TABLE 27-16 (Continued)

ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>Apex of heart:</i> Note pulsation, thrill, or heave.</p> <p>Palpate high in epigastric region for pulsations, bruits, or masses.</p>	<p>Pulsations thrusting upward against the fingerpads are caused by aorta.</p> <p>No bruits or masses.</p>	<p>Bruit (aneurysm).</p> <p>A mass and strong pulsations (abdominal aortic aneurysm).</p> <p>Notify primary care provider immediately if signs of aneurysm are detected.</p>
<p><i>Auscultate heart sounds:</i> In every area auscultated, distinguish S₁ and S₂ sounds.</p>	<p>S₁: Usually auscultated at all sites; louder at apical area.</p> <p>S₂: Usually heard at all sites; louder at base of heart.</p> <p>S₃: In children and young adults.</p> <p>S₄: In many older adults.</p>	<p>Increased or decreased intensity.</p> <p>Varying intensity with different beats.</p> <p>Increased intensity at aortic area.</p> <p>Increased intensity at pulmonic area.</p> <p>S₃ in older adults.</p> <p>S₄ may be a sign of hypertension.</p>

Delmar/Cengage Learning

- Atrial fibrillation: rapid, random contractions of the atria with irregular ventricular beats
- Bundle branch block: conduction abnormality of the cardiac impulse through the bundle of His fibers
- Heart failure: circulatory congestion caused by a cardiac disorder
- Coronary artery disease: any abnormal condition that may affect the arteries of the heart
- **Ischemia**: local and temporary lack of blood supply to the heart
- **Myocardial infarction**: necrosis of the heart muscle
- Thrombophlebitis: inflammation of a vein with a formed blood clot

NURSING PROCESS HIGHLIGHT

Assessment

Classification of Murmurs

- Grade I: Barely audible
- Grade II: Audible immediately
- Grade III: Moderate intensity
- Grade IV: Loud, may be associated with a thrill
- Grade V: Loud, with palpable thrill, audible with stethoscope in contact with chest wall
- Grade VI: Louder, heard without stethoscope, palpable thrill

Vascular System

Both the central vessels (carotid arteries and jugular veins) directly affect brain functioning by transporting nutrients and waste products. The carotid arteries must be carefully assessed for patency since they are the only source of blood to the brain. During auscultation, determine the presence of a bruit; if a bruit is discovered, palpate for a thrill. Both thrills and bruits at the carotid arteries indicate turbulent blood flow, which results from obstruction of the vessels; see the Safety First display.

The jugular veins return blood from the brain to the superior vena cava and right side of the heart. By assessing the jugular veins for distention and pulsations, the nurse can assess the adequacy of function of the right side of the heart. Bilateral jugular vein distention (JVD) is usually an indicator of right-sided heart failure. See Table 27-17 on page 575 for assessment of the vascular system.

SAFETY FIRST

ASSESSING CAROTID ARTERIES

Never palpate both carotid arteries simultaneously as this may occlude blood flow to the brain. Palpate first one artery, then the other, to avoid impeding adequate circulation.

TABLE 27-17 Assessing the Vascular System

ASSESSMENT AREAS/TECHNIQUES	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>Inspection, palpation, and auscultation:</i></p> <p>Assist client to supine position with head elevated 30°–45° and drape to expose only areas being assessed.</p>		
<p><i>Carotid arteries:</i></p> <p>Inspect right carotid artery along margin of sternocleidomastoid muscle.</p> <p>Palpate carotid artery at lower half of neck (to avoid carotid sinus). Instruct client to turn head toward right side. Place fingerpads of index and middle fingers around medial edge of sternocleidomastoid muscle.</p> <p>Instruct client to hold breath.</p> <p>Auscultate carotid artery, and listen for bruits.</p> <p>Repeat on left side.</p>	<ol style="list-style-type: none"> 1. Absence of kinks or bulging. 2. Pulses are equal in rate and rhythm. 3. No bruits. 	<ol style="list-style-type: none"> 1. Kinks or bulges (hypertension, arteriosclerosis). 2. Decreased pulsations (arterial narrowing or occlusion). 3. Bruits (narrow or obstructed artery).
<p><i>Jugular veins:</i></p> <p>Inspect and palpate.</p> <p>Assist client to supine with head elevated 30°–45°. Avoid neck hyperextension or flexion.</p> <p>Inspect right internal jugular vein.</p> <p>Measure the vertical distance in centimeters from the sternal angle (angle of Louis) to top of distended neck vein to obtain an indirect jugular venous pressure.</p> <p>Repeat on left side.</p>	<p>Measurement of 1–2 cm above the angle of Louis with head of bed elevated 45°.</p>	<p>Distended jugular veins (greater than 2 cm) with client in sitting position (fluid volume overload, e.g., rapid infusion of intravenous solution).</p> <p>Increased jugular venous pressure accompanied by a third heart sound (heart failure).</p>
<p><i>Peripheral pulses:</i></p> <p>Inspect and palpate.</p> <p>Starting with temporal artery, palpate pulses in sequential pattern (upper extremities to lower extremities).</p> <p>Note rhythm, rate, quality, and volume at each pulse site.</p> <p>If unable to palpate a pulse, use an ultrasound stethoscope (Doppler) to amplify sound.</p>	<p>Bilateral equality and symmetry of peripheral pulses.</p>	<p>Markedly diminished or absent pulses indicate arterial occlusion and inadequate circulation.</p>
<p><i>Tissue perfusion:</i></p> <p>Inspect and palpate.</p> <p>Perform the Allen test to determine patency of radial and ulnar arteries (see Figure 27-28 on page 576).</p>	<p>Palms should turn pinkish color promptly when pressure is removed.</p>	<p>Persistence of pallor when one artery is manually compressed indicates occlusion of the other artery.</p> <p>Edema or ulceration (venous stasis).</p>

TABLE 27-17 (Continued)

ASSESSMENT AREAS/TECHNIQUES	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
-----------------------------	-----------------	--

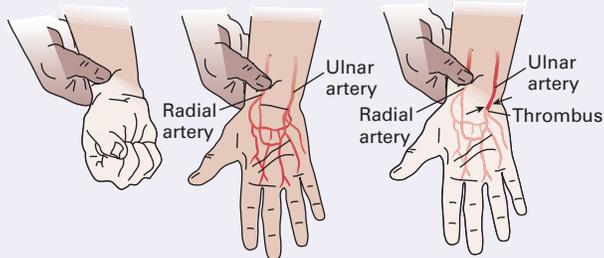

FIGURE 27-28 Allen Test: A. Pallor is initiated by compressing the radial artery with client's fist clenched. B. A patent ulnar artery reveals the return of palm perfusion despite radial artery compression. C. An occluded ulnar artery results in continued pallor of the hand while the radial artery is still compressed. DELMAR/CENGAGE LEARNING

- Firmly compress arteries and instruct client to open the hand.
- Note color of palms.
- Repeat on other hand. Inspect both legs from groin and buttocks to feet. Note venous enlargement, redness or discoloration, and ulcers over saphenous veins.

Tenderness, pain, warmth, redness, or discoloration (thrombophlebitis).

Dilated, tortuous veins are varicosities.

Data from D'Amico, D., & Barbarito, C. (2007). *Health & physical assessment in nursing*. Upper Saddle River, NJ: Pearson Prentice Hall; Estes, M. E. Z. (2010). *Health assessment and physical examination* Clifton Park, NY: Delmar/Cengage Learning (4th ed.); Jarvis, C. (2007). *Physical examination & health assessment* (5th ed.). Philadelphia: Elsevier.

To assess blood perfusion of peripheral vessels and skin, the nurse should note changes in skin temperature, color, sensation, and the pulses. Because the position of the extremities can affect the skin temperature and appearance, always assess extremities at heart level and at normal room and body temperature. Feeling the toes for warmth and color provides important information relative to peripheral circulation and tissue perfusion. Peripheral pulses should be compared bilaterally, and changes in strength and quality should be noted (Estes, 2010).

BREASTS AND AXILLAE

Inspection and palpation are used to assess breasts of both males and females. Palpation is used for assessment of the axillae and lymph nodes of all clients.

The breasts are divided into four quadrants, inclusive of the tail of Spence, by lines crossing at the nipples (see Figure 27-29

on page 577). These quadrants are used in a sequential fashion during assessment. Figure 27-30 on page 577 shows a cross section of breast tissue.

See Table 27-18 on page 577, which presents specific areas of the female breast and axillae to be examined and the normal and significant findings with possible causes. This table does not describe the physiological changes associated with pregnancy.

The technique for assessing male breasts and axillae are similar to those used in assessing females; see the accompanying Nursing Checklist on page 581. The inspected areas should be free of erythema, edema, rashes, and nodules. A firm disc at the areolar area may indicate gynecomastia (glandular enlargement of the male breast). Rashes may indicate allergies to soap or deodorant. Indicators of possible carcinoma include enlarged tender nodes and distortion of nipple and areola.

Palpation of the supraclavicular, infraclavicular, and axillary nodes is included in the assessment of the breasts. The

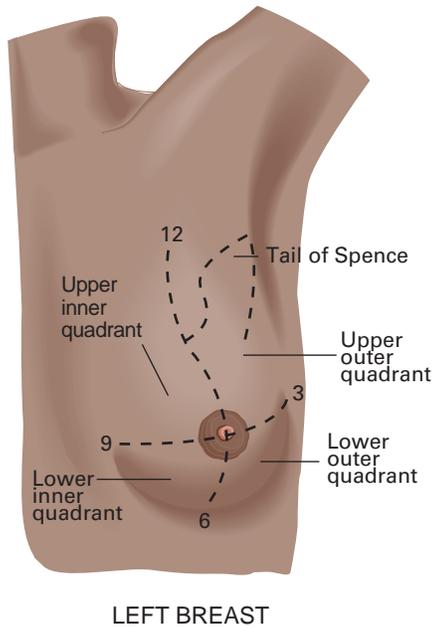

FIGURE 27-29 Quadrants of the Left Breast DELMAR/CENGAGE LEARNING

TABLE 27-18 Assessment of Breasts and Axillae, Female

AREA OF ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p>Breasts, Areolar Area, Nipples, and Axillae</p> <p><i>Inspection:</i> Assist client to sitting position on edge of exam table or bed facing you. Have client disrobe to waist. Inspect breasts for color, vascularity, thickening or edema, size, symmetry, contour, lesions, masses, or exudate. Inspect for each of the above with the client:</p> <ol style="list-style-type: none"> Raising arms on each side above the head (accentuates retraction if present). Pressing hands into hips (contracts pectoral muscles and accentuates any retraction). Leaning forward to allow breasts to hang freely away from chest. 	<p>Flesh-colored breasts. Areolar areas and nipples have darker pigmentation. Moles, nevi, and terminal hair may be present on areolar areas. Superficial vascular patterns are diffuse and symmetrical. Breast on same side as dominant arm is usually larger. Nipples should point upward and laterally or outward and downward. Supernumerary nipples (extra nipples) appear as pigmented moles along the “milk line.” Convex breast without flattening, retractions, or dimpling.</p>	<p>Reddened areas (inflammation, infection, inflammatory carcinoma). Striae, red or silvery-white streaks (rapid stretching of skin with resultant damage to elastic fibers of dermis; see Figure 27-31A on page 578). Local or unilateral superficial vascular patterns may indicate tumor formation (see Figure 27-31B). Thickening or edema of breast tissue or nipple causes enlarged skin pores, giving the appearance of orange rind (peau d’orange), which may indicate obstruction of lymphatic drainage (e.g., tumor) (Figure 27-31C). Significant differences in size or symmetry may indicate tumor (Figure 27-31D). Asymmetrical nipple direction or recent nipple inversion, flattening, or depression indicates nipple retraction (Figure 27-31E).</p>

(Continues)

TABLE 27-18 (Continued)

AREA OF ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES

FIGURE 27-31 Abnormal Breast Findings: A. Striae; B. Superficial Vascular Patterns; C. Peau d'Orange; D. Asymmetry of Breasts; E. Asymmetry of Nipples with Deviation COURTESY OF DR. S. EVA SINGLETARY, MD, UNIVERSITY OF TEXAS, M. D. ANDERSON CANCER CENTER

Thickening of a previously inverted nipple may indicate a tumor.

Unilateral reduction of breast tissue or structures (trauma, surgery).

Scaly, eczema-like nipple erosion or persistent dermatitis may indicate Paget's disease (malignant neoplasm).

Nipple discharge in nonpregnant or non-lactating woman (oral contraceptives, tranquilizers, manual stimulation, infection, or benign breast disease).

(Continues)

TABLE 27-18 (Continued)

AREA OF ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>Palpation of axillae:</i> Palpate in sequential manner. Stand in front of client. Instruct client to place arms at side. Place client's head in a flexed position (relaxes sternocleidomastoid muscle). Simultaneously palpate supraclavicular nodes (see Figure 27-32A on page 580). Place fingerpads over client's clavicles, lateral to sternocleidomastoid muscle. Proceed with a rotary motion of the palmar surfaces of index fingers. Probe deeply in scalene triangles to palpate nodes. Using rotary motion, palpate infraclavicular nodes (see Figure 27-32B).</p>	<p>Palpable lymph nodes should be less than 1 cm in diameter with no enlargement of axillary lymph nodes.</p>	<p>Fixed, firm, immobile lymph nodes greater than 1 cm in diameter (metastasis, i.e., spread of malignant cancer cells to other body parts). Enlarged, painful, or tender nodes that are matted together (systemic infection, carcinoma).</p>
<p><i>Palpate breasts:</i> Stand at right side facing client. Instruct client to place arms at side. Support the inferior aspect of the breast. Begin palpation at outer quadrant of breast. NOTE: For small-breasted clients, use dominant hand to palpate tissue against chest wall. Use both hands with pendulous breasts. Palpate in a downward, sweeping manner from outer quadrants to sternal border of each breast. Repeat with client's arms raised above the head (enhances retraction).</p>	<p>Tissue consistency or elasticity varies with age, menses, pregnancy, and breast size. Firm elasticity of young breasts and a less firm, granular feel of older breasts. Premenstrual fullness, nodules, and tenderness are common. Large breasts may have a firm transverse ridge of compressed tissue along the lower edge; not to be confused with a tumor.</p>	<p>Significant tenderness may indicate benign inflamed lactiferous duct. Hard, poorly circumscribed nodules, loss of elasticity, and bloody discharge (cancer). Breast augmentation surgery produces a feeling of being fluid-filled or firmness throughout the tissue, with inferior suture line scars.</p>
<p>Lymph Nodes: Palpate and Inspect 1. <i>Client in sitting position:</i> Note any rash, unusual pigmentation, or nodes. Instruct client to take a deep breath and relax shoulders and arms. Use left hand to adduct client's left arm close to chest wall, and place client's left forearm on your right shoulder or arm.</p>	<p>Painless palpation of one or two soft, nontender nodes less than 1 cm in diameter without enlarged lymph nodes in other regions.</p>	<p>Rashes (allergic response, e.g., soap, deodorant). Redness and inflammation (infection of sweat glands). Enlarged, painful, or tender nodes that are matted together (systemic infection, carcinoma). Fixed, firm, immobile, irregular lymph nodes greater than 1 cm in diameter (metastasis). Loss of nipple elasticity or nipple thickening (tumor).</p>

(Continues)

TABLE 27-18 (Continued)

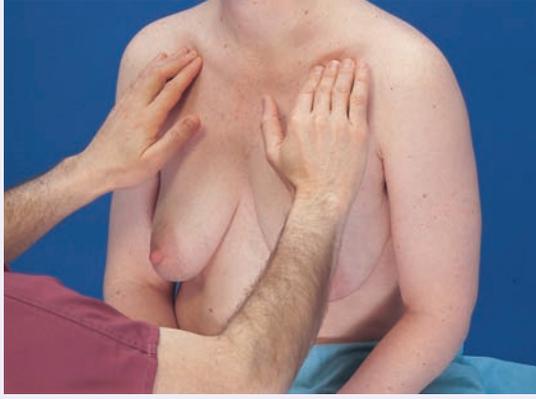

AREA OF ASSESSMENT	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p>Place fingerpads of right hand into apex of client's axilla (behind pectoral muscles), and gently roll the tissue against chest wall and axillary muscles.</p> <p>Work downward to locate and palpate the four axillary lymph node groups (see Figure 27-32C):</p> <ol style="list-style-type: none"> Posterior (subscapular) at anterior edge of latissimus dorsi muscle Central (midaxillary) at thoracic wall of axilla Anterior (pectoral) behind lateral edge of pectoralis major muscle Lateral (brachial) on inner aspect of upper aspect of humerus close to axillary vein <p>Repeat on client's right axilla.</p> <p>2. <i>Supine position:</i> Place client in supine position (spreads breast tissue thinly and evenly over chest wall).</p> <p>Stand on client's right side, and place client's left arm above head.</p> <p>With fingerpads, palpate left breast by compressing mammary tissue gently against chest wall by either (a) concentric circles that move from periphery to nipple or (b) in wedge sections from periphery to nipple.</p> <p>Proceed with palpation to include tail of Spence, periphery, and areola.</p> <p>Compress the nipple to express any discharge. If present, palpate breast along wedge radii to distinguish from which lobe the discharge originates.</p> <p>Repeat on opposite breast.</p>		<p>White, milky discharge in nonpregnant, nonlactating, woman (hormone-induced discharge from lesions or anterior pituitary, or drug-induced).</p> <p>Nonmilky discharge from nipple (benign or malignant breast disorder).</p> <div style="text-align: center;">  <p>A.</p>  <p>B.</p>  <p>C.</p> </div>

FIGURE 27-32 Palpating Lymph Nodes: A. Palpation of Supraclavicular Nodes; B. Palpation of Infraclavicular Nodes; C. Palpation of the Axillary Lymph Nodes

DELMAR/CENGAGE LEARNING

NURSING CHECKLIST

Assessing Male Breasts and Axillae

- Place client in sitting position facing you.
- Have client disrobe to the waist.
- Inspect nipple and areola, looking for nodules, edema, or ulcerations.
- Palpate the areola and note nodules.
- Inspect and palpate the axillae for presence of rash, erythema, and nodes.
- Repeat on other side.

pattern of lymph drainage is illustrated in Figure 27-33. Note that not all the lymphatics drain into the axilla; therefore, depending on the location of a malignant lesion, the spread of cancer cells may occur directly to the infraclavicular nodes, deep into the chest or abdomen, or to the opposite breast.

The American Cancer Society (ACS, 2009) reports that breast cancer is the second-leading cause of cancer death of American women. The chance that breast cancer will be the cause of a woman's death is about 1 in 35 (about 3%). The rate of deaths from breast cancer continues to decline, primarily as a result of early screening and treatment (ACS, 2009).

FIGURE 27-33 Lymph Drainage Patterns: Left Breast

DELMAR/CENGAGE LEARNING

Breast Self-Examination

Long-term survival rates for breast cancer have a direct correlation to early detection of the disease. Nurses play a major role in women's health by teaching breast self-examination (BSE) and by supporting women in achieving healthier lifestyles believed to decrease the risk factors of breast cancer (Estes, 2010).

The nurse should use the time during the assessment to educate the client about BSE and encourage the client to ask questions. See the Client Teaching Checklist for Breast Self-Examination.

ABDOMEN

Physical examination of the abdomen provides essential data relative to the various functions of the gastrointestinal and genitourinary systems and the abdominal aorta. The sequence of abdominal assessment is inspection, auscultation, percussion, and palpation. Auscultation is performed as the second step because palpation and percussion may alter the frequency of bowel sounds. The abdominal landmarks used for assessment are presented in Figure 27-35 on page 582.

CLIENT TEACHING CHECKLIST

Breast Self-Examination

1. Lie down and place your right arm behind your head. Slightly elevate your shoulders.
2. Use the fingerpads of the three middle fingers on your left hand to feel for lumps in the right breast, making overlapping, dime-sized circular motions of the fingerpads to feel the breast tissue; see Figure 27-34A on page 582.
3. Apply three different levels of pressure to feel all the breast tissue: light pressure to feel tissue closest the skin, medium pressure to feel deeper tissue, and firm pressure to feel tissue closest to the chest and ribs. A firm ridge in the lower curve of each breast is normal.
4. Move your hand in an up-and-down pattern from the underarm to the sternum or a vertical pattern from the clavicle to the ribs, checking the entire breast area.
5. Repeat the exam on your left breast, using the fingerpads of the right hand.
6. Stand in front of the mirror with your hands pressing firmly down on your hips (contracts the chest wall muscles and enhances any breast changes), and look at your breasts for any changes in size, shape, contour, or dimpling; see Figure 27-34B.
7. While sitting or standing and with your arm slightly raised, examine each underarm. (Raising your arm up straight tightens the tissue in this area and makes it difficult to examine.)

A.

B.

FIGURE 27-34 Breast Self-Examination: A. Lying Down: Palpating Breast; B. Before Mirror: Hands Pressed into Hips DELMAR/CENGAGE LEARNING

During inspection, note the presence of abdominal distention, for which there are many causes. A mnemonic device for remembering the possible causes of abdominal distention is shown in the accompanying Nursing Process Highlight.

Auscultate the four quadrants, as shown in Figure 27-36, when assessing bowel sounds and listening for vascular bruits. Assessment should always begin in the right lower quadrant (RLQ). Table 27-19 on page 583 presents the specific areas of the abdomen to be examined and the normal and key findings of this assessment.

The nurse should percuss all four quadrants in the same systematic fashion. During percussion of the abdomen, note when **tympany** (a musical drumlike sound that occurs over air-filled cavities) changes to **dullness** (a muffled thudlike sound that occurs over dense tissue). Tympany usually occurs over the stomach, which is filled with gas; dullness is heard over thicker organs, such as the liver.

Light palpation of the abdomen is done in all four quadrants, beginning in the RLQ, for resistance, tenderness, and

NURSING PROCESS HIGHLIGHT

Assessment

The Seven Fs of Abdominal Distention: Etiological Factors

- Fat
- Fluid (**ascites**, excessive fluid accumulation in abdominal cavity)
- Flatus
- Feces
- Fetus
- Fatal growth (malignancy)
- Fibroid tumor

TABLE 27-19 (Continued)

ASSESSMENT AREA/TECHNIQUES	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
 <p>FIGURE 27-37 Directional Pattern of Abdominal Percussion <small>DELMAR/CENGAGE LEARNING</small></p> <p><i>Palpation:</i> Perform light palpation. Never palpate over areas where bruits are auscultated. Instruct client to cough. If client experiences pain in a quadrant, palpate that area last. Depress abdominal wall 2 cm in each quadrant. Note texture and consistency of underlying tissue.</p> <p><small>Delmar/Cengage Learning</small></p>	Smooth texture with consistent softness.	Tenderness, accompanied by warm skin (inflammation). Large masses (feces, tumors).

rebound tenderness. Deep palpation is not addressed because this assessment technique usually requires supervision during the learning process. Detection of abdominal organs (gallbladder, liver, spleen, fecal-filled colon, flatus-filled cecum) by palpation is an abnormal finding and, thus, should be reported.

MUSCULOSKELETAL SYSTEM

The musculoskeletal system provides clients with the ability to maintain and change their positions in response to both internal and external stimuli. Muscle tone and bone strength allow the client to maintain an erect position. The musculoskeletal system consists of bones, joints, skeletal muscles, and supportive connective tissue (see Figure 27-38 on page 585).

Inspection, palpation, range of motion (ROM), and muscle testing are performed on the major skeletal muscles and joints. Table 27-20 on page 587 presents the specific

areas of the musculoskeletal system to be examined and the normal and key findings of this assessment.

Assessment may reveal several findings indicative of musculoskeletal dysfunction. The following are some of these findings:

- Pain and limited ROM in the vertebrae may be caused by herniation of vertebral discs, arthritis, or degenerative joint disease.
- Hard, painless nodules on the dorsolateral aspects of the interphalangeal joints (Heberden's nodes) indicate osteoarthritis.
- Flexion contracture of the little, ring, and middle fingers (Dupuytren's contracture) is associated with arthritis.
- Bilateral swelling of the wrists occurs with rheumatoid arthritis. A painful, asymmetrical elbow with a misaligned forearm occurs with subluxation (dislocation) of the elbow. Localized tenderness and pain with impaired ROM of the elbow indicate epicondylitis, resulting from repetitive motion of the joint.

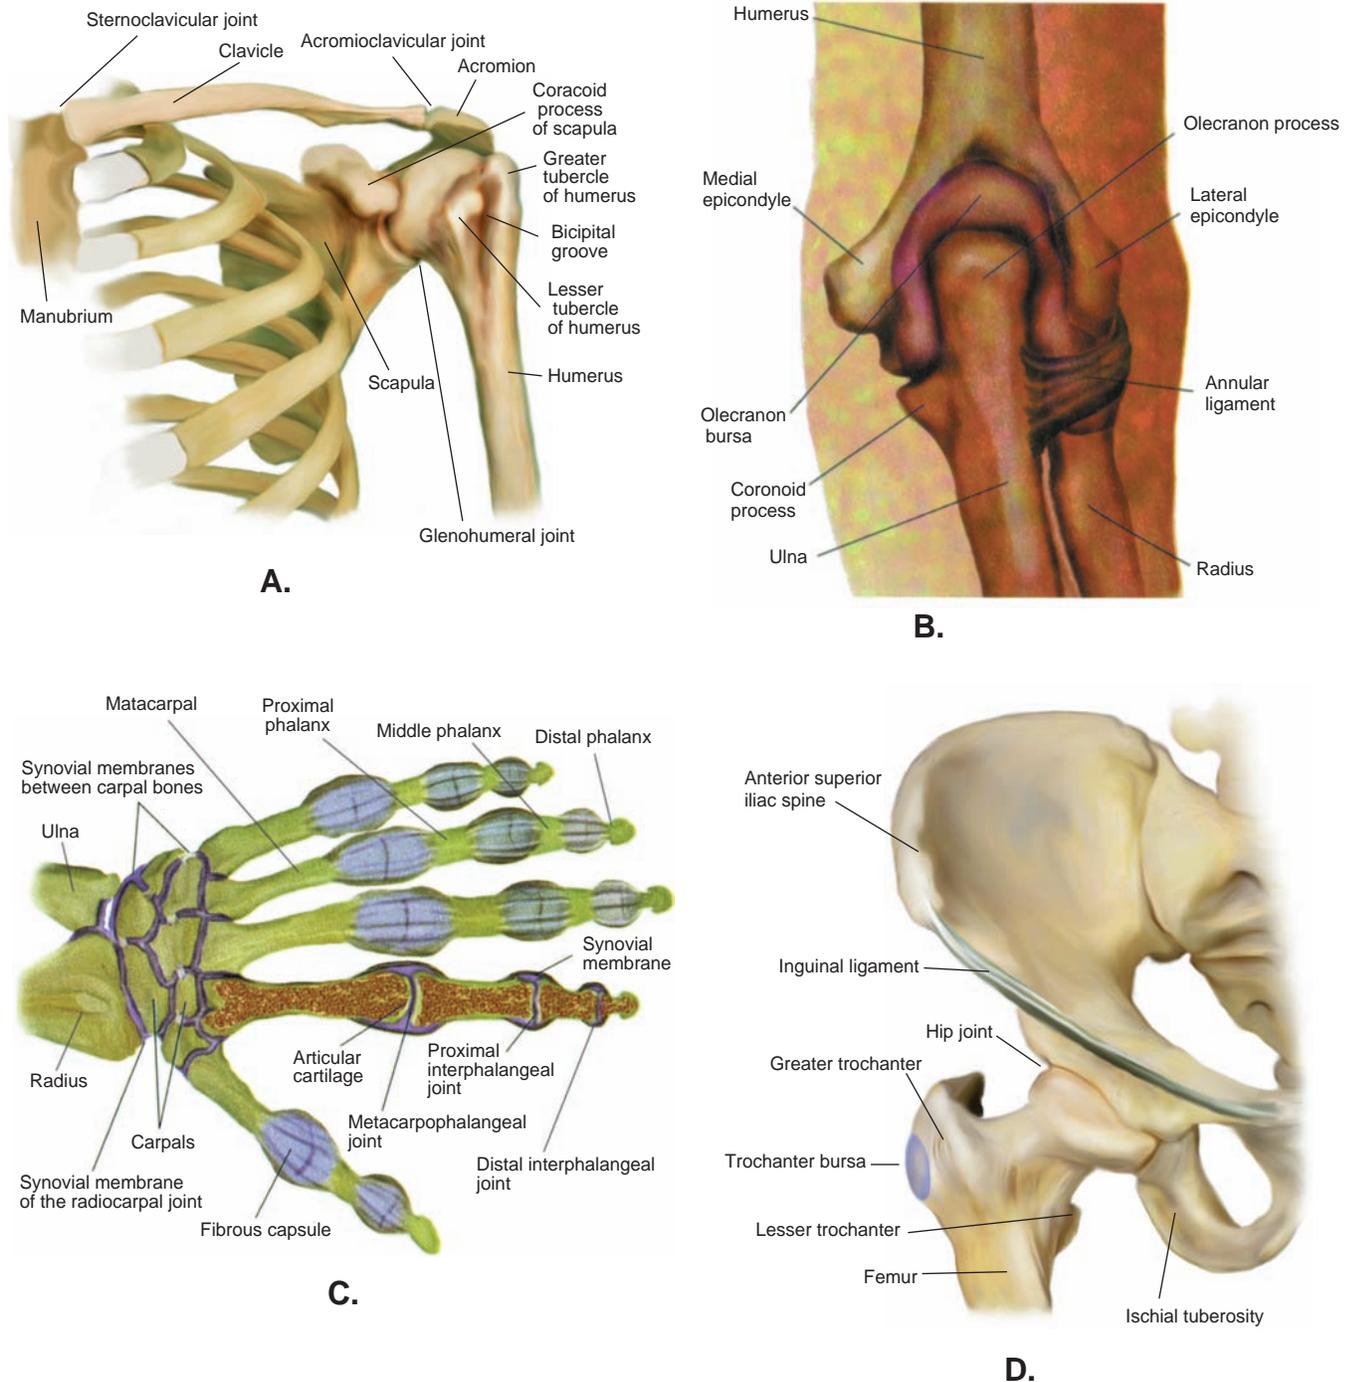

FIGURE 27-38 Musculoskeletal System: A. Shoulder; B. Elbow; C. Wrist and Hand; D. Hip; E. Leg; F. Knee; G. Ankle and Foot
 DELMAR/CENGAGE LEARNING

- Pain, swelling, and redness of the first metatarsophalangeal joint usually indicate gouty arthritis.

A complete musculoskeletal examination requires the full assessment of ROM. A **goniometer** is a protractor with two movable arms (see Figure 27-39 on page 587) used to measure the angle of a skeletal joint during ROM.

Skeletal muscles provide contour for the body and promote joint mobility. Muscle contour is affected by the exercise and activity patterns of the client. **Hypertrophy** refers

to an increase in muscle size and shape due to an increase in muscle fiber. **Atrophy** refers to thin, flabby muscles due to a reduction in muscle size and shape. Increased muscle tone (**hypertonicity**) causes resistance with joint movement. **Hypotonicity** refers to a flabby muscle with poor tone.

Joints are normally nontender and move freely. **Arthritis** is an inflammation of the joints that causes pain and swelling. Degenerative joint disease or **osteoarthritis** (the most common type of degenerative arthritis, in which the joints

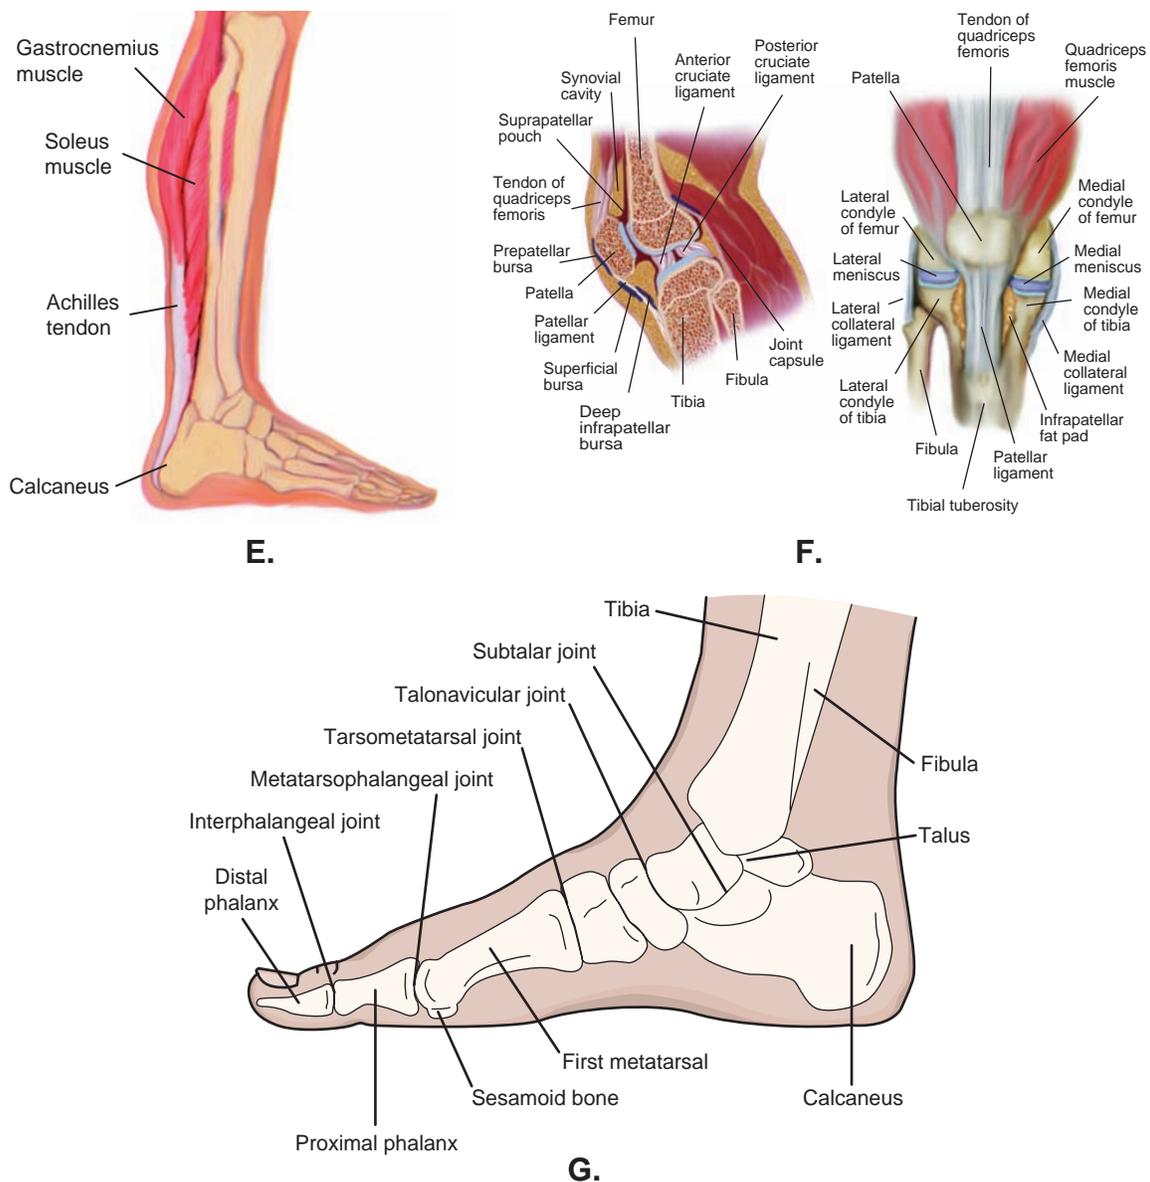

FIGURE 27-38 (Continued)

become stiff and tender to touch) causes the joints to undergo degenerative changes. ROM and activities of daily living are compromised by the loss of joint mobility. Crepitus is often palpated in joints affected by degenerative joint disease. See Chapter 36 for information on nursing care of clients with mobility problems.

NEUROLOGICAL SYSTEM

A complete neurological examination includes an assessment of mental status, sensation, cranial nerves, motor functioning, cerebellar function, and reflexes. See Chapter 38 for a complete discussion of cranial nerve function. Clients with minor or intermittent neurological symptoms may require only a screening assessment; see Table 27-21 on page 588.

Mental Status

The mental status assessment should be done during the interview and health history. A complete assessment should

be performed if the client exhibits any signs of neurological deficit, such as:

- Known brain lesion (stroke, tumors, trauma)
- Suspected brain lesion (new seizures, headaches, behavioral changes)
- Memory deficits
- Confusion
- Vague behavioral complaints (by significant others if client unaware of or denies behavioral changes)
- Aphasia
- Irritability
- Emotional lability
- Change in level of consciousness

PHYSICAL APPEARANCE AND BEHAVIOR Pertinent information relative to mental status is assessed by observing the client's posture and movements, dress and grooming, and facial expressions. The nurse should note the client's gait and posture to determine whether it is relaxed, slumped, or rigid.

TABLE 27-20 Assessment of Musculoskeletal System

ASSESSMENT AREA/TECHNIQUE	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>Muscles—Inspection and palpation:</i></p> <ol style="list-style-type: none"> 1. Compare muscles on one side of body to corresponding muscles on opposite side. Inspect for size, using a tape measure for accuracy. 2. Inspect muscles for tremors and shortening (i.e., contractures). 3. To assess muscle tone, palpate muscles at rest. 4. Test muscle strength on both sides of body. 	<ol style="list-style-type: none"> 1. Equal on both sides of body. 2. Absence of contractures and tremors. 3. Firm muscles. 4. Strength equal on both sides. 	<ol style="list-style-type: none"> 1. Asymmetry, atrophy, or hypertrophy. 2. Misalignment of body part (e.g., foot drop occurs with plantar flexion). 3. Lack of muscle tone. 4. Spasticity or flaccidity.
<p><i>Bones—Inspection and palpation:</i></p> <ol style="list-style-type: none"> 1. Inspect skeleton for alignment and structure. 2. Palpate bones for tenderness and edema. 	<ol style="list-style-type: none"> 1. Skeletal alignment with intact bones. 2. <p><i>Joints—Inspection and palpation:</i> Inspect and palpate for size, tenderness, swelling, crepitus, nodules, or masses. Assess ROM in each joint.</p>	<p>No swelling, tenderness, nodules, or masses.</p> <p>Absence of crepitation.</p> <p>Joints move smoothly.</p> <p>ROM will vary according to individual's usual degree of physical activity.</p>	<p>Tenderness, crepitus, and limited ROM (arthritis, bursitis, bone misalignment).</p>

Delmar/Cengage Learning

FIGURE 27-39 Use of Goniometer to Measure Joint ROM
DELMAR/CENGAGE LEARNING

The client should appear relaxed but with the appropriate amount of concern regarding the assessment. The client should exhibit an erect posture, smooth gait, and symmetrical body movements.

Dress and grooming are influenced by the client's economic status, age, home situation, and cultural background. Information obtained from the health history assists the nurse in determining appropriate dress and grooming for each client. It is also helpful to ask clients directly about their grooming and hygiene routines.

Facial expressions should be symmetric and appropriate to the content of the conversation. Facial expressions may demonstrate anxiety or depression. The nurse should observe the client's verbal and nonverbal behaviors and note if the client's affect appears labile, blunted, or flat. Affect refers to the emotional feeling tone that is reflected by one's facial expression.

COMMUNICATION Client communication should be assessed throughout the entire interview, health history, and physical examination. The client should be able to produce spontaneous, coherent speech with an effortless flow and normal inflections, volume, pitch, articulation, rate, and rhythm. The message

TABLE 27-21 Neurological Screening Assessment

AREA OF ASSESSMENT	ASSESSMENT PARAMETER	OUTCOME FINDINGS
Mental status/level of consciousness	Note general appearance, affect, speech content, memory, logic, judgment, and speech patterns during the health history. Perform the Glasgow Coma Scale (GCS) with motor assessment component and pupil assessment.	If any abnormalities are evident, perform a full mental status assessment. If the GCS < 15, perform a full assessment of mental status. If motor assessment is abnormal or asymmetrical, perform a complete motor and sensory assessment.
Sensation	Assess pain and vibration in the hands and feet with light touch on the limbs.	If deficits are identified, perform a complete sensory assessment.
Cranial nerves (CNs)	Assess CN II, III, IV, VI: visual acuity, gross fields, fundoscopic, pupillary reactions, and extraocular movements. Assess CN VII, IX, X, XII: facial expression, gross hearing, voice, and tongue.	If any abnormalities exist, perform complete assessment of all 12 CNs.
Motor system	Assess muscle tone and strength, abnormal movements, and grasps.	If deficits are noted, perform a complete musculoskeletal assessment.
Cerebellar function	Observe the client's gait and ability to walk heel to toe and to perform shallow knee bends. Perform Romberg's test: Ask the client to stand erect, feet together and arms at side, first with eyes open, then closed. The nurse should stand close to the client to catch the client in the event of a fall. Note the client's ability to maintain balance with eyes open and closed for 20 seconds with minimum swaying.	If any deficits exist, perform a complete cerebellar assessment.
Reflexes	Assess the muscle stretch reflexes and the plantar response.	If an abnormal response is elicited, perform a complete reflex examination.

Delmar/Cengage Learning

should make sense. Comprehension of language should be intact, and the client's ability to read and write should be commensurate with educational level.

Aphasia is an impairment of language functioning that results from injury to the cortex. Aphasia is classified as sensory (receptive), motor (expressive), or global (mixed sensory and motor). In receptive aphasia, auditory comprehension is impaired as well as the content of speech. The client is unaware of the deficits, and his or her ability to name people and objects is severely impaired. With expressive aphasia, speech is slow, repetitive, and hesitant. The client has difficulty selecting and organizing words, and writing is impaired. Oral and written comprehension are severely impaired with global aphasia.

LEVEL OF CONSCIOUSNESS Consciousness is the level of awareness of the self and the environment. Conscious behavior requires arousal (or wakefulness) and awareness (or cognition and affect). Awareness is a higher-level function of the cerebral cortex that includes judgment and thinking, which are usually assessed as part of the cognitive assessment.

The **Glasgow Coma Scale** (GCS) is an international scale used in grading neurological responses to determine the client's level of consciousness; see Chapter 38 for a detailed discussion.

Cognitive Abilities and Mentation

Assessment of cognitive function includes testing for attention, memory, judgment, insight, spatial perception, calculation, abstraction, thought process, and thought content. See Chapter 38 for a complete discussion about assessment of these abilities.

Sensation

Sensation should be tested early in the neurological assessment because of the detail involved and the need for client cooperation. If the client becomes fatigued, the findings may be unreliable. The assessment is divided into three sections:

- **Exteroceptive sensations:** superficial sensations that originate in the sensory receptors in the skin and mucous membranes (light touch, pain, heat, and cold)

- Proprioceptive sensations: deep sensations that originate in the sensory receptors in the muscles, joints, tendons, and ligaments (motion, position, and vibration sense)
- Cortical sensations: sensations that compose cerebral integration and discrimination abilities

Some examples of impaired cortical sensations are **stereognosis** (ability to identify objects by manipulation and touch), **graphesthesia** (ability to identify numbers, letters, or shapes drawn on the skin), and **extinction** (ability to discriminate the points of distance when two body parts are simultaneously touched).

The sensory **dermatome map** (cutaneous area whose sensory receptors and axons feed into a single dorsal root of the spinal cord) is used to assess the major sensory nerves (see Figure 27-40). The map of dermatomes is helpful in identifying the areas of pain and altered sensation. Although several dorsal roots may receive input from a single dermatome, the map is helpful in identifying where a neurological lesion may exist. For example, pain localized in the posterior area of the neck would suggest a possible lesion in the third cervical spinal cord segment.

The neurological assessment is performed with the client's eyes closed so that the client's ability to perceive the stimulus can be determined. The nurse should observe the client's reactions by watching for facial grimacing or with-

drawal of the stimulated extremity. Compare the client's sensation on the corresponding areas bilaterally. The nurse should note the proximal to distal sensory differences on all four extremities, evaluate whether any sensory deficits follow a dermatome distribution, and map the borders of any area exhibiting changes in sensation.

Cranial Nerves

A complete assessment of the 12 cranial nerves is necessary for a baseline assessment, if a tumor of a specific cranial nerve is suspected, or when periodic assessment is required after surgery or radiation treatments. An abbreviated cranial nerve assessment is an integral part of a neurological screening. Pupil assessment (cranial nerve III, oculomotor) is included in the screening assessment and is tested with the trochlear and abducens (cranial nerves IV and VI) because all three cranial nerves supply the muscles of the eye.

Motor Function

Assessment of the motor system involves testing for muscle size, tone, and strength under voluntary movements. Cerebellar assessment can be done either with motor testing or separately as follows.

Cerebellar Function

Assessment of cerebellar function includes observation of coordination, balance, and gait. Cerebellar muscular activity requires the motor coordination of various muscle groups to execute smooth, precise, and harmonious movements. Coordination is an integrated process that involves complicated neural integration of the motor and premotor cortex, basal ganglia, cerebellum, vestibular system, posterior columns, and peripheral nerves.

COORDINATION Equilibratory coordination is concerned with maintenance of an upright stance and depends on the vestibular, cerebellar, and proprioceptive systems. Nonequilibratory coordination is concerned with smaller movements of the extremities and involves the cerebellar and proprioceptive mechanisms.

To test coordination, the nurse should position the client comfortably with eyes open. Clients who wear glasses should be wearing their glasses before coordination is assessed. Instruct the client to first touch the index finger to the nose, then to alternate rapidly with the index finger of the opposite hand. Ask the client to close the eyes and continue to rapidly touch the nose with alternate index fingers. Tell the client to open the eyes, touch the finger to the nose, and touch the nurse's index finger, which is held about 18 inches away from the client. The test is repeated with the client using the opposite hand. Throughout testing, the nurse should observe for intention tremor or over- or undershooting of the client's finger.

To assess rapid alternate movements of the upper extremities, ask the client to alternately pat the knees with rapid supinating and pronating of the hands. Test the lower extremities for rapid alternating movement by asking the

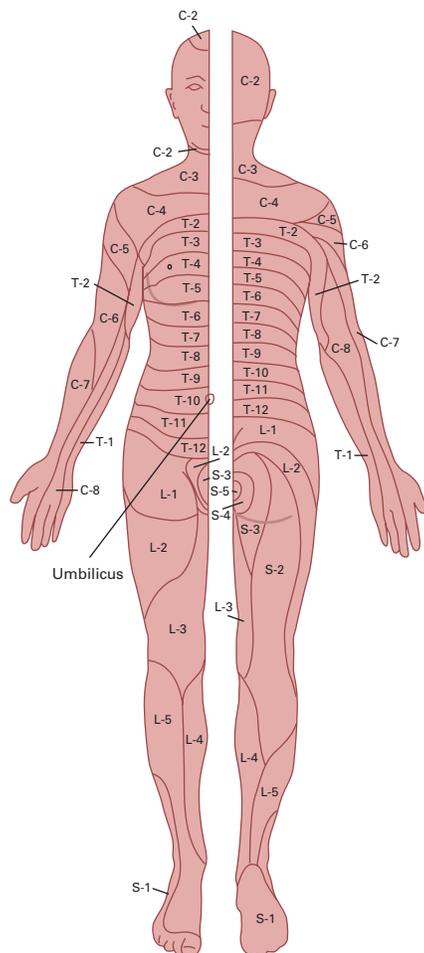

FIGURE 27-40 Dermatome Map DELMAR/CENGAGE LEARNING

client to rapidly extend the ankle (“tap your foot”) and to place the heel just below the knee on the shin of the opposite leg and slide it down to the foot.

The client should be able to rapidly alternate touching finger to nose and moving finger from nose to the nurse’s finger in a coordinated fashion. Also, the client should be able to perform alternating movements in a purposeful, rapid, coordinated manner. The client should demonstrate the ability to purposefully and smoothly run the heel down the shin.

BALANCE AND GAIT The performance of Romberg’s test is previously described in Table 27-21. A positive Romberg sign exists if the client becomes unsteady and tends to fall when the eyes are closed.

Assessment of gait begins when the client enters the room and continues throughout the examination. The nurse must consider the client’s age, activity level, and degree of alertness. The tandem walk is tested by having the client walk in a straight line touching the ground heel to toe. The arms should be held at the side, and the eyes should be open. Note the client’s posture and ability to maintain balance. Posture should be upright with a narrow base and the gait smooth with arms swinging opposite the movement of the legs. Heel-to-toe walk should be in a straight line without losing balance.

Reflexes

A reflex action is a specific, involuntary response to an adequate stimulus. The stimulus can occur in a joint, a muscle, or the skin and is transmitted through the sensory and motor pathways of the reflex arc and specific spinal cord segments. To elicit a muscle stretch reflex, the nurse should briskly tap the client’s tendon with a reflex hammer.

Normal reflexes are classified into two main categories: muscle stretch (deep tendon) reflexes (DTR) and superficial (cutaneous) reflexes. During reflex testing, clients should be relaxed and positioned so that their extremities are symmetrical. The nurse should hold the reflex hammer loosely between the thumb and index finger and strike the tendon with a brisk motion from the wrist. The reflex hammer should make contact with the correct point on the tendon in a quick, direct manner.

Table 27-22 on pages 591–592 discusses the assessment of common DTRs: biceps, triceps, brachioradialis, patellar, Achilles, and plantar (Babinski). When testing the reflexes, the nurse should observe the degree and speed of response of the muscle after the reflex hammer makes contact. The reflex responses between the right and left sides should be compared. The normal response to taps in the correct area should elicit a brisk (++ or +++) contraction of the muscles involved; see the accompanying Nursing Process Highlight.

REPRODUCTIVE SYSTEM

Assessment of the genitalia may produce feelings of fear, anxiety, indignity, and loss of control in some clients. These feelings may be reduced by the sensitivity of the nurse before,

NURSING PROCESS HIGHLIGHT

Assessment

Reflex Grading Scale

Scale	Response
0	Absent
+	Present but diminished
++	Normal
+++	Mildly increased but not pathologic
++++	Markedly hyperactive; clonus may be present

during, and after the assessment. The nurse must respect the client’s wishes regarding privacy and take into consideration cultural issues concerning this aspect of health assessment. For example, many Middle Eastern women will remain veiled during an assessment. By using techniques to diminish client discomfort and by empowering the client through education and participation in the assessment process, nurses offer a path for clients in the management of their own health care; see the accompanying Spotlight On display. Many states require that a male nurse be accompanied by a female nurse or assistant during a gynecologic examination.

See Chapter 19 for discussion of physiological changes of aging that affect sexuality in both men and women.

FEMALE GENITALIA

Assessment of the female genitalia uses the techniques of inspection and palpation. Table 27-23 on page 593 presents specific areas of the female external genitalia to be examined and the normal and key findings of this assessment. Speculum

SPOTLIGHT ON...

Caring

Physical Examination of the Female Genitalia

- Encourage client to verbalize any concerns about the examination.
- Be nonjudgmental while listening to the client.
- Inform client that the examination should not be painful, even though it may be uncomfortable at times.
- Assure client that privacy will be maintained during the examination.
- Provide explanation of interventions prior to performing them.
- Ask client if she has any questions before, during, and after the examination.

assessment of the internal genitalia is not discussed because this function is usually within the scope of advanced practice registered nurses or other registered nurses prepared in expanded roles.

In preparation for the examination, place the client in the lithotomy position with knees flexed perpendicular to bed. Instruct client to relax thighs in order to allow each leg

to abduct to the sides. Elevate the client's head for comfort, and drape to expose only the area being examined. Wash hands and don gloves prior to examining the genitalia.

There are many types of abnormal lesions that affect the female genitalia; some of the more common ones are:

- **Chancere:** A reddish, round ulcer with a depressed center and raised edges that appears during the primary phase of

TABLE 27-22 Assessment of Common Deep Tendon Reflexes

TYPE	ASSESSMENT	NORMAL REFLEX
<p>Biceps</p> 	<p>Flex client's arm between 45° and 90°. Place your thumb firmly on the biceps tendon just above the crease of antecubital fossa and tap thumb with reflex hammer.</p>	<p>Flexion of arm at elbow</p>
<p>Triceps</p> 	<p>Flex client's arm between 45° and 90°. Tap triceps tendon just above elbow.</p>	<p>Extension of elbow</p>
<p>Brachioradialis</p> 	<p>Flex client's arm 45° and place in lap with the arm in semipronation. Tap brachioradialis tendon on thumb side of wrist.</p>	<p>Flexion of forearm</p>

TABLE 27-22 (Continued)

TYPE	ASSESSMENT	NORMAL REFLEX
------	------------	---------------

Patellar

Ask client to sit in a chair or on edge of bed with legs hanging freely or in a supine position with knee flexed. Tap patellar tendon just below the patella.

Extension of leg below the knee

Achilles

Ask client to sit with feet dangling and partially dorsiflexed or in a supine position with leg flexed at knee and thigh externally rotated. Tap the Achilles tendon just above heel.

Plantar flexion of foot

Plantar (Babinski)

Position the client's ankle firmly against the bed and slowly stroke client's sole with the handle of the reflex hammer.

Bending of the toes downward

Delmar/Cengage Learning

- syphilis at the site where the treponema enters the body. It lasts for 4 weeks, then disappears.
- Condyloma acuminatum: White, dry, painless growth (wart) that has a narrow base that is caused by the human papillomavirus.

- Condylomata lata: Raised, round, wartlike plaque with a moist surface covered by a gray exudate that appears during the secondary stage of syphilis.
- Herpes simplex: Small, red vesicles that fuse together to form a large ulcer that may be painful and itchy.

TABLE 27-23 Assessment of Female Genitalia

ASSESSMENT AREA/ TECHNIQUE	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p>Inspection</p> <p>Look for distribution, amount, and characteristics of pubic hair.</p> <p>Inspect skin for color, edema, and lesions.</p> <p>Separate labia majora and labia minora for a thorough inspection.</p>	<p>Even hair distribution.</p> <p>Clear skin except for nevi.</p> <p>Labia majora and minora are symmetrical, with a smooth to wrinkled surface that is intact.</p> <p>Skin of vulva is slightly darker than surrounding areas.</p> <p>No nodules, ecchymosis, edema, lesions, or rashes.</p> <p>Sebaceous cysts (nontender, yellow-colored nodules smaller than 1 cm) may be present.</p>	<p>Scant pubic hair (hormonal changes).</p> <p>Ecchymosis over mons pubis or labia (trauma, e.g., accidental injury, intentional abuse).</p> <p>Rash over mons pubis or labia (dermatitis, parasitic infestation).</p> <p>Labial edema (hematoma, Bartholin’s cyst, or obstruction of lymphatic system).</p> <p>Painless mass with pruritus or a cauliflower-like growth (malignancy).</p> <p>Varicose veins (pregnancy, prolonged standing, or congenital disposition).</p>
<p>Inspect clitoris, urethral meatus, and vaginal introitus when separating labia minora.</p>	<p>Free from lesions.</p> <p>Clitoris is less than 1 cm in width and less than 2 cm in length.</p> <p>Urethral meatus appears as a small slit and is same color of surrounding tissue.</p> <p>Absence of discharge, redness, and edema.</p> <p>Introitus mucosa is pink and moist with a clear to white discharge.</p> <p>Free of odor and bulging.</p>	<p>Clitoral hypertrophy (androgen excess).</p> <p>Foul-smelling discharge of any color (urinary tract infection, vaginitis, or cervicitis).</p> <p>Redness or edema around the urethra meatus (infection of Skene’s glands, urethral carcinoma, prolapse of urethral mucosa).</p> <p>Pale color and dryness occur with atrophy (topical steroids, aging).</p> <p>External tear of vaginal introitus (trauma).</p> <p>Bulging of anterior vaginal wall may indicate a cystocele (protrusion of urinary bladder through the wall of the vagina) due to weak ligaments.</p>

Delmar/Cengage Learning

MALE GENITALIA

Assessment of the male genitalia includes the essential organs (testes and gonads), the accessory organs (seminal vesicles and bulbourethral glands), several ducts (epididymis, ductus [vas] deferens, ejaculatory), and the urethra. The supporting structures include the scrotum, penis, and spermatic cord. Table 27-24 on page 594 presents the specific areas of the male genitalia to be examined and the normal and key findings of this assessment.

In preparation for the examination, place the client in the supine position with legs slightly spread apart. If the client is unable to tolerate the supine position, the standing position also allows for a thorough examination of the genitalia. Wash hands and don gloves prior to the examination. It is important to be sensitive to the client’s feelings during the

examination; see the accompanying Respecting Our Differences display and Table 27-24.

RESPECTING OUR DIFFERENCES

Before beginning the examination, consider the client’s cultural background. What are his beliefs, attitudes, and feelings about the examination? Does the client’s culture prohibit a female nurse from examining a male client? Are there cultural prohibitions on a male nurse examining a male client?

TABLE 27-24 Assessment of Male Genitalia

ASSESSMENT AREA/TECHNIQUE	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
<p><i>Pubic hair:</i> Look for distribution, amount, and characteristics.</p>	Triangular distribution, often spreading up the abdomen.	Scant amount or absence of hair (hormonal problems).
<p><i>Penis:</i> Inspect the anterior and posterior surfaces by lifting the penis. Retract foreskin on uncircumcised clients. Note lesions, edema, and inflammation. Palpate the penile shaft. Note pulsations, tenderness, swelling, masses, or plaques. Inspect the urethral meatus. Note location, color, and presence of discharge.</p>	<p>Foreskin retracts easily. Glans penis varies in size and shape. A small amount of smegma (oily, pasty material consisting of desquamated epidermal cells and sebum). Pulsations are present on dorsal sides of penis. Meatus is centrally located on tip of penis and pink.</p>	<p>Phimosis (inability of foreskin to be retracted over glans penis) may develop in uncircumcised males. Paraphimosis occurs when retracted foreskin causes proximal constriction to glans; penis distal to foreskin becomes edematous and gangrenous. Priapism is a continuous penile erection. Absent pulsations indicate vascular insufficiency. Varied placement of meatus may result from congenital defects, epispadias (meatus opens on dorsal side of penis), and hypospadias (meatus opens on underside of penis).</p>
<p><i>Scrotum:</i> Gently move penis to one side to assess scrotal skin. Lift up posterior side. Note lesions, inflammation, and edema. Begin scrotal palpation at right testicle. Proceed to the epididymis, then to the spermatic cord and the external ring. Note consistency and presence of tenderness or masses.</p>	<p>Scrotal skin is thin and wrinkled. Scrotal skin hugs testicles firmly in young males; becomes elongated and flaccid in older adults. Left scrotal sac is lower than the right. Testicles are sensitive to pressure and are firm, ovoid, smooth, and equal in size bilaterally.</p>	<p>Unilateral edema with a hard, fixed nodule (malignancy). Enlarged testicle with extreme sensitivity (testicular torsion, i.e., “twisting”). Swollen, indurated, tender (inflammation, i.e., epididymis). Warm scrotal skin, tenderness, and acute onset of edema indicate orchitis, i.e., testicular inflammation (associated with the mumps).</p>
<p><i>Inguinal area:</i> Have client stand, if possible. Inspect first while client is at rest, then instruct client to bear down. Observe for bulges. Begin palpation on client’s right side. Invaginate (telescope) loose scrotal skin with index finger. Follow spermatic cord upward to opening of external inguinal ring. Ask client to cough or bear down to check for mass or bulging. Bearing down may make hernia visible.</p>	<p>Inguinal area is smooth and free from edema or bulges.</p>	<p>Swelling above the inguinal ligament may indicate presence of inguinal hernia (protrusion of portion of the bowel through the external inguinal ring). A mass medial to the femoral vessels and inferior to the inguinal ligament indicates a femoral hernia (protrusion of portion of the bowel or omentum through the femoral wall).</p>

Delmar/Cengage Learning

Common abnormal lesions of the external male genitalia are:

- **Candidiasis:** Multiple, discrete, flat pustules with scaling and surrounding edema that are superficial mycotic infections of moist cutaneous sites associated with diabetes mellitus, deficiencies in systemic immunity, and antibiotic therapy
- **Chancroid:** Tender, ulcerated, exudative, papular lesion with an erythematous halo surrounding edema and a friable base that results from small breaks in epidermal tissue and inoculation of *Haemophilus ducreyi*
- **Tinea cruris:** Erythematous plaques with scaling, papular lesions with sharp margins caused by fungal infections of the groin

Chancre, condyloma acuminatum, and herpes simplex are also common abnormal lesions of the external male genitalia. These lesions are described in the section for common abnormal lesions of the external female genitalia.

Many nurses may feel anxious about examining the male genitalia. Nurses who feel uncomfortable about this assessment need to work through their feelings about sexuality and reproduction in order to communicate effectively with clients; see the accompanying Spotlight On display.

Assessment of the genitalia provides an opportunity for client teaching. For example, uncircumcised clients often need information on proper hygiene. Instruct the client to retract the foreskin daily so that the underlying skin can be washed with warm water and soap. Tell the client to return the foreskin to its original position once the underlying skin is thoroughly dried.

Some health care agencies do not allow nurses to perform a digital examination of the anus and rectum. Nurses must check the agency's policies relative to this part of the physical examination. Nursing students should have a quali-

fied registered nurse with them the first time they perform a digital examination. After this procedure has been done, the color of feces on the gloved finger should be noted. Bright red or tarry black stools are indicative of bleeding and should be reported. Usually a sample of the feces is tested for occult blood.

Early detection and treatment decrease testicular cancer mortality rates. Monthly testicular self-examination (TSE) allows for early detection of testicular cancer. During the scrotal examination, the client needs to be taught how to perform a TSE; see the accompanying Client Teaching Checklist.

ANUS AND RECTUM

The anorectal examination is an important part of a comprehensive physical assessment.

The assessment includes the anus and rectum in clients of both genders; for males, the prostate gland is also examined. These assessments should be performed on a regular basis as they provide screening for diseases such as cancer.

Prior to the actual examination, the nurse should assess the client's degree of apprehension and reassure the client that some anxiety over this part of the examination is normal. The anorectal examination is usually done as the last part of the complete physical examination, after trust has been established between client and nurse. A step-by-step explanation, description of the expected sensations, reassurance, and a gentle technique will minimize client embarrassment and discomfort; see the accompanying Spotlight On display on page 596.

It is important to use a systematic approach to examination. For females, proceed from the anus to the rectum; with

SPOTLIGHT ON...

Professionalism

Demonstrating Confidence while Examining the Male Genitalia

Nurses, both male and female, may feel anxious about examining the male genitalia. It is important that you work through your own feelings in order to help clients discuss their concerns. Some ways to increase your confidence are to:

- Practice interviewing with a male friend or classmate.
- Practice using correct terminology.
- Familiarize yourself with lay terminology, as many clients do not know the correct anatomic terms for body parts.

CLIENT TEACHING CHECKLIST

Testicular Self-Examination

- Ask the client if monthly TSE is performed.
- Explain to the client that monthly TSE will allow for early detection of testicular cancer.
- Review the anatomy of the scrotum by describing that the testicles are ovoid structures that feel firm and rubbery and that the epididymis, located behind the testicles, is softer and feels ropelike.
- Instruct the client to perform the examination during a warm shower using the thumb and first two fingers to gently feel each testicle and the epididymis. The testicles should move freely within the scrotum and have a smooth surface; the epididymis should be softer.

SPOTLIGHT ON...

Professionalism

It is important to maintain a professional, nonjudgmental approach while performing the anorectal examination. How would you respond if the following situations occurred during the assessment?

- Prior to the examination, the client is unable to sit still on the exam table.
- The client develops an erection.
- The client passes flatus.
- The client loses bowel control.

males, proceed from the anus to the prostate. See Table 27-25 which presents the specific areas of the anus and rectum to be examined.

In 2008, more than 186,000 men died from prostate cancer, which primarily affects older males (National Cancer

RESPECTING OUR DIFFERENCES

Incidence of Prostate Cancer Rates by Race

- African American: 248 per 100,000 men
- Caucasian: 156 per 100,000 men
- Hispanic: 138 per 100,000 men
- Asian/Pacific Islander: 93 per 100,000 men
- American Indian/Alaska Native: 73 per 100,000 men

Data from National Cancer Institute. (2008). *Surveillance Epidemiology and End Results*. Retrieved January 26, 2009, from <http://seer.cancer.gov/statfacts/html/prost.html>.

Institute, 2008). The median age at diagnosis for cancer of the prostate is 68 years. In addition to age, race is also a risk factor; see the Respecting Our Differences display.

TABLE 27-25 Assessment of the Anus and Rectum

ASSESSMENT AREA/TECHNIQUE	NORMAL FINDINGS	SIGNIFICANT FINDINGS AND POSSIBLE CAUSES
Assist client to side-lying position. Drape to expose only areas to be examined. Spread client's buttocks.		
Inspect perineum and anus. Observe for excoriation, inflammation, rashes, and nodes. Palpate any nodules for tenderness. Lubricate gloved index finger of dominant hand. Instruct client to inhale and exhale deeply. Inspect anus for hemorrhoids, fissures, excoriation. As sphincter relaxes, insert fingertip into the anal canal. Note sphincter tone, tenderness, or nodules. Insert finger further and palpate as much of rectal wall as possible, noting nodules or tenderness.	Perineum is smooth, intact, and slightly darker than surrounding skin. Anus is dark, puckered, and pink to dark brown. Skins tags usually present. Strong rectal sphincter tone. Smooth rectal wall.	Fissure or tear (abscess, trauma). Venous prominence on anus (external hemorrhoids).
With males: Palpate surface of prostate gland. Extend fingertip above prostate gland, and instruct client to bear down. Note size, shape, consistency, and mobility of prostate.	Prostate gland is small, smooth, and mobile.	Firm, hard, or indurated nodules on prostate (cancer). Firm, tender mass (abscess). A tender, warm prostate may indicate acute bacterial prostatitis associated with a bladder infection.

Data from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning; Jarvis, C. (2007). *Physical examination & health assessment* (5th ed.). Philadelphia: Elsevier.

POSTASSESSMENT CARE OF THE CLIENT

A physical examination is taxing on the client, especially if the complete assessment is performed in one session. The nurse should assess the client's needs after this process and respond appropriately. The nurse should also dispose of soiled articles in the proper container and clean and store equipment. Thanking the client for cooperating during the physical examination demonstrates concern and caring.

Outpatient Setting

If the physical examination is conducted in the community, the nurse should acknowledge the client's rights to privacy and confidentiality; see the accompanying Community Considerations display. The client should be offered assistance, for example, with toileting or dressing. If a family member is in the home, the nurse should notify that person when the assessment is completed. If the client is home alone, the nurse should verify that the client is capable of meeting his or her own needs before leaving. Listen carefully to the client's remarks, and provide information regarding the assessment.

Inpatient Setting

Nursing students should check with their instructors before conducting the assessment to ascertain the amount of information that they can share with the client during and after the examination. This varies in different agencies and according to the primary care provider. It is best to secure this information before beginning the examination.

After concluding the assessment, dispose of soiled articles and clean and store the equipment. The bed should be returned to a low position, with side rails up and call light in place. Check on the client after assessment to monitor the client's condition.

Nurses who practice in community settings provide the same essential services to clients as those performed in inpatient settings. Essential services include:

- Advocacy for clients unable to do so for themselves
- Delivery of legal and ethical care (e.g., respect for client rights, use of standard precautions)
- Health promotion (client education)
- Medication education
- Pain management

DATA DOCUMENTATION

Reporting information is a critical part of documentation. If findings require immediate attention (e.g., bright red blood or a change in the nature and character of a previous symptom), report the findings and document in the medical record the actions taken.

Health care agencies have specific forms for recording the assessment findings. Review these forms before initiating the assessment, and record the findings on the appropriate form as the data are gathered. Some data (e.g., vital signs) may need to be recorded on more than one form.

Documentation should reflect the objective data obtained from the examination regarding the client's current condition. Avoid phrases such as *client appears lethargic*; instead, record the GCS score. Abnormal assessment findings must be documented and reported.

KEY CONCEPTS

- The physical examination provides a complete picture of the client's physiological functioning; when combined with a health and psychosocial assessment, it forms a database to direct decision making.
- Because the client will experience some anxieties regarding the examination, it is important for the nurse to keep the client informed while performing the examination.
- The purposes of draping the client are to prevent unnecessary exposure and chilling during the examination.
- The physical examination is done in a sequential, head-to-toe fashion to ensure a thorough assessment of each system.
- Assessment begins with initial contact with the client.
- Use the landmarks and visualize the internal organs when assessing the thorax, heart, and abdomen.
- The order of abdominal assessment is inspection, auscultation, percussion, and palpation because palpation and percussion can alter the bowel sounds.
- Nurses play a major role by teaching breast self-examination (BSE) and testicular self-examination (TSE) and by supporting clients in achieving healthy lifestyles.
- Nurses must be aware of their own feelings in order to communicate with clients effectively during the physical examination.
- Reporting information is a critical part of documentation; if assessment findings require immediate attention, report the findings and document actions in the medical record.

- Know the agency's policies relative to performing and documenting a physical assessment.
- Documentation should reflect the objective data obtained from the examination.

REVIEW QUESTIONS

- A nurse is performing assessment of a client's vascular system. Which of the following actions must the nurse avoid?
 - Auscultate for bruits at the carotid arteries.
 - Check nail beds for capillary refill.
 - Palpate both carotid arteries simultaneously.
 - Perform the Allen test.
- Which of the following methods is useful for assessing skin turgor?
 - Indenting the ankle
 - Pinching a skin fold
 - Touching to determine degree of moisture
 - Using the goniometer
- List the order in which assessment techniques should be performed during physical examination of the abdomen.
 - _____ Auscultation
 - _____ Inspection
 - _____ Palpation
 - _____ Percussion
- A client becomes irritable, has labile emotions, and experiences sudden onset of headache. Which of the following assessments is most important for the nurse to perform?
 - Cardiovascular
 - Integumentary
 - Neurological
 - Visual
- The client is a 72-year-old African American male. He weighs 235 pounds, and his current blood pressure is 178/102. Which of the following is a modifiable risk factor for cardiovascular disease presented by this client?
 - Family history
 - Gender
 - Obesity
 - Race
- The nurse is performing a physical assessment of the heart. Which of the following assessment findings should be reported immediately to the primary care provider?
 - A mass and strong pulsations in the epigastric region
 - Absence of bruits
 - Absence of heaves
 - Slight pulsations over the aorta
- Which of the following assessment findings indicates cyanosis in a client with dark skin?
 - Blue nail beds
 - Bluish coloration on lips
 - Dark, dull, lifeless-looking skin
 - Generalized mottled, dusky-blue hue
- Which of the following tests would the nurse perform to test cerebellar function?
 - Allen
 - Romberg
 - Rinne
 - Weber
- The nurse is caring for a client who is on steroid therapy. Which of the following assessment findings would the nurse expect this client to exhibit?
 - Enlarged skull
 - Masklike facial expression
 - Round, moon face
 - Sunken eyeballs
- Which assessment finding should the nurse report when assessing a client with light skin?
 - Bright cherry-red cheeks and neck
 - Pigmented areas on breast nipples that are darker than surrounding skin
 - Pink nail beds
 - White sclera

*If the nurse is an intelligent being, and not a mere carrier of diets to and from the patient,
let her exercise her intelligence in these things.*

—FLORENCE NIGHTINGALE (IN SKRETKOWICZ, 1992)

CHAPTER 28

Diagnostic Testing

COMPETENCIES

1. Discuss the relevant client teaching guidelines for the care of the client before, during, and after diagnostic testing.
2. Describe the common specimen collection methods.
3. Describe common invasive and noninvasive diagnostic procedures.
4. Discuss nursing interventions for the common diagnostic procedures.

