Patient Communication Problems on the Risk of Preventable Adverse Events in Acute Care Settings”

AUTHORS

G. Bartlett, R. Blais, R. Tamblyn, R. J. Clermont, and B. MacGibbon

PURPOSE

To assess whether communication problems are associated with an increased risk of preventable adverse events.

METHODS

A total of 2,355 medical records were randomly selected and reviewed to assess the cause of adverse events. Reviewers abstracted client characteristics, including communication problems, in order to examine the cause of adverse events that occurred in general hospitals.

FINDINGS

Clients with preventable adverse events were significantly more likely than those without such events to have communication problems.

IMPLICATIONS

Clients with communication problems appeared to be at higher risk for preventable adverse events. Interventions to reduce the risk for these clients need to be developed.

Bartlett, G., Blais, R., Tamblyn, R., Clermont, R. J., & MacGibbon, B. (2008). Impact of patient communication problems on the risk of preventable adverse events in acute care settings. *Canadian Medical Association Journal*, 178(12), 1573–1574.

PLANNING AND OUTCOME IDENTIFICATION

After identifying communication problems, the nurse and client work together to develop goals and outcomes. The nurse then formulates nursing interventions to promote goal achievement. A major goal for every client is to develop an ability to communicate effectively, whether by verbalization or alternate means. See the Nursing Checklist on page 276 for guidelines in dealing with language barriers.

IMPLEMENTATION

Communication is the major tool by which nurses deliver safe, effective care. Research evidence indicates that effective communication increases client safety (Bartlett, Blais, Tamblyn, Clermont, & MacGibbon, 2008). Therefore, it is crucial that nurses communicate effectively with all clients. See the Uncovering the Evidence display.

It is extremely challenging for nurses to communicate with clients experiencing communication disorders. Technological advances have led to the development of telecommunication relay services (TRS), which often can be used with clients experiencing communication disorders. See Table 15-9 on page 277 for a description of methods for communicating with clients who have special needs. Also see Chapter 21 for specific guidelines on communicating with children, adolescents, and elderly clients.

EVALUATION

Evaluation of communication effectiveness involves both nurse and client. Communication is a major tool for evaluating a client's achievement of expected outcomes. For example, the nurse observes nonverbal behavior, talks with the client, and listens actively to the client's comments. The nurse uses critical thinking to analyze the client's responses as well as his or her own use of communication skills.

KEY CONCEPTS

- Communication is a vital aspect of all phases of nursing practice.
- The five components of the communication process are the sender, message, channel, receiver, and feedback.
- Factors such as perception, cultural context, space and distance, and time influence communication.
- The three levels of communication are intrapersonal, interpersonal, and group.
- Using language or other symbols, the sender produces verbal, paraverbal, and nonverbal messages that are delivered through a channel (visual, auditory, or kinesthetic) to a receiver.
- Interdisciplinary communication is a type of interaction by which members of the health care team collaborate on a client's care.
- Therapeutic communication is the use of communication for the purpose of creating a beneficial outcome for the client.
- Elements of effective therapeutic communication include empathy, trust, honesty, validation, caring, and active listening.
- The nurse needs to observe specific principles and techniques in order to initiate and maintain therapeutic communication with clients.
- Barriers such as language differences, sociocultural differences, gender, health status, developmental level, knowledge differences, emotional distance, emotions, and daydreaming can pose challenges for nurses in communication with clients.
- Communication barriers can be overcome if creativity, innovation, awareness, sensitivity, and critical thinking skills are used by the nurse.

REVIEW QUESTIONS

1. A client who is crying states, "I just don't understand why they won't let me get up." Which of the following nursing responses demonstrates the use of clarification?
 - a. "I'm sure they are just doing what they think is best for you."
 - b. "Maybe you just misunderstood them."
 - c. "Tell me who they are."
 - d. "Well, of course, you can get up. I'll help you."
2. A nurse is conducting a medication education class. Which of the following client behaviors indicates that a client's dominant sensory channel is visual?
 - a. Asking the nurse to explain in more detail about the medications
 - b. Asking the nurse to repeat the information
 - c. Demonstrating self-administration of an injection
 - d. Reading the handout distributed by the nurse
3. A nurse manager is meeting with a staff nurse to provide feedback on inferior performance of a specific task. Which of the following actions by the manager demonstrates the effective use of feedback? Select all that apply.
 - a. Avoiding discussion of the poor performance in order to boost the staff nurse's self-confidence
 - b. Discussing the staff nurse's performance in a staff meeting
 - c. Scheduling the feedback session immediately following the poor performance
 - d. Stating exactly what needs to be done to show improvement
 - e. Using words that clearly describe the unsatisfactory performance
 - f. Waiting to discuss the staff nurse's actions at the annual performance evaluation
4. Which of the following communication techniques encourages the client to be spontaneous during an interaction?
 - a. Confronting
 - b. Making observations
 - c. Open-ended comments
 - d. Focusing
5. Which of the following nursing comments demonstrates the use of reassuring?
 - a. "I think you should talk with your friend about that."
 - b. "That's the way the cookie crumbles."
 - c. "You shouldn't feel like that."
 - d. "You will feel better soon."
6. A client who is scheduled for surgery tomorrow tells the nurse that he is afraid. Which of the following nursing responses is therapeutic for this client?
 - a. "Are you saying you've changed your mind about having the surgery?"
 - b. "I'm sure you will be fine."
 - c. "Tell me more about that."
 - d. "You have nothing to worry about. Your surgeon is the best!"

—HIPPOCRATES

CHAPTER 16

Health and Wellness Promotion

COMPETENCIES

1. Differentiate health, illness, and wellness.
2. Identify assumptions of selected theoretical models of health.
3. Relate the achievement of basic needs to health status.
4. Explain the relationship of variables such as lifestyle, locus of control, self-efficacy, health care attitudes, and self-concept to health behaviors.
5. Discuss the impact of holism on health and health care delivery.
6. Discuss nursing's role in health promotion.
7. Discuss the nurse's role in promoting the sexual health of clients.

KEY TERMS

acute illness	health promotion	self-concept
adaptation	health-seeking behaviors	self-efficacy
basic human needs	heterosexuality	self-esteem
behavior	high-level wellness	sex roles
bisexuality	homeostasis	sexuality
body image	homosexuality	sexual orientation
chronic illness	illness	spirituality
gender identity	locus of control	transsexuality
health	need	wellness
health-promoting behaviors	psychoneuroimmunology	

Health and illness can be defined in many ways. Health is a concept that includes physical and mental status, emotional well-being, and spiritual well-being. Historically, Western cultures have defined health as the absence of illness. It is easier to measure illness than it is to measure health because definite parameters can be used to determine whether an individual has symptoms indicative of disease processes. What criteria are used for determining one's health? Is health merely the absence of disease, or is health more comprehensive?

In addition to examining these questions, this chapter describes health promotion activities with an emphasis on nursing's role. There is a discussion of holism, basic human needs, and the physiological, psychological, sociocultural, intellectual, spiritual, and sexual dimensions of the individual.

HEALTH, ILLNESS, AND WELLNESS

Health, the process through which a person seeks to maintain an equilibrium that promotes stability and comfort, is a dynamic process that varies according to a person's perception of well-being. The traditional definition of health as the absence of illness is a narrow concept. **Illness** is the inability of an individual's adaptive responses to maintain physical and emotional balance with subsequent impairment of functional abilities. **Wellness** is the condition in which an individual functions at optimal levels. An in-depth discussion of wellness appears later in this chapter.

Health is a global term because it refers to every aspect of a person's life, including:

- Physical status
- Emotional well-being
- Social relationships
- Intellectual functioning
- Spiritual condition
- Sexuality

MODELS OF HEALTH

There are several theoretical models of health (see Table 16-1 on page 283). These models help clarify the link between the states of well-being and illness and clients' responses to these processes.

Dossey and Guzzetta (2008) describe health as a maintenance of harmony and balance among body, mind, and spirit. Balance refers to **homeostasis**, which is an equilibrium among psychological, physiological, sociocultural, intellectual, and spiritual needs. The process by which a person adjusts to achieve homeostasis is called **adaptation**. When people describe their health status, three basic areas are considered:

- Presence or absence of symptoms (physical and emotional)
- How they feel (emotionally and physically)
- What they are able to do (ability to function)

Health can be studied both in individuals and in groups (e.g., families and communities). Health status is influenced by:

- Beliefs and attitudes
- Cultural factors
- Lifestyle behaviors

An individual, within the context of the family unit, gives meaning to health and makes adjustments necessitated by the illness. A family's adaptation to changes in health status is strongly influenced by each member's personal resources and support systems (i.e., social, spiritual).

Cultural Influences on Health

Health-related concepts evolve within the context of one's culture; that is, culture affects how an individual views health and illness. Cultural background influences health-related behaviors and expectations of treatment when illness occurs. For example, how an individual cares for himself or herself is directly related to cultural norms. See Chapter 20 for a complete discussion of cultural beliefs and behaviors affecting health.

TABLE 16-1 Theoretical Perspectives of Health

MODEL	THEORIST	ASSUMPTIONS
Clinical model	Traditional perspective	Health is the absence of illness. Individuals who are not “sick” (i.e., experiencing a disease) are healthy.
Health-belief model	Rosenstock	Expectations direct behaviors that lead to fulfillment of the expectations. Group values exert influence on beliefs about health. Beliefs may change as a person grows and develops.
High-level wellness model	Dunn	Health is influenced by the interaction between the individual, family, and community. Health is viewed as an attempt to achieve one’s fullest potential.
Social learning theory	Bandura, Rosenstock	Beliefs strongly influence actions. Behavior is influenced by expectations and reinforcements (or incentives).
Host-agent-environment model (“ecologic” model)	Leavell and Clark	Health depends on the interaction of host, agent, and environment. Balance among these elements results in health. Illness occurs when there is an imbalance in one of the three elements. Model is used most often in predicting risk of illness.
Health promotion model	Pender	Model focuses on activities that improve wellness and prevent disabilities. People use health-promoting activities when they: <ul style="list-style-type: none"> • Value health • Perceive health as being within their control • Can identify benefits in self-care activities • Have a positive perception of their own health status

Data from Bandura, A. (1977). *A social learning theory*. Englewood Cliffs, NJ: Prentice-Hall; Becker, M. H. (1974). Becker (Ed.), *The health belief model and personal health behavior*. Thorofare, NJ: Charles B. Slack.

Family Influences on Health

Because health is defined uniquely by each client’s culture, the nurse must assess the family’s health definitions and beliefs. Generally, families are the first to identify signals of impending illness. Also, families help determine the following:

- Whether to seek treatment
- What type of treatment is appropriate
- Who should provide the treatment or care
- Where the treatment or care should be provided

See the accompanying Community Considerations display.

Families are often the major caregivers for individuals experiencing illness. Extended families and communities have traditionally acted as a buffer against excessive stress and illness. Lack of social support from family or significant others often results in psychological and spiritual isolation, which negatively affects a person’s physiological state. Thus, it is

Rewarding Healthy and Unhealthy Behaviors

In general, Western society does not reward health-promoting behaviors. For example, children get attention when they are sick, not when they are well. This attention takes the form of goodies, treats, and relief from responsibilities such as homework and chores. This attention reinforces the value of being sick to children. Another example of our society’s rewarding illness occurs in the workplace. Most employees are entitled to sick days, but time off is not given for “well days.” What message is communicated by such behaviors?

important to help clients identify, strengthen, and use their social support systems. Sometimes, families need guidance in order to optimize healthy behaviors. Nursing assessment must include the client's and family's perspectives of the most pressing problem. See the Community Considerations display for a listing of nursing actions that promote family collaboration.

ILLNESS PERSPECTIVES

Illness means different things to different people and is more than just the existence of physical signs and symptoms. Illness is the result of a disease (either physiological or psychological) or injury that affects functioning and occurs when there is an inability to meet one's needs.

There are two major classifications of illness: acute and chronic. An **acute illness** is a disruption in functional ability usually characterized by a rapid onset, intense manifestations, and a relatively short duration. Acute illnesses are usually reversible. A **chronic illness** is a disruption in functional ability usually characterized by a gradual, insidious onset with lifelong changes that are usually irreversible. Chronic illnesses last a long time, frequently throughout the individual's life. An example of an acute illness is influenza; arthritis is an example of a chronic illness. It is possible for a person to have both a chronic illness and an acute illness at the same time, for example, the person with diabetes (chronic) who also develops pneumonia (acute).

Chronic illness affects individuals across the life span. Approximately 20% of American children are affected by disabilities, such as learning or behavioral problems (Cagle, 2006, p. 583). Adolescents experiencing chronic illnesses need two major nursing interventions: support and education.

COMMUNITY CONSIDERATIONS

Actions to Promote Collaboration with Families

- Listen as family members express feelings.
- Assess the extent to which family members wish to be involved in the treatment process.
- Involve family members to the extent they desire.
- Encourage participation in problem-solving activities.
- Participate in family support groups.
- Answer questions asked by client and family.
- Allow time for everyone to talk.
- Discuss aftercare plans to promote continuity of care.

Even though many elderly individuals have multiple chronic conditions, it is important to remember that chronicity is *not* an experience unique to the elderly. However, as life expectancy continues to increase, an increasing number of people are living with chronic illness. The implications for nursing are far reaching. Some of the goals of caring for people with chronic illnesses include:

- Coping with lifestyle changes and the subsequent modification of self-care activities
- Coping with long-term discomfort or pain
- Establishing or maintaining a sense of personal control
- Maintaining a positive self-esteem (Edelman & Mandel, 2006)

WELLNESS PERSPECTIVES

Wellness further describes health status by putting health on a continuum from one's optimal level (wellness) to a maladaptive state (illness); see Figure 16-1. Wellness is a dynamic process that is ever changing. The well person usually has some degree of illness, and the ill person usually has some degree of wellness. This concept of a health continuum negates the idea that wellness and illness are opposite because they may occur simultaneously in the same person in varying degrees. The classic description of wellness was developed by Dunn in the early 1960s. According to Dunn (1961), **high-level wellness** means functioning to one's maximum health potential while remaining in balance with the environment.

HEALTH BEHAVIORS

To understand how people influence their health status, it is important to know about health behaviors. **Behavior** is defined as the observable response of an individual to external stimuli. An important concept to remember when caring for clients is that *all behavior has meaning*. In other words, behavior is the individual's attempt to achieve satisfaction of needs. Nurses must sometimes act as detectives to determine the need(s) underlying client behavior. Thorough assessment is the key for nurses in determining the meaning of client behavior. **Health-seeking behaviors** are those activities directed toward attaining and maintaining a state of well-being.

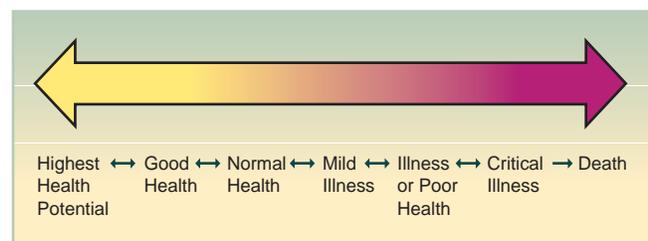

FIGURE 16-1 Health Continuum DELMAR/CENGAGE LEARNING

VARIABLES INFLUENCING HEALTH BEHAVIORS

There are several variables that influence health including:

- Lifestyle
- Perceived locus of control
- Perceived ease or difficulty in accomplishing a task (self-efficacy)
- Health care attitudes
- Self-concept

Lifestyle

Individuals determine their health status through their actions (see Figure 16-2). Lifestyle consists of a person's usual daily activities and routines that are acceptable practices in the person's life. Such routines and habits influence health status. For example, smoking and a sedentary lifestyle negatively affect health status. Lifestyles are developed within one's family and one's cultural environment. The family is the primary influence on a child's development of health-promoting (or health-defeating) behaviors.

FIGURE 16-2 Through exercise, this woman is demonstrating a lifestyle choice that will enhance her health status. How does this type of behavior promote wellness? DELMAR/CENGAGE LEARNING

When lifestyle modifications are necessary to improve health, many individuals have difficulty implementing the suggested changes. Individuals are less likely to comply with recommended lifestyle changes if there is a perception of increased inconvenience and cost. Also, the required degree of change in lifestyle may affect compliance.

Locus of Control

Locus of control refers to individuals' sense of being able to influence events and situations affecting their lives. A person with an external locus of control feels like a victim with little, if any, control over life events. However, people with an internal locus of control feel able to influence significant events and occurrences affecting them; that is, they see themselves as responsible for their own lives. Thus, those with an internal locus of control are more willing to make lifestyle changes that lead to wellness.

Self-Efficacy

Bandura (1977) used the term **self-efficacy** to describe an individual's perception of one's own ability to perform a certain task. Self-efficacy has a powerful impact on initiating behavior change.

Self-efficacy is a form of self-confidence that leads to successful behavior performance. As described by Bandura (1986), self-efficacy encompasses two types of expectations:

1. *Outcome expectations:* Beliefs about whether behavior will produce desirable results
2. *Efficacy expectations:* Beliefs the person has about his or her own ability to perform the behavior

Health implies moving toward self-care, in other words, becoming and remaining independent. Self-responsibility, as it relates to health-promoting activities, is a fairly new concept to many Americans. For years, individuals have looked to prescribing practitioners to "fix things" and "make it better." Only when individuals enter into active partnerships with their primary health care provider (nurse, physician, or other healer) will self-responsibility for health become a reality. See the Uncovering the Evidence display on page 286.

When clients are able to make informed decisions about their health behaviors and feel that they are successful in these areas, they are more likely to attempt behavior change. Thus, an essential component of nursing care is to provide opportunities for clients to achieve this level of self-motivation. For example, when teaching a client how to self-administer injections, the nurse breaks the task down into small manageable objectives and asks the client to do a return demonstration. The client receives immediate feedback, which encourages further success.

Health Care Attitudes

Beliefs are powerful shapers of behavior. Health behaviors are based on beliefs. Attitudes about health and personal vulnerability (which are initially learned in the family unit)

UNCOVERING THE

Evidence

TITLE OF STUDY

“Incorporating Self-Efficacy and Interpersonal Support in an Intervention to Increase Physical Activity in Older Women”

AUTHORS

C. Costanzo and S. N. Walker

PURPOSE

The purpose of this study was twofold: (1) to compare the efficacy of five sessions versus one session of behavioral counseling in a 12-week intervention to increase self-efficacy and family and friend support for activity and (2) to examine self-efficacy and support as mediators of activity among 45 urban older women.

METHODS

This was a randomized, controlled trial in which outcomes were examined with repeated-measures analysis of variance and path analysis.

FINDINGS

No significant change was observed in self-efficacy in the five-session group; however, a significant decrease was observed in the one-session group. Family and friend support increased significantly in the five-session group. The intervention effect on activity was mediated through change in self-efficacy and family support.

IMPLICATIONS

Self-efficacy can be increased and/or maintained through repeated counseling sessions and family support.

Costanzo, C., & Walker, S. N. (2008). Incorporating self-efficacy and interpersonal support in an intervention to increase physical activity in older women. *Women & Health, 47*(4), 91–108.

Self-Concept

Self-concept is an individual’s perception of self. It includes **self-esteem** (an individual’s perception of self-worth) and **body image** (perception of one’s physical self). The relationship between self-concept and health is strong.

Self-concept influences individuals’ health behaviors in that people who think highly of themselves will tend to take care of themselves. On the other hand, a person with a negative self-concept may engage in reckless or self-destructive behaviors that endanger health. People with a low self-concept frequently ignore their own needs because they are perceived to be less important than the needs of other people.

Self-concept is dynamic and may change according to health status. Not only does self-concept influence health, but changes in health status may also influence self-concept. For example, consider the person who has lost a limb due to amputation. This person’s self-concept might be altered as a result of the physical change. See Chapter 22 for further discussion of self-efficacy.

HEALTH PROMOTION

Prior to the 1990s, most health-related research focused on behaviors that prevent illness. Currently, however, the trend among health care professionals is to emphasize behaviors that promote wellness. Health promotion refers to any activity that improves the quality of health and well-being of individuals, families, and communities. The aim of health promotion is to empower people to make choices regarding lifestyles and activities (Maville & Huerta, 2007).

The U.S. Department of Health and Human Services (DHHS) (2005), in its Healthy People initiative, focuses on the individual’s responsibility in promoting health. Individuals are viewed as having the ability to influence their own health and also that of the country. There are several approaches to health maintenance:

- Health promotion
- Health protection
- Disease prevention (U.S. DHHS, 2005)

COMMUNITY CONSIDERATIONS

The Media and Health Beliefs

The media are extremely powerful in shaping attitudes and beliefs. Here are some examples of how various media discourage health-promoting behaviors:

- Advertising foods with high sugar, salt, and fat content
- Promoting alcohol use
- Encouraging use of tobacco products

What other examples can you identify? Recently, there seems to be an emerging trend to advertise healthier lifestyles. What examples come to mind?

greatly influence behavior. Socialization (which occurs within the family) influences the development of beliefs about health care. Societal values also affect the development of beliefs about health care; see the accompanying Community Considerations display. These beliefs determine the person’s willingness to participate in health care. For example, if the person believes in the use of herbs or folk healers, these practices could either enhance or interfere with traditional treatment approaches.

Nurses must be sensitive to the fact that all clients do not share the same beliefs about health care issues. Using a nonjudgmental attitude helps the nurse to be more accepting of clients with diverse beliefs and behaviors.

In 1979, the U.S. DHHS mobilized public health agencies to work toward developing healthier Americans. This initiative, Healthy People, is now in its fourth decade and is called Healthy People 2020. The program, coordinated by the Office of Disease Prevention and Health Promotion under the U.S. DHHS, focuses on allowing equal access of all Americans to preventive health care services. Most states use the Healthy People framework to guide the development and implementation of local health policies and programs. Healthy People 2020 recognizes the need to focus on improving the quality of life as well as reducing disparities in the type of health care services received by Americans.

The Healthy People initiative is implemented through the efforts of health care agencies, both public and private. The leading health indicators, which are used to measure the nation's health, reflect the major health concerns of the nation; they include the following:

- Physical activity
- Overweight and obesity
- Tobacco use
- Substance abuse
- Responsible sexual behavior
- Mental health
- Injury and violence
- Environmental quality
- Immunization
- Access to health care (U.S. DHHS, 2005)

HEALTH PROMOTION ACTIVITIES

Health promotion is a process undertaken to increase the levels of wellness in individuals, families, and communities. It involves activities and programs provided by nurses and other health care providers to foster lifestyle behaviors conducive to optimum health status. Major goals of health promotion activities include the following:

- Respect and support clients' right to make decisions
- Identify and use client strengths and assets
- Empower clients to promote their own health or healing

Nurses identify high-risk individuals and determine and strengthen their social support, thus encouraging disease prevention. Clients who are attempting to adopt **health-promoting behaviors** (actions that increase well-being or quality of life) must receive support and reinforcement for their attempts. As beginning health care providers, nursing students are encouraged to develop their own health-promoting behaviors in order to be better role models for clients. See the accompanying Spotlight On display.

Individuals are becoming more aware of the relationship between daily behavior and health status. Types of health promotion programs can include smoking cessation, nutrition, and exercise. Changing health behaviors means focusing on the whole person within the context of the environment.

Health promotion activities are holistic in that they target physical and emotional health concerns. Some

SPOTLIGHT ON...

Caring

Nurses as Healthy Role Models

Nurses have an opportunity to model healthy behaviors. Think about the messages many nurses communicate through certain behaviors such as smoking, overwork, and inadequate use of stress management techniques.

Do you think nurses have an obligation to demonstrate healthy behaviors? Explain the rationale for your answer.

What type of health-promoting behaviors do you demonstrate?

nursing activities that promote and protect mental health include:

- Teaching conflict resolution skills
- Providing support to grieving families
- Monitoring for abuse of children, partners, and elders
- Teaching stress management techniques

HEALTH PROTECTION ACTIVITIES

Health protection includes a variety of activities. Prevention of accidental injury in the home, at school, and in the workplace is an example. Programs that focus on occupational safety and health are designed to protect employees' health. Governmental efforts to ensure the safety of food and drug products are another example of health protection. Environmental strategies, such as water purification, sewage disposal, and air quality control, are used to protect the health of individuals and communities.

DISEASE PREVENTION ACTIVITIES

Disease prevention occurs on a continuum, from averting the development of disease to limiting its course once developed. The purpose of *primary prevention* is to decrease the person's vulnerability to disease. Primary preventive measures include parenting education, attention to personal hygiene, and avoidance of toxins. The goal of *secondary prevention* is early detection of disease to initiate early intervention. Examples of secondary preventive activities are screening for particular diseases and preventing the spread of communicable disease. When a disease (such as a chronic condition) already exists, *tertiary prevention* is used to minimize its effects and to prevent further disability.

Nurses who work in rehabilitation settings, including the home, are engaged in tertiary prevention. The focus is on restorative care, that is, therapeutic interventions directed at helping clients reach and maintain their optimal level of functioning.

NURSE'S ROLE IN HEALTH PROMOTION

Nurses play a major role in promoting health and wellness. Health promotion enables the individual to develop behavior patterns that promote a healthy lifestyle and reduce the risk of disease. When behaviors that once worked for the individual are no longer effective, the client must give up the old behaviors in order to be able to adopt new, healthier ones. The challenge for nurses is to find ways to motivate clients and families to develop health-promoting behaviors. Client teaching is a major intervention for promoting health (see Figure 16-3). An essential component of teaching is encouraging clients to make necessary lifestyle changes to promote health.

Motivation is a key component of achieving and maintaining health. Nurses can better help clients engage in healthy behaviors by considering the client's beliefs and experiences when planning care. How do nurses encourage the development of healthy behaviors in clients? Merely providing information is not the key. The key is to inspire clients to want to change. Price (2006) refers to this process as getting the attention of the client. Many factors help clients feel motivated to change health behaviors:

- Perception of self as able to succeed (self-efficacy)
- Belief that health status will improve
- Response to attempts to change in the form of feeling healthier and receiving confirmation of these changes from others

HEALTH PROMOTION AND VULNERABLE POPULATIONS

Risk factors that threaten the health of individuals include poverty and chronic disease (Go, 2006). The health of certain population groups is threatened; especially vulnerable groups include:

- Children
- Older adults

FIGURE 16-3 To promote the health of this expectant couple and their baby, the nurse is providing information about nutritional intake during pregnancy. What incentives can the nurse offer in this situation that would encourage these clients to practice health-promoting behaviors? DELMAR/CENGAGE LEARNING

RESPECTING OUR DIFFERENCES

Inexpensive Health-Promoting Behaviors

Several behaviors, such as walking and breastfeeding, are relatively inexpensive and promote health.

Think of some other examples of inexpensive behaviors that nurses can encourage people of all socioeconomic groups to incorporate into their lifestyles.

- Those who are economically disadvantaged
- Those who are immunocompromised
- The homeless

One primary variable affecting health promotion is socioeconomic status. Middle- and upper-income families are more likely to demonstrate healthy behaviors as they have the financial means to purchase nutritional foods, buy exercise equipment, and pay for recreation. The monies of lower socioeconomic families are typically used in meeting basic needs such as food, shelter, and acute medical care. Health-promoting options must be affordable and readily available to people of all economic levels; see the accompanying Respecting Our Differences display. Political involvement is one avenue for nursing to advance the health status of all. Nurses must be actively involved in shaping health care policy in order to influence the establishment of resources for underserved, disenfranchised groups.

Another variable affecting health is age. Elderly individuals tend to describe themselves as well when they are physically active, relatively free from pain, and able to maintain meaningful social ties. Maintaining independence and quality of life are of great importance for most elders. Nurses must promote self-care activities with elders to facilitate wellness.

THE INDIVIDUAL AS A HOLISTIC BEING

Due to the interwoven nature of the body and mind, it is impossible to separate physiological needs from psychosocial ones. **Psychoneuroimmunology** (the study of the complex relationship between the cognitive, affective, and physical aspects of individuals) is based on recognition of the concept that mind, body, and spirit are one. For example, a person who is physically ill also experiences psychosocial disruptions. On the other hand, when a person is anxious or depressed, physical manifestations occur.

The practice of body-mind medicine is not new and is rooted in the origins of healing, as shown in the following examples:

- Hippocrates taught physicians to establish trust with their patients.

- Hippocrates taught physicians to observe the emotional states of patients.
- Socrates suggested that curing the soul leads to healing.
- The fundamental principle of traditional Chinese medicine is to honor the spirit.
- Florence Nightingale understood the connection between the physical and spiritual aspects of clients.

Holism guides the total care of the individual as a *complete being* rather than fragmented care focused on parts of the person. Only when nurses treat clients as individuals and not as “cases” to be “cured” do nurses respond in a holistic, caring way. A major role for nurses is to put the *caring* back into the process of healing.

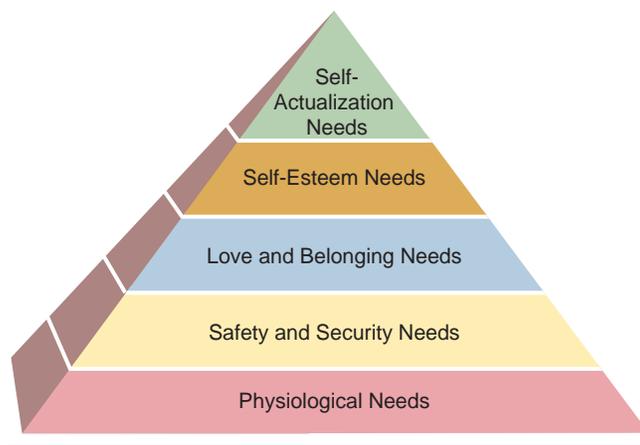

FIGURE 16-4 Maslow’s Hierarchy of Needs ADAPTATION BASED ON MASLOW’S HIERARCHY OF NEEDS

NEEDS AND HEALTH

Since human beings are not merely physiological creatures, basic needs occur in the emotional, sociocultural, intellectual, and spiritual realms as well as the physiological realm. The entire person (body, mind, and spirit) is influenced by satisfaction of needs. A variety of needs emerge, are met, and reemerge in each area of a person’s life.

A **need** is anything that is absolutely *essential* for one’s existence. **Basic human needs** (also known as universal needs) are those that are necessary for every person’s survival. Table 16-2 provides an overview of basic needs.

Maslow (1970) classified human needs on a tier, with the most basic needs as the foundation of the hierarchy (see Figure 16-4). These basic needs must be met before the individual can satisfy higher-level needs. For example, an individual who is starving must be fed before achieving the need for acceptance. An individual with a deficient self-esteem and who is hemorrhaging must have the biologic needs met first. The satisfaction of basic needs enhances wellness. Con-

versely, an impairment in the satisfaction of basic needs can result in a client’s altered health status.

The following section describes basic needs related to the physiological, psychological, sociocultural, intellectual, spiritual, and sexual dimensions. There is extensive discussion of the nursing process as it relates to spirituality and sexuality to demonstrate how the process can be applied to all dimensions of an individual’s being. See Chapter 24 for further further discussion of spiritual needs.

PHYSIOLOGICAL DIMENSION

Providing physiological care focuses on achievement of the basic needs such as oxygenation, circulation, sleep and comfort, nutrition, and elimination. Refer to Chapters 32, 34, 35, and 39 for a thorough discussion of the nurse’s role in helping to meet these basic physiological needs.

PSYCHOLOGICAL DIMENSION

Individuals have psychological needs for security, a sense of belonging, and self-esteem. Nursing actions that promote a sense of emotional comfort include the following:

- Treating the client as a unique individual
- Protecting confidentiality and privacy
- Using touch and personal space in a therapeutic manner
- Recognizing and respecting cultural differences
- Decreasing anxiety through stress management techniques

Goals for clients experiencing unmet psychological needs usually revolve around the following issues:

- Improve self-esteem
- Establish trusting relationships
- Develop social skills
- Cope with losses

SOCIOCULTURAL DIMENSION

As social creatures, all people rely on others to some extent. It is difficult for some people to ask for help or to accept

NEED	EXAMPLE
Physiological	Oxygen, water, food, temperature (shelter and clothing), elimination, sleep, activity, and sex
Psychological	Self-esteem, feelings of security, happiness, sadness
Sociocultural	Feelings of belonging, relationships
Intellectual	Thinking, learning
Spiritual	Being connected to others, having a sense of purpose

Delmar/Cengage Learning

assistance when it is offered. Nurses need to assess the client's degree of dependence. Often, the nurse becomes involved in a balancing act in an effort to maintain equilibrium between the client's needs for dependence and independence.

Empowerment is a process of enabling others to do for themselves. It consists of encouraging the client to be an active participant in treatment rather than a passive recipient of care. Nurses empower clients by teaching them and their families how to develop skills for self-care and for healthier living.

INTELLECTUAL DIMENSION

The intellectual dimension consists of cognitive functions such as judgment, orientation, memory, and the ability to take in and process information. See Chapter 38 for information on cognition and perception.

Piaget conducted landmark studies on children to determine how children think at various developmental stages. See Chapter 18 for a complete discussion of cognitive development throughout the life cycle.

Intellectual functioning can be impaired by multiple factors, including infection, exposure to toxins, substance abuse, trauma, and psychological problems. It is important for nurses to determine the client's intellectual abilities in order to communicate effectively. Using words that are easily comprehended by the client and implementing teaching strategies appropriate to developmental level promote client learning.

SPIRITUAL DIMENSION

Spirituality is multidimensional in that it refers to one's relationship with one's self, a sense of connection with others, and a relationship with a higher power or divine source. Spirituality assists a person in determining the sense of meaning or purpose in one's life. It is an integral component of one's being. Spirituality is somewhat difficult to define as it is determined at an individual level.

Spirituality is *not* the same as religion, which refers to a set of beliefs and practices associated with a particular church, synagogue, mosque, or other formal organized group. Spirituality is a personal, individualized set of beliefs and practices that are not church related.

Health status can have an impact on spiritual beliefs and vice versa. For example, when they are seriously ill, many people turn to religion for support. On the other hand, serious illness may cause some people to question their beliefs; see Chapter 24.

PROMOTING SEXUAL HEALTH

Sexuality is a complex set of human characteristics that refers not just to genital sex but to all the aspects of being male or female, including feelings, attitudes, beliefs, and behavior. Sexuality is a pervasive aspect of the total self from

birth to death and is an important aspect of health for people of all ages. Sexuality includes a person's attitudes toward relationships with people of the same sex, toward relationships with those of the opposite sex, and about touching and being touched. The ways in which people dress, talk, and relate to others are indicators of their sexuality.

Sex roles are culturally determined patterns associated with being male and female. These patterns are developed as a result of cultural expectations, customs, norms, habits, and traditions. For example, the differences between the sexes are evident in the ways infants are treated during their first days of life. Infant boys and infant girls are talked to, cuddled, and, many times, dressed differently. In many cultures, the role of the man is to be strong and protective, whereas the woman is expected to be passive and nurturing. Sex roles change as societal norms change and may be accepted or rejected by individuals. "In North American culture, gender roles are more strictly enforced for males than for females, and males are socially punished for female behavior" (Fontaine, 2009, p. 406).

DEVELOPMENT OF SEXUALITY

Physiological sexual development begins with conception. Chromosomes from each parent transport programming information to the embryo. During the first 6 weeks of fetal development, there is no anatomic difference between males and females. At approximately 7 to 8 weeks, if there is a high level of testosterone, testes develop. Ovaries form in fetuses with lower levels of testosterone (Guyton & Hall, 2005).

Human sexual feelings develop throughout the life span. Feelings, attitudes, and behavior related to sexuality are learned in the family of origin and reflect the cultural context. See the Respecting Our Differences display.

GENDER IDENTITY

Gender identity is a person's sense of identity as a male or female. It is how the person expresses sexuality in behaviors with others of the same and opposite sex. This perspective on one's sexuality is not inborn but rather evolves throughout the life span (Fontaine, 2009).

Sexual orientation describes an individual's preference for ways of expressing sexual feelings. Like all human behavior, sexual behavior is complex. Sexual orientation is a dynamic lifelong process of growth. The prevailing sexual orientation in current Western society is **heterosexuality** (sexual activity between a man and a woman). There are

RESPECTING OUR DIFFERENCES

There are no universally accepted sexual values. For example, a sexual practice that is considered normal in one culture may be prohibited in another culture.

many other types of sexual orientation, including **homosexuality** (sexual activity between two members of the same sex), **bisexuality** (having an equal or almost equal preference for partners of either sex), and **transsexuality** (the belief that one is psychologically of the sex opposite his or her anatomic gender). In many cultural groups, homosexuals, bisexuals, and transsexuals are discriminated against due to their alternative lifestyles. Nurses must respect all individuals, regardless of sexual orientation.

SEXUAL NEEDS

Sexual integrity is an integral part of a person's well-being. Even though there are no universal values about sexuality, individuals do experience some common sexual needs, including:

- Tenderness
- Intimacy
- Sensuality
- Attachment
- Caring
- Procreation

HUMAN SEXUAL RESPONSE

The human sexual response is a combination of physiological responses and emotional responses (thoughts and feelings). Masters and Johnson (1966) were the first to describe the physiological phases that occur during the sexual response. These four phases are experienced by both men and women:

- **Excitement:** Begins with sexual stimulation; characterized by vasocongestion of the genitals (results in vaginal lubrication and penile erection)
- **Plateau:** Characterized by maintenance of sexual arousal and the building of excitement leading to orgasm
- **Orgasm:** A highly pleasurable reflex characterized by muscle spasms and male ejaculation
- **Resolution:** Characterized by a gradual return to the pre-excitement phase

SEXUALITY AND HEALTH

Nurses often encounter clients whose sexuality is threatened. Illness, disability, surgery, medications, and hospitalization may impair a person's sexual integrity. Chronic illnesses may also negatively affect sexuality. Other conditions that may contribute to the development of sexual problems appear in the accompanying box, which lists risk factors for sexual dysfunction.

Medications, especially those used to treat hypertension, diabetes, and depression, can also interfere with normal sexual activity. In such cases, the medication should be changed if possible. Also, clients and their sexual partners need to be informed about the cause of the problems. Chronic pain may also interfere with clients' sexual functioning. Clients who experience chronic pain need to be taught methods for increasing their comfort level (e.g., relaxation techniques). Clients

RISK FACTORS FOR SEXUAL DYSFUNCTION

Anemia	Hypertension
Anxiety	Multiple sclerosis
Cardiovascular disease	Previous traumatic sexual experience
Cigarette smoking	Prostate surgery
Concern about sexual performance	Renal failure
Depression	Spinal cord injuries
Diabetes	Substance abuse
Hormonal imbalances	Thyroid abnormalities
Hyperlipidemia	Vascular bypass surgery

who are hospitalized may experience sexual dysfunction for a variety of reasons. For example, being in unfamiliar surroundings, separation from significant others, and loss of privacy all may interfere with sexual function. Nurses who are sensitive create an atmosphere that communicates consideration of the client's need for confidentiality and a nonjudgmental manner. See the accompanying Spotlight On display on page 292.

NURSING PROCESS AND SEXUALITY

Sexuality is a significant part of health, whether the client is sexually active or not. Talking and listening to clients promotes intimacy. Some nurses, as well as clients, are embarrassed to talk about sexuality. It is imperative to deal with one's own feelings in order to decrease the client's discomfort. Nurses must not express shock or disapproval regarding a client's sexual practices. It is not necessary to change beliefs and attitudes, but it may be necessary to suspend them in order to spare the client any judgment, directly or indirectly. A question as simple as "what sexual concerns do you have?" may be used to introduce the topic of sexuality in a non-threatening manner. Questions about sexual orientation must be asked in a nonjudgmental, matter-of-fact manner.

Assessment

Discussion about sexuality must be sensitive to cultural and religious differences. The sensitive nurse will establish an atmosphere that encourages clients to freely discuss their concerns. Some actions that are conducive to such discussion include the following:

- Ensure privacy and maintain confidentiality.
- Use simple, direct language.
- Provide explanations in terms understood by the client.
- Allow time for the client's questions.
- Demonstrate respect by adopting a nonjudgmental attitude.
- Use open-ended questions to elicit more information.

Sexual assessment may produce feelings of fear, anxiety, indignity, and loss of control in many people. These feelings

SPOTLIGHT ON...

Values

Client's Sexual Activity

You walk into an adult client's room and find her engaged in sexual intercourse with a visitor. You know that the visitor is not the married client's husband. What should you do?

can be alleviated by the sensitivity of the nurse throughout the assessment process.

Before beginning the genitalia examination, consider the client's cultural background and the beliefs that may affect the examination. For example, some cultures forbid assessment of a female by a male caregiver. The accompanying Nursing Checklist describes some guidelines useful in preparing for the sexual assessment.

Diagnosis

The North American Nursing Diagnosis Association International (2009) has established two diagnoses related to sexuality; see Table 16-3.

Planning and Outcome Identification

It is impossible to provide holistic client care without considering the client as a person with sexual needs. In order to plan accurate delivery of nursing care, it is necessary to ask all clients, regardless of age, about their sexual history. Some nurses do not discuss sexual concerns with adolescents due to their own values about adolescents, sexual behavior, and engaging in sexual behavior prior to marriage. In such instances, the nurses are countertherapeutic to clients. Many nurses reflect the societal belief that older adult clients are asexual. Acting on such a belief ignores clients' needs.

Planning takes into consideration the age-specific variations regarding the need for information on sexuality; see Table 16-4 on page 293. Planning of care also calls for consideration of the client's history of possible sexual abuse. No client, regardless of age, should be excluded from evaluation for sexual abuse. See the Safety First display on page 293 for signs of sexual abuse.

TABLE 16-3 Diagnoses Related to Sexuality

DIAGNOSIS	DEFINITION	DEFINING CHARACTERISTICS	RELATED FACTORS
<i>Sexual dysfunction</i>	Change in sexual function that is viewed as unsatisfying, unrewarding, inadequate	<ul style="list-style-type: none"> • Values conflicts • Changed interest in self and others • Verbalization of a sexual problem • Alterations in achieving perceived sex role • Actual or perceived limitations as a result of disease or treatment 	<ul style="list-style-type: none"> • Misinformation or lack of knowledge • Abusive relationships • Physical abuse • Inability to achieve desired satisfaction • Altered body structure or function • Lack of privacy
<i>Ineffective sexuality pattern</i>	Expressions of concern regarding own sexuality	<ul style="list-style-type: none"> • Verbalized difficulties, limitations, or changes in sexual behaviors or activities 	<ul style="list-style-type: none"> • Lack of significant other • Conflict with sexual orientation • Fear of acquiring a sexually transmitted disease • Fear of pregnancy • Ineffective or absent role models • Lack of privacy • Lack of knowledge

Data from North American Nursing Diagnosis Association International. (2009). *Nursing diagnoses—Definitions and classification 2009–2011*. Philadelphia: John Wiley & Sons, Inc.

 **NURSINGCHECKLIST**

PREPARING FOR THE SEXUAL ASSESSMENT

- Review the client’s medical history.
- Greet the client and explain the assessment techniques that you will be using.
- Assess the client’s anxiety level, and provide reassurance that this is normal.
- Ensure that the room temperature is warm and comfortable.
- Use a quiet room that will be free from interruptions; it may be necessary to post a “do not disturb” sign on the door of the client’s room or the examination room.
- Have the client void prior to the examination.

SAFETY FIRST

INDICATORS OF SEXUAL ABUSE

- Bruises, lacerations, scars in genital area
- Presence of sexually transmitted diseases
- Extreme anxiety or guarding during the physical examination
- Suspiciousness or reluctance in answering questions
- Lack of eye contact

TABLE 16-4 Sexual Information: Age-Specific Needs

Children	<ul style="list-style-type: none"> • Parenting skills to decrease possibility of child abuse • Children need to learn to differentiate “good” touching and “bad” touching • Teach children how to say “no” when they are uncomfortable with any touch • The importance of reporting any sexual advances to parents, teachers, or other adults
Adolescents	<ul style="list-style-type: none"> • Education about physiological changes (i.e., signs of onset of puberty; growth and development concepts) • Information on psychosocial responses to physiological changes (i.e., body image changes) • Sexual abuse prevention (including date rape) • Safe sex education (contraception, STD prevention) • Information on sexual preference or orientation
Young adults	<ul style="list-style-type: none"> • Safe sex education (contraception, STD prevention) • Establishment and maintenance of intimate relationships • Pregnancy and childbirth • Parenting skills
Middle-aged adults	<ul style="list-style-type: none"> • Effects of aging on sexuality (e.g., menopause, erectile dysfunction) • STD prevention • Contraception
Older adults	<ul style="list-style-type: none"> • Effects of aging on sexuality • STD prevention • Ways other than intercourse to express sexuality and to meet intimacy needs • Specific information for older women: (1) If vaginal secretions are decreased, use a water-soluble lubricant. (2) Extended foreplay may help in achieving orgasm. (3) Provide a reminder that there is no pregnancy risk. • Specific information for older men: (1) Avoid factors that interfere with circulation (i.e., smoking, alcohol abuse, sedentary lifestyle). (2) Encourage dietary changes to reduce fat and cholesterol. (3) Stress management. (4) Compliance with medications prescribed for diabetes and cardiovascular disorders. (5) Need for a relaxed atmosphere and patience.

Delmar/Cengage Learning

Most states have laws mandating nurses to report suspected incidences of abuse. It is important to also know the employing agency's policies about reporting abuse and suspected abusive situations. It is critical that the nurse plan to establish an environment that communicates a sense of safety to clients who may have experienced abuse, neglect, or exploitation. See Chapter 19 for more information about elder abuse.

Implementation

When addressing sexual concerns of clients, there are two major nursing interventions that must be employed: communication and education. These nursing activities should be implemented in order to help promote clients' sexual health.

Communication skills are necessary to ensure optimal exchange of essential information regarding sexual concerns. Reminding the client that the information discussed is confidential helps reinforce a trusting relationship. Self-awareness can help improve communication and, therefore, overall effectiveness when working with sexual issues, particularly issues that can be value laden such as sexually transmitted diseases (STDs). It is helpful for nurses to assess their attitudes toward sexual practices and STDs. Other nursing actions useful in working with clients with STDs include maintenance of a nonjudgmental approach, avoiding imposing one's own values on the client, and not talking down to the client. See the Spotlight On display.

Education is an integral part of treating clients with sexual problems. The nurse must teach prevention of STDs. It is also important to discuss the effects of aging on the sexual response to allay clients' anxieties and to correct any misperceptions.

Another essential education topic related to sexuality focuses on preventive measures: breast self-examination (BSE)

SPOTLIGHT ON...

Compassion and Values

Clients With Recurrent Sexually Transmitted Diseases

Ask yourself how you feel about clients who seek treatment for recurrent STDs. Will your personal feelings influence the quality of nursing care you provide? How would you feel if such a client showed no interest in learning about ways to avoid contracting STDs?

and testicular self-examination (TSE). See Chapter 27 for details on performing BSE and TSE.

Evaluation

To determine the client's achievement of expected outcomes, nurses use observation and communication. Client and partner verbalizations help in evaluating outcome achievement. The nurse observes the client and partner for expressions of intimacy. During the evaluation process, it is important that the nurse remain open-minded and nonjudgmental when working with clients who may have sex alone, with one partner of the opposite gender, with one partner of the same gender, or with several partners of either gender. Personal values can interfere with, or encourage, the client's achievement of expected outcomes and, thus, discourage or promote the client's sexual wholeness.

Because sexuality is such an integral part of individuals and their health status, it is addressed throughout the remainder of this text when relevant.

KEY CONCEPTS

- Health is a process through which the person seeks to maintain an equilibrium that promotes stability and comfort and varies depending on context and situation.
- Illness is the inability of an individual's adaptive responses to maintain physical and emotional balance and results in an impairment in functional ability.
- Wellness is the condition in which an individual functions at optimal levels and is a dynamic process that occurs in varying degrees.
- The various theoretical models of health, such as the clinical, health-belief, high-level wellness, social learning, host-agent-environment, and health promotion models, help nurses to understand the relationship between the experience of health and illness and clients' behaviors in response to this process.
- The two major classifications of illness are acute and chronic. Acute illness is usually characterized by rapid onset, short duration, and intense symptoms. Chronic illness is usually characterized by a gradual insidious onset, lifelong duration, and irreversible changes.
- Lifestyle, locus of control, self-efficacy, health care attitudes, and self-concept are examples of variables that influence health-promoting behaviors.
- The three approaches to health maintenance (health promotion, health protection, and disease prevention) are centered on the individual's responsibility in promoting one's own health.
- Nurses play a key role in helping clients to adopt healthy lifestyles and use approaches such as role modeling and formal teaching to motivate client change.

- Nurses must focus their efforts on improving the health status of vulnerable populations.
- The satisfaction of basic human needs, such as physiological, psychological, sociocultural, intellectual, and spiritual needs, is necessary for every person's survival.
- An impairment in meeting basic needs results in an altered health status.
- A holistic viewpoint helps nurses to recognize the body-mind connection and see the client as a whole person rather than fragmented parts.
- Spirituality is the aspect of a person that seeks a sense of meaning and purpose in life and that also can provide support in times of stress.
- Sexuality affects an individual's relationships with others, male and female, and evolves throughout a person's life.

REVIEW QUESTIONS

- Which of the following client statements indicates self-efficacy?
 - "Every problem has a solution."
 - "I've been on so many diets before, why should this one work?"
 - "I've solved problems before, so I can probably do so again."
 - "There's no point in trying to change."
- Which of the following statements accurately describes Pender's health promotion model? Select all that apply.
 - A person is more likely to perform health-promoting behaviors when he or she can identify the benefits of the behavior.
 - Group values exert much influence on an individual's behaviors.
 - Health is viewed as an attempt to achieve one's fullest potential.
 - Individuals who perceive health as being within their control are more likely to perform healthy behaviors.
 - People engage in self-promoting behaviors when they value health.
 - People who are ill are more motivated than healthy ones to develop health-promoting behaviors.
- Which of the following nursing statements encourages a client to rely on an internal locus of control?
 - "I think that an exercise program is just what you need."
 - "We'll have to see what the prescribing practitioner recommends for you."
 - "What has worked for you in the past?"
 - "You should start losing weight as soon as possible."
- Listed below are nursing activities implemented to promote a client's health. Rank them in terms of priority according to Maslow's hierarchy of needs. Rank in order of 1 = to be done first, 2 = to be done second, and so forth.
 - _____ Administering analgesic medication for a headache
 - _____ Identifying client strengths in order to boost self-esteem
 - _____ Lowering the client's bed and placing the call light within reach
 - _____ Referring the client to a support group that consists of peers with similar health problems
- A nurse is preparing to talk to a client about healthy lifestyle changes. Which of the following actions must the nurse do initially with the client?
 - Assess the client's motivation for change
 - Assess the client's pain level
 - Determine the client's current knowledge level
 - Distribute teaching materials that are written at the client's level of comprehension

CHAPTER 17

Family and Community Health

COMPETENCIES

1. Discuss family structure, types, roles, and functions.
2. Describe characteristics of healthy families.
3. Discuss theoretical perspectives of family development.
4. Discuss domestic violence as a threat to family integrity.
5. Identify health-related community needs.
6. Differentiate community health nursing and public health nursing.
7. Discuss nursing's role in promoting community health.
8. Describe nursing's role in disaster preparedness.

KEY TERMS

aggregates
community
community health nursing
disaster

enmeshment
epidemiology
family
family functions

family roles
family structure

Individuals do not exist in a vacuum, but instead interact with and are products of families and communities. Families and communities benefit from nursing care, as do individuals. This chapter describes the health-related needs of families and communities and the nursing responses that address those needs.

FAMILY HEALTH

A **family** is a dynamic system of people living together who are united by significant emotional bonds. The family is the basic unit of society in that it provides the foundation for a person's view of the world and social interactions.

Due to sociocultural changes, the American family is undergoing transformation. For example, increasing divorce rates, cohabiting adults, and adoption by unmarried individuals have led to a proliferation of single-parent families. The traditional concept of family is being challenged by many living arrangements in current society; for example, many individuals who are unrelated through biological or legal bonds and live together often are considered to be a family. It is necessary for the nurse to ask clients who they consider to be their family members in order to include significant others in the provision of health care. The family performs a variety of functions, including the transmission of cultural values from one generation to the next. The family also teaches socially acceptable behaviors and provides a sense of belonging to its members. Early family interactions help children learn important skills such as problem solving and communication.

FAMILY STRUCTURE

Family structure is the form that a family takes in order to maintain function. Family structures vary depending on cultural context. There is no “typical” family structure even though the nuclear family is often portrayed as such by the media; see Figure 17-1. Types of families include, but are not limited to, the following:

- Nuclear family—composed of husband, wife, and children (naturally conceived, adopted, or both)
- Blended family—combination of two divorced families through remarriage; may include stepchildren, half-siblings, or combinations
- Extended family—usually members of a nuclear family and other blood-related people (such as grandparents, aunts, uncles, and cousins)

Table 17-1 on page 299 further describes various forms of families.

The structure of a family affects its health status. An extended family has several members living in one household;

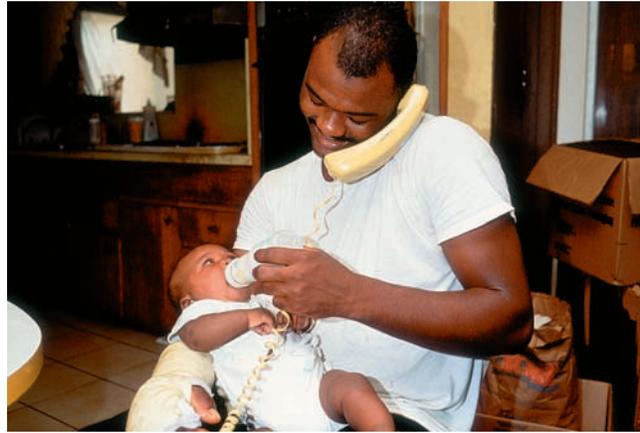

FIGURE 17-1 There are diverse family structures and types, as shown in these photographs DELMAR/CENGAGE LEARNING

therefore, people are available to help care for the sick. A person living in a nuclear family often experiences self-reliance. A client who has a nuclear family “often has different needs from

TABLE 17-1 Various Family Forms

FAMILY STRUCTURE	EXAMPLES
Legally married	<ul style="list-style-type: none"> • Traditional nuclear • Blended • Coparenting
Dual-career	<ul style="list-style-type: none"> • Both adults in same household are employed • Commuter marriages
Adoptive	<ul style="list-style-type: none"> • Adults (either married or single) and one or more children
Foster	<ul style="list-style-type: none"> • Adults (either married or single) who care for children on a temporary basis
Voluntarily childless	<ul style="list-style-type: none"> • Married adults who have decided not to procreate
Unmarried	<ul style="list-style-type: none"> • Adults who never married • Cohabitation, with or without children • Same-sex relationship
Formerly married	<ul style="list-style-type: none"> • Widowed • Divorced (includes custodial parent, joint custody parents, and noncustodial parents)

Extended family	<ul style="list-style-type: none"> • Grandparents, parents, and children • Adult children who move back home with parents • Siblings living together, with or without parents or children

Delmar/Cengage Learning

the client with numerous extended family members living in the same household or nearby” (Hunt, 2009, p. 10).

FAMILY ROLES AND FUNCTIONS

Family roles are the behaviors expected of family members. These roles are learned and transmitted within the family unit and help the family to fulfill its functions. Roles also provide the foundation for the children’s future interactions as adults. **Family functions** are the roles that allow family members to adapt in order to develop as individuals and as members of the family unit. Family roles include, but are not limited to, the following:

- Nurturance and support
- Allocation of resources
- Development of life skills
- Division of labor
- Socialization of members (Antai-Otong, 2007)

CHARACTERISTICS OF HEALTHY FAMILIES

The family unit exerts much influence on the health of its individual members. For example, the family that places a

high value on proper nutrition will encourage children to develop dietary practices that will promote health throughout the life cycle. Each family is a dynamic system whose members form a unit that interacts with the community. Differentiating healthy and unhealthy families is often difficult. Some traits of a healthy family are as follows:

- Supporting members
- Teaching respect for others
- Helping with problem solving
- Communicating

Healthy families are often described as functional, in that they are able to cope with stressors and deal with crises as they arise. Eggenberger and Nelms (2007) state that “being a family unit is what gives most families the ability to endure the emotional upheaval and suffering that come with the critical illness experience” (p. 1628). See the accompanying Uncovering the Evidence display on page 300. *Dysfunctional* families, on the other hand, often lack problem-solving skills and deteriorate in adaptive abilities when confronted with stressors. Table 17-2 on page 301 compares healthy and unhealthy families. Healthy families typically have family rituals, or traditions, that promote bonding between family members; see the accompanying Spotlight On display.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Being Family: The Family Experience When an Adult Member Is Hospitalized with a Critical Illness”

AUTHORS

S. K. Eggenberger and T. P. Nelms

PURPOSE

To understand the family experience when an adult family member is hospitalized for treatment of a critical illness.

METHODS

Semistructured interviews were conducted with 11 families of critically ill, hospitalized adults. The family experience was examined according to Van Manen’s concepts of lived space, lived relation, lived body, and lived time.

FINDINGS

Most families are able to cope with the stressors of a critical illness and hospitalization as a result of a strong sense of being a family. Family bonds increase the strength of family members during a crisis.

IMPLICATIONS

Nurses can exert a powerful influence on families by acting on a commitment to be with the family. Family caring is increased by the presence of caring nurses.

Eggenberger, S. K., & Nelms, T. P. (2007). Being family: The family experience when an adult member is hospitalized with a critical illness. *Journal of Clinical Nursing*, 16(9), 1618–1628.

FAMILY DEVELOPMENT THEORIES

The developmental approach to viewing families is similar to the developmental approach to viewing individuals. That is, the family unit has a developmental process with expected tasks that are to be achieved at each developmental stage. The family that achieves specific developmental tasks is considered to be a healthy family. The way in which a family achieves the tasks of one developmental stage greatly influences the family’s ability to handle subsequent developmental issues.

The classic work of Duvall and Miller (1985) is often used as the basis for assessing a family’s developmental progress. However, Duvall’s theory is somewhat limited in that it assumes that the family unit consists of a married couple that becomes involved in child-rearing activities. From Duvall’s perspective, the nuclear family is the standard by which all others are assessed. Duvall’s model describes eight stages of the family life cycle.

SPOTLIGHT ON...

Family Rituals

Apply the following questions to your own family:

What are some traditions valued by your family (e.g., special holiday celebrations)?

Are there rituals performed by your family (e.g., having a special meal or going to a special place on vacation)?

How have these traditions and rituals strengthened your sense of family?

A newer perspective of the family development cycle was proposed by Carter and McGoldrick in 1989, with several revisions over time. Carter and McGoldrick’s (2004) model describes six stages of the family life cycle that are more reflective of adult needs in current society. Table 17-3 on page 302 compares the models developed by Duvall and by Carter and McGoldrick.

THREATS TO FAMILY INTEGRITY

A healthy family supports and protects its members from harm. However, several variables, such as violence and poverty, can interfere with the family’s health and integrity. One major threat is domestic violence, which is becoming an increasing problem for many family units.

Domestic Violence

Domestic violence, which occurs in all socioeconomic groups, is an ever-increasing social problem; see the accompanying Spotlight On display. Approximately 10% of children in the United States live in homes with reported violence (Moore, Probst, Tompkins, Cuffe, & Martin, 2007). In addition to its impact on specific victims, domestic violence has negative effects on communities. Several studies document the harmful effects of family violence that may include acute trauma, death, unwanted pregnancy, depression, suicide, posttraumatic stress disorder, and substance abuse (Binder et al., 2008; Bradley et al., 2008; Moore et al., 2007; Widom, DuMont, & Czaja, 2007). Victims of violence within families are primarily children, older adults, and female spouses or intimate partners. Children are affected by family violence even if they are not the direct victims; witnessing domestic violence can have adverse effects on a child’s emotional well-being. Domestic violence becomes a repetitious cycle in that people who were abused as children learn that violence is normal behavior; thus, they will use violence in an attempt to solve problems.

CHILD ABUSE According to the Administration for Children and Families, U.S. Department of Health and Human Services (2008), 950,000 children were victims of abuse or

TABLE 17-2 Comparison of Healthy and Unhealthy Families

CHARACTERISTIC	FUNCTIONAL (HEALTHY) FAMILY UNIT	DYSFUNCTIONAL (UNHEALTHY) FAMILY UNIT
Communication	<ul style="list-style-type: none"> • Clear, direct, and truthful 	<ul style="list-style-type: none"> • Ambiguous, indirect, dishonest

Delmar/Cengage Learning

neglect in 2006. This number most likely does not reflect the total number of children abused because underreporting is common. Young children are more vulnerable to abuse than are older ones; see Figure 17-2.

Many factors are related to child abuse and neglect. These factors include stress, financial problems, inadequate parenting skills, parental substance abuse, parental impulsivity, social isolation, and parents themselves being abused as

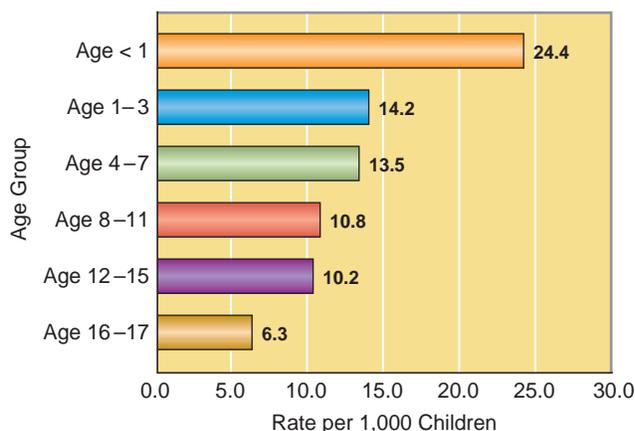

FIGURE 17-2 Child Victimization Rates by Age Group, 2006
 DATA FROM ADMINISTRATION FOR CHILDREN AND FAMILIES, U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES. RETRIEVED FROM [HTTP://WWW.ACF.HHS.GOV/PROGRAMS/CB/PUBS/CM06.PDF](http://www.acf.hhs.gov/programs/cb/pubs/cm06.pdf).

children. Child abuse results in physical pain and emotional damage that may last a lifetime.

OLDER ADULT ABUSE Maltreatment of older adults takes many forms, including physical, sexual, and psychological abuse and financial exploitation. In the majority of cases, the perpetrator of abuse of older adults is a family member, usually an adult child or spouse. Factors associated with abuse of older adults include increasing age, nonwhite race, low income status, functional impairment, and impaired cognitive ability. Older adults who have chronic illnesses are also at increased risk. Social isolation is a serious problem that affects many elderly, especially those with chronic illnesses (Holley, 2007). Lack of transportation, lack of employment, and strained relationships with caregivers may lead to inadequate care, including maltreatment. See Chapter 19 for more discussion on maltreatment of older individuals.

SPOUSE AND PARTNER ABUSE The vast majority of assaults by partners are directed at women. Women are also at greater risk than men for being killed during intimate partner violence (Hunt, 2009, p. 299). The greatest cause of injury to women in the United States is violence (Fontaine, 2009). Some of the risk factors for intimate partner abuse include young age, low income status, pregnancy, mental health problems, substance abuse by victims or perpetrators, separated or divorced status, and history of childhood sexual or physical abuse.

TABLE 17-3 Family Developmental Stages

DUVALL	CARTER AND MCGOLDRICK	DEVELOPMENTAL TASKS
No formal stage identified	1. The unattached young adult	<ul style="list-style-type: none"> • Successfully separate from parents as a young adult • Develop financial independence • Accept emotional responsibility for self
1. Marriage: the beginning family	2. The newly married couple	<ul style="list-style-type: none"> • Develop and commit to a new family unit (establishment of couple identity) • Adjust to parenthood
2. Childbearing families	3. Families with young children	<ul style="list-style-type: none"> • Establish and maintain a household • Incorporate new members into the family unit
3. Families with preschool children		<ul style="list-style-type: none"> • Nurture children • Adjust to separation by parents and children
4. Families with school-aged children		<ul style="list-style-type: none"> • Socialize and educate children • Adapt as a family to school influences
5. Families with teenagers	4. Families with adolescents	<ul style="list-style-type: none"> • Balance adolescents' freedom and responsibility
		<ul style="list-style-type: none"> • Develop flexibility to respond to increased independence of children • Extend caring activities to previous generation (aging parents, grandparents)
6. Families launching young adults	5. Launching children	<ul style="list-style-type: none"> • Let go of young adult children • Accept exits from and entrances into family unit • Renegotiate marital relationship
7. Middle-aged parents (empty nest up to retirement)		<ul style="list-style-type: none"> • Reinvest in couple identity • Accept changes in generational roles (i.e., grandparenting)
8. Retirement to death of both spouses	6. Families in later life	<ul style="list-style-type: none"> • Review life and integrate it • Accept the reality of death

Adapted from Carter, B., & McGoldrick, M. (2004). *The expanded life cycle: Individual, family, and societal perspectives* (3rd ed.). Boston: Allyn & Bacon; Duvall, E. M., & Miller, B. C. (1985). *Marriage and family development* (6th ed.). New York: Hitchcock, J. E. (2006). Frameworks for assessing families. In J. E. Hitchcock, P. E. Schubert, & S. A. Thomas (Eds.), *Community health nursing: Caring in action* (2nd ed.). Ventura, CA: CRAM101.

NURSING RESPONSE TO FAMILY VIOLENCE The best treatment of family violence is prevention; see Table 17-4 on page 303. Prevention is based on assessment and education; therefore, nurses in every practice setting and specialty must be vigilant for signs of violence. Nurses who work in schools, emergency departments, outpatient clinics, and women's health and geriatric settings should be especially vigilant for signs of abuse. When abuse is suspected, the nurse should document the findings and report them to the appropriate protective services agencies. Documentation should include verbatim statements of the victim, photographs, and description of the injuries. Telephone numbers of local shelters and crisis lines should be given to the client. Clients who have been abused also need to be referred to mental health professionals for counseling.

Nurses who work in the community have a unique opportunity to detect early signs of domestic violence. For example, school nurses are often the first people to detect signs of abuse in children; home health nurses may be the first to detect signs of abuse of older adults.

Individuals who have suffered abuse, regardless of age, need an environment in which they feel safe to talk about their experiences. The nurse establishes a sense of psychological safety by establishing rapport and laying the foundation for trust. In order to do this, the nurse must be nonjudgmental when talking with both the abused person and the suspected perpetrator. Self-awareness helps the nurse increase sensitivity when listening to clients discussing emotional issues such as abuse and neglect.

TABLE 17-4 Levels of Prevention of Child Abuse

LEVEL OF PREVENTION	EXAMPLES
Primary	<ul style="list-style-type: none"> Parenting classes that provide information about childhood growth and development Identification of at-risk households Telephone “hot lines” for parents who are feeling out of control
Secondary	<ul style="list-style-type: none"> Behavior management programs for at-risk families, such as those referred to child protective services Assessment of signs of abuse
Tertiary	<ul style="list-style-type: none"> Removal of children from homes with abusive parents Family therapy for abusive parents

Data from Kaakien, J. R., Hanson, S. M., & Birenbaum, L. K. (2007). Family development and family nursing assessment. In M. Stanhope & J. Lancaster (Eds.), *Community and public health nursing* (7th ed.). St. Louis, MO: Mosby.

SPOTLIGHT ON...

Prevalence of Violence

Do you believe that family violence is prevalent in your community? Read your local newspaper for 1 week. Observe the number of stories that are printed about domestic violence. Consider what public initiatives could be taken to reduce the incidence of domestic violence in your community.

Poverty

Food insecurity means having limited access to nutrients; obviously, there is a link between poverty and food insecurity. As defined by the Economic Research Service of the U.S. Department of Agriculture (2006), food insecurity occurs when a member of a household has an altered eating pattern as a result of lack of money for food. There are higher rates of health problems in families affected by food insecurity. “Mental health problems in mothers and children are more common when mothers are food insecure, a stressor that can potentially be addressed by social policy” (Whitaker, Phillips, & Orzol, 2006, p. 868). Nurses have an opportunity to improve the health status of families through advocacy and education of legislators who develop social policies.

Detecting Abuse

Home health and public health nurses have a unique opportunity to detect indicators of abuse (in children, elders, and intimate partners). Assessing the home and community environment can provide cues to abuse and, thus, trigger early intervention.

COMMUNITY HEALTH

Every **community** (a group of people united by some common element or shared interest) is different and, therefore, has its own specific needs. However, all communities need to be safe and promote the health of their constituents. The safety and health of any community may be threatened by epidemics or disasters, either natural or man-made. “The measure of a healthy community, then, is not the complete absence of problems, but rather how well the community prepares for and responds to them” (Dreher, Shapiro, & Asselin, 2006, p. 120). Community health is achieved through meeting the collective needs of the community and society by identifying problems and supporting community participation in the process. One way to measure the health of a community is to assess its progress in achievement of the Leading Health Indicators established by the U. S. public health department’s Healthy People initiative; see Chapter 16 for further discussion. Community-based nursing focuses on individuals, families, and **aggregates** (subgroups) living and working within a community. An aggregate is a particular population of people with a common identifying variable; there are no relationships among members of an aggregate other than similar factors. Examples of aggregates include teenage pregnant girls, persons who smoke cigarettes, and people with tuberculosis.

When working with an individual or family, the community health nurse considers them within the context of the entire community. The specialty area of **community health nursing** is divided into public health and home health care nursing. The major goal of community health nursing is the preservation and improvement of the health of populations and communities worldwide. In order to accomplish this goal, community health nurses practice in neighborhoods and homes in rural and urban areas. Settings in which community health nurses commonly practice include:

- Primary care offices
- Schools
- Workplaces
- Public health units

The services provided by community health nurses range from examining infants in a clinic setting to providing case

management services to frail older adults in the home. Community health nurses also identify vulnerable populations, such as the homeless, those living in poverty, those exposed to communicable diseases, and those living in violence-prone neighborhoods, in order to plan specific strategies to address the special needs.

Community health nurses conduct epidemiological investigations and participate in health policy analysis and decision making. **Epidemiology** is the study of the distribution and determinants of health-related states or events in populations. For example, “invasive methicillin-resistant *Staphylococcus aureus* (MRSA) infection affects certain populations disproportionately. It is a major public health problem ...” (Klevens et al., 2007, p. 1763). One study (Hota et al., 2007) states that the risk for development of community-associated methicillin-resistant *Staphylococcus aureus* (CA-MRSA) is increased in people who are incarcerated or who live in public housing complexes. Community health nurses target these at-risk populations for surveillance and preventive education. Community nursing uses a holistic approach that requires both disease prevention and health promotion activities, including education and advocacy. Nurses who work in the community make a commitment to improving the health of the entire community.

The nursing process can be applied to individuals, families, and aggregates. Use of the nursing process enables nurses to:

- Determine needs and health concerns that could lead to potential health risks
- Formulate a plan of care incorporating health promotion activities such as teaching and counseling
- Evaluate plans of care to determine whether they are promoting client well-being

PUBLIC HEALTH NURSING

Public health nursing, a specialization within community-based nursing, has never before been so essential to the health of U.S. citizens. The emergence of new infectious diseases (such as SARS, H1N1 virus, and *Clostridium difficile* infections) and bioterrorism threats increase the demand for services from a health care system at a time when the nursing workforce is becoming more scarce.

The public health perspective focuses on prevention as opposed to illness. In order to promote community health, public health nurses perform the following functions:

- Prevention of epidemics and spread of disease
- Protection against environmental hazards
- Prevention of injuries
- Promotion of health behaviors
- Response to disasters

Some public health initiatives have led to improvements in blood pressure control, automobile safety restraints, and cessation of tobacco use by many. See Table 17-5 for a listing of some of the factors affecting the public’s health, with specific nursing interventions.

DISASTER PREPAREDNESS

A **disaster** is any event (human-made or natural) that causes destruction that cannot be relieved without assistance. See the Community Considerations display on page 305 for examples.

The disaster plan for any community must include preparation for both physical and emotional reactions to the disaster. Nurses have always been actively involved in disaster preparedness and response. Nurses play a vital role in disaster response and usually work in extremely challenging

TABLE 17-5 Nursing Responses to Factors Affecting Public Health

VARIABLE	EXAMPLES	NURSING RESPONSES

Types of Disasters

Natural Disasters

- Blizzards
- Droughts
- Earthquakes
- Floods
- Forest fires (i.e., ignited by lightning)
- Hurricanes
- Tornadoes

Human-Made Disasters

- Bombings
- Fires (arson)
- Toxic spills
- Transportation accidents
- Wars

circumstances to deliver necessary care. For example, the nurse may need to provide care in the absence of electricity, water, adequate number of care providers, or other essential resources. In 2008, the American Nurses Association (ANA) developed guidelines for adapting standards of care during disasters and other emergencies. According to the ANA (2008, p. 10):

Decision-making during extreme conditions, however, shifts ethical standards to a utilitarian framework in which the clinical goal is the greatest good for the greatest number of individuals. As a result, not everyone may receive the optimal services that might be available at other times or places.

Nursing Process in a Disaster

Imagine yourself as part of the disaster response team following the devastation of two hurricanes. Consider the potential human responses of the hurricane victims as you study these questions.

What is being done to meet the public's needs?
What are the potential human responses to the disaster?

What is being done to help the internal environment of the individuals affected?

What is being done to help the community cope and rebuild?

Consider how your answers might vary if these questions were applied to victims of a terrorist act.

Nurses are expected to meet the following standards, which have been identified by the ANA as the most critical standards for provision of care during an extreme emergency:

- Maximize safety of care provider and client
- Maintain respiration and circulation
- Maintain or establish infection control interventions (ANA, 2008, p. 16)

The accompanying Spotlight On display lists questions to consider when applying the nursing process in a disaster.

KEY CONCEPTS

- A family is a dynamic system of people living together who are united by significant emotional bonds.
- The family is the basic unit of society in that it provides the foundation for a person's view of the world and social interactions.
- The nurse must ask clients who they consider to be their family members in order to include significant others in the provision of health care.
- Family structure is the form that a family takes in order to maintain function. Family structures vary depending on cultural context.
- Family roles are the behaviors expected of family members. These roles are learned and transmitted within the family unit and help the family to fulfill its functions.
- Family functions are the roles that allow family members to adapt in order to develop as individuals and as members of the family unit.
- A healthy family is characterized by these traits: communicates and listens, supports its members, teaches respect for others, develops trust, plays and shares a sense of humor, has a strong sense of family (as evidenced by rituals and traditions), and seeks help with problems as necessary.
- Healthy families are often described as functional, in that they are able to cope with stressors and deal with crises as they arise.
- Dysfunctional families lack problem-solving skills and deteriorate in adaptive abilities when confronted with stressors.

- The family unit has a developmental process with expected tasks that are to be achieved at each developmental stage.
- Domestic violence, which occurs in all socioeconomic groups, is an ever-increasing social problem.
- Domestic violence becomes a repetitious cycle in that people who were abused as children learn that violence is normal behavior; thus, they may use violence in an attempt to solve problems.
- In the majority of cases, the perpetrator of abuse of older adults is a family member.
- The vast majority of assaults by partners are directed at women.
- The best treatment of family violence is prevention.
- Community-based nursing focuses on individuals, families, and aggregates living and working within a community.
- The major goal of community health nursing is the preservation and improvement of the health of populations and communities worldwide.
- Community health nurses practice in neighborhoods and homes in rural and urban areas. Settings in which community health nurses commonly practice include primary care offices, schools, workplaces, and public health units.
- Public health nursing is a specialization within community-based nursing practice.
- New infectious diseases and bioterrorism threats are increasing the demand for public health services.
- The public health perspective focuses on prevention as opposed to illness.
- Public health nurses perform the following functions: prevention of epidemics and spread of disease; protection against environmental hazards; prevention of injuries; promotion of health behaviors; and response to disasters.
- A disaster is any event (human-made or natural) that causes destruction that cannot be relieved without assistance.
- Nurses have always been actively involved in disaster preparedness and response.

REVIEW QUESTIONS

1. A school nurse is teaching a class on domestic violence to high school students. Which of the following student statements indicates a need for further teaching?
 - a. "Abusers are often excessively jealous and possessive."
 - b. "If you are educated and have money, abuse does not happen."
 - c. "The abuser will often apologize and promise to stop."
 - d. "Violence often begins in a dating relationship."
2. The community health nurse is teaching a parenting skills class to new parents. Which of the following parent statements indicates that the teaching has been effective? Select all that apply.
 - a. "In order to be considered a family, those living together must be related by blood."
 - b. "My family is typical because we have a husband, wife, and soon-to-be two children."
 - c. "My husband has a child by another marriage, so when our child is born we will be a blended family."
 - d. "Our family's beliefs may affect the health of our children."
 - e. "There are many different types of families."
3. Which of the following is a trait of a functional (healthy) family?
 - a. Ambiguous communication
 - b. Enmeshment
 - c. Hierarchy of rules
 - d. Timely feedback
4. Approximately _____% of children in the United States live in homes with reported violence. (Fill in the blank.)
5. Two priority actions of the community nurse that address family violence are:
 - a. Assessment
 - b. Diagnosing
 - c. Education
 - d. Interdisciplinary communication
 - e. Planning
 - f. Political advocacy
6. Which of the following is an example of tertiary prevention activities for the nurse to perform with abused children?
 - a. Assessing for signs of child abuse
 - b. Identifying at-risk households
 - c. Performing family therapy for abusive parents
 - d. Teaching parenting classes on developmental milestones

7. According to the American Nurses Association, which of the following standards of care must be implemented during response to a disaster? Select all that apply.
- a. Airway, breathing, and circulation maintenance
 - b. Confidentiality
 - c. Documentation of care
 - d. Elective procedures
 - e. Infection control practices
 - f. Safety for both nurse and client(s)

The strongest principle of growth lies in human choice.

—GEORGE ELIOT (IN HERRMANN, 1990)

CHAPTER 18

The Life Cycle

COMPETENCIES

1. Discuss basic principles of growth and development.
2. Explain factors that influence growth and development.
3. Discuss the major theories related to physiological, psychosocial, cognitive, moral, and spiritual development.
4. Identify critical milestones for each developmental stage.
5. Describe specific nursing interventions that are relevant to each developmental stage.

KEY TERMS

accommodation
 adaptation
 adolescence
 anorexia nervosa
 assimilation
 bonding
 bulimia
 critical period
 development
 developmental tasks
 embryonic stage
 fetal alcohol syndrome

fetal stage
 fixation
 germinal stage
 growth
 infancy
 intrapsychic theory
 learning
 maturation
 menarche
 middle adulthood
 moral maturity
 neonatal period

obesity
 older adulthood
 preadolescence
 prenatal period
 preschool stage
 puberty
 school-age period
 self-concept
 teratogenic substance
 toddler
 young adulthood

From conception to death, individuals are constantly changing. Physical growth, psychosocial development, emotional maturation, cognitive development, moral development, and spiritual growth occur throughout life. Progression through each developmental stage influences health status. A thorough understanding of developmental concepts is essential for the delivery of quality nursing practice. This chapter discusses the changes occurring in each stage of the life cycle.

FUNDAMENTAL CONCEPTS OF GROWTH AND DEVELOPMENT

Development occurs continuously through the life span. Adults continue to have transition periods during which growth and development occur. Individuals experience changes in all dimensions of life, from conception to death.

Growth is the quantitative (measurable) changes in physical size of the body and its parts, such as increases in cells, tissues, structures, and systems. Examples of growth are physical changes in height, weight, bone density, and dental structure. Even though growth is not a steady process through the life cycle, growth patterns can be predicted. Variations in growth, such as rapid increases contrasted with slower rates of physical change, occur with each individual. Rapid growth is most common in the prenatal, infant, and adolescent stages. **Development** refers to behavioral changes in functional abilities and skills. Thus, developmental changes are qualitative, that is, not easily measured. **Maturation** is the process of becoming fully grown and developed and involves physiological and behavioral aspects of an individual. Maturation depends on biological growth, functional changes, and **learning** (assimilation of information with a resultant change in behavior). During each developmental stage of the life cycle, certain goals (**developmental tasks**) must be achieved. These developmental tasks set the stage for future learning and adaptation.

The **critical period** is the time of the most rapid growth or development in a particular stage of the life cycle.

During these critical periods, an individual is most vulnerable to stressors of any type.

Growth, development, maturation, and learning are interdependent processes. For learning to occur, the individual must be mature enough to grasp the concepts and make required behavioral changes. Cognitive maturation precedes learning. Physical growth is also a prerequisite for many types of learning; for example, a child must have the physical ability to control the anal sphincter before toilet training skills are learned.

PRINCIPLES OF GROWTH AND DEVELOPMENT

All persons have individual talents and abilities that contribute to their development as unique entities. *There are no absolute rules in predicting the exact rate of development for an individual.* However, some general principles relate to the growth and development of all humans (see Table 18-1 on page 311).

The sequence of development is predictable even though the emergence of specific skills varies with each person. For example, not all infants roll over at the same age, but most roll over before they crawl.

FACTORS INFLUENCING GROWTH AND DEVELOPMENT

Multiple factors such as heredity, life experiences, health status, and cultural expectations influence a person's growth and development. The interaction of these factors greatly influences how an individual responds to everyday situations. The choices a person makes regarding health behaviors are also greatly determined by these factors.

Heredity

A complex series of processes transmits genetic information from parents to children. The genetic composition of an individual determines physical characteristics such as skin

TABLE 18-1 Principles of Growth and Development

PRINCIPLE	EXAMPLE/DESCRIPTION
Development occurs in cephalocaudal (head-to-toe) direction.	An infant raises the head before sitting up.
Development occurs in a proximodistal manner.	The infant is able to move the arms before picking up objects with the hands and the fingers. Functions closer to the midline (proximal) of the body develop before functions farther away from the body's midline (distal).
Development occurs in an orderly manner from simple to complex and from the general to the specific.	An infant crawls before walking. A child holds a crayon with the entire hand before being able to grasp it between thumb and finger. Gross motor control is achieved before fine motor coordination.
The pattern of growth and development is continuous, orderly, and predictable. However, growth and development do not proceed at a consistent rate.	Periods of rapid growth (similar to growth spurts of adolescence) alternate with periods of slower growth (as seen in middle adulthood).
All individuals go through the same developmental processes.	Individual differences occur, but the process is consistent.
Every person proceeds through stages of growth and development at an individual rate.	A child who grows more slowly may be shorter than other children of the same age.
Every stage of development has specific characteristics.	An infant is dependent on others for physical and emotional survival. Adolescence is characterized by a search for identity.
Each stage of development has certain tasks to be achieved or acquired during that specific time. Tasks of one developmental stage become the foundation for tasks in subsequent stages.	An infant must master the psychological task of developing trust in order to mature as an adolescent who can establish a separate identity.
Some stages of growth and development are more critical than others.	The first trimester of pregnancy is a critical time for fetal development. During this critical phase, the developing human is most vulnerable to damage from toxins (e.g., drugs, chemicals, viruses).

Delmar/Cengage Learning

color, hair texture, facial features, body structure, as well as a predisposition to certain diseases (e.g., Tay-Sachs, sickle cell anemia). Heredity is a genetic blueprint from which an individual grows and develops; it determines to a great extent the rate of physical and mental development. See the accompanying Respecting Our Differences display.

Life Experiences

A person's experiences can also influence the rate of growth and development. For example, compare physical growth rates of a child whose family can afford food, shelter, and health care with those of a child whose family has little, if any, resources. The child whose family is economically disadvantaged has a higher risk of experiencing physical and mental delays in growth and development.

RESPECTING OUR DIFFERENCES

Nature or Nurture?

What determines a person's behavior—heredity or environment? This "nature versus nurture" issue remains a controversy today. What do you think is most important in determining a person's behavior: an individual's genetic predisposition or the response of other people and socialization? This question has no simple answers. As you continue to develop in your professional role, keep an open mind regarding the factors influencing behavior.

Another example of the influence of life experiences is an older adult who is enjoying retirement and has both an adequate income and an active support system. If this individual had an impairment in any of these variables, psychological development would likely be affected in a negative way.

Health Status

Individuals experiencing wellness are progressing normally along the life cycle. However, illness or disability can interfere with the achievement of developmental milestones. Individuals with chronic conditions will often experience a delay in meeting developmental milestones.

Cultural Expectations

Society expects people to master certain skills in each developmental period. The age at which an individual masters a particular task is determined in part by culture. For example, the time for mastery of toilet training is greatly influenced by cultural norms. The following are examples of how societal expectations hinder one's growth and development:

- A child who grows up in an economically deprived home may receive inadequate food, shelter, emotional nurturing, and intellectual stimulation with resultant impairments in physical, psychosocial, and cognitive development.
- A woman may not be expected to fully use her intellectual abilities; thus, she has altered cognitive development.
- A man may be discouraged from showing tenderness and nurturing behaviors; such discouragement results in dysfunctional psychosocial development.

See the accompanying Spotlight On display.

THEORETICAL PERSPECTIVES OF HUMAN DEVELOPMENT

Nurses must have a thorough understanding of human growth and development in order to provide individualized care. It is necessary to remember that chronological age and developmental age are not synonymous. An overview of the major developmental theories is presented in the following text. These theories are discussed more fully in the specific sections about each developmental period.

SPOTLIGHT ON...

Values

Stereotyping

Consider how people are stereotyped today. Society labels certain characteristics as "masculine" or "feminine." How do you think these gender stereotypes influence a child's development?

PHYSIOLOGICAL DIMENSION

Physiological growth (physical size and functioning) of an individual is influenced primarily by interaction of genetic predisposition, the central nervous system (CNS), the endocrine system, and maturation. The role of heredity in human development is complex and not yet fully understood. Genetics is the foundation for achievement of specific tasks. Factors such as the psychosocial environment and health status influence individuals' ability to achieve their genetic potential.

PSYCHOSOCIAL DIMENSION

The psychosocial dimension of growth and development consists of subjective feelings and interpersonal relationships. A favorable **self-concept** (view of one's self, including body image, self-esteem, and ideal self) is likely the most important key to a person's success and happiness. Following are characteristics of an individual with a positive self-concept:

- Self-confidence
- Willingness to take risks
- Ability to receive criticism without defensiveness
- Ability to adapt effectively to stressors
- Innovative problem-solving skills

People with a healthy self-concept believe in themselves; as a result, they set goals that can be achieved. Goal achievement reinforces the positive belief about one's self. See Chapter 22 for a complete discussion about self-concept.

A person with a positive self-concept is likely to engage in health-promoting activities. For example, a person who values him- or herself is more likely to change unhealthy habits (such as smoking and sedentary lifestyle) in order to improve health status. There are many different psychosocial theories that explain the development of self-concept. This chapter presents the intrapsychic and interpersonal models of personality development.

Intrapsychic Theory

Intrapsychic theory (also called psychodynamic) focuses on an individual's unconscious processes. Feelings, needs, conflicts, and drives are considered to be motivators of behavior, learning, and development. Sigmund Freud and Erik Erikson are two major intrapsychic theorists.

Freud's theories, developed in the early 1930s, continue to influence current concepts related to human development. A basic belief of the Freudian model is that *all behavior has some meaning*.

According to Freud (1961), in order to mature, a person must successfully travel through five stages of development (see Table 18-2 on page 313). In each stage, there is a task to be mastered; if the task is not achieved, the individual is halted (develops a fixation) at this stage. A **fixation** is characterized as either inadequate mastery or failure to achieve a developmental task. A fixation in earlier stages inhibits healthy progression through subsequent stages.

Erikson (1968) expanded Freud's concept of developmental stages by theorizing that psychosocial development

TABLE 18-2 Freud's Stages of Psychosexual Development

STAGE	AGE	DESCRIPTION
Oral	Birth–18 months	Management of anxiety by using mouth and tongue
Anal	18 months–3 years	Control of muscles, especially those controlling urination and defecation
Phallic (“Oedipal”)	3–6 years	Awareness of sex and genitalia
Latency	6–12 years	Exhibition of latent sexual development and energy
Genital	12 years–adulthood	Reemergence of sexual interests and development of relationships with potential sexual partners

Data from Freud, S. (1961). *Civilization and its discontents*. New York: Norton.

is a lifelong process that does not stop at the end of adolescence. Just as physical growth patterns can be predicted, certain psychosocial tasks must be mastered in each developmental stage. Erikson's model proposes that psychosocial development is a series of conflicts that can have favorable or unfavorable outcomes. These conflicts occur in eight developmental stages of life that are described in Table 18-3.

Havighurst (1972) theorized that there are six developmental stages of life, each with essential tasks to be achieved. Mastery of a task in one developmental stage is essential for mastery of tasks in subsequent stages. When a task in one stage is mastered, it is learned for life, independent of subsequent neurological change (which may occur with disease or injury). Table 18-4 on page 314 presents Havighurst's developmental stages and associated tasks.

TABLE 18-3 Erikson's Stages of Psychosocial Development

STAGE	AGE	TASK TO BE ACHIEVED	IMPLICATIONS
Trust vs. mistrust	Birth–18 months	Develop a sense of trust in others	Consistent, affectionate care promotes successful mastery. Inadequate, inconsistent care produces an unfavorable outcome at this stage.
Autonomy vs. shame and doubt	18 months–3 years	Learn self-control	The child needs support, praise, and encouragement to use newly acquired skills of independence. Shaming or insulting the child will lead to unnecessary dependence.
Initiative vs. guilt	3–6 years	Initiate spontaneous activities	Give clear explanations for events, and encourage creative activities. Threatening punishment or labeling behavior as “bad” leads to development of guilt and fears of doing wrong.
Industry vs. inferiority	6–12 years	Develop necessary social skills	To build confidence, recognize the child's accomplishments. Unrealistic expectation or excessively harsh criticism leads to a sense of inadequacy.

(Continues)

TABLE 18-3 (Continued)

STAGE	AGE	TASK TO BE ACHIEVED	IMPLICATIONS
Identity vs. role diffusion	12–20 years	Integrate childhood experiences into a personal identity	Help the adolescent make decisions. Encourage active participation in home events. Assist with planning for the future.
Intimacy vs. Isolation	18–25 years	Develop commitments to others and to a life work (career)	Teach the young adult to establish realistic goals. Avoid ridiculing romances or job choices.
Generativity vs. stagnation	21–45 years	Establish a family and become productive	Provide emotional support. Recognize individual accomplishments and provide appropriate praise.
Integrity vs. despair	45+ years	View one's life as meaningful and fulfilling	Explore positive aspects of one's life. Review contributions made by the individual.

Data from Erikson, E. (1968). *Childhood and society*. New York: Norton; Varcarolis, E., & Halter, M. J. (2008). *Essentials of mental health psychiatric nursing: A communication approach to evidence-based care*. St. Louis, MO: Elsevier.

TABLE 18-4 Havighurst's Developmental Stages and Tasks

DEVELOPMENTAL STAGE	DEVELOPMENTAL TASKS
Infancy and early childhood	<ul style="list-style-type: none"> • Eat solid foods • Walk • Talk • Control elimination of wastes • Relate emotionally to others • Distinguish right from wrong • Learn sex differences and sexual modesty • Achieve psychological stability • Form simple concepts of social and physical reality
Middle childhood	<ul style="list-style-type: none"> • Learn physical skills required for games • Build healthy attitudes toward oneself • Learn to socialize with peers • Learn appropriate masculine or feminine role • Gain basic reading, writing, and mathematical skills • Develop concepts necessary for everyday living • Formulate a conscience based on a value system • Achieve personal independence • Develop attitudes toward social groups and institutions

(Continues)

TABLE 18-4 (Continued)

DEVELOPMENTAL STAGE	DEVELOPMENTAL TASKS
Adolescence	<ul style="list-style-type: none"> • Establish more mature relationships with same-age individuals of both sexes • Achieve a masculine or feminine social role • Accept own body • Establish emotional independence from parents • Achieve assurance of economic independence • Prepare for an occupation • Prepare for marriage and establishment of a family • Acquire skills necessary to fulfill civic responsibilities • Develop a set of values that guides behavior
Early adulthood	<ul style="list-style-type: none"> • Select a partner • Learn to live with a partner • Start a family • Manage a home • Establish self in a career or occupation • Assume civic responsibility • Become a part of a social group
Middle adulthood	<ul style="list-style-type: none"> • Fulfill civic and social responsibilities • Maintain an economic standard of living • Assist adolescent children to become responsible, happy adults • Relate to one's partner • Adjust to physiological changes • Adjust to aging parents
Later maturity	<ul style="list-style-type: none"> • Adjust to physiological changes and alterations in health status • Adjust to retirement and altered income • Adjust to death of spouse • Develop affiliation with one's age group • Meet civic and social responsibilities • Establish satisfactory living arrangements

Data from Havighurst, R. J. (1972). *Developmental tasks and education*. New York: Longman.