KEY TERMS

agglutination	echocardiogram	phagocytosis
agglutinins	electrocardiogram	phlebotomist
agglutinogens	electroencephalogram	pneumothorax
Allen test	electrolyte	polyp
amniocentesis	endoscopy	Port-a-Cath
analytes	enzymes	predictive value
aneurysm	erythrocytes	radiofrequency ablation
angiography	general anesthesia	radiography
anions	hematuria	red cell indices
antibodies	hemoconcentration	regional anesthesia
antigens	hemoglobin electrophoresis	sensitivity
ascites	hemolysis	signal-averaged
aspiration	incidence	electrocardiography
atherosclerotic plaque	invasive	specificity
biopsy	ketones	spherocytes
cardiac catheterization	late potentials	stress test
cations	leukocytes	thallium
central line	lipoproteins	thoracentesis
cholinesterase	local anesthesia	thrombus
computed tomography	lumbar puncture	transducer
conscious procedural sedation	magnetic resonance imaging	trocár
contrast medium	mammography	type and crossmatch
culture	necrosis	ultrasound
digital subtraction angiography	noninvasive	urobilinogen
disseminated intravascular	occult	venipuncture
coagulation	Papanicolaou test	void
Doppler	paracentesis	

With the arrival of health care reform, reimbursement practices such as managed care, and medicolegal concerns, health care is redefining the importance of history taking and physical examinations with a decreasing reliance on diagnostic tests. In the last two decades, before reform acts, health care relied heavily on the use of diagnostic testing to determine the nature of the client's condition.

Health care providers are using the findings from a thorough history and physical to determine the need for diagnostic testing. The client's history and presenting symptoms determine which diagnostic procedures are necessary to formulate a medical diagnosis and the course of treatment. The challenge of cost-effective health care pushes practitioners to rely on basic assessment and to be selective with expensive diagnostic tests. To reflect the emphasis on cost containment, the nurse's role has changed from doing for the client to teaching clients to do for themselves. The role of the nurse is to teach the client, family, and significant others about the procedures involved with diagnostic testing, the

steps to be taken in preparation for the specific test, and the care that will follow the procedure. Although the primary focus is on teaching, the nurse may assist in performing various noninvasive and invasive procedures. Nurses must be aware of the implications of diagnostic testing so as to deliver appropriate nursing care to the client.

To understand the nature of diagnostic tests, nurses need to review anatomy and physiology. Knowing the anatomical and physiological functions of the body will assist nurses in relating certain diagnostic tests to specific disease processes.

This chapter discusses the most common diagnostic tests. The terms *test* and *procedure* are used interchangeably throughout the chapter. The term *prescribing practitioner* is used in this chapter to refer to either the physician or other authorized prescribers. Most state boards of nursing allow advanced practice registered nurses to order and perform certain diagnostic tests. See Chapter 11 for a discussion of professional responsibility.

OVERVIEW OF NONINVASIVE AND INVASIVE DIAGNOSTIC TESTING

Diagnostic tests are either noninvasive or invasive. **Noninvasive** means the body is not entered with any type of instrument. The skin and other body tissues, organs, and cavities remain intact. **Invasive** means accessing the body’s tissue, organ, or cavity through some type of instrumentation procedure.

NURSING CARE OF THE CLIENT

Diagnostic testing is a critical element of assessment (see Chapters 6 and 27). Assessment data are used to formulate nursing diagnoses, a plan of care, and outcome measures in collaboration with the client. Ongoing client assessment and evaluation of the client’s expected outcomes require the incorporation of diagnostic findings.

Preparing a Client for Diagnostic Testing

The nurse plays a key role in scheduling and preparing the client for diagnostic testing. “The emphasis of pretest is on appropriate test selection, proper patient preparation, individualized patient education, and emotional support” (Fischbach & Dunning, 2008, p. 9). When tests are not scheduled correctly, the client is inconvenienced. It may also delay interventions, which places the client’s health status at risk. The institution

is also at risk to lose money. Table 28-1 presents a sample protocol of the nursing care to prepare a client for diagnostic testing.

The nursing care contained in the protocol provides a systemic format, based on the nursing process, to prepare the client for most diagnostic studies. During the assessment of the client, make sure the client is wearing an identification band (see Figure 28-1). The identification band is a key factor to ensure client safety in all health care settings.

FIGURE 28-1 Nurse and client prepare for diagnostic testing.
DELMAR/CENGAGE LEARNING

TABLE 28-1 Protocol: Preparing the Client for Diagnostic Testing

Purpose	To increase the reliability of the test by providing client teaching on why the test is being performed, what the client can expect during the test, and the outcomes and side effects of the test To decrease the client’s anxiety about the test and the associated risk
Level	Independent
Supportive data	Increasing the client’s knowledge promotes cooperation, enhances the quality of the testing, and decreases the time required to perform the study with an outcome of increased cost-effectiveness. Proper physical preparation prevents delays.
Assessment	Check to be sure the client is wearing an identification band. Review the medical record for herbal supplements, allergies, and previous adverse reactions to dyes and other contrast media; a signed consent form; and the recorded findings of diagnostic tests relative to the procedure. Assess for presence, location, and characteristics of physical and communicative limitations or preexisting conditions. Monitor the client’s knowledge of why the test is being performed and what to expect during and after testing. Monitor vital signs for clients scheduled for invasive testing to establish baseline data. Assess client outcome measures relative to the practitioner’s preferences for preprocedure preparations.

(Continues)

TABLE 28-1 (Continued)

	Monitor level of hydration and weakness for clients who are NPO (nothing by mouth), especially geriatric and pediatric populations.
Report to practitioner	Notify practitioner of herbal supplements, allergies, previous adverse reactions, or suspected adverse reactions following administration of drugs. Notify practitioner of any client or family concerns you were not able to alleviate.
Interventions	Clarify with practitioner if regularly scheduled medications are to be administered. The NPO status is determined by the type of test. Administer cathartics or laxatives as denoted by the test's protocol; however, there must be a specific practitioner order to give children and infants a laxative. Instruct clients who are weak, especially geriatric clients, to call for assistance to bathroom. Teach relaxation techniques, such as deep breathing and imagery. Establish intravenous (IV) access if necessary for procedure.
Evaluation	Evaluate client's knowledge of what to expect. Evaluate client's anxiety level. Evaluate client's level of safety and comfort. Monitor that someone will accompany a child to the department where the test is to be performed and remain with the child during the tests if not at risk of harmful exposure.
Client teaching	Discuss the following with the client and family as appropriate to the specific test: <ul style="list-style-type: none"> • Explain reason for test and what to expect • An estimation of how long the test will take • NPO (if oral medication to be taken, how much water to drink) • Cathartics or laxative: how much, how often • Sputum: cough deeply, do not clear throat • Urine: voided, clean-catch specimen, time to collect • No objects (jewelry or hair clips) to obscure x-ray film • Barium: taste, consistency, aftereffects (stools lightly colored for 24–72 hours, can cause obstruction or impaction) • Iodine: metallic taste, delayed allergic reaction (itching, rashes, hives, wheezing and breathing difficulties) • Positioning during the test • Positioning posttest (e.g., angiography)—immobilize limb • Posttest, encourage fluids if not contraindicated
Documentation	Record the following in the client's medical record: <ul style="list-style-type: none"> • Practitioner notification of allergies or suspected adverse reactions to contrast media • Presence, location, and characteristics of symptoms • Teaching and the client's response to teaching • Response to interventions (client's outcomes)

Delmar/Cengage Learning

Other key nursing measures to ensure client safety are to establish baseline vital signs, identify known allergies, and assess the effectiveness of teaching. As more Americans increase their usage of herbal products, nurses need to identify and report these herbal supplements when ordering laboratory tests. Some herbal products may cause abnormal test results and confusion in proper diagnosis (e.g., Dan Shen, ginseng, devil's

claw, and dong quai may interact with warfarin, an anticoagulant with a narrow therapeutic range). In the ambulatory and outpatient centers, the nurse might have only one opportunity to assess and record the vital signs; it is important for the nurse to confirm that these findings are *normal values* for the client. To accurately assess the client's response to anesthetic agents and the procedure, the nurse has to compare

the vital signs taken during and after the procedure with the baseline data.

The client needs to know what to expect during the procedure. Teaching can increase the client's level of cooperation and should decrease the degree of anxiety. The client's family should also know what will happen during the procedure and approximately how long the procedure normally lasts.

▼ SAFETY FIRST ▼

DIAGNOSTIC TESTING: SAFETY MEASURES

Use Standard Precautions whenever performing invasive and noninvasive testing to protect your health and safety as well as that of other health care providers and the client.

Reference is made to Table 28-1 throughout this chapter. This protocol provides the nurse with the direction and guidance needed to plan nursing care. Nurses must also know the institution's protocols and procedures because these are not standardized in all practice settings.

Care of the Client during Diagnostic Testing

Although the care of the client needs to be individualized for a specific procedure, general guidelines for client care during a procedure are given in Table 28-2. Protocols are used to assist the nurse with client care.

Standard Precautions are initiated when exposure to body fluids presents a threat to the safety of the caregiver. Protective barriers, such as gloves and a gown, should be used during invasive procedures. The nurse is responsible for labeling any specimen with the client's name, room number (hospitalized clients), date, time, and source of the specimen. Some specimens may need to be taken immediately to the laboratory or placed on ice (e.g., arterial blood gases).

In order to promote the client's comfort and cooperation during diagnostic tests, nurses must consider the management of procedural pain. Although not all procedures are painful, advances in diagnostic and therapeutic studies have placed clients at risk for painful procedures. Clients who are repeatedly subjected to painful procedures without adequate analgesia become anxious and anticipate pain; if pain is experienced during one procedure, the client is reluctant to return for the same procedure or other tests.

TABLE 28-2 Protocol: Care of the Client during Diagnostic Testing

Purpose	To increase cooperation and participation by allaying the client's anxiety and to provide the maximum level of safety and comfort during a procedure
Level	Interdependent
Supportive data	Increasing the client's participation and comfort encourages relaxation of muscles to facilitate instrumentation. Proper preparation of the client ensures efficient use of time during the test and reliable results.
Assessment	Check the client's identification band to ensure the correct client. Review the medical record for allergies. Assess the preprocedure sedatives administered to the client before the administration of anesthesia during the procedure. Assess airway maintenance and gag reflex if a local anesthetic is sprayed into the client's throat. Assess vital signs throughout the procedure and compare with baseline data. Assess the client's ability to maintain and tolerate the prescribed position. Assess the client's comfort level to ensure the effectiveness of the anesthetic agent. Assess for related symptoms indicating complications specific to the procedure (e.g., accidental perforation of an organ).
Report to practitioner	Notify the practitioner if the client has any concerns or questions that you were not able to resolve. Notify the practitioner if the client has family members present and where they are waiting during the procedure. Notify the practitioner when the client is positioned properly and the anesthetic agent has been administered to the client.

(Continues)

TABLE 28-2 (Continued)

Interventions	<p>Institute Standard Precautions or appropriate aseptic technique for the specific test.</p> <p>Report to all personnel involved with the test any known client allergies.</p> <p>Place client in the correct position, drape, and monitor to ensure that breathing is not compromised.</p> <p>Remain with the client during the administration of anesthesia.</p> <p>If the procedure requires the administration of a dye, ensure the client is not allergic to the dye; if the client has not received the dye before, perform the skin allergy test according to the drug manufacturer's instructions that accompany the medication.</p> <p>Maintain the client's airway and keep resuscitative equipment available.</p> <p>Assist the client to relax during insertion of the instrument by telling the client to breathe through the mouth and to concentrate on relaxing the involved muscles.</p> <p>Explain what the practitioner is doing so that the client will know what to expect.</p> <p>Label and handle the specimen according to the type of materials obtained and the testing to be done.</p> <p>Report to the practitioner any symptoms of complications.</p> <p>Secure client transport from the diagnostic area.</p> <p>Posttest in the diagnostic area:</p> <ol style="list-style-type: none"> 1. Assist client to a comfortable, safe position. 2. Provide oral hygiene and water to clients who were NPO for the test if they are alert and able to swallow. 3. Remain with the client awaiting transport to another area.
Evaluation	<p>Evaluate client's ventilatory status and tolerance of the procedure.</p> <p>Evaluate client's need for assistance.</p> <p>Evaluate client's understanding of what was performed during the procedure.</p> <p>Evaluate client's understanding of findings identified during the procedure.</p> <p>Evaluate client's knowledge of what to expect after the procedure.</p>
Client teaching	<p>Discuss the following with the client and family as appropriate to the specific test:</p> <ul style="list-style-type: none"> • Explain what occurred during the procedure. • Answer questions and concerns of the client or family member. • Explain what to expect during the immediate recovery phase. • Explain what to report to the nurse during the immediate recovery phase.
Documentation	<p>Record in the client's medical record:</p> <ul style="list-style-type: none"> • Who performed the procedure • Reason for the procedure • Type of anesthesia, dye, or other medications administered • Type of specimen obtained and where it was delivered • Vital signs and other assessment data, such as client's tolerance of the procedure or pain and discomfort level • Any symptoms of complications • Who transported the client to another area (designate the names of persons who provided transport and place of destination)

Delmar/Cengage Learning

Recognizing that diagnostic procedures are performed in various settings, conscious procedural sedation (conscious sedation) is often used to manage pain during diagnostic testing.

Conscious procedural sedation is a minimally depressed level of consciousness during which the client retains the ability to maintain a continuously patent airway and respond appropriately to physical stimulation or verbal

DIAGNOSTIC PROCEDURES THAT MAY REQUIRE ANALGESIA OR SEDATION

- Bone marrow aspiration or biopsy
- Cardioversion
- Endoscopy
- Lumbar puncture
- Paracentesis
- Placement of catheters, lines, and tubing
- Radiologic procedures (CT and MRI)
- Thoracentesis
- Tissue biopsies
- Venipuncture

commands (Fischbach & Dunning, 2008). The nurse managing conscious sedation is usually functioning in an expanded role that requires additional education and demonstrated ability beyond basic education. See the accompanying display for some procedures that may require analgesia or sedation.

Ongoing assessment of the client’s status is required during the procedure. Always assess the patency of the client’s airway, which may be compromised by the client’s position, anesthesia, or the procedure itself. During an invasive procedure, the nurse needs to monitor for signs and

symptoms of accidental perforation of an organ (e.g., sudden changes in vital signs).

The nurse has additional responsibilities:

- Preparing the room (e.g., adequate lighting)
- Gathering and charging for supplies used during the procedure
- Testing the equipment to ensure it is functional and safe
- Securing proper containers for specimen collection

Practitioners usually have *preference cards* within the diagnostic testing area that specify the type of equipment to be used, the position to place the client, and the type of sedation or anesthesia.

Care of the Client after Diagnostic Testing

Nursing care postprocedure is directed toward restoring the client’s prediagnostic level of functioning (see Table 28-3). Nursing assessment and interventions are based mainly on the nature of the test and whether or not the client received anesthesia. Anesthesia can be administered in one of three ways:

- **Local anesthesia**—client loses sensation to a localized body part—spraying the back of the throat with lidocaine to decrease the gag reflex
- **Regional anesthesia**—client loses sensation in an area of the body—laparoscope for a tubal sterilization
- **General anesthesia**—client loses all sensation and consciousness—major surgical procedures

See Chapter 40 for additional discussion of anesthesia.

TABLE 28-3 Protocol: Care of the Client after Diagnostic Testing

Purpose	To restore the client’s prediagnostic level of functioning by providing care and teaching relative to what the client can expect after a test and the outcomes or side effects of the test
Level	Interdependent
Supportive data	Increasing the client’s participation and knowledge of expected outcome measures after a diagnostic test. Proper postprocedure care and client teaching alerts the client to what signs and symptoms need to be reported to the practitioner.
Assessment	Check the identification band, and call the client by name. Assess the client closely for signs of airway distress, adverse reactions to anesthesia or other medications, and other signs that may indicate accidental perforation of an organ. Assess body area(s) where a biopsy was performed for bleeding. Assess the client’s color and skin temperature. Assess vascular access lines or other invasive monitoring devices. Assess the client’s ability to expel air if air was instilled during a gastrointestinal test. Assess the client’s knowledge of what to expect during the recovery phase.

(Continues)

TABLE 28-3 (Continued)

Report to practitioner	<p>Notify the practitioner of any signs of respiratory distress, bleeding, or changes in vital signs; adverse reactions to anesthetic, sedative, or dye; and other signs of complications.</p> <p>Notify the practitioner regarding client or family concerns or questions that you are not able to answer.</p> <p>Notify the practitioner when any results are obtained from the diagnostic test.</p> <p>Notify the practitioner when the client is fully alert and recovered for an order to discharge.</p>
Interventions	<p>Implement the practitioner's orders regarding the postprocedure care of the client.</p> <p>Institute Standard Precautions or surgical asepsis as appropriate to the client's care needs.</p> <p>Position the client for comfort and accessibility to perform nursing measures.</p> <p>Monitor vital signs according to the frequency required for the specific test.</p> <p>Observe the insertion site for a hematoma or blood loss; replace pressure dressing as needed.</p> <p>Monitor the client's urinary output and drainage from other devices.</p> <p>Enforce activity restrictions appropriate to the test.</p> <p>Schedule client appointments as directed by the practitioner.</p>
Evaluation	<p>Evaluate the client's respiratory status to any anesthetic agents.</p> <p>Evaluate the client's tolerance of oral liquids.</p> <p>Evaluate the client's understanding of procedural findings or the time frame that written results should be reported to the practitioner.</p> <p>Evaluate the client's knowledge of what to expect after discharge.</p>
Client teaching	<p>Based on client assessment and evaluation of knowledge, teach the client or family about the following:</p> <ul style="list-style-type: none"> • Dietary or activity restrictions • Signs and symptoms that should be reported immediately to the practitioner • Medications
Documentation	<p>Record in the client's medical record on the appropriate forms:</p> <ul style="list-style-type: none"> • Assessment data, nursing interventions, and achievement of client expected outcomes • Client or family teaching and demonstrated level of understanding • Written instructions given to the client or family members

Delmar/Cengage Learning

The client is monitored closely for signs of respiratory distress and bleeding. Some diagnostic procedures require that the vital signs be measured every 15 minutes for the first hour, then gradually decreased in frequency until the client is stable (alert and vital signs within the client's normal range).

Some diagnostic tests require the use of medications that are excreted through the kidneys; the nurse monitors the client's intake and output for 24 hours. The client is taught how to monitor intake and output. Instruct the client to report **hematuria**, the presence of blood in the urine. Clients receiving radioactive iodine must have their urine collected and properly discarded in a special container, according to agency policy for handling radioactive medical wastes.

When clients are discharged after diagnostic tests, they should receive written instructions. Most agencies have discharge

forms for the nurse to document teaching regarding medications, dietary and activity restrictions, and signs and symptoms to be reported immediately to the practitioner. Clients may also need to have follow-up appointments made for them.

LABORATORY TESTS

Common laboratory studies are usually simple measurements to determine how much or how many **analytes** (a substance dissolved in a solution, also called a solute) are present in a specimen. Laboratory tests are ordered by prescribing practitioners to:

- Detect and quantify the risk of future disease
- Establish and exclude diagnoses

- Assess the severity of the disease process and determine the prognosis
- Guide the selection of interventions
- Monitor the progress of the disorder
- Monitor the effectiveness of the treatment

Nurses are often the first to view results of laboratory studies, and they need to know the terminology regarding laboratory tests: purpose, process, procedure, and normal test values. The clinical value of a test is related to (Fischbach & Dunning, 2008):

1. **Specificity**—the ability of a test to correctly identify those individuals who do not have the disease.
2. **Sensitivity**—the ability of a test to correctly identify those individuals who have the disease.
3. **Incidence**—the prevalence of a disease in a population or community; the predictive value of the same test can be different when applied to people of differing ages, genders, and geographic locations.
4. **Predictive value**—the ability of screening test results to correctly identify the disease state; a true positive correctly identifies persons who actually have the disease, whereas a true negative correctly identifies persons who do not actually have the disease.

Laboratory test results are based on normal range values. Le Système International d'Unités (SI), the International System of Units, is an international normal range reference established for reporting laboratory results (Pagana & Pagana, 2006). For example, the SI reference range for reporting red blood cell count for a woman is 4.0 to $5.2 \times 10^{12}/L$; the conventional range would appear as 4,000,000 to 5,200,000/ mm^3 of blood.

SPECIMEN COLLECTION

The scheduling and sequencing of laboratory tests is an important function of the nurse. All tests requiring **Venipuncture**, the puncturing of a vein with a needle to aspirate blood, are grouped together so that the client is subjected to only one venipuncture. Fasting laboratory and radiologic studies are scheduled on the same day so that the client has to fast for only one day. Appropriate scheduling increases the client's comfort level and satisfaction.

“Communication errors account for more incorrect results than do technical errors” (Fischbach & Dunning, 2008, p. 13). Accuracy in laboratory testing requires that:

- The practitioner's order is transcribed onto the correct requisition form.
- All information requested should be written onto the form (e.g., the client's full name and medical number).
- Pertinent data that could influence the test's results, such as medication taken or herbal supplements, must be included.
- Collection of the specimen from the correct client is confirmed by the identification band.
- Laboratory results are placed on the correct client's medical record.

The risk for error increases when clients have the same last name. To improve client safety in health care settings, the Joint

Commission has established annual safety goals based on sentinel events associated with errors. The Joint Commission 2009 *Hospitals' National Patient Safety Goals* address the need to:

- Improve the accuracy of client identification by using two client identifiers and conducting a verification process before starting procedures.
- Improve the effectiveness of communications among caregivers by reading back verbal orders, creating a list of abbreviations not to be used, and reporting critical tests and critical results in a timely manner.
- Reduce the risk of health care-associated infections by meeting hand hygiene guidelines and sentinel events resulting from infection.
- Encourage clients' active involvement in their own care as a client safety strategy (Joint Commission, 2008).

Point-of-care testing (POCT) is a common practice in critical care settings and is proving to be a cost-effective, quality intervention for both clients and agencies. With advances in POCT technology over the past two decades, critical care nurses can perform a blood analysis and within seconds to minutes have a measurement upon which to change or implement an intervention. Nurses should be involved in the implementation and evaluation process of POCT since accuracy of the test is contingent on correct calibration and correct usage by the test performer. The following advantages are inherent in POCT (McConnell, 1999; Schallom, 1999):

- Prompt client diagnosis, treatment, and monitoring by decreasing turnaround time (TAT)
- Decreasing the risk for error by eliminating many of the steps in conventional laboratory testing
- Decreasing prolonged hospital stays and avoiding unnecessary hospitalizations by facilitating appropriate triage from emergency departments and prehospital settings
- Decreasing delays or cancellations of surgical procedures due to unavailable laboratory results, and the actual time the client spends in surgery
- Minimizing blood loss due to phlebotomy since POCT devices usually require only a few microliters or drops of blood versus 25 to 125 microliters per day for the critically ill client due to laboratory testing

Studies regarding POCT's clinical and financial value have revealed positive results: improved overall day-stay unit operations

SAFETY FIRST

DOCUMENTATION

Document on the laboratory requisition slip and in your nurses' notes any difficulty you experience while collecting the specimen. Such problems may be indicative of adverse effects that clients may experience due to the nature of the test and are conditions that must be reported and treated immediately.

and client services as well as earlier therapeutic decision-making time when blood test results are required for emergency room clients. Although studies have proven positive results in settings where the client's condition is acute and unstable, critical care applications may be quite different from those on a general medical or surgical unit. Studies will need to document the usefulness of POCT as a quality intervention in nonacute care settings.

Venipuncture

Venipuncture can be performed by various members of the health care team. Laboratories employ a **phlebotomist**, an individual who performs venipuncture, to collect blood specimens; however, it is the responsibility of a nurse to know *how* to perform a venipuncture. Nurses routinely perform venipuncture in the home, long-term care settings, and hospital critical care units.

Venipuncture can be performed by using either a sterile needle and syringe or a vacuum tube holder with a sterile two-sided needle. Test tubes are used to collect blood specimens. Test tubes have different colored stoppers to indicate the type of additive in the test tube. Collecting tubes are universally color coded as follows:

- Red—no additive
- Lavender—EDTA (ethylenediaminetetraacetic acid)
- Light blue—sodium citrate
- Green—sodium heparin
- Gray—potassium oxalate
- Black—sodium oxalate

There are three sources of venipuncture variability that can cause inaccurate results. **Hemoconcentration** is the reduced volume of plasma water and the increased concentration of blood cells, plasma proteins, and protein-bound constituents. It occurs with increased capillary hydrostatic pressure that causes water to shift from the intravascular into the interstitial space.

Hemoconcentration can be caused by prolonged standing or a prolonged time of application of a tourniquet during venipuncture. Alterations in the circulating blood volume can also cause hemoconcentration, such as occurs with dehydrated and burned clients.

Hemolysis is the breakdown of red blood cells and the release of hemoglobin. Hemolysis occurs with the rapid flow of blood through small-bore needles and exposure to large negative pressures. A negative pressure exists inside the collecting test tubes and syringe. To minimize the possibility of hemolysis, use a large-bore needle, moderate flow rates, and moderate negative pressures.

The third source of variability occurs when a blood specimen is drawn from a site above an intravenous (IV) infusion. The specimen is contaminated with IV solutions. Blood should be drawn from the client's other arm or below the infusion site.

Venipuncture is an invasive procedure. Health care providers performing venipuncture are at risk for the transmission of bloodborne organisms, such as human immunodeficiency virus (HIV) and hepatitis. HIV is the causative agent for

SAFETY FIRST

PREVENTING HEMOCONCENTRATION

Keep to a minimum both the length of time a client stands before venipuncture and the length of time of tourniquet application during venipuncture. These actions lower the risk of hemoconcentration and increase the rate of accuracy in laboratory tests.

acquired immunodeficiency syndrome (AIDS). Health care providers with weeping dermatitis or other exudative lesions should avoid handling all invasive equipment because the pathogens from these conditions can contaminate the equipment and spread infection to clients.

Correct selection (see Figure 28-2) and preparation of equipment and vein provides for a safe and efficient venipuncture (see Procedure 28-1). The gauge of the needle should be appropriate to the size of the vessel to prevent hemolysis. Review of the client's health history and physical assessment data will assist in identifying special client considerations. Venipuncture should not be performed on a flaccid arm of clients who have suffered a stroke. The normal muscle contraction, known as the venous pump, helps force blood back to the heart. These muscle contractions also help prevent blood backflow by forcing upper vein valves to open and lower valves to close. If an arm is paralyzed, the venous pump is lost, greatly increasing the risk of vein thrombosis ("Advice P.R.N.," 2008). If the client has a bleeding disorder or is taking anticoagulant therapy, apply pressure to the puncture site for 3 to 5 minutes after the removal of the needle.

Arterial Puncture

Assessment of arterial blood gases (ABG) reveals the ability of the lungs to exchange gases by measuring the partial

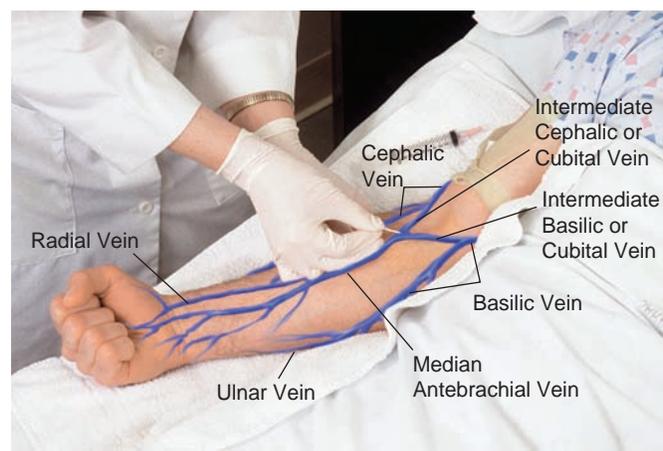

FIGURE 28-2 Nurse selects site for venipuncture. DELMAR/CENGAGE LEARNING

pressures of oxygen (PO_2) and carbon dioxide (PCO_2) and evaluates the pH of arterial blood. Blood gases are ordered to evaluate:

- Oxygenation
- Ventilation and the effectiveness of respiratory therapy
- Acid-base level of the blood

Arterial blood samples are drawn from a peripheral artery (e.g., radial or femoral) or from an arterial line. The arterial blood sample is collected in a 5-mL heparinized syringe. The syringe is then rotated to mix the blood with the heparin to prevent clotting. The blood sample is placed on ice to reduce the rate of oxygen metabolism.

In some agencies it is within the scope of nursing practice to perform radial artery puncture; however, femoral artery puncture is usually performed only by an advanced practitioner. An increased risk of hemorrhage exists with a femoral puncture. Although it is not common practice for student nurses to draw ABG samples, students often have to assist with the procedure and care for the client after the procedure.

Arterial punctures should not be performed:

- If the client is hyperthermic
- Immediately after breathing and suctioning treatments (wait 20 minutes)
- If there have been changes on ventilator settings

Arterial samples are also contraindicated in the following conditions:

- Anticoagulant therapy
- Clotting disorders
- Symptomatic peripheral vascular disease
- Negative Allen test

An **Allen test** is performed to measure the collateral circulation to the radial artery. See Chapter 27 for the Allen test procedure.

Regardless of who performs the arterial puncture, the nurse is responsible for assessing the client for symptoms of

bleeding or occlusion postpuncture. Direct pressure must be applied to the puncture site until all bleeding has stopped, a minimum of 5 minutes if the radial artery is used and 10 minutes for the femoral. Ensure that all bleeding has stopped before releasing the pressure. Symptoms of impaired circulation include:

- Numbness, tingling, and pain
- Bluish color
- Absence of a peripheral pulse

Capillary Puncture

Skin punctures are performed when small quantities of capillary blood are needed for analysis or when the client has poor veins. Capillary puncture is also commonly performed for blood glucose analysis, discussed later in this chapter.

The common sites for capillary punctures are the:

- Heel—most common site for neonates and infants
- Fingertip—the inner aspect of palmar fingertip used most commonly in children and adults
- Earlobe—when the client is in shock or the extremities are edematous

To perform a skin puncture, assemble the equipment, prepare the client, and select the appropriate site (see Procedure 28-2).

Central Lines

Blood samples can be collected from central lines. A **central line** refers to a venous catheter inserted into the superior vena cava through the subclavian, internal, or external jugular vein. A central line is inserted when a peripheral route cannot be obtained, for treatment, and to withdraw blood for analysis. Central lines are used to treat alterations in fluid or electrolytes. The client's nursing diagnoses may include the following: *Deficient fluid volume related to nausea and/or vomiting or Imbalanced nutrition, less than body requirement related to anorexia.*

Nurses need to know the type and location of the central line catheter. There are various types of central lines. Central lines can have either one or more lumens inside the catheter. For example, a central venous catheter has either one or two lumens, whereas a Hickman multilumen catheter may have either two or three catheters contained in one sheath.

It is standard practice to mark each lumen of a multilumen catheter with the name of the infusion (e.g., fluid or medication). Lumens are marked to prevent the mixing of medications. Lumens without continuous infusion of fluids are capped with an infusion plug and flushed with a heparin solution every 8 hours according to agency protocol. Heparin prevents obstruction of the catheter lumen with a blood clot. The first sample of blood drawn from the central line cannot be used for diagnostic testing; it must be discarded. The amount of discard volume is directly related to the dead space (catheter size). The agency's protocol should indicate the volume to discard relative to the type and size of catheter.

SPOTLIGHT ON...

Diagnostic Testing and Confidentiality

Mr. Takahashi comes to the Ambulatory Surgery Clinic for his preoperative diagnostic testing. You overheard the staff saying that Mr. Takahashi has had a history of hepatitis. Your instructor gathers all the student nurses and asks, "Who needs the experience of performing a venipuncture?" Two of your classmates indicate to the instructor that they have not had the opportunity to perform this procedure. Should you say anything to the instructor? Would you share with your classmates Mr. Takahashi's history? If you said something, would this be a breach of client confidentiality?

Delmar/Cengage Learning

The nursing care of central lines requires strict sterile technique (see Chapter 29). The prescribing practitioner has to write an order to allow a blood sample to be obtained from a central line. See the Nursing Checklist for how to draw a blood sample from a central line.

Implanted Port

Some clients have a **Port-a-Cath** (a port that has been implanted under the skin) over the third or fourth rib. The port has a catheter that is inserted into the superior vena cava or right atrium through the subclavian or internal jugular vein. The implanted port is used for the same purpose as the central lines.

Blood can be withdrawn for sampling by accessing the port using strict sterile technique. Accessing a port should be performed only by a nurse with proper education. Students are not usually taught how to access an implanted port.

Urine Collection

The kidneys are responsible for maintaining homeostasis of the body's buffering systems and the volume and ionic and osmotic composition of its fluid compartments; see Chapter 39 for a complete discussion of the composition of fluid compartments. As with blood, all urine collection requires the use of Standard Precautions to prevent the transmission of microorganisms among clients, nurses, and other health care providers.

NURSING CHECKLIST

Obtaining a Blood Sample from a Central Line

- Gather equipment (the sizes of the needle and syringe to obtain the blood sample are determined by the amount of blood needed for the test and the type and size of central line catheter).
- Check the client's identification band.
- Wash hands and don gloves to prevent exposure to bloodborne organisms.
- Select a port that is not used routinely for an infusion.
- Cleanse the port of the lumen with an antiseptic.
- Insert the needle into the port and aspirate the discard volume according to agency protocol; dispose of the syringe containing the discard blood into a sharps container.
- Access the port and withdraw the blood sample.
- Apply the same principles used in venipuncture to prevent the hemoconcentration and hemolysis of blood when withdrawing the sample.
- Transfer the sample into the correct collection tubes, and discard the contaminated needle and syringe into the sharps container.
- Instill the required heparin solution to prevent the lumen from clotting.
- Transport specimen to the laboratory.
- Remove gloves, and wash hands.

Urine can be collected for various studies. The type of testing determines the method of collection. The different methods of urine collection are:

- Random collection (routine analysis)
- Timed collection
- Collection from a closed urinary drainage system
- Clean-voided specimen

The urine from a closed urinary drainage system is a sterile specimen. Client teaching depends on the client's age and the method of collection. Initiate the protocol for preparing the client for testing (see Table 28-1). The method of collection should be written on the laboratory requisition.

RANDOM COLLECTION The prescribing practitioner usually writes the order for a UA (routine urine analysis), which is also called a random collection. It can be collected at any time using a clean cup. The urine does not have to be collected in a sterile container. Instruct the client to urinate into the specimen cup or into a clean bedpan or urinal. Wearing gloves, transfer the urine into a clean container. Seal the lid tightly, label, and place in a biohazard bag for transport to the laboratory. Urine should be refrigerated if the specimen cannot be sent to the laboratory within 1 hour; after an hour, unrefrigerated urine becomes alkaline because bacteria begin to split urea into ammonia.

TIMED COLLECTION Timed collection is done over a 24-hour period. The urine is collected in a plastic gallon container that contains preservative(s), some of which are caustic. The laboratory usually adds the preservatives to the container. If the analyte to be studied is light sensitive, a dark plastic container is necessary.

Provide the client with specific instructions. The client is told to **void** (the process of urine evacuation) and discard the specimen at the beginning of the collection. The 24-hour collection begins with the first discarded voiding. For example, if the client is instructed to void at 1000 hours (24-hour clock time frame), discard the urine and save all other voided specimens until 1000 hours the following day. The client can void throughout the test into a clean container, then pour the urine into the collection bottle. Toilet tissue should not be dropped into the container used to catch the urine.

The collection container should be refrigerated or kept on ice throughout the 24 hours. This retards bacterial growth and stabilizes the analytes. The last urine collection, at 1000 hours, should be a complete, forced voiding at the exact timed period. Seal the labeled container tightly, and take it immediately to the lab.

COLLECTION FROM A CLOSED DRAINAGE SYSTEM A sterile specimen can be collected from a client with an indwelling Foley catheter with a closed drainage system. A sterile specimen is used to culture the urine. *The urine specimen should not be obtained from the drainage bag.* The analytes in the urine drainage bag change; this will cause inaccurate results. Bacteria grow quickly in the drainage bag. The catheter's closed drainage tubing has an aspiration port that is used for a sterile specimen collection (see Procedure 28-3).

CLEAN-VOIDED SPECIMEN Clean-voided (clean-catch, or midstream) specimen collection is done to secure a

specimen uncontaminated by skin flora. A clean-voided specimen should be obtained on first voiding in the morning. Most adult clients are capable of following instructions to perform this test.

Different aseptic techniques are used for women and men. Poor technique in cleaning the perineum can contaminate the specimen. Instruct the female client to cleanse from the front to the back (see Procedure 28-4).

Instruct the male client to perform the same procedure except for the cleansing of the perineal area; men should cleanse from the tip of the penis downward (see Procedure 28-4). The Nursing Checklist describes the procedure for obtaining a clean-voided specimen from a man.

When obtaining a clean-voided specimen from infants and small children, secure assistance. Follow the Nursing Checklist that describes the procedure for obtaining a clean-voided specimen from an infant or child.

Stool Collection

Explain to the client why the stool specimen is being collected. Instruct the client to defecate into a clean bedpan or

NURSINGCHECKLIST

Clean-Voided Specimen, Male

- Check the client's identification band.
- Instruct the client on the procedure.
- Wash hands and don gloves if the client needs assistance with the procedure.
- If uncircumcised, retract the foreskin, and hold retracted.
- Cleanse the head of the penis with a towelette using a circular motion. Cleanse the meatus and glans beginning with the urethral opening, and make one complete circle around the penis, moving down the glans shaft.
- Discard the towelette.
- Repeat the procedure until all three towelettes have been used.

NURSINGCHECKLIST

Clean-Voided Specimen, Infant and Child

- Check the identification band.
- Explain the procedure to family member present with infant or child. If the child can cooperate, tell child what to do before having someone hold him or her in position.
- Wash hands and don gloves.
- Place in a supine position with hips externally rotated.
- Have parent or assistant flex and abduct the knees, and hold the knees throughout the procedure.
- Cleanse the perineal area as you would for an adult.
- Place a sterile collection bag over the perineum or penis and scrotum, and apply a diaper.
- Remove the collection bag immediately after voiding.
- Transfer the urine into the labeled collection container, close lid tightly, and place in biohazard bag for immediate transport to the laboratory.

container, discarding tissue into the toilet. Stools can be collected for either a one-time defecation or over 24, 48, or 72 hours. If a specimen is needed over a prolonged period of time, all stools must be placed into a container and refrigerated. Once collected, label the container with the client's name, date, time, and the test to be performed on the specimen. All stool specimens are placed in a biohazard bag before transport to the laboratory.

HEMATOLOGIC SYSTEM

Understanding the hematologic system requires a knowledge of the blood's composition and its functions. Table 28-4 discusses the origin, normal range values, and the major function for each of the three types of cells found in blood:

TABLE 28-4 Types of Blood Cells

CELL	ORIGIN	NORMAL VALUES	MAJOR FUNCTION
Erythrocytes	Bone marrow	F: $4.0\text{--}5.2 \times 10^{12}/\text{L}$ M: $4.5\text{--}5.9 \times 10^{12}/\text{L}$	Transport hemoglobin
Leukocytes	Granulocytes and monocytes from bone marrow Lymphocytes and plasma cells from lymph tissue	$5.0\text{--}10.0 \times 10^9/\text{L}$	The body's protective system
Platelets	Megakaryocytes in bone marrow	$140\text{--}400 \times 10^3/\text{mm}^3$	Vascular repair

Fischbach, F., & Dunning, M. (2008). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott, Williams & Wilkins.

- Red blood cells (**erythrocytes**)
- White blood cells (**leukocytes**)
- Platelets

About 40% to 45% of the blood's volume is composed of blood cells; the remaining blood volume is plasma, as shown in Figure 28-3. Plasma is part of the body's extracellular fluid system, consisting of water and analytes. Blood proteins form the largest portion of the plasma analytes. The average plasma volume for a normal adult is 3 L.

Red Blood Cells

Red blood cells (RBCs), in embryonic life, are produced first in the yolk sac until the middle trimester; then the liver becomes the main organ of RBC production. RBC production becomes the exclusive function of the bone marrow by the end of gestation, after birth, and throughout life. RBC bone marrow site production changes with age:

- From birth to age 5—all bone marrow
- From 5 to 20 years—the shaft of the long bones (tibia and femur)
- After 20 years—the membranous bones (ilia, ribs, sternum, and vertebrae). As part of the normal aging process, the production of RBCs decreases with age.

Functions of the RBCs include:

- Transporting oxygen-carrying hemoglobin
- Transporting carbon dioxide in the form of sodium bicarbonate
- Being an acid-base buffer for whole blood

White Blood Cells

There are six types of white blood cells (WBCs, leukocytes) found in the blood.

- Neutrophils
- Eosinophils
- Basophils
- Monocytes
- Lymphocytes
- Plasma cells

The polymorphonuclear cells, neutrophils, eosinophils, and basophils have a granular appearance, hence, the name granulocytes or polys. The granulocytes and monocytes are responsible for **phagocytosis**, the process by which certain cells engulf and dispose of foreign bodies. The lymphocytes and plasma cells function mainly as the body's immune system.

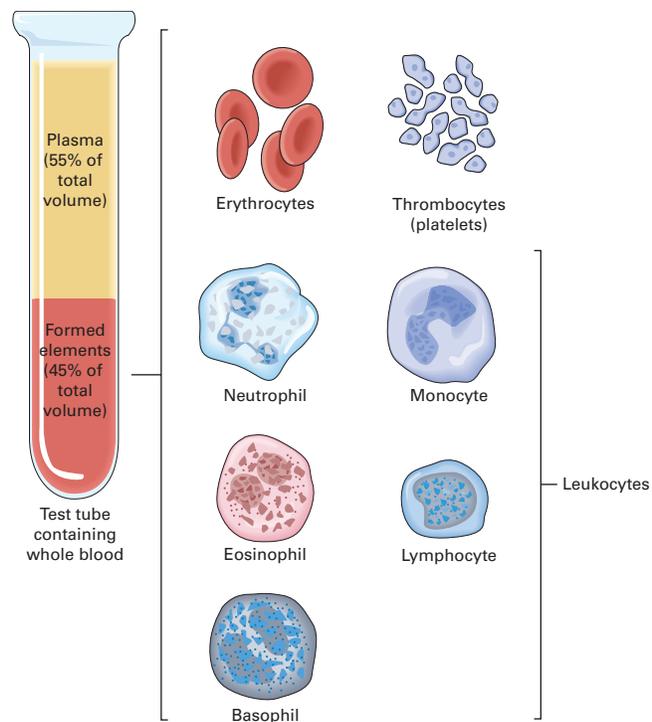

FIGURE 28-3 Blood Cells DELMAR/CENGAGE LEARNING

The WBCs are formed and stored in the bone marrow until needed by the body. Table 28-5, on page 615, presents laboratory studies for a complete blood count with SI values and when each analyte is either increased or decreased in clinical situations.

Red Cell Indices

Red cell indices measure the size and hemoglobin content of the RBCs. The RBC indices are:

- Mean red cell hemoglobin (MCH)
- Mean red cell hemoglobin concentration (MCHC)
- Mean red cell volume (MCV)

The indices are diagnostic in determining the type of anemia. For example, an elevated MCHC means that **spherocytes** (smaller, thicker red cells) are present; this occurs in acquired hemolytic anemia.

Platelets

Platelets are fragments of a seventh type of WBC found in the bone marrow, the megakaryocytes. Platelets maintain hemostasis and blood coagulation by being the active mechanism of the blood in vascular repair. The active factors necessary for blood to coagulate are found in the cytoplasm of platelets. Blood coagulation is a comprehensive, sequential process of the body's response to injury.

The blood coagulation flow chart (see Figure 28-4 on page 616) reviews the key elements of vascular constriction and coagulation. Prothrombin (factor II) is a plasma protein, formed in the liver, and requires vitamin K for synthesis. It is activated when blood vessels are damaged. Prothrombin

SAFETY FIRST

STOOL FROM A CLIENT WITH HEPATITIS

When collecting a stool specimen from a client with hepatitis, write on the lab requisition form that the client has hepatitis. This increases the laboratory personnel's awareness to be extra careful when handling the specimen.

TABLE 28-5 Complete Blood Count with Clinical Significance

ANALYTE	NORMAL VALUES	INCREASED	DECREASED
Red blood cell count	F: $4.0\text{--}5.2 \times 10^{12}/\text{L}$ M: $4.5\text{--}5.9 \times 10^{12}/\text{L}$	Dehydration, induced hypoxia, polycythemia	Anemias, hypothyroidism, leukemias
Hemoglobin (Hb)	F: 120–150 g/L M: 139–163 g/L	Chronic obstructive lung disease, polycythemia, high altitudes, burns, shock	Anemia, severe hemorrhage
Whole blood	0–75 mg/L		
Fetal plasma	<0.01		
Hematocrit (Hct)	F: 0.36–0.46 M: 0.41–0.53	Dehydration, polycythemia	Leukemia, hemorrhage
Mean red cell Hb	26–34 pg/RBC	Macrocytosis	Microcytic hypochromic anemia
Mean red cell Hb concentration	310–370 g/L	Spherocytosis	Chronic iron deficiency anemia
Mean red cell volume	80–100 fL	Aplastic anemia, cirrhosis, folic acid, vitamin B ₁₂	Chronic iron deficiency, thalassemias, chronic anemia
White Blood Cell (WBC)			
Total count	$5.0\text{--}10.0 \times 10^9/\text{L}$	Acute leukemia, infections, surgery, trauma	Acute chronic leukemias, aplastic anemia, agranulocytosis
WBC Differential			
	% of total WBC		
Band neutrophils	3–6	Severe bacterial disease	
Segmented neutrophils	50–62	Diabetic acidosis, infarctions, inflammatory diseases, malignancies	
Lymphocytes	25–40		
Monocytes	3–7	Chronic lymphocytic leukemia	Lupus erythematosus, Hodgkin's disease
Eosinophils	0–3	Chronic inflammatory diseases	
Basophils	0–1	Allergies, parasites Myelofibrosis	

Fischbach, F., & Dunning, M. (2008). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott, Williams & Wilkins.

activator causes the conversion of prothrombin into thrombin, which then causes fibrinogen to form threads. This whole process takes 10 to 15 seconds. Prothrombin activator is the governing element in blood coagulation. Prothrombin time (PT) measures the defects in this extrinsic clotting mechanism, specifically fibrinogen (factor I), prothrombin (factor II), and factors V, VII, and X (Pagana & Pagana, 2009).

Drugs can either increase or decrease the PT. Common drugs that increase the PT include salicylates, steroids, sulfonamides, oral anticoagulants, antibiotics, quinidine, Dilantin, Aldomet, Tagamet, cathartics, and alcohol. Other drugs can decrease the PT: digitalis, oral contraceptives, corticosteroids,

chloral hydrate, barbiturates, vitamin K, Placidyl, Doriden, griseofulvin, Alupent, and rifampin. Be sure to list the drugs the client is taking on the laboratory requisition for the PT test.

Partial thromboplastin (PTT) or activated partial thromboplastin time (APTT) measures the intrinsic clotting mechanism factors (I, II, V, X, XI, and XII). There are five primary screening tests to diagnose suspected coagulation disorders (Fischbach & Dunning, 2008; Pagana & Pagana, 2009):

1. Platelet count, size, and shape
2. Bleeding time—the ability of platelets to function normally and the ability of capillaries to constrict their

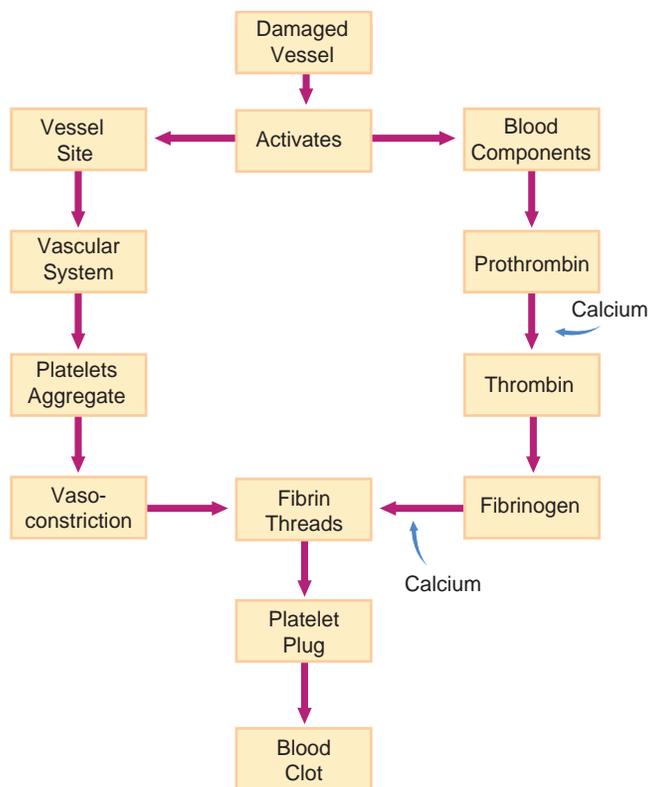

FIGURE 28-4 Blood Coagulation Flow Chart DELMAR/CENGAGE LEARNING

walls; prolonged with deficiencies in platelets and other clotting factors

3. PTT—measures the ability of the blood to clot; prolonged with any intrinsic factor deficiencies such as hemophilia A (factor VIII) and hemophilia B (factor X)
4. PT—measures the total quantity of prothrombin in the blood, monitors the effectiveness of coumarin therapy; prolonged with deficiencies in the extrinsic factors and vitamin K
5. Fibrinogen level—investigates abnormal PT and APTT, and screens for **disseminated intravascular coagulation** (DIC) (an acquired hemorrhagic syndrome characterized by uncontrolled formation and deposition of thrombi) and fibrin-fibrinogenolysis; levels increase with acute inflammatory reactions, trauma, coronary heart disease, and cigarette smoking and decrease in liver disease, DIC, cancer, primary fibrinolysis, and congenital hypofibrinogenemia.

Thrombin time (TT) measures the fibrinogen portion of the hemostatic mechanism; it is infrequently used today to evaluate the fibrinogen-to-fibrin reaction. Direct measurements of fibrinogen level and the increasing use of other tests have decreased the usefulness of TT (Pagana & Pagana, 2009).

Sickle Cell Test

The sickle cell test (hemoglobin S) is used to identify the sickle cell trait and sickle cell disease. A negative result, which is normal, indicates the absence of hemoglobin S. The presence of sickle cells causes a positive result, thus requiring

hemoglobin electrophoresis to determine the presence of the genetically transmitted deficit.

Hemoglobin electrophoresis refers to a laboratory test that uses an electromagnetic field (an anode [+], and a cathode [-], which are separated by cellulose acetate or starch gel) to identify various types of hemolytic anemia. Electrophoresis distinguishes between genetically transmitted homozygous and heterozygous hemoglobin S, which is responsible for sickle cell anemia. For example, if both genes carry hemoglobin S, it is called homozygous and the client has sickle cell disease; however, if only one gene has the abnormal hemoglobin S and the other gene has the normal hemoglobin A, the client is heterozygous, having the sickle cell trait. Electrophoresis is also used to identify fetal hemoglobin and distinguishes between thalassemia minor and major.

Sickle cell anemia is a blood disorder with multiple, recurring symptoms that not only causes the client pain from the clumping of RBCs in the joints but has widespread effects on other systems. Figure 28-5, on page 617, demonstrates the pathologic changes in the body and the resulting effects of sickle cell anemia.

Other common laboratory tests that measure hematologic functions are presented in Table 28-6 on page 618.

TYPE AND CROSSMATCH

A **type and crossmatch** is a laboratory test that identifies the client's blood type and determines the compatibility of blood between a potential donor and recipient (client). There are four basic blood types (A, B, AB, and O) that are determined by the presence or absence of A or B antigens, as shown in Figure 28-6 on page 619. **Antigens** are substances, usually proteins, that cause the formation of and react specifically with antibodies. **Antibodies** are immunoglobulins produced by the body in response to bacteria, viruses, or other antigenic substances. Type A and type B are antigens that are classified as **agglutinogens**, which are substances that cause **agglutination** (clumping of RBCs). **Agglutinins** are specific kinds of antibodies whose interaction with antigens is manifested as agglutination.

Blood types are also designated as either positive or negative, depending on the presence or absence of the Rh factor. Rh factor refers to an antigen found on the RBC. Rh positive means the antigen is present; Rh negative means the antigen is absent.

When factoring the four basic blood types with either the Rh-positive or Rh-negative factor, there are eight possible combinations (see the accompanying display on basic blood types). An individual's blood type is determined by heredity.

BASIC BLOOD TYPES

- A positive
- B positive
- AB positive
- O positive
- A negative
- B negative
- AB negative
- O negative

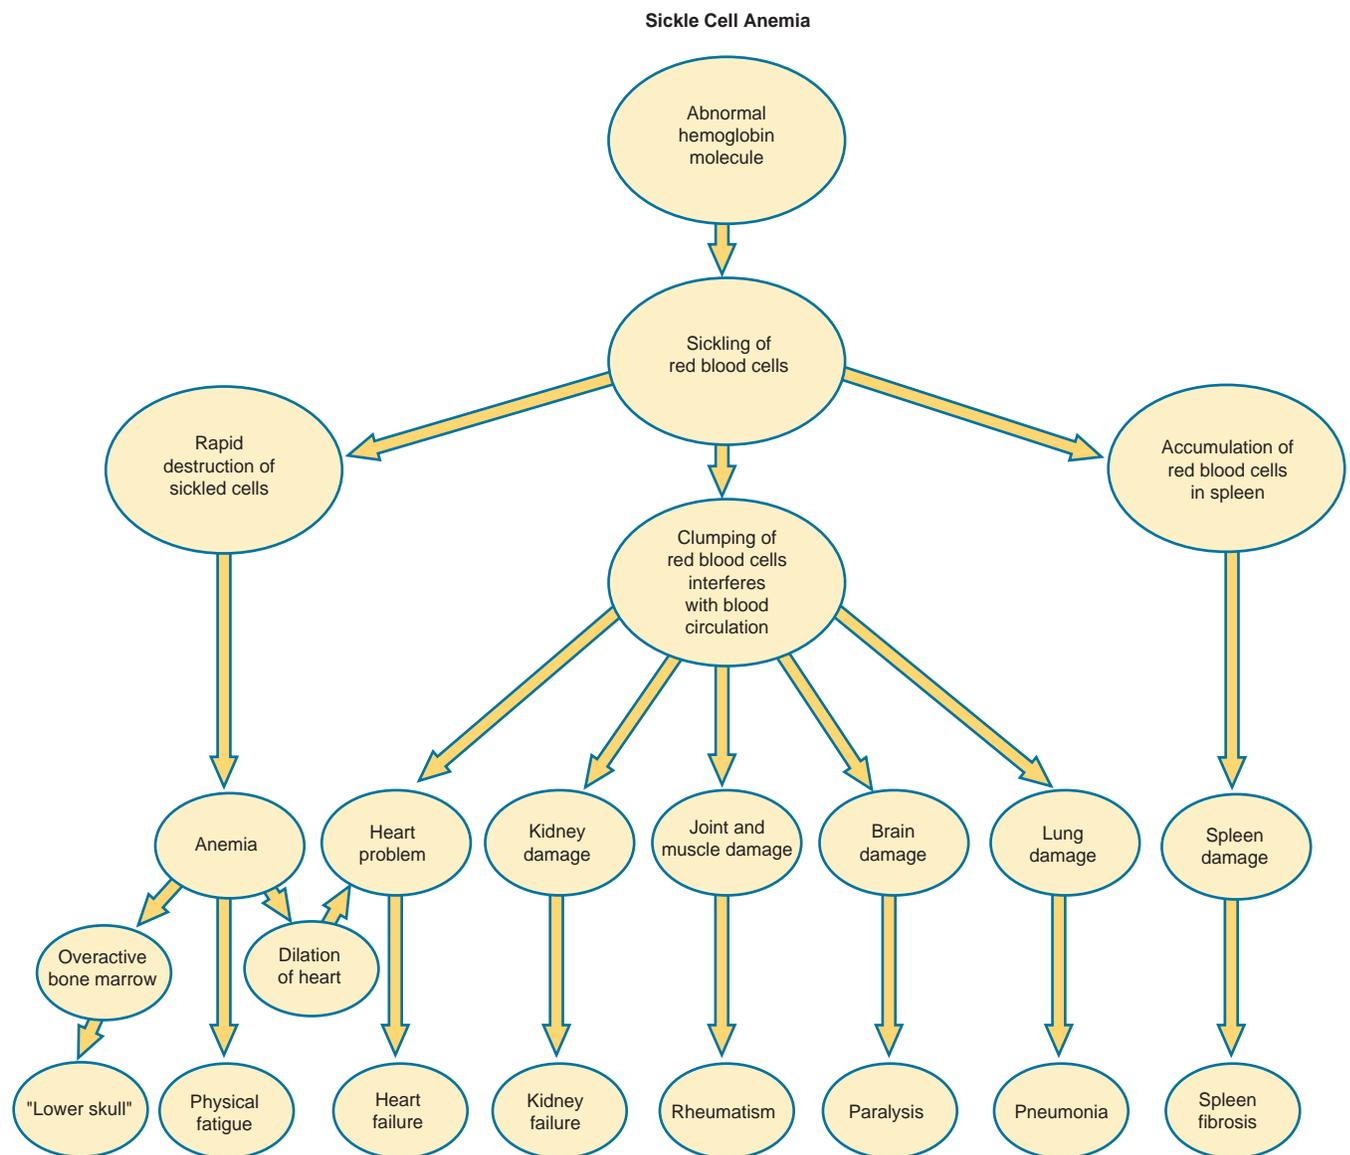

FIGURE 28-5 Sickle cell anemia: the clumping of red blood cells with their resulting effects on the body. DELMAR/CENGAGE LEARNING

Crossmatch determines the compatibility of the donor's blood with that of the recipient. In the laboratory, a sample of the recipient's blood is mixed with the blood of a possible donor. If the blood sample is compatible, the mixed sample does not agglutinate. For example, blood type A negative means that the person's blood contains the A antigen but does not contain the anti-Rh agglutinins. The first time the person is exposed to A-positive blood, either through a transfusion or by giving birth to an Rh-positive child, agglutination does not occur because the body has no antibodies against the antigen. However, once the body has had time to build up antibodies (agglutinins), agglutination will occur.

BLOOD CHEMISTRY

Sophisticated automated instrumentation makes it possible to conduct a wide variety of blood chemistry testing identifiers on a single sample of blood. The tests are grouped

under such headings as electrolytes, blood sugar, lipids, hormones, vitamins, minerals, and drug investigation. By measuring several blood chemicals at one time, a pattern of abnormalities is established, which allows for unsuspected diseases to be identified and which can lead to early diagnosis when symptoms are vague or absent (Fischbach & Dunning, 2008). The results may be reported as normal, low, high, panic, or toxic.

Blood Glucose

Glucose is a simple sugar formed from the digestion of carbohydrates and used by the cells for energy. Insulin is needed to transport glucose into the cells. Advances in technology have enabled the nurse, client, or caregiver to perform some laboratory tests at the bedside and in the home environment. Blood glucose monitoring, using either reagent strips or glucose meters, combined with a skin puncture lancet, is an example of

TABLE 28-6 Hematologic Function Studies

TEST	NORMAL RANGES	DIAGNOSTIC VALUE
Erythrocyte sedimentation rate (ESR or sed rate)	Westergren: F: <50 yr 0–25 mm/h >50 yr 0–30 mm/h M: <50 yr 0–15 mm/h >50 yr 0–20 mm/h	Alterations in the plasma proteins cause aggregation of the RBCs with an elevated ESR: moderately, with inflammatory diseases; high, with multiple myeloma, macroglobulinemias, hyperfibrinogenemias.
Haptoglobin	0.10–0.30 g/L 12–35 μmol/L	Haptoglobins bind with free hemoglobin released from the destruction of RBCs, conserving iron; decreased in any condition causing hemolysis of RBCs: hemolytic anemias (sickle cell anemia, hereditary spherocytosis, erythroblastosis fetalis), thalassemia, liver disease, transfusion reactions, systemic lupus erythematosus, prosthetic heart valve implants; increased with acute and chronic infections, inflammation, malignancies, steroid therapy, rheumatoid arthritis, ulcerative colitis, peptic ulcer, oral contraception, pregnancy.
Glucose-6-phosphate dehydrogenase (G6PD) (red blood cell)	F: 7.4–9.4 International Units/g hemoglobin, whites 6.5–9.3 International Units/g hemoglobin, African Americans M: 7.4–9.4 International Units/g hemoglobin, whites 6.6–10.8 International Units/g hemoglobin, African Americans	G6PD is an enzyme in RBCs that metabolizes glucose. The test measures enzyme deficiencies that are hereditary, sex-linked conditions carried on the female X chromosome, which causes hemolytic anemia. Clinical disease traits are found in males.
Osmotic fragility <0.30% saline >0.50% saline	0.30%–0.45% saline	Test measures the fragility of RBCs to aid in the diagnosis of hereditary spherocytosis. Increased in hereditary spherocytosis, spherocytosis resulting from autoimmune hemolytic anemia, severe burns, chemical poisoning, erythroblastosis fetalis, transfusion reactions, prosthetic heart valve transplantation. Decreased in sickle cell and iron deficiency anemia, polycythemia vera, hemoglobin C disease, thalassemia major, liver disease, obstructive jaundice, splenectomy.
Reticulocyte count (results reported in % of total erythrocytes)	Adults 0.5%–2.0% Children 0.5%–2.0% Infants 0.5%–3.5% Newborns 2.5%–6.0%	Used to differentiate between hypoproliferative and hyperproliferative anemias; to assess blood loss and bone marrow response to therapy. Increased in hemolytic and sickle cell anemia; hereditary spherocytosis; treatment of anemias from iron, vitamin B ₁₂ , and folic acid deficiencies. Decreased in aplastic, iron deficiency, and untreated pernicious anemias; chronic infection; radiation therapy.

Delmar/Cengage Learning

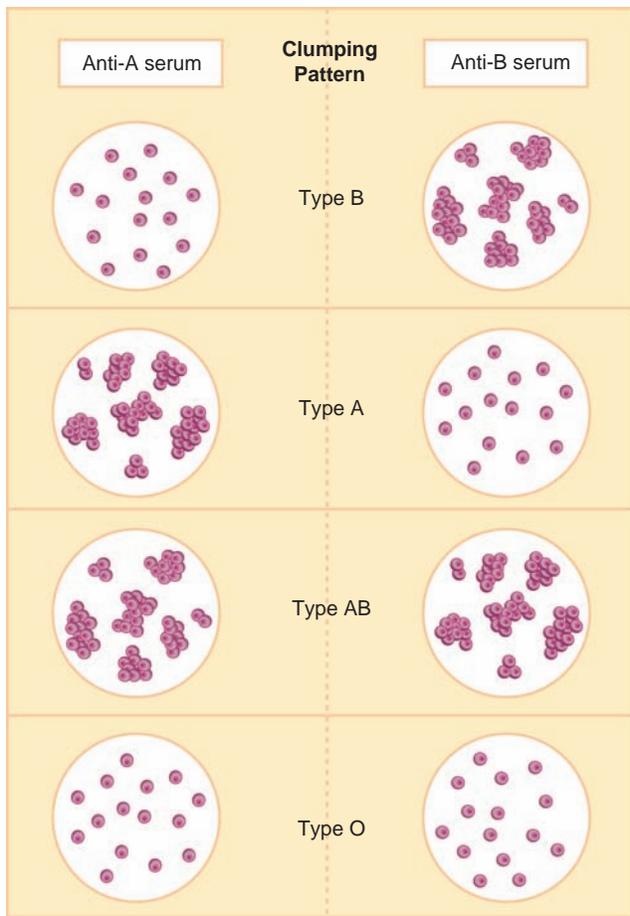

FIGURE 28-6 Blood Types DELMAR/CENGAGE LEARNING

such technology. The convenience of these tests has changed the clinical management of many clients with diabetes.

Obtaining a capillary blood sample through skin puncture is the preferred method of testing when frequent blood glucose monitoring is needed. There are primarily two methods used to measure capillary blood glucose. Both methods require a large drop of capillary blood obtained through skin puncture with a sterile lancet and a reagent strip. The first method requires that a drop of blood be applied to a special chemical reagent strip. The participant visually compares the reagent strip to a color chart on the reagent container. Accuracy may be compromised if the result falls between two colors and the participant must estimate the blood glucose level. Examples of reagent strips include Chemstrip BG, Glucostix, and TrendStrips.

A second method of blood glucose monitoring replaces the visual comparison method with the use of a portable meter. Once the blood is placed on the reagent strip, the meter provides an accurate measurement of the blood glucose level. Depending on the type of meter, some reagent strips must be inserted into the meter by the participant while other meters require that the blood droplet be applied to the strip that is already in the meter; see Procedure 28-5. Examples of meters include Accu-Chek Advantage (Accu-Chek), Accu-Chek Active (Accu-Chek), Bayer

Elite (Bayer), Glucometer (Bayer), OneTouch II (LifeScan), SureStep Pro (LifeScan), InDuo (LifeScan), and Precision (MediSense). With the variety of meters available, it is essential that the nurse and client using the device review the specific manufacturer's operating instructions and be familiar with the equipment. Failure to do so could compromise the test results.

Glucose measurement is also performed by venipuncture: fasting blood sugar (FBS) or nonfasting (usually 2 hours postprandial). The normal fasting value is 70 to 115 mg/dL and less than 120 mg/dL postprandial. The 2-hour postprandial blood sugar is drawn 2 hours after the client eats a meal. This test is used to screen for diabetes mellitus; if the results are abnormal, the practitioner may order a glucose tolerance test.

A glucose tolerance test is the most accurate test for diagnosing hypoglycemia and hyperglycemia (diabetes mellitus). The client is asked to fast until the test begins. The test is conducted as follows:

- Initial blood and urine specimens are obtained.
- An oral loading dose of glucose is administered.
- Blood and urine specimens are obtained at 30 minutes, 1 hour, 2 hours, 3 hours, and sometimes 4 hours after loading dose.

Figure 28-7 is a graphic presentation of the results of a glucose tolerance test, showing results that indicate hyperglycemia, normal glucose, and hypoglycemia.

Glucose results reveal deficits in either the digestion of carbohydrates or glucose metabolism (e.g., diabetes mellitus). Drugs, especially diuretics and steroids, can cause physiological changes resulting in elevated blood glucose values. Clients receiving IV fluids with a high glucose content need to have their glucose levels monitored for hyperglycemia.

Serum Electrolytes

An **electrolyte** is an element or compound that when dissolved in water or another solvent, separates into ions and provides for cellular reactions. Some electrolytes act on the cell membrane and allow for the transmission of electrochemical impulses in nerve and muscle fibers. Other electrolytes determine the activity of different enzymatically catalyzed reactions that are necessary for cellular metabolism.

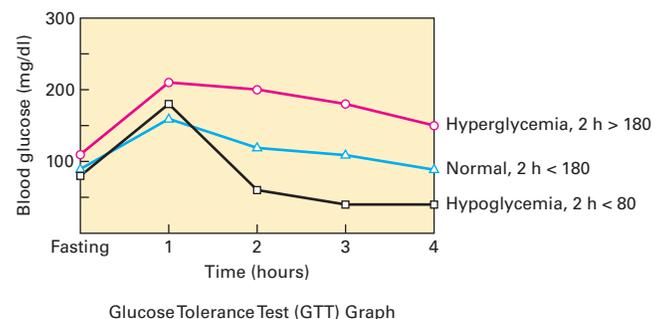

FIGURE 28-7 Glucose Tolerance Test (GTT) Graph DELMAR/CENGAGE LEARNING

Cations are ions that have a positive charge: sodium (Na^+), potassium (K^+), calcium (Ca^{++}), and magnesium (Mg^{++}). **Anions** are ions that have a negative charge: chloride (Cl^-) and phosphate (HPO_4^-).

The routine electrolyte laboratory tests are presented in Table 28-7. These tests measure the serum concentration of sodium, potassium, calcium, chloride, magnesium, and phosphate. See Chapter 33 for a detailed discussion of the intracellular and extracellular functions of electrolytes.

Blood Enzymes

Enzymes are globular proteins produced in the body that catalyze chemical reactions within the cells by promoting the oxidative reactions and synthesis of various chemicals, such as lipids, glycogen, and adenosine triphosphate (ATP). Enzyme tests play a key role in diagnosing the degree of tissue damage mainly to the myocardium and, to a lesser degree, to the brain.

TABLE 28-7 Routine Serum Electrolytes

ELECTROLYTE	NORMAL RANGES	CLINICAL SIGNIFICANCE
Sodium	135–148 mEq/L, adult 138–144 mEq/L, children 133–144 mEq/L, newborns	<ul style="list-style-type: none"> <i>Increased:</i> excessive intake of sodium without water; salt water drowning; high solute concentration (tube feeding, IV, hyperalimentation) without fluid correction; diarrhea; diabetes insipidus; primary aldosteronism; renal failure. <i>Decreased:</i> excessive intake of water without sodium (oral, IV therapy, tap water enemas); heart failure; cirrhosis; nephrosis and massive diuretic therapy.
Potassium (serum)	3.5–5.0 mEq/L, adult 3.4–4.7 mEq/L, children 3.7–5.9 mEq/L, newborns	<ul style="list-style-type: none"> <i>Increased:</i> high potassium intake (oral, IV therapy, rapid infusion of aged blood); renal disease; drugs (adrenal steroids, potassium-conserving diuretics, potassium penicillin, chemotherapeutic agents); Addison's disease; burns and other massive tissue trauma; metabolic and respiratory acidosis. <i>Decreased:</i> drugs (diuretics, digitalis); metabolic alkalosis; primary aldosteronism; Cushing's disease; vomiting and gastric suction.
Calcium	Total 8.4–10.5 mg/dL Ionized 1.13–1.32 mmol/L	<ul style="list-style-type: none"> <i>Increased:</i> hyperparathyroidism; bone catabolism (multiple myeloma, leukemia, bone tumors); immobility. <i>Decreased:</i> renal failure; sprue; pancreatitis; Crohn's disease; hyperphosphatemia; drugs (aminoglycosides, antacids containing aluminum, caffeine, cisplatin, corticosteroids, loop diuretics, Mithracin, phosphate).
Chloride	96–109 mEq/L, adult 98–105 mEq/L, children 94–112 mEq/L, newborn	<ul style="list-style-type: none"> <i>Increased:</i> hyperparathyroidism; drugs (ammonium chloride, ion exchange resin, phenylbutazone); metabolic acidosis; respiratory acidosis; dehydration. <i>Decreased:</i> prolonged vomiting and gastric suction; diarrhea; diuretics (ethacrynic acid and furosemide).
Magnesium	1.3–2.0 mEq/L, adult 1.6–2.6 mEq/L, children 1.4–2.9 mEq/L, newborn	<ul style="list-style-type: none"> <i>Increased:</i> chronic renal failure, drugs (magnesium sulfate, antacids, enemas containing magnesium, sedatives); acute adrenocortical insufficiency. <i>Decreased:</i> chronic diarrhea and alcoholism; nontropical sprue; steatorrhea; hereditary malabsorption; starvation; bowel resection; diuretics (mannitol, urea, glucose); hypoparathyroidism.
Phosphate	2.7–4.5 mg/dL, adult 4.5–5.5 mg/dL, children 4.5–6.7 mg/dL, newborn	<ul style="list-style-type: none"> <i>Increased:</i> renal insufficiency; intake, IV solutions and enemas; blood transfusion; muscle necrosis; hypoparathyroidism. <i>Decreased:</i> alcohol withdrawal; hyperventilation; diabetic ketoacidosis; phosphate-binding antacids.

Fischbach, F., & Dunning, M. (2008). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott, Williams & Wilkins.

Elevations in plasma levels of intracellular enzymes occur during myocardial **necrosis** (tissue death as the result of disease or injury). Enzymes are released into the bloodstream in proportion to the degree of cellular damage.

Enzymes are not used as single diagnostic values in determining a diagnosis but are viewed in relation to other diagnostic studies. The results from several diagnostic procedures will assist the practitioner in determining the cause of clinical symptoms.

Creatine phosphokinase (CPK) is an enzyme used to convert creatine to phosphocreatine and adenosine diphosphate (ADP) to ATP. ATP provides energy to the cells to carry on metabolism. CPK levels indicate the degree of normal tissue catabolism. Elevated values of CPK reflect the damage that has occurred in tissue with a high CPK content. For example, the myocardium has a high CPK content; when the client has a myocardial infarction (MI), CPK is elevated because the heart's tissue has been damaged, requiring ATP to repair the damaged myocardium.

CPK has three isoenzymes of differing molecular structure that are present in different tissue (see Table 28-8). The isoenzymes provide clinical data to the practitioner in diagnosing the site and extent of tissue injury.

Aspartate aminotransferase (AST) is one of two enzymes that catalyze the transfer of the nitrogenous portion of an amino acid to an acid residue. It is an intracellular enzyme found mainly in the liver, heart, skeletal muscles, kidney, pancreas, and RBCs. The normal range is:

- Adults and children: 4–36 International Units/L
- Newborns: 4 times as high as those of adults

Blood for AST is drawn to determine:

- A recent MI (together with the CPK and lactic dehydrogenase levels)
- Acute hepatic disease

ISOENZYME	NORMAL RANGES	TISSUE SOURCE
CPK ₁ (BB)	0%	Primarily in brain; indicative of cerebrovascular accident
CPK ₂ (MB)	0%–4%	Exclusively in myocardium; indicative of myocardial infarction
CPK ₃ (UU)	96%–100%	Found in skeleton and myocardium/skeletal muscle disorders

Fischbach, F., & Dunning, M. (2008). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott, Williams & Wilkins.

- The client's progress and prognosis in cardiac and hepatic diseases

Certain drugs may increase the AST (see the accompanying display). Remember to note drugs on the laboratory requisition when a client is taking a drug that can influence the results of testing.

Lactate dehydrogenase (LDH), a cellular enzyme that contributes to carbohydrate metabolism, catalyzes the reversible conversion of muscle pyruvic acid into lactic acid. The diagnostic value of serum LDH is limited because it is present in almost all body tissue; however, through electrophoresis, five isoenzymes can be related to specific tissue (see Table 28-9).

The percentage of isoenzymes changes with tissue damage. For example, in an acute MI the LHD₁ becomes greater than LDH₂ 12 to 48 hours postinfarction.

DRUGS THAT CAN ELEVATE ASPARTATE AMINOTRANSFERASE (AST)

- Antibiotics
- Contraceptives
- Cortisone
- Digitalis
- Flurazepam
- Guanethidine
- Indomethacin
- Isoniazid
- Mithramycin
- Narcotics
- Pyridoxine
- Rifampin
- Salicylate
- Theophylline
- Vitamin A

ISOENZYME	RANGES OF % OF TOTAL LDH	TISSUE SOURCE
LDH ₁	17–27	Primarily in heart, kidneys, RBCs
LDH ₂	29–39	Primarily in heart, kidneys, RBCs
LDH ₃	19–27	Primarily in lungs, to a lesser extent in pancreas, thyroid, adrenal glands, lymph nodes
LDH ₄	8–16	Liver and skeletal tissue
LDH ₅	6–16	Liver and skeletal tissue

Fischbach, F., & Dunning, M. (2008). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott, Williams & Wilkins.

α -Hydroxybutyrate dehydrogenase (HBD) is the total LDH forced to act on α -ketobutyric acid rather than lactic or pyruvic acid. It is a serum measurement used when the assay of isoenzymes of LDH is not available in the laboratory. Once an MI has been diagnosed, the HBD has clinical significance by indicating the duration of tissue injury. HBD will remain elevated up to 2 weeks after infarction.

Alkaline phosphatase (a zinc-dependent enzyme) influences bone calcification and lipid and metabolite transport. The normal plasma range is 30 to 120 International Units/L. Alkaline phosphatase is used to detect:

- Osteoblastic activity
- Hepatic tumors or abscess
- Impaired zinc status
- The response of vitamin D in the treatment of deficiency-induced rickets

Certain drugs can cause a mild to moderate elevation in the alkaline phosphatase (see the accompanying display).

Acid phosphatase is an enzyme found primarily in the adult male prostate gland. It is used clinically to distinguish between encapsulated and metastatic carcinoma of the prostate gland. If the cancer cells are contained within a capsule, the acid phosphatase levels remain normal (0.2 to 0.8 International Units/L).

Glucose-6-phosphate dehydrogenase is an RBC enzyme. The normal range and the clinical significance are shown in Table 28-6.

The main proteolytic enzymes for digestion are contained in the pancreatic juices (trypsin, chymotrypsin, and carboxypeptidase). The common laboratory tests for measuring the digestive enzymes are presented in Table 28-10. Client must fast 1 to 2 hours before having a serum amylase drawn. If the client has eaten and receives a narcotic at the same time, the serum results could be invalidated.

DRUGS THAT CAN ELEVATE ALKALINE PHOSPHATASE

- Allopurinol
- Antibiotics
- Ergosterol
- Estrogen
- Isoniazid
- Methyldopa
- Methyltestosterone
- Oral contraceptives
- Phenothiazine tranquilizers
- Procainamide
- Propranolol
- Sulfonamides
- Tolbutamide

Cholinesterase is an enzyme manufactured in the liver that is responsible for the breakdown of acetylcholine and other choline esters. The normal range for cholinesterase in adults and children is 8 to 18 International Units/L. It is elevated in diabetes, hyperthyroidism, and nephrotic syndrome. Decreases in cholinesterase can result from severe anemias and infections, exposure to some insecticides, liver disease, malnutrition, shock, and uremia.

Prostate-Specific Antigen

Prostate-specific antigen (PSA) is a glycoprotein found in the prostate tissue. PSA is used in combination with digital rectal examinations to detect prostate cancer; see Chapter 27 for a discussion regarding digital rectal examinations. The normal values are: men less than 40 years, <2.0 ng/mL (<2.0 mcg/L) and men 40 years and older, <2.8 ng/mL (<2.8 mcg/L). PSA may fluctuate over time, and therefore the test results should be confirmed several weeks after the initial testing before proceeding with further invasive testing such as prostate biopsy.

TABLE 28-10 Digestive Enzymes

ENZYMES	NORMAL RANGES	CLINICAL SIGNIFICANCE
Alanine aminotransferase	10–60 units/L	Hepatocellular damage
Aldolase	1.5–8.1 units/L	Anemia (hemolytic and megaloblastic); granulocytic leukemia; metastatic carcinoma; skeletal muscle tissue damage
Amylase	25–125 units/L	Pancreatitis
Aspartate aminotransferase	5–40 units/L	Hepatitis; infectious mononucleosis; cirrhosis
Lipase	10–140 units/L	Acute pancreatitis
5'-Nucleotidase	0–17 units/L	Biliary cirrhosis; extrahepatic obstruction; hepatic carcinoma; metastatic neoplasia of liver

Fischbach, F., & Dunning, M. (2008). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott, Williams & Wilkins.

Blood Lipids

Coronary heart disease (CHD) is the number one killer of both men and women in the United States. According to the National Center for Health Statistics (1999), some 7 million Americans suffer from CHD and more than 500,000 Americans die of heart attacks caused by CHD each year. The National Cholesterol Education Program and the American Heart Association have published guidelines and recommendations regarding the need to improve laboratory detection of hypercholesterolemia and treatment. Total blood cholesterol is the most common measurement of blood cholesterol. Cholesterol is measured in milligrams per deciliter of blood (mg/dL). Blood cholesterol for adults is classified by levels.

Exogenous cholesterol is present in the diet and absorbed into the gastrointestinal tract. Endogenous cholesterol is formed in the liver and other cells in the body. As much as 80% of cholesterol is converted into cholic acid to form bile salts. Cholesterol is also needed:

- Throughout the body for the formation of membranes
- By the adrenal glands to form adrenocortical hormones
- By the ovaries to form progesterone and estrogen
- By the testes to form testosterone
- By the skin to provide a water-soluble barrier

Cholesterol and other fats cannot dissolve in the blood; they have to be transported to and from the cells by special carriers called **lipoproteins** (blood lipids bound to protein). The types of lipoproteins are described in the following, but the ones to be most concerned about are low-density lipoprotein (LDL) and high-density lipoprotein (HDL).

- Chylomicrons—mainly ingested triglycerides
- Very low-density lipoproteins (VLDLs)—mainly endogenous triglycerides
- LDLs—moderate amounts of phospholipids with 50% cholesterol
- HDLs—50% protein

LDL is the major cholesterol carrier in the blood. When too much LDL circulates in the blood, it can slowly build up in the walls of the arteries feeding the heart and brain. The buildup of LDL and other substances causes the formation of **atherosclerotic plaque**, a thick, hard deposit that can clog the arteries in the heart and brain. A **thrombus** (a blood

clot) can develop around the plaque that blocks the flow of blood to part of the heart muscle and causes an MI. If the thrombus blocks the flow of blood to part of the brain, it results in a cerebrovascular accident (CVA). High levels of LDL cholesterol (more than 130 mg/dL) increase the risk for CHD; this type of cholesterol is often called bad cholesterol.

HDL accounts for one-third to one-fourth of blood cholesterol and carries the cholesterol away from the arteries and back to the liver, where it is removed from the blood. HDL removes excess cholesterol from atherosclerotic plaques, slowing their growth. HDL is known as good cholesterol because a high level of HDL seems to decrease the risk of CHD.

Triglycerides are the chemical form in which most fat exists in food as well as in the body; they account for more than 90% of dietary intake and comprise 95% of fat stored in tissues. Triglycerides are insoluble in water and are the main plasma glycerol ester. An increase in triglyceride levels can be detected by plasma measurements; this test evaluates suspected atherosclerosis and measures the body's ability to metabolize fat.

Table 28-11 shows the relationship of lipids to a client being at risk for CHD. The practitioner must examine all of the lipid levels together. For instance, a client whose total cholesterol, LDL cholesterol, and triglycerides are all slightly elevated and whose HDL is slightly decreased is at a greater risk for CHD than someone whose cholesterol is elevated but whose HDL is also high.

The nurse must prepare clients for the lipid level testing by teaching them to:

- Eat a regular diet 3 to 7 days before the test
- Fast 12 to 14 hours before the test
- Refrain from vigorous exercise 24 hours before the test
- Refrain from caffeine and nicotine 24 hours before the test
- Per practitioner order, withhold drugs 24 hours before the test (many drugs affect the serum triglyceride level)
- Be aware that repeat tests may be necessary to confirm elevated levels because results can vary 15% or more from day to day

Diurnal variation causes triglycerides to be lowest in the morning and highest around noon (Fischbach & Dunning, 2008).

TABLE 28-11 Relationship of Lipids to Coronary Heart Disease Risk

LIPID	DESIRABLE LEVELS	BORDERLINE CHD RISK	HIGH CHD RISK
Cholesterol	<200 mg/dL	200–239 mg/dL	>240 mg/dL
LDL cholesterol	<130 mg/dL	130–159 mg/dL	>160 mg/dL
HDL cholesterol	>40 mg/dL	35–40 mg/dL	<35 mg/dL
Triglyceride	<250 mg/dL	250–500 mg/dL	>500 mg/dL

Fischbach, F., & Dunning, M. (2008). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott, Williams & Wilkins.

Several factors can affect the test results. The client's position, such as lying down, causes a redistribution between vascular and extravascular compartments. For instance, after 5 minutes in a recumbent position, total plasma cholesterol may be significantly reduced (10%–15% decrease after 20 minutes). Recent trauma and severe infections may decrease the cholesterol level by 10% to 30%. Because pregnancy increases the HDL, LDL, and VLDL levels 20% to 30%, postpone testing 3 to 4 months postdelivery.

Therapeutic Drug Monitoring

Therapeutic drug monitoring is performed when a quantitative relationship exists between the drug concentration and drug response or toxicity is known. For a drug concentration to be significant:

- It must be determined in a blood sample drawn after the drug has been completely absorbed from the oral or intramuscular route.
- It has had an opportunity to be distributed to its site of action.
- Its steady state has been reached (e.g., four to five half-lives must have passed).

For instance, with digoxin (a cardiac medication, administered on a daily schedule) the absorption and distribution phases may take 6 to 12 hours to complete. For a meaningful interpretation, the blood specimen should be drawn at least midway through the elimination phase (6 hours before the next dose). If the specimen is drawn just before the next dose, one obtains a trough concentration, whereas a specimen drawn 6 to 12 hours after dosing yields a peak concentration. For digoxin, the swing between peak and trough would be expected to be minimal because the drug is given at intervals that are less than the drug's terminal half-life (42 ± 19 hours). Generally, such sampling is most significant after steady state has been reached (about 8 days for digoxin). Trough and peak sampling help the practitioner to determine the dose rate, keeping the drug level below toxic value.

Arterial Blood Gases

Blood gas results are reported in millimeters of mercury (Hg). Normal ABG ranges are:

- P_{O_2} 75–100 mm Hg
- P_{CO_2} 35–45 mm Hg
- pH 7.35–7.45

The clinical interpretation of gases studies the relationship between the gases. For example, a low P_{O_2} combined with a high P_{CO_2} may indicate bronchiole obstruction or that the alveoli are filled with fluid. In both situations, there is an impairment of gaseous exchange. See Chapter 32 for a complete discussion.

URINE ANALYSIS

Urine is an ultrafiltrate of plasma that contains many of the substances carried in the blood. Urine samples are easy to obtain and provide the practitioner with information to evaluate the client's health status.

Reagent dipsticks provide the nurse with a means of simple and quick testing for routine screening urinary evaluations of protein, glucose, ketones, hemoglobin, urobilinogen, nitrates, and pH. The sticks contain a reagent that changes colors in the presence of specific substances; the color change is observed and compared to a chart for the presence of abnormal levels of substances.

The components of the routine urinalysis are identified, and certain components are described; urine studies that measure electrolytes, enzymes, hormones, and other substances are not presented in this chapter. Urine is examined for cytology to detect cell changes caused by malignancies or inflammation. Toxicological analysis of urine is performed to detect drugs that have been used and abused.

Routine Urinalysis

The two major components of a routine urinalysis (UA) are macroscopic analysis and microscopic analysis. Macroscopic analysis includes color, appearance, odor, specific gravity, pH, protein, glucose, ketones, blood, bilirubin and urobilinogen, nitrite, and leukocyte esterase. Microscopic analysis includes RBCs, WBCs, epithelial cells, casts and crystals, and other substances such as bacteria, yeast, mucus, spermatozoa, and parasites. See the accompanying display for some of the normal urine values.

The best time to collect urine for a UA is in the morning after the first voiding; urine that has accumulated in the bladder overnight is concentrated and may lead to invalid results. The urine sample should be evaluated within 1 hour of collection or refrigerated until it can be examined; allowing the sample to be exposed to room temperature may alter the components (e.g., the glucose level may drop or bacteria may grow).

The pH is governed by the hydrogen ion concentration of the urine. Disorders such as diabetes mellitus, dehydration, diarrhea, emphysema, and starvation make the urine acidic. Chronic renal failure, renal tubular acidosis, urinary tract infections, and salicylate poisoning cause the urine to be alkaline.

Urine specific gravity (USG) measures the density and concentration of particles in the urine with the density of water, which is 1.000. USG measurement provides information regarding the client's hydration status and functional ability of the kidneys. Nurses measure USG as part of an assessment of fluid balance using one of three methods:

- The refractometer, which resembles a small telescope, is the most accurate method (Flasar, 2008). Place a drop of urine on a slide at the end of the scope, keeping the instrument level; hold the refractor up to a light. The beam of light deviates when it enters the solution, giving the refractive index; for example, if the light beam is at the 1.022 mark, this figure is recorded as the USG. The refractor also measures the protein content in the same drop of urine; protein in the urine can cause the USG to be falsely high.
- The multiple-test dipstick has a separate area with a reagent USG. As the indicator changes color, compare it with the chart that accompanies the dipstick for the numeric value of the USG.

- The urinometer or hydrometer is the oldest method of bedside monitoring of USG. Put a sample of 10 to 20 mL in the small cylinder, then float the bulb-shaped instrument in the urine; read the USG at the meniscus, using the calibrated scale as shown in Figure 28-8.

When questions arise regarding the accuracy of the USG, obtain a urine osmolality test. The osmolality test is more accurate because it measures the total number of particles in a solution.

When the blood levels of glucose exceed the renal threshold (180 mg/dL), glucose spills into the urine. Multiple agents are available for measuring the glucose content of urine. These agents are not as accurate a test method as blood glucose levels.

Some of the reducing agents can measure other products, such as protein and blood, along with the glucose (Clini-test and Clinitix). Each product has specific step-by-step

instructions for performing the test and reading the results. Teach the client how to perform these urine tests.

Ketones are products of fatty acid metabolism and are completely metabolized by the liver under normal conditions. The most common cause of ketonuria is diabetes. However, with strenuous exercise, starvation, and sustained febrile and hypoxic conditions, an increase in fatty acid metabolism causes ketoacidosis, resulting in ketone bodies in the urine.

Normally the urine is free from blood cells and casts. When the renal system is impaired as in renal damage or failure, nephritis, and stones and infections in the urinary tract, the following can occur:

- Bleeding with resulting RBCs in the urine
- Accumulation of epithelial cells with cast formation
- WBCs, which indicate infections

NORMAL URINE VALUES

• pH	4.6–8.0	Adults and children
	5.0–7.0	Newborns
• Color	Amber-yellow	
• Specific gravity	1.010–1.020	
• Protein:		
Qualitative	None	
Quantitative	10–100 mg/24 h	
• Glucose	None	
• Ketones	None	
• Blood	0–2 RBCs	

STOOL ANALYSIS

Stool analysis is used to determine the various constituents of the stool for diagnostic purposes such as diseases of the gastrointestinal tract, the liver, and the pancreas. The normal constituents found in stool include epithelial cells shed from the gastrointestinal tract, small amounts of fats, bile pigments in the form of urobilin, gastrointestinal and pancreatic secretions, and electrolytes. The bacterial degradation of bile pigments to stercobilin causes the brown color of feces, and the characteristic odor is caused by bacterial action on proteins and other residues. The distal portion of the colon causes the shape and caliber of normal stools, and the normal consistency is described as “plastic.” The nurse may observe alterations in color, odor, shape, or consistency; these changes may indicate the presence of disease.

Urobilinogen is derived from the normal bacterial action of intestinal flora on bilirubin. It is increased with severe hemolysis of RBCs and decreased with most biliary obstructions.

Occult Blood

Chemical screening for occult blood is the most commonly performed test of feces. When blood is invisible on inspection, it is said to be **occult**; it is blood that can be detected only through a microscope or by chemical means. In the gastrointestinal tract, the digestive process acts on blood, making it occult. Random sampling for occult blood is done to diagnose gastrointestinal bleeding, ulcers, and malignant tumors. Colorectal cancer is a leading cause of cancer deaths in the United States. Most colorectal cancers begin as a **polyp**, a small abnormal growth of tissue, in the wall of the colon. As the polyp grows, it may cause bleeding from the rectum, blood in the stool, or a change in the shape of the stool. Screening for colorectal cancer begins with fecal occult blood testing. The American Cancer Society (ACS, 2008) recommends that people over 50 who are at average risk have a fecal occult blood test every year.

See Chapter 27 for the complete set of guidelines for colorectal screening as developed by the ACS. (See Table 28-14 later

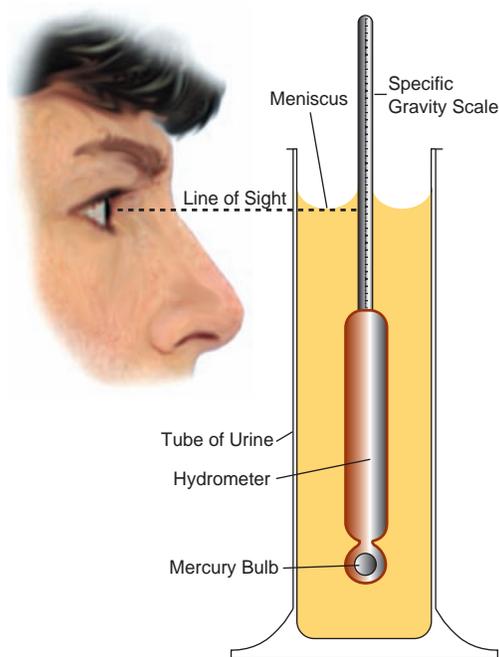

FIGURE 28-8 Urinometer DELMAR/CENGAGE LEARNING

TABLE 28-12 Common Contrast-Mediated Studies

STUDY	VISUALIZATION/TECHNIQUE	INDICATIONS
Barium swallow (esophagography)	Esophageal; swallowing a barium solution, using fluoroscopic and cineradiographic techniques	Dysphagia, heartburn, or regurgitation of food, esophageal reflux, stricture, polyps, and other diseases
Upper gastrointestinal series (UGI)	Lower esophagus, stomach, duodenum, and upper jejunum; ingestion of a solution of barium sulfate using x-ray and fluoroscopic techniques	Pain, heartburn, diarrhea, weight loss, anorexia, nausea or vomiting of unknown etiology, strictures and varices in lower esophagus, ulcer, inflammation of stomach or small bowel, tumor, obstructions
Barium enema (BE) or lower gastrointestinal series (LGI)	Colon; x-ray and fluoroscopic techniques after rectal instillation of both air and barium (double-contrast study)	Rectal bleeding, weight loss, anemia of unknown etiology, small lesions and polyps, suspected abnormality in bowel motility or obstruction, diverticula, megacolon, or other structural changes
Oral cholecystography (OCG)*	Gallbladder; 12 to 14 hours after oral ingestion of dye, usually iopanoic acid the evening before	Pain of unknown etiology, suspected gallstones, tumor, or a fistula between the biliary system and GI tract
Intravenous cholangiography (IVC)*	Hepatic and common bile ducts for stones and stricture; IV contrast medium iodipamide with plain and tomographic films taken 15 minutes after the injection and periodically for up to 8 hours	Gallbladder not visualized on an OCG, if the client is unable to absorb the oral dye for an OCG, or if the symptoms persist after cholecystectomy
T-tube cholangiogram*	Common bile ducts and gallbladder; during surgery after placement of the tube in the duct or 7 to 10 days after gallbladder surgery, injection of an iodinated contrast medium into the T-tube with x-ray and fluoroscopic techniques	Patency of the common bile duct before T-tube removal, detection of stones, duct fistula, or biliary tract strictures and neoplasms
Percutaneous transhepatic cholangiogram (PTHC)*	Intrahepatic, extrahepatic, and biliary ducts, and gallbladder; an iodinated contrast medium is injected into the liver and, with the aid of fluoroscopy, into the bile duct	Jaundice to determine obstruction to biliary flow caused by stones, tumor, stricture, or anatomic abnormalities
Antegrade pyelography	Kidneys' collecting system; injection of an iodinated contrast medium into the renal pelvis with the aid of fluoroscopy or ultrasound and a pressure reading within the kidney, measured by a manometer	Kidneys are unable to excrete dye given for intravenous pyelography, if ureteral obstruction is present, or if a cystoscopy is contraindicated
Retrograde urethrography	Male urethral membranous, bulbar, and penile areas or female urethra; instillation of an iodinated contrast medium into a catheter with films and fluoroscopy techniques	Men postoperatively to evaluate urethral repair and to detect urethral abnormalities
Retrograde cystography*	Urinary bladder; air or an iodinated contrast medium is instilled into a bladder catheter, the catheter is clamped, and films are taken while the catheter is clamped (if films are taken during emptying of the bladder, the test is called a voiding cystourethrogram)	Detect rupture and pathology of the urinary bladder

(Continues)

TABLE 28-12 (Continued)

STUDY	VISUALIZATION/TECHNIQUE	INDICATIONS
Retrograde ureteropyelography* (retrograde pyelogram)	Ureters and renal collecting system; diatrizoate sodium is injected via ureteral catheters inserted by cystoscopy, x-rays are taken with the catheters in place and during and after their removal	Detect presence and location of a ureter or kidney stone, abnormalities or pathology of the renal system, when the client is allergic to iodinated contrast medium
Intravenous pyelogram (IVP)* (excretory urogram [EUG])	Calyces and pelves of the kidneys, ureters, and urinary bladder (KUB); an abdominal x-ray is taken (KUB), followed by an injection of an iodinated contrast medium and serial x-rays	Abnormalities of the kidneys, ureter, or bladder
Sialography	Salivary ducts: sublingual, submaxillary, submandibular, and parotid; injection of an iodinated contrast medium into the duct with films taken with the client placed in various positions	Persistent pain and edema in the salivary glands, detect inflammation of the gland or stones, tumors, or strictures that obstruct the salivary ducts
Arthrography	Joint and soft tissues: meniscus, cartilage, ligaments, and structures of the joint capsule; rotator cuff, subacromial bursa; joint site anesthetized and injected with a contrast medium and various x-ray views of the joint site	Unexplained joint pain, traumatic ligament disorders (tears and lacerations), dislocations, and to detect abnormalities of the synovial membrane or shoulder, evaluate injury following onset of arthritis, or perform minor surgical procedures on a joint
Bronchography	Tracheobronchial tree; injection of an iodinated oil contrast medium via a catheter inserted into the trachea and bronchi with x-rays taken with the client placed in various positions	Detect obstructions caused by tumors, cyst, or foreign object; determine cause of persistent hemoptysis and recurring pneumonia
Hysterosalpingography	Uterine cavity and fallopian tube; injection of a water-soluble or oil-based iodinated contrast medium via a cannula inserted into the cervix, the flow of the medium is viewed fluoroscopically and x-rays are taken	Abnormalities of the female reproductive system such as tubal patency, obstructions, adhesions; to detect cause of repeated spontaneous abortions; and to evaluate tubal ligation or tubal reanastomosis
Myelogram	Spinal subarachnoid space or the spinal canal; injection of a contrast medium into the spinal canal via lumbar puncture under fluoroscopy to view the flow of the medium toward the head as the table is tilted and x-rays are taken	Determine abnormalities and cause of persistent, chronic pain, and to detect lesions of the spinal cord (meningeal tumors, cysts, or ruptured intervertebral disks)

Note: *Test should be performed before any study using barium as the contrast medium.
Delmar/Cengage Learning

in this chapter for the diagnostic procedures: colonoscopy and proctosigmoidoscopy.)

When the practitioner is using occult blood to confirm suspicions of a gastrointestinal disorder, the client is placed on a 3-day diet free of meat, poultry, and fish to decrease the possibility of a false-positive result. Common drugs that can cause a positive test for occult blood are salicylate, steroids, and indomethacin.

Parasites

The gastrointestinal tract can harbor parasites and their eggs (ova). Some of these parasites are harmless, whereas others cause clinical symptoms. With the exception of pinworms (which can enter the body through both the oral and anal routes), all other common parasites gain portal entry through the mouth by ingesting contaminated water or food. Roundworm, hookworm,

whipworm, tapeworm, *Trichinella spiralis*, and *Entamoeba histolytica* are common parasites found in the United States.

CULTURE AND SENSITIVITY TESTS

Culture refers to the growing of microorganisms to identify the pathogen. Any secreted or excreted body fluid, drainage, or tissue sample can be cultured for microorganism identification: blood, eye and ear, nose and throat, skin, nails, hair, genital and rectal areas, sputum, bronchial washings, feces, urine, tissue biopsy, cerebrospinal tissue, semen, gastrointestinal fluid, and other body fluids. In combination with the culture, microorganisms are tested for sensitivity to specific antibiotics. Culture and sensitivity (C&S) tests are performed to identify both the nature of the invading organisms and their susceptibility to commonly used antibiotics. Sensitivity allows the practitioner to select the appropriate antibiotic therapy.

The nurse is usually responsible for collecting specimens for C&S testing; refer to Table 28-1. Standard precautions are used to collect the specimen from the site at a time when the microorganisms are present in large numbers, before the initiation of antibiotic therapy. The specimens are collected in sterile, disposable containers that take into consideration the microorganism's special needs for survival, such as anaerobic environment or special media requirements such as liquid (broth), solid (agar), or cell culture lines. Label the specimens with all pertinent information such as the client's history and status (e.g., temperature), site, time, and test ordered; take the specimen to the laboratory immediately to avoid overgrowth or death of the microorganisms.

PAPANICOLAOU TEST

Papanicolaou test (smear method of examining stained exfoliative cells), commonly called a Pap smear, is done to evaluate the cell maturity, metabolic activity, and morphologic variations of the cervical tissue. Papanicolaou testing can also be used for tissue specimens from other organs, such as bronchial aspirations and gastric secretions.

The ACS recommends the revised clinical guidelines of the American College of Obstetricians and Gynecologists for the frequency of Pap tests other cervical screening and still recommends an annual gynecology exam that includes an annual pelvic examination for women age 21 and older. ACOG guidelines are evidence based and incorporate new tests for detecting cervical changes as well as improved understanding of the pathology and evolution of cancer. The ACS (2008) recommends:

- First screen: First Pap test approximately 3 years after first intercourse or at age 21, whichever occurs first
- Up to age 30: annual cervical cytology because women under 30 are at higher risk for acquiring human papillomavirus (HPV) that may cause precancerous changes
- Women age 30 and older: Two options are available:
 1. Cervical cytology testing alone: If a woman age 30 or older has negative results on three consecutive annual cervical cytology tests, then she may be rescreened with cervical cytology alone every 2 to 3 years.

2. Women who test negative on a cervical cytology test and an FDA-approved test for HPV should be rescreened with both tests every 3 years; women who test negative on only one of the tests should be screened more frequently.

Exceptions are women who are infected with HIV, are immunosuppressed, were exposed to diethylstilbestrol (DES) in utero, or were previously diagnosed with cervical cancer; such women may require more frequent cervical screening. Women who have had a hysterectomy but have a history of abnormal cell growth should be screened yearly until they have three consecutive negative vaginal cytology tests, after which time routine screening may be discontinued.

Screening may be discontinued in women who have had a hysterectomy with removal of the cervix for benign reasons and with no history of abnormal or cancerous cell growth. The ACS calls for cessation of testing in the not-high-risk groups at age 70 and the U.S. Prevention Services Task Force by age 65.

To increase the accuracy of a cervical specimen, the client should be told to avoid intercourse, douches, and vaginal creams for 24 hours before the test. The vaginal speculum should not be lubricated. This test should not be performed if the client is menstruating because the specimen will be unsuitable for cytologic study.

RADIOLOGIC STUDIES

Radiography (the study of x-rays or gamma ray–exposed film through the action of ionizing radiation) is used by the prescribing practitioner to study internal organ structure. Radiographic procedures can be either noninvasive or invasive, and client preparation varies accordingly. Although noninvasive procedures such as plain-film x-rays, tomography, and barium sulfate as a contrast medium do not require a signed consent form, the clients should be told what to expect. The exception is mammography, which uses xeroradiography; these clients are required to sign consent forms. Invasive radiographic procedures such as IV cholangiography, antegrade pyelography, and bronchography use an iodinated dye that is administered intravenously or directly into an organ or tissue to be examined; these studies require the client to sign a consent form and are performed under sterile conditions using Standard Precautions.

Tomography is an imaging technique in which a selected body plane is isolated from the tissues on either side. It is particularly useful in visualizing air-filled structures such as the lungs, paranasal sinuses, and kidneys. Fluoroscopy is an imaging technique that allows the viewer to observe movement on a fluorescent viewing screen in the area being filmed while the study is in progress. It is valuable in evaluating movement of the diaphragm, heart, and digestive system; it is also used in catheter placement during angiography, needle insertion for biopsy or removal of fluid from a body cavity, and nasogastric tube insertion for precise placement in the stomach or small bowel. Cineradiography is a rapid-sequence filming technique similar to that used in motion pictures; it

creates a photographic record of the motion under study, such as swallowing.

Xeroradiography is an x-ray imaging technique that uses a photoelectric process rather than the photochemical process of conventional x-rays; the images are printed on paper like that of a typical office copier. While distinct images are produced with excellent contrast, this process reduces the amount of radiation exposure to the client. It is most useful in studying soft tissues for small-point abnormalities and is used primarily for x-rays of the breasts.

CONTRAST-MEDIATED STUDIES

Contrast-mediated studies use a **contrast medium** to enhance the viewing of soft tissue details. The contrast medium may be administered orally, rectally, by IV, intrathecally, or by insufflation; when injected to visualize blood vessels and lymphatics, the studies are called angiography. Barium sulfate and the organic iodides are the most commonly used contrast media. These radiopaque substances block the passage of the x-rays, resulting in the images on film; see Table 28-12 for the most common contrast-mediated studies. Barium solutions should not be used if perforation of the bowel is suspected. Barium studies should be sequenced as follows: barium enema before the upper gastrointestinal series (UGI) and the UGI before the barium swallow, if the UGI series and barium swallow are performed as separate studies. Iodine injections may cause the client to experience temporary symptoms of shortness of breath, nausea, and a warm or hot, flushed sensation.

PLAIN FILMS

Plain films are radiologic (x-ray and roentgenogram) studies that use external beams to evaluate bones and soft tissues

of the body. X-rays are produced by applying an electron beam to a vacuum tube containing tungsten; the resulting rays have a shorter wavelength than that of visible light rays and are able to penetrate many substances that are opaque to visible light.

Chest X-Ray

The most common radiologic study is the noninvasive, non-contrasted chest x-ray. The best results are obtained when the films are taken in the radiology department; however, a portable chest x-ray can be performed at the bedside.

Radiographic projection positions of chest x-ray films are taken from various views (see Figure 28-9). Multiple views of the chest are necessary for the practitioner to assess the entire lung field. To prepare the client for a chest x-ray, remove metal objects (jewelry) and all clothing from the waist up and replace with a gown. Metal will appear on the x-ray film, thereby obscuring visualization of parts of the chest. Pregnant women are draped with a metal apron to protect the fetus.

Chest films can indicate the following alterations and diseases:

- Lesions (tumors, cysts, masses) in the lung tissue, chest wall, bony thorax, or heart
- Inflammation of lung tissue (pneumonia, atelectasis, abscesses, tuberculosis); pleura (pleuritis); and pericardium (pericarditis)
- Fluid accumulation in the lung tissue (pulmonary edema, hemothorax); pleura (pleural effusion); and pericardium (pericardial effusion)
- Bone deformities and fractures of the rib and sternum
- Air accumulation in the lungs (chronic obstructive pulmonary disease, emphysema) and pleura (pneumothorax)
- Diaphragmatic hernia

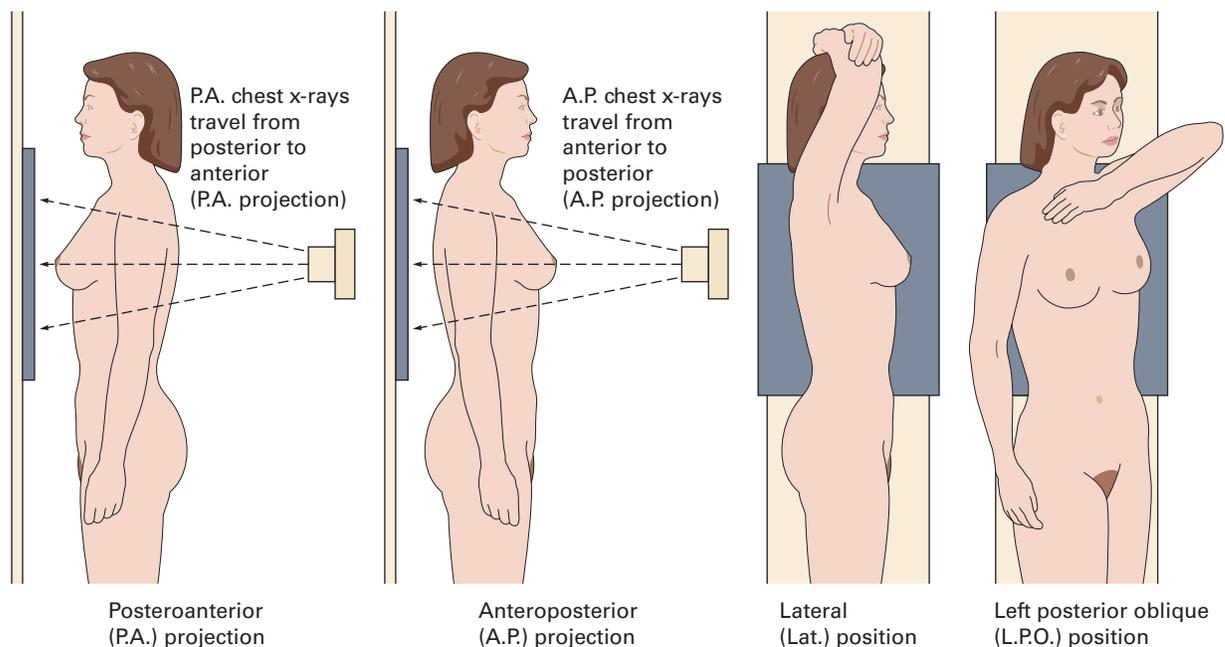

FIGURE 28-9 Radiographic Projection Positions DELMAR/CENGAGE LEARNING

RISKS OF EXPOSURE TO RADIATION

All radiation studies carry risks of exposure to radiation. Certain cells are at greater risk for adverse effects (e.g., gonadal and somatic cells). Children should be exposed to x-rays only when absolutely necessary for diagnostic purposes. Women who are pregnant should not be x-rayed because the cells of the developing embryo are sensitive to radiation. The adverse effects of radiation therapy include genetic mutations, cancer, and congenital anomalies.

MAMMOGRAPHY

Mammography (a low-dose radiographic study of breast tissue) is used to reveal congenital abnormalities and lesions. The ACS (2008) recommends that women age 40 and older at average risk should have an annual screening mammogram and clinical breast examination (CBE) by a health professional. Women at increased risk should talk with their health professional regarding individualized approaches to screening; see Chapter 27 for a discussion of breast cancer screening.

ANGIOGRAPHY STUDIES

Angiography allows visualization of the vascular structures through the use of fluoroscopy with a contrast medium. Films are taken in rapid sequence after the injection of an iodinated contrast medium into the vessel or vascular system to be examined. Angiograms are serial radiographs of blood vessels that are used to evaluate the size, shape, and patency of the veins (venograms); arteries (arteriograms) of organs and tissues; or lymph vessels and nodes (lymphograms). Angiography is also useful in diagnosing an **aneurysm** (weakness in the wall of a blood vessel).

Digital subtraction angiography is a computerized imaging of the vasculature with visualization on a monitor screen after the IV injection of iodine through a catheter. The results reveal the presence of vascular malformations (stenosis, occlusion, obstruction, ulceration, plaques, and aneurysms), lesions, and emboli.

Cardiac Angiography

Cardiac catheterization reveals defects in the heart chambers, valves, and coronary arteries. Using fluoroscopy, a cardiologist inserts a catheter into one or both sides of the heart and measures pressures and cardiac output; blood samples may be obtained for oxygen saturation testing. With the injection of a contrast medium the cardiologist can further define cardiac structures, including the coronary arteries, and assess cardiac wall motion. Cardiac catheterization is performed to diagnosis myocardial ischemia, syncope, valvular heart disease, and acute MI; it may also be indicated after an MI, coronary artery bypass surgery, percutaneous transluminal coronary angioplasty in clients having recurring symptoms, and after a heart transplant to monitor rejection.

Prepare the client as described in Table 28-1. The femoral and brachial arteries are common catheter insertion sites; the radial artery is also an option. Mark pulses on the arm or leg that will be used to assist with pulse assessment postprocedure. The

procedure lasts 30 minutes to 1 hour, but the entire test, including pre- and postcatheterization care, may take up to 4 hours.

Postcatheterization the nurse should:

- Place the client on telemetry.
- Apply manual pressure (for 30 minutes or longer) when the catheter sheath is removed, and then apply a pressure dressing.
- Keep the client on bed rest with the involved extremity straight and immobile.
- Monitor and record vital signs to include the presence, quality, and character of peripheral pulses and the color, temperature, and tactile sensation of the involved extremity.
- Encourage oral fluids and record intake and output.
- Instruct the client to report any warm, tickling sensations at the puncture site that would indicate bleeding.
- Monitor for procedural complications: bleeding or hematoma formation at the site; allergic reactions; and cardiovascular, pulmonary, and neurologic changes.

Other Angiographic Procedures

See Table 28-13, on page 631, for a description of other angiographic procedures that are named for the type of vessel and the method or route of the injection.

ULTRASONOGRAPHY

Ultrasound (echogram) is a noninvasive study that uses high-frequency sound waves to visualize deep body structures. This test should be scheduled before any studies using a contrast medium or air to ensure accuracy because an ultrasound *does not* require any contrast medium. The client is instructed to lie still during the procedure.

Ultrasound is used to evaluate the brain, thyroid gland, heart, vascular structure, abdominal aorta, spleen, liver, gallbladder, pancreas, and pelvis. An ultrasound is commonly done during pregnancy to evaluate the size of the fetus and placenta; a full bladder is needed to ensure visualization. Instruct the mother to drink 6 to 8 glasses of water and to avoid urination before testing.

A coupling agent (lubricant) is placed on the surface of the body area to be studied to increase the contact between the skin and the **transducer**, an instrument that converts electrical energy to sound waves. The transducer emits waves that travel through the body tissue and are reflected back to the transducer and recorded. The varying density of body tissues deflects the waves into a differentiated pattern on an oscilloscope. Photographs can be taken of the sound wave pattern on the oscilloscope.

ECHOCARDIOGRAMS

An **echocardiogram** is an ultrasonographic procedure used to reveal abnormal structure or motion of the heart wall and thrombi. This test is also used after **radiofrequency ablation** (the delivery of low-voltage, high-frequency alternating electrical current to cauterize the abnormal myocardial tissue) to identify the potential complications of pericardial effusion.

TABLE 28-13 Angiographic Procedures

ANGIOGRAM	DESCRIPTION	MAJOR INDICATIONS
Cerebral	Cerebral vessels, the carotid and vertebral arteries	Detection of vessel displacement caused by tumors, abscess, edema, hematoma, narrowing or occlusion of vessels, aneurysm, increased intracranial pressure
Adrenal	Adrenal gland arteries or veins	Arteriogram: detect tumors or hyperplasia. Venogram: secure blood samples for testing cortisol, catecholamines, and hormone levels
Pulmonary	Pulmonary vessels	Arterial and venous abnormalities and pulmonary embolism
Hepatic and portal	Hepatic artery and portal vein	Hepatic: malignant tumor. Portal: hepatocellular carcinoma from hepatitis and cirrhosis
Renal	Large and small arteries of the renal vasculature and parenchyma or of the veins and their branches	Detect tumors and other abnormalities and prospective renal donors
Mesenteric	Gastrointestinal vasculature	Abnormalities of the aorta, stomach, pancreas, and small and large intestines to identify acute bleeding source and perform perfusion or embolization to control hemorrhage
Fluorescein	Retinal vasculature and circulation	Eye abnormalities caused by changes in the retinal vascularity
Lymphangiography	Lymphatic flow and nodal patterns	Detect pathologic nodes identified by enlargement or filling defects and the presence of obstructed lymphatic flow patterns
Upper extremity	Hand or arm	Detect obstruction, ischemia vasospasms, lesions, or trauma
Lower extremity	Leg or foot	Filling defects, vasospasms, lesions, stenosis, and occlusion associated with aortic, arterial, or venous disease

Delmar/Cengage Learning

DOPPLER ULTRASONOGRAPHY

Doppler, a handheld transducer, transmits high-frequency sound waves to the artery or vein being studied. The sound waves strike the moving RBCs and are reflected back to the transducer, which amplifies the sound and produces a graphic recording. Doppler ultrasonography reveals blood clots and peripheral vascular disease.

NONNUCLEAR SCAN STUDIES

Nonnuclear scan studies are noninvasive and use a special machine and scanning system as opposed to radiopharmaceuticals. Computed tomography and magnetic resonance imaging use computer-generated images on a screen for viewing and recording. A signed informed consent form is required for MRI procedures and CT studies if a contrast medium is used.

COMPUTED TOMOGRAPHY

Computed tomography (CT; computed axial tomography or computed transaxial tomography) uses x-ray combined with a special scanning machine, detectors that determine the amount of radiographic beams absorbed by tissues, and a computer that processes these readings and reconstructs a body region by calculating the differences in tissue absorption of the radiographic beams. CT scanning produces a series of three-dimensional, cross-sectional anatomic views of the tissue structure of solid organs and the difference between soft tissue and water. Figure 28-10, on page 632, demonstrates the direction of sagittal, transverse, and coronal planes taken during CT scanning. Figure 28-11, on page 633, shows the direction of CT scan waves. Contrast media may be used to further clarify or enhance findings such as to determine tissue density, differentiate a specific organ from other structures, or identify small tumors. It is primarily used in diagnosing tumors and inflammatory disorders.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Predictors of Time from Hospital Arrival to Initial Brain-Imaging among Suspected Stroke Patients. The North Carolina Collaborative Stroke Registry.”

AUTHORS

K. Rose, W. Rosamond, S. Huston, C. Murphy, and C. Tegeler

PURPOSE

To examine the client demographics, hospital characteristics, and clinical predictors of delay time from hospital arrival until CT among 20,374 clients enrolled in the North Carolina Collaborative Stroke Registry (January 2005 to April 2008).

METHODS

Delay time was log-transformed in linear regression analyses and dichotomized (<25 minutes, >25 minutes) in logistic regression analyses to correspond to the 1999 National Institute of Neurological Disorders and Stroke (NINDS) guidelines.

FINDINGS

In multiple linear regression analyses, prehospital delay time, mode of transport, race, gender, presumptive diagnosis, time of day, weekday versus weekend arrival, and hospital type were significantly associated with CT delay. Among clients arriving within 2 hours of symptom onset, the strongest independent predictors of meeting the NINDS guidelines were arrival by emergency medical services versus other modes of transportation and a presumptive diagnosis of transient ischemic attack versus unspecified stroke type.

IMPLICATIONS

Although most clients do not arrive at the hospital in a timely manner and cannot be considered for time-dependent therapies, among those who do, disparities exist in the time to receipt of CT scan, suggesting room for improvement in hospital-level stroke systems of care.

Rose, K., Rosamond, W., Huston, S., Murphy, C., & Tegeler, C. (2008). Predictors of time from hospital arrival to initial brain-imaging among suspected stroke patients. *The North Carolina Collaborative Stroke Registry. Stroke*, 39(12), 3262–3267. Retrieved August 26, 2008, from <http://stroke.ahajournals.org/cgi/content>.

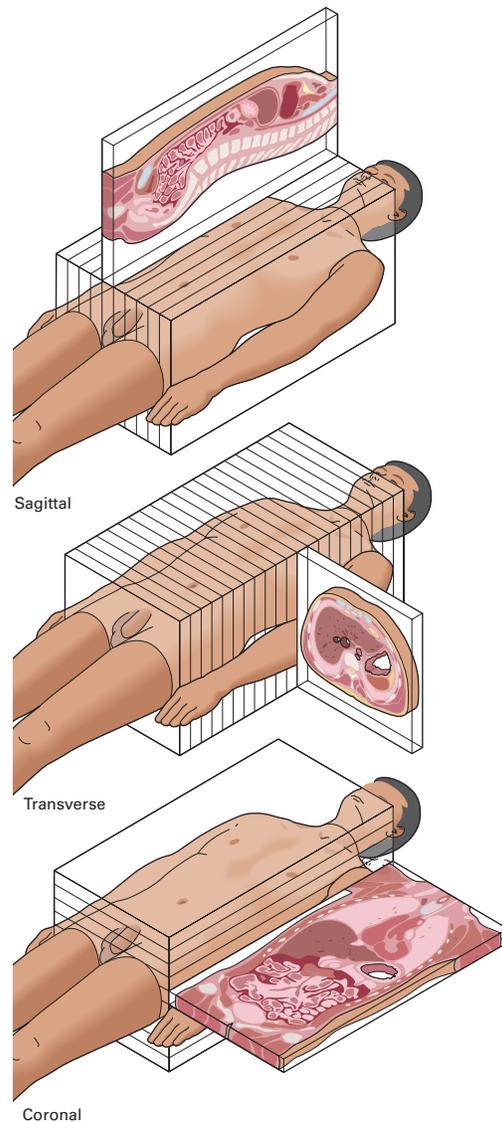

FIGURE 28-10 Computed Tomography DELMAR/CENGAGE LEARNING

client is instructed to wear earphones to decrease the discomfort from the machine’s clanging sound. A noniodine IV paramagnetic contrast agent may be used during the study. The study reveals lesions and changes in the body’s organs, tissues, vascular, and skeletal structures.

RADIOACTIVE STUDIES

Radionuclide imaging (nuclear scanning) uses radionuclides (or radiopharmaceuticals) to image the morphologic and functional changes in the body’s structure. A scintigraphic scanner is placed over the area of study to detect the radiation emission and to produce a visual image of the structure on film. Radiopharmaceutical agents are administered by various routes with consideration given to time delays of absorption. The results reveal congenital abnormalities,

MAGNETIC RESONANCE IMAGING

Magnetic resonance imaging (MRI) is an imaging technique that uses radio waves and a strong magnetic field to make continuous cross-sectional images of the body. The

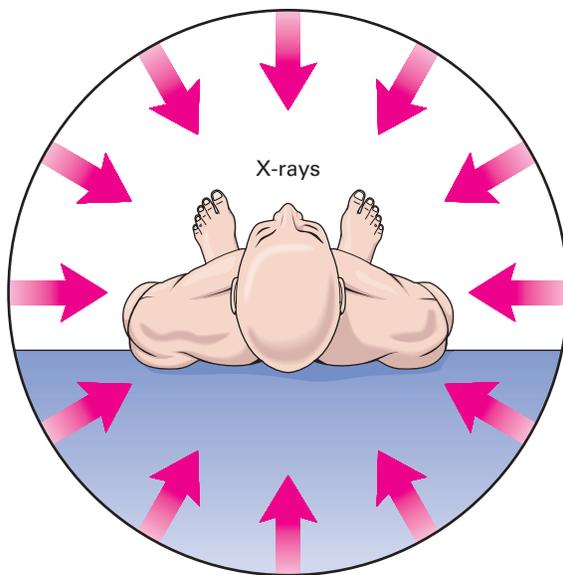

FIGURE 28-11 Direction of Computed Tomography Scan Rays DELMAR/CENGAGE LEARNING

lesions, skeletal changes, infections, and gland and organ enlargement.

ELECTRODIAGNOSTIC STUDIES

These diagnostic tests use devices to measure the electrical activity of the heart, brain, and skeletal muscles. Electrical sensors (electrodes) are placed at certain anatomic points to measure the tone, velocity, and direction of the impulses. The impulses are then transmitted to an oscilloscope or printed on graphic paper.

ELECTROCARDIOGRAPHY

An **electrocardiogram** (ECG or EKG) is a graphic recording of the heart's electrical activity. The client may be asked not to smoke or drink caffeinated beverages 24 hours before the test. Nicotine and caffeine can affect the heart rate.

Electrodes are applied to the chest wall and extremities. A lubricating gel applied to the electrodes increases the conduction of electrical activity between the skin and electrode. The client is instructed to lie still during the pain-free test. The test can reveal abnormal transmission of impulses and electrical position of the heart's axis.

A portable cardiac monitor (Holter monitor) is a device that records the heart's electrical activity. It produces a continuous recording over a specified period of time (e.g., 24 hours). The portable unit allows the client to ambulate and perform regular activities. Clients are instructed to maintain a log of activities that occur when they feel their heart beating faster or irregularly. The practitioner reviews the ECG tracing in relation to the client's log to determine if certain activities, such as walking, are associated with abnormal transmission of impulses.

Signal-Averaged Electrocardiography

Signal-averaged electrocardiography (SAECG) is a surface ECG that amplifies **late potentials**, the electrical activity that occurs after normal depolarization of the ventricles. The test requires a specialized ECG machine and small computer to detect the late potentials. It is performed on clients who have had an MI. The test reveals the client's risk for ventricular tachycardia.

Stress Test

A **stress test** measures the client's cardiovascular response to exercise tolerance. It demonstrates the ability of the myocardium to respond to increased oxygen requirements (the result of exercise) by increasing the blood flow to the coronary arteries.

The client walks on a treadmill while connected to an ECG machine, and the heart rate and blood pressure are monitored. The speed and grade of the treadmill are increased every 3 minutes until the client tires or achieves the target heart rate, or until clinical signs develop (e.g., angina or an arrhythmia). The test is suited for clients who can exercise and who are not taking cardiac medications such as beta blockers that prevent the heart rate from increasing (King, 2004).

RADIONUCLIDE STUDIES. Radionuclide studies, thallium-201 scintigraphy, and technetium-99m sestamibi use isotopes to highlight differences in coronary perfusion at rest and with stress (King, 2004). **Thallium**, a radionuclide that is the physiological analogue of potassium, is normally absorbed into normal myocardial tissue from the circulating blood. During the test, thallium is administered intravenously to detect damaged myocardial tissue (necrotic or ischemic). Because thallium is not absorbed by the damaged tissue, the degree of heart damage can be estimated.

There are two types of thallium tests: resting imaging or stress imaging. Resting imaging is performed a few hours after MI. The thallium is injected and an ECG tracing is performed. Stress imaging (thallium stress test) is performed while the client is on the treadmill with ECG monitoring. At peak stress the IV thallium is injected; scanning is done 3 to 5 minutes postinjection. The test is stopped immediately if the client becomes symptomatic for ischemia.

ELECTROENCEPHALOGRAPHY

An **electroencephalogram** (EEG) is the graphic recording of the brain's electrical activity. The procedure is painless and takes about an hour. The test is performed in a quiet, nonstimulating environment. It can reveal the presence and type of seizure disorder and intracranial lesion. The absence of brain's electrical activity is used to confirm death.

During the procedure, electrodes are placed on the client's scalp. The electrodes transmit the impulses from the brain to an EEG machine. The machine amplifies the brain's impulses and makes a recording of the waves on strips of paper.

SPOTLIGHT ON...

Participating in Diagnostic Testing

A client comes to an outpatient clinic for a laparoscopy to retrieve an egg for in vitro fertilization. You are to assist the practitioner with this procedure. How would you handle this situation if your own religious beliefs were in conflict with the procedure being performed? Would it make any difference if the client had had an abortion as a teenager?

ENDOSCOPY

Endoscopy is the visualization of a body organ or cavity through a scope. The procedure is performed with an endoscope (a metal or fiberoptic tube) being inserted directly into the body structure to be studied (see Figure 28-12). A light at the end of the scope allows the practitioner to assess for lesions and structural problems. The endoscope has an opening at the distant tip that allows the practitioner to administer an anesthetic agent, lavage, and suction as well as biopsy tissue. Common endoscopic procedures are presented in Table 28-14 on page 635.

General client preparation and positioning depend on the structure being studied, as discussed in Table 28-14. As with all invasive procedures, the client needs to sign a consent form and the nurse needs to establish baseline vital signs before administering sedative agents.

Postprocedure the nurse monitors the vital signs, observes for bleeding, and assesses for procedural risks (e.g., return of the gag and swallowing reflexes following an esophagogastroduodenoscopy with local anesthesia).

ASPIRATION AND BIOPSY

Aspiration is performed to withdraw fluid that has abnormally collected or to obtain a specimen. Aseptic technique and Standard Precautions are used during aspiration. Aspiration

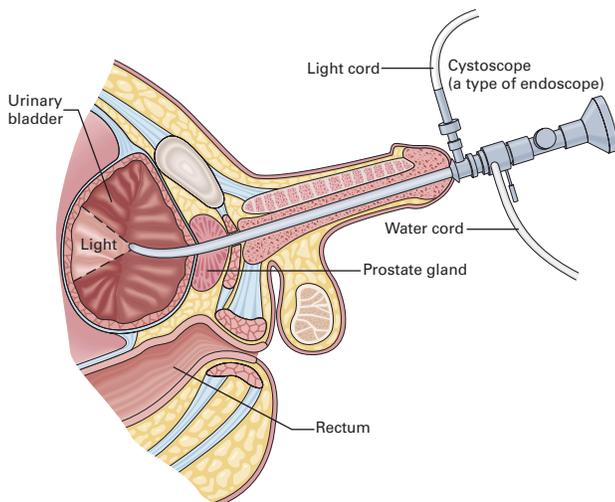

FIGURE 28-12 Cystoscope DELMAR/CENGAGE LEARNING

diagnostic studies are invasive; implement the protocols for diagnostic tests. A local anesthetic is administered in the area being studied to decrease the client's discomfort when the skin is pierced by the needle.

A stylet needle with an outer, hollow-bore needle is used to pierce the skin. Once the needle is in place, the stylet is withdrawn, leaving only the outer needle to aspirate the fluid. A tissue **biopsy**, the excision of a small amount of tissue, can be obtained during aspiration or with other diagnostic tests (e.g., bronchoscopy). A biopsy can be taken from most of the body's tissue.

AMNIOCENTESIS

Amniocentesis is the withdrawal of amniotic fluid to obtain a sample for specimen examination. The amniotic fluid increases during pregnancy from 50 mL at the end of the first trimester to an average of 1000 mL near term. This test is indicated when:

- Maternal age exceeds 35.
- A spontaneous abortion occurred with a previous pregnancy.
- There is a family history of genetic, chromosomal, or neural tube defects.

The amniocentesis is performed when the amniotic fluid volume reaches 150 mL, usually after the 16th week of pregnancy.

There are no restrictions on fluids or food. The procedure usually lasts 10 to 15 minutes. Instruct the mother to void to prevent the risk of puncturing a full bladder. Position the client supine and assesses the fetal heart tones.

The abdomen is prepped and injected with lidocaine hydrochloride, a local anesthetic agent. The practitioner withdraws 10 to 20 mL amniotic fluid by transabdominal needle aspiration. Postprocedure the nurse monitors the client's vital signs and fetal heart tones and assesses for signs of labor. Instruct the client to notify the practitioner of any signs of labor or infection.

BONE MARROW ASPIRATION AND BIOPSY

The sternum and iliac crest are the common sites for bone marrow puncture. During a bone marrow puncture, a fluid specimen (aspiration) or a core of marrow cells (biopsy) can be obtained. Both tests are commonly done concurrently to obtain the best marrow specimen. The test can reveal anemias or cancer, such as leukemia, multiple myeloma, or Hodgkin's disease, or the client's response to chemotherapy.

There are no restrictions on fluids or food before the puncture. The nurse should explain the procedure to elicit the client's support during the procedure. The client must lie perfectly still throughout the procedure. The client is usually fearful; allay the client's fear with relaxation methods or sedation. Infants and small children are restrained by holding them throughout the procedure.

TABLE 28-14 Endoscopic Procedures

PROCEDURE AND AREA STUDIED	PREPARATION/POSITION	CLINICAL SIGNIFICANCE
Arthroscopy—examines joint structures, primarily the knee	Instruct client to fast after midnight; test is usually performed under local anesthesia, may be done under spinal or general anesthesia if surgery is necessary. Position the joint for accessibility.	Diagnose torn meniscus, patellar, condylar, and synovial disorders; perform surgery. Also used to monitor the progression of a disease or effectiveness of therapy.
Bronchoscopy—examines the bronchus and bronchial tree	Instruct client to fast 6–12 hours before the test; test is usually done under local anesthesia. Position client supine or sitting upright.	Identify the origin of bleeding, lesions, or obstruction; collect a specimen for bacteriologic and cytologic examination (diagnose abnormal cells); remove foreign bodies, lesions, mucus plugs, or excessive secretions.
Colonoscopy—examines the large intestine	Instruct client to maintain a clear liquid diet for 48 hours before the test and to take the prescribed laxative the evening before the examination; place client on left side with knees flexed and drape.	Identify origin of bleeding or lesions; evaluate inflammatory and ulcerative bowel disease and recurrence of polyps or malignant lesions.
Colposcopy—examines the cervix and vagina following a positive Pap smear	No restriction on food or liquids. Place client in lithotomy position.	Evaluate abnormal cytology or grossly suspicious lesions and perform a biopsy or take photographs of suspicious lesions.
Cystoscopy (see cystourethroscopy)		
Cystourethroscopy—uses two instruments: a cystoscope to examine the bladder and ureter openings, and a urethroscope to examine the bladder neck and the urethra	Food and fluids are restricted only if the client is to receive general anesthesia; regional anesthesia is usually given. Place client in a lithotomy position.	Identify bladder lesions and urethral strictures, ulcers, inflammation, and an enlarged prostate gland.
Esophagogastroduodenoscopy (EGD)—examines the esophagus, stomach, and upper duodenum	Instruct client to fast 6–12 hours before the test. An intravenous tranquilizer may be given, then a local anesthetic is sprayed into the back of the throat to decrease the gag reflex (swallowing will seem difficult). Place client in a sitting position.	Identify diverticula, varices, Mallory-Weiss syndrome, esophageal rings and hiatal hernia, and esophageal and gastric stenoses. When combined with histologic and cytologic tests, may indicate acute or chronic ulcers, benign or malignant tumors, and inflammatory disease.
Laparoscopy—examines the peritoneal cavity: pelvis and abdomen	Instruct client to fast 8 hours before the surgery; the test is performed either with a local or general anesthetic agent. Place the client in a lithotomy position; catheterize the client to ensure the bladder is empty (avoids puncture of the bladder during the test with the laparoscope).	Used to detect cysts, adhesions, fibroids, and infections of the uterus, fallopian tubes, and ovaries; ectopic pregnancies; and liver lacerations and cirrhosis. May also be used for lysis of adhesions, ovarian biopsy, tubal sterilization, foreign body removal, and fulguration of endometriotic implants.

(Continues)

TABLE 28-14 (Continued)

PROCEDURE AND AREA STUDIED	PREPARATION/POSITION	CLINICAL SIGNIFICANCE
Proctosigmoidoscopy—three steps: 1. Digital examination to dilate the anal sphincters to detect obstruction that might hinder passage of the endoscope. 2. A sigmoidoscope to examine the distal sigmoid colon and rectum. 3. A proctoscope to examine the lower rectum and anal canal.	Instruct client according to prescribing practitioner orders relative to dietary restrictions and bowel preparation (these are usually based on prescribing practitioner preference). If the client has rectal inflammation, a local anesthetic agent is applied to decrease discomfort. Secure the client to a tilting table that rotates into horizontal and vertical positions.	Identify internal hemorrhoids, hypertrophic anal papillae, polyps, fissures, fistulae, and rectal and anal abscesses.

Delmar/Cengage Learning

Client positioning is determined by the site to be used, supine (sternum) or side-lying (iliac crest). The site is prepped for puncture to decrease the skin's normal flora. Explain to the client that pressure may be experienced as the specimen is withdrawn. The client should not move when the specimen is being withdrawn; a sudden movement may dislodge the needle.

Postprocedure the client should be on bed rest for an hour. The nurse monitors vital signs to assess for bleeding (rapid pulse rate, low blood pressure). Instruct the client to report to the practitioner any bleeding or signs of inflammation.

PARACENTESIS

Paracentesis is the aspiration of fluid from the abdominal cavity. This test can either be diagnostic, therapeutic, or both. For instance, with end-stage liver or renal disease there is **ascites**, an accumulation of fluid in the abdomen. Pressure caused from the ascites can interfere with breathing and gastrointestinal functioning. Aspiration in this instance is therapeutic. If a culture specimen is taken, it is also diagnostic.

Have the client void and obtain a body weight before the procedure. Place the client in a high Fowler's position in a chair or sitting on the side of the bed. The skin is prepped, anesthetized, and punctured with a **trocar**, a large-bore abdominal paracentesis needle. The trocar is held perpendicular to the abdominal wall and advanced into the peritoneal cavity. When fluid appears, the trocar is removed, leaving the inner catheter in place to drain the fluid. Observe the client for pressure changes that can result from the rapid removal of fluid.

Postprocedure apply a sterile dressing to the puncture site. Monitor the client for changes in vital signs and electrolytes. Instruct the client to record the color, amount, and consistency of drainage on the dressing after discharge.

THORACENTESIS

Thoracentesis is the aspiration of fluids from the pleural cavity. The pleural cavity normally contains a small amount of fluid to lubricate the lining between the lungs and pleura. Infection, inflammation, and trauma may cause an increased production of fluid, which can impair ventilation.

Position the client with arms crossed and resting on a bedside table to allow access to the rib cage (see Figure 28-13). Instruct the client not to cough during insertion of

FIGURE 28-13 Client Position for Thoracentesis DELMAR/CENGAGE LEARNING

the needle. The practitioner selects, preps, and anesthetizes the puncture site. The needle is usually inserted into the intercostal space at the location of maximum dullness to percussion. Posteriorly, the site should be above the ninth rib, and laterally, above the seventh rib.

During the procedure, monitor the client for symptoms of a **pneumothorax** (collection of air or gas in the pleural space causing the lungs to collapse), such as dyspnea, pallor, tachycardia, vertigo, and chest pain. Postprocedure observe for cardiopulmonary changes and a mediastinum shift as assessed by vital signs and bloody sputum.

CEREBROSPINAL FLUID ASPIRATION

Lumbar puncture (“spinal tap”) is the aspiration of cerebrospinal fluid (CSF) from the subarachnoid space. The specimen is examined for organisms, blood, and tumor cells. A spinal tap is also performed:

- To obtain a pressure measurement when blockage is suspected
- During a myelogram, as discussed earlier
- To instill medications (anesthesia, antibiotics, or chemotherapy)

A spinal tap is contraindicated in clients with increased intracranial pressure, hemorrhagic diathesis, and an infection at the proposed puncture site.

Place the client in a lateral recumbent position with the craniospinal axis parallel to the floor and flat of the back perpendicular to the procedure table. Have the client assume a flexed knee-chest position to bow the back. This position separates the vertebrae. Most clients will require assistance in maintaining this position throughout the procedure. To assist, the nurse stands facing the client with one hand across the client’s posterior shoulder blades and the other hand over the buttocks.

The practitioner selects, preps, and anesthetizes the puncture site (usually interspace L₃-L₄, L₄-L₅, or L₅-S₁). The needle and stylet are inserted into the midsagittal space and advanced through the longitudinal subarachnoid space (see Figure 28-14).

Once in the subarachnoid space, the stylet is removed, leaving the needle in place. An initial CSF pressure reading is taken:

- A three-way stopcock with a manometer (calibrated column) is securely connected to the spinal needle.
- The stopcock is opened toward the manometer to allow the CSF to rise in the column. Under normal conditions, the CSF will fluctuate in the column with respirations.
- When the CSF stabilizes, a pressure reading is taken.

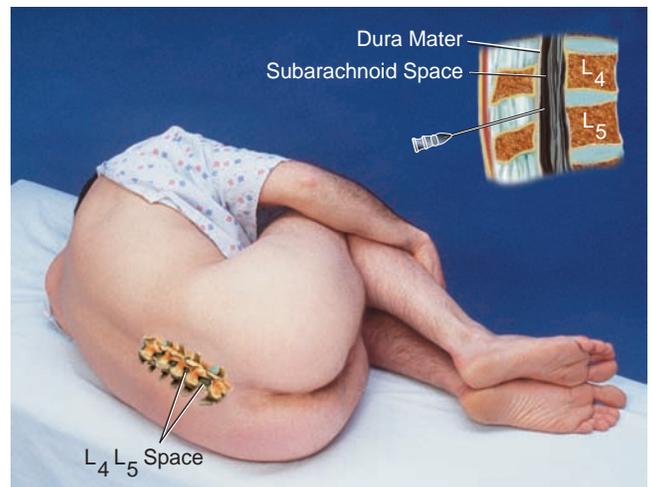

FIGURE 28-14 Lumbar puncture: position of client and insertion of the needle into the subarachnoid space. DELMAR/CENGAGE LEARNING

If the pressure reading is greater than 200 mm H₂O or falls quickly, only 1 or 2 mL CSF is obtained for analysis. If the pressure is less than 200 mm H₂O, an adequate specimen sampling is withdrawn slowly.

After the pressure reading is taken, the stopcock is turned to allow the CSF to slowly flow into a sterile test tube. A sterile cap is placed on the test tube, and the sample is transported to the laboratory for analysis. Rapid withdrawal of CSF can cause a transient postural headache. Throughout the procedure, monitor the client’s cardiorespiratory status.

Postprocedure, pressure is applied and then a sterile bandage. Assess the bandage for leakage of CSF and the client’s neurologic and cardiorespiratory status. A postural headache is the most common complication of a lumbar puncture; using a small-bore spinal needle minimizes the chances of a headache.

SAFETY FIRST

TAKING THE PRESSURE READING

The client should be relaxed and quiet during the initial pressure reading; straining increases the CSF.

PROCEDURE
28-1
Performing Venipuncture
EQUIPMENT

- Disposable gloves
- Alcohol swabs
- Rubber tourniquet
- Sterile 2 × 2 gauze pads
- Band-Aid or adhesive tape (precut)
- Appropriate blood collection tubes
- Labels for each collection tube with the appropriate client information included
- Completed laboratory requisition forms
- Needle/equipment disposal container
- Small pillow or folded towel to support the extremity if needed
- Syringe method: sterile needles: 20 to 21 gauge for adults, 23- to 25-gauge butterfly for older adults, 23- to 25-gauge butterfly for children
- Vacutainer method: Vacutainer tube with needle holder; sterile double needles (20 to 21 gauge for adults, 23 to 25 gauge for children)

ACTION
RATIONALE

ACTION	RATIONALE
1. Greet client by name and validate client's identification.	1. Proper client identification ensures safety for the client and the nurse.
2. Explain the procedure to the client.	2. Client rights dictate that any action be explained to the client. The client always has the right to refuse a procedure. Information decreases anxiety.
3. Wash hands/hand hygiene.	3. Reduces transmission of microorganisms.
4. Bring equipment to bedside or client exam room. Transfer client to the procedure room, especially for small children, as it is important to keep their hospital room a "safe haven."	4. Provides an organized approach to the procedure.
5. Close curtain or door.	5. Provides privacy.
6. Raise or lower bed and table to comfortable working height.	6. Maintains good body mechanics for the nurse during the procedure.
7. Position client's arm; extend arm to form a straight line from shoulder to wrist. Place pillow or towel under upper arm to enhance extension. Client should be in a supine or semi-Fowler's position.	7. Helps stabilize the arm. The bed should support the client's body (when possible) in case client should feel faint during the procedure.
8. Apply disposable gloves.	8. Reduces the risk of infection to both the client and the nurse (Standard Precautions).
9. Apply the tourniquet 3 to 4 inches above the venipuncture site. Most often the antecubital fossa site is used. The tourniquet should be able to be removed by pulling the end with a single motion.	9. Tourniquet provides improved visibility of the veins as they dilate in response to decreased venous return of blood flow from the extremity to the heart.
10. Check for the distal pulse. If there is no pulse felt, then the tourniquet is applied too tightly and must be reapplied more loosely.	10. If the pressure is too tight, it may impede arterial flow to the extremity.
11. Have client open and close fist several times, leaving fist clenched prior to venipuncture.	11. Increases the venous distension and enhances visibility of the vein. Vigorous motion, however, may result in hemoconcentration of the specimen.