Levinson (1978) studied men to determine developmental phases of young and middle adulthood. As a result of Levinson's research, five "seasons" or "eras" (phases) were identified; see Table 18-5 on page 316. The midlife transition, which begins at approximately age 40, includes examining and structuring one's life to one's own satisfaction (Edelman & Mandle, 2006).

Interpersonal Theory

Harry Stack Sullivan (1953) theorized that relationships with others influence how one's personality develops. Approval and disapproval from significant others shape the formation of one's personality. To form satisfying relationships with others, an individual must complete six stages of development, which are shown in Table 18-6 on page 316.

COGNITIVE DIMENSION

The cognitive dimension is characterized by the intellectual process of knowing (which includes perception, memory,

and judgment) and develops as an individual progresses through the life span. Intelligence is an adaptive process used by individuals to adapt by changing the environment to meet their needs and by altering their responses to environmental stressors. The ability to change behavior in response to the demands of an ever-changing environment is characteristic of intelligent beings. Four factors are catalysts to intellectual development:

1. Maturation of the endocrine and nervous systems
2. Action-centered experience that leads to discovery ("learning by doing")
3. Social interaction, with opportunities for receiving feedback
4. A self-regulating mechanism that responds to environmental stimuli (Murray, Zentner, & Yakimo, 2008)

Piaget (1963) studied the differences between children's thinking patterns at different ages and how intelligence is used to solve problems and answer questions. He theorized that children learn to think by playing.

TABLE 18-5 Levinson's Seasons of Adulthood

SEASON (PHASE)	AGE	CHARACTERISTICS
Early adult transition	18–20 years	Seeks independence by separating from family
Entrance into the adult world	21–27 years	Experiments with different careers and lifestyles
Transition	28–32 years	Makes lifestyle adjustments
Settling down	33–39 years	Experiences greater stability
Pay-off years	45–65 years	Is self-directed and engages in self-evaluation

Data from Levinson, D. (1978). *The seasons of a man's life*. New York: Knopf.

Piaget and Inhelder (1969) categorized intellectual development into four phases: sensorimotor, preoperational, concrete operations, and formal operations. Table 18-7 on page 317 provides a description of each phase. Each phase is characterized by the ways in which the child interprets and uses the environment. Approximate ages are indicated for each phase, but there is great variation among individuals.

The individual learns by interacting with the environment through three processes: assimilation, accommodation,

and adaptation. **Assimilation** is the process of taking in new experiences or information. **Accommodation** allows for readjustment of the cognitive structure (mindset) to take in the new information; thus, understanding is increased. **Adaptation** refers to the changes that occur as a result of assimilation and accommodation (Murray et al., 2008).

MORAL DIMENSION

The moral dimension consists of a person's value system that helps in differentiating right and wrong. **Moral maturity**, the ability to independently decide for oneself what is "right," is closely related to emotional and cognitive development. Kohlberg (1977) established a framework for understanding how individuals determine a moral code to guide their behavior. Kohlberg's model states that a person's ability to make moral judgments and behave in a morally correct manner develops over a period of time.

Kohlberg defines six stages of moral development. Each stage is built on the previous stage and becomes the foundation for successive stages. Moral development progresses in relationship to cognitive development. Individuals who are able to think at higher levels have the necessary reasoning skills on which to base moral decisions. Table 18-8 on page 318 provides an overview of Kohlberg's stages of moral development. Kohlberg (1977) stated that individuals move through the six stages in a sequential fashion; however, not everyone reaches Stages 5 and 6 in their development of personal morality.

Gilligan's theory of moral development is based on research that focused on women. Women tend to describe moral issues in the context of human relationships and seek to avoid hurting others (Gilligan, 1982). Women's moral judgment revolves around three basic issues: a concern with survival, a focus on goodness, and an understanding of others' need for care (Gilligan & Attanucci, 1988). Table 18-9 on page 318 provides an overview of Gilligan's theory.

TABLE 18-6 Sullivan's Interpersonal Model of Personality Development

STAGE	AGE	DESCRIPTION
Infancy	Birth–18 months	Infant learns to rely on caregivers to meet needs and desires.
Childhood	18 months–6 years	Child begins learning to delay immediate gratification of needs and desires.
Juvenile	6–9 years	Child forms fulfilling peer relationships.
Preadolescence	9–12 years	Child relates successfully to same-sex peers.
Early adolescence	12–14 years	Adolescent learns to be independent and forms relationships with members of opposite sex.
Late adolescence	14–21 years	Person establishes an intimate, long-lasting relationship with someone of the opposite sex.

Data from Sullivan, H. S. (1953). *Interpersonal theory of psychiatry*. New York: Norton.

TABLE 18-7 Piaget's Phases of Cognitive Development

PHASE	AGE	DESCRIPTION
Sensorimotor	Birth–2 years	Sensory organs and muscles become more functional.
Stage 1: Use of reflexes	Birth–1 month	Movements are primarily reflexive.
Stage 2: Primary circular reaction	1–4 months	Perceptions center around one's body. Objects are perceived as extensions of the self.
Stage 3: Secondary circular reaction	4–8 months	Becomes aware of external environment. Initiates acts to change the environment.
Stage 4: Coordination of secondary schemata	8–12 months	Differentiates goals and goal-directed activities.
Stage 5: Tertiary circular reaction	12–18 months	Experiments with methods to reach goals. Develops rituals that become significant.
Stage 6: Invention of new means	18–24 months	Uses mental imagery to understand the environment. Uses fantasy ("make-believe").
Preoperational	2–7 years	Emerging ability to think.
Preconceptual stage	2–4 years	Thinking tends to be egocentric. Exhibits use of symbolism.
Intuitive stage	4–7 years	Unable to break down a whole into separate parts. Able to classify objects according to one trait.
Concrete Operations	7–11 years	Learns to reason about events in the here and now.
Formal Operations	11+ years	Able to see relationships and to reason in the abstract.

Data from Piaget, J. (1963). *The origins of intelligence in children*. New York: Norton.

SPIRITUAL DIMENSION

The spiritual dimension is characterized by a sense of personal meaning. Spirituality refers to relationships with one's self, with others, and with a higher power or divine source. Spirituality does not refer to a specific religious affiliation; rather, it can be defined as the core of a person. Development of spirituality is an ongoing, lifelong process. See the accompanying Spotlight On display.

SPOTLIGHT ON...

Caring

Spiritual Awareness

The term *spirit* is derived from the Latin word meaning breath, air, and wind. Thus, spirit refers to whatever gives life to a person. What animates you? What is the core of your spirituality (life force)? The answers to these questions are truly individual. Remember that each client has a personalized definition of spiritual self, even though some clients seem to be unaware of their spiritual nature.

Fowler's (1981) theory of spiritual development, which was influenced by the works of Erikson, Piaget, and Kohlberg, is composed of a prestage and six distinct stages of faith development. Even though individuals will vary in the age at which they experience each stage, the sequence of stages remains the same. Table 18-10 on page 319 describes Fowler's theory.

HOLISTIC FRAMEWORK FOR NURSING

Providing care to the whole person is a basic concept of professional nurses. Knowledge of growth and development concepts is essential because nursing interventions must be appropriate to each client's developmental stage. Nursing's holistic perspective recognizes the progression of individual development across the life span. Developmental progress, or lack of progress, in one aspect affects all other dimensions of life. Figure 18-1 on page 319 illustrates the holistic nature of individuals.

Growth and development theories are useful to nurses as assessment parameters because alterations in expected patterns are indicators for early intervention. Following are situations in which knowledge of developmental milestones

TABLE 18-8 Kohlberg's Stages of Moral Development

LEVEL AND STAGE	AGE	DESCRIPTION
Level I: Preconventional	Birth–9 years	Authority figures are obeyed.
Stage 1: Punishment and obedience orientation		Misbehavior is viewed in terms of damage done. A deed is perceived as “wrong” if one is punished; the activity is “right” if one is not punished.
Stage 2: Instrumental-relativist orientation		“Right” is defined as that which is acceptable to and approved by the self. When actions satisfy one’s needs, they are “right.”
Level II: Conventional	9–13 years	Cordial interpersonal relationships are maintained.
Stage 3: Interpersonal concordance		Approval of others is sought through one’s actions. Authority is respected.
Stage 4: Law and order orientation		Individual feels “duty bound” to maintain social order. Behavior is “right” when it conforms to the rules.
Level III: Postconventional	13+ years	Individual understands the morality of having democratically established laws.
Stage 5: Social contract orientation		It is “wrong” to violate others’ rights.
Stage 6: Universal ethics orientation		The person understands the principles of human rights and personal conscience. Person believes that trust is basis for relationships.

Data from Kohlberg, L. (1977). *Recent research in moral development*. New York: Holt, Rinehart, & Winston.

TABLE 18-9 Gilligan's Theory of Moral Development

LEVEL	CHARACTERISTICS
I. Orientation of individual survival transition	<ul style="list-style-type: none"> • Concentrates on what is best for self • Is selfish • Is dependent on others
Transition 1: From selfishness to responsibility	<ul style="list-style-type: none"> • Recognizes connections to others • Makes responsible choices in terms of self and others
II. Goodness as self-sacrifice	<ul style="list-style-type: none"> • Puts needs of others ahead of own • Feels responsible for others • Is dependent • May use guilt to manipulate others when attempting to “help”
Transition 2: From goodness to truth	<ul style="list-style-type: none"> • Makes decisions based on intentions and consequences, not on others’ responses • Considers needs of self and others • Wants to help others while being responsible to self • Increases social participation
III. Morality of nonviolence	<ul style="list-style-type: none"> • Sees self and others as morally equal • Assumes responsibilities for own decisions • Holds basic tenet to hurt no one, including self • Experiences conflict between selfishness and selflessness • Is not dependent on others’ perceptions for self-judgment but rather on consequences and intentions of actions

Data from Gilligan, C., & Attanucci, D. (1988). Two moral orientations: Gender differences and similarities. *Merrill-Palmer Quarterly*, 34(3), 332-333; Gilligan, C. (1982). *In a different voice: Psychologic theory and women's development*. Cambridge, MA: Harvard University Press.

TABLE 18-10 Fowler’s Stages of Faith

STAGE	AGE	CHARACTERISTICS
Prestage: Undifferentiated faith	Infant	<ul style="list-style-type: none"> Trust, hope, and love compete with environmental inconsistencies or threats of abandonment
Stage 1: Intuitive-projective faith	Toddler, preschooler	<ul style="list-style-type: none"> Imitates parental behaviors and attitudes about religion and spirituality Has no real understanding of spiritual concepts
Stage 2: Mythical-literal faith	School-aged child	<ul style="list-style-type: none"> Accepts existence of a deity Religious and moral beliefs are symbolized by stories Appreciates others’ viewpoints Accepts concept of reciprocal fairness
Stage 3: Synthetic-conventional faith	Adolescent	<ul style="list-style-type: none"> Questions values and religious beliefs in an attempt to form own identity
Stage 4: Individuative-reflective faith	Late adolescent and young adult	<ul style="list-style-type: none"> Assumes responsibility for own attitudes and beliefs
Stage 5: Conjunctive faith	Adult	<ul style="list-style-type: none"> Integrates other perspectives about faith into own definition of truth
Stage 6: Universalizing faith	Adult	<ul style="list-style-type: none"> Makes concepts of love and justice tangible

is essential for prompt identification of problems and comprehensive intervention:

- The infant who does not sit, crawl, or walk at expected times

- The adolescent girl who has not experienced menarche at the expected time
- The adult who has failed to develop adequate problem-solving skills

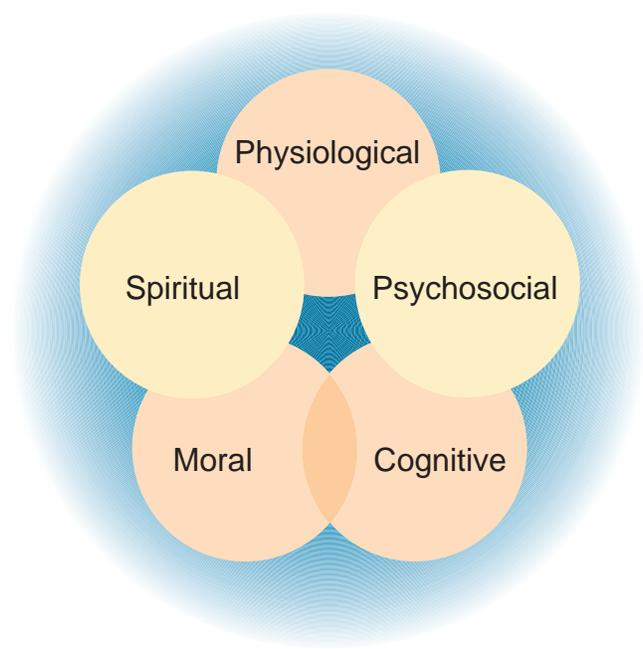

FIGURE 18-1 Holistic Nature of Human Beings DELMAR/CENGAGE LEARNING

STAGES OF THE LIFE CYCLE

For purposes of this discussion, 11 developmental stages are presented: prenatal period, neonate, infant, toddler, preschooler, school-age child, preadolescent, adolescent, young adult, middle adult, and older adult. For each stage, the manifestations of growth and development in the physiological, psychosocial, cognitive, moral, and spiritual dimensions are discussed with the relevant nursing implications.

Nurses can intervene to promote health and wellness during each stage of the life cycle. The Centers for Disease Control and Prevention (2007a) has developed health protection goals that are specific to each developmental stage; see Table 18-11 on page 320.

PRENATAL PERIOD

The **prenatal period**, the developmental stage beginning with conception and ending with birth, is a critical time in a human being’s development and consists of three developmental phases: the germinal, embryonic, and fetal stages. The **germinal stage** begins with conception and lasts approximately 10 to 14 days. This stage is characterized by

TABLE 18-11 Centers for Disease Control and Prevention's Health Protection Goals: Healthy People in Every Stage of Life

DEVELOPMENTAL STAGE	GOAL	DESCRIPTION
Infants and toddlers (ages 0–3)	Start strong	Increase the number of infants and toddlers who have a strong start for healthy and safe lives.
Children (ages 4–11)	Grow safe and strong	Increase the number of children who grow up healthy, safe, and ready to learn.
Adolescents (ages 12–19)	Achieve healthy independence	Increase the number of adolescents who are prepared to be healthy, safe, independent, and productive members of society.
Adults (ages 20–49)	Live a healthy, productive, and satisfying life	Increase the number of adults who are healthy and able to participate fully in life activities and enter their later years with optimum health.
Older adults and seniors (ages 50+)	Live better, longer	Increase the number of older adults who live longer, high-quality, productive, and independent lives.

Centers for Disease Control and Prevention. (2007a). *Health protection goals*. Atlanta, GA: Author. Retrieved November 20, 2008, from <http://www.cdc.gov/osi/goals/people/index.html>. (Courtesy of U.S. Centers for Disease Control and Prevention.)

rapid cell division and implantation of the fertilized egg in the uterine wall. In this very early stage, the central nervous system (CNS) is already beginning to form.

The **embryonic stage**, the first 2 to 8 weeks after fertilization of an egg by a sperm, is characterized by rapid cellular differentiation, growth, and development of the body systems. This critical period is when the embryo is most vulnerable to noxious stimuli, which may lead to a spontaneous abortion (miscarriage) (Murray et al., 2008).

The **fetal stage**, the intrauterine developmental period from 8 weeks to birth, is characterized by rapid growth and differentiation of body systems and parts. Table 18-12 on page 321 provides an overview of fetal development.

Nursing Implications

Pregnant women need to have physical examinations and screenings during the entire pregnancy. Early prenatal care is essential for a positive pregnancy outcome. See the accompanying Spotlight On display.

Learning that one is pregnant is accompanied by several emotions: happiness, fear, sadness, excitement, and anxiety. Emotions lead to alterations in biochemicals; therefore, the mother's emotional state can bring about biochemical changes in the fetus. By teaching pregnant women how to relax, the nurse can promote a supportive environment for the developing embryo and fetus.

WELLNESS PROMOTION The uterus is the primary environment affecting prenatal growth and development. Ideally, this environment nurtures positive growth of the embryo and fetus.

An ample supply of nutrients must be provided by the gestating woman. Women who consume insufficient amounts

SPOTLIGHT ON...

Ethical

Nutrition and the Economically Disadvantaged

Do you think it is the responsibility of the federal government to ensure that pregnant women have adequate diets? What would happen if government-sponsored nutritional programs for pregnant women were abolished?

of protein during pregnancy have a high risk of giving birth to premature and low-birth-weight infants. Such infants are at risk for developmental alterations.

When teaching the pregnant woman about nutrition, the nurse must emphasize that vitamin supplements are *not* to be substituted for adequate intake of nutritious food. Other nursing interventions that promote prenatal health include:

- Screening (e.g., maternal blood pressure measurement and urine glucose analysis)
- Teaching (e.g., nutritional guidelines)
- Counseling (e.g., guidance about bonding with the child and incorporating a child into a family unit)
- Promoting the use of complementary and alternative modalities (e.g., imagery) to reduce stress
- Working with economically disadvantaged clients to obtain prenatal care

SAFETY CONSIDERATIONS The fetus is especially vulnerable to substances consumed by the mother. In addition to

TABLE 18-12 Embryo and Fetus: Growth and Development

AGE	CHARACTERISTICS
Weeks 1–3	<ul style="list-style-type: none"> • Rapid cell differentiation • Heart starts to pulsate • CNS formation • Presence of all organs
Week 4	<ul style="list-style-type: none"> • Beginnings of respiratory system • Basic structures for eyes and ears • Limb buds distinguishable
Week 5	<ul style="list-style-type: none"> • Embryo has a C-shaped body with a tail and large head • Each body system present in at least a rudimentary form • Umbilical cord developed • Brain vesicles developed • Nerve tissues more fully developed
Week 6	<ul style="list-style-type: none"> • Establishment of circulatory pathway (including heart with septa) • Limbs distinguishable as arms and legs • Intestine elongating • Lungs formed, with bronchi beginning to branch out • Liver begins production of blood cells
Week 9	<ul style="list-style-type: none"> • Fingers, toes, eyelids, nose, and jaw evident
Week 12	<ul style="list-style-type: none"> • Body growth speeds up while growth of head slows
Week 16	<ul style="list-style-type: none"> • Ossification of skeleton begins • Fingers and toes separated
Week 20	<ul style="list-style-type: none"> • Fetal movement felt by mother • Wake and sleep cycles evident • Formation of small amounts of body fat
Week 24	<ul style="list-style-type: none"> • Circulation of blood in vessels is visible • Accelerated weight gain • Ovaries or testes developed • Kidney tubules branch out • Brain grows rapidly
Week 28	<ul style="list-style-type: none"> • Eyes open and close • Thick hair on head • Lanugo (thick coating of body hair) is present • Rhythmic breathing patterns begin to be established
Week 32	<ul style="list-style-type: none"> • Maturation of respiratory system and temperature-regulating mechanism • Fat deposited in arms and legs • Fingernails and toenails present
Week 36	<ul style="list-style-type: none"> • Protrusion of mammary glands in both sexes • Lack of melanin leads to white skin in all fetuses at this stage
Week 40	<ul style="list-style-type: none"> • Completion of fetal development • Fetus is ready for extrauterine environment • Optimal time for birth

SAFETY FIRST

TOBACCO AND ALCOHOL USE DURING PREGNANCY

Total abstinence from cigarette smoking is advised during pregnancy. Because there has been no determination of “safe” amounts of alcohol consumption, caution all pregnant women to avoid drinking alcohol.

providing the fetus with wholesome nutrients, maternal blood can also transport toxins.

Cigarettes contain several toxic substances, such as nicotine, that cross the placental barrier and interfere with the transport of oxygen to the fetus. Such toxins often result in increased risk of premature birth, retarded growth, learning difficulties, and fetal death.

Use of alcohol during pregnancy can result in **fetal alcohol syndrome** (FAS), a condition in which fetal development is impaired and is manifested in the infant by characteristic physical attributes and intellectual problems. Typically, FAS infants are small, have facial abnormalities (such as thin upper lips and short, upturned noses), and may have some degree of brain damage. Alcohol consumption is most dangerous during the first 3 months of pregnancy when the embryo’s brain and other vital organs are developing. The effects of alcohol on the fetus are permanent. FAS is considered to be the leading cause of mental retardation among infants, and the incidence continues to increase (Hockenberry, Wilson, & Jackson, 2006).

In addition to nicotine and alcohol, there are many other teratogenic substances. A **teratogenic substance** is any substance that can cross the placental barrier and impair normal growth and development. See the accompanying Safety First display.

Client education consists of teaching pregnant women to check labels of *all* medicines for information about potential effects on the fetus; this includes over-the-counter (OTC) medications and herbal remedies. The Food and Drug Administration requires that all manufactured drugs list their potential for causing birth defects. The use of illegal drugs by pregnant women presents a very serious threat to the unborn. Substance abuse prevention programs can be effective in preventing or reducing this risk.

NEONATAL PERIOD

The **neonatal period**, the first 28 days of life following birth, is a time of major adjustment to extrauterine life. The energies of the neonate (newborn) are focused on achieving equilibrium through stabilization of major body systems. Table 18-13 on page 323 describes neonatal development.

The neonate’s activities, which are reflexive in nature, consist primarily of sucking, crying, eliminating, and sleeping (see Figure 18-2 on page 324). The neonate blinks in response to bright lights and demonstrates the startle reflex in response to loud noises. Neonatal reflexes play a major role in

SAFETY FIRST

NEONATAL REFLEXES

A complete assessment of neonatal reflexes should be performed immediately after birth. Early detection of problems is essential in order to perform life-saving interventions.

the ability to survive. Table 18-14 on page 325 lists the reflexive activities of the neonate.

During the first month of life, the neonate progresses developmentally from a mass of reflexes to behavior that is more goal directed (purposeful). In addition to the major physiological adjustments necessitated by extrauterine life, the neonate also undergoes psychological adaptation.

The major psychological task of neonates is to adjust to the parental figures. **Bonding**, the formation of attachment between parent and child, begins at birth when the neonate and parent make initial eye contact. The quality of parent-neonate bonding lays the foundation for trust that is necessary for the development of future interpersonal relationships. Figure 18-3 on page 325 shows bonding between neonate and parent.

Nursing Implications

A complete and thorough assessment of the neonate, which is performed immediately after delivery, includes evaluation of the neonate’s reflexes. In addition to focusing on the reflexes, the assessment also evaluates respiratory and cardiac functioning. Table 18-15 on page 325 shows the Apgar assessment tool that is performed by the nurse at 1 minute and again at 5 minutes after birth.

In the first few hours after birth, encourage the parents to cuddle the newborn. Explain the neonate’s interactive abilities. Encourage mutual eye contact between neonate and parents by showing parents how to hold the child facing them.

WELLNESS PROMOTION Teaching is one of the most important nursing activities for promoting neonatal wellness. First-time parents need information about basic newborn needs (to be held, rocked, and talked to), nutrition, infection control (especially handwashing and hygienic diaper changing practices), care of the umbilicus, and incorporating the newborn into the family unit.

Knowledge of growth and development milestones is necessary for parents to provide appropriate neonatal stimulation and have realistic expectations.

Other nursing interventions that promote neonatal wellness are the following:

- Continually assessing the neonate’s physiological status
- Providing a warm environment (Neonates breathe more easily when they are warm.)
- Monitoring nutritional status (It is normal for neonates to lose up to 10% of birth weight during the first week of life.)
- Providing a clean environment to protect neonates from infection and teaching parents that neonates need a clean environment, not a sterile one

TABLE 18-13 Neonate: Growth and Development

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Physiological	Circulatory function shifts from the umbilical cord to heart.	Accurately assess neonate's cardiovascular status.
	Gas exchange (oxygen and carbon dioxide) is transferred from placenta to lungs. Respiratory reflexes are activated seconds after birth.	Immediately after birth, hold the neonate with head lower than body to allow for drainage of fluids that may block respiratory passages. If spontaneous respirations do not occur, resuscitate immediately.
	Weak neck and shoulder muscles.	Carefully support the neonate's head.
	Immature temperature-regulating mechanism.	To conserve heat: <ul style="list-style-type: none"> • Dry neonate immediately after birth and place in a warmed bassinet. • Place a stockinette cap on neonate's head.
	Incomplete ossification (process of cartilage changing to bone).	Protect the anterior fontanelle on neonate's skull.
	Poor visual acuity; visual focus is generally rigid.	Instruct parents to be directly in front of the neonate (about 9–12 inches away from child's face) when communicating.
Motor	Reflexes direct the majority of movement.	
	The full-term neonate has some limited ability to hold the head erect. Able to lift head slightly when lying prone.	Support neck and head when lifting.
Psychosocial	Crying is the neonate's method of communication. There is a reason for the cry.	Teach parents about the dynamics of crying to avoid having the neonate labeled as "fussy" or the parents developing the misconception that they are inadequate caregivers. Encourage parents to learn to discriminate crying patterns.
	The bonding process begins shortly after birth.	Teach parents the importance of interacting with the neonate during every contact (feeding, bathing, changing, cuddling).
Cognitive	Neonates learn through sensory experiences. Learning is enhanced by an environment that provides stimuli without bombarding the neonate. Learning occurs by repeated exposure to stimuli.	To promote learning, encourage parents to provide frequent sensory stimuli (touching, talking, looking the neonate in the eyes).

Data from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning; Murray, R. B., Zentner, J. P., & Yakimo, R. (2008). *Nursing assessment and health promotion through the lifespan* (8th ed.). Upper Saddle River, NJ: Prentice-Hall; Hockenberry, M. J., Wilson, D., & Jackson C. (2006). *Wong's nursing care of infants and children* (8th ed.). St. Louis, MO: Elsevier.

- Conducting screening tests (e.g., the blood test for phenylketonuria (PKU), a genetic disorder that, if untreated, can lead to impaired intellectual functioning)
- Promoting early parent-neonate interaction

Selection of a feeding method for the neonate is a major decision for parents. Breastfeeding is the most natural option. However, commercially prepared formula is sometimes used due to the neonate's special needs or parental choice. For a

comparison of feeding methods, see the discussion about infant nutrition.

SAFETY CONSIDERATIONS Safety is of primary concern when caring for neonates because they are totally dependent on others to meet their needs. Accidents are the primary cause of neonatal mortality (Murray et al., 2008). One of the most important neonatal accident prevention methods is to teach

FIGURE 18-2 Selected Neonatal Reflexes: A, rooting; B, sucking; C, grasp; D, Moro; E, tonic neck. DELMAR/CENGAGE LEARNING

parents about the proper use of infant car seats. Under current federal law, neonates and infants must be secured in an approved infant car seat *every* time the child travels in a car.

In addition to accidents, infections pose a serious health risk to the neonate. Newborns should not be in contact with anyone experiencing an infectious disease. The skin is the body's major defense against invasion by disease-producing microorganisms; therefore, it is essential that the neonate's skin integrity be maintained. Parents must be taught the importance of skin cleanliness. Diaper rash is a common skin problem for newborns and infants because of the ammonia from urine in wet diapers. The ammonia burns and irritates the skin, resulting in localized irritation, blisters, or fissures. In addition to prompt changing of wet diapers, bathing and use of protective creams are useful in preventing skin breakdown.

INFANCY

Infancy, the developmental stage from the first month to the first year of life, is a time of continued adaptation. During

this stage, the infant experiences rapid physiologic growth and psychosocial development (see Figure 18-4 on page 326). Table 18-16 on page 327 provides an overview of infant development in the physical, motor, psychosocial, cognitive, moral, and spiritual dimensions.

Nursing Implications

The nurse caring for an infant must focus on safety, prevention of infection, and teaching parents about incorporating the child into the family. Nursing care involves the provision of support, reassurance, and information to the parents.

WELLNESS PROMOTION Nurses promote infant wellness by teaching growth and development concepts to parents and other caregivers. Knowledge of the type of behavior to expect at certain times during infancy serves as both guidance and reassurance for parents. Three specific areas in which parents need guidance from the nurse in caring for their infants are nutrition, protection from infection, and promotion of sleep.

TABLE 18-14 Major Neonatal Reflexes

REFLEX	DESCRIPTION
Rooting	Turning the mouth and nose in the direction of any facial touch
Sucking	Using the tongue and mouth to take in liquid or food
Swallowing	Movement of throat muscles to push food from mouth to esophagus
Grasp	Firm contraction of hand muscles around an object
Babinski	When foot stroked, toes fan upward and outward
Moro	When startled, arms and legs swing quickly out, then immediately back, and neonate curls up into a ball
Smiling	Turning lips upward; neonate looks “happy”
Blinking	Rapid closing and opening of eyelids
Sneezing	A violent, spasmodic, sudden expiration of breath
Coughing	Explosively expelling air from the lungs
Crying	Making a loud, wailing sound
Tonic neck	When head is turned to side, arm and leg on same side are extended in a fencing posture
Extrusion	Tongue pushes outward when touched by an object at the tip
Head turning	Moving face to one side or the other when airway is blocked by a surface, such as a bed or pillow

Delmar/Cengage Learning

FIGURE 18-3 Bonding between a parent and neonate. Consider the factors that may have an impact on the early attachment between this father and daughter. DELMAR/CENGAGE LEARNING

A major factor influencing health maintenance of the infant is the provision of adequate nutrients delivered in a loving, consistent manner. Caregivers should be taught that the nutrients must be germ free and provide the recommended amounts of carbohydrates, protein, calcium, iron, and vitamins. It is recommended that infants be breastfed for the first 6 to 12 months (Murray et al., 2008). Breast milk has several benefits over commercially prepared formulas, including that it:

- Boosts immune functioning (e.g., contains immunoglobulins, lymphocytes, and other bacteria growth retardants)
- Is more easily digested because of smaller curds than those in cow’s milk and formula
- Promotes absorption of fat and calcium
- Is readily available and economical

TABLE 18-15 Apgar Assessment Tool

SIGN	VALUE		
	0	1	2
Heart rate	Absent	Less than 100 beats per minute	Over 100 beats per minute
Respiratory effort	Absent	Slow and irregular	Crying
Muscle tone	Flaccid	Some flexion of extremities	Active movement
Reflex irritability	No response	Weak cry or grimace	Vigorous cry
Color	Blue or pale	Pink body, cyanotic extremities	Entire body is pink

Delmar/Cengage Learning

FIGURE 18-4 These children are exploring their world and are demonstrating mastery of both the physiological and cognitive dimensions of their development. DELMAR/CENGAGE LEARNING

The act of breastfeeding promotes maternal-infant bonding (Hockenberry et al., 2006). There are some cultural sanctions against breastfeeding, and some cultures view bottle-feeding as a status symbol.

Normal growth and development can occur without breastfeeding. “There is no doubt that human breastmilk is the perfect formulation for growth, development and the establishment of an infant’s immunity. Sometimes, breastfeeding is not an option so if a mother chooses to partially or totally feed her baby with formula there is no reason for her to feel guilty” (Mainstone, 2008, p. 612). Special formulas are available for infants who are hypersensitive to protein, who have PKU, and who experience fat malabsorption. Whole cow’s milk is not recommended for infants under 1 year of age. Human milk and commercially prepared formula are more easily digested. Soy-based formulas have been developed for the infant with lactose deficiency or who is allergic to regular formula. Infants who are formula fed generally have greater deposits of subcutaneous fat (Murray et al., 2008). The Nursing Checklist on page 329 provides teaching strategies for parents of bottle-fed infants. See the accompanying Safety First and the Uncovering the Evidence displays. It is important that the nurse provide accurate information about the types of feeding available and support the parents’ decision about the method chosen.

Solid foods are usually introduced at 3 to 4 months of age. Rice cereal is the first solid food of choice because it has the fewest allergic responses (Murray et al., 2008).

Infants are especially vulnerable to developing infections because the immune system is not fully matured. Immunizations are of utmost importance in preventing infections.

SAFETY FIRST

BOTTLE FEEDING

Never prop a bottle in the baby’s mouth because choking may result.

Nurses should confirm that infants receive all necessary immunizations. Figure 18-5 on page 328 provides a recommended schedule for childhood immunization.

Parents often need information about normal sleep patterns of infants and how the patterns change with maturation. Activities that promote sleep include:

- Providing a quiet room for the infant
- Scheduling feedings and other care activities during periods of wakefulness instead of drowsy times
- Developing sensitivity to the unique sleep and rest periods established by the infant

UNCOVERING THE

Evidence

TITLE OF STUDY

“Complex Pediatric Feeding Disorders: Using Teleconferencing Technology to Improve Access to a Treatment Program”

AUTHORS

B. Clawson, M. Selden, M. Lacks, A. V. Deaton, B. Hall, and R. Bach

PURPOSE

The overall goal of this study was to provide treatment options to children in order to help them eat effectively, thereby improving their overall health status. The study was done to determine the efficacy of teleconferencing in improving children’s access to treatment for feeding disorders.

METHODS

This pilot study included children with complex feeding disorders referred from locations from 300 to 3,500 miles from the treatment center. Fifteen teleconferencing visits were carefully planned, implemented, and evaluated. Follow-up to the teleconferencing sessions was accomplished by phone, letter, and a questionnaire.

FINDINGS

Of the initial consultations, 50% resulted in recommendations that allowed the children to be treated in their communities. The reduced cost of care for teleconferencing was an advantage for families of children with feeding disorders.

IMPLICATIONS

The availability of teleconferencing as an option for screening and follow-up care enables children with complex feeding disorders to be treated effectively within their communities.

Clawson, B., Selden, M., Lacks, M., Deaton, A. V., Hall, B., & Bach, R. (2008). Complex pediatric feeding disorders: Using teleconferencing technology to improve access to a treatment program. *Pediatric Nursing, 34*(3), 213–216.

TABLE 18-16 Infant: Growth and Development

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Physiological	<ul style="list-style-type: none"> Physical growth is rapid. Birth weight usually triples by end of first year. Height increases by approximately 50%. Progressive maturation of all body systems. Body temperature stabilizes. Heart rate slows (approximately 80–130 beats per minute). Blood pressure rises. At approximately 4–6 months, eruption of teeth begins. Rapid growth of brain (reaches about half the adult size). 	<ul style="list-style-type: none"> Inform parents of the developmental norms. Encourage parents to have “well-baby checkups” as recommended.
	<ul style="list-style-type: none"> Posterior fontanel closes at approximately 2 months. Eyes begin to focus. 	<ul style="list-style-type: none"> Protect infant’s skull.
Motor	<ul style="list-style-type: none"> Physical maturation allows for development of motor skills. Primitive reflexes are replaced by movement that is more voluntary and goal directed. Motor skills develop rapidly: <ul style="list-style-type: none"> 6 months: rolls over voluntarily 6–7 months: crawls 8 months: sits alone Grasping objects is reflexive for first 2–3 months and gradually becomes voluntary. 	<ul style="list-style-type: none"> Teach parents anticipated ages for motor skill development.
Psychosocial	<ul style="list-style-type: none"> <i>Freud</i>: Oral stage <i>Erikson</i>: Trust vs. mistrust A sense of self begins to develop. Responds to caregiver’s voice. Anxiety separation occurs at approximately 6 months. 	<ul style="list-style-type: none"> Seeks immediate gratification of needs. Receives pleasure and comfort through mouth, lips, and tongue. Encourage parents to feed in a prompt, consistent manner (feed on demand rather than a fixed schedule). Other activities that promote trust are providing warmth, diapering, and comforting.
	<ul style="list-style-type: none"> <i>Havighurst</i>: Learns to eat solid food, crawl, walk, and talk. 	<ul style="list-style-type: none"> Teach parents approximate ages that developmental milestones are expected to occur.
Cognitive	<ul style="list-style-type: none"> <i>Piaget</i>: Sensorimotor stage Infant learns by interacting with the environment. 	<ul style="list-style-type: none"> Encourage parents to provide a variety of sensory stimuli: visual, sensory, auditory, and tactile (e.g., colorful mobiles; musical toys; soft plush animals; rubbing, patting, stroking the infant’s skin).
	<ul style="list-style-type: none"> Language development includes babbling, repetition, and imitation. 	<ul style="list-style-type: none"> Caregivers need to talk to infant often. Encourage caregivers to name objects that are the focus of infant’s attention.
Moral	<ul style="list-style-type: none"> <i>Kohlberg</i>: Preconventional stage 	<ul style="list-style-type: none"> Teach parents that now is the time to start teaching (by role modeling) the difference between “right” and “wrong.”
Spiritual	<ul style="list-style-type: none"> <i>Fowler</i>: Stage of undifferentiated faith 	<ul style="list-style-type: none"> Encourage caregivers to model the values they want the infant to learn.

- Providing comfort and security measures (e.g., rocking, singing)
- Establishing routine times for sleep

SAFETY CONSIDERATIONS The majority of infant injuries and deaths are related to motor vehicle accidents. Therefore, the consistent, proper use of infant car seats is one of the most effective measures parents can take to ensure their infant’s safety.

▼ **SAFETY FIRST** ▼

AIDING THE CHOKING INFANT
 Never use the Heimlich maneuver on an infant who is choking. Instead, use alternating back blows and chest compressions to dislodge the object.

NURSING CHECKLIST

Bottle Feeding

- The baby should be in a semireclining position cradled close to the mother's body with the mother in a comfortable position.
- Use care if heating bottles. Do not warm bottles in the microwave because the hot liquid can cause esophageal and oropharyngeal burns.
- Avoid using the bottle as a pacifier because this action may result in tooth decay and set the stage for future obesity.

During this oral phase of development, infants tend to test out their environment and seek pleasure through the mouth. Aspiration accidents are common with infants who choke on objects such as buttons, coins, and food. The Heimlich maneuver is *not* used with infants because it may force the foreign object further down the trachea. Figure 18-6 illustrates the proper technique to use with an infant who is choking. See the accompanying Safety First display on page 328 and Client Teaching Checklist below for guidelines that the nurse can share with parents to prevent infant accidents.

CLIENT TEACHING CHECKLIST

PREVENTING ACCIDENTS IN INFANTS

- To avoid vehicular accidents: Use infant seats, and keep the infant out of the paths of automobiles and other vehicles. Many infants can crawl very quickly.
- To prevent burns: Keep infant away from open heaters, furnaces, fireplaces, hot stoves, and matches.
- To protect from falls: Keep crib rails up at all times, never leave the infant lying unattended on furniture, and use protective gates and barriers to block stairways.
- To prevent drowning: Never leave the infant unattended near water (bathtubs, buckets, swimming pools).
- To prevent electrocution: As the infant begins to crawl, use plastic safety plugs to cover all electrical outlets and keep electrical cords out of infant's reach.
- To prevent choking: Closely monitor the infant who is exploring the environment.

FIGURE 18-6 Intervention for a choking infant. Emergency care for an infant who is choking consists of a series of five blows to the back between the shoulder blades, followed by five thrusts midline on the chest approximately 1 inch below the nipple line. DELMAR/CENGAGE LEARNING

TODDLER

The **toddler** period begins at 12 to 18 months of age, when a child starts to walk alone, and ends at approximately age 3. The family is very important to the toddler in that the family promotes language development and teaches toileting skills. During this stage, the child becomes more independent. Frequently, when attempts to demonstrate autonomy are prevented, the child will have a temper tantrum; thus, this stage is often referred to as “the terrible twos.” Parents must understand that the toddler’s frequent use of the word “no” is an expression of developing autonomy.

Nurses can greatly influence the quality of parent-child interaction by teaching parents about developmental concepts. This information helps parents form realistic expectations of the toddler’s behavior. Setting firm limits in a consistent manner helps the toddler learn while providing parameters for safe and socially acceptable behavior. Table 18-17 on page 330 describes the toddler’s growth and development in the physiological, motor, psychosocial, cognitive, moral, and spiritual dimensions.

Nursing Implications

Nurses who work with toddlers must be sensitive to the fact that children of this age are likely to be anxious and fearful in the presence of strangers. The establishment of rapport with the child will help alleviate this stranger anxiety. Play is an effective tool for building rapport with toddlers.

When toddlers are hospitalized (for an extended time or only a day), fear and anxiety can make the experience a negative one. The major stressor resulting from hospitalization is the toddler’s separation from parents. An unfamiliar environment also results in stress for the toddler. Nurses can help reduce stress in the hospitalized toddler by teaching both the child and parents about procedures. Parents can alleviate the toddler’s stress by holding the child and talking in a calm manner when in the presence of the health care provider (see Figure 18-7 on page 331).

TABLE 18-17 Toddler: Growth and Development

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Physiological	<ul style="list-style-type: none"> • Overall rate of growth slows. By 24 months, the toddler usually weighs four times more than at birth. • Rapid growth of brain. • Bones in extremities grow in length. • Physiological readiness for bowel and bladder training develops. 	<ul style="list-style-type: none"> • Instruct parents on need for vitamin D, calcium, and phosphorus. • Recognize that “growing pains” are normal. • Instruct parents of timing for toilet training and need for consistency and patience.
Motor	<ul style="list-style-type: none"> • Walks and runs. • Becomes more coordinated. 	<ul style="list-style-type: none"> • Assess home environment for safety as toddler becomes more mobile.
Psychosocial	<ul style="list-style-type: none"> • <i>Freud</i>: Anal stage (receives pleasure from contraction and relaxation of sphincter muscles) • <i>Erikson</i>: Autonomy vs. shame and doubt • <i>Havighurst</i>: Developmental tasks include: <ul style="list-style-type: none"> —Beginning to learn sex differences —Learning to talk • Engages in parallel play (playing near other children but not necessarily interacting with them). • A reemergence of separation anxiety often occurs. • By age 3, most toddlers are able to tolerate being left with strangers. 	<ul style="list-style-type: none"> • Instruct parents to avoid overemphasis on toilet training. • Teach parents to encourage toddler’s attempts at independence (e.g., trying to feed and dress self). • Explain that sexual curiosity is normal. • Encourage parents to talk to child frequently. • Provide opportunities for child to socialize with peers. • Reassure child that parents will return.
Cognitive	<ul style="list-style-type: none"> • <i>Piaget</i>: Preoperational stage • Concrete thought processes. • Short attention span. • Can follow simple directions. • Is able to anticipate future events. • Comprehends self as a separate entity. • Language: At approximately 1 year, can make two-syllable sounds (e.g., ma-ma, da-da). • At approximately 2 years, can form short sentences. • Has a vocabulary of approximately 900 words. 	<ul style="list-style-type: none"> • Instruct parents to give only one direction at a time. • Use a calendar to show today’s date and the number of days until a significant event. • Teach caregivers importance of calling child by name. • Talk to child frequently, avoiding use of “baby talk.”
Moral	<ul style="list-style-type: none"> • <i>Kohlberg</i>: Preconventional stage • Learns to distinguish right from wrong. 	<ul style="list-style-type: none"> • Parents need to be consistent in setting limits. • Understand the significance of modeling desired behavior to child. • Spiritual
Spiritual	<ul style="list-style-type: none"> • <i>Fowler</i>: Intuitive-projective stage of faith 	<ul style="list-style-type: none"> • Instruct parents to provide simple answers to questions related to religion. • Instruct on importance of incorporating religious rituals and ceremonies into daily life.

J., Wilson, D., & Jackson, C. (2006). *Wong’s nursing care of infants and children* (8th ed.). St. Louis, MO: Elsevier.

FIGURE 18-7 By participating in this health examination, this mother is helping her son overcome his anxiety. DELMAR/CENGAGE LEARNING

Some specific nursing approaches to use with toddlers are the following:

- Explain what is being done in a calm tone of voice.
- Use play to alleviate anxiety (e.g., have the child examine a teddy bear or doll).
- Give short, simple directions.
- After a painful procedure, comfort the child (cuddling, rocking).
- Encourage parents' active participation in the care.

WELLNESS PROMOTION Teaching is done with both toddlers and their parents. Play can be used to establish an effective relationship with the child. Play is a valuable process for toddlers in that it is the primary mechanism for socialization and learning. To facilitate learning, approach toddlers at eye level and use terminology that they can understand.

Respiratory infections are common health threats to the toddler. Parasitic diseases are also fairly common. Toddlers need to have regular health examinations, and immunizations remain an essential part of health care. Encourage parents to be involved during the examination and immunizations. Teaching parents preventive measures becomes the focus of wellness promotion.

Nutritional needs change during the toddler period as the rate of growth slows. The need for calories decreases from the requirements for infants. The required amount of protein is also lower than that of the infant; however, toddlers still need more protein than do older children. The toddler needs fewer fluids than the infant (Hockenberry et al., 2006). Because most toddlers become selective (“picky”) about the foods they enjoy, it is sometimes difficult to provide increased intake of calcium and iron due to the toddler’s food habits. The toddler should consume an average of 2 to 3 cups of milk a day to ensure adequate calcium intake. The toddler who drinks more than a quart of milk per day is at increased risk of developing anemia because the high milk consumption limits the amount of other nutrients taken in (Hockenberry et al., 2006).

Nurses can play a key role in the toddler’s nutritional counseling. The following points should be shared with parents about dietary practices:

- Avoid using food as a reward because this may encourage overeating.
- Do not serve large helpings because the child may be overwhelmed and refuse to eat.
- Expect sporadic eating patterns (e.g., toddler eats a lot one day and very little the next; enjoys one food for several days and then suddenly will refuse it).
- Avoid power struggles related to meals. Trying to force a child to eat is counterproductive to establishing healthy eating habits.
- Establish a mealtime routine and follow it (rituals are comforting to toddlers).
- Provide nutritional snacks to meet dietary requirements.

SAFETY CONSIDERATIONS Accidents, especially those involving automobiles, are the most frequent cause of disability and death in toddlers (Edelman & Mandel, 2006; Murray et al., 2008). The information on the use of car seats for neonates and infants is applicable to toddlers.

Another common type of accident occurring with toddlers involves toys. Parents need to be taught to inspect toys for age appropriateness, sharp objects, small parts that can be swallowed, and flammable or toxic materials (e.g., lead-based paint). As children gain new skills, parents should be taught to reassess the safety of toys and of the home environment.

Toddlers, with their increased mobility and curiosity, are especially prone to accidental poisonings. Parents should be informed of the need for careful observation of the toddler and childproofing the home.

PRESCHOOLER

The developmental stage from the ages of 3 to 6 is called the **preschool stage**. During this stage, physical growth slows and psychosocial and cognitive development are accelerated. Table 18-18 on page 332 describes preschool development in detail.

During this period of childhood, curiosity becomes pronounced and the child is better able to communicate. When teaching the parents, let them know that the child’s frequent use of the word “why” is necessary for normal cognitive and psychosocial development.

The child’s world begins to expand outside the immediate home environment. Play is the mechanism used by the preschooler to learn about and develop relationships.

Nursing Implications

Play is a tool that can be used by nurses with preschoolers to help reduce fear and anxiety. Through the use of play, preschoolers learn about the environment, incorporate socially defined expectations for behavior, and reduce tension (see Figure 18-8 on page 333).

WELLNESS PROMOTION When working with a preschooler, it is important for the nurse to communicate at the

TABLE 18-18 Preschooler: Growth and Development

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Physiological	<ul style="list-style-type: none"> Physical growth slows; average weight at age 5 is 45 pounds. Size of head is approximate adult size. 	<ul style="list-style-type: none"> Can eat larger meals and a variety of foods.
Motor	<ul style="list-style-type: none"> Has a full set of deciduous teeth; these “baby teeth” start to fall out and be replaced by permanent teeth. Development of fine motor skills (e.g., ability to skip, throw a ball overhand, use scissors, tie shoelaces). 	<ul style="list-style-type: none"> Provide a safe environment for play and exploration. Praise attempted independent activities.
Psychosocial	<ul style="list-style-type: none"> <i>Freud</i>: Phallic stage Oedipal conflict leads to development of superego (conscience) <i>Erikson</i>: Initiative vs. guilt <i>Havighurst</i>: Developmental tasks include: <ul style="list-style-type: none"> — Learning sex differences and modesty — Increasing language development and basic ability to formulate concepts — Developing reading readiness — Distinguishing right from wrong 	<ul style="list-style-type: none"> Inform parents that preschoolers learn self-control through interacting with others. Inform parents to provide sex education information at the child’s comprehension level. Encourage parents to read to child.
Cognitive	<ul style="list-style-type: none"> <i>Piaget</i>: Preoperational stage Improved ability to use reason and logic and increased curiosity result in frequent use of questioning. Play becomes more reality based. As a result of increased ability to communicate, there is greater socialization with peers. 	<ul style="list-style-type: none"> Parents need to know that children of this age learn through frequent use of the word “why.”
Moral	<ul style="list-style-type: none"> <i>Kohlberg</i>: Preconventional stage A conscience begins to develop. Child fears wrongdoing. Child seeks parental approval. 	<ul style="list-style-type: none"> Teach child basic values, ideally by role modeling. Provide consistent praise and acceptance of child.
Spiritual	<ul style="list-style-type: none"> <i>Fowler</i>: Intuitive-projective stage of faith Not yet able to understand spiritual concepts. Imitates parental behaviors. 	<ul style="list-style-type: none"> Remind parents that teaching by example is the best approach for a child this age.

Data from Murray, R. B., Zentner, J. P., & Yakimo, R. (2008). *Nursing assessment and health promotion through the lifespan* (8th ed.). Upper Saddle River, NJ: Pearson; Hockenberry, M. J., Wilson, D., & Jackson, C. (2006). *Wong's nursing care of infants and children* (8th ed.). St. Louis, MO: Elsevier.

child’s level of comprehension without talking down to the child. Include the child in activities and decisions as much as possible. The preschool years are the optimum time for the child to begin showing interest in health. The astute nurse capitalizes on this by making health education fun in order to promote the development of lifelong health-promoting lifestyles.

A major wellness intervention for preschoolers is immunization. Teach parents about and encourage them to adhere

to the recommended schedules. Each state in the United States has immunization requirements as prerequisites for school admission. The nurse should encourage parents to have children immunized and to keep the immunization records current.

SAFETY CONSIDERATIONS Accidents are the leading cause of death in young children. Eagerness to explore the environment and cognitive immaturity lead to the

FIGURE 18-8 Play is an important tool for socializing among preschoolers. Describe a few health care activities that nurses can incorporate through play that would correspond to a preschooler's level of development. DELMAR/CENGAGE LEARNING

preschooler's risk for accidents. Children in this stage often act impulsively and cannot be expected to remember and follow all safety rules. Parents must understand the importance of teaching young children the meaning of "no" to prevent accidents. Common accidents that affect preschoolers are automobile accidents, burns, falls, drowning, animal bites, and ingestion of poisonous substances.

It is important for the nurse to emphasize education about protection from potential hazards. The safety practices that are developed by the preschooler will tend to be lifelong. Adults can best teach preschoolers about accident prevention through role modeling. For example, parents who buckle their seat belts every time they get into a car are not only protecting themselves but are also teaching their children an important accident preventive measure.

SCHOOL-AGE CHILD

During the **school-age period** (developmental stage from the ages of 6 to 12 years), physical changes occur at a slow, even, continuous pace. Table 18-19 on page 334 gives an overview of growth and development of the school-age child.

The school-age child's world expands greatly. Participation in school activities, team sports, and play contributes to an enlarging social network. For children in school, play time becomes more structured and less spontaneous. Communication

increases and vocabulary expands greatly to accommodate the expression of needs, thoughts, and feelings.

As the school-age child's cognitive abilities expand, creativity is expressed in a variety of unique ways. Involvement in academics, sports, and social activities stimulates the development of creativity and provides outlets for its expression.

Nursing Implications

The most common health problems of school-age children are accidents and minor illnesses such as upper respiratory infections. Health promotion teaching is a major role of the nurse caring for school-age children.

WELLNESS PROMOTION Lifestyles begin to be established during childhood; nurses can intervene to promote the development of healthy lifestyles with children in schools. Schools are an area in which health promotion behaviors can be taught in a cost-effective manner. Nurses can promote wellness in the school-age child by teaching parents to:

- Encourage healthy lifestyles (nonsedentary activities, nutritious meals)
- Provide nutritious meals
- Have children immunized
- Teach children appropriate hygienic measures
- Schedule regular checkups with the primary health care provider
- Schedule dental checkups and encourage daily brushing and flossing
- Establish sleep patterns alternating with periods of activity
- Report any symptoms of illness immediately to the health care provider
- Teach safety precautions

SAFETY CONSIDERATIONS Many accidents experienced by school-age children occur during play. Injuries related to the use of skates, skateboards, in-line skates, bicycles, and scooters are common. Children should be taught safety rules for use of such toys (e.g., use of protective equipment; Figure 18-9 on page 335). Parents must frequently remind children of the danger of playing near traffic. Children in this developmental stage must also be taught to use caution with strangers because of the possibility of abductions.

PREADOLESCENT

Preadolescence, the developmental stage from the ages of 10 to 12 years, is marked by rapid physiological changes with accompanying psychological and social implications. The child is beginning to experience hormonal changes that will result in the onset of **puberty** (appearance of secondary sex characteristics). Girls generally experience preadolescence at a younger age than boys—approximately age 9 to 10 for girls and age 10 to 11 for boys (Edelman &

TABLE 18-19 School-Age Child: Growth and Development

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Physiological	<ul style="list-style-type: none"> Physical growth is steady (approximately 3–6 pounds and 2–3 inches per year). Due to changes in amount and distribution of fat, body has an overall slimmer shape. Maturation of CNS is nearly completed. 	<ul style="list-style-type: none"> Emphasize with parents the need for a balanced diet to sustain growth requirements.
	<ul style="list-style-type: none"> By age 12, all permanent teeth are present (except second and third molars). 	<ul style="list-style-type: none"> Teach parents need for dental hygiene (daily brushing and flossing) and regularly scheduled visits to dentist. Instruct to change toothbrushes every 3 months.
Motor	<ul style="list-style-type: none"> Continued development of motor control. 	<ul style="list-style-type: none"> Encourage participation in physical activities.
	<ul style="list-style-type: none"> Becomes less dependent on parents for activities of daily living. 	<ul style="list-style-type: none"> Provide praise for independent activities.
Psychosocial	<ul style="list-style-type: none"> <i>Freud</i>: Latency stage Same-gender companions preferred. <i>Erikson</i>: Industry vs. inferiority 	<ul style="list-style-type: none"> To develop a sense of confidence, encourage child to: <ul style="list-style-type: none"> —Participate in both group and individual activities —Become involved in a variety of activities
	<ul style="list-style-type: none"> Develops initiative and high level of self-esteem as shown in school and sports. Exhibits less dependency on family. <i>Havighurst</i>: Developmental tasks include ability to perform more complex motor functions (e.g., ride a bicycle, catch a ball) 	<ul style="list-style-type: none"> Encourage parents to praise child's efforts.
Cognitive	<ul style="list-style-type: none"> <i>Piaget</i>: Concrete operations stage 	<ul style="list-style-type: none"> Encourage child to engage in group activities.
	<ul style="list-style-type: none"> Ability to cooperate with others and begins to be able to see the other's point of view, which leads to more meaningful communication. Reasoning ability moves from intuitive toward logical and rational. 	
	<ul style="list-style-type: none"> Ability to think in the abstract is not fully developed. Develops the concept of time: <ul style="list-style-type: none"> —Knows difference between past and present —Begins to learn to tell time —Understands the process of aging better Able to order, categorize, and classify groups of objects as evidenced in increased interest in collections (coins, stamps, rocks). Sees relationships between objects. 	<ul style="list-style-type: none"> Communicate at child's level of comprehension.
Moral	<ul style="list-style-type: none"> <i>Kohlberg</i>: Conventional stage 	<ul style="list-style-type: none"> Provide consistent limits.
	<ul style="list-style-type: none"> Can understand what society deems as unacceptable behavior but cannot always choose between right and wrong without assistance. 	<ul style="list-style-type: none"> Role-model appropriate behavior. Provide praise for appropriate behavior.
Spiritual	<ul style="list-style-type: none"> <i>Fowler</i>: Mythical-literal stage of faith 	<ul style="list-style-type: none"> Encourage parents to discuss their beliefs.
	<ul style="list-style-type: none"> Accepts existence of a deity. 	<ul style="list-style-type: none"> Storytelling and use of parables can reinforce understanding of spiritual concepts.
	<ul style="list-style-type: none"> Beliefs are symbolized through stories. 	

Data from Edelman, C. L., & Mandel, C. L. (2006). *Health promotion throughout the lifespan* (6th ed.). St. Louis, MO: Mosby; Murray, R. B., Zentner, J. P., & Yakimo, R. (2008). *Nursing assessment and health promotion through the lifespan* (8th ed.). Upper Saddle River, NJ: Pearson.

FIGURE 18-9 The use of equipment, such as safety helmets, helps to protect school-age children from injury. DELMAR/CENGAGE LEARNING

Mandle, 2006). Table 18-20 on page 336 provides an overview of preadolescent development.

In girls, breast development begins between the ages of 10 and 11. Further breast development is stimulated by the release of estrogen that occurs during puberty. Premature adrenarche refers to early onset of secretion of adrenal androgens, which results in the isolated development of pubic hair before the age of 8 years in girls and 9 years in boys. Premature adrenarche may result in the development of polycystic ovary syndrome and/or syndrome X (Leung & Robson, 2008). Nurses must inform parents of the need for observation and reporting of indicators of adrenarche. The pattern of female breast development is described in Table 18-21 on page 338. Other aspects of female sexual development are described in Table 18-22 on page 339.

Approximately 2 years after the appearance of breast buds, **menarche** (onset of the first menstrual period) occurs. The first menstrual periods are usually irregular and scant, and they may or may not be accompanied by ovulation. The average age of menarche in the United States is 12.8 years, which has gradually declined over the past century. This is probably due to improved general health status, particularly nutrition and sanitation (Hockenberry et al., 2008).

The menstrual cycle is a complex blend of physiological and psychological changes that occur approximately every month. After approximately the first 6 to 12 months, a girl's cycle will become established in a regular pattern. Some girls may have received inadequate or incorrect information regarding the onset of menstruation. Client teaching should include information about the physiological changes, emotional changes, and hygienic practices. Teaching should emphasize that the cyclical hormone-induced changes are normal.

In preadolescent boys, the first signs of puberty are:

- Testicular enlargement
- Penile enlargement
- The scrotum becomes thinner and redder
- Pubic hair growth

Table 18-23 on page 340 illustrates the physiological changes in boys during sexual development of male genitalia.

Nursing Implications

Sensitivity is essential for the nurse working with the preadolescent. To increase one's sensitivity, the nurse uses a non-judgmental approach and attends to the child's body language. It is imperative that the nurse establish a trusting relationship with the preadolescent in order to encourage the child to ask questions about any health-related concerns.

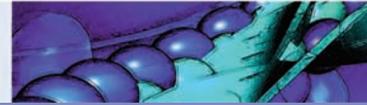

WELLNESS PROMOTION The preadolescent needs information about nutrition, rest and activity, and physiological changes that are occurring. The child must learn about the growth spurt, sexual changes, and psychosocial changes. By preparing the preadolescent for upcoming changes, the nurse is promoting physical and emotional health.

SAFETY CONSIDERATIONS The preadolescent is at risk for injury from sports and play activities. Another major health risk posed to many preadolescents is violence, both in and away from the home. Education is a major preventive approach to violence; it is the tool for helping break the intergenerational cycle of child abuse.

Other topics for promoting preadolescent safety are substance abuse prevention, sex education, and development of healthy lifestyles.

ADOLESCENT

Adolescence, the developmental stage from the ages of 13 to 20 years, begins with the onset of puberty. During adolescence, the individual undergoes the major transition from child to adult. Numerous physiological changes and rapid physical growth occur during this stage. The rapid changes that occur during adolescence are not only physical. Many psychosocial adjustments must be made by the adolescent. Establishing a sense of personal identity uses a great amount of the adolescent's psychic energy. Questions such as "Who am I?" and "What is *really* important?" are common for adolescents to consider. See Table 18-20 for an overview of adolescent development.

TABLE 18-20 Preadolescent and Adolescent: Growth and Development

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Physiological <i>Physiological changes</i>	<ul style="list-style-type: none"> Accelerated physical growth with changes in body proportion. Extremities grow first, then trunk and hips. Growth in skull and facial bones results in changes in physical appearance. 	<ul style="list-style-type: none"> Teach the child and parents about expected growth spurts. Provide reassurance that it is not uncommon for facial appearance to change in only a few months.
<i>Reproductive and sexual changes</i>	<ul style="list-style-type: none"> Hypothalamus stimulates secretion of pituitary gonadotropins, leading to reproductive maturity. Development of both primary and secondary sex characteristics. Beginning of puberty is evidenced in girls by: <ul style="list-style-type: none"> Breast development Pubic and axillary hair growth Menarche (onset of menses) Increases in height Beginning of puberty is evidenced in boys by: <ul style="list-style-type: none"> Genital development Growth of facial, pubic, and axillary hair Nocturnal ejaculations Height increases Voice changes 	<ul style="list-style-type: none"> Provide support and information about emerging sexual changes. Remember that the physiological changes are accompanied by psychological and social alterations.
<i>Musculoskeletal changes</i>	<ul style="list-style-type: none"> Ossification of bones. Increased muscle mass and strength. 	<ul style="list-style-type: none"> Encourage physical activities and intake of adequate amounts of calcium.
<i>Cardiovascular changes</i>	<ul style="list-style-type: none"> Heart increases in size and strength. Heart rate decreases to adult norms. Increased blood volume and blood pressure. 	
<i>Respiratory changes</i>	<ul style="list-style-type: none"> Rate decreases to an average of 15–20 respirations per minute. Increased respiratory volume and vital capacity. Growth of larynx, laryngeal cartilage, and vocal cords and deepening of voice pitch. 	<ul style="list-style-type: none"> Instruct about anticipated changes.
<i>Gastrointestinal and genitourinary changes</i>	<ul style="list-style-type: none"> Spleen, liver, kidneys, and digestive tract enlarge but experience no functional changes. 	
<i>Dental changes</i>	<ul style="list-style-type: none"> Eruption of last four molars. 	<ul style="list-style-type: none"> Emphasize importance of continued dental hygiene.
<i>Integumentary changes</i>	<ul style="list-style-type: none"> Skin becomes thicker and tougher. Activation of sebaceous glands leads to possibility of acne. Appearance of pubic hair. 	<ul style="list-style-type: none"> Teach proper skin care: <ul style="list-style-type: none"> Wash two to three times daily with soap and water. Avoid vigorous scrubbing. Females should avoid cosmetics with a fat or grease base.

TABLE 18-21 Sexual Maturity Rating for Female Breast Development

DEVELOPMENTAL STAGE

**1. Preadolescent state (before age 10)**

- Nipple is small, slightly raised.

2. Breast bud stage (after age 10)

- Nipple and breast form a small mound.
- Areola enlarges.
- Height spurt begins.

3. Adolescent stage (10–14 years)

- Nipple is flush with breast shape.
- Breast and areola enlarge.
- Menses begin.
- Height spurt peaks.

4. Late adolescent stage (15–19 years)

- Nipple and areola form a secondary mound over the breast.
- Height spurt ends.

5. Adult stage.

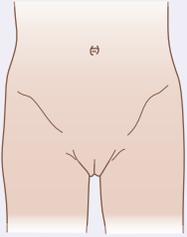

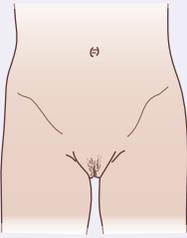

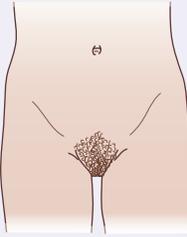

- Nipple protrudes.
- Areola is flush with the breast shape.

Data from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning.

Most adolescents are greatly concerned about their appearance. This emphasis on physical attractiveness sometimes results in eating disorders, such as **anorexia nervosa**, a self-imposed starvation that results in a 15% loss of body weight. Approximately 1% to 2% of female adolescents are

affected by anorexia; the rate in males is much lower—about 5% to 10% of the anorectic population is male (Kneisl & Trigoboff, 2009). Other types of eating disorders common in adolescents are **bulimia** (episodic binge eating followed by purging) and **obesity** (weight that is 20% or more above the

TABLE 18-22 Sexual Maturity Rating for Female Genitalia

DEVELOPMENTAL STAGE	
	Stage 1 (before age 11) No pubic hair, only body hair (vellus hair).
	Stage 2 (11–12 years) Sparse growth of long, slightly dark, fine pubic hair, slightly curly and located along the labia.
	Stage 3 (12–13 years) Pubic hair becomes darker, curlier, and spreads over the symphysis.
	Stage 4 (13–15 years) Texture and curl of pubic hair are similar to those of an adult but not spread to thighs.
	Stage 5 (adult stage) Adult appearance in quality and quantity of pubic hair. Growth is spread to inner aspect of thighs and abdomen.

Data from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning.

ideal body weight). See the accompanying Client Teaching Checklist for essential information about eating disorders to share with clients and families.

Nursing Implications

Nurses support adolescents by providing information about the numerous bodily changes. Adolescents should be encouraged to share their health concerns with parents. However, the nurse must honor the adolescent's choice to withhold sensitive information from parents. The use of a nonjudgmental attitude is essential to the establishment of rapport when working with adolescents. Adolescents should be treated in a respectful, dignified manner. Avoid using a condescending attitude when communicating with them. The accompanying Nursing Checklist discusses therapeutic approaches that can be used when working with adolescent clients.

WELLNESS PROMOTION The nurse promotes the adolescent's wellness primarily through teaching. Areas to be emphasized in health education of adolescents include hygiene, nutrition, sex education, developmental changes, and substance abuse prevention.

Adolescents need education about the physical changes they are undergoing. Health teaching is often done by school nurses, and the establishment of nurse-managed clinics in schools is one avenue for promoting wellness among adolescents.

SAFETY CONSIDERATIONS Unhealthy behaviors contribute to the three major causes of adolescent death: accidents, homicide, and suicide. The following developmental factors increase the adolescent's risk for accidents:

- Impulsive behavior
- Sense of being invulnerable to accidents (a feeling that "It can never happen to me!")
- Testing limits
- Rebelling against adult advice

As a result, many adolescents engage in unhealthy behaviors such as smoking, consuming alcohol and other drugs, reckless driving, violence, and unprotected sexual activity. See the accompanying Respecting Our Differences display on page 341.

Many health problems in adolescents are related to sexual behaviors, including acquired immunodeficiency syndrome (AIDS), sexually transmitted diseases (STDs), and unplanned pregnancy. The effect of teen pregnancy on families and communities is great. Many pregnant teens become trapped in a cycle of school failure (or dropout), limited employment opportunities, and poverty. Adolescents who

CLIENT TEACHING CHECKLIST

Preventing Eating Disorders

- Promote an increased sense of self-esteem.
- Emphasize the importance of a healthy lifestyle rather than physical appearance.
- Avoid pressuring children to seek perfection or to strive for unrealistic goals.
- Recognize the indicators of eating disorders.

TABLE 18-23 Sexual Maturity Rating for Male Genitalia

	PUBIC HAIR	PENIS	SCROTUM
	Developmental Stage 1 No pubic hair, only fine body hair (vellus hair).	Preadolescent; childhood size and proportion	Preadolescent; childhood size and proportion
	Developmental Stage 2 Sparse growth of long, slightly dark, straight hair.	Slight or no growth	Growth in testes and scrotum; scrotum reddens and changes texture
	Developmental Stage 3 Becomes darker, coarser, and slightly curled and spreads over symphysis.	Growth, especially in length	Further growth
	Developmental Stage 4 Texture and curl of pubic hair are similar to an adult's but hair does not spread to thighs.	Further growth in length; diameter increases; development of glans	Further growth; scrotum darkens
	Developmental Stage 5 Adult appearance in quality and quantity of pubic hair; growth is spread to medial surface of thighs.	Adult size and shape	Adult size and shape

Data from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning.

become pregnant experience developmental difficulties in that they must make adult decisions. Infants born to adolescent mothers are likely to experience health-related problems such as prematurity and low birth weight. The pregnant

adolescent needs expert prenatal care, a supportive environment, and information. Client teaching must emphasize the prevention of STDs because the pregnancy itself is evidence of high-risk (unprotected) sexual activity.

NURSINGCHECKLIST
Therapeutic Approaches with the Adolescent Client

- Treat the adolescent as an active participant in health care to form a collaborative partnership.
- Answer all questions honestly.
- Be especially sensitive to nonverbal clues. Adolescents are often too embarrassed to initiate discussion of their health-related concerns.
- Remember that the peer group is of major importance to adolescents, and use group settings whenever possible to provide health education.
- Demonstrate acceptance of the adolescent, especially if limits need to be established to intervene with unhealthy or inappropriate behaviors.
- Questioning adult authority is a normal part of adolescent rebelliousness. Do not personalize testing behaviors. Nurses who personalize client behavior become defensive and lose their interpersonal effectiveness with adolescents.

STDs present a serious health threat for adolescents. Diseases such as genital herpes virus, human papillomavirus (which causes genital warts), chlamydia, syphilis, and gonorrhea are spread through sexual contact. The human immunodeficiency virus (HIV), which causes AIDS, is also transmitted through unprotected sexual activity. Table 18-24 on page 342 describes the most common STDs. Nurses must educate adolescents about methods for preventing the spread of STDs. Preventive education should include the following topics:

- Methods of transmission
- Incubation period
- Clinical manifestations
- Treatment methods
- Consequences of lack of or inadequate treatment
- Notification of sexual partner(s)

Nurses who teach adolescent clients about safe sex practices need to be especially sensitive to cultural influences on sexual activity. See the accompanying Spotlight On display.

RESPECTING OUR DIFFERENCES
Adolescent Behaviors

Think of the type of behaviors adolescents often demonstrate to prove that they are “grown up.” Which of these behaviors have a negative impact on health? Which have a positive impact?

SPOTLIGHT ON...
Values
Values Clarification

As a nurse, you will often encounter clients whose value systems conflict with your own beliefs. How will you provide care to sexually active adolescents if you think their behavior is immoral or “wrong”? Is it ethical for you to try to change the adolescent’s values to be congruent with yours? Should you change your values to be congruent with those of the client?

Laws concerning the dissemination of information about STDs vary among states and provinces. However, most have legislation that requires nurses to report the names of clients with certain STDs to the state or provincial health department. The nurse must know the requirements for his or her state or province.

Another major health problem during adolescence is the high risk of suicide. Often, suicide is perceived by the adolescent as the only alternative to an overwhelming situation. Low self-esteem, lack of maturity, and impulsive behaviors may increase the risk of suicidal behavior. The rate of suicide is higher among adolescent males than females.

When assessing for suicidal potential, the nurse should always directly question the adolescent about any plans for harming or killing him- or herself. Signs indicative of suicide risk in adolescents include:

- Writing suicide notes
- Talking about suicide
- Substance abuse
- Preoccupation with death
- Giving away treasured objects
- Sudden changes in behavior
- Verbal cues (e.g., “You won’t have to worry about me much longer”)

When teaching suicide prevention, inform people to *immediately* contact a health care professional if someone is exhibiting any of the indicators of suicide risk. Many communities have a special telephone suicide-cope-line available. See the accompanying Safety First display.

SAFETY FIRST

SUICIDE PREVENTION

Never leave the suicidal adolescent alone. Close observation is a strong deterrent to suicide.

TABLE 18-24 Sexually Transmitted Diseases: An Overview

DISEASE	CHARACTERISTICS	NURSING IMPLICATIONS
Acquired immunodeficiency syndrome (AIDS)	<ul style="list-style-type: none"> Incurable and often fatal disease In addition to sexual activity, other modes of transmission are: <ul style="list-style-type: none"> — Direct exposure to infected blood or blood products — Intrauterine transmission from infected woman to fetus 	<ul style="list-style-type: none"> Know that the incubation period can range up to 15 years from time of initial exposure. The only “cure” is prevention. Teach safe sex methods (use of latex condoms). Provide information about the disease. Treatment is primarily supportive. Provide physical care and psychological support. Always follow standard precautions guidelines.
Chancroid	<ul style="list-style-type: none"> A small, irregular-shaped papule (on the penis, labia, or vaginal opening) that develops into a painful ulcer that drains pus or blood Dysuria (painful urination) Painful regional lymph nodes (inguinal tenderness) 	<ul style="list-style-type: none"> Partner(s) having sex within 10 days before onset of client’s symptoms need to be assessed. Client should be reassessed within 7 days after treatment begins. Instruct in proper use of condoms. Medication education.
Chlamydia	<p><i>Males:</i></p> <ul style="list-style-type: none"> Painful urination Urethral discharge <p><i>Females:</i></p> <ul style="list-style-type: none"> Usually none May experience purulent discharge Note: If untreated, pelvic inflammatory disease (PID) can develop. 	<ul style="list-style-type: none"> Instruct client to notify sexual partner(s) of past 2 months of their need for treatment. Instruct clients to avoid sexual activity or to use condoms until both client and partner(s) are symptom free. Medication education.
Genital herpes: herpes simplex virus 2 (HSV-2)	<ul style="list-style-type: none"> Vesicles on penis, vagina, labia, perineum, or anus Can progress to painful ulceration Lesions may last up to 6 weeks Recurrence is common Note: May be asymptomatic 	<ul style="list-style-type: none"> Refer sexual partner(s) for examination. Teach that virus can be transmitted even when the person is asymptomatic. Instruct in use of condoms. Teach females of need for annual Pap smear. Medication education.
Gonorrhea	<p><i>Males:</i></p> <ul style="list-style-type: none"> Urethritis (inflammation of the urethra) Purulent discharge Urinary frequency Epididymitis (inflammation of the epididymis) <p><i>Females:</i></p> <ul style="list-style-type: none"> Is often asymptomatic May lead to PID or salpingitis (inflammation of the fallopian tube) Can occlude the fallopian tubes, with resultant sterility 	<ul style="list-style-type: none"> Instruct client to return for further treatment if symptoms persist. Sexual partner(s) within past 60 days need to be assessed. Instruct to avoid sexual activity until symptoms subside in both client and partner(s). Medication education.

TABLE 18-24 (Continued)

DISEASE	CHARACTERISTICS	NURSING IMPLICATIONS
Hepatitis B virus (HBV)	<ul style="list-style-type: none"> Varies greatly from asymptomatic state to severe hepatitis to cancer 	<ul style="list-style-type: none"> Partner(s) should receive medical prophylaxis within 14 days after exposure. For client and partner(s): Recommend three-dose immunization series when this episode has abated.
Human papillomavirus (genital warts)	<ul style="list-style-type: none"> Fleshy, cauliflower-like growth on genitalia 	<ul style="list-style-type: none"> Inform and treat sexual partner(s). Medication education.
Syphilis	<ul style="list-style-type: none"> Disease consists of four stages with distinct manifestations: <p><i>Primary:</i></p> <ul style="list-style-type: none"> A painless papule on penis, vagina, or cervix Serologic blood test usually negative Highly infectious during this stage <p><i>Secondary:</i></p> <ul style="list-style-type: none"> Rash, especially prevalent on palms and soles Low-grade fever Sore throat Headache <p><i>Early Latency:</i></p> <ul style="list-style-type: none"> Infectious lesions may occur, otherwise asymptomatic. Reactive serologic tests <p><i>Late Latency:</i></p> <ul style="list-style-type: none"> Lesions may be present in central nervous and cardiovascular systems. Noninfectious except to fetus of pregnant woman 	<ul style="list-style-type: none"> Interview client to identify sexual contacts. Protect confidentiality of all involved. All those exposed to the disease should be given penicillin. Educate client and sexual contacts about the disease. Medication education. Counsel and educate client. Counsel and educate client.
Trichomoniasis	<ul style="list-style-type: none"> Petechial lesions Profuse urethral or vaginal discharge that is foul smelling, yellow, and foamy 	<ul style="list-style-type: none"> Treat sexual partners simultaneously with metronidazole (Flagyl). Medication education.

Data from Hale, P. J. (2006). HIV, hepatitis, and sexually transmitted diseases. In M. Stanhope & J. Lancaster (Eds.), *Foundations of community health nursing* (2nd ed.). St. Louis, MO: Mosby; Ignatavicius, D. D., & Workman, M. L. (2009). *Medical-surgical nursing: Critical thinking for collaborative care* (6th ed.). St. Louis, MO: Elsevier.

Another significant health problem for many adolescents is substance abuse. Using alcohol or other drugs is a common maladaptive attempt to cope with the stressors of adolescence. Some indicators of substance abuse in adolescents are:

- Decline in academic performance
- Mood swings
- Changes in personality (e.g., confusion, euphoria, belligerence, withdrawal)
- Fatigue

- Drowsiness
- Behaviors indicative of depression (e.g., appetite changes, insomnia, weight loss, apathy)

Nurses can play a key role in substance abuse prevention with adolescents. A comprehensive substance abuse prevention educational program includes:

- Hazards of drug use
- Misuse of legal substances, such as tobacco and alcohol
- Self-esteem-boosting methods

- Assertive communication skills (how to say “no” to peers)
- Adaptive coping mechanisms for dealing with stress

By providing such information, nurses can help adolescents make responsible, informed decisions before experimentation with drugs begins.

YOUNG ADULT

Physical growth stabilizes during **young adulthood**, the developmental stage from the age of 21 to approximately 40 years. Young adults experience physical and emotional changes at a slower rate than adolescents. Table 18-25 on page 345 describes the development of young adults. Young adulthood is a time of transition from an adolescent to a person capable of assuming adult responsibilities and making adult decisions.

Pregnancy, a time of transition and lifestyle adjustment, is experienced by many young women. Table 18-26 on page 346 lists a few of the changes commonly experienced during pregnancy. Throughout pregnancy, women experience changes in self-concept and may need reassurance that such changes are normal.

Nursing Implications

Usually, young adulthood is the healthiest time in a person’s life. Consequently, concern for health is low among people in this age group, and wellness is often taken for granted. Preventive measures for young adults focus on three primary areas:

1. Avoidance of accident, injury, and violence
2. Development of health-promoting behaviors (e.g., lifestyle modification)
3. Maintenance of current recommended immunizations (see Figure 18-10 on page 346)

The nurse plays an important role in each of these areas of health promotion by teaching and counseling. Other topics that are developmentally appropriate for the nurse to address are vocational counseling and establishing relationships.

WELLNESS PROMOTION Decision making by young adults affects their health status. Since young adults tend to take excessive risks, they are at greater risk for death from accident, suicide, or homicide (Edelman & Mandle, 2006). For example, driving recklessly, driving while intoxicated, engaging in unprotected sex, and participating in gang activities illustrate the lack of a sense of fear that is demonstrated by many young adults.

STD is a leading cause of infection with resultant reproductive dysfunction in young adults. The information presented about STDs in the discussion of safety considerations for adolescents is also applicable to young adults. Nurses should teach women how to perform a monthly breast self-examination (BSE). Men need to learn how to perform a testicular self-examination (TSE); see Chapter 27.

SAFETY CONSIDERATIONS Because vehicular accidents are a major cause of health problems for young adults, providing information about driving safety is a must. Another activity that poses a health risk for many young adults is sunbathing. Exposure to direct sunlight with the resultant radiation or use of tanning salons is directly linked to skin cancer. Nurses can be influential in decreasing the occurrence of skin cancer through teaching and by role modeling safe behaviors.

MIDDLE-AGED ADULT

Middle adulthood, the developmental stage from the ages of 40 to 65 years, is characterized by productivity and responsibility. For most middle-aged adults, the majority of activity revolves around work and parenting, and success and achievement are measured in terms of career accomplishments and family life.

Physiological changes that affect many of the body systems occur during middle adulthood. Table 18-27 on page 348 lists the major changes experienced by the middle-aged person.

The primary developmental task of the middle-aged adult revolves around the conflict of generativity (a sense that one is making a contribution to society) versus stagnation (a sense of nonmeaning in one’s life). When an individual successfully resolves this developmental conflict, acceptance of age-related changes occurs. Achievement of the developmental task is indicated by the following:

- Demonstrating creativity
- Guiding the next generation
- Establishing lasting relationships
- Evaluating goals in terms of achievement

The evaluation of goals often leads to a midlife crisis, especially if individuals feel they have accomplished little or failed to live up to earlier self-expectations.

Nursing Implications

A large proportion of the U.S. population consists of middle-aged adults (Edelman & Mandle, 2006). Individuals of the baby-boom generation have entered their midlife stage and will require more nursing care to maintain wellness and cope with illness.

Nurses have the opportunity to help middle-aged clients improve their health status (and thus quality of life) by identification of risk factors and early intervention. The major risk factors for adults in the middle years can be modified because they are primarily environmental and behavioral. Assisting the middle-aged client to change unhealthy behaviors can be done through one-to-one intervention or in group settings.

WELLNESS PROMOTION As health educators, nurses can encourage middle-aged adults to assume more responsibility for their own health (see Figure 18-11 on page 347). Self-care education topics appropriate for the middle-aged adult include:

- Acceptance of aging
- Nutrition

TABLE 18-25 Young Adult: Growth and Development

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Physiological <i>Physiological changes</i>	<ul style="list-style-type: none"> Physical growth stabilizes. Time of optimum physical functioning. Maturation of body systems complete. 	<ul style="list-style-type: none"> The person is at physical peak and therefore less likely to be concerned with own health. Teach importance of health promotion behaviors. Encourage development of healthy lifestyles.
<i>Cardiovascular changes</i>	<ul style="list-style-type: none"> Men are more likely to have increased cholesterol levels than women. 	
<i>Gastrointestinal changes</i>	<ul style="list-style-type: none"> After age 30, decreased digestive juices. 	
<i>Dental changes</i>	<ul style="list-style-type: none"> By mid-20s, dental maturity is achieved with emergence of last four molars (“wisdom teeth”). 	
<i>Musculoskeletal changes</i>	<ul style="list-style-type: none"> At approximately age 25, skeletal growth is complete. 	
<i>Reproductive and sexual changes</i>	<ul style="list-style-type: none"> System is completely matured. <i>Women:</i> Ages 20–30 are optimal years for reproduction. <i>Men:</i> Beginning at about age 24, male hormones slowly decrease; does not affect ability to reproduce.

Recommended Adult Immunization Schedule UNITED STATES - 2009

Note: These recommendations *must* be read with the footnotes that follow containing number of doses, intervals between doses, and other important information.

VACCINE ▼	AGE GROUP ▶	19–26 years	27–49 years	50–59 years	60–64 years	≥65 years
Tetanus, diphtheria, pertussis (Td/Tdap) ^{1,2}		Substitute 1-time dose of Tdap for Td booster; then boost with Td every 10 yrs				Td booster every 10 yrs
Human papillomavirus (HPV) ^{2,3}		3 doses (females)				
Varicella ^{3,4}		2 doses				
Zoster ⁴					1 dose	
Measles, mumps, rubella (MMR) ^{5,6}		1 or 2 doses		1 dose		
Influenza ^{6,7}		1 dose annually				
Pneumococcal (polysaccharide) ^{7,8}		1 or 2 doses				1 dose
Hepatitis A ⁹		2 doses				
Hepatitis B ¹⁰		3 doses				
Meningococcal ¹¹		1 or more doses				

¹Covered by the Vaccine Injury Compensation Program.

For all persons in this category who meet the age requirements and who lack evidence of immunity (e.g., lack documentation of vaccination or have no evidence of prior infection)

Recommended if some other risk factor is present (e.g., on the basis of medical, occupational, lifestyle, or other indications)

No recommendation

FIGURE 18-10(A) Recommended Adult Immunization Schedule, by vaccine and age group. COURTESY OF THE U.S. CENTERS FOR DISEASE CONTROL AND PREVENTION BY VACCINE AND AGE GROUP

Vaccines that might be indicated for adults based on medical and other indications

INDICATION ▶ VACCINE ▼	Pregnancy	Immuno-compromising conditions (excluding human immunodeficiency virus [HIV]) ¹³	HIV infection ^{2,12,13}		Diabetes, heart disease, chronic lung disease, chronic alcoholism	Asplenia ¹² (including elective splenectomy and terminal complement deficiencies)	Chronic liver disease	Kidney failure, end-stage renal disease, receipt of hemodialysis	Health-care personnel
			CD4+ T lymphocyte count						
			<200 cells/ μ L	\geq 200 cells/ μ L					
Tetanus, diphtheria, pertussis (Td/Tdap) ^{1,2}	Td	Substitute 1-time dose of Tdap for Td booster; then boost with Td every 10 yrs							
Human papillomavirus (HPV) ^{2,2}		3 doses for females through age 26 yrs							
Varicella ^{2,2}	Contraindicated	2 doses							
Zoster ⁴	Contraindicated	1 dose							
Measles, mumps, rubella (MMR) ^{5,2}	Contraindicated	1 or 2 doses							
Influenza ^{6,2}	1 dose TIV annually								1 dose TIV or LAIV annually
Pneumococcal (polysaccharide) ^{7,8}	1 or 2 doses								
Hepatitis A ²	2 doses								
Hepatitis B ^{10,2}	3 doses								
Meningococcal ^{11,2}	1 or more doses								

*Covered by the Vaccine Injury Compensation Program.

For all persons in this category who meet the age requirements and who lack evidence of immunity (e.g., lack documentation of vaccination or have no evidence of prior infection)

 Recommended if some other risk factor is present (e.g., on the basis of medical, occupational, lifestyle, or other indications)
 No recommendation

FIGURE 18-10(B) Vaccines that might be indicated for adults based on medical and other indications COURTESY OF THE U.S. CENTERS FOR DISEASE CONTROL AND PREVENTION

- Exercise and weight control
- Substance abuse prevention
- Stress management
- Recommendations for health screening (cholesterol screening, prostate examination, mammogram, Papanicolaou [Pap] test).

SAFETY CONSIDERATIONS Automobile accidents, especially those involving the use of alcohol, are a serious health problem for middle-aged adults. Another significant problem is occupational health hazards, such as exposure to environmental toxins. Middle adulthood is also the time when a life-long accumulation of unhealthy lifestyle practices, such as smoking, sedentary habits, inadequate nutrition, and overuse of alcohol, begins to exert adverse effects.

Most middle-aged individuals have increased leisure time. Consequently, there is an increased risk for recreational accidents (e.g., boating accidents, sports-related injuries, jogging mishaps).

OLDER ADULT

Older adulthood is the developmental stage occurring from age 65 and beyond. Chapter 19 provides an in-depth discussion of the elderly adult. Therefore, this section only highlights the concepts of growth and development as they relate

FIGURE 18-11 Through activities such as running, these middle-aged adults have taken responsibility for their health and are learning to cope with the physiological changes that occur during this stage. DELMAR/CENGAGE LEARNING

to the older adult. Table 18-28 on page 351 provides an overview of growth and development in the older adult.

Older adults have several psychosocial tasks to accomplish, such as:

- Developing a sense of satisfaction with the life that one has lived (to find meaning in one's life)

TABLE 18-27 Middle Adult: Growth and Development

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Physiological <i>Cardiovascular changes</i>	<ul style="list-style-type: none"> Decreased functional aerobic capacity results in decreased cardiac output. Blood vessels become thicker and lose elasticity. 	<ul style="list-style-type: none"> Decreased capacity for physical activity. Instruct client about necessity of remaining physically active. Predisposition for hypertension (high blood pressure), coronary artery disease, and cerebral vascular accidents (“strokes”). Teach client about lifestyle modifications related to cardiovascular health: <ul style="list-style-type: none"> Smoking cessation Avoiding secondary tobacco smoke Nutrition (low fat, low cholesterol) Engaging in physical activity
<i>Neurological changes</i>	<ul style="list-style-type: none"> Cellular changes (regulation, repair, and atrophy) occur gradually. A gradual loss in efficiency of nerve conduction to impaired sensation of heat and cold. 	<ul style="list-style-type: none"> Explain age-related changes. Provide support and reassurance. Teach safety precautions regarding: <ul style="list-style-type: none"> Exposure to sunlight Sensitivity to heat stroke Sensitivity to frostbite
<i>Gastrointestinal changes</i>	<ul style="list-style-type: none"> Slower gastrointestinal motility results in constipation. 	<ul style="list-style-type: none"> Teach client about: <ul style="list-style-type: none"> Nutrition (high-fiber foods; adequate amounts of fluid) Maintaining physical activity
<i>Genitourinary changes</i>	<ul style="list-style-type: none"> Nephron units diminish in number and size; diminished blood supply to kidneys. Decreased glomerular filtration rate leads to decrease in urinary output with resultant dehydration. 	<ul style="list-style-type: none"> Teach normal age-related changes. Teach signs indicative of dehydration. Inform client of need to maintain adequate fluid intake.
<i>Integumentary changes</i>	<ul style="list-style-type: none"> Decreased moisture and turgor of skin and loss of subcutaneous fat lead to development of wrinkles. Hair thins and turns gray. 	<ul style="list-style-type: none"> Instruct client about effects of sun and cigarette smoking on the skin. Assess client for body image alterations. Use nonjudgmental listening. Provide support.
<i>Musculoskeletal changes</i>	<ul style="list-style-type: none"> Decreased bone mass and density. Slight loss of height may occur (1–4 inches). Thinning of intervertebral disks. Generalized decrease in muscle tone; “flabby” appearance and less agility. 	<ul style="list-style-type: none"> Instruct client about: <ul style="list-style-type: none"> Need for calcium intake Importance of decreasing caffeine and alcohol consumption Effects of sedentary versus active lifestyle on osteoporosis Increased risk of injury. Instruct client of need for proper posture (especially sitting), exercise, and adequate fluid intake. Instruct client on need for adequate physical activity.
<i>Endocrine changes</i>	<ul style="list-style-type: none"> Decreased metabolism results in reduced production of enzymes and increased hydrochloric acid. Lead to acid indigestion and belching. 	<ul style="list-style-type: none"> Instruct client to: <ul style="list-style-type: none"> Avoid foods that are spicy or fried Avoid eating within 2 hours before bedtime

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Moral	<p><i>Kohlberg</i>: Postconventional stage <i>Gilligan</i>:</p> <ul style="list-style-type: none"> • Women tend to judge morality of issues according to a sense of fairness and avoiding hurt to others. • Establishes moral beliefs that are independent of what others think. 	<ul style="list-style-type: none"> • Use nonjudgmental approach when client discusses values. • Respect personal differences by individualizing care.
Spiritual	<p><i>Fowler</i>: Conjunctive faith</p> <ul style="list-style-type: none"> • Is able to appreciate others' belief systems. • Becomes less dogmatic with own beliefs. • Religion is usually a source of comfort. 	<ul style="list-style-type: none"> • Encourage use of spiritual support. • Refer to clergy if desired by client.

Data from Edelman, C. L., & Mandle, C. L. (2006). *Health promotion throughout the lifespan* (6th ed.). St. Louis, MO: Mosby; Ignatavicius, D. D., & Workman, M. L. (2009). *Medical-surgical nursing: Critical thinking for collaborative care* (6th ed.). St. Louis, MO: Elsevier.