(Continues)

PROCEDURE 28-1 Performing Venipuncture (Continued)

ACTION	RATIONALE
12. Maintain tourniquet for only 1 to 2 minutes.	12. Prolonged time may increase client discomfort and alter some laboratory results (i.e., falsely elevated serum potassium).
13. Identify the best venipuncture site through palpation; the ideal site is a straight prominent vein that feels firm and slightly rebounds when palpated. Palpate potential site.	13. Straight, intact veins are easier to puncture. A thrombosed vein is rigid, or rolls easily, and is difficult to stick.
14. Select the vein for venipuncture. (If the tourniquet has been on too long, release it and let the client rest for 1 to 2 minutes before reapplying the tourniquet.)	14. Allowing the client to rest increases client comfort and ensures accurate laboratory results.
15. Prepare to obtain the blood sample. Technique varies depending on equipment used: <ul style="list-style-type: none"> • Syringe method: Have syringe with appropriate needle attached. • Vacutainer method: Attach double-ended needle to Vacutainer tube and have the proper blood specimen tube resting inside the Vacutainer. Do not puncture the rubber stopper yet. 	15. <ul style="list-style-type: none"> • A needle with a very small bore can damage the red cells as the blood is drawn and lead to inaccurate test results. • The long end of the needle is used to puncture the vein, and the short end enters the blood tube.
16. Cleanse the venipuncture site with alcohol swab or chlorhexidine alcohol using a circular method at the site and extending the motion 2 inches beyond the site (see Figure 28-15). Allow the alcohol to dry.	16. The alcohol solution and mechanical cleaning motion cleans the skin surface of bacteria that may cause infection at the site. Allowing the alcohol to dry reduces the stinging sensation that the client may experience.

FIGURE 28-15 After applying the tourniquet, cleanse the skin at the venipuncture site. Do not let the tourniquet stay on longer than 2 minutes. If you need more time, remove the tourniquet for a couple of minutes to allow the client to rest and begin again. DELMAR/CENGAGE LEARNING

- | | |
|---|---|
| 17. Remove the needle cover and warn that client will feel the needle stick for a few seconds. | 17. Clients will be better able to control their reaction if they know what to expect. |
| 18. Place the thumb or forefinger of the nondominant hand 1 inch below the site and pull the skin taut. | 18. Helps stabilize the vein during insertion. |
| 19. Hold syringe needle or Vacutainer at a 15° to 30° angle from the skin with the bevel up. | 19. This angle reduces the chance of penetrating through the vein during insertion. The needle causes less trauma to the skin and vein when the bevel is up during insertion. |

(Continues)

PROCEDURE 28-1 Performing Venipuncture (Continued)

ACTION	RATIONALE
<p>20. Slowly insert needle/Vacutainer (see Figure 28-16).</p> <p>21. Technique varies depending on equipment used:</p> <ul style="list-style-type: none"> • Syringe method: Gently pull back on syringe plunger and look for blood return. Obtain desired amount of blood into the syringe. • Vacutainer method: Hold Vacutainer securely and advance specimen tube into needle of holder. Be careful not to advance the needle into the vein. The blood should flow into the collection tube. After the collection tube is full, grasp the Vacutainer firmly, remove the tube, and insert additional specimen collection tubes as indicated (see Figures 28-16 and 28-17). 	<p>20. Prevents puncture through the other side of the vein.</p> <p>21. <ul style="list-style-type: none"> • If blood does not appear, the needle is not in the vein. • Pushing the needle through the stopper breaks the vacuum and causes the flow of blood into the collection tube. Failure of blood to appear in the collection tube indicates the vacuum in the tube has been lost or the needle is not in the vein. </p>

FIGURE 28-16 Hold the Vacutainer and needle assembly securely and press the specimen tube into the holder. The needle inside the holder will pierce the specimen tube and blood should begin to flow into the tube. DELMAR/CENGAGE LEARNING

FIGURE 28-17 Allow the tube to fill with blood. When it is full, remove the tube and insert additional tubes as needed. DELMAR/CENGAGE LEARNING

- | | |
|--|--|
| <p>22. After the specimen collection is completed, release the tourniquet.</p> <p>23. Apply 2 × 2 gauze over the puncture site without applying pressure and quickly withdraw the needle from the vein.</p> <p>24. Immediately apply pressure over the venipuncture site with the gauze for 2 to 3 minutes or until the bleeding has stopped. Tape the gauze dressing over the site (or apply the Band-Aid).</p> | <p>22. Reduces bleeding from pressure when the needle is removed.</p> <p>23. Positions the gauze for removal and helps to gently prevent the skin from pulling with the needle removal.</p> <p>24. Direct pressure stops the bleeding and minimizes formation of a hematoma. You may avoid using tape or a Band-Aid if after applying pressure no bleeding is present. Many clients are sensitive to tape, and its removal can be painful.</p> |
|--|--|

(Continues)

PROCEDURE 28-1 Performing Venipuncture (Continued)

ACTION	RATIONALE
25. Syringe method: Using one hand, insert the syringe needle into the appropriate collection tube and allow vacuum to fill. <ul style="list-style-type: none"> You may also remove the stopper from each Vacutainer collection tube, remove the needle from the syringe, fill the tube, and replace the stopper. 	25. Using a one-handed method to fill the syringe helps reduce the chance of needlestick injury. <ul style="list-style-type: none"> This alternative method allows you to control the speed and amount of fill in the collection tubes.
26. If any of the blood tubes contain additives, gently rotate back and forth 8 to 10 times.	26. Ensures that the additive is properly mixed throughout the specimen.
27. Inspect the client's puncture site for bleeding. Reapply clean gauze and tape if necessary.	27. Keeps site clean and dry.
28. Assist client into a comfortable position. Return bed to low position with side rails up if appropriate.	28. Provides comfort and safety for the client.
29. Check tubes for any external blood and decontaminate with alcohol as appropriate.	29. Prevents contamination to other equipment and personnel.
30. Check tubes for proper labeling. Place tubes into appropriate bags and containers for transport to the laboratory.	30. Ensures the specimens are properly identified.
31. Dispose of needles, syringe, and soiled equipment into proper container.	31. Prevents spread of disease and needlestick injury.
32. Remove and dispose of gloves.	32. Reduces transmission of microorganisms.
33. Wash hands/hand hygiene.	33. Reduces transmission of microorganisms.
34. Send specimens to the laboratory.	34. Facilitates timely handling of specimens and accurate results.

delegation tip

The procedure of performing a venipuncture for the purposes of blood drawing is frequently delegated to properly trained ancillary personnel. Documentation of their competency and skill should be available to the nurse, and periodic reevaluation should occur according to agency and state policy. The ancillary personnel should be reminded to not obtain blood specimens from an extremity above the site of infusing fluids and to report to the nurse any complications or concerns the client might express postprocedure.

nursing tips

Clients with a depressed white blood cell count are susceptible to infection. Whenever you have to puncture the skin of a client with a depressed white blood cell count, cleanse the puncture site for 2 to 3 minutes.

PROCEDURE 28-2

Performing a Skin Puncture

EQUIPMENT

- Antiseptic 70% isopropanol or povidone-iodine
- Microhematocrit tubes or micropipette (collection tubes)
- Sterile 2 × 2 gauze
- Sterile lancet
- Nonsterile gloves
- Hand towel or absorbent pad

(Continues)

PROCEDURE 28-2 Performing a Skin Puncture (Continued)

ACTION	RATIONALE
1. Wash hands/hand hygiene. 2. Check the client's identification band if appropriate.	1. Reduces transmission of microorganisms. 2. Ensures the correct client.
3. Explain the procedure to the client.	3. Allays anxiety and encourages cooperation.
4. Prepare supplies: <ul style="list-style-type: none"> • Open sterile packages. • Label specimen collection tubes. • Place in easy reach. 	4. Ensures efficiency.
5. Apply gloves.	5. Decreases the health care provider's exposure to bloodborne organisms.
6. Select site: lateral aspect of the fingertips in adults and children; heel for neonates and infants.	6. Avoids damage to nerve endings and calloused areas of the skin.
7. Place the hand or heel in a dependent position; apply warm compresses if fingers or heel are cool to touch.	7. Increases the blood supply to the puncture site.
8. Place hand towel or absorbent pad under the extremity.	8. Prevents soiling the bed linen.
9. Cleanse puncture site with an antiseptic and allow to dry. Use 70% isopropanol if the client is allergic to iodine (see Figure 28-18).	9. Reduces skin surface bacteria; povidone-iodine must dry to be effective.
10. With nondominant hand, apply gentle milking pressure above or around the puncture site. Do not touch the puncture site.	10. Increases blood to puncture site and maintains asepsis.
11. Read directions carefully before using the lancet. <ul style="list-style-type: none"> • With the sterile lancet at a 90° angle to the skin, use a quick stab to puncture the skin (about 2 mm deep) (see Figure 28-19). • With the automatic Unistik, push the lancet into the body of Unistik until it clicks. Hold the body of the Unistik and twist off the lancet cap. Place the end of the Unistik tightly against the client's finger and press the lever. The needle automatically retracts after use. 	11. Provides a blood sample with minimal discomfort to the client.

FIGURE 28-18 Cleanse the puncture site and allow it to dry. DELMAR/CENGAGE LEARNING

FIGURE 28-19 Use a quick stab to puncture the skin. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 28-2
Performing a Skin Puncture (Continued)

ACTION	RATIONALE
12. Wipe off the first drop of blood with sterile 2 × 2 gauze; allow the blood to flow freely (see Figure 28-20).	12. The first drop may contain a large amount of serous fluid, which could affect the results. Pressure at the puncture site can cause hemolysis.
13. Collect the blood into the tube(s). If blood for a platelet count is to be collected, obtain this specimen first (see Figure 28-21).	13. Allows blood collection; avoids aggregation of platelets at the puncture site.
14. Apply pressure to the puncture site with a sterile 2 × 2 gauze (see Figure 28-22).	14. Controls bleeding.
15. Place contaminated articles into a sharps container.	15. Reduces the risk of needlestick.
16. Remove gloves; wash hands.	16. Reduces transmission of microorganisms.
17. Position client for comfort with call light in reach.	17. Provides for comfort and communication.
18. Wash hands/hand hygiene.	18. Reduces transmission of microorganisms.

FIGURE 28-20 Allow the blood to flow from the puncture site to ensure an adequate amount can be obtained. DELMAR/CENGAGE LEARNING

FIGURE 28-21 Collect a small sample of blood. DELMAR/CENGAGE LEARNING

FIGURE 28-22 Apply pressure to the puncture site to stop further bleeding. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 28-2 Performing a Skin Puncture (Continued)

delegation tip

Properly trained ancillary personnel may perform skin puncture. Agency policy usually dictates certification and recertification requirements for this skill. Proper client and specimen identification are of the utmost importance and must be consistently demonstrated by the ancillary personnel.

nursing tips

- Visualize urine before tests to look for contamination.
- Read instructions before dipping stick or test tape in urine.
- Have at least 20 cc of urine for urinometer.
- Verify that the urine is second-voided specimen and explain this need to the client.

PROCEDURE 28-3

Obtaining a Residual Urine Specimen from an Indwelling Catheter

EQUIPMENT

- Nonserrated clamp or rubber band
- Nonsterile gloves
- Syringe with needle (1 inch), 10 cc
- Specimen container, plastic bag, and labels
- Povidone-iodine swabs

ACTION	RATIONALE
1. Wash hands/hand hygiene.	1. Reduces transmission of microorganisms.
2. Check health care provider's order.	2. Determines test and container needed for the specimen.
3. Explain procedure to the client and provide privacy.	3. Informs client and maintains client dignity.
4. Check for urine in the tubing.	4. Determines if there is sufficient urine in the collecting tubing for a specimen. Urine from the collection bag should not be used for sterile specimens.
5. If more urine is needed, clamp the tubing using a nonserrated clamp or a rubber band for 10 to 15 minutes (see Figure 28-23 on page 645).	5. Collects 10 cc of urine, which is needed for most urinalyses.
6. Put on clean gloves.	6. Practices Standard Precautions.
7. Clean sample port with a povidone-iodine swab.	7. Prevents entrance of microorganisms into the system.
8. Insert sterile needle and syringe into the sample port or catheter at a 45° angle and withdraw 10 mL of urine (see Figure 28-24 on page 645).	8. Obtains specimen with sufficient volume for most urine tests.
9. Put urine into sterile container and close tightly, taking care not to contaminate the lid of the container.	9. Prevents contamination of specimen and spill of urine.

(Continues)

PROCEDURE 28-3
Obtaining a Residual Urine Specimen from an Indwelling Catheter (Continued)

ACTION	RATIONALE
	
<p>FIGURE 28-23 Clamp the tubing by folding it over and securing it with a rubber band to collect an adequate sample. <small>DELMAR/CENGAGE LEARNING</small></p> <ol style="list-style-type: none"> Remove clamp and rearrange tubing, avoiding dependent loops. Label specimen container, put it in a plastic bag, and send to the laboratory. Wash hands/hand hygiene. 	<p>FIGURE 28-24 Cleanse the sample port and insert a sterile needle and syringe into the port. <small>DELMAR/CENGAGE LEARNING</small></p> <ol style="list-style-type: none"> Reestablishes urine flow and drainage into the system. Ensures right test and controls transfer of pathogens. Reduces transmission of microorganisms.

delegation tip

Obtaining a urine specimen from an indwelling catheter requires the skill and problem-solving ability of a nurse. This task cannot be delegated to ancillary personnel.

nursing tips

When doing catheter care, do not allow urine to drain back into the bladder.

PROCEDURE
28-4

Collecting a Clean-Catch Midstream Urine Specimen

EQUIPMENT

- Sterile collection container with lid and label
- Toilet paper
- Nonsterile latex-free gloves
- Sterile midstream kit, antiseptic towelettes, or cotton balls with antiseptic solution
- Sterile gauze (optional)

ACTION	RATIONALE
<ol style="list-style-type: none"> Wash hands/hand hygiene. Assess the client's ability to complete the procedure, including understanding, mobility, and balance. Assess the client for signs and symptoms of urinary abnormalities. 	<ol style="list-style-type: none"> Provides for organization and reduces the transmission of microorganisms. Improves compliance and likelihood of obtaining sterile specimen. Improves compliance and provides baseline data.

(Continues)

PROCEDURE 28-4 Collecting a Clean-Catch Midstream Urine Specimen (Continued)

ACTION	RATIONALE
<p>4. Check the client's identification.</p> <p>5. If the client is to complete the procedure in privacy, explain the procedure, give equipment to the client, and wait for specimen. If the client has decreased personal hygiene, perform the procedure after a bath or have the client wash the perineal area before the procedure.</p> <p>6. If the nurse is to perform the procedure, wash hands and apply gloves. If the client is to perform the procedure, instruct the client to wash hands before and after the procedure. If the client is more comfortable, allow him or her to wear gloves.</p> <p>7. Provide privacy.</p> <p>8. Instruct the client. Female client: Sit with legs separated on the toilet. Male client: Sit down to help control splashing.</p> <p>9. Using sterile procedure, open kit or towelettes (see Figure 28-25). Open sterile container, placing the lid with sterile side up on a firm surface (see Figure 28-26).</p> <p>10. Female client: Use the thumb and forefinger to separate the labia, or have the client separate the labia with fingers (see Figure 28-27 on page 647). With the labia separated, use a downward stroke (from the top of the labia down toward the rectal area), and cleanse one side of the labia with the towelette (see Figure 28-28 on page 647). Discard the towelette and repeat the procedure on the other side with another towelette, keeping the labia separated at all times. With a third towelette, use a downward stroke from the top of the urethral opening to the bottom. Discard the towelette.</p>	<p>4. Ensures accuracy.</p> <p>5. Increases compliance. Protects client from embarrassment.</p> <p>6. Decreases transmission of microorganisms.</p> <p>7. Decreases embarrassment.</p> <p>8. Increases compliance and understanding.</p> <p>9. Prevents contamination of the specimen.</p> <p>10. Provides access for cleaning the labia. Cleanses area and prevents contamination of clean area. Prevents contamination by feces. Keeping labia separated avoids contamination and decreases microorganisms in specimen.</p>

FIGURE 28-25 Open specimen cup and kit or cleansing towel packages prior to beginning the procedure. DELMAR/CENGAGE LEARNING

FIGURE 28-26 Place the lid on a firm surface, sterile side up. Do not touch the inside of the lid. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 28-4
Collecting a Clean-Catch Midstream Urine Specimen (Continued)

ACTION

RATIONALE

FIGURE 28-27 Separate the labia with the fingers of the nondominant hand. DELMAR/CENGAGE LEARNING

FIGURE 28-28 Cleanse each side and down the middle using a single downward stroke for each towelette. Keep the labia separated. DELMAR/CENGAGE LEARNING

11. Male client: Pull back the foreskin (if present in uncircumcised male) and clean with a single stroke around meatus and glans. Use a circular motion starting with the head of the penis at the urethral opening, moving down the glans shaft. Discard the towelette and repeat the procedure with another towelette, keeping the foreskin retracted. Cleanse the head of the penis three times using a circular motion. Use a new towelette each time.
12. Ask the client to begin to urinate into the toilet. After the stream starts with good flow, place the collection cup under the stream of urine. Avoid touching the skin with the container. Fill the container with 30 to 60 cc of urine and remove the container before urination ceases. Wipe with toilet paper.
13. Place the sterile lid back onto the container and close tightly (see Figure 28-29). Clean and dry the outside of the container with a towelette. Wash hands. Label and enclose in a plastic biohazard bag (see Figure 28-30), and follow facility policy for transporting specimen to the laboratory.
14. Remove and dispose of gloves and perform hand hygiene.

11. Prevents contamination of microorganisms from foreskin. Single strokes and moving away from opening prevent contamination of the urethral opening.
12. The specimen is collected midstream to avoid contamination of urine that touches the labia. The initial urine flushes bacteria from the orifice, and the end urine may have contact with the meatus or labia and, hence, be contaminated.
13. Prevents contamination of sterile specimen, prevents spillage, and ensures accuracy.
14. Decreases transmission of microorganisms.

FIGURE 28-29 Replace the lid and close tightly. DELMAR/CENGAGE LEARNING

FIGURE 28-30 Label the container with the name of the client, date, and time the specimen was collected. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 28-4 Collecting a Clean-Catch Midstream Urine Specimen (Continued)

delegation tip

Collection of a clean-catch specimen may be delegated to ancillary personnel properly trained in the technique of cleaning the client and obtaining the voided specimen.

nursing tips

- Labia may be slippery after cleansing; therefore, use sterile dry gauze to hold apart during urination.
- Clients often do not understand the need to remove the specimen container before completing urination; therefore, carefully explain the purpose for midstream collection.
- If the client is unable to void, run tap water within hearing distance or place a warm compress over the bladder.

PROCEDURE 28-5

Measuring Blood Glucose Levels

EQUIPMENT

- Reagent strips
- Disposable latex-free gloves
- Lancet or automatic lancing device
- Paper towels
- Alcohol wipe
- 2 × 2 gauze
- Cotton ball
- Blood glucose meter

ACTION

1. Review orders, identify the client, and review the manufacturer's instructions for meter usage.
2. Wash hands/hand hygiene.
3. Assemble the equipment at the bedside (see Figure 28-31 on page 649).
4. Have the client wash hands with soap and water, and position the client comfortably in a semi-Fowler's position or upright in a chair.
5. Remove a reagent strip from the container and reseal the container cap. Then, turn on meter.
6. Following the manufacturer's instructions, calibrate the meter by inserting the strip into the meter.

RATIONALE

1. Prevents performing an invasive procedure on the wrong client and promotes accuracy of results.
2. Reduces transmission of microorganisms.
3. Allows for a smooth procedure.
4. Reduces transmission of microorganisms and increases blood flow to the puncture site. Avoids having the client stand during the procedure, as some clients may be prone to fainting.
5. Tight closure of the container keeps strips from discoloring from environmental factors. Activates meter for test.
6. Some meters need to be calibrated; others require the timer to be adjusted; each meter has different requirements when setting it up for use.

(Continues)

PROCEDURE 28-5 Measuring Blood Glucose Levels (Continued)

ACTION

FIGURE 28-31 Supplies for blood glucose testing. DELMAR/CENGAGE LEARNING

7. Remove the unused reagent strip from the meter and place it on a clean, dry surface (paper towel) with the test pad facing up.
8. Apply disposable gloves.
9. Select appropriate puncture site and perform skin puncture (see Figure 28-32).
10. Wipe away the first drop of blood from the site.
11. Gently squeeze the site to produce a large droplet of blood.
12. Transfer the drop of blood to the reagent strip by carefully moving the site over the strip. The droplet should transfer without smearing (see Figure 28-33).
13. Quickly press the timer on the meter and lay the strip next to the meter on a clean, dry surface.
14. Apply pressure to the puncture site (see Figure 28-34).

FIGURE 28-33 Transfer a drop of blood to the test strip. DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 28-32 Perform the skin puncture. DELMAR/CENGAGE LEARNING

7. Moisture may alter the test results.
8. Protects from contamination by blood.
9. Collects blood necessary for the test.
10. This drop may impede accurate results because it may contain a large amount of serous fluid.
11. Do not contaminate the site by touching it; the droplet of blood needs to be large enough to cover the test pad on the reagent strip.
12. The test pad must absorb the droplet of blood for accurate results. Smearing of the blood will alter results.
13. Timing is critical to produce accurate results. Always check the manufacturer's instructions because the technique varies between meters.
14. This will stop the bleeding at the site.

FIGURE 28-34 Apply pressure to the site. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 28-5 Measuring Blood Glucose Levels (Continued)

ACTION	RATIONALE
15. After 60 seconds, wipe the blood from the test pad with a cotton ball; place the strip into the meter. (Note: This step may vary with the type of meter.) Allow the timer to continue.	15. This step is specific to certain meters (e.g., Accu-Chek III) that require the strip to enter the meter dry.
16. Read the meter for results found on the unit display.	16. Each meter has a specified time for the reading to occur.
17. Turn off the meter and properly dispose of the test strip, cotton ball, and lancet.	17. Reduces contamination by blood to other individuals; sharps must always be handled properly to protect others from accidental injury.
18. Remove disposable gloves and place them in the appropriate receptacle.	18. Reduces transmission of microorganisms.
19. Wash hands/hand hygiene.	19. Reduces contamination by microorganisms.
20. Review tests results with the client.	20. Promotes participation in health care.
21. Notify the health care provider of the test results.	21. Results will be used to determine the client's treatment plan.
22. Wash hands/hand hygiene.	22. Reduces transmission of microorganisms.

delegation tip

Properly trained ancillary personnel may measure blood glucose levels. Agency and state health department policies usually dictate certification and recertification requirements for this skill. Proper client and specimen identification are of the utmost importance and must be consistently demonstrated by the ancillary personnel. Proper recording of results and prompt reporting to the nurse of abnormal findings are essential.

nursing tips

- Have client hold hand in a dependent position while you are setting up the equipment to promote venous engorgement in the fingertips.
- Be sure client's hands are warm.
- Use client's nondominant hand, if possible.

KEY CONCEPTS

- Most invasive procedures require the client's written consent and a thorough understanding of the reasons the test is being performed. Nurses explain the purpose of the diagnostic test and the reasons it has been ordered.
- Nurses prepare clients for diagnostic testing by ensuring client understanding and compliance with preprocedural requirements.
- Clients, families, and significant others need to be involved in the testing process; advise them of the estimated time the procedure requires.
- Nurses teach the client how to perform relaxation and imagery techniques to cope with the discomfort and anxiety experienced during procedures.
- After a procedure, the nurse provides care and teaches the client what to expect following a diagnostic test and the outcomes or side effects of the test.
- Specimen collection methods include punctures such as venipuncture, arterial puncture, capillary puncture, catheter insertion, and bone marrow aspiration. Specimens collected by noninvasive methods include urine, stool, sputum, throat tissue, and cervical tissue.
- Invasive procedures include endoscopy, angiography, aspiration, biopsy, and other procedures in which body cavities are punctured.
- Noninvasive procedures include radiography, fluoroscopy, mammography, computed tomography, radioisotope scanning, ultrasonography, magnetic resonance imaging, and electrodiagnostic studies.
- The role of the nurse in diagnostic procedures is to facilitate the scheduling of diagnostic tests, perform client teaching, perform or assist with procedures,

- and assess the client for adverse responses to the procedures.
- Nurses should schedule diagnostic procedures to promote client comfort and cost containment.
 - Standard Precautions are used when obtaining a specimen for diagnostic examination or assisting with an invasive procedure.
 - Before the procedure, the nurse is responsible for obtaining baseline vital signs and assessing the client's preparation for testing.
 - Nurses may assist the practitioner in performing invasive procedures.
 - After the procedure, the nurse assesses the client for secondary procedural complications and provides any necessary nursing interventions.

REVIEW QUESTIONS

1. Preparing the client for diagnostic testing includes which of the following? Select all that apply.
 - a. Appropriate preparation
 - b. Individualized education
 - c. Placing in the correct position
 - d. Initiating Standard Precautions
 - e. Providing emotional support
 - f. Documenting the diagnostic outcomes
2. The purpose of the Joint Commission's 2009 *Hospitals' National Patient Safety Goals* is to do which of the following?
 - a. Improve the hospital's rating
 - b. Decrease client error
 - c. Increase hospital revenues
 - d. Increase the image of nursing
3. Decreasing the length of time a client stands prior to venipuncture and the length of time the tourniquet is left on the client's arm helps to prevent which of the following?
 - a. Hemoconcentration
 - b. Hemorrhage
 - c. Homeostasis
 - d. Hypoxemia
4. After drawing arterial blood gases (ABG), the nurse should
 - a. Pack the blood sample in ice for transport to the laboratory.
 - b. Keep pressure on the radial artery puncture site for at least 1 minute.
 - c. Transfer the blood sample to a heparinized test tube.
 - d. Draw the second sample in 10 minutes.
5. When there is a delay in sending a urine sample to the laboratory for analysis, the nurse should
 - a. Notify the prescribing practitioner.
 - b. Discard the urine sample.
 - c. Place the sample in a plastic bag and refrigerate.
 - d. Write "stat" on the requisition and demand that the laboratory pick up the sample.
6. Which best defines culture and sensitivity?
 - a. It is a common screening test.
 - b. It allows the bacteria to grow and multiply so that the exact organism can be identified by various methods of analysis.
 - c. It identifies both the nature of the invading organism(s) and their susceptibility to commonly used antibiotics.
 - d. It evaluates the cell maturity, metabolic activity, and morphologic variations.
7. Which of the following are contrast-mediated studies? Select all that apply.
 - a. Barium swallow
 - b. Bronchography
 - c. Intravenous cholangiography
 - d. Mammography
 - e. Myelogram
 - f. Ultrasonography
8. List the following steps in the correct order for instructing a male client to obtain his own clean-catch midstream urine specimen.
 - a. Wash hands.
 - b. Pull back the foreskin (uncircumcised) and clean with a single stroke around the meatus and glans with a towelette using a circular motion starting with the head of the penis at the urethral opening, moving down the glans shaft. Discard the towelette and cleanse the head of the penis three times using a circular motion and new towelette each time.
 - c. Open the sterile procedure kit and place the lid face down on a firm surface.
 - d. Begin to urinate into the toilet; after the stream starts to flow, place the collection cup under the stream of urine, and collect 30 to 60 cc of urine without touching the skin with the container.
 - e. Tightly place the lid on the container.
 - f. Label the container and place in a plastic biohazard bag.

CHAPTER 29

Safety, Infection Control, and Hygiene

COMPETENCIES

1. Describe the factors affecting environmental safety.
2. Describe the chain of infection.
3. Explain the principles of medical and surgical asepsis.
4. Contrast the various types of isolation precautions.
5. Discuss the factors that influence a client's personal hygiene practices.
6. Explain the role of assessment in maintaining a safe environment.
7. Discuss the nursing interventions that can be used to resolve environmental hazards in institutional and home settings.
8. Describe the nursing interventions that promote a client's personal hygiene.

KEY TERMS

acquired immunity	disinfectants	pathogens
agent	disinfection	perineal care
airborne transmission	equipment accidents	physical agents
anthropogenic	erythema	physical restraints
antibodies	floras	poison
antigens	germicide	prodromal stage
antiseptic hand rub	gingivitis	pyorrhea
antiseptic handwash	halitosis	resident floras
asepsis	hand hygiene	restraints
aseptic technique	handwashing	risk for infection
autoimmune disorders	health care–associated infections (HAIs)	sebum
biological agents	hospital-acquired conditions (HACs)	self-care deficit
body image	host	sensory overload
cavities	humoral immunity	spores
chain of infection	hygiene	sterilization
chemical agents	illness stage	stomatitis
chemical restraints	incubation period	surgical asepsis
clean objects	infection	surgical hand antisepsis
cleansing	infectious agents	susceptible host
client behavior accidents	inflammation	systemic infections
colonization	localized infections	therapeutic procedure accidents
communicable agents	lymphokines	transient floras
communicable diseases	medical asepsis	vaccination
compromised host	mode of transmission	vectorborne transmission
contact transmission	pathogenicity	vehicle transmission
convalescent stage		virulence
dirty (soiled) objects		

Safe care is a basic need of all clients, regardless of the setting. Registered nurses (RNs) are responsible for providing the client with a safe environment through the delivery of professional, quality nursing care that incorporates safety precautions, infection control practices, and hygiene assistance. This chapter describes the RN's role in each of these areas.

CREATING A CULTURE OF CLIENT SAFETY

A culture of safety pertains to environmental safety in health care settings, including the home. A landmark report published by the Institute of Medicine (IOM) of the National Academy of Sciences in 1999, *To Err Is Human: Building a Safer Health Care System*, brought national attention to the problem of hospital medical errors. Historical, medical error review was based on the underlying assumption that most injuries were the result of incompetent, negligent behavior or corporate greed; therefore, error and error analysis focused

on humans as the unreliable sources of error. However, the IOM report found that most medical errors did not result from individual carelessness but from basic flaws in the health care delivery systems.

The IOM report served as a catalyst of reform in health care organizations, educational institutions, and regulatory and accrediting agencies to remove the blame from health care providers and to improve health care systems. Client safety is defined as “freedom from accidental injury” and error as a “failure of a planned action to be completed as intended or the use of a wrong plan to achieve an aim” (Kohn, Corrigan, & Donaldson, 1999, pp. 13–14). In a later report, client safety practices were defined as “a type of process or structure whose application reduces the probability of adverse events resulting from exposure to the health care system across a range of diseases and procedures” (Shojania, Duncan, & McDonald, 2001, p. 13).

The challenge to current health care organizations is to create a culture of client safety and to focus on change rather than blame. The Patient Safety and Quality Improvement Act of 2005 amended the Public Health Service Act to

encourage a culture of safety in health care organizations. The act provides legal protection of information voluntarily reported to the client safety organizations. The National Patient Safety Foundation of the American Medical Association, the U.S. Department of Veterans Affairs, and the Joint Commission have made a commitment to develop policies, conduct research, and establish standards that foster a culture of client safety.

Professional nursing has initiated an agenda of developing evidenced-based practices promoting health care cultures of client safety. A key role for nurse administrators is to help improve RN access to evidence-based literature to enable RNs to interact more proactively for safety.

In 2003, the Joint Commission established the first National Patient Safety Goals (NPSGs) to promote specific improvements in client safety. Based on the data collected annually, the Joint Commission publishes and revises the NPSGs as evidence-based recommendations. The 2009 NPSGs are to:

- Identify clients correctly
- Improve staff communications
- Use medicines safely
- Prevent infection
- Check client medicines
- Prevent clients from falling
- Help clients to be involved in their care
- Identify client safety risks
- Watch clients closely for changes in their health and respond quickly if they need help
- Prevent errors in surgery

To improve the quality of care during a hospital stay, the Centers for Medicare and Medicaid Services (CMS) identified certain **hospital-acquired conditions (HACs)** that are deemed reasonably preventable by following evidence-based guidelines and are either costly or common. The HACs are called “never events” because they are events that should never happen in a hospital. The Medicare Modernization Act and Deficit Reduction Act of 2005 granted the CMS the right to reduce, withhold, or refuse reimbursement

to hospitals for certain HACs. The Medicare law went into effect in October 2008. Medicare will no longer reimburse hospitals at a higher rate for the increased costs that result from HACs; however, Medicare will continue to pay for prescribing practitioner and other covered items or services that are needed to treat the HAC, including postacute care. The HACs include:

- Foreign object (e.g., sponge or needle) inadvertently left in clients after surgery
- Air embolism
- Transfusion with the wrong type of blood
- Severe pressure ulcers
- Falls and trauma
- Catheter-associated urinary tract infection
- Vascular catheter-associated infection
- Manifestations of poor control of blood sugar levels
- Surgical site infection following coronary artery bypass graft
- Surgical site infection following certain orthopedic procedures
- Surgical site infection following bariatric surgery for obesity
- Deep vein thrombosis and pulmonary embolism following certain orthopedic procedures (CMS, 2008)

It is the intent of Medicare to add documents to the list of HACs as needed to ensure client safety. “If at discharge, there is a selected condition that was either not identified by the hospital as present on admission, or could not be identified based on data and clinical judgment at admission, it is considered hospital-acquired” (CMS, 2008, p. 2). Emerging is a number of different lists by hospital and private insurers that expands the Medicare list.

FACTORS AFFECTING SAFETY

Client safety is influenced by several factors such as age, lifestyle, sensory and perceptual alterations, mobility, emotional state, and staffing.

Age

Risk for injury varies with chronological age and developmental stage. Health education about preventive measures can facilitate injury prevention for various age groups.

As infants mature, their potential for injury increases. Infants, toddlers, and preschoolers are explorers of their environment. Most accidents involving these age groups are avoidable with careful adult supervision to prevent falls from bed, burns, electrical hazards, choking on small objects, and drowning.

As school-age children explore their environment outside of the home, their risk for injury increases. Prevention measures during this stage focus on not accepting candy, food, gifts, or rides from strangers; bicycle, skating, and swimming safety; and substance abuse.

Adolescents and young adults usually enjoy good physical health; however, their lifestyles put them at risk for injury. Since this age group spends much time away from home, collaborative educational efforts among parents, schools, and

SPOTLIGHT ON...

Legal and Ethical

Reporting Errors

Registered nurses are taught in nursing school to safeguard our clients and do them no harm. When mistakes occur, nurses are reluctant to report the error. Nurses worry about resultant harm to clients, families, their career, and themselves. No matter how hesitant a nurse may be to report an error, the ethical response is to inform the client and family. What can nurses do to create a culture of support when a nursing colleague is involved in errors that have unintentionally caused harm?

community health care providers need to focus on environmental safety. High-risk factors for injury and death are automobile accidents, substance abuse, violence, unwanted pregnancies, and sexually transmitted diseases.

Studies indicate that adolescents who initiate substance use in middle school and continue into high school are likely to become multisubstance users (tobacco, alcohol, and drugs). The progression from lighter to heavier use of illicit substances during adolescence leads to more serious multisubstance use careers.

Adult risk for injury is generally related to lifestyle, work practices, and behaviors. Prevention measures during this period emphasize nutrition, exercise, and occupational safety. High-risk factors for this age group include fatigue, anxiety, sleep pattern disturbances, caregiver role strain, and altered health maintenance.

The older adult is prone to falls, especially in the bathroom, bedroom, and kitchen, because of a loss of agility and visual acuity, a predisposition to dizziness and syncope, and side effects from medications. Every year one in three Americans over the age of 65 years experiences a fall and, of these, 30% cause injury requiring medical treatment (Cassels, 2008). Prevention measures for this age group emphasize slow positional changes, good lighting, hand rails, and skidproof strips in the bathtub or shower and under rugs and carpets.

Lifestyle

Lifestyle practices can increase a person's risk for injury and potential for disease. Individuals who operate machinery; experience

stress, anxiety, and fatigue; use alcohol and drugs (prescription and nonprescription); and live in high-crime neighborhoods are at risk for injury. Risk-taking behaviors such as daredevil activities, driving vehicles at high speeds, and smoking are factors associated with accidents (Figure 29-1).

Sensory and Perceptual Alterations

Sensory functions are essential for the accurate perception of environmental safety. If one of the senses is altered, then the other senses compensate to facilitate perception of the environment. For instance, a blind person usually will develop a keen sense of touch and hearing. Clients who have visual, hearing, taste, smell, communication, or touch perception impairments are at increased risk for injury. These clients are often not able to perceive a potential danger. See Chapter 38 for a complete discussion on sensory or perceptual alterations.

Mobility

Clients who have impaired mobility are at increased risk for injury, especially falls. Mobility impairments may be a result of poor balance or coordination, muscle weakness, or paralysis. Immobility may also precipitate physiological and emotional complications such as decubitus and depression, respectively. See Chapter 36 for a complete discussion on mobility.

Emotional State

Emotional states such as depression and anger affect a client's perception of environmental hazards and degree of risk-taking

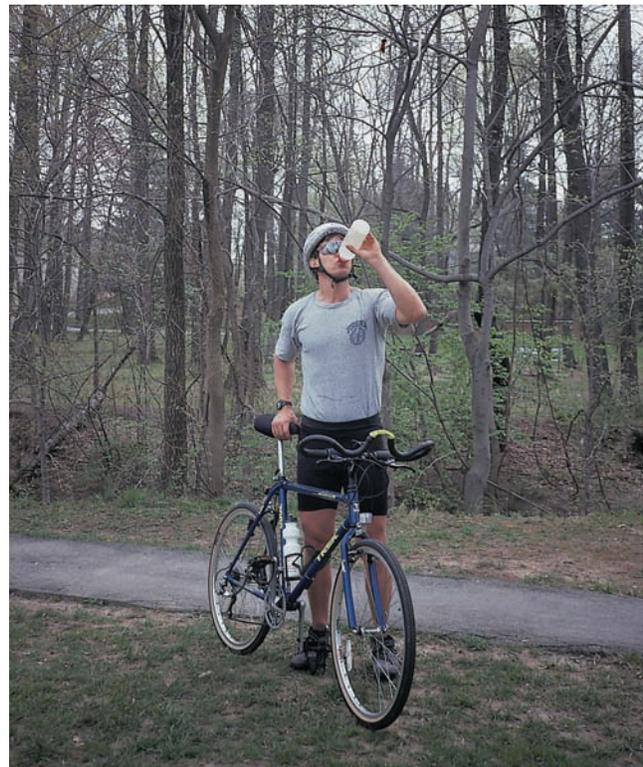

FIGURE 29-1 Lifestyle practices that can either increase or decrease a client's risk of injury. Can these practices be easily reversed, in terms of risky behavior, or adopted, in terms of promoting healthy approaches, by clients? DELMAR/CENGAGE LEARNING

behavior. These emotional states alter a client's thinking patterns and reaction time. Usual safety precautions may be forgotten during periods of emotional stress. Self-confidence decreases when older adults fall; they tend to limit their activities because they fear falling again.

TYPES OF ACCIDENTS

In the health care setting, accidents are categorized by their causative agent: client behaviors, therapeutic procedures, or equipment:

1. **Client behavior accidents** occur when the client's behavior or actions precipitate the incident, for example, poisoning, burns, and self-inflicted cuts and bruises.
2. **Therapeutic procedure accidents** occur during the delivery of medical or nursing interventions, for example, medication errors, client falls during transfers, contamination of sterile instruments or wounds, and improper performance of nursing activities.
3. **Equipment accidents** result from the malfunction or improper use of medical equipment, for example, electrocution and fire.

National and institutional policies establish safety standards; for example, the risk for equipment accidents can be reduced by having the biomedical engineering department check the equipment inspection label prior to use. All accidents and incident reports must be fully documented according to institutional protocol.

Staffing

As Hinshaw describes nurse staffing and client safety, “balancing the development of cultures of safety with nursing workforce challenges is similar to navigating the perfect storm” (2008, p. S4). The perfect storm is characterized as a tempest of extreme intensity that rarely happens and is a result of multiple factors that end in a situation worse than previously experienced. The climate of change is demanding client safety (the Joint Commission, NPSGs, the CMS) while nursing is being confronted with a shortage of nurses and nursing faculty. The response to this storm from health care organizations is to create cultures of safety, recognizing the importance of public policy for client safety, the need for health systems reforms, and the use of appropriate evidence-based practice. Nursing will be held more and more accountable for assessment and client advocacy skills and for incorporating solid scientific evidence into practice.

POTENTIAL OCCUPATIONAL HAZARDS

Nurses and other health care providers are at risk for injury in the workplace. The Occupational Safety and Health Administration (OSHA), a division of the Department of Labor, has the power to enforce safety standards and to cite and discipline agencies that are not in compliance with the standards.

Numerous hazards exist in today's workplace, such as latex allergies, bloodborne pathogens, work-related musculoskeletal disorders (MSDs), chemotherapeutic agents, environmental pollution, and violence. Nurses who prepare or administer

chemotherapeutic agents are exposed to occupational hazards from dermal absorption, ingestion, and inhalation from aerosolization of powder or liquid during reconstitution or from spillage. The salient points regarding latex allergy and MSDs are discussed here; bloodborne pathogens are discussed later in this chapter.

Latex Allergy

The National Institute for Occupational Safety and Health (NIOSH, 1997) issued an *Alert* titled *Preventing Allergic Reactions to Natural Rubber Latex in the Workplace*. Latex products are manufactured from a milky fluid derived from the Brazilian rubber tree, *Hevea brasiliensis*. The allergic response is attributed to the proteins contained in the milky fluid and to the chemicals that are added during the processing and manufacture of commercial latex. There are three types of latex reactions: irritant contact dermatitis; allergic contact dermatitis, the most common type of reaction; and immediate hypersensitivity, a systemic reaction, also called type I IgE-mediated reaction.

Since 1992, when OSHA issued regulations requiring health care workers to wear gloves and other protective devices such as surgical masks and goggles as a safeguard against bloodborne pathogens, health care workers have been placed at risk for developing latex allergy. Commercial latex is in more than 20,000 medical products such as blood pressure cuffs, stethoscopes, catheters, and wound drains, to name a few, as well as in many household items. Reports indicate that 1%–6% of the general population and about 8%–12% of regularly exposed health care workers are sensitive to latex (NIOSH, 1997).

The NIOSH (1997) recommends that employers and employees take a commonsense approach based on current knowledge to protect workers from latex exposure and allergy in the workplace; refer to the accompanying display on page 658 on the NIOSH's recommendations to prevent latex exposure. The NIOSH recommends that if latex gloves are worn, they should be powder free and low allergen because these gloves are less likely than powdered ones to produce allergic responses. Latex-allergic clients should wear MedicAlert identification, carry two doses of epinephrine, and carry several pairs of nonlatex gloves for use by emergency medical personnel (Ricci, 2008).

Work-Related Musculoskeletal Disorders

Work-related back pain affects 38% of nurses. The predominant cause of nurse back pain is lifting clients. OSHA has recommendations for nursing home employers to help reduce the number and severity of MSD conditions such as low back pain, sciatica, rotator cuff injuries, epicondylitis, and carpal tunnel syndrome. The recommendations in these guidelines are based on a review of existing practices and programs, state OSHA programs, and available scientific information. These guidelines are also available to hospitals and other health care providers to reduce the risk of MSD. OSHA ergonomic standards state that a 51-pound stable object with handles is the heaviest amount that can be safely lifted. Health care providers are being challenged, in the midst of personnel cutbacks, to develop and implement safety policies that protect the provider and support OSHA's ergonomic regulations.

NIOSH RECOMMENDATIONS TO PREVENT LATEX EXPOSURE

EMPLOYERS

- Provide workers with nonlatex gloves.
- Provide appropriate barrier protection for workers handling infectious materials; if latex gloves are chosen, provide reduced-protein, powder-free gloves to protect workers from infectious materials.
- Provide good housekeeping to remove latex-containing dust, and ensure that workers change ventilation filters and vacuum bags frequently in latex-contaminated areas.
- Provide education programs regarding latex allergy.
- Periodically screen high-risk workers for latex allergy symptoms.
- Evaluate current policies whenever a worker is diagnosed with a latex allergy.

WORKERS

- Use nonlatex gloves for contact with noninfectious materials.
- Use CDC-appropriate barrier protection when handling infectious materials; if latex gloves are chosen, use reduced-protein, powder-free gloves to reduce exposure and reactions to latex chemical additives (allergic contact dermatitis).
- Use appropriate work practices when wearing latex gloves: Avoid oil-based hand creams or lotions that can cause glove deterioration unless they have been shown to reduce latex-related problems and maintain glove barrier protection; wash hands with a mild soap and dry thoroughly after removing latex gloves; use good housekeeping practices to remove latex-containing dust.
- Attend latex allergy educational programs to become knowledgeable about procedures and to recognize the symptoms of a latex allergy: skin rashes; hives; flushing; itching; nasal, eye, or sinus symptoms; asthma; and shock.
- Avoid direct contact with latex gloves and other products if you develop symptoms until you have been seen by a prescribing practitioner experienced in treating latex allergies.
- If you have a latex allergy, consult your prescribing practitioner regarding exposure precautions, contact with gloves and other latex-containing products, and areas that contain latex powder from gloves worn by other workers; inform your employer and health care providers that you have a latex allergy.
- Carefully follow your prescribing practitioner's instructions regarding allergic latex reactions.

Adapted from National Institute for Occupational Safety and Health Centers for Disease Control and Prevention. (1997). *Preventing allergic reactions to natural rubber latex in the workplace* (DHHS [NIOSH] Publication No. 97-135U). Washington, DC: U.S. Department of Health and Human Services, Public Health Service, Centers for Disease Control and Prevention, National Institute for Occupational Safety and Health.

The ergonomic standards require that all employers must provide workers with the following information: common MSD hazards, signs and symptoms of MSDs and the importance of reporting them early, how to report MSD signs and symptoms, and a summary of the requirement of OSHA standards. The standards require the employer to ensure pay and benefits in the event that an employee needs to take time off or go on lighter duty because of a work-related MSD.

INFECTION CONTROL PRINCIPLES

Client safety in the health care environment requires the reduction of microorganism transmission. Infection control practices are directed at controlling or eliminating sources of

infection in the health care agency or home. Nurses are responsible for protecting clients and themselves by using infection control practices. Nurses and clients must be educated about the types of infections, modes of transmission, risks for susceptibility, and infection control practices required to control or prevent further transmission.

PATHOGENS, INFECTION, AND COLONIZATION

Pathogenicity is the ability of a microorganism to produce disease. Microorganisms that cause diseases in humans are called **pathogens**. Five types of microorganisms can be pathogenic: bacteria, viruses, fungi, protozoa, and *Rickettsia*. **Virulence** is the degree of pathogenicity of an infectious microorganism (pathogen).

Infection and colonization are not synonymous. **Infection** is an invasion and a multiplication of microorganisms in body tissue that result in cellular injury. These microorganisms are called **infectious agents**. Infectious agents that are capable of being transmitted to a client by direct or indirect contact through a vehicle (or vector) or airborne route are also called **communicable agents**. Diseases produced by these agents are referred to as **communicable diseases**. **Colonization** is the multiplication of microorganisms on or within a host that does not result in cellular injury. However, microorganisms that are colonized on a host may be a potential source of infection, especially if host susceptibility declines or if the microorganism's virulence increases.

Some microorganisms reside on the human body as normal flora. This is synonymous with colonization. **Floras** are microorganisms on the human body. There are two types of flora: resident and transient. **Resident floras** are microorganisms that are always present, usually without altering the client's health. Handwashing with soap and water alone is not sufficient to remove resident flora; there must be considerable friction, which is created by rubbing the hands and scrubbing the nails. **Transient floras** are microorganisms that are episodic. They attach to the skin for a brief period of time but do not continually live on the skin. Transient flora is usually acquired from direct contact with the microorganisms on environmental surfaces. Handwashing with soap and water is an effective means of removing transient flora.

CHAIN OF INFECTION

A susceptible host or the presence of a pathogen alone does not mean that an infectious process will occur. The **chain of infection** describes the phenomenon of developing an infectious process. There must be an interactive process that involves the agent, host, and environment. This interactive process must involve several essential elements, or links in the chain, for transmission of microorganisms to occur. Figure 29-2 on page 660 identifies the six essential links (elements) in the chain of infection. Without the transmission of microorganisms, an infectious process cannot occur. Therefore, knowledge about the chain of infection for an infectious process permits control or elimination of the microorganism by breaking the links in the chain of infection. Breaking the chain of infection occurs by altering the interactive process of agent, host, and environment, as shown in Figure 29-2.

Agent, Host, and Environment

An **agent** is an entity that is capable of causing disease. Agents that cause disease may be:

- **Biological agents:** Living organisms that invade the host, such as bacteria, viruses, fungi, protozoa, and *Rickettsia*
- **Chemical agents:** Substances that can interact with the body, such as pesticides, food additives, medications, and industrial chemicals
- **Physical agents:** Factors in the environment that are capable of causing disease, such as heat, light, noise, radiation, and machinery

In the chain of infection, the main concern is biological agents and their effect on the host.

A **host** is a simple or complex organism that can be affected by an agent. Generally, a human being is considered a host. A **susceptible host** is a person who lacks resistance to an agent and is thus vulnerable to disease. A **compromised host** is a person whose normal defense mechanisms are impaired and who is therefore susceptible to infection.

Interaction between agent and host occurs in the environment; the environment consists of everything other than the agent and host. Environmental factors that affect the chain of infection are water, food, plants, animals, housing conditions, noise, meteorological conditions, and environmental chemicals. Many of the conditions that promote the transmission of microorganisms are **anthropogenic**, reflecting changes in the relationship between humans and their environments.

The causes of most emerging infectious diseases are the same today as throughout recorded history: the transfer and dissemination of existing agents to new host populations (a process called “global microbial traffic”). For instance, cholera probably originated in Asia in ancient times; in the nineteenth century it spread to Europe and the New World because of increased global travel. Cholera entered South America for the first time in 1992 through the possible contaminated bilge water released from a Chinese freighter. The causes of emerging infectious diseases and outbreaks require careful consideration of environmental changes and especially of anthropogenic factors.

Modes of Transmission

The **mode of transmission** is the process that bridges the gap between the portal of exit of the biological agent from the reservoir or source and the portal of entry of the susceptible “new” host. Most biological agents have a primary mode of transmission; however, some microorganisms may be transmitted by more than one mode. Almost anything in the environment can become a potential means of transmitting infection, depending on the agent.

The most important and frequent mode of transmission is **contact transmission**, which involves the direct physical transfer of an agent from an infected person to a host through direct contact with a contaminated object or close contact with contaminated secretions. Sexually transmitted diseases are examples of diseases spread by direct contact.

Airborne transmission occurs when a susceptible host contacts droplet nuclei or dust particles that are suspended in the air. Vehicle and vectorborne transmission are indirect modes of transmission, because transmission occurs by an intermediate source. **Vehicle transmission** occurs when an agent is transferred to a susceptible host by contaminated inanimate objects such as water, food, milk, drugs, and blood. **Vectorborne transmission** occurs when an agent is transferred to a susceptible host by animate means such as mosquitoes, fleas, ticks, lice, and other animals.

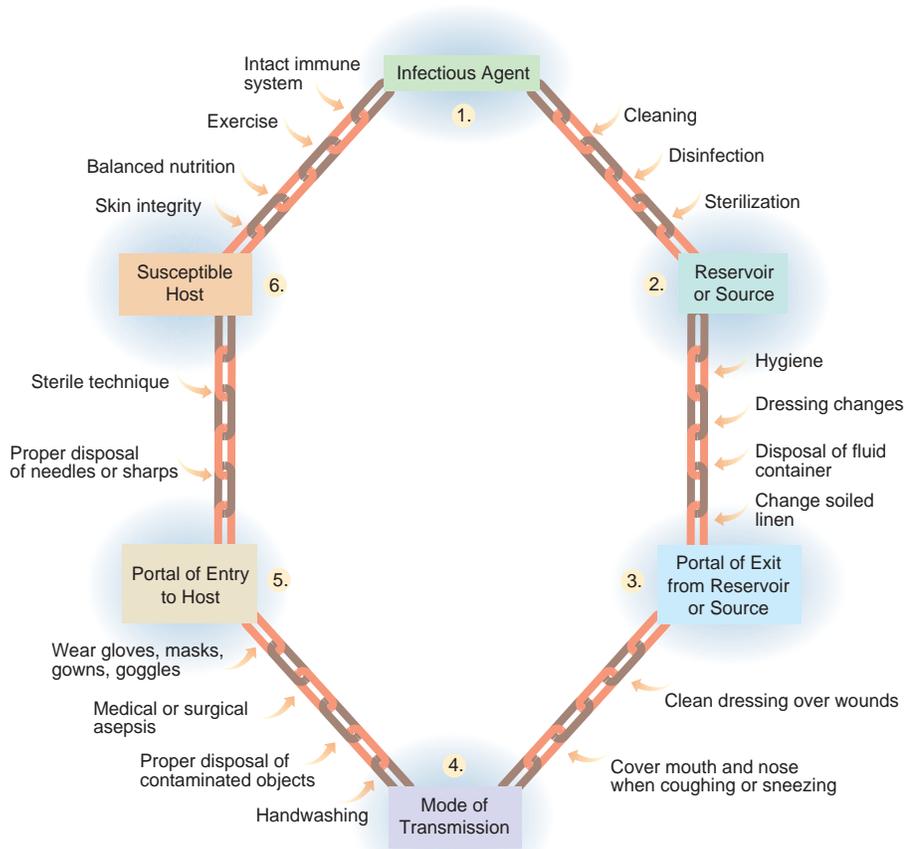

FIGURE 29-2 Breaking the chain of infection. Preventive measures follow each critical link in the chain of infection. DELMAR/CENGAGE LEARNING

Breaking the Chain of Infection

Nurses focus on breaking the chain of infection by applying proper infection control practices to interrupt the mode of transmission. The chain of infection can also be broken by interrupting or blocking the agent, portal of exit, or portal of entry or by destroying the agent or decreasing the host's susceptibility. Refer to Figure 29-2, which shows preventive measures that break the chain of infection. Host susceptibility is dependent on the immune system to function as a defense mechanism.

NORMAL DEFENSE MECHANISMS

A host's immune system serves as a normal defense mechanism to resist the transmission of infectious agents. A unique feature of the immune system is its ability to recognize "self" and "nonself"; that is, the immune system recognizes which agents are not consistent with the genetic composition of the host (self). These agents are usually referred to as antigens (nonself). **Antigens** are foreign proteins. An immune response is mounted against an antigen, which is recognized as nonself, to protect the body from infection. The immune defenses are categorized as nonspecific and specific immune defenses. Nonspecific and specific immune defenses work in harmony to defend the host from pathogens.

Nonspecific Immune Defense

The nonspecific immune defense mounts a response to protect the host from all microorganisms; it is not dependent on prior exposure to the antigen. Nonspecific immune defenses are skin and normal flora; mucous membranes; sneeze, cough, and tearing reflexes; elimination and acidic environment; and inflammation.

SKIN AND NORMAL FLORA Intact skin is the first line of defense against infection, serving as a physical barrier to infectious agents. Skin cells are shed along with potentially harmful microorganisms. **Sebum** is produced by the skin and contains fatty acids that kill some bacteria. The normal flora that resides on the skin competes with pathogenic flora for food and inhibits their multiplication. The balance of normal flora may become disrupted as a result of the inappropriate use of antibiotics, which allows pathogenic organisms to proliferate and causes infection or superinfection.

MUCOUS MEMBRANES AND SNEEZE, COUGH, AND TEARING REFLEXES Mucous membranes also function as a physical barrier to infectious agents. Mucus produced by these membranes entraps infectious agents and contains substances such as antibodies, lactoferrin, and lysozyme, which inhibit bacterial growth. Cilia of the respiratory tract trap and propel

mucus and microorganisms away from the lungs. The sneeze and cough reflexes physically expel mucus and microorganisms from the respiratory tract and oral cavity with force. Tears protect the eyes by continually flushing away microorganisms.

ELIMINATION AND ACIDIC ENVIRONMENT Elimination patterns and an acidic environment normally prevent the microbial growth of pathogenic organisms. Resident flora of the large intestines prevents the growth of pathogens. The mechanical process of defecation evacuates the bowel of feces and microorganisms. Acidity of the urine prevents microbial growth. The flushing action of urination cleanses the bladder neck and urethra of microorganisms and prevents microorganisms from ascending into the urinary tract.

Normal vaginal flora prevents growth of several pathogens. At puberty, lactobacilli ferment and produce sugars in the vagina that lower the pH to an acidic range. The acidic environment of the vagina prevents pathogenic growth. Inappropriate use of antibiotics destroys the lactobacilli and their protective function.

INFLAMMATION **Inflammation** is a nonspecific cellular response to tissue injury or infection. Tissue injury caused by bacteria, trauma, chemicals, heat, or any other phenomenon releases multiple substances that produce dramatic secondary changes in the injured tissue. This entire complex of tissue changes and response to injury is referred to as the inflammatory process (see Table 29-1). The inflammatory process has

five stages, facilitating the localization, neutralization, and resolution of the offending agent within the damaged tissue. The result of the body's response to injury produces the characteristic local and systemic signs of inflammation, discussed in the assessment section of this chapter.

The intensity of the inflammatory process is usually in proportion to the degree of tissue injury. For example, when staphylococci invade the tissues, they release lethal cellular toxins that cause the inflammatory process to develop quickly; the staphylococcal infection is characteristically walled off rapidly before the organism can multiply and spread. Streptococci, on the other hand, do not cause such intense local tissue destruction, and the walling-off process develops slowly, allowing the organism to reproduce and migrate. Therefore, the streptococci have a far greater tendency than do staphylococci to spread throughout the body and cause death, even though staphylococci are far more destructive to the tissue.

Specific Immune Defense

The specific immune defense mounts an immune response that is specific to the invading antigen. Unfortunately, the specific immune defense sometimes inappropriately reacts to the host's own tissue (**autoimmune disorders**).

The specific immune defense is activated by the failure of phagocytes to completely destroy the antigen; this causes the production of T lymphocytes (T cells) that regulate the immune response by activating other cells. Stimulated T cells

TABLE 29-1 Stages of the Inflammatory Process

STAGE	DESCRIPTION	RESULT
1	Initial injury precipitates release of chemicals: histamine, bradykinin, serotonin, prostaglandins (reaction products of the complement and blood-clotting systems), and lymphokines (hormonal substances released by sensitized T cells).	Activates the inflammation process.
2	Increased blood flow to the inflamed area (erythema).	Produces characteristic signs of redness and increased warmth.
3	Increased capillary permeability with leakage of large quantities of plasma out of the capillaries into the damaged tissue; tissue spaces and lymphatics blocked by fibrinogen clots.	Initiates the inflammation process; infection is "walled off," and nonpitting edema occurs.
4	Damaged tissue infiltrated by leukocytes, which engulf the bacteria and necrotic tissue. After several days, these leukocytes eventually die and form a cavity of necrotic tissue and dead leukocytes (mainly neutrophils and some macrophages).	Produces purulent exudate (pus).
5	Destroyed tissue cells are replaced with identical or similar structural and functioning cells and/or fibrous tissue.	Promotes tissue healing or the formation of fibrous (scar) tissue, which may reduce the functional capacity of the tissue.

Delmar/Cengage Learning

are referred to as sensitized T cells. T cells migrate to the area of injury and release chemical substances called **lymphokines**. Lymphokines attract other phagocytes and lymphocytes to the area of injury and assist in antigen destruction.

T cells also stimulate the production of B cells that differentiate into plasma cells, producing antibodies specific to the antigen. **Antibodies** are protein substances that counteract and neutralize the effects of antigenic toxins and destroy bacteria and other cells. Antibodies destroy the antigen. Stimulation of B cells and antibody production are referred to as **humoral immunity**.

B-cell activation causes formation of memory B cells. Memory B cells remember the antigen and prepare the host for future antigen invasion. Therefore, when the antigen enters the body again, the immune response will occur more rapidly by producing antibodies faster. The formation of these antibodies is referred to as **acquired immunity**, which protects the individual against invading agents such as lethal bacteria, viruses, toxins, and even foreign tissues from other animals.

The process of **vaccination** provides acquired immunity against specific diseases. There are three ways an individual can be vaccinated:

1. By injection of dead organisms that are no longer capable of causing disease but still have their chemical antigens, such as typhoid fever, whooping cough, and diphtheria.
2. By toxins that have been treated with chemicals so that their toxic nature has been destroyed even though their antigens for causing immunity are still intact, such as tetanus and botulism.
3. By infection with live organisms that have been attenuated (grown in a special culture media or passed through a series of animals for mutation; the organisms then do not cause the disease but still carry the specific antigen). Attenuated vaccines protect against poliomyelitis, yellow fever, measles, smallpox, and many other viral diseases.

See Chapter 18 for a detailed discussion on vaccination and immunization schedules for children, teens, and adults.

STAGES OF THE INFECTIOUS PROCESS

Activation of the immune response indicates the occurrence of infection. Infection results from tissue invasion and damage by an infectious agent. There are two types of infectious responses:

1. **Localized infections** are limited to a defined area or single organ with symptoms that resemble inflammation (redness, tenderness, and swelling).
2. **Systemic infections** affect the entire body and involve multiple organs.

Localized or systemic infections progress through four stages of infection:

- Incubation
- Prodromal
- Illness
- Convalescence

The **incubation period** is the time interval between entry of an infectious agent in the host and the onset of symptoms. During this time period, the infectious agent invades the tissue and begins to multiply to produce an infection.

The **prodromal stage** is the time interval from the onset of nonspecific symptoms until specific symptoms of the infectious process begin to manifest. During this period, the infectious agent continues to invade and multiply in the host. A client may also be infectious to other persons in this time period.

The **illness stage** is when the client is manifesting specific symptoms of an infectious process. The period of time from the beginning of the disappearance of acute symptoms until the client returns to the previous state of health is referred to as the **convalescent stage**.

EMERGING INFECTIONS

Homelessness is an increasing social and public health problem, with an estimated 100 million persons homeless worldwide (Badiaga, Raoult, & Brouqui, 2008). Without physical shelter or with a compromised physical shelter that does not meet basic standards of health and safety, such as access to safe water and sanitation, personal safety, and protection from the elements, homeless persons are at risk for many communicable infections. The primary health concerns for this population are the overcrowded living conditions that expose the homeless to airborne infections, especially tuberculosis (TB). The lack of personal hygiene and clothing changes can cause exposure to scabies, body lice infestations, and louseborne disease.

The incidence of TB is higher in the homeless populations than in the general population. Most TB cases occurring in the homeless are primary infections caused from recent person-to-person transmission leading to outbreaks. Frequently, the homeless are injection drug users and engage in risky sexual behavior, which cause exposure to bloodborne and sexually transmitted infections such as human immunodeficiency virus (HIV), hepatitis C virus (HCV), and hepatitis B virus (HBV; Badiaga et al., 2008).

The outbreak in 2003 of SARS-CoV, a coronavirus that causes severe acute respiratory distress syndrome, was characterized by nonspecific symptoms that included fever, discomfort, and mild respiratory symptoms. Although no new cases of SARS have been reported, the 2003 outbreak prompted the Centers for Disease Control and Prevention (CDC) to implement new measures of infection control at the first point of encounter within a health care setting, such as emergency departments. These new measures are discussed later in this chapter.

The major hepatitis viruses are HAV, HBV, HCV, HDV, HEV, and HGV. HAV is a virus that is most commonly transmitted by close contact with an infected person, after eating items contaminated with infected feces. Children in diapers or those who come into contact with other children in diapers are at risk for HAV because of inadequate handwashing in day care centers. HAV causes mild flulike symptoms, jaundice, severe stomach pains, and diarrhea. The hepatitis A vaccine is not administered to children 2 years of age and under.

HCV is the most common bloodborne pathogen in the United States. An estimated 4 million Americans have tested positive for HCV, with 25,000 new HCV infections occurring annually. HCV is a member of the *Flaviviridae* family, which also causes the West Nile virus; it mutates rapidly and evades the body's attempts to develop an effective antibody response. No vaccine is available. Transmission is primarily by exposure to blood, including illicit intravenous (IV) drug use; occupational exposure to blood by needlestick injury; perinatal exposure, HCV-infected mother; blood transfusion or organ transplant before 1990; exposure to contaminated equipment; and sexual contact with an infected person. Persons infected are usually asymptomatic or have general flulike symptoms. In 80% of HCV-infected persons, the disease becomes chronic and progresses to chronic liver disease, liver cancer, and liver transplantation. Nurses need to recognize the higher risk of HCV than HIV infection from an accidental needlestick.

The West Nile virus was first isolated in 1937; the first cases in the Western Hemisphere were reported in New York in 1999. This *Flavivirus* is usually transmitted when a mosquito feeds on an infected bird and then bites a human; however, data released from the CDC show that with the West Nile virus, the most common pathogens are transmitted through transfusions. It is similar to the virus that causes St. Louis encephalitis, and if it crosses the blood-brain barrier and causes encephalitis, it may be fatal.

Viral hemorrhagic fevers (VHFs), such as Ebola hemorrhagic fever, belong to the family of RNA viruses, the *Filoviridae*. The largest Ebola outbreak occurred in Uganda in 2000, resulting in more than 400 cases and 110 deaths. The disease is transmitted through direct contact with blood, secretions, and excretions of acutely ill persons or with tissues during autopsy. The only reported incidence in the United States occurred with a shipment of infected monkeys from the Philippines; although the virus did not cause illness, several workers became infected with and developed antibodies. This incident occurred in Reston, Virginia; therefore, it was named the Ebola-Reston hemorrhagic fever virus.

HIV infection or acquired immunodeficiency syndrome (AIDS) is present in most body fluids. HIV is a bloodborne pathogen that is transmitted with some exchange of body fluid, mainly blood. Transmission occurs by contaminated IV needles, anal intercourse, vaginal intercourse, oral-genital sex, and transfusion of blood and blood products. Vulnerable populations include gay men, IV drug users, their partners, their children, and those who receive contaminated blood, such as clients with hemophilia. Research continues for treatments and vaccines. The disease is usually fatal.

HEALTH CARE—ASSOCIATED INFECTIONS

Health care–associated infections (HAIs) are infections acquired in the hospital or other health care facilities that were not present or incubating at the time of the client's admission. HAIs are also referred to as health care–acquired infections. HAIs include those infections that become symptomatic after the client is discharged as well as infections

among medical personnel. Most HAIs are transmitted by health care personnel who fail to practice proper handwashing procedures or to change gloves between client contacts.

Hospitalized clients are at risk for HAIs because the environment provides exposure to a variety of virulent organisms that the client has not been exposed to in the past; therefore, the client has not developed any resistance to these organisms. In addition, illness, often the reason for hospital admission, impairs the body's normal defense mechanisms. According to the CDC (2008), HAIs are one of the top 10 leading causes of death in the United States.

The most common endemic infections in hospitals affect the urinary tract, upper and lower respiratory tracts, gastrointestinal tract, conjunctiva, and skin. Hospitalized clients have multiple comorbidities that increase their risk of infection. For example, urologic abnormalities (prostatic hypertrophy) are associated with urinary tract infections. Chronic obstructive lung disease and congestive heart failure increase a client's risk of developing pneumonia. Diabetes or vascular insufficiency may lead to more frequent and severe skin infections (pressure ulcers, cellulitis, and vascular ulcers). Since these high-risk clients are housed together, the transmission of pathogens is increased among residents. For instance, organisms may be transmitted through the air (e.g., TB, influenza), on the hands of staff members (e.g., *Staphylococcus aureus* or uropathogens), and by contaminated items (e.g., *Escherichia coli*).

HAIs are receiving increased attention because of the development of multiple-drug-resistant organisms (MDROs). The two most common MDROs are bacteria—methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant enterococcus (VRE)—in both hospital and long-term care clients; other drug-resistant organisms include TB bacilli and *Clostridium difficile* (*C. difficile*).

MRSA has become a prevalent pathogen in the United States. In the hospital setting, the most important reservoirs of MRSA are infected or colonized clients. MRSA is transmitted mainly through the hands of health care workers who may have become contaminated by contact with colonized or infected clients or body sites of the personnel themselves, or devices, items, or environmental surfaces contaminated with body fluids containing MRSA. When a hospitalized client gets an MRSA infection, it is difficult to treat and often leads to serious problems such as pneumonia, wound, and blood infections (Holcomb, 2008). According to the CDC (2007), approximately 18,650 persons died during a hospital stay because of related MRSA infections. The main way to prevent the spread of MRSA is to utilize Standard Precautions, discussed later in this chapter.

C. difficile causes diarrhea that may range from mild diarrhea to severe colitis. It is transmitted by factors that cause an overgrowth of *C. difficile* and by contact with the organism. According to Harris (2006), antibiotics such as cephalosporins, ampicillin, amoxicillin, and clindamycin and invasive bowel procedures such as surgery or colonoscopy disrupt normal bowel flora and cause an overgrowth of *C. difficile*. Clients may also acquire *C. difficile* from a health care provider's poor hand hygiene, direct contact with environmental surfaces contaminated with *C. difficile*, and ineffective

disinfection practices (Todd, 2006). *C. difficile* A and B bacteria are diagnosed in the stool; two or three stool specimens are required for the enzyme-linked immunosorbent assay (ELISA).

There is controversy regarding the use of alcohol-based hand rubs when dealing with *C. difficile*. An anaerobic spore-forming organism, *C. difficile* is not susceptible to alcohol in the spore state; however, most *C. difficile* organisms released in disease outbreaks are in the vegetative form, and these can be killed by alcohol (“Advice P.R.N.,” 2008). The CDC has no clear guidelines regarding the use of alcohol-based hand rubs but recommends not using them during *C. difficile* outbreaks. Nurses need to adhere to agency policies, which should be based on the CDC’s recommendations on the latest evidence-based practices.

Hand hygiene is the most important intervention in preventing and controlling the transmission of infection. Clients at risk for infection must understand the measures needed to reduce or prevent the spread and growth of microorganisms. Because hygienic care requires close contact with the client, the nurse promotes a caring therapeutic relationship by using this time for assessment, teaching, and counseling.

HYGIENE

Hygiene is the science of health. Hygienic care promotes cleanliness, provides for comfort and relaxation, improves self-image, and promotes healthy skin. Client hygiene is an extension of providing client safety and protecting the client’s defense mechanisms. The health of the body’s first line of defense (skin and mucous membranes) is promoted by client hygiene. Nurses are responsible for ensuring that the client’s hygienic needs are met. The type of hygienic care provided depends on the client’s ability, needs, and practices.

FACTORS INFLUENCING HYGIENIC PRACTICE

Hygienic needs and practices are unique to each client; nurses should provide individualized care based on these needs and practices. Hygienic practices are influenced by several factors, including body image, social and cultural practices, personal preferences, socioeconomic status, and knowledge.