- Establishing meaningful roles
- Adjusting to infirmities (if any exist)
- Coping with losses and changes
- Preparing for death

Nursing Implications

Professional nursing care is important in assisting aging people to develop a sense of well-being. Nurses who work with older adults must be especially sensitive to their own feelings, attitudes, and beliefs about aging and be aware of the effect of these responses on their care.

When assessing the older adult for health-related needs, the nurse needs to learn about the client's background, family history, work history, hobbies, and achievements (see Figure 18-12). Clients should be encouraged to talk about their life experiences. When planning care, it is important to build on the client's lifelong interests. By recognizing each client's unique experiences and assets, the nurse is more likely to individualize care.

When clients express dissatisfaction and regrets about the past, the nurse should listen in a nonjudgmental manner and avoid trying to convince them that things are really better than they remember or perceive. It is important, however, to help clients put disappointments into perspective by

balancing them with accomplishments and achievements. Nurses should encourage families to engage in a positive life review with older adult clients. Most nursing interventions for older adults center around introspection and reflection on their lives. Life review (or reminiscence therapy) promotes a positive self-concept in older people (Kneisl & Trigoboff, 2009).

FIGURE 18-12 This older adult is able to maintain her independence and self-esteem through volunteer work. Describe the importance of incorporating information such as the ability and desire to make a contribution to society into an older adult's nursing care. DELMAR/CENGAGE LEARNING

Resources for Senior Citizens

Many communities have senior citizens' centers to promote socialization. What types of resources are available in your community that help improve functional abilities of older citizens?

TABLE 18-28 Older Adult: Growth and Development

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Physiological <i>Cardiovascular changes</i>	<ul style="list-style-type: none"> • Reduced elasticity of heart muscle and arteries. Less efficient functioning of cardiovascular system; increased systolic blood pressure. • Increased fat deposits on heart lead to reduced oxygen supply. • Thickening of aortic and mitral valves leads to incomplete closure; murmurs may occur. • Arterial diameter decreases as a result of arteriosclerosis. • Orthostatic hypotension may occur as the inelastic vessels are unable to constrict rapidly in response to postural changes. • Thickening of venous walls leads to decreased elasticity. • Development of varicose veins is common. 	<ul style="list-style-type: none"> • Decreased capacity for physical activity. Instruct client about the importance of remaining physically active and to balance activity with adequate rest and sleep. • Teach client lifestyle modifications that promote cardiovascular health: <ul style="list-style-type: none"> — Avoid smoking and other use of tobacco. — Avoid secondary tobacco smoke. — Maintain proper diet (low fat, low cholesterol). — Avoid sedentary lifestyle.
<i>Neurological changes</i>	<ul style="list-style-type: none"> • Decreased number of neurons. • Fewer neurotransmitters. • Slower transmission of nerve impulses. • Decreased sensory threshold. • The vestibulocochlear nerve (associated with balance and equilibrium) has decreased number of fibers. 	<ul style="list-style-type: none"> • A generalized slower response to environmental changes leads to increased risk for falls, burns, and other injuries. • Teach safety measures. • Teach fall preventive measures.
	<p><i>Vision</i></p> <ul style="list-style-type: none"> • Pupils decrease in size and are less responsive to light. • Cataracts or glaucoma often occurs. • Fewer tears are produced by the lacrimal glands, so the cornea is likely to become irritated. • Decreased ability to see colors; pastels fade; monotonies, blacks, and whites are difficult to see. 	<ul style="list-style-type: none"> • Be aware of client’s increased sensitivity to glare; allow time for eyes to accommodate changes in lighting. • The use of eye drops or artificial tears is helpful. • Brighter colors compensate for decline in color discrimination.
	<p><i>Hearing</i></p> <ul style="list-style-type: none"> • Ear canal may become blocked with cerumen (wax), which diminishes transmission of sound. • Tympanic membrane is thinner and may become sclerotic. • Diminished ability to hear high-frequency sounds. 	<ul style="list-style-type: none"> • Teach proper hygiene for cleaning ears. • Caution client to avoid inserting objects into ear during cleaning. • Lower tone of voice and rate of speech; instruct family members to do likewise.
	<p><i>Taste and smell</i></p> <ul style="list-style-type: none"> • General decline in taste perception. • Diminished salivation often occurs with aging. • Olfactory nerve cells decrease in number. 	<ul style="list-style-type: none"> • Many elders prefer more highly seasoned foods, salt, and sugar; teach healthy diet plans. Increased loss of appetite often occurs; make food visually appealing and know the client’s food preferences. • Be alert for safety hazards associated with decreased sense of smell (inability to detect smoke, leaking gas, or spoiled food).
<i>Respiratory changes</i>	<ul style="list-style-type: none"> • Decreased elasticity and muscle tone. • Fewer functioning alveoli. 	<ul style="list-style-type: none"> • Instruct client how to deep breathe and cough effectively.

(Continues)

TABLE 18-28 (Continued)

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
	<ul style="list-style-type: none"> • Calcification of chest wall and rib cage. • Decreased number of cilia results in ineffective clearing of respiratory system. • Lungs tend to remain hyperinflated on exhalation, which causes decreased vital capacity. 	<ul style="list-style-type: none"> • Encourage a balance between exercise/activity and rest/sleep.
<i>Musculoskeletal changes</i>	<ul style="list-style-type: none"> • Loss of calcium from bones. • Bone loss is a greater problem in women since it is accelerated by menopause. • A gradual decrease in height results from bone loss. • Less flexibility; muscle stiffness due to decreased number of elastic fibers in muscle tissues. • General posture is flexion. • Center of gravity shifts, with resultant changes in movement and balance. 	<ul style="list-style-type: none"> • Instruct women of all ages about importance of calcium consumption. • Encourage the elderly to engage in physical activity, especially walking. • Teach safety measures, including fall preventive measures. • Encourage exercise to promote flexibility. • Perform passive range-of-motion exercises for those who need it.
<i>Gastrointestinal changes</i>	<p><i>Mouth</i></p> <ul style="list-style-type: none"> • Atrophy of oral mucosa. • Connective tissue loses elasticity. • Decreased number of nerve cells. • Saliva production is decreased and becomes more alkaline. • Ability to chew food is impaired by loss of teeth, gum recession, and degeneration of jaw bone. <p><i>Gastrointestinal tract</i></p> <ul style="list-style-type: none"> • Peristalsis slows; decreased emptying of esophagus and stomach; slowed intestinal motility. • Shrinkage of gastric mucosa leads to decreased amounts of hydrochloric acid. • Reduction of pancreatic enzymes. • Delayed time for emptying gallbladder; bile is thicker. • Elimination is often impaired. 	<ul style="list-style-type: none"> • Decreased absorption of nutrients as a result of changes. • Instruct on importance of adequate nutrition, especially fluids and bulky foods. • Keep client well hydrated; instruct client to drink at least 8 glasses of fluid daily. • Provide foods that are easily chewed. • Encourage client to remain physically active. • Teach importance of having a regular time for toileting. • Avoid spicy and fried foods. • Avoid eating within 2 hours of bedtime.
<i>Endocrine changes</i>	<ul style="list-style-type: none"> • Metabolism slows. • Alteration in pancreatic activity. 	<ul style="list-style-type: none"> • Inform client of need for fewer calories.
<i>Reproductive and sexual changes</i>	<ul style="list-style-type: none"> • Decreased amounts of growth hormone, estrogen, and testosterone blood levels. <p><i>Men:</i></p> <ul style="list-style-type: none"> • Enlargement of prostate gland. • Decreased reserves of testosterone. • Testes softer and smaller. • Sperm production decreased or inhibited. • Ejaculations less forceful. <p><i>Women:</i></p> <ul style="list-style-type: none"> • Breast tissue loses elasticity (starts to sag). 	<ul style="list-style-type: none"> • Provide information about the normal changes associated with aging. • Use nonjudgmental approach when client discusses sexual issues. • Teach about effects of aging on reproduction and sexuality. • Teach STD preventive measures.

(Continues)

TABLE 18-28 (Continued)

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
	<ul style="list-style-type: none"> • Decreased size of uterus and fallopian tubes. • Vaginal walls thin. • Vaginal secretions decrease. • Vulva and external genitalia shrink (due to loss of subcutaneous body fat). 	
<i>Integumentary changes</i>	<ul style="list-style-type: none"> • Decreased activity of sebaceous glands leads to drying. • Decreased turgor. • Thinning of epidermal layer. • Decreased number of sweat glands (can result in heat exhaustion). • Loss of subcutaneous fat increases susceptibility to cold. • Wrinkles become more pronounced. • Hair turns gray and thins. 	<ul style="list-style-type: none"> • When bathing: <ul style="list-style-type: none"> —Avoid excessive use of soap, hot water, and brisk rubbing. —Pat, do not rub, skin dry. —Use tepid water. • Use lotion for itching and dryness. • Avoid prolonged pressure on bony prominences. • Protect from temperature extremes. • Assess for body image alterations. • For those with body image alterations: <ul style="list-style-type: none"> —Assist with grooming as necessary. —Use photographs to help adjust to changing appearance. —Use touch to help clarify body boundaries.
Psychosocial	<p><i>Erikson:</i> Integrity vs. despair</p> <ul style="list-style-type: none"> • Accepts one’s life as it is. • Feels a sense of worth when helping others. <p><i>Havighurst:</i></p> <ul style="list-style-type: none"> • Adjusts to retirement and changed financial status. • Adjusts to decline in physical strength. • Fulfills civic responsibilities. • Meets social obligations. • Adjusts to death of significant others. • Develops affiliation with peers and age group (sees self as “old”). • Retirement from employment affects finances, social activities, leisure time, and role identity (may be positive or negative impact). • Potential for social isolation as significant others and peers die. 	<ul style="list-style-type: none"> • Ask the older person for advice. • Identify and use the older adult’s strengths. • Encourage the use of reminiscence (life review). • Encourage to express feelings concerning aging. • Promote socialization with peers.
Cognitive	<p><i>Piaget:</i> Formal operations stage</p> <ul style="list-style-type: none"> • There is no decline in IQ associated with aging. • Reaction time is usually slowed. <hr/> <p><i>Memory</i></p> <ul style="list-style-type: none"> • Short-term: decreased capacity for recall. • Long-term: remains unchanged. 	<ul style="list-style-type: none"> • Allow client time to respond to questions or instructions. <hr/> <ul style="list-style-type: none"> • Be alert for the possibility of medication-induced confusion with resultant impact on memory.
Moral	<ul style="list-style-type: none"> • <i>Kohlberg:</i> Postconventional stage • Makes moral decisions according to own principles and beliefs. 	<ul style="list-style-type: none"> • Support decision making. • Respect client values even when different from own.

TABLE 18-28 (Continued)

DIMENSION	CHARACTERISTICS	NURSING IMPLICATIONS
Spiritual	<p><i>Fowler:</i></p> <ul style="list-style-type: none"> • Universalizing stage of faith. • Is generally satisfied with one's spiritual beliefs. • Tends to act on beliefs. 	<ul style="list-style-type: none"> • Listen carefully to determine spiritual needs. • Acknowledge losses and encourage appropriate grieving.

Data from Ebersole, P., Hess, P., Luggen, A. S., Touhy, T., & Jett, K. (2007). *Toward healthy aging: Human needs and nursing response* (7th ed.). St. Louis, MO: Elsevier; Edelman, C. L., & Mandle, C. L. (2006). *Health promotion throughout the lifespan* (6th ed.). St. Louis, MO: Mosby; Ignatavicius, D. D., & Workman, M. L. (2009). *Medical-surgical nursing: Critical thinking for collaborative care* (6th ed.). St. Louis, MO: Elsevier; Murray, R. B., Zentner, J. P., & Yakimo, R. (2008). *Nursing assessment and health promotion through the lifespan* (8th ed.). Upper Saddle River, NJ: Prentice-Hall.

WELLNESS PROMOTION Health promotion activities should be implemented with older adults in order to maintain functional independence. Health promotion activities are aimed at maximizing the person's abilities and strengths. Specific topics that are developmentally appropriate for older clients are use of leisure time, increased socialization, engaging in regular physical activity, maintaining a positive mental attitude, and developing and maintaining healthy lifestyles.

SAFETY CONSIDERATIONS Falls pose a major health threat to older adults. See Chapter 29 for information related to fall prevention and other specific safety promotion practices for older individuals. See Chapter 19 for information on other safety measures for older adults.

KEY CONCEPTS

- Growth is the quantitative changes in physical size of the body and its parts.
- Development refers to behavioral changes in functional abilities and skills.
- Maturation is the process of becoming fully grown and developed and involves both physiological and behavioral aspects of an individual.
- During each developmental stage, certain developmental tasks must be achieved for normal development to occur.
- Growth and development of an individual are influenced by a combination of factors, including heredity, life experiences, health status, and cultural expectations.
- According to Freud, certain developmental tasks must be achieved at each developmental stage; failure to achieve or a delay in achieving the developmental task results in a fixation at a previous stage.
- Erikson stated that psychosocial development is a series of conflicts that occur during eight stages of life.
- Sullivan stated that personality development is strongly influenced by interpersonal relationships.
- Piaget's theory states that there are four stages of cognitive development: sensorimotor, preoperational, concrete operations, and formal operations. Each stage is characterized by the ways in which the person interprets and uses the environment.
- Kohlberg's theory describes six stages of moral development through which individuals determine a moral code to guide their behavior.
- Gilligan states that women's moral judgment revolves around three issues: a concern with survival, a focus on goodness, and an understanding of others' need for care.
- Fowler's theory states that there are six distinct stages of faith development and, even though individuals will vary in the age at which they experience each stage, the sequence of stages remains the same.
- Providing care to the whole person is a basic concept of professional nurses, and knowledge of growth and development concepts guides holistic care of clients.
- The stages of the life cycle are the prenatal, neonate, infant, toddler, preschooler, school-age child, preadolescent, adolescent, young adult, middle adult, and older adult.
- Nurses have important roles in promoting the health and safety of individuals at each stage of the life cycle.

REVIEW QUESTIONS

1. During a clinic visit, a mother of a 4-month-old child tells the nurse, “My baby is not sitting up yet. Does this mean there’s a problem?” Which of the following is the most therapeutic nursing response?
 - a. “Be sure to tell the doctor so he can order some tests for your baby.”
 - b. “Every child develops at his or her own pace.”
 - c. “Most babies start to sit alone at about 8 months of age.”
 - d. “Oh, don’t worry, your baby’s fine.”
2. Which of the following are developmentally appropriate for older adults? Select all that apply.
 - a. Acceptance of life as it is
 - b. Decreased reaction time
 - c. Expanded circle of friends
 - d. False sense of immunity
 - e. Questioning one’s values and beliefs
 - f. Sense of generativity
3. When teaching accident prevention to high school students, which of the following topics is most important for the nurse to include?
 - a. Fall prevention
 - b. Fire prevention
 - c. Motor vehicle safety
 - d. Transmission of STDs
4. Which of the following statements made by a woman in the first trimester of pregnancy indicates a need for further prenatal teaching?
 - a. “Every morning I feel so sick to my stomach, like I’m going to vomit.”
 - b. “I feel tired most of the time.”
 - c. “I take prenatal vitamins every day.”
 - d. “It’s OK for me to drink wine as long as I do so in moderation.”
5. Which of the following statements made by a 50-year-old person indicates achievement of developmental tasks?
 - a. “At this stage of my life, everyone should take care of me.”
 - b. “I’m busy with my family and job.”
 - c. “I’m not sure which direction my life is going.”
 - d. “I’ve had a full, happy life and am ready to die when my time is up.”

CHAPTER 19

The Older Client

COMPETENCIES

1. Discuss theories of aging.
2. Refute common myths about aging.
3. Describe the impact of physical changes associated with aging on functional ability.
4. Explain ways in which the older adult adapts to the physiological changes associated with aging.
5. Discuss the psychosocial impact that retirement, changes in social relationships, changes in living arrangements, and loss may have on the older client.
6. Define polypharmacy and its significance for nurses caring for older clients.
7. Identify physical and psychological signs of abuse in older adults.
8. Outline safety considerations for the older adult living at home.
9. Discuss the use of the nursing process with older adult clients.

KEY TERMS

ageism
chronological age

lentigo senilis
polypharmacy

presbycusis
restorative nursing care

For most of the history of humankind, aging has been the problem of a fortunate few. Before 1900, when the average life expectancy was 47, relatively few people lived to be 50 years old. In the twentieth century, great strides were made in medicine, sanitation, hygiene, and control of infectious diseases. People have learned how to live longer, with life expectancy now over 75 years, but are still trying to learn how to live well. The present challenge is not adding years to one's life, but rather to improve the quality of an extended life span.

DEFINING OLD AGE

It is difficult to define *old age* in an era when factors such as medical breakthroughs and advanced health care techniques have extended the average lifetime. The most obvious measure of age is a person's **chronological age**, or the exact age of a person from birth. But a person's chronological age does not dictate the state of health, attitude toward daily life, or beliefs about living. There are enormous differences among individuals. People in their 70s may look and act more as if they were 50, whereas some people in their 30s think and act in ways that reinforce negative stereotypes of the older generation. For these reasons, age is difficult to define.

When does old age begin? For many centuries, people in their 50s were considered old. Today, Americans in their 50s generally consider themselves still young and, if asked at what age old age begins, are likely to respond "80" (see Table 19-1). The U.S. population is rapidly aging, as the

baby boomers (individuals born between 1946 and 1964) start turning age 65 in 2011. The number of older people will subsequently increase rapidly during the period of 2010–2030 (Federal Interagency Forum on Aging Related Statistics, 2007); see Figure 19-1 on page 359.

The rapidly expanding population will have an enormous impact on health care as the graying of America's baby boomers increases the demand for nurses and other health care providers. It will be essential that nurses are sensitive to and understanding of the needs, requirements, and capabilities of the older adult.

THEORIES OF AGING

Aging is a complex process of biological, psychosocial, cultural, and experiential changes. No one theory completely embraces and explains all the many facets of aging. Following is a discussion of several biological and psychosocial theories that offer a frame of reference for providing nursing care to older adults.

Biological Theories

There are several biological theories that address the physical changes of aging. The *stress theory* suggests that irreversible structural and chemical changes occur in the body as a result of stress throughout the life span and that individuals must learn to adapt to these changes. The *cross-linkage theory* describes the deterioration of tissues and organs as the cause of loss of flexibility and functional mobility that occurs with aging. The *somatic mutation theory* states that changes in DNA that are not repaired lead to replication of mutated cells, which brings about decreased cellular functioning and loss of organ efficiency. The *programmed aging theory* states that life span is determined by heredity and that an internal genetic clock is responsible for the rate at which an individual develops, ages, and eventually dies.

Psychosocial Theories

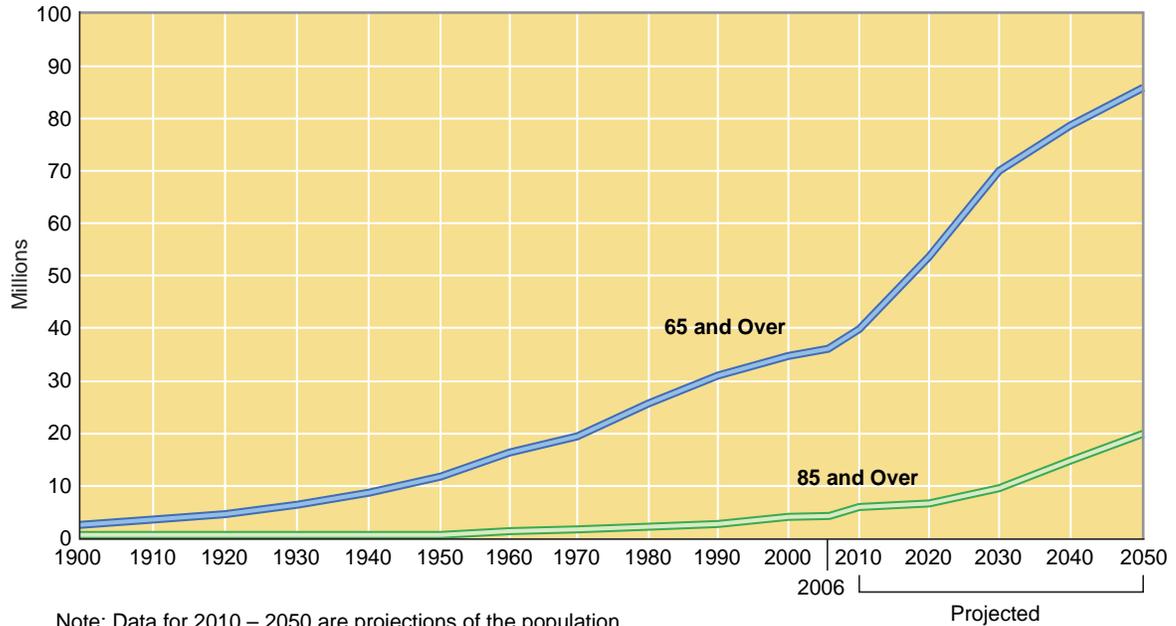

Psychosocial theories on aging present the position that many factors in addition to genetics contribute to the aging process. The *disengagement theory* posits that as individuals age, they inevitably withdraw from society and society withdraws from them in a process of separation. The *continuity theory* suggests that an individual's values and personality develop over a lifetime and that goals and individual characteristics will remain constant throughout life. An individual thus learns to adapt to changes and will tend to repeat those reactions and behaviors that led to success in the past. The *activity theory* proposes that an individual's satisfaction

TABLE 19-1 Chronological Classification of Age Groups

AGE	CLASSIFICATION
65–74	Young-old
75–84	Old
85–94	Old-old
95 and older	Elite-old, chronologically gifted

RETRIEVED NOVEMBER 22, 2008, FROM [HTTP://WWW.AGINGSTATS.GOV/AGINGSTATSDOTNET/MAIN_SITE/DATA/2008_DOCUMENTS/POPULATION.PDF](http://www.agingstats.gov/agingstatsdotnet/main_site/data/2008_documents/population.pdf).

with life depends on involvement in new interests, hobbies, roles, and relationships. Volunteering is one way that many retirees stay connected to the community. In addition to providing social connection, volunteer activities provide a daily routine, a way to make a contribution, and a sense of being needed.

MYTHS AND STEREOTYPES OF AGING

In the youth-obsessed society of the United States, old age has a negative connotation. In many cultures, older adults are accorded a position of respect, and young people feel a moral and familial responsibility to care for parents and older

relatives. In American culture, misconceptions about older adults abound; see Table 19-2, on page 360, for common myths about older adults. There are many reasons these myths develop and persist. For example, many young people today have little personal contact with older family members such as grandparents; also, health care providers usually see only older people who are acutely or chronically ill, and are hospitalized or live in a long-term care setting.

Older adults are often stereotyped as being ill, bald, hard of hearing, forgetful, rigid, grumpy, or boring, simply on the basis of their age and regardless of their competencies and individual characteristics. Many younger Americans also believe that all older people live in nursing homes and fail to consider the independence of the older generation and their contributions to society. These types of attitudes are known as **ageism** (the process of stereotyping and discriminating against people because they are old).

To many, aging is synonymous with death; these individuals have a negative view of the aging process, which usually results from fear, lack of exposure to older individuals, and a lack of understanding of how varied experiences can enhance the overall quality of life. Surprisingly, many older adults have negative attitudes toward other older adults; these often result from fear of stereotypes and social stigmas, or a sense of anxiety over “guilt by association.” Nurses need to be aware of these myths and stereotypes and to separate them from the realities of the aging process in order to provide sensitive and appropriate care to older clients.

RESPECTING OUR DIFFERENCES

Personal Views on Aging

Consider your own beliefs about aging. Do you feel that one of these theories best represents the older adult population? Would you classify your opinion of older adults as basically positive or basically negative? On what information have you based your views?

TABLE 19-2 Refuting Common Myths about Older Adults

MYTH	FACT
Most older Americans are economically disadvantaged.	In 2006, approximately 9% of Americans over age 65 lived below the poverty threshold. This is a great improvement as compared to 1951 when the percentage of elders living in poverty was 35%.
The majority of older individuals are ill.	During 2004–2006, 74% of people age 65 and older rated their health as good or better.
Most older people live in extended care facilities.	In 2005, 5% of people age 65–84 and 17% of those aged 85 or older lived in long-term facilities.
Older individuals are uninterested in or unable to engage in sexual activity.	Most people ages 57–85 think of sexuality as an important part of life. The frequency of sexual activity declines slightly during the 50s, 60s, and 70s.

QUALITY OF LIFE AMONG OLDER ADULTS

Quality of life is gaining more emphasis in today's aging society. The increasing life span has both positive and negative outcomes. One of the greatest fears associated with advancing age is poor health. Most people want to live a long life, as long as it is a long healthy life. Older adults do have more chronic health problems than the general population.

Currently, the trend is for people to live longer and healthier lives. Many Americans over 65 live in relative financial comfort, able to continue working or start enjoying their retirement years. Good nutrition, proper exercise, continued work, travel, recreation, hobbies, and companionship are just a few of the healthy lifestyle choices many older people now have the means to afford.

A positive outlook and adaptive ability contribute to the high quality of life enjoyed by many older adults today. Although many people over 65 have some kind of chronic health problem, most have found ways to keep these ailments from interfering with their enjoyment of life. Most older people accept a certain amount of declining health as a normal, expected part of aging, but do not allow health issues to interfere with the vigorous pursuit of enjoyment; see Figure 19-2.

CHANGES ASSOCIATED WITH AGING

Change is an ongoing part of life. People who have a difficult time accepting change, and therefore adapt poorly

to it, will experience problems. Changes of aging can be viewed as developmental, physiological, or psychosocial in nature.

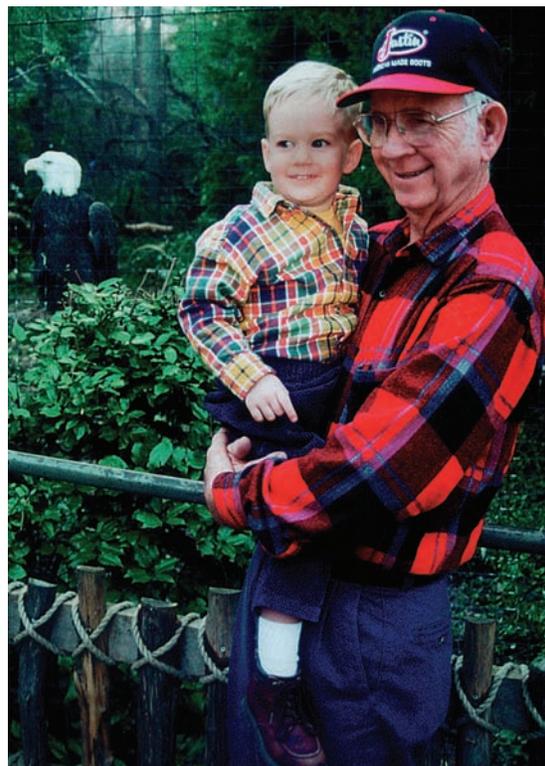

FIGURE 19-2 Older adults often assume new roles, such as grandparent, as they mature, and can gain immense pleasure in spending time with family and sharing wisdom and ideas with the younger generation. DELMAR/CENGAGE LEARNING

DEVELOPMENTAL CHANGES

At every stage of life, including old age, new developmental challenges constantly arise. Like developmental challenges faced earlier in life, these occasions are opportunities for success or failure. Older people may experience feelings of satisfaction or success over completing certain developmental tasks associated with aging, such as:

- Gaining insight or wisdom, even if physical powers are in decline
- Developing improved social skills, with more same-sex friendships
- Becoming more open-minded and tolerant
- Finding an active and pleasurable sexual dimension
- Seeing children transform into responsible, successful adults
- Becoming a grandparent
- Holding civic and community positions of responsibility
- Achieving mastery of one's occupation or skills
- Developing new skills, hobbies, and avocations
- Renewing and deepening one's relationship with one's spouse
- Gaining new knowledge and experiences
- Adjusting to physical changes associated with aging
- Coping with aging spouses and friends

On the other hand, any person would be challenged to find successful ways to cope with other developmental events of aging, such as:

- Adjusting to the death of a spouse or partner
- Adapting to major declines in health or physical ability
- Adjusting to the loss of social role, prestige, occupation, income, or sense of usefulness
- Accepting loss of independent living
- Adjusting to loneliness or loss without boredom or depression

It is important for the nurse to assess the nature of any developmental challenges a client may be experiencing because a client's adaptation to changes can have a profound effect on health status.

PHYSIOLOGICAL CHANGES

From the moment of birth, the human body begins the aging process. Each person ages differently as the rate of age-related changes varies from one individual to the next. However, some generalized physiological changes occur with the aging process, including:

- Decreased rate of cell mitosis
- Deterioration of specialized nondividing cells (i.e., neurons)
- Decreased elasticity and increased rigidity of connective tissue
- Decreased functional capacity

Some of the physical changes of aging, such as graying of hair and decreased visual acuity, are readily apparent. Other changes are more subtle and may go undetected until a problem occurs.

The rate of aging is influenced by:

- Genetic composition
- Lifestyle (dietary and exercise patterns)
- Presence of chronic illnesses
- Previous experience (e.g., adaptive responses to stressors)

Neurological Changes

Aging brings about several changes in the nervous system that alter sensory and perceptual responses. Murray, Zentner, and Yakimo (2008) identify some of the age-related neurological changes as:

- Fewer neurons
- Transmission of nerve impulses slowed
- The number of neurotransmitters (chemical messengers of the central nervous system) decreased
- Sensory threshold decreased (affects pain and tactile sensations)

As a result of these changes, reaction time is usually slowed. The generalized slower response to environmental changes leads to increased risk for falls, burns, and other injuries.

It is important that the nurse allow older clients time to respond to questions and instructions. Teaching safety measures is a preventive aspect of nursing that must not be overlooked when dealing with older clients.

Sensory and Perceptual Changes

Sensory changes are progressive and may cause some limitations in later years. The resultant changes may impair the individual's ability to enjoy life to the fullest as well as present related health problems.

VISION The aging process causes some visual changes. For example, pupils decrease in size and are less responsive to light. Usually a loss of visual acuity occurs because of degenerative changes related to aging. By the age of approximately 42, the lens cortex becomes thicker, impairing its ability to change shape and focus. This condition, presbyopia, causes farsightedness and is corrected by the use of bifocals.

Cataracts, glaucoma, and age-related macular degeneration are the most common pathological visual problems experienced by older adults. Cataracts (or opacity of the lens) can be surgically corrected. If untreated, glaucoma can result in blindness; thus, annual screening is recommended for all individuals over age 40. Age-related macular degeneration is the loss of central vision; magnification must be used to compensate for the changes. Diabetes, hypertension, and other systemic diseases will exacerbate macular degeneration. As a result of aging, fewer tears are produced by the lacrimal glands, so the cornea is likely to become irritated. Most older adults normally experience a decreased ability to see colors; pastels fade, and monotones, blacks, and whites are difficult to see.

The nurse caring for older clients must be aware of the client's increased sensitivity to glare and allow time for the

eyes to accommodate changes in lighting. The use of eye-drops or artificial tears may also be beneficial. Brighter colors compensate for the decline in color discrimination.

HEARING Generally, hearing is diminished with age. There is a drying and wrinkling of the auricle with a noticeable increase of hair in the auditory canal. Cerumen becomes drier and can cause impaction, which blocks transmission of sounds. The hearing loss associated with old age is called **presbycusis**. In the middle ear, bony joints show some degeneration. However, the major changes occur in the inner ear, where degeneration of the vestibular system and simultaneous atrophy of the cochlea and the organ of Corti produce deficits in equilibrium and hearing.

Nurses need to be very patient in their approach to the older client. With anticipated changes in sensory perception, it is important that nurses face their clients, speak slowly and clearly, and protect them from injury. It is important when teaching clients that nurses ask for feedback and evaluate client comprehension.

TASTE AND SMELL With aging, taste perception declines and salivation is diminished. Many older clients prefer highly seasoned foods, with additional salt and sugar to compensate for a decreased sensation of taste. Increased loss of appetite often occurs and may be medication-related in some individuals. It may be helpful for older adults to eat small portions frequently throughout the day. The nurse seeks to make food visually appealing and know the client's food preferences. It is important to teach clients about healthy eating patterns.

Olfactory nerve cells decrease in number. The nurse should instruct family members and other caregivers to be alert for safety hazards associated with decreased sense of smell, such as the inability to detect smoke, leaking gas, or spoiled food.

Cardiovascular Changes

As a result of aging, functioning of the cardiovascular system becomes less efficient. Reduced elasticity of the heart muscle and arteries causes a subsequent increase in systolic blood pressure. Increased fat deposits in the blood vessels lead to a reduced supply of oxygen. The arterial diameter decreases as a result of arteriosclerosis. Thickening of venous walls leads to decreased elasticity. Thickening of aortic and mitral valves leads to incomplete closure; heart murmurs may occur in some older people. The development of varicose veins is common. As a result of decreased cardiac output, many older people experience a decreased capacity for physical activity. A diminished cardiac output is problematic when the older person becomes physically, mentally, or emotionally impaired (Ebersole, Hess, Luggen, Touhy, & Jett, 2007).

The nurse should instruct the client about the importance of remaining physically active and the need to balance activity with adequate rest and sleep. Older clients also need information on lifestyle modifications that promote

cardiovascular health. Such instruction would include the following:

- Avoid smoking and use of other forms of tobacco.
- Avoid secondary tobacco smoke.
- Eat a healthy diet (low fat, low cholesterol).
- Avoid a sedentary lifestyle, which can result in impaired cardiac output with resultant fatigue.

Respiratory Changes

Most older adults experience a decreased functional respiratory reserve capacity, with a generalized decreased elasticity and tone of muscles, including the muscles necessary for respiration. Physical changes in the lungs include fewer functioning alveoli and a decreased number of cilia. Therefore, ineffective clearing of the respiratory system occurs. Calcification of the chest wall and rib cage causes the lungs to remain hyperinflated on exhalation, thereby decreasing vital capacity.

To deal with respiratory changes, the nurse teaches the client how to breathe deeply and cough effectively. The client needs to establish a balance between exercise and activity to conserve respiratory effort while at the same time improving vital capacity. Because physical exercise increases lung capacity, nurses should encourage older clients to walk.

Gastrointestinal Changes

Aging brings about several alterations in gastrointestinal functioning. The major changes are described in the following sections.

MOUTH Many older people lose their teeth for a variety of reasons, including years of inadequate dental hygiene and extended use of medication (e.g., anticonvulsant drugs). Other physiological changes include atrophy of oral mucosa, loss of elasticity in connective tissue, and a decreased number of nerve cells that control chewing, swallowing, and taste. Saliva production is decreased, and saliva becomes more alkaline. The older person's ability to chew food is often impaired by loss of teeth, gum recession, and degeneration of the mandible. The nurse should instruct the client and caregivers to have available foods that are easily chewed and swallowed.

GASTROINTESTINAL TRACT There is a decrease in peristaltic action with a relaxation of the lower esophageal sphincter. This causes a decreased emptying of the esophagus and stomach. Shrinkage of gastric mucosa leads to changes in the levels of hydrochloric acid, with subsequent heartburn. Older adults often have an inability to tolerate large amounts of foods containing fat.

Elimination is often impaired in older clients; as a result, there is decreased absorption of nutrients. Intestinal motility is slowed, and some loss of sphincter control may be noted. Nurses should instruct older clients about the importance of adequate nutrition, especially fluids and high-fiber foods. Keep clients well hydrated by instructing them to drink at least 8 glasses of fluid daily. Other methods to prevent

constipation are physical activity and adhering to a regular time for toileting.

Genitourinary Changes

Major changes in the structure and function of the urinary system are associated with aging. The kidneys, bladder, and ureters are all affected by the aging process.

The loss of some muscle tone in the bladder and urethra can result in incomplete emptying of the bladder. Residual urine can lead to bladder infection. Decreased bladder capacity may cause subsequent nocturia and polyuria.

Renal function is the major determinant of an individual's fluid and electrolyte balance. In older adults, renal function is often affected by diminished blood flow to the kidneys as a result of arteriosclerosis, hypertension, and other cardiovascular disorders. The glomerular filtration rate slows, and there are fewer functioning nephrons.

The risk of renal failure increases with age, as does fluid retention. Dehydration is a very real threat for many older adults. The aging body loses some of its functional ability to adapt to changes in total body water, which is essential for metabolism. The composition of body water declines to about 40% of an older adult's total body weight.

Nursing measures address the underlying problems that result in a fluid and electrolyte imbalance. For example, if clients are dehydrated, they should be instructed to drink 2000 mL (10 glasses) of liquid a day. Note that the fluid intake should be limited to 2 hours before bedtime to decrease the likelihood of nocturia.

Endocrine Changes

During the aging process, the following changes occur in the endocrine system:

- Slowing of metabolism
- Alteration in pancreatic activity
- Decreased blood levels of growth hormone, estrogen, and testosterone

As a person ages, the number of hormonal receptors in the adrenal and thyroid glands decreases. Thus, the person's ability to respond effectively to stress is diminished. Aging is associated with altered functioning of the pancreas; there is an increased level of insulin and circulating glucose.

The major changes of aging that affect men are enlargement of the prostate gland (benign hypertrophy) and decreased reserves of testosterone. The age-related changes for women include a loss of elasticity in breast tissue with resultant sagging of the breasts, decreased size of the uterus and fallopian tubes, and decreased motility in fallopian tubes.

The nurse must provide information about the normal changes associated with aging. It is also necessary to listen in a nonjudgmental manner when clients discuss their concerns about the physical changes.

Reproductive and Sexual Changes

To promote discussion of sexuality, it is important for the nurse to adopt an understanding and accepting attitude.

Sensitivity to verbal and nonverbal cues will also promote the client's expression of concerns. The nurse must not assume that the older client is heterosexual, sexually inactive, or uninterested in sex (Figure 19-3). It is important to recognize older clients as sexual beings and to provide privacy to promote intimacy. See the accompanying *Respecting Our Differences* display, on page 364, for a listing of age-related changes in sexual responses in older adults.

Older adults who are sexually active may need education about sexually transmitted diseases (STDs), including AIDS. This is one learning need that is frequently overlooked in health promotion for older people.

When caring for clients of either gender, the nurse should teach about the effects of aging on reproduction and sexuality. It is important that nurses use a nonjudgmental approach when clients discuss sexual issues.

CHANGES IN MEN As men age, the testes become softer and smaller as a result of decreased concentration of testosterone in the bloodstream. The production of sperm is inhibited or decreased, and ejaculations are less forceful. Sexual dysfunction increases in prevalence with aging; however, it is not an inevitable result of the aging process. Several factors contribute to the possible development of erectile dysfunction (ED), also referred to as impotence. Some factors that contribute to ED in older men are anemia, diabetes, hypertension, and medications.

CHANGES IN WOMEN Older women experience a decline in serum levels of estrogen. As a result, the vaginal walls thin and vaginal secretions decrease. The vulva and external genitalia shrink because of loss of subcutaneous body fat. Postmenopausal changes, such as vaginal dryness, may cause the woman to experience pain during intercourse. The nurse needs to explain that using water-soluble lubricants helps relieve the pain and discomfort that may occur during intercourse.

FIGURE 19-3 Older adults need companionship, as intimacy and sexuality remain important throughout the entire life span.

DELMAR/CENGAGE LEARNING

Age-Related Changes in Sexual Responses

Women

- Nipple erections during sexual excitement may last several hours postorgasm.
- Orgasms are usually unchanged, except that vaginal contractions may be of shorter duration.
- Vaginal lubrication is decreased.
- Urinary frequency and urgency occur after intercourse.
- Clitoral response to stimulation is the same as in youth.
- Skin is less flushed due to superficial vasocongestive skin response.

Men

- It takes longer to achieve an erection.
- More direct physical stimulation is required for erection.
- Erection is more readily lost after interruption.
- There is an increased ability to prolong time before ejaculation.
- Ejaculation may be less forceful or may not occur.
- Orgasm is similar to that experienced in youth.
- Less flushing of skin occurs.

Data from Dowdall, S. M., Taplay, K., Flores-Vela, A., & Maville, J. A. (2007). Promoting health in the older adult. In J. A. Maville & C. G. Huerta (Eds.), *Health promotion in nursing* (2nd ed.). Clifton Park, NY: Delmar Cengage Learning; Kautz, D. D. (2006). Appreciating diversity and enhancing intimacy. In K. L. Mauk (Ed.), *Gerontological nursing: Competencies for care*. Boston: Jones & Bartlett.

Musculoskeletal Changes

Many people experience a decrease in height as they age. Long bones take on a disproportionate size, and many older people assume a stooped posture. These postural changes occur primarily as a result of calcium loss from bone, creating osteoporosis and kyphosis. These conditions are more common in women than in men and are implicated in estrogen loss that occurs with aging.

Ligaments, tendons, and joints are also affected by age. They show results of collagen loss and become thicker, more rigid, less flexible, and predisposed to tears. Cartilage wears down around the joints, making flexion painful. Walking and a consistent exercise pattern can promote function and prevent the disabling effects of many of these changes (Ebersole et al., 2007).

The nurse should instruct women about the importance of calcium consumption. Foods with a high calcium content include dairy products and green leafy vegetables. Encourage

exercise, especially walking, to promote flexibility and perform passive range-of-motion exercises for those who need it. It is essential to teach safety measures, including fall prevention measures, to both clients and caregivers.

Integumentary Changes

Older adults frequently experience dry, wrinkled, flaccid skin. This is an expected condition that occurs with aging because the skin loses many of the properties that help make it appear youthful. It takes approximately 20 days for epidermal cells to be replaced in a young person, whereas in the older adult, this process takes about 30 days. Therefore, it takes longer for an older client's wounds to heal. Because of collagen loss, the skin of an older person loses its ability to stretch, and thus tears more easily. Loss of subcutaneous fat, moisture content of the skin, and elastic fibers causes the older person's skin to wrinkle, dry, and sag, leading to the development of elongated ears, jowls, and double chin. If the client has had years of sun exposure, skin drying is accelerated. For the aging smoker, dehydration of the skin is further exacerbated.

The development of **lentigo senilis** (brown pigmented areas on the face, hands, and arms of older people) can cause older adults concern over their appearance. Sometimes called liver spots or age spots, these colorations are benign. Some cosmetic agents may lighten or almost eliminate these spots.

Skin appendages (hair and nails) also undergo changes associated with aging. Hair loses its original color as the production of melanin decreases, turning it gray and, eventually, white. Hair also tends to thin, both on the head and elsewhere on the body. Nails thicken and become more brittle. Care of the toenails often becomes a problem for many older people because they may not have the flexibility to reach their feet easily. Referrals to a podiatrist may be necessary for an older person to receive adequate care of the toenails.

As a person ages, the number of sweat glands decreases; this decrease can result in heat exhaustion. The decreased amount of subcutaneous fat may lead to increased susceptibility to cold.

The accompanying Client Teaching Checklist on page 365 provides guidelines for dealing with integumentary changes. Some older clients will have body image changes as a result of these visible signs of aging. The nurse must assess for body image alterations. If the client has an altered body image, it may be appropriate to:

- Assist with grooming as necessary.
- Use photographs of client to help adjust to changing appearance.
- Use touch to help clarify body boundaries.

Alterations in Mental Status

Alterations in mental status that occur with aging can be mild and have little impact on a client's functioning, or they can be severe and require the older adult to have assistance in managing psychosocial and physical needs. The nurse must understand the types of cognitive deficits and their impact on the client's health status.

CLIENT TEACHING CHECKLIST

Responding to the Older Adult's Integumentary Alterations

- Instruct client to avoid excessive use of soap, hot water, and brisk rubbing when bathing.
- Teach client to pat skin dry instead of briskly rubbing.
- Inform client of the need to use tepid bathwater.
- Use lotion for itching and dryness.
- Use a humidifier to help reduce dryness.
- Avoid prolonged pressure on bony prominences.
- Protect the skin from temperature extremes.
- Protect skin from sun exposure (wear protective clothing, hats, and sunglasses, and use sunblock with a high sun protection factor [SPF]).
- Soak nails in water before trimming.
- Dress appropriately for weather and climate.

Acute confusion is a state of diminished awareness and attention, usually with a short duration (hours to weeks). The level of confusion often varies according to the time of day, worsening at night; this may cause sleep pattern disturbances. The individual is usually unaware of the setting, time of day, or day of the week and needs frequent reorientation to reality. Acute confusion occurs as a result of many conditions, many of which are reversible with appropriate treatment. Dehydration, infection, trauma, and medications may result in acute states of confusion.

Some individuals with dementia experience chronic confusion, usually of a long duration (months to years). Individuals with dementia may exhibit personality changes, difficulty with sequential speech and thoughts, and a lack of orientation to reality. Alzheimer's disease is a type of dementia that causes numerous deficits, including diminished intellectual abilities, confusion, and impaired judgment.

Depression is an altered state of mood that lasts at least 6 weeks. Individuals suffering from depression typically are alert and oriented to their environment but are characterized by exaggerated sadness, apathy, and preoccupation with negative thoughts. Table 19-3, on page 366, offers guidelines for differentiating acute confusion, dementia, delirium, and depression in older adults. Many people believe that it is normal for older adults to become sad and withdrawn. This is a false assumption that leads to lack of diagnosis and treatment of a serious health problem. Late-life depression can be successfully treated if it is not dismissed as an inevitable part of the aging process.

PSYCHOSOCIAL CHANGES

The multitude of physical changes that occur with aging are accompanied by numerous psychosocial changes. Major life events such as retirement, changes in social relationships and

roles, changes in living arrangements, and dealing with loss are usually experienced during the later years of life and can affect an individual's health status and outlook on life.

Retirement

An individual's view of retirement is a product of many factors, including overall life attitude, support of significant others, financial status, and personal expectations. For individuals who, during their adult years, defined themselves and their success according to their work contributions, retirement is likely to produce feelings of uneasiness and anxiety. An individual who views retirement as the end of the productive years will dread the change in life pattern and social status and may fear being a burden to others, both socially and financially.

Many adults, though, look forward to retirement as their reward for years of hard work and contributions and fill their days with activities, travel, hobbies, and interests that time constraints had prohibited them from pursuing during their earlier years (see Figure 19-4). These individuals typically led more balanced lives during their working years, viewing their value as a combination of many factors including work, family, and community involvement; they adjust more easily to the loss of employment status by balancing this change with other positive aspects of their lives. The transition to retirement involves two major challenges: adjustment to the loss of the work role and the social ties of work (van Solinge & Henkens, 2008). Individuals who have planned for retirement and made arrangements (financial, housing, social) ahead of time tend to adjust more readily to this change in work status.

Social Relationships and Roles

Relationships and roles change over time as an individual grows and develops. For the older adult, these changes may

FIGURE 19-4 Retirement often means having time to develop new hobbies or interests. DELMAR/CENGAGE LEARNING

TABLE 19-3 Distinguishing Acute Confusion, Delirium, Dementia, and Depression

PARAMETER	ACUTE CONFUSION	DELIRIUM	DEMENTIA	DEPRESSION

Delmar/Cengage Learning

take on even more meaning because activities and involvement in other areas of life may change or diminish. One study (Radina, Lynch, Stalp, & Manning, 2008) suggests that belonging to groups, such as social clubs, provides connections and prevents social isolation. Club membership offers older people the opportunity to obtain instrumental and social support. Changes in relationships and roles typically occur in conjunction with major life events, such as marriage, divorce, birth, death, relocation, and change in employment status. For instance, the older adult who has been a husband for 40 years will find his life and his roles greatly changed when

he becomes a widower. The birth of his children's children will bring him new status as a grandparent, and his retirement will remove him from the full-time workforce and present opportunities for the development of new relationships.

A key to successful aging is staying connected to others. One way in which many older adults maintain connections is by volunteering. Several studies (Ayalon, 2008; Hao, 2008; Piliavin & Siegl, 2008; Windsor, Anstey, & Rodgers, 2008) suggest a strong relationship between volunteerism and well-being in older individuals. Volunteering is one way for older adults to add a sense of purpose and to establish social connections.

Another type of relationship that many older adults experience is grandparenthood. This relationship may be a source of pride and happiness, or it can become a negative stressor. For many older Americans, grandparenting has become a full-time responsibility, as they are the sole caretakers of grandchildren. Over 4.5 million families in the United States are maintained by grandparents (American Association of Retired Persons Foundation, 2007). Some grandparents who assume the role of rearing grandchildren experience anger about the extra responsibilities (Belsky, 2007). However, not all grandparents are overwhelmed by the role of childrearing for a second generation; many find it rewarding.

Following are some of the factors that have contributed to the increasing numbers of grandparents who are raising their grandchildren on a full-time basis:

- Divorce
- Unemployment
- Teen pregnancy
- Death of a grandchild's parent
- Abuse or neglect of the child
- Substance abuse

Nurses should be knowledgeable about potential areas of stress imposed by the additional responsibilities of the grandparenthood role. Also, knowledge of community resources is essential for appropriate referral. Some grandparents may also need information about current childhood problems that were not as prevalent when they were parenting their own offspring (e.g., cyberporn, school violence).

Living Arrangements

Advancing age often brings with it changes in living arrangements. Older people have many living options depending on income, health status, activity level, functional ability, level of independence, and family or other support systems; see Figure 19-5. A change in living arrangements is a significant event for any individual, but for older adults, this change may mean leaving family, friends, neighbors, and routines that have been a part of life for decades. Most older adults prefer to remain in their homes or dwellings, in a familiar environment and with familiar routines. In some cases, older adults may move in with their adult children and their families or have the adult children move in with them. The degree of physical, psychological, and financial independence of the older adult, and the status of the relationship with the children, will likely determine the success of this arrangement.

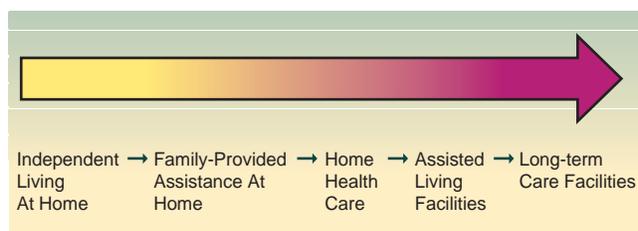

FIGURE 19-5 Continuum of Living Arrangements for Older Adults DELMAR/CENGAGE LEARNING

Older adults needing assistance to remain in their homes may take advantage of home care services, which provide assistance in the tasks of daily living, or day care services, which provide limited health and rehabilitation intervention. Assisted living facilities (ALFs) are a new option to help ease the transition between living independently at home and residing in a nursing home. Other options include foster care, group living arrangements, and hospice. When health needs necessitate extensive or full-time supervision and care, a long-term care facility (such as a nursing home) may be the best living option. Nursing homes offer a variety of services to support the medical, personal, and psychosocial needs of the aging client.

“Personal autonomy—the ability to make freely self-directed choices in one’s life—is considered critical to an older person’s quality of life” (Matsui & Capezuti, 2008, p. 141). Older adults who are able to participate in the decisions regarding their living arrangements generally adapt better to such changes than those who are unable to participate or are not involved in their care decisions. Nurses can enhance an older client’s autonomy by encouraging independence, providing information, and working with the client’s support system.

Coping with Loss

Loss is an inevitable part of life, and the longer a person lives, the more losses will be experienced. Losing a lifetime partner is one of the most stressful loss experiences an individual can face, and many older people will face loss through death of a spouse at some point in their lives. As the years pass, deaths of children and friends may leave older adults grieving and feeling as if everyone they have known and loved is gone. Feelings of isolation and hopelessness may arise; these can be compounded if the individual suffers multiple losses within a short period of time.

Individuals who feel isolated and abandoned often feel angry and hopeless. Helping older adults stay connected with others in the community is an effective intervention for those who are experiencing loss and resultant depression. Some avenues for helping older adults develop a social support system are churches, senior citizen centers, neighborhood and apartment associations, and community support groups. Often, loss will lead older clients to reflect on their lives and their relationships and to review their successes and shortcomings.

Nursing actions that promote a sense of hope in older adults include making time to involve the client in the discussion and asking about daily plans. It is imperative that nurses avoid expressing pity toward lonely older clients, as pity decreases hope and exacerbates the sense of loss. See the accompanying Spotlight On display on page 368.

MEDICATIONS AND THE OLDER ADULT

Many older adults take multiple medications for both acute and chronic conditions. As a result, nurses need to focus on

SPOTLIGHT ON...

Understanding the Meaning of Loss

Consider the perspective of an older client who has experienced the loss of loved ones, such as a spouse of 50 years or a child. How many losses of this magnitude have you experienced? Do you feel you will be able to relate to and show empathy to an older adult whose life experiences may differ dramatically from your own? What steps can you take to ensure that you treat these clients with dignity, respect, and compassion?

two major issues, response to medication and compliance, both of which are discussed in the following sections.

RESPONSES TO MEDICATION

The physiological changes of aging can complicate drug therapy in the older adult. For example, the normal effects of aging alter the body's metabolism and excretion of drugs. Therefore, older adults are more sensitive to both the toxic and therapeutic effects of medications. Another factor affecting the older person's drug use is **polypharmacy** (the concurrent use of several medications). Older adults take more medicine than those who are young, and as a result, they are at greater risk for adverse drug reactions (ADRs). The presence of multiple diseases and the use of several medications place the older person at risk. In addition to increased risk of an ADR, other problems associated with polypharmacy are:

- Medication errors
- Inappropriate prescribing
- Excessive drug costs
- Noncompliance

The symptoms of many ADRs are subtle and often are confused with the changes of aging or chronic illnesses. For example, confusion, constipation, fatigue, and dizziness are nonspecific symptoms of many conditions, including ADRs. The effectiveness of drug therapy in the older individual depends on the properties of the particular drug and the impact of age-related changes (Table 19-4).

The older client's response to drugs is highly individualized. Therefore, the nurse must accurately monitor the client for therapeutic effectiveness and signs of ADRs. See the accompanying Safety First display.

MEDICATION COMPLIANCE

In addition to assessing the client's responses to medications, the nurse also must assess the client's knowledge of medications being used. Knowledge about the medication, its intended effects, possible side effects, and how to alleviate the side effects can increase the client's compliance with the

TABLE 19-4 Factors Affecting Pharmacokinetics in Older Clients

FACTOR	AGING-RELATED CHANGES
Absorption	<ul style="list-style-type: none"> • Increased gastric pH • Decreased gastrointestinal motility and gastrointestinal blood flow
Distribution	Decreased total body water, lean body mass, serum albumin, and body fat
Hepatic metabolism	Decreased liver size, liver blood flow, and enzyme activity
Renal clearance	Decreased renal blood flow, glomerular filtration, and tubular secretion
Excretion	Decreased creatinine clearance, increased half-life

Data from Cowely, J., Diebold, C., Gross, J. C., & Hardin-Fanning, F. (2006). Management of common problems. In K. L. Mauk (Ed.), *Gerontological nursing: Competencies for care*. Boston: Jones & Bartlett.

SAFETY FIRST

MONITORING DRUG USE

Watch for nonspecific side effects, such as appetite disturbance, altered behavior, and falls. Many side effects of medication use are subtle and, therefore, not detected.

medication regimen. Factors that may negatively affect medication compliance are as follows:

- Complicated dosing schedules and regimens
- Multiple dosing throughout the day
- Polypharmacy
- Cost of drugs
- Limited mobility and range of motion (e.g., the client with arthritis who is unable to open childproof containers)
- Impaired memory (e.g., omission—the client forgets to take the medication; overdosing as a result of not remembering whether the medicine was taken)
- Clients who need assistance and live alone

Educating older clients and caregivers about medication, self-administration, and ways to increase compliance is a major nursing intervention. See the accompanying Nursing Checklist on page 369.

NURSING CHECKLIST

Improving Medication Compliance

- Provide easily understood information about the medications.
- Schedule administration of the medication around certain activities of daily living as a reminder to the client.
- Provide the client with a name and telephone number of a person to contact when questions arise.
- Assess how the medications are stored and arranged in the client's home. Make sure the medication is accessible.
- Perform a complete drug history to determine all medications being taken. Instruct the client or caregiver to provide this information to the prescribing practitioner.
- Encourage client and caregiver to discuss any concerns regarding the medication.

MISTREATMENT OF THE OLDER ADULT

Mistreatment of the older adult (elder abuse) is a serious and ever-increasing problem and disturbing trend. Approximately 1 out of 20 older adults is abused each year in the United States (Dowdall et al., 2007). There are many forms of abuse, including:

- *Physical abuse*—willful infliction of injury
- *Neglect*—withholding goods or services (such as food, attention) to the detriment of the older person's physical or mental health
- *Psychological abuse*—withholding affection or imposing social isolation
- *Exploitation*—dishonest or inappropriate use of the older person's property, money, or other resources

Nurses in the home, clinic, hospital emergency department, and long-term care settings are often the first to identify signs of mistreatment in older people; see the accompanying display on signs of physical mistreatment. Abused older adults may either cling to or act in a very guarded manner toward the abuser. Another indicator of possible abuse is vague explanations offered for the cause of the injuries. Psychosocial indicators of abuse may be anger and rage, depression, anxiety, and conflictual interactions between the older adult and the abuser.

When assessing for mistreatment, the nurse must be nonjudgmental and avoid any signs of disapproval that may evoke further feelings of anger or shame in the older client. A private setting should be used for interviewing to promote disclosure; if the older victim thinks the perpetrator is able to hear the interview, the victim may withhold information or

Upper Saddle River, NJ: Pearson Prentice Hall; Wallace, M. (2006). Older adult. In C. L. Edelman & C. L. Mandle (Eds.), *Health promotion throughout the lifespan* (6th ed.). St. Louis, MO: Elsevier.

refuse to talk. It is essential that the interview findings be documented in an accurate and unbiased manner.

Nursing interventions for the abused older client are primary, secondary, and tertiary. Primary intervention strategies emphasize prevention. Secondary nursing interventions consist of early identification and prompt treatment to minimize the long-term effects of the abuse. Tertiary interventions occur after the abuse and promote recovery and rehabilitation. Tertiary interventions are restorative in nature.

If the nurse suspects abuse or neglect, this concern should first be addressed with the client. Many abused older adults may not admit to abuse because of embarrassment and fear of reprisal. Most states and many local governments have an Adult Protective Services program. Nurses are responsible for knowing the local statutes on mandatory reporting of abuse, as these laws may vary.

NURSING PROCESS AND THE OLDER ADULT

An ever-increasing number of nurses will provide care to older clients. Client education is a major nursing intervention that helps people change their behavior in order to take advantage of increased longevity. Some areas in which older adults need to develop health-promoting behaviors are nutrition, exercise, and the use of health screenings. Increasing numbers of gerontological nurses are needed to provide

quality of care. Professional standards for gerontological nurses were developed by the American Nurses Association in 1995 and revised in 2001. These standards are addressed in the next section.

ASSESSMENT

The data-gathering phase of assessment begins with the first encounter with the older adult client. Overall appearance, dress, gait, presentation, and general behavior can be noted during the first meeting with a client. Assessment of the older client can be a time-consuming yet rewarding process when the nurse works thoughtfully and sensitively with the client in order to discover strengths, resources, and limitations.

When interviewing the older client in the home, it is important to also include the client's caregivers in the assessment. The home care nurse assesses:

- Family interactions
- Caregiver motivation to participate in the rehabilitation process
- The motivational impact of the caregivers on the older person to accept some control over his or her own care
- Feelings of caregivers toward their role (i.e., level of satisfaction or burnout)

Health History

Older adults are not only individuals of age and vintage, but also individuals with a long history that deserves telling. The nurse's role in conducting a health history with the older client is to draw out facts and interpretations from the client that will shed light on current health status and health concerns. Eliciting these data requires time and patience on the part of both nurse and client, but it can be a rewarding and interesting process. To gather pertinent health data, the nurse may interview the client and the client's support members to determine the client's past coping strategies, strengths, and health habits. A holistic approach will include discussion of physical, emotional, psychological, spiritual, and sociocultural aspects that contribute to the client's overall health. The nurse respects the client's dignity and independence during the interview process by facing the client, speaking directly to the client in a clear manner, and reacting appropriately to client concerns and needs.

Physical Examination

The nurse must be knowledgeable about the normal changes of aging in order to conduct an accurate physical examination of the older client. The physical changes must be noted; the impact these changes have on the client's quality of life and activities of daily living (ADL) must also be determined. The assessment tools may need to be adjusted to the older person's abilities and limitations. For instance, the physical examination may need to be performed in more than one session to prevent client fatigue. Client positioning may need to be adjusted according to client comfort. The client may need assistance with disrobing or position changes, and the

nurse must always be alert to protect the client from potential injury, such as falls.

NURSING DIAGNOSIS

Nursing diagnoses developed from assessment of older clients will be as varied as the clients themselves. Nurses must keep in mind that older clients may present with many needs, both physical and psychosocial, and that the nursing diagnoses will need to be prioritized. Client status may change frequently, so reevaluation of nursing diagnoses on a regular basis is warranted. Selected nursing diagnoses (North American Nursing Diagnosis Association International, 2009) that are frequently seen in older clients include:

- Physical
 - *Impaired physical mobility* related to intolerance to activity or decreased strength and endurance; pain or discomfort; perceptual/cognitive impairment; neuromuscular impairment; musculoskeletal impairment; depression or severe anxiety
 - *Activity intolerance* related to bed rest or immobility; generalized weakness; sedentary lifestyle
 - *Dressing/grooming self-care deficit* related to intolerance to activity; decreased strength and endurance; physical, perceptual, or cognitive impairment
- Psychosocial
 - *Impaired social interaction* related to absence of supportive significant others; alterations in physical appearance; alterations in mental status; inadequate personal resources
 - *Risk for loneliness*: risk factors include affectional deprivation; physical isolation; social isolation
 - *Ineffective role performance* related to change in self-perception of role; change in physical capacity to resume role; change in usual patterns of responsibility
 - *Impaired home maintenance* related to disease or injury; insufficient finances; impaired cognitive or emotional functioning; inadequate support systems
 - *Acute confusion* related to age; dementia; alcohol abuse; drug abuse; delirium

OUTCOME IDENTIFICATION AND PLANNING

Outcomes must be developed and individualized for each client. Outcomes identified in the plan of care must be developed in partnership with the older client and the client's support system. Outcomes should be realistic for the client's current status and desired goals and should be targeted to maintaining a certain level of health or restoring the client to a former state of health. See the accompanying Client Teaching Checklist, on page 371, for a discussion of a teaching plan for an older client.

IMPLEMENTATION

Nursing interventions for the older client will typically focus on the areas of maintaining physical health, supporting

CLIENT TEACHING CHECKLIST

Teaching Plans for Older Adults

When developing a teaching plan:

- Plan for a quiet, private environment that is conducive to learning.
- Assess the client's readiness to learn as well as previous knowledge.
- Treat the client as a partner whose input is valuable in the planning and outcome identification process.
- Assess sensory status, especially sight and hearing, and adjust actions according to client needs.
- Use language that is clear and easy to understand.
- Encourage clients to ask questions and verbalize their understanding of what is being taught. For instance, state, "I want you to feel free to ask questions; all your questions are important."
- Plan to include the family and significant others in the teaching session, not as a substitute for the client, but for support and reinforcement.
- Plan for active learning experiences (e.g., use examples, simulations, games, and audiovisuals when appropriate).
- Pace the learning. Do not give too much information at one time, and progress at the individual's learning pace. Stop if you see that the client is distracted or fatigued.
- Plan to summarize and reinforce what has been taught.

psychosocial well-being, promoting safety, and providing restorative care. Three major interventions used effectively with older adults are education, communication, and life review. See Chapter 21 for specific guidelines for teaching older clients. The Nursing Checklist provides information on communicating effectively with older adults.

Life review (reminiscence therapy) is a structured intervention in which the nurse guides the client through remembrance of life, stage by stage. This intervention is especially therapeutic for clients who feel alienated and depressed, as it helps people develop a sense of meaning and promotes achievement of the sense of integrity identified by Erikson (1968). Some of the therapeutic outcomes of reminiscence are that it:

- Provides an outlet for catharsis ("getting things off one's chest")
- Assists in resolving conflicts
- Maximizes long-term memory when short-term memory is impaired
- Maintains identity and self-esteem

NURSING CHECKLIST

Communicating with Older Clients

- Get the client's attention before you speak.
- Minimize environmental stimuli.
- Sit directly facing the client and maintain eye contact.
- Speak slowly and clearly.
- Use short, simple sentences.
- Give the client time to respond.
- Speak loudly enough for the client to hear you, but avoid yelling.

- Promotes ability to attain perspective and find meaning (Trigoboff, 2009)

See the accompanying Spotlight On display.

Maintain Physical Health

During the assessment phase, the nurse will identify which physical changes are the result of normal aging and which have underlying pathology. Clients will need to be educated as to what these changes mean, what impact they may have on daily activities, and what strategies can be used to meet needs. It is critical to emphasize clients' assets and abilities, instead of focusing on limitations, in order to maintain a healthy self-concept and to show clients how much independence they still maintain.

Specific interventions related to the physical changes of aging will depend on the nature of the alterations. For instance, skin changes such as dryness, wrinkling, or flaccidity can be partially overcome through the use of oils, moisturizers, and a humidifier. If deteriorating eyesight is a problem, nurses should instruct the client to avoid reading when fatigued, to use large-print materials, and to ensure that the reading environment is well lit with an overhead light and desk lamp that do not create glare. If cardiovascular changes result in fatigue and shortness of breath on exertion, nurses should help clients learn the signs indicating their activity tolerance level and to adjust activity accordingly (e.g., plan for

SPOTLIGHT ON...

Compassion

As the nurse manager of a nursing home, you want to establish a program to encourage clients to engage in life review. You decide to conduct a weekly class for interested residents who want to share their life experiences. How would you prepare for the class? What agenda would you establish? How would you evaluate the effectiveness of the class?

frequent rest periods, sit or lie down when fatigued, avoid carrying heavy parcels when ambulating).

Support Psychosocial Well-Being

An older client's psychosocial health is as important as physical well-being. The use of touch and therapeutic communication helps the client overcome feelings of isolation and enhances a positive self-concept. Encouraging the older adult to be active in social groups, leisure activities, and hobbies supports a higher level of self-esteem and pleasure with life and helps the client to focus on positive traits and abilities.

The client's significant others can have a major impact on maintaining the client's psychosocial functioning. They can assist the client in maintaining a relatively independent lifestyle and may be able to help the client sustain ADL outside of an institutional environment. For clients without support systems, teaching how to cope with alterations in mental status (e.g., using calendars to orient to reality, reading the daily paper to keep aware of current events) and how to work within those parameters can help clients maintain a sense of independence and dignity.

Promote a Safe Environment

Many environmental factors may negatively affect an older person's safety, including:

- Decreased visual acuity
- Poor vision in dimly lit areas
- Less foot and toe lift when walking
- Altered center of gravity
- Slower reflexes
- Impaired muscle control
- Orthostatic hypotension (blood pressure related to posture)
- Urinary frequency (Ebersole et al., 2007)

Ongoing assessment includes observing the client's immediate environment for safety. This is especially critical for clients who will be remaining in a home situation where they, not the health care staff, are responsible for maintaining a safe environment. Significant others should be included in the efforts to create a safe environment for the older client (see Figure 19-6).

FIGURE 19-6 Educating the older client and family is an essential nursing function that is facilitated by the use of clear step-by-step instructions. DELMAR/CENGAGE LEARNING

Falls are a major safety issue with many older adults. See Chapter 29 for additional information on safety and preventing falls.

In order to promote a safe home environment for the older client, the nurse may suggest the following environmental actions:

- Provide adequate nonglare lighting.
- Place night-lights in bedroom, bathroom, and hall.
- Install slip-proof mats in tub and shower.
- Place a chair in tub and shower.
- Install grab bars in tub and shower, and next to toilet.
- Have handrails next to stairs and in long hallways.
- Use sturdy chairs with armrests.

Over the past 20 years, the older population has had an increased crime victimization rate. According to the U.S. Department of Justice (2008), property crime is the major type of attack on people over age 65. Older people are often easy targets for car theft, robbery, and burglary. Nurses can educate older clients on protecting themselves from crime by reminding them to lock doors and windows at home, install an alarm system, have income checks deposited directly into the bank, and be alert for false claims of "miracle cures" to health problems.

NURSING CARE PLAN

An Older Adult Who Is Confused

CASE PRESENTATION

Winston Evans, an 82-year-old man, is a retired grocer who was widowed 6 years ago. Until last year, Mr. Evans lived alone in a small home, was involved with his family, went to church regularly, and enjoyed socializing with peers at the community senior center. He now lives in his daughter's home. His daughter brings him to the clinic today, stating, "We can't go on like this! Last night he walked out of the house and was missing for hours. The policeman brought him home while we were looking for him." This is Mr. Evans's

(Continues)

NURSING CARE PLAN (Continued)

fourth episode of wandering within the past 3 months. The daughter also states that Mr. Evans is unable to take care of himself. "I have to feed and bathe him every day." Mr. Evans is unable to state the date, day of week, month, or year. He also does not know where he is, even though he has been treated by the nurse practitioner (NP) for several years at the clinic. He cannot remember the names of any family members except his daughter. He is observed by the NP to be restless, and his speech is rambling and confused. Mr. Evans tells the NP, "Get away from me. No one's gonna hurt me." His medical diagnosis is severe arthritis, glaucoma, and congestive heart failure. He weighs 115 pounds (a weight loss of 24 pounds over the past 4 months). He "picks at his food," is constipated, sleeps most of the day, and is usually loud and restless at night. During the assessment, Mr. Evans is agitated and cries out several times, "Help me, help me!"

ASSESSMENT

- Disoriented
- Forgetful
- Restless
- Paranoid
- Wandering behavior
- Insomnia
- Decreased appetite
- Constipation

NURSING DIAGNOSIS 1: *Risk for injury* related to confused mental status

NOC: Risk control

NIC: Environmental management

EXPECTED OUTCOME

Mr. Evans will be free from injury to himself or others.

INTERVENTIONS/RATIONALES

1. Approach in a calm, nonthreatening manner. To decrease anxiety level, which impairs mental status.
2. Determine the presence of personal or environmental risk factors. Identification of safety hazards is the first step in minimizing such hazards.
3. Orient Mr. Evans regularly to his environment. To decrease client's frustration level and better understand client needs.
4. Closely supervise Mr. Evans at night to assess safety. To determine which risk factors are present and what safety measures should be implemented.
5. Set limits on self-destructive behavior. To promote safety of client and others.
6. Monitor judgment, decision-making ability, and impulse control. Impaired judgment and impulsivity increase the likelihood of unsafe behaviors.
7. Minimize specific hazards in the home (e.g., remove stove knobs, store cleaning products and medications in a locked area, clear floor and hallway of obstacles). To make the home environment safer.
8. Keep night-lights on at night. To decrease the potential for falls.
9. Provide an ID bracelet for Mr. Evans to wear at home, and participate in local police registry if available. To increase possibility of client's quick return to home if he wanders away.
10. Instruct family to install an alarm system on all exit doors. To minimize the possibility of wandering.

EVALUATION

Goal met. Mr. Evans remains free from physical injury and does not injure anyone else. He has not wandered off alone in the past week.

(Continues)

NURSING CARE PLAN (Continued)

NURSING DIAGNOSIS 2: *Sleep deprivation* related to altered mental status

NOC: Sleep

NIC: Environmental management

EXPECTED OUTCOME

Mr. Evans will experience at least 4 hours of uninterrupted sleep at night.

INTERVENTIONS/RATIONALES

1. Monitor and keep a record of sleep patterns. To determine a baseline for future evaluation of progress or lack of progress.
2. Minimize daytime napping. Older adults need less sleep, so daytime napping only subtracts from amount of sleep occurring at night.
3. Schedule exercise 2 hours prior to scheduled bedtime. To provide relaxation.
4. Teach simple relaxation techniques. Keeping instructions simple helps the client who is confused to better absorb the information. Relaxation techniques can be used to promote sleep.
5. Limit caffeine intake. Caffeine exerts an energizing effect and thus can interfere with sleep.
6. Ensure quiet environment with a soft night-light. To promote relaxation and a sense of comfort.
7. Provide comfort measures and teach such measures to family. The use of back rubs and rearranging linens can promote comfort and relaxation.

EVALUATION

Goal partially met. Family reports that Mr. Evans is sleeping every night in approximately 3-hour intervals.

NURSING DIAGNOSIS 3: *Bathing/hygiene self-care deficit* related to cognitive impairment

NOC: Self-care: Activities of daily living (ADL)

NIC: Self-care: Assistance: Bathing/hygiene

EXPECTED OUTCOME

Mr. Evans will perform ADL with optimal independence.

INTERVENTIONS/RATIONALES

1. Monitor ability to perform ADL. To determine the client's level of functional ability and the amount of assistance that is needed.
2. Encourage client to perform the skills that are present. To prevent functional disuse and to promote independence and self-esteem.
3. If necessary, give step-by-step directions in clear simple terms with only one step at a time. Breaking a task down into small segments increases the likelihood of successful completion.
4. Instruct family to purchase clothing (or modify existing wardrobe) with Velcro fasteners instead of buttons and zippers. Decreases amount of effort client must expend to dress himself appropriately without assistance.

EVALUATION

Goal partially met. Mr. Evans is able to dress himself if the clothes are laid out by someone else. He follows step-by-step directions but is unable to initiate or complete the task alone.

From Carpenito, J. L. (2007). *Handbook of nursing diagnosis* (12th ed.). Philadelphia: Lippincott, Williams & Wilkins; Doenges, M. E., Moorhouse, M. F., & Geissler, A. C. (2006). *Nursing care plans: Guidelines for individualizing patient care* (7th ed.). Philadelphia: F. A. Davis; North American Nursing Diagnosis Association International. Restorative Care

Restorative nursing care (also referred to as rehabilitative care) seeks to assist the client in regaining maximal functional ability. Restorative care is provided to clients who have residual impairment from disease or injury in order to increase the client's independence. Nurses providing restorative care understand that sometimes the impairment in functional ability will remain. In such cases, the goal is to help the client function at the maximal level possible. Nurses constantly balance the client's need for dependence with the need for independence. In other words, nurses provide care as needed while encouraging the client to do for himself or herself as much as possible. Restorative care is provided in home health, assisted living, and long-term care facilities (e.g., nursing homes).

See the Nursing Checklist for interventions most useful in providing restorative care. Nurses need to be especially alert in monitoring follow-up care for seniors living in poverty. "Low-income seniors frequently have more multiple chronic medical conditions for which they often fail to receive the recommended standard of care" (Counsell et al., 2007, p. 2673); see the Uncovering the Evidence display.

EVALUATION

Evaluation is a major determinant of the need for continuing care of older clients. The nurse must decide whether the original assessment is still pertinent and if its

NURSINGCHECKLIST

Guidelines for Providing Restorative Care

- Encourage independence.
- Use a positive, reassuring approach.
- Be alert to limitations and client-expressed need for help.
- Encourage client decision making.
- Communicate with words easily understood by clients. Ask clients to repeat directions in order to assess their comprehension.
- Provide positive reinforcement often.
- Use repetition through words and actions (i.e., demonstration).
- Provide rest periods as needed.
- Ensure client safety by safeguarding against injury at all times.

UNCOVERING THE

Evidence

TITLE OF STUDY

"Geriatric Care Management for Low-Income Seniors: A Randomized Controlled Trial"

AUTHORS

S. R. Counsell, C. M. Callahan, D. O. Clark, W. Tu, A. B. Buttar, T. E. Stump, and G. D. Ricketts

PURPOSE

To test the effectiveness of a geriatric care management model on improving the quality of primary care for low-income older adults.

METHODS

This controlled clinical trial was conducted on 952 adults 65 years or older with an annual income below poverty level. One group of study participants received 2 years of home-based management care provided by a nurse practitioner (NP) and social worker. The control group received no home-based management care from the NP and social worker.

FINDINGS

Data analysis reveals significant improvements for the clients who received the intervention. The improvements occurred in four areas: general health, vitality, social functioning, and mental health.

IMPLICATIONS

Home-based geriatric care leads to improved quality of care and better quality of life for elderly low-income persons.

Counsell, S. R., Callahan, C. M., Clark, D. O., Tu, W., Buttar, A. B., Stump, T. E., et al. (2007). Geriatric care management for low-income seniors: A randomized controlled trial. *Journal of the American Medical Association*, 298(22), 2673–2674.

accompanying diagnoses have been resolved. New diagnoses need to be established on the basis of client progress and changing needs. New goals must be developed in order to foster maximum health status based on the client's abilities and capabilities to provide continuity of care. The nurse should consider the ongoing needs of the client and offer resources or make referrals to ensure that the health and well-being of the client will continue to be monitored and enhanced.

KEY CONCEPTS

- Persons in the late adulthood years are often classified as “young-old” (those between 65 and 75); “middle-old” (those between 75 and 85); and “old” (those 85 and older).
- Biological theories of aging state that the physical changes of aging are universal and inevitable.
- Psychosocial theories of aging consider factors other than genetics when describing the aging process.
- Numerous myths about aging can be viewed as ageism, which is stereotyping and discrimination based on age.
- Advances in medicine and technology have greatly improved life expectancy as well as the quality of life for the older adult.
- Developmental tasks of the older adult include enhancing skills, gaining and sharing wisdom, renewing relationships, expanding knowledge, and adjusting to losses and change.
- The multiple physical changes associated with aging can have a profound impact on an older adult’s functional ability and performance of ADL.
- Retirement, changes in social relationships, changes in living arrangements, and loss may affect an older client’s self-esteem and lead to feelings of isolation.
- Individuals who have had a positive outlook on the aging process over the years tend to adapt better to life changes than do individuals who fear or do not understand the aging process.
- Physical assessment of the older client will need to be tailored to the client’s functional level and activity tolerance.
- Including significant others in planning and implementing care for older clients enhances achievement of outcomes.
- Restorative nursing care (also referred to as rehabilitative care) seeks to assist the client in regaining maximal functional ability.
- Restorative care is provided to clients who have residual impairment as a result of disease or injury; it aims to increase the client’s ability to perform self-care independently.
- Safety is a primary concern when caring for older clients; this can be addressed through comprehensive assessment and through client and family teaching.

REVIEW QUESTIONS

1. The nurse is administering medications to an older client. Which of the following is most important for the nurse to assess in order to prevent drug toxicity?
 - a. Central nervous system function
 - b. Genitourinary system function
 - c. Renal function
 - d. Thyroid function
2. A female client says to the nurse, “I just don’t think I can go on. It’s too much for me to raise my grandchildren.” Which of the following nursing responses is most therapeutic?
 - a. “How could your daughter abandon her children?”
 - b. “I think your grandchildren are very lucky to have you care for them.”
 - c. “Many people your age are raising grandchildren, and they do just fine.”
 - d. “You sound overwhelmed. Let’s look at some options for you.”
3. A resident of a nursing home says to the nurse, “Most of the other people here are much older than I am, and a lot of them are sicker than I am. Is that what I have to look forward to?” Which of the following is the most therapeutic nursing response?
 - a. “Every resident is here for a different reason.”
 - b. “Everyone ages at his or her own rate.”
 - c. “They are not that much older than you.”
 - d. “You just need to concentrate on yourself and not worry about others.”
4. Which of the following nursing interventions is appropriate for an older female client in order to promote bone health?
 - a. Encourage to avoid physical activity
 - b. Instruct to eat dairy products
 - c. Remind of need to be more sedentary
 - d. Teach the importance of consuming antioxidants
5. A nurse is discussing a client’s complaint of pain in the lower back and legs. A nursing assistant replies, “What do you expect? The client is 90 years old.” Which of the following is the best response by the nurse to the assistant?
 - a. “Pain is not an expected result of aging.”
 - b. “The client is probably exaggerating.”
 - c. “The client is probably just seeking attention.”
 - d. “Yes, everyone’s pain level increases as they get older.”
6. Which of the following age-related physiological changes may lead to the development of hypertension (high blood pressure)? Select all that apply.
 - a. Calcification of the chest wall
 - b. Decreased elasticity of blood vessels
 - c. Decreased percentage of body fat

- d. Increased cardiac output
 - e. Development of heart murmurs
 - f. Decreased arterial diameter
7. Which of the following statements about older adults is true?
- a. Most older adults live in poverty.
 - b. Older adults have sexual needs.
 - c. The majority of older adults see themselves as ill.
 - d. The majority of older adults reside in extended care facilities.
8. Which of the following nursing actions should be implemented for a client experiencing age-related visual changes?
- a. Instruct on the need to avoid use of artificial tears
 - b. Suggest the use of eyedrops
 - c. Use monotone colors to avoid sensory overload
 - d. Use pastel colors to reduce eyestrain
9. A nursing assistant is helping an older client bathe. Which of the following statements by the nursing assistant indicate the need for further teaching? Select all that apply.
- a. "Be sure to use hot water when you're able to get into the bathtub."
 - b. "Here's some lotion for your feet."
 - c. "I must add water to your room humidifier."
 - d. "I need to rub your back well with the towel to make sure it's dry."
 - e. "You need to use a lot of soap."
 - f. "You should not use any kind of cream or lotion."
10. Which of the following foods is not helpful in promoting musculoskeletal health of older adults?
- a. Cheese
 - b. Red meat
 - c. Spinach
 - d. Yogurt

There is a richness to diversity that is lacking in a homogeneous environment. We need to embrace and cultivate that richness.

—FRALIC (1995)

CHAPTER 20

Cultural Diversity

COMPETENCIES

1. Discuss the concepts of culture, ethnicity, race, ethnocentrism, and stereotyping.
2. Describe dominant values in the United States.
3. Discuss the six organizing phenomena of culture.
4. Discuss the impact of culture on health beliefs and health behaviors.
5. Recognize the impact of cultural values on utilization of health care services.
6. Describe the process of transcultural nursing.
7. Explain the process for maintaining sensitivity to cultural diversity.
8. Discuss nursing strategies that ensure delivery of culturally competent care.

KEY TERMS

acculturation
 cultural assimilation
 cultural competence
 cultural diversity
 culture

dominant culture
 ethnicity
 ethnocentrism
 minority group
 oppression

race
 racism
 stereotyping
 transcultural nursing

Every aspect of a person’s life is influenced by culture. Behavior, including behavior affecting health, is culturally determined. As the population of the United States continues to diversify, recognition of cultural differences and their impact on health care becomes more critical. Nurses provide health care to culturally diverse client populations in a variety of settings. Knowledge of culturally relevant information is essential for delivery of competent nursing care. This chapter discusses the various concepts related to culture, the importance of diversity in American society, the influence of culture on health, and transcultural nursing.

CONCEPTS OF CULTURE

Each individual is culturally unique. Behavior, self-perception, and judgment of others all depend on one’s cultural perspective. This section discusses the concepts of culture, race, ethnicity, and stereotyping and provides an overview of the dominant cultural values in the United States. To provide holistic care, the nurse needs a thorough understanding of the following concepts.

CULTURE

Culture refers to knowledge, beliefs, behaviors, ideas, attitudes, values, habits, customs, languages, symbols, rituals, ceremonies, and practices that are unique to a particular group of people. This structure of knowledge, behaviors, and values provides a group with a “blueprint” or a road map for ways to think and act.

Culture is not static, nor is it uniform among all members within cultural groups. Culture represents adaptive dynamic processes learned through life experiences. People have culturally predetermined values and beliefs that may change as new information is gained. There is much diversity among cultural groups. Cultural messages are transmitted in a variety of ways such as through families, schools, and churches. The various media are also powerful transmitters and shapers of culture.

People learn about culture through traditions. When people state “That’s how we’ve always done it,” they are describing cultural traditions. Cultural beliefs, values, customs, and behaviors are transmitted from one generation to another. Grandparents, other elders, and parents teach children cultural expectations and norms through role modeling,

demonstration, and discussion (see Figure 20-1). Differences exist among cultural groups and among individuals within a single culture. Despite these variances, all cultures exhibit the characteristics shown in Table 20-1.

FIGURE 20-1 Cultural expectations and traditions are shared through formal and informal activities such as meal times. DELMAR/ CENGAGE LEARNING

TABLE 20-1 Characteristics of Culture	
CHARACTERISTIC	EXPLANATION
Learned and taught	Culture is transmitted from one generation to another. Cultural concepts are learned through socialization.
Shared	Sharing common practices provides a group with part of its cultural identity.
Social in nature	Culture develops in groups. Cultural practices are communicated within groups.
Dynamic and adaptive	Cultural change occurs slowly in response to group needs. Adaptation allows a culture to survive.
Delmar/Cengage Learning	

ETHNICITY AND RACE

Ethnicity is a cultural group's perception of themselves (group identity). This self-perception influences how the group's members are perceived by others. Ethnicity is a sense of belongingness and a common social heritage that is communicated from one generation to the next. Members of an ethnic group demonstrate their shared sense of identity in common customs and traits.

Race refers to a grouping of people based on biological similarities. Members of a racial group have similar physical characteristics such as blood group, facial features, and color of skin, hair, and eyes. There is often overlap between racial and ethnic groups because the cultural and biological commonalities support one another (Spector, 2008). The similarities of people in racial and ethnic groups reinforce a sense of commonality and cohesiveness.

LABELING AND STEREOTYPING

Problems arise when differences across and within cultural groups are misunderstood. Misperception, confusion, and ignorance often accompany people's expectations of others. There are numerous ways in which people are different and, thus, classified by others. See the accompanying Respecting Our Differences display.

Members of some cultural groups have historically and globally experienced oppression in the forms of racism, sexism, and classism. The basic underlying premise of these biases is that one way is assumed to be better or "right" and every other way is inferior. **Ethnocentrism** is the belief that one's own culture is superior to all others. Ethnocentrism results in **oppression**, which occurs when the rules, modes, and ideals of one group are imposed on another group. Oppression is based on cultural biases, which stem from values, beliefs, tradition, and cultural expectations. **Racism**, a form of oppression, is defined as discrimination directed toward individuals who are misperceived to be inferior due to biological differences.

Stereotyping is an expectation that all people within the same racial, ethnic, or cultural group act alike and share the same beliefs and attitudes. Stereotyping results in labeling people based on the values of cultural preconceptions; therefore, an individual's unique identity is often ignored.

DOMINANT VALUES IN THE UNITED STATES

Cultural differences refer to values, practices, and rituals that vary from those of the dominant culture. The dominant culture of the United States is white middle-class Protestants of European ancestry. A **dominant culture** is the group whose values prevail within a society. The European value orientation has had an important influence on U.S. culture, as illustrated by the following dominant beliefs:

- Achievement and success
- Individualism, independence, and self-reliance
- Activity, work, and ownership
- Efficiency, practicality, and reliance on technology

RESPECTING OUR DIFFERENCES

Ways in Which People Differ

- Age
- Gender
- Educational level
- Language
- Occupation
- Residence (rural, urban, suburban)
- Socioeconomic status
- Religion
- Functional abilities
- Cognitive abilities
- Racial composition
- Nationality
- Family structure and ties

- Material comfort
- Competition and achievement
- Youth and beauty

See the accompanying Respecting Our Differences display.

Frequently, these dominant values (which may be blatant or subtle) conflict with the values of minority groups. A **minority group** can be composed of an ethnic, racial, or religious group that constitutes less than a numerical majority of the population. Minority groups are labeled and treated differently from others in the society. Minority groups are usually considered to be less powerful than the dominant group (Spector, 2008).

People assume the characteristics of the dominant culture through **acculturation** (process of learning the norms, beliefs, and behavioral expectations of a group). Acculturation is encouraged through schools and the media. **Cultural assimilation** occurs when individuals from a minority group are absorbed by the dominant culture and take on the characteristics of the dominant culture. "Through assimilation, a person develops a new cultural identity" (Spector, 2008, p. 82).

RESPECTING OUR DIFFERENCES

Comparison of Personal Values with Dominant U.S. Values

Consider the dominant U.S. values, and compare them with your personal beliefs. For example, how do you measure success? Are you results oriented? How important are independence and self-reliance to you? Do you value material comfort? If so, what are you willing to do to gain it? How do you feel about older adults? How do you feel about people who have a physical appearance that is different from yours?

MULTICULTURALISM IN THE UNITED STATES

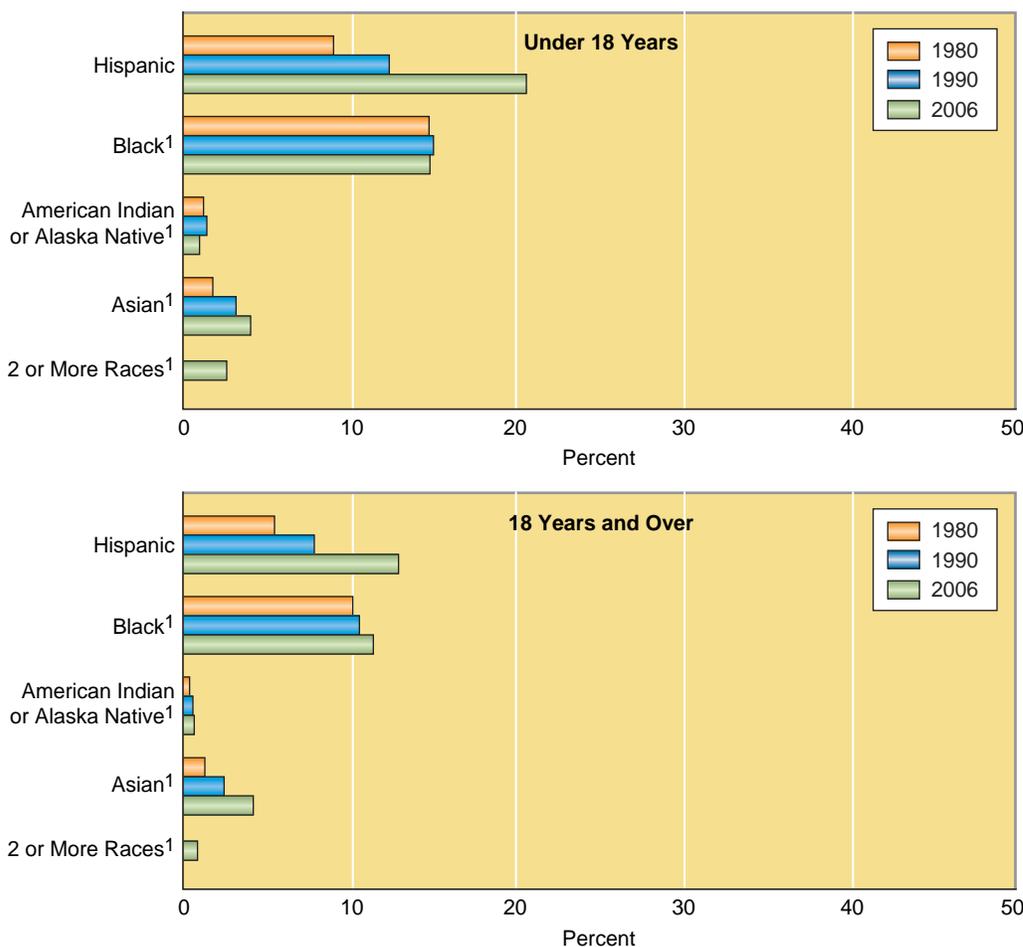

Cultural diversity is ever increasing in the United States. The numbers of immigrants and refugees entering the United States from non-European countries have added to this multicultural composition within the American universal culture. It is estimated that by the year 2050, one of every four persons in the United States will be of Hispanic ethnicity (Weidel, Provencio-Vasquez, Watson, & Gonzales-Guarda, 2008). “The percentage of Americans who identify themselves as Hispanic or Asian continues to increase” (National Center for Health Statistics, 2007, p. 20); see Figure 20-2.

VALUE OF DIVERSITY

Cultural diversity refers to the differences among people that result from ethnic, racial, and cultural variables. The

United States has a vast potential of human resources that, with divergent viewpoints and behaviors, enriches the sociopolitical climate. New ideas, varying perspectives, diverse problem-solving approaches, and increased tolerance are all outcomes of a diverse population. In addition to these advantages, there are also some disadvantages to living and working within such a culturally diverse environment. For example, the amount and types of variances can lead to ethnocentrism and discrimination.

Cultural diversity presents special challenges for nurses who must provide care that is congruent with a person’s expectations. Nurses caring for clients who are different from themselves must remember to determine the client’s perception and significance (meaning) of the event (illness). The nurse honors each individual’s differences while understanding that culture influences how clients are viewed and treated within health care settings.

¹Not Hispanic.

Notes: Persons of Hispanic origin may be of any race. Race data for 2006 are not directly comparable with data for 1980 and 1990. Individuals could report only one race in 1980 and 1990, and more than one race in 2006. Persons who selected only one race in 2006 are included in single-race categories; persons who selected more than one race in 2006 are shown as having 2 or more races and are not included in single-race categories. In 1980 and 1990, the Asian category included Asian and Native Hawaiian or Other Pacific Islander; in 2006, this category includes only Asian.

Adapted from U.S. Census Bureau.

HEALTH, UNITED STATES, 2007: WITH CHARTBOOK ON TRENDS IN THE HEALTH OF AMERICANS. HYATTSVILLE, MD: AUTHOR. RETRIEVED DECEMBER 19, 2008, FROM [HTTP://WWW.CDC.GOV/NCHS/DATA/HUS/HUS07.PDF](http://www.cdc.gov/nchs/data/hus/hus07.pdf).

ORGANIZING PHENOMENA OF CULTURE

Cultural factors determine the worth of behaviors, whether behaviors are acceptable, and whether behaviors are incorporated into daily living. When these behavioral concepts are applied to health, they influence the individual's expectation of health care. The nurse must be sensitive to the client's cultural context in order to provide care that meets individual needs. Each cultural group has the following basic organizational factors:

- Communication
- Space
- Orientation to time
- Social organization
- Environmental control
- Biological variations

Following is a discussion of the six organizing factors that must be considered when delivering culturally competent care. Table 20-2, on page 384, presents specific examples of cultural variances in these six phenomena.

COMMUNICATION

Communication is the vehicle for transmitting and preserving culture. To share complete and accurate information, nurses must be aware of the cultural variances related to communication. Culturally appropriate nurses attend to both verbal and nonverbal messages and are aware that messages can be easily misinterpreted due to cultural variances.

Nurses provide information to clients by using two types of communication: verbal and nonverbal. Verbal communication consists of words, both spoken and written. When cultural variances exist, communication problems may occur; see the Safety First display. The nurse must validate the meaning of and interpret words to ensure that clients receive the intended message. For example, a communication barrier exists when different languages are spoken by the client and nurse. In such cases, the use of an interpreter facilitates communication. Even when client and nurse speak the same language, communication problems may occur because words have different meanings according to the cultural context.

SAFETY FIRST

ASSUMPTIONS AND COMMUNICATION

When the nurse assumes that the client understands the intended message and fails to confirm client understanding, cultural blindness can hamper the communication process. Thus, client safety can be severely compromised.

Nonverbal communication consists of body language (e.g., facial expressions, posture, gestures), the use of silence, and paralinguistic cues (e.g., voice tone, pitch, rate). An example of how nonverbal communication can be culturally misunderstood is the presence or absence of eye contact. For example, in Native American and Asian American cultures, eye contact is considered intrusive and disrespectful. However, in the dominant U.S. cultural group, eye contact between individuals indicates trustworthiness.

SPACE

An individual's personal space includes one's body, the surrounding environment, and objects and people within that environment; see Chapter 15. Culture determines the amount of social distance tolerated by a person. People of British and German heritages usually require more personal space than do people of Hispanic and French backgrounds (Spector, 2008).

Nurses must be aware of the client's degree of comfort with closeness, since diverse groups have varying norms for the use of touch. Touch may be perceived as invasive by clients from some cultures. Who can touch a person, when a person can be touched, and what forms of touch are appropriate are culturally determined. For example, members of the dominant U.S. culture often greet each other with handshakes while it is commonly accepted in European cultures to greet others with a kiss on the cheek.

ORIENTATION TO TIME

Time orientation (being focused on the past, the present, or the future) varies according to cultural group. European Americans are future oriented as evidenced by their development of plans, such as retirement savings. Many Native Americans have a different concept of time in that they tend to live in the present moment (Spector, 2008); see the Respecting Our Differences display. For many Native Americans, watching the clock and timeliness or tardiness have little importance. Time is considered a circular, rather than a linear, process. The nurse's nonverbal behavior can be changed to build interpersonal rapport by spending time, sitting down with clients, and demonstrating presence.

RESPECTING OUR DIFFERENCES

Time Orientation

In the mainstream American culture, time is a valuable commodity (i.e., "Time is money!"). When caring for clients of diverse cultures, be sensitive to the fact that they may view time differently. Avoid jumping to conclusions that the client who is late for an appointment is lazy or inconsiderate.

TABLE 20-2 Application of Cultural Phenomena to Nursing Care

Data from Berry-Caban, C. S., & Crespo, H. (2008). Cultural competency as a skill for health care providers. *Hispanic Health Care International*, 6(3), 115–121; Spector, R. E. (2008). *Cultural diversity in health and illness* (7th ed.). Upper Saddle River, NJ: Prentice-Hall; Stanhope, M., & Lancaster, J. (2006). *Foundations of community health nursing* (2nd ed.). St. Louis, MO: Mosby.

SOCIAL ORGANIZATION

Social organization refers to the ways in which groups determine rules of acceptable behavior and roles of individual members. Examples of social organizations include family and other kinship ties, religious groups, and ethnic groups.

Family

General systems theory (GST) considers the family to be a system that seeks to maintain balance. From the GST perspective, the family functions as a unit. Thus, if an event affects one family member, all the other members will be affected in one way or another. Nurses must know which family members will be involved in making health care decisions. Including the family according to their cultural expectations is a hallmark of quality nursing care. Various types of family structures are described in Table 20-3. Family patterns usually are of one of three types: linear, collateral, or individualist. See Table 20-4 for an explanation of these types of family patterns.

In many cultures, the family assumes greater importance than the individual (see Figure 20-3 on page 390). For example, in most Native American tribes, the extended family is the basic family structure. The extended family is also extremely important in Hispanic American cultural groups. In some Hispanic groups, the family may include third and fourth cousins as well as close friends who are not related by ties of kinship.

GENDER

Gender roles vary according to cultural context. For example, in families with a patriarchal structure (the man is the head

TABLE 20-3 Types of Family Structures

TYPE	DEFINITION
Nuclear	Parents and children
Extended	Parents, children, and other relatives (e.g., grandparents, cousins)
Attenuated	Single parent with children
Incipient	Married couple with no children
Blended	Married couple and their children from previous unions; may indicate stepparents, stepsiblings, half siblings

Delmar/Cengage Learning

of the household and chief authority figure), the husband and father is the dominant person. Such expectations are the cultural norm for Latino, Hispanic, and traditional Muslim families. The husband and father is the one who makes decisions regarding health care for all family members. Also, in such cultures, the wife is responsible for child care and household maintenance, whereas the father's role is to protect and support the family members (Munoz & Luckmann, 2005).

TABLE 20-4 Family Patterns

KINSHIP PATTERN	EXPLANATION	MOST COMMON CULTURAL CONTEXT
Linear	<ul style="list-style-type: none"> Goals focus on needs of extended and hereditary family. Patriarchal structure is present. Enculturation of children is an important function. Elders are respected. 	<ul style="list-style-type: none"> Asian Middle Eastern Upper-class Euro-American
Collateral	<ul style="list-style-type: none"> Individual members' goals are less important than those of the family. Nuclear family is present. Men are "head of household," yet women contribute to decision making (especially about child care). Children are highly valued. Socialization revolves around family groups. 	<ul style="list-style-type: none"> Hispanic Native American
Individualist	<ul style="list-style-type: none"> Individuals' goals take precedence over those of family. Emphasis is on individual accountability and self-responsibility. There is less respect for authority figures. Elders are not as honored. Family responsibilities are shared between men and women. 	<ul style="list-style-type: none"> Middle-class Euro-American Single-parent family Gay family

Delmar/Cengage Learning

FIGURE 20-3 Within this family, decisions about health care are made on a very personal level among the parents and children. DELMAR/CENGAGE LEARNING

LIFESTYLE

In addition to an increased heterogeneity of population groups in the United States, lifestyles are also becoming more diverse. Some examples of alternative lifestyles are homosexual couples and communal groups. Nurses must demonstrate respect for clients' lifestyles even when they differ from those of the nurse. Some specific ways in which nurses can respect clients with differing lifestyles are:

- Use self-awareness to determine the impact of own beliefs and values.
- Be aware of own tendency to be ethnocentric.
- Be sensitive to client's needs, especially those expressed nonverbally.

Often the nurse and client are of different cultural backgrounds; see Figure 20-4. The nurse must be culturally sensitive in order to promote the development of a therapeutic nurse-client relationship.

FIGURE 20-4 Provision of culturally sensitive care depends on establishing a therapeutic nurse-client relationship. DELMAR/CENGAGE LEARNING

RELIGION

Religious beliefs influence a person's response to major life events such as birth, illness, and death. Religious practices are a source of comfort during stressful life events and provide support for many people during the healing process. Table 24-3 presents an overview of the practices of selected major world religions that relate to issues such as diet, birth, death, and health care. Crises such as illness and treatment modalities are often the catalyst for increased spiritual needs.

CULTURAL DISPARITIES IN HEALTH AND HEALTH CARE DELIVERY

Language and other cultural differences often result in barriers to necessary health care including:

- Appointment procedures
- Transportation
- Written directions

Language and culture strongly affect access and response to health care services (Berry-Caban & Crespo, 2008). It has been noted that in the United States, "many measures of disease and disability differ significantly by race and ethnicity" (National Center for Health Statistics, 2007, p. 20). There are disparities in the health of Americans. "Racial and ethnic minorities often receive lower-quality health care than white patients ..." (Smith et al., 2007, p. 654). One of the major objectives established by the U.S. Office of Public Health in its *Healthy People* objectives is the elimination of disparities in health status by providing equitable services for people of all groups (U.S. Department of Human Services, n.d.).

VULNERABLE POPULATIONS

As a result of societal changes, more people are at risk for health problems. Groups that are especially susceptible to health-related problems include the poor, the homeless, migrant workers, abused individuals, older adults, pregnant adolescents, and people with sexually transmitted diseases (STDs) such as acquired immunodeficiency syndrome (AIDS).

The United States is currently facing many economic, social, and political challenges related to the delivery of health care services to vulnerable population groups (Edelman & Mandel, 2006). As a result, many vulnerable populations are underserved because of the high demand for services, lack of services, and limited availability and access to services.

The Indigent

Poverty affects health status and accessibility to health care services. Living in poverty means being unable to meet the financial demands of basic living expenses, such as food, shelter, and clothing. Socioeconomic status is determined by family income, educational level, and occupation. In 2007,

the average poverty threshold for a family of four was \$21,203 (U.S. Census Bureau, 2008). The poor population has more complex health problems including a higher incidence of chronic illness; see the accompanying Spotlight On display.

Increasing numbers of federally mandated health care initiatives are being implemented to address the historic racial and class disparities in health care. Entitlement programs imply that the government is legally mandated to provide services to the programs' eligible populations. Entitlement programs such as Medicare, Medicaid, and Women, Infants, and Children (WIC) were developed, in part, because of social and political pressures. WIC, a special supplemental food program for women, infants, and children, is a U.S. Public Health–sponsored program that targets low-income pregnant and breastfeeding mothers and their children age 5 years or younger. WIC links health care services, food supplements, and health education into a combined service package for eligible members. Medicaid is a program designed to provide access to health care for medically needy infants, children, and adults. Medicare is an entitlement program that finances health care services for individuals over the age of 65; see Chapter 4.

Poverty interferes with a child's ability to be housed, clothed, and fed adequately and can deprive the child of a safe (physical and psychological) environment. Children with access to health care have the possibility of getting necessary health care services. Children with health insurance (public or private) are much more likely than children without insurance to have a regular and accessible source of health care. In 2008, over 9 million children in the United States were uninsured (National Conference of State Legislatures, 2008). Basic health care services, such as routine screenings and immunizations, establish the foundation of healthy lives for children. However, the lack of insurance prevents receipt of such services by children who live in poverty.

SPOTLIGHT ON...

Values

Socioeconomic Status and Health Care

Think about the following questions regarding poverty and health:

When you see a child who is hungry, what do you feel?

When an adult approaches you on the street asking for money, what do you do?

What do you think causes a person to be economically impoverished? Is poverty a result of socioeconomic, political conditions; the individual's lack of initiative; or other factors?

How do you feel about a person who cannot afford adequate health care services?

The Homeless

Millions of people are homeless in the United States. Societal factors that contribute to homelessness are:

- Lack of affordable housing
- Increasingly stringent criteria for public assistance
- Decreased availability of social services
- Inadequate or lack of employment
- A history of psychosocial trauma
- Deinstitutionalization of clients from mental health facilities without adequate community support (such as halfway houses and group homes)

One reason that homelessness is such a major problem is that there are multiple causative factors that cross lines of age, gender, and socioeconomic status (Edelman & Mandel, 2006). See the accompanying Community Considerations display.

Many homeless people are on the streets because they have some form of mental illness or are addicted to alcohol or other drugs. Those who are homeless are at greater risk for illness and injuries (Edelman & Mandel, 2006), including STDs, and substance abuse. Access to basic health care services is limited because the homeless lack health insurance coverage. Those few facilities that do provide services to the homeless are not always accessible due to lack of transportation. See Table 20-5, on page 392, on common health problems of homeless people.

ENVIRONMENTAL CONTROL

Environmental control refers to the relationships between people and nature and to a person's perceived ability to control activities of nature, such as factors causing illness. Environmental factors that affect health status include air quality, water pollution, soil contamination, noise pollution, and sanitation. See Table 20-6, on page 392, for other examples of environmental health problems and see the Uncovering the Evidence display, on page 394, that discusses a social-environmental problem.

FOLK MEDICINE

The use of a folk medicine system (also referred to as alternative medicine) can present challenges to nurses caring for clients from diverse cultures. In order to work effectively with clients who use folk remedies, the nurse needs to have knowledge of cultural beliefs about illness. See Chapter 31

COMMUNITY CONSIDERATIONS

Is Basic Shelter a Guarantee?

Every person in this country has a basic right to shelter. Do you agree or disagree with this statement? Consider the ethical ramifications of this statement. In light of the current political and social climate, what do you think the homeless population can expect from government and society?

TABLE 20-5 Common Health Problems Experienced by Homeless People

PROBLEM	IMPACT OF HOMELESSNESS
Diabetes	<ul style="list-style-type: none"> Lack of regularly scheduled nutritious meals Inadequate rest Insufficient exercise
AIDS	<ul style="list-style-type: none"> Higher rate of sexual assault Intravenous drug use Lack of treatment or inadequate follow-up
Respiratory diseases (e.g., tuberculosis, pneumonia)	<ul style="list-style-type: none"> Crowded living conditions Inadequate nutrition Limited or no access to treatment facilities
Cardiovascular diseases	<ul style="list-style-type: none"> Impaired peripheral circulation as a result of extended time walking on the streets or sleeping in upright, seated position Food served in many shelters has a high sodium content Consumption of alcohol and tobacco products
Parasitic infestations	<ul style="list-style-type: none"> Shared personal items (clothing, bedding, hairbrushes) Close physical contact (as in shelters) Lack of facilities for baths, showers Inability to treat all those in contact with the affected person

Stanhope, M., & Lancaster, J. (2006). *Foundations of community health nursing* (2nd ed.). St. Louis, MO: Mosby.

for a complete discussion of complementary and alternative treatment methods.

Folk healers are knowledgeable about cultural norms and are usually familiar to the one seeking care (Edelman & Mandle, 2006). Table 20-7 on page 393 presents the various healers within different cultures and describes common folk healing practices within these cultures. Nurses must be able to relate care and treatment to the client's cultural context to incorporate informal caregivers, healers, and other members of the clients' support system as allies in treatment.

BIOLOGICAL VARIATIONS

Biological variations that distinguish one cultural group from another include enzymatic differences and susceptibility

TABLE 20-6 Environmental Health Problems

ENVIRONMENTAL AREA	POTENTIAL PROBLEMS
Air quality	<ul style="list-style-type: none"> Gaseous pollutants Spraying of herbicides and pesticides Disappearing ozone layer
Food quality	<ul style="list-style-type: none"> Bacterial contamination Altered food chain as result of ecosystem destruction Food additives Genetic engineering/alteration
Living patterns	<ul style="list-style-type: none"> Exposure to secondhand smoke Noise exposure Substance abuse Urban crowding Violence/unsafe neighborhoods
Radiation threats	<ul style="list-style-type: none"> Nuclear facility emissions Radioactive hazardous wastes Radon gas X-ray exposure

Adapted from Hall, J. M., Robinson, C. H., & Broyles, T. J. (2007). Environmental health. In M. A. Nies & M. McEwen (Eds.), *Community/public health nursing: Promoting health of populations* (4th ed., p. 237). Philadelphia: Saunders Elsevier.

to disease (Spector, 2008). Enzymatic differences account for diverse responses of some groups to dietary therapy and drugs (see Table 20-8 on page 394). "Cultural variations and differences may affect the breakdown, distribution, and action of pharmacologic agents for ethnically and culturally diverse persons" (Warren, 2008, p. 293). Nutritional variations include food preferences that may contribute to health problems (see Table 20-9 on page 395).

TRANSCULTURAL NURSING

Acknowledgment and acceptance of cultural differences and understanding of culturally specific responses to illness are prerequisites for providing safe and effective care. The conceptual framework for understanding cultural diversity and providing culturally competent care is based on Leininger's transcultural nursing theory. **Transcultural nursing**, according to Leininger (2005), focuses on the study and analysis of different cultures and subcultures with respect to cultural

TABLE 20-7 Folk Medicine: Healers and Practices

CULTURAL GROUP	TRADITIONAL HEALERS	HEALING PRACTICES
African American	<ul style="list-style-type: none"> • Elderly women healers • “Community Mother” or “Granny” • “Root doctor” • Voodoo healer (“Mambo” or “oungan”) • Spiritualist 	<ul style="list-style-type: none"> • Herbs, roots • Poultices • Oils • Religious healing through rituals (e.g., laying on of hands) • Talismans are worn around the wrist or neck, or carried in a pouch to ward off disease
Asian American	<ul style="list-style-type: none"> • Herbalist • Physician 	<ul style="list-style-type: none"> • Use of hot and cold foods • Herbs (e.g., ginseng root, which is used as a restorative potion) • Soups • Cupping, pinching, and rubbing • Meditation • Acupuncture (puncturing the skin at specified areas with metal needles) • Acupressure (applying pressure with the fingertips to specified areas of the body) • Application of tiger balm (a salve) to relieve muscular pains • Energy to restore balance between yin and yang
European American	<ul style="list-style-type: none"> • Nurse • Physician 	<ul style="list-style-type: none"> • Exercise • Medication (prescribed and over the counter) • Modified diets • Amulets • Religious healing rituals
Hispanic American	<ul style="list-style-type: none"> • <i>Curandero</i> • <i>Espiritualista</i> • <i>Yerbero</i> (herbalist) • <i>Brujo</i> (healer who uses witchcraft) • <i>Sobadora</i> • <i>Santiguadora</i> 	<ul style="list-style-type: none"> • Hot and cold foods to treat some conditions • Herbal teas, such as Manzanilla, used to treat gastrointestinal problems, insomnia, and menstrual cramps • Prayers and religious medals • Massage • <i>Azabache</i>, a black stone worn as a necklace or bracelet to ward off the “evil eye” • Some Haitian mothers practice the “three baths” ritual: They bathe for the first 3 postpartum days in water boiled with special leaves
Native American	<ul style="list-style-type: none"> • Shaman • Medicine man or woman 	<ul style="list-style-type: none"> • Use of plants and herbs • Medicine bundle or bag filled with herbs that have been blessed by a medicine man or woman during a healing ceremony • Sweet grass (herbs) burned to purify the ill person • <i>Estafiate</i> (dried leaves) boiled to produce a tea for treating stomach disorders • The Blessingway ceremony (a healing ritual conducted by the medicine man or woman) • In some Navajo tribes, the medicine man or woman uses sand painting as a diagnostic method

UNCOVERING THE

Evidence

TITLE OF STUDY

“Is Immigrant Status Relevant in School Violence Research? An Analysis with Latino Students”

AUTHOR

A. A. Peguero

PURPOSE

To investigate the effect of immigrant status and English proficiency on the experiences of Latino students with school violence–related outcomes.

METHODS

This investigative study is based on data from the Education Longitudinal Study of 2002. The study examined 1,457 nationally representative public school Latino students’ experiences with school violence–related outcomes.

FINDINGS

Data analysis reveals that third-generation immigrant students were more likely than first- and second-generation students to be victimized while at school. First-generation immigrant students were the most likely to feel unsafe at school. Nonnative English-speaking students were more likely to report being a victim of school violence in comparison to native English speakers.

IMPLICATIONS

There is a great need for further study of school and community characteristics of immigration and assimilation and their impact on children’s lives. Children’s exposure to violence must be investigated more thoroughly in school and community settings.

Peguero, A. A. (2008). Is immigrant status relevant in school violence research? An analysis with Latino students. *Journal of School Health*, 78(7), 397–404.

care, health beliefs, and health practices with the goal of providing health care within the context of the client’s culture.

A basic assumption of transcultural nursing is that health care providers who see problems from the client’s cultural viewpoint are more open to understanding, appreciating, and working effectively with these clients (Figure 20-5 on page 396). Other assumptions of transcultural nursing theory are:

- Every culture has some type of system for health care that is based on values and behaviors.
- Cultures have certain methods for providing health care. These methods of care are often unknown to nurses from other cultures (Leininger, 2005).

TABLE 20-8 Effects of Biological Variations on Selected Drugs

CULTURAL GROUP	EFFECT OF BIOLOGICAL VARIANCE ON DRUGS
African American	<ul style="list-style-type: none"> • Isoniazid (drug used to treat tuberculosis) is rapidly metabolized, thus becoming inactive quickly; occurs in approximately 60% of population. • An enzyme deficiency interferes with metabolism of primaquine (used to treat malaria); occurs in approximately 35% of population. • Antihypertensive drugs (e.g., propranolol) need to be administered in higher doses to produce same effects as in European Americans.
Asian American	<ul style="list-style-type: none"> • Isoniazid (drug used to treat tuberculosis) is rapidly metabolized, thus becoming inactive quickly; occurs in approximately 85%–90% of population. • Rapid metabolism of alcohol results in excessive facial flushing and other vasomotor symptoms. • Chinese men need only about half as much propranolol (antihypertensive drug) as European American men. • Asian people need smaller doses of alprazolam (anti-anxiety drug) to achieve same blood levels as their European American counterparts; the drug is also metabolized more slowly (remains in the bloodstream longer) in Asian men.
European American	<ul style="list-style-type: none"> • Due to liver enzyme differences, caffeine is metabolized and excreted faster than by people of other cultural groups.
Native American	<ul style="list-style-type: none"> • Isoniazid (drug used to treat tuberculosis) is rapidly metabolized, thus becoming inactive quickly; occurs in approximately 60%–90% of population. • Rapid metabolism of alcohol results in excessive facial flushing and other vasomotor symptoms.

Data adapted from Spector, R. E. (2008). *Cultural diversity in health and illness* (7th ed.). Upper Saddle River, NJ: Prentice-Hall.

Due to rapid globalization, every nurse must have an understanding of human conditions in diverse societies. Nurses do not need to travel to foreign countries to engage in international nursing. Nurses encounter cultural diversity

everywhere—from inner-city hospitals to suburban clinics, from technologically sophisticated institutions to homes in rural, inner-city, and suburban areas.

CULTURAL COMPETENCE

Community, social and kinship ties, religion, language, food, and cultural perceptions of illness are all areas that need to be considered by the nurse when working with clients. Diversity challenges nurses to bridge gaps with clients by providing culturally relevant care. An understanding of the client's cultural context permits nurses to become familiar with the client as a person instead of focusing only on the illness or problem.

Cultural competence is the process through which the nurse provides care that is appropriate to the client's cultural context. Culturally competent nurses are those who demonstrate understanding of the client's values related to health and illness. Also, nurses who provide care in a culturally sensitive manner are flexible in their approaches and thinking.

CULTURAL COMPETENCE AND NURSING PROCESS

Cultural sensitivity is required in every phase of the nursing process. The nurse's role in providing culturally competent care includes performing a cultural assessment, formulating nursing diagnoses, identifying expected client outcomes, planning care to assist clients in achieving the expected

outcomes, intervening to address the client's nursing diagnoses, and evaluating the plan of care. The College of Nurses of Ontario (2008) identifies four elements of providing culturally sensitive care: self-reflection, facilitating client choice, gaining cultural knowledge, and effective communication. These four elements permeate the nursing process.

ASSESSMENT

Caring for a client from a different culture can be challenging to the nurse. With every client, take time, listen carefully, and convey warmth, openness, and honesty when collecting information. Using the client's strengths and respecting the client's values are essential components of effective nursing care. To begin providing culturally competent care, the nurse should use questions to gather information about the client's cultural background. Factors pertinent to cultural assessment are listed in the Nursing Process Highlight on page 396. Cultural assessment can either be incorporated into a general nursing assessment or performed separately.

NURSING DIAGNOSIS

Diagnoses approved by the North American Nursing Diagnosis Association (NANDA, 2009) are used extensively by nurses. However, one stated disadvantage to NANDA diagnostic statements is that sometimes the diagnoses are worded in ways that result in cultural bias (Munoz & Luckmann, 2005). The accompanying Nursing Process Highlight, on page 396, lists some diagnoses that may be culturally biased.

FIGURE 20-5 The relationship between this nurse and client is based on a mutual acceptance of each other's cultural viewpoints. In your interactions with clients, what factors or cultural phenomena would you explore to ensure acknowledgment of the client's cultural beliefs and values? DELMAR/CENGAGE LEARNING

Consider the following examples of ways in which these diagnoses may be used in a culturally inappropriate manner:

- Applying the diagnosis *Impaired verbal communication* to clients who speak a language different from the nurse

NURSING PROCESS HIGHLIGHT

Assessment

Cultural Assessment Factors

- Client's ethnic heritage
- Family role and function
- Religious practices
- Food preferences
- Native language
- Social networks
- Educational experiences (formal and informal)
- Health care beliefs
- Family patterns of health care

NURSING PROCESS HIGHLIGHT

Diagnosis

Nursing Diagnoses That May Be Culturally Biased

- Noncompliance
 - Impaired verbal communication
 - Impaired social interaction
 - Deficient knowledge
 - Disturbed thought processes
 - Powerlessness
- Using the diagnosis *Noncompliance* with clients who reject a prescribed treatment method in order to adhere to their culturally sanctioned folk healing methods

PLANNING AND OUTCOME IDENTIFICATION

Cultural groups are not homogeneous; there are individual variations in personality, behavior, and expectations. It is important not to consider one member of a particular group to be like all the others of that same group.

In order to develop effective plans of care, nurses need to understand cultural definitions of health and illness. It is also necessary to consider how the client's beliefs may affect the plan of care. Cultural beliefs greatly influence perceptions about health and, therefore, may create barriers to adhering to prescribed treatment plans.

IMPLEMENTATION

Caring for culturally diverse clients requires three major nursing interventions: self-awareness, use of a nonjudgmental approach, and client education. Each of these aspects are discussed in the following sections. The accompanying Community Considerations display, on page 397, offers guidelines for providing culturally sensitive care for clients at home.

Self-Awareness

In an increasingly diverse society, the nurse must be aware of the potential for bias or misunderstanding and see the influence of the nurse's cultural background on the delivery of care. Self-awareness can be used to help nurses recognize their own stereotypes, biases, and prejudices about clients who are culturally different. Further experience, introspection, and study empower nurses to appreciate their own cultural perspectives as well as the strengths of other cultures.

Nonjudgmental Approach

A nonjudgmental attitude is essential in the provision of culturally sensitive care. When caring in a manner sensitive to the client's cultural background, the nurse enables the client to offer open, honest feedback; to disagree; and to discuss

Providing Culturally Sensitive Nursing Care in the Home

- The setting for care is controlled by the client and family, not by the health care provider.
- The nurse is often viewed as a guest by the client and family. Social chatter may be necessary to facilitate rapport.
- The nurse must be nonjudgmental about the condition of the home (e.g., presence of clutter and disarray).
- Show respect and consideration for the client. For example:
 - Wipe your feet before entering the home.
 - Ask permission to use sink or bathroom to wash your hands.
 - Ask permission before moving client's belongings, and replace items after you have finished the task.
- Take advantage of the home environment to assess cultural values and norms. Cultural clues may include:
 - Orderliness and decor of the home
 - Assignment of family roles and tasks
 - Types of interactions among family members
 - Value placed on privacy
 - Value placed on possessions

real or perceived problems. A health care partnership is the outcome of such an approach.

Client Education

Educating clients is an integral part of nursing practice. Education not only must be relevant to the client's needs but also must be provided in a culturally sensitive manner. See the Client Teaching Checklist for culturally sensitive teaching guidelines.

EVALUATION

The final phase of the nursing process, evaluation, is extremely important in determining the client's achievement of expected outcomes and the efficacy of nursing interventions in delivery of culturally sensitive care.

CLIENT TEACHING CHECKLIST

Culturally Sensitive Teaching Guidelines

When caring for clients from diverse cultures, the nurse should consider the following guidelines for client teaching.

- Assess and incorporate family history of health care:
 - Fluency in English
 - Extent of family support or disintegration of family
 - Community resources
 - Level of education
 - Change of social status as a result of coming to this country
- Affirm client strengths and potential for growth.
- Recognize informal caregivers (family members and significant others) as an integral part of treatment.
- Evaluate the client's current knowledge base by asking the client to state what he or she knows about the specific topic.
- To ascertain the client's perception of need, ask the client/family what they need/want to learn.
- Observe the interaction between the client and family to determine family roles and authority figures. Include the dominant family member in your teaching.
- Use language easily understood by the client.
- Clarify your verbal and nonverbal messages with the client.
- Have the client repeat the information taught. If feasible, have the client do a return demonstration of material taught.

Provision of culturally competent care requires that the nurse view the client as an actively participating partner of the health care team. It is important to demonstrate caring behaviors rather than just tolerating cultural variations in client behavior. Awareness of cultural similarities and variations allows nurses to accept and appreciate the impact of culture on health care. Evaluation of client response provides valuable data about the efficacy of nursing care.

KEY CONCEPTS

- Every aspect of a person's life is influenced by culture.
- Behavior affecting health is culturally determined.
- Culture is a dynamic structure of behaviors, ideas, attitudes, values, habits, beliefs, customs, languages, rituals, ceremonies, and practices that are unique to a particular group of people. This structure of knowledge, behaviors, and values provides a group with a blueprint for behavior.
- Cultural norms are transmitted from one generation to another.

- Ethnicity is described as a sense of belongingness that is shared by other members of the same group. Ethnic groups are usually composed of people with the same racial composition.
- Race refers to a grouping of people based on biological similarities. Members of a racial group have similar physical characteristics, such as blood type, facial features, and color of skin, hair, and eyes.
- Members of some racial and ethnic groups have experienced oppression in the forms of racism, sexism, ageism, and classism.
- The dominant values of the United States include achievement and success; individualism, independence, and self-reliance; activity, work, and ownership; efficiency, practicality, and reliance on technology; material comfort; competition and achievement; and youth and beauty.
- There is great value in cultural diversity, including a broader perspective of others, enhanced problem-solving ability and creativity, and improved productivity in the workplace.
- The six organizing phenomena of culture are communication, space, orientation to time, social organization, environmental control, and biological variations.
- Transcultural nursing is based on the belief that nurses who view problems from clients' cultural viewpoints are more open to understanding and working effectively with clients from other cultures.
- Understanding and accepting cultural differences and responses to illness are prerequisites for providing quality nursing care.
- The provision of culturally sensitive care is achieved through the use of approaches such as nonjudgmental attitudes and self-awareness and tools such as cultural assessment guides and client education strategies.

REVIEW QUESTIONS

1. A nurse tells a client who recently emigrated from Asia, "You will have to follow the rules here in order to get better." Which of the following is illustrated by the nurse's statement?
 - a. Cultural competence
 - b. Cultural sensitivity
 - c. Ethnocentrism
 - d. Transcultural nursing
2. Which of the following are examples of culturally competent nursing care? Select all that apply.
 - a. Asking who makes health care decisions for the client
 - b. Contacting a rabbi to see a Jewish client before consulting with the client
 - c. Determining client food preferences
 - d. Explaining how the client must comply with the hospital regulations
 - e. Including family members in client teaching
 - f. Insisting that family members leave when answering client questions
3. Which of the following nursing actions is culturally inappropriate for an Asian American client?
 - a. Avoiding physical closeness when feasible
 - b. Limiting eye contact with the client
 - c. Patting the client's child on the head
 - d. Using very few hand gestures when talking with the client
4. Which of the following actions would be appropriate for the nurse when caring for a client of Hispanic culture?
 - a. Avoid touching a child you are admiring.
 - b. Communicate with the female head of household.
 - c. Expect the client to adhere to an exact time schedule.
 - d. Touch the client frequently during communication.
5. When performing an admission assessment on a Native American client, the nurse should understand which of the following?
 - a. Absence of eye contact indicates attentiveness.
 - b. Interactions should include the client and members of the immediate (nuclear) family.
 - c. Limit visitors to only two or three at a time.
 - d. The client should be encouraged to touch the deceased.
6. When assessing a homeless client in an outpatient clinic, the nurse must look for indicators of which of the following?
 - a. Breast cancer
 - b. Cataracts
 - c. Hearing deficits
 - d. Parasitic infestations

CHAPTER 21

Client Education

COMPETENCIES

1. Explain the importance of client education in today's health care climate.
2. Relate principles of adult education to client teaching.
3. Identify common barriers to learning.
4. Explain how learning varies throughout the life cycle.
5. Discuss the nurse's professional responsibilities related to teaching.
6. Relate the teaching-learning process to the nursing process.
7. Describe teaching strategies that make learning meaningful to clients.

KEY TERMS

affective domain
auditory learners
cognitive domain
kinesthetic learners
learning

learning plateaus
learning style
philosophy
psychomotor domain
readiness for learning

self-efficacy
teaching
teaching-learning process
teaching strategies
visual learners

Client education is an integral part of nursing care. It is the nurse's responsibility to assist the client to identify the learning needs and resources to help restore and maintain an optimal level of functioning. Client education is extremely important today in a health care environment that demands cost-effective measures. With shorter hospital stays, clients are being discharged to the home or other health care settings in more critical conditions than ever before. Client education, a hallmark of quality nursing care, is a fiscally responsible intervention that encourages health care consumers to engage in self-care and to develop healthy lifestyle practices. This chapter offers an overview of the teaching-learning process, including learning barriers and teaching responsibilities of nurses.

THE TEACHING-LEARNING PROCESS

The **teaching-learning process** is a planned interaction for promoting behavioral change that is not a result of maturation or coincidence. **Teaching** is an active process in which one individual shares information with others to provide them with the information to make behavioral changes. Teaching refers to all the activities used by a teacher to assist the learner to absorb new information; it consists of activities that promote change. Teaching is a goal-directed process that provides the opportunity for learning.

Learning is the process of assimilating information with a resultant change in behavior. Nurses and clients have shared responsibilities in the teaching-learning process. Knowledge is power. By sharing knowledge with clients, the nurse empowers clients to achieve their maximum level of wellness. The teaching-learning process will be familiar to nurses in that it mirrors the steps of the nursing process: assessment, identification of learning needs (nursing diagnosis), planning, implementation of teaching strategies, and evaluation of learner progress and teaching efficacy.

PURPOSES OF CLIENT TEACHING

According to Edelman and Mandle (2006), the goal of health education is to help individuals achieve optimum states of health through their own actions. Teaching, one of the most important nursing functions, addresses clients' need for information. Often, a knowledge deficit about the course of illness and self-care practices hinders a client's recovering from illness or engaging in health-promoting behaviors. The

nurse's charge is to help bridge the gap between what a client knows and what a client needs to know in order to achieve optimum health. (See Table 21-1.)

Client teaching is done for a variety of reasons, including:

- Promotion of wellness
- Prevention of disease and injury
- Restoration of health
- Facilitation of coping abilities

Client education focuses on the client's ability to practice healthy behaviors. The client's ability to care for himself or herself is enhanced by effective education.

In order to be more effective teachers, nurses need a basic understanding of learning theories. There are many schools of thought (theories) about how people learn. Table 21-2, on page 403, provides an overview of major learning theories.

TABLE 21-1 Client Education Topics

Health promotion	<ul style="list-style-type: none"> • Parenting Skills • Nutrition • Exercise • Family planning
Health restoration	<ul style="list-style-type: none"> • Medication information • Community resources • Information about treatment modalities
Illness and injury prevention	<ul style="list-style-type: none"> • Immunizations • Health screenings • Smoking cessation • Breast self-examination • Safety measures (e.g., car seat, restraining devices)
Facilitating coping	<ul style="list-style-type: none"> • Safe use of medical equipment • Dietary modifications • Information about the disease process • Counseling related to anger, grief, self-esteem • Stress management

Delmar/Cengage Learning

TABLE 21-2 Overview of Learning Theories

THEORIST	DESCRIPTION
John Watson	Learning is a result of conditioning and experiences; it is encouraged by changing the environment.
Ivan Pavlov	The learner is passive, controlled by the environment.
B. F. Skinner	Teaching is the deliberate manipulation of the environment.
Edward L. Thorndike	Learning can be transferred from one situation to another. Assessment of learner's behavior is necessary.
John Dewey	The learner must have an understanding of the goals. Education should promote learner independence.
Jerome Bruner	Learning is affected by culture and value system. The learner is an active participant in the learning process.
Robert Gagne	Learning occurs in an orderly fashion, from the simple to the complex, from the concrete to the abstract.
Albert Bandura	Behavior is regulated by internal mechanisms, such as self-efficacy

Delmar/Cengage Learning

Each nurse needs to develop an individual **philosophy** (statement of beliefs that is the foundation for behavior) of learning. When formulating a philosophy about teaching-learning, nurses need to consider the common beliefs about learning listed in the accompanying Spotlight On display.

FACILITATORS OF LEARNING

Certain fundamental principles of education can be used by nurses to facilitate client learning. Knowles (1984) stated four basic assumptions about adult learners, which are applicable to client education:

- *Assumption:* An individual's personality develops in an orderly fashion from dependence to independence. *Nursing application:* Plan teaching-learning activities that promote client participation, thus encouraging independence; this increases client control and self-care through empowerment.
- *Assumption:* Learning readiness is affected by developmental stage and sociocultural factors. *Nursing application:* Conduct a thorough psychosocial assessment before planning the teaching-learning activities.
- *Assumption:* An individual's previous learning experiences can be used as a foundation for further learning. *Nursing application:* Perform a complete assessment to determine

SPOTLIGHT ON...

Professionalism

Your Beliefs about Learning

Consider the information in Table 21-2. Which statements mirror your own philosophy about learning? Which statements are most congruent with a nursing philosophy that views clients not as recipients of care but as partners in the caring and healing process?

what the client already knows and build on that knowledge base.

- *Assumption:* Immediacy reinforces learning. *Nursing application:* Provide opportunities for immediate application of knowledge and skills. Incorporate feedback as a continuous part of each nurse-client interaction.

Table 21-3 describes key learning principles.

TABLE 21-3 Principles of Learning

PRINCIPLE	EXPLANATION
Relevance	The material should be: <ul style="list-style-type: none"> • Meaningful to client • Easily understood by client • Related to previously learned information
Motivation	Client should: <ul style="list-style-type: none"> • Want to learn • Perceive value of information
Readiness	Client should be able and willing to learn.
Maturation	Client should be developmentally able to learn and have requisite cognitive and psychomotor abilities.
Reinforcement	Feedback to learner should be: <ul style="list-style-type: none"> • Positive • Immediate
Participation	Active involvement promotes learning.
Organization	The material should: <ul style="list-style-type: none"> • Incorporate previously learned information • Be presented in sequence of simple to complex
Repetition	Retention of material is reinforced by practice, repetition, and presentation of same material in a variety of ways.

Delmar/Cengage Learning

Learning plateaus, or peaks in effectiveness of teaching and depth of learning, will occur in relation to the client’s motivation, interest, and perception of relevance of the material. Frequent reinforcement of learning through immediate feedback and continual reassessment of effectiveness will enhance the value of the learning process. Making the information acquisition process as user-friendly as possible will also increase satisfaction and success. This can be done by organizing content from the simple to the complex and from the familiar to the new, making learning as creative and interesting as possible, and adopting a flexible approach to allow the learning process to be dynamic.

BARRIERS TO LEARNING

Receiving information does not, in and of itself, guarantee that learning will occur. Several barriers can impede the learning process. In a nursing situation, learning barriers can be classified as either internal (psychological or physiological) or external (environmental or sociocultural). Examples of these barriers are shown in Table 21-4. See the accompanying Spotlight On display.

The nurse must assess for the presence of barriers in order to facilitate the learning process. Specific assessment information is presented later in this chapter.

DOMAINS OF LEARNING

Bloom, in his classic work (1977), identified three areas or domains in which learning occurs: the **cognitive domain** (intellectual understanding), the **affective domain** (emotions and attitudes), and the **psychomotor domain** (motor skills). Each domain responds to and processes information

External Barriers	
Environmental	<ul style="list-style-type: none"> • Interruptions • Lack of privacy • Multiple stimuli
Sociocultural	<ul style="list-style-type: none"> • Language • Value system • Educational background
Internal Barriers	
Psychological	<ul style="list-style-type: none"> • Anxiety • Fear • Anger • Depression • Inability to comprehend
Physiological	<ul style="list-style-type: none"> • Pain • Fatigue • Sensory deprivation • Oxygen deprivation

Delmar/Cengage Learning

SPOTLIGHT ON...

Caring

Barriers to Learning

Do you think knowledge acquisition alone results in learning (behavior change)? Why or why not? Consider, for example, all the information available regarding the harmful effects of smoking. Every cigarette package has a similar statement: “Warning: Cigarette smoking can cause lung cancer, heart disease, emphysema, and interfere with pregnancy.” However, dissemination of this information has not led to complete cessation of smoking in our society. Why do you think this is so? What learning barriers may be interfering with smokers’ taking action in response to this warning?

in very different ways. Table 21-5 briefly describes the three domains of learning through clinical examples.

Nurses need to be sensitive to all three domains of learning when developing effective teaching plans and use **teaching strategies** (techniques to promote learning) that will tap into each of the domains. For instance, teaching a diabetic client the need to measure the proper daily balance of insulin against glucose levels is within the cognitive domain. Helping this client learn to self-administer insulin falls within the psychomotor domain. Helping the client learn to view

DOMAIN	DEFINITION	CLINICAL EXAMPLE
Cognitive	Learning that involves the acquisition of facts and data. Used in problem solving and decision making.	Client states the name and purpose of prescribed medications.
Affective	Learning that involves changing attitudes, emotions, beliefs. Used in making judgments.	Client accepts that he or she has a chronic illness.
Psychomotor	Learning that involves gaining motor skills. Used in physical application of knowledge.	Client gives himself or herself an injection.

Delmar/Cengage Learning

diabetes as only one part of an entire individual is an example of affective learning.

PROFESSIONAL RESPONSIBILITIES RELATED TO TEACHING

Through teaching, the nurse empowers clients in their self-care abilities. Teaching is the tool for providing information to clients about specific disease processes, treatment methods, and health-promoting behaviors.

LEGAL ASPECTS

The American Nurses Association (2003), in its *Social Policy Statement*, identifies health teaching as an essential function of nursing. Each state has its own definition of nursing practice; in most states, teaching is a required function of nurses. For example, as stated by the Louisiana State Board of Nursing (2004, p. 9), “The practice of a registered nurse includes such activities as health instruction, and health counseling.”

Client teaching is also mandated by several accrediting bodies, such as the Joint Commission. The American Hospital Association (2003) calls for the client’s understanding of health status and treatment approaches. Informed consent for treatment procedures can be given only by clients who are well informed. The nurse assesses the client’s level of understanding about treatment methods and corrects any knowledge deficits. The nurse is often an interpreter to the client—explaining in easily understood terms, clarifying, and referring messages between the client and other health care providers.

Teaching supports behavior change that leads to positive adaptation. Thus, teaching involves decreasing the fear of change. Reducing anxiety and anticipatory stress is an important component of teaching.

Client teaching is an essential function of every professional nurse regardless of the practice setting. Table 21-6 outlines learning needs as they relate to the three phases of nursing care: primary, secondary, and tertiary. Clients who are hospitalized need information regarding their condition, the hospital environment, and expectations regarding treatment.

DOCUMENTATION

The reasonable, prudent standard calls for nurses to document client education. See Chapter 12 for a discussion of this standard. From a legal perspective, if the nurse teaches the client and fails to document it, then the educational activities never occurred. Documentation of teaching promotes continuity of care and facilitates accurate communication to other health care providers.

Many different approaches can be used to document client teaching. Figure 21-1, on page 406, provides one example of documentation for client teaching in an inpatient setting. Because client education is a standard and essential component of nursing practice, teaching interventions and the client’s response must be documented. Elements for documenting client education in all practice settings include:

TABLE 21-6 Learning Needs in Various Phases of Care

PRIMARY: HEALTH MAINTENANCE	SECONDARY: DIAGNOSIS AND TREATMENT	TERTIARY: FOLLOW-UP
<ul style="list-style-type: none"> • Disease prevention • Health care services availability • Growth and development • First aid • Nutrition • Hygiene 	<ul style="list-style-type: none"> • Disease process • Methods of care and treatment • Health care setting 	<ul style="list-style-type: none"> • Care at home • Medications • Dietary modifications • Activity • Rehabilitation plans • Safety • Prevention and recurrence of complications

Delmar/Cengage Learning

- Teaching methods used
- Who was taught (e.g., client, which family member, other caretaker)
- Client and family response to teaching activities

LEARNING THROUGHOUT THE LIFE CYCLE

One basic assumption underlies teaching effectiveness—all people are capable of learning. This ability to learn varies from person to person and from situation to situation. Most clients—because of anxiety, pain, or other stressors related to illness—have only limited adaptive resources. They may not have much energy or interest to invest in learning.

Learning needs and learning abilities change throughout life. The client’s chronological age and developmental stage greatly influence the ability to learn. The principles of learning discussed earlier in this chapter have relevance to learners of all ages. However, teaching approaches must be modified according to the client’s developmental stage and level of understanding. Specific information about teaching children, adolescents, and older adults is provided in the following sections. Table 21-7, on page 407, lists teaching strategies for different age groups.

CHILDREN

Readiness for learning (evidence of willingness to learn) varies during childhood according to maturational level. Responding to knowledge deficits of young children requires the nurse to work closely with the child’s caretaker. Including the family or significant others in teaching is essential when caring for young children.

Young children learn primarily through play, which can be incorporated into teaching activities (Figure 21-2 on page 408).

TABLE 21-7 (Continued)

	TEACHING STRATEGY	NURSING IMPLICATIONS
Middle-aged adults	<ul style="list-style-type: none"> Printed materials geared to level of comprehension Discussion Demonstration Role-play 	<ul style="list-style-type: none"> Increased awareness of personal vulnerability Generally, a recognition of the need for lifestyle changes Assess reading skills. <p>Learning needs: Nutrition, exercise, stress management, warning signs of illness</p>
Older adults	<ul style="list-style-type: none"> Assess for reading skills Frequent repetition Demonstration Discussion Assess for sensory perceptual changes and match with corresponding materials. 	<ul style="list-style-type: none"> May need large-print materials Often a strong desire for independence; offer choices. Chronic illness (e.g., arthritis) may impair mobility and dexterity. Aging does not lead to an overall decreased intelligence. <p>Learning needs: Loss and grief, disease-specific information, stress management, socialization skills, elimination patterns, dental hygiene</p>

Data from Edelman, C. L., & Mandle, C. L. (2006). *Health promotion throughout the life span* (6th ed.). St. Louis, MO: Elsevier Mosby; Hunt, R. (2009). *Introduction to community-based nursing* (4th ed.). Philadelphia: Lippincott, Williams & Wilkins.

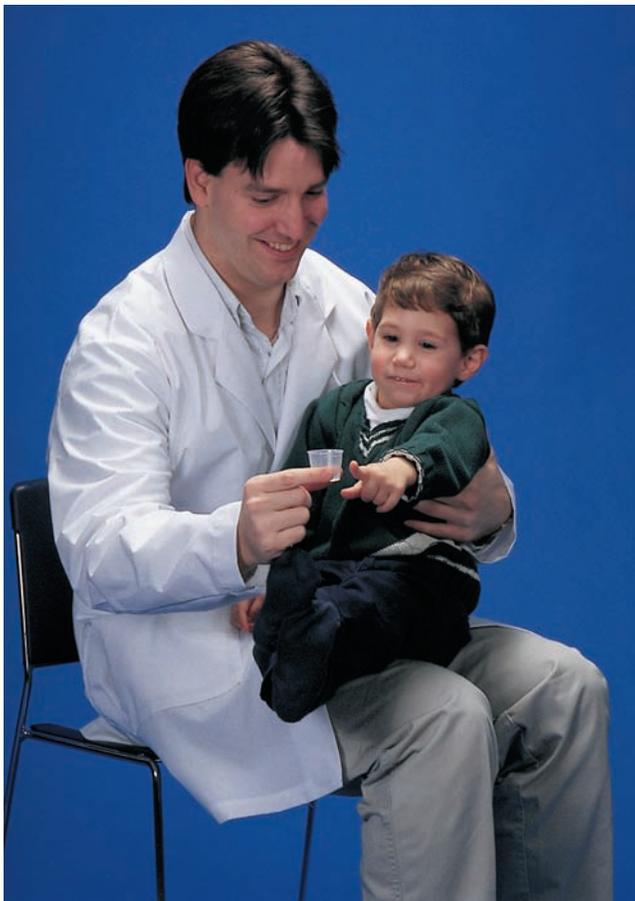

FIGURE 21-2 The use of play and games helps children learn and decreases their anxiety about the health care setting. DELMAR/

CENGAGE LEARNING

For example, puppets, toys, and coloring books can be effective teaching tools for the young child.

Older children can also benefit from the use of art materials and medical supplies (e.g., medicine cups, putting bandages on dolls). While the child is involved in play, the nurse is alleviating anxiety by teaching the child what to expect

NURSING CHECKLIST

GUIDELINES FOR TEACHING CHILDREN

- Make sure the client is comfortable.
- Encourage caregiver participation.
- Assess developmental level. Do not equate age with developmental level.
- Assess client's learning readiness and motivation.
- Assess client's psychological status.
- Determine self-care abilities of client and caregiver.
- Use play, imitation, and role-play to make learning fun and meaningful.
- Use different visual stimuli such as books, chalkboards, and videos to convey information and check understanding.
- Use terms that are easily understood by the client and caregiver.
- Provide frequent repetition and reinforcement.
- Develop realistic goals that are consistent with developmental abilities.
- Verify client's understanding of information presented.

regarding treatment procedures. The accompanying Nursing Checklist provides guidelines for teaching children.

ADOLESCENTS

As children approach adolescence, they are better able to conceptualize relationships between things. Usually, reading skills and comprehension ability have advanced, and the adolescent can understand more complex information. One of the strongest influences on an adolescent is peer support; therefore, group sessions are often useful in teaching (see Figure 21-3). Nurses also teach by acting as role models and relating to adolescents on their level. See the accompanying Respecting Our Differences display. Listening allows the nurse to hear the adolescent's feedback relative to learning needs. It is also important when teaching adolescents to focus on the present and to be aware of their need to maintain control. The nurse must assist the adolescent as needed while at the same time encouraging as much independence as possible. Show respect for adolescents by recognizing that they still have to gain the knowledge and experience of adulthood while struggling to break away from the grasp of childhood. The accompanying Nursing Checklist provides additional guidelines for teaching adolescents.

OLDER ADULTS

Aging is accompanied by many physiological changes. As a result of these changes, some older adults have perceptual impairments such as impaired vision and hearing. The nurse must assess for perceptual changes and adjust teaching materials accordingly. For example, provide large-print written material and make sure the client can hear all the nurse's instructions and directions. The accompanying Nursing Checklist on page 410 provides guidelines for teaching older adults.

FIGURE 21-3 Adolescents are greatly influenced by peer pressure. How can this concept be used when teaching adolescent clients? DELMAR/CENGAGE LEARNING

RESPECTING OUR DIFFERENCES

Do As I Say

The adage "Do as I say and not as I do" goes against all wisdom. Individuals learn from examples set by role models. Adolescents are especially sensitive to discrepancies between an adult's words and actions. How does this apply to you as a beginning practitioner of nursing? What messages are communicated by your health behaviors?

TEACHING-LEARNING AND THE NURSING PROCESS

The teaching-learning process and the nursing process are similar. Both are dynamic and consist of the same phases: assessment, diagnosis, planning, implementation, and evaluation. Figure 21-4, on page 410, compares the nursing process and the teaching-learning process. See Chapter 5 for more information about the nursing process.

ASSESSMENT

Primary and secondary data sources are used by nurses for assessment of learning needs. See Chapter 6 for a discussion of these sources. Communicating with the client and family or significant others is the foundation of assessment related to learning. Several factors need to be considered during assessment, including:

- Learning styles
- Learning needs
- Potential learning needs

NURSING CHECKLIST

GUIDELINES FOR TEACHING ADOLESCENTS

- Boost adolescents' confidence by asking for their input and opinions on health care matters.
- Encourage adolescents to explore their own feelings about self-concept and independence.
- Be sensitive to peer pressure.
- Help adolescents identify their positive qualities and build on those.
- Use language that is clear yet appropriate to the health care setting.
- Gear teaching to the adolescent's developmental level.
- Engage adolescents in problem-solving activities to encourage independent and informed decision making.

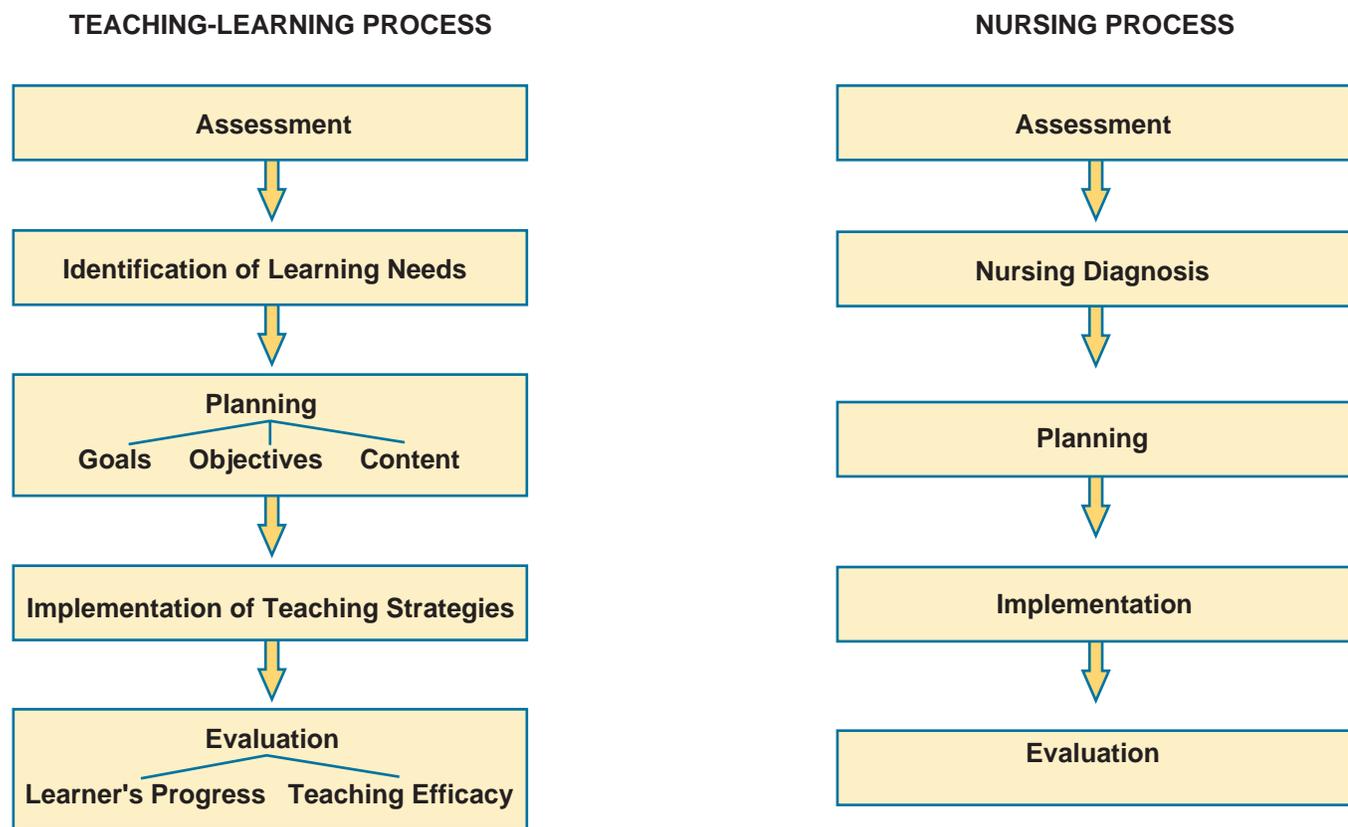

FIGURE 21-4 Teaching-Learning Process and Nursing Process: A Comparison DELMAR/CENGAGE LEARNING

NURSING CHECKLIST

GUIDELINES FOR TEACHING OLDER ADULTS

- Offer positive reinforcement for every attempt by the older learner to participate.
- Use silence as a reflective tool to allow older learners additional time to process information.
- Encourage reflection, particularly when sensitive issues are being discussed.
- Stimulate both visual and auditory senses in the presentation of the material to increase the probability that content matter will be retained.
- Use a variety of teaching methods, such as role-playing, games, examples, open discussion, charts, and reading material.
- Use true/false, multiple-choice, or open-ended questions to evaluate progress.
- Ask specific questions designed to elicit a response from participants. Avoid general inquiries such as “Do you have any questions?”
- Utilize the older learner’s experience and expertise.

Data from Ebersole, P., Hess, P., Luggen, A. S., Touhy, T., & Jett, K. (2007). *Toward healthy aging: Human needs and nursing response* (7th ed.). St. Louis, MO: Elsevier.

- Ability to learn
- Readiness to learn
- Client strengths
- Previous experience and knowledge base

Learning Styles

Each individual has a unique way of processing information. The manner in which an individual incorporates new data is called **learning style**. Some people learn information by seeing it (**visual learners**), others by listening to words (**auditory learners**), and others by doing (**kinesthetic learners**). The nurse should use a variety of techniques (e.g., lecture, discussion, small group work, role-play, return demonstration, imitation, problem solving, games, question-and-answer sessions) to match different learning styles of clients. A good way to discover learning style is to ask the client, “What helps you to learn?” or “What kinds of things do you enjoy doing?”

Learning Needs

Everyone who receives health care services has some need for information. Client teaching may be indicated when a client:

- Has a need for new skills
- Expresses a need for information to make decisions

- Desires to make modifications in lifestyle
- Is in an unfamiliar environment

Comprehensive assessment is a mutual process between client and nurse. A crucial step in teaching is to determine the client’s learning needs—what the client needs to know and what the client already knows. The nurse must evaluate the client’s knowledge about the content that is to be taught. This previous knowledge can then be used as a foundation for new concepts. If the client is misinformed, the nurse develops a remediation plan. Determination of the client’s learning needs is accomplished in a variety of ways, including:

- Questioning the client directly
- Observing client behaviors
- Interacting with the client’s family or significant others

It is imperative that the nurse first address the client’s immediate need for knowledge. This is facilitated by assessing the client’s perception of learning needs and prioritizing those needs with client input. See the accompanying Nursing Process Highlight for needs assessment guidelines.

Potential Learning Needs

The nurse also assesses for potential learning needs. These potential needs influence anticipatory planning to avert a relapse in recovery and to maintain wellness. Some examples of anticipatory learning needs include:

- A female client is pregnant for the first time. *Potential learning need:* Infant care
- A male client has just been diagnosed with diabetes that is currently controlled by dietary modifications. He has been told that he may have to take insulin daily in the future. *Potential learning need:* Self-administration of insulin

NURSING PROCESS HIGHLIGHT

Assessment

Needs Assessment

Listen to what the client’s words and actions are communicating.

- Does the client express uncertainty or anxiety over an upcoming procedure?
- Is the client able to tell you about medications, purposes, and side effects?
- Can the client describe necessary lifestyle modifications?
- Does the client perform self-care activities correctly?
- Is the client able to demonstrate necessary treatment procedures (e.g., colostomy irrigations, injections, blood glucose monitoring)?

Ability to Learn

The nurse assesses the client for characteristics that will hinder or facilitate learning. One such characteristic is the client’s developmental stage. For example, do not automatically assume that an adult client has mastered the developmental tasks of childhood. Age is not synonymous with developmental level; observation of behavior provides the clearest clue to developmental level.

The client’s maturity level greatly influences the ability to learn information. Every developmental stage is characterized by unique skills and abilities that affect the response to various teaching tools. Developmental stage greatly determines the type of data to be taught, the method(s) to be used, the language that is used, and the location for teaching. In addition to developmental stage, assessment should include evaluation of the client’s cognitive skills, problem-solving abilities, and attention span.

Readiness to Learn

Another characteristic to be assessed is the client’s learning readiness. Table 21-8 shows some factors that influence readiness.

Readiness is closely related to growth and development; for example, does the client have the requisite cognitive and psychomotor skills for learning a particular task? Can the client comprehend the information? Learning readiness is present when the client asks questions. Another indicator that the client is ready to learn is client participation in learning activities, such as actively participating in return demonstration of a dressing change. Some behaviors that indicate lack

TABLE 21-8 Factors Influencing Learning Readiness

CAPABILITY	COMFORT	MOTIVATION
<ul style="list-style-type: none"> • Maturity level • Physical ability • Cognitive ability • Attitude 	<ul style="list-style-type: none"> • Basic physiological needs met • Feelings of safety and security • Low degree (or absence of) pain • Pleasant surroundings with few distractions • Rapport with caregiver 	<ul style="list-style-type: none"> • Care for self • Get well • Achieve a higher level of wellness • Know and understand • Return to work • Please others • Be a “good patient” • Avoid complications and relapse

Delmar/Cengage Learning

of client readiness are anxiety, avoidance, denial, lack of participation in discussion or demonstration, and lack of participation in self-care activities.

Closely related to readiness is client motivation. Individuals must believe that they need to learn the information before learning occurs. Does the client perceive relevance (meaningfulness) in the current information to be taught? If an individual sees the information as being personally valuable, the information is more likely to be learned. However, if the client does not think that the content is relevant, learning is less likely to occur. Relevance is determined individually; the nurse must assess the personal meaning of learning content for each client.

Bandura (1977) described the concept of **self-efficacy** (a belief that one will succeed in attempts to change behavior) as having a profound influence on motivation; see Chapter 16. If clients feel they will not achieve the goals, they will lack motivation to try. To maximize motivation, keep the teaching-learning goals realistic. Break the content down into small steps that are achievable and provide feedback on the progress.

Client Strengths

Identifying the client's strengths and limitations provides a foundation for realistic expectations. An understanding of the client's strengths and weaknesses allows the nurse to plan successful teaching-learning experiences. Determination of client strengths assists the nurse in selecting appropriate teaching methods.

Previous Experience and Knowledge Base

The client has a knowledge base acquired through life experiences. Previous knowledge affects the client's attitudes about learning and perception of the importance of information to be learned and is related to the client's type of educational experiences.

Culture plays an important role in knowledge acquisition. Attitudes (which are derived from a cultural context) toward what is appropriate to learn and who should teach may require alterations in the nurse's approach. The nurse's sensitivity to cultural values affects every aspect of the teaching-learning process.

NURSING DIAGNOSIS

Several nursing diagnoses are applicable when barriers to the learning process exist. When lack of knowledge is the primary barrier to learning, the diagnosis of *Deficient knowledge* is applicable. For example:

- A client who does not understand how to use crutches for assisted ambulation may have the diagnosis of *Deficient knowledge: Crutchwalking* related to inexperience as evidenced by multiple questions and hesitancy to walk.
- A client who has had a colostomy and will be discharged soon may have a diagnosis of *Deficient knowledge: Follow-up care* related to colostomy care and maintenance as evidenced by requests for information.

An inadequate knowledge base may also be a component of other nursing diagnoses in which risk or impaired behavior exists. For instance, *Risk for infection* may relate to a

client's compromised health status; this risk can be modified or reduced through certain physical and environmental changes and also through proper client education. A client presenting with a diagnosis of a *Bathing/hygiene self-care deficit* may need assistance in acquiring the physical supplies to remedy the deficit as well as instruction in techniques.

PLANNING AND OUTCOME IDENTIFICATION

Informal teaching can occur in any setting at any time; formal teaching is planned and goal directed. Teaching is a goal-directed, purposeful process, which means that teaching-learning activities must be planned. Learning does not just happen by chance—it is planned. Planning, an ongoing phase of the teaching process, involves consideration of the following:

- What to teach
- How to teach
- Who will teach and who will be taught
- When teaching will occur
- Where teaching will be done

Content

Determination of *what* to teach is done through comprehensive assessment. The content to be taught depends greatly on the client's knowledge base, readiness to learn, and current health status. Examples of teaching topics are disease processes, medications, self-care activities, and health promoting behaviors.

Methods

Deciding *how* to teach involves matching teaching strategies with client's learning needs, readiness, and ability. The nurse who is an effective teacher uses methods that capture the client's interest. A variety of teaching methods (e.g., discussion, demonstration, written materials) can be used to match the client's learning styles.

Individuals

Planning also means deciding *who* will teach the client. Effective client education is the result of a multidisciplinary effort. However, the nurse is the coordinator of the health care team's teaching activities. Responsibility for planning a comprehensive teaching approach, from admission to postdischarge, remains with the nurse. Continuity of care is greatly affected by the teaching plan.

The "who" part of planning also means determining who should be taught. In addition to the individual client, the nurse must determine who else in the family needs to be taught about the illness and recovery process. An enormous wealth of health educational materials is available to families.

Timing

The decision of *when* to teach should be carefully planned. The nurse recognizes that *every* interaction with the client is

an opportunity for informal teaching. Whenever a client asks a question, there is an opportunity for teaching. These windows of teaching opportunities must never be closed. Nothing destroys a client's motivation for learning more quickly than hearing such comments as "Ask your doctor that" or "We'll talk about that later, right now take your medicine." The best time for teaching is when the client is comfortable—physically and psychologically.

In addition to capitalizing on informal teaching time, the nurse must plan time during which formal teaching can be done. Teaching must match the pace of the client's progress. Some clients learn more quickly than others; some need much repetition. Timing of the teaching session is crucial. The more information presented, the more a client is likely to forget. Therefore, teaching sessions should be kept brief in order to avoid overwhelming the client. Throughout the teaching session, use repetition and frequently ask the client questions to help pace the delivery of information.

Location

The location for teaching activities must also be well planned. *Where* teaching occurs affects the quality of learning. Some factors to be considered in determining the location of teaching include provision for privacy and availability of equipment. Selection of teaching methods is often determined by the location. For example, videos can often be used effectively in inpatient settings; however, the same information may need to be presented with flipcharts or brochures in the home setting. The nurse needs to determine whether environmental factors (e.g., loud noises, uncomfortable room temperature) are present that may interfere with learning.

Goal Setting

An important part of planning in the teaching-learning process is goal setting. The client and family or significant others must be involved in setting goals since mutually determined learning goals promote learning. Specific learning goals should include these elements:

- Measurable behavioral change
- Time frame
- Methods and intervals for evaluation

Teaching-learning goals must be realistic, that is, based on the abilities of both learner and teacher.

Establishing teaching-learning goals involves setting priorities. One way to prioritize goals is to teach the "need-to-know" information (that which is necessary for survival) before moving on to the "nice-to-know" content. For example, a client who is in her first trimester of pregnancy *must* know guidelines for diet and exercise ("need-to-know" goal); learning about infant care can occur later in the pregnancy ("nice-to-know" goal).

Teaching Vulnerable Populations

When planning to teach individuals with special needs, it is important that the usual teaching strategies be modified according to the client's individual needs. This section

describes education of individuals who experience developmental delays, chronic illness, low literacy skills, and sensory impairments.

DEVELOPMENTAL DELAYS Individuals with limited cognitive abilities have a medical diagnosis of mental retardation if the IQ level is 70 or less (American Psychiatric Association, 2000). The client's learning depends upon the degree of cognitive impairment, so teaching strategies must be selected accordingly. For example, a client who has mild mental retardation (IQ level of 50–70) may be able to learn by discussion of simple concepts that are stated in easily understood terms. Note that it is important to use concrete language and frequent repetition with clients in this category; the use of simple games is often effective. On the other hand, a client who is profoundly mentally retarded (IQ level below 25) may be unable to learn in the traditional sense. Frequent communication and repetition are required when working with a client with this degree of mental impairment. See the Respecting Our Differences display.

CHRONIC ILLNESS Clients who experience chronic illness (e.g., arthritis, hypertension, diabetes, asthma) have many learning needs, both actual and potential. Some chronic disorders, such as arthritis, may impair mobility and thus interfere with learning psychomotor skills as a result of decreased flexibility and dexterity of the fingers. Other chronic illnesses, such as diabetes, require ongoing assessment of the client level of understanding about self-care (e.g., diet, exercise, and lifestyle changes). Essential hypertension, another chronic disease process, often leads to client noncompliance with the prescribed treatment regimen. Ongoing education related to antihypertensive medication helps improve compliance.

LOW LITERACY SKILLS Health literacy involves reading, comprehension, basic mathematical abilities, and the ability to make health care decisions (Schaefer, 2008). Low health literacy levels are linked to poor health status. It is imperative that nurses assess the reading and comprehension abilities of clients before using printed educational materials. The majority of health care teaching involves the use of printed materials. However, approximately one-third of the U.S. population has limited health literacy (Weld, Padden, Ramsey, &

RESPECTING OUR DIFFERENCES

When working with clients with low IQ levels, you will demonstrate respect by making expectations clear. The use of repetition is necessary to help clients with developmental delays to learn. What other techniques will you use to teach clients who are cognitively impaired?

Bibb, 2008). It is a common mistake to equate the highest educational level achieved with reading level. When teaching clients with low literacy skills, it is helpful for nurses to use simple, noncomplex terms and give examples. Other therapeutic approaches are to avoid the use of medical terminology and provide clear definitions and explanations. See the accompanying Respecting Our Differences display.

SENSORY IMPAIRMENTS Many clients have sensory impairments as a result of illness, injury, or the aging process (see Figure 21-5). Effective nurses modify their teaching approaches in order to accommodate such impairments. A common mistake many people make when talking with someone who has a sensory impairment is to talk loudly. Screaming and yelling do not help the person who has auditory or visual impairments. See the accompanying Nursing Checklist for guidelines in working with clients who have visual, auditory, or memory impairments.

IMPLEMENTATION

There are several characteristics of nurses that influence the outcome of the teaching-learning process. Nursing self-awareness, an all-important first step in teaching, focuses on the concepts discussed in the following sections. The Client Teaching Checklist on page 415 provides some implementation guidelines for making teaching more meaningful to clients.

FIGURE 21-5 If a hearing aid is used, make sure it is functional before client teaching begins. For example, is the hearing aid turned on? Are the batteries working? DELMAR/CENGAGE LEARNING

Knowledge Base

It is impossible for nurses to teach if they lack the knowledge or skills that are to be taught. Staying current in knowledge and proficient in skills is the first step to maintaining efficacy and credibility as a teacher. It is impossible for one individual to be an expert in every area of nursing. Therefore, knowing when to refer the client to others for teaching can augment learning.

Interpersonal Skills

Effective teaching is based on the nurse's ability to establish rapport with the client. The nurse who is empathic to the client shows sensitivity to the client's needs and preferences. An atmosphere in which the client feels free to ask questions

NURSING CHECKLIST

GUIDELINES FOR TEACHING CLIENTS WITH SENSORY IMPAIRMENTS

For memory-impaired clients:

- Use repetition.
- Use a variety of cues (verbal, written, pictures, and symbols).

For visually impaired clients:

- Provide large-print materials.
- Provide prescription eyeglasses and magnifying glasses.
- Provide adequate lighting while reducing glare.

For hearing-impaired clients:

- Face the client directly when you speak.
- Use short sentences and words that are easily understood.
- Use signals to reinforce verbal information—point, gesture, demonstrate.
- Eliminate distracting noises or activities from the environment as much as possible.

Data from Ebersole, P., Hess, P., Luggen, A. S., Touhy, T., & Jett, K. (2007). *Toward healthy aging: Human needs and nursing response* (7th ed.). St. Louis: Elsevier; Mauk, K. L. (2010). Teaching older adults. In K. L. Mauk (Ed.), *Gerontological nursing: Competencies for care*. Boston: Jones & Bartlett.

RESPECTING OUR DIFFERENCES

Checking Literacy

“Lscean uyro sdhna. Seu yver dloc rweat.”

The preceding statement is what many of your clients will see when you give them printed educational materials. Be sure to assess clients' ability to comprehend written materials, and avoid making assumptions about your clients' literacy level. Check for comprehension through return explanation of the written material.

promotes learning. Activities that help establish an environment conducive to learning include:

- Showing genuine interest in the client.
- Including the client in *every* step of the teaching-learning process.
- Using a nonjudgmental approach.
- Communicating at the client's level of understanding.

The effective nurse will deliberately plan to communicate a sense of empathy and caring. See the accompanying Spotlight On display.

Teaching Clients at Home

Clients who are recovering at home and their families have significant learning needs. A primary role of the home health nurse is to teach clients how to care for themselves at home; this often involves teaching family members how to provide care (Figure 21-6). Home-based clients need information regarding their illness, accident, or injury. They also need to learn how to achieve and maintain a maximum state of wellness. Accurate teaching plans for the home-based client and family are established by assessing multiple factors, some of which are listed in Table 21-9 on page 416. See the accompanying Community Considerations display.

EVALUATION

Evaluation of teaching-learning is a twofold process:

1. Determining what the client has learned
2. Assessing teaching effectiveness of the nurse

CLIENT TEACHING CHECKLIST

GUIDELINES FOR EFFECTIVE CLIENT TEACHING

- Assess client's knowledge and needs.
- Focus on client's perceived needs.
- Relate material to prior knowledge.
- Encourage client's active participation.
- Provide opportunity for immediate application of knowledge or skill.
- Expect learning plateaus to occur.
- Reinforce learning frequently.
- Provide immediate feedback to facilitate learning.
- Ensure a comfortable environment.
- Organize content from the simple to the complex, building on what the client already knows.
- Use a variety of teaching methods.
- Emphasize verbal instructions with writing and pictures.
- Stay flexible in your approach.
- Be creative!

FIGURE 21-6 Preparing clients to reenter their home environment often means including family members in the teaching process. DELMAR/CENGAGE LEARNING

The evaluation process is ongoing and may lead to changes in the teaching plan and strategies used by the nurse.

COMMUNITY CONSIDERATIONS

Client Teaching in the Home Setting

Preparing the client and family for home care begins not at the time of hospital discharge but rather with hospital admission. Effective teaching is the key to thorough follow-up care in the home. Discharge planning considers the current learning needs of clients and caregivers as well as potential needs after discharge. Thus, teaching includes consideration of community resources and possible referral.

SPOTLIGHT ON...

Professionalism

Medical Jargon and Teaching

Consider the language used by most nurses—think of the terms nurses take for granted. When you ask a client to “void,” does the client understand what is meant? Think of the following frequently used terms, which can easily be misunderstood by clients and families: ambulate, defecate, dangle, NPO, vital signs, contraindicated.

Listen to the language you use when communicating with clients. How can you communicate without using professional jargon?

TABLE 21-9 Factors Affecting Learning Needs of Home Health Clients

TYPE	EXAMPLE
Environmental	<ul style="list-style-type: none"> • Accessibility of home to client with physical disability • Need for availability of equipment and supplies • Space to accommodate special needs of client • Need for information about environmental cleanliness as it relates to health • Need for assistance with self-care activities
Economic	<ul style="list-style-type: none"> • Ability to purchase medications, equipment, and supplies • Available financial assistance
Support system	<ul style="list-style-type: none"> • Persons available to assist with caregiving • Caregiver's deficient knowledge regarding necessary care
Community resources	<ul style="list-style-type: none"> • Resources in the immediate area • Awareness of and access to support services • Available respite to the family

Delmar/Cengage Learning

Evaluation of Learning

Evaluation, a continuous process, consists of determining what the client has learned. Is there a behavior change? Is the behavior change related to learning activities? Is further change necessary? Will continued behavior change promote health? The following strategies can be used to evaluate client learning:

- Verbal questioning
- Observation
- Return demonstration
- Written follow-up (e.g., questionnaires)

The accompanying Nursing Process Highlight provides guidelines for evaluation of learning.

Evaluation of Teaching

A major purpose of evaluation is to assess the effectiveness of the teaching activities and decide which modifications, if any, are necessary. When learning objectives are not met,

NURSING PROCESS HIGHLIGHT

Evaluation

Evaluation of Learning

- Did the client meet mutually established goals and objectives?
- Can the client demonstrate skills?
- Have the client's attitudes changed?
- Can the client cope better with illness-imposed limitations?
- Does the family understand health problems and know how to help?

UNCOVERING THE

Evidence

TITLE OF STUDY

“Discharge Knowledge and Concerns of Patients Going Home with a Wound”

AUTHORS

B. Pieper, M. Sieggreen, C. K. Nordstrom, B. Freeland, P. Kulwicki, M. Frattaroli, D. Sidor, M. T. Palleschi, J. Burns, and D. Bednarsk

PURPOSE

To examine clients' wound care knowledge prior to discharge from an acute care hospital.

METHODS

This is a comparative descriptive study of 67 persons, ages 20 to 83 years, who were all scheduled for discharge from a large urban acute care hospital; 58 clients had acute wounds, and 9 had chronic wounds. A questionnaire was completed by each participant.

FINDINGS

Data reveal that the participants' greatest concerns about going home were activity restrictions, wound pain, and watching for complications, including infection. Participants had appropriate knowledge about handwashing, nutrition, going out of the home, and cigarette smoking. They had incorrect information about drying out wounds and leaving them open to promote healing.

IMPLICATIONS

Client concerns about discharge can be used to help plan discharge teaching. Teaching literature could include ways to avoid misinformation about wound care. Discharge teaching needs to begin early so that clients have adequate time to learn and ask questions.

Pieper, B., Sieggreen, M., Nordstrom, C. K., Freeland, B., Kulwicki, P., Frattaroli, M., et al. (2007). Discharge knowledge and concerns of patients going home with a wound. *Journal of Wound and Ostomy Continence Nursing*, 34(3), 245–253.

NURSING CARE PLAN

The Client with Ineffective Breastfeeding

CASE PRESENTATION

Mrs. Gozalo is a 32-year-old attorney who presents to the clinic requesting help in breastfeeding her 3-day-old daughter. She states that her first few attempts at breastfeeding in the hospital were marginally successful and that her baby was given formula by the staff prior to her discharge. Since being home, she has given the baby bottled formula when she cannot get the baby to latch on and suck successfully; these unsuccessful attempts at breastfeeding have made her question whether the effort to breastfeed is worthwhile. She says her husband has suggested using only bottle feedings, and she is frustrated and confused but wants to be successful at breastfeeding, which she describes as “the right thing to do.”

ASSESSMENT

- Verbalizations of desire to be successful at breastfeeding
- Lack of understanding of correct latch-on procedure

NURSING DIAGNOSIS: *Ineffective breastfeeding* related to unsatisfactory breastfeeding process as evidenced by infant’s receiving supplemental feedings with artificial nipple, interruption in breastfeeding, maternal anxiety, and deficient knowledge

NOC: Knowledge: Breastfeeding

NIC: Teaching: Individual

EXPECTED OUTCOMES

The client will:

1. Explain and demonstrate correct latch-on and breastfeeding procedure (cognitive and psychomotor domains)
2. Express confidence that breastfeeding will be successful (affective domain)
3. Demonstrate desire to continue efforts at breastfeeding (affective domain)

INTERVENTIONS/RATIONALES

1. Ask client, or determine through the interview process, what teaching strategies (lecture, literary, visuals) are most likely to be effective for her, and tailor teaching accordingly. Matching teaching strategies to learning styles and needs increases the chance of successful education.
2. Explain briefly the mechanics of the breastfeeding process, such as milk letdown, signs of breastfeeding readiness, and signs of infant hunger and satisfaction. Knowledge of the process of correct breastfeeding will help bring client expectations in line with reality.
3. Demonstrate correct infant holds and maternal postures. Proper position of both the child and mother facilitates breastfeeding.
4. Teach client effective techniques for latch-on, such as supporting the breast to correctly position it in the baby’s mouth and tickling the baby’s lips or cheeks to stimulate rooting. Use of correct techniques greatly enhances the likelihood of latch-on.
5. Show client video or literature demonstrating successful breastfeeding. Seeing other women breastfeed successfully helps promote confidence and maintain desire to learn correct process.
6. Encourage client to have her husband participate in the breastfeeding process by bringing the baby to her when she cries, stroking the baby’s head while she is nursing, and burping the baby after each feeding. Partner support and involvement in the breastfeeding process will boost client’s confidence and strengthen desire to continue breastfeeding process.

EVALUATION

Client verbalizes confidence and comfort level with attempts at breastfeeding. Client achieves correct latch-on with minimal difficulty. Client states the signs of successful breastfeeding and states that she will look for such signs as the breasts feeling less full and the infant sucking strongly and seeming content at each feeding.

reassessment is the basis for planning modification of teaching-learning activities. Several activities can be used to evaluate teaching effectiveness, including the following:

- Feedback from the learner
- Feedback from colleagues
- Situational feedback
- Self-evaluation

Evaluation is facilitated through the use of goals that are measurable and specific. Use of the accompanying Nursing Checklist facilitates evaluation of teacher effectiveness. See the Uncovering the Evidence display on page 416.

NURSING CHECKLIST

EVALUATION OF TEACHER EFFECTIVENESS

- Was content presented clearly and at the client's level of comprehension?
- Did the nurse use a variety of teaching aids?
- Were the teaching aids appropriate for the client and the content?
- Was client participation encouraged?
- Was the nurse supportive?
- Did the nurse communicate an interest in the client and in the material?
- Did the nurse give frequent feedback and allow for immediate return demonstration?
- Were learning objectives stated in behavioral terms (i.e., easy to evaluate)?

KEY CONCEPTS

- Client education is done to help individuals achieve and maintain optimum states of health.
- The teaching-learning process is a planned interaction that promotes behavioral change that is not a result of maturation or coincidence.
- Teaching supports behavioral change that leads to positive adaptation.
- Learning is the process of assimilating information with a resultant change in behavior.
- Learning occurs in three domains: the cognitive (intellectual), the affective (emotional), and the psychomotor (motor skills).
- Learning readiness is affected by developmental and sociocultural factors and is a lifelong process that occurs in every developmental stage.
- Elements for documenting client education include the content taught, teaching methods used, who was taught, and response of the learners.
- The teaching-learning process and the nursing process are interdependent dynamic processes.
- Evaluation of the teaching-learning process involves two aspects: (1) determination of what the client has learned and (2) efficacy of the teacher.

REVIEW QUESTIONS

1. Which of the following methods can be used by the nurse to determine the client's dominant channel for learning new information? Select all that apply.
 - a. Administering the client a written questionnaire on learning styles
 - b. Asking clients how they learn best
 - c. Asking family members what types of activities are enjoyed by the client
 - d. Observing a client's behaviors
 - e. Using a variety of teaching strategies
2. A client with hearing loss is being started on a new medication. Which of the following nursing actions is most appropriate for this client?
 - a. Avoid the use of gestures.
 - b. Face the client directly when speaking.
 - c. Raise voice pitch and tone.
 - d. Speak loudly.
3. The nurse is teaching a client how to self-administer insulin. Which of the following statements indicates the client's readiness to learn?
 - a. "Are you sure this won't hurt a lot?"
 - b. "I always watched my mother give herself injections."
 - c. "I don't think I can ever get used to sticking myself."
 - d. "I need to learn how to do this so I can take care of myself."
4. A nurse is planning to teach an adolescent client about skin care, focusing on hygiene. Which of the following teaching strategies would best promote client learning?
 - a. Have the client initiate questions, then provide answers.
 - b. Include the client in a group session on hygiene.

- c. Provide one-on-one instruction.
 - d. Show a video that demonstrates the relationship between cleanliness and healthy skin.
5. Which of the following activities addresses the client's psychomotor learning needs?
 - a. Asking a client to describe his feelings about self-administering injections
 - b. Encouraging the client to accept a recent diagnosis of a chronic illness
 - c. Helping the client read instructions on a prescription label
 - d. Showing a client how to self-administer an injection
 6. Which of the following nursing statements is most helpful for teaching a postoperative client how to safely ambulate?
 - a. "If you don't get out of bed, you could develop pneumonia."
 - b. "Walking will help you recover more quickly."
 - c. "You must ambulate in order to avoid complications."
 - d. "You need to dangle your feet before getting up to ambulate."
 7. Which of the following is a priority nursing action for client education?
 - a. Assessing client learning needs
 - b. Selecting teaching methods
 - c. Self-awareness
 - d. Using clear, simple terms when teaching
 8. The nurse is teaching a client who has an IQ of 68. Which of the following nursing actions is appropriate for meeting this client's learning needs?
 - a. Ask multiple questions to capture the client's interest.
 - b. Avoid repeating the information.
 - c. Incorporate simple games into learning sessions.
 - d. Use abstract terms when communicating.
 9. Which of the following factors will most likely interfere with the client's ability to learn?
 - a. Curiosity
 - b. Decreased self-efficacy
 - c. Headache
 - d. Knowledge deficit
 10. A client says, "I don't understand why my prescribing practitioner wants me to get out of bed so much." Which of the following nursing responses would encourage teaching-learning to occur?
 - a. "I don't know what the prescribing practitioner was trying to say."
 - b. "I will come back to talk with you after I finish giving medications to the other clients."
 - c. "You need to ask your prescribing practitioner about that."
 - d. "You sound confused about the need to walk."

CHAPTER 22

Self-Concept

COMPETENCIES

1. Describe the four components of self-concept.
2. Explain the development of self-concept throughout the life span.
3. Discuss factors affecting self-concept.
4. Describe behaviors indicative of altered self-concept.
5. Discuss application of the nursing process with clients experiencing self-concept alterations.

KEY TERMS

body image
identity

role
role conflict

self-concept
self-esteem

Self-concept (an individual’s perception of self) affects every aspect of life, including relationships, functional abilities, and health status. No two people have an identical self-concept as self-concept is what helps make each individual unique. Everyone has both positive and negative self-assessments in the physical, emotional, intellectual, and functional dimensions, which change over time and according to the context of the situation. Because self-concept is an individual’s frame of reference for perceiving and interacting with the world, it exerts a powerful influence on one’s life. Though neither visible nor tangible, a positive self-concept is one of the greatest strengths a person can possess.

One’s view of self affects the ability to function. A person who sees himself or herself as a competent individual will behave competently and vice versa. Individuals with a positive self-concept approach new experiences and tasks with confidence; they expect to be accepted by others and to succeed. Conversely, the person with a negative self-concept tends to shy away from others and to avoid challenges. Self-concept greatly influences health status. For example, a person with a positive self-concept is more likely to care for one’s self—physically, emotionally, and spiritually. The relationship of the components of self-concept and mental health are discussed in Table 22-1.

COMPONENTS OF SELF-CONCEPT

Self-concept is composed of four components: identity, body image, self-esteem, and role performance (see Figure 22-1). By considering these four elements of self-concept, nurses can respond more effectively to clients.

IDENTITY

A sense of personal **identity** is what sets one person apart as a unique individual. A well-formulated identity provides the answer to the question “Who am I?” Identity includes a person’s name, gender, ethnic identity, family status, occupation, and various roles.

During childhood, a person begins to develop identity, which is constantly reinforced and modified throughout life. First, parents or caretakers provide a child with elements of an emerging identity. Children may be told they are good or naughty, shy or outgoing, creative or dull, powerless or powerful. Children believe what they are told by others, and these beliefs influence their developing identities. During adolescence, conflict often arises as the teenager struggles to become independent and establish a unique identity. Eventually, people learn to observe themselves objectively, as their social environment expands. Feedback from others may support and strengthen an aspect of identity already implanted, or it may contradict an aspect and be a catalyst for change.

BODY IMAGE

Body image is an attitude about one’s physical attributes and characteristics, appearance, and performance. Body

TABLE 22-1 Self-Concept and Mental Health

COMPONENT OF SELF-CONCEPT	RELATIONSHIP TO MENTAL HEALTH
Strong sense of identity	<ul style="list-style-type: none"> The person experiences self as a unique, valuable individual.
Accurate and positive body image	<ul style="list-style-type: none"> A healthy awareness of one’s body is based on reality testing.
Positive self-esteem	<ul style="list-style-type: none"> A person with a high degree of self-esteem respects self and treats self with dignity.
Satisfying role performance	<ul style="list-style-type: none"> The person with healthy role performance relates well with others and receives gratification from fulfilling role expectations.

Delmar/Cengage Learning

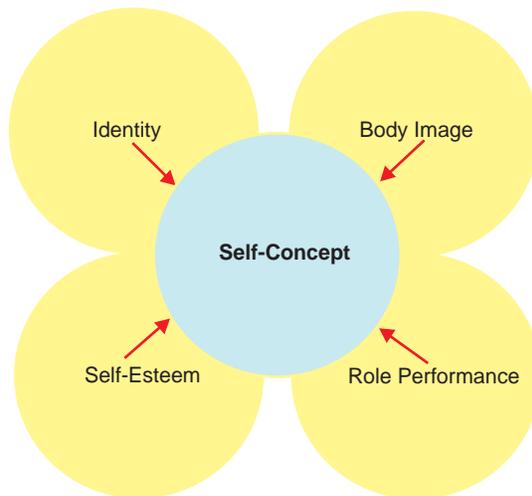

FIGURE 22-1 The Interrelationship of Components of Self-Concept DELMAR/CENGAGE LEARNING

image is dynamic because any change in body structure or function, including the normal changes of growth and development, can affect body image. Adolescence is an example of the interplay between an individual's physical changes and a developing sense of body image. Many teenagers have harmless body image distortions. It is not at all uncommon for adolescents to feel self-conscious because they think their noses are too big, or their hips too wide, or their blemishes too prominent. Usually, these are normal concerns. Adolescents generally find that their perceptions continue to evolve as their physical development progresses, resulting in a healthy body image.

SELF-ESTEEM

Self-esteem is an individual's generalized sense of worth and value, or how a person regards himself or herself. Self-esteem refers to an individual's self-evaluation, whereas self-concept is a broader term encompassing an individual's overall self-description.

The level of self-esteem at any given moment can be influenced by many factors. Individuals make decisions on what life factors (e.g., physical attributes, skills, social accomplishments) they deem important and calculate their self-esteem on the basis of their achievement of the factors they value most highly. These values are based on the individual's familial and cultural backgrounds and influenced by societal standards. Self-esteem varies over time, depending on the situation (e.g., new job), the environment (e.g., cocktail party with strangers), and an individual's level of development and overall self-confidence.