Body Image

Body image is the client’s subjective belief about his or her own physical appearance. Body image is associated with the client’s emotions, mood, attitude, and values. See Chapter 22 for a complete discussion of this concept. A client’s body image directly affects the type of personal hygiene practiced; this may change if the client’s body image is altered because of illness or surgical procedures. During this time, the nurse should help the client maintain hygienic practices in accordance with the client’s pre-illness level of hygiene and personal preferences.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Invasive Methicillin-Resistant *Staphylococcus aureus* Infections in the United States”

AUTHORS

R. Klevens, M. Morrison, J. Nadle, S. Petit, K. Gershman, S. Ray, L. Harrison, R. Lynfield, G. Dumyati, J. Townes, A. Craig, E. Zell, G. Fosheim, L. McDougal, R. Carey, and S. Fridkin

PURPOSE

To describe the incidence and distribution of invasive MRSA disease in nine U.S. communities and to estimate the burden of invasive MRSA infections in the United States in 2005.

METHODS

Active, population-based surveillance was performed for invasive MRSA in nine sites participating in the Active Bacterial Core surveillance (ABCs)/Emerging Infections Program Network from July 2004 through December 2005.

FINDINGS

Most MRSA infections were health care associated. There were 8987 observed cases of invasive MRSA reported: 5250 (58.4%) were community-onset infections, 2389 (26.6%) were hospital-onset infections, 1234 (13.7%) were community-associated infections, and 114 (1.3%) could not be classified. Incidence rates were highest among persons 65 years and older, blacks, and males. There were 1598 in-hospital deaths among clients with MRSA infections during the study.

IMPLICATIONS

MRSA infection is a major public health problem related mainly to health care but no longer limited to intensive care units, acute care hospitals, or any health care institution. Invasive MRSA infection affects certain populations disproportionately.

Klevens, R., Morrison, M., Nadle, J., Petit, S., Gershman, K., Ray, S., et al. (2007). Invasive methicillin-resistant *Staphylococcus aureus* infections in the United States. *Journal of the American Medical Association*, 298(15), 1763–1771.

Social and Cultural Practices

Social and cultural practices also directly influence hygienic practices. Clients are socialized to their hygienic practices by family practices in early childhood. As a person ages, hygienic practices are influenced by maturational development and socialization with people outside of the family. For example, teenagers are usually concerned with peer acceptance and

follow the latest trends in personal hygiene. In later adulthood, hygienic practices may be influenced by coworkers and social networks.

Cultural practices and beliefs are derived from family, religious, and personal values developed during maturation. See Chapter 20 for a complete discussion of cultural diversity. Clients from diverse cultural backgrounds will have differing hygienic practices. For example, some cultures do not permit women to submerge their bodies in water during the time of menstruation because of the fear that the woman may drown. In North America, people typically bathe daily and use numerous deodorant products. In Europe, people do not bathe daily and seldom use deodorant products. Europeans do not consider the smell of human perspiration as offensive as do North Americans. Nurses should have a nonjudgmental attitude when assessing or providing hygienic care to clients from different social or cultural backgrounds.

Personal Preferences

Personal preferences influence when bathing occurs, what products are used, and what type of bath is performed. For example, some male clients may shave before bathing, while others prefer to wait until after the bath. Some clients prefer to bathe in the morning to facilitate waking, while others prefer to bathe before bedtime to encourage relaxation and sleep. Unless a client's health is affected, the nurse should permit clients to practice their usual routine and use the hygienic products that they prefer. Individualized nursing care should incorporate the client's personal hygiene preferences.

Socioeconomic Status

A client's hygienic practices may be influenced by socioeconomic status. Limited economic resources may affect the type, frequency, and extent of hygiene practiced. Assessment of socioeconomic status provides information about the availability of

hygiene supplies. Some clients may not be able to afford deodorants, perfumes, soaps, shampoo, and toothpaste. The nurse can function as an advocate for the client by making referrals to community agencies that provide assistance to needy persons, for example, Catholic Charities or a local chapter of the American Association of Retired Persons.

Knowledge

Knowledge level influences the client's understanding about the relationship between hygiene and health. Thus, knowledge should influence a client's hygienic practices. In addition to being knowledgeable, before clients perform basic hygiene, they must be motivated and believe that they are capable of self-care.

Frequently, an illness or a surgical procedure results in deficient knowledge about basic hygienic practices. In these situations, the client may not know the correct procedures or types of hygiene that can be performed. The nurse is responsible for providing the necessary education about hygiene during an illness. Sometimes the nurse may have to perform all hygienic practices for a client during an illness until the client is able to regain this ability.

ASSESSMENT

The nursing process facilitates an understanding of the scope of challenges inherent in the nursing care of clients at risk for injury, infections, or a self-care deficit. The assessment data should direct the prioritization of the client's problem and accompanying nursing diagnoses. Clients at risk for injury or infection require frequent reassessment of their status with appropriate changes in the plan of care and expected outcomes.

The assessment and physical examination data are correlated with the laboratory indicators to identify those clients who are at risk for problems relating to safety, infection, or hygiene. One of the assessment models should be used to provide structure to the assessment. See Chapter 6 for a complete discussion of assessment models. Appropriate risk appraisals may be incorporated into the nursing health history interview. These core elements of assessment are discussed in relation to clients in ambulatory, institutional, and home settings. Refer to the accompanying display on page 666 for a sample format for developing minimum safety standards applicable to all health care settings.

HEALTH HISTORY

The nursing health history interview is the first part of assessment; it provides the client's subjective, specific health data. Key elements of relevant data regarding the client at risk for safety and infection are obtained in the health history. See Chapter 6 for a sample of a nursing health history tool.

The client is often asked to complete a health history questionnaire; however, depending on the client's status, the nurse may have to perform an interview to obtain these data. If the client is unable to provide the subjective data, the nurse must designate on the questionnaire or in the nursing progress notes who provided the information.

Hygiene and Personal Preferences

What role do values have in relation to self-care needs? Do you believe that a client's hygienic activities demonstrate personal preferences and idiosyncrasies that are based on family, culture, religion, and other factors? What should you do to avoid projecting your own values onto the client? If the client states, "I feel uncomfortable about you bathing me," what should you do? Another area that requires sensitivity on your part deals with a client's use or failure to use hygienic products, for example, deodorant. How do you feel about caring for a client who does not use deodorant or whose hygiene habits differ greatly from your own?

STANDARD OF CARE: SAFETY**CLIENT OUTCOME**

The client will receive care in a safe health care environment and remain free of preventable injuries.

NURSING PRACTICE STANDARDS

1. Perform a client injury risk appraisal upon admission and prior to therapeutic nursing interventions. Risk factors for injury include, but are not limited to, age, altered mental status, previous history of falls, impaired mobility, sensory deficits, perceptual deficits, and inability to communicate.
2. Eliminate or modify risk elements when possible, such as assisting with mobility and placing bed rails up with bed in the lowest position.
3. Implement environmental precautions, such as hand rails, nonslip mats or rugs, and adequate lighting.
4. Use infection control practices that prevent or control the transmission of pathogens.
5. Maintain IV access according to IV protocols.
6. Implement emergency measures in accordance with American Heart Association guidelines for cardiopulmonary resuscitation (CPR) and advanced life support.
7. Know and comply with the institution's Environmental Health and Safety guidelines.
8. Implement emergency measures during fires and disasters.
9. Use mechanical, radiant, chemical, and thermal equipment according to the manufacturer's guidelines and the institution's policy and procedures.
10. Use a multidisciplinary approach to enhance client safety, as indicated.

During the nursing health history interview, assess the client's general health perception and management status to determine how the client manages self-care. This information will provide data regarding the client's routine self-care and health promotion needs. Sample questions that relate specifically to habits that foster safe, healthy patterns of behavior are presented in the accompanying display. These questions are appropriate for home health and ambulatory care settings as well as inpatient settings.

PHYSICAL EXAMINATION

A complete health assessment includes a systematic physical examination, generally conducted from head to toe, in order to obtain objective data relative to the client's health status

KEY INTERVIEW QUESTIONS ABOUT SAFETY, INFECTION CONTROL, AND HYGIENE

- Describe the things you do to stay healthy.
- How do you typically spend a day (e.g., home or work)?
- What are your health care concerns?
- Do you need assistance with bathing and dressing?
- Do you regularly visit the dentist and eye doctor?
- Do you use dental floss on a regular basis?
- Have you recently come into contact with someone who has an infectious disease?
- Do you wash your hands when preparing food?
- Do you keep meats and dairy products refrigerated until ready to use?
- Is there a smoke detector or fire extinguisher in your home?
- Are emergency phone numbers readily available?

and presenting problems. See Chapter 27 for a complete discussion of a physical examination.

When assessing the client to determine the level of risk for injury or infection and hygienic deficits, focus the physical examination on the following areas and signs:

- Level of consciousness, using the Glasgow Coma Scale to evaluate this attribute (see Chapter 38 for discussion of this tool)
- Range of motion or total immobilization of an extremity
- Localized infection: Redness, swelling, warmth, tenderness, pain, and loss of movement in a specific body part
- Systemic infection: Fever, with a corresponding increase in pulse and respirations; weakness; anorexia, with possible accompanying findings of nausea, vomiting, and diarrhea; enlarged and/or tender lymph nodes
- Secretions or exudate of the skin or mucous membranes and detection of crackles, rhonchi, or wheezes in the lungs on auscultation

The condition of the skin is a good indicator of a client's general health status. Assessment of skin integrity provides data concerning a client's nutritional and hydration status, continuity of intact skin, hygienic practices, and overall physical abilities. Similarly, a client with limited mobility is at risk for developing joint contractures, skin breakdown, and muscle atrophy.

Risk Factors

A comprehensive nursing assessment involves using specifically developed risk assessment tools and appraising the

client's environment to detect potential hazards. The client's self-care abilities, used for determining the level of assistance needed in providing hygienic care, are appraised during the health history. The analysis of relevant risk factors alerts the nurse to actual or possible risks. Skin integrity is usually compromised when a person is placed on bed rest.

A skin integrity risk appraisal such as the Braden scale (see Chapter 37) should be completed to assist with planning care.

Client in an Inpatient Setting

Inpatient clients should be assessed for fall and infection risk factors. The hospitalized or institutionalized client's risk for falls is identified after compiling specific assessment data that are correlated with contributing factors. Each of these indicators carries a specific weight, as shown in the accompanying display, Fall Risk Appraisal, to determine the client's risk. The inpatient client should be assessed for falls every shift or as designated by institutional policy. To minimize the chance of falls, make sure the client's environment is safe: The bed is kept in a low position, side rails are up, personal belongings are in easy reach, and assistive devices (e.g., walker) are nearby, as shown in Figure 29-3 on page 668.

To determine risk for infection, review or listen to the client's response to the health history and interview questions related to "exposure to infectious diseases," "invasive procedures," and "behaviors you think you should change." An infection risk appraisal is based on the defining characteristics that place a client at risk for an infection. These factors are listed in the section titled Nursing Diagnosis.

Client in the Home

An injury risk appraisal will provide the nurse with assessment data to determine the client's level of safety knowledge, as previously discussed in the standard of care for safety. Injuries in the home are primarily the result of falls, fires, electrical malfunctions, suffocation, weapons, and household and medication poisonings. Home health nurses may use a safety risk appraisal; refer to the accompanying display on fall risks.

The safety risk data assessed in the home environment direct the nurse in planning for the client's and caregiver's education. The home health nurse needs to prioritize these data when planning the client's care. Assessment, teaching, and outcome evaluation of all safety hazards can take several home visits.

DIAGNOSTIC AND LABORATORY DATA

Appraising the client's risk for injury should also include an evaluation of laboratory findings relative to an abnormal blood profile (e.g., altered clotting factors, anemic conditions, or leukocytosis). See Chapter 28 for a complete discussion of abnormal blood profiles. Malnourished clients are at risk for injury.

The laboratory indicators for an infection are:

1. An elevated leukocyte (white blood cell [WBC]) and WBC differential:
 - Neutrophils: Increased in acute, severe inflammation

FALL RISK APPRAISAL

Area of Assessment	Score
General Factors	1
Restraint (Posey, arm, leg)	
Orthostatic changes	
History of falls/crawling out of bed/syncope (brief loss of consciousness)	
Seizure disorder	
Elimination Function	2
Decreased bladder/bowel tone	
Urgency/frequency	
Incontinence	
Nocturia (excessive urination at night)	
Age	3
Over 65	
Level of Consciousness/ Mental Status	4
Lethargic (slow to respond)	
Inability or refusal to follow directions	
Inability or refusal to call for help	
Impaired judgment, memory, awareness	
Confused, disoriented	
Sensory Deficits	5
Diminished visual acuity, blind, blurred vision	
Slow reaction time	
Mobility/Physical Limitations	6
Decreased mobility in lower extremities	
Up with assistance	
Amputee/joint difficulties	
Weakness, dizziness, fatigability, vertigo (dizziness), syncope	
Cast, splint	
Use of crutches, cane, walker	
Hemiparesis (one-sided paralysis), paraparesis (loss of function), hemiplegic, paraplegic (loss of function in lower limbs)	
Ataxia (unsteady gait)	
Improper-fitting/smooth-soled/no footwear	
Unsteady gait, decreased balance, imbalance	
Medications	7
Sedatives/hypnotics/tranquilizers	
Diuretics/antihypertensives/laxatives	
Narcotics/analgesics/anesthetics	
Antihistamines	
Antiseizures	
Barbiturates/phenothiazines	
Eye drops	
Antipsychotics/antidepressants	

Scoring: If the client is over 65 years of age, the indicator has a weight of 3. If the client is also receiving a diuretic, which has a weight of 7, the total risk factor for this client is 10. This would place the client at high risk for falls and would require the implementation of special fall measures.

Adapted from the Patient Care Documentation Sheet, courtesy of Tulane University Hospital & Clinic, New Orleans, LA

FIGURE 29-3 This client's risk of falls has been assessed and responded to through the measures shown here. Do all clients within the hospital setting need to be assessed for the risk of falls, regardless of their health status or reason for hospitalization? DELMAR/CENGAGE LEARNING

- Lymphocytes: Increased in chronic bacterial and viral infections
 - Monocytes: Increased in some protozoan and rickettsial infections and TB
 - Eosinophils and basophils: Unaltered in an infectious process
2. An elevated erythrocyte sedimentation rate (ESR): Increased in the presence of inflammation
 3. An elevated pH of involved body fluids (gastric, urine, or vaginal secretions): Indicates the presence of microorganisms
 4. Positive cultures of involved body fluids (blood, sputum, urine, or other drainage): Indicates the growth of microorganisms

Refer to Chapter 28 for the age-related normal laboratory values for each of the preceding tests.

NURSING DIAGNOSIS

After data collection and analysis, the nurse is able to formulate a nursing diagnosis. If Gordon's Functional Health

Patterns model is used to conduct the assessment, the nurse can use the classification of nursing diagnoses by functional health patterns that relate to safety, infection, and hygienic deficits, for example:

- I. Health perception–health management pattern
 - Risk for injury
 - Risk for infection
- II. Activity-exercise pattern
 - Bathing/hygiene self-care deficit
 - Dressing/grooming self-care deficit
 - Toileting self-care deficit

RISK FOR INJURY

The primary nursing diagnosis *risk for injury* exists when the client is at risk for injury as a result of environmental conditions interacting with the individual's adaptive and defensive resources (North American Nursing Diagnosis Association [NANDA], 2009-2011). Although this diagnostic label does not have defining characteristics as set forth by NANDA, it is categorized as having either internal or external potential hazards. An internal biochemical risk factor for a client with impaired vision would be stated as *risk for injury* related to sensory dysfunction. In contrast, a home health nurse's assessment data that identify drugs on a nightstand with a toddler in the home as creating an external chemical risk factor for the toddler would be stated as *risk for injury* related to drugs (pharmaceutical agents).

NANDA (2009-2011) has six defined subcategories of specific risk factors for this diagnostic labeling:

1. *Risk for suffocation*: An accentuated risk of accidental suffocation
2. *Risk for poisoning*: An accentuated risk of accidental exposure to, or ingestion of, drugs or dangerous products in doses sufficient to cause poisoning
3. *Risk for trauma*: An accentuated risk of accidental tissue injury (e.g., wound, burn, fracture)
4. *Risk for aspiration*: Risk for entry of gastrointestinal secretions, oropharyngeal secretions, solids, or fluids into the tracheobronchial passages
5. *Risk for disuse syndrome*: Risk for deterioration of body or body systems as the result of prescribed or unavoidable musculoskeletal inactivity
6. *Risk for latex allergy response*: Risk for allergic response to natural latex rubber products

These six subcategories of nursing diagnoses provide the nurse with the opportunity to relate specific nursing interventions to the diagnosed problem. For example, the specific nursing diagnosis for the situation of a toddler in the home environment encountering medications on a nightstand would be *risk for poisoning* related to medicines not stored in locked cabinets and accessible to children. The level of risk would be increased if the medications on the client's nightstand were in open containers or the closed containers failed to have childproof caps. The subcategory diagnosis provides specific nursing interventions directed at the level of risk for the toddler and the need for client teaching.

HOME SAFETY RISK APPRAISAL

INFANT

- Crib has side rails that stay in the up position while infant is in the crib.
- Infants are not left unattended, especially on elevated surfaces or in the bath.
- Bath water temperature is 37.8°C–40.6°C (100°F–105°F). Check temperature for comfort with wrist.
- Environment is kept warm and draft-free at bath time.
- Bottles are sterilized and formula is refrigerated.
- Toys are soft without detachable pieces.
- Car seat has restraint strap and is used consistently.
- Stroller and carry seat are sturdy with a restraint strap.
- Fire, police, and poison control numbers are posted by telephones.
- Caregivers know infant CPR.

TODDLER/PRESCHOOLER

- Sharp objects are placed out of reach and out of sight.
- Poisons are labeled and placed in a locked cabinet.
- Medications and other toxins have childproof lids and are stored in a locked cabinet.
- Small, hard food objects (peanuts, candy) are kept in locked cabinets.
- Stairs and floor furnaces have gates or barriers.
- Safety locks are on doors and windows.
- Electrical outlets are covered.
- Burners on the stove are not left on and unattended.
- Pots with hot liquids are placed on back burners with handles facing toward the back wall.
- Home and yard are free from poisonous plants.
- Play equipment is kept in proper functioning condition; toys have no small parts; crayons are nontoxic.
- Outdoor play is supervised in a fenced area with locks on gates.
- Car seat/belt is used consistently.
- Supervision is given to child when she or he is crossing the street.
- Caregivers know child CPR and the Heimlich maneuver.

SCHOOL-AGE CHILD

- Play and sports are supervised.
- Play equipment is kept in proper functioning condition and free from hazards.
- Outdoor play is limited to soft surfaces.
- Bicycle helmet is worn consistently.

- Child is taught to not open the door or speak to strangers while at play.
- Firearms are kept unloaded in locked cabinets.
- Caregivers know child CPR and the Heimlich maneuver.
- Seat belt is worn at all times.

ADOLESCENT

- Firearm safety is taught.
- Seat belt is worn at all times.
- Teenagers take drivers' education and are cautioned about drinking and driving.
- Caregivers know adult CPR and the Heimlich maneuver.

ADULT

- Firearms have safety latches.
- A smoke detector and a fire extinguisher are installed in the home.
- Sharp-edged objects are safely stored.
- A nondrinking designated driver is chosen.
- Emergency phone numbers are readily available.
- Caregivers know adult CPR and the Heimlich maneuver.

OLDER ADULT

- Stairs have adequate lighting and nonskid surfaces, and rails are in good condition.
- Throw rugs are not present.
- Hallways are uncluttered.
- Carpets are free from frayed ends/pieces.
- Phone and other cords are behind furniture.
- Bathtub has rails and a nonslip surface.
- Shower stall has a seat.
- Bathroom is free from drafts.
- Shoes fit properly, with nonskid soles.
- Home is adequately ventilated and heated.
- Home is free of space heaters.
- Pilot lights are functional for gas appliances.
- Electrical appliances are in good working condition.
- Food is properly refrigerated.
- Medications are kept in properly labeled containers with readable print.
- Emergency phone numbers are readily available.
- Fire and police departments are aware of older adult at home alone.
- Caregivers know adult CPR and the Heimlich maneuver.

RISK FOR INFECTION

Risk for infection is the state in which an individual is at increased risk for being invaded by pathogenic organisms (NANDA, 2009–2011). The risk factors that increase the client's vulnerability to infections are:

- Inadequate primary defenses (broken skin, traumatized tissue, decrease in ciliary action, stasis of body fluids, change in pH of secretions, and altered peristalsis)
- Inadequate secondary defenses, acquired immunity, and immunosuppression
- Tissue destruction and increased environmental exposure
- Chronic diseases and malnutrition
- Invasive procedures and pharmaceutical agents
- Trauma
- Rupture of amniotic membranes
- Insufficient knowledge to avoid exposure to pathogens (NANDA, 2009–2011)

SELF-CARE DEFICITS

A **self-care deficit** exists when the client is not able to perform one or more of the activities of daily living (ADL). NANDA (2009–2011) identifies three self-care deficits related to hygienic practices. These diagnostic labels, together with their defining characteristics and related factors, are presented in Table 29-2.

OTHER NURSING DIAGNOSES

Clients who are at risk for injury and infection or who have a self-care deficit may have other problems. These associated physiological and psychological problems are discussed in detail in other chapters in this unit. The common nursing diagnoses that often accompany diagnostic labels for risk or self-care deficits are:

- *Imbalanced nutrition (specify less than body requirements or more than body requirements)*
- *Ineffective protection*
- *Impaired tissue integrity*
- *Impaired oral mucous membrane*
- *Impaired skin integrity*
- *Social isolation*
- *Risk for loneliness*
- *Ineffective coping*
- *Impaired physical mobility*
- *Hopelessness*
- *Powerlessness*
- *Deficient knowledge (specify)*
- *Acute pain*
- *Anxiety*
- *Fear*

This list is not all-inclusive but indicates the number of related problems that need to be considered when planning care.

SPOTLIGHT ON...

Caring and Compassion

Self-Care Deficits

Imagine that you are unable to feed yourself, you cannot dress yourself, and you are incontinent and must rely on others to clean you. You are completely dependent on caregivers since you have no family or friends to assist you. How do you feel about being dependent on caregivers to meet your basic needs? What happens if the caregivers do not respond when you ask for help? How do you feel when others make decisions for you?

OUTCOME IDENTIFICATION AND PLANNING

The primary nursing goal is to provide safe care through the identification of actual or potential hazards and the implementation of safety measures. The assessment data are reviewed with the client, and the nurse records the areas in which the client indicates a need for change and health teaching, for example, age-related exercise or maintaining a safe environment. These findings are incorporated into the plan of care, reflecting the individualized needs of each client.

During the planning phase, the nurse collaborates with the client and other health care providers to determine the goals, outcomes, and interventions and manipulates the external environment to reduce the risk of injury and infection. Identified outcomes provide direction for the nursing care that is implemented to reduce the risk of injury and infection.

Another critical element of the care plan is client/caregiver education related to the identification of potential hazards and health promotion practices. The nursing care plan should include safety measures that educate clients about preventive actions and modification of an unsafe environment, for example, proper use of a call light or the side effects of medications.

Table 29-3 on page 672 discusses the basic components of care planning and measurements for clients at risk of or with a self-care deficit. Sample statements of goals are included in the table. The nursing interventions are statements taken from the Nursing Intervention Classification system. For each of these nursing interventions, there are specific actions taken by the nurse to individualize the care for each client. The nurse could use Gordon's Functional Health Patterns to plan care. These may be used for clients at risk of or with a self-care deficit, including health perception–health management; activity-exercise pattern; and cognitive-perceptual pattern. Nursing actions are discussed in detail in the following section.

IMPLEMENTATION

Nursing care implemented for clients with alterations in health perception–health management or activity and exercise involves continual assessment of client health risks and prioritization of risk reduction nursing interventions, such as:

- Administration of prescribed medications (see Chapter 30)
- Provision of balanced nutritional intake (see Chapter 34)
- Promotion of adequate rest and exercise (see Chapters 35 and 36)
- Decreasing the spread of infection

Implementation of safety measures may require an alteration in the physical environment as directed by the fall prevention protocol or Standard Precautions; see Table 29-4 on page 674. Chapter 36 provides additional information on fall prevention.

Nursing measures to counter common physical hazards that impair environmental safety are maintaining electric beds in the low position with side rails up and call light within easy reach and keeping the bedroom and bathroom uncluttered to prevent falls. Some states consider side rails a form of restraint. Nurses must be knowledgeable about statutory provisions relative to health care in their state.

The implementation of Standard Precautions is the most effective nursing measure to prevent and control the spread of infections. Standard Precautions are discussed in detail later in this chapter.

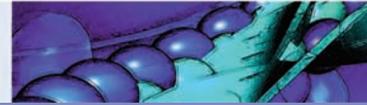

RAISE SAFETY AWARENESS AND KNOWLEDGE

Nurses in all settings must demonstrate an awareness of safety hazards and teach clients accordingly. Clients must be aware of and knowledgeable about safety precautions in order to prevent injuries. Clients may also need specific safety information on oxygen, IV equipment, use of heating devices, and automatic bed controls.

A Food and Drug Administration (FDA) safety alert addressed entrapment hazards with side rails on hospital beds. The FDA received 102 reports of head and body entrapment incidents that resulted in 68 deaths, 22 injuries, and 12 entrapments without injury that occurred in hospitals, long-term care facilities, and private homes. All reported that entrapments occurred in one of the four ways identified in Figure 29-4 on page 673.

PREVENT FALLS

Falls occur among clients who are weak, fatigued, uncoordinated, paralyzed, confused, or disoriented. Since falls are often due to more than one cause, no single intervention will prevent all clients from falling (Ferris, 2008). Capezuti and colleagues (2008) studied the difference between lower leg length of frail nursing home clients and the height of the toilets and beds in the lowest position and found that bed and toilet height was greater than the clients' lower leg lengths, thereby increasing the risk for falls. Tinetti and associates (2008) studied the utilization of fall prevention tools and

TABLE 29-3 Planning the Care of Clients at Risk for Injury or Infection and/or with a Self-Care Deficit

NURSING DIAGNOSIS AND DEFINITION	GOALS	NURSING OUTCOMES	NURSING INTERVENTIONS
<i>Risk for injury</i>	<ol style="list-style-type: none"> 1. The client will identify factors that increase the potential for injury. 2. The client will remain free of bodily injury. 	<ul style="list-style-type: none"> • Safe home environment: Physical arrangements to minimize environmental factors that might cause physical harm or injury in the home 	<ul style="list-style-type: none"> • Risk identification: Analysis of potential risk factors, determination of health risks, and prioritization of risk reduction strategies for an individual • Fall prevention: Instituting special precautions with client at risk for injury
<i>Risk for infection</i>	<ol style="list-style-type: none"> 1. The client will remain free of health care–associated infections. 2. The client will reduce exposure to known infectious agents. 	<ul style="list-style-type: none"> • Infection severity: Severity of infection and associated symptoms 	<ul style="list-style-type: none"> • Infection protection: Prevention and early detection of infection in a client at risk • Infection control: Minimizing the acquisition and transmission of infectious agents
<i>Bathing/hygiene self-care deficit</i>	<ol style="list-style-type: none"> 1. The client will maintain an optimum functional level of hygienic practices in a safe and an effective manner. 2. The client’s skin will remain clean and intact. 	<ul style="list-style-type: none"> • Self-care: Bathing: Ability to cleanse own body independently with or without assistive device • Self-care: Hygiene: Ability to maintain own personal cleanliness and kempt appearance independently with or without assistive device 	<ul style="list-style-type: none"> • Bathing: Cleaning of the body for the purpose of relaxation, cleanliness, and healing • Dressing: choosing, putting on, and removing clothes for a person who cannot do this for self • Skin surveillance: Collection and analysis of client data to maintain skin and mucous membrane integrity • Perineal care: Maintenance of perineal skin integrity and relief of perineal discomfort
<i>Deficient knowledge: related to health hazard</i>	The client will not sustain injuries.	<ul style="list-style-type: none"> • Risk control: Personal actions to prevent, eliminate, or reduce modifiable health threats 	<ul style="list-style-type: none"> • Teaching, individualized: Planning, implementation, and evaluation of a teaching program designed to address a client’s particular needs

Moorhead, S., Johnson, M., & Maas, M. (Eds.). (2008). *Nursing outcomes classification (NOC)* (4th ed.). St. Louis, MO: Elsevier Health Sciences; McCloskey Dochterman, J. C., & Bulechek, G. M. (Eds.). (2008). *Nursing interventions classification (NIC)* (5th ed.). St. Louis, MO: Elsevier Health Sciences.

found that dissemination of evidence about fall prevention, coupled with interventions to change clinical practice, may reduce fall-related injuries in elderly clients. The data obtained from the client's fall risk appraisal will identify which clients require special nursing measures to prevent falls. The risk for falls can be reduced by:

- Good supervision
- Orienting clients to the environment and call system
- Providing ambulatory aids (wheelchairs or walkers)
- Placing personal belongings on tables near the bed
- Keeping hospital beds in lowest position with side rails up
- Using nonslip mats and rugs
- Illuminating the environment

Although falls do not necessarily constitute malpractice, they are a major reason nurses are involved in lawsuits.

Restraints

Restraints are protective devices used to limit the physical activity of a client or to immobilize a client or extremity. They are used to protect the client, allow for treatment in a safe environment, and reduce the risk of injury to others.

The use of restraints has become very controversial because of resultant client injuries. The Omnibus Budget Reconciliation Act of 1987 and the Health Care Financing Administration regulations of 1999 governing clients' rights are forcing a reexamination of how clients are cared for in acute and critical care settings. In response to more individualized care regarding the use of restraints, the Joint Commission revised its standards for restraint use with nonpsychiatric clients; see the accompanying display on Joint Commission-revised standards on page 675.

Nurses must document, according to the institutional protocol, the application and care of the client in restraints (see the accompanying display on restraints). Refer to Chapter 12 for additional information regarding the use of restraints and their legal implications.

Restraints used to either limit physical activity or immobilize a client can be physical or chemical. **Physical restraints**

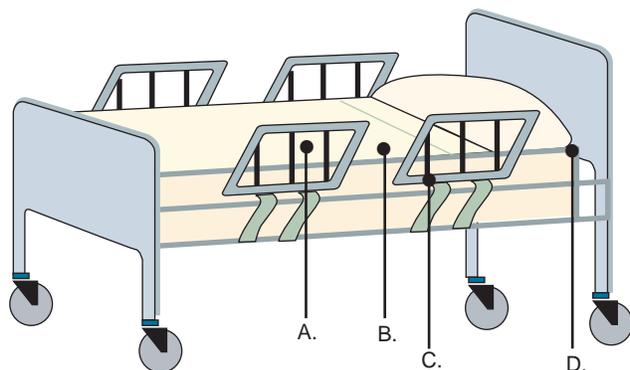

FIGURE 29-4 Entrapment hazards with hospital bedside rails. A. Through the bars of an individual side rail; B. through the space between split side rails; C. between the side rail and mattress; or D. between the headboard or footboard, side rail, and mattress. FROM FOOD AND DRUG ADMINISTRATION, SAFETY ALERT, AUGUST 23, 1995.

KEY ELEMENTS OF RESTRAINT DOCUMENTATION

- Reason for the restraint
- Method of restraint
- Application: Date, time, and client's response
- Duration
- Frequency of observation and client's response
- Safety: Release from restraint with periodic, routine exercise and assessment for circulation and skin integrity
- Assessment of the continued need for restraint
- Client outcome

reduce the client's movement through the application of a device. Most states require a prescribing practitioner's order for the application of physical restraints. **Chemical restraints** are medications used to control the client's behavior. Commonly used chemical restraints are anxiolytics and sedatives.

This chapter limits discussion to the common types of physical restraints:

- Jacket (body restraint): A sleeveless vest with straps that cross in front or back of the client and are tied to the bed frame or chair legs (see Figure 29-5A on page 676).
- Belt: Straps or belts applied across the client to secure him or her to the stretcher, bed, or wheelchair (see Figure 29-5B).
- Mitten or hand: Enclosed cloth material applied over the client's hand to prevent injury from scratching (see Figure 29-5C).
- Elbow: A combination of fabric and plastic or wooden tongue blades that immobilize the elbow to prevent flexion (see Figure 29-5D).
- Limb or extremity: Cloth devices that immobilize one or all limbs by securely tying the restraint to the bed frame or chair (see Figure 29-5E).
- Mummy: A blanket or sheet that is folded around the child to limit movement. Mummy restraints are used to perform procedures on children (see Figure 29-5F).

SAFETY FIRST

RESTRAINTS

Jacket or belt restraints should not restrict respiratory effort. Placing a restraint too tight on the diaphragm will inhibit the expansion of the lungs.

TABLE 29-4 Adult Fall Prevention Protocol

Purpose	To direct the nursing management of the client at risk for falls
Level	Interdependent nursing function
Supportive Data	Assessment of risk factors from falls and/or a history of falls is a prerequisite of intervention. Risk factors for falls include age, dizziness, confusion, use of medications (prescribed and over the counter), and physical or mental alterations. Fall prevention is used to increase staff awareness of clients at risk for falls and to provide preventive safety measures.
Content	
Assessment	<ol style="list-style-type: none"> 1. Perform client injury risk appraisal and identify fall risks. Update status of fall risks daily and as needed on nursing care plan. 2. Perform a balance and gait screening on those clients who report a single fall. 3. Assess effects of medications administered that increase risk of falling. 4. Implement institution's fall prevention program.
Report to prescribing practitioner	<ol style="list-style-type: none"> 5. Notify prescribing practitioner of previous fall history and identify risk factors for a fall. 6. Notify prescribing practitioner of adverse effects of medications that may increase the client's risk of falling.
Client teaching	<ol style="list-style-type: none"> 7. Orient client to environmental surroundings on admission and as necessary. 8. Instruct client and significant others on safety measures. 9. Instruct client and significant others on correct use of hospital equipment. 10. Instruct client with risk for falls to call for assistance when ambulating or performing activities of daily living (ADL).
Environmental interventions	<ol style="list-style-type: none"> 11. Install an electronic sensing device on beds that measures and signals when a client shifts to a rising position. 12. Keep bed in lowest position, brakes locked, and side rails up. 13. Keep call light and frequently used objects within easy reach at the bedside. 14. Keep environment clean and clutter free. 15. Provide adequate lighting at all times. 16. Lock wheels on wheelchair, bed, and stretcher at all times. 17. Provide nonslip footwear, mats, and rugs. 18. Keep hospital furniture in the same place throughout hospital stay. 19. Provide call cord in bathroom. 20. Encourage use of handrails in bathroom and hallways. 21. Provide nonslip mats in the tub or shower. 22. Place high-risk clients in a room near the nurses' station. 23. Request an environment assessment of the older client's home by a qualified professional prior to discharge.
Direct nursing care	<ol style="list-style-type: none"> 24. Respond promptly to call lights and verbal requests for assistance. 25. Provide assistance with ADL. 26. Maintain close supervision by performing hourly safety assessments. 27. Encourage significant others to stay with high-risk clients. 28. Provide proper equipment for ambulation and elimination needs. 29. Communicate client's injury risk status in shift report.
Evaluation	<ol style="list-style-type: none"> 30. Evaluate client's knowledge of safety measures. 31. Evaluate effectiveness of environmental interventions. 32. Evaluate changes in client's injury risk status. 33. Evaluate effectiveness of direct nursing care. 34. Provide focused training based on each incident.

Proactive management breaks the fall cycle. *Nursing Management*, 35(6), 37–38.

Text not available due to copyright restrictions

The nursing plan of care should include safety measures to reduce the potential for injury from restraints (see Procedure 29-1 on pages 695–699). Additional safety measures to observe when using restraint devices:

- Restraints can be changed and released easily, using only a clove hitch knot (see Figures 29-6 and 29-7 on page 677).
- Restraints should not interfere with any treatments (e.g., IV therapy) or aggravate the client's health problem.
- There should be enough slack on the straps so that the client can move both arms and legs and for range-of-motion exercises.
- At least once every 2 hours, the nurse must perform circulation and neurological exams, assessing the color, sensation, temperature, motion, and capillary refill in the area distal to the restraint.
- There should be a provision for psychological support of client and significant others.

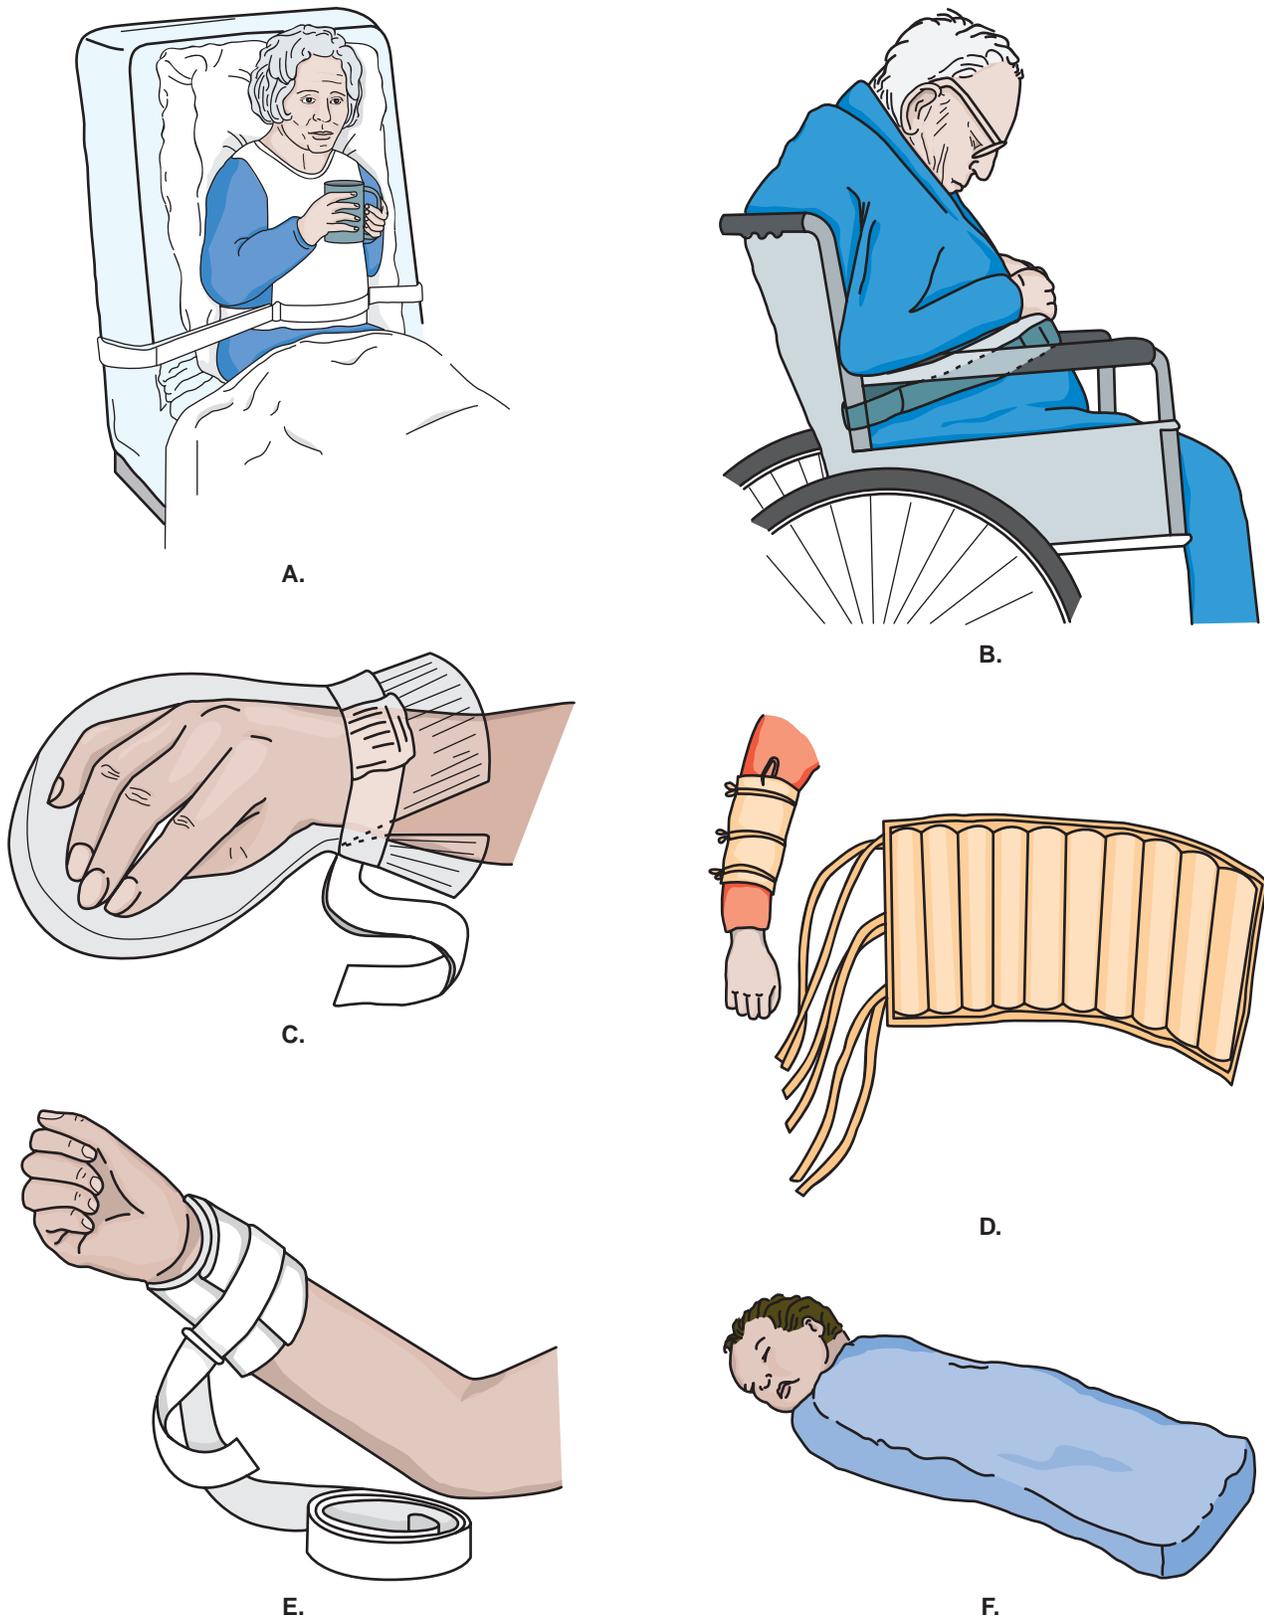

FIGURE 29-5 Types of Physical Restraints: A. Jacket; B. Belt; C. Mitten or Hand; D. Elbow; E. Limb or Extremity; and F. Mummy.

DELMAR/CENGAGE LEARNING

Figures 29-6 and 29-7 demonstrate how to make a clove hitch knot used in applying restraints. Note how the clove hitch restraint, made from a strip of gauze, does not tighten when force is applied against it. The restraint strap is secured to the bed frame, *not to the side rail*, so as to avoid accidental injury to the extremity in the event that the side rail is released while the restraint strap is attached to it.

Environment

Adequate lighting assists in the visualization of environmental hazards. Rooms should be adequately lit so the client can safely perform ADL and health care providers can perform procedures. Lighting can be supplemented by lamps and night-lights. It can also assist in protecting the home against crime.

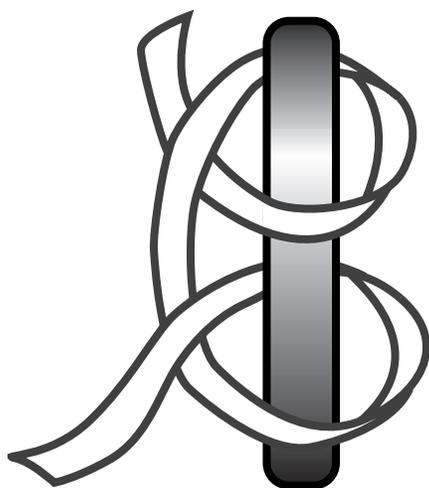

FIGURE 29-6 Clove Hitch Knot DELMAR/CENGAGE LEARNING

SPOTLIGHT ON...

Caring and Compassion

Use of Restraints

Gloria Hernandez is an 83-year-old widow who fractured her hip when she fell in the bathtub. She had hip replacement surgery yesterday. Tonight she is very confused and is trying to dislodge the bandage and stitches. Mrs. Hernandez is now being restrained for protection. What other nursing activities could have been implemented prior to the use of restraints? Do you think that restraints will affect Mrs. Hernandez's mental status? If so, in what ways? What are some other effects Mrs. Hernandez may experience as a result of being restrained? How would you feel about the use of restraints if Mrs. Hernandez were your grandmother?

A.

B.

C.

FIGURE 29-7 Making a Clove Hitch Knot: A. Make a figure-eight; B. Pick up the loops; and C. Put the limb through the loops and secure. DELMAR/CENGAGE LEARNING

Obstacles in heavily traveled areas of health care facilities or homes are a risk to the client's safety. Older adults or persons who are unfamiliar with the environment are at greatest risk of injury from obstacles. The risk that obstacles pose can be reduced by keeping hallways clear, removing excess furniture from heavily traveled areas, removing all electrical cords or taping them securely to the floor, removing throw rugs, applying nonslip pads to rugs, cleaning up spills immediately, and removing objects that could fall from the tops of appliances.

Bathrooms pose a threat to the client in the home because of the presence of water and storage of medication. Common bathroom accidents are falls, scalds or burns, and poisonings. Bathroom accidents can be reduced by the use of grab bars near the tub, shower, and toilet; nonslip mats in the tub and shower; and a secured bathroom rug near the tub or shower. Other safety measures include checking the temperature of the water before entering the tub or shower; checking the thermostat setting on the water heater; and storing medications in a locked cabinet, out of reach of children or disoriented or confused adults.

PREVENT FIRE

Fire is a potential danger to all people in an institutional or a home environment. Immobilized or incapacitated clients are at increased risk during a fire. Common causes of fire are smoking in bed, discarding cigarette butts in trash cans, and faulty electrical equipment. Fire occurs with the interaction of three elements: sufficient heat to ignite the fire, combustible material, and oxygen to support the fire.

Nursing goals are fire prevention and protection of clients during a fire. Nursing interventions aimed at preventing or reducing the risk of fire include:

- Clearly marking fire exits
- Knowing locations of fire extinguishers and their operation
- Practicing fire evacuation procedures
- Posting emergency phone numbers by all telephones
- Keeping open spaces and hallways clear of clutter
- Checking electrical cords and outlets for exposed or damaged wires
- Reporting identified electrical hazards
- Educating clients about fire hazards

In the event of a fire, follow institutional policy and procedures for fire containment and evacuation. Nursing interventions during a fire are directed at *protecting the client from injury and containing the fire*. Nurses should be familiar with the locations of fire alarm pull boxes. If a fire occurs, the nurse should utilize the nearest fire box for notification and move clients to safety.

Nurses should be familiar with the use of fire extinguishers and their locations. The fire extinguisher should be directed toward the base of the fire. The four types of fire extinguishers used are water, carbon dioxide, regular dry chemical, and multipurpose dry chemical. Each type of fire extinguisher is used for a specific class of fire, as discussed in Table 29-5.

ENSURE SAFE OPERATION OF ELECTRICAL EQUIPMENT

Clients have contact with a variety of electrical equipment in the hospital environment, such as bed controls and IV and client-controlled analgesia pumps. All electrical equipment should have a three-pronged electrical plug that is grounded. A grounded plug transmits any stray electrical current from equipment to the ground. To protect the client from electri-

TABLE 29-5 Fire Extinguishers

TYPE	CLASS OF FIRE
Water (Type A)	Paper, wood, draperies, upholstery, or rubbish
Carbon dioxide or dry chemical (Types B and C)	Flammable liquids, flammable gases, or electrical fires
Multipurpose dry chemical (Types A, B, and C)	Any type of fire

Delmar/Cengage Learning

cal injury, the nurse should read the warning labels on all equipment, use only grounded electrical equipment, check for frayed electrical cords, avoid overloading circuits, and report any shocks received from equipment to the biomedical department (see Figure 29-8).

If a client receives an electrical shock, the nurse should turn off or remove the electric source before touching the client. Then, the client's pulse should be checked. If the client has no pulse, CPR should be initiated. If the client has a pulse, the nurse should assess vital signs, mental status, and skin integrity for burns. A prescribing practitioner should be notified of the event. The nurse should note points of entry and exit of electrical current to assess for potential complications.

REDUCE EXPOSURE TO RADIATION

Clients are exposed to radiation during diagnostic testing and therapeutic interventions. Injury can occur from radiation if there is overexposure or exposure to untargeted tissues. Exposure to untargeted tissues can occur with radiation implants that become dislodged. General principles of

FIGURE 29-8 Warning Label on Electrical Equipment DELMAR/ CENGAGE LEARNING

radiation exposure and protection are based on time, distance, and shielding. Protection from radiation therapy includes:

- Minimizing time in contact with radiation source (implants or client)
- Maximizing distance from radiation source (implants or client)
- Using appropriate radiation shields
- Monitoring radiation exposure with a film badge
- Labeling all potentially radioactive material
- Never touching dislodged implants or body fluids of client

Both the client and the nurse are at risk for radiation injury. The client's risk for injury can be reduced by education about radiation treatment and necessary precautions, placing the client in a private room, and providing a lead apron when necessary to protect nontargeted body tissues. The nurse's risk for injury can be reduced by observing all radioactive labels, wearing gloves when handling radioactive body discharges, washing hands, wearing a lead apron, disposing of radioactive substances in special containers, reducing time of client contact, and wearing a badge that measures the amount of radiation exposure.

PREVENT POISONING

A **poison** is any substance that causes an alteration in the client's health, such as injury or death, when inhaled, injected, ingested, or absorbed by the body. Antidotes and treatments are available for some but not all types of poisonings. Direct and indirect causes of poisonings are:

- Inadequate supervision of children
- Ingestion of household plants
- Improper storage of toxic substances
- Insect or snake bites
- Accidental ingestion of a toxic substance or medication overdose

The poison control center should be notified when poisoning is suspected. The person reporting the poisoning should be prepared to state the amount and type of poison ingested, inhaled, or injected; the client's age; and the symptoms. Clients who have ingested poison should be turned on their side to prevent aspiration while awaiting further treatment. Client education about safety measures can prevent some accidental poisonings. The following Client Teaching Checklist provides some safety measures to prevent accidental poisoning. Keep syrup of ipecac available at all times.

REDUCE NOISE POLLUTION

Noise pollution, a situation that results when the noise level becomes uncomfortable for the client or staff, frequently occurs in the health care setting as a result of visitor traffic, medical equipment, and personnel. It can result in a disorganized environment, hearing loss, and **sensory overload**. Sensory overload is an increased perception of the intensity of auditory and visual stimuli. Sensory overload can alter a client's recovery by increasing anxiety, paranoia, hallucinations, and depression. Safety measures include maintaining a quiet

environment, controlling traffic, and providing earplugs. Taylor-Ford, Catlin, LaPlante, and Weinke (2008) conducted a study regarding sound levels in a hospital and concluded that the use of sound-absorbing materials in the hospital's physical structure may be the most effective measure in reducing sound levels. See Chapter 38 for a discussion of sensory overload.

ENSURE ASEPSIS

Nurses are responsible for providing the client with a safe environment, which includes preventing the transmission of HAIs. **Asepsis** is the absence of microorganisms. Providing nursing care using aseptic technique decreases the risk and spread of HAIs. **Aseptic technique** is the infection control practice used to prevent the transmission of pathogens. Two types of asepsis are medical and surgical.

Medical Asepsis

Medical asepsis uses practices to reduce the number, growth, and spread of microorganisms. Medical asepsis is also referred to as "clean technique." Objects are generally referred to as "clean" or "dirty" in medical asepsis. **Clean objects** are considered to have the presence of some microorganisms that are usually not pathogenic. **Dirty (soiled) objects** are considered to have a high number of microorganisms, with some that are potentially pathogenic. Common medical aseptic measures used for clean or dirty objects are handwashing, gloves, changing linens daily, and cleaning floors and hospital furniture daily.

HAND HYGIENE The CDC (2002) published new handwashing guidelines: *Hand Hygiene in Health-Care Settings: Recommendations of the Healthcare Infection Control Practice Advisory Committee and the HICPAC/SHEA/APIC/IDSA Hand Hygiene Task Force*. These guidelines provide new terminology and definitions:

CLIENT TEACHING CHECKLIST

SAFETY MEASURES TO PREVENT ACCIDENTAL POISONINGS

- Store medications in child-resistant containers.
- Do not take medications in front of children.
- Never call medicine candy.
- Limit the number of tablets in a medicine container.
- Place toxic substances in a locked cabinet out of reach of children.
- Never remove labels from containers.
- Do not place poisonous substances in food or beverage containers.
- Place poison stickers on toxic substances.
- Display poison control center phone numbers near telephones.

- **Hand hygiene.** “A general term that applies to either handwashing, antiseptic handwash, antiseptic hand rub, or surgical hand antiseptics” (CDC, 2002, p. 4).
- **Handwashing.** “Washing hands with plain (i.e., nonantimicrobial) soap and water” (CDC, 2002, p. 4).
- **Antiseptic handwash.** “Washing hands with water and soap or other detergents containing an antiseptic agent” (CDC, 2002, p. 4).
- **Antiseptic hand rub.** “Applying an antiseptic hand rub product to all surfaces of the hands to reduce the number of microorganisms” (CDC, 2002, p. 4).
- **Surgical hand antiseptics.** “Antiseptic handwash or antiseptic hand rub performed preoperatively by surgical personnel to eliminate transient and reduce resident hand flora. Antiseptic detergent preparations often have persistent antimicrobial activity” (CDC, 2002, p. 4).

The CDC guidelines are evidenced based, with more than 230 references and research studies (see the accompanying Safety First display for a summary of these guidelines). The report stresses the common mode of transmission of health care–associated pathogens from frequently colonized areas of normal intact skin with such bacteria as *Staphylococcus aureus* and *Klebsiella*. These organisms are identified during activities such as lifting the client; taking a pulse, blood pressure, or oral temperature; and touching the client’s hands or shoulders or an inanimate object in the room. When hands are visibly soiled, showing dirt or contaminated with proteinaceous material, blood, or other body fluids, such as fecal material or urine, the CDC recommends handwashing (see Procedure 29-2 on pages 699–701).

The Task Force reviewed clinical trials using various products for hand hygiene (alcohols, chlorhexidine, hexachlorophene, iodophors, PCMZ, and triclosan, as well as plain or antibacterial soap and water; see the accompanying display on CDC hand hygiene). The Task Force acknowledged the efficacy of alcohol-based products. Alcohol-based hand rubs reduce the number of microorganisms on the skin, are fast acting, and cause less skin irritation. Although gloves reduce hand contamination by 70% to 80%, prevent cross-contamination, and protect clients and health care providers from infection, hand hygiene is still required.

The CDC recommends evaluation of hand hygiene products based on the efficacy of antiseptic agents against various pathogens and the acceptability for usage (smell, consistency, color, and effect of dryness on hands). Accordingly, health care agencies need to develop and implement a system for measuring improvements in adherence to hand hygiene recommendations, such as periodic monitoring of personnel adherence to hand hygiene recommendations and focused assessment of the adequacy of practice when outbreaks of infection occur. Health care providers should be encouraged to report contact dermatitis due to alcohol hand rubs, although this occurrence is rare.

Surgical Asepsis

Surgical asepsis, or sterile technique, consists of those practices that eliminate all microorganisms and spores from an

SAFETY FIRST

CDC HAND HYGIENE

- Adhere to hand hygiene using alcohol-based hand rubs by health care personnel before and after each client encounter.
- Use handwashing for visibly soiled hands.
- Use soap and water for hand hygiene in non-health care settings.
- Use hand hygiene when wearing gloves.
- Apply an alcohol-based product to the palm of the hand and rub hands together, covering all surfaces of hands and fingers until hands are dry (the volume needed to reduce the number of bacteria on hands varies by product) after client contact.
- Avoid wearing artificial nails, and keep natural nails less than one-quarter of an inch long if providing client care.

object or area. **Spores** are single-celled microorganisms or microorganisms in the resting or inactive stage. Surgical asepsis refers to handwashing, the donning of surgical attire (caps, masks, and eyewear), the handling of sterile instruments and equipment, and establishing and maintaining sterile fields.

Surgical asepsis is practiced by the nurse in the operating room, during labor and delivery, and for many diagnostic and therapeutic interventions at the client’s bedside. Common nursing procedures that require sterile technique are:

- All invasive procedures, either intentional perforation of the skin (injections, insertion of IV needles or catheters) or entry into a bodily orifice (tracheobronchial suctioning, insertion of a urinary catheter)
- Nursing measures for clients with disruption of skin surfaces (changing a surgical wound or IV site dressing) or destruction of skin layers (trauma and burns)

DONNING STERILE GLOVES There are two methods for applying sterile gloves: open and closed. The open method is used most frequently when performing procedures that require the sterile technique, such as dressing changes (see Procedure 29-3 on pages 701–705 for applying sterile gloves

SAFETY FIRST

HAND HYGIENE

Perform hand hygiene before and after every client contact. The most common cause of HALs is contamination from the hands of health care providers.

by the open method). The closed method is used when the nurse wears a sterile gown.

DONNING SURGICAL ATTIRE Surgical nurses are required to wear a surgical mask and a clean cloth or paper cap that covers all of the hair. After the cap is applied, the nurse positions the mask to cover the nose and mouth (see Procedure 29-4 on pages 705–709). Protective eyewear (glasses or goggles) is worn during all procedures that pose a threat of splashing body fluids into the eyes.

SURGICAL HAND ANTISEPSIS Surgical hand antiseptic or scrub is used to remove soil and most transient microorganisms from the skin. Nurses working in the operating room perform surgical hand antiseptic to decrease the client's risk for an infection. The skin on the nurse's hands and arms should be intact (free of lesions). Agency policy determines how to perform the scrub with regard to method and timing (see Procedure 29-5 on pages 710–713 for the basic principles of performing surgical hand antiseptic).

GOWNING AND CLOSED GLOVING Nurses in the operating room and special procedure areas such as cardiac catheterization labs use the closed gloved method when donning a sterile gown. After the surgical scrub, the nurse proceeds to don the sterile gown and gloves using the closed method (see Procedure 29-6 on pages 714–716). The sterile gown serves as a barrier to decrease the risk of wound contamination. The sterile gown also allows the nurse to move freely in the environment with sterile drapes and objects.

REDUCE OR ELIMINATE INFECTIOUS AGENTS

Transmission of microorganisms to clients may also occur through contact with inanimate objects. Cleansing, disinfecting, and sterilizing can break this link in the chain of infection by reducing or destroying microorganisms on objects. Cleansing, disinfection, and sterilization are usually the responsibility of nursing, housekeeping, and central supply departments. These infection control practices can and should also be practiced in the home care setting.

Cleansing

Cleansing is the removal of soil or organic material from instruments and equipment used in providing client care. Nurses are involved in cleansing instruments after assisting in or performing an invasive procedure. Reusable objects are cleansed prior to sterilization and disinfection to reduce the amount of contamination and loosen the material on the object. Cleansing involves the use of water, mechanical action, and sometimes a detergent. Contaminated objects are cleaned using a soft-bristled brush to scrub the surface. The steps for proper cleansing are:

1. Rinse object under cold water, since warm water causes proteins in organic material to coagulate and stick.

2. Apply detergent and scrub object under running water with soft-bristled brush.
3. Rinse the object under warm water.
4. Dry the object prior to sterilization or disinfection.

Cleansing presents a potential hazard to the nurse through the splashing of contaminated material onto the body. Nurses should wear gloves, masks, and goggles during cleansing.

Disinfection

Disinfection is the elimination of pathogens, except spores, from inanimate objects. **Disinfectants** are chemical solutions used to clean inanimate objects. Bedpans, blood pressure cuffs, linens, stethoscopes, thermometers, and some types of endoscopes are disinfected in the hospital setting. The U.S. Environmental Protection Agency licenses (registers) disinfection products and monitors the products to ensure that they work as claimed on the label. Common disinfectants are alcohol, sodium hypochlorite, quaternary ammonium, phenolic solutions, and glutaraldehyde. In the home, Lysol and bleach are common disinfectants that are capable of eliminating several pathogens. A **germicide** is a chemical that can be applied to both animate and inanimate objects to eliminate pathogens. Antiseptic preparations such as alcohol and silver sulfadiazine are germicides and may be used on skin.

Sterilization

Sterilization is the total elimination of all microorganisms, including spores. Instruments that are used for invasive procedures must be sterilized. Methods of achieving sterilization are moist heat or steam, radiation, chemicals, and ethylene oxide gas. The method of sterilization depends on the type of contamination, amount of contamination, and object to be sterilized.

Autoclaving sterilization, which uses moist heat or steam, is the most common sterilization technique used in the hospital setting. Boiling water is not an effective sterilization measure, as some viruses and spores can survive boiling water. Objects that have been boiled in water for 15 to 20 minutes at 121°C (249.8°F) are considered clean but not sterilized. However, boiling water is still the best and most common sterilization measure used in the home. For example, boiling baby bottles and nipples makes them safe for use.

Home Health Care

Home care and hospice nurses are faced with significant challenges when adapting acute care infection control practice to the home care setting, such as cleaning and disinfecting equipment and using clean versus sterile technique. Common practice of home care organizations requires special practice regarding the handling of the *nursing supply bag*; see the accompanying display on page 682 on a basic nursing bag technique procedure that may be followed in the home.

Disposal of Infectious Waste

All health care facilities must have guidelines for the disposal of infectious waste materials as deemed by the OSHA Act of

NURSING SUPPLY BAG TECHNIQUE PROCEDURE

- Place the bag on a clean, dry surface.
- Wash hands with soap and running water prior to direct client contact. For MRSA or VRE clients, wash hands with antibacterial soap and running water. Cleanse hands with a waterless product if running water is not available.
- Remove the necessary supplies from the nursing bag, and place them on a clean, dry surface.
- Perform client care.
- Clean and disinfect semicritical equipment such as an oral thermometer with a 70% isopropyl alcohol prep pad, and return the equipment to the supply bag.
- Clean noncritical equipment such as a blood pressure cuff, stethoscope, or scale, if soiled, and return to the bag. If the client is infected or colonized with multidrug-resistant (MDR) bacteria, and equipment has not been designated for the client's individual use, clean and disinfect the equipment with a disinfectant of the home care or hospice organization's choice prior to replacing the noncritical items in the bag.
- Remove personal protective items such as a gown and gloves if worn.
- Wash hands with soap and running water prior to direct client contact. For MRSA or VRE clients, wash hands with antibacterial soap and running water. Cleanse hands with a waterless product if running water is not available, and wash hands with soap and running water as soon as possible.

Adapted from Friedman, M., & Rhinehart, E. (2000). Improving infection control home care: From ritual to science-based practice. *Home Healthcare Nurse*, 18(2), 99–106.

1991 (see the accompanying display on the disposal of biological materials). Always observe the biological hazard symbol, and handle all infectious materials as a hazard. OSHA regulations mandate that “immediately after use, sharps shall be disposed of in closable, puncture-resistant, disposable containers that are leakproof on the sides and bottom and are labeled or color coded.” Dispose of soiled and infectious items in the home; do not place in car to dispose elsewhere.

When disposing of infectious waste:

- Wear gloves.
- Use the proper containers (red or one labeled with the biological hazard symbol as required by the facility); leakproof plastic bags for waste from client areas (soiled dressings, gloves, linens); and sharps containers for needles, scalpels, and other sharp instruments or devices (see Figure 29-9 on page 683).
- Ensure that all infectious waste is properly labeled.
- Use care when handling plastic bags to avoid punctures and tearing.
- Disinfect carts used to carry infectious waste.
- Dispose of waste in designated areas only.
- Wash hands after disposing of hazardous materials.

Containers for contaminated sharps should be readily accessible to personnel and maintained in an upright position.

Sharps-Related Hazards

The Needlestick Safety and Prevention Act of 2000 and the 2001 revised OSHA Bloodborne Pathogens Standards (BPS) require implementation of safety-engineered sharp devices. Although these mandates require institutions to convert to safety products, sharps-related hazards to health care workers persist. According to a study conducted by the American Nurses Association (ANA) regarding workplace safety and needlestick injuries, nurses stated that needlestick injuries and bloodborne infections remain major concerns. The study also revealed that 55% of the nurses experienced needlestick injuries from needles contaminated by blood or body fluids (ANA, 2008). The CDC estimates that 384,325 health care workers are injured annually by needles and other sharps. Of these injuries, about 44% are sustained by nurses, according to Exposure Prevention Information Network (EPINet) data for 2001. The EPINet is a computer-based sharps injury surveillance program that provides for agencies to track injuries by individual departments such as the operating room. Health care workers can file

DISPOSAL OF BIOLOGICAL MATERIALS

- Laboratory wastes
- Blood, blood products, and all other body fluids
- Client care items: soiled bed linens and protection pads soiled with visible blood, urinals, and bedpans
- Disposable instruments
- Medication and soiled treatment items
- Surgical waste

SAFETY FIRST

NEEDLE DISPOSAL

Used needles should not be recapped, bent, or broken. Needles should be placed in a puncture-resistant marked or color-coded container close to the work site. Correct disposal decreases the risk of needle punctures to caregivers.

FIGURE 29-9 Sharps Disposal and Infectious Waste Containers
DELMAR/CENGAGE LEARNING

complaints regarding the violation of either the Occupational Safety and Health Act or the BPS with OSHA (see <http://www.osha.gov/as/opa/worker/complain.html>).

PRACTICE STANDARD AND ISOLATION PRECAUTIONS

In 2007 the CDC issued revised isolation guidelines that contain a two-tiered approach established in the 1996 guidelines. The first tier is Standard Precautions (see Front Page). Standard Precautions include a group of infection prevention practices that are based on the assumption that every person is potentially infected or colonized with an organism that could be transmitted in the health care setting. These practices include hand hygiene; personal protective equipment (PPE), which is the use of gloves, gown, mask, eye protec-

tion, or face shield, depending on the anticipated exposure; and safe injection practices. Items or equipment in the client's environment that may have been contaminated with infectious body fluids must be handled in a manner to prevent transmission of infectious agents. Three new practices were added to the revised 2007 guidelines that focus on protection of clients: respiratory hygiene/cough etiquette; safe infection practices; and use of masks for insertion of catheters or injections of material into spinal or epidural spaces through lumbar puncture procedures. The safe injection practices apply to the use of needles, cannulas that replace needles, and, where applicable, IV delivery systems.

The Transmission-Based Precautions are the second tier of the CDC's revised guidelines. These guidelines are used when the route of transmission is not completely interrupted using the Standard Precautions. There are three categories of Transmission-Based Precautions: contact, droplet, and airborne transmission (see Figure 29-10A–C on pages 684–686). Transmission-based precautions are to be used for specific syndromes that are highly suspicious for infections until a diagnosis is confirmed (see Table 29-6 on page 687). Immunosuppressed clients require transmission-based precautions, as described in Table 29-6.

Nurses use isolation precautions to protect the host's normal defense mechanisms by preventing the transmission of pathogens (HAIs). Isolation precautions include barrier protection that breaks the chain of infection.

When the nurse cares for a client in isolation, additional precautions are used along with handwashing and gloves. A mask and eye protection (or face shield) are worn to protect the mucous membranes of the eyes, nose, and mouth during interventions that are likely to produce splashes or sprays of blood, body fluids, secretions, and excretions. A nonsterile gown is also worn to protect the skin and clothing against splashes or sprays.

Nurses caring for clients with TB (an infectious disease caused by the tubercle bacillus *Mycobacterium tuberculosis*) are required to wear special masks since transmission occurs between individuals through respiratory contact. There are two types of TB masks: the high-efficiency particulate air (HEPA) mask used for suspected or confirmed MDR TB and the disposable submicrometer mask used for confirmed TB. These masks form a tight-fitting seal against particulates 1 to 5 mm.

Isolation precautions are usually ordered by the prescribing practitioner; however, nurses may initiate these precautions whenever there is a nursing diagnosis related to the infectious process, for example, *risk for infection* related to decreased resistance of the immune system. Most agencies require nurses to obtain a culture from a draining body area and to initiate isolation precautions when positive cultures are reported. Once isolation precautions have been instituted, visitors and all personnel should comply with the agency's policy regarding isolation precautions. Signs should be posted in a prominent location outside of the client's room, indicating the type of isolation precautions, preparation prior to entering the room, and necessary supplies that should be readily available.

CONTACT PRECAUTIONS

(in addition to Standard Precautions)

STOP VISITORS: Report to nurse before entering.

Gloves

Don gloves upon entry into the room or cubicle.

Wear gloves whenever touching the patient's intact skin or surfaces and articles in close proximity to the patient.

Remove gloves before leaving patient room.

Hand Hygiene

Hand Hygiene according to Standard Precautions.

Gowns

Don gown upon entry into the room or cubicle.

Remove gown and observe hand hygiene before leaving the patient-care environment.

Patient Transport

Limit transport of patients to medically necessary purposes.

Ensure that infected or colonized areas of the patient's body are contained and covered.

Remove and dispose of contaminated PPE and perform hand hygiene prior to transporting patients on Contact Precautions.

Don clean PPE to handle the patient at the transport destination.

Patient-Care Equipment

Use disposable noncritical patient-care equipment or implement patient-dedicated use of such equipment.

FIGURE 29-10A Transmission-Based Precautions: Contact Precautions FROM BREVIS CORPORATION, 3310 S. 2700, SALT LAKE CITY, UT 84109, COPYRIGHT © 2007 BREVIS CORPORATION.

DROPLET PRECAUTIONS

(in addition to Standard Precautions)

STOP VISITORS: Report to nurse before entering.

Use Droplet Precautions as recommended for patients known or suspected to be infected with pathogens transmitted by respiratory droplets that are generated by a patient who is coughing, sneezing or talking.

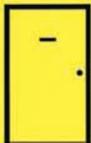

Personal Protective Equipment (PPE)

Don a mask upon entry into the patient room or cubicle.

Hand Hygiene

Hand Hygiene according to Standard Precautions.

Patient Placement

Private room, if possible. Cohort or maintain spatial separation of 3 feet from other patients or visitors if private room is not available.

Patient transport

Limit transport and movement of patients to **medically-necessary purposes**.

If transport or movement in any healthcare setting is necessary, instruct patient to **wear a mask** and follow Respiratory Hygiene/Cough Etiquette.

No mask is required for persons transporting patients on Droplet Precautions.

DPR7

FIGURE 29-10B Transmission-Based Precautions: Droplet Precautions FROM BREVIS CORPORATION, 3310 S. 2700, SALT LAKE CITY, UT 84109, COPYRIGHT © 2007 BREVIS CORPORATION.

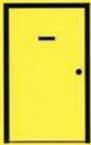

AIRBORNE PRECAUTIONS

(in addition to Standard Precautions)

VISITORS: Report to nurse before entering.

Use Airborne Precautions as recommended for patients known or suspected to be infected with infectious agents transmitted person-to-person by the airborne route (e.g., *M. tuberculosis*, measles, chickenpox, disseminated herpes zoster).