ROLE PERFORMANCE

Role refers to a set of expected behaviors that are determined by familial, cultural, and social norms. Individuals fulfill several roles simultaneously—parent, sibling, friend, spouse, student nurse. Each role has a set of expected behaviors, that is, a belief about how a person in that role should behave. See the accompanying Respecting Our Differences display on the sick role.

RESPECTING OUR DIFFERENCES

Sick Role

It is difficult enough for a healthy person to manage multiple roles, conflicts, and stresses. But what happens when illness forces an individual to assume the "sick role"? What are the social expectations of a sick person, and what effect does this new and often unexpected role have on all the other roles of the individual?

The nurse may assume several different roles (defined by Peplau, 1959), such as counselor, teacher, leader, or surrogate parent. As the relationship progresses, the client feels free to express feelings to the nurse because the nurse has assumed the roles of listener and counselor. As counselor, the nurse responds to the client's feelings or behavior, helping the client to gain insight, self-care, and a health-affirming outlook. As teacher, the nurse may provide information to the client or correct misconceptions.

Stressors Affecting Role

Roles have accompanying responsibilities. Whenever a person is unable to fulfill role responsibilities, self-concept is impaired. When an individual has too many roles to fulfill simultaneously, overload can occur. The person becomes overwhelmed by multiple demands of several roles. The individual feels unable to cope since coping skills are greatly taxed.

In addition to overload, another common problematic role experience is **role conflict**, which occurs when the expectations of one role compete with the expectations of other roles. The person may feel unable to establish priorities among competing role expectations. See the accompanying Spotlight On display and Table 22-2, on page 426, which describe the various types of role conflict.

DEVELOPMENT OF SELF-CONCEPT

Self-concept evolves throughout life and depends to an extent on an individual's developmental level. Self-concept changes during each developmental stage. According to Stuart and Laraia (2008), the ongoing process of self-concept development is facilitated by the following:

- Interpersonal and cultural experiences
- Self-perceived competence
- Self-actualization (living up to one's potential)

SPOTLIGHT ON...

Professionalism

Personal Roles

Consider the various roles you currently fulfill. What are some of the potential conflicts inherent in your multiple roles? For example, your role of student may at times conflict with your role of friend or parent (e.g., you need to be in class at the same time you need to attend a parent-teacher conference or be available to your friend who is undergoing a crisis). Or your need to study for an examination (student role) is superseded by your need to work (role of wage earner).

TABLE 22-2 Types of Role Conflict

TYPE	DESCRIPTION	EXAMPLE
Interrole conflict	Expectations of one role oppose expectations of another role.	A woman's job requires travel at the same time her child's dance recital is scheduled.
Interpersonal role conflict	Incompatible role expectations are held by one or more people.	A husband and wife disagree on parental expectations (e.g., disciplinary methods).
Role overload	Excessive demands of numerous roles have conflicting priorities.	A nurse must decide which urgent task to do first.
Person-role conflict	The individual's values are violated by demands of a role.	A nurse who believes in always telling the truth is directed by the supervisor to withhold a diagnosis from a client.

Delmar/Cengage Learning

Self-concept is developed primarily in response to social interactions and experiences. Sullivan (1953) stated that self-concept is developed according to perceptions mirrored by others to the individual. A person's concept of self depends, to an extent, on what one thinks that others think about oneself. As individuals mature, they can accept or reject the appraisals of others and change their behavior in ways that lead to a more positive self-concept.

CHILDHOOD

Self-concept is not innate; rather, it develops throughout the life cycle as a result of social interactions. An infant whose basic needs are met in a warm, consistent manner develops positive feelings about self. Formation of self-concept occurs in the following manner: (1) During infancy, the child develops a self-perception of being separate from the environment (including parents); (2) as the child ages, perspectives (especially of the parents) are internalized; and (3) society's norms (e.g., expectations of appropriate behavior) are then internalized by the child.

A child's sense of self is shaped by family experiences and interactions with parents and other relations. Children learn about their individual worth and their ability to be competent in the family unit, and their sense of self changes as they move through each developmental stage. Infants learn to trust based on the degree to which their needs are met, and they begin to develop a sense of self as distinct from the primary caretaker and their surroundings. As new skills are mastered, toddlers begin to develop a sense of autonomy and self-image, yet they still remain very self-centered. Preschoolers have increasing initiative and self-awareness as their expanding language and motor skills broaden their horizons, and they begin to have an awareness of emotions and values that are held by their families. When children reach school age, they will incorporate experiences and values of their new contacts and environments into their image of self and may start to have an understanding of their strengths as well as their shortcomings (see Figure 22-2).

Positive experiences, role models, and family environment are all crucial to the healthy self-concept of the growing child. The impact of early parent-child experiences on the shaping of a child's self-concept was emphasized by Sullivan (1953), whose interpersonal theory of psychiatry has greatly influenced nursing. The child develops a sense of self according to the type of feedback received from significant others (parental figures). Positive feedback reinforces the development of a "Good-Me" sense of self. A negative self-concept ("Bad-Me") is reinforced by feedback that is consistently negative and anxiety provoking (Sullivan, 1953).

ADOLESCENCE

The numerous changes in physical, emotional, and psychosocial status that characterize the adolescent years bring about rapid changes in self-concept. Impressions about self from childhood may be internalized or challenged. The primary benchmark for arriving at an overall perception of self can

FIGURE 22-2 For a school-aged child, praise from teachers and a feeling of accomplishment in school can boost self-esteem. DELMAR/CENGAGE LEARNING

SAFETY FIRST

ADOLESCENTS AND SELF-CONCEPT

Due to the emphasis on body image, teens are at particular risk for feelings of disturbed body image, which may lead to serious health concerns such as anorexia nervosa and bulimia nervosa.

change from family values to those held by peers or embodied in desired role models. Teens typically invest tremendous energies in physical appearance and social status and often fail to see their positive traits if they feel deficient in these areas. Adolescents often cannot separate their opinion of their own body image from their overall self-concept. For example, the teen who views herself as fat, when in fact she is emaciated, is likely to have a disturbed self-concept based on her distorted body image, regardless of what other positive qualities she may possess. The nurse needs to learn to distinguish between what might be a normal body image distortion (“I wish I were 3 inches taller”) and one that can have serious, even fatal, consequences (“Weighing 100 pounds is the most important thing in the world for me”). Determining a teen’s self-concept will help the nurse differentiate perceptions that are normal reactions to the changes of adolescence and those that are potentially harmful.

ADULTHOOD

Self-concept continues to develop and change as an individual progresses through the adult years. Periods of relative stability in self-image may be interspersed with realizations of physical changes in body size, proportion, characteristics, and energy levels, all of which will influence perception of self. Involvement in family, work, and community obligations and activities contributes significantly to an individual’s self-concept, as roles and responsibilities change and new roles are introduced. Healthy adjustment to these changes results in a positive self-concept (see Figure 22-3).

As the years pass, the older adult’s perception of self continues to develop. Learning to adapt to the numerous physical changes that normally occur with aging (e.g., diminished eyesight and hearing, lower stamina levels, loss and change in color of hair) can be a true challenge for many individuals; see Figure 22-4. Accompanying these changes is often the desire to look back on one’s life and evaluate its overall success. Such reminiscence is usually a critical factor in an older adult’s self-concept.

FACTORS AFFECTING SELF-CONCEPT

There is a universal need for positive self-concept, which includes a high degree of self-esteem and self-acceptance.

FIGURE 22-3 The mature adult’s self-concept can be enhanced by learning new skills and enjoying new activities. DELMAR/CENGAGE LEARNING

Any type of threat (real or imagined, actual or anticipated) may challenge one’s self-concept.

ALTERED HEALTH STATUS

Illness evokes anxiety in most people; in turn, anxiety can result in illness. Every client will have some element of anxiety

FIGURE 22-4 Older adults need to adjust their self-concept, especially body image, in accordance with physical changes that affect appearance. DELMAR/CENGAGE LEARNING

that influences behavioral and emotional responses. Most ill people are somewhat uneasy, especially if they are being treated in an unfamiliar environment or by a new health care provider. When anxiety level is heightened, recovery is compromised. Nurses, as professionals who focus on the human response to illness, must be aware of client anxiety level in order to promote effective adaptation. Table 22-3 shows common stressors frequently experienced during illness.

By their very nature, some illnesses may impair self-concept. For example, there is a social stigma against mental illness; the reactions of other people to the mentally ill person affect the client's self-perceptions. Many people fear cancer and isolate those affected with the disease. A diagnosis of acquired immunodeficiency syndrome (AIDS) may also carry a stigma that affects client self-esteem. Society often shuns those with AIDS, which may make them feel embarrassed or ashamed about their illness. To improve the client's quality of life, the nurse caring for individuals with any of these disorders must intervene to promote positive self-concept.

Compromised health status that requires surgery can also lead to several psychological alterations, including an impaired body image. Altered body image may result from loss of a body part or function after surgical procedures. Some procedures (e.g., mastectomy, amputation, colostomy)

may leave the individual feeling mutilated or flawed. Bodily changes as a result of surgery have different meanings to different individuals. For example, consider a mastectomy. The woman whose feminine identity is symbolized by a voluptuous shape will likely be adversely affected by the surgery. Other common sequelae of surgery—decreased independence, loss of control, and disruption of routine—can also negatively affect self-concept. Self-esteem deficits related to surgery often include interference with role performance and impaired sexuality.

DEVELOPMENTAL TRANSITIONS

Developmental processes may affect self-concept by introducing changes or challenges to an individual's identity, body image, self-esteem, and role expectations. For example, pregnancy is a process with resultant changes in all these factors of self-concept; see Figure 22-5. In the early part of pregnancy, the woman incorporates the baby into her self-image. As the pregnancy progresses, the woman's body image adjusts to accommodate the idea that the baby is a separate individual (Edelman & Mandel, 2006). After delivery, the woman who has positive self-esteem will accept and love the

TABLE 22-3 Stressors Associated with Illness

THREAT	EXAMPLE
Threats to physical safety	Undergoing painful procedures (the thought of receiving an injection evokes anxiety in many) Fear of pain Fear of death
Threat to psychological integrity	One's image of self is threatened or challenged by new situations (such as moving to a nursing home)
Inability to exert control	Having little or no input into important decisions; clients often feel as if they have no input into decision making regarding their treatment plan Loss of control may have a negative impact on self-concept and self-esteem, which in turn evokes anxiety
Unmet biological needs	Hunger Thirst Urge to eliminate and lack of bathroom or privacy for toileting Physical pain, discomfort

Delmar/Cengage Learning

FIGURE 22-5 Body image changes with developmental events such as pregnancy. What do this client's nonverbal cues indicate about her self-concept? DELMAR/CENGAGE LEARNING

baby. One who feels unlovable or unattractive may make disparaging remarks about the infant (Edelman & Mandel, 2006) and have difficulty bonding appropriately and adjusting to the life changes a new baby introduces. The role of parent needs to be incorporated into a revised self-concept, and identity and self-esteem must be adjusted on the basis of new expectations.

Another example of a developmental issue that can affect the self-concept of an individual is menopause. The nurse must understand the meaning of this transitional period to the client and know that it varies with each individual. This normal developmental transition may have a negative psychological impact on some women. Some people view the female climacteric (menopausal phase) as an indication of loss of femininity with resultant decrease in value as a person. Other women view menopause as a sign of freedom from the risk of childbearing. Some common misconceptions about menopause are:

- Menopause is a disease.
- The menopausal woman has decreased sex drive.
- Menopause means the end of femininity.
- A woman who has experienced menopause is “old.”
- The physical symptoms of menopause are unbearable.

EXPERIENCE

Self-concept is also influenced by an individual's experiences. Individuals who have experienced several failures begin to view themselves as failures. Their behavior often becomes self-fulfilling in that they perform at an unsuccessful level because they feel that is all they are capable of achieving. A negative self-concept is the result of repeated failures. On the other hand, people who achieve a task begin to see themselves in a positive manner, thus establishing the foundation for a positive self-concept.

NURSING PROCESS AND SELF-CONCEPT

Nursing care is individualized for each client as determined by specific needs. Therefore, client self-concept greatly influences application of the nursing process. Each phase of the nursing process must consider the client's perception of self.

ASSESSMENT

When assessing a client's self-concept, the nurse must consider both the client's developmental level and chronological age. Clients need to be addressed at a level that reflects their current condition as well as their cognitive competence. For example, very young clients and those with low literacy skills may not be able to read; thus, the use of pictures or diagrams may be helpful.

It is necessary to determine the client's perception of self-concept and the factors affecting it. For example, an adjustment to and recovery from an appendectomy may

be uneventful for one person and difficult for another. The person who sees the surgery as a means to recovery will be healthier than the one who feels mutilated by scarring.

Behavior, thoughts, and emotions are affected by self-concept. It is important to attend to the client's verbal and nonverbal cues. Self-concept is reflected in a person's behavior and conversation. Individuals who feel they are unable to accomplish goals will experience changes in eating, sleeping, and activity patterns (Edelman & Mandel, 2006).

The accompanying Nursing Process Highlight offers some questions useful in assessing body image and self-esteem. Table 22-4, on page 430, lists some indicators of high and low levels of self-esteem. To provide quality care, the nurse must determine the client's strengths. Doing so enables assessment of characteristics that can be used for coping and problem solving. The client's strengths are a foundation on which to build therapeutic interventions. Some areas to assess include the client's ability to:

- Develop and maintain appropriate relationships
- Care for himself or herself in order to meet basic needs
- Adapt to stressors in a positive manner

The nurse should encourage clients to make a list of all the positive things they have done and then review the list. Also, the nurse can help clients identify how they have handled problems in the past: “When you were in a similar situation, what did you do? Was it helpful? Are you able to try that now? If not, what else can you do?”

The nurse should ask clients to describe their appearance and abilities. This information is an indicator of awareness of strengths as well as limitations; it is also important to assess clients' personal meaning of these assets and liabilities.

NURSING PROCESS HIGHLIGHT

Assessment

Questions for Assessing Body Image and Self-Esteem

Body Image

- What do you like best about your body?
- What do you like least about your body?
- If you could change how you look, what would you change?

Self-Esteem

- What do you like best about yourself?
- What do you like least about yourself?
- How do you describe yourself to others?
- How would others describe you?
- What are your strengths and weaknesses?

TABLE 22-4 Indicators of High and Low Self-Esteem

	HIGH SELF-ESTEEM	LOW SELF-ESTEEM
Communication	<ul style="list-style-type: none"> • Assertive • Direct and honest 	<ul style="list-style-type: none"> • Passive or aggressive • Indirect, dishonest
Posture	<ul style="list-style-type: none"> • Erect • Moves briskly 	<ul style="list-style-type: none"> • Stooped • Slow movement and activity
General appearance	<ul style="list-style-type: none"> • Well groomed 	<ul style="list-style-type: none"> • Unkempt and dirty
Eye contact	<ul style="list-style-type: none"> • Frequent and appropriate to context of situation 	<ul style="list-style-type: none"> • Avoidance or intrusive staring
Speech	<ul style="list-style-type: none"> • Well modulated • Speech flows smoothly 	<ul style="list-style-type: none"> • Monotone • Mumbling • Hesitant
Self-care	<ul style="list-style-type: none"> • Attends to own needs 	<ul style="list-style-type: none"> • Denies or minimizes own needs • Neglects own needs by always caring for others first

Delmar/Cengage Learning

DIAGNOSIS

Individuals experiencing self-concept disturbances usually have feelings of anxiety, hostility, guilt, and shame. Self-concept alterations affect every aspect of a person's life: emotions, relationships, and functional ability.

The nurse must conduct a thorough assessment to determine the nature and extent of problems in order to formulate accurate nursing diagnoses. Because of the extensive impact of self-concept problems, several diagnoses may be established by the nurse. The accompanying Nursing Process Highlight, on page 431, lists some primary nursing diagnoses associated with self-concept disturbances as defined by the North American Nursing Diagnosis Association (2009).

OUTCOME IDENTIFICATION AND PLANNING

For clients with an altered self-concept, a major nursing goal is to promote the client's sense of well-being and to facilitate growth. This involves teaching coping skills and the effective use of personal resources.

Together the nurse and client develop specific goals because mutually established goals encourage the client to assume an active role in recovery. Realistic planning involves examination of options. What is available to use in helping a client regain responsibility for self-care? Realistic goals should be stated in terms of specific behavior that is

Text not available due to copyright restrictions

measurable and should have an appropriate time frame for evaluation of outcome achievement.

IMPLEMENTATION

Regardless of the setting in which they practice, nurses will inevitably encounter clients who are experiencing alterations in self-concept. Whether a client is experiencing an optimal level of health or an alteration in health, a high degree of self-esteem is necessary for a positive outcome. The nurse needs to find ways to support positive self-esteem. A high degree of self-esteem can be associated with several different dimensions of the person, such as success in relationships, intelligence, or being a member who is held in high regard by an ethnic or cultural group. In attempting to support the client's high self-esteem, the nurse should learn sources of self-esteem for the client and seek to reinforce them. "Respect is the act of esteeming another. Demonstrated by word and deed, it is fostered by attending to the whole person by involving the patient and family in decision making ..." (Rushton, 2007, p. 155).

Initiate Therapeutic Interaction

Self-concept, or lack of it, affects the nurse-client relationship. The nurse is a role model of an individual who has self-respect and also respects others. By using a nonjudgmental approach, the nurse encourages clients to feel more positive about themselves.

The use of open-ended statements facilitates honest communication. Active listening is essential in working with clients experiencing self-concept alterations. By thoughtfully applying therapeutic communication skills, the nurse facilitates the development of trust and rapport.

Support Healthy Defense Mechanisms

Use of defense mechanisms is a common reaction to anxiety or a perceived threat. See Chapter 23 for a discussion of defense mechanisms. When caring for a client with altered or threatened self-concept, it is wise to first identify the client's strengths and successful coping mechanisms before formulating and implementing a plan of care. It is important to avoid taking away a client's defensive processes until another method of coping with anxiety has been developed. For example, breaking through a client's denial too soon can result in overwhelming anxiety. On the other hand, encouraging the use of denial beyond its time of therapeutic value will result in reality distortion.

Ensure Satisfaction of Needs

The relationship between satisfaction of basic needs and psychological comfort is undeniable. When needs are unmet, anxiety increases. Nursing interventions must be focused on helping clients fulfill basic needs.

PHYSICAL NEEDS Self-concept stems in part from the client's perception of personal appearance, competencies, and limitations. It includes the client's self-perception as well as others' perceptions. By assisting the client to maintain personal appearance, the nurse is also helping the client improve self-esteem. Being unable to meet one's basic needs usually results in self-concept impairment. Self-esteem is generally decreased as a person becomes more dependent on others.

Providing for the client's well-being and comfort is the foundation of quality nursing care. When clients are treated in a caring, competent manner and their physical needs are met, self-concept is positively influenced.

PSYCHOSOCIAL NEEDS Uncertainty escalates anxiety. All clients in every health care setting need clear statements of expected behavior. Explain procedures, telling the client what is expected and what is going to occur. The following nursing actions promote the client's psychological safety:

- Respect a client's privacy. Loss of privacy triggers anxiety in most individuals. During treatment in any setting, personal probing questions must be asked; procedures often violate physical space and can be offensive; elimination activities often occur in the presence of others. Be sure to protect privacy as much as possible.
- Treat each client as an individual worthy of dignity. This means being sensitive to the feelings of others.
- Encourage the client to be as independent as possible while providing assistance as needed.

Promote Positive Self-Esteem across the Life Span

The nurse understands that self-esteem is affected by developmental level. Thus, nursing interventions are planned and implemented differently according to a client's placement in the life span.

CHILDHOOD The child's self-concept develops over time and is greatly influenced by interactions and experiences with others. The child who feels successful and competent with tasks has a more positive self-concept than does the child who fails to achieve task mastery.

Some of the changes occurring with physical growth and maturation may be anxiety provoking for the child; for instance, anxiety may result when the child loses baby teeth or experiences menstruation for the first time. The onset of physical changes of puberty can be frightening or unsettling to the child. The nurse is most effective by providing education and support. The accompanying Client Teaching Checklist provides information essential in helping parents promote positive self-concept development in children.

ADOLESCENCE An adolescent's sense of self is greatly influenced by others, especially peers. Acceptance and a sense of belonging to a peer group influence the adolescent's sense of worth and well-being; see Figure 22-6. Feelings about one's self intensify during puberty. Adolescents may become very self-conscious because they often think everyone else is watching them.

As adolescents' bodies change, they must keep revising their body images. A severe or deep-rooted distortion of body image may be a manifestation of a mental illness, such as anorexia nervosa or bulimia nervosa, which occur primarily during adolescence. The nurse needs to help the adolescent redirect energies, focus on positive traits, and view himself or herself as a compilation of many factors, not just one (e.g., weight). See the Uncovering the Evidence display.

FIGURE 22-6 Peers exert much influence on the adolescent's changing self-concept. DELMAR/CENGAGE LEARNING

UNCOVERING THE

Evidence

TITLE OF STUDY

“Ecological Strategies to Promote Healthy Body Image among Children”

AUTHORS

R. R. Evans, J. Roy, B. F. Geiger, K. A. Werner, and D. Burnett

PURPOSE

To examine approaches that may be used to promote development of healthy body images in children.

METHODS

This study systematically applied the ecological model to components of coordinated school health, including attitudes and behaviors about eating; exercise and physical appearance modeled by parents, teachers, and peers; opportunities to learn new habits; and social praise for healthy choices. Strategies for each component were developed in the areas of health education, exercise science, and dietetics.

FINDINGS

For each strategy, applicable health and physical education standards and resources were provided to assist educators in supporting healthy body images among students.

IMPLICATIONS

Educators and school nurses may effectively use a coordinated approach to guide multiple activities aimed at increasing healthy habits and the development of healthy body images of children.

Evans, R. R., Roy, J., Geiger, B. F., Werner, K. A., & Burnett, D. (2008). Ecological strategies to promote healthy body image among children. *Journal of School Health, 78*(7), 359–367.

CLIENT TEACHING CHECKLIST

Actions of Parents to Promote Positive Self-Concept in Children

- Encourage expression of feelings.
- Promote mutual respect and trust by establishing and maintaining open lines of communication
- Demonstrate a willingness to talk about any subject.
- Listen carefully to children, and use words they understand.
- Use examples and anecdotes to promote learning.
- Teach by example. Role-model problem solving and coping skills.
- Encourage children's talents and accept their limitations. Be realistic in your expectations, and avoid comparing one child to another.
- Celebrate children's accomplishments.
- Demonstrate confidence in their abilities.
- Provide children with unconditional love.

ADULTHOOD As adults continue to mature, self-concept changes in response to new self-perceptions and roles. Young adults make a transition to independent living without parental assistance. The degree of ease or discomfort in making such a transition affects the young adult's self-concept by demonstrating a sense of competency.

The self-concept of an older person is the culmination of a variety of factors, including life experiences and interactions with others. Some life experiences that shape the older adult's self-concept are adjusting to role loss and dealing with the loss of significant others. Spending time with significant others may increase the older client's self-esteem by making him or her feel valued; see Figure 22-7.

Throughout life, the individual has developed coping resources. Because self-concept is intertwined with competency, it is important for nurses to allow older clients the time to complete tasks that are meaningful to them. Some of the many factors that may negatively affect the older adult's self-esteem are shown in the accompanying Respecting Our Differences display. When caring for older clients, it is important to plan activities that promote a healthy self-concept.

EVALUATION

A client's behavior and attitudes will reflect the degree of progress toward restoring an altered self-concept. The nurse must reconsider the alignment of the client's targeted self-concept with the plan of care to assess if the two are still congruent. Input from family members or significant others can be useful in seeing the client in a larger context of differing roles and expectations and may also highlight some of the similarities and differences between the client's perceived self-image and the impressions of those closest to him or her.

Another crucial factor in evaluating the success of attaining goals is the consideration of time. Because self-concept is based on personal attitudes, feelings, and impressions, it

FIGURE 22-7 Identify some factors that may contribute positively to this older client's self-esteem. DELMAR/CENGAGE LEARNING

RESPECTING OUR DIFFERENCES

Factors Contributing to Self-Concept Alterations in the Older Client

- Changes in environment
- Ageism (social stigma against older adults)
- Loss of significant others (including pets)
- Social isolation
- Illness, acute or chronic
- Financial change

NURSING CHECKLIST

Promoting Self-Concept in the Older Client

- Increase socialization.
- Encourage involvement and participation in care.
- For clients in the home setting, urge family members to allow client to be involved with household tasks and routines as much as possible.
- Elicit client feedback.
- Use touch to decrease feelings of isolation and to promote feelings of security and acceptance.
- Modesty is often important to the older client; therefore, maintain and promote privacy. For example, perform physical examinations or procedures without completely exposing the client.
- Do not remove all personal belongings because these are often invested with symbolic meaning (e.g., let the older woman keep her purse at her bedside).
- Demonstrate patience; allow clients time to complete sentences and to finish one task before moving on to the next.
- Involve family or significant others as much as possible in the provision of care.
- Encourage the client to reminisce, especially focusing on individual strengths and accomplishments.

often requires months or even years to change. Nurses, clients, and families all need to learn to be patient and to work together to improve or restore a client's self-concept.

NURSING CARE PLAN

The Client with Ineffective Role Performance

CASE PRESENTATION

Todd Lloyd is a 31-year-old civil engineer who has just left his job of 10 years to care full-time for his newborn daughter, Sarah. He and his wife decided that after their child was born, she would return to work full-time outside the home, and he would be the primary caregiver for their daughter during the day. Mr. Lloyd presents at the clinic stating, "I am very eager and excited about being a full-time dad, but I'm also a little nervous because I really don't know what to expect."

ASSESSMENT

- Lack of knowledge about new parenting role
- Concern over changes in responsibilities

NURSING DIAGNOSIS

Ineffective role performance related to change in roles and usual patterns of responsibility, as evidenced by verbalization of concern over lack of knowledge about new role

NOC: Parenting Performance

NIC: Parent Education: Infant Care

EXPECTED OUTCOMES

The client will:

1. Explain specific concerns about new roles.
2. Demonstrate role competence.
3. Verbalize satisfaction with role performance.

INTERVENTIONS/RATIONALES

1. Encourage the client to express his feelings about his new role. Opens the door to communication and problem solving.
2. Outline with client what aspects of his role(s) will be changing and what will be the same. Helps client identify the ways in which his role is changing, so he can face the changes from a realistic frame of mind. Also highlights similarities, not just differences, between his past and present roles, thus helping client feel less overwhelmed.
3. Assist the client in identifying concerns he has regarding the change in roles. Helps the client determine his specific concerns so they can be addressed.
4. Encourage client to discuss concerns with wife and to seek help together. Support of spouse will be critical to client's success in overcoming concerns about changing roles.
5. Help client gain confidence and competence with new role by demonstrating new role behaviors, offering literature and resources, and providing referral to parenting courses or counselors. Assures client that resources are available to help him meet his needs and helps lessen his anxiety and his feeling of being overwhelmed.
6. Have client return demonstrate new behaviors and offer encouragement and additional teaching. Allows client to try out new behaviors in a "safe" environment and provides a means for immediate feedback.
7. Ask client for feedback on the new behaviors and information acquired. Provides chance for client to evaluate progress in new role, which will increase client's confidence.

EVALUATION

Mr. Lloyd is able to identify specific concerns about his new role as parent and has demonstrated a growing competence in some of the behaviors that will support this new role. He read the literature and has ordered a videotape designed for new parents. He is also planning to subscribe to a newsletter entitled "The Full-Time Father." Mr. Lloyd agrees that his wife's input would be very valuable to his gaining comfort and confidence in his new role, and he agrees to visit the clinic again with her in a week.

KEY CONCEPTS

- Self-concept (an individual's perception of self) affects every aspect of a person's life.
- People who see themselves as competent individuals will behave competently and vice versa.
- Self-concept consists of four interrelated components: identity, body image, self-esteem, and role performance.
- A well-formulated identity provides the answer to the question "Who am I?" and may consist of a person's name, family status, occupation, and various roles.
- Body image refers to a person's mental picture of and attitudes about his or her body. It includes physical attributes and characteristics, appearance, and performance.
- Self-esteem is the individual's generalized sense of worth and value.
- Role refers to a set of expected behaviors that are determined by social norms.
- The development of self-concept begins at birth and depends, to a degree, on interactions with others as the child grows and matures.
- The person's developmental level affects self-concept; with maturity comes a stronger self-concept.
- Illness evokes anxiety in most people, and anxiety can exacerbate illness. Any threat to self-concept arouses anxiety. When anxiety level is heightened, recovery is compromised.
- Surgery can result in body image disturbances. Altered body image results from loss of a body part or function and distortion of body image.
- Assessment of self-concept must consider both developmental level and chronological age.
- Identification of client strengths enables the nurse to determine the presence of factors the client can use for coping and problem solving.

REVIEW QUESTIONS

1. Which of the following are indicators that a person has a high degree of self-esteem? Select all that apply.
 - a. Appropriate decision-making skills
 - b. Assertive communication
 - c. Disheveled clothing
 - d. Erect posture
 - e. Intrusive staring
 - f. Mumbling, hesitant speech
2. A student nurse is teaching a group of clients how to improve self-esteem. Which of the following client statements indicates that further teaching is needed?
 - a. "I will do something, like take a walk, the next time I feel down."
 - b. "If I just wait long enough, I'll start to feel better."
 - c. "When I feel bad, I should think of something positive."
 - d. "When I feel good about myself, I have good self-esteem."
3. When working with a client who has anorexia nervosa, which of the following nursing diagnoses is most applicable?
 - a. Anxiety
 - b. Chronic low self-esteem
 - c. Disturbed body image
 - d. Social isolation
4. A student nurse has clinical scheduled at the same time as his child's parent-teacher conference. Which of the following is the student nurse experiencing?
 - a. Body image disturbance
 - b. Person-role conflict
 - c. Role conflict
 - d. Role overload
5. Which of the following are client strengths that may be used in health promotion?
 - a. Ability to perform self-care
 - b. History of multiple job changes
 - c. Relying on others for assistance with activities of daily living
 - d. Role overload
6. The nurse is planning a parenting class on building self-esteem in children. Which of the following topics is important for the nurse to include when teaching parenting skills classes? Select all that apply.
 - a. Accept the child's limitations and strengths.
 - b. Compare younger siblings to older ones to encourage the development of competition.
 - c. Provide conditional love to children.
 - d. Role-model expected behaviors.
 - e. Talk to children in adult terms so they will develop language skills quickly.
 - f. Use abstract terms when talking to young children.
7. Which of the following client statements indicates a high degree of self-esteem?
 - a. "I am so tired of failing."
 - b. "I've solved problems before so feel like I can do so now."

- c. “There’s no use in trying because nothing will change.”
 - d. “Why bother! Everything I do turns out wrong anyway.”
8. Which of the following factors is most influential on the development of an adolescent’s body image?
- a. Life experiences
 - b. Parental feedback
 - c. Peer approval
 - d. The need for modesty
9. Which of the following actions can be implemented by the nurse to improve the self-concept of older clients?
- a. Decrease socialization in order to lower anxiety level.
 - b. Encourage the client to talk about current events, instead of those in the past.
 - c. Remove personal items to keep the health care environment free of clutter.
 - d. Use touch to promote feelings of acceptance.

CHAPTER 23

Stress, Anxiety, Adaptation, and Change

COMPETENCIES

1. Discuss stress, anxiety, and adaptation as they affect health.
2. Identify factors contributing to the stress response.
3. Describe the general adaptation syndrome (GAS).
4. Explain stressors inherent in the change process.
5. Discuss the role of the nurse as a change agent.
6. Explain nursing interventions that promote positive adaptation to stress.
7. Develop an individualized stress management plan for use as a nurse.

KEY TERMS

adaptation	defense mechanisms	local adaptation syndrome
anxiety	depersonalization	maladaptation
burnout	distress	paradigm
catharsis	endorphins	proactive
change	eustress	progressive muscle relaxation
change agent	fight-or-flight response	secondary gain
cognitive reframing	general adaptation syndrome	stress
crisis	guided imagery	stressor
crisis intervention	homeostasis	suppression

Stress, a universal experience, can be the catalyst for positive change or it can be the source of discomfort and pain. Nurses help clients learn to cope with the stress imposed by illness, injury, disability, or treatment approaches. How does stress affect nurses? Caring for clients who are experiencing high levels of anxiety can be stress-provoking for nurses. Successful stress management is necessary for wellness of both clients and nurses. This chapter discusses the major concepts related to stress, anxiety, and adaptation and presents strategies for coping with stress and change.

STRESS, ANXIETY, AND ADAPTATION

Stress is the body's physiological reaction to any stimulus that evokes a change. Any situation, event, or agent that threatens a person's security is a **stressor**. A stressor is a stimulus that evokes the need to adapt and can be internal or external. For example, a headache is an internal stressor, whereas a difficult assignment is an external stressor. A stressor can be physical (e.g., a laceration), physiological (e.g., hypertension), or psychosocial (e.g., graduation from school). Even pleasant events can be stressful in that they evoke the need to adapt. Stressors in themselves are neutral; in other words, a stressor is neither good nor bad. The individual's perception of the stressor greatly determines whether the outcome is positive or negative.

Anxiety, a pervasive feeling of dread or apprehension, is a subjective response that occurs when a person experiences a threat to well-being. There is a close relationship between stress and anxiety. Stress is the person's physiological response to a stimulus, whereas anxiety is the psychological response to a threat. Anxiety can be both an activator of stress and a response to stress. It is usually activated by stress and may, in and of itself, lead to more stress.

Adaptation is an ongoing process by which individuals adjust to stressors in order to achieve **homeostasis** (equilibrium between physiological, psychological, sociocultural, intellectual, and spiritual needs). Adaptation is a holistic response that involves all dimensions of an individual.

Individuals, as holistic beings, seek to maintain a *steady state* (another term for homeostasis) in all dimensions of life: physiological, psychological, cognitive, social, and spiritual. Wellness is an adaptive state; that is, the well person is one who is coping effectively with stressors to maintain a high level of well-being. The nurse's goal is to identify and support the client's positive adaptive responses.

SOURCES OF STRESS

Individuals experience stress from multiple sources, primarily their bodies, their thoughts, and the environment. A situation or event that evokes stress in one person may not affect another. Examples of factors contributing to stress are shown in Table 23-1 on page 441.

RESPONSES TO STRESS

Every individual has unique responses to stress. A person's response to stress is influenced by several variables: mental attitude, lifestyle, perception, and heredity.

PHYSIOLOGICAL RESPONSE

The stress response, which can be adaptive or maladaptive, is the nonspecific response of the body to any demand (Selye, 1974). When the response is adaptive, the individual achieves and is able to maintain homeostasis. If the stress response is maladaptive, health status is altered.

General Adaptation Syndrome

Selye (1976) introduced the concept of the **general adaptation syndrome** (GAS), the physiological response to stress. The GAS is the same whether the stressor is actual or imagined, present or potential. In other words, the physiological reactions of the body are essentially the same regardless of the source of the stress. For example, the mind can imagine a stressor, and the physiological response (GAS) will be the same as if the body had actually experienced the stressor.

TYPE OF STRESSOR	EXAMPLES
Physiological	<ul style="list-style-type: none"> • Maturation (moving from one developmental stage to another) • Trauma • Illness • Poor nutrition • Sleep disturbances • Hunger • Discomfort • Pain
Psychological	<ul style="list-style-type: none"> • Worry • Fear • Anger • Happiness
Cognitive	<ul style="list-style-type: none"> • Thoughts • Perceptions • Interpretation of events
Environmental	<ul style="list-style-type: none"> • Temperature (weather) • Air pollution • Noise pollution • Crowding • Time pressures
Sociocultural	<ul style="list-style-type: none"> • Job loss or promotion • Changes in interpersonal relationships • Interpersonal conflict • Living conditions

Delmar/Cengage Learning

See the accompanying Respecting Our Differences display. According to Selye, all stress reactions involve similar physiological reactions. The three stages of the GAS are described in Figure 23-1.

RESPECTING OUR DIFFERENCES

Anticipatory Stress

Each person worries about different stressors. Consider what happens when you worry about a situation. Your thoughts are stressors that trigger the GAS. While you are reviewing these “movies of the mind,” your body responds as if you were actually experiencing the events in the present moment.

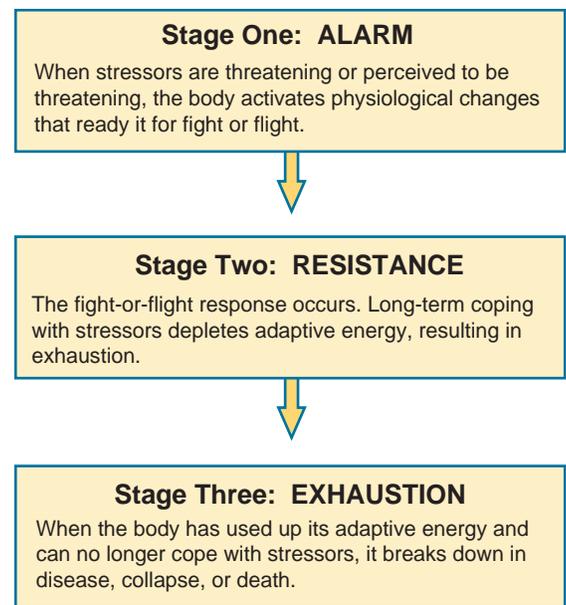

FIGURE 23-1 Stages of the General Adaptation Syndrome (GAS) DELMAR/CENGAGE LEARNING

FIGHT-OR-FLIGHT RESPONSE During the resistance stage of the GAS, an individual attempts to defend against the stressor through the **fight-or-flight response**. The body becomes physiologically ready to defend itself by either fighting or running away from the danger (stressor). Hormones, such as adrenaline and norepinephrine, are secreted, causing various biological changes. Arousal of the autonomic nervous system (ANS) characterizes the fight-or-flight phenomenon (see Figure 23-2 on page 442). The endocrine system is also involved in maintaining physiological homeostasis.

Local Adaptation Syndrome

The **local adaptation syndrome** (LAS) is the physiological response to a stressor (e.g., trauma, illness) affecting a specific part of the body. For example, if a person experiences a puncture wound on the foot, the LAS is activated, resulting in localized inflammation. The classic symptoms of inflammation (redness, warmth, and edema) occur at the injured site. The LAS is usually a temporary process that is resolved when the traumatic area is restored to its steady state. However, if the inflammation is not resolved with the LAS, the individual will then experience the GAS as the entire body becomes affected.

MANIFESTATIONS OF STRESS

The manifestations of stress are numerous and affect every dimension of a person. Common manifestations of stress are described in Table 23-2 on page 442.

OUTCOMES OF STRESS

Stress is an experience that provides the individual with two possibilities: (1) an opportunity for personal growth or (2) the risk of disorganization and distress. When stressors are

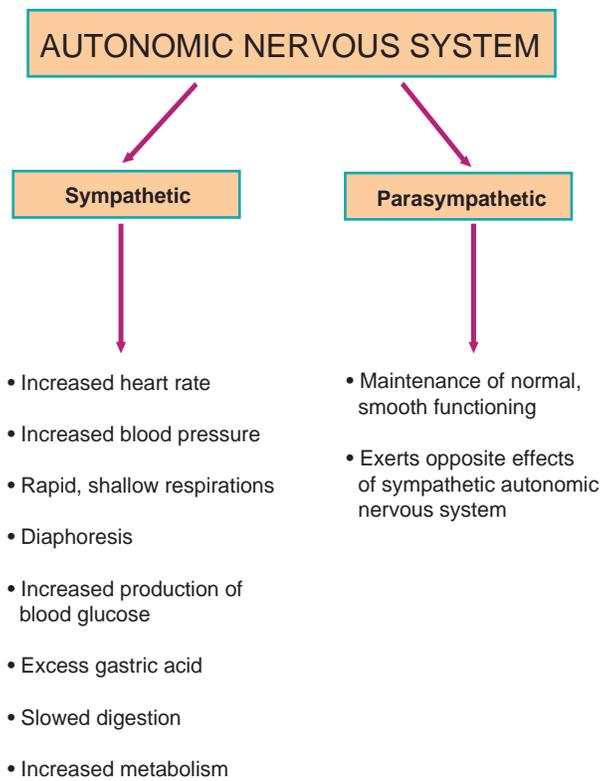

FIGURE 23-2 Physiology of Autonomic Nervous System: Arousal and Homeostasis ADAPTED FROM DELAUNE, S. C. (2009). ANXIETY AND DISSOCIATIVE DISORDERS. IN C. R. KNEISL & E. TRIGOBOFF (EDS.), *CONTEMPORARY PSYCHIATRIC-MENTAL HEALTH NURSING* (2ND ED.). UPPER SADDLE RIVER, NJ: PRENTICE-HALL.

responded to appropriately, adaptation is successful and the body returns to its normal steady state.

When stress is not resolved within a short period of time, however, problems may occur. Individuals who experience chronic periods of stress are the ones who have the greatest risk of becoming ill. Selye (1976) refers to the effects of chronic stress as “dis-ease,” which occurs in the third stage of the GAS, exhaustion. The person becomes dis-eased when coping mechanisms are ineffective. The inability to adapt to continued demands of stress can have harmful results such as illness. The process of coping ineffectively with stressors is referred to as **maladaptation**.

The term **eustress** is used to describe a type of stress that results in positive outcomes. Consider, for example, students who have an examination scheduled the following week. The stress over the impending test motivates them to study early. As a result, they pass the examination.

When stressors evoke an ineffective response, **distress** is experienced. For example, consider students who have an examination scheduled for the next day. They had plenty of time to study, but because they delayed studying until the last minute, they take the examination unprepared. As a result of studying all night, they are not alert, do not know the material, and fail the examination; they are experiencing distress. In general, when people say *stress* they are referring to distress, the negative outcomes of an ineffectual stress response. See the Respecting Our Differences display on page 443.

TABLE 23-2 Manifestations of Stress

TYPE OF STRESSOR	EXAMPLES
Physiological	<ul style="list-style-type: none"> • Cardiovascular and respiratory effects <ul style="list-style-type: none"> – Increased pulse – Increased blood pressure – Rapid, shallow breathing • Neurological effects <ul style="list-style-type: none"> – Dizziness – Headaches – Dilated pupils • Gastrointestinal effects <ul style="list-style-type: none"> – Nausea – Altered appetite – Diarrhea or constipation • Genitourinary effects <ul style="list-style-type: none"> – Polyuria • Musculoskeletal effects <ul style="list-style-type: none"> – Tension – Twitching • Endocrine effects <ul style="list-style-type: none"> – Increased levels of blood glucose and cortisol
Psychological	<ul style="list-style-type: none"> • Irritability • Increased sensitivity (feelings are easily hurt) • Sadness, depression • Feeling “on edge”
Cognitive	<ul style="list-style-type: none"> • Impaired memory • Confusion • Impaired judgment and decision making • Delayed response time • Altered perceptions • Inability to concentrate
Behavioral	<ul style="list-style-type: none"> • Pacing • Sweaty palms • Rapid speech • Insomnia • Withdrawal • Exaggerated startle reflex
Spiritual	<ul style="list-style-type: none"> • Alienation • Social isolation • Feeling of emptiness
Delmar/Cengage Learning	

RESPECTING OUR DIFFERENCES

Everyone Responds to Stress Differently

Personal Stressors: Eustressful

Think about some of the stressors in your life. Identify those that are eustressful, that is, stimulating and positive.

Personal Stressors: Distressful

Think of the last time you felt “stressed out” and anxious. How did your body respond? What did you feel? What were you thinking? How did you respond behaviorally?

Crisis

When stressors exceed the person’s ability to cope, a crisis develops. A **crisis** (an acute state of disorganization) occurs when the individual’s usual coping mechanisms are no longer effective. Crisis is characterized by extreme anxiety, inability to function, and disorganized behavior. A crisis is time limited; that is, no one can remain in acute disequilibrium for a long period of time because of the degree of discomfort that is experienced. See the Safety First display on page 444. The treatment method of crisis intervention is discussed later in this chapter.

A crisis can be a negative experience, but it also has the potential to be an opportunity for growth and learning. The outcome of crisis is unique according to each individual’s

perception and coping abilities. Nurses are challenged to help clients discover the opportunity in their crises to adapt in a positive, healthy manner.

Not every person will experience a crisis as a result of stressful events. Each crisis is unique according to the individual and circumstances. However, there are some characteristics common to all crises, including the following:

- A crisis is experienced as a sudden event.
- A crisis has an identifiable precipitating event.
- The situation is perceived as overwhelming or life threatening.
- The situation cannot be resolved with usual coping skills.
- Intervention is required for equilibrium to be achieved.

A crisis is *not* a mental illness even though it is not uncommon for a person experiencing the acute discomfort and anxiety to fear “I’m losing my mind.” There are three types of crises; see Table 23-3.

BALANCING FACTORS There are three factors that influence a person’s resolution of a crisis (Stuart & Laraia, 2008); see Figure 23-3. During a crisis, one (or sometimes more) of these factors is out of balance. When the factors return to a balanced state, the individual is better able to resolve the

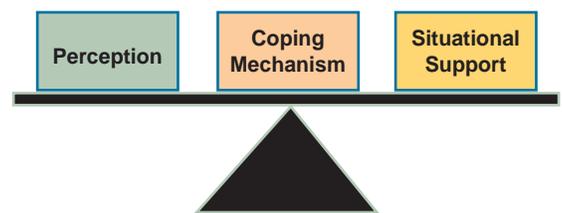

FIGURE 23-3 Balancing Factors of a Crisis ADAPTED FROM AGUILERA, D. C. (1997). *CRISIS INTERVENTION: THEORY AND METHODOLOGY* (8TH ED.). ST. LOUIS, MO: MOSBY

TABLE 23-3 Types of Crises

TYPE	DEFINITION	EXAMPLES
Developmental or maturational	<ul style="list-style-type: none"> • Occur as a person ages and moves from one developmental stage to another • Are universal 	<ul style="list-style-type: none"> • An adolescent attempting to gain independence from parents • A middle-aged woman experiencing menopause
Situational	<ul style="list-style-type: none"> • Can occur at any time and are not predictable • Are not experienced by everyone • Occur when there is change in role or function 	<ul style="list-style-type: none"> • Illness • Loss (death, divorce) • Graduation • Job promotion • Retirement
Adventitious	<ul style="list-style-type: none"> • Are unpredictable events that rarely occur 	<ul style="list-style-type: none"> • Being in an airplane crash • Losing one’s home in a tornado • Being a victim of a school shooting • Winning a \$10 million lottery

Delmar/Cengage Learning

SAFETY FIRST

Because of the time-limited nature of a crisis, a client experiencing a crisis needs immediate intervention in order to reach a successful resolution.

crisis effectively. Nursing interventions focus on reestablishing equilibrium among these factors.

Anxiety

Anxiety is the most common emotional (affective) response to stress. Individuals feel anxious whenever they are threatened, whether the threat is perceived or actual. Anxiety occurs on a continuum; some degree of anxiety is necessary as it serves as a motivator for adaptation. High levels of anxiety, however, can overwhelm the person and impair the ability to think and function. As the severity of anxiety increases, the person becomes less able to function effectively; see Table 23-4 on page 445.

COPING BEHAVIORS There are many ways to cope with stress. The following are frequently used coping strategies:

- Talking
- Crying
- Laughing
- Exercising

These strategies can result in successful adaptation. However, they become ineffective if they are the only coping methods used by the individual.

DEFENSE MECHANISMS Just as the body has physiological mechanisms (e.g., the immune system, the inflammatory response) to defend against infection and disease, the mind has psychological protective mechanisms. **Defense mechanisms** are unconscious operations that protect the mind from anxiety (see Table 23-5 on page 446). Defense mechanisms are employed to achieve and maintain psychological homeostasis. Illness and the resultant treatment evoke anxiety in everyone; thus, all clients use defense mechanisms (also called mental mechanisms).

Defense mechanisms are universal. Their use does not indicate psychosocial imbalance or mental illness; however, defense mechanisms are pathological when they become a stereotyped pattern, that is, the only way that an individual responds to a threat. Defense mechanisms are also considered to be pathological when they limit the individual's ability to function.

Defense mechanisms operate at the unconscious level of awareness and are involuntary and automatic; that is, the individual does not consciously decide to use a defense mechanism. **Suppression** is a conscious mechanism whereby a

person decides to avoid dealing with a stressor at the present time. See the Nursing Process Highlight.

The nurse who is unfamiliar with defense mechanisms is likely to be judgmental about clients who do not respond according to the nurse's expectations. If, for example, the nurse tries to break through a client's denial too quickly by presenting reality, the client will likely be overwhelmed by anxiety and will panic. See the Safety First display.

STRESS AND ILLNESS

Everyone experiences stress and accompanying anxiety; this anxiety is increased during illness and the recovery process. Illness and stress are interwoven to such a degree it is difficult to determine which precedes the other. When a person's adaptive attempts are unsuccessful, illness occurs; a person who is ill has fewer adaptive resources available to cope with stressors. Even though some stressors may not directly cause illness, stress is a significant component in the onset and progression of many diseases. Table 23-6, on page 447, lists some disorders commonly associated with stress.

A major outcome of prolonged periods of stress is impairment of the immune system. As the body continues to

NURSING PROCESS HIGHLIGHT

Planning

Clinical Example: Suppression

Mrs. James, a 34-year-old mother of two small children, has just been informed by her prescribing practitioner that she has cervical cancer. She is also told that her prognosis is dire; she has about 3 months left to live. Mrs. James asks questions and appears to be very calm. Later, the nurse asks Mrs. James if she wants to talk. Mrs. James replies, "I can't deal with this right now. I'll wait until my family is here and then I'll talk to you." How does suppression affect Mrs. James's plan of care?

SAFETY FIRST

TO PREVENT PANIC

To prevent panic, never attempt to take away a defense mechanism until the client has learned another method of coping. Denying a client the use of a defense mechanism will cause more anxiety.

TABLE 23-4 Levels of Anxiety

ANXIETY LEVEL	CHARACTERISTICS OF ANXIOUS PERSON	NURSING IMPLICATIONS
Mild	<ul style="list-style-type: none"> • Increased degree of alertness • Increased vigilance 	<ul style="list-style-type: none"> • Optimal time for client teaching because of heightened awareness and increased perceptual field
Moderate	<ul style="list-style-type: none"> • Subjective distress • Decreased perception and attention 	<ul style="list-style-type: none"> • Help the client to determine a cause-and-effect relationship between stressor and anxiety
Severe	<ul style="list-style-type: none"> • Increased subjective distress • Selective attention • Distorted perception 	<ul style="list-style-type: none"> • Encourage verbalization • Engage in motor activity • Give specific directions
Panic	<ul style="list-style-type: none"> • Major perceptual distortion • Immobilization; inability to function • Impaired communication 	<ul style="list-style-type: none"> • Provide limits and structure • Maintain client safety (both physical and psychological)

Data from Peplau, H. E. (1952). *Interpersonal relations in nursing*. New York: Putnam; and Sullivan, H. S. (1953). *The interpersonal theory of psychiatry*. New York: Norton.

fight off the threat (actual or perceived), steroid production is increased. Increased steroid production is helpful on a short-term basis because steroids speed up the healing process. However, increased steroid production over a period of time will impair the immune system. Thus, the body is less able to protect itself from disease.

IMPACT OF ILLNESS AND TREATMENT

Everyone entering the health care system experiences a change in their usual routine. For example, hospitalization, surgery, receipt of home health care, and admission to a long-term care facility are major disruptions in one’s routine. Such changes evoke the stress response. See the Community Considerations display.

COMMUNITY CONSIDERATIONS

Client Role Stressors

Individuals do not have to be hospitalized to experience stressors associated with the client role. Consider, for example, the person having “minor” surgery at an outpatient center, the employee being treated at an industrial clinic for a work-related injury, or the adolescent being treated by the school nurse. Even clients who are treated by home health agencies experience stressors associated with having a health care provider enter their personal environment.

Being in an unfamiliar environment, losing control over one’s schedule, and being dependent on others for care are all issues with which clients must cope. Each of these issues is a stressor that requires adaptation in order to maintain a steady state. Most clients do not have the energy to cope with the numerous changes simultaneously. Some cues that a person may be reacting adversely to assumption of the client role include:

- Increased stress response
- Higher levels of anxiety
- Increased or impaired use of coping mechanisms
- Inability to function
- Disorganized behavior

The greater the threat (or perceived threat), the greater the level of the client’s anxiety. The nurse must be sensitive to stress and anxiety stemming from the multiple changes imposed by illness on the client, family, and significant others. The nurse’s sensitivity to the client’s stress reduces the risk of depersonalizing the client. See the Respecting Our Differences display.

RESPECTING OUR DIFFERENCES

Stressors Associated with Illness

Think of some major changes that people experience when they are ill. Can you identify at least three changes? What can you do to significantly reduce threats (real or perceived) in acute care settings? In long-term care settings? In outpatient settings?

TABLE 23-5 Common Defense Mechanisms

MECHANISM	DESCRIPTION	EXAMPLE
Denial	Negation of reality of threatening situations, despite factual evidence	The client refuses to admit to anger, even though the situation warrants it and the client's voice indicates anger.
Projection	Attribution of one's own thoughts, feelings, or impulses to others	"I'm not attracted to him. My best friend is."
Repression	Unconscious blocking from awareness material that is threatening or painful	"I never got angry at my father; our family lived in harmony and love" (when such descriptions of the family life would not fit with anyone else's interpretation of the events).
Rationalization	Intellectual explaining away of threatening circumstances	"The test had too many trick questions; I really knew all the material, but our instructor was out to get me."
Introjection	Incorporating, without examination or thought, the qualities or attitudes of others	An adolescent takes on all the values and styles of an admired teacher.
Displacement	Transfer of feelings or reactions evoked by one topic or event to another that is less threatening	A husband who is angry at his wife yells at the family dog rather than dealing directly with his anger.
Reaction formation	Expression of a feeling that is the opposite of one's authentic feeling or of feelings that would be appropriate in the situation	A client brings gifts to the nurse with whom he is really angry.
Regression	Retreat to a previous developmental level	A child starts to suck his thumb (after 2 years of not thumb sucking) when admitted to the hospital.
Suppression	Conscious attempt to keep threatening material out of consciousness	A student nurse decides not to think about a family problem at the moment so he can study for an upcoming examination.
Sublimation	Channeling of socially unacceptable impulses into socially acceptable activities	A young man deals with aggression by playing football.
Symbolization	Use of an object, idea, or act to express emotion that is not expressed directly	The client leaves the nurse a flower rather than directly saying she cares about the nurse.

Delmar/Cengage Learning

Depersonalization describes the process in which an individual is treated as an object instead of as a person. Literally, it involves taking away clients' unique aspects by treating them as nonhuman. Nurses who demonstrate caring and compassion avoid depersonalizing clients. In order to prevent depersonalization, nursing interventions focus on helping the client reduce feelings of unfamiliarity and loss of control. The accompanying Nursing Checklist, on page 447, suggests some actions for promoting client control.

STRESS AND CHANGE

Change, a dynamic process in which an individual's behavior is altered in response to a stressor, is an inherent part of life. It is the process that causes individuals to adapt. Whether it is planned or unplanned, change is both inevitable and constant. Change, whether constructive or destructive, is stressful to individuals because it activates the GAS. Some characteristics of change are that it:

- Is an inevitable part of life.
- May be eustressful or distressful.

**TABLE 23-6 Stress-Related Disorders:
A Partial List**

Respiratory disorders	<ul style="list-style-type: none"> • Chronic bronchitis • Asthma
Cardiovascular disorders	<ul style="list-style-type: none"> • Hypertension • Cardiac arrhythmias • Migraine headaches
Endocrine disorders	<ul style="list-style-type: none"> • Thyroid problems • Amenorrhea, anovulation • Diabetes • Excessive weight gain or weight loss
Musculoskeletal disorders	<ul style="list-style-type: none"> • Chronic back pain • Arthritis

Integumentary disorders	<ul style="list-style-type: none"> • Eczema • Hives • Psoriasis
Delmar/Cengage Learning	

- Can be self-initiated or externally imposed.
- Can occur abruptly or have a gradual onset with insidious progression.
- Requires energy to effect as well as to resist.

The pace of change is rapidly increasing in health care agencies, which have been changing and continue to change in response to consumer demands. Some changes that have evolved from consumer demands and needs include:

- Sports medicine clinics
- Substance abuse treatment programs
- Day treatment programs for geriatric and psychiatric clients
- Weight control programs
- Exercise programs
- Emergency department fast-track programs

TYPES OF CHANGE

Change is either planned or unplanned. Unplanned change is the change that “just happens”; it is unpredictable and may

NURSING CHECKLIST

Actions to Promote Client Control

- Communicate clearly. Use terms easily understood by clients and families. Avoid using medical jargon with clients.
- Answer questions thoroughly. Validate client’s and family’s level of understanding.
- Teach the use of relaxation techniques, such as progressive muscle relaxation (a stress management technique involving the tensing and relaxing of muscles) and guided imagery (a relaxation technique in which the individual uses the imagination to experience a pleasant, soothing image).
- Instruct clients on the use of cognitive reframing (a technique in which individuals change their negative perception of a situation or event to a more positive, less-threatening perspective).
- Provide support and reassurance. The nurse’s presence (“being with” the client) can alleviate anxiety levels. The most therapeutic tool in alleviating client anxiety is the nurse’s therapeutic use of self.
- Break down the information shared with clients. Too much information at once can make the client feel overwhelmed and less likely to listen. When clients have adequate information, they can make informed decisions and maintain some degree of control over their lives.

be imposed by others or by uncontrollable natural events (e.g., losing one’s home in a flood). On the other hand, planned change results from a deliberate effort to improve a situation. In addition to planned and unplanned change, there are other types of change (see Table 23-7 on page 448).

THEORIES OF CHANGE

Nurses must be able to initiate and cope with change. Proficiency in critical thinking and problem-solving skills is necessary to initiate positive change. Two major theories of change are discussed in the following text.

Lewin’s Theory

A classic theory of change was developed by Lewin (1951), who stated that the change process occurs in three stages: unfreezing, moving, and refreezing (see Figure 23-4 on page 448). In the unfreezing stage, the person recognizes a need for change and becomes motivated to move in a new direction. Stage 2, changing, is the actual implementation of the change. In the third stage, refreezing, new changes are incorporated into behavior and these new behaviors stabilize. Because the change process is dynamic, these stages are not rigid. The process of change may quickly move through all stages, or it may become stuck in one stage.

TABLE 23-7 Types of Change

TYPE OF CHANGE	DESCRIPTION
Developmental	<ul style="list-style-type: none"> Physical and emotional changes that occur at different stages of the life cycle Generally predictable Usually occur gradually
Reactive	<ul style="list-style-type: none"> Adaptive responses to external stimuli Efforts to cope with change imposed by others
Covert	<ul style="list-style-type: none"> Occur without person's conscious awareness
Overt	<ul style="list-style-type: none"> Person is aware of the change Usually not under individual's direct control

Delmar/Cengage Learning

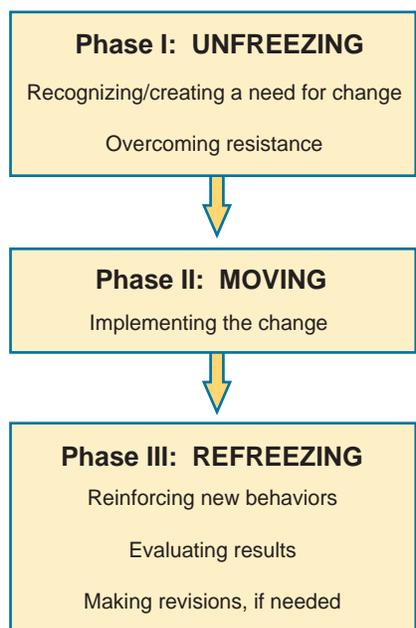

FIGURE 23-4 Lewin's Theory of Change DATA FROM LEWIN, K. (1951). *FIELD THEORY IN SOCIAL SCIENCE*. NEW YORK: HARPER.

Lippitt's Theory

Lippitt, Watson, and Westley (1958) proposed a theory of change that consists of seven phases:

1. Diagnose the problem (need for change).

2. Assess the change target's motivation and capacity for change.
3. Assess the change agent's motivation and capacity for change.
4. Establish objectives for change.
5. Determine the role of the change agent.
6. After change has occurred, maintain it.
7. Terminate the role of the change agent.

RESISTANCE TO CHANGE

Many people tend to resist change because of the energy required to adapt. Conversely, energy is also required to resist change, or to maintain the status quo. Individuals differ in their ability to tolerate (or even thrive on) change.

There are many reasons people tend to resist change (see Table 23-8 on page 449). There are no absolute guarantees that the change activity will lead to positive outcomes; this uncertainty about outcomes is a major barrier to change.

CHANGING PARADIGMS

Changing involves questioning and frequently results in the development of a new **paradigm** (a pattern, model, or mind-set that strongly influences one's decisions and behaviors). One's paradigm greatly colors one's behaviors. By changing paradigms, an individual can determine what is positive in the old system and use it to create a newer, better system (Alfaro-LeFevre, 2008).

It is risky to initiate change, to challenge one's own paradigms and those of others. One of the first signs of the need for change is questioning. The nurse who wonders "Why?" or "Why not?" or "What if?" is the nurse who will likely take risks to initiate change activity. The risk taker who is effective is neither reckless nor overly cautious. Successful risk takers consider possible outcomes before initiating action. See the Spotlight On display.

Overcoming Barriers to Change

Because change is inevitable, learning how to deal with it is crucial for nurses. Resistance occurs when the individual rejects proposed new ideas without critically thinking about the proposal.

SPOTLIGHT ON...

Professionalism

Nurses as Risk Takers

Do you think nurses are encouraged to be risk takers? What empowers you to take risks as a student? What barriers to risk taking can you identify in academic and health care settings?

TABLE 23-8 Reasons People Resist Change

Conformity	Often referred to as “groupthink”; complying with the group’s expectations; going along with others to avoid conflict.
Dissimilar beliefs and values	Differences in attitudes and expectations regarding health and illness behaviors; differences between client and nurse that can impede positive change.
Fear	Fear of failure and fear of the unknown especially block change.
Habits	Routine, “set” behaviors are often hard to change.
Satisfaction with status quo	Seeing only advantages to the present system can blind one to the possible need for change. Satisfaction with the way things are now reinforces resistance to change.
Secondary gains (outcomes other than alleviation of anxiety)	Benefits or payoffs of the sick role (e.g., gaining attention and sympathy, avoiding responsibilities, getting financial compensation or reward) often are so desirable that the client has little incentive to change.
Threats to satisfying basic needs	Change may be perceived as a threat to self-esteem, security, or survival.
Unrealistic goals	Set up the individual for failure in change efforts.

Delmar/Cengage Learning

Overcoming this barrier doesn’t mean embracing every new idea uncritically. It means being willing to suspend judgment long enough to make an informed decision on whether the change is worthwhile. (Alfaro-LeFevre, 2008, p. 32)

Coping with change of any type calls for flexibility, adaptability, and resilience.

NURSE AS CHANGE AGENT

Initiating change is an expectation for professional nurses. Nurses experience stress daily as a result of changes within their immediate work environment as well as changes in the entire health care delivery system. Uncertainty about the

future of health care is very distressful to some nurses. Others see opportunity for positive change in the future.

In bringing about change to promote positive adaptation, the nurse serves as a **change agent** (a person who intentionally initiates and creates change). True change agents constantly seek ways to make improvements. They use critical thinking skills to develop creative, innovative solutions. Critical thinking is also required to determine the outcomes of change. Evaluating the effects of change is key to bringing about positive change.

To be most effective, change should be planned and directed by people who are **proactive** (initiating change rather than responding to change imposed by others). Proactive individuals assume responsibility for their own lives. On the other hand, a reactive person responds only to externally imposed change. Proactive nurses are change agents who affect the entire health care system as well as individual clients.

Change agents keep the change process moving toward a positive outcome. As an advocate for change, the nurse empowers the client to initiate change in order to adapt more successfully; client education is a powerful tool for initiating change. Teaching a client about a disease process, a treatment modality, or a lifestyle alteration provides the client with an opportunity to change. In fact, learning results in behavioral changes.

ASSESSMENT

When caring for an anxious client, the nurse must first determine the client’s perception of the situation. This determination is done by directly asking for the client’s input and carefully listening to the client’s response. Because the nurse’s nonverbal behavior can affect the client’s anxiety level, nurses must be aware of their own body language. Anxiety is a subjective experience; thus, it cannot be directly observed. Therefore, the nurse must look for the signs indicative of anxiety (previously discussed in Table 23-2).

A thorough assessment of stress and anxiety levels includes eliciting client input to evaluate the following factors:

- Patterns of stressors
- Typical responses to stressful situations
- Cause-and-effect relationships between stressors and thoughts, feelings, and behaviors
- Past history of successful coping mechanisms

Assessing the client’s coping abilities can be done in various ways. For example, use open-ended questions to determine previously used coping mechanisms. Some sample questions are:

- “What is the problem?”
- “What have you tried before?”
- “How well did it work?”
- “Who is available to help you?”

Identification of the client’s coping abilities assists in establishing appropriate nursing diagnoses and developing an

effective plan of care. Assessment, which relies heavily on the nurse's observation and listening skills, provides the data necessary for formulating nursing diagnoses.

NURSING DIAGNOSIS

There are several nursing diagnoses that may apply to clients experiencing anxiety. See Table 23-9, on page 451, for selected diagnoses and their defining characteristics and related factors. In addition to the four diagnoses listed in Table 23-9, the following North American Nursing Diagnosis Association International (2009) diagnoses may also be appropriate for anxious clients.

- *Impaired adjustment*
- *Ineffective role performance*
- *Disturbed thought processes*
- *Ineffective coping*
- *Fear*
- *Posttrauma syndrome*
- *Impaired social interaction*
- *Spiritual distress*

OUTCOME IDENTIFICATION AND PLANNING

Client involvement in planning care is essential because helping clients learn to cope successfully is part of the empowerment process. Planning means exploring with the client self-responsibility issues. Here are some issues to consider when planning care for an anxious client. The client:

- Identifies situations that increase stress and anxiety levels.
- Verbalizes a plan to decrease effects of common stressors.
- Differentiates positive and negative stressors in his or her life.
- Classifies stressors into categories of those that can be eliminated, can be controlled, or cannot be controlled directly by himself or herself.
- Demonstrates the accurate use of selected stress management exercises (e.g., progressive muscle relaxation, guided imagery, thought stopping).
- Verbalizes a plan for stress management, including necessary lifestyle modifications.

IMPLEMENTATION

Teaching, a major nursing intervention for managing stress, is inherent in holistic nursing practice. Stress management approaches can be taught to clients of every age and developmental stage in all health care settings: acute care (inpatient and outpatient), long-term care, and the home.

Teaching clients to reduce their own levels of stress is a major step in promoting self-care; client education provides clients with options. Clients who have a thorough understanding of their options can make informed decisions about necessary lifestyle changes (see Figure 23-5). Following is a

FIGURE 23-5 By discussing options for care with this client, the nurse is providing him with the information he needs to plan effective lifestyle changes. What methods can the nurse use to assess whether the client fully understands the information?

DELMAR/CENGAGE LEARNING

discussion of some of the many interventions that can be used with anxious clients.

MEETING BASIC NEEDS

There is a close relationship between basic physiological needs and stress. Anything that interferes with the satisfaction of basic needs evokes the stress response and attendant anxiety. Clients who are cold, hungry, or in pain have higher anxiety levels than those who are comfortable. When anxiety levels increase, so does the perception of pain. Nurses who empower clients to meet basic needs are building the foundation for a less stressful, more caring treatment process. By reducing anxiety, the nurse is improving the client's healing potential.

ENVIRONMENTAL STRATEGIES

Because an individual's immediate environment can influence stress levels, it is important for the nurse to decrease environmental stimuli that may contribute to anxiety. Some specific ways to limit environmental stimuli are:

- Close the door to the client's room.
- Turn off the television.
- Lower the tone of the telephone ringer or take the phone off the hook if feasible.
- Turn off the lights or close the blinds.
- Limit the number of visitors (unless isolation increases the client's anxiety).
- Decrease environmental clutter.
- Personalize the environment.

VERBALIZATION

Encouraging clients to express their feelings is especially valuable in stress reduction. Freud (1959) used the term **catharsis** to describe the process of talking out one's feelings. People instinctively know the value of "getting things off their chest" through verbalization. Verbalization promotes

Text not available due to copyright restrictions

relaxation primarily in two ways. First, when a feeling is described, it becomes *real*. Once the problem is identified, the person can begin to deal effectively with it. Also, the actual activity of talking uses energy and, therefore, reduces anxiety.

INVOLVEMENT OF FAMILY AND SIGNIFICANT OTHERS

The client's developmental stage influences the type of intervention for stress management. Children and adolescents have varying coping skills; children of all ages rely on their parents to some degree for security and support. It is important to include the entire family in the care of the client whenever possible (see Figure 23-6). Such an approach is useful in decreasing the stress levels of everyone involved because families provide essential support for clients.

Family members who are extremely anxious often have a negative impact on the client's health status. Therefore, nurses often need to help family members relax; one way to accomplish this is by providing explanations and information. Thus, it is often necessary for nurses to teach stress management techniques to the client's family.

STRESS MANAGEMENT

There are a variety of stress management techniques that can easily be taught to clients and significant others. Many of these techniques are considered to be complementary (integrative) modalities as they are used in conjunction with traditional medical treatment methods (i.e., medication, radiation therapy). Some of the most frequently used approaches for managing stress are discussed in the following text.

Exercise

Physical exercise is a powerful way to reduce anxiety and can be used by clients of all ages and with varying physical

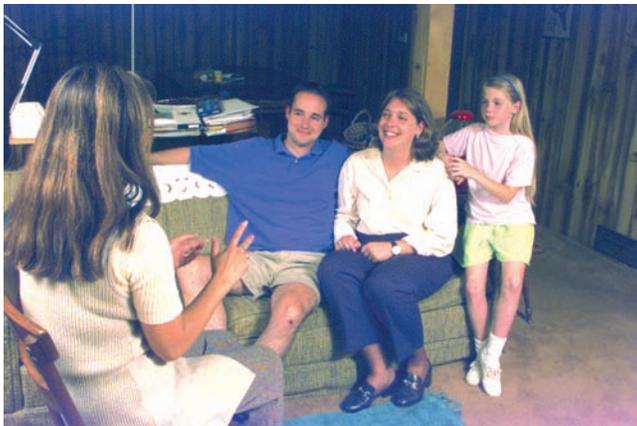

FIGURE 23-6 Nurses can encourage the interaction of clients with family members and significant others in various health care settings. This involvement is helpful in easing the client's anxiety and can also serve as a method through which family members are kept informed about the client's care. DELMAR/CENGAGE

LEARNING

abilities; see Figure 23-7. Client teaching should emphasize the need for incorporating exercise into one's lifestyle (see the accompanying display, on page 453, on establishing an exercise program). In other words, if exercise is to reduce anxiety, it must be done on an ongoing and regular basis. The physiological benefits of regular exercise are shown in Table 23-10 on page 453.

Lack of physical exercise contributes to obesity, which leads to many health problems. Approximately 34% of adults in the United States are obese; for children and adolescents, the obesity rate is 17% (Centers for Disease Control and Prevention, 2008). People who are overweight or obese are at higher risk for developing hypertension and diabetes than are people of normal weight. Sedentary people are at greater risk for developing conditions associated with obesity.

In addition to the physical benefits, individuals who exercise regularly also experience psychological benefits, such as the following:

- Enhanced feelings of well-being
- Improved concentration and memory
- Reduced depression
- Reduced insomnia
- Reduced dependence on external stimulants or relaxants
- Increased self-esteem
- Sense of self-control over anxiety

FIGURE 23-7 Exercise provides physiological and psychological benefits to individuals of all ages with varying degrees of functional abilities. Notice that the individuals in this figure are also experiencing socialization during the physical activity. DELMAR/CENGAGE

LEARNING

TABLE 23-10 Physiological Benefits of Exercise

EFFECT OF EXERCISE	BENEFIT
Promotes metabolism of adrenalin and thyroxine	<ul style="list-style-type: none"> Decreased amounts of these substances in the bloodstream minimize autonomic arousal and hypervigilance.
Reduces musculoskeletal tension	<ul style="list-style-type: none"> Reduction of the tension in muscles reduces feelings of being tense and “uptight.”

Improves elimination (through lungs, skin, bowels)	<ul style="list-style-type: none"> Reduces buildup of toxins in the body.

Data from Keegan, L. (2008). Nutrition, exercise, and movement. In B. M. Dossey & L. Keegan (Eds.), *Holistic nursing: A handbook for practice* (5th ed.). Boston: Jones & Bartlett; Rentfro, A. R. (2006). Health promotion and the individual. In C. L., Edelman & C. L., Mandle (Eds.), *Health promotion throughout the lifespan* (6th ed.). St. Louis, MO: Mosby.

Relaxation Techniques

There are several approaches that help individuals relax. See Chapter 31 for a discussion of complementary and alternative modalities (e.g., aromatherapy, herbals, music, humor) that promote relaxation. A discussion of some specific relaxation techniques that are easily learned and can be effective for a variety of stressors follows.

GUIDELINES FOR ESTABLISHING AN EXERCISE PROGRAM

- Explore the availability of different exercise programs.
- Consult with a health care provider about the safety of a specific exercise program.
- Set realistic goals.
- Plan a routine, and allow for a warm-up and cool-down period using stretch exercises.
- Engage in activity that increases heart rate for a period of time and is followed by a cool-down period.

PROGRESSIVE MUSCLE RELAXATION *Progressive muscle relaxation* (PMR) is a method of inducing relaxation by tensing and releasing various muscle groups. For example, the individual tightens the hands into a fist, holds the tension for a few seconds, then slowly relaxes the fingers and hands, paying particular attention to the different sensations of tension and relaxation (see Figure 23-8). This tense-release action is applied to all muscle groups of the body. PMR is especially helpful in promoting sleep. PMR is a technique that can successfully be taught to clients for use in any health care setting, including the home (see the Client Teaching Checklist on page 454).

GUIDED IMAGERY Another technique for helping clients manage stress successfully is *guided imagery*, a process in which the person uses all the senses to experience the sensation of relaxation. During guided imagery, the client is

FIGURE 23-8 This nurse is demonstrating the technique of progressive muscle relaxation in a client education program. How does instruction in this method enhance the self-responsibility that clients need to develop in order to manage their stress? DELMAR/CENGAGE LEARNING

CLIENT TEACHING CHECKLIST

Progressive Muscle Relaxation

After explaining the purpose and process of progressive muscle relaxation (PMR), instruct the client to:

1. Assume a comfortable position in a quiet environment.
2. Close eyes and keep them closed until the exercise is completed.
3. Inhale deeply to a count of 4.
4. Hold breath for a count of 4.
5. Exhale to a count of 4.
6. Continue to breathe slowly and deeply.
7. Tense both feet until muscle tension is felt. Caution the client to tighten the muscles only until the muscles are tensed, not to the point of pain. Hold a gentle state of tension in both feet for a count of 3.
NOTE: If muscle cramps occur, stop the procedure and gently massage the affected area. Then begin the cycle of slight muscle tension and relaxation again.
8. Slowly release the tension from the feet.
9. Fully experience the difference between tension and relaxation.
10. Repeat Steps 3–6.

Repeat the above sequence with all the muscle groups to experience relaxation throughout your body. To be effective, this procedure requires approximately 20 to 30 minutes. Like all other relaxation exercises, PMR is most effective with repetition.

directed to concentrate on a pleasant scene or image in order to become more relaxed. In many situations, music is a helpful adjunct to guided imagery (see Figure 23-9). The Client Teaching Checklist, on page 455, describes the steps

FIGURE 23-9 To help relieve this client's stress, the nurse is encouraging the client to listen to music. In your opinion, are there any situations in which this type of intervention may be inappropriate? DELMAR/CENGAGE LEARNING

THOUGHT STOPPING: A COGNITIVE REFRAMING TECHNIQUE

- Listen to self-talk (thoughts).
- Recognize when the self-talk is negative.
- When a negative thought is detected, do something physical to stop the train of thought. For example, clap your hands or snap a rubber band on your wrist. Tell yourself, "Stop!"
- Replace the negative thought with one that is both positive and realistic.

Like all other relaxation exercises, thought stopping becomes more effective with repetition.

involved in using this technique. See Chapter 31 for further discussion of guided imagery. Note that imagery is not recommended for individuals experiencing emotional instability.

COGNITIVE REFRAMING AND THOUGHT STOPPING

Cognitive reframing is a technique based on a theory proposed by Aaron Beck (1976), who stated that a person's emotional response is determined by the meaning attached to an event. For example, if an event is perceived to be threatening, the client is likely to feel anxious. If the interpretation of the event can be modified, the client will be less anxious. Reframing is a technique used to alter one's perceptions and interpretations by changing one's thoughts. The accompanying display describes the thought-stopping process, a cognitive behavioral technique.

CRISIS INTERVENTION

Some clients will be in an acute crisis state and require **crisis intervention**, a specific technique that helps clients regain equilibrium. This approach views clients as having the ability to control their own lives. The five steps of crisis intervention are illustrated in Figure 23-10 on page 455.

The client is an active participant in the process of resolving the crisis in order to restore equilibrium. If the client is unable to participate in problem solving (e.g., because of delayed developmental stage or altered mental status), then crisis intervention should not be attempted. However, the family can be approached with the crisis intervention method.

Sometimes clients need more assistance than the nurse is able to provide. Recognition of such situations calls for prompt consultation with and, sometimes, referral to other health care providers, such as:

- Psychiatric clinical nurse specialists
- Nurse psychotherapists

CLIENT TEACHING CHECKLIST

Guided Imagery

After explaining the purpose and process of guided imagery, instruct the client to:

- Assume a comfortable position in a quiet environment.
- Close eyes and keep them closed until the exercise is completed.
- Inhale deeply to a count of 4.
- Hold breath for a count of 4.
- Exhale to a count of 4.
- Continue to breathe slowly and deeply.
- Think of a favorite place and prepare to take an imaginary journey there. Select a place in which you are relaxed and at peace.
- Picture in your mind's eye your favorite place. Look around you. See all the colors, the light and shadows. Look at all the pleasant sights.
- Listen to all the sounds. Pay attention to what you hear.
- Feel all the physical sensations . . . the temperature . . . the textures . . . the movement of the air.
- As you take in a deep breath, smell the aromas of your favorite place.
- Taste the foods and drinks you usually consume in your favorite place. Savor each taste fully.
- Focus all your attention totally on your favorite place.
- Inhale deeply to a count of 4.
- Hold breath for a count of 4.
- Exhale to a count of 4.
- Resume your usual breathing pattern.
- Slowly open your eyes and stretch, if desired.

This procedure works best when all five senses are used. Like all other relaxation exercises, guided imagery becomes more effective with repetition. This technique (like all imagery exercises) is not recommended for individuals with emotional instability.

EVALUATION

Evaluating the effectiveness of clients' coping abilities is an ongoing comprehensive process that must include client input. It is imperative that the nurse evaluate client outcomes as well as the process of delivering nursing care.

In addition to eliciting verbal input from the client and significant others, nurses also collect evaluation data by observation of client behavior. See the accompanying Nursing

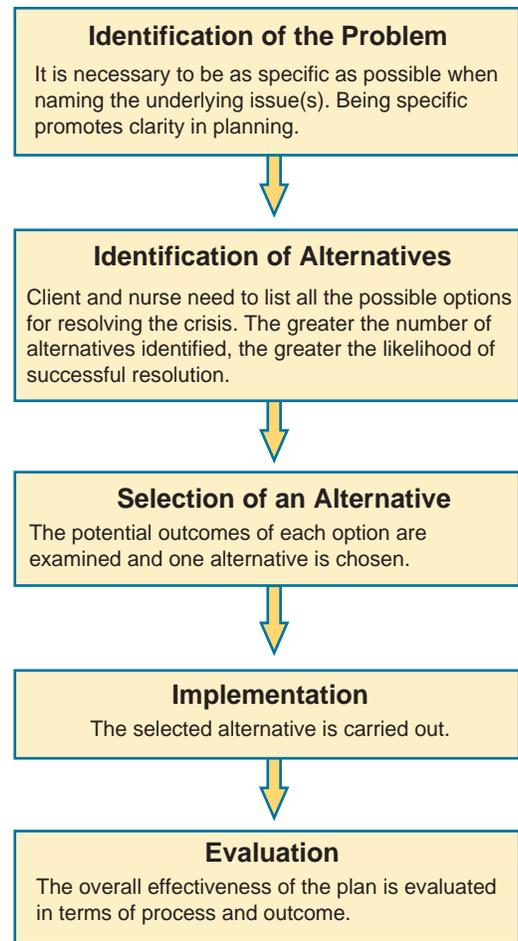

FIGURE 23-10 Steps of Crisis Intervention DELMAR/CENGAGE LEARNING

Process Highlight for some questions that the nurse may consider in evaluating the effectiveness of interventions to reduce anxiety.

NURSING PROCESS HIGHLIGHT

Evaluation

Evaluating Client Response to Relaxation Techniques

Consider these questions when evaluating the effectiveness of anxiety-reducing interventions:

- Does the client exhibit decreased fidgeting and pacing?
- Is the client's tone of voice calm?
- Is the client's problem-solving ability unimpaired?
- Is the ability to concentrate intact?
- Are the vital signs within normal limits (client's baseline)?

PERSONAL STRESS MANAGEMENT APPROACHES FOR THE NURSE

There are many stressors inherent in nursing. Therefore, nurses must learn effective coping skills. Two major reasons nurses must cope successfully with stress are to maintain their own wellness and to model health-promoting behaviors to others. In order to help clients learn to manage stress, nurses must first be able to manage their own stress. “Before nurses can care for clients, they must first learn to value and care for themselves” (Fontaine, 2004, p. 18).

Caring for one’s self includes the following activities:

- Taking time out for oneself
- Using effective communication skills with coworkers, family, and significant others
- Managing conflict effectively (intrapersonal and interpersonal)

See the accompanying Spotlight On display on page 457.

Here are some complementary and alternative methods that nurses can use to promote self-care:

- Imagery
- PMR
- Prayer
- Humor
- Music
- Communion with nature
- Journaling
- Meditation

NURSING BURNOUT

High stress levels among nurses are associated with **burnout**, a state of physical and emotional exhaustion that occurs when caregivers deplete their adaptive energy. Nurses who have experienced such an overwhelming degree of stress tend to treat clients in depersonalizing ways. Such nurses also lack feelings of personal accomplishment. Burnout exacts a high price not only on individual nurses themselves but also on the profession. Highly qualified professionals leave nursing and, as a result, the quality of care declines. “Creating a healthy work environment for nursing practice is crucial to maintain an adequate nursing workforce; the stressful nature of the profession often leads to burnout, disability, and high absenteeism, and ultimately contributes to the shortage of nursing” (Shirley, 2006, p. 256).

Several work-related factors can contribute to the development of nursing burnout:

- Cost-containment measures
- Nursing shortages
- Innate job-related stress (for example, the stress evoked by caring for dying people)
- Workload
- Interpersonal conflict in the work environment
- Rapid restructuring of health care organizations (e.g., mergers, partnerships)

In order to avoid developing the classic symptoms of burnout—absenteeism, poor morale, and illness—nurses need to nurture themselves. Burnout prevention and recovery depend on stress management.

There are many strategies that nurses can use to help manage professional and personal stress (see Table 23-11). The following Nursing Checklist, on page 457, provides some other strategies that are also helpful in managing professional stress. See the Uncovering the Evidence display on page 457. Guidelines that are helpful in changing from a negative to a positive outlook include these points:

- Expect to be successful.
- Remember the power of self-fulfilling prophecies and deliberately focus on the positive.

TABLE 23-11 Strategies for Coping with Professional Stress

STRATEGY	EXPLANATION
Use time management methods.	Encourages recognition of your own needs as priorities.
Focus on accomplishments instead of uncompleted tasks.	Being focused on unfinished business increases anxiety; paying attention to successes boosts self-esteem.
Practice slow, focused breathing.	Alleviates muscle tension by increasing the amount of oxygenated blood. Consciously thinking about breathing serves as a diversionary tactic.
Do not assume personal responsibility for others’ behaviors or problems.	Encourages avoidance of assuming a rescuer role.
Know your own limits.	Clarifies expectations, strengths, and limitations. Learn to differentiate what’s really important. Know when a problem is beyond your control.
Whenever possible, distance yourself from stressors that have a negative impact.	Avoids exposure to needless stress and subsequent draining of adaptive resources.
Identify and change the stressors that you can directly influence.	Increases your sense of personal power; avoids needless expenditure of energy.
Vary tasks between physical and mental activities.	Helps restore a sense of balance; conserves energy by reducing fatigue.

Delmar/Cengage Learning

NURSINGCHECKLIST

Managing Professional Stress

- Develop and maintain active support systems, both at work and away from work. Having friends who are not health care providers helps maintain a sense of balance and separateness between personal and professional domains.
- Develop decision-making skills. For example, break large tasks down into small, realistic, achievable objectives. This strategy avoids your becoming overwhelmed by the seemingly impossible task before you.
- Avoid consumption of noxious substances. Practice a substance-free lifestyle to manage stress well. Do not depend on these unhealthy behaviors as avenues to relaxation: smoking, overeating, drinking alcohol and caffeine.
- Nourish your body with a healthy diet and adequate amounts of sleep and rest balanced with activity and exercise. Care for yourself as you would for clients.
- Maintain a sense of humor while you work. Humor helps a person maintain a positive outlook; therefore, it can be used to reframe situations to reduce distress (see Figure 23-11).

FIGURE 23-11 Humor helps nurses manage the stress created by the nature and intensity of their work. What can you do to help your fellow nursing students cope with the anxiety that is inherent in this stage of your academic experience? DELMAR/CENGAGE LEARNING

UNCOVERING THE

Evidence

TITLE OF STUDY

“Relationships among the Nurse Work Environment, Self-Nurturance and Life Satisfaction”

AUTHORS

M. A. Nemcek and G. D. James

PURPOSES

(1) To determine the relationship among self-nurturance, perceived Magnet features, and life satisfaction and (2) to evaluate the predictive effects of self-nurturance and Magnet features on life satisfaction.

METHODS

This descriptive, correlational study is based on a survey of a convenience sample of 310 registered nurses (RNs).

FINDINGS

Self-nurturing RNs were more satisfied with life and perceived that more Magnet features were present in the workplace.

IMPLICATIONS

Higher levels of perceived Magnet features and frequent self-nurturance choices have a positive effect on RNs' life satisfaction. Increased life satisfaction reduces job dissatisfaction and improves retention rates.

Nemcek, M. A., & James, G. D. (2007). Relationships among the nurse work environment, self-nurturance and life satisfaction. *Journal of Advanced Nursing*, 59(3), 240–247.

- Let go of the need to be perfect.
- Listen to your self-talk.
- Encourage the use of appropriate humor in the workplace.

Nurses who cultivate the hardiness factor will likely be resilient to stress. Kobasa (1979) originated the concept of

SPOTLIGHT ON...

Caring

Self-Nurturers

Society often labels people who take care of themselves as selfish. Do you agree? Why or why not? Consider how taking care of yourself can help you be a better care provider to others. What are some specific things you can do now to take better care of yourself?

hardiness in the late 1970s. Hardiness consists of a set of attitudes, beliefs, and behaviors that result in individuals being more resilient (or hardy) to the negative effects of stress. There are three components to stress hardiness:

- *Commitment.* Becoming involved in what one is doing
- *Challenge.* Perceiving change as an opportunity for growth rather than an obstacle or threat
- *Control.* Believing that one is influential in directing what happens to oneself rather than feeling helpless and victimized

According to studies (Kobasa, 1979; Kobasa, Maddi, & Kahn, 1982), individuals who have higher degrees of hardiness are healthier than are individuals with low degrees of hardiness. Such people develop fewer illnesses when they experience multiple stressors.

Many nurses need to relearn the value of play and to know when to stop working. Nursing students, who spend many hours a week working and studying, may need to schedule some time for play as it is a method to manage stress and, thereby, to become a more effective care provider.

NURSING CARE PLAN

The Client Experiencing Anxiety

CASE PRESENTATION

Kathryn Markham is a 38-year-old female who is seeking treatment in the emergency department of a metropolitan hospital. She is tearful, pacing, and wringing her hands. She is complaining of severe chest pain, a pounding headache, and back pain. She is sweating profusely and exhibits fine hand tremors. Her blood pressure and pulse are elevated, and her respirations are rapid and shallow. She says that she hasn't slept well since her husband left her 3 months ago. She states that "I'm afraid I'm losing my mind! My heart is racing and I can't sit still. Help me! I feel like I'm going to die."

ASSESSMENT

- Autonomic hyperactivity (rapid pulse, elevated blood pressure)
- Verbalized feelings of apprehension and uneasiness
- Restlessness

NURSING DIAGNOSIS

Anxiety related to feelings of powerlessness and lifestyle change

NOC: Anxiety self-control

NIC: Coping enhancement

EXPECTED OUTCOMES

The client will:

1. Identify effective coping mechanisms.
2. Report that anxiety is reduced to a manageable level.
3. Demonstrate relaxation skills.

INTERVENTIONS/RATIONALES

1. Establish a trusting relationship. The client may perceive the nurse or emergency department as a threat, and thus anxiety will increase.
2. Have the client identify and describe physical and emotional feelings. The first step in coping with anxiety is to recognize the anxiety and become aware of feelings in order to link emotions with maladaptive coping responses.
3. Help the client to relate cause-and-effect relationships between stressors and anxiety. Increases the client's sense of control and power over the situation.
4. Encourage the client to use coping mechanisms that have previously been successful. Increases confidence in own abilities to cope.

(Continues)

NURSING CARE PLAN (Continued)

5. Teach the client relaxation techniques (such as imagery and meditation). The relaxation response is the opposite of the stress response and, therefore, counters the physiological effects of the stress response. The relaxation response leads to lowered blood pressure, decreased heart rate, and deeper and slower respirations.
6. Administer antianxiety medication as indicated. Antianxiety agents provide relief from the immobilizing effects of anxiety. **NOTE:** This is a collaborative dependent nursing action.

EVALUATION

The client is visibly relaxed. Vital signs are within normal limits. The client verbalizes that she is calmer and no longer afraid.

KEY CONCEPTS

- Stress is an individual's physiological response to stimuli.
- Individuals who experience prolonged periods of stress are at risk for developing stress-related diseases.
- Anxiety is the psychological response to a threat to the health and well-being of an individual and activates the stress response.
- An individual seeks equilibrium through the process of adaptation. When adaptation is effective, homeostasis (the body's self-regulation of physiological processes) is maintained.
- Many factors, such as physiological, psychological, cognitive, or environmental changes, contribute to stress.
- The general adaptation syndrome (GAS), the physiological response to stress, consists of three stages: alarm, resistance, and exhaustion. The GAS is the same whether the stressor is actual or imagined, present or potential.
- Illness and hospitalization are major stressors for individuals and their families. To alleviate the stress of hospitalization, nursing interventions should reduce the client's feelings of unfamiliarity and loss of control.
- Change can be perceived as stressful because of a fear of failure, a threat to security, a potential for loss of self-esteem, and the need to develop new paradigms.
- Nurses act as change agents by consciously empowering the client through education to initiate change.
- Nursing interventions that promote positive adaptation to stress are the empowerment of clients to meet basic needs; the minimization of environmental stimuli; the encouragement of verbalization of feelings; the inclusion of significant others into client care; and the use of various relaxation techniques, such as progressive muscle relaxation (PMR) and guided imagery.
- Stress management techniques can be used by both clients and nurses to facilitate effective coping.
- The thought-stopping technique, a cognitive approach to stress management, involves removing or reducing anxiety by changing negative thoughts to positive and realistic thoughts.
- Burnout occurs when the nurse is overwhelmed by stress. As a result, the nurse experiences physical, emotional, and behavioral dysfunction, including decreased productivity.
- Elements of a stress management plan for professional nurses consist of maintaining support systems, developing time management and decision-making skills, identifying and changing stressors that can be managed, and knowing personal limits.

REVIEW QUESTIONS

1. When assessing a client for anxiety, which of the following indicators would the nurse look for? Select all that apply.
 - a. Decreased blood pressure
 - b. Dry skin
 - c. Increased pulse rate
 - d. Increased respiratory rate
 - e. Rapid, shallow breathing
 - f. Shortness of breath verbalized by client

2. A medical-surgical unit has just reorganized its scheduling system. Members of the nursing staff have become comfortable with the new system and state they are pleased with the new self-scheduling method. According to Lewin's theory, the nursing staff is best defined as being in which phase of change?
 - a. Moving
 - b. Refreezing
 - c. Status quo
 - d. Unfreezing
3. Which of the following statements accurately describes a crisis situation?
 - a. A crisis can be successfully resolved without intervention from others.
 - b. Crisis has a slow, insidious onset.
 - c. Prompt intervention is necessary to prevent an extended period of crisis.
 - d. The client perceives the event as overwhelming.
4. Which of the following is an example of suppression used by a nursing student?
 - a. Arguing with a roommate instead of expressing concerns to the instructor
 - b. Deciding to go to bed early the night before the exam instead of cramming
 - c. Stating that poor performance was a result of poorly written test questions
 - d. Stating that the instructor was "out to get me"
5. Which of the following is an example of a situational crisis?
 - a. Being a victim of a school shooting
 - b. Hospitalization following an automobile accident
 - c. Losing one's home due to a hurricane
 - d. Sadness experienced by a woman during menopause
6. A nurse is planning to teach a client about safe medication usage. Which of the following activities should the nurse do first?
 - a. Administer medication to help the client relax.
 - b. Assess the client's anxiety level.
 - c. Determine the client's need for information.
 - d. Develop a specific teaching plan.
7. A unit nurse manager wants to implement a new system for making staff assignments. When planning the change process, which of the following should the nurse expect?
 - a. Change efforts should be stopped if the staff members verbalize negative comments.
 - b. Staff morale could be permanently damaged by the change.
 - c. Staff may resist the change.
 - d. Staff will quickly embrace the change.
8. A mother brings her 4-year-old son to the clinic for an annual checkup. The mother tells the nurse that the child began sucking his thumb 2 months ago when his little brother was born. The nurse recognizes the child's behavior as an example of which of the following defense mechanisms?
 - a. Denial
 - b. Reaction formation
 - c. Regression
 - d. Symbolization
9. Which of the following environmental strategies can be performed by the nurse to reduce client anxiety?
 - a. Assign the client to a room across from the nurses' station.
 - b. Keep the door to the client's room open.
 - c. Keep the room brightly lit.
 - d. Remove clutter from the room.
10. A nurse has been teaching a client the thought-stopping technique for stress reduction. Which of the following client statements indicates a need for further teaching?
 - a. "I need to pay attention to what I'm thinking."
 - b. "I should tense and relax my muscles whenever I feel anxious."
 - c. "I will try to replace my negative thoughts with positive ones."
 - d. "This technique needs to be repeated several times a day."

CHAPTER 24

Spirituality

COMPETENCIES

1. Describe the characteristics of spirituality.
2. Describe the connection between health and spiritual well-being.
3. Describe ways in which nurses help clients regain a sense of balance and harmony.
4. Discuss application of the nursing process as it relates to client spirituality.

KEY TERMS

faith

hope

mindfulness

religion

spiritual distress

spiritual well-being

spirituality

Throughout history, people have dealt with pain, illness, and healing in spiritual ways. Ancient Babylonians and Egyptians performed elaborate healing rituals in temples; the ancient Greeks used dream-inducing methods to treat various disorders. In many primitive cultures, the roles of physician, psychiatrist, and priest were combined into one.

Nurses are entrusted with the holistic care of clients, that is, caring for the soul and spirit as well as for the body. The holistic framework challenges nurses to assess and respond to the physical, mental, emotional, and spiritual dimensions of each client.

SPIRITUALITY DEFINED

Spirituality is multidimensional in that it refers to one's relationship with one's self, a sense of connection with others, and a relationship with a higher power or divine source. Spirituality assists people in determining the sense of meaning or purpose in their lives. It is an integral component, or core, of one's being.

The classic work of Frankl, *Man's Search for Meaning* (1985), emphasized that the need for meaning is the primary motivating force in a person's life. By asking questions such as "what does this mean?" and "why me?" a person seeks to find meaning. According to Frankl, people find meaningfulness by what they take from the world, what they give to the world, and the attitude they choose for themselves in response to suffering. See the Respecting Our Differences display.

Spiritual Questions

Questions are powerful tools in shaping our thoughts, feelings, and behaviors. Allow yourself some silence in which to ponder your answers to the following questions:

- What are the questions that I live with?
- In what ways do I ask these questions?
- How do I seek responses to these questions?
- What makes life meaningful to me?
- What sense do I make of pain and suffering?
- Where do I see beauty in the world?

Be open to whatever arises within as you consider these questions. Know that your answers to these questions are strongly influenced by your cultural heritage.

The challenge that nurses face today is emphasizing the importance of spirituality in a health care system affected by advancing technology, ongoing organizational change, and limited resources. According to Pipe and colleagues,

Hospitalized patients may be at risk for experiencing a sense of fear and anxiety. Today's shorter hospital stays make it more challenging for the patient and health care team to form a meaningful relationship. This transpersonal connection may be even more important as the health care environment becomes more complex and efficiency focused. (2008, p. 248)

In order for nurses to meet this challenge, they must first begin their own healing journeys, caring for the soul and spirit as well as the body. Promoting **spiritual well-being** (a sense of connectedness between self, others, nature, and a higher power that can be accessed through prayer or other means) is a goal of holistic nursing. "Gaining an understanding of patients' expectations regarding spiritual care is essential to entering into a truly holistic, caring relationship with patients" (Davis, 2006, p. 1).

Healing, **faith** (a belief in and relationship with a higher power), spirituality, religiosity, and **hope** (a factor that enables one to cope with distressing events) are interrelated. When individuals deal with a life-threatening illness, serious medical condition, or loss, they often rely on spiritual support.

Spirituality is *not* the same as **religion**, which refers to a set of beliefs and practices associated with a particular church, synagogue, mosque, or other formal organized group. Spirituality is a personal, individualized set of beliefs and practices that are not affiliated with an institution or sect. See Table 24-1 for a comparison of religion and spirituality. Table 24-2 on page 465 describes the characteristics of spirituality.

Factors that affect spirituality include cultural context, family, developmental stage, and health status. Families influence a person's development of spiritual beliefs. Nurses

TABLE 24-2 Characteristics of Spirituality

CHARACTERISTIC	DESCRIPTION
Relationship with self	Knowledge of who one is and one's capabilities
Relationship with others	Caring for others when they need help
	Sharing of self
Harmony with nature	Knowledge of plants and animals
	Preserving nature
	Communing with nature (being outdoors)
Relationship with a higher power	Meditation
	Prayer
	Participating in religious services
	Performing religious rituals

Data from Burkhardt, M. A., & Nagai-Jacobson, M. G. (2008). Transcultural and spiritual issues. In M. A. Burkhardt & A. K. Nathaniel (Eds.), *Ethics & issues in contemporary nursing* (3rd ed.). Clifton Park, NY: Delmar/Cengage Learning.

understand the importance of families in providing spiritual support and encourage the provision of that support. Spirituality evolves throughout one's life. See Chapter 18 for a discussion of the development of spirituality related to Fowler's stages of faith.

Health status can also have an impact on spiritual beliefs and vice versa. For example, when they are seriously ill, many people turn to religion for support. On the other hand, serious illness may cause some people to question their beliefs. In some cases, a person's belief system may interfere with the prescribed medical treatment regimen. For example, a person's religious or spiritual beliefs may require fasting. Acceptance or rejection of prescribed therapies may be rooted in spiritual beliefs (see Figure 24-1). Table 24-3 on page 466 presents an overview of the practices of selected major world religions that can relate to issues such as diet, birth, death, and health care.

Individuals with spiritually satisfying lives are those people who have a source of inner strength. Spiritual beliefs can enhance self-esteem and help protect individuals from stress. Such beliefs help people adjust to stressful events such as illness, injury, and loss. There are several health-related benefits of engaging in spiritual practices, some of which include reduced stress levels, decreased blood pressure, lower cholesterol levels, and improved sleep patterns. According to several studies (Dew, Daniel, Goldston, & Koenig, 2008;

FIGURE 24-1 Rituals such as prayer may be an integral part of some individuals' expressions of spirituality. DELMAR CENGAGE LEARNING

Koenig, 2007; Newlin, Melkus, Tappen, Chyun, & Koenig, 2008; Reyes-Ortiz et al., 2008), religiousness and spirituality predicted fewer physical symptoms and better cognitive function in people experiencing medical and mental disorders.

NURSING PROCESS AND SPIRITUALITY

Spiritual care is an essential component of holistic care. The International Council of Nursing (2006) ethical code calls for nurses to promote an environment that respects the client's spiritual beliefs. Spiritual care, in addition to being an ethical duty of nurses, is now a requirement of some accreditation organizations. The right of clients to receive care that respects spiritual values was added to the Joint Commission's accreditation standards in 1998. In response to these criteria, some hospitals have revised policies to reflect the staff's duty to minister to persons of diverse cultural and religious backgrounds.

ASSESSMENT

Assessment primarily consists of observation and communication, which is based on a therapeutic nurse-client relationship. Some clients may be hesitant or embarrassed to discuss their spiritual beliefs. The nurse's presence communicates to the client that it is appropriate for clients to discuss all their concerns and issues. Presence helps establish the nurse-client relationship that is built on trust. As clients develop trust in the nurse, they are more likely to discuss sensitive issues. The use of open-ended questions and indirect questions encourages discussion of spiritual concerns. Hoffert,

(2007). <i>Transcultural nursing: Assessment and intervention</i> (5th ed.). St. Louis, MO: Mosby Elsevier; Hockenberry, M. L., Wilson, D., & Jackson, C. (2006). <i>Wong's nursing care of infants and children</i> (8th ed.). St. Louis, MO: Elsevier Science.</p>				

Henshaw, and Mvududu (2007) suggest the use of these questions: “What gives you strength?” and “Who do you turn to in tough times?” (p. 68). See Table 24-4 on page 470, which provides a tool for assessing clients’ spirituality.

DIAGNOSIS

Nurses must differentiate spiritual well-being from **spiritual distress** in a client. Spiritual distress is the client’s perception that the client’s belief system, or the client’s place within it, is threatened. Following are some ways in which spiritual distress is manifested:

- Expressed anger toward God (e.g., “It’s not fair! Why is God doing this to me?”)
- Inner conflict about one’s beliefs (e.g., “I’m not even sure what the right thing to do is anymore. Things used to be so clear.”)
- Questions about the meaning of life, illness, death (e.g., “I wonder what I’m supposed to learn from all this.”)
- Crying and sighing
- Withdrawn behaviors

- Verbal requests for spiritual assistance (e.g., “Keep me in your prayers.”)

Spirituality helps individuals to find meaning in suffering. Receiving a diagnosis of a terminal condition such as cancer or acquired immunodeficiency syndrome (AIDS) often triggers a spiritual crisis. The North American Nursing Diagnosis Association International (NANDA) has established three diagnoses related to spirituality; see Table 24-5 on page 471.

PLANNING AND OUTCOME IDENTIFICATION

Planning of nursing care is directed at helping clients meet their needs, including spiritual needs.

In order to be healthy and respond appropriately to daily stress, an individual must experience a balance among mind, body, and spirit. The spiritual dimension provides the beliefs that affect the mind-body response to stress. Spiritual beliefs provide one with one’s own uniqueness and

TABLE 24-4 Spiritual Assessment Tool

DIMENSION	QUESTIONS
Meaning and purpose	<ul style="list-style-type: none"> • What gives your life meaning? • Do you have a sense of purpose in your life? • How hopeful are you about getting better?
Inner strengths	<ul style="list-style-type: none"> • What brings you peace and joy? • What do you like about yourself? • What are your life goals? • What do you believe in?
Interconnectedness	<ul style="list-style-type: none"> • Who are the important people in your life? • Do you belong to any groups? • Can you ask others for help when you need it? • Do you participate in any religious activities? • Do you believe in God or a higher power?

creativity, allowing one to listen to the inner voice and respond accordingly. Just as the mind and body must be fed, the spirit must be nourished. Spiritual nourishment may be in the form of prayer, reading, meditation, visualization, massage, music, art, or quiet time alone or in the presence of a loved one. **Mindfulness**, a form of meditation in which one focuses only on the present moment, is one way to heighten an appreciation of spiritual aspects in one's life. It is very difficult for many people to experience mindfulness because they are too busy, have too many things on their minds, or are worrying about the past or anticipating the future. Deliberately slowing down one's thinking helps one to experience an awareness of the present moment. See the accompanying Spotlight On display on page 472.

IMPLEMENTATION

Addressing the spiritual needs of clients often evokes anxiety in nurses. "Nurses who have reviewed their personal beliefs are likely to be more comfortable discussing the spiritual needs of a patient" (Loustalot, 2008, p. 22). However, it is

imperative that nurses use self-awareness to prevent their own feelings from interfering with the fulfillment of clients' needs. The Nursing Checklist on page 472 provides guidelines for working with clients who need spiritual intervention.

Nurses are the professionals who are there to "just listen" and communicate compassion and support. Being there and listening to clients is a demonstration of nursing presence, which communicates caring and compassion. Essential nursing interventions directed at spiritual needs include helping clients to find meaning in their current situations and assisting clients to use their sources of strength.

Instillation of hope helps clients meet their spiritual needs. Hope is necessary for coping with severe stressors, such as illness. "People are partly enabled to endure suffering by maintaining hope in one or both of two ways: i) trusting in a higher being and ii) finding meaning through relationships with a higher being and/or with other people" (Vivat, 2008, p. 859). Spirituality provides a feeling that one is not alone. Nurses must determine the personal meaning of clients' experiences to help bolster spiritual support. The nurse should determine the client's source of hope, which may include the following:

- Relationships with others
- Positive emotions
- Anticipating the future
- Availability of resources

It has been proposed that religious and spiritual interventions could provide support for individuals experiencing chronic diseases, such as cancer and cardiovascular disease (Griffin, Salman, Lee, Seo, & Fitzpatrick, 2008).

Interventions for clients experiencing spiritual distress relate to (1) nursing priorities for assessing contributing factors, (2) assisting people to deal with feelings and the situation, and (3) promoting wellness. Examples of specific interventions include:

- Noting expressions of inability to find meaning in life
- Listening to expressions of anger or alienation from God
- Determining religious or spiritual orientation and influence of beliefs
- Asking how the nurse can be of the most help
- Providing a quiet setting
- Developing a therapeutic relationship that supports free expression of feelings and concerns
- Assisting client in developing goals for dealing with illness and other distressing situations
- Assisting client in identifying spiritual resources and other supports (Burkhardt & Nagai-Jacobson, 2008)

The nurse who takes time to be with clients in a caring way communicates a strength that can promote healing. The nurse's caring manner can act as a catalyst to promote self-healing by restoring a spiritual sense of balance and harmony. Use of meditative techniques helps clients to mentally

TABLE 24-5 Diagnosis Related to Spiritual Needs

DIAGNOSIS	DEFINITION	RELATED FACTORS
Spiritual distress	Impaired ability to experience and integrate meaning and purpose in life through a person's connectedness with self, others, art, music, literature, nature, or a power greater than oneself	<ul style="list-style-type: none"> • Self-alienation • Loneliness or social alienation • Anxiety • Sociocultural deprivation • Death and dying of self or others • Pain • Life change • Chronic illness of self or others
Readiness for enhanced spiritual well-being	Ability to experience and integrate meaning and purpose in life through connectedness with self, others, art, music, literature, nature, or a power greater than oneself	Not identified by NANDA
Risk for spiritual distress	At risk for an impaired ability to experience and integrate meaning and purpose in life through a person's connectedness with self, other persons, art, music, literature, nature, and/or a power greater than oneself	Risk factors: <ul style="list-style-type: none"> • Energy-consuming anxiety • Low self-esteem • Mental illness • Physical illness • Poor relationships • Blocks to self-love • Physical or psychological stress • Substance abuse • Loss of loved one • Natural disasters • Situational losses • Maturational losses • Inability to forgive

Data from North American Nursing Diagnosis Association International (NANDA). (2009). *Nursing Diagnoses—Definitions and Classification 2009–2011* © 2009, 2007, 2005, 2003, 2001, 1998, 1996, 1994 NANDA International. relax, relieve tension, and honor their own intuition. Fostering trust through the demonstration of respect and empathy encourages the client to express feelings and spiritual beliefs. See the Uncovering the Evidence display.

Collaboration

The Joint Commission has criteria regarding spiritual care delivery that health care providers must meet. Clients should be asked if they would like to see their spiritual leader or advisor, with the understanding that not all clients will want to meet with a clergy member. Nurses need to know and use

various resources available for providing spiritual support to clients. Many inpatient facilities have pastoral care departments that conduct formal services, visit and pray with clients, and conduct support groups (e.g., bereavement). Family members are the major spiritual support for some clients. Nurses can also identify colleagues who have more experience in dealing with spiritual concerns and use those individuals as resources.

EVALUATION

Evaluation focuses on client achievement of expected outcomes or objectives and on the efficacy of nursing care

provided. Estes (2010) identifies the following as indicators that the client's spiritual distress has lessened:

- Acceptance of spiritual support from the source with which the client feels most comfortable
- Decrease in restlessness, insomnia, and crying
- Decrease in statements of worthlessness and hopelessness
- Verbalization of satisfaction with spiritual beliefs and the comfort provided by them

SPOTLIGHT ON...

Caring

Spiritual Nourishment

In what ways do you nurture your spiritual self? Think of your favorite "soul food" ingredients, for example, talking with a loved one, experiencing solitude, or enjoying nature.

NURSING CHECKLIST

Providing Spiritual Care

- Listen actively. Avoid using cliches, and take the client's concerns seriously.
- Demonstrate an interested, empathetic response to the client's comments.
- Respect the client's beliefs. For example, allow the client to pray without interruption.
- Provide privacy for the client to perform religious practices or rituals. For example, if the client's religious practice involves chanting, find a location where this can be done.
- Make referrals to clergy when appropriate. Ask the client's permission first to avoid imposing the nurse's own values on the client.

UNCOVERING THE

Evidence

TITLE OF STUDY

"A Prospective Descriptive Study Exploring Hope, Spiritual Well-Being, and Quality of Life in Hospitalized Patients"

AUTHORS

T. B. Pipe, A. Kelly, G. LeBrun, D. Schmidt, P. Aterton, and C. Robinson

PURPOSE

To explore the relationships among hope, spiritual well-being, and quality of life in hospitalized clients across the time points spanning admission, discharge, and 6 weeks after discharge.

METHODS

A prescriptive, longitudinal, descriptive design was used. Selected data elements were collected from reviews of the participants' medical records. Participants responded on three occasions to interviews using standardized surveys that measured hope, spiritual well-being, and quality of life. Open-ended questions were also included pertaining to aspects of care that participants found most meaningful.

FINDINGS

Hope, spiritual well-being, and quality of life were correlated significantly and positively with each other at all three time intervals.

IMPLICATIONS

Clients often rely on nurses to provide psychosocial and spiritual care and comfort. Much of nursing is grounded in the transpersonal relationship that emphasizes caring. Psychosocial needs were associated with length of stay, reinforcing the need to identify these needs early. Findings suggest that nursing care can impact quality of life and length of stay.

Pipe, T. B., Kelly, A., LeBrun, G., Schmidt, D., Atherton, P., & Robinson, C. (2008). A prospective descriptive study exploring hope, spiritual well-being, and quality of life in hospitalized patients. *MEDSURG Nursing, 17*(4), 247–257.

KEY CONCEPTS

- Nurses are entrusted with the holistic care of clients, that is, caring for the soul and spirit as well as for the body.
- Spiritual care is a component of holistic care.
- Spirituality helps one determine a sense of meaning or purpose in one's life.
- Spirituality is not the same as religion, which refers to a set of beliefs and practices associated with a formal organized group.
- Factors affecting spirituality include cultural context, family, developmental stage, and health status.
- Spirituality develops across the life span.

- Nurses must emphasize the importance of spirituality in a health care system affected by advancing technology, ongoing organizational change, and limited resources.
- During assessment, nurses must differentiate spiritual well-being and spiritual distress in a client.
- There are three primary nursing diagnoses related to spirituality: spiritual distress, risk for spiritual distress, and readiness for enhanced spiritual well-being.
- When planning for client care, the nurse seeks to help the client maintain a balance among mind, body, and spirit.
- When implementing spiritually based care, the nurse must listen actively, demonstrate empathy, respect client beliefs, provide privacy, and make referrals to clergy as appropriate.
- Indicators that the client's spiritual distress has lessened are acceptance of spiritual support from others; decreased restlessness, insomnia, and crying; decreased statements of worthlessness and hopelessness; and verbalization of satisfaction with spiritual beliefs and the comfort provided by them.

REVIEW QUESTIONS

- Parents of which of the following religious groups are most likely to request infant baptism for their very ill infant? Select all that apply.
 - Baptist
 - Buddhism
 - Christian Science
 - Hinduism
 - Roman Catholic
 - Russian Orthodoxy
- Which of the following examples illustrates nursing sensitivity to a client's spiritual needs?
 - Delivering a dinner tray to a Hindu client that has the following foods: green salad, cheeseburger, gelatin, and milk
 - Insisting that a Jehovah's Witness client be given a blood transfusion
 - Placing a do not disturb sign on the door of an Islamic client who is praying
 - Scheduling an elective procedure for a Jewish client on Saturday
- When should a nurse perform a spiritual assessment on a hospitalized client?
 - At time of discharge
 - Just prior to discharge or transfer to another facility
 - On admission
 - When client is admitted and throughout hospitalization
- Which of the following is the initial nursing action when providing spiritual care to a client?
 - Assessment of client needs
 - Calling the clergy to minister to the client
 - Praying with the client
 - Self-awareness
- A client has recently been informed of a terminal diagnosis. The client says, "I wonder why God is doing this to me. It's not fair!" Which of the following nursing diagnoses is appropriate for this client?
 - Energy field disturbance
 - Readiness for enhanced spiritual well-being
 - Risk for spiritual distress
 - Spiritual distress
- The practice of focusing only on the present moment is known as:
 - Collaboration
 - Mindfulness
 - Mysticism
 - Spiritual distress
- A client who is dying says, "You know I wonder what will happen to me after I die?" Which of the following nursing responses demonstrates provision of spiritual care?
 - "I hate to interrupt your prayer but it's time for your pain medication."
 - "I have asked my pastor to add your name to the prayer list."
 - "Oh, don't talk like that. You'll feel better soon."
 - "You sound anxious. Let's talk about it."

Everyone can master grief but he that has it.

—SHAKESPEARE

CHAPTER 25

Loss and Grief

COMPETENCIES

1. Discuss theoretical perspectives of loss, grief, and dying.
2. Describe various losses that affect individuals across the life span.
3. Describe characteristics of an individual experiencing grief.
4. Differentiate adaptive grief and pathological grief.
5. Explain the relationship between loss and grief.
6. Discuss the holistic needs of the dying person and family.
7. Discuss use of the nursing process with a grieving individual.
8. Describe end-of-life (EOL) care, including hospice.
9. Discuss nursing responsibilities when a client dies.
10. Describe ways in which nurses can cope with their own grief.

KEY TERMS

algor mortis
 anticipatory grief
 autopsy
 bereavement
 complicated grief
 dysfunctional grief

grief
 grief work
 hospice
 liver mortis
 loss
 maturational loss

mourning
 palliative care
 rigor mortis
 situational loss
 uncomplicated grief

In contemporary society, individuals constantly experience loss. Frequent episodes of terrorism, natural disasters, and personal crises result in the universal experience of loss. Throughout the life cycle, people are faced with loss, without which growth would not continue. Many people consider loss only in terms of death and dying; however, loss of every type occurs daily. Nurses must be aware of the potential for loss in today's world, as well as the processes by which individuals adapt.

Every day nurses encounter clients who are responding to grief associated with losses. Thus, nurses must have an understanding of the major concepts related to loss and grieving. Grief is a response to losses of all types. Nurses also care for dying clients. This chapter provides information on meeting the special needs of terminally ill clients and their families.

LOSS

Loss is any situation (either actual, potential, or perceived) in which a valued object is changed or is no longer accessible to the individual. Because change is a major constant in life, everyone experiences losses. Loss can be actual (e.g., a spouse is lost through divorce) or anticipated (a person is diagnosed with a terminal illness and has only a short time to live). A loss can be tangible or intangible. For example, when a person is fired from a job, the tangible loss is income, whereas the loss of self-esteem is intangible.

Losses occur as a result of moving from one developmental stage to another. An example of such a **maturational loss** is the adolescent who loses the younger child's freedom from responsibility. Other examples of losses associated with growth and development are discussed later in this chapter. A **situational loss** occurs in response to external events, usually beyond the individual's control (such as the death of a significant other).

LOSS AS CRISIS

Loss precipitates anxiety and a feeling of vulnerability—which may lead to crisis. When a significant other dies, one's sense of safety and security is disrupted. Grieving is a mechanism for crisis resolution. When an individual feels overwhelmed by stress and the usual coping mechanisms are no longer effective, crisis occurs. Crisis intervention may be

necessary to help the person grieve successfully. See Chapter 23 for a discussion of crisis and crisis intervention.

TYPES OF LOSS

Loss occurs when a valued object is changed or is no longer available. Not everyone responds to loss in the same way because the significance of the lost object or person is determined by individual perceptions. There are many types of loss, including:

- *Actual loss:* Death of a loved one, theft of one's property
- *Perceived loss:* Occurs when a sense of loss is felt by an individual but is not tangible to others
- *Physical loss:* Loss of an extremity in an accident, scarring from burns, permanent injury
- *Psychological loss:* Such as a woman feeling inadequate after menopause and resultant infertility

There are four major categories of loss: loss of external objects, loss of familiar environment, loss of aspects of self, and loss of significant other.

Loss of an External Object

When an object that a person highly values is damaged, changes, or disappears, loss occurs. The significance of the lost object to the individual determines the type and amount of grieving that occurs. The valued object may be a person, pet, prized possession, or one's home. The loss of a pet, especially for those who live alone, can be devastating.

Loss of Familiar Environment

The loss of a familiar environment occurs when a person moves to another home or a different community, changes schools, or starts a new job. Also, a client who is hospitalized or institutionalized experiences loss when faced with new surroundings. This type of loss evokes anxiety caused by fear of the unknown.

Loss of Aspect of Self

Loss of an aspect of self can be physiological or psychological. A psychological aspect of self that may be lost is ambition, a sense of humor, or enjoyment of life. An example of physiological loss is loss of physical function as a result of illness or injury. Loss also occurs when there is disfigurement or disappearance of a body part, such as having an

amputation or mastectomy. Loss of an aspect of self can result from illness, trauma, or treatment methodologies (e.g., surgery).

Loss of Significant Other

The loss of a loved one is a significant loss. Such a loss can be the result of separation, divorce, running away, moving to a different area, or death. Responses to loss are highly individualized, as each person perceives the meaning of loss differently. For example, the death of a spouse is generally perceived differently by men and women (see Figure 25-1).

GRIEF

Grief is a series of intense physical and psychological responses that occur following a loss. It is a normal, natural, necessary, and adaptive response to a loss. Loss leads to the adaptive process of **mourning**, the period of time during which the grief is expressed and resolution and integration of the loss occur. **Bereavement** is the period of grief following the death of a loved one.

THEORIES OF THE GRIEVING PROCESS

There is no one comprehensive theory to explain the grief process, which may consist of a series of phases. Several theories have allowed us to delineate predictable symptoms and

FIGURE 25-1 Losing a spouse or partner who has been a part of their lives for many years is common for older adults. How can nurses support these individuals during the grieving process? DELMAR/CENGAGE LEARNING

states in response to loss. When reviewing the following theories, remember that everyone does not experience each phase in the order described. The theories of Lindemann, Engle, Bowlby, and Worden are discussed in the following sections.

Lindemann

In 1944, after the Coconut Grove fire in Boston, in which over 400 people died, Lindemann studied survivors of the disaster and their families. Lindemann coined the phrase **grief work**, which is still used today to describe the process experienced by the bereaved. During grief work, the person experiences freedom from attachment to the deceased, becomes reoriented to the environment in which the deceased is no longer present, and establishes new relationships (Lindemann, 1944). Lindemann's classic work is the foundation for current crisis and grief resolution theories. See Table 25-1, which provides a description of Lindemann's concepts.

TABLE 25-1 Lindemann's Theory: Reactions to Normal Grief

STAGE	DESCRIPTION
Somatic distress	Episodic waves of discomfort in duration of 10–60 minutes Multiple somatic complaints Emotional pain
Preoccupation with image of the deceased	A sense of unreality Emotional detachment from others Overwhelming preoccupation with visualizing the deceased
Guilt	Bereaved consider the death to be a result of their own negligence or lack of attentiveness Look for evidence of how they could have contributed to the death
Hostile reactions	Relationships with others become impaired owing to the bereaved's desire to be left alone, irritability, anger
Loss of patterns of conduct	Inability to sit still (generalized restlessness) Continually searching for something to do

Data from Lindemann, E. (1944). Symptomatology and management of acute grief. *American Journal of Psychiatry*, 101, 141–148.

Engle

Grief is a typical reaction to loss of a valued object. There are three stages of mourning, and progression through each stage is necessary for healing. The grieving process, which may take several years to complete, cannot be accelerated. The goal of the grieving process is for the mourner to accept the loss and let go of the deceased. See Table 25-2, which provides an overview of Engle's theory of grief.

Bowlby

Bowlby stated that grief results when an individual experiences a disruption in attachment to a love object. His theory

proposes that grief occurs when attachment bonds are severed. There are four phases that occur during grieving:

- Numbing
- Yearning and searching
- Disorganization and despair
- Reorganization (Bowlby, 1982)

Worden

Worden (1982) has identified four tasks that an individual must perform in order to successfully deal with a loss:

- Accept the fact that the loss is real.
- Experience the emotional pain of grief.
- Adjust to an environment without the deceased.
- Reinvest the emotional energy once directed at the deceased into another relationship.

Worden categorized the behavioral responses that grieving individuals experience; see Table 25-3 on page 479.

TYPES OF GRIEF

Grief is a universal, normal response to loss. Grief drains people, both emotionally and physically. Because grief consumes so much emotional energy, relationships may be impaired and health status may become altered. There are different types of grief including uncomplicated ("normal"), dysfunctional, and anticipatory.

Uncomplicated Grief

Many individuals use the term *normal grief*. Engle (1961) proposed use of the term **uncomplicated grief** to describe a grief reaction that normally follows a significant loss. Uncomplicated grief runs a fairly predictable course that ends with the relinquishing of the lost object and resumption of the previous life. Even though the bereaved person's life is changed forever, the person is able to regain the ability to function.

Some common responses experienced by grieving individuals are shown in Table 25-4 on page 479. Not every mourner will experience all the reactions, but the reactions most often experienced in response to a recent loss are listed.

Many grieving people experience feelings of anger or blame; these feelings may be directed toward those perceived to have caused or contributed to the death. Often the anger associated with grief is directed at one's self, that is, expressed as guilt or depression. Some survivors have a strong need to assign blame. If someone else can be blamed, then the survivors can rid themselves of any responsibility. Those who are experiencing grief must be provided an opportunity to express feelings—both positive and negative—in order to alleviate guilt.

Nurses play an important role in assisting mourners to develop and understand the normal grieving process and the complex feelings exhibited when grief becomes more complicated. Nurses with a sound knowledge base of both normal grief and dysfunctional grief will be better prepared to assist the survivors than nurses who believe that all grief is the same.

TABLE 25-2 Engle's Theory of Grief: Three Stages of Mourning

STAGE	CHARACTERISTICS
Stage I: Shock and disbelief Can last from minutes to days	Disorientation Perceived helplessness Denial gives protection until person is able to face reality
Stage II: Developing awareness May last from 6 to 12 months	Emotional pain occurs with increased reality of loss Recognition that one is powerless to change the situation Feelings of helplessness Anger and hostility may be directed at others Guilt Sadness Isolation Loneliness
Stage III: Restitution and resolution Marks the beginning of the healing process and may take up to several years	Emergence of bodily symptoms May idealize the deceased Mourner starts to come to terms with the loss Establishment of new social patterns and relationships

Data from Engle, G. L. (1961). Is grief a disease? *Psychosomatic Medicine*, 23, 18–22; Engle, G. L. (1964). Grief and grieving. *American Journal of Nursing*, 64(9), 93–98.

Delmar/Cengage Learning

Dysfunctional Grief

Persons experiencing **dysfunctional grief** do not progress through the stages of overwhelming emotions associated with grief, or they may fail to demonstrate any behaviors commonly associated with grief. The person experiencing pathologic grief continues to have strong emotional reactions, does not return to a normal sleep pattern or work routine, usually remains isolated, and has altered eating habits. The bereaved may have the need to endlessly tell and retell the story of loss but without subsequent healing. Visits to the grave site or mausoleum may be made often or not at all.

Dysfunctional grief is a demonstration of a persistent pattern of intense grief that does not result in reconciliation

of feelings. A person experiencing chronic grief continues to focus on the deceased, may overvalue objects that belonged to the deceased, and may engage in depressive brooding. The pathologically grieving person is unable to reestablish a routine. Several factors predispose a person to experience dysfunctional grieving, including:

- Uncertain, sudden, or overcomplicated circumstance surrounding the loss
- A loss that is socially unspeakable or socially negated (e.g., suicide)
- A relationship with the deceased characterized by ambivalence or excessive dependency (Worden, 1991)

Anticipatory Grief

Anticipatory grief is the occurrence of grief work before an expected loss. Anticipatory grief may be experienced by the terminally ill person as well as family. This phenomenon promotes adaptive grieving by freeing up the mourner's emotional energy. Although anticipatory grieving may be helpful in adjusting to the loss, it may also result in some disadvantages. For example, for the dying client, anticipatory grieving may lead to family members' distancing themselves and not being available to provide support. Also, if the family members have separated themselves emotionally from the dying client, they may seem cold and distant and thus may not meet society's expectations of mourning behavior. This response can prevent the mourners from receiving their own much-needed support from others.

FACTORS AFFECTING GRIEF

The experience of grief is individual and is influenced by various factors. Factors that influence grief include the person's developmental level, religious and cultural beliefs, relationship to the lost object, and the cause of death.

Developmental Considerations

Certain kinds of loss at key developmental points may have a profound effect on a person's ability to work through grief and may result in inadequate achievement of the developmental task. Depending on a client's developmental level, the grief response to a loss will be experienced differently. For example, a pregnant woman will, to some degree, experience loss after delivery, even delivery of a normal healthy infant. See Table 25-5 for other examples of developmental losses that may precipitate grieving.

TABLE 25-5 Losses Associated with Developmental Stage

DEVELOPMENTAL STAGE	RELATED LOSS
Infants	Intrauterine environment (warmth and protection) Comfort of sucking breast or bottle
Toddlers and preschoolers	Spontaneity of bodily function as a result of toilet training Immediate gratification of needs as child gains independence Familiar environment as child attends day care or nursery school
School-aged children	Periodic loss of body function caused by normal childhood illnesses and injuries Friends and significant others (teachers, coaches) as they progress through school
Adolescents	Familiar body with onset of puberty Childhood freedoms in response to social expectation to act mature First love (as adolescent "crushes" end) functions Familiar environment when leaving home for work or education
Young adults	Friends through leaving school, moving, changing jobs Financial support from parents when leaving home Freedom when assuming more adult responsibilities Sexual partner
Middle adults	Spouse, through separation, divorce, or death Children as they leave home Friends through job changes, moving, or death Parents through death "Youth" (as related to physical appearance, libido, and physical stamina) Women experience loss of fertility through menopause

Delmar/Cengage Learning

CHILDHOOD Children vary in their ability to comprehend the meaning of death. It is important to understand how a child's concept of death evolves because it varies with developmental level (see Table 25-6).

Well-meaning adults often try to protect children from the realities of death by excluding them from mourning rituals. However, children need to be included in family activities as appropriate to their developmental level. Children who are grieving need explanations about death that are

honest and in language that they can easily understand. See Table 25-7, on page 482, for suggestions on talking to children about death.

ADOLESCENCE Most adolescents value physical attractiveness and athletic abilities. Grief may occur when the adolescent suffers the loss of a body part or function. Because of the strong influence of peer groups, adolescents seek approval from their friends and fear being rejected if a loss

TABLE 25-6 Perception of Death by Children and Adolescents

DEVELOPMENTAL STAGE	PERCEPTION	POTENTIAL DEVELOPMENTAL DISRUPTIONS
Infancy and toddler	<ul style="list-style-type: none"> Is not aware of death Is aware of disruptions in normal routine Can react to family's expressions of grief 	<ul style="list-style-type: none"> If the mother or surrogate dies during the first 2 years of life, the child may have significant, long-lasting psychosocial problems
Preschool	<ul style="list-style-type: none"> Views death as a temporary separation Able to react to the gravity of death in accordance with the reactions of parents or other adults 	<ul style="list-style-type: none"> May have significant psychosocial problems if either parent is lost at this stage, especially between ages 4 and 6 (owing to magical thinking, in which children may believe death is their fault)
School-age	<ul style="list-style-type: none"> Appreciates that death is final and inevitable Fantasizes about and tends to personify death ("the bogeyman") 	<ul style="list-style-type: none"> May have nightmares May engage in death-avoidance behaviors (e.g., hiding under the covers, leaving the lights on, closing closet doors) May experience intense guilt and a sense of responsibility for the death
Preadolescent and adolescent	<ul style="list-style-type: none"> Recognizes that death is final Understands that death is inevitable Preadolescents: tend to worry about dying Adolescents: tend to deny that death could happen to them 	<ul style="list-style-type: none"> Loss of a parent may interfere with mastery of the young adulthood task of forming intimate relationships with members of opposite sex

Delmar/Cengage Learning

TABLE 25-7 Communicating with Children about Death

THERAPEUTIC

- Use simple, concrete language.
- Involve the child in mourning rituals (e.g., take to funeral home and cemetery); explain what is going to happen.
- Encourage the child to express feelings.
- Reassure children that they will not be abandoned.
- Answer all questions truthfully.

NONTHERAPEUTIC

- Use of euphemisms (e.g., “he’s gone to sleep” or “she went away”)
- Overexplanations
- Minimizing child’s experience
- Judgmental statements

Delmar/Cengage Learning

affects their acceptance by others (e.g., grief after a disfiguring accident is usually intense in adolescents). Even though they have an intellectual understanding of death, adolescents feel they are immune to death and therefore do not accept the possibility of their own mortality. This perception is caused by the sense of invulnerability that normally occurs during adolescence.

EARLY ADULTHOOD In the young adult, grief is usually precipitated by loss of role or status. For example, unemployment or breakup of a relationship causes significant grief for the young adult. The concept of death in this age group is primarily a reflection of cultural values and spiritual beliefs.

MIDDLE ADULTHOOD During middle adulthood the potential for experiencing loss increases. The death of parents begins to occur. As an individual ages, it can be especially threatening for peers to die because their death forces acknowledgment of one’s own vulnerability to death. Other losses frequently experienced during middle age are those associated with changes in employment and relationships (e.g., divorce), children leaving home, and decreasing functional abilities.

OLDER ADULTHOOD During late adulthood, most individuals recognize the inevitability of death. Most older adults experience numerous losses as they age. Losses commonly experienced by older adults include loss of (Bowlby, 1961):

- Loved ones and friends
- Occupational role as a result of retirement
- Material possessions
- Dreams and hopes

In the United States, women live longer than men and are, therefore, more likely to experience the loss of a spouse. According to the U.S. Census Bureau (2008), in 2007 the population of those age 75 years or older is 4.7% male and 7.5% female. Regardless of gender, the bereaved may need to develop new skills in order to adapt. For example, a man who was married for 50 years may have to learn meal preparation after his wife dies.

Religious and Cultural Beliefs

Religious and cultural beliefs can have a significant effect on an individual’s grief. Every culture has certain religious beliefs about the significance of death as well as rituals for care of the dying; see Table 25-8. See Chapters 20 and 24 for

TABLE 25-8 Religious Traditions Related to Death

RELIGION

BELIEFS AND RITUALS

Buddhism

May prefer quality of life rather than quantity

Last-rite chanting at bedside

Cremation usually preferred

Catholicism

Believe life should be prolonged by ordinary, not extraordinary, means

Sacrament of the sick

Organ donation and autopsy acceptable

Practice of “waking” (keeping watch) over the dead is common

Usually burial instead of cremation

(Continues)

TABLE 25-8 (Continued)

RELIGION	BELIEFS AND RITUALS
Christian Science	Opposed to euthanasia
	No organ transplantation
	Disposal of body to be decided by the family
Greek Orthodox	May isolate dying person and withhold truth about prognosis
	Dying at home is important
	Widow wears dark mourning clothes for rest of life
Hinduism	Believe in reincarnation
	Autopsy and organ donation are acceptable
	Religious chanting before and after death
	Cremation is preferred
	Non-Hindus should not touch the body
	Thread is tied around wrist of the deceased to signify a blessing
Islam	Euthanasia forbidden
	Organ donation acceptable
	Autopsy only if legally or medically necessary
	Deceased body is washed only by Muslim of same gender
	Body usually remains at home, wrapped in white cloth
	Burial within 24 hours of death
Jehovah's Witness	Euthanasia prohibited
	Autopsy only for legal purposes
	Organ donation forbidden
Judaism	Euthanasia forbidden
	No autopsy or organ donation
	Relatives remain with dying person
	Do not mandate life support
	Body is ritually washed
	Eyes must be closed at death
	Burial is done within 24 hours or as soon as possible
	Recognize a 7-day period of mourning
Protestantism	May be some restrictions on prolonging life
	Uphold individual decisions regarding autopsy, organ donation, and burial or cremation

Data from Spector, R. E. (2008). *Cultural diversity in health and illness* (9th ed.). Upper Saddle River, NJ: Prentice-Hall.

discussion of the impact of religious and cultural beliefs. Beliefs about an afterlife and faith in a higher power, redemption of the soul, and reincarnation are important aspects that often assist one in grief work.

Relationship with the Lost Object

It is usually more difficult to cope with the loss of an ambivalent relationship, as such relationships are characterized by many “if only” and “I should have” thoughts. Unfinished business and regrets about the deceased make coping with the loss more problematic. When individuals in conflicted relationships have time to work on issues prior to the death, grieving is usually facilitated.

In general, the more intimate the relationship with the deceased, the more intense the grief experienced by the bereaved. The death of a child poses a particular risk for dysfunctional grieving. The death of a parent or a sibling can pose a major challenge for children. The child’s feelings may often go unrecognized by adults who fail to understand the child’s need to mourn.

Individuals experiencing parental grief usually have intense reactions and responses. It is expected that children outlive their parents. When a child dies, the parent not only loses the child but also experiences losses of the parental role. Bowlby (1961) describes parents who talk about losing a part of themselves as a result of their child’s death. The uniqueness of parental grief for a deceased child may be the loss of the perceived potential for the child who has died. It is the loss of the hopes of the parents for the child, for “the things that could have been.” Table 25-9, on page 485, provides a listing of characteristics of parents whose children have died.

Cause of Death

The intensity of the grief response changes according to the cause of death, be it unexpected, traumatic, or a suicide.

UNEXPECTED DEATH The loss occurring with an unexpected death poses particular difficulty for the bereaved in achieving closure. Unanticipated death, such as a death resulting from a natural disaster or other tragedy (e.g., airplane crash), leaves survivors shocked and bereaved. Often, the inability to say goodbye compounds the trauma of the death and may be a factor contributing to altered grieving.

TRAUMATIC DEATH **Complicated grief** is associated with traumatic death such as death by homicide or suicide. Although traumatic death does not necessarily predispose the survivor to complications in mourning, survivors suffer emotions of greater intensity than those associated with normal grief.

When loved ones die violently, the grievers may suffer from traumatic imagery, that is, reliving the terror of the incident or imagining the feelings of horror felt by the victim. Traumatic imagery is a common occurrence with traumatic death. Such thoughts, coupled with intense grief, can lead to

posttraumatic stress disorder (PTSD). Nurses must be aware of the possibility of PTSD and be alert for the presence of symptoms, which may include:

- Sleep disturbances, such as recurrent, terror-filled nightmares
- Psychological distress
- Chronic anxiety

Unless complicated grief is recognized and the survivors are encouraged to express the intense feelings, they will not be able to progress through the normal, adaptive grieving process.

SUICIDE The loss of a loved one to suicide is frequently compounded by feelings of blame in the survivors. They feel guilty for failing to recognize clues that may have enabled the victim to receive help. These feelings of guilt and self-blame can be transformed into anger at the victim for inflicting such pain, at themselves, and at caregivers. Feelings of shame for having a suicide in the family may also be present.

NURSING CARE OF THE GRIEVING PERSON

Resolution of a loss is a painful process and must be done by clients in their own way. Grief changes people by affecting self-esteem, triggering the development of new ways of coping, and precipitating a change in lifestyle without the deceased.

Nurses can play an active role in assisting people to grieve. Encourage clients to do their grief work, that is, to experience their feelings to the fullest in order to work through them. Provide support and explain to the bereaved that it will take time to grieve the loss and to gain some closure to the relationship.

Assessment

A thorough assessment of the grieving client and family begins with a determination of the personal meaning of the loss. Another key assessment area is deciding where the person is in terms of the grieving process. The nurse understands that the stages of grieving are not necessarily mastered sequentially, but that instead individuals may vacillate in progression through the stages of grief. Levin (1998) recommends that assessment be done to differentiate the signs of healthy grieving from at-risk behavior.

Diagnosis

The North American Nursing Diagnosis Association International (NANDA, 2009) defines *Complicated grieving* as “a disorder that occurs after the death of a significant other, in which the experience of distress accompanying bereavement fails to follow normative expectations and manifests in functional impairments” (p. 98); see the Nursing Process Highlight on page 486.

TABLE 25-9 Characteristics of Parents Whose Children Die

DEATH	CHARACTERISTICS
Spontaneous abortion (miscarriage) and stillbirth	Parents may have feelings of intense sadness, anger, or guilt.
	The death is often unacknowledged by others, especially if the loss occurs in early weeks of pregnancy.
	The death may be considered a personal failure.
	Parents may dwell on details, designating blame to themselves or others.
	Grief from previous losses may be relived.
	Anticipatory grief may occur if the infant's condition is known early.
	Ambivalence experienced in early pregnancy may increase grief.
	Hopes for the future must be modified or changed.
Neonatal death	Despair may peak when the parents must leave the hospital without the baby.
	Feelings are similar to stillbirth.
	Parents have had time to form a bond with the infant, intensifying the grief.
Sudden infant death syndrome (SIDS)	Grief may be intense for both parents.
	Death is unexplainable and unexpected.
	Pain is increased by lack of knowledge and misinformation.
	Parental bonding is complete.
	Death is silent, with no signs of distress.
	Guilt is often present.
	Police may investigate, adding to the guilt.
Abortion	Grief is acute due to lack of time to prepare.
	Parents may be preoccupied with the details of the death.
	Shame, secrecy, and guilt may accompany grief.
	Highly ambivalent feelings may be present.
	Little support or comfort is offered by others.
	Feelings of relief are expected, but despair and depression may surface.
	No guilt may be felt, especially if the woman did not want a child.

Delmar/Cengage Learning

Outcome Identification and Planning

It is important to clarify the expected outcomes when planning care for the grieving client. Following are some expected outcome criteria for the person experiencing grief:

- Verbalize feelings of grief
- Share grief with significant others
- Accept the loss
- Renew activities and relationships

Some of these expected outcomes will take a long period of time to achieve, and some must be achieved before others are mastered. For example, to accept the loss, the person must begin to share grief with others by verbalizing feelings. Two expected outcomes for mourners are discussed in the sections that follow.

ACCEPTANCE OF THE LOSS Only by going through grief work are individuals able to reach some acceptance and,

NURSING PROCESS HIGHLIGHT

Diagnosis

Complicated Grieving

Defining Characteristics (partial listing):

- Decreased functioning in life roles
- Decreased sense of well-being
- Depression
- Fatigue
- Preoccupation with thoughts of the deceased
- Searching for the deceased

Related Factors (partial listing):

- Death of a significant other
- Emotional instability
- Lack of social support

Data from North American Nursing Diagnosis Association International. (2009). *Nursing Diagnoses—Definitions and Classification 2009–2011* © 2009, 2007, 2005, 2003, 2001, 1998, 1996, 1994 NANDA International. Used by arrangement with Wiley-Blackwell Publishing, a company of John Wiley & Sons, Inc.

ultimately, resolution of feelings about the loss. Often, people try to find some meaning in their situations. This search involves introspection in which spiritual support is of therapeutic value.

RENEWAL OF ACTIVITIES AND RELATIONSHIPS The very core of grief work revolves around acceptance of the fact that the needs met by key people in one's life can be met in other ways and by other people. The deceased cannot be replaced; however, enough healing must occur so that new relationships can be initiated.

How long does the process of adaptive grieving take? Grief work takes time. There are no definite time frames in which grief should occur. The length of time for grief to be resolved is as individual as the person experiencing it and its intensity. Each person grieves in his or her own way and at his or her own pace. See the accompanying Spotlight On display.

Implementation

Therapeutic nursing care is based on an understanding of the significance of the loss to the client. To understand the client's perspective, the nurse must spend time listening. As the client expresses feelings, the nurse must demonstrate acceptance, even if the client is not responding according to the nurse's expectations or belief system. The nurse's nonjudgmental, accepting attitude is essential while listening to the bereaved. The nurse communicates an understanding of the client's anger—and avoids personalizing and using defensive behaviors.

SPOTLIGHT ON...

Compassion

Allowing Time to Grieve

Your coworker, who is also your friend, has just lost a loved one whose funeral was today. Tomorrow your friend must return to work because his 3-day bereavement leave is over. He is dealing with many intense emotions as well as a lack of energy. Society dictates that he return to work. How do you deal with his lack of productivity at work? How do you provide support to him?

Grieving people need reassurance, counseling, and support; see Figure 25-2. One mechanism of providing support on a long-term basis is support groups. Thus, the nurse needs to be aware of the availability of such groups within the community in order to make appropriate referrals. When bereaved people join support groups, they will be with others who have experienced similar situations. This sharing decreases the feelings of loneliness and social isolation that are so common in grief. The accompanying Nursing Checklist, on page 487, provides guidelines for nurses working with grieving clients.

Evaluation

People follow their own time schedule for grief work. In general, it takes months or years for resolution of grief. It is important to teach grieving individuals that resolution of the loss is generally a process of lifelong adjustment. Therefore, nurses usually do not have an opportunity to be with the bereaved family when grief work is completed. However, the nurse has a unique opportunity to lay the foundation for adaptive grieving by encouraging the bereaved to share their

FIGURE 25-2 Note the nurse's nonverbal expression of support for this couple's grief over the loss of their child. What specific actions can the nurse implement to provide support? DELMAR/ CENGAGE LEARNING

NURSINGCHECKLIST

CARING FOR GRIEVING CLIENTS

- Approach the client with a nonjudgmental attitude.
- Understand that each person's expression of grief is individualized.
- Encourage clients to express feelings at their own pace.
- Demonstrate compassion.
- Employ empathy, not sympathy.

feelings and continue to verbalize their experience with significant others. Goals mutually established with client and family are the foundation for evaluation.

DEATH

In today's social climate, death is viewed as something to be avoided at all costs; medicine, with its technological advances, pursues immortality. Death is considered to be an unusual occurrence by many Americans. "People in our country deny death, believing that medical science can cure any patient. Death is often seen as a failure of the health care system rather than a natural aspect of life" (American Association of Colleges of Nursing [AACN], 2008, p. 1). Scientific advances do not change the fact that death is a part of every human existence.

STAGES OF DEATH AND DYING

In her classic works, Elizabeth Kübler-Ross (1969, 1974) identified five possible stages of dying experienced by clients and their families (Table 25-10). Every person does not move sequentially through each stage. These stages are experienced in varying degrees and for varying lengths of time. The client may express anger and, a few minutes later, express acceptance of the inevitable, then express anger again. The value in Kübler-Ross's work is that it helps increase sensitivity to the needs of the dying client.

Denial

In the first stage of dying, the initial shock can be overwhelming. Denial, which is an immediate response to loss experienced by most people, is a useful tool for coping. It is an essential and protective mechanism that may last for only a few minutes or may manifest itself for months.

Anger

The initial stage of denial is followed by anger. The client's security is being threatened by the unknown. All the normal daily routines have become disrupted. The client has no control over the situation and thus becomes angry in response

TABLE 25-10 Kübler-Ross's Stages of Dying and Death

STAGE	EXAMPLE
First stage: Denial	<i>Verbal:</i> "This can't be happening to me!" <i>Behavioral:</i> Client is diagnosed with terminal lung cancer; client continues to smoke two packs of cigarettes daily.
Second stage: Anger	<i>Verbal:</i> "Why me?" <i>Behavioral:</i> Client strikes out at caregivers.
Third stage: Bargaining	<i>Verbal:</i> Client prays, "Please, God, just let me live long enough to see my grandchild graduate." <i>Behavioral:</i> Client tries to "make deals" with caregivers.
Fourth stage: Depression	<i>Verbal:</i> "Go away. I just want to lie here in bed. What's the use?" <i>Behavioral:</i> Client withdraws and isolates self.
Fifth stage: Acceptance	<i>Verbal:</i> "I feel ready. At least, I'm more at peace now." <i>Behavioral:</i> Client gets financial or legal affairs in order. Client says good-bye to significant others.

Data from Kübler-Ross, E. (1969). *On death and dying*. New York: Macmillan.

to this powerlessness. The anger may be directed at himself or herself, God, and others. Often the nurse is the recipient of the anger when the client lashes out; see Figure 25-3 on page 488.

Bargaining

The anticipation of the loss through death brings about bargaining through which the client attempts to postpone or reverse the inevitable. The client promises to do something (e.g., be a better person, change lifestyle) in exchange for a longer life.

Depression

When the realization comes that the loss can no longer be delayed, the client moves to the stage of depression. This depression is different from dysfunctional depression in that it helps the client detach from life in order to be able to accept death.

Acceptance

The final stage of acceptance may not be reached by every dying client. Verbalization of emotions facilitates acceptance.

FIGURE 25-3 Anger is a common response of grieving individuals. What is the nurse's priority action in the situation with this angry client? DELMAR/CENGAGE LEARNING

With acceptance comes growing awareness of peace and contentment. The feeling that all that could be done has been done is often expressed during this stage. Reinforcement of the client's feelings and a sense of personal worth are important during this stage.

ETHICAL IMPLICATIONS

Death is associated with ethical dilemmas that occur almost daily in health care settings. Many health care agencies have ethics committees to develop and implement policies that deal with end-of-life issues. See Chapter 12 for a discussion of the ethical implications of euthanasia, assisted suicide, and refusal of treatment. One of the most difficult dilemmas is determining the difference between killing and allowing someone to die by withholding life-sustaining treatment methods.

The American Nurses Association (ANA) differentiates relieving pain and mercy killing (euthanasia or assisted suicide). Pain relief is a central value in nursing, whereas euthanasia is unethical. "Nurses, individually and collectively, have an obligation to provide comprehensive and compassionate end-of-life care, which includes the promotion of comfort and the relief of pain, and, at times, supporting the patient in foregoing life-sustaining treatments" (ANA, 1997).

ASSESSMENT

Nursing interventions are based on a thorough assessment of the client's holistic needs. Pertinent information to be determined when assessing a terminally ill client includes:

- Client's awareness of the terminal nature of illness
- Availability of support systems

- Physical condition
- Emotional status
- Presence of advance directives for health care decisions
- History of previous positive coping skills
- Unfinished business expressed by client or family

DIAGNOSIS

One NANDA-approved nursing diagnosis that is applicable for many dying clients is *Powerlessness*, that is, the "perception that one's own action will not significantly affect an outcome; a perceived lack of control over a current situation or immediate happening" (NANDA, 2009, p. 168). Another response that is often experienced by the dying is described by the diagnosis *Hopelessness*, a "subjective state in which an individual sees limited or no alternatives or personal choices available and is unable to mobilize energy on own behalf" (NANDA, 2009, p. 107). See Table 25-11, on page 489, for description of these two diagnoses.

OUTCOME IDENTIFICATION AND PLANNING

The dying client must be treated as a unique individual worthy of respect rather than as a diagnosis or a case to be cured. Essential elements to consider when planning care of the dying person include:

- Schedule time to be available to client.
- Offer to contact clergy.
- Balance the client's need for independence and need for assistance.
- Respect the client's confidentiality.
- Answer all questions and provide factual information to client and family.

Nursing care promotes the optimal quality of life, which means treating the client and family in a respectful manner and providing a safe environment for the expression of feelings. Sensitive nursing care recognizes and respects the cultural, ethnic, spiritual, and religious beliefs of clients and families. Planning focuses on meeting the holistic needs of the client and family.

IMPLEMENTATION

The nurse's first priority is to communicate a caring attitude to the client. Establishment of rapport facilitates the client's verbalization of feelings. The nurse establishes a safe environment in which the client does not feel chided or chastised for experiencing those feelings. Nonverbal communication can be used very effectively with dying individuals.

End-of-Life (EOL) Care

No one expects to die. It is something that happens to someone else and to someone else's loved ones. Dying was once considered to be a normal part of the life cycle, whereas today it is often considered to be a medical problem that

Text not available due to copyright restrictions

should be handled by health care providers. Technological advances in medicine have caused care of those who are dying to become depersonalized and mechanical.

In an attempt to humanize care of the dying, proponents of improved EOL care are looking to nurses. The highly technological health care environment calls for application of high-touch intervention with the dying. In other words, appropriate care of the dying is administered by compassionate nurses who are both technically competent and able to demonstrate caring. The United States is facing the realities of an aging population, recognition of the limits and inappropriate use of technological resources, and concerns about the capabilities of health care providers. Additionally, the increase in demand for assisted suicide and apprehensions of

the public about suffering and expenses associated with dying that may be prolonged unnecessarily by technology contribute to a renewed interest in humane EOL care (AACN, 2008).

Proficient nursing care during the final stage of life requires a unique knowledge base and skills. In 1999, the AACN developed a list of competencies necessary to provide quality EOL care. These competencies are revised as necessary by the AACN (2004); see the accompanying display, on page 490, on competencies necessary for nurses to provide quality EOL care. These competencies follow the position of the International Council of Nurses (1997) that nurses have the primary responsibility for a person's experiencing a peaceful death. See the Uncovering the Evidence display on page 490.

COMPETENCIES NECESSARY FOR NURSES TO PROVIDE HIGH-QUALITY CARE TO CLIENTS AND FAMILIES DURING THE TRANSITION TO THE END OF LIFE: AACN

1. Recognize changes (social, demographic, economic) necessitating improved end-of-life (EOL) care.
2. Promote provision of comfort care to the dying.
3. Communicate with client, family, and colleagues about EOL issues.
4. Recognize one's own attitudes, feelings, values, and expectations about death; acknowledge diversity (individual, cultural, and spiritual) in beliefs and customs.
5. Demonstrate respect for the client's view and wishes during EOL care.
6. Collaborate with interdisciplinary team members during EOL care.
7. Use scientifically based standardized tools to assess symptoms experienced by client at the end of life.
8. Use assessment data to plan and intervene using traditional and complementary approaches.
9. Evaluate the impact of traditional, complementary, and technological therapies on client-centered outcomes.
10. Assess and treat multiple dimensions (physical, psychological, social, and spiritual needs) to improve quality at the end of life.
11. Assist client, family, colleagues, and one's self in coping with suffering, grief, loss, and bereavement in EOL care.
12. Apply legal and ethical principles in the analysis of complex EOL issues.
13. Identify barriers and facilitators to clients' and caregivers' effective use of resources.
14. Demonstrate skill at implementing a plan for improved EOL care.
15. Apply knowledge gained from palliative care research to EOL education and care.

Adapted from American Association of Colleges of Nursing. (2004). *Peaceful death: Recommended competencies and curricular guidelines for end-of-life nursing care*. Retrieved January 2, 2009, from <http://www.aacn.nche.edu>.

Physiological Needs

According to Maslow's hierarchy of needs, physiological needs must be met prior to others because they are essential for existence. Areas that are often problematic for the terminally ill client are nutrition, respiration, elimination, comfort,

UNCOVERING THE

Evidence

TITLE OF STUDY

“Practice of Expert Critical Care Nurses in Situations of Prognostic Conflict at the End of Life”

AUTHORS

C. M. Robichaux and A. P. Clark

PURPOSE

To (1) explore the practice of expert critical care nurses in end-of-life (EOL) conflicts and (2) describe actions taken when the nurses thought continued aggressive medical interventions were unwarranted.

METHODS

A qualitative design was used with analysis of interview data. Data were collected from interviews with 21 nurses who were nominated as experts by their coworkers.

FINDINGS

Three recurrent themes emerged from data analysis: (1) protecting or advocating for clients, (2) presenting a realistic picture (to clients and families), and (3) experiencing frustration and resignation.

IMPLICATIONS

The transition from curative to EOL care in the critical care setting is often accompanied by ambiguity and frustration. Expert nurses demonstrated the ability and willingness to actively protect and speak up for their clients even in situations in which the nurses' actions did not directly influence the outcomes.

Robichaux, C. M., & Clark, A. P. (2006). Practice of expert critical care nurses in situations of prognostic conflict at the end of life. *American Journal of Critical Care, 15*(5), 480–490.

and mobility. Table 25-12, on page 491, provides information on meeting the client's physiological needs.

Promoting Comfort

The primary activities directed at promoting physical comfort include pain relief, keeping the client clean and dry, and providing a safe, nonthreatening environment. The nurse who demonstrates a respectful, caring attitude promotes the client's psychological comfort by establishing rapport. Use of **palliative care** (a focus on alleviating symptoms rather than finding a cure) is rapidly increasing in the United States. Palliative care is not confined to EOL situations; it can be provided at any time during the course of illness and disability (Center to Advance Palliative Care, 2009). The goal of palliative care is to promote comfort in all dimensions—physiological, psychosocial, and spiritual.

TABLE 25-12 Meeting the Physiological Needs of the Terminally Ill Client

AREA OF NEED	DISCUSSION	NURSING IMPLICATIONS
Nutrition	Presence of nausea and vomiting decreases appetite.	<ul style="list-style-type: none"> Identify the cultural, social, and ethnic practices that influence eating patterns.
	Psychological factors (e.g., depression) may interfere with appetite.	<ul style="list-style-type: none"> Use specific measures that promote food intake and retention, such as favorite foods, easy-to-swallow foods, and eating small amounts frequently.
	Some treatment modalities (e.g., chemotherapy, radiation) affect appetite and impair immune functioning.	<ul style="list-style-type: none"> Give antiemetic drugs as needed. Recommend that client avoid fried foods, alcoholic drinks, and gas-producing vegetables (corn, cauliflower, beans, broccoli). Instruct client to avoid raw meat and raw eggs.
Energy	Weakness and exhaustion may occur as a result of metabolic demands.	<ul style="list-style-type: none"> Schedule care activities to ensure uninterrupted times for rest.
	Fatigue and weakness may impair self-care abilities.	<ul style="list-style-type: none"> Encourage client to conserve energy (do strenuous tasks for the client).
Hygiene	Diaphoresis and incontinence often occur in final stages of illness.	<ul style="list-style-type: none"> Provide bed bath as necessary. Perform oral care. Change linens frequently to keep client dry (promotes skin integrity).

Delmar/Cengage Learning

Clients may experience many fears related to death. They may fear helplessness, dependence on others, loss of abilities, mutilation, or uncontrollable pain. The fear of a painful death is almost universal. Many, though certainly not all, dying clients experience pain. Comfort should be maximized by management of pain and other discomforting factors. The Nursing Checklist provides a list of interventions to promote comfort. See Chapter 35 for further discussion of pain management.

Hospice Care

Hospice, a type of care for the terminally ill, is founded on the concept of allowing individuals to die with dignity and be surrounded by those who love them. Hospice care is one of the fastest-growing segments of the health care industry. Clients enter hospice care when aggressive medical treatment is no longer an option or when the client refuses further aggressive medical treatment. Clients are usually referred to hospice when life expectancy is approximately 6 months or less (Hospice Foundation of America, 2008). Hospice, which provides an environment that emphasizes caring instead of curing, initiated the concept of palliative care.

Managing the care of a dying person requires many skills. Because of the complexity of care required by the

NURSING CHECKLIST

MEETING THE COMFORT NEEDS OF THE TERMINALLY ILL CLIENT

- Encourage client to verbalize presence of pain.
- Discuss pain relief options with client and family.
- Administer medication on a regular schedule instead of prn basis to ensure maximum pain relief.
- Assist client and family to identify the stressors that influence pain.
- Teach noninvasive pain relief measures:
 - Relaxation techniques such as deep breathing, imagery
 - Use of heat and cold
 - Massage
 - Topical ointments, such as soothing salves, deep-heating rubs, herbal-scented lotions
 - Aromatherapy

hospice client, an interdisciplinary team is essential for delivering quality, compassionate care. The interdisciplinary team consists of nurses, physicians, social workers, psychologists, clergy, ancillary personnel, and volunteers.

Home Care

A dying person is often not given the opportunity to be surrounded by family and friends. Many Americans die in hospitals or nursing homes. Home care is an alternative for the dying client, if the family members are physically and emotionally able to provide care. Hospices provide therapeutic interventions to bereaved family members. Ideally, health care providers should share the responsibility of home care of the dying with the family through respite time and frequent visits.

Psychosocial Needs

Death presents a threat not only to one's physical existence but also to psychological integrity. See Table 25-13 for a discussion of ways to meet the psychosocial needs of the dying client.

Spiritual Needs

In times of crisis, such as death, spirituality may be a source of comfort and support for the client and family. Spiritual and religious beliefs often determine the appropriate course of action. Nurses respect clients' reliance on spiritual support by listening and contacting clergy and spiritual guides if requested.

Nurses play a major role in promoting the dying client's spiritual comfort. Dying is a personal and, frequently, lonely

TABLE 25-13 Meeting the Psychosocial Needs of the Terminally Ill Client

PROBLEM	DISCUSSION	NURSING IMPLICATIONS
Anxiety	<ul style="list-style-type: none"> A combination of factors contribute to anxiety of the dying client and family: <ul style="list-style-type: none"> — Client's fear of death (and loss of the known world) — Caregiver's fear of loss of the loved one — Client's sense of abandonment by the family, friends, and health care providers Loss of independence and social isolation increase anxiety. 	<ul style="list-style-type: none"> Spend as much time as possible with the dying client. Encourage verbalization of feelings. Listen in nonjudgmental manner. Answer all questions in an honest, factual manner. Provide explanation of all procedures. Encourage family and friends to spend time with client.
Decreased independence	<ul style="list-style-type: none"> Independence is threatened by powerlessness. Independence is promoted by having control over one's life. 	<ul style="list-style-type: none"> Seek client's opinion on treatment issues. Involve client in developing plan of care. Encourage continued interaction of client with family and friends. Assist the client to develop goals that are realistic within the limitations of the illness (realistic hope). Avoid always focusing only on limitations. Allow client and family to ventilate feelings about not being able to change the course of events. Help the client to identify those things over which he or she does have power.
Social interaction	<ul style="list-style-type: none"> Loneliness is increased when others detach themselves in order to disengage from the dying person's pain. Health care providers tend to avoid interacting with the dying. Sensory deprivation (dimly lit rooms and out-of-the-way rooms) can increase feelings of abandonment. 	<ul style="list-style-type: none"> Encourage family to remain with the dying person. Stay with the dying person as much as possible. Provide support through your presence and active listening. Be available to discuss the client's situation. Use touch to communicate caring. Provide meaningful sensory stimuli.

process. The nurse can serve as a sounding board for the client who expresses values and beliefs related to death. The following are therapeutic nursing interventions that address the spiritual needs of the dying:

- Communicating empathy
- Playing music
- Using touch
- Praying with the client
- Contacting the clergy if requested by the client
- Reading religious literature aloud at the client's request

Family Support

Family members need to be involved in the care of their dying loved one. Unrealistic guilt is increased by feelings of powerlessness; thus, it is important to involve family members in the caregiving. Families facing the impending death of a loved one require much support from nurses and other caregivers. The nurse's presence, just being there with the family, is extremely important.

Learning Needs of Client and Family

Bereaved families need much support and information; thus, the nurse must teach family members what they need to know. For instance, families must be assisted with acquiring the tools that will help them help their loved one. An example may be for the family to understand that the dying person needs to conserve energy. One simple action on the part of the family to assist with energy conservation would be to schedule activities after a rest period or early in the morning when the client is strongest. This is not an earth-shattering revelation, but simple interventions can be overlooked during this highly charged emotional time.

Client and family knowledge deficits can be related to:

- Insufficient information about physical condition
- Insufficient information about the treatment regimen
- Inability to anticipate medical crises
- Inexperience with personal threat of death
- Unfamiliarity with protocol to follow for emergency care when not in the hospital

The accompanying Client Teaching Checklist provides guidelines for educating families of dying people.

CARE AFTER DEATH

Caring for the deceased body and meeting the needs of the grieving family are nursing responsibilities. This section discusses care of the body and responding to the needs of families of the deceased.

CARE OF THE BODY

The body of the deceased needs to be treated in a way that respects the sanctity of the human body. Nursing care includes maintaining privacy and preventing damage to the body.

CLIENT TEACHING CHECKLIST

GUIDELINES FOR TEACHING A FAMILY CAREGIVER

- Discuss the nature and extent of the disease process.
- Use adult education principles.
- Reinforce material frequently.
- Clearly explain the purpose of palliative care while maintaining a sense of realistic hope.
- Inform client and family of available community resources; reassure them that they are not alone.
- Teach steps for caregiver to follow if an emergency arises at home.
- Provide written instructions for caregiver to follow. These should include important telephone numbers and persons to be contacted.
- Inform about the purpose of hospice.

Physiological Changes

Several physiological changes occur after death. The body temperature decreases with a resultant lack of skin elasticity (**algor mortis**). Therefore, the nurse must use caution when removing tape from the body to avoid skin breakdown. Another physiological change, **liver mortis**, is the bluish purple discoloration that is a by-product of red blood cell destruction. This discoloration occurs in dependent areas of the body; therefore, the nurse should elevate the head to prevent discoloration from the pooling of blood. Approximately 2 to 4 hours after death, **rigor mortis** occurs; this is stiffening of the body caused by contraction of skeletal and smooth muscles. To prevent disfiguring effects of rigor mortis, as soon as possible after death the nurse should close the eyelids, insert dentures (if applicable), close the mouth, and position the body in a natural position.

In preparing the body for family viewing, the nurse seeks to make the body look comfortable and natural. This means removing all tubes and positioning the body as previously described. After the family has viewed the body, the nurse places identification tags on the body's toe and wrist. The body is then placed in a plastic or fabric shroud, and the shroud is tagged. Then the body is transported to the morgue according to the agency's policy. The nurse is also responsible for returning the deceased's possessions to the family. Jewelry, eyeglasses, clothing, and all other personal items are returned to the family.

LEGAL ASPECTS

In most states, the physician is legally responsible for determining the cause of death and signing the death certificate. The nurse may, in certain situations, be the person responsible for certifying the death. It is important for nurses to

know their legal responsibilities, which are defined by their state or provincial board of nursing.

Autopsy

An **autopsy** (postmortem examination to determine the cause of death) is mandated in situations in which an unusual death has occurred. For example, an unexpected death and a violent death are circumstances that would necessitate an autopsy. As with all other aspects of postmortem care, the nurse must be sensitive to the family's cultural beliefs. For example, some religious groups (e.g., Judaism) prohibit autopsy. Other religious sects (e.g., Islam and Jehovah's Witness) allow autopsy only when legally mandated.

Organ Donation

The donation of organs for transplantation is a matter that requires compassion and sensitivity from the caregivers. It is

essential that families of the deceased know the importance of and process for organ donation. There is an inadequate supply of organs and tissues to meet the demand for transplants. The following organs and tissues are used for transplantation:

- Kidneys
- Heart
- Lungs
- Liver
- Pancreas
- Skin
- Corneas
- Bones (long bones and middle ear bones)

At the time the family gives consent for donation, the nurse notifies the donor team that an organ is available for transplant. Time is of the essence because the organ or tissue must be harvested and transplanted quickly to maintain viability. Health care agencies are required to have policies

NURSING CARE PLAN

Terminally Ill Client with Lung Cancer

CASE PRESENTATION

Mr. Charles Jefferson is a 57-year-old man who is terminally ill with lung cancer. He has a wife, three adult children who are married, and two grandchildren. He was employed until 2 months ago, when radiation therapy, chemotherapy, and cancer (which has metastasized to his bones and other vital organs) rendered him too weak to pursue regular daily activities. He is a religious man who is considered by all to be the "heart" of his family. He has always been generous, and his friends are many. He is currently bedridden. His cognitive abilities and sense of humor remain intact. His current problems include pain, nausea, constipation, difficulty urinating, and dry skin. He has lost 60 pounds. He has not yet received his Social Security disability income or pension money. Tomorrow he is being discharged from the hospital; he states he is going home to die.

ASSESSMENT

- 60-pound weight loss
- Constipation
- Urinary difficulty
- Dry skin

NURSING DIAGNOSIS 1: *Imbalanced nutrition:* Less than body requirements

NOC: Mr. Jefferson will report adequate energy levels.

NIC: Provide a variety of high-calorie, nutritious foods from which to select.

EXPECTED OUTCOMES

1. Mr. Jefferson will identify factors that affect the consumption and retention of food and fluids.
2. Mr. Jefferson will maintain his current body weight.

INTERVENTIONS/RATIONALES

1. Ask client to state his food preferences. Including the client in problem solving increases the likelihood of compliance. Knowing the client's food preferences helps in planning a diet that is more likely to be appealing.

(Continues)

NURSING CARE PLAN (Continued)

2. Discuss findings about dietary preferences with the family. Providing information to family members is essential because they are the ones preparing meals at home.
3. Weigh the client at the same time of day while he is wearing similar clothing. Provides an accurate reflection of weight stability and fluctuations.

EVALUATION

Goal partially met. Mr. Jefferson stated his food likes and dislikes to the home health nurse. He has lost 2 more pounds because, he states, "I'm just not hungry anymore."

NURSING DIAGNOSIS 2: *Acute pain* related to metastasis of cancer

NOC: Mr. Jefferson will use analgesic and nonanalgesic relief measures appropriately.

NIC: Correct any misconceptions about narcotic or opioid analgesics, and teach the use of nonpharmacologic techniques.

EXPECTED OUTCOME

1. Mr. Jefferson will verbalize pain relief.

INTERVENTIONS/RATIONALES

1. Communicate your understanding of his pain. Validation of client's experience reduces anxiety.
2. Provide frequent opportunities to rest. Pain is exacerbated by fatigue.
3. Provide pain medication at a level that it is effective. For a terminally ill client, pain relief is the primary goal of care.
4. Teach the client and family noninvasive pain relief measures (massage, deep breathing, imagery). Knowledge of noninvasive methods helps the client and family feel in control. Such methods complement the effectiveness of medication in pain relief.

EVALUATION

Goal partially met. Mr. Jefferson reports being pain-free for up to 2 hours at a time.

related to the referral of potential donors to organ procurement agencies.

CARE OF THE FAMILY

At the time of death, the nurse provides invaluable support to the family of the deceased. Informing the family of the type and circumstances surrounding the death is extremely important. The nurse provides information about viewing the body, asks the family about donating organs, and offers to contact support people (e.g., other relatives, clergy). Sometimes, the nurse needs to help the family with decision making regarding a funeral home, transportation, and removal of the deceased's belongings. Demonstrating compassion is essential in providing information and support to families.

NURSE'S SELF-CARE

Working with dying clients can evoke both a personal and a professional threat in the nurse. Because many nurses are

confronted with death and loss daily, grief is a common experience for nurses. Frequent exposure to death can interfere in the nurse's effectiveness because of subsequent anxiety and denial.

Whether working in a hospice, hospital, long-term care facility, or home, nurses are at particular risk for experiencing negative effects from caring for the dying. Often nurses do not want to confront their grief and will use some of the common defenses against grieving, such as keeping busy, taking care of others, being strong, and suffering in silence. Nurses need to stop pretending that they do not experience grief and subsequent suffering by talking about the intense emotions associated with caregiving.

To cope with their own grief, nurses need support, education, and assistance in coping with the death of clients. Staff education should focus on decreasing staff anxiety about working with grieving clients and families, how to seek support, and how to provide support to coworkers; see the accompanying Spotlight On display on page 496.

Often, the nurses' fears and doubts about death cause anxiety related to feelings about their own mortality. Even though such feelings are normal, caring for the dying client and the family can be emotionally draining. Therefore, nurses must remember to care for themselves.

SPOTLIGHT ON...

Caring

Nurses and the Vulnerability of Grieving

Nurses need to feel as free to ask for help in dealing with feelings about a dying client as they would in asking for assistance in lifting and repositioning a client in bed. Asking for help means taking a risk to be vulnerable; some nurses fear appearing emotionally vulnerable or overwhelmed. How can nurses support each other in dealing with the grief of caring for dying people?

KEY CONCEPTS

- Loss is a universal response experienced by an individual when someone (or something) of value is no longer available.
- Grief is a psychological response to loss characterized by deep mental anguish and sorrow. Grieving people experience various stages of grief.
- The difference between normal and pathologic grief is the inability of the individual with pathologic grief to adapt to life without the loved one.
- There are five psychological stages involved in the dying process: denial, anger, bargaining, depression, and acceptance.
- Complicated grief is associated with traumatic death such as homicide or suicide.
- Hospice care offers terminally ill clients an alternative to hospitalization when aggressive medical treatment is no longer an option.
- After death, the nurse focuses on supporting the family and caring for the deceased body.
- Nurses must care for themselves in order to provide quality, compassionate care to the dying person.

REVIEW QUESTIONS

1. Which of the following nursing actions is therapeutic for dying clients?
 - a. Apply nursing presence.
 - b. Avoid the use of touch.
 - c. Discuss only issues over which the client has control.
 - d. Limit family visits in order to conserve client energy.
2. Which of the following postmortem activities by the nurse helps decrease the effects of rigor mortis?
 - a. Close the body's eyelids and mouth.
 - b. Lower the head of the bed.
 - c. Place the body in high-Fowler's position.
 - d. Remove tape carefully from skin.
3. A client who has just learned that she is terminally ill with breast cancer says, "Not me. This can't be happening to me!" Which stage of death and dying as described by Kübler-Ross is this client exhibiting?
 - a. Anger
 - b. Bargaining
 - c. Denial
 - d. Depression
4. A client is admitted to the hospital and is in the terminal stage of cancer. The nurse enters the client's room to administer some medicine and finds the client crying. Which of the following is the most therapeutic nursing action?
 - a. Administer the client's medication and leave so the client can cry in private.
 - b. Call the family to come to the hospital to stay with the client.
 - c. Sit down and hold the client's hand.
 - d. Tell the client that you will call the client's minister.
5. A terminally ill client has been referred to hospice care. Which of the following information should a nurse give this client and family?
 - a. "Hospice uses minimal pain medication in order to improve the quality of life."

- b. “Hospice will make you accept the impending death.”
 - c. “The focus of hospice is to make you more comfortable.”
 - d. “The major purpose of hospice is to support the family after their loss.”
6. A recently widowed client describes how she is having difficulty sleeping. She states that last night she woke up because she heard the voice of her husband calling her name. Which nursing response is most therapeutic?
- a. Inform the prescribing practitioner that the client needs a prescription for sleeping pills.
 - b. Reassure the client that these behaviors are a normal part of grieving.
 - c. Refer the client to a mental health clinic for immediate assessment.
 - d. Tell the client that she will feel better soon.
7. The nurse is providing postmortem care for a client. Which of the following interventions would be appropriate prior to allowing the family to visit?
- a. Call the prescribing practitioner to verify the time of death before allowing the family to see the body.
 - b. Keep the sheet over the client’s face until the family is comfortably seated in the room.
 - c. Prepare the body to look as clean and natural as possible.
 - d. Wear sterile gloves to pack the anal canal with gauze.

Nurses [need] to have technical skills and a strong knowledge base, [yet] it is especially important to be fully present with patients, and listen to the story they have to tell ...

—DOSSEY (IN GRAY, 1995)

CHAPTER 26

Vital Signs

COMPETENCIES

1. Describe the physiological mechanisms governing temperature, pulse, respiration, and blood pressure.
2. Identify the normal age-related variations for vital sign measurements.
3. Select the appropriate equipment used to take vital signs and perform a physical examination.
4. Describe the correct positioning of the client for performing a physical examination.
5. Identify the sites for measuring vital signs.
6. Assess temperature, pulse, respiration, and blood pressure.

KEY TERMS

apnea monitor	eupnea	pulse pressure
atherosclerosis	evaporation	pulse quality
auscultatory gap	expiration	pulse rate
basal metabolic rate (BMR)	external respiration	pulse rhythm
baseline values	hemodynamic regulation	pulse volume
blood pressure	hypertension	pyrexia
bradycardia	hyperventilation	pyrogens
bradypnea	hypotension	radiation
cachexia	hypoventilation	respiration
cardiac output	insensible heat loss	stroke volume
conduction	inspiration	systole
convection	internal respiration	tachycardia
costal (thoracic) breathing	neurogenic fever	tachypnea
cyanosis	orthostatic hypotension	thermoregulation
degrees	osteoporosis	vasoconstriction
diaphragmatic (abdominal) breathing	oximeter	vasodilation
diastole	piloerection	vital capacity
dyspnea	pleura	vital signs
dysrhythmia	pulse	
	pulse deficit	

Assessing and monitoring a client's clinical condition is the main reason nursing care is required. Nursing decisions are based on assessment data. One of the most frequent data collection interventions a nurse performs is taking **vital signs**, meaning the measurement of a client's temperature (T), pulse (P), respiration (R), and blood pressure (BP). These measurements indicate the physiological functioning of the circulatory, respiratory, neural, and endocrine systems. The data obtained from these measurements are used by the nurse, in conjunction with a client's physical assessment and health history, to determine a client's clinical care.

The body's physiological responses in terms of temperature, pulse, respiration, and blood pressure, how these responses are measured, and special nursing considerations, as appropriate, will be presented in this chapter. The latest research released by the National High Blood Pressure Education Program (*The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure* [JNC 7]; National Institutes of Health [NIH], 2003) is presented in the section on hypertension. This report is referred to throughout the chapter as the JNC 7. The eighth report of the JNC is scheduled for release in 2009.

VITAL SIGNS

Vital signs are fundamental to assessment to establish baseline values of the client's cardiorespiratory integrity. **Baseline values** establish the norm against which subsequent measurements can

be compared. Variations from normal findings may indicate potential problems regarding the client's health status. Nurses should confirm "normal" measurements with clients because the perception of what is normal may vary among clients.

Vital signs are taken whenever the client is admitted to a health care facility or service, for example, home health care, clinic, or other ambulatory setting, and on a routine basis in the hospital. The frequency of vital sign measurements for the hospitalized client is determined by the client's health status, the prescribing practitioner's orders, and the established standards of care for the particular clinical setting or service. Whenever a change is suspected in the client's status, the nurse should measure the vital signs, regardless of the setting.

The sequence for recording vital signs measurement in the nurses' notes is T-P-R and BP. Agencies usually have special graphic forms to record vital signs findings. These forms facilitate data comparison at a glance because the data are plotted on a graph.

PHYSIOLOGICAL FUNCTION

Healthy people have the ability to meet their own needs; however, during illness, people need assistance (in proportion to the degree of dysfunction) in meeting their basic needs. The assessment of physiological functioning provides specific data regarding the client's current condition. Data analysis allows the nurse to plan nursing care that is responsive to the preventive and restorative needs of the client. See Chapters 5 through 10 for a complete discussion of the steps of the nursing process.

Thermoregulation

Thermoregulation is the body's physiological function of heat regulation to maintain a constant internal body temperature. The heat of the body is measured in units called **degrees**. The "core" internal temperature of 98.6° Fahrenheit (F) (37° centigrade [C]) does not vary more than 1.4°F (0.77°C) and is higher than the skin and external temperatures. In contrast, the skin temperature rises and falls in accordance with changes in environmental temperature.

HEAT PRODUCTION Heat is produced in the body's cells through food metabolism that results in the release of energy. The body converts energy supplied by metabolized nutrients to energy forms that can be used directly by the body. One form of this energy is thermal energy for regulation of body temperature. Energy is measured in terms of heat. A kilocalorie is an energy value (heat measure) of a given food; 1 kilocalorie equals 1,000 calories (the amount of heat required to raise the temperature of 1 kilogram of water 1°C). This type of heat liberation is usually expressed as the metabolic rate and measured as the **basal metabolic rate**, or **BMR** (the rate of energy use in the body needed to maintain essential activities). See Chapter 34 for a complete discussion of calories, kilocalories, and metabolic rate.

Factors that affect the metabolic rate of heat liberation, such as age and exercise, are discussed later in this chapter. The thyroid hormones thyroxine and triiodothyronine increase basal metabolism by breaking down glucose and fat. Muscular activity also produces heat from the breakdown of carbohydrates and fats and through shivering.

Body temperature is controlled by balancing metabolic heat production with heat loss. Most heat production comes from the deep tissue organs (brain, liver, and heart) and the skeletal muscles. The skin, subcutaneous tissues, and fat of the subcutaneous tissues serve as heat insulators for the body. Sweat glands in the dermis are innervated by sympathetic nerves of the autonomic nervous system and are controlled by the anterior hypothalamus to regulate sweating.

When body heat rises, the hypothalamus transmits impulses to reduce body heat by triggering perspiration, **vasodilation** (the widening of blood vessels), and the inhibition of heat production. The opposite physiological functioning occurs in response to a decrease in body heat. In this situation the hypothalamus transmits impulses to stimulate heat production through **vasoconstriction** (the narrowing of blood vessels), muscle shivering, and **piloerection** (hairs standing on end).

HEAT LOSS Most body heat is lost from the skin's surface to the environment by the processes of radiation, conduction, convection, and evaporation (see Table 26-1 on page 504). **Insensible heat loss** is the heat that is lost through the continuous, unnoticed water loss that occurs with vaporization, accounting for 10% of basal heat production. Evaporation accounts for the greatest heat loss when body heat increases.

BEHAVIORAL CONTROL OF BODY TEMPERATURE In addition to the heat production and heat loss mechanisms described earlier, the body has another potent mechanism for temperature control, known as behavioral control. In response to the body's signaling conditions of being either overheated or too cold, the person makes appropriate environmental adjustments to reestablish comfort. Guyton and Hall (2007) recognize this mechanism as the most effective one for body heat control in severely cold environments.

Respiration

Respiration is the act of breathing. Respiration is defined by physiological functioning as:

- **External respiration**—the exchange of oxygen and carbon dioxide between the alveoli of the lungs and the pulmonary blood system
- **Internal respiration**—the interchange of oxygen and carbon dioxide between the circulating blood and cells throughout the body
- **Inspiration** (inhalation)—the intake of air into the lungs
- **Expiration** (exhalation)—the movement of gases from the lungs to the atmosphere
- **Vital capacity**—the amount of air exhaled from the lungs after a minimal full inspiration

These five major physiological pulmonary functions provide oxygen to the tissues and remove carbon dioxide:

1. Ventilation—the inflow and outflow of air between the atmosphere and the lung alveoli
2. Circulation—the quantity of blood flowing through the lungs is approximately 4 to 6 L/min
3. Diffusion—the exchange of oxygen and carbon dioxide between the alveoli and the blood
4. Transport—the carrying of oxygen and carbon dioxide in the blood and body fluids to and from the cells
5. Regulation—the neurogenic system that adjusts the rate of alveolar ventilation to meet the demands of the body. The arterial blood oxygen pressure (PO₂) and arterial blood carbon dioxide pressure (PCO₂) may be altered during times of strenuous exercise and other types of respiratory stress. See Chapter 32 for a complete discussion about oxygenation.

The mechanics of pulmonary ventilation depend on abdominal recti and internal intercostal muscles that cause lung expansion and contraction. Normal breathing is accomplished by:

1. The downward and upward movement of the diaphragm to lengthen or shorten the chest cavity
2. The elevation and depression of the ribs to increase and decrease the anteroposterior diameter of the chest cavity

Children and men normally breathe with their diaphragm muscles; adult women generally breathe with their upper chest muscles.

Hemodynamic Regulation

Hemodynamic regulation is the physiological function of blood circulating to maintain an appropriate environment in

TABLE 26-1 Methods of Heat Loss

METHOD	CHARACTERISTICS	EXAMPLE
Radiation: Loss of heat in the form of infrared rays	All objects that are not at absolute zero radiate heat rays from the surface of one object to the surface of another object that is not in physical contact with the first object.	If the temperature of the body is greater than the surroundings, heat is lost from the body to the environment. A nude person in a room with normal temperature will lose about 60% of total loss by radiation.
Conduction: Loss of heat to an object in contact with the body	Heat is lost to other objects that are cooler than the skin. As much as 15% of the body's total heat loss is transferred to the air. Once the temperature of the air adjacent to the skin equals the skin temperature, there is no further loss of body heat.	Bathing a client in cool or tepid water will lower the client's temperature.
Convection: Movement of heat away from the body's surface	Convection accompanies conduction when the warmed air or water is replaced with cooler elements.	The use of fans enhances convected heat loss by air. Water adjacent to the skin can absorb far greater quantities of heat than can air. Clothing entraps air next to the skin, decreasing heat loss from the body by conduction and convection.
Evaporation: Continuous insensible water loss from the skin and lungs when water is converted from a liquid to a gas	It takes approximately 0.58 calories of heat for a gram of water to evaporate.	Insensible water loss is continuous. Insensible loss occurs regardless of body temperature; thus, it is not a major regulator of temperature.

Delmar/Cengage Learning

tissue fluids. Circulation transports nutrients to the tissues, removes waste products, and carries hormones from one part of the body to another. When the body's circulatory needs change, the heart rate either accelerates or decelerates. This is a compensatory mechanism under the control of the cardiac centers that are located in the medulla of the brain stem. The sensory receptors in the tissues transmit impulses to the cardiac centers, which in turn trigger a change in the heart rate through the sympathetic and parasympathetic nervous systems that innervate the heart. When the physiological needs of the tissues are met, the heart rate returns to normal.

Systemic circulation supplies blood to all the tissues of the body except the lungs (which is accomplished through pulmonary circulation). Approximately 84% of the entire blood volume is in the systemic circulation, with the heart containing 7% and the pulmonary vessels containing 9%. The circulatory system is composed of:

- Arteries—large vessels that transport systemic blood under high pressure to the tissues
- Arterioles—the smallest branches of the arterial system that act as control valves to release blood into the capillaries
- Capillaries—thin-walled vessels permeable to small molecular substances that exchange fluids, nutrients, electrolytes,

hormones, and other substances between the blood and interstitial fluid

- Venules—vessels that collect blood from the capillaries and gradually coalesce into progressively larger veins
- Veins—vessels that transport systemic blood from the tissues back to the heart and serve as a reservoir for extra blood

The normal physiological function of the cells requires continuous blood flow and appropriate volume and distribution of blood to the cells that need nutrients. This is accomplished through the heart's contraction and ejection of blood into the aorta and the distensibility of the arterial system. The combination of arterial distensibility and resistance reduces the pressure pulsations, allowing continuous blood flow to the tissues. The dynamics of distensibility and resistance maintain a constant blood flow; otherwise, blood would flow to the tissues only during **systole** (phase in which the ventricles contract to eject blood) with an absence of blood flow during **diastole** (phase in which ventricles are relaxed and no blood is being ejected).