Patient placement

Place patients in an **AIIR** (Airborne Infection Isolation Room).
Monitor air pressure daily with visual indicators (e.g., flutter strips).

Keep door closed when not required for entry and exit.

In ambulatory settings instruct patients with a known or suspected airborne infection to wear a surgical mask and observe Respiratory Hygiene/Cough Etiquette. Once in an AIIR, the mask may be removed.

Patient transport

Limit transport and movement of patients to **medically-necessary purposes**.

If transport or movement outside an AIIR is necessary, instruct patients to **wear a surgical mask**, if possible, and observe Respiratory Hygiene/Cough Etiquette.

Hand Hygiene

Hand Hygiene according to Standard Precautions.

Personal Protective Equipment (PPE)

Wear a fit-tested NIOSH-approved **N95** or higher level respirator for respiratory protection when entering the room of a patient when the following diseases are suspected or confirmed: Listed on back.

FIGURE 29-10C Transmission-Based Precautions: Airborne Precautions FROM BREVIS CORPORATION, 3310 S. 2700, SALT LAKE CITY, UT 84109, COPYRIGHT © 2007 BREVIS CORPORATION.

TABLE 29-6 Transmission-Based Precautions

CATEGORY	PRIVATE ROOM	GLOVES	GOWNS	MASKS
Contact precautions	If possible; cohort if not available	Required	If anticipate contact with soiled items; client is incontinent; or there is diarrhea, ileostomy, colostomy, or wound drainage	Not required
Droplet precautions	If possible; cohort or maintain separation of 3 feet	Not required	Not required	Required when within 3 feet
Airborne precautions	Required. Negative air pressure, 6–12 air changes per hour, keep door closed, discharge air outdoors or HEPA filter	Not required	Not required	N95 respirator required for known or suspected tuberculosis and measles or varicella if not immune

Delmar/Cengage Learning

Clients should be placed in a private room with adequate ventilation and have their own supplies. Personal belongings should be kept to a minimum, and health care providers should use disposable supplies and equipment. All articles leaving the room, such as soiled linens and collected specimens, should be labeled and either placed in impermeable bags or double bagged (see Procedure 29-7 on pages 718–719). Home health nurses should provide the client and family with appropriate written isolation instructions relative to the specific precautions.

Isolation precautions are for the client's protection; however, clients who are placed on isolation precautions may experience psychological discomfort (see Figure 29-11). Nurses

FIGURE 29-11 This nurse is interacting with a client who requires isolation precautions. Although both the client and nurse are observing isolation precautions, they are still able to communicate with one another. In planning the care of this client, what would the nursing outcomes be regarding these interventions? DELMAR/CENGAGE LEARNING

should be alert for symptoms of anxiety, depression, rejection, guilt, or loneliness. Clients should be educated on which isolation precautions will be practiced and their purposes. Nurses should encourage clients to verbalize their feelings regarding the isolation precautions and provide clients with intellectual stimulation. Visitors should be encouraged to prevent the clients' feelings of isolation and loneliness. The Nursing Checklist lists some psychological interventions.

COMPLEMENTARY AND ALTERNATIVE THERAPIES

The ANA, in its 1995 *Social Policy Statement*, recognizes holistic, complementary, and alternative practices for the client. More and more clients are seeking alternative therapy

NURSING CHECKLIST

Psychological Interventions for Clients Requiring Isolation Precautions

- Explain isolation procedure and rationale.
- Discuss client's feelings about isolation procedures.
- Convey a sense of empathetic understanding.
- Permit visitors in accordance with isolation precautions.
- Support existing coping mechanisms.
- Visit with the client.

for common medical conditions, mainly chronic conditions. Hospitals are becoming more responsive to client demands by incorporating new practice models to allow the client choices and requests for alternative options as part of a holistic approach to both curing and healing. The Massachusetts and Louisiana state boards of nursing have issued statements regarding the role and scope of RN practice and holistic care.

Documentation of the client's alternative or complementary practices should be included in the health history to ensure an integration of alternative and conventional care. Nurses need to have a knowledge of herbal products and their effects to avoid possible adverse reactions when prescribed drugs are used in combination with the client's herbal regimen. A brief discussion regarding herbal baths and the use of herbs for infections is presented; see Chapter 31.

Herbal Baths

Herbal baths are a safe home method of treatment for all clients, especially infants and the elderly, and can be made just for the specific part of the body, such as the hands, hips, or feet, or can be a full body bath. A bath made from freshly grated ginger root stimulates circulation, alleviates aches and pains, breaks a cold, helps arthritis, and warms the body. To calm the mind and relax the body, combine equal parts of lavender, rose, chamomile, and skullcap in the bath water. To stimulate circulation and relieve fever and chills, combine equal parts bayberry bark, ginger, and prickly ash and one-fourth part cayenne pepper in the bath water. Clients using herbs in bath water for the first time should do a simple patch test to rule out a possible allergic response.

Herbs for Infections

Herbs are used in two ways for infections. Through their antimicrobial action, they work directly against microbes. They also augment and vitalize the body's own defenses. Although research may not always be available to explain exactly how herbs work, many plants have a direct toxic effect upon microbes. Common antimicrobials to combat infections safely include echinacea, eucalyptus, garlic, myrrh, nasturtium, thyme, wild indigo, and wormwood.

PROVIDE FOR CLIENT BATHING NEEDS

Bathing clients is an essential component of nursing care. Whether the nurse performs the bath or delegates the activity to another health care provider, the nurse retains the responsibility for ensuring that the hygienic needs of the client are met. The type of bath provided will depend on the purpose of the bath and the client's self-care ability. The two general categories of baths are cleaning and therapeutic.

Cleaning Baths

Cleaning baths are provided as routine client care. The purpose of a cleaning bath is personal hygiene. The five types of cleaning baths are shower, tub, self-help or assisted bed bath, complete bed bath, and partial bath.

SHOWER Most ambulatory clients are capable of taking a shower. Clients with limited physical ability can be accommodated by placing a waterproof chair in the shower (see Figure 29-12). The nurse provides minimal assistance with a shower. The Nursing Checklist, on page 689, discusses guidelines for helping clients with tub or shower baths.

TUB BATH Clients frequently prefer and enjoy tub baths. A tub bath permits washing and rinsing in the tub. Tub baths can also be therapeutic. Clients with limited physical ability should be assisted with entering and exiting the tub.

SELF-HELP BATH A self-help, or assisted, bed bath is used to provide hygienic care for clients who are confined to bed. In the self-help bed bath, the nurse prepares bath equipment but provides minimal assistance. This assistance is usually limited to washing difficult-to-reach body areas such as the feet and back.

COMPLETE BED BATH A complete bed bath is provided to dependent clients confined to bed. The nurse washes the client's entire body during a complete bed

FIGURE 29-12 Shower Seat for Client Safety DELMAR/CENGAGE LEARNING

NURSING CHECKLIST

Tub or Shower Bath

- Schedule use of tub or shower, and provide necessary equipment.
- Assist with ambulation to and from tub or shower.
- Place bath mat in tub or shower. Provide shower seat if necessary.
- Place “occupied” sign on door.
- Adjust room temperature and temperature of water.
- Half fill the tub with water. Do not allow the client to soak longer than 20 minutes.
- Assist the client with getting into and out of the tub or shower. Provide with a call system.
- Assist with cleaning as necessary.
- Clean tub or shower after use according to agency policy.

bath. Procedure 29-8 on pages 720–723 outlines the actions involved in giving a complete bed bath.

PARTIAL BATH A partial (or an abbreviated) bath consists of cleaning only body areas that would cause discomfort or odor if not washed thoroughly. These areas are the face, axillae, hands, and perineal area. The nurse or client may perform a partial bath depending on the client’s self-care ability. Partial baths may be performed with the client lying in bed or standing at the sink.

Therapeutic Baths

Therapeutic baths require a prescribing practitioner’s order stating the type of bath, temperature of water, body surface to be treated, and type of medicated solutions to use. A therapeutic bath is usually performed in a tub and lasts about 20 to 31 minutes. Therapeutic baths are classified as hot or warm water, cool or tepid water, soak, sitz, oatmeal or Aveeno, cornstarch, or sodium bicarbonate, depending on the prescribed type of bath.

Hot or warm-water tub baths are used to reduce muscle spasms, soreness, and tension; however, they have the potential for causing skin burns. Cool or tepid baths are used to relieve tension or lower body temperature. The nurse needs to prevent chilling and rapid temperature fluctuations during a cool or tepid bath.

A soak can include the entire body or can be limited to only one body part. A soak consists of applying water, with or without a medicated solution, to reduce pain, swelling, or irritation or to soften or remove dead tissue.

Sitz baths cleanse and reduce inflammation in the perineal and anal areas. They are commonly used for hemorrhoids or anal fissures and after perineal or rectal surgery. Skin irritations can be soothed with oatmeal or Aveeno, cornstarch, or sodium bicarbonate baths.

PROVIDE CLEAN BED LINENS

After a bath, clean linens are placed on the bed to promote comfort. If the client is able to get out of the bed, assist the client to a chair and proceed with making the bed. Procedure 29-9 on pages 724–728 describes the steps involved with making an unoccupied bed. After surgery, the client should be returned to a clean bed with the linens folded to the foot of the bed to promote easy client transfer.

If the client is unable to get out of the bed, refer to Procedure 29-10 on pages 729–732 for a description of the steps involved in making an occupied bed. Assistance will be needed if the client is in traction or cannot be turned. Care must be taken to avoid disturbing the traction weights. If the client cannot be turned, change the linens from head to toe. Place a waterproof drawsheet on the beds of clients who are incontinent or have profuse drainage.

PROVIDE SKIN CARE

The skin functions as a protective barrier between the internal and external environments. In addition, it functions to regulate body temperature, secrete sebum, excrete sweat, transmit sensations, and facilitate the absorption of vitamin D.

Skin care provides cleansing and conditioning to promote the optimal functioning of the skin. It consists of providing adequate nutrition, baths, perineal care, and back rubs. Excessive or abrasive skin care can damage skin and result in loss of function. Performing skin care provides an excellent opportunity for the nurse to assess skin integrity.

Perineal Care

Perineal care is the cleansing of the external genitalia, perineum, and surrounding area. Perineal care is also referred to as “peri-care” or “perineal-genital” care. The purposes of perineal care are to prevent or eliminate infection and odor, promote healing, remove secretions, and provide comfort. Perineal care can be provided alone or as part of the bed bath.

Perineal care may be an embarrassing procedure for both the client and the nurse, especially if the client is of the opposite sex. Clients who are embarrassed may elect to perform their own perineal care. In this situation, the nurse should provide the client with warm water, a moistened washcloth, soap, a dry towel, and privacy. If the client is unable to perform perineal care, the nurse is responsible for providing this care in a professional and private manner (see Procedure 29-11 on pages 732–734).

Back Rubs

Back rubs and massages stimulate the client’s circulation, relax muscles, and relieve muscle tension as well as provide the nurse with an opportunity for skin assessment. Emollient creams and lotions are used to facilitate the rubbing and lubrication of the skin during a back rub or massage.

The client is positioned prone or on the side. Nurses create friction and pressure by rubbing their hands on the client’s skin. The friction creates heat, which dilates the

peripheral circulation and increases the blood supply to the skin. The pressure provides manual stimulation to muscle fibers, which relaxes the muscles. Chapter 31 presents the technique for performing a back rub.

Prior to performing a back rub or massage, the nurse must assess for contraindications. Caution should be exercised when massaging limbs. Massaging limbs, especially the lower limbs, could dislodge a thrombus (blood clot), creating an embolus (circulating blood clot). Bony prominences should be massaged lightly to avoid damaging underlying tissue.

PROVIDE FOOT AND NAIL CARE

Proper foot and nail care is essential for ambulation and standing. This is often ignored until problems exist. Common problems with feet and nails may be a direct result of abuse and neglect, such as from inadequate foot and nail hygiene, fingernail and cuticle biting, incorrect nail trimming, poorly fitted shoes, and exposure to harsh chemicals. These problems result in alterations of skin integrity with the potential for infection.

The first signs of foot and nail problems are usually pain or tenderness. These symptoms affect a client's posture and may result in limping with subsequent strain on certain muscle groups. Clients with illnesses such as diabetes mellitus need special foot and nail care. Clients with diabetes mellitus experience alterations in circulation that predispose them to foot problems.

The purposes of foot and nail care are to prevent infection and soft tissue trauma from ingrown or jagged nails and to eliminate odor. Hygienic care of feet and nails consists of regular trimming of nails; cleaning under nails; cleaning, rinsing, and drying feet and nails; and wearing properly fitted shoes. The Nursing Checklist discusses the specific interventions that should be taken in providing foot and nail care.

Soaking nails assists with their cleaning if they are dirty or thickened. An orangewood stick is used to clean under nails since a metal instrument can roughen the nail and cause it to harbor dirt. The safest instrument to trim nails is the nail clipper; however, some clients feel that cutting the nails makes them brittle. If the client chooses not to cut the nails, the nails should be filed straight across. Special attention should be given to drying the areas between the toes. An emollient, such as cold cream, helps keep nails and cuticles soft.

Callused areas should never be cut. Repeated soaking usually facilitates the removal of calluses. Lotion should be applied to the foot to maintain moisture and soften callused areas. If the client's feet retain excessive moisture (sweat), then water-absorbent powder should be applied between the toes.

The client should wear clean, properly fitted shoes. The fit should not be extremely tight but should be snug enough to provide support to the foot. An arch support should be in each shoe. Shoe size should be large enough so that the shoe is one-half inch longer than the longest toe. Common foot problems can often be alleviated by assessing footwear and providing proper education on footwear and foot and nail care.

NURSING CHECKLIST

Foot and Nail Care

- Soak feet in warm water and a detergent or in warm oil.
- Use an orangewood stick to clean the nails and release the cuticle growth from the nail.
- File or cut the nails straight across to prevent ingrown nails.
- Trim the cuticles as necessary.
- Pat all areas dry with a clean towel.
- Apply an emollient.

PROVIDE ORAL CARE

The oral cavity functions in mastication, secretion of mucus to moisten and lubricate the digestive system, secretion of digestive enzymes, and absorption of essential nutrients. Common problems occurring in the oral cavity are:

- Bad breath (**halitosis**)
- Dental caries (**cavities**)
- Plaque
- Periodontal disease (**pyorrhea**)
- Inflammation of the gums (**gingivitis**)
- Inflammation of the oral mucosa (**stomatitis**)

Poor oral hygiene and loss of teeth may affect a client's social interaction and body image as well as nutritional intake. Daily oral care is essential to maintain the integrity of the mucous membranes, teeth, gums, and lips (see Procedure 29-12 on pages 735–740). Through preventive measures, the oral cavity and teeth can be preserved. Preventive oral care consists of fluoride rinsing, flossing, and brushing.

Fluoride

Researchers have determined that fluoride can prevent dental caries. This finding has led to the fluoridation of water supplies in many communities. Fluoride is a common component of mouthwashes and toothpastes. However, persons with excessive dryness or irritated mucous membranes should avoid commercial mouthwashes because of the alcohol content, which dries out mucous membranes.

Fluoride supplements are available without a prescription. Infants can be given fluoride drops as early as 2 weeks of age to prevent dental caries. Nurses should educate clients about fluoride as an excellent preventive measure against dental caries. However, excessive fluoride usage can affect the color of tooth enamel. To prevent discoloration, fluoride should be administered with a dropper directed toward the back of the throat.

Flossing

Flossing should be performed daily in conjunction with brushing teeth. Flossing prevents the formation of plaque,

removes plaque between the teeth, and removes food debris. Dental caries and periodontal disease can be prevented by regular flossing. Flossing is best performed after toothpaste is applied to the teeth but before brushing (see Procedure 29-12). This order permits the fluoride in the toothpaste to come into direct contact with the tooth surfaces, thus preventing dental caries. Flossing can also be performed after brushing, but brushing first does not maximize the fluoride's contact with the tooth surfaces.

Brushing

Brushing teeth should follow flossing. Teeth should be brushed after each meal. Brushing should be performed using a dentifrice (toothpaste) that contains fluoride to aid in preventing dental caries. An effective homemade dentifrice is the combination of two parts salt and one part baking soda. Brushing removes plaque and food debris and promotes blood circulation of the gums. Dentures should be brushed using the same brushing motion as that used for brushing teeth. Refer to Procedure 29-12 for brushing teeth and denture care.

Oral Care for the Unconscious Client

Oral care for the unconscious client maintains a clean oral cavity and intact mucous membranes (see Procedure 29-12). Special care should be exercised when performing oral care for unconscious clients to prevent client aspiration or injury to the nurse (client biting because of gag reflex).

PROVIDE HAIR CARE

Hair affects a client's personal appearance and body image. It functions to maintain the body temperature and as a receptor for the sense of touch. Assessment of hair texture, growth, and distribution provides information on a client's general health status.

Common hair problems are dandruff, hair loss, tangled or matted hair, and infestations such as pediculosis and lice. Hair problems can be reduced by daily hair care, which helps promote hair growth; prevent hair loss, infections, or infestations; promote circulation of the scalp; evenly distribute oils along hair shafts; and maintain the client's physical appearance. Hair care consists of brushing and combing, shampooing, shaving, and mustache and beard care.

Brushing and Combing

Hair should be brushed or combed daily according to the client's preferred hairstyle. Brushing and combing stimulate circulation to the scalp, distribute oils along hair shafts, and arrange the placement of hair. A clean brush or comb should be used. Hair should be brushed from the scalp toward the hair ends. Sensitive scalps should be brushed or combed gently. Wetting the hair with water before brushing or combing can prevent damage to the hair and painful pulling of the scalp.

Clients who are immobilized may have tangled or matted hair. Care should be taken to prevent pain when combing by holding the tangled hair near the scalp while combing. If the client permits, the hair can be braided to avoid tangling

Cultural Influences on Hygiene

Keep in mind that all self-care and hygiene practices are influenced by the client's background and cultural values. Always ask clients about preferences prior to performing care, and show sensitivity to those practices that may differ from your own.

or matting, but braiding the hair tightly should be avoided since tight braids may cause pain and hair loss. A nurse must receive written, informed consent to cut a client's hair.

Shampooing

When soiled, hair should be shampooed according to the client's usual routine. The purposes of shampooing are to stimulate scalp circulation, remove soil from hair, and facilitate brushing and combing. Hair can be shampooed in the tub, in the shower, at the sink, or in the bed, depending on the client's abilities and preferences.

Clients confined to bed can have their hair shampooed with water or with shampoos that do not require water (see Nursing Checklist: Shampooing Hair in Bed, on page 692). Hair is shampooed by thoroughly wetting all hair, applying about a teaspoon of shampoo, lathering shampoo, and gently massaging the scalp with the pads of the fingertips. Hair should be rinsed thoroughly after shampooing, then dried with an absorbent towel. Brush or comb in the client's preferred hairstyle.

Shaving

Shaving is the removal of hair from the skin surface. Males often shave to remove facial hair, and women may shave to remove leg and/or axillary hair. Operative procedures may also require skin preparation for shaving an area of the body.

Shaving may be performed before, during, or after the bath. Care should be used to avoid cutting the skin. Prior to shaving, the area should be washed with soap and warm water to soften the hair. A warm washcloth may be placed over the area for a few minutes to assist with softening. A shaving cream or mild soap is applied to the area to ease hair removal. To shave, the skin should be pulled taut. The razor is held at a 45° angle and moved over the skin in short, firm strokes in the direction of hair growth. After the skin is shaved, it should be washed, rinsed, and patted dry.

Mustache and Beard Care

Mustaches and beards require daily care, consisting of keeping the hair clean, trimmed, and combed. Mustaches and beards can be washed with soap or shampoo. Frequently, they require only a gentle wiping with a moist washcloth. A mustache or beard should never be shaved by the nurse without written, informed consent.

NURSING CHECKLIST

Shampooing Hair in Bed

- Remove pillow. Position the client with head and shoulders near edge of bed. Cotton may be placed in the external ear canal.
- Place a linen protector or plastic head-washing tray under the head to protect the bed from becoming wet and to facilitate the draining off of water and shampoo.
- Offer the client a towel to cover eyes, if desired (see Figure 29-13).
- Shampoo hair beginning at the hair line and working toward the back of the head.
- Rinse thoroughly to remove all residue from the scalp. Repeat washing and rinsing until hair squeaks when fingers move through hair.
- Squeeze excess water from hair. Wrap a towel around client's head and rub hair and scalp with towel. Remove linen protector or plastic tray and complete drying of hair.

FIGURE 29-13 Shampooing Hair in Bed DELMAR/CENGAGE LEARNING

SAFETY FIRST

SHAVING

Review the client's medical record and the facility's policy regarding the use of razors for shaving. Clients prone to bleeding, such as those on anticoagulants, should be instructed to use only electric razors for shaving.

PROVIDE EYE, EAR, AND NOSE CARE

Eye, ear, and nose care should be included in routine hygienic care.

Eyes

Eyes are continually cleansed by the production of tears and the movement of eyelids over the eyes. Eyelids should be washed daily with a warm washcloth from the inner to outer canthus. Eyelashes function to prevent foreign material from entering the eyes and conjunctival sacs. Eyelashes and eyebrows should be washed as necessary.

A client's artificial eye (prosthetic) may require daily cleaning. The eye must be removed from the eye socket and washed (see Procedure 29-13 on pages 741–745). Some artificial eyes are permanently implanted.

Comatose clients have special eye care needs since they lack a blink reflex. These clients require frequent instillations of lubricants or eyedrops to prevent corneal abrasions. The accompanying Nursing Checklist describes eye care for the comatose client.

CONTACT LENSES The nursing history should indicate whether the client wears contact lenses, and the routine care and level of assistance should be recorded on the client's care plan. Clients who can insert, remove, and manage the care of their lenses will require minimal assistance from the nurse. If the client is unable to assist with lens care and also has corrective eyeglasses, suggest that he or she wear the eyeglasses during hospitalization. There are two types of contact lenses: hard and soft. Each type requires different cleaning and care (see Procedure 29-13). During emergency situations, the nurse should remove the lenses and place them in the appropriate solution.

Ears

Hearing can be affected by foreign material or wax in the external ear canal. Cleaning the ears involves cleaning the external ear canal and auricles. Objects should not be inserted into the ear canal. Excess wax or foreign material should be

NURSING CHECKLIST

Eye Care for the Comatose Client

- Cleanse eyelids, eyelashes, and eyebrows with warm washcloth at least every 4 hours. Clean from inner to outer canthus.
- If eyes remain open and blink reflex is absent, liquid tear solutions should be applied to prevent corneal drying and ulcerations.
- Eyes can be closed and covered with an eye patch or a protective shield. The eye patch or a protective shield should be removed at least every 4 hours to assess eyes and provide eye care.

removed by gently washing the external ear and auricles with a warm washcloth while pulling the ear downward in the adult client. Irrigation of the ear may be necessary to remove dried wax. The prescribing practitioner should be notified prior to irrigation of the ear.

HEARING AIDS Hearing aids amplify sound. The health history should indicate whether the client is wearing a hearing

aid, and the plan of care should address the cleaning schedule of this aid. Clients with hearing aids should clean the ear mold regularly to ensure proper functioning. There are four types of hearing aids: bodyworn, eyeglass, behind the ear, and in the ear. Some hearing aids have a telephone switch that can be turned on and off.

If the hearing aid is not functioning properly, check the on-off switch and volume control, battery (replace as necessary),

NURSING CARE PLAN

Client at Risk for Injury

CASE PRESENTATION

Mr. Simon, age 75, is admitted to the hospital with coronary heart disease (CHD). He has a family history of CHD. He smokes two packs of cigarettes a day, has diabetes mellitus, and is obese.

ASSESSMENT

- Weight gain of 7 pounds in past month
- Blood cholesterol 320 mg/dL
- High-density lipoproteins (HDL) 28 mg/dL
- Blood pressure 186/116
- Diminished visual acuity
- Decreased bladder tone
- Weakness and syncope
- Glasgow Coma Scale (GCS) score of 12

NURSING DIAGNOSIS 1

Risk for injury related to sensory dysfunction and altered level of consciousness.

EXPECTED OUTCOME

The client will be protected from injury during the hospitalization.

INTERVENTIONS/RATIONALES

1. Initiate the fall prevention protocol. Identifies and reduces risk for injury.
2. Reassess the client's injury status every 4 hours. Identifies changes and highlights need to modify plan of care.
3. Place the client in a room as close as possible to the nurses' station. Facilitates faster response time to client's needs.
4. Place fall alert signs on the client's door and head of bed. Alerts other health care workers to client's risk status.
5. Turn on the bed alarm. Helps monitor client status and facilitates prompt response if client tries to get out of bed unassisted.
6. Monitor the client and the environment every 2 hours and whenever a caregiver passes by the client's room. Provides information on status, progress, and needs of client; encourages team approach to client care.
7. Instruct all caregivers to respond promptly to call light. Ensures rapid response to client's needs.
8. Teach the client to use the call light; reinforce teaching each time before leaving the client alone. Ensures that client has means and knowledge to call for assistance if necessary.

EVALUATION

Fall prevention protocol implemented; client discharged on third day of hospitalization free from injury.

plastic tubing for cracks and loose connections, and telephone switch, which should be in the off position unless the client is using the phone. The hearing aid should be handled carefully since dropping or bumping it can damage its delicate mechanisms. When not in use, the hearing aid should be stored in a container because dust and dirt can damage the mechanism.

When communicating with a client who has a hearing aid, the nurse should address her or him by name and then wait for the client to face the nurse before speaking further. Always face the client and speak in a slow, natural voice. Shouting causes distortion of sound and usually makes the client feel uncomfortable.

Nose

The nose provides the sense of smell, prevents entrance of foreign material into the respiratory tract, humidifies inhaled air, and facilitates breathing. Excessive or dried secretions may impair nasal function. Excessive nasal secretions are removed by inserting a cotton-tipped applicator moistened with water or saline into the nostrils. The applicator should not be inserted beyond the cotton tip. Infants may have excessive nasal secretions removed by a suction bulb. Clients with a nasogastric tube should receive meticulous skin care to the nose area to prevent skin breakdown.

EVALUATION

Evaluation is based on the achievement of goals and client expected outcomes, regardless of the setting. Clients with alterations in the health perception–health management pattern or activity-exercise pattern are at risk for injury, infection, and self-care deficits. Keeping clients free from injury and infection requires frequent reassessment through the use of risk appraisals, with timely adjustments made in the plan of care in order for nursing interventions to be effective. When falls occur, every client warrants a postfall assessment to identify new risk factors and suggest new interventions to prevent the next fall (Ferris, 2008).

It is imperative that clients not only be free of injury during hospitalization but also develop a true awareness of

SAFETY FIRST

The use of restraints or other protective devices on confused clients usually increases clients' confusion, placing them at a greater risk for injury. Restraints should be used only when all other nursing measures are ineffective in providing client safety.

the internal and external factors that increase the risk for injury. Achievement of this outcome measure is directly related to the behaviors clients observe while in the hospital and through client teaching. Modification of a home to a safe environment is evidence for the home health nurse that learning has taken place.

Adherence to barrier precautions is critical in preventing the spread of infectious agents, especially HAIs, to clients, self, and other health care workers. The nurse needs to correlate the client's diagnostic laboratory results and temperature in evaluating the expected outcome of remaining free of signs and symptoms of infection. If the nurse is caring for a client with an infection, the evaluation should indicate the stage of the inflammatory process (see Table 29-1).

The therapeutic value of hygiene is maximized when the client can participate and is kept free from infection and alterations in skin integrity. Evaluation should identify the client's level of functioning in self-care activities.

At the time of discharge from the hospital, appropriate referrals should be made to home health care agencies to assist the client in achieving optimum functioning levels for safety and hygienic practices. Clients at risk for infection should have follow-up visits by the home health nurse to measure the effectiveness of client teaching and resources in the home to prevent the transmission of infections.

PROCEDURE
29-1

Applying Restraints

EQUIPMENT (See Figures 29–14, 29–15, and 26–16)

- Restraints appropriate to the client’s condition and type of restraint required
- Cotton batting or foam padding

FIGURE 29-14 Locking Belt Restraint DELMAR/CENGAGE LEARNING

FIGURE 29-15 Mitten Restraints DELMAR/CENGAGE LEARNING

FIGURE 29-16 Jacket Restraint DELMAR/CENGAGE LEARNING

ACTION

RATIONALE

CHEST RESTRAINT

1. Wash hands/hand hygiene.
2. Explain that the client will be wearing a jacket attached to the bed. Explain that this is for safety.
3. Place the restraint over the client’s hospital gown or clothing.
4. Place the restraint on the client with the opening in the front (see Figure 29-17 on page 696).
5. Overlap the front pieces, threading the ties through the slot/loop on the front of the vest.

1. Prevents the spread of microorganisms.
2. Promotes client cooperation.
3. Provides for client privacy and prevents the restraint from rubbing the client’s skin.
4. Allows movement but restricts freedom.
5. Secures the restraint.

(Continues)

PROCEDURE 29-1
Applying Restraints (Continued)

ACTION	RATIONALE
<p>6. If the client is in bed, secure the ties to the movable part of the mattress frame with a half-knot (see Figure 29-18).</p> <p>7. If the client is in a chair, cross the straps behind the seat of the chair and secure the straps to the chair's lower legs, out of the client's reach (see Figure 29-19). If it is a wheelchair, be sure the straps will not get caught up in the wheels.</p> <p>8. Step back and assess the client's overall safety. Be sure the restraint is loose enough not to be a hazard to the client but tight enough to restrict the client from getting up and harming himself or herself.</p> <p>9. Wash hands/hand hygiene.</p>	<p>6. Allows the restraint to move with the bed if the head of the bed is raised or lowered.</p> <p>7. Provides support for the client to sit up while restricting freedom.</p> <p>8. Looking at the overall picture can allow the nurse to see dangers that might have been missed.</p> <p>9. Prevents the spread of microorganisms.</p>

FIGURE 29-17 Place the jacket restraint on the client. Make sure the restraint is the proper size for the client and has been applied correctly. DELMAR/CENGAGE LEARNING

FIGURE 29-18 Secure ties to the movable part of the frame. DELMAR/CENGAGE LEARNING

FIGURE 29-19 Secure restraining straps out of the client's reach. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-1 Applying Restraints (Continued)

ACTION	RATIONALE
APPLYING WRIST OR ANKLE RESTRAINTS	
10. Wash hands/hand hygiene.	10. Prevents the spread of microorganisms.
11. Explain to the client that you will be placing a wrist or ankle band that will restrict movement.	11. Promotes client cooperation.
12. Place padding around the client's wrist/ankle.	12. Prevents the restraint from chafing the skin.
13. Wrap the restraint around the client's wrist/ankle, pull the tie through the loop in the restraint, and tie a square knot (see Figure 29-20).	13. Secures the restraint and prevents the restraint from overtightening at the wrist.
14. Tie the restraint ties to the movable portion of the mattress frame.	14. When the head or foot of the client's bed is moved, the restraint will move with it.
15. Slip two fingers under the restraint to check for tightness. Be sure the restraint is tight enough that the client cannot slip it off but loose enough that the neurovascular status of the client's extremity is not impaired.	15. If the restraint is too tight, the client's neurovascular status may be impaired, causing injury.
16. Step back and assess the client's overall safety. Be sure the restraint is loose enough not to be a hazard to the client but tight enough to restrict the client from getting up and harming himself or herself (see Figure 29-21 on page 698).	16. Looking at the overall picture can allow the nurse to see dangers that might have been missed.
17. Place the call light within the client's reach.	17. Allows the client to contact the nurse to have any needs met. Provides the client with an increased sense of safety.
18. Check on the client every half hour while restrained. Assess the safety of the restraint placement and the client's neurovascular status.	18. Assures that the client remains safe. Clients may try to escape from restraint and injure themselves in the attempt. States and institutions may have regulations outlining the frequency of client checks if the client is in restraints. Be aware of any regulations that apply.
19. Wash hands/hand hygiene.	19. Prevents the spread of microorganisms.

FIGURE 29-20 Wrap restraint around the client's wrist. DEL-
MAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-1 Applying Restraints (Continued)

FIGURE 29-21 Restraints should not be too tight or loose.
Check frequently. DELMAR/CENGAGE LEARNING

delegation tip

Delegation of the application of restraints to ancillary personnel is acceptable if appropriate orders are in place and proper training has occurred. The assessment of the need for and the type of restraints required and their proper application and maintenance requires the professional nurse's observation and documentation per facility policy.

nursing tips

- Know facility policies and state laws that govern the use of restraints. Determine whether treatment plan authorizes a client to be restrained or monitored in accordance with medical orders and regulations. Know the laws regarding specified person to prescribe restraints. Reassess according to regulations.
- Become familiar with restraint equipment: vest, limb, mitt, belt, body (Posey), and leather restraints.

(Continues)

PROCEDURE 29-1 Applying Restraints (Continued)

nursing tips

- *Be safe and efficient when applying restraints. Always have organized and available assistance when placing restraints on a client. A team effort can provide simultaneous client teaching by one health care professional while another applies the restraint.*
- *Ensure that client comfort is not compromised. Provide frequent checks. Assess need for padding bony prominences to avoid pressure ulcers. Provide assistance with nutrition, elimination, repositioning, and general care.*
- *Always keep the client and family well informed regarding the rationale for restraints and the associated care required.*
- *Continuously assess client need for restraints. Allow changes in condition to dictate withdrawing or maintaining restraints.*
- *Restraints must be sized properly and according to the client's body build and weight. If restraints are loose, and smaller ones are unavailable, use gauze pads or soft towels to build them up, and then tape securely.*
- *If leather restraints are used, have a key that fits the locks readily available.*
- *Pad bony prominences before applying protective devices.*
- *Attach the device to the movable bed frame, not the side rails.*
- *Check client's respiratory status if a chest device is used.*
- *Check position of chest device so it is not constricting the client's neck.*
- *Restrain client on side if risk of aspiration is assessed.*
- *Do not secure four restraints to one side of the bed.*
- *When applying two-point restraints, restrain one arm and the opposite leg.*
- *Never apply restraint above an IV site.*
- *Do not restrain a client in the prone position.*
- *Provide frequent repositioning, massage, and surveillance of bony prominences.*
- *Be sure to place the client's call light within reach.*

PROCEDURE 29-2

Handwashing: Visibly Soiled Hands

EQUIPMENT

- Soap
- Sink
- Paper or cloth towels
- Running water

ACTION

1. Remove jewelry. Wristwatch may be pushed up above the wrist (midforearm). Push sleeves of uniform or shirt up above the wrist at mid-forearm level.

RATIONALE

1. Provides access to skin surfaces for cleaning. Facilitates cleaning of fingers, hands, and forearms.

(Continues)

PROCEDURE 29-2 Handwashing: Visibly Soiled Hands (Continued)

ACTION	RATIONALE
2. Assess hands for hangnails, cuts, or breaks in the skin and areas that are heavily soiled.	2. Intact skin acts as a barrier to microorganisms. Breaks in skin integrity facilitate development of infection and should receive extra attention during cleaning.
3. Turn on the water. Adjust the flow and temperature. Temperature of the water should be warm.	3. Running water removes microorganisms. Warm water removes less of the natural skin oils.
4. Wet hands and lower forearms thoroughly by holding under running water. Keep hands and forearms in the down position with elbows straight. Avoid splashing water and touching the sides of the sink.	4. Water should flow from the least contaminated to the most contaminated areas of the skin. Hands are considered more contaminated than arms. Splashing of water facilitates transfer of microorganisms. Touching of any surface during cleaning contaminates the skin.
5. Apply about 5 mL (1 tsp) of liquid soap. Lather thoroughly.	5. Lather facilitates removal of microorganisms. Liquid soap harbors less bacteria than bar soap.
6. Vigorously rub hands together for about 10 to 15 seconds. Interlace fingers and thumbs, and move back and forth to wash between digits. Rub palms and back of hands with circular motion (see Figure 29-22). Special attention should be provided to areas such as the knuckles and fingernails, which are known to harbor organisms (see Figure 29-23).	6. Friction mechanically removes microorganisms from the skin's surface and loosens dirt from soiled areas.
7. Rinse with hands in the down position, elbows straight. Rinse in the direction of forearm to wrist to fingers.	7. Flow of water rinses away dirt and microorganisms.
8. Blot hands and forearms to dry thoroughly. Dry in the direction of fingers to wrist and forearms. Discard the paper towels in the proper receptacle.	8. Blotting reduces chapping of skin. Drying from cleanest (hand) to least clean area (forearms) prevents transfer of microorganisms to cleanest area.
9. Turn off the water faucet with a clean, dry paper towel (see Figure 29-24 on page 701).	9. Prevents contamination of clean hands by a less clean faucet.

FIGURE 29-22 Lather thoroughly, and rub hands together.

DELMAR/CENGAGE LEARNING

FIGURE 29-23 Give special attention to fingernails and knuckles.

DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-2 Handwashing: Visibly Soiled Hands (Continued)

FIGURE 29-24 Turn off faucet with a clean, dry paper towel. DELMAR/CENGAGE LEARNING

delegation tip

All hospital personnel are expected to maintain proper handwashing technique and routinely apply Standard Precautions.

nursing tips

- If in doubt, it is dirty.
- Wash hands before and after every client contact. The most common cause of HAIs is contaminated hands of health care providers.
- When you turn on the faucet of a sink with which you are unfamiliar (especially in the home care setting), you might get wet! Be a bit tentative the first time until you investigate the water pressure and the faucet.

PROCEDURE 29-3

Applying Sterile Gloves via the Open Method

EQUIPMENT (See Figure 29-25)

- Package of proper-size sterile gloves

FIGURE 29-25 Sterile Gloves DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-3 Applying Sterile Gloves via the Open Method (Continued)

ACTION	RATIONALE
1. Wash hands/hand hygiene. 2. Read the manufacturer's instructions on the package of sterile gloves; proceed as directed in removing the outer wrapper from the package (see Figure 29-26 on page 703), placing the inner wrapper onto a clean, dry surface (see Figure 29-27 on page 703). Open inner wrapper to expose gloves (see Figure 29-28 on page 703).	1. Prevents the spread of microorganisms. 2. Manufacturers package gloves differently; the instructions will indicate how to open properly to avoid contamination of the inner wrapper; any moisture on the surface will contaminate the gloves.
3. Identify right and left hand; glove dominant hand first.	3. Dominant hand should facilitate motor dexterity during gloving.
4. Grasp the 2-inch- (5-cm-) wide cuff with the thumb and first two fingers of the nondominant hand, touching only the inside of the cuff (see Figure 29-29 on page 703).	4. Maintains sterility of the outer surfaces of the sterile glove.
5. Gently pull the glove over the dominant hand, making sure the thumb and fingers fit into the proper spaces of the glove (see Figure 29-30 on page 703).	5. Prevents tearing the glove material; guiding the fingers into proper places facilitates gloving.
6. With the gloved, dominant hand, slip your fingers under the cuff of the other glove, gloved thumb abducted, making sure it does not touch any part on the nondominant hand (see Figure 29-31 on page 703).	6. Cuff protects gloved fingers, maintaining sterility.
7. Gently slip the glove onto your nondominant hand, making sure the fingers slip into the proper spaces (see Figures 29-32 and 29-33 on page 704).	7. Contact is made with two sterile gloves.
8. With gloved hands, interlock fingers to fit the gloves onto each finger. If the gloves are soiled, remove by turning inside out as described in the following steps.	8. Promotes proper fit over the fingers.
9. Slip gloved fingers of the dominant hand under the cuff of the opposite hand, or grasp the outer part of the glove at the wrist if there is no cuff.	9. Contact is made with two sterile gloves.
10. Pull the glove down to the fingers, exposing the thumb (see Figure 29-34 on page 704).	10. Frees the thumb for the next step.
11. Slip the uncovered thumb into the opposite glove at the wrist, allowing only the glove-covered fingers of the hand to touch the soiled glove (see Figure 29-35 on page 704).	11. Contact is made with two sterile gloves.
12. Pull the glove down over the dominant hand almost to the fingertips, and slip the glove onto the other hand (see Figure 29-36 on page 704).	12. Removes glove without contact with soiled surfaces.
13. With the dominant hand touching only the inside of the other glove, pull the glove over the dominant hand so that only the inside (clean surface) is exposed.	13. Exposes only the clean surface of the gloves.
14. Dispose of soiled gloves according to institutional policy (see Figure 29-37 on page 704).	14. Prevents the transfer of microorganisms.
15. Wash hands/hand hygiene.	15. Prevents the spread of microorganisms.

(Continues)

(Continues)

PROCEDURE 29-3
Applying Sterile Gloves via the Open Method (Continued)

delegation tip

Sterile gloving is delegated only if personnel are specifically trained, such as in a surgical suite or a testing laboratory setting.

nursing tips

- Touch only dirty to dirty, clean to clean, and sterile to sterile.
- Be aware of the immediate environment when applying sterile gloves to avoid accidental contamination.
- Be sure to have everything you need ready before donning sterile gloves.

PROCEDURE
29-4

Donning and Removing Clean and Contaminated Gloves, Cap, and Mask

EQUIPMENT

- Gloves, clean—sterile, if necessary
- Gown, sterile or clean
- Cap
- Mask

ACTION

RATIONALE

<ol style="list-style-type: none"> 1. Wash hands/hand hygiene. Gather equipment (see Figure 29-38 A–D on page 706). 2. The first item of apparel donned should be the cap or surgical hat/hood. Hair should be tucked in a manner so that all hair is covered (see Figure 29-39 on page 706). 3. Apply a mask around mouth and nose, and secure in a manner that prevents venting. For masks with strings (see Figure 29-40 on page 706): <ol style="list-style-type: none"> a. Hold mask by top, and pinch center (metal strip) over bridge of nose. b. Pull top two strings over ears, and secure at top, back of head. c. Tie two lower ties around back or nape of neck so bottom of mask fits snugly under chin (see Figure 29-41 on page 707). 4. Open gown, slip arms into sleeves, and secure at neck and side (see Figure 29-42 A and B on page 708). 	<ol style="list-style-type: none"> 1. Prevents the spread of microorganisms. 2. “Hair acts as a filter when left uncovered and collects bacteria in proportion to its length, curliness, and oiliness. Strands of hair may fall in the surgical area. Shedding from hair has been shown to lead to surgical wound infection” (Association of periOperative Registered Nurses [AORN], 2004). 3. Masks are worn to contain and filter droplets of microorganisms that are expelled when talking, sneezing, or coughing. Masks prevent the transmission of oral and nasopharyngeal organisms between the nurse and client. 4. Gowns act as a protective barrier and should be worn to reduce exposure to blood, body fluid, or other potentially infectious liquids.

PROCEDURE 29-4
Donning and Removing Clean and Contaminated Gloves, Cap, and Mask (Continued)

A.

C.

B.

D.

FIGURE 29-38 A. Masks; B. Caps; C. Clean Gloves; D. Sterile Gloves. DELMAR/CENGAGE LEARNING

ACTION

RATIONALE

5. Protective eyewear should be worn whenever the health care provider or client is at risk for splash and contamination. Eyewear is applied as goggles/glasses or face shields, which have elastic ties for around the ears.

5. Protective eyewear reduces the incidence of contamination to the eyes. If eyewear or face shields become contaminated, they should be discarded immediately and replaced with a clean barrier.

FIGURE 29-39 Caps and surgical caps should cover the head, and hair should be tucked in. DELMAR/CENGAGE LEARNING

FIGURE 29-40 Secure mask around mouth and nose. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-4 Donning and Removing Clean and Contaminated Gloves, Cap, and Mask (Continued)

FIGURE 29-41 Bottom of the mask should fit snugly under chin. DELMAR/CENGAGE LEARNING

ACTION	RATIONALE
<p>6. Don clean gloves. If sterile gloves are required for a procedure, use the open or closed method.</p>	<p>6. Gloves are worn to prevent gross contamination of the hands. They should be changed between clients, and hands should be washed. The open method is used when performing procedures that require sterile technique but do not require donning a sterile gown, or when both gloves need to be changed without assistance during a surgical procedure. The closed method is used by scrubbed personnel in the operating room (see Procedure 29-6).</p>
<p>7. The open glove technique:</p> <ol style="list-style-type: none"> Slide the hands into the gown all the way through the cuffs on the gown. Pick up the cuff of the left glove using the thumb and index finger of the right hand. Pull the glove onto the left hand, leaving the cuff of the glove turned down. Take the gloved left hand and slide the fingers inside the cuff of the right glove, keeping the gloved fingers under the folded cuff. Pull the glove onto the right hand. Rotate the arm as the cuff of the glove is pulled over the gown. 	<p>7. The open glove method is commonly used for sterile procedures or when both gloves need to be changed without assistance during a surgical procedure.</p>
<p>8. The closed glove technique:</p> <ol style="list-style-type: none"> Slide the hands into the gown all the way through the cuffs on the gown. Use right hand to pick up left glove. Place the glove on the upward-turned left hand—palm side down thumb to thumb with the fingers extending along the forearm and pointing toward the elbow. Hold the glove cuff and sleeve cuff together with the thumb of the left hand. 	<p>8. The closed glove technique is used by the scrubbed personnel in the operating room. This is preferred, as the possibility of the glove touching the skin is eliminated.</p>

Minimizes anxiety and feelings of isolation. |
| <ul style="list-style-type: none"> 9. Enter the client's room, and explain the rationale for wearing isolation attire. | <ul style="list-style-type: none"> 10. Reduces transmission of organisms. |
| <ul style="list-style-type: none"> 10. After performing necessary tasks, remove gown, gloves, mask, and cap before leaving the room. | <ul style="list-style-type: none"> 11. Reduces transmission of organisms. |
| <ul style="list-style-type: none"> 11. Removal of gown: Untie gown and remove from shoulders. Fold and roll gown down in front into a ball so contaminated area is rolled onto center of gown. Dispose in approved receptacle. | <ul style="list-style-type: none"> 12. a. Reduces risk of contamination. b. Reduces risk of contamination. |
| <ul style="list-style-type: none"> 12. Removal of gloves: <ul style="list-style-type: none"> a. Grasp outside cuff of one glove and pull off, turning inside out. Hold it with the remaining gloved hand (see Figure 29-43 on page 709). b. Pull the second glove off without touching the outside of the second glove. Turn the second glove as it is removed (see Figure 29-44 on page 709). Dispose into receptacle with first glove. | <ul style="list-style-type: none"> 13. Prevents contaminated surface of mask from contacting uniform. |
| <ul style="list-style-type: none"> 13. Removal of mask: Untie bottom strings of mask first, then top strings, and lift off face. Hold mask by strings and discard. | <ul style="list-style-type: none"> 14. Minimizes contact of hands to hair. |
| <ul style="list-style-type: none"> 14. Removal of cap: Grasp top surface of cap and lift from head. | <ul style="list-style-type: none"> 15. Prevents the spread of microorganisms. |
| <ul style="list-style-type: none"> 15. Wash hands/hand hygiene. | |

(Continues)

PROCEDURE 29-4 Donning and Removing Clean and Contaminated Gloves, Cap, and Mask (Continued)

FIGURE 29-43 Grasp the outside cuff, and turn the glove inside out. DELMAR/CENGAGE LEARNING

FIGURE 29-44 Turn the second glove over the first glove. DELMAR/CENGAGE LEARNING

delegation tip

Donning and removing gloves, caps, and masks is a skill that is required of all personnel, including ancillary personnel. Proper technique should be monitored by the nursing staff.

nursing tips

- Post signs on the doors of clients who require specific barrier methods using words and/or pictures that are clear and understandable.
- Review isolation procedures regularly.
- Provide a supply of the appropriate barrier at the doorway of the client's room.
- If you need equipment such as an item you are carrying in your pocket, you will not be able to reach your pocket after you don your gown. You will not be able to touch needed items if your gloves and gown are contaminated. Think ahead. Plan.
- Remember, masks become ineffective if worn too long, become wet, or are not changed between clients.
- Remember that anything you touch with a contaminated glove will be contaminated. Think: Sterile can touch sterile; clean can touch clean.

PROCEDURE
29-5
Surgical Hand Antisepsis
EQUIPMENT

- Surgical scrub items (antimicrobial soap, two brushes, and nail file)
- Surgical shoe covers (booties) and cap, face mask, sterile gown, and proper-size gloves
- Sterile towel

ACTION
RATIONALE

- | | |
|--|---|
| <ol style="list-style-type: none"> 1. Rings, watches, and bracelets should be removed prior to beginning the surgical scrub. | <ol style="list-style-type: none"> 1. Decreases resident and transient microorganisms. The Association of periOperative Registered Nurses recommends washing and rinsing moistened hands and forearms with an approved surgical scrub agent before beginning the surgical scrub procedure. |
| <ol style="list-style-type: none"> 2. Use a deep sink with side or foot pedal to dispense antimicrobial soap and control water temperature and flow. | <ol style="list-style-type: none"> 2. Prevents hands and forearms from touching a soiled surface. |
| <ol style="list-style-type: none"> 3. Have two surgical scrub brushes and nail file (see Figure 29-45). | <ol style="list-style-type: none"> 3. Enhances mechanical friction during the scrub. |
| <ol style="list-style-type: none"> 4. Apply surgical shoe covers and cap to cover hair and ears completely. | <ol style="list-style-type: none"> 4. Prevents introduction of contaminants into environment. |
| <ol style="list-style-type: none"> 5. Apply mask (see Figure 29-46). | <ol style="list-style-type: none"> 5. Provides a respiratory barrier. |
| <ol style="list-style-type: none"> 6. Before beginning the surgical scrub: <ol style="list-style-type: none"> a. Open the sterile package containing the gown; using aseptic technique, make a sterile field with the inside of the gown's wrapper. b. Open the sterile towel, and drop it onto the center of field. c. Open the outer wrapper from the sterile gloves, and drop the inner package of gloves onto the sterile field beside the folded gown and towel. | <ol style="list-style-type: none"> 6. Preparing the sterile items prior to the scrub decreases the risk of contaminating scrubbed hands. |
| <ol style="list-style-type: none"> 7. At a deep sink with foot or knee controls (see Figure 29-47 on page 711), turn on warm water; under flowing water, wet hands, beginning at tips of fingers, to forearms—keeping hands at level above elbows. Prewash hands and forearms to 2 inches above the elbow. | <ol style="list-style-type: none"> 7. Water should flow from the hands to the elbow to promote elimination of contaminants from the hands. |

FIGURE 29-45 Surgical Scrub Items. DELMAR/CENGAGE LEARNING

FIGURE 29-46 Apply cap and mask. DELMAR/CENGAGE LEARNING

PROCEDURE 29-5 Surgical Hand Antisepsis (Continued)

ACTION	RATIONALE
8. Apply a liberal amount of soap onto hands, and rub hands and arms to 2 inches above elbows (see Figures 29-48 on page 711 and 29-49 on page 711).	8. Reduces number of microorganisms on hands.
9. Using nail file under running water, clean under each nail of both hands, and drop file into sink when finished (see Figure 29-50 on page 711).	9. Removes dirt that harbors microorganisms.
10. Wet and apply soap to scrub brush, if needed. Open prepackaged scrub brush if available (see Figure 29-51 on page 712). With brush in dominant hand, using a circular motion, scrub nails and all skin areas of nondominant hand and arm (10 strokes to each of the following areas): a. Nails b. Palm of hand and anterior side of fingers	10. Removes resident bacteria from the skin's surface; the circular motion mechanically removes microorganisms. Scrubbing the nondominant hand first sets a routine you can remember if you should get interrupted during the scrub.
11. Rinse brush thoroughly, and reapply soap.	11. Decreases transfer of microorganisms.
12. Continue with scrub of nondominant arm with a circular motion for 10 strokes each to the lower, middle, and upper arm; drop brush into the sink.	12. Decreases transfer of microorganisms from the arm; dropping the brush avoids contamination.

FIGURE 29-47 Handwashing Sink with Knee Controls. DELMAR/CENGAGE LEARNING

FIGURE 29-48 Apply a liberal amount of soap. DELMAR/CENGAGE LEARNING

FIGURE 29-49 Scrub hands and arms. DELMAR/CENGAGE LEARNING

FIGURE 29-50 Use a nail file under running water to clean fingernails. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-5 Surgical Hand Antisepsis (Continued)

ACTION	RATIONALE
13. Maintaining the hands and arms above elbow level, place the fingertips under running water, and thoroughly rinse the fingers, hands, and arms (allow the water to run off elbows into the sink); take care not to get uniform wet (see Figure 29-52).	13. Allows flow of water to cleanse from the area of least contamination to the area of most contamination. Water conducts microorganisms, and keeping uniform dry aids in maintaining sterility of gown.
14. Take the second scrub brush and repeat Actions 10–13 on dominant hand and arm.	14. See Rationales 10–13.
15. Keep arms flexed and proceed to area (operating or procedure room) with sterile items (see Figure 29-53).	15. Prevents water from flowing from least (elbows) to most (hands) clean area.
16. Secure sterile towel by grasping it on one edge, opening the towel, full length, making sure it does not touch uniform.	16. Maintains the sterility of the towel.
17. Dry each hand and arm separately; extend one side of the towel around fingers and hand, and dry in a rotating motion up to the elbow (see Figure 29-54 and Figure 29-55 on page 713).	17. Prevents contamination by drying from cleanest to least clean area.
18. Reverse the towel and repeat the same action on the other hand and arm, thoroughly drying the skin.	18. Prevents contamination of the gown.
19. Discard the towel into a linen hamper.	19. Keeps the environment clean.

FIGURE 29-51 Prepackaged Scrub Brush. DELMAR/CENGAGE LEARNING

FIGURE 29-52 Thoroughly rinse fingers, hands, and arms. DELMAR/CENGAGE LEARNING

FIGURE 29-53 Keep arms flexed, and proceed to area. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-5 Surgical Hand Antisepsis (Continued)

FIGURE 29-55 Dry arms up to the elbows. DELMAR/CENGAGE LEARNING

delegation tip

Surgical scrubbing is delegated only if the personnel are specifically trained, such as in a surgical suite or a testing laboratory.

nursing tips

- Be sure to keep hands and forearms above elbow level.
- Avoid products with iodine if an allergy is present.
- Make sure you are not splashed by another person washing his or her hands.

PROCEDURE 29-6

Applying Sterile Gloves and Gown via the Closed Method

EQUIPMENT

- Sterile gown
- Sterile and proper-size gloves

ACTION

RATIONALE

GOWNING

1. Wash hands/hand hygiene.
2. The sterile gown is folded inside out.
3. Grasp the gown inside the neckline, step back, and allow the gown to open in front of you; keep the inside of the gown toward you; do not allow it to touch anything (see Figure 29-56 on page 714).

1. Prevents the spread of microorganisms.
2. Allows ungloved hands to touch only the inside.
3. Keeps the outside of the gown sterile.

(Continues)

PROCEDURE 29-6 Applying Sterile Gloves and Gown via the Closed Method (Continued)

ACTION

4. With hands at shoulder level, slip both arms into the gown; keep your hands inside the sleeves of the gown (see Figure 29-57).
5. The circulating nurse will step up behind you and grasp the inside of the gown, bring it over your shoulders, and secure the ties at the neck and waist.

FIGURE 29-56 Allow the gown to fall open. DELMAR/CENGAGE LEARNING

RATIONALE

4. Prevents the gown from touching nonsterile objects; allows sterile items to come into contact only with other sterile items.
5. Prevents any part of the gown from touching a nonsterile object; provides complete coverage of undergarments.

FIGURE 29-57 Slip both arms into the gown. DELMAR/CENGAGE LEARNING

CLOSED GLOVING

6. With hands still inside the gown sleeves, open the inner wrapper of the gloves on the sterile gown field (see Figure 29-58 on page 715).
7. With nondominant sleeved hand, grasp the cuff of the glove for the dominant hand and lay it on the extended dominant forearm (see Figure 29-59 on page 715); with palm up, place the palm of the glove against the sleeved palm, with fingers of the glove pointing toward elbow (see Figure 29-60 on page 715).
8. Manipulate the glove so the sleeved thumb of dominant hand is grasping the cuff; with nondominant hand, turn the cuff over the end of dominant hand and gown's cuff.
9. With sleeved nondominant hand, grasp the cuff of the glove and the gown's sleeve of the dominant hand; slowly extend the fingers into the glove, making sure the cuff of the glove remains above the cuff of the gown's sleeve (see Figure 29-61 on page 715).
10. With the gloved dominant hand, repeat Actions 8 and 9 (see Figures 29-62 and 29-63 on page 716).
11. Interlock gloved fingers; secure fit.
12. Wash hands/hand hygiene.

6. Maintains sterility of the gloves.
7. Only sterile items come into contact with each other.
8. Prevents the hands from contaminating the sterile glove.
9. Provides a closed sterile method for gloving; the glove cuff over the gown prevents contamination of the operative field with microorganisms.
10. Only sterile items can touch each other.
11. Promotes dexterity of gloved hands.
12. Prevents the spread of microorganisms.

(Continues)

PROCEDURE 29-6 Applying Sterile Gloves and Gown via the Closed Method (Continued)

(Continues)

PROCEDURE 29-6 Applying Sterile Gloves and Gown via the Closed Method (Continued)

FIGURE 29-62 Place the second glove on the gown. DELMAR/
CENGAGE LEARNING

FIGURE 29-63 Extend the fingers into the second glove. DELMAR/CENGAGE LEARNING

delegation tip

Sterile gloving and gowning is delegated only if the personnel are specifically trained, such as in a surgical suite or a testing laboratory setting.

nursing tips

- *Touch only sterile to sterile.*
- *Do not lean against the scrub sink.*
- *Be careful not to get scrub uniform wet. This will contaminate the sterile gown.*

PROCEDURE 29-7

Removing Contaminated Items

EQUIPMENT

- Disposable gloves
- Labeled bag for disposal of soiled linens; bag should be hot-water soluble; bag may also be colored (red) for easy identification. (Note: Some agencies may require linens to be double bagged for removal.)
- Self-supporting stand for linen bag
- Second linen bag if double-bagging technique used

(Continues)

PROCEDURE 29-7 Removing Contaminated Items (Continued)

ACTION	RATIONALE
REMOVAL OF SOILED LINEN	
<ol style="list-style-type: none"> 1. Wash hands/hand hygiene when entering the client's room or use an alcohol-based hand rub. 2. Wear disposable gloves; wear other protective items (gowns, goggles) as determined by the situation and agency's policies. 3. Place labeled linen bag in stand (see Figure 29-64). 	<ol style="list-style-type: none"> 1. Prevents the spread of microorganisms. 2. Protects the nurse from contamination from blood and body fluids. 3. Proper labeling or identification of the linen bag ensures proper handling by other agency personnel. Check agency policy for issues of confidentiality with regard to labeling.
<ol style="list-style-type: none"> 4. Gather linens and separate from disposable items. 5. Do not allow any linens to touch the floor. 	<ol style="list-style-type: none"> 4. Prevents waste from being placed in linen bag. 5. The floor is always considered a contaminated area.
<ol style="list-style-type: none"> 6. Place soiled linens in the linen bag; keep clean linens in a different area (see Figure 29-65). 7. Take care not to shake the linens when removing items from the bed or bathroom. 	<ol style="list-style-type: none"> 6. It is important to prevent cross-contamination to clean supplies and linen. 7. Minimizing movement of the linens through the air helps reduce the risk of transmission of microorganisms.
<ol style="list-style-type: none"> 8. Do not allow the soiled linens to come into contact with clothing. Carry linens with arms extended outward. 	<ol style="list-style-type: none"> 8. Prevents contamination of the nurse and cross-contamination to other clients.
<ol style="list-style-type: none"> 9. Do not overfill the bag. 10. Tie ends of the bag securely. 11. Check for any punctures or tears in the bag. 	<ol style="list-style-type: none"> 9. Ensures proper closure of bag. 10. Prevents linens from spilling out of the bag. 11. The linen bag must be intact to prevent transmission of microorganisms.
<ol style="list-style-type: none"> 12. Double bag items if there is concern that the outside of the bag is contaminated or torn. 	<ol style="list-style-type: none"> 12. This is necessary to prevent cross-contamination and transmission of microorganisms to other personnel or other areas.
<ol style="list-style-type: none"> 13. Wash hands/hand hygiene. 	<ol style="list-style-type: none"> 13. Prevents the spread of microorganisms.

FIGURE 29-64 Biohazard bags and gloves are used to handle and dispose of contaminated items. DELMAR/CENGAGE LEARNING

FIGURE 29-65 Place soiled linen in a bag. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-7 Removing Contaminated Items (Continued)

ACTION	RATIONALE
DOUBLE-BAGGING TECHNIQUE	
14. With double bagging of linens, follow Actions 1–11. Then place the first bag into a second bag. Either a second nurse holds the second bag, or it is in a stand immediately outside of the room.	14. Some agencies require double bagging of linens to reduce the possibility of transmission of microorganisms. In most situations, it is not necessary unless the single bag is not sturdy enough to hold the items or if the outside of the single bag has become contaminated.
15. The second bag is properly labeled and secured.	15. Proper labeling or identification of the linen bag ensures proper handling by other agency personnel. Most agencies will have bags marked <i>biohazardous</i> .
16. The linens are then ready for the laundry.	16. Linens should be disposed of as soon as possible per agency policy.
17. Wash hands/hand hygiene.	17. Prevents the spread of microorganisms.
REMOVAL OF OTHER CONTAMINATED ITEMS	
18. Removal and bagging of trash bag follow the same procedure as for linens (see Figure 29-66 on page 719).	18. Check agency policy to determine whether double bagging is required.
19. Sharps containers need to be removed when three-quarters full or if the outside of the container becomes contaminated. Lock down the lid if available, and follow hospital policy for removal (see Figure 29-67 on page 719). Never reach into a container with your hand.	19. Overfilling a sharps container can lead to injuries to staff members.
20. Perform hand rub.	20. Proper hand hygiene reduces transmission of microorganisms.
21. Use disposable equipment when able (see Figure 29-68 on page 719).	21. Reduces the possibility of transmission of microorganisms.
22. Properly bag, label, and remove any nondisposable equipment that will require special cleaning (disinfection and sterilization).	22. Proper handling and labeling of items will ensure proper handling by other agency personnel.
23. Disassemble special procedure trays into disposable and nondisposable parts. Send nondisposable items (after proper bagging) to central services for decontamination.	23. Some agencies require that items that can be sterilized by autoclave (glass, metal) be separated from rubber and plastic items.
24. Laboratory specimens should be placed in a leakproof container and require no other precautions. Check to see that containers are not visibly contaminated on the outside (see Figure 29-69 on page 719).	24. Personnel handling laboratory specimens must utilize Standard Precautions.
25. Wash hands/hand hygiene.	25. Prevents the spread of microorganisms.

(Continues)

PROCEDURE 29-7 Removing Contaminated Items (Continued)

FIGURE 29-66 Bag all trash prior to removal. DELMAR/CENGAGE LEARNING

FIGURE 29-67 Remove and replace full sharps containers to avoid needlestick injuries from pushing sharp items into a full container. DELMAR/CENGAGE LEARNING

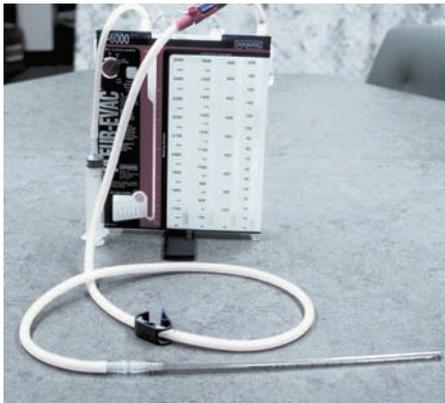

FIGURE 29-68 Using disposable equipment reduces contamination risks. DELMAR/CENGAGE LEARNING

FIGURE 29-69 Place specimens in leakproof containers to avoid contamination. DELMAR/CENGAGE LEARNING

delegation tip

Infection control measures are used for all clients. Careful handling of all contaminated items from the client's environment is the responsibility of all personnel involved in the client's care. The registered nurse may delegate these activities but is responsible for adhering to Standard Precautions.

nursing tips

- Check supplies (bags, labels) before beginning bagging of items for removal.
- Always wash hands before and after entering a room and bagging soiled items, even when wearing gloves.
- Use disposable equipment and supplies when possible.
- Do not take items such as a stethoscope into another client's room for use without proper cleaning when there is risk of transmission of infection.
- Review your agency's policies for specific guidelines. Some institutions may require double bagging for some items.
- Recheck labels and restock special bags as needed so that supplies are readily available for other caregivers and personnel.

PROCEDURE 29-8

Bathing a Client in Bed

EQUIPMENT

- Bath towels
- Washcloths
- Bath blanket
- Washbasin
- Soap
- Soap dish
- Lotion
- Deodorant
- Clean gown
- Clean linens
- Disposable, latex-free gloves

ACTION

RATIONALE

- | | |
|--|--|
| <ol style="list-style-type: none"> 1. Assess the client's preferences about bathing. 2. Explain procedure to client. Gather supplies (see Figure 29-70). 3. Prepare environment. Close doors and windows, adjust temperature, provide time for elimination needs, and provide privacy (see Figure 29-71). 4. Wash hands/hand hygiene. Apply gloves. Gloves should be changed when emptying water basin. 5. Lower side rail on the side close to you. Position client in a comfortable position close to the side near you. 6. If bath blankets are available, place over top sheet. Remove top sheet from under bath blanket. Remove client's gown. Bath blanket should be folded to expose only the area being cleaned at that time. (Top sheets or towels may also be used for bath blankets.) 7. Fill washbasin two-thirds full. Permit client to test temperature of water with hand. Water should be changed when a soap film develops or water becomes soiled. 8. Wet the washcloth and wring it out (see Figure 29-72 on page 721). | <ol style="list-style-type: none"> 1. Provides client with the opportunity to participate in care. 2. Enhances cooperation. 3. Protects from chills during bath and increases sense of privacy. 4. Prevents the spread of microorganisms. 5. Prevents unnecessary reaching. Facilitates use of good body mechanics. 6. Prevents exposure of client. Promotes privacy. Protects from chills. 7. Prevents accidental burns or chills. 8. Prevents unnecessary wetting of the client. |
|--|--|

FIGURE 29-70 Emesis and bath basins, soap, towels, and lotion are used to bathe the client. A razor and shaving cream are used to groom the male client. DELMAR/CENGAGE LEARNING

FIGURE 29-71 Close doors and/or curtains, and provide privacy prior to beginning the bath. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-8 Bathing a Client in Bed (Continued)

ACTION	RATIONALE
<p>9. Make a bath mitten with the washcloth. To make a mitten, grasp the edge of the washcloth with the thumb; fold a third over the palm of the hand; wrap remainder of cloth around hand and across palm, and grasp the second edge under the thumb; and fold the extended end of the washcloth onto the palm, and tuck under the palmar surface of the cloth.</p> <p>10. Wash the face (see Figure 29-73). Ask about the client's preference for using soap on the face. Use a separate corner of the washcloth for each eye, wiping from inner to outer canthus. Wash neck and ears. Rinse and pat dry. Male clients may want to shave at this time. Provide assistance with shaving as needed.</p> <p>11. Wash arms, forearms, and hands (see Figure 29-74). Wash forearms and arms using long, firm strokes in the direction of distal to proximal (see Figure 29-75 on page 722). Arm may need to be supported while being washed. Wash axilla. Rinse and pat dry. Apply deodorant</p>	<p>9. Prevents ends of washcloth from dragging across skin. Promotes friction during bath.</p> <p>10. Some clients may not use soap on the face. Using separate corners of the washcloth reduces the risk of transmitting microorganisms. Patting dry reduces skin irritation and drying.</p> <p>11. Long strokes promote circulation. Soaking hands softens nails and loosens soil from skin and nails. Strokes directed distal to proximal promote venous return.</p>

FIGURE 29-72 Wet the washcloth and wring out the excess water. The nurse is wearing a mask and gown because the client is in isolation. DELMAR/CENGAGE LEARNING

FIGURE 29-73 Wash the client's face first. DELMAR/CENGAGE LEARNING

FIGURE 29-74 Wash the hands and arms next. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-8 Bathing a Client in Bed (Continued)

ACTION	RATIONALE
<p>or powder if desired. Immerse client's hand into basin of water. Allow hand to soak about 3 to 5 minutes. Wash hands, interdigit area, fingers, and fingernails. Rinse and pat dry.</p>	
<p>12. Wash chest and abdomen. Fold bath blanket down to umbilicus. Wash chest using long, firm strokes. Wash skin fold under the female client's breast by lifting each breast. Rinse and pat dry. Fold bath blanket down to suprapubic area. Use another towel to cover chest area. Wash abdomen using long, firm strokes. Rinse and pat dry. Replace bath blanket over chest and abdomen. Cover chest or abdomen area in between washing, rinsing, and drying to prevent chilling.</p>	<p>12. Promotes privacy and prevents chills. Long strokes promote circulation. Perspiration and soil collect within skin folds.</p>
<p>13. Wash legs and feet. Expose leg farthest from you by folding bath blanket to midline. Bend the leg at the knee. Grasp the heel, elevate the leg from the bed, and cover bed with bath towel. Place washbasin on towel. Place client's foot into washbasin (see Figure 29-76). Allow foot to soak while washing the leg with long, firm strokes in the direction of distal to proximal. Rinse and pat dry. Clean soles, interdigits, and toes. Rinse and pat dry. Perform same procedure with the other leg and foot.</p>	<p>13. Supports joints to prevent strain and fatigue. Soaking foot loosens dirt, softens nails, and promotes comfort.</p>

FIGURE 29-75 (A–C) Wash from distal to proximal—from hands to forearms to upper arms. DELMAR/CENGAGE LEARNING

FIGURE 29-76 Place feet in basin. Clean interdigits and soles of feet. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-8 Bathing a Client in Bed (Continued)

ACTION	RATIONALE
14. Wash back. Assist client into prone or side-lying position facing away from you. Wash the back and buttocks using long, firm strokes. Rinse and pat dry. Give back rub and apply lotion.	14. Exposes back and buttocks for washing. Back rub promotes relaxation and circulation.
15. Perineal care: Assist client to supine position. Perform perineal care (see Figures 29-77 and 29-78).	15. Removes genital secretions and soil.
16. Apply lotion as desired or needed. Apply clean gown.	16. Lotion lubricates skin. Powder absorbs excess perspiration.
17. Document skin assessment, type of bath given, and client outcomes and responses.	17. Provides evidence of nursing care.
18. Wash hands/hand hygiene.	18. Prevents the spread of microorganisms.

FIGURE 29-77 Clean the female perineal area. DELMAR/CENGAGE LEARNING

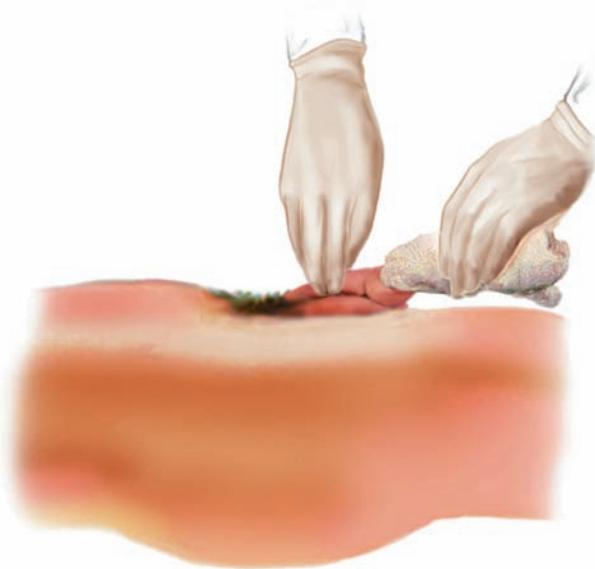

FIGURE 29-78 Clean the male perineal area. DELMAR/CENGAGE LEARNING

delegation tip

This skill is routinely delegated to ancillary personnel, who should allow the client to perform as much of the bath as possible or permitted. The caregiver employs Standard Precautions, properly positions the client, and observes and reports the client's skin condition and color to the nurse. The nurse retains the responsibility to assess the client.

nursing tips

- Be sure to thoroughly rinse soap off the client. Soap can cause drying and chafing.
- Be sure to thoroughly dry the client, especially skin folds and areas that rub together often. Leaving water in these areas can cause cracking and irritation.
- Use this time to assess the client's skin integrity. Are there any rashes or open or reddened areas?
- Encourage clients to assist in the bath as much as they are able. Self-care for basic needs is a way to maintain a sense of self-control and self-esteem during illness.