The cardiac cycle has two phases: systole and diastole. At the onset of systole there is an increase in ventricular pressure that causes the mitral and tricuspid valves to close. The closing of these valves produces the first heart sound (S_1).

Ventricular pressure continues to increase until it exceeds the pressure in the pulmonary artery and the aorta, causing the aortic and pulmonic valves to open and allowing the ventricles to eject blood into these arteries. Ventricular emptying and relaxation cause a decrease in ventricular pressure and closure of the aortic and pulmonic valves. Closure of these valves produces the second heart sound (S_2). During diastole the pressure in the ventricles is less than that in the atria, causing the mitral and tricuspid valves to open and allowing blood to flow from the atria into the ventricles until the end of diastole, when the atria contract to send the rest of the blood into the ventricles. Ventricular filling causes an increase in pressure that closes the mitral and tricuspid valves (the beginning of systole) and starts another cardiac cycle.

Stroke volume is the measurement of blood that enters the aorta with each ventricular contraction. With each ventricular contraction, the heart ejects 60 to 70 mL of blood into the aorta. **Cardiac output** is the volume of blood pumped by the heart in 1 minute and is measured by multiplying the heart rate by the ventricle's stroke volume. For example, a client with a heart rate of 80 beats per minute times a stroke volume of 60 mL of blood would have a cardiac output of 4,800 mL. **Pulse pressure** is a measurement of the ratio of stroke volume to compliance (total distensibility) of the arterial system.

PULSE The **pulse** is the bounding of blood flow in an artery that is palpable at various points on the body. The pulse is caused by the stroke volume ejection and distension of the walls of the aorta, which creates a pulse wave as it travels rapidly toward the distal ends of the arteries. As the pulse wave reaches a superficial peripheral artery and travels over an underlying bone or muscle, the pulse can be palpated by applying gentle pressure over a pulse point (a specific area where the peripheral pulses can be palpated). Figure 26-1 shows the location of pulse points throughout the body.

BLOOD PRESSURE Both the blood pressure and pulse are measurements that determine the volume of ejected blood into the arterial system with each ventricular contraction. **Blood pressure** is the measurement of pressure pulsations exerted against the blood vessel walls during systole and diastole. It is measured in terms of millimeters of mercury (mm Hg). In a healthy young adult, the pressure at the height of each pulse (the systolic pressure) is less than 120 mm Hg, and the pressure at the lowest point of each pulse (diastolic pressure) is less than 80 mm Hg. The pulse pressure is the difference between these pressures, which is 40 mm Hg. If 1 mm Hg caused a vessel originally containing 10 mL of blood to increase its volume by 1 mL, the distensibility would be 0.1/mm Hg, or 10%/mm Hg (Guyton & Hall, 2007).

The body has four hemodynamic regulators for blood pressure control:

1. Blood volume—the volume of blood in the circulatory system. Blood pressure is proportional to the blood volume. Hemorrhage causes a loss in blood volume that, in turn, lowers the blood pressure. Rapid infusion

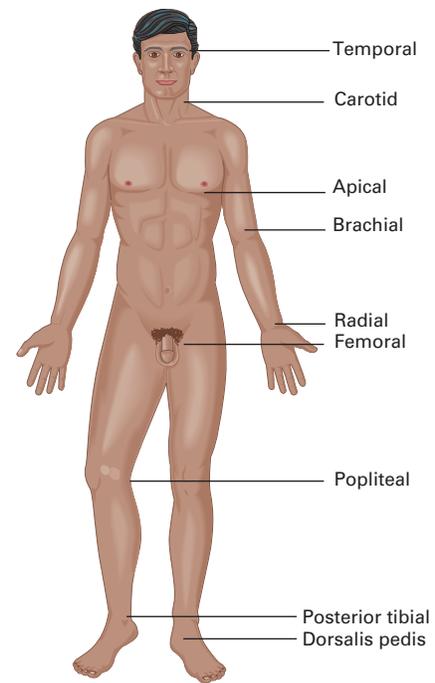

FIGURE 26-1 Pulse Points DELMAR/CENGAGE LEARNING

of intravenous fluids causes an increase in volume and a subsequent rise in pressure.

2. Cardiac output—the major factor that influences systolic pressure.
3. Peripheral vascular resistance—the size and distensibility of the arteries, which is the most important determinant of diastolic pressure. Arterial resistance (decreased distensibility) is encountered when the left ventricle pumps blood from the heart under pressure during the systolic phase. The arteries contain smooth muscles that allow them to contract, which decreases their compliance (tone) and causes resistance. The varying degrees of tone allow some of the arterioles to remain constricted while others dilate to protect the body's circulatory system from accommodating a greater blood capacity than the actual blood volume. If all of the arterioles were to dilate at one time, there would not be enough blood to fill them.
4. Viscosity—the thickness of the blood based on the ratio of proteins and cells to the liquid portion of blood. The greater the viscosity, the harder the heart must work to pump blood, with a resultant increase in blood pressure.

These regulators work in unison to create a constant blood pressure. For instance, when the blood volume decreases, the body compensates with an increased heart rate and vasoconstriction that increases peripheral resistance to maintain normal pressure and functions of the vital organs.

Blood pressure is a result of the cardiac output and peripheral vascular resistance. Normal arteries expand during systole and contract during diastole, creating two distinct pressure phases:

- Systolic blood pressure is a measurement of the maximal pressure exerted against arterial walls during systole (when

myocardial fibers contract and tighten to eject blood from the ventricles), primarily a reflection of cardiac output.

- Diastolic blood pressure is a measurement of pressure remaining in the arterial system during diastole (period of relaxation that reflects the pressure remaining in the blood vessels after the heart has pumped), primarily a reflection of peripheral vascular resistance.

Serial blood pressure readings provide significant clinical data relative to the client's cardiovascular and fluid volume status. See Chapter 33 for a complete discussion of maintenance of fluid volume.

FACTORS INFLUENCING VITAL SIGNS

Several factors can cause changes in one or more of the vital signs: age, gender, heredity, race, lifestyle, environment, medications, pain, and other factors such as exercise and metabolism, anxiety and stress, postural changes, diurnal variations, and hormones.

AGE

The normal values and variations in vital sign measurement are usually based on age. Tables 26-2, 26-3, and 26-4 present age-related changes in temperature, pulse, and respiration. In newborns, thermoregulation and the respiratory center are immature. The newborn's temperature fluctuates with the environment. Clothing must be adequate to maintain body heat. For example, the newborn's head should be covered because up to 30% of body heat can be lost through the head. The newborn's respiratory rate is from 30 to 50 breaths per minute, with a slightly irregular rhythm. Temperature regulation becomes stable when children reach puberty.

TABLE 26-2 Normal Age-Related Variations in Body Temperature

AGE		NORMAL RANGE	
		CELSIUS	FAHRENHEIT
Newborn	Axillary	35.5–39.5°C	96.0–99.5°F
1 year	Oral	37.7°C	99.7°F
3 years	Oral	37.2°C	99.0°F
5 years	Oral	37.0°C	98.6°F
Adult	Oral	37.0°C	98.6°F
	Axillary	36.4°C	97.6°F
	Rectal	37.6°C	99.6°F
70+ years	Oral	36.0°C	96.8°F

Delmar/Cengage Learning

TABLE 26-3 Normal Age-Related Variations in Resting Pulse

AGE	NORMAL RANGE	AVERAGE RATE/MINUTE
Newborn	100–170	140
1 year	80–170	120
3 years	80–130	110
6 years	75–120	100
10 years	70–110	90
14 years	60–110	90
Adult	60–100	80

Delmar/Cengage Learning

TABLE 26-4 Normal Age-Related Variations in Resting Respiration

AGE	NORMAL RANGE	AVERAGE RATE/MINUTE
Newborn	30–50	40
1 year	20–40	30
3 years	20–30	25
6 years	16–22	19
14 years	14–20	17
Adult	12–20	18

Delmar/Cengage Learning

In the elderly, the efficiency of thermoregulation is reduced by the physiological changes of aging, including loss of subcutaneous fat, decreased sweat gland activity, reduced metabolism, and poor vasomotor control. Financial status and environmental conditions experienced by the elderly may also affect diet, activity, and ability to control the external temperature.

The normal aging process causes changes in the elderly person's respiratory functions. Major physiological alterations include:

- Ventilation—Bony changes in the thorax and vertebrae and the decline in respiratory and abdominal musculature reduce the ability of the lungs to distend.
- Circulation and diffusion—The increase in dead air space in the respiratory tree decreases the quantity of blood flowing through the lungs and gaseous exchange.
- Transport—**Atherosclerosis** (plaques in the inner walls of arteries) and **dysrhythmia** (irregular heartbeat) reduce the amount of blood flow available to tissues.

- Regulation—The inability of lung function to perform maximal breathing for extended periods of time reduces the rate of alveolar ventilation to meet the demands of the body.

See Chapter 19 for a complete discussion of the physiological changes that occur in the older client.

Blood pressure varies throughout life (see Table 26-5). From early childhood throughout adolescence, the blood pressure varies according to body size. An adult's blood pressure continues to increase with age. The JNC 7 (NIH, 2003) states that men over age 45 and women over age 55 are at higher risk for developing high blood pressure (hypertension). In some women, blood pressure can increase if they use birth control pills, become pregnant, or take hormone therapy during menopause.

GENDER

Women usually experience greater temperature fluctuations than men because of hormonal changes. Temperature variations occur during the menstrual cycle mainly in response to the progesterone level. As the progesterone level increases during ovulation, temperature gradually rises. During menopause, the instability of the vasomotor controls may cause periods (30 seconds to 5 minutes) of intense body heat and sweating. Males in general have higher blood pressure than do females of the same age.

HEREDITY

Although many studies have been conducted to relate hereditary factors to specific cardiovascular disease occurrence, the results are often inconclusive regarding the influence of hereditary versus environmental factors. For example, studies have been conducted to relate elevated blood cholesterol levels to a single gene. Giger and Davidhizar (2008) describe studies of Jews and non-Jews and compare Ashkenazi Jews with Oriental Jews based on the theory that elevated blood

cholesterol levels may be caused by a single gene. These studies indicate a higher occurrence of elevated blood cholesterol levels among Jews than among non-Jews and that Ashkenazi Jews may have a higher frequency of the gene than Oriental Jews. The conclusion of this research indicates a need for further studies to be done to determine the frequency of heart disease among Jews as well as the interplay between heredity and environment (Giger & Davidhizar, 2008). Genetic and environmental factors also are believed to be contributing factors to hypertension in African Americans. A family history of hypertension increases one's chances of developing hypertension (NIH, 2003).

RACE

Some ethnic groups are more susceptible than others to hemodynamic alterations. African Americans have a higher prevalence and greater severity of hypertension than do other minorities and whites. Hypertension-related deaths are higher in this population.

LIFESTYLE

Lifestyle factors, such as cigarette smoking, cause chronic changes in the lungs as manifested by impaired ventilation. Stimulants such as caffeinated beverages and tobacco elevate the heart rate. Eating too much salt and not enough potassium and consuming alcohol also can raise blood pressure (NIH, 2003). The effects of exercise and stress are discussed later.

ENVIRONMENT

Environmental factors such as temperature and noise level can alter the heart rate. Acid rain and industrialized areas are often associated with a high occurrence of respiratory conditions, such as infections and chronic lung diseases.

Primary prevention is a major role of occupational (industrial) health nurses. A health screening examination relies heavily on vital sign measurements and physical examination findings. The occupational health nurse should perform health screening examinations that focus on the short-term results of certain environmental conditions (diseases) and monitor for the development of chronic trends; see the accompanying Respecting Our Differences display, on page 508, on health screening criteria.

MEDICATIONS

Some medications can directly or indirectly alter the pulse, respiration, or blood pressure. Digitalis preparations (cardiac glycosides) decrease the pulse rate. Narcotic analgesics (pain medications) can depress the rate and depth of respirations and lower the blood pressure.

Always ask clients what medications they are currently taking, and be aware of the side effects of any medications administered. Certain drugs may either increase or decrease pulse rate and blood pressure. If the drug alters the client's pulse, respiration, or blood pressure, provide appropriate

TABLE 26-5 Normal Age-Related Variations in Blood Pressure

AGE	BLOOD PRESSURE (MM HG)
Newborn	Up to 70/45
5 years	Up to 115/75*
6 to 12 years	Up to 125/80*
13 to 15 years	Up to 126/78*
16 to 18 years	Up to 132/82*
Over 18 years	<120/80

The Heart Center Online. Retrieved September 8, 2008, from <http://www.heartcenteronline.com>.

RESPECTING OUR DIFFERENCES

The performance of a health screening examination is justified when the disease being screened for has:

- A significant effect on the longevity or the quality of life
- A sufficiently high prevalence rate to justify the cost of the screening program
- Been shown to have better therapeutic results if detected in the early stage and worse results with delayed detection and treatment
- A significant asymptomatic period allowing an opportunity for detection and treatment that will reduce the rate of morbidity and mortality
- An acceptable method of treatment

Data from Edelman, C. L., & Mandle, C. L. (2006). *Health promotion throughout the life span* (6th ed., p. 231). St. Louis, MO: Elsevier Health Sciences.

client teaching so that the client is able to compensate for the variations in these functions.

PAIN

Each person reacts to pain in varying degrees. With acute pain, sympathetic stimulation increases the heart rate, which

increases the cardiac output and vasoconstriction, causing increased peripheral vascular resistance. These changes result in increased pulse and respiratory rates, depth of respirations, and blood pressure. Chronic pain causes parasympathetic stimulation and decreases the pulse rate. See Chapter 35 for a complete discussion about pain and measures to promote comfort.

OTHER FACTORS

Table 26-6 discusses the effects of exercise and metabolism, anxiety and stress, postural changes, and diurnal (daily) variations (also called circadian) on vital sign measurements. Routine exercise increases metabolism and heat production and strengthens the cardiac muscles. The normal, untrained person can increase cardiac output fourfold with exercise, and the trained athlete can increase cardiac output about sixfold (Guyton & Hall, 2007).

Anxiety and stress stimulate the sympathetic nervous system to:

- Increase the production of epinephrine and norepinephrine, with a resultant increase in metabolic activity and heat production
- Increase the heart rate, which, in turn, increases the cardiac output and causes vasoconstriction with a subsequent increase in peripheral vascular resistance

Sympathetic stimulation causes an increase in the pulse rate and blood pressure. See Chapter 23 for a complete discussion about stress, anxiety, adaptation, and change.

TABLE 26-6 Factors Influencing Vital Signs

FACTOR	TEMPERATURE	PULSE	RESPIRATION	BLOOD PRESSURE
Exercise and metabolism	Increases	Short-term: increases • Long-term: lowers the resting rate and return time to the resting rate postexercise	Rate and depth increase	Increases
Anxiety and stress	Increases	Increases	Increases	Increases
Postural changes	No change	Increases with sitting or standing; decreases when lying down	Decreases with stooped or slumped positions due to decreased chest expansion	Decreases with sitting or standing
Diurnal variations (circadian rhythm)	Lowest level: 0400–0600 h Highest level: 2000–2400 h	Decreases during sleep	None	Lowest level: early morning Highest level: late afternoon or early evening

Delmar/Cengage Learning

Postural changes occur in response to stimulation of the baroreceptors (spray-type nerve endings of the autonomic nervous system) that are located in the walls of the arteries. The baroreceptor reflex is the primary mechanism for maintaining a relatively constant arterial pressure. When a person stands up after lying down, the arterial pressure in the head and upper part of the body immediately tends to fall. This falling pressure elicits an immediate baroreceptor reflex, resulting in strong sympathetic discharges throughout the body. This response minimizes the decrease in pressure in the head and upper body (Guyton & Hall, 2007). The person's blood pressure decreases when going from a lying to a sitting or standing position. However, the pulse is lower in a lying position and increases in a sitting or standing position.

Each person has a different temperature pattern, with a normal variance ranging from 0.5°C to 1°C (0.9°F–1.8°F) for a 24-hour period. Table 26-6 identifies when the lowest temperature and pulse variances occur.

The skin temperature rises and falls with a change in environmental temperature. Infants and older adults are most susceptible to environmental changes because their temperature-regulating mechanisms are less effective. Warm environments decrease conduction and increase body temperature, which, in turn, increases the metabolic rate, resulting in an increased pulse rate. Improper clothing in cold climates may lead to a decrease in body temperature through radiation and conductive heat loss that results in shivering to raise body temperature.

Other factors can contribute to vital signs being above or below the established normal limits. A review of the client's health history data will reveal pertinent information regarding the factors that influence vital signs.

MEASURING VITAL SIGNS

Measuring a client's vital signs is a routine yet important nursing function that all nurses must master and execute skillfully.

EQUIPMENT

The measurement of the client's vital signs requires the appropriate instruments. All pieces of equipment should be maintained to function accurately. Table 26-7 on page 510, describes the common types of equipment used to assess vital signs.

Equipment should be gathered before entering the client's room. However, certain pieces of equipment, such as the sphygmomanometer, may be permanently installed in the examination and inpatient rooms. The nurse should observe what equipment is in the client's room during the first visit. The necessary equipment for clients who are maintained on isolation precautions should be kept inside the room because items should not be taken in and out of isolation rooms.

MEASUREMENT OF HEIGHT AND WEIGHT

Measuring height and weight is as important as assessing the client's vital signs. Routine measurement provides data related to growth and development in infants and children and signals the possible onset of alterations that may indicate illness in all age groups. The client's height and weight are routinely taken upon admission to acute care facilities and during visits to prescribing practitioners' offices, clinics, and other health care settings.

Height

Measurement of height is expressed in inches (in.), feet (ft), centimeters (cm), or meters (m). See the accompanying display on conversion equivalents for height measurements from one system to another.

A scale for measuring height, calibrated in either inches or centimeters, is usually attached to a standing weight scale. This type of scale is used for measuring the height of children and adults. The nurse should ask the client to stand erect on the scale's platform. The metal rod attached to the back of the scale should be extended to gently rest on top of the client's head, and the measurement should be read at eye level.

When measuring an infant's length, the nurse should place the infant on a firm surface. Extend the knees, with the feet at right angles to the table. Measure the distance from the vertex (top) of the head to the soles of the feet with a measuring tape. The procedure usually requires two nurses, one to hold the infant still and the other to measure the length. If the nurse needs to perform the measurement without assistance, an object should be placed at the infant's head, the infant's knees should be extended, and a second object should be placed at the infant's feet. Lift the infant and measure the distance between the two objects.

Height increases gradually from birth to the prepubertal growth spurt. Girls usually reach their adult height between the ages of 16 and 17 years, whereas boys usually continue to grow until the ages of 18 to 20 years. The older adult usually decreases in height as a result of a gradual loss of muscle mass and changes in the vertebrae that occur in conditions such as **osteoporosis** (a process in which reabsorption exceeds accretion of bone).

Weight

Measurement of weight is expressed in ounces (oz), pounds (lb), grams (g), or kilograms (kg); see the accompanying display, on page 512, on conversion equivalents. Weight

CONVERSION EQUIVALENTS FOR HEIGHT MEASUREMENT

1 in. = 2.5 cm 1 cm = 0.4 in.
1 ft = 30.5 cm or 0.3 m 1 m = 39.4 in. or 3.28 ft

TABLE 26-7 Equipment Used for Vital Signs Measurement

INSTRUMENT

DESCRIPTION

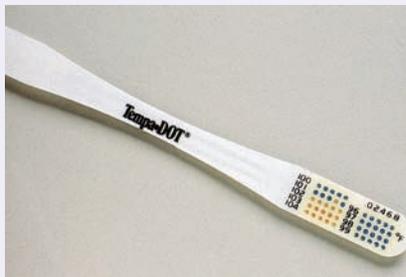

Thermometer

Electronic

Battery-powered display unit with a sensitive probe (blue for oral and red for rectal) covered with a disposable plastic sheath for individual use.

Disposable (chemical), single-use

Thin strips of plastic with chemically impregnated dots that change color to reflect temperature.

Tympanic

Battery-powered display unit with disposable speculums and infrared-sensing electronics. (Photograph courtesy of The Gillette Company)

Stethoscope

Acoustic

Closed cylinder that prevents dissipation of sound waves and amplifies the sound through a diaphragm. Flat-disc diaphragm transmits high-pitched sounds, and the bell-shaped diaphragm transmits low-pitched sounds.

(continues)

TABLE 26-7 (Continued)

INSTRUMENT	DESCRIPTION
Ultrasound (Doppler)	Battery-operated headset with earpieces attached to a volume-controlled audio unit and ultrasound transducer that detects movement of red blood cells through a vessel.
Sphygmomanometer Mercury manometer	Wall unit that contains a mercury-filled glass column, calibrated in millimeters; the mercury rises and falls in response to pressure created when the cuff is inflated.
Aneroid manometer	Portable unit with a glass-enclosed gauge containing a needle to register millimeter calibration and a metal bellows within the gauge that expands and collapses in response to pressure variations from the inflated cuff.

Delmar/Cengage Learning

CONVERSION EQUIVALENTS FOR WEIGHT MEASUREMENT

1 lb = 0.45 kg 1 kg = 2.2 lb
1 oz = 28.4 g 1 g = 0.35 oz

increases gradually from birth until the prepubertal growth spurt. Height and weight changes occur in the adolescent's torso. The resulting redistribution of body fat gives the body an adult appearance. (See Table 26-8 for the normal ranges of body height and weight according to age.) The loss of muscle mass and changes in dietary habits usually cause weight loss in older adults.

When a client has an order for "daily weight," the weight should be obtained at the same time of the day on the same scale, with the client wearing the same type of clothing. Standing scales are used for clients who can bear their own weight (see Figure 26-2). When standing on a scale, the client should wear some type of light foot covering, such as disposable operating room slippers, to prevent the transmission of infection and to enhance comfort. The Nursing Checklist describes the procedure for calibrating a scale and measuring the weight for children and adults (see Figure 26-3 on page 513).

Several types of scales, such as stretcher, chair, and bed scales, are available for clients who are unable to bear weight or who are confined to bed. Figure 26-4 on page 513, shows a scale that is equipped with a mechanical lift. A sheet should be placed between the client's skin and the surfaces of the belts.

FIGURE 26-2 Weighing a Client on a Standing Scale DELMAR/CENGAGE LEARNING

TABLE 26-8 Normal Age-Related Variations in Height and Weight

AGE	HEIGHT	WEIGHT
Newborn	50 cm (20 in.)	3.38 kg (7.5 lb)
1–6 mos	63 cm (25 in.)	2 × birth weight
6–12 mos	71 cm (28 in.)	3 × birth weight
Toddler	75–83 cm (30–33 in.)	15 kg (33 lb)
Preschooler	100 cm (40 in.)	18.2–20.5 kg (40–45 lb)
School-age	115–140 cm (46–56 in.)	35.5–38.6 kg (75–85 lb)
Growth Spurt		
Girls 8–14 yrs	120–160cm (48–64 in.)	40.9–63.6 kg (90–140 lb)
Boys 10–16 yrs	125–170 cm (50–68 in.)	40.9–68.2 kg (90–150 lb)

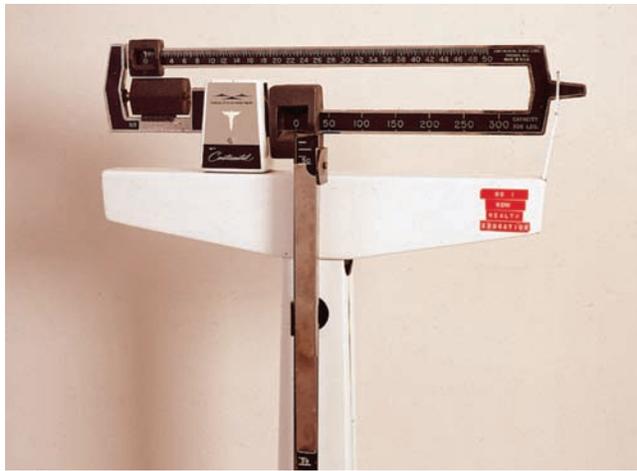

Delmar/Cengage Learning

NURSING CHECKLIST

Calibrating the Scale and Measuring Weight of Children and Adults

- Calibrate the standing scale by setting both weight indicators to zero. The balance beam will be at the top (Figure 26-3A). When calibrated, the balance beam will be at the midway point.
- Digital display scales should read zero. If they do not, follow the manufacturer's instructions to recalibrate the scale.
- Assist the client to a standing position. Have the client empty his or her bladder before the weight measurement.
- Make sure the scale is sitting evenly on the floor, and assist the client onto the scale. Instruct the client to remain still. Avoid touching him or her.
- Slowly move the standing scale's weight indicators on the balance beam until the tip of the beam registers in the middle of the mark (Figure 26-3B). Digital scales will automatically display the weight.
- Read and record the weight.
- Assist the client back to the former position.

A

B

FIGURE 26-3 Calibrating the Scale and Weighing the Client. **A.** Set both weight indicators to zero. **B.** With the client standing on the scale, move the weight indicators on the balance beam until the tip of the beam registers in the middle of the mark. DELMAR/CENGAGE LEARNING

Infants can be weighed on platform or cradle scales. Before weighing the infant, the nurse should make sure the room is warm. The infant's clothing and diaper should then be removed, and the nurse should place a light blanket on the scale's surface. The nurse should face the infant, keeping one hand over the top of the infant to prevent accidental injury while adjusting the scale with the other hand. The reading should be noted as quickly as possible, and the nurse should return the infant to the crib and dress her or him.

Nursing Considerations

Accurate recordings of weight are imperative because they are used in drug dosage calculations and in evaluating the effectiveness of drug, fluid, and nutritional therapy. Weights above the normal range may indicate obesity or fluid retention. Weights below the normal range may indicate malnutrition, delayed growth and development, or **cachexia** (weight loss marked by weakness and emaciation that usually occurs with a chronic illness such as tuberculosis or cancer). Height is compared with weight to evaluate growth of infants and children.

FIGURE 26-4 Scales equipped with mechanical lifts are used for clients who are either unable to bear their weight on standing scales or who are confined to bed. PHOTO COURTESY OF HEALTH O METER

DOCUMENTATION The height and weight measurements are recorded on the appropriate form, such as the admit assessment form. Daily weights are usually recorded on the vital signs record. If the weight is taken at a different time or on a different scale, the variation should be recorded.

THE NURSING PROCESS AND VITAL SIGNS

Monitoring vital signs is a critical nursing intervention that provides data necessary to evaluate the client's condition and prevent complications. The nursing process, in order to be an effective tool of assessment and accountability, must have a system of measurement based on nursing vocabularies and taxonomies (Moorhead, Johnson, & Maas, 2008). The ongoing work of the North American Nursing Diagnosis Association (NANDA) International, Nursing Outcomes Classification (NOC), and Nursing Interventions Classification (NIC) is to create vocabularies and taxonomies that define nursing; see Unit 2 for a complete discussion of the nursing process.

NURSING PROCESS AND THERMOREGULATION

When heat production exceeds heat loss and body temperature rises above the normal range, **pyrexia** occurs. This

condition is caused by an elevation of the body's set point in the hypothalamus. When the body's temperature rises above 37.4°C (101°F) orally or 38°C (100.4°F) rectally, the client is said to be febrile.

Pyrogens (bacteria, viruses, fungi, and some antigens) are endogenous or exogenous substances that cause fever. When a pyrogen enters the body, it causes an increased production of white blood cells and raises the set point of the hypothalamus. It takes the body several hours to generate and conserve sufficient heat to achieve the new set point. It is during this time that the person experiences the clinical symptoms of chills and shivering. When the temperature and set point are equal, chills subside and fever is manifested clinically.

There are four patterns of occurrence that are used to describe fever and provide information regarding the fever's cause:

- **Intermittent:** The temperature returns to normal at least once every 24 hours; it is associated with gram-negative or gram-positive sepsis, abscesses, and infectious endocarditis.
- **Remittent:** The temperature does not return to normal but varies only a few degrees in either direction; it is associated with viral upper respiratory tract, *Legionella*, and *Mycoplasma* infections.
- **Sustained:** The temperature remains above normal with minimal variations, less than 1 degree; it is usually caused by drugs.
- **Recurrent (relapsing):** This pattern is characterized by one or more episodes of fever, each as long as several days, with one or more days of normal temperature

between episodes; it is caused by various infectious diseases, including fungal.

The fever cycle continues until the body overcomes the pyrogen either naturally or through clinical intervention (e.g., administration of antibiotics). See Chapter 29 for a nursing care plan for the febrile client.

Age, gender, and hormonal levels can influence "normal" physiological function. For example, an older adult with a serious infection may trigger only a modest fever or no fever at all. These factors account for the differences in individual temperature measurements relative to fever. When a person is exposed to extreme environmental conditions, several alterations in thermoregulation can occur (see Table 26-9).

Assessment

Body temperature is measured by using one of the instruments described in Table 26-7. Frequent monitoring is required for clients who have or who are at risk for infection, for example, postoperative clients or those with a suppressed white blood cell count. Accuracy of temperature measurement is essential in the clinical management of clients because it guides nursing and medical decision making and interventions.

TEMPERATURE SCALES The nurse should consistently measure and record the temperature using either the centigrade or Fahrenheit scale as defined in specific health care agency policies. A centigrade-calibrated scale ranges from

TABLE 26-9 Alterations in Thermoregulation

ALTERATION	DEFINITION	CHARACTERISTICS
Heat exhaustion	An increase in body temperature (38°C–40°C, 100.4°F–104.0°F) in response to environmental conditions that, in turn, causes diaphoresis (profuse perspiration)	Loss of excessive amounts of water and sodium from perspiring leads to thirst, nausea, vomiting, weakness, and disorientation.
Heat stroke	A critical increase in body temperature (41°C–44°C, 100.6°F–112.0°F) resulting from exposure to high environmental temperatures	Dry, hot skin is the most important sign. The person becomes confused or delirious and experiences thirst, abdominal distress, muscle cramps, and visual disturbances. Loss of consciousness occurs if untreated.
Hypothermia	A body temperature of 35°C (95°F) or lower resulting from cold weather exposure or artificial induction	Decrease in metabolism leads to impaired mental functioning and depressed pulse, respiration, and blood pressure; can result in cardiac arrest if untreated.
Frostbite	Freezing of the body's surface areas (earlobes, fingers, and toes) in extremely low temperatures	Circulatory impairment may be followed by gangrene.

Delmar/Cengage Learning

34°C to 42°C, and a Fahrenheit-calibrated scale ranges from 94°F to 108°F. Conversions from one scale to another are based on the formula that 0°C is equal to 32°F (see the accompanying display on centigrade and Fahrenheit conversion formulas).

SITES Although the prescribing practitioner may order a specific site to measure the temperature, nursing judgment usually determines the best site based on the client's age and physical and mental condition. Traditional sites for measuring the body's internal (core) temperature are oral (OT), rectal (RT), and axillary (AT), using either glass or electronic thermometers.

Advances in clinical thermometry provide other devices and sites, such as thermistors for pulmonary artery temperature (PAT) and infrared thermometers for ear canal temperature (ET). ET is the most common site used for temperature measurements in adults because it is a safe and an efficient method; however, it is less sensitive in detecting fever in infants and young children. ET should not be used in infected or draining ears or if adjacent lesions or incisions exist. The most reliable measure of core temperature is PAT. Since PAT requires placement of a thermodilution pulmonary artery catheter, it is impractical for routine care.

Oral and rectal temperature measurements are higher than axillary because the measuring device is in contact with the mucous membrane. Rectal measurements are higher than oral because of the seal created by the anal sphincter, which decreases contact with environmental air. With the availability of electronic measuring devices, a glass thermometer should never be used for oral readings because of the possibility of the client biting and breaking the thermometer.

The axilla is commonly used as a site for infants and children with disabilities because it is the safest, even though the least accurate, method. Axillary or rectal sites are used for clients who are uncooperative or comatose, or who have a nasogastric or feeding tube in place. Rectal temperature measurement is contraindicated in clients with cardiovascular alterations because the thermometer may stimulate the vagus nerve and cause an irregular cardiac rhythm. It is also contraindicated in leukemia and rectal surgery clients because the insertion of the thermometer may traumatize the mucosa or incision line, causing bleeding.

Temporal artery (TA) thermometers measure temperature using a scanning infrared thermometer that compares arterial temperature in the temporal artery of the forehead to the temperature in the room and calculates the heat balance to approximate the core temperature of the blood in the pulmonary artery. Place the TA probe in the middle of the forehead. With the red button depressed, slide the probe slowly from the midline across the forehead to the hairline. Lift the probe from the forehead, touch it on the neck just behind the earlobe, and release the button. The probe is touched behind the earlobe if the client has perspiration; this allows the thermometer to compensate for evaporative cooling (Exergen Corporation, 2008).

ASSESSING BODY TEMPERATURE Assess the client for the most appropriate site and gather the necessary equipment; refer to Table 26-7 for the devices that are used to measure temperature. The mercury-in-glass thermometer was once the standard device for measuring temperature; however, federal regulation prohibits the use of mercury-containing medical devices because of potential health and environmental hazards. Mercury is a reproductive toxin and a potent neurotoxin affecting both the brain and central nervous system. Basically two types of thermometers are used in health care facilities: electronic and disposable. A third type, the glass gallium-indium-tin (galinstan), is available commercially for in-home use. Nurses must understand the limitations of each device and must receive training on proper thermometry technique.

When checking the client's oral temperature, the nurse should confirm that the client has consumed neither hot or cold food or beverages or smoked for 15 to 30 minutes before the measurement. Mouth breathing and tachypnea may also cause an inaccurate oral reading. Herpes viruses are extremely contagious and require implementation of Standard Precautions of the Centers for Disease Control and Prevention. Clients with herpetic lesions should have their own glass thermometer to prevent transmission to others.

When using a glass thermometer stored in a disinfectant solution, the nurse should rinse it under cold water to remove the solution. Hot water should not be used on the thermometer because it will cause the mercury to expand and could break the thermometer. Procedure 26-1 describes the actions involved in measuring body temperature according to site.

Nursing Diagnosis

The nurse examines the assessment data and clusters the defining characteristics to form a nursing diagnosis for clients with altered body temperature; see the accompanying display, on page 516, on body temperature alterations. A diagnosis identifies a client's state that is altered or has the potential to be altered or improved; nursing diagnoses describe problems, actual or potential, that the nurse seeks to resolve through interventions. For example, a decrease in body temperature below the normal range, pallor, shivering, cyanotic nail beds, and blood pressure and pulse above the normal range are the defining characteristics for the diagnosis

CENTIGRADE AND FAHRENHEIT CONVERSION FORMULAS

- Centigrade to Fahrenheit conversion: multiply the centigrade reading by 9/5 and add 32:

$$^{\circ}\text{F} = (^{\circ}\text{C} \times 9/5) + 32$$
- Fahrenheit to centigrade conversion: deduct 32 from the Fahrenheit reading and multiply by 5/9: $^{\circ}\text{C} = (^{\circ}\text{F} - 32) \times 5/9$

SAFETY FIRST

Children left in vehicles in sweltering summer temperatures are at high risk for hyperthermia. The temperature inside the car can climb 20°F within 10 minutes, even with the windows rolled down.

hypothermia. Once the diagnosis is made, the nurse must determine the related factor(s): exposure to a cold environment and evaporation from the skin in a cold environment; medications causing vasodilation; or decreased metabolism. In hypothermia, a related factor of exposure to a cold environment will result in different interventions than a related factor of medications causing vasodilation. Once the nursing diagnosis is formulated, *hypothermia* related to exposure to a cold environment, the nurse then establishes nursing goals and client outcomes to measure the effectiveness of interventions.

Planning and Outcome Identification

During the planning phase, the nurse synthesizes assessment findings and integrates all client data to formulate nursing goals, interventions, and outcomes for clients with body temperature alterations. Care plan development must involve the client and/or the family, must be based on professional standards of care, and must utilize research findings or best practices.

When a client has a fever, nursing care includes treating the cause as prescribed and providing supportive care. Controversy exists regarding whether or not to treat the fever itself since fever acts as a protective mechanism. In order for bacteria to multiply, bacteria need large amounts of iron and zinc, but during fever, the liver and spleen do not release these elements (Beard & Day, 2008). Since fever increases

metabolism, this action helps the body to heal itself. One study suggests that aggressively treating fever may lead to higher mortality rates in certain clients (Schulman, 2005).

Implementation

Once the client's plan of care is defined, the nurse implements those interventions that will assist the client in achieving the specific outcomes. Vital signs measurements are often delegated by the professional nurse to other health care providers. Since professional nurses may delegate certain nursing interventions to other nursing personnel, either licensed or unlicensed, certified or uncertified, it is imperative that nurses document the competency of those individuals performing the nursing interventions. Delegation is a legal action, as defined in nurse practice acts by the various state boards of nursing. Although an intervention may be delegated to other nursing personnel, such as a licensed practical nurse or unlicensed ancillary personnel, the registered nurse is held responsible and accountable for the outcome. (See Chapter 11 for a complete discussion regarding delegation.)

The nurse teaches the client health-seeking behaviors to promote a balance between heat production and heat loss, such as client activity and clothing and environmental temperature. Health education and self-modification assistance for a client who exercises should address the need to wear light-fitting, light-colored clothing; to be exposed gradually to a hot climate; to exercise only in well-ventilated areas; to avoid strenuous exercise in hot, humid weather; and to drink fluids such as water before, during, and after exercise.

The nurse should place the client experiencing heat exhaustion in a cool environment. The goal of nursing care is to stop diaphoresis by administering fluid and electrolytes as prescribed by a prescribing practitioner. See Chapter 33 for a complete discussion of fluid and electrolyte therapy.

Victims of heat stroke do not perspire because of severe electrolyte loss and impaired hypothalamic function, as discussed in Table 26-9. Heat stroke victims are usually discovered outdoors, with emergency measures instituted to lower the temperature during transport to an emergency center. Nursing's primary role relative to heat stroke is prevention. The nurse is usually involved in teaching preventive measures, such as drinking liquids before, during, and after exercise; avoiding strenuous exercise in humid, hot weather; and wearing light-colored, loose-fitting clothing and covering the head when working outdoors in hot climates.

Hypothermia and frostbite victims found injured in cold weather or who were immersed in cold water are

NURSING DIAGNOSES: BODY TEMPERATURE ALTERATIONS

- *Risk for imbalanced body temperature*—at risk for failure to maintain body temperature within normal range
- *Hyperthermia*—body temperature elevated above normal range
- *Hypothermia*—body temperature below normal range
- *Ineffective thermoregulation*—temperature fluctuation between hypothermia and hyperthermia

COMMUNITY CONSIDERATIONS

Homeless

Clients most at risk for hypothermia are homeless persons who lack adequate heating, shelter, diet, or clothing.

SAFETY FIRST

ORAL LESIONS

Assess for oral lesion, especially herpetic lesions, because herpes viruses are highly contagious and require the implementation of Standard Precautions; clients with herpetic lesions should have their own disposable thermometer to prevent transmission to others.

treated while in transit to an emergency center with heating blankets and instillation of warm fluids into the stomach. Nursing's role is to teach preventive measures to groups at risk, such as the homeless, and to parents or guardians of mentally challenged or handicapped clients who live in cold environments.

Many clients with traumatic brain injury such as a skull fracture may develop **neurogenic fever**, described as a long-term elevation of body temperature thought to result from a disruption of the normal body temperature set point. Neurogenic fever is caused by damage to the hypothalamus from central nervous system trauma, intracerebral bleeding, or an increase in intracranial pressure. Neurogenic fever increases the metabolic demands on the body and can increase swelling of the brain, further increasing the risk of neurological damage. Nurses should monitor traumatic brain injury clients with unexplained temperature elevation to facilitate early diagnosis and treatment of neurogenic fever.

DOCUMENTATION Record the temperature measurement and the site on the designated medical record form. Temperature measurements are usually plotted on a graph to identify alteration patterns, such as sharp elevations and declines in temperature (a condition known as spiking).

Evaluation

Nursing interventions are evaluated by comparing the client's actual response to the nursing-sensitive client outcome, such as body temperature that is maintained within the normal range. If the client is not able to achieve the outcome, with body temperature increased to 38.8°C (101.8°F), then the plan of care may require revisions. After any nursing intervention, the nurse measures the client's temperature at a time that is appropriate to assess the client's response to the intervention. The nurse also uses other evaluative measures such as palpation of the skin and assessment of pulse and respiration when evaluating the client's response to nursing interventions. Based on the client's ability to respond effectively to nursing interventions, the body temperature and other vital signs will return to normal ranges, and the client will report a feeling of comfort.

PULSE

Pulse assessment is the measurement of a pressure pulsation created when the heart contracts and ejects blood into the aorta. Assessment of pulse characteristics provides clinical

data regarding the heart's pumping action and the adequacy of peripheral artery blood flow.

Sites

There are multiple pulse points. The most accessible peripheral pulses are the radial and carotid sites. Because the body shunts blood to the brain whenever a cardiac emergency such as hemorrhage occurs, the carotid site should always be used to assess the pulse in these situations.

Variations exist among health care agencies regarding which pulse sites to assess. The common sites for each type of assessment are:

- Complete physical assessment—apical and all bilateral peripheral pulses
- Initial assessment—apical and bilateral peripheral radial and dorsalis pedis pulses
- Routine vital signs assessment—apical and radial pulses in adults and apical and temporal pulses in infants and children.

Disorders that alter the client's cardiovascular status require different pulse point assessments (Table 26-10 on page 518). Whenever circulation is compromised, the corresponding pulse point should be assessed.

Assessing Pulse Rate

The nurse should begin the assessment by speaking with the client about the normal pulse rate. The client's medical record should be reviewed for baseline data, if available, and any medications that could affect the heart rate should be noted. Because physical activity increases the heart rate, ensure that the client rests 5 to 10 minutes before the pulse is assessed.

Clinical data regarding the efficacy of blood circulation to an extremity are obtained by assessing the characteristics (quality, rate, rhythm, and volume) of the peripheral pulses. These attributes are described in the section entitled Pulse Characteristics. Palpate a peripheral pulse by placing the first two fingers on the pulse point with moderate pressure. A firm pressure will obliterate the pulse; if the pressure is too light, the pulse cannot be felt.

A Doppler ultrasound stethoscope (DUS) is used on superficial pulse points to detect and magnify heart sounds and pulse waves when the peripheral pulse cannot be palpated. The DUS, which has an earpiece similar to that of a stethoscope, is connected by a cord to a volume-control audio unit with an ultrasound transducer. See Chapter 32 for a complete discussion about other devices to monitor the heart rate.

Normal radial and apical pulses are identical in rate. The stethoscope is used to auscultate the heart's rate and rhythm. The stethoscope should be placed on the fifth intercostal space at the midclavicular line, as described in Procedure 26-2. Count the rate for a full minute, noting the regularity (rhythm).

When an irregular peripheral pulse is present, the nurse needs to assess for a **pulse deficit** (condition in which the apical pulse rate is greater than the radial pulse rate). A pulse deficit results from the ejection of a volume of blood that is too small to initiate a peripheral pulse wave. When a discrepancy exists between the apical and radial pulses, the deficit is assessed by simultaneously measuring the apical and radial pulses for a

TABLE 26-10 Pulse Point Assessment

PULSE POINT	ASSESSMENT CRITERIA
Temporal: over temporal bone, superior and lateral to eye	Accessible; used routinely for infants and when radial is inaccessible
Carotid: bilateral, under lower jaw in neck along medial edge of sternocleidomastoid muscle	Accessible; used routinely for infants and during shock or cardiac arrest when other peripheral pulses are too weak to palpate; also used to assess cranial circulation
Apical: left midclavicular line at fourth to fifth intercostal space	Used to auscultate heart sounds and assess apical-radial deficit
Brachial: inner aspect between groove of biceps and triceps muscles at antecubital fossa	Used in cardiac arrest for infants, to assess lower arm circulation, and to auscultate blood pressure
Radial: inner aspect of forearm on thumb side of wrist	Accessible; used routinely in adults to assess character of peripheral pulse
Ulnar: outer aspect of forearm on finger side of wrist	Used to assess circulation to ulnar side of hand and to perform the Allen's test
Femoral: in groin, below inguinal ligament (midpoint between symphysis pubis and anterosuperior iliac spine)	Used to assess circulation to legs and during cardiac arrest
Popliteal: behind knee, at center in popliteal fossa	Used to assess circulation to legs and to auscultate leg blood pressure
Posterior tibial: inner aspect of ankle between Achilles tendon and tibia (below medial malleolus)	Used to assess circulation to feet
Dorsalis pedis: over instep, midpoint between extension tendons of great and second toe	Used to assess circulation to feet

Delmar/Cengage Learning

minute. This procedure is usually performed by two nurses; however, it can be performed by one nurse if necessary.

PULSE CHARACTERISTICS A normal pulse has defined characteristics: quality, rate, rhythm, and volume (strength or amplitude). **Pulse quality** refers to the “feel” of the pulse, its rhythm and forcefulness.

Pulse rate is an indirect measurement of cardiac output obtained by counting the number of apical or peripheral pulse waves over a pulse point. A normal pulse rate for adults is between 60 and 100 beats per minute. **Bradycardia** is a heart rate less than 60 beats per minute in an adult. **Tachycardia** is a heart rate in excess of 100 beats per minute in an adult.

Pulse rhythm is the regularity of the heartbeat. It describes how evenly the heart is beating: regular (the beats are evenly spaced) or irregular (the beats are not evenly spaced). Dysrhythmia (arrhythmia) is an irregular rhythm caused by an early, late, or missed heartbeat.

Pulse volume is a measurement of the strength or amplitude of force exerted by the ejected blood against the arterial wall with each contraction. It is described as normal (full, easily palpable), weak (thready and usually rapid), or strong (bounding). To facilitate data comparison of this measurement, a standard pulse volume scale should be used in documenting findings (see Table 26-11 on page 519). Procedure 26-2 describes the actions involved in assessing the pulse rate.

SAFETY FIRST

CAROTID PULSE ASSESSMENT

When assessing a carotid pulse, apply light pressure to only one carotid artery to avoid disruption of cerebral blood flow.

Nursing Considerations

An irregular pulse rate, if not previously documented in the medical record, should be reported immediately. The following equipment is used to identify the type of dysrhythmia causing the irregular heartbeat:

- Electrocardiogram (ECG or EKG) provides an electrical representation of the heart's activity. The primary pacemaker of the heart is the sinoatrial (SA) node. If another

TABLE 26-11 Pulse Volume Scale

SCALE	DESCRIPTION OF PULSE
0	Absent pulse
1+	Weak and thready pulse
2+	Normal pulse
3+	Bounding pulse

Delmar/Cengage Learning

site within the heart initiates the electrical activity, the ECG tracing will identify the area serving as the pacemaker.

- A Holter monitor is a portable device worn for a 24-hour interval to identify the dysrhythmia pattern.
- Cardiac telemetry transmits the heart's electrical activity to a site for continuous monitoring.

See Chapter 32 for additional information regarding these cardiac monitoring devices.

Clients on certain cardiac medications, such as cardiovascular agents and cardiac glycosides, need to monitor their pulse rate. Clients receiving cardiovascular agents (verapamil hydrochloride) and cardiac glycosides (digoxin) may experience an irregular pulse or pulse rate change that should be reported to their prescribing practitioner. In addition, clients who follow an exercise regimen should assess their pulse rate to measure their heart's response to the exercise. Routine or regular exercise lowers the resting and activity pulses. When teaching clients how to monitor their own heart rate, nurses should show them the procedure in assessing the radial or carotid pulse points.

DOCUMENTATION All pulse measurements are documented by recording in the client's medical record on the appropriate forms (e.g., the vital signs flow sheet). The nurse should report and document an irregular pulse.

RESPIRATIONS

Respiratory assessment is the measurement of the breathing pattern. Assessment of respirations provides clinical data regarding the pH of arterial blood.

Sites

Normal breathing is slightly observable, effortless, quiet, automatic, and regular. It can be assessed by observing chest wall expansion and bilateral symmetrical movement of the thorax. Another method the nurse can use to assess breathing is to place the back of the hand next to the client's nose and mouth to feel the expired air.

Assessing Respirations

When assessing respirations, ascertain the rate, depth, and rhythm of ventilatory movement. The nurse should assess the rate by counting the number of breaths taken per minute.

Note the depth and rhythm of ventilatory movements by observing the normal thoracic and abdominal movements and symmetry in chest wall movement. Normal respirations are characterized by a rate ranging from 12 to 20 breaths per minute. Procedure 26-3 describes the actions involved in assessing respirations.

One inspiration and expiration cycle is counted as one breath. The nurse should observe the rise and fall of the chest wall and count the rate by placing the hand lightly on the chest to feel its rise and fall. Count the number of respirations as explained in Procedure 26-3.

MOVEMENT OF THE DIAPHRAGM When the chest wall moves, so do the lungs because the lungs are attached to the inner wall of the thoracic cavity by the outer layer of the **pleura** (lining of the chest cavity). The movement of the chest wall should be even and regular, without noise and effort. On inspiration, the chest changes shape and expands as the rib cage is raised and the diaphragm is lowered. Before inspiration, the pressure inside the chest cavity is negative (-4.5 to -9.0 mm Hg below atmospheric pressure). Air flows along the concentration gradient from a higher atmospheric pressure to the lower intrathoracic pressure.

The opposite action occurs with expiration. The muscles relax, causing the rib cage to lower and the diaphragm to rise, compressing the chest. Intrathoracic pressure decreases to -3 to -6 mm Hg to allow the air to escape into the atmosphere.

CHARACTERISTICS OF NORMAL AND ABNORMAL BREATH SOUNDS Different respiratory wave patterns are characterized by their rate, rhythm, and depth. See Chapter 32 for a complete discussion of wave patterns. **Eupnea** refers to easy respirations with a normal rate of breaths per minute that is age specific. **Bradypnea** is a respiratory rate of 10 or fewer breaths per minute. **Hypoventilation** is characterized by shallow respirations. **Tachypnea** is a respiratory rate greater than 24 breaths per minute. **Hyperventilation** is characterized by deep, rapid respirations.

The nurse can also observe alterations in the movement of the chest wall: **costal (thoracic) breathing** occurs when the external intercostal muscles and the other accessory muscles are used to move the chest upward and outward; **diaphragmatic (abdominal) breathing** occurs when the diaphragm contracts and relaxes as observed by movement of the abdomen. **Dyspnea** refers to difficulty in breathing as observed by labored or forced respirations through the use of accessory muscles in the chest and neck to breathe. Dyspneic clients are acutely aware of their respirations and complain of shortness of breath.

Nursing Considerations

Respiratory alterations may cause changes in skin color as observed by a bluish appearance in the nail beds, lips, and skin. The bluish color (**cyanosis**) results from reduced oxygen levels in the arterial blood. Changes in the level of consciousness may also occur with decreased oxygen levels. Dyspneic clients will assume a forward-leaning position to increase the expansion capacity of the lungs.

SAFETY FIRST

POSITIONING FOR DYSPNEIC CLIENTS

Dyspneic clients should never be placed flat in bed; maintain them in a semi-Fowler's or Fowler's position. To facilitate maximal lung expansion, place the client in a forward-leaning position over a padded, raised overbed table with arms and head resting on the table.

Clients with respiratory alterations require additional nursing assessment. Noninvasive oxygen assessment can be performed with an **oximeter** (a machine that measures the oxygen saturation of the blood through a probe clipped to the fingernail or earlobe) or an **apnea monitor** (a machine with chest leads that monitors the movement of the chest). Both noninvasive machines have alarm features that are set to specific parameters. For example, if the client's respirations fall below 6 breaths per minute, the apnea monitor alarm will sound. The apnea monitor is used in the home environment for apneic clients; when the alarm sounds, it wakes the person and causes him or her to breathe.

DOCUMENTATION Document the assessment findings for the respiratory rate, depth, rhythm, and character on the appropriate form (e.g., the vital signs flow sheet). Report a respiratory rate outside of the normal age range, an irregular rhythm, an inadequate depth, or any abnormal characteristics such as dyspnea.

BLOOD PRESSURE

Blood pressure measurement is performed during a physical examination, at initial assessment, and as part of a routine vital signs assessment. Depending on the client's condition, the blood pressure is measured by either a direct or an indirect technique. The direct method requires an invasive procedure in which an intravenous catheter with an electronic sensor is inserted into an artery and the artery-transmitted pressure on an electronic display unit is read. The indirect method requires use of the sphygmomanometer and stethoscope for auscultation and palpation as needed.

Sites

The most common site for indirect blood pressure measurement is the client's arm over the brachial artery. When the client's condition prevents auscultation of the brachial artery, the nurse should assess the blood pressure in the forearm or leg sites (see the accompanying display on contraindications for brachial artery blood pressure measurement).

When pressure measurements in the upper extremities are not accessible, the popliteal artery, located behind the knee, becomes the site of choice. The nurse can also assess

CONTRAINDICATIONS FOR BRACHIAL ARTERY BLOOD PRESSURE MEASUREMENT

When the client has any of the following, *do not* measure blood pressure on the involved side:

- Venous access devices, such as an intravenous infusion or arteriovenous fistula for renal dialysis
- Surgery involving the breast, axilla, shoulder, arm, or hand
- Injury or disease to the shoulder, arm, or hand, such as trauma, burns, or application of a cast or bandage

the blood pressure in other sites, such as the radial artery in the forearm and the posterior tibial or dorsalis pedis artery in the lower leg. Because it is difficult to auscultate sounds over the radial, tibial, and dorsalis pedis arteries, these sites are usually palpated to obtain a systolic reading.

Assessing Blood Pressure

Selecting the proper equipment and following procedural technique are basic to ensuring an accurate reading. Psychomotor skills, acquired with practice, are needed to manipulate the blood pressure equipment. Procedure 26-4 describes the actions involved in assessing blood pressure.

As shown in Table 26-7, a sphygmomanometer is a device used to measure indirect blood pressure. A sphygmomanometer consists of a mercury or an aneroid manometer and a cuff that contains an inflatable rubber bladder connected to two pieces of rubber tubing. One piece of tubing connects the bladder to the manometer or gauge, and the second tubing is attached to a pressure bulb with a release valve to inflate and deflate the cuff. When pressure is applied to the bulb, air enters the bladder and inflates the cuff.

The sphygmomanometer wears with usage. If there is a defect in any part of the system, the blood pressure reading will be inaccurate. The aneroid gauge needle or mercury in the manometer column should be at a zero reading when the cuff is deflated and should rise evenly when pressure is applied to the bulb. The valve should turn freely, and all tubing should be intact, with secured connections to prevent air from leaking out of the system.

An accurate reading also requires the correct width of the blood pressure cuff as determined by the circumference of the client's extremity. The bladder cuff must encircle the width and length of the site. The bladder width should be approximately 40% of the circumference or 20% wider than the diameter of the midpoint of the extremity. To measure the width of the bladder, the nurse should place the cuff lengthwise on the client's extremity and extend the width to

cover 40% of the extremity’s circumference (see Figure 26-5). The length of the sphygmomanometer bladder should be twice the width. Table 26-12, recommends bladder sizes based on different arm circumferences. A falsely elevated reading will result if the bladder is too narrow, and a falsely low reading will result if it is too wide.

Electronic sphygmomanometers are used by clients for self-measurements. A stethoscope is not required because the device electronically inflates and deflates the cuff while simultaneously reading and displaying the systolic and diastolic pressures. The electronic device is useful for clients who must monitor their own pressure at home. However, it must be recalibrated routinely to ensure an accurate reading.

AUSCULTATION A stethoscope is used to auscultate the blood pressure (hear the sounds created by blood flowing through the artery). As discussed in Procedure 26-4, the blood pressure cuff is inflated 30 mm Hg higher than the palpated pressure so that the inflated pressure causes the artery to collapse; blood flow ceases, and sound is absent on auscultation. As the pressure is released from the bladder, blood begins to flow through the artery and creates the first sound, which is the systolic pressure.

The Korotkoff’s sounds, described in Table 26-13 and Procedure 26-4, are named after the Russian surgeon who first identified the five distinct phases of sound heard with a stethoscope during auscultation. Korotkoff’s sounds are correlated to the pressure dynamics of measurement.

Bilateral readings should be done with the initial blood pressure assessment. A pressure variance of 5 to 10 mm Hg normally exists between arms. The arm with the higher reading should be used for routine measurements.

When measuring a popliteal blood pressure, the nurse should select a cuff wide and long enough to fit the girth of the thigh. Although the American Heart Association does not specify cuff sizes for thigh BP readings, the association emphasizes that the cuff should be wider and longer than an arm cuff to allow for the greater girth. Place the client in a supine position with the legs in a nondependent position for at least 10 minutes. (A prone position is also acceptable.) Apply the

bladder cuff to the client’s thigh with the center of the bladder over the popliteal artery. Wrap the cuff snugly, and place it far enough above the popliteal fossa to allow for auscultation of arterial sounds. Help the client slightly flex the knee and abduct the hip. This position will facilitate palpation of the pulse and placement of the stethoscope. Place the diaphragm of the stethoscope over the area where the pulse was palpated, and follow the same procedure as presented for brachial artery auscultation (see Procedure 26-4). When the BP cuff is removed, inspect the area, and note abnormalities such as bruising, hematoma, or skin tear. Document in the medical record the systolic and diastolic BP, the site, and the size of the BP cuff. In the thigh, systolic readings may be 10 to 40 mm Hg higher than in the arm, but diastolic readings are generally the same.

UNCOVERING THE

Evidence

TITLE OF STUDY

“A Comparison of Blood Pressure Measurement over a Sleeved Arm versus a Bare Arm”

AUTHORS

G. Ma, N. Sabin, and M. Dawes

PURPOSE

To determine whether the measurement of blood pressure over a sleeved arm varies from that taken on a bare arm.

METHOD

Between September 2004 and November 2006, 376 clients (ages 18 to 85 years) were recruited from a family medicine clinic. All clients had their blood pressures recorded using the same automatic oscillometric device, with the cuff placed over their bare arms for the first reading. Each client was then randomly assigned to either the bare-arm group, for which the second blood pressure reading was also taken on a bare arm, or the sleeved-arm group, for which the second reading was taken with the cuff placed over the sleeved arm.

FINDINGS

No clinically important differences were found between the bare-arm group and the sleeved-arm group in age, sex, or body mass index.

IMPLICATIONS

There was no significant difference in blood pressure recorded over a sleeve or on a bare arm. The decision to measure blood pressure on a bare arm or over a sleeved arm should be left to the judgment of the health care professional taking the blood pressure.

Ma, G., Sabin, N., & Dawes, M. (2008). A comparison of blood pressure measurement over a sleeved arm versus a bare arm. *Canadian Medical Association Journal*, 178(5), 585–589.

PALPATION When the client’s hemodynamic regulation is compromised to the degree that Korotkoff’s sounds cannot be heard, such as with myocardial infarction or shock, the blood pressure has to be monitored by palpation or direct measurement. To palpate the systolic blood pressure, apply the cuff over the brachial artery, inflate the cuff, place the fingers over the radial artery, slowly release the pressure, and note the reading on the manometer when the first pulse (systole) is felt. With palpation, it is difficult to assess the diastolic pressure. Direct measurement is obtained with the insertion of an intravenous catheter.

HYPOTENSION Hypotension refers to a systolic blood pressure less than 90 mm Hg or 20 to 30 mm Hg below the client’s normal systolic pressure. Hypotension is caused by a disruption in hemodynamic regulation, such as:

- Decreased blood volume (e.g., hemorrhage)

- Decreased cardiac output (e.g., myocardial infarction [heart attack])
- Decreased peripheral vascular resistance (vascular dilation; e.g., shock)

A hypotensive client manifests symptoms relative to the degree of hypotension regardless of the cause.

One of the initial compensatory responses to a falling blood pressure is an increased pulse rate. For example, if a blood vessel cauterized during surgery begins to bleed internally, at the point at which the circulating blood volume is compromised the heart will automatically beat faster to compensate for the decreased circulating volume. If the falling pressure is untreated, the body’s compensatory mechanisms will fail and the client will exhibit the symptoms of shock: cool, clammy skin; fast, thready pulse; a gradual decrease in urinary output; and disruption to cerebral blood flow that causes confusion, progressing to coma.

Orthostatic hypotension (postural hypotension) refers to a sudden drop of 25 mm Hg in systolic pressure and 10 mm Hg in diastolic pressure when the client moves from a lying to a sitting or a sitting to a standing position. Orthostatic hypotension usually occurs with aging and is a common antiadrenergic side effect of several medications, such as chlorpromazine hydrochloride. When measuring orthostatic blood pressure:

1. Place the client in a supine position for 5 minutes to allow for equilibration of the blood pressure, and measure the pulse and blood pressure.
2. Assist the client to a standing position, and wait 1 minute to obtain a full evaluation of the initial orthostasis, then recheck the pulse and blood pressure.
3. Reassess the vital signs after 2 minutes to allow for an evaluation of the client’s mechanisms to compensate for the presence of any orthostasis.

Clients with orthostatic hypotension should be advised to rise slowly from a supine position and to sit down immediately if they feel faint.

HYPERTENSION Hypertension increases the risk for cardiovascular disease, the leading cause of death in the United States. Until May 2003, people with blood pressure measurements below 140/90 mm Hg were considered normal; however, with the release of the JNC 7 (NIH, 2003), people with systolic pressures of 120 to 139 mm Hg or diastolic pressures of 80 to 89 mm Hg were classified as prehypertensive, at higher risk than those with lower blood pressures. They are advised to adopt healthy lifestyles to decrease the risk of cardiovascular disease (see Table 26-14 on page 523). Prior to the JNC 7, hypertension was classified into three stages; the new classification provides for prehypertension and stage 1 and stage 2 hypertension. When systolic and diastolic blood pressures fall into different categories, the higher category should be used to classify blood pressure level. For example, 160/80 mm Hg would be stage 2 hypertension.

The adoption of health-promoting lifestyles is critical for the prevention and management of hypertension. According to the JNC 7 (NIH, 2003), the following major lifestyle changes have been shown to lower blood pressure:

- Maintain normal body weight.

TABLE 26-14 Categories for Blood Pressure Levels in Adults (Ages 18 Years and Older*)

CATEGORY	BLOOD PRESSURE LEVEL (MM HG)	
	SYSTOLIC	DIASTOLIC
Normal	<120	and <80
Prehypertension	120–139	or 80–89
High Blood Pressure		
Stage 1 hypertension	140–159	or 90–99
Stage 2 hypertension	>160	or >100

*For adults 18 and older who are not on medicine for high blood pressure, do not have a short-term serious illness, or do not have another condition such as diabetes or kidney disease.

Source: National High Blood Pressure Education Program, National Institutes of Health. (2003). *The Seventh Report of the Joint National Committee on prevention, detection, evaluation, and treatment of high blood pressure*. Retrieved September 8, 2008, from <http://www.nhlbi.nih.gov/guidelines/hypertension/jnc7full.pdf>.

- Adopt the Dietary Approaches to Stop Hypertension (DASH) eating plan, which includes a diet rich in fruits, vegetables, and low-fat dairy products with a reduced content of saturated and total fat.
- Reduce dietary sodium intake to 2.4 g sodium or 6 g sodium chloride.
- Engage in regular aerobic physical activity, such as brisk walking at least 30 minutes a day, most days of the week.
- Limit alcohol consumption: men, two drinks a day, women, one drink a day.

By making the dietary changes just discussed, a 1,600-mg-sodium DASH eating plan has an effect similar to single-drug therapy; a combination of two (or more) lifestyle modifications can achieve greater results (NIH, 2003).

SAFETY FIRST

LUER CONNECTORS

Some automatic blood pressure monitoring devices are designed with male and female Luer connectors, the same type of connectors used on intravenous tubing. Normally the BP device cycles at preset intervals, inflating the cuff with more than 500 mL of air at pressures up to 300 mm Hg; if no resistance is met with an inflated cuff, two additional cycles occur. If the BP Luer is inadvertently connected to an intravenous line when the device cycles, more than 1,500 mL of air can enter the client's vascular system.

SPOTLIGHT ON...

Professionalism

Vital Signs Measurement

What happens when we do anything routinely? Do we recognize the significance of a routine action? Vital signs are taken routinely. The nurse should be able to identify possible negative consequences of this routine nursing action.

The majority of clients will require medications to achieve their goal blood pressure reading of less than 140/90 mm Hg. According to the JNC 7 (NIH, 2003), stage 1 hypertension should be treated with a thiazide-type diuretic, and stage 2 hypertension will require two or more antihypertensive medications.

Another strategy addressed in the new guidelines is to build trusting provider-client relationships that will motivate clients to achieve good health. Clients' attitudes are influenced by their cultural backgrounds, beliefs, and previous experiences with the health care system; thus, the plan of therapy must be client centered.

Nursing Considerations

Before checking a blood pressure, review the client's chart for brachial artery contraindications, and make sure that the client has not exercised or eaten for the past 30 minutes. Clients who have recently eaten, ambulated, or experienced an emotional upset will have a falsely high blood pressure reading. When the vital signs are taken correctly in sequence (T-P-R and BP), the client should be calm from sitting or lying quietly.

Faulty techniques that constrict blood flow will produce a falsely high pressure reading:

- A cuff too narrow for the extremity
- A cuff that does not fit snugly around the extremity
- A cuff that is deflated too slowly

Other false high readings occur when the mercury column in the manometer is not positioned flat on a firm surface or is read above eye level or the extremity is below the heart's apex level.

False low readings occur when the extremity is above the heart's apex level, the cuff is too wide for the extremity, or the mercury column in the manometer is read below eye level. If the nurse fails to recognize the **auscultatory gap**, the temporary disappearance of sounds at the end of Korotkoff's sounds phase I and beginning of phase II, the systolic pressure is read at a falsely low pressure.

DOCUMENTATION The nurse should record the blood pressure measurement on the appropriate form. If the brachial artery is not used for the measurement, indicate the site when recording the results. If the pressure was obtained by palpation, record "80 systolic by palpation."

Monitoring blood pressure changes in relation to T-P-R measurements is one of the major responsibilities of the registered nurse. One element of critical thinking is having concrete, objective clinical data, as provided by vital signs measurements, to direct decision making.

PROCEDURE
26-1
Measuring Body Temperature
EQUIPMENT

- Thermometer (one of the following)
 - Electronic thermometer with disposable protective sheathing
 - Tympanic membrane thermometer with probe cover
 - Disposable, single-use chemical strip thermometer
- Lubricant for rectal thermometer
- Two pairs of nonsterile gloves
- Tissues

ACTION
RATIONALE

- | | |
|---|---|
| 1. Review medical record for baseline data factors that influence vital signs. | 1. Establishes parameters for client's normal measurements, provides direction in device selection, and helps determine site to use for measurement. Vital signs are measured in the order of temperature, pulse, and respiration (TPR) and blood pressure (BP), usually without interruptions, to provide the nurse with an objective clinical database to direct decision making. |
| 2. Explain to the client that vital signs will be assessed. Encourage the client to remain still; refrain from drinking, eating, and smoking; and avoid mouth breathing, if possible. | 2. Encourages participation, allays anxiety, and ensures accurate measurements. Cold or hot liquids and smoking alter circulation and body temperature. Mouth breathing can alter temperature. |
| 3. Assess client's toileting needs, and proceed as appropriate. | 3. Prevents interruptions during measurements, communicates caring, and promotes client's comfort. |
| 4. Gather equipment. | 4. Facilitates organized assessment and measurement. |
| 5. Provide for privacy. | 5. Decreases embarrassment. |
| 6. Perform hand hygiene/wash hands, and apply gloves when appropriate. | 6. Reduces transmission of microorganisms. Hands are washed before and after every contact with a client. Gloves are worn to avoid contact with bodily secretions and to reduce transmission of microorganisms. |

ORAL TEMPERATURE—ELECTRONIC THERMOMETER

- | | |
|---|--|
| 7. Repeat Actions 1 to 6. | 7. See Rationales 1 to 6. |
| 8. Place disposable protective sheath over probe (see Figure 26-6 on page 525). | 8. Reduces transmission of microorganisms. |
| 9. Grasp top of the probe's stem. Avoid placing pressure on the ejection button. | 9. Pressure on the ejection button releases the sheath from the probe. |
| 10. Place tip of thermometer under the client's tongue and along the gumline to the posterior sublingual pocket lateral to center of the lower jaw (see Figure 26-7 on page 525). | 10. Sublingual pocket contains superficial blood vessels. |

(Continues)

PROCEDURE 26-1 Measuring Body Temperature (Continued)

FIGURE 26-6 Place disposable sheath over probe. DELMAR/CENGAGE LEARNING

- | | |
|---|--|
| <ol style="list-style-type: none"> 11. Instruct client to keep mouth closed around thermometer. 12. Thermometer will signal (beep) when a constant temperature registers (see Figure 26-8). 13. Read measurement on digital display of electronic thermometer. Push ejection button to discard disposable sheath into receptacle, and return to storage well. 14. Inform client of temperature reading. 15. Remove gloves and perform hand hygiene. 16. Record reading according to institution policies. 17. Return electronic thermometer unit to charging base. 18. Wash hands/hand hygiene. | <ol style="list-style-type: none"> 11. Maintains thermometer in proper place and decreases amount of time required for an accurate reading. 12. Signal indicates final temperature reading. 13. Reduces transmission of microorganisms. Ensures that the electronic system is ready for next use. 14. Promotes client's participation in care. 15. Reduces transmission of microorganisms. 16. Accurate documentation by site allows for comparison of data. 17. Ensures charging base is plugged into electrical outlet and ready for next use. 18. Reduces transmission of microorganisms. |
|---|--|

FIGURE 26-8 Listen for audible beep signal when temperature registers. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 26-1 Measuring Body Temperature (Continued)

TYMPANIC TEMPERATURE: INFRARED THERMOMETER

19. Repeat Actions 1 to 6.
20. Position client in Sims' or sitting position.
21. Remove probe from container, and attach probe cover to tympanic thermometer unit (see Figure 26-9).
22. Turn client's head to one side. For an adult, pull pinna upward and back; for a child, pull down and back. Gently insert probe with firm pressure into ear canal (see Figure 26-10).
23. Remove probe after the reading is displayed on digital unit (usually 2 seconds).
24. Remove probe cover and replace in storage container.
25. Return tympanic thermometer to storage unit.
26. Record reading according to institution policy.
27. Wash hands/hand hygiene.
19. See Rationales 1 to 6.
20. Promotes access to ear.
21. Prevents contamination.
22. Provides access to ear canal. Gentle insertion prevents trauma to external canal. Firm pressure is needed to ensure probe will record an accurate temperature.
23. Reading is displayed within seconds.
24. Prevents damage to the reusable probe.
25. Recharges batteries of unit for future use.
26. Promotes accurate documentation for data comparison.
27. Reduces transmission of microorganisms.

FIGURE 26-9 Attach disposable probe cover to unit.
DELMAR/CENGAGE LEARNING

FIGURE 26-10 Insert temperature probe into ear canal.
DELMAR/CENGAGE LEARNING

ORAL GLASS THERMOMETER

28. Repeat Actions 1 to 6.
29. Hold end (tip will be blue) of glass thermometer by fingertips (see Figure 26-11 on page 527), rinse under cool water, and wipe dry with a tissue from bulb's end toward fingertips.
30. Read mercury level while gently rotating thermometer at eye level. It should read 35.5°C (96°F). If the mercury is above desired level, grasp tip of thermometer securely, stand away from solid objects, and sharply flick wrist downward.
31. Place thermometer into oral sublingual pocket as shown in Figure 26-7; leave thermometer in place 3 minutes.
28. See Rationales 1 to 6.
29. A blue tip usually denotes an oral thermometer. Rinsing removes disinfectant, and cool water prevents expansion of the mercury. Holding the thermometer at the opposite end reduces contamination of the bulb.
30. Thermometer must be below normal body temperature. Briskly shaking lowers mercury level in glass tube.
31. Ensures contact with large blood vessel under the tongue.

(Continues)

PROCEDURE 26-1 Measuring Body Temperature (Continued)

Remove thermometer, and wipe off secretions with a clean tissue, moving toward the bulb. With the thermometer at eye level, read finding. Shake thermometer down, cleanse with soapy water, rinse with cool water, and store thermometer in storage container.

32. Wash hands/hand hygiene.
33. Record temperature, indicate the method, and discard the thermometer.
34. Repeat Actions 1 to 6.
35. Position the client in a sitting or lying position with the head of the bed elevated from 45 degrees to 60 degrees for measurement of all vital signs except those designated otherwise.

RECTAL TEMPERATURE—ELECTRONIC THERMOMETER

36. Repeat Actions 1 to 9.
37. Place client in the Sims' position with upper knee flexed. Adjust sheet to expose only anal area.
38. Place tissues in easy reach. Apply gloves.
39. Lubricate tip of rectal probe (a rectal probe usually has a red cap; see Figure 26-11).
40. With dominant hand, grasp top of the probe's stem. With other hand, separate buttocks to expose anus (see Figure 26-12 on page 528).
41. Instruct the client to take a deep breath. Insert the probe gently into anus: infant, 1.2 cm (0.5 inches); adult, 3.5 cm (1.5 inches). If resistance is felt, do not force insertion.
42. Repeat Actions 12 to 18.

Thermometer must stay in place long enough to obtain an accurate reading. Mucus on the thermometer may interfere with disinfectant solution's effectiveness. Wipe from area of least contamination to area of most contamination. Ensures accurate reading.

32. Reduces transmission of microorganisms.
33. Nursing documentation, practice clean technique.
34. See Rationales 1 to 6.
35. Promotes comfort, and improves site access for all measurements. Activity and movement can elevate heart and respiratory rates.

36. See Rationales 1 to 6.
37. Proper positioning ensures visualization of anus. Flexing knee relaxes muscles for ease of insertion.
38. Tissue is needed to wipe anus after device is removed.
39. Promotes ease of insertion of thermometer or probe.
40. Aids in visualization of anus.
41. Relaxes anal sphincter. Gentle insertion decreases discomfort to client and prevents trauma to mucous membranes.
42. See Rationales 12 to 18.

AXILLARY TEMPERATURE

- | | |
|---|---|
| <p>43. Repeat Actions 1 to 10.</p> <p>44. Remove client's arm and shoulder from one sleeve of gown. Avoid exposing chest.</p> <p>45. Make sure axillary skin is dry; if necessary, pat dry.</p> <p>46. Place probe into center of axilla. Fold the client's upper arm straight down, and place arm across the client's chest.</p> <p>47. Repeat Actions 12 to 18.</p> | <p>43. See Rationales 1 to 10.</p> <p>44. Exposes axillary area.</p> <p>45. Removes moisture and prevents a false low reading.</p> <p>46. Puts device into contact with axillary blood supply. Maintains the device in proper position.</p> <p>47. See Rationales 12 to 18.</p> |
|---|---|

DISPOSABLE (CHEMICAL STRIP) THERMOMETER

- | | |
|---|---|
| <p>48. Repeat Actions 1 to 6.</p> <p>49. Apply tape to appropriate skin area, usually forehead.</p> <p>50. Observe tape for color changes.</p> <p>51. Record reading and indicate method.</p> <p>52. Wash hands/hand hygiene.</p> | <p>48. See Rationales 1 to 6.</p> <p>49. Tape must be in direct contact with the client's skin.</p> <p>50. Color indicates temperature reading (refer to the manufacturer's instructions).</p> <p>51. Promotes accurate documentation for data comparison.</p> <p>52. Reduces transmission of microorganisms.</p> |
|---|---|

delegation tip

The skill of temperature measurement is often delegated to ancillary personnel; however, the nurse retains responsibility for knowledge of the client's temperature and appropriate actions. The expectation is that ancillary personnel will have documented instruction and competency validation of their ability to:

- Select the correct route for measurement of the temperature
- Correctly position the client for measurement
- Correctly perform the measurement according to established guidelines and record on the appropriate flow sheet (clinical record)
- Recognize and report abnormal findings to the nurse

nursing tips

After giving antipyretic medication to a client, a temperature measurement should be taken 30 minutes after the intervention and then every 2 to 4 hours. Nursing intervention policy may vary across institutions.

PROCEDURE 26-2

Assessing Pulse Rate

EQUIPMENT

- Watch with a second hand
- Stethoscope
- Alcohol swab
- Gloves

ACTION

RATIONALE

TAKING A RADIAL (WRIST) PULSE

- | | |
|---|--|
| <ol style="list-style-type: none"> 1. Wash hands/hand hygiene. 2. Inform client of the site(s) where pulse will be measured. 3. Flex client's elbow and place lower part of arm across chest. 4. Support client's wrist by grasping outer aspect with thumb. 5. Place index and middle fingers on inner aspect of client's wrist over the radial artery, and apply light but firm pressure until pulse is palpated (see Figure 26-13). 6. Identify pulse rhythm. 7. Determine pulse volume. 8. Count pulse rate by using second hand on watch (see Figure 26-14). | <ol style="list-style-type: none"> 1. Reduces transmission of microorganisms. 2. Encourages participation and allays anxiety. 3. Maintains wrist in full extension and exposes artery for palpation. Placing client's hand over chest will facilitate later respiratory assessment without undue attention to the nurse's action. (It is difficult for any person to maintain a normal breathing pattern when someone is observing and measuring.) 4. Stabilizes wrist and allows for pressure to be exerted. 5. Fingertips are sensitive, facilitating palpation of pulsating pulse. The nurse may feel his or her own pulse if palpating with thumb. Applying light pressure prevents occlusion of blood flow and pulsation. 6. Palpate pulse until rhythm is determined. Describe as regular or irregular. 7. Quality of pulse strength is an indication of stroke volume. Describe as normal, weak, strong, or bounding. 8. An irregular rhythm requires a full minute of assessment to identify the |

(Continues)

PROCEDURE 26-2
Assessing Pulse Rate (Continued)

- | | |
|--|---|
| <p>17. Note regularity of rhythm.</p> <p>18. Start to count while looking at second hand of watch. Count lub-dub sound as one beat:</p> <ul style="list-style-type: none"> • For a regular rhythm, count rate for 30 seconds and multiply by 2. • For an irregular rhythm, count rate for a full minute, noting number of irregular beats. <p>19. Share findings with client.</p> <p>20. Record by site the rate, rhythm, and, if applicable, number of irregular beats.</p> <p>21. Wash hands/hand hygiene.</p> | <p>(heartbeats are evenly spaced) before counting.</p> <p>17. Establishment of a rhythmic pattern determines length of time to count the heartbeats to ensure accurate measurement.</p> <p>18. Ensures sufficient time to count irregular beats.</p> <p>19. Promotes client participation in care.</p> <p>20. Record rate and characteristics at bedside to ensure accurate documentation.</p> <p>21. Reduces transmission of microorganisms.</p> |
|--|---|

delegation tip

The radial pulse assessment is often delegated to trained ancillary personnel; however, the nurse is responsible for knowing the results. Assessment of the apical pulse may be delegated to specially prepared staff. The assessment of peripheral circulation is delegated after proper training in the monitoring of peripheral sites for the presence of abnormal color, motion, or sensation in the extremity. The absence of pulses must be immediately reported for further assessment by the nurse, and the nurse is responsible for reviewing the data collected in a timely manner and revalidating the results, if indicated. The institution's policy should clearly indicate the training and validation requirements before the nurse delegates the monitoring of apical pulses and peripheral vascular assessments on stable clients. These tasks should not be delegated if the client is unstable.

nursing tips

If taking an apical pulse, have the client breathe normally through the nose; breathing through the nose decreases breath sounds and makes the heart sounds easier to hear.

PROCEDURE
26-3

Assessing Respiration

EQUIPMENT

- Watch with a second hand
- Stethoscope, if needed

ACTION

RATIONALE

- | | |
|---|--|
| <p>1. Wash hands/hand hygiene.</p> <p>2. Be sure chest movement is visible. Client may need to remove heavy clothing.</p> | <p>1. Reduces transmission of microorganisms.</p> <p>2. Facilitates observation of chest wall and abdominal movements.</p> |
|---|--|

(Continues)

PROCEDURE 26-3 Assessing Respiration (Continued)

ACTION	RATIONALE
3. Observe one complete respiratory cycle. If it is easier, place the client's hand across the abdomen and your hand over the client's wrist.	3. Helps determine what constitutes a breath. Helps determine what to count. Hand rises and falls with inspiration and expiration.
4. Start counting with first inspiration while looking at the second hand of a watch (see Figure 26-17). <ul style="list-style-type: none"> • Infants and children: Count a full minute. • Adults: Count for 30 seconds and multiply by 2. If an irregular rate or rhythm is present, count for a full minute. 	4. Respiratory rate is one complete cycle (inspiration and expiration). <ul style="list-style-type: none"> • Infants and children usually have an irregular rate.
5. Observe character of respirations: <ul style="list-style-type: none"> • Depth of respirations by degree of chest wall movement (shallow, normal, or deep) • Rhythm of cycle (regular or interrupted) 	5. Reveals volume of air movement into and out of the lungs.
6. Replace client's gown if needed.	6. Prevents embarrassment and chilling.
7. Record rate and character of respirations.	7. Record rate and characteristics at bedside to ensure accurate documentation.
8. Wash hands/hand hygiene.	8. Reduces transmission of microorganisms.

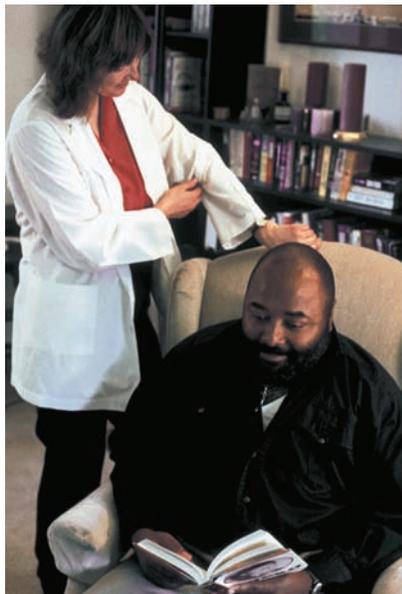

FIGURE 26-17 Count inspirations for a full 30 seconds. Multiply by 2. DELMAR/CENGAGE LEARNING

delegation tip

The skill of respiratory rate measurement is often delegated to properly trained ancillary personnel; however, the nurse is responsible for this information and appropriate action. Respiration counts over 30 (adult) or 60 (child) should immediately be reported to the nurse for further assessment.

nursing tips

Fear, pain, and anger can easily raise the respiratory rate. If these emotions are present, consider assessing the rate again at a later time when the client appears calmer.

PROCEDURE 26-4

Assessing Blood Pressure

EQUIPMENT

- Stethoscope
- Gloves, if required
- Alcohol swabs
- Sphygmomanometer/bladder with mercury column or aneroid dial

ACTION

RATIONALE

AUSCULTATION METHOD USING BRACHIAL ARTERY

- | | |
|--|--|
| <ol style="list-style-type: none"> 1. Wash hands/hand hygiene. 2. Determine which extremity is most appropriate for reading. Do not take a pressure reading on an injured or a painful extremity or one in which an intravenous line is running. 3. Select a cuff size appropriate for the client. Estimate by inspection or measure with a tape the circumference of the bare upper arm at the midpoint between the shoulder (acromion) and the elbow (olecranon process) (see Figure 26-18). 4. Have the client's bare arm resting on a support so the midpoint of the upper arm is at the level of the heart. Extend the elbow with palm turned upward. 5. Make sure the bladder cuff is fully deflated and the pump valve moves freely. Place the manometer so the center of the mercury column or aneroid dial is at eye level and easily visible to the observer. 6. Palpate the brachial artery, in the antecubital space, and place the cuff so that the midline of the bladder is over the arterial pulsation. Next, wrap and secure the cuff snugly around the client's bare upper arm. The lower edge of the cuff should be 1 inch (2 cm) above the antecubital fossa (bend of the elbow), where the head of the stethoscope is to be placed (see Figures 26-19 and 26-20 on page 534). | <ol style="list-style-type: none"> 1. Reduces transmission of microorganisms. 2. Cuff inflation can temporarily interrupt blood flow and compromise circulation in an extremity already impaired or a vein receiving intravenous fluid. 3. The bladder inside the cuff should encircle 80% of the arm in adults and 100% of the arm of children less than 13 years old. If in doubt, use a larger cuff to ensure equalization of pressure on the artery and accurate measurement. 4. Blood pressure increases when the arm is below the level of the heart and decreases when the arm is above the level of the heart. 5. Equipment must be visible and must function properly to obtain an accurate reading. 6. Ensures even pressure distribution over the brachial artery. Rolling up the sleeve may form a tourniquet around the upper arm. Always use a bare arm. |
|--|--|

FIGURE 26-18 Select proper cuff size. An obese client may need a larger-size cuff to obtain an accurate reading. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 26-4 Assessing Blood Pressure (Continued)

FIGURE 26-19 Palpate the brachial artery to determine placement of the stethoscope. DELMAR/CENGAGE LEARNING

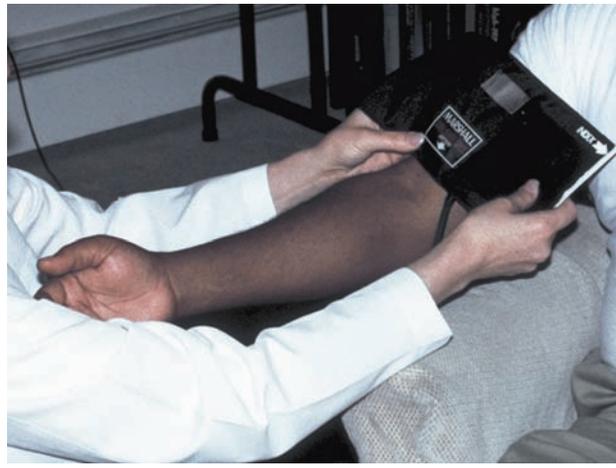

FIGURE 26-20 Center the blood pressure cuff over the brachial artery. DELMAR/CENGAGE LEARNING

ACTION

7. Inflate the cuff rapidly to 70 mm Hg and increase by 10-mm increments while palpating the radial pulse. Note the level of pressure at which the pulse disappears and subsequently reappears during deflation.
8. Insert the earpieces of the stethoscope into the ear canals with a forward tilt to fit snugly.
9. Relocate the brachial artery with nondominant hand, and place the bell of the stethoscope over the brachial artery pulsation. The bell should be held firmly in place, ensuring that the head is in direct contact with the skin and not touching the cuff (see Figure 26-21 on page 535).
10. With dominant hand, turn the valve clockwise to close. Compress the pump to inflate the cuff rapidly and steadily until the manometer registers 20 to 30 mm Hg above the level previously determined by the palpation (see Figure 26-22 on page 535).
11. Partially unscrew (open) the valve counterclockwise to deflate the bladder at 2 mm/sec while listening for the appearance of the five phases of Korotkoff's sounds. Note the manometer reading for these sounds.
 - I. A faint, clear, tapping sound that increases in intensity
 - II. Swishing sound
 - III. Intense sound

RATIONALE

7. The palpatory method provides the necessary preliminary approximation of systolic blood pressure to ensure an accurate reading. When frequent measurements are required, such as every 15 minutes, the palpatory method is generally not incorporated with each pressure check.
8. The bell, the low-frequency position of the stethoscope, enhances sound transmission from chestpiece to ears.
9. Sound is heard best directly over the artery. Wedging the head of the stethoscope under the edge of the cuff results in considerable extraneous noise and may cause an inaccurate reading.
10. Prevents air leaks during inflation. Ensures the cuff is inflated to a pressure greater than the client's systolic pressure.
11. Maintains constant release of pressure to ensure hearing first systolic sound. Identify manometer readings for each of the five phases.
 - For children less than 13 years old, use phase IV sounds as the diastolic level. Even though five phases of Korotkoff's

(Continues)

PROCEDURE 26-4
Assessing Blood Pressure (Continued)

ACTION	RATIONALE
IV. Abrupt, distinctive, muffled sound V. Sound disappears (See Table 26-13 for more information about Korotkoff's sounds.)	sounds have been identified, most clients have only two clearly distinct sounds (phase I and V), identified as the systolic and diastolic sounds.
12. After the last Korotkoff's sound is heard, deflate the cuff slowly for at least another 10 mm Hg to ensure that no other sounds are audible; then, deflate rapidly and completely (see Figure 26-23).	12. Prevents arterial occlusion and client discomfort from numbness or tingling.

FIGURE 26-21 The stethoscope chestpiece should not touch the blood pressure cuff. DELMAR/CENGAGE LEARNING

FIGURE 26-22 Compress the pump to inflate the blood pressure cuff. DELMAR/CENGAGE LEARNING

FIGURE 26-23 Deflate the cuff completely and wait at least 2 minutes before taking a second reading. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 26-4 Assessing Blood Pressure (Continued)

ACTION	RATIONALE
13. Allow the client to rest for at least 30 seconds and remove cuff. Take two or more additional readings and average them. (The American Heart Association recommends that the repeated measurements should be done after 30-minute intervals in the same or opposite arm; the Joint National Commission recommends a 2-minute interval between repeated measurements.)	13. Releases trapped blood in the vessels. Ensures accurate measurement.
14. Inform the client of the reading.	14. Promotes client's participation in health care.
15. The systolic (phase I) and diastolic (phase V) pressure should be immediately recorded, rounded off (upward) to the nearest 2 mm Hg.	15. Ensures accuracy. In children and when sounds are heard nearly to the level of 0 mm Hg, the phase IV pressure should also be recorded.
16. If appropriate, lower bed, raise side rails, and place call light within easy reach.	16. Promotes client's safety.
17. Put all equipment within proper place.	17. Fosters maintenance of equipment.
18. Wash hands/hand hygiene.	18. Reduces transmission of microorganisms.

delegation tip

The measurement of blood pressure is often delegated to ancillary personnel who have been properly educated to use both manual and electronic equipment; however, the nurse is responsible for carefully monitoring this information for significant changes and taking appropriate action. The measurement of blood pressure would be reserved for a client in stable physical condition and measured at sites without intravenous solutions infusing, dialysis shunt or fistula, painful extremity, or recent mastectomy.

nursing tips

A blood pressure cuff that is too small for the client's arm will often come unfastened as it is inflated.

KEY CONCEPTS

- Baseline values establish the norm; variations from normal may indicate possible problems with the client's health status.
- The assessment of physiological functioning provides specific data regarding the client's current condition.
- Thermoregulation is the body's physiological function of heat regulation to maintain a constant internal body temperature.
- Hemodynamic regulation is the body's physiological function of blood circulation to maintain an appropriate environment in all the tissue fluids.
- The pulse is caused by the stroke volume ejection and distension of the walls of the aorta, which creates a pulse wave as it travels rapidly toward the distal ends of the arteries.
- Blood pressure is the measurement of pressure pulsations exerted against the blood vessel walls during

cardiac systole and diastole. It is measured in terms of millimeters of mercury (mm Hg).

- Several factors cause changes in one or more of the vital signs: age, sex, exercise and metabolism, anxiety and stress, postural and diurnal variations, hormones, pain, medications, and alterations in physiological functions.
 - The normal values and variations in vital signs measurement are usually based on age.
 - All pieces of equipment used to measure the vital signs and to perform a physical assessment should be maintained to function accurately.
- Clinical data regarding the efficacy of blood circulation to an extremity are obtained by assessing all of the characteristics (rate, quality, rhythm, and volume) of the peripheral pulses.
 - When assessing ventilation, ascertain the rate, depth, and rhythm of ventilatory movement.
 - Before checking a blood pressure, review the client's chart for brachial artery contraindications, and make sure the client has not exercised or eaten for the past 30 minutes.

REVIEW QUESTIONS

1. The measurement of blood that enters the aorta with each ventricular contraction is called the _____.
 - a. Pulse
 - b. Stroke volume
 - c. Cardiac output
 - d. Pulse pressure
2. A 69-year-old woman is admitted with dizziness, confusion, and dyspnea. Which vital sign should not be delegated to trained ancillary personnel?
 - a. Temperature
 - b. Pulse
 - c. Respiratory rate
 - d. Blood pressure
3. Prioritize your nursing interventions based on the vital signs.
 - a. Temperature 102.4°F (39.1°C), oral, electronic thermometer
 - b. Heart rate 130 beats/min, apical
 - c. Respiratory rate 25 breaths/min
 - d. BP 145/80
4. A client is admitted with a head injury and may develop neurogenic fever. Which nursing diagnosis would be most appropriate for this client?
 - a. *Risk for imbalanced body temperature*
 - b. *Hyperthermia*
 - c. *Hypothermia*
 - d. *Ineffective thermoregulation*
5. According to the JNC's seventh report, a BP reading of 144/96 would be considered _____.
 - a. Normal
 - b. Prehypertension
 - c. Stage 1 hypertension
 - d. Stage 2 hypertension
6. Developing a trusting provider-client relationship encourages the client to _____.
 - a. Talk about his or her feelings and needs
 - b. Take his or her medicines
 - c. Live a productive life
 - d. Maintain a positive attitude toward his or her illness

CHAPTER 27

Physical Assessment

COMPETENCIES

1. Describe the correct positioning of the client for performing a physical examination.
2. Explain techniques used in conducting a physical examination.
3. Describe the significance of assessment findings obtained from a physical examination.
4. Discuss documentation of data obtained from a physical examination.

KEY TERMS

adventitious breath sounds	extinction	regurgitation
aneurysm	Glasgow Coma Scale	rhonchi
angina	goniometer	Snellen chart
aphasia	graphesthesia	stenosis
arthritis	heaves	stereognosis
ascites	hypertonicity	striae
atrophy	hypertrophy	stridor
bronchial sounds	hypotonicity	supernumerary nipples
bronchovesicular sounds	integumentary system	tactile fremitus
bruits	ischemia	thrills
crackles	murmur	tympany
crepitus	myocardial infarction	vesicular sounds
cystocele	nystagmus	wheezes
dermatome map	osteoarthritis	
dullness	pleural friction rub	

The physical examination is performed in all health care settings on clients of every age in order to gather comprehensive, pertinent assessment data. The physical examination provides a complete picture of the client's physiological functioning. When combined with a health and psychosocial assessment, it forms a database to use in decision making. See Chapter 6 for a discussion of psychosocial assessment and health history. The nurse uses information from the assessment, health history, and physical examination to develop a client profile. Health history ascertains the client's chief complaint and directs the focus of physical examination.

PURPOSES OF PHYSICAL EXAMINATION

The physical examination provides the database from which all interventions are planned. The complete assessment data are used to:

- Ascertain the client's level of health and physiological function
- Identify factors placing the client at risk for problems
- Determine areas of preventive nursing
- Confirm alterations, disease, or inability to perform the activities of daily living
- Identify the need for additional testing or examination
- Evaluate the outcomes of treatment and therapy

The physical examination is done in a sequential, head-to-toe fashion to ensure a thorough assessment of the client. This method not only prevents the nurse from forgetting to examine an area, it also decreases the number of times the nurse and the client have to change positions.

After gaining proficiency in performing the physical examination, nurses should be able to integrate assessment into daily care activities. For example, while weighing the client,

observe posture, motor activity, and gait. This chapter provides in-depth information with detailed descriptions for conducting a complete physical examination. Keep in mind that none of these skills should override the nurse's use of observation and inspection; see the Uncovering the Evidence display on page 542.

PREPARATION FOR PHYSICAL EXAMINATION

Many clients become anxious about being physically exposed and/or experiencing pain during the examination. Because the client will experience some anxieties, it is important for the nurse to keep the client informed while performing the examination. The nurse needs to be organized and demonstrate respect for the client's apprehension during the examination.

It is important that the nurse appear calm, organized, and competent. A review of the agency's physical examination form before meeting with the client ensures that the nurse can fully explain the actions that will be performed and prevents omission of any area required to be assessed.

Environment

The client and the environment require special consideration. The nurse needs to determine that the environment will accommodate any special needs of the client. Adjust the environment to allow for placement of the equipment on a surface that is clean and free from movement. Remove from the floor any items that would place the client at risk for falling.

The room needs to be quiet, warm, without drafts, and adequately lit. Depending on the setting, make the necessary adjustments to ensure privacy. Inform other personnel about the time of the examination to avoid interruptions, which are frustrating to both client and nurse.

Equipment

The nurse should review the protocol relative to a physical examination and secure the forms required for documenting the assessment findings. Wash hands and gather the necessary equipment. Table 27-1 discusses the equipment needed to conduct a physical examination. Several other items that are frequently used in the physical examination include:

- Aromatic substances (e.g., vanilla) to test the 1st cranial (olfactory) nerve

- Cotton balls to assess sensory response to light touch
- Toothpick to assess sensory response to slight pain
- Drapes to cover the client
- Gloves to reduce the transmission of microorganisms
- Calibrated tape measure for assessing circumference, length, and width
- Tongue depressor to inspect mouth and to stimulate gag reflex for assessing 9th and 10th (glossopharyngeal and vagus) cranial nerves

TABLE 27-1 Equipment and Supplies Used for a Physical Examination

INSTRUMENT		DESCRIPTION AND USAGE
Laryngeal mirror		Metal instrument with mirror to inspect pharynx and oral cavity
Lubricant		Facilitates insertion of instruments into body cavities
Ophthalmoscope		Lighted instrument attached to a battery tube to visualize the eye's interior
Otoscope		Special ear speculum that attaches to an ophthalmoscope to visualize external and middle ear (eardrum)
Penlight		Flashlight to test pupillary reaction to light and assess third, fourth, and sixth (oculomotor, trochlear, and abducens) cranial nerves
Percussion hammer		Instrument with rubber head to test reflexes
Tuning fork		Metal fork that vibrates when tapped and is used to perform Rinne test to assess eighth (acoustic) cranial nerve

Delmar/Cengage Learning

UNCOVERING THE

Evidence

TITLE OF STUDY

“A Survey of Physical Assessment Techniques Performed by RNs: Lessons for Nursing Education”

AUTHOR

Jean F. Giddens

PURPOSE

To identify physical examination skills performed by nurses in the clinical setting to better understand the competencies needed by nursing school graduates.

METHODS

This is a descriptive study that involved the administration and analysis of a survey of registered nurse participants. The participants, who were randomly selected, were direct care providers in both inpatient and outpatient settings. The survey consisted of a list of 126 physical examination techniques; participants indicated the average frequency they performed each of the techniques. Eighty percent of the surveys were returned. Simple descriptive statistical applications were used to analyze the data.

FINDINGS

Thirty core techniques were identified by the sample. The majority of these techniques involve inspection and general observation. One-third of the techniques are associated with cardiovascular and respiratory assessment.

IMPLICATIONS

The findings suggest that this sample of registered nurses incorporates a small set of physical examination skills into practice on a regular basis. The majority of these skills involve inspection. The implication for nurse educators is to help students develop greater skills in observing and recognizing cues indicative of changes in client status; in order to do this, it is suggested that less time be spent in great detail on physical examination techniques that are not actually used in clinical practice.

Giddens, J. F. (2007). A survey of physical assessment techniques performed by RNs: Lessons for nursing education. *Journal of Nursing Education*, 46(2), 83–87.

embarrassment elicit tension and restlessness and may decrease the client’s ability to cooperate. The drapes also prevent the client from being chilled.

The drape may be paper or cloth, for example—a bath blanket, sheet, or towel. The client’s gown can be rearranged to expose or cover different body parts. When the client is in a sitting, supine, Sims’, or prone position, use a gown or towel to cover the upper chest and a bath blanket or sheet to cover the rest of the body.

Draping a client in the lithotomy position requires a sheet and boots. The nurse should apply the boots, if available, to cover each of the client’s feet and legs. Fold and place the sheet in a diamond-shaped arrangement over the body: top diamond under chin with opposite corner pointing toward the toes and lateral corners pointing toward the sides of the table. Ask the client to flex the knees, and with the lateral corners of the sheet, wrap it in a spiral fashion around the legs and feet. The bottom corner covers the perineum and is folded back over the abdomen to expose the perineum when the examination begins.

GENERAL SURVEY

Assessment begins at the initial contact with the client. Proper terminology and agency-approved abbreviations should be used when recording assessment data.

Assess the following areas during a general survey:

- Signs of distress: labored breathing, pallor or cyanosis, protection of a painful part, sweating or cold moist palms, anxious face
- Client’s state of health, stature, and sexual development
- Weight, height, and vital signs
- Posture, motor activity, and gait; dress, grooming, and personal hygiene; and any odors of body and breath
- Client’s facial expressions; behaviors; and manner, affect, and reaction to persons and things in environment
- Quality of speech and level of consciousness (See Chapter 38.)

When performing the general survey, it is important to remember the client’s cultural context; see the Respecting Our Differences display on page 544. Document general survey data in an organized fashion to portray a clinical picture of the client. Certain clients, such as those who are older, disabled, or abused, will require special consideration during the physical examination.

Sexual History

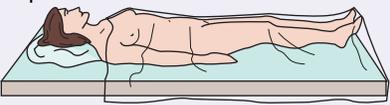

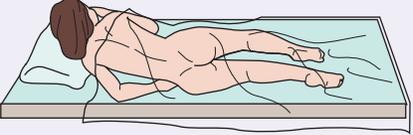

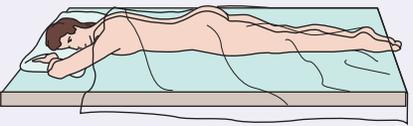

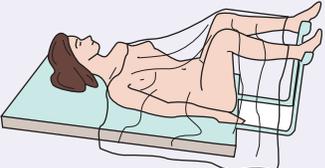

Prior to performing a physical examination of the genitalia, the nurse should refer to the information obtained from the client’s sexual history. Illness and medical interventions can interfere with sexual functioning; for example, antihypertensive medication can cause men to experience ejaculation or erection difficulties. Sexual responsiveness can be altered in both men and women who are taking narcotics, sedatives, antidepressants, and antispasmodic medications. Prolonged therapies, such as chemotherapy or radiation, may cause physiologic changes that affect sexual desire and function; refer to the Nursing Process Highlight on page 544 for elements of a sexual history. “While not every nurse can be a sexual counselor, listening to concerns of

Positioning and Draping

The nurse should position the client to ensure accessibility to the body part being assessed. Table 27-2 on page 543 presents the positions used in conducting a physical examination; contraindications for each position are also described.

The primary purpose of draping the client is to prevent unnecessary exposure during the examination. Feelings of

TABLE 27-2 Positioning for a Physical Examination

Delmar/Cengage Learning

patient and family, presenting factual information in a non-threatening manner, managing noncomplex disease and treatment related symptoms, and providing appropriate referrals can be easily incorporated into routine care” (Krebs, 2007, p. 529).

Older Adults

When nurses assess older clients, it is important to know the normal changes that result from aging. See Chapter 19 for a

NURSING PROCESS HIGHLIGHT

Assessment

Sexual History

- Age at which sexual activity began
- History of sexual activity with women, men, or both
- Number of current sexual partners
- Satisfaction in current relationship
- Concerns regarding sexuality or sexual identity
- History of sexually transmitted diseases (STDs)
- Desire for parenting, at present or in the future
- Current or past contraceptive methods
- History of childhood or adult sexual trauma, rape, or domestic abuse

Data from Krebs, L. U. (2007). Sexual assessment: Research and clinical. *Nursing Clinics of North America*, 42(4), 525–529.

complete discussion about caring for older clients. Aging may reduce the body's resistance to illness and tolerance of stress and increase the time needed to recuperate from illness. Make sure the client understands and can follow instructions, and allow extra time if the client has difficulty changing positions.

Disabled Clients

Determine the client's ability to participate before conducting the examination. When assessing disabled clients, nurses should adapt their interactions to the client's ability; for example, a hearing-impaired client should be given a written questionnaire. An intellectually impaired client might require simple, direct sentences and questions or use of pictures. To allay the disabled client's fears and anxiety, allow a family member to remain with the client during the examination. The nurse should ascertain and encourage the client's level of independence.

RESPECTING OUR DIFFERENCES

Cultural Values and Assessment

Cleanliness is highly valued by mainstream American society. However, in some cultures, a daily bath is not perceived as necessary or desirable. Some cultures do not define natural body odors as offensive. It is important to consider the client in the context of cultural beliefs before labeling a client. Think of the terms "dirty," "unkempt," or "foul smelling." These value-laden terms can cloud the assessment process and subsequently the care provided to the client.

Abused Clients

Nurses need to be observant for signs of abuse, especially in children and older adults. The symptoms may be psychological as well as physical, for example, not wanting to be touched, unable to maintain eye contact, or unwillingness to talk about bruises, burns, or other injuries. Abuse-related bruises or lacerations usually appear on breasts, buttocks, thighs, or genitalia. The nurse should also inspect for healed scarring or burns. The nurse needs to know state laws and agency policies for reporting possible abuse. See the accompanying Spotlight On display.

Clients who have been sexually abused require special care. Registered nurses with specialized education and clinical training may serve as a sexual assault nurse examiner (SANE). The SANE nurse is responsible for collecting forensic evidence, documenting the forensic examination, providing appropriate counseling and referral, and coordinating communication with other involved agencies. Many SANE programs provide follow-up with the victim and postexamination services.

ASSESSMENT TECHNIQUES

Chapter 6 describes the assessment techniques of inspection, palpation, percussion, and auscultation; this section demonstrates how these techniques are used in performing a physical examination. The specific techniques used to assess each body system are identified and explained within the context of the assessment. See the assessment tables throughout this chapter to reinforce appropriate techniques for assessment of each body system.

The nurse should use the senses of sight, hearing, smell, and touch when gathering information during the physical examination. The nurse uses the sense of sight by visually inspecting the client's body parts and assessing the client's normal behaviors. For example, the skin is inspected for color, tone, texture, and presence of scars, lesions, abrasions, and rashes. Throughout the examination the nurse should visually observe the client's movement, motor dexterity, contour and symmetry of the body, and abnormalities.

The nurse uses the sense of touch when performing palpation. The skin is thinner on the backs of the hands and more sensitive to temperature changes. The back of the hand can be used to assess skin temperature over an inflamed joint or a leg with impaired circulation. The fingerpads are also sensitive and are used to palpate the size, position, and consistency of various body parts, such as lymph nodes and breast tissue. Figure 27-1 on page 545 demonstrates how to perform light palpation.

SPOTLIGHT ON...

Legal

Caring for Abused Clients

What would you do if a child in the emergency room in which you were practicing showed signs of abuse?
How would you conduct the physical examination?

FIGURE 27-1 Light Palpation DELMAR/CENGAGE LEARNING

Learning the technique of percussion is challenging; it can be practiced on any surface to improve accuracy. See Figure 27-2, and practice percussion as follows:

1. Hyperextend the middle (pleximeter) finger of the nondominant hand and press its distal phalanx and joint firmly on the surface to be percussed (see Figure 27-2A). Only the distal phalanx and joint should be touching the surface. Having other parts of the hand in contact with the surface will dampen the vibrations.
2. Position the forearm of the dominant hand close to the surface, with the hand cocked upward (see Figure 27-2B) and the middle finger partially flexed, relaxed, and poised to strike.
3. With a quick, sharp, but relaxed *wrist* motion, strike the pleximeter finger with the tip of the right plexor finger of the dominant hand (see Figure 27-2C). Only the wrist joint is flexed, not the finger or elbow.
4. Quickly withdraw the plexor finger to avoid damping the vibration.
5. Strike one or two blows in one location, then move on, using the lightest percussion that will produce a clear note.

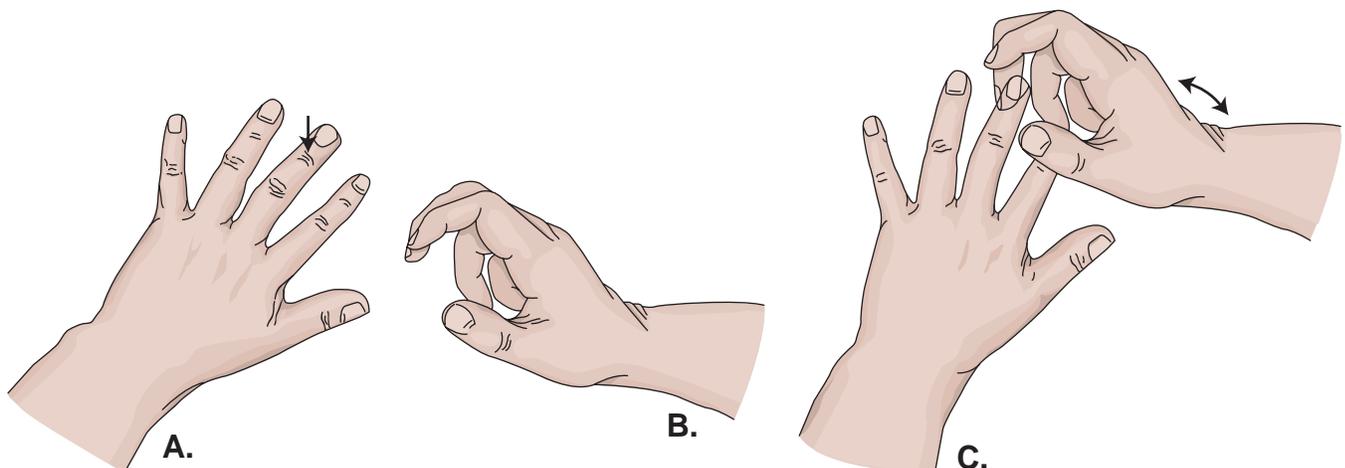

FIGURE 27-2 Percussion. **A.** Hyperextend the pleximeter finger and press the distal phalanx and joint firmly on the surface to be percussed. **B.** Cock the dominant hand upward with the middle finger partially flexed and poised to strike. **C.** Strike the pleximeter finger with the tip of the plexor finger. DELMAR/CENGAGE LEARNING

If the client becomes fatigued, encourage frequent rest periods. Adjust the client's position for comfort without compromising the ability to visualize the area of assessment.

The nurse uses the sense of hearing during the physical examination when performing auscultation. A stethoscope allows the nurse to listen to sounds produced in the heart, lungs, abdomen, and blood vessels.

Besides auscultation, the nurse should listen to what clients say relative to their health status during the examination. Throughout the entire examination, the nurse uses the senses of hearing and smell. Smell is used to investigate any environmental, body, or fluid odors, such as drainage from a wound. Also, the nurse can often detect the use of alcohol or tobacco products through the sensation of smell.

INTEGUMENT

The **integumentary system** (skin, hair, scalp, and nails) provides the body with external protection, regulates temperature, and is a sensory organ for pain, temperature, and touch. The sebaceous and sweat glands are considered appendages of the skin. Nurses should routinely assess the skin of older and debilitated clients for primary lesions that may lead to the development of secondary lesions such as pressure ulcers. See Chapter 37 for a complete discussion of skin integrity.

To facilitate learning and psychomotor proficiency, the integumentary system is assessed separately. However, once skills are established, the integumentary system assessment can be integrated into the examination of other systems.

Skin

The skin is the largest organ system of the body, with its surface area covering approximately 20 square feet in the average adult. Skin assessment provides a noninvasive observation of the body's physiological functions. See Table 27-3 on pages 547–548, which presents information on assessing the skin.

See the Respecting Our Differences display on page 546 for ways to detect color changes in light and dark skin.

RESPECTING OUR DIFFERENCES

Skin Color Variations in Light Skin and Dark Skin

Carotenemia: Yellow-orange tinge; result of increased amount of carotene in bloodstream; caused by ingestion of foods high in carotene (e.g., carrots, sweet potatoes), endocrine disorders (e.g., diabetes mellitus), and anorexia nervosa

Light Skin

- On forehead, palms, and soles.
- No discoloration of mucous membranes or sclerae.

Dark Skin

- On palms and soles.
- No discoloration of mucous membranes or sclerae.

Cyanosis: Mottled bluish color; result of reduced oxygenated hemoglobin; may be caused by anxiety, exposure to cold, and chronic heart and lung disease

Light Skin

- Dusky blue.

Dark Skin

- Dark, dull, and lifeless.
- Most noticeable in conjunctivae, oral mucosa, and nail beds.

Erythema: Redness; result of increased visibility of oxygenated hemoglobin; may be caused by emotions (blushing, hearty laughter), fever, warm ambient temperature, local inflammation, consumption of alcohol, and carbon monoxide poisoning

Light Skin

- Generalized red or bright pink.
- Generalized or in local areas (i.e., inflammation, pressure on bony prominence).

Dark Skin

- Difficult to detect.
- Check for redness in lips.
- Localized areas of inflammation appear darker than surrounding skin.

Note: Bright cherry-red coloration in face and neck occurs with carbon monoxide poisoning.

Jaundice: Yellowish discoloration as result of increased serum bilirubin; may be caused by liver inflammation or hemolytic disease (e.g., after severe burns)

Light Skin

- Yellow sclera.
- Discoloration may be generalized; seen in sclera, hard palate, and mucous membranes.

Dark Skin

- Most noticeable in palms of hands and juncture between hard and soft palates.

Pallor: Loss of color in skin; result of absence of oxygenated hemoglobin; may be caused by

smoking, cold environment, stress, shock, hypotension, anemia, and prolonged elevation of body part

Light Skin

- Skin looks dull.
- Loss of rosy tone in white skin.
- Yellow-toned skin appears more yellow.

Dark Skin

- Skin appears dull.
- Brown skin has yellowish hue.
- Yellow-toned skin appears more yellow.
- Black skin appears ashen gray.

Data from D'Amico, D., and Barbarito, C. (2007). *Health & physical assessment in nursing*. Upper Saddle River, NJ: Pearson Prentice Hall; Jarvis, C. (2007). *Physical examination & health assessment* (5th ed.). Philadelphia: Elsevier.

Lesions of the skin vary from superficial, involving only the epidermis, to penetrating the dermis or subcutaneous layers of the skin. Tables 27-4 on page 548 and 27-5 on page 550 describe the common skin lesions.

Hair

Hair is distributed over the body except for the palmar and plantar surfaces, lips, nipples, and the glans penis. The amount and texture of hair vary with age, gender, and race. Men have coarser, thicker chest and facial hair growth than women. The two types of body hair are:

- Vellus: Fine, unpigmented hair that covers most of the body.
- Terminal hair: Coarser, darker hair of scalp, eyebrows, and eyelashes; axillary and pubic hair become terminal with the onset of puberty.

See Table 27-6 on page 552 for details on assessing the hair and scalp.

Nails

The nail plate is the translucent protective tissue that covers the distal portion of the digits. See Tables 27-7, on page 552, and 27-8, on page 553, for a description of nail assessment. Careful assessment of nails and nail beds elicits valuable information because they may exhibit changes indicative of systematic diseases.

HEAD AND NECK

Areas to be included in the head and neck examination are the skull, face, eyes, ears, nose, mouth, pharynx, and neck. The carotid artery assessment is conducted either as part of the neck examination or with peripheral artery assessment. Inspection and palpation are used throughout this assessment. Auscultation is used if the carotid arteries are assessed as part of the head and neck examination.

Skull and Face

Assessment of the skull and face involves inspection and palpation. During inspection, observe the shape of the skull and

TABLE 27-5 Common Skin Lesions

PRIMARY LESIONS

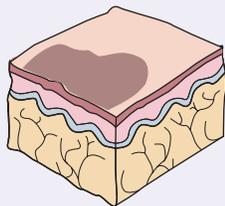

NONPALPABLE

PALPABLE

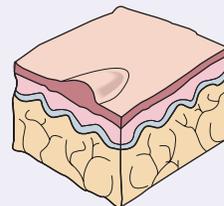

FLUID-FILLED CAVITIES WITHIN THE SKIN

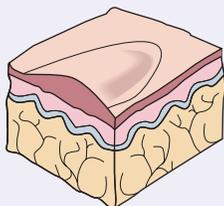

Macule: Localized changes in skin color greater than 1 cm in diameter (e.g., freckles, measles)

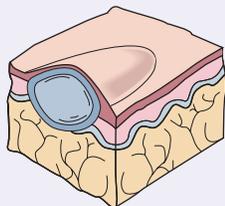

Papule: Solid, elevated lesion 0.5 cm in diameter (e.g., elevated nevi)

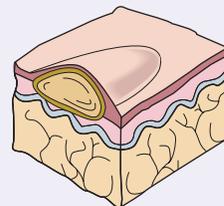

Vesicle: Elevated mass containing serous fluid accumulation between the upper layers of the skin (e.g., herpes simplex and zoster, chickenpox, second-degree burns)

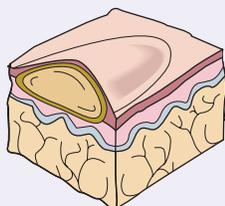

Plaque: Solid, elevated lesion wider than 1 cm in diameter (e.g., psoriasis)

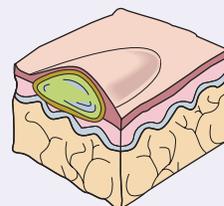

Patch: Localized changes in skin of 1 cm (e.g., vitiligo, stage 1 pressure ulcer)

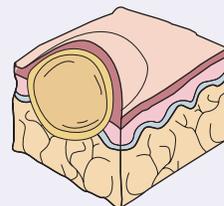

Bullae: Same as vesicle, larger than 1 cm (e.g., contact dermatitis, large second-degree burns, bulbous impetigo, pemphigus)

Nodule: Solid and elevated; extends deeper than papule into the dermis or subcutaneous tissues, 0.5–2.0 cm (e.g., lipoma, erythema, cyst)

Pustule: Pus-filled vesicle or bulla, 0.5 cm in diameter (e.g., acne, impetigo, carbuncles)

Cyst: Subcutaneous or dermis mass (e.g., sebaceous or epidermoid cyst)

(Continues)

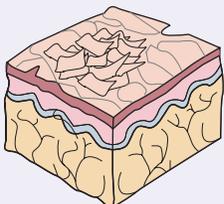

TABLE 27-5 (Continued)

SECONDARY LESIONS

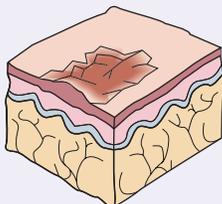

ABOVE THE SKIN SURFACE

BELOW THE SKIN SURFACE

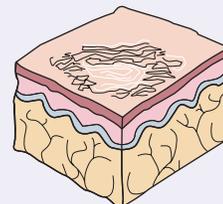

BELOW THE SKIN SURFACE

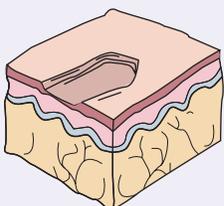

Scales: Flaking of the skin's surface (e.g., dandruff, psoriasis)

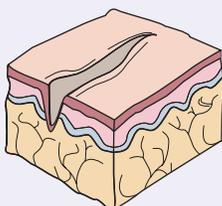

Erosion: Loss of epidermis (e.g., ruptured chickenpox vesicle)

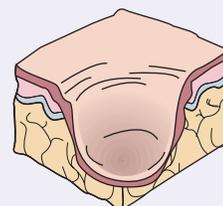

Atrophy: Thinning of skin surface and loss of markings (e.g., striae, aged skin)

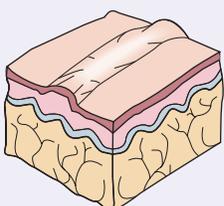

Crust: Dried serum, blood, or pus on skin's surface (e.g., impetigo)

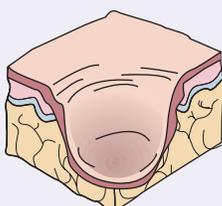

Fissure: Linear crack in the epidermis that can extend into the dermis (e.g., chapped hands or lips, athlete's foot)

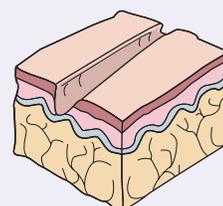

Ulcer: Depressed lesion of the epidermis and upper papillary layer of the dermis (e.g., stage 2 pressure ulcer)

Scar: Fibrous tissue that replaces dermal tissue after injury (e.g., surgical incision)

Keloid: Enlarging of a scar past wound edges due to excess collagen formation (more prevalent in dark-skinned persons)

Excoriation: Loss of epidermal layers exposing the dermis (e.g., abrasion)

Delmar/Cengage Learning

determine whether the size of the head is proportionate to body size. Normally, the skull is rounded with a smooth contour; see the Safety First display.

When inspecting facial features, look for symmetry and involuntary muscle movements. Palpate for presence of edema and masses. The normal skull and face will have no abnormal movements (i.e., tics), and there will be neither edema nor masses detected during palpation. Note that sunken eyes, cheeks, and temples are often seen with malnutrition and dehydration. The client's face has its own unique characteristics influenced by factors such as race, emotions, and health status. Facial

▼ SAFETY FIRST ▼

An enlarged skull may indicate hydrocephalus, which occurs with increased intracranial pressure. This finding must be reported immediately to the primary care provider.

TABLE 27-6 Assessment of Hair and Scalp

AREA OF ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
Inspect and palpate scalp to determine quality, distribution, and pattern of hair loss.	Thick and even distribution	Thin and brittle (hypothyroidism) Alopecia (aging, chemotherapeutic drugs, hair grooming products) Hirsutism (genetic, some medications)
Inspect for parasitic infestation.	Free of infestation	White ovoid nits (<i>Pediculus capitis</i> , <i>P. corporis</i> , and <i>P. pubis</i>)
Part the hair all over the scalp; inspect for scales and scars.	Shiny and smooth without lesions, lumps, or masses	Masses or lumps (sebaceous cysts, trauma, tumors)
Beginning at front of scalp, palpate down midline and each side. Note any tenderness, pain, lesions, lumps, or masses.	Absence of pain, redness, or scales	Dry flaking scales (seborrhea) Red patches covered by thick, dry, silvery, adherent scales (psoriasis)

Data from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning.

anomalies provide information relevant to the overall health status and many indicate the presence of disease, for example:

- An elongated head with prominent forehead, nose, and lower jaw and enlarged nose, lips, and ears (acromegaly) results from excessive amounts of growth hormone.
- A round “moon” face with excessive hair growth occurs with Cushing’s syndrome, which is caused by excessive amounts of adrenal hormones (i.e., corticosteroids).
- Protrusion or bulging of the eyes (exophthalmos) results from increased pressure in the eye orbit, often caused by inflammation or tumor.
- Pale, edematous tissue around the eyes occurs in people with chronic renal failure.
- Decreased facial mobility and expressions (a masklike facies) result from progressive degenerative neurological disorders, for example, Parkinson disease.

TABLE 27-7 Assessment of the Nails

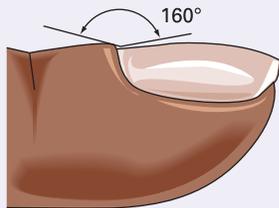

AREA OF ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
Inspect and palpate nails and nail beds, noting color, shape, and texture.	Firm when palpated. Pinkish color in light-skinned people. Longitudinal streaks of brown or black pigmentation in dark-skinned people. Angle between nail and base of finger is 160°.	See Table 27-8 on page 553 for variations and abnormalities of nail bed.
Test for capillary refill: Press nail between your thumb and index finger. Note degree of blanching and return of normal color.	Nail promptly returns to its normal color when pressure is released.	Delayed return of color to nail bed (circulatory impairment).
Inspect tissue surrounding nails. Note any lesions.	Tissue is intact.	Paronychia (inflammation of skin around the nails).

Data from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning.

TABLE 27-8 Variations of the Nail Bed

NORMAL NAIL ANGLE

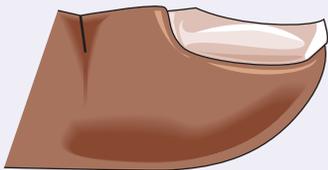

Normal nail angle

Normal nail: Has an angle of approximately 160° between the fingernail and nail base; nail feels firm when palpated.

Clubbing: Hypoxia causes an angle greater than 180° between the fingernail and nail base; nail feels springy when palpated. (Robert A. Silve-man, MD, Pediatric Dermatology, Georgetown University)

Koilonychia (spoon nail): Characterized by concave curves; associated with iron-deficiency anemia.

Beau's line: Characterized by transverse depression in the nails; associated with injury and severe systemic infections. (Robert A. Silve-man, MD, Pediatric Dermatology, Georgetown University)

Paronychia: Characterized by an inflammation at the nail base (may be swollen, red, or tender); associated with trauma and local infection.

Eyes

Active client participation is necessary for assessment of vision. Age-related physiological change is one factor that affects vision; see the accompanying Respecting Our Differences and Safety First displays. A complete eye assessment examines both visual acuity and anatomic structures. Visual acuity should be assessed prior to physically examining the eye. Every nurse uses the technique of inspection; however, the use of the ophthalmoscope falls within the scope of advanced nursing practice.

Assessment of visual acuity is a simple, noninvasive procedure that uses the **Snellen chart**, a chart that contains various-sized letters with standardized numbers at the end of each line of letters; see Figure 27-5. The standardized numbers (denominators) indicate the degree of visual acuity when the client is able to read the line of letters at a distance of 20 feet. Visual acuity of 20/20 is considered normal. A value of 20/40 indicates that the client can read the Snellen chart from a distance of 40 feet. See the Nursing Checklist for visual acuity assessment guidelines.

Testing of visual fields is done to determine what the client can see when looking straight ahead; see the accompanying Nursing Checklist on page 558. Loss of peripheral vision may be a gradual process that occurs as a physiological, age-related change or may be indicative of glaucoma. Glaucoma is a circulatory disturbance that increases intraocular (aqueous fluid) pressure.

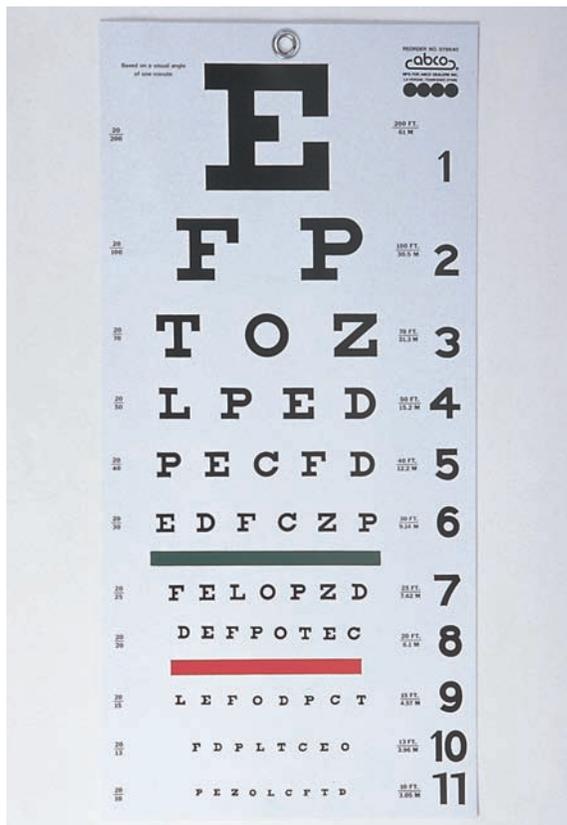

FIGURE 27-5 Snellen Chart DELMAR/CENGAGE LEARNING

RESPECTING OUR DIFFERENCES

Effects of Aging on Vision

- Dryness and burning as a result of decreased tear production
- Decreased elasticity of lens leads to decreased accommodation of lens (presbyopia)
- Floater as a result of debris in vitreous
- Cataract formation (lens opacity)
- Increased ocular pressure (glaucoma)
- Macular degeneration (loss of central vision)

Data from Jarvis, C. (2007). *Physical examination & health assessment* (5th ed.). Philadelphia: Elsevier.

SAFETY FIRST

Aging people often need more light in order to see because of decreased adaptation to darkness. Clients should be informed of this age-related change, which may impair night driving.

NURSING CHECKLIST

Assessing Visual Acuity

- Position the client 20 feet away from and facing the Snellen chart.
- Remove any corrective lenses.
- Instruct client to cover one eye and read as many lines as possible.
- Note the number of the last line that the client reads correctly.
- Repeat the test with the other eye.
- Document findings as "s-c" (without correction) or "c-c" (with correction).

Visual acuity may be affected by many types of refractive errors, including:

- Astigmatism: An unequal spherical curve of the cornea that prevents the light rays from being focused directly in a point on the retina
- Hyperopia (farsightedness): Refraction error in which rays of light are brought into focus behind the retina
- Myopia (nearsightedness): Elongation of the eyeball that causes the parallel rays to focus in front of the retina
- Presbyopia (farsightedness): Refraction error that results from loss of elasticity of the lens; occurs with aging

See Table 27-9 on pages 555–557 for guidelines on assessing the anatomic structures of the eye.

TABLE 27-9 Assessment of Eye Structures and Function

STRUCTURE/FUNCTION ASSESSED	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p>Extraocular Muscle Function</p> <p>Instruct client to let eyes follow your finger, which is held 6–10 inches in front of client’s face.</p> <p>Move your finger through the eight visual fields (Figure 27-6).</p>	<p>Movements are symmetrical and controlled. Both eyes follow direction of the gaze.</p> <p>Upper eyelids cover only the uppermost part of the iris.</p> <p>Eye movement is steady and controlled.</p>	<p>Nystagmus, involuntary rhythmical oscillation of eyes (localized injury, cranial nerve disorder)</p>

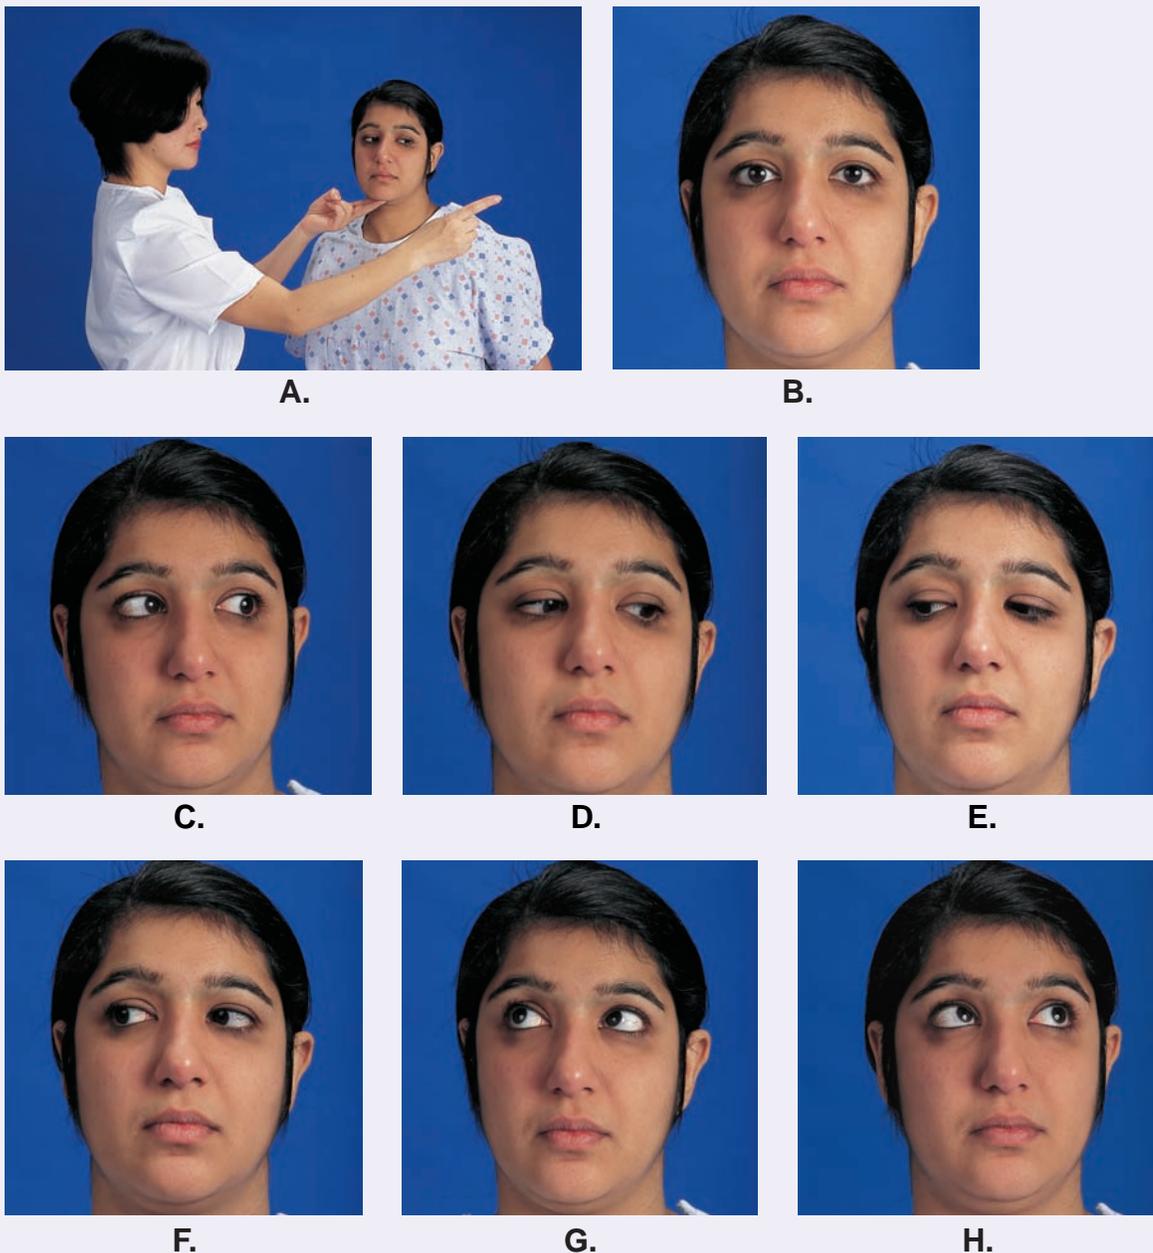

FIGURE 27-6 Testing Extraocular Muscle Function. A. Basic Position. B. Normal Resting Position. C. Conjugate Left Lateral Gaze. D. Left Down and Lateral Gaze. E. Right Down and Lateral Gaze. F. Conjugate Right Lateral Gaze. G. Right Up and Lateral Gaze. H. Left Up and Lateral Gaze. DELMAR/CENGAGE LEARNING

(Continues)

TABLE 27-9 (Continued)

STRUCTURE/FUNCTION ASSESSED	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
-----------------------------	-----------------	--

Observe for parallel eye movement.
 Pause during upward and lateral gaze to detect involuntary movement of eyes.
 Note any lags in eye movement as client follows finger.

External Anatomic Structures

(see Figure 27-7)

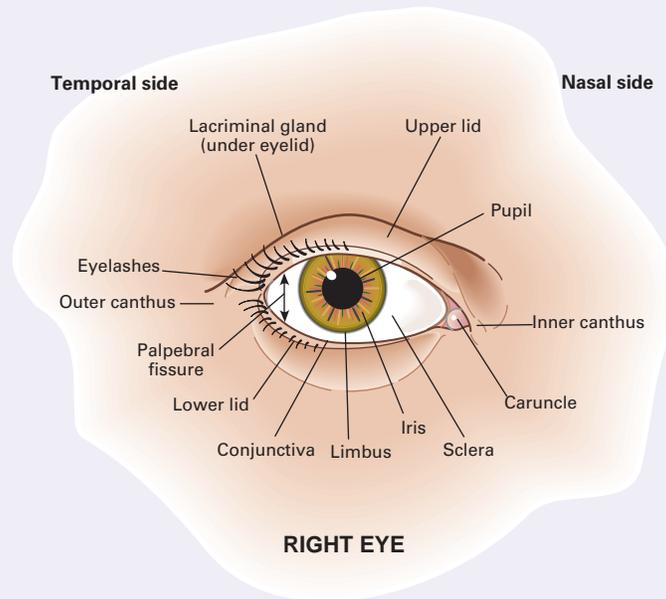

FIGURE 27-7 External Structures of the Eye DELMAR/CENGAGE LEARNING

Observe upper eyelid. Inspect eyes and lids for inflammation, crusting, edema, or masses.	Overlaps the iris; should not overlap pupil. Free from inflammation, crusting, edema, or masses.	Inflammation, crusting, edema, or masses (blepharitis, inflammation of eyelids; hordeolum or sty; chalazion, chronic inflammatory lesion of meibomian gland) Papule with a pearly border and ulcerated center (basal cell carcinoma)
--	---	---

<i>Lacrimal glands and sacs:</i> Inspect for edema. Palpate lacrimal sac and observe for regurgitation of tears.	Lacrimal gland not palpable. Tears flow freely over cornea and conjunctiva.	Edema of lacrimal sac (inflammation, tumor) Regurgitation of tears through the puncta (blocked lacrimal duct)
--	--	--

<i>Conjunctivae and sclera:</i> Instruct client to look upward while you depress lower lid with your thumb.	Conjunctiva should be transparent. In people with light skin, sclerae are a white porcelain color. In people with dark skin, sclerae have a pale yellow hue.	Bright red conjunctiva with rusty drainage (conjunctivitis) Pale conjunctiva (anemia) Bright red patch on the exposed bulbar conjunctiva indicating subconjunctival hemorrhage (trauma, sudden increase in venous pressure)
--	--	---

(Continues)

TABLE 27-9 (Continued)

STRUCTURE/FUNCTION ASSESSED	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>Cornea, lens, pupil, and iris:</i> Inspect.</p>	<p>Pupils are black, round, and equal in size; 3–7 mm in diameter (see Figure 27-8). Margins of iris are intact.</p>	<p>Cloudy pupils and lens opacity (cataracts)</p>

FIGURE 27-8 Pupil Size in Millimeters DELMAR/CENGAGE LEARNING

Pupillary response and reaction:

Dim lights.
Instruct client to look straight ahead.
Move penlight from side of client’s face directly in front of pupil (Figure 27-9A).
Note quickness of response to light.
Shine light into same eye, observing response of opposite pupil for equality of size (Figure 27-9B).

Pupil constricts quickly in direct response to light; opposite pupil should also constrict.
Pupils are equal in size.
Pupillary accommodation causes constriction in response to objects that are near.
Dilation occurs to accommodate distant vision.

Altered pupillary reaction time and inequality (increased intracranial pressure, lesions on third cranial nerve, trauma, some medications)
Pupillary constriction (inflammation of the iris, medications)
Pupillary dilation (trauma, neurological disorders, glaucoma, some medications)

A.

B.

FIGURE 27-9 A. Move penlight from side of client’s face to eye. B. Shine penlight into the eye and observe response of the opposite pupil. DELMAR/CENGAGE LEARNING

Instruct client to gaze at your finger held 4–6 inches from client’s nose, then to glance at a distant object while you note pupillary reflex.

Move finger toward the bridge of client’s nose, noting response of both pupils.

Normal responses are documented as:

- P** upils
- E** qual
- R** ound and
- R** eactive to
- L** ight
- A** ccommodation

Data from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning.

**NURSING CHECKLIST****Testing the Visual Field**

- Stand 2 feet in front of the client.
- Instruct the client to cover the right eye while you cover your left eye.
- Ask the client to look into your eye directly opposite to create one visual field.
- Using the eight directions of gaze (as shown in Figure 27-6), move your finger outside the vision field and slowly bring your finger back to the midpoint of the vision field for each direction of gaze.
- Instruct the client to state when your finger becomes visible.
- Note if you see the finger before the client does.
- Repeat for each visual field.

Note: Consensual peripheral vision should occur when the nurse's finger comes into the client's visual field.

Ears

Physical assessment of the ears consists of auditory screening, inspection and palpation of the external ear, and otoscopic examination; see Table 27-10 on page 559, which lists guidelines for assessing the ears.

The nurse must observe the client for signs of hearing difficulty, such as turning the head, lipreading, and speaking in a loud voice. See the accompanying Nursing Process Highlight and Table 27-11 on pages 560–561.

Nose and Sinuses

Assessment is limited to inspection and palpation of the external nose and nasal passages using a penlight. An examination with a nasal speculum to inspect the nasal chambers is

usually performed by an advanced nurse practitioner because the nasal chambers are lined with respiratory mucosa. Clients with nasal impairments are at risk of developing respiratory infections. Sinus assessment is limited to palpation of the frontal and maxillary sinuses. Transillumination of the sinuses is usually performed by advanced practitioners. See Table 27-12 on page 562 for a description of nose and sinus assessment.

Mouth and Pharynx

Physical assessment of the oral cavity includes the lips, tongue, buccal mucosa, gums and teeth, hard and soft palates, pharynx, and the breath. Breath odors can provide clues to underlying disorders; see the accompanying Nursing Process Highlight. If the client is wearing dentures or removable orthodontia, remove these devices before examination to visualize and palpate the gums. The oral cavity can yield significant information regarding the client's health because systemic diseases may manifest initially in the oral cavity; see Table 27-13 on page 563.

See the accompanying Nursing Process Highlight for a description of lesions that commonly affect the lips.

NURSING PROCESS HIGHLIGHT**Assessment****Abnormal Breath Odors**

- A “fruity” smell (acetone breath) indicates ketoacidosis and is present in malnutrition (e.g., dietary fasting) and diabetes.
- A musty smell is caused by breakdown of nitrogen and may indicate liver disease.
- An ammonia smell occurs with accumulation of urea during end-stage renal disease.

NURSING PROCESS HIGHLIGHT**Assessment****Assessing Clients with Hearing Impairments**

If the client uses a hearing aid, asking these questions can be helpful:

How long has the client used the device?

Does the client use the device continuously or only on certain occasions?

Is the hearing aid turned on?

When were the batteries last changed?

Is the device comfortable?

If pain is associated with use of the device, is the pain on the outer ear or in the ear canal?

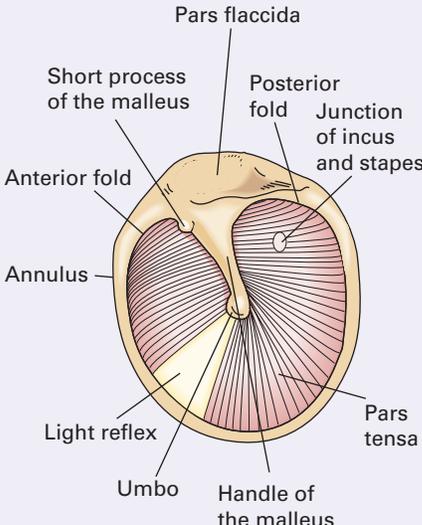

NURSING PROCESS HIGHLIGHT**Assessment****Common Lip Lesions**

Herpes simplex: Painful vesicular lesions that rupture and crust over, for example, cold sores or fever blisters

Chancre: Reddish, round, painless lesion with a depressed center and raised edges; often appears on lower lip; primary lesion of syphilis

Squamous cell carcinoma: A thickened plaque, ulcer, or wartlike growth; usually involves lower lip; most common form of oral cancer

TABLE 27-10 Assessing Structural Components of the Ears

AREA ASSESSED	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>External ear</i> (Figure 27-10): Inspect for placement, symmetry, and color.</p>	<p>Symmetrical, with upper attachment at same level as eye's corner (lateral canthus). Flesh colored.</p>	<p>Ears set below lateral canthus (congenital anomalies, e.g., Down syndrome). Erythema (inflammation, fever). Clear drainage may be cerebrospinal fluid; if present, stop the examination and notify the primary care provider immediately.</p>
		
<p>FIGURE 27-10 External Structures of the Ear DELMAR/CENGAGE LEARNING</p>		
<p><i>Auricle:</i> Observe for discharge, edema, and erythema. Palpate for lesions or tenderness.</p>	<p>Firm, smooth, free from lesions and pain.</p>	<p>Flaky, scaly skin (seborrhea). Keloids, or scar tissue, on lobe (piercing). Yellow or green discharge, itching, or pain (otitis media).</p>
<p><i>Ear canal:</i> Select the largest speculum that can comfortably fit in the ear canal. Attach speculum to otoscope to inspect canal and eardrum. Tilt client's head slightly toward opposite shoulder. Pull the pinna up and back on an adult and older child. Pull the pinna down on infants and young children. Insert speculum and look for ear wax, foreign bodies, discharge, scaling, erythema, or edema. Inspect tympanic membrane. Identify the color, light reflex, umbo, and short process and long handle of malleus (see Figure 27-11). Look for perforations, lesions, bulging, or retraction of membrane; dilation of blood vessels; bubbles; or fluid level. Gently withdraw speculum and repeat procedure in opposite ear. Clean speculum before inserting into other ear.</p>	<p>Canal is pink and dry. Cerumen (yellow-brown waxy substance) is normal. Intact tympanic membrane is translucent or pearly gray. Light reflex is seen at 5 o'clock position in right ear and 7 o'clock position in left ear.</p>	<p>Accumulation of cerumen may cause temporary hearing loss due to impaction. If foreign body is present, stop the examination and notify primary care provider. Red, bulging membrane (otitis media). Nontender, nodular swelling deep in ear canal (osteoma, a tumor composed of bone tissue). Whitish appearance on tympanic membrane (pus in the middle ear). Perforation of eardrum (infection, trauma).</p>
		
<p>FIGURE 27-11 Tympanic Landmarks DELMAR/CENGAGE LEARNING</p>		

Data from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning.

TABLE 27-11 Assessing Auditory Acuity

EXAMINATION PROCEDURE	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>Whispered voice test:</i> Instruct client to tightly cover one ear and repeat words when heard.</p> <p>Stand 1–2 feet away from client, out of view to avoid client lipreading.</p> <p>Stand on side of open ear and softly whisper words.</p> <p>Increase volume until client identifies words correctly.</p> <p>Repeat procedure on other ear.</p>	<p>Able to repeat whispered words correctly.</p>	<p>Inability to hear words may indicate high-frequency hearing loss (excessive exposure to loud noises).</p>
<p><i>Weber test:</i> Strike tuning fork against your fist or pinch the prongs together.</p> <p>Hold the base of the vibrating fork with thumb and index finger.</p> <p>Center base of fork on top of client's head (see Figure 27-12).</p> <p>Ask client to describe the sound.</p> <p>Repeat test on opposite ear.</p>	<p>Sound perceived equally in both ears = a negative Weber test.</p>	<p>A positive Weber occurs when sound lateralizes to affected ear with a unilateral conductive hearing loss (cerumen impaction, perforated tympanic membrane).</p> <p>Sound can also be lateralized to unaffected ear with sensorineural hearing loss (inner ear disorder, auditory nerve damage, ototoxic drugs, prolonged exposure to excessive noise levels).</p>

FIGURE 27-12 Weber Test: Place the base of the tuning fork on top of the client's head. DELMAR/CENGAGE LEARNING

(Continues)

TABLE 27-11 (Continued)

EXAMINATION PROCEDURE	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>Rinne test:</i> Vibrate prongs of tuning fork, place base of fork on mastoid process of ear being tested, and note time until client no longer hears sound (see Figure 27-13A). Move the vibrating fork in front of ear canal, noting length of time sound is heard (see Figure 27-13B).</p>	<p>Sound is heard longer in front of auditory meatus than on mastoid process because air conduction is twice as long as with bone.</p>	<p>Bone conduction that is equal to or greater than air conduction occurs with conductive hearing loss (disease, obstruction, trauma).</p>

A.

B.

FIGURE 27-13 Rinne Test: A. Place the base of the fork on the mastoid process. B. Place tuning fork in front of ear canal. DELMAR/CENGAGE LEARNING

Delmar/Cengage Learning

Neck

Physical examination of the neck includes the neck muscles, lymph nodes of the head and neck, thyroid gland, and trachea. The lymph nodes are normally not easily palpable unless infection is present. If the client has an enlarged

thyroid gland, the blood supply will be increased, causing a fine vibration that can be auscultated with the diaphragm of the stethoscope. Frequently, assessment of the neck is done in conjunction with pharyngeal assessment; see Table 27-14 on pages 565–566.

TABLE 27-12 Assessing the Nose and Sinuses

AREA OF ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
Inspect nose for symmetry, edema, inflammation, and discharge.	Located symmetrically, midline of face. Absence of edema, bleeding, lesions, or masses.	Edema (surgery, trauma, e.g., fracture).
<i>Test patency of each nostril:</i> Instruct client to close mouth, apply pressure on one naris, and breathe. Repeat test on opposite naris.	Each nostril is patent.	Inability of air to move through nostril (deviated septum, foreign body, upper respiratory infection, allergies, nasal polyps).
Inspect nasal cavities with a penlight. Extend client's head back and lift tip of nose. Inspect mucosa of each nostril for edema and discharge. Inspect nasal septum for deviation, perforation, lesions, or bleeding.	Mucosa is pink or dull red with no edema or polyps. A small amount of clear watery discharge is normal. Septum is midline and intact.	Red, swollen mucosa with copious clear, watery discharge (common cold). Purulent discharge (bacterial infection). Pale, edematous mucosa with clear, watery discharge (allergies). Normal mucosa with clear, watery discharge that tests positive for glucose usually indicates leakage of cerebrospinal fluid. NOTE: If present, stop the examination and immediately notify the primary care provider.
Palpate nasal sinuses (see Figure 27-14). Apply gentle upward pressure on frontal and maxillary areas. Percuss area and note the sound.	Nontender, air-filled cavities, resonant to percussion.	Pain or tenderness (allergy, viral or bacterial infection). Dull sound on percussion (obstruction, e.g., congestion).

A.

B.

FIGURE 27-14 Palpating Sinuses: A. Frontal; B. Maxillary DELMAR/CENGAGE LEARNING

TABLE 27-13 Assessing the Mouth and Pharynx

ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p>Stand 12–18 inches in front of client and smell the breath.</p>	<p>Fresh smell.</p>	<p>Halitosis (tooth decay, gum disease, tonsillitis, sinusitis, poor oral hygiene).</p>
<p><i>Inspect lips and mucosa:</i> Instruct client to open mouth. Retract buccal mucosa with tongue depressor. Inspect color and hydration. Look for lesions or signs of inflammation (see Figure 27-15). Invert lower lip with your thumbs on inner oral mucosa; note muscle tone. Repeat with upper lips using thumbs and index fingers.</p>	<p>Pink, firm, and moist with no lesions or inflammation.</p>	<p>Pale or cyanotic lips (hypoxia). Dry, cracked lips (dehydration, exposure to weather). Angioneurotic edema, i.e., swollen lips (allergic reactions).</p>
		
<p>FIGURE 27-15 Inspecting Buccal Mucosa DELMAR/CENGAGE LEARNING</p>		
<p><i>Inspect cheeks:</i> Remove dentures, if present. Retract cheeks with a tongue depressor and inspect gingivae (gums). Note color, edema, bleeding, retraction, and lesions.</p>	<p>Pink, smooth, moist, and firm.</p>	<p>Pale gums that bleed easily (periodontal disease, vitamin C deficiency).</p>
<p><i>Inspect teeth:</i> Instruct client to lightly clench teeth. Note position and alignment. Use tongue depressor to expose the molars. Note color, tartar, cavities, and extractions.</p>	<p>Properly aligned, smooth, white, and shiny.</p>	<p>Chalky discoloration of enamel (early formation of dental caries). Brown or black discoloration (caries).</p>
<p><i>Inspect tongue:</i> Instruct client to protrude tongue. Inspect dorsum of tongue. Note color, hydration, symmetry, texture, and presence or absence of fasciculation (see Figure 27-16 on page 564). Using a penlight, inspect sides and ventral surface. Note size, texture, nodules, or ulcerations. Grasp tongue with gauze. Gently pull it to one side and palpate the full length of tongue.</p>	<p>Medium red or pink. Midline position when protruded. Moist and smooth along lateral margins. Moves freely. Ventral surface is lightly rough (taste buds).</p>	<p>Enlarged tongue (acromegaly, amyloidosis, stomatitis). Glossitis, deep red with smooth surface (chemotherapy, deficiencies of vitamin B₁₂, niacin, or iron). Thick, white coating with red, raw surface, i.e., candidiasis (immunosuppression).</p>

(Continues)

TABLE 27-13 (Continued)

ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
Using a penlight, inspect floor of mouth, salivary glands, and duct openings.		Lesions on ventral surface or hardened areas or ulcerations on lateral surface (cancer).

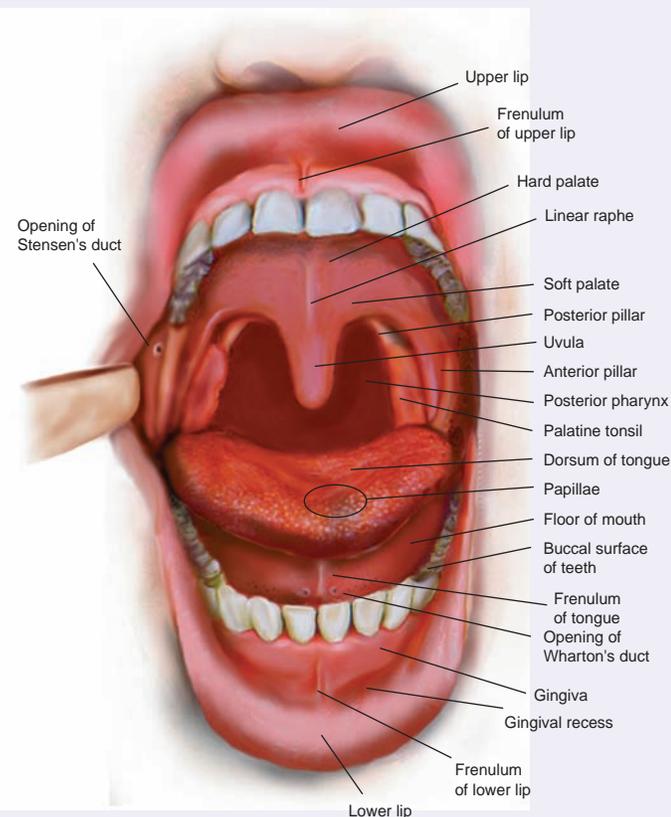

FIGURE 27-16 Structures of the Tongue DELMAR/CENGAGE LEARNING

Inspect hard and soft palates:

Instruct client to extend head backward and hold mouth open.
 Using a penlight, inspect the hard palate (roof of mouth) and soft palate. Note color, shape, and lesions.

Both palates are concave and pink.
 Hard palate has ridges.
 Soft palate is smooth.

Cleft palate (incomplete fusion of maxillary processes) is a congenital defect.
 Red, edematous, tender palates (infection).
 Eroded lesion on hard palate (cancer).

Inspect pharynx:

Instruct client to tilt head back and open mouth.
 Place tongue depressor on middle third of tongue and shine penlight into back of throat.
 Instruct client to say "ah." Note the position, size, and appearance of tonsils and uvula.
 If palate and uvula fail to rise symmetrically with phonation, elicit the gag reflex and have client say "ah."

Pharynx is pink, vascular, and lesion free.
 With phonation, the soft palate and uvula rise symmetrically.

Reddened, edematous uvula and tonsillar pillars with yellow exudate (pharyngitis).
 Swollen, gray membranes and tonsillar enlargement (acute tonsillitis, mononucleosis, diphtheria).

Delmar/Cengage Learning

TABLE 27-14 Assessment of the Neck

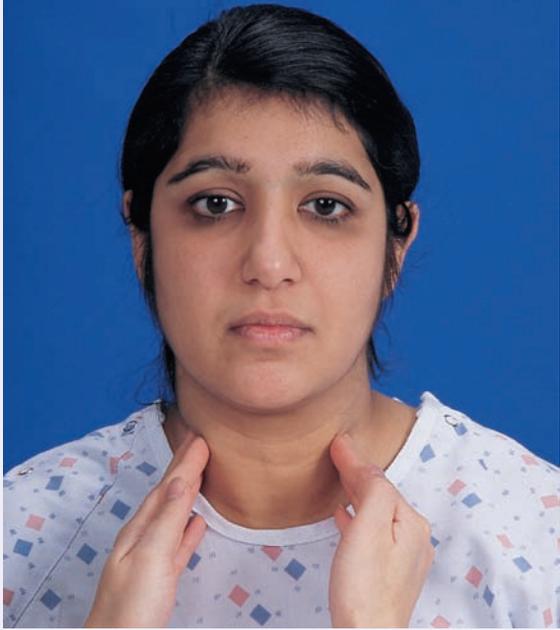

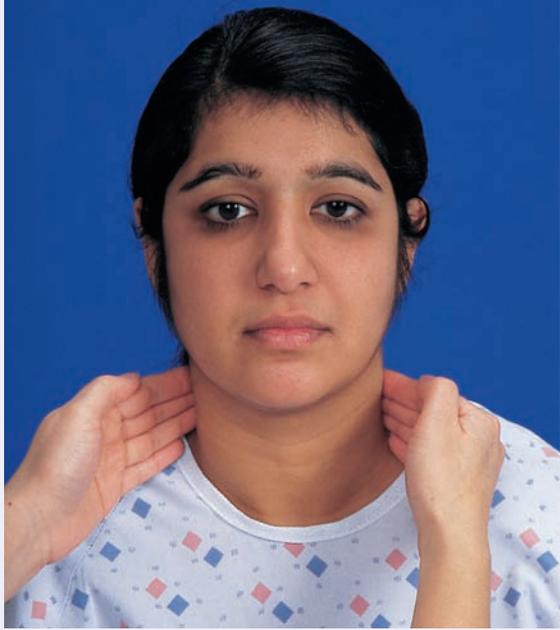

ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p>Inspect for symmetry and musculature.</p> <p>Instruct client to flex chin to chest and to each side and shoulder.</p> <p>Instruct client to hyperextend neck backward.</p>	<p>Movement through full range of motion (ROM) with no limitation or discomfort.</p>	<p>Pain upon flexion or rotation of head (muscle spasm, inflammation of muscles or meninges, vertebral diseases).</p> <p>Torticollis, i.e., prominent lateral deviation of sternocleidomastoid muscle (inflammation, trauma, sleeping with head in one position).</p> <p>Decreased ROM (degenerative osteoarthritis).</p>
<p><i>Palpate lymph nodes:</i></p> <p>Instruct client to relax and flex neck slightly forward.</p> <p>Stand in front of client and systematically palpate anterior cervical nodes and posterior cervical nodes (see Figure 27-17).</p> <p>Note size, shape, mobility, consistency, and tenderness.</p>	<p>Palpable lymph nodes.</p> <p>Small, movable nodes are insignificant.</p>	<p>Palpable nodes (infection, malignancy).</p>
<div style="display: flex; justify-content: space-around; align-items: center;"> <div style="text-align: center;">  <p>A.</p> </div> <div style="text-align: center;">  <p>B.</p> </div> </div>		
<p><i>Inspect and palpate trachea:</i></p> <p>Note position.</p> <p>Place thumbs and index fingers on sides of trachea.</p> <p>Apply gentle pressure and palpate.</p>	<p>Midline position in suprasternal notch.</p>	<p>Lateral displacement (neck mass, mediastinal mass, pulmonary disorders).</p>

THORAX AND LUNGS

Physical assessment includes inspection, palpation, percussion, and auscultation of the posterior, lateral, and anterior thorax and lungs. Figure 27-19 depicts the landmarks of the thorax. Landmarks are imaginary lines that are based on anatomic structures such as the spine and sternum. These landmarks assist with locating the underlying organs for percussion and auscultation and for accurate documentation of findings. The angle of Louis is a landmark for identifying the ribs in the midclavicular line. Each intercostal space (ICS) is named for the number of the rib directly above it; that is, the space between the third and fourth ribs is the third ICS. When used together, landmarks and ICSs identify the specific lobes of the lungs for percussion and auscultation. See Chapter 32 for a description of structural changes that may occur in the thorax.

Respiratory auscultation reveals the presence of normal and abnormal breath sounds. During auscultation, the client should be instructed to breathe only through the mouth because mouth breathing decreases air turbulence that could interfere with an accurate assessment. Figure 27-20 on page 568 shows the anterior, posterior, and right lateral positions of the lung lobes. Table 27-15 on page 568 (containing Figures 27-21 through 27-26) presents the specific areas of the thorax and lungs to be examined and the normal and key findings of this assessment.

Auscultation of breath sounds is a skill that develops with practice. There are many factors that may interfere with correctly assessing breath sounds; see the accompanying Nursing Process Highlight.

There are three distinct types of normal breath sounds with their own unique pitch, intensity, quality, location, and relative duration in the inspiratory and expiratory phases of respiration. These normal breath sounds are:

- **Vesicular sounds:** soft, breezy, and low-pitched sounds heard longer on inspiration than expiration that result from air moving through the smaller airways over the lung's periphery, with the exception of the scapular area
- **Bronchovesicular sounds:** medium-pitched and blowing sounds heard equally on inspiration and expiration

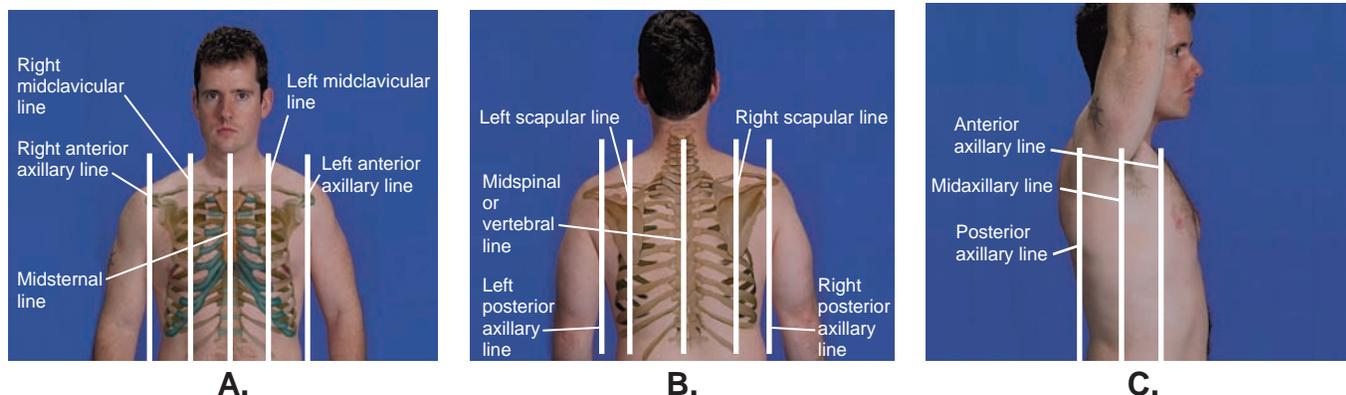

FIGURE 27-19 Landmarks of the Thorax: A. Anterior Thorax; B. Posterior Thorax; C. Right Lateral Thorax DELMAR/CENGAGE LEARNING

NURSING PROCESS HIGHLIGHT

Assessment

Factors Affecting Auscultation of Breath Sounds

- **Rustling of paper drapes or gowns.** Ask client to remain still while you are listening to the breath sounds.
- **Chest hair:** Course or dense hair may sound like crackles. Dampen the hair to prevent distortion of findings.
- **Shivering or chattering of teeth.** Determine why client is shivering or chattering, and correct the problem.
- **Mechanical ventilator tubing:** A gurgling sound can be caused by water condensing in mechanical ventilator tubing. Clear all tubing of moisture prior to auscultation.
- **Secretions in upper airway:** Oropharyngeal secretions may cause respirations to be loud and gurgling. Ask client to clear throat, or perform oropharyngeal or nasopharyngeal suctioning if necessary.

Data from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning.

from air moving through the large airways, posteriorly between the scapula and anteriorly over bronchioles lateral to the sternum at the first and second ICSs

- **Bronchial sounds:** loud and high-pitched sounds with a hollow quality heard longer on expiration than inspiration from air moving through the trachea

These normal breath sounds must be auscultated over the correct location, for example, bronchial sounds over the trachea. Otherwise, bronchial sounds in clients with emphysema are heard in the peripheral lung areas where normal vesicular sounds should be heard.

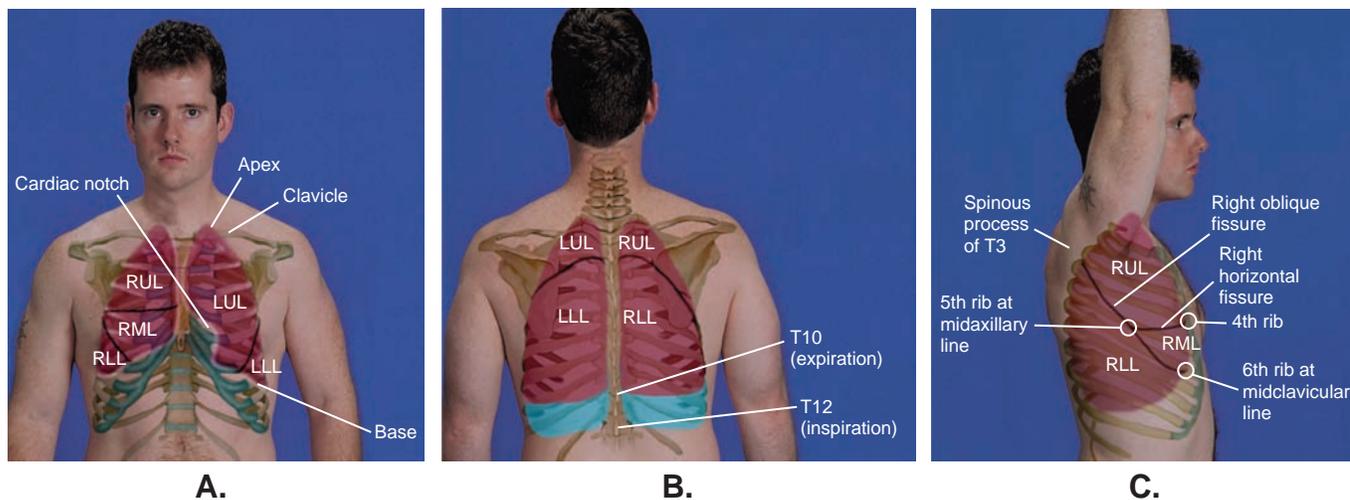

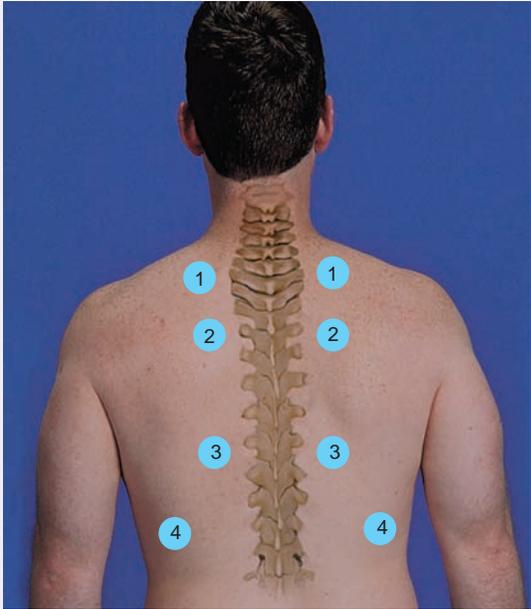

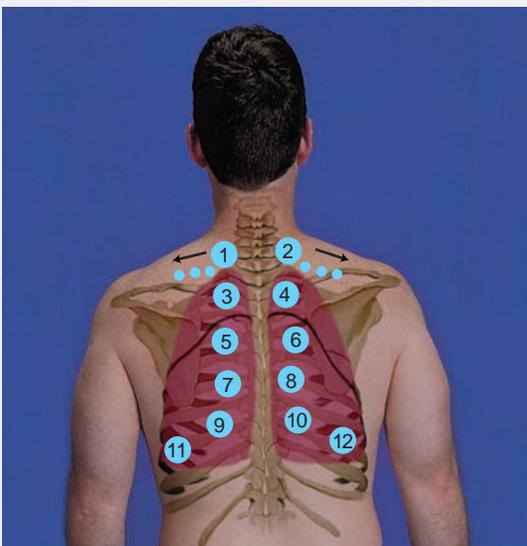

FIGURE 27-20 Positions of the Lung Lobes: A. Anterior View with Ribs; B. Posterior View with Ribs; C. Right Lateral View with Ribs
DELMAR/CENGAGE LEARNING

TABLE 27-15 Assessment of Thorax and Lungs

ASSESSMENT AREA/TECHNIQUES	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>Inspect posterior thorax:</i> Place client in a sitting position, with arms folded across chest (to separate scapulae) and back exposed. Inspect shape and symmetry of chest. Note respiratory rate, rhythm, and movement of chest wall. Note any signs of distress. Estimate the anteroposterior diameter in proportion to lateral diameter.</p>	<p>Respirations are quiet, regular, and effortless, with rate of 12–20 per minute. Thorax rises and falls in unison with respiratory cycle. Ribs slope across and downward, without movement or bulging in the intercostal space (ICS). The adult ratio of anteroposterior to lateral chest diameter ranges from 2:2 to 5:7.</p>	<p>Horizontal slope of ribs (emphysema). Bulging in ICS (increased respiratory effort). Retraction of ICS during inspiration (airway obstruction, e.g., asthma). Impaired respiratory movement (diseases of lungs or pleurae). Increased anteroposterior diameter (barrel chest as a result of chronic obstructive pulmonary disease).</p>
<p><i>Palpate posterior thorax:</i> Palpate lesions or areas of tenderness. Palpate thoracic expansion at 10th rib: Place thumbs close to client’s spine and spread hands over thorax (see Figure 27-21 on page 569). Note divergence of thumbs; feel for range and symmetry of movement during deep inhalation and full exhalation. Place ulnar aspect of open hand on each location as shown in Figure 27-22 on page 569. Instruct client to say “99” and palpate for tactile fremitus (vibrations created by sound waves). Note areas of increased or decreased fremitus. Move hands from side to side, with client repeating “99” with same intensity every time hands are placed on back.</p>	<p>Posterior thorax is free from tenderness, lesions, and pulsations. Thumbs should separate an equal distance (approximately 3–5 cm) and in the same direction during inhalation and meet at the midline on expirations. Fremitus is equal on both sides of thorax, strongest at level of tracheal bifurcation.</p>	<p>Tenderness (trauma, e.g., fractured rib). Unilateral decreased thoracic expansion (pneumonia, pneumothorax). Bilateral decreased expansion (emphysema, pleurisy). Absent or decreased fremitus (decreased voice tone; bronchial obstruction; accumulation of fluid, air, or solid tissue in pleural space). Fremitus is increased over consolidated areas of lungs.</p>

<p><i>Percuss chest systematically</i> (see Figure 27-23):</p> <p>Start at lung apices. Move hands from side to side across top of each shoulder. Note sound produced from each percussion strike and compare with contralateral sound.</p> <p>Continue downward in posterior lateral movement, palpating over every other ICS (see Figure 27-24). Note intensity, pitch, duration, and quality of percussion.</p>	<p>Air-filled lungs create a resonant sound.</p> <p>Identify contralateral sound; bones (e.g., ribs, spine) create a flat sound.</p> <p>Thorax is more resonant in children and thin adults.</p>	<p>Hyperresonance in adults (pneumothorax, asthma, emphysema).</p> <p>Dull sound (pneumonia, pleural effusion, tumors).</p> <p>NOTE: Pleural fluid sinks to lowest part of pleural space (fluids collect in posterior lobes in supine client).</p>
		
<p>FIGURE 27-23 Percussion Pattern of Posterior Thorax <small>DELMAR/CENGAGE LEARNING</small></p>	<p>FIGURE 27-24 Palpating Anterior Thoracic Expansion <small>DELMAR/CENGAGE LEARNING</small></p>

TABLE 27-15 (Continued)

ASSESSMENT AREA/TECHNIQUES	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>Auscultate posterior and lateral surfaces:</i> Place stethoscope diaphragm on right lung apex.</p> <p>Instruct client to inhale and exhale deeply and slowly when stethoscope is felt on the back.</p> <p>Repeat on left lung apex.</p> <p>Move downward every other ICS and auscultate, placing stethoscope in the same position on both sides of chest.</p> <p>Auscultate the lateral aspect by placing the stethoscope directly below the right axilla.</p> <p>Instruct client to breathe only through the mouth and to inhale and exhale slowly.</p> <p>Proceed downward, every other ICS on the same side.</p>	<p>A large chest produces decreased breath sounds.</p>	<p>Decreased breath sounds (obstruction, e.g., foreign object, emphysema, atelectasis).</p> <p>Absent breath sounds (empyema, hemothorax, pneumothorax, pneumonectomy).</p>
<p><i>Inspect anterior thorax:</i> Place client in sitting or supine position.</p> <p>Inspect for symmetry and depth of respiration, rhythm of respirations, slope of ribs, and presence of musculoskeletal deformities.</p>	<p>Scapulae at same height.</p> <p>Thorax rises and falls in unison with respiratory cycle; ribs are at a 45° angle with sternum.</p> <p>Inhalation breath sounds inaudible at a distance of more than 2–3 cm from the mouth.</p>	<p>One scapula higher than the other (scoliosis).</p> <p>Rib angle of less than 45° (emphysema, cystic fibrosis).</p> <p>Chest retraction on inspiration obstructs free inflow of air (asthma, tracheal/laryngeal obstruction, tumor).</p>
<p><i>Palpate anterior thorax:</i> Place fingerpads on right lung apex, above the clavicle. Move downward to each rib and ICS. Note tenderness, pulsation, masses, and crepitus (a grating or crackling sensation caused by two rough surfaces rubbing together). Repeat on left side.</p> <p>Assess respiratory expansion by placing thumbs along each costal margin with hands on lateral rib cage.</p> <p>Instruct client to inhale deeply. Note divergence of thumbs on expansion; feel range and symmetry of respiratory movement. Palpate for tactile fremitus (see Figure 27-25 on page 571).</p>	<p>Same as normal findings for posterior palpation.</p> <p>Note that fremitus is usually decreased or absent over the precordium (chest wall).</p>	<p>Pulsations (thoracic aortic aneurysm).</p> <p>Pain or tenderness (fractured rib).</p> <p>Unilateral decreased thoracic expansion (pneumonia, pneumothorax).</p> <p>Crepitus occurs when air escapes the lung and is trapped in subcutaneous tissue (any condition that interrupts the pleurae, e.g., pneumothorax, thoracic surgery).</p>
<p><i>Percuss anterior thorax:</i> Percuss symmetrically (see Figure 27-26 on page 571).</p> <p>Percuss 2–3 strikes along right lung apex; repeat on left lung apex. Proceed downward and percuss in every other ICS going from right to left in same position on both sides. Gently lift breast tissue as necessary.</p>	<p>Resonant sound over lung tissue (hyperresonance in children and thin adults).</p> <p>Cardiac, liver, and gastric silhouettes emit dull sound.</p> <p>Ribs emit flat sound.</p>	<p>Dullness over lung tissue (pneumonia, tumors).</p>

TABLE 27-15 (Continued)

ASSESSMENT AREA/TECHNIQUES	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
 <p>FIGURE 27-25 Palpation Pattern for Tactile Fremitus: Anterior Thorax <small>DELMAR/CENGAGE LEARNING</small></p> <p>In each thoracic area, assess for:</p> <ol style="list-style-type: none"> Resonant lung field Cardiac dullness: third to fifth ICS left of sternum Liver dullness: Place pleximeter finger parallel to upper border of expected liver dullness in right mid-clavicular line; percuss downward. Gastric air bubble: Repeat procedure performed for liver dullness on left side. 	 <p>FIGURE 27-26 Percussion Pattern for Anterior Thorax <small>DELMAR/CENGAGE LEARNING</small></p>	<p><i>Auscultate anterior thorax:</i> Instruct client to breathe through mouth. Compare symmetrical areas of the lungs while moving stethoscope downward. Listen to breath sounds. Note intensity, and identify abnormal variations. If breath sounds are diminished, ask client to breathe hard and fast with mouth open.</p>
<p>Delmar/Cengage Learning</p>	<p>A large chest wall will normally produce decreased breath sounds.</p>	<p>Absent breath sounds (empyema, hemothorax, pneumothorax, pneumonectomy).</p>

Breath sounds that are not normal are described as either abnormal or **adventitious breath sounds** (superimposed sounds on the normal vesicular, bronchovesicular, and bronchial breath sounds). Abnormal breath sounds are characterized by decreased or absent sounds. The five types of adventitious breath sounds are:

- **Crackles:** heard predominantly on inspiration over the base of the lungs as an interrupted fine crackle (dry, high-pitched crackling, popping sound of short duration) that sounds like a piece of hair being rolled between the fingers in front of the ear or a coarse crackle (moist, low-pitched crackling, gurgling sound of long duration) that

sounds like water going down the drain after the plug has been pulled on a full tub of water

- **Rhonchi:** heard predominantly on expiration over the trachea and bronchi as a continuous, low-pitched musical sound
- **Wheezes:** heard predominantly on expiration all over the lungs as a continuous sonorous wheeze (low-pitched snoring) or sibilant wheeze (high-pitched musical sound)
- **Pleural friction rub:** heard on either inspiration or expiration over the anterior lateral lungs as a continuous creaking, grating sound
- **Stridor:** heard predominantly on inspiration as a continuous crowing sound

During the assessment of the thorax and lungs, the nurse should monitor the client for symptoms of hyperventilation (light-headedness or dizziness). If this occurs, continue the assessment when the client's dizziness is gone and breathing is normal.

HEART AND VASCULAR SYSTEM

Heart and vascular system assessment techniques consist of inspection, palpation, and auscultation. The nurse should review the client's health history for cardiac risk factors such as family history, cigarette smoking, and dietary and exercise habits. Many people can reduce their risk of cardiac problems by making lifestyle alterations. Nurses are key in providing information that helps clients promote cardiovascular health and wellness; see the accompanying Client Teaching Checklist.

Heart

Inspection, palpation, and auscultation are performed in a systematic manner using specific cardiac landmarks. The cardiac landmarks (see Figure 27-27) are defined as follows:

- Aortic area is the second ICS to the right of the sternum.
- Pulmonic area is the second ICS to the left of the sternum.

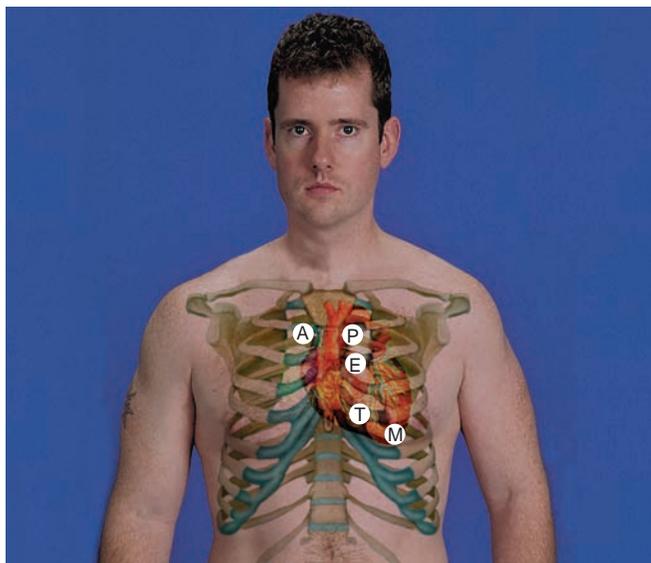

FIGURE 27-27 Cardiac Landmarks: A, aortic area; P, pulmonic area; E, Erb's point; T, tricuspid area; and M, mitral area.

DELMAR/CENGAGE LEARNING

CLIENT TEACHING CHECKLIST

Promoting Cardiovascular Health

- Determine risk as a result of family history.
- Avoid cigarette smoking and passive smoke inhalation.
- Control hypertension and hyperlipidemia through diet, exercise, and prescribed medications.
- Control glucose intolerance/diabetes through diet, exercise, and prescribed medications.
- Engage in physical activity.
- Maintain healthy body weight and body mass index.
- Engage in stress management/relaxation techniques regularly.

- Erb's point is located in the third ICS to the left of the sternum.
- Tricuspid area (right ventricular area or septal area) is the fifth ICS to the left of the sternum.
- Mitral area (left ventricular or apical area) is the fifth ICS at the left midclavicular line.

The mitral area is correlated anatomically with the apex of the heart, and the aortic and pulmonic areas are correlated anatomically with the base of the heart. Assessment proceeds either from the base of the heart to the apex or from the apex to the base.

The first heart sound (S_1) occurs with closure of the atrioventricular valves, signaling the beginning of systole. S_1 , which sounds like "lub," can be heard across the left chest but is loudest at the apex. The second heart sound (S_2) indicates the end of systole and sounds like "dub." Additional heart sounds (S_3 and S_4) may also be heard during auscultation. S_3 (also called a ventricular gallop) may be heard in the tricuspid and mitral areas during the early to mid-diastole following the S_2 sound. S_3 is heard best when the client is in the left lateral recumbent position. S_4 (also called atrial diastolic gallop) may be heard in the tricuspid and mitral areas during the late phase of diastole, before S_1 of the next cardiac cycle. S_4 is heard best when the client is in the supine position.

An S_3 can be a normal physiological sound in children and young adults; in adults it may be indicative of cardiac dysfunction (Estes, 2010). An S_4 may occur with or without any evidence of cardiac decompensation, or it can be indicative of coronary artery disease and heart failure (Estes, 2010).

There are distinct abnormal findings found on palpation and auscultation of the chest and heart. During palpation, the nurse should assess for **thrills** (vibrations that feel similar to what one feels when a hand is placed on a purring cat) and **heaves** (lifting of the cardiac area secondary to an increased workload and force of left ventricular contraction). Abnormal heart sounds relative to **stenosis** (a narrowing or constriction of a blood vessel or valve) or **regurgitation** (the backward flow of blood through a diseased heart valve, also

known as insufficiency) can be heard during auscultation as a click (a high-pitched systolic sound created by the opening of the valve) or a **murmur** (swishing or blowing sounds of long duration heard during the systolic and diastolic phases created by turbulent blood flow through a valve). Other abnormal sounds heard on auscultation are a pericardial friction rub (high-pitched, multiphasic, scratchy, or grating sound that does not change with respirations) and **bruits** (blowing sounds that are heard when the blood flow becomes turbulent as it rushes past an obstruction).

Murmurs are characterized by their:

- Location: area where the murmur is heard loudest (e.g., mitral, pulmonic).
- Radiation: transmission of sound from a specific valve to other adjacent structures (mitral murmurs can radiate to the axilla).
- Timing: phase in the cardiac cycle. If the murmur occurs simultaneously with the pulse, it is a systolic murmur. If the murmur is not related to the pulse, it is a diastolic murmur.
- Intensity: the loudness or character.

- Quality: sound produced (harsh, rumbling, blowing, or musical).
- Pitch: high, medium, or low (auscultated with the bell of a stethoscope for low-pitched murmurs and the diaphragm for high-pitched murmurs).
- Configuration: pattern that the murmur makes over time; described as crescendo (soft to loud), decrescendo (loud to soft), crescendo-decrescendo (soft to loud to soft), and plateau (sustained sound) (Estes, 2010).

See the accompanying Nursing Process Highlight on page 574 for a classification scale for murmurs. Table 27-16 presents the specific areas to be examined and the normal and key findings of assessment of the heart. Some common terms associated with cardiac assessment are:

- **Aneurysm:** localized (aortic) abnormal dilation of a blood vessel wall
- **Angina:** pain in chest, neck, or arm resulting from myocardial ischemia
- **Arteriosclerosis:** buildup of plaques in the inner layers of the walls of large to medium-sized arteries