PROCEDURE
29-9
Changing Linens in an Unoccupied Bed
EQUIPMENT

- Bottom sheet (fitted, if available)
- Top sheet
- Mattress pad
- Pillowcase (each pillow on the bed)
- Drawsheet (regular top sheet may be used)

ACTION
RATIONALE

- | | |
|--|--|
| <ol style="list-style-type: none"> 1. Wash hands/hand hygiene. 2. Place hamper by client's door if linen bags are not available (see Figure 29-79 on page 725). Explain procedure to client. Assess condition of blanket and/or bedspread. 3. Gather linens and gloves. Place linens on a clean, dry surface in reverse order of usage at the client's bedside (pillowcases, top sheet, drawsheet, bottom sheet). 4. Apply gloves. 5. Inquire about the client's toileting needs and attend as necessary. 6. Assist client to a safe, comfortable chair. 7. Position bed: flat, side rails down, and height adjusted to waist level. 8. Remove and fold blanket and/or bedspread. If clean and reusable, place on clean work area. 9. Remove soiled pillowcases by grasping the closed end with one hand and slipping the pillow out with the other. Place the soiled cases on top of the soiled sheet, and place the pillows on clean work area. 10. Remove soiled linens: Start on the side of the bed closest to you; free the bottom sheet and mattress pad by lifting the mattress and rolling soiled linens to the middle of the bed. Go to the other side of the bed. Repeat action. 11. Fold (do not fan or flap) soiled linens: head of bed to middle, foot of bed to middle. Place in linen bag or hamper, keeping soiled linens away from uniform. 12. Check mattress. If mattress is soiled, clean it with an anti-septic solution and dry it thoroughly. 13. Remove gloves, wash hands, and apply a second pair of clean gloves (when appropriate). 14. Open the clean mattress pad lengthwise onto the bed with the seamed side of the sheet toward the mattress. Unfold half of the pad's width to the center crease, and smooth the pad flat. If there are elastic bands to hold the pad in place, slide them under the corners of the mattress. 15. Proceed with placing the bottom sheet onto the mattress. Linens differ from facility to facility. Bottom sheets may be fitted or they may be flat. Proceed to the appropriate action for the linens available. | <ol style="list-style-type: none"> 1. Prevents the spread of microorganisms. 2. Provides for proper disposal of soiled linens. Encourages client cooperation. Allows for organization of supplies. 3. Provides easy access to items. 4. Reduces risk of infection from soiled, contaminated linens. 5. Provides for client comfort and prevents interruptions during bed making. 6. Increases client's comfort and decreases risk of falls. 7. Promotes good body mechanics and decreases back strain. 8. Keeps reusable bed linens clean. 9. Allows easy removal of the pillowcases without contamination of uniform by soiled linens and keeps pillows clean. 10. Prevents tearing and fanning of linens. Linens are folded from cleanest to most soiled area to prevent contamination. 11. Fanning or flapping linens increases the number of microorganisms in the air. Folding linens reduces the risk of transmission of infection to others. 12. Reduces the transmission of microorganisms. 13. Reduces the transmission of microorganisms to clean linens. 14. Facilitates making bed in an organized, time-saving manner by not having to go from one side of the bed to the other. 15. Use linens available at the facility. |
|--|--|

(Continues)

PROCEDURE 29-9 Changing Linens in an Unoccupied Bed (Continued)

FIGURE 29-79 Clean linens and a laundry hamper for used linens are brought to the bedside to make the unoccupied bed. Gloves help reduce the transmission of microorganisms. DELMAR/CENGAGE LEARNING

FITTED BOTTOM SHEET

- | | |
|---|---|
| <p>16. Position yourself diagonally toward the head of the bed.</p> <p>17. Start at the head with seamed side of the fitted sheet toward the mattress.</p> <p>18. Lift the mattress corner with your hand closest to the bed; with your other hand, pull and tuck the fitted sheet over the mattress corner; secure at the head of the bed.</p> <p>19. Pull and tuck the fitted sheet over the mattress corners at the foot of the bed.</p> | <p>16. Ensures good body mechanics and efficient procedure.</p> <p>17. Placement of seamed side toward mattress prevents irritation of the client's skin.</p> <p>18. Prevents straining of back muscles; decreases the chance that the sheet will pull out from under the mattress.</p> <p>19. Prevents straining of back muscles; decreases the chance that the sheet will pull out from under the mattress.</p> |
|---|---|

FLAT REGULAR SHEET

- | | |
|--|---|
| <p>20. Unfold the bottom sheet with the seamed side toward the mattress. Align the bottom edge of the sheet with the edge of the mattress at the foot of the bed.</p> <p>21. Allow the sheet to hang 10 inches (25 cm) over the mattress on the side and at the top of the bed.</p> <p>22. Position yourself diagonally toward the head of the bed. Lift the top of the mattress corner with the hand closest to the bed, and smoothly tuck the sheet under the mattress.</p> <p>23. Miter the corner at the head of the bed using the information in the steps that follow.</p> <p>24. Face the side of bed and lift and lay the top edge of the sheet onto the bed to form a triangular fold.</p> <p>25. With your palms down, tuck the lower edge of sheet (hanging free at the side of the mattress) under the mattress.</p> | <p>20. Placement of the seamed side toward the mattress prevents irritation to the client's skin. Ensure proper placement of the sheet so that it can be tightly secured at the top and on both sides of the bed.</p> <p>21. Proper placement of linens ensures adequate sheeting for all sides of the bed.</p> <p>22. Prevents straining of back muscles; decreases the chance that the sheet will pull out from under the mattress.</p> <p>23. Secures sheet tightly to the mattress, with the triangular fold providing a smooth tuck to keep the linen in place.</p> <p>24. Forms the base for the tuck.</p> <p>25. Forms the first half of the tuck.</p> |
|--|---|

(Continues)

PROCEDURE 29-9 Changing Linens in an Unoccupied Bed (Continued)

26. Grasp the triangular fold, and bring it down over the side of the mattress. Allow the sheet to hang free at the side of the mattress.
27. Place the drawsheet on the bottom sheet, and unfold it to the middle crease (see Figure 29-80 on page 727).
28. Face the side of the bed, palms of hands down. Tuck both the bottom and drawsheets under the mattress. Ensure that the bottom sheet is tucked smoothly under the mattress all the way to the foot of the bed.
29. Go to the other side of the bed, unfold the bottom sheet, and repeat the actions used to apply the mattress pad and bottom sheet.
30. Unfold the drawsheet, if used, and grasp the free-hanging sides of both the bottom and drawsheets. Pull toward you, keeping your back straight, and with a firm grasp (sheets taut) tuck both sheets under the mattress. Use your arms and open palms to extend the linen under the mattress. Place the protective pad on the bottom sheet.
31. Place the top sheet on the bed and unfold lengthwise, placing the center crease (width) of the sheet in the middle of the bed. Place the top edge of the sheet (seam up) even with the top of the mattress at the head of the bed. Pull the remaining length toward the bottom of the bed.
32. Unfold and apply the blanket or spread. Follow the same technique used in applying the top sheet (see Figure 29-81 on page 727).
33. Miter the bottom corners. With your palms down, tuck the lower edge of the sheet under the mattress. Grasp the triangular fold and bring it down over the side of the mattress (see Figures 29-82, 29-83, and 29-84 on page 727).
34. Face the head of the bed and fold the top sheet and blanket over 6 inches (15 cm). Fanfold the sheet and blanket (from the foot to the middle of the bed) (see Figure 29-85 on page 727).
35. Apply a clean pillowcase on each pillow (see Figure 29-86 on page 728). With one hand, grasp the closed end of the pillowcase. Gather the pillowcase and turn it inside out overhand. With same hand, grasp the middle of one end of the pillow. With the other hand, pull the case over the length of the pillow. The corners of the pillow should fit snugly into the corners of the case.
36. Return the bed to the lowest position and elevate the head of the bed 30° to 45°. Put side rails up on side farthest from client.
37. Inquire about toileting needs of the client; assist as necessary.
38. Assist the client back into the bed and pull up the side rails; place call light in reach; take vital signs.
26. Will form the final portion of the mitered corner when tucked in.
27. Provides a sheet to lift and move the client in bed without having to use the bottom sheet and remake the bed. Helps keep the bottom sheet clean.
28. Keeps sheet taut, in place, and wrinkle free, thereby decreasing the risk of skin irritation.
29. Unfolding decreases air current; air currents can spread microorganisms.
30. Uses your body's weight in pulling the sheet taut and prevents strain on your back muscles.
31. Making one side of the bed at a time saves time and movement. Seam will be folded down to prevent contact with the client's skin, which can result in irritation.
32. Provides warmth.
33. Secures linen at the foot of the bed.
34. Allows the client easy access to the bed.
35. Keeps clean pillowcase away from uniform.
36. Provides for client safety.
37. Saves client energy and provides time to care for client's needs.
38. Promotes client safety and a means to call for assistance. Sitting up in a chair and movement may cause changes in the client's vital signs.

| <p>39. Remove gloves; wash hands/hand hygiene.</p> <p>40. Document your actions and the client's response during the procedure and to sitting up in a chair.</p> | <p>39. Prevents the spread of microorganisms.</p> <p>40. Documents completion of procedure and assessment findings of client's tolerance.</p> |
|--|---|

delegation tip

Bed making is usually delegated to ancillary personnel. Their instruction should include safety precautions for themselves and the client and understanding the appropriate use of Standard Precautions.

nursing tips

- If the bed raises and lowers, raise it up to a comfortable height to prevent back strain.
- Make one side of the bed completely, and then move to the other side to save time and steps.
- Be careful not to carry the dirty linens close to your uniform to prevent contamination.

PROCEDURE 29-10

Changing Linens in an Occupied Bed

EQUIPMENT

- Linen hamper
- Top sheet, drawsheet, bottom sheet
- Pillowcase
- Blanket
- Bath blanket

ACTION

RATIONALE

- | | |
|---|---|
| <p>1. Explain procedure to client. Gather equipment (see Figure 29-87 on page 729).</p> <p>2. Wash hands/hand hygiene.</p> <p>3. Bring equipment to the bedside (see Figure 29-88 on page 729).</p> | <p>1. Promotes client cooperation.</p> <p>2. Prevents the spread of microorganisms.</p> <p>3. Facilitates a smooth procedure.</p> |
|---|---|

(Continues)

PROCEDURE 29-10 Changing Linens in an Occupied Bed (Continued)

ACTION

FIGURE 29-87 Top and bottom sheets, drawsheet, and pillowcase are used to make the occupied bed. Gloves reduce the transmission of microorganisms. DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 29-88 Bring clean linens and empty linen hamper to the bedside. DELMAR/CENGAGE LEARNING

4. Remove top sheet and blanket. Loosen bottom sheet at foot and sides of bed. Lower side rail nearest the nurse, if necessary, for access. Client may be covered with a bath blanket (see Figure 29-89 on page 730).
 5. Position client on side, facing away from you. Reposition pillow under head.
 6. Fanfold or roll bottom linens close to client toward the center of the bed (see Figure 29-90 on page 730).
 7. Smooth wrinkles out of mattress. Place clean bottom linens with the center fold nearest the client. Fanfold or roll clean bottom linens nearest client and tuck under soiled linens (see Figure 29-91 on page 731). Maintain an adequate amount of sheet at head and foot of bed for tucking.
 8. Miter bottom sheet at head of bed, then at foot of bed. To miter, lift the mattress and tuck the sheet over the edge of the mattress, lift edge of sheet that is hanging to form a triangle, and lay upper part of sheet back onto bed; tuck the lower hanging section under the mattress. Repeat for each corner. Tuck the sides of the sheet under the mattress.
 9. Fold the drawsheet in half. Identify the center of the drawsheet, and place it close to the client. Fanfold or roll drawsheet closest to client and tuck under soiled linens (see Figure 29-92 on page 731). Smooth linen. Add protective padding if needed. Tuck drawsheet under mattress, working from the center to the edges. drawsheet should be positioned under the lower back and buttocks.
 10. Logroll client over onto side facing you. Raise side rail.
4. Facilitates easy removal of linens. Lowering only side rail close to nurse reduces client's risk of falls. Bath blanket prevents exposure and chills.
 5. Provides space to place clean linens.
 6. Keeps soiled linens together. Promotes comfort when client later rolls to other side.
 7. Provides for maximum fit of sheets and decreases chance of wrinkles.
 8. Holds linens firmly in place.
 9. drawsheet facilitates moving and lifting clients while in bed.
 10. Positions client off of soiled linens. Protects client from falling.

(Continues)

PROCEDURE 29-10 Changing Linens in an Occupied Bed (Continued)

ACTION	RATIONALE
11. Move to other side of bed. Remove soiled linens by rolling into a bundle, and place in linen hamper without touching uniform.	11. Prevents cross-contamination.
12. Unfold/unroll bottom sheet, then drawsheet. Look for objects left in the bed. Grasp each sheet with knuckles up and over the sheet and pull tightly while leaning back with body weight (see Figure 29-93 on page 731). Client may be positioned supine.	12. Tight sheets keep linens wrinkle free and decrease the risk of skin irritation. Leaning back uses body weight for good body mechanics.
13. Place top sheet over client with center of sheet in middle of bed. Unfold top of sheet over client. Remove bath blankets left on client to prevent exposure during bed making. Place top blanket over client, same as the top sheet.	13. Provides client with top sheet and blanket to prevent chilling.
14. Raise foot of mattress and tuck the corner of the top sheet and blanket under. Miter the corner. Repeat with other side of mattress. Bend the knees and not the back for proper mechanics.	14. Secures top sheet and blanket into place.
15. Grasp top sheet and blanket over client's toes and pull upward, then make a small fanfold in the sheet.	15. Permits client to move feet under the sheets. Provides room under the tight top sheet and blanket. Prevents toe decubitus and sheet burns from pressure.
16. Remove soiled pillowcase. Grasp center of clean pillowcase, and invert pillowcase over hand/arm. Maintain grasp of pillowcase while grasping center of pillow. Use other hand to pull pillowcase down over pillow. Place pillow under client's head. While changing pillowcase, client can be instructed to rest head on bed, or place a blanket under client's head.	16. Provides clean pillowcase without shaking pillow or pillowcase. Promotes comfort.
17. Document procedure used to change linens and client's condition during the procedure.	17. Provides documentation of nursing care and assessment of client's status.
18. Wash hands/hand hygiene.	18. Prevents the spread of microorganisms.

FIGURE 29-89 Client may be covered with a bath blanket for warmth and modesty while top sheet and blanket are removed. DELMAR/CENGAGE LEARNING

FIGURE 29-92 Fanfold the drawsheet close to the client, and tuck under the soiled linens. DELMAR/CENGAGE LEARNING

FIGURE 29-93 Grasp the bottom sheet and drawsheet and pull tightly. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-10 Changing Linens in an Occupied Bed (Continued)

delegation tip

Bed making is usually delegated to ancillary personnel. Their instruction should include the appropriate use of Standard Precautions and safety precautions for themselves and the client, such as the proper movement of the client in bed, how to manage drains and dressings, and the use of proper body mechanics. In certain situations where the client is in critical condition and multiple tubes, especially chest tubes, are present, the nurse should assist.

nursing tips

- Roll or fold the linens under the client. Do not put them underneath the client.
- Be aware of wrinkles and seams upon which the client may be lying. They can cause pressure areas on the client's skin.
- Check for personal belongings in the client's bed when changing the linens. Clients may keep important items near them in bed.
- Be sure to keep the side rails up on the opposite side of the bed.
- Get help from another caregiver if the client is combative or difficult to move.

PROCEDURE 29-11

Perineal and Genital Care

EQUIPMENT

- Personal protective equipment (gloves, gown)
- Toilet paper/washcloths
- Waterproof pads
- Cleansing solution if needed
- Perineal wash bottle (fill with plain, warm water)
- Water receptacle (bedpan or toilet if client is ambulatory)
- Dry towels
- Perineal treatment (i.e., ointment or lotions) if necessary
- Linen receptacle
- Room deodorizer

ACTION

RATIONALE

- | | |
|--|--|
| <ol style="list-style-type: none"> 1. Wash hands/hand hygiene, and wear gloves. Gather equipment (see Figure 29-94 on page 733). If appropriate and splashing is likely, wear gown, mask, and goggles. 2. Close privacy curtain or door. 3. Position client. 4. Place waterproof pads under the client in the bed or under bedpan if used. | <ol style="list-style-type: none"> 1. Prevents the spread of microorganisms. 2. Provides privacy. 3. If client is ambulatory, perineal care may be done either with client on or standing at the toilet. If perineal care is to be performed in the bed, place the client on the side or over a deep bedpan. 4. Protects bed linens. |
|--|--|

(Continues)

PROCEDURE 29-11 Perineal and Genital Care (Continued)

ACTION	RATIONALE
5. Remove fecal debris with disposable paper, and dispose in toilet.	5. May require several attempts. If performing at the bedside, may collect paper in disposable pad or linens until end of procedure.
6. Spray perineum with washing solution if indicated. Alternatively, plain water may be used.	6. Several perineal solutions are available, which may or may not require rinsing. Carefully evaluate this requirement. Solutions that require rinsing may cause skin breakdown if left on the skin.
7. Cleanse perineum with wet washcloths (front to back on females), changing to clean area on washcloth with each wipe. Cleanse the penis on the male (see Figure 29-95).	7. Maximizes cleansing; prevents spread of rectal flora to vagina.
8. Carefully examine gluteal folds and scrotal folds for debris. Gently examine vulva for debris.	8. Fecal material causes irritation and skin breakdown rapidly when left in contact with skin.
9. If soap is used, spray area with clean water from the peri-bottle.	9. Rinses soap, which can irritate the skin, from the area.
10. Change gloves.	10. Reduces the transmission of microorganisms.
11. Dry perineum carefully with towel.	11. Residual moisture provides an ideal environment for the growth of microorganisms.
12. If indicated, apply barrier lotion or ointment.	12. Barrier ointments may be used if client is incontinent or skin folds tend to harbor moisture.
13. Reposition or dress client as appropriate.	13. Promotes client comfort.
14. Dispose of linens and garbage according to hospital policy.	14. Prevents spread of disease or bacteria.

FIGURE 29-94 Toilet paper, soap, lotion, towels, gloves, and a basin are all used to provide perineal care. DELMAR/CENGAGE LEARNING

FIGURE 29-95 Cleanse the penis with a warm, wet washcloth. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 29-11 Perineal and Genital Care (Continued)

ACTION	RATIONALE
15. Deodorize room if appropriate.	15. Promotes client comfort. This may also be done at the beginning of the procedure.
16. Wash hands/hand hygiene.	16. Reduces the transmission of microorganisms.

delegation tip

This skill is routinely delegated to ancillary personnel, who should be trained in Standard Precautions and proper client positioning and to report color, odor, and amount of any discharge, if present, to the nurse.

nursing tips

- When performing perineal care on a client in bed, make sure bed height is adjusted to permit proper body mechanics.
- Perineal care and bed linen changes may be performed at the same time. Begin by performing peri-care, then wrap soiled linens under the client, and place clean linens to the edge of soiled linens. Roll the client to the other side, and proceed with linens change.
- Always wash hands after performing perineal care. Gloves do not provide a flawless barrier.
- When performing peri-care for an adult or a child, it is important to be sensitive to developmental considerations. Peri-care is usually learned early, and inability or difficulty performing this basic task for oneself can evoke feelings of embarrassment, worthlessness, and incompetence. It is critical that the nurse convey respect in an age-appropriate and a culturally sensitive manner. Perineal care should be performed as often as necessary. Some procedures will necessitate a schedule. If peri-care is necessary after elimination, do not delay. Even short delays can result in unnecessary suffering.
- Ask the client about soap/iodine allergies. Often, clients will not disclose this upon admission. Some perineal procedures will require use of iodine preparations.
- In uncircumcised males, gently retract the foreskin to clean smegma and other debris from the area around the glans. This procedure is not universal, however, and it is appropriate to ask the client whether this is acceptable. Care should be taken to replace the foreskin as soon as possible to prevent edema of the glans.
- Many cultures prescribe cleansing from the “front to the back” of the female perineum to prevent rectal debris and germs from coming into contact with the vulva. Be aware that this is also a cultural preference and if necessary may be followed for medical reasons (for example, interruptions in vaginal or perineal integrity).
- If possible, have a same-sex health care provider perform peri-care.
- Some clients may prefer to perform their own peri-care; however, they may not be able to complete adequate care and may require assistance.

**PROCEDURE
29-12**

Oral Care

EQUIPMENT

BRUSHING AND FLOSSING

- Toothbrush
- Toothpaste with fluoride
- Emesis basin
- Towel
- Cup of water
- Nonsterile gloves
- Dental floss
- Mirror
- Lip moisturizer

DENTURE CARE

- Denture brush
- Denture cleaner
- Emesis basin
- Towel
- Cup of water
- Nonsterile gloves
- Tissue
- Denture cup

SPECIAL CARE ITEMS FOR CLIENTS WITH IMPAIRED PHYSICAL MOBILITY OR WHO ARE UNCONSCIOUS (COMATOSE)

- Soft toothbrush or toothette
- Tongue blade
- 3 × 3 gauze sponges
- Cotton-tip applicators
- Prescribed solution
- Plastic Asepto syringe
- Suction machine and catheter

ACTION

RATIONALE

SELF-CARE CLIENT: FLOSSING AND BRUSHING

**PROCEDURE 29-12
Oral Care (Continued)**

ACTION	RATIONALE
b. Proceed with the actions for oral care for a full-care client except: <ul style="list-style-type: none"> • Do not floss. • Use a soft toothbrush, toothette, or a tongue blade padded with 3 × 3 gauze sponges to gently swab teeth and gums. • Dispose of padded tongue blade into a biohazard bag according to institutional policy. • Rinse with tepid water. 	b. <ul style="list-style-type: none"> • Decreases risk of bleeding and trauma to gums. • Decreases risk of bleeding and trauma to gums. • Promotes proper disposal of contaminated waste. • Cleanses mouth.
40. Infection: <ol style="list-style-type: none"> a. Assess oral cavity with a tongue blade and flashlight for signs of infection. b. Culture lesions as ordered. c. Proceed with the actions for oral care for a full-care client except: <ul style="list-style-type: none"> • Do not floss. • Use prescribed antiseptic solution. • Use a tongue blade padded with 3 × 3 gauze sponges to gently swab the teeth and gums. • Dispose of padded tongue blade into a biohazard bag according to institutional policy. • Rinse mouth with tepid water. • Apply additional solution as prescribed. 	40. <ol style="list-style-type: none"> a. Determines appearance, integrity, and general condition. b. Identifies growth of specific microorganisms. c. <ul style="list-style-type: none"> • Prevents irritation, pain, and bleeding. • Antiseptic solutions decrease growth of microorganisms. • Promotes proper disposal of contaminated materials. • Cleanses mouth. • Provides a coating that promotes healing of the tissue.
41. Ulceration: <ol style="list-style-type: none"> a. Assess oral cavity with a tongue blade and flashlight for signs of ulceration. b. Culture lesions as ordered. c. Proceed with actions for oral care for a full-care client except: <ul style="list-style-type: none"> • Do not floss. • Use prescribed antiseptic solution. • Use a tongue blade padded with 3 × 3 gauze sponges to gently swab the teeth and gums. • Dispose of padded tongue blade into a biohazard bag according to institutional policy. • Rinse mouth with tepid water. • Apply additional solution as prescribed. 	41. <ol style="list-style-type: none"> a. Determines appearance, integrity, and general condition. b. Identifies growth of specific microorganisms. c. <ul style="list-style-type: none"> • Prevents irritation, pain, and bleeding. • Antiseptic solutions decrease growth of microorganisms. • Promotes proper disposal of contaminated materials. • Cleanses mouth. • Provides a coating that promotes healing of the tissue.
UNCONSCIOUS (COMATOSE) CLIENT	
42. Assemble articles for flossing and brushing.	42. Promotes efficiency.
43. Provide privacy.	43. Relaxes client.
44. Wash hands/hand hygiene, and apply gloves.	44. Reduces the transmission of microorganisms and exposure to body fluids.
45. Explain the procedure to the client.	45. Demonstrates respect for the client.

(Continues)

PROCEDURE 29-12 Oral Care (Continued)

ACTION	RATIONALE
46. Place the client in a lateral position, with the head turned toward the side.	46. Prevents aspiration.
47. Use a floss holder, and floss between all teeth.	47. Prevents transfer of microorganisms from a client bite.
48. Moisten toothbrush or toothette, and brush the teeth and gums using friction in a vertical or circular motion. Do not use toothpaste. On inner and outer surfaces of teeth, hold brush at 45° angle against teeth and brush from sulcus to crowns of teeth. On biting surfaces, move brush back and forth in short strokes. All surfaces of teeth should be brushed from every angle.	48. Permits cleaning of back and sides of teeth and decreases microorganism growth in mouth. Toothpaste may foam and cause aspiration.
49. After flossing and brushing, rinse mouth with an Asepto syringe (do not force water into the mouth), and perform oral suction.	49. Promotes cleansing and removal of secretions and prevents aspiration.
50. Dry the client's mouth.	50. Prevents skin irritation.
51. Apply lip moisturizer.	51. Maintains skin integrity of lips.
52. Leave the client in a lateral position with head turned toward side for 30 to 60 minutes after oral hygiene care. Suction one more time. Remove the towel from under the client's mouth and face.	52. Prevents pooling of secretions and aspiration.
53. Dispose of any contaminated items in a bio-hazard bag and clean, dry, and return all articles to the appropriate place.	53. Promotes proper disposal of contaminated materials.
54. Remove gloves, wash hands/hand hygiene, and document care.	54. Reduces the transmission of microorganisms and documents nursing care.

delegation tip

Oral care is routinely delegated to ancillary personnel, who should allow the client to perform as much of the oral care as possible or permitted. The caregiver should be trained to employ Standard Precautions, to properly position the client, and to observe and report the condition and color of the client's mucous membranes to the nurse.

nursing tips

- *Never place your fingers in a client's mouth. A bite block or padded tongue blade can be used to hold the client's mouth open.*
- *The unconscious client's head should be turned to one side, with a basin placed under the mouth. Oral suction should be available. Only small amounts of water should be used.*
- *Be careful when handling and cleaning dentures or other oral appliances. They can be slippery when wet and may break if dropped into the sink or onto the floor.*
- *Clients with orthodontic appliances may have special oral care needs. Ask the client or the client's family about any special cleaning needs or special appliance care.*
- *Avoid using oil-based products around oxygen and oxygen equipment because oil and grease are flammable. Petroleum jelly may be used on clients receiving oxygen, but it should not be used on oxygen equipment.*
- *Avoid breathing directly on client to avoid transmission of microorganisms.*
- *Wear a mask and goggles if within distance of splashes or sprays from the client's coughing.*

PROCEDURE 29-13

Eye Care

EQUIPMENT

ARTIFICIAL EYE

- Storage container
- Mild soap
- 3 × 3 gauze sponges
- Cotton balls
- Towel
- Emesis basins
- Eye irrigation syringe (optional)
- Running water
- Sterile gloves
- Biohazard bag
- Saline solution

CONTACT LENSES

- Lens container
- Soaking solution—type used by client
- Nonsterile gloves
- Towel
- Suction cup (optional)
- Scotch tape (optional)

ACTION

RATIONALE

ARTIFICIAL EYE REMOVAL

- | | |
|--|---|
| <ol style="list-style-type: none"> 1. Inquire about client's care regimen, and gather equipment accordingly (see Figure 29-103 on page 742). 2. Provide privacy. 3. Wash hands/hand hygiene. Apply gloves. 4. Place client in a semi-Fowler's position. 5. Place the cotton balls in an emesis basin filled halfway with warm tap water. 6. Place 3 × 3 gauze sponges in bottom of second emesis basin, and fill halfway with mild soap and tepid water. 7. Grasp and squeeze excess water from a cotton ball. Cleanse the eyelid with the moistened cotton ball, starting at the inner canthus and moving outward toward the outer canthus. After each use, dispose of cotton ball in biohazard bag. Repeat procedure until eyelid is clean (without dried secretions). 8. Remove the artificial eye: <ol style="list-style-type: none"> a. Using dominant hand, raise the client's upper eyelid with index finger, and depress the lower eyelid with thumb. b. Cup nondominant hand under the client's lower eyelid. c. Apply slight pressure with index finger between the brow and the artificial eye, and remove it. Place it in an emesis basin filled with warm, soapy water. | <ol style="list-style-type: none"> 1. Promotes continuity of care. 2. Relaxes the client. 3. Prevents the spread of microorganisms. 4. Facilitates procedure and client participation. 5. Dry cotton balls could cause irritation. 6. Gauze serves as padding to prevent breakage of the prosthesis. 7. Eliminating the excess water prevents water from running down the client's face. Cleansing the eyelid prevents contamination of the lacrimal system (inner canthus area). Disposal of cotton balls reduces transmission of microorganisms to other health care workers. 8. Cleanses the artificial eye. <ol style="list-style-type: none"> a. Promotes removal of the artificial eye. b. Cupping reduces dropping and possible breaking of the eye. c. Applying pressure will help the prosthesis slip out. |
|--|---|

(Continues)

PROCEDURE 29-13 Eye Care (Continued)

FIGURE 29-103 Commercial soaking and eye care solutions. Many types of soaking solutions are available. Select the type normally used by the client whenever possible. DELMAR/CENGAGE LEARNING

ACTION

9. Grasp a moistened cotton ball and cleanse around the edge of the eye socket. Dispose of the soiled cotton ball in biohazard bag.
10. Inspect the eye socket for any signs of irritation, drainage, or crusting. *Note:* If the client's usual care regimen or a prescribing practitioner's order requires irrigation of the socket, proceed with Action 11; otherwise, go to Action 12.
11. Eye socket irrigation:
 - a. Lower the head of the bed and place the client in a supine position. Place protector pad on bed. Turn head toward socket side, and slightly extend neck.
 - b. Fill the irrigation syringe with the prescribed amount and type of irrigating solution (warm tap water or normal saline).
 - c. With nondominant hand, separate the eyelids with your forefinger and thumb while resting fingers on the brow and cheekbone.
 - d. Hold the irrigating syringe in dominant hand several inches above the inner canthus; with thumb, gently apply pressure on the plunger, directing the flow of solution from the inner canthus along the conjunctival sac.
 - e. Irrigate until the prescribed amount of solution has been used.
 - f. Wipe the eyelids with a moistened cotton ball after irrigating. Dispose of soiled cotton ball in biohazard bag.
 - g. Pat the skin dry with the towel.
 - h. Return the client to a semi-Fowler's position.
 - i. Remove gloves, wash hands/hand hygiene, and apply clean gloves.

RATIONALE

9. Cleanses the eye socket. Disposal of cotton ball reduces transmission of microorganisms to other health care workers.
10. Indicates an infection.
11. Cleanses the eye socket and removes secretions.
 - a. Positioning of client facilitates ease in performing the procedure and client's comfort.
 - b. Ensures compliance with client's regimen or prescribed orders.
 - c. Keeps the eyelid open and the socket visible.
 - d. Prevents injury to the client.
 - e. Ensures compliance with client's regimen of prescribed orders.
 - f. Reduces the transmission of microorganisms to prosthesis.
 - g. Prevents maceration of the skin.
 - h. Promotes client's comfort.
 - i. Reduces the transmission of microorganisms.

(Continues)

PROCEDURE 29-13 Eye Care (Continued)

ACTION	RATIONALE
12. Rub the artificial eye between index finger and thumb in the basin of warm, soapy water.	12. Creates cleaning with friction and prevents breakage of the prosthesis.
13. Rinse the prosthesis under running water or place in the clean basin of tepid water. Do not dry the prosthesis. <i>Note:</i> Either reinsert the prosthesis (Action 14) or store in a container (Action 15).	13. Removes soap and secretions. Keeping the artificial eye wet prevents irritation from lint or other particles that might adhere to it and facilitates reinsertion.
14. Reinsert the prosthesis: a. With the thumb of the nondominant hand, raise and hold the upper eyelid open. b. With the dominant hand, grasp the artificial eye so the indented part is facing toward the client's nose, and slide it under the upper eyelid as far as possible. c. Depress the lower lid. d. Pull the lower lid forward to cover the edge of the prosthesis.	14. Allows for client comfort. a. Facilitates reinsertion of the prosthesis without discomfort to the client. b. Positions the prosthesis for insertion. c. Allows the prosthesis to slide into place. d. Holds the prosthesis in place.
15. Place the cleaned artificial eye in a labeled container with a saline or tap water solution.	15. Protects the prosthesis from scratches and keeps it clean.
16. Grasp a moistened cotton ball and squeeze out excessive moisture. Wipe the eyelid from the inner to the outer canthus. Dispose of the soiled cotton ball in a biohazard bag.	16. Squeezing the cotton ball removes moisture. Cleansing the eyelid prevents contamination of lacrimal system. Disposal of cotton ball reduces the transmission of microorganisms to other health care workers.
17. Clean, dry, and replace equipment.	17. Promotes a clean environment.
18. Reposition the client, raise side rails, and place call light in reach.	18. Promotes client's comfort, safety, and communication.
19. Dispose of biohazard bag according to institutional policy.	19. Reduces the transmission of microorganisms to other health care workers.
20. Remove gloves. Wash hands/hand hygiene.	20. See Rationale 19.
21. Document procedure, client's response and participation, and client teaching and level of understanding.	21. Demonstrates that the procedure was done and the level of client participation and learning.

CONTACT LENS REMOVAL

22. Assemble equipment for lens removal.	22. Promotes efficiency.
23. Assess level of assistance needed, provide privacy, and explain the procedure to the client.	23. Level of assistance determines level of intervention. Privacy reduces anxiety. Explanation of procedure promotes cooperation.
24. Wash hands/hand hygiene.	24. Prevents the spread of microorganisms.
25. Assist the client to a semi-Fowler's position if needed.	25. Facilitates removal of lens.
26. Drape a clean towel over the client's chest.	26. Provides a clean surface and facilitates the location of a lens if it falls out during removal.

(Continues)

PROCEDURE 29-13 Eye Care (Continued)

27. Prepare the lens storage case with the prescribed solution.
 28. Instruct the client to look straight ahead. Assess the location of the lens. If it is not on the cornea, either you or the client should gently move the lens toward the cornea with the pad of the index finger (see Figure 29-104 on page 745).
 29. Remove the lens.
 - a. Hard lens:
 - Cup nondominant hand under the eye.
 - Gently place index finger on the outside corner of the eye and pull toward the temple. Ask client to blink. Catch the lens in your nondominant hand.
 - b. Soft lens:
 - With nondominant hand, separate the eyelid with your thumb and middle finger.
 - With the index finger of the dominant hand gently placed on the lower edge of the lens, slide the lens downward onto the sclera and gently squeeze the lens.
 - Release the top eyelid (continue holding the lower lid down), and remove the lens with your index finger and thumb.
 - *Note:* If Action 29 is unsuccessful, secure a suction cup to remove the contact lens. If you are unable to remove the lens, notify the prescribing practitioner or qualified practitioner.
 30. Store the lens in the correct compartment of the case (“right” or “left”). Label with the client’s name.
 31. Remove and store the other lens by repeating Actions 29 and 30.
 32. Assess eyes for irritation or redness.
 33. Store the lens case in a safe place.
 34. Dispose of soiled articles, and clean and return reusable articles to proper location.
 35. Reposition the client, raise side rails, and place call light in reach.
 36. Remove gloves. Wash hands/hand hygiene.
 37. Document procedure, client’s response and assessment findings, and the storage place of the lenses.
27. Hard lenses can be stored dry or in a special soaking solution. Soft lenses are stored in sterile normal saline without a preservative.
 28. Client’s position promotes easy removal of lens. Positioning lens on the cornea aids removal. Use of the finger pad of the index finger prevents damage to cornea and lens.
 29. Provides for cleaning and storage of the lens.
 - a.
 - Cupping the hand under the eye helps catch the lens to prevent breakage.
 - Pulling the corner of the eye tightens the eyelid against the eyeball. Pressure on the upper edge of the lens causes the lens to tip forward.
 - b.
 - Separating the eyelid exposes the lower edge of the lens.
 - Positions the lens for easy grasping with the pad of the index finger, which prevents injury to the cornea and lens. Squeezing the lens allows air to enter and release the suction.
 - Ensures control of the lens.
 - Suction cup is used to remove a lens from an unconscious or a dependent client.
 30. Storage prevents damage to the lenses and ensures that each lens will be reinserted into the correct eye.
 31. See Rationales 29 and 30.
 32. Reveals signs of corneal irritation.
 33. Prevents damage or loss.
 34. Reduces the transmission of infection.
 35. Promotes client comfort, safety, and communication.
 36. Prevents the spread of microorganisms.
 37. Documents the removal of lenses, condition of the cornea, and where the lenses are stored.

(Continues)

PROCEDURE 29-13 Eye Care (Continued)

FIGURE 29-104 If the lens is not on the cornea, gently move it toward the cornea with the pad of the index finger. DELMAR/CENGAGE LEARNING

delegation tip

Eye care requires the assessment and intervention of the nurse. Delegation to ancillary personnel is inappropriate.

nursing tips

- Be aware of right and left. Take care not to mix up a client's contacts.
- Prostheses are slippery. Be careful not to drop while handling them.
- Place a towel or washcloth over the bottom of the sink when cleaning contacts or a prosthesis to prevent breakage if dropped and to prevent loss down the drain.
- If the client has glasses as well as contacts, encourage the client to send the contacts home with family and to wear glasses while in the hospital.
- Place a towel in front of the client when an eye prosthesis is removed to catch it if it slips out of your hand.

KEY CONCEPTS

- Factors influencing client safety are age, lifestyle, sensory and perceptual alterations, mobility, and emotional state.
- Types of accidents that can occur in the health care setting are client behavior, therapeutic procedure, and equipment.
- Assessment of a safe environment consists of performing an injury risk appraisal.
- Nurses can help clients maintain a safe environment by resolving or alleviating hazards related to falls, lighting, obstacles, bathroom hazards, fire, electricity, radiation, poisoning, and noise pollution.
- The chain of infection involves a biological agent, a reservoir of the agent, a portal of exit, a mode of transmission, a portal of entry of the agent into the host, and a susceptible host.
- Medical and surgical asepsis prevents the transfer of microorganisms by implementation of practices to reduce the number, growth, or spread of microorganisms from an object or area.
- The guidelines from the CDC require that transmission-based precautions be used for specific syndromes that are highly suspicious for infections until a diagnosis is confirmed.

- Hygienic practices are influenced by body image, social and cultural practices, personal preference, socioeconomic status, and knowledge.
- Basic hygienic practices include bathing, skin care, perineal care, back rubs, foot and nail care, oral care, hair care, and eye, ear, and nose care.

REVIEW QUESTIONS

- Which action provided for legal protection of information voluntarily reported to an organization regarding safety issues?
 - Public Health Service Act
 - Report of the Institute of Medicine in 1999
 - Centers for Disease Control and Prevention
 - Patient Safety and Quality Improvement Act of 2005
- The physiological changes of aging increase the risk for which of the following?
 - Choking
 - Electrical hazards
 - Falls
 - Substance abuse
- When an infectious disease is transmitted to a person by direct or indirect contact, it is called a:
 - Portal of entry to a host
 - Susceptible host
 - Communicable disease
 - Portal of exit from a reservoir
- The family member of a client diagnosed with hepatitis A asks the nurse how to avoid infecting other family members. The nurse's response would be based on the understanding that hepatitis A is primarily spread by:
 - Sexual contact with an infected person who does not show symptoms of the disease
 - Contaminated needles from a person who has some form of hepatitis
 - Blood transfusions of improperly prepared blood
 - Fecal contamination or contaminated food or water from person to person
- One of the major concerns of nurses in the workforce is:
 - The threat of malpractice
 - Job security
 - Exposure to bloodborne infection by needlestick injuries
 - Exposure to contaminated equipment
- What kills bacteria most effectively?
 - Warm water scrub
 - Soap and water handwash
 - Alcohol-based hand rubs
 - Antiseptic handwash
- When performing a venipuncture, which Standard Precaution should be implemented?
 - Gloves
 - Face shield
 - Goggles
 - Gloves, face shield, and goggles
- Which hospitalized client does the nurse identify to be at greatest risk for the development of a urinary tract HAI?
 - A 48-year-old male suspected of Parkinson's disease who had been jogging prior to admission
 - A 75-year-old male who has pancreatic cancer
 - A 34-year-old male who drinks 2500 mL of fluid daily, following a fracture of the fibula
 - A 60-year-old obese female with cholecystitis
- When considering the client's personal preferences for hygiene, which factor should the nurse deem as primary?
 - Keep the nursing aides on schedule.
 - Hygiene is a routine procedure.
 - No two persons perform hygiene in the same manner.
 - Get all hygiene procedures performed before the family comes to visit.
- The primary goal in providing oral hygiene to an unconscious client is to prevent:
 - Mouth odors
 - Mouth ulcers
 - Aspiration
 - Dental caries

Words are the most potent drug that mankind uses.

—KIPLING (IN EDLIN & GOLANTY, 1988)

CHAPTER 30

Medication Administration

COMPETENCIES

1. Define the key terms and abbreviations frequently used in medication administration.
2. Describe the influence of drug standards and legislation on medication administration.
3. Discuss the nurse's legal responsibilities in preparation and administration of medications.
4. Explain the principles of pharmacokinetics, including absorption, distribution, metabolism, and excretion of drugs.
5. Describe the factors that can affect a drug's action.
6. Identify the responsibilities of the nurse for each type of medication order.
7. Differentiate between allergic reaction, side effect, toxic effect, and idiosyncratic reaction to medications.
8. Correctly calculate appropriate dosage for medications as prescribed.
9. Discuss principles of safe medication administration including the five rights of medication administration.
10. Correctly explain procedures for the different methods of medication administration including the choice of route and site.
11. Discuss potential liabilities for the nurse administering medications.
12. Develop teaching guidelines for clients regarding medication in the home.

KEY TERMS

absorption	enteral instillation	pharmacokinetics
addiction	excretion	phlebitis
adverse reactions	half-life	plateau
aspiration	idiosyncratic reaction	prn
bioavailability	infiltration	side effect
buccal	intra dermal (ID)	stat order
dependence	intramuscular (IM)	stock supplied
dissolution	intravenous (IV)	subcutaneous
distribution	metabolism	sublingual
drug allergy	onset of action	therapeutic range
drug incompatibility	parenteral	toxic effect
drug interaction	patency	trough
drug tolerance	peak plasma level	unit-dose form
duration	pharmacognosy	Z-track (zigzag) technique

Alterations in health related to acute or chronic conditions lead clients to seek relief of their symptoms through various treatment options. One modality frequently used to help alleviate symptoms and restore health is a medication regime. Medications are substances prescribed by the client's prescribing practitioner to help in the treatment, relief, or cure of the cause of the client's health alterations or in the prevention of such alterations. The term *prescribing practitioner* refers to any health care provider who is authorized to prescribe medications (e.g., physicians, dentists, advanced practice nurses).

Medication management requires the collaborative efforts of many health care providers. Once prescribed, pharmacists are licensed to prepare and dispense medications. Nurses are responsible for administering medications. Dietitians are often involved in identifying possible food and drug interactions.

Nurses play an essential role in the administration of, education about, and evaluation of the effectiveness of prescribed medications. The nurse's role changes with the setting of the client. In the home care community setting, clients take their own medication as prescribed by the prescribing practitioner. Nurses are responsible for educating clients about their medications and the possible side effects as well as for evaluating the outcome of the prescribed therapy in restoring and maintaining clients' health. In the acute care setting, nurses spend a great deal of time administering medications and evaluating their effectiveness. Nurses are responsible for teaching clients how to take their medications safely upon discharge.

Medication administration requires specialized knowledge, judgment, and nursing skill based on the principles of pharmacology. The focus of this chapter is to assist the student in applying principles of pharmacology and in acquiring skills in the safe administration of medications. The nursing

process is used to direct nursing decisions relative to safe drug administration and to ensure compliance with standards of practice.

DRUG STANDARDS AND LEGISLATION

A drug is a chemical substance intended for use in the diagnosis, treatment, cure, mitigation, or prevention of a disease. When a drug is given to a client, there is an intended specific effect. An assumption made by nurses before administration of any medication is that the drug will be safe for the client to consume if the dose, frequency, and route are within the therapeutic range for that drug. This assumption is implied in accord with standards that are set to ensure drug uniformity in strength, purity, efficacy, safety, and **bioavailability** (readiness to produce a drug effect).

STANDARDS

Standards have been developed to ensure drug uniformity so that effects are predictable. The *United States Pharmacopeia* and *National Formulary* (USP and NF) are books of drug standards for usage in the United States. The USP and NF list drugs that have been recognized as being in compliance with legal standards of purity, quality, and strength.

The USP has been providing standards for pharmaceutical preparations since its first edition in 1820. The NF was published in 1898 by the American Pharmaceutical Association to provide a listing of drugs that complied with established standards. The *British Pharmacopoeia* is the British complement to the USP, and the *Canadian Formulary* provides a listing of drugs commonly used in Canada.

FEDERAL LEGISLATION

The Pure Food and Drug Act of 1906 designated the USP and the NF as the official references to establish drug standards. It also gave the federal government the authority to enforce these standards.

The federal Food, Drug, and Cosmetic Act of 1938 empowered the Food and Drug Administration (FDA) to test all new drugs for toxicity before granting a pharmaceutical company approval to market a drug. The federal Food, Drug, and Cosmetic Act of 1938 was amended in 1952 to distinguish prescription (legend) drugs from nonprescription (over-the-counter) drugs and to regulate the dispensing of prescriptions. Testing for drug effectiveness materialized with the Kefauver-Harris Act of 1962.

The Harrison Narcotic Act of 1914 classified habit-forming drugs as narcotics and began regulating these substances. This law and other drug abuse laws have been replaced with the Comprehensive Drug Abuse Prevention and Control Act (Controlled Substance Act) of 1970. This act defines a *drug-dependent person* in terms of physical and psychological dependence and provides for strict regulation of narcotics and other controlled drugs such as barbiturates through the establishment of five categories of scheduled drugs (see the accompanying display on controlled substances). Any controlled substance must be recorded by the dispensing pharmacist. The Drug Enforcement Administration employs pharmacists to inspect all types of records, including prescriptions, to detect the illicit distribution of these substances.

STATE AND LOCAL LEGISLATION

Within an individual state, the nurse's functions and responsibilities are defined by the state nurse practice act. The wording of a state's practice act may be general so that it gives the nurse a broad range of responsibilities, or it may be

very specific in the limitations it sets. The nurse is responsible for knowing the boundaries set by the state practice act in the particular state of practice. A health care institution may develop policies that are more restrictive than the nurse practice act but cannot expand the scope of practice outlined by the state legislation. The primary intent of all state practice acts is to protect the public by defining required education and skill levels of all state-licensed nurses.

State and local regulations of medications must conform with federal legislation. States, however, have the power to enforce additional regulations that impose stricter control of substances. For example, the Controlled Substance Act has codeine in antitussives as a schedule V drug, but an individual state that identifies abuse of antitussives with codeine may place this drug in the schedule II category, which is more restrictive.

HEALTH CARE INSTITUTION REGULATIONS

All health care institutions are required to meet minimum standards set by federal, state, and local agencies. In addition to these standards, most institutions have established specific policies that regulate administration of medication within the institution. Institutional policies are typically more restrictive and more specific than federal and state regulations. Health care institutions are trying to prevent problems stemming from medication administration. For example, institutional policies may set the times for medication administration (e.g., medications ordered for every 8 hours are given at 0600 [6 AM], 1400 [2 PM], and 2200 [10 PM]) or may mandate discontinuation of medications unless reordered by the prescribing practitioner (e.g., antibiotics must be reordered every 5 days).

CONTROLLED SUBSTANCES

- Schedule C-I: High abuse potential, no current accepted medical use (e.g., heroin, marijuana, LSD)
- Schedule C-II: High abuse potential for severe dependence (e.g., narcotics, amphetamines, dronabinol, some barbiturates)
- Schedule C-III: Less abuse potential than schedule II drugs for moderate dependence (e.g., nonbarbiturate sedatives, nonamphetamine stimulants, limited amounts of certain narcotics)
- Schedule C-IV: Lower abuse potential than schedule III drugs for limited dependence (e.g., sedatives, antianxiety agents, nonnarcotic analgesics)
- Schedule C-V: Limited abuse potential (e.g., codeine used as antitussive, antidiarrheals)

PHARMACOKINETICS

For a drug to achieve a therapeutic effect, it must proceed from the point of entry into the body to the tissue with which it will react. The effectiveness is further affected by the dosage of the drug and the amount of time the drug spends in the body before it is excreted.

Pharmacokinetics refers to the study of the absorption, distribution, metabolism, and excretion of drugs to determine the relationship between the dose of a drug and the drug's concentration in biological fluids. The knowledge of pharmacokinetics is used by prescribing practitioners in medication management.

The prescribing practitioner, when ordering a drug, is concerned mainly with dose and route to produce the most therapeutic effects; prescribing practitioners, pharmacists, and nurses are all involved in identifying appropriate times for drug administration and for avoiding interactions with other substances that could alter the drug's actions. Prescribing practitioners and nurses monitor the client's response to the drug's action. Drug actions are dependent on four properties: absorption, distribution, metabolism, and excretion.

ABSORPTION

The degree and rate of **absorption**, or passage of a drug from the site of administration into the bloodstream, depend on several factors: the drug's physicochemical effects, its dosage form, its route of administration, its interactions with other substances in the digestive system, and various client characteristics such as age. Oral preparations, such as tablets and capsules, must first disintegrate into smaller particles for gastric juices to dissolve and prepare the drug for absorption in the small intestines. **Dissolution** is the rate at which a drug becomes a solution. After ingestion, a pill, capsule, or caplet must disintegrate before it can be dissolved and then absorbed by the body for therapeutic use. The more rapid the rate of dissolution, the more quickly the drug can be absorbed. Oral drugs in liquid form are more readily absorbed by the gastrointestinal tract than are tablets. Figure 30-1 shows the process of absorption of solid drugs.

Drugs administered intramuscularly are absorbed through the muscle into the bloodstream. Suppositories are absorbed through the mucous membranes into the blood. Intravenous drugs are immediately bioavailable because of their direct injection into the blood to produce a drug effect.

Blood flow to the absorption site is a major factor in drug absorption. A rich blood supply facilitates absorption, whereas a poor blood supply will slow absorption. **Sublingual** (under the tongue) medications, such as Nitrostat (for angina), are absorbed more quickly than are medications such as insulin that are injected into subcutaneous tissue. A person in shock, which results in poor peripheral circulation, may not absorb intramuscular medications as well as a person with normal circulation. Circulation is enhanced by exercise, so a diabetic who has exercised hard may experience low blood sugar (hypoglycemia) because of more rapid absorption of the insulin from increased peripheral circulation.

The solubility of the drug is also a factor in absorption. To be absorbed, the drug must be in a liquid form. The more soluble the drug, the faster it will be absorbed. Because cells have a fatty acid layer, drugs that are more lipid in content

are absorbed more rapidly. Chemicals and minerals that are insoluble in the gastrointestinal tract, such as barium salts, are not absorbed. When given parenterally, drugs with an oily base such as streptomycin (an anti-infective) are absorbed more slowly than are drugs dissolved in a water base.

The pH of the drug is another factor in absorption. A drug that is acidic (e.g., aspirin) can be more easily absorbed in an acidic environment such as gastric content. A drug that is more basic in composition is not absorbed in the stomach but passes on to the small intestine, where it is absorbed.

Drugs that are highly concentrated (e.g., epinephrine) tend to be absorbed more quickly than drugs that are lower in concentrations. Less well researched is the effect ethnicity and culture have on the therapeutic effects of medications. Some studies have identified differences in required drug levels as well as responses to medications (e.g., antihypertensive drugs and the African American client). Drugs do not have the same effect in all people. Diet is a factor as well as adherence to herbal and homeopathic remedies (e.g., the herb ginseng can act as an accelerant or inhibitor of certain medications). Prescribing practitioners need to be aware of and sensitive to these cultural variations that may affect clients in their care (Institute for Safe Medication Practices [ISMP], 2003).

Another factor affecting absorption is the ingestion of food before taking oral medications. Interactions of some medications with food change the chemical structure of the drug, thereby affecting absorption. For example, tetracycline (an anti-infective) should not be taken with dairy products. Clients taking warfarin (an anticoagulant) should avoid or limit their intake of food high in vitamin K, which is an antidote for warfarin. Some medications, when given together, interact with each other to impair absorption.

The administration time of dosages needs to be regulated to ensure adequate absorption of drugs. For example, it may be best to take certain medications a half hour before meals. The nurse needs to use this knowledge to be sure prescribed medications are administered properly.

DISTRIBUTION

Distribution refers to the movement of drugs from the blood into various body fluids and tissues. The rate at which the drug reaches the specific site of action is affected by blood flow, cell membrane permeability, and the protein-binding capacity of the medication.

How fast the drug reaches the organs and tissues depends on the cardiac output (blood flow) of the person. When conditions exist that decrease blood flow (e.g., cardiogenic shock) or when circulation to the tissue is poor (e.g., peripheral vascular disease from atherosclerosis), the distribution of the drug will be slowed. When conditions exist that increase blood flow (e.g., strenuous exercise), distribution will be facilitated.

To be distributed to the tissue, the drug must cross the cell membrane. Some membranes act as a barrier for distribution of medications. The blood-brain barrier, for example, allows only fat-soluble medications to pass through (e.g., alcohol, general anesthetics, penicillin G).

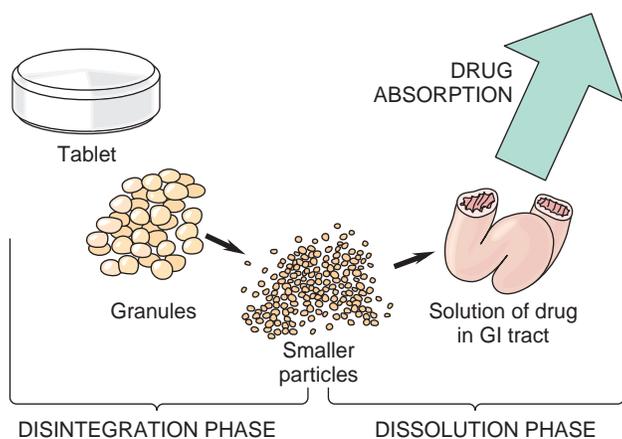

FIGURE 30-1 Phases of Solid Drug Absorption DELMAR/CENGAGE LEARNING

Once the drug enters the circulation, it may become attached to proteins, mostly albumin. This protein binding decreases the amount of free drug available to reach the site of action. This is because the protein–drug molecule is trapped in the blood flow, as it is too large to diffuse through the cell membrane. While medications vary in the extent to which they bind with proteins, most drugs have some protein-binding properties. Some diseases (e.g., malnutrition, liver disease) cause a decrease in circulating albumin that results in more free drug. This can result in increased distribution of the drug (enhanced pharmacologic effect) and toxicity if not carefully monitored.

Body composition also affects the distribution of medications. Many drugs are prescribed based on body weight. An increase in body fat (in an obese person, for example) causes longer drug duration because of slower distribution. The less a person weighs, the higher the concentration of medication in the circulation, which results in a more powerful drug effect. This needs to be monitored very closely in older adults who have changes in body composition naturally related to aging and often lose weight due to a decreased appetite.

METABOLISM

After the medication is absorbed and distributed, the body eliminates the drugs. The process of **metabolism** (also known as biotransformation) refers to the physical and chemical processing of the drug. In metabolism, the drug is inactivated and changed into a water-soluble compound that can be excreted by the body. The liver is the primary source of biotransformation. The rate of metabolism is determined by the presence of enzymes in the liver cells that detoxify the drugs. Diseases that affect the liver (e.g., cirrhosis) affect the body's ability to biotransform medications. Other conditions that affect metabolism are blood flow to the liver, the presence of other substances that affect liver function, and age. If drug metabolism is inhibited, there will be a buildup of the medication, causing a cumulative effect. This will be exhibited as a prolonged response to a normal dose of medication. If metabolism is enhanced (as in high blood flow states), the medications will be inactivated faster than expected, resulting in a shorter response to medications. A client's race and ethnic heritage can influence how drugs are metabolized (see the section on cultural diversity).

EXCRETION

Excretion is the process in which drugs are eliminated from the body. Excretion occurs primarily through hepatic biotransformation and renal excretion; it refers to the movement of a drug or its metabolites from the tissues back into circulation and from the circulation into the organs of excretion.

Factors that affect the kidneys' ability to excrete drugs include maturity of the kidneys, circulation, and disease. As kidney function decreases, there can be an accumulation of drugs, which can result in toxicity. If the kidneys are not functioning normally, a decreased dosage of medications may be needed. Adequate fluid intake aids in the elimination

of drugs in a healthy individual. Other organs, such as exocrine glands, the skin, the gastrointestinal tract, and the lungs, contribute to the elimination of some drugs.

DRUG NOMENCLATURE

A drug may be used as an aid in the diagnosis, treatment, or prevention of disease; in abnormal conditions for the relief of pain or suffering; or to improve any physiological or pathologic condition. The terms *drug*, *medication*, and *medicine* are often used interchangeably by health care providers and laypersons.

Drugs can be identified by their chemical, generic, official, or trade names. The *chemical name* is a precise description of the drug's composition (chemical formula). The *nonproprietary*, or *generic*, name in the United States is the name assigned by the U.S. Adopted Names Council to the manufacturer who first develops the drug. When the drug is approved, it is given an *official name* that may be the same as the nonproprietary name. Drugs with a proven therapeutic value are listed in the USP and NF by their official names. When pharmaceutical companies market the drug, they assign a *proprietary name*, also called a *trade* or *brand name*; therefore, one generic drug may have several trade names based on the number of companies marketing the drug. For example, ibuprofen is a generic name; common trade names for this drug are Advil, Excedrin IB, Motrin, and Nuprin. See the accompanying display on trade and generic drug names for additional examples.

DRUG ACTION

Drug action refers to a drug's ability to combine with a cellular drug receptor. Depending on the location of different cellular receptors affected by a given drug, a drug can have a local effect, a systemic effect, or both local and systemic effects. For example, when diphenhydramine hydrochloride (Benadryl) cream is applied to the skin, it elicits only a local effect; however, when this drug is administered in a tablet or injectable form, it causes both systemic and local effects.

PHARMACOLOGY

Pharmacology is the study of the effects of drugs on living organisms. This section discusses the pharmacologic activities

SAMPLE TRADE AND GENERIC DRUG NAMES

TRADE NAME	GENERIC NAME
Bayer	Aspirin
Benadryl	Diphenhydramine hydrochloride
Robitussin	Guaifenesin
Zovirax	Acyclovir

of drug action as it relates to medication management, drug classification, drug preparation, and routes of administration.

Medication Management

The purpose of medication management is to produce the desired drug action by maintaining a constant drug level. Drug action is based on the half-life of a drug.

A drug's **half-life** refers to the time it takes the body to eliminate half of the blood concentration level of the original drug dose. For example, if a drug has a half-life of 6 hours, 50% of the drug's original dose is present in the blood 6 hours after administration; in 12 hours after administration, 25% of the original drug is present. Because of a drug's half-life, repeated doses are often required to maintain the drug level over a 24-hour interval.

The nurse should understand other terms used to describe drug action: onset, peak plasma level, trough, duration, and plateau. **Onset of action** is the time it takes the body to respond to a drug after administration. Onset is affected by route of administration and pharmacokinetic factors already discussed. A **peak plasma level** is the highest blood concentration of a single drug dose before the elimination rate equals the rate of absorption. Once the peak plasma level is achieved, the blood concentration level will decrease steadily unless another drug dose is given. **Trough** is the lowest blood serum concentration of a drug in a person's system. This is measured immediately before the next scheduled dose. Trough levels help adjust dosage to prevent toxicity or drug buildup. **Duration** is the time a drug remains in the system in a concentration great enough to have a therapeutic effect. The accompanying display defines the common terms associated with the medical management of medication administration. If a series of scheduled drug doses are administered, the blood

concentration level is maintained; maintenance of a certain level is called a **plateau**.

Classification

Drugs are commonly classified by the body system that they interact with (e.g., cardiovascular) or in accord with the drug's approved therapeutic usage (e.g., antihypertensive). Drugs with multiple therapeutic uses are usually classified in accordance with their most common usage.

Preparation and Route

Drugs are available in many forms for administration by a specific route. (See the accompanying display on drug preparations on page 755.) The route refers to how the drug is absorbed: oral, buccal, sublingual, rectal, parenteral (hypodermic routes), topical, and inhalation.

Drugs prepared for administration by one route should not be substituted by other drug forms. For example, when a client has difficulty swallowing a large tablet or capsule, *the nurse should not administer an oral solution or elixir of the same drug without first consulting the prescribing practitioner because a liquid may be more easily and completely absorbed, producing a higher blood level than a tablet.*

The nurse should be aware of the various drug forms and how they are administered. Certain drug preparations require special consideration regarding administration. For example:

- Chewable tablets are designed to be chewed before swallowing because chewing enhances gastric absorption.
- Buccal and sublingual medications must be allowed to dissolve completely before the client can drink or eat.
- Suspensions and emulsions should be administered immediately after shaking and pouring from the bottle.

ORAL ROUTE Most drugs are administered by the oral route because it is the safest, most convenient, and least expensive method. The disadvantage of the oral route is that it is slower acting than the other routes, such as injectables. Drugs may not be given orally to clients with gastrointestinal intolerance or those on NPO (nothing by mouth) status. Oral drugs should be given with caution to clients who have difficulty swallowing, such as a client who has had a cerebrovascular accident (stroke). Oral administration is also precluded by unconsciousness.

When small amounts of drugs are required, the **buccal** (cheek) or sublingual route is used. Drugs administered through these routes act quickly because of the oral mucosa's thin epithelium and large vascular system, which allows the drug to quickly be absorbed by the blood.

Certain oral drugs are prepared for sublingual or buccal administration to prevent their destruction or transformation in the stomach or small intestines. Buccal drugs are designed to be placed in the buccal pocket (superior-posterior aspect of the internal cheek next to the molars) for absorption by the mucous membrane of the mouth. Sublingual medications are designed to dissolve quickly when placed under the tongue. For example, erythryl tetranitrate (an antianginal) can be given either sublingually or buccally as prescribed,

COMMON TERMS ASSOCIATED WITH MEDICAL MANAGEMENT

- **Half-life:** The time it takes the body to eliminate half the blood concentration level of the original drug dose
- **Onset:** The time it takes the body to respond after medication administration
- **Peak plasma level:** The time it takes for a drug to reach the highest blood concentration after a single dose before the elimination rate equals the rate of absorption
- **Trough:** The lowest blood serum concentration immediately before the next scheduled dosage
- **Duration:** The time a drug remains in the system in a therapeutic concentration
- **Plateau:** Blood concentration level maintained after a series of scheduled drug doses is administered

whereas isoproterenol hydrochloride (a bronchodilator) and nitroglycerin (an antianginal) are given sublingually, and methyltestosterone (an androgen) is given only buccally.

PARENTERAL ROUTE By definition, **parenteral** means introduction of a medication by any route other than the oral-gastrointestinal route. However, medical usage of this term refers to injecting medication into body tissue. Sterile technique is always used for any medication injection. The four routes that nurses commonly use to administer parenteral medications are as follows:

- **Intradermal (ID)** is an injection into the dermis.
- **Subcutaneous** is an injection into the subcutaneous tissue.
- **Intramuscular (IM)** is an injection into the muscle.
- **Intravenous (IV)** is an injection into a vein.

Other parenteral routes (e.g., intrathecal or intraspinal, intracardiac, intrapleural, intra-arterial, and intra-articular) are used by prescribing practitioners and in some cases by advanced practice registered nurses for medication administration.

TOPICAL ROUTE Most topical drugs are given to deliver a drug at, or immediately beneath, the point of application. Although a large number of topical drugs are applied to the skin, other topical drugs include eye, nose and throat, ear, rectal, and vaginal preparations. Drugs applied directly to the skin are absorbed through the epidermal layer into the dermis, where they create local effects or are absorbed into the bloodstream. Drug action varies with the vascularity of the skin, usually requiring several applications over a 24-hour period to cause the desired therapeutic effect.

DRUG PREPARATIONS

ORAL SOLIDS

- **Tablets:** compressed or molded substances to be swallowed whole, chewed before swallowing, or placed in the buccal pocket or under the tongue (sublingual)
- **Capsules:** substances encased in either a hard or a soft soluble container or gelatin shell that dissolves in the stomach
- **Caplets:** gelatin-coated tablets that dissolve in the stomach
- **Powder and granules:** finely ground substances
- **Troches, lozenges, and pastilles:** similar preparations of drugs designed to dissolve in the mouth
- **Enteric-coated:** coated tablets that dissolve in the intestines
- **Time-release capsules:** encased substances that are further enclosed in smaller casings that deliver a drug dose over an extended period of time
- **Sustained-release:** compounded substances designed to release a drug slowly to maintain a steady blood medication level

TOPICAL

- **Liniments:** substances mixed with an alcohol, oil, or soapy emollient that are applied to the skin
- **Ointments:** semisolid substances for topical use
- **Pastes:** semisolid substances, thicker than an ointment, that are absorbed slowly through the skin
- **Transdermal patches:** contain medication that is absorbed through the skin over an extended period of time
- **Suppositories:** gelatin substances designed to dissolve when inserted in the rectum, urethra, or vagina

INHALANTS

- **Inhalations:** drugs or dilution of drugs administered by the nasal or oral respiratory route for a local or systemic effect

SOLUTIONS

- **Solutions:** contain one or more soluble chemical substances dissolved in water
- **Enemas:** aqueous solutions for rectal instillation
- **Douches:** aqueous solutions that function as a cleansing or antiseptic agent that may be dispensed in the form of a powder with directions for dissolving in a specific quantity of warm water
- **Suspensions:** particle or powder substances that must be dissolved in a liquid (shaken vigorously) before administration
- **Emulsion:** a two-phase system in which one liquid is dispersed in the form of small droplets throughout another liquid
- **Syrups:** substances dissolved in a sugar liquid
- **Gargles:** aqueous solutions
- **Mouthwashes:** aqueous solutions that may contain alcohol, glycerin, and synthetic sweeteners and surface-active flavoring and coloring agents
- **Nasal solutions:** aqueous solutions in the form of drops or sprays
- **Optic (eye) and otic (ear) solutions:** aqueous solutions that are instilled as drops
- **Elixirs:** nonaqueous solutions that contain water, varying alcohol content, and glycerin or other sweeteners

Transdermal patches, another type of topical preparation, are used to deliver medications such as nitroglycerin (antian-ginal) and certain supplemental hormone replacements for absorption by the blood to produce systemic effects. An adhesive disk secures the medication ointment to the skin. The frequency for changing the patch varies with the specific drug. The medication can last from 24 hours to 7 days.

Some topical drugs, such as eye and nasal drops and vaginal and rectal suppositories, can be applied directly to the mucous membranes. These drugs are absorbed quickly into the bloodstream, and, depending on the drug's dose (strength and quantity), may cause systemic effects.

The client may complain of a burning sensation when the nurse instills eye or nasal drops because the cornea of the eye and nasal mucous membranes are often sensitive to medications. Eyedrops should never be applied onto the sensitive cornea.

Inhalants Inhalants (e.g., oxygen and most general anesthetics) deliver gaseous or volatile substances that are almost immediately absorbed into the systemic circulation. The inhalants are delivered into the alveoli of the lungs, which promote fast absorption owing to:

- The permeability of the alveolar and vascular epithelia
- An abundant blood flow
- A very large surface area for absorption

Oropharyngeal handheld inhalers deliver topical drugs to the respiratory tract to create local and systemic effects. There are three types of inhaler: metered-dose inhaler or nebulizer, turbo-inhaler, and nasal inhaler. They are explained later in this chapter.

Intraocular Route Intraocular medications are administered by applying a clear, flexible, elliptical-shaped disk similar to a contact lens to the conjunctival sac. This provides continuous treatment of diseases such as open-angle glaucoma. Pilocarpine, a medication to treat glaucoma, can be administered in this manner. The disk can remain in the client's eye for up to a week. This route increases compliance and decreases the number of times a client must administer medication.

DRUG INTERACTION

Drug interaction refers to the effect one drug can have on another. Drug interactions may occur when one drug is administered in combination with a second drug or when a short time interval exists between the administration of two different drugs. Drugs can be combined deliberately to produce a positive effect, as when hydrochlorothiazide (a potassium-depleting diuretic) is combined with spironolactone (a potassium-sparing diuretic) to maintain a normal blood level of potassium.

A positive drug combination can also occur when one drug, such as a preoperative medication, is deliberately given to potentiate the action of another drug.

Not all drug combinations are therapeutic. Some drug combinations can interfere with the absorption, effect, or excretion of other drugs. For example, calcium products and magnesium-containing antacids can cause inadequate absorption of tetracycline (an antibiotic) in the digestive tract.

SIDE EFFECTS AND ADVERSE REACTIONS

Drug effects other than those that are therapeutically intended and expected are called **adverse reactions**. A nontherapeutic effect may be mild and predictable (**side effect**) or unexpected and potentially hazardous (adverse effect). There are several types of adverse reactions: drug allergy, drug tolerance, toxic effect, and idiosyncratic reactions.

Drug allergy (hypersensitivity) is an antigen-antibody immune reaction that occurs when an individual who has been previously exposed to a drug has developed antibodies against the drug. The type of reaction may be mild (skin rash, urticaria, headache, nausea, or vomiting) or severe (anaphylaxis). Drug reactions are often manifested in the skin because of its abundant blood supply.

Anaphylaxis is an immediate, life-threatening reaction to a drug (e.g., penicillin) characterized by respiratory distress, sudden severe bronchospasm, and cardiovascular collapse. If emergency measures (administration of epinephrine, bronchodilators, and antihistamines) are not instituted immediately, anaphylaxis can be fatal.

Drug tolerance occurs when the body becomes so accustomed to a specific drug that larger doses are needed to produce the desired therapeutic effect. For example, cancer clients with severe pain may require larger and larger doses of morphine (narcotic analgesic) to control the pain as the body builds up a tolerance to the morphine.

A **toxic effect** occurs when the body cannot metabolize a drug, causing the drug to accumulate in the blood. Toxic reactions can result after prolonged intake of high doses of medication or after only one dose.

An **idiosyncratic reaction** is a highly unpredictable response that may be manifested by an overresponse, under-response, or atypical response. For example, 1 of 40,000 clients will develop aplastic anemia after receiving chloramphenicol (an antibiotic).

Food and Drug Interactions

Medication management requires avoidance of possible food and drug interactions. There are three primary types of food and drug interaction:

1. Certain drugs may interfere with the absorption, excretion, or use in the body of one or more nutrients.
2. Certain foods may increase or decrease the absorption of a drug into the body.
3. Certain foods may alter the chemical actions of drugs, preventing their therapeutic effect on the body.

Most interaction problems occur with the use of diuretics, oral antibiotics, and anticoagulant and antihypertensive drugs (see the accompanying display on common food and drug interactions on page 757). Clients on sodium-restricted diets should be advised to consult with a pharmacist regarding the sodium content in prescription and over-the-counter drugs. Some drugs can contain almost one-half the total daily allowance of sodium. Alcohol is also considered a drug. Small amounts of alcohol interact with many drugs (e.g., antibiotics,

antihistamines, anticoagulants, sleeping pills). Food and drug interactions can vary depending on the dose and the form in which the drug is taken and the client's age, sex, body weight, nutritional status, and specific medical condition.

FACTORS INFLUENCING DRUG ACTION

Individual client characteristics such as genetic factors, age, height and weight, and physical and mental conditions can influence the action of drugs on the body. Sometimes mistaken for drug allergies, genetic factors can interfere with drug metabolism and produce an abnormal sensitivity to certain drugs.

The nurse should consider age-related factors that can influence drug action and dosing. For example, neonates and infants have underdeveloped gastrointestinal systems, muscle mass, and metabolic enzyme systems and inadequate renal function; older adults clients often experience decreased hepatic or renal function and diminished muscle mass.

The prescribing practitioner often correlates the client's age, height, and weight when determining the dosage for many drugs. The nurse should make sure that this information is recorded accurately in the client's medical record. The amount of body fat may also alter drug distribution because some drugs such as digoxin (inotropic) are poorly distributed to fatty tissues.

The client's physical condition can also alter the effects of drugs. For example, in an edematous client, the drug must be distributed to a larger volume of body fluids than for a nonedematous client; therefore, the edematous client may require a larger drug dose to produce the drug action, whereas a dehydrated client would require a smaller dosage. Diseases that affect liver and renal functions can alter the metabolism and elimination of most drugs.

PROFESSIONAL ROLES IN MEDICATION ADMINISTRATION

The prescribing practitioner determines the therapeutic drug plan and conveys the plan to others by initiating orders or a prescription. In health care settings (long-term care facilities and hospitals), medication orders are written on a prescribing practitioner's order form. Prescribing practitioners can also write medication orders on legal prescription pads or through the computer terminal. When allowed by organizational policy, the prescribing practitioner may also give medication orders via telephone or as verbal orders.

When the prescribing practitioner gives a medication order orally, either directly or over the telephone, the nurse enters the information on the medical record. This information includes the name of the prescribing practitioner who ordered the medication, the name of the medication, the

COMMON FOOD AND DRUG INTERACTIONS

DRUG EFFECTS ON NUTRITIONAL STATUS

- Abuse of antacids can lead to phosphate depletion, which can cause a vitamin D deficiency, resulting in osteomalacia, or softening of the bones due to loss of calcium.
- Excessive use of diuretics may result in the loss of electrolytes, especially potassium, that places clients with cardiac conditions at a higher risk for serious rhythm problems. Potassium loss is greatest in clients taking digitalis as well as diuretics, making the heart more sensitive to the drug.
- Prolonged use of oral contraceptives by women may cause folacin and vitamin C deficiencies if their diets are inadequate in these nutrients.
- Hydralazine (antihypertensive drug) can deplete the body's supply of vitamin B₆.

FOOD EFFECTS ON DRUG ABSORPTION

- Calcium in milk and milk products may decrease the absorption of certain antibiotics such as tetracycline.
- Certain liquids (e.g., soda pop and high-acid fruit or vegetable juices) can cause an increase in the stomach acidity that can dissolve some drugs

before they reach the intestine. Because most drugs are absorbed in the intestines, this interaction will decrease the amount of drug that can be absorbed into the body.

- Certain foods such as fatty foods can increase the rate of absorption of some drugs (e.g., griseofulvin, an antifungal).

FOOD EFFECTS ON DRUG UTILIZATION

- The effects of anticoagulants can be decreased by certain foods in the liver such as green leafy vegetables that contain vitamin K, which is used by the body to promote blood clotting.
- Aged or fermented foods (e.g., aged cheese, chicken livers) and other foods can decrease the metabolism in the body of monoamine oxidase inhibitors that are used to treat depression and high blood pressure.
- Long-term use of licorice and licorice-flavored candy or drugs can counteract the effect of high blood pressure medication.

dosage, the frequency, the route of administration, and the nurse's name. Most institutions require the prescribing practitioner to confirm oral orders within 24 hours; the nurse is responsible for ensuring that the verbal order is clear. The verbal or telephone orders should be verified (i.e., read back) verbatim by the person receiving the order. See Chapter 13 for a complete discussion of written and verbal orders and the role of the nurse in transcribing orders.

The pharmacist processes the prescribing practitioner's orders, clarifies any entries that are unclear, and prepares the medications for administration. The pharmacist is responsible for filling prescriptions and for making sure they are valid entries. Pharmacists also assess medication plans, monitoring for incompatibilities and, at times, recommending the best time to administer a medication to obtain therapeutic benefit (e.g., Lovastatin, a cholesterol-lowering drug, is most effective if taken in the evening). The pharmacist participates in calculating the appropriate dosage of certain medications such as anti-infective drugs (e.g., gentamicin). These dosages are based on the client's body weight and kidney function and may be adjusted during the course of therapy by the pharmacist with the prescribing practitioner's consent. Nurses frequently consult with pharmacists in determining compatibility if IV medications are to be administered simultaneously. Pharmacists also answer medication-related questions for both nurses and clients.

Nurses spend a great deal of time with their clients and have specific knowledge and skills that qualify them to administer medication and to evaluate a medication's effectiveness. Nurses understand why particular medications are ordered for clients and what physiological changes may result from the medications that cause therapeutic effects. Because of their knowledge, skills, and frequent client contact, nurses can readily assess changes in a client's condition and can determine whether it is appropriate to administer a medication on the basis of the client's condition.

Nurses are responsible for teaching clients to self-administer medications (e.g., insulin) and for assessing the client's ability to self-administer correctly. Before discharge, nurses teach clients about the medications they will be taking at home and how to assess for side effects and adverse reactions. Client education includes demonstration by the nurse and return demonstration by the client on how to prepare and administer the medication (e.g., an insulin injection). Even though time may be a limiting factor, it is only the nurse's observation of client performance by demonstration that ensures that clients can safely and successfully administer their own medications.

Most agencies have policies relative to medication administration, such as stop dates for certain types of drugs, regularly scheduled times to administer medications as specified in the drug order, and a listing of abbreviations officially accepted for use in the agency. The agency's medical records department maintains the official listing of abbreviations adopted by the medical staff; only abbreviations from the official list can be used in any part of the client's medical record. See the accompanying display for a list of common abbreviations used in medication orders.

The ISMP and the National Coordinating Council for Medication Error Reporting and Prevention (NCC MERP), with the support of accrediting and professional organizations, stress the importance of avoiding dangerous abbreviations and dosage expressions when communicating information about medications. For example, the apothecary symbol for dram (ʒ) is often misunderstood or misread for "3." Only the metric system should be used when communicating a medication dose, since abbreviations can be confusing. The Latin abbreviation for ear (AU, *aurio uterque*), for example, may be mistaken for the Latin abbreviation for eye (OU, *oculo uterque*). Ear or eye should be spelled out, not abbreviated. Besides the ISMP and the NCC MERP, the Joint Commission's National Patient Safety Goals specify that certain abbreviations must appear on a "do not use" list. For example, the use of U or u can easily be mistaken for a zero (4 U can be misread as 40), causing a 10-fold (or more) overdose. See Table 30-1 on page 759 for the NCC MERP listing of dangerous abbreviations that should be avoided.

TYPES OF MEDICATION ORDERS

The prescribing practitioner prescribes medications in different ways, depending on their purpose. Medications can be prescribed as stat, single-dose, standing, and prn orders.

COMMON ABBREVIATIONS USED IN MEDICATION ORDERS

ABBREVIATION	MEANING
a.c.	before meals
ad lib	freely, as desired
b.i.d.	two times a day
̄	with
cap	capsule
elix	elixir
h	hour
hrly	hourly
ID	intra dermal
IM	intra muscular
IV	intra venous
IVPB	intra venous piggyback
p.c.	after meals
per	by
PO	by mouth
prn	as needed
q	every
q2h	every 2 hours
q.i.d.	four times a day
qs	sufficient quantity
stat	immediately
supp	suppository
susp	suspension
tab	tablet
t.i.d.	three times a day
Tr or tinct	tincture

TABLE 30-1 Dangerous Abbreviations

ABBREVIATION	INTENDED MEANING	COMMON ERROR
U	Units	Mistaken for a zero (0) or a four (4), resulting in overdose. Also mistaken for “cc” (cubic centimeters) when poorly written.
µg	Micrograms	Mistaken for “mg” (milligrams), resulting in a 1000-fold overdose.
Q.D., QD, q.d., qd	Latin abbreviation for every day	The period after the “Q” has sometimes been mistaken for an “l,” and the drug has been given “QID” (four times daily) rather than daily.
Q.O.D., QOD, q.o.d., qod	Latin abbreviation for every other day	Misinterpreted as “QD” (daily) or “QID” (four times daily). If the “O” is poorly written, it looks like a period or “l.”
SC or SQ	Subcutaneous	Mistaken for “SL” (sublingual) when poorly written.
T I W	Three times a week	Misinterpreted as “three times a day” or “twice a week.”
D/C	Discharge; also discontinue	Clients’ medications have been prematurely discontinued when D/C (intended to mean “discharge”) was misinterpreted as “discontinue” because it was followed by a list of drugs.
HS	Half strength	Misinterpreted as the Latin abbreviation “HS” (hour of sleep).
cc	Cubic centimeters	Mistaken for “U” (units) when poorly written.
AU, AS, AD	Latin abbreviations for both ears; left ear; right ear	Misinterpreted as Latin abbreviations “OU” (both eyes), “OS” (left eye), or “OD” (right eye).
MgSO ₄	Magnesium sulfate	Mistaken for morphine sulfate.
MS, MSO ₄	Morphine sulfate	Mistaken for magnesium sulfate.

Stat Orders

When the prescribing practitioner writes orders, the nurse should read all of the orders to determine if any stat orders have been prescribed. A **stat order** is an order for a single dose of medication to be given immediately. Stat drugs are often prescribed in emergency situations to modify a serious physiological response; a stat dose of nitroglycerin may be ordered for a client experiencing chest pain. The nurse should assess and document the client’s response to all stat medications.

Single-Dose Orders

Single-dose orders are one-time medications or may require the administration of drops or tablets over a short period of time. The nurse should administer single-dose orders only once, either at a time specified by the prescribing practitioner or at the earliest convenient time. These drugs are often prescribed in preparation for a diagnostic or therapeutic procedure; for example, radiopaque tablets may be administered in

preparation for a gallbladder test, or a one-time order may be given for a preoperative medication.

Standing Orders

Standing orders are also referred to as *scheduled orders* because they are administered routinely as specified until the order is canceled by another order. The standing orders stay in effect until the prescribing practitioner discontinues or modifies the dosage or frequency with another order or until a prescribed number of days has elapsed as determined by agency policy. The purpose of a standing medication order is to maintain the desired blood level of the medication.

Agency policy determines the actual times for administering medications for a 24-hour time interval. For example, t.i.d. drugs may be administered at 0800, 1400, and 2000 or at 0900, 1500, and 2100. Medications ordered every day may have a specified time identified in the order, such as isophane (NPH) insulin 10 units subcutaneously at 0600, or they may be given at the agency’s designated time, for example, Lanoxin 0.25 mg PO every day at 0900.

When the order specifies the number of days or the number of dosages of the drug the client is to receive, the order has an automatic stop date to discontinue the drug. For example, the order may read tetracycline 250 mg PO q6h for 5 days. The nurse should execute this order by administering 250 mg tetracycline orally every 6 hours for 5 days for a total of 20 doses. Day 1 begins with the administration of the drug and the time the first dose is given. If the first dose of tetracycline is given on a Tuesday at 1200, and then every 6 hours, the last dose will be given on Sunday at 0600. Although the medication is given over 6 consecutive days, it totals 20 doses as ordered. Most agencies have an automatic stop date to discontinue certain medications, such as 5 or 7 days for antibiotics and 48 or 72 hours for narcotics.

prn Orders

A drug may be ordered on a **prn** (as needed) basis as circumstances indicate. The drug is administered when, in the nurse's judgment, the client's condition requires it. Before administering a prn medication, the nurse must thoroughly assess the client, using both objective and subjective data in determining the appropriateness of administering the medication. This type of order is commonly written for analgesics, antiemetics, and laxatives.

The order written by the prescribing practitioner indicates how frequently a prn medication can be given. A nurse cannot administer a prn medication more frequently than the order indicates without consulting with the prescribing practitioner for a change in that order. Examples of prn orders are meperidine (a narcotic analgesic) 75 mg IM q3–4 hours prn incisional pain and Tylenol 650 mg q4 hours prn headache. When the prn medication has been administered, the nurse documents the assessment and the time of administration. In addition, the nurse is responsible for monitoring the effectiveness of the medication and documenting the effect in the client's medical record. The nurse administers the pain medication on the basis of the assessment of the client's pain and as specified in the order.

PARTS OF THE DRUG ORDER

All orders should be written clearly and legibly, and the drug order should contain seven parts:

1. The name of the client
2. The date and time when the order is written
3. The name of the drug to be administered
4. The dosage
5. The route by which it is to be administered and special directives about its administration
6. The time of administration and frequency
7. The signature of the prescribing practitioner writing the order (e.g., the prescribing practitioner or advanced practice registered nurse)

Drug prescriptions written in settings other than acute care facilities may also specify whether the generic or trade name of the drug is to be dispensed, the quantity to be dispensed, and how many times the prescription can be refilled.

SYSTEMS OF WEIGHT AND MEASURE

Medication administration requires the nurse to have a knowledge of weight and volume measurement systems. In North America, three systems of measurement are used in medication management: metric, apothecary, and household.

METRIC SYSTEM

The metric system of weights and measures was adopted by the USP in 1890 and the *British Pharmacopoeia* in 1914 to the exclusion of all other systems except for equivalent dosages. The Council on Pharmacy and Chemistry of the American Medical Association adopted the metric system exclusively in 1944. Resistance to changing established customs interfered with the exclusive adoption of the metric system. Today, the metric system is used in every major country of the world and is used almost exclusively in U.S. medical practice.

The metric, or decimal, system is a simple system of measurement based on units of 10. The basic units can be multiplied or divided by 10 to form secondary units. The decimal point is moved to the right for calculating multiples, and the decimal point is moved to the left for division.

The basic units of measurement in the metric system are the meter (linear), the liter (volume), and the gram (mass). The metric system uses prefixes derived from Latin to designate subdivisions of the basic units and prefixes derived from Greek to designate multiples of the basic units (see the accompanying display on metric system prefixes). When the metric system is used, a zero is always placed in front of the decimal for values less than 1 (e.g., 0.5) to prevent error.

APOTHECARY SYSTEM

The apothecary system, which originated in England, is based on the weight of one grain of wheat. Therefore, the basic unit of weight is the grain (gr), and the basic unit of volume is the minim (the approximate volume of water that weighs a grain). The grain is expressed in fractions such as morphine gr 1/4. The minim (*m*) is the smallest unit of

METRIC SYSTEM PREFIXES

LATIN PREFIXES—SUBDIVISIONS OF THE BASIC UNIT

deci (1/10, or 0.1)
centi (1/100, or 0.01)
milli (1/1000, or 0.001)

GREEK PREFIXES—MULTIPLES OF THE BASIC UNIT

deka (10)
hecto (100)
kilo (1000)

volume, followed in ascending order by the fluid dram (D), fluid ounce (Z), pint (pt), quart (qt), and gallon (gal).

HOUSEHOLD SYSTEM

The household system of measurement is similar to the apothecary system of liquid measures and is the least accurate of the three systems. The units of liquid measure are drop (gtt), teaspoon (tsp), tablespoon (Tbsp), cup, and glass. Household units are often used to inform clients of the size of a liquid dose.

The USP recognizes the use of the teaspoon as the ordinary practice for household medication administration and states that the teaspoon may be regarded as representing 5 mL. Household spoons are not appropriate when accurate measurement of a liquid dose is required; therefore, the USP recommends that a calibrated oral syringe or dropper be used for accurate measurement of liquid drug doses.

APPROXIMATE DOSE EQUIVALENTS

The conversion of metric doses with the apothecary and household systems are *approximate dose equivalents* (see the accompanying display on approximate metric system equivalents on page 762). The approximate dose equivalents represent the quantities usually ordered by prescribing practitioners when using either the metric or apothecary system of weights and volumes for drug doses. If the prepared dosage form is prescribed in the metric system, the pharmacist may dispense the corresponding approximate equivalent in the apothecary system and vice versa. For example, if the prescribing practitioner prescribes morphine gr 1/4, the pharmacist may dispense morphine 15 mg. The USP and NF reference *exact equivalents* that must be used to calculate quantities in pharmaceutical formularies and prescription compounding.

CONVERTING UNITS OF WEIGHT AND VOLUME

The nurse has to apply the knowledge of measurement systems and their conversions when the prescribing practitioner prescribes a drug dosage in one system and the pharmacy dispenses the equivalent dose in another. Given the above example of morphine, if the prescribing practitioner orders morphine gr 1/4 and the pharmacist dispenses morphine 15 mg, the nurse is responsible for ensuring the correct dose. The nurse knows that 1 grain equals 60 milligrams; to convert the ordered dose to milligrams, the nurse should use the following calculation:

$$\begin{aligned} 1 \text{ gr} &= 60 \text{ mg} \\ x &= 1/4 \text{ gr} \times 60 \text{ mg/gr} \\ &\text{(the grains cancel out)} \\ x &= 60/4 \text{ mg} \\ x &= 15 \text{ mg} \end{aligned}$$

Measurement Conversions within the Metric System

Because the metric system is based on units of 10, dose equivalents within the system are computed by simple arithmetic, either dividing or multiplying. For example, to change milligrams to grams (1000 mg equals 1 g) or milliliters to liters (1000 mL equals 1 L), divide the number by 1000:

$$\begin{aligned} 250 \text{ mg} &= x \text{ g} \\ &\text{(move the decimal point three places to the left)} \\ x &= 0.25 \text{ g} \\ &\text{or} \\ 500 \text{ mL} &= x \text{ L} \\ &\text{(move the decimal point three places to the left)} \\ x &= 0.5 \text{ L} \end{aligned}$$

To convert grams to milligrams or liters to milliliters, the nurse multiplies the number by 1000:

$$\begin{aligned} 0.005 \text{ g} &= x \text{ mg} \\ &\text{(move the decimal point three places to the right)} \\ x &= 5 \text{ mg} \\ &\text{or} \\ 0.725 \text{ L} &= x \text{ mL} \\ &\text{(move the decimal point three places to the right)} \\ x &= 725 \text{ mL} \end{aligned}$$

The nurse may need to convert the volumes of liters and milliliters for enemas and irrigating solutions such as for bladder and wound irrigations. IV solutions are sterile, prepackaged solutions dispensed in volumes as ordered by the prescribing practitioner, such as 50 mL, 100 mL, 250 mL, 500 mL, and 1000 mL (1 liter).

Measurement Conversions between Systems

When converting grains to milligrams, the nurse must multiply by 60. For example, if the prescribing practitioner orders nitroglycerin (an antianginal) 1/150 gr PO for chest pain, the dispensed dose will be 0.4 mg:

$$\begin{aligned} 1 \text{ gr} &= 60 \text{ mg} \\ x &= 1/150 \text{ gr} \times 60 \text{ mg/gr} \\ &\text{(the grains cancel out)} \\ x &= 1/150 \times 60/1 \text{ mg} \\ x &= 60/150 \text{ mg} \\ &\text{(divide 60 by 150)} \\ x &= 0.4 \text{ mg} \end{aligned}$$

The nurse converts between pounds and kilograms (2.2 lb = 1 kg) by dividing or multiplying by 2.2. For example, if the ordered dose is 10 mg/kg and the client weighs 150 lb:

$$\frac{150 \text{ lb}}{2.2 \text{ lb/kg}} \times \frac{10 \text{ mg/kg}}{x}$$

APPROXIMATE METRIC SYSTEM EQUIVALENTS

LIQUID MEASURE (VOLUME)

METRIC	APOTHECARY	HOUSEHOLD
5 mL	= 1 fluid dram	= 1 teaspoonful
10 mL	= 2 fluid drams	= 1 dessertspoonful
15 mL	= 4 fluid drams	= 1 tablespoonful
30 mL	= 1 fluid ounce	= 1 ounce
60 mL	= 2 fluid ounces	= 1 wineglassful
120 mL	= 4 fluid ounces	= 1 teacupful
240 mL	= 8 fluid ounces	= 1 tumblerful
500 mL	= 1 pint	= 1 pint
1000 mL	= 1 quart	= 1 quart
4000 mL	= 1 gallon	= 1 gallon

WEIGHT

METRIC	APOTHECARY
1 mg	= 1/60 grain
4 mg	= 1/15 grain
10 mg	= 1/6 grain
15 mg	= 1/4 grain
30 mg	= 1/2 grain
60 mg	= 1 grain
1 g	= 15 grains
4 g	= 1 dram
30 g	= 1 ounce
500 g	= 1.1 pound
1000 g (1 kg)	= 2.2 pounds

(the lb and kg cancel out)

$$x = 68.2 \times 10 \text{ mg}$$

$$x = 682 \text{ mg}$$

In clinical settings, household measures are used for bedside recording of intake so that the client or family member can record the volume ingested by the client. Agencies have a legend on their intake form with the approximate conversions from household to metric volume measures based on the type of containers used in that specific agency. See Chapter 33 for the procedure for measuring intake and output. Home health nurses often have to convert a liquid dose to an approximate household unit.

DRUG DOSE CALCULATIONS

Several formulas may be used by the nurse when calculating drug doses. One formula uses ratios based on the *dose on hand* and the *dose desired*. For example, cephalexin (antibiotic cephalosporin) 500 mg PO q.i.d. (dose desired) is ordered by the prescribing practitioner; the dose on hand is 250 mg/5 mL. The formula is as follows:

$$\frac{250 \text{ mg (dose on hand)}}{5 \text{ mL (dose on hand)}} = \frac{500 \text{ mg (dose desired)}}{x(\text{dose desired})}$$

(cross-multiply)

$$250x = 5 \times 500$$

$$x = \frac{5 \times 500}{250}$$

$$x = 10 \text{ mL}$$

The ratio formula can be used in calculating dosages. For example, the prescribing practitioner orders heparin (anticoagulant) 10,000 units SC; the dose on hand is 40,000 units/mL:

$$\frac{40,000 \text{ units}}{1 \text{ mL}} \times \frac{10,000 \text{ units}}{x}$$

(units cancel out)

$$40,000x = 10,000$$

$$x = \frac{10,000}{40,000}$$

$$x = 1/4$$

$$x = 0.25 \text{ mL}$$

Pediatric Dosages

Several rules have been devised to calculate infants' and children's dosages (e.g., *Young's rule*, *Clark's rule*, and *Fried's rule*), but these rules give only approximate dosages. Even when pediatric drug dosages are calculated on body surface area, weight, and age of the child, they are based on a proportion of the usual adult dose (approximate). Regardless of the method used in calculating pediatric drug dosages, the nurse should realize that dosages are approximate and often need adjustment based on the child's response.

The body surface area method of determining pediatric doses is based on the body surface area of an adult weighing 150 lb. The body surface area of an adult weighing 150 lb is 1.73 square meters. The approximate child dose is calculated as follows:

$$\frac{\text{Body surface area of child}}{\text{Body surface area of adult}} \times \text{adult dose}$$

$$= \text{approximate child dose}$$

$$\frac{\text{Body surface area of child (m}^2\text{)}}{1.73 \text{ m}^2} \times \text{adult dose}$$

$$= \text{approximate child dose}$$

Nomograms based on height and weight are used to compute the body surface area (see Figure 30-2 on page 763). A straight line is drawn from the client's height in the left column to the client's weight in the right column. The point at which this line intersects the body surface area column (designated SA) indicates the body surface area. Nomograms are used primarily in calculating pediatric drug dosages; however, they are also used when calculating some adult drug dosages (e.g., aminoglycosides and antineoplastic agents).

Text not available due to copyright restrictions

5 rights. Sometimes other system failures occur; for example, during the ordering, transcribing, and dispensing process, errors may occur. In an effort to further reduce medication errors, some institutions have enlarged the 5 rights to 7 or 10 rights, such as right reason or right documentation. Standards of nursing practice still refer to the basic right 5s, as shown in the accompanying display.

Right Drug

Before administering any medication, the nurse compares the medications listed on the MAR, other recording forms, or computer orders against the prescribing practitioner's order. When administering a medication, the nurse should check the label written on the container against the MAR at least three times before giving the drug. The nurse should:

1. Check the label when removing the drug container from the client's medication drawer.
2. Check the drug when removing it from the container.
3. Check the drug before returning it to the client's medication drawer.

Some medications come in a unit-dose prepackaged form. The nurse should check the medication a third time even though there would be no container to return to the drawer. This third check should be done at the bedside before opening the unit-dose medication.

The nurse should give only medications that the nurse has prepared and checked. The nurse who administers the medication is the responsible party should an error occur. If a client questions a medication to be administered, the nurse should never ignore the question. Clients are active participants in their care and usually know when a medication is different from that usually taken. The nurse should withhold this medication until the order can be rechecked. Frequently, the medication order has changed, but the client question can stop an error before it occurs.

If the client refuses a medication, it should be discarded rather than returned to the original container. Unit-dose medications that have not been opened can be saved.

Right Dose

The unit-dose system was implemented to help decrease medication errors. However, there are times when medications on hand are in a larger volume or strength than needed. Careful calculation is especially important when the prescribing

SAFE DRUG ADMINISTRATION

Nurses must administer numerous drugs daily in a safe and efficient manner. The nurse should administer drugs in accord with nursing standards of practice and agency policy. The safe storage and maintenance of an adequate supply of drugs are other responsibilities of the nurse.

The nurse documents the actual administration of medications on the medication administration record, or MAR. The MAR is a medical record form that contains the drug's name, dose, route, and frequency of administration. Drug data are entered either by the nurse when transcribing the order (handwritten onto the form) or by the pharmacist when dispensing the order (a computer-generated pharmacy MAR form is shown in Figure 30-3 on page 764).

GUIDELINES FOR MEDICATION ADMINISTRATION

To protect the client from medication errors, nurses have traditionally used as a guideline the "5 rights" of drug administration. The 5 rights help prevent medication error; however, errors can still occur even when nurses diligently follow the

FIGURE 30-3 Computerized Pharmacy Medication Administration Record (MAR) DELMAR/CENGAGE LEARNING

practitioner orders a unit of measurement different from what is supplied by the pharmacy.

The nurse must know how to reduce the risk of error by correctly calculating doses and having them double-checked before administration. Policy in some agencies, for instance, mandates that two nurses check insulin dosages to ensure accuracy. After calculations have been completed, the nurse should prepare the medication using appropriate measurement devices such as graduated measuring cups, syringes, and droppers.

To prepare scored or crushed medications, the nurse should make sure scored tablets are broken evenly. This practice will prevent overdosage or underdosage of a medication. If the medication has to be crushed with a mortar and pestle, the nurse should thoroughly cleanse the pestle after each use. Cleansing the pestle will avoid mixing of different medications and will prevent the client from receiving minute amounts of a medication that may cause serious adverse effects.

Right Client

The nurse should correctly identify the client by using at least two client identifiers. Compare the client's name and one other identifier, usually the hospital identification number on the identification bracelet with the MAR (see Figure 30-4 on page 765). Ask the client to state his or her name, if possible, for a third identifier. Identification bracelets that become blurred or are missing for any reason should be replaced. The nurse needs to obtain a new identification band for the client. Verify the identification by asking the client to state his or her full name before placing the new band on the client's arm.

Right Route

The route of the medication is specified in the written order. The nurse should consult the prescribing practitioner whenever a route is not identified in the prescription, when the route indicated differs from the recommended one, or when the

FIGURE 30-4 Check a client's identification band before administering medication. DELMAR/CENGAGE LEARNING

nurse questions the choice of route prescribed. For example, the nurse should not substitute an oral medication for an IM medication simply because the oral medication is available and the IM one is not.

Injecting a medication designed to be administered orally can cause adverse reactions such as a sterile abscess at the injection site. Medications for parenteral injections should be prepared from medications designed for this purpose. Manufacturers of medications label medications that can be used for parenteral injections as “for parenteral use only.”

Right Time

Medications are generally ordered on a schedule. Nurses are responsible for knowing why a medication is ordered on a certain schedule and for following that schedule as closely as possible. A drug should not be given more than a half hour before or after the scheduled time (according to organizational policy) without first checking with the prescribing practitioner. Some computerized programs, such as bar coding, discussed later in this chapter, have increased the window for administering medications from 1 hour to 2 hours to provide the nurse with additional time to avoid having to document a “late” dose of medication.

To maintain the drug's effect, the nurse has to give the medication in a timely manner. Some medications must be given at a certain time for proper therapeutic effect; for example, insulin should be given at a set time before meals. These types of drugs should be administered as ordered. See the Nursing Checklist on page 766 for guidelines that ensure the safe administration of medications.

In the home health and community care settings (e.g., a retirement home), the nurse has different responsibilities regarding drug safety (see Figure 30-5). The nurse should promote drug safety measures that are appropriate to the environment and inherent risk factors (see the accompanying display on drug safety considerations on page 766).

FIGURE 30-5 A pill box correlated to the days of the month can help the client follow her medication regimen. DELMAR/CENGAGE

LEARNING

DOCUMENTATION OF DRUG ADMINISTRATION

A critical element of drug administration is documentation. The standard is “if it was not documented it was not done.” Many drug errors can be avoided with appropriate documentation. The nurse responsible for administering the medication must initial the medication on the MAR near the time the drug is scheduled after the client has taken the drug. Usually there is a space available for a full signature on the record.

If the client refuses to take a medication once it has been prepared, the nurse must indicate that a dose was missed. In some hospitals, a circle is placed around the time the medication was scheduled to be given. The nurse should write in the record why the dose was missed and notify the prescribing practitioner. The client may have refused because the tablet was too large. The medication may be supplied as a liquid so an alternate form of the medication can be given; the nurse must request that the prescribing practitioner change the order to a liquid. Clients do have the right to refuse medications. However, if clients understand the actions of the medication, they may be willing to take the medication. Clients who are scheduled for various diagnostic tests or treatments at the time the medication is to be administered will need to have the medication times rescheduled.

DRUG SUPPLY AND STORAGE

Drugs are dispensed by the pharmacy to nursing units through various methods to accommodate the agency's medication system. Once the pharmacy delivers the drugs to a nursing unit, the nurse is responsible for their safe storage.

Scheduled drugs for each client are usually dispensed in a **unit-dose form**. Unit dose is a system of packaging and labeling each dose of medication by the pharmacy, often to supply a 24-hour time period. The pharmacy usually delivers the drugs and stores the drugs in the designated area for each client. Unit-dose drugs are usually stored in a medication cart that contains individual drawers for each client's medication supply or in the medication room in a separate, organized

NURSING CHECKLIST

Guidelines for Safe Administration of Medications

- Never administer medications that are prepared by another nurse. The nurse is responsible for a medication error when administering a medication that was inaccurately prepared by another nurse.
- Nurses should listen carefully to the client who questions the addition or deletion of a medication. Most clients are aware of their prescribed medications. If a client questions the drug or dose the nurse is preparing to administer, the nurse should recheck the order.
- If a medication is withheld, indicate the exact reason why in the client's record. Legally the nurse is accountable for giving ordered medications to the client; however, circumstances may prevent the nurse from giving a medication as ordered. Medications may be held for some diagnostic tests, or the client receiving antihypertensive medications may have a blood pressure that is lower than normal. If the nurse gave the antihypertensive, the blood pressure would decrease, causing further hypotension.
- *Do not leave medications at the client's bedside for any reason.* The client may forget to take the medication, medications can accumulate, and the client could take two or more of the same medication, causing an overdose, or another client who is confused could take the medicine.
- Initial the MAR only for those medications actually administered. This practice ensures accurate charting by clearly indicating which actions the nurse has performed.
- Advise clients not to take medications belonging to others and not to offer their medications to others. Medications are ordered for each client on the basis of the history, physical examination, and effectiveness of the medication.

container for each client. The unit-dose system has made it easier for nurses to administer the correct dose, thereby reducing the number of medication errors.

The nurse, usually at the beginning of each shift, checks the medications in each client's drawer. Some medication carts are locked, and the nurse keeps the key. Medication drawers should be removed only one at a time from the cart when the nurse is preparing the medication for administration. The client's drawer should never be left unattended on top of the cart. Drugs should not be removed from one client's supply for administration to another client.

DRUG SAFETY CONSIDERATIONS IN HOME HEALTH AND COMMUNITY CARE SETTINGS

- Help the client remove outdated prescriptions and over-the-counter drugs from medication cabinets. The chemical composition may change over time, causing a different drug action. Over-the-counter drugs may interact with prescription drugs, either by decreasing or potentiating the effects of the prescription medication.
- Encourage the client or caregivers to maintain drug refills to decrease the risk of missing scheduled medications.
- Use a mechanism such as a paper clock, reminder calendar, or pill box to help the client or caregiver remember to take or administer prescribed medications as scheduled.

Certain drugs are **stock supplied** (dispensed and labeled in large quantities) and stored in the medication room or other area on the nursing unit. Stock supplies are kept together in a secured area.

Certain IV fluids and medications must be stored in the medication refrigerator to preserve the integrity of the drug. The Public Health Department and accrediting agencies mandate that only drugs can be stored in the medication refrigerator.

Narcotics and Controlled Substances

Health care agencies have forms to record the supply on hand and the administration of narcotics and controlled substances in accord with federal regulations. These forms usually require the recording of the following information for each drug administered:

- Name of the client receiving the drug
- Amount of the drug used
- Time the drug was administered
- Name of the prescribing practitioner
- Name of the nurse administering the drug

Nursing practice usually requires that nurses count the narcotics and controlled substances at specified intervals. For example, at the change of shifts, one nurse who is going off duty counts the drugs with a nurse coming on duty. Each drug used must be accounted for on the narcotic record. When the narcotic count does not check, the nurse must report the discrepancy immediately. Narcotics and controlled substances are kept in a double-locked drawer, box, room, or medication-dispensing cart. The law requires these safety precautions in the use of narcotics and controlled substances to aid in the control of drug misuse. If for any reason a narcotic has to be discarded, a second person should act as a witness and that person should also sign the narcotic sheet.

DRUG ABUSE

Federal, state, and local rules regulate the appropriate use of drugs. Despite these rules, some people use drugs for purposes other than their proper use, seriously jeopardizing their health. Misuse of drugs also creates problems for family members and the community as a whole. “The American Medical Association and the World Health Organization have both recognized addiction as an illness, not a lack of willpower” (Dossey & Keegan, 2008, p. 514). **Addiction** is defined as a physiological or psychological dependence on a substance, such as alcohol or morphine, or a behavior such as eating, gambling, working, or engaging in sexual intercourse. The rest of this discussion focuses only on substance abuse.

Nursing practice requires the nurse to be knowledgeable about the addictive process in order to assess and care for clients with drug toxicity or overdose and withdrawal. Continual or periodic use of drugs may lead to **dependence** (reliance on or need to take a drug). The term *chemical dependence* is often used as a more inclusive term than *drug dependence* because it includes problems with *all mind-altering substances that have the potential of creating dependence* (Crosby & Bissell, 1989).

Addiction implies more than a physical dependence alone, and it does not refer exclusively to illicit drugs. Illicit drugs are substances sold illegally, such as cocaine, PCP (angel dust), hallucinogenic agents (LSD and peyote), and cannabinoids (marijuana and hashish). There are two types of drug dependence that can occur separately or together:

- **Physiological dependence:** the biochemical changes in body tissues that occur when the tissue depends on a substance for normal functioning; cessation of the substance causes physical withdrawal symptoms.
- **Psychological dependence:** the emotional reliance on a substance to maintain a sense of well-being; the degree of psychological dependence can vary from a mild desire to an intense craving or compulsion for the substance.

Although there are many types of addictions to various substances, alcohol addiction is the most prevalent one in the United States, afflicting at least 11 million people (Dossey & Keegan, 2008). The nurse should be able to identify the characteristics of substance abuse (see the accompanying display on the characteristics of alcoholism) and work together with other health care team members in planning the care for clients experiencing the disorder.

Nurses and other health care providers (prescribing practitioners, dentists, and pharmacists) are at risk for substance abuse because of their access to drugs such as benzodiazepines (Valium, Librium), sedative hypnotics (Nembutal, Placidyl), amphetamines (Dexedrine, Benzedrine), and narcotics (meperidine, morphine). The actual incidence of chemical dependence among nurses and other health care professionals is difficult to document; however, it is estimated that 6% to 16% of registered nurses in the United States are chemically dependent (Crosby & Bissell, 1989). The difficulty of obtaining factual data for the number of chemically addicted nurses is often related to the reluctance of professionals to report one another.

COMMON CHARACTERISTICS OF ALCOHOLISM

- Denial that there is a drinking problem
- Rationalization
- Restlessness, impulsiveness, anxiety
- Selfishness, self-centeredness, lack of consideration
- Irritability, anger, rage
- Physical cruelty; child, spouse, or older adult abuse
- Depression, isolation, self-destruction
- Low self-esteem, shame, guilt, remorse, loneliness
- Susceptibility to disease

From Dossey, B. M., & Keegan, L. (2008). *Holistic nursing: A handbook for practice* (5th ed.). Sudbury, MA: Jones & Bartlett.

Although it may be uncomfortable to report an addicted colleague, nurses have a moral responsibility to report the situation to the appropriate authority. Nurses who are addicted may display suspicious behaviors such as insisting on carrying the narcotic keys and volunteering to administer all of the narcotics during the shift. See the accompanying display for other behavioral characteristics of drug-addicted nurses on page 768.

In 1983, Florida was the first state to enact a “diversion” law as an alternative to disciplinary proceedings against substance abusers. Florida’s diversion program is called the Intervention Project for Nurses and has served as a model for other states to create similar programs such as impaired nurse programs. “A structured recovery program which identifies the problem, helps restore the individual to a state of biological, psychological, social and spiritual well-being, and provides monitoring during recovery can contribute to the return to safe practice” (Tallant, 2008, p. 6). These programs provide support, confidentiality, and stringent on-the-job monitoring and allow the nurse to maintain licensure as long as the nurse complies with the program. An impaired nurse program is a welcomed alternative for nurses with addictive behaviors and has increased the reporting of nurses with addiction problems. (Contact the state board of nursing office to inquire about alternative programs to disciplinary measures.)

More recently, some hospitals have taken a proactive role in combating the problem of drug abuse among nurses with the use of a computer-controlled dispensing system (see Figure 30-6 on page 768). With this system, the likelihood of the nurse’s abusing narcotics is markedly decreased. The nurse enters a private security code. The system will provide the nurse with a printout of the medications given to the client and will charge the client. This dispensing system eliminates stock supplies of narcotics and controlled drugs, decreasing the nurse’s access to these drugs.

CHARACTERISTICS OF DRUG-ADDICTED NURSES IN THE WORKPLACE

- Exhibit extreme and rapid mood swings
- Always wear long sleeves
- Sign out more controlled drugs than anyone else
- Report frequent spills and breakage of controlled drugs
- Commit multiple medication errors
- Practice illogical or sloppy charting
- Are frequently absent from work
- Come to work early and stay late
- Frequently use sick leave

MEDICATION COMPLIANCE

Medication compliance can be associated with the client's understanding of why a medication was ordered and how a medication can decrease the likelihood of getting a disease or how it can lessen the effects of an existing disease. When clients do not consistently take their prescribed medications, or when they adjust the scheduling or dose of the medication, they are *noncompliant*.

There are several reasons why clients choose not to take ordered medications. If a hypertensive client is asymptomatic (without distress), it may be difficult for the client to understand the need to take prescribed medications. If medications are taken, the dose may be altered at the discretion of the client. Medications are costly, and the client may be on a fixed income or unemployed. If the medication does not provide prompt relief, the client may consider the medication useless and discontinue it. The medication may be discontinued if the client experiences undesirable side effects, such as dizziness, impotence, or weight gain.

Compliance can be enhanced if the client is given information on the medication to take home when discharged

Legal and Ethical

Chemical Dependence

If you were practicing in a state where the only action from the state board of nursing in the situation of an addicted nurse was license suspension or revocation, would you report a fellow nurse? If you did not, what could happen to the clients under the nurse's care, and what would be the legal implications for you? Likewise, if you were addicted, what would be the implications for your continued nursing practice?

from the hospital. Large-type print or illustrations should be used with older clients. Caregivers should be included when educating the client. Scheduling the medications around certain activities of daily living may serve as a reminder to the client that the medication must be taken. Providing the client with a telephone number and the name of a nurse to call if questions arise can ensure compliance.

The nurse in the community has an opportunity to see how medications are arranged in the client's home. Outdated medications must be discarded. After consulting with the client and caregiver, the nurse can make suggestions that may improve compliance.

Nurses have to remember that many older clients take a multitude of drugs. Some drugs actually cancel each other out when taken together, thus eliminating the therapeutic response. A client taking BuSpar and digoxin may experience digoxin toxicity. BuSpar may displace the serum binding of digoxin and increase the toxic levels of that drug. Nurses must sort through the medications with the client and report back to the prescribing practitioner the drugs taken in addition to those ordered by that practitioner.

LEGAL ASPECTS OF ADMINISTERING MEDICATIONS

Clients are awarded settlements in malpractice suits when nurses are negligent in their practice. Negligence exists any time the nurse fails to do something that a reasonable nurse would do under similar circumstances or does something that a reasonable nurse would not do. Malpractice is any professional misconduct or unreasonable lack of skill in professional duties. See Chapter 12 for related information on legal issues.

MEDICATION ERRORS

Nurses have learned the five rights as a guideline to safe administration of medications. If the nurse gives the wrong medicine to the wrong person, an error has been made. If the

nurse has the right medicine but wrong dose or wrong route, a medication error has been made. If the nurse gives the medication at the wrong time, an error has been made. Nurses must inform the prescribing practitioner of the error made. If an antidote must be given, the prescribing practitioner needs accurate information to make appropriate care decisions.

Medication errors must be reported in a timely manner. Knowing the actions and the side effects of drugs will help the nurse assess the client's response and health status. Event reports are required in some institutions to document medication errors. A report of a medication error must include the name of the medication, the dose given, the route, the time the medication was administered, the specific error that occurred, the time the prescribing practitioner was contacted about the error, and what countermeasures were taken. Sometimes nurses discover errors made by other nurses. These must also be documented and reported. Brooke (2008) recommends documentation of all nursing care associated with the error, including interventions and any follow-up care, in the client's medical record, stating only the facts without blaming anyone or expressing one's opinion. The event report should not be mentioned in the medical record, or it may become admissible in court if a lawsuit develops.

Questioning the Medication Order

The nurse is responsible and held accountable for questioning any medication order if, in the nurse's judgment, the order is unclear or in error. The nature of the error may be in any part of the drug order, and the nurse should seek clarification from the prescribing practitioner. A drug error has serious legal implications if the nurse involved could have been expected, on the basis of knowledge and experience, to have noted the error.

If the prescribing practitioner disregards the nurse's query, another line of authority must be pursued by the nurse to prevent a drug error. The medication in question should not be administered until the order has been clarified. The nurse should withhold any drug when the client's health may be jeopardized. Notify the prescribing practitioner of the need to withhold the medication and the reason withholding it is necessary. Document the reason for withholding the drug (e.g., withholding a dose of an antihypertensive medication due for a client who is currently experiencing hypotension) on the MAR and the nurse's notes.

When the nurse is not able to read or understand the order, the prescriber should be contacted for clarification. The nurse should not *guess* what the prescriber who wrote the order is trying to communicate; the only safe nursing action is to validate the order with the prescribing practitioner.

PREVENTING MEDICATION ERRORS

In the United States, medication errors are responsible for one death every day and injure an estimated 1.3 million people annually. The number of serious drug errors continues to increase. According to the FDA:

- Errors doubled between 1998 (34,966) and 2005 (89,842).

- The number of fatal adverse drug events increased 2.7-fold during the same period.
- The medications most frequently implicated in deaths included oxycodone, fentanyl, clozapine, morphine, acetaminophen, infliximab, interferon beta, and etanercept (Moore, 2007).

The public's awareness of medication errors in health care has been heightened by media coverage in recent reports; the public's response has been a demand for a safe health care system. The NCC MERP defines *medication error* as follows:

A medication error is any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professional, patient, or consumer. Such events may be related to professional practice, health care products, procedures, and systems, including prescribing; order communication; product labeling, packaging, and nomenclature; compounding; dispensing; distribution; administration; education; monitoring; and use. (2008, p. 1)

The NCC encourages the use of their medication error definition by researchers, software developers, and institutions to ensure a common taxonomy.

In 1999 the Institute of Medicine (IOM) released its report *To Err Is Human: Building a Safer Health System*. Two consecutive IOM reports, *Crossing the Quality Chasm* and *Priority Areas for National Action: Transforming Health Care*, positioned medication errors as a priority and recommended that immediate action be taken to improve this aspect of health care. The IOM reports recommended the creation of a center for client safety within the Agency for Healthcare Research and Quality (AHRQ). In 2001 Congress established a new Center for Quality Improvement and Patient Safety in the AHRQ. This center is responsible for monitoring medication errors.

Since the publication of the IOM reports, health care providers, policy makers, and accreditation and professional organizations (e.g., the Joint Commission and the American Nurses Association [ANA]) have reviewed the process of medication administration to identify the true incidence of errors and to assist with the development of national standards to promote safe medication practices. Although many of the studies regarding medication errors recognize that the systems in place or the lack of these systems, and not the prescribing practitioners, account for many of the errors, the nurse has an obligation to provide safe client care in accordance with standards of practice.

Besides the dangers inherent in certain abbreviations or dose designations for medications, discussed previously, errors may also occur as a result of misreading drugs, drug abbreviations, and decimals. These errors are a result of similar brand and generic names, compounded by illegible handwriting, new drugs, and similar packing or labeling of drugs. The abbreviation for magnesium sulfate is $MgSO_4$; however, it may be misinterpreted for morphine sulfate (MSO_4). The use of decimals and zeros is another cause of errors. For example, a zero used after the decimal in 1.0 mg may cause the dose to be misread as 10 mg if the decimal point is not

seen; likewise, when a zero is not used before the decimal in a dose of .5 mg, the dose may be misread as 5 mg. Zeros should always be used before a decimal when the dose is less than a whole unit, and terminal zeros should not be used for doses expressing whole numbers.

Many of the solutions under study to create a safer health care system for medication administration rely on computer programs. In 2003, the FDA proposed regulation requiring drug manufacturers to place bar codes on the labels of all prescription and over-the-counter drugs that are frequently used in hospitals; pharmaceutical manufacturers, drug repackagers, and distributors would have 3 years to comply. According to the FDA, the bar code would have the drug's national drug code (NDC) that uniquely identifies the drug, its strength, and its dosage form. The FDA indicated that a bar-coding system coupled with a computerized order entry system would promote compliance of the five rights of medication administration for all health care workers. A client's medical regimen and MAR would be entered into the hospital's database and encoded in the client's identification armband and would be accessible to a nurse through a handheld device. When the armband was scanned by the device, the client's MAR would be displayed from the hospital's database. The nurse would scan the bar code, the client's identification armband, and the code on his or her identification badge; the mainframe computer would process the scanned information, updating the MAR and regimen appropriately.

The Veterans Health Administration (VHA) pioneered a computer-based bar-coding system, Bar Coding in Medication Administration (BCMA), in one of its facilities in 1995. Although only 2% of U.S. hospitals use bar codes, in 2000 all 173 VHA facilities nationwide were directed to have bar codes on all medications that could be scanned by a nurse using a handheld device. Although the VHA nurses documented this new system for medication administration as being safer, it is more time consuming. Reports generated by the bar-coding system identify all "late" entries as an error; errors are tracked by the system. Therefore, the VHA adjusted the "right time" to provide medication from the standard 30 minutes to an

hour before or after the prescribed time. The warning for avoiding errors caused by the use of terminal zeros with doses expressed in whole numbers is applicable with computer prescribing as well as handwritten entries.

ASSESSMENT

Drug administration is based on assessment data obtained by reviewing the client's medical history, eliciting a drug history, performing a physical examination, and obtaining and interpreting relevant laboratory results. Assessment is an ongoing process and requires the knowledge, skills, and abilities of a licensed professional.

MEDICAL HISTORY

The client's medical history is obtained by the nurse when conducting the interview assessment and by reviewing the client's medical record. The nurse should identify all chronic diseases and disorders and correlate these data with the drugs prescribed by the prescribing practitioner. Because the client may have more than one prescribing practitioner, the admitting prescribing practitioner might not be aware of all the drugs the client is taking, including over-the-counter medications. It is the nurse's responsibility to gather this information and document it on the client's chart.

Preexisting conditions such as liver and kidney dysfunction may require drug alteration because they prolong drug action, thereby increasing the potential for toxicity. The nurse needs to elicit this type of information during the medical history so that these clients can be closely monitored for signs of adverse reactions to drugs.

DRUG HISTORY

A drug history is obtained on admission to a health care facility. The drug history should contain specific questions about the client's background: allergies, prescription and over-the-counter drugs, herbal supplements, medical history, biographical data, lifestyle and beliefs, and sensory and cognitive status. See Chapter 6 for a complete discussion of taking a health history. If the client is unable to answer the questions, the nurse should contact a family member to obtain the data. Drug history data are used by nurses in determining the client's plan of care and learning needs.

Allergies

The nurse should inquire about all food and drug allergies. If the client has had an allergic reaction to a drug, the nurse should have the client describe the details of the reaction: name of the drug; dosage, route, and number of times the drug was taken before the reaction; onset of the reaction; and manifestations of the reaction. The nurse should question the client about possible contributing factors to the allergic reaction, such as concurrent use of stimulants (tobacco, alcohol, or illegal drugs) or significant changes in nutritional status.

SPOTLIGHT ON...

Legal & Ethical

Medication Error

While monitoring a client who has an order for Solu-Cortef (an anti-inflammatory drug) intravenously, you notice that Solu-Medrol (an anti-inflammatory drug) is in the client's room. You recheck the order to make sure that the original order was for Solu-Cortef and that the order was not changed. What should your next action be? How do you feel about the nurse who made the medication error but did not recognize it?

The nurse should also ask about allergies to foods because drugs may contain the same elements or nutrients that cause allergic reactions to some foods. For example, clients who are allergic to shellfish may also experience a reaction to drugs containing iodine. Vaccines are commonly derived from chick embryos and would be contraindicated in clients with allergies to eggs.

Allergies to food and drugs, including over-the-counter drugs and herbal supplements, should be noted in the client's record, in the admission note, on the MAR, and on the history and physical examination forms. The pharmacy should be notified of any drug or food allergies. In hospitals, clients wear allergy alert bands that list all medications to which the person is allergic. Nurses in all settings should discuss the use of medical alert bracelets by clients with allergies. These bracelets inform prescribing providers of allergies should the person not be able to speak.

Prescription Drugs

The nurse should have the client identify all current prescription drugs and describe:

- Why the drug was prescribed and by whom
- The drug's dosage, route, and frequency
- The client's knowledge of the drug's action: side and adverse effects, when to notify the prescribing practitioner, and special administration considerations such as with or without foods

If the client is receiving any drug that requires monitoring before administration such as insulin (antidiabetic hormone), the nurse needs to make sure the client is checking blood sugar and that the results are within normal limits.

Over-the-Counter Drugs

Clients usually have to be questioned separately about nonprescription drugs because they often fail to identify these drugs when asked to list all the medications they take routinely. For example, the nurse must determine if the client takes aspirin, antacids, or laxatives routinely. The client should describe the dosage, route, and frequency of these drugs. Because many drugs are available in topical form, the nurse should also inquire about the use of creams, ointments, patches, or sprays. Clients admitted to inpatient facilities should be asked if they have any over-the-counter drugs with them.

The nurse should explain to the client in a sensitive manner why these questions are necessary in order to allay any anxieties that might arise from this nature of questioning. Depending on the dosage and frequency, nonprescription drugs may have a profound effect on the client's treatment.

Complementary Therapy

The practice of healing has always incorporated the use of herbs as medicines. The World Health Organization recognizes that of 119 plant-derived pharmaceutical medicines, about 74% are used in modern medicine in ways that are correlated directly with their traditional uses as plant medicines by native cultures. An estimated 25% of all pharmaceuticals

are derived directly from plants (White & Foster, 2007): For example, quinine (an extract from the South American *cinchona*) is used to treat malaria; digitalis, which comes from foxglove, is an inotropic drug used to treat congestive heart failure; and the active components of periwinkle, vinblastine, and vincristine are used in the treatment of certain cancers.

Herbal medicine, also known as botanical medicine (and in Europe, as phytotherapy or phytomedicine), refers to the use of a plant or plant part to make medicine, food flavors, or aromatic oils for soaps and fragrances. An herbal medicine can come from a leaf, flower, stem, seed, root, fruit, bark, or any other plant part. Herbs are often used to season foods (culinary herbs) or to maintain or restore health (medicinal herbs).

The traditional use of herbs was based on trial and error. The process of discovery produced both positive and negative results, since many herbs contain poisonous substances that counteract the main ingredients for which they might be taken. **Pharmacognosy**, the study of the biochemical aspects of natural products, seeks to standardize herbal products so that they consistently include the same amount of active ingredients and are free of any harmful components that the plant may contain.

Herbs are classified by the U.S. government as dietary supplements (vitamins, minerals, enzymes, hormones, amino acids, and other nutritional products). Congress passed the Dietary Supplement Health and Educational Act of 1994 and “grandfathered” most botanical products as a new class of products known as dietary supplements. Although dietary supplements are not regulated by the FDA, product labeling of herbal medicines is restricted to structure and function claims. Manufacturers can indicate on a product label how the herb can affect a normal body structure or function, but promotional material and packaging cannot claim to treat or prevent a disease. For example, a product label for ginkgo can say “increases microcirculation in the brain,” but it cannot say “cures early-stage Alzheimer’s” or “alleviates tinnitus” even though there is research to support the effectiveness of standardized ginkgo extracts in the treatment of these diseases.

Herbs and supplements are regulated by other organizations such as the American Botanical Council (ABC), the American Herbal Products Association (AHPA), and the Natural Nutritional Foods Association (NNFA). The ABC promotes the safe and effective use of medicinal plants by educating the public, government agencies, research institutions, industry, and the media on the scientific research that can guide decisions about producing and consuming herb-based products that benefit health and well-being. The AHPA is a group of herbalists, researchers, and manufacturers that created a code of ethics that members adhere to and releases product safety alerts regarding adulteration—that is, contamination with an unlabeled substance—of herbal products. The AHPA publishes the *Botanical Safety Handbook*, a reference on the safe and effective use of herbs. The NNFA is a group of manufacturers and retailers concerned with product quality and truth in packaging and advertising. The NNFA supports a True Label Program to ensure that products produced by its members actually contain what their labels claim.

It is estimated that 1 out of every 3 Americans uses one or more herbal products (White & Foster, 2007). Although herbal medicines generally have fewer and far milder side effects than drugs, problems can arise if they are used improperly or in combination with drugs. Nurses need to know which herbs can alter the activity of certain drugs. For example, garlic and ginkgo may increase the effects of blood thinners, whereas goldenseal, Oregon grape root, and barberry may counteract short-acting blood thinners. Refer to Chapter 31 for additional information on the safe, effective use of herbal medicines.

HERBAL SUPPLEMENTS As the use of herbal products increases in the United States, nurses must have their clients identify these products and indicate their usage when performing certain laboratory tests (e.g., therapeutic drug monitoring, trough and peak plasma levels). Certain herbal supplements may interfere with the desired effects of drugs; for example, St. John's wort may cause a decrease of trough serum digoxin concentration by 33% and peak concentration by 26% (Dasgupta, 2003). Other herbs (e.g., Chan Su, Dan Shen, Uzara root, Siberian and Asian ginseng) may also interfere in the therapeutic drug monitoring of digoxin.

BIOGRAPHICAL DATA

The client's biographical data, including age, education, occupation, and insurance coverage, may influence the nursing care plan and teaching plan. These data are also used by the nurse when helping a client develop a drug regimen that complements the client's daily routine.

CULTURAL DIVERSITY

The large number of ethnic cultures in the United States challenges professional nurses to be culturally competent. One in 4 Americans are of a race other than white (e.g., African American, Hispanic, Asian). In order for nurses to properly assess and teach clients regarding their medications, they need an understanding of cultural differences, as they may enhance compliance and minimize adverse events.

Ethnic culture affects one's beliefs about health, illness, and medications; how one interacts with health care providers; compliance with treatment regimens; and how one responds physiologically to medications. Studies have shown that a person's race or ethnic background affects the metabolism of drugs; common genetic polymorphisms, enzymes used for drug metabolism, influence the metabolism of many medications. For example, Asians and Eskimos require lower doses of anxiolytics than whites, while African Americans respond faster to neuroleptics and anxiolytics; and Asians, Indians, and Pakistanis need lower doses of lithium and anti-psychotic drugs, while Hispanics usually require lower doses of antidepressants than whites. Since certain drugs within the same class are often cleared by different metabolic pathways, ethnic differences may impair metabolism, increasing or decreasing the expected drug effect.

Ethnic beliefs also play a role in the early discontinuation of prescribed drugs. When symptoms abate, African and

Native Americans and Hispanics question the continued need for the drug, often discontinuing use of drugs such as antibiotics and antidepressants before the disease is cured. Diabetes is rare among Asians, so it is difficult for Asian Americans to grasp the relationship between blood sugar and diet. See Chapter 20 for additional information regarding cultural variances of drugs.

LIFESTYLE AND BELIEFS

The client's lifestyle and beliefs affect attitudes toward health, use of the health care system, and daily activity patterns. These factors often determine the client's dietary habits and nontherapeutic use of drugs such as tobacco, alcohol, and illegal drugs.

SENSORY AND COGNITIVE STATUS

The nurse should assess for and inquire about sensory deficits such as vision or hearing impairments, weakness or paralysis, or loss of sensation in one or more extremities. These deficits may impair a client's ability to comply with a prescribed drug plan, administer a subcutaneous injection, break a scored tablet, or open a medication container.

The nurse should assess the client's cognitive abilities throughout the drug history interview by noting whether the client is alert and oriented and interacts appropriately. Clients who are not able to express their thoughts coherently or who exhibit impaired memory function will require special consideration by the nurse when planning the client's care and teaching plan. See Chapter 38 for a complete discussion of sensory and cognitive impairments.

PHYSICAL EXAMINATION

The nurse conducts a physical assessment to identify those body systems that may be affected by a particular drug the client is currently taking or will be taking. The nurse assesses the client's condition before administering any drug to establish the client's baseline, or normal, health status. For example, the nurse assesses the client's apical pulse before administering Lanoxin (an inotropic) so that the heart rate after receiving the drug can be compared with the baseline measurement. During the physical examination, the nurse should carefully inspect the skin of those clients who self-administer medications such as insulin and heparin to ensure they are using proper technique.

DIAGNOSTIC AND LABORATORY DATA

Common laboratory values, such as electrolytes, blood urea nitrogen, creatinine, glucose, complete blood count, and a white blood cell count, are usually monitored over a period of time to identify trends and to measure the body's response to medications. Laboratory results are evaluated on the basis of the client's clinical condition, physical assessment, and drug therapies. See Chapter 28 for a complete discussion of laboratory testing.

NURSING DIAGNOSIS

The nurse analyzes the assessment data to determine the client's ability to self-administer medications and to identify any potential or actual drug-related problems. Once the nurse identifies the actual or potential problems, relevant nursing diagnoses can be formulated. The common nursing diagnoses specifically related to medication administration are (North American Nursing Diagnosis Association, 2009):

- *Deficient knowledge*
- *Ineffective health maintenance*
- *Impaired physical mobility*
- *Disturbed sensory perception*
- *Readiness for enhanced knowledge*

The addictive client may have a different set of nursing diagnoses, such as:

- *Imbalanced nutrition*
- *Impaired verbal communication*
- *Disabled family coping*
- *Impaired social interaction*
- *Social isolation*
- *Spiritual distress*
- *Readiness for enhanced spiritual well-being*

Selecting the most appropriate nursing diagnosis will identify the client's teaching needs. For example, the nursing diagnosis for clients who inquire about the side effects of their medications would be *Readiness for enhanced knowledge: Expresses an interest in learning*.

PLANNING AND OUTCOME IDENTIFICATION

Nurses need to carefully plan nursing care activities to ensure safe administration of medications. Reviewing scheduled diagnostic tests, laboratory results, and the overall plan of care helps to ensure that clients receive medications at the appropriate time and that medications that should not be given are withheld until their administration can be clarified with the prescribing practitioner. For example, digoxin might be withheld if the lab test indicates an above-normal level.

Medication administration is a good time for nurses to incorporate client teaching. Adequate planning provides for questions and discussion by the client and demonstration of skills learned (as in self-administration of insulin injections).

The nurse develops goals and plans the care on the basis of the nursing diagnosis. Nursing interventions are identified and incorporated into the plan of care to promote the attainment of goals and to assist the client in achieving outcomes. See the accompanying display for the nursing outcomes classification (NOC) defined for medication administration. The NOC outcome Self-Care: Parenteral Medication is discussed in Chapter 33.

Most clients admitted to a hospital or a long-term care facility have one or more nursing diagnoses related to alterations that precipitated the admission. Inherent in their nursing care plans are outcomes related to medication administration. For

example, the nursing diagnosis *Ineffective breathing pattern* related to decreased energy may have as a client outcome "demonstrates correct use of a metered-dose inhaler."

IMPLEMENTATION

The primary nursing interventions related to medication management are assessment, administration, and teaching. *Medication administration* is defined as "preparing, giving, and evaluating the effectiveness of prescription and nonprescription drugs" (Bulechek, Butcher, McCloskey, & Dochterman, 2008, p. 477). The nurse should use the time spent with the client during medication administration to assess the client's knowledge and response to the drug's action and adverse reactions.

The administration of medication requires the implementation of safety guidelines, following the five rights. Medications are administered in accordance with set procedures based on the prescribed route. This section presents procedures and guidelines for medication administration by the following routes: oral, including sublingual, buccal, and enteral; parenteral; site-specific topical applications; and inhalation.

Once the teaching plan has been developed, the nurse should initiate discharge teaching of drug therapy. Assessment data, especially the client's history, help the nurse in determining who should be included in the teaching session. For example, an older client living alone is physically capable

NOC—MEDICATION ADMINISTRATION

1. *Knowledge: Medication*. Definition: Extent of understanding conveyed about the safe use of medication; Sampling of indicators: Description of actions of medication(s); Descriptions of precautions for medication(s); Description of self-monitoring technique; Description of proper use of alert identification.
2. *Medication response*. Definition: Therapeutic and adverse effects of prescribed medication; Therapeutic indicators: Expected therapeutic effects; Expected change in blood chemistries; Expected change in symptoms; Maintenance of therapeutic blood levels of medication; Adverse indications: Allergic reaction; Adverse effects; Drug interaction; Drug intolerance.
3. *Self-care: Nonparenteral Medication*. Definition: Ability to administer oral and topical medications to meet therapeutic goals independently with or without assistance; Sampling of indicators: Identifies medication; Monitors therapeutic response; Uses monitoring equipment accurately; Stores medications properly; Obtains needed laboratory tests.

Moorhead, S., Johnson, M., Maas, M., & Swanson, E. (2008). *Nursing outcomes classification (NOC)* (4th ed.). St. Louis, MO: Elsevier Health Sciences.

of self-administering but may have short-term memory loss. In this situation the nurse should obtain the client's permission to include a family member, neighbor, or friend in the teaching session.

Drug teaching usually occurs in two phases. The first phase involves a formal teaching session. The nurse explains the drug's action, route, side and adverse effects, and the specific signs of a drug reaction that require prescribing practitioner notification. Clients often need assistance in developing a drug schedule that promotes compliance and complements their lifestyle. Self-administration may require the nurse to teach the client specific procedural techniques, such as subcutaneous injection.

The second phase of client teaching is ongoing, occurring whenever the nurse administers a drug. The nurse should assess and reinforce the client's knowledge of drugs at each interaction. If the client is being taught self-administration, the drug teaching plan should identify the dates for teaching, and expected outcomes should identify a date for client achievement of targeted goals.

MEDICATION ADMINISTRATION: ORAL

Oral administration of drugs is the most common route; however, there are potential risk factors that the nurse must consider. Before administering oral drugs, the nurse should assess the client's ability to take the medication as prescribed. This assessment includes the client's gag reflex, state of consciousness, and presence of nausea and vomiting.

The nurse should protect the client against aspiration when administering any form of oral drug. **Aspiration** refers to the inhalation of regurgitated gastric contents into the

pulmonary system. If a client has a weak gag reflex or difficulty swallowing water, medication can be inhaled during medication administration. To prevent aspiration, the nurse confirms the client's gag reflex and ability to swallow. When administering an oral drug, the nurse prepares the medication, correctly identifies the client, and provides some form of liquid. See Procedure 30-1 for administering an oral medication. The nurse should remain with the client until *all* of the medications have been swallowed. If there is doubt that the client has swallowed the pill, the nurse should don a non-sterile glove and visually inspect the client's mouth with a tongue depressor (see Figure 30-7).

Medication Administration: Sublingual and Buccal

Sublingual and buccal drugs are types of oral medications. Certain drugs are given by these routes to prevent their destruction or transformation in the stomach or small intestines. The nurse should assess the integrity of the mucous membranes by inspecting underneath the client's tongue and in the buccal cavity. If the membranes are excoriated or painful, the nurse should withhold the medication and notify the prescribing practitioner. Some buccal drugs may irritate the mucosa, requiring the nurse to use alternate sides of the mouth to prevent irritation of the mucosa.

Sublingual and buccal administration of drugs (see Figure 30-8 on page 775) requires the nurse to use Standard Precautions because the nurse's hand may come into contact with oral secretions. Drugs given by these routes are quickly absorbed by the mucosa's thin epithelium and the abundant blood supply.

MEDICATION ADMINISTRATION: ENTERAL

Enteral instillation refers to the delivery of drugs through a gastrointestinal tube. Enteral tubes provide a means of direct instillation of medications into the gastrointestinal system of clients who cannot ingest them orally.

COMMUNITY CONSIDERATIONS

The American Nurses Association and various governing bodies support written medication information for clients that is "scientifically accurate, unbiased in content and tone, sufficiently specific and comprehensive, presented in an understandable and legible format, timely, up to date, and useful."

Written medication information should:

- Be appropriate to client literacy levels
- Reflect print size appropriate to client's visual abilities
- Give straightforward instructions
- Include brand and trade names
- Prominently display drug warnings
- Outline indications for use, contraindications, and precautions
- List possible adverse reactions and risks, storage, and use

From American Nurses Association. (1997, March/April). *American Nurse*, 29(2), 11.

FIGURE 30-7 Check the client's mouth to ensure that medications have been swallowed. DELMAR/CENGAGE LEARNING

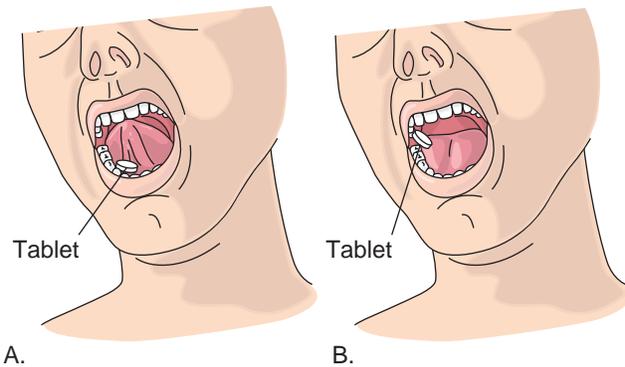

FIGURE 30-8 A. Sublingual Administration of a Tablet;
B. Buccal Administration of a Tablet DELMAR/CENGAGE LEARNING

There are several types of enteral tubes. A *nasogastric tube* (NG) is a soft rubber or plastic tube that is inserted through a nostril and into the stomach. The *gastrostomy tube* is surgically inserted into the stomach through the creation of an artificial fistula. The prescribing practitioner uses an endoscope to insert a *percutaneous endoscopic gastrostomy* (PEG) tube into the stomach.

The nurse should assess the client for the presence of bowel sounds and check the tube for **patency** (openness) and placement before administering a medication. The most reliable method for verification of placement of enteral tubes is x-ray examination. The measurement of pH secretions withdrawn from the feeding tube helps differentiate the location of the tube (see the Nursing Checklist on verifying placement of an enteral tube). The instillation of drugs is contraindicated when the tube is obstructed or improperly placed, when the client is vomiting, or if bowel sounds are absent. See Chapter 34 for a complete discussion of the purpose, insertion, and nursing care of clients with enteral tubes.

The nurse prepares the medication for instillation as prescribed by the prescribing practitioner once the patency and placement of the tube have been determined. It is preferable to instill liquid medications into tubes, especially PEG tubes that have a small lumen. Tablets can clog the tube unless they are finely crushed. When the prescribing practitioner orders a drug in the tablet or capsule form, the nurse should crush the tablet into minute particles and dissolve the crushed tablet in 15 to 30 mL of warm water before instillation. Some tablets cannot be crushed without altering their therapeutic effect. The nurse should check with the pharmacist if unsure. The instillation of cold solution may cause abdominal cramps. Capsules are prepared for administration by opening the capsule and emptying the contents into a liquid. When the drug is prepared, the nurse is ready to instill the medication (see the Nursing Checklist, on page 776, on instilling drugs into enteral tubes).

The nurse should question the prescribing practitioner if oily medications and enteric-coated or sustained-release tablets are ordered because these drug forms should not be given through a tube. Oily preparations may cling to the sides of the tube and resist mixing with the irrigating solution. Crushing

enteric-coated or sustained-release tablets destroys their intended effect. Do not crush buccal or sublingual tablets. Never attempt to give whole or undissolved medications through an enteral tube. See the accompanying display, on page 776, on special considerations for enteral tube management.

MEDICATION ADMINISTRATION: PARENTERAL

Parenteral medications are given through a route other than the alimentary canal; these routes are ID, subcutaneous, IM, or IV. The angle of injection and the depth of penetration will indicate the type of injection. Many clients have broadly classified the parenteral route into one category: “injections” or “shots.” The nurse should provide the client with an explanation of the various routes used when administering parenteral drugs. To prepare and administer parenteral medications, the

NURSING CHECKLIST

Verifying Placement of an Enteral Tube

The nurse checks the patency and placement of a nasogastric tube before adding any water or medications by performing the following actions:

- Wash hands/hands hygiene, and don nonsterile gloves.
- Unclamp the tube.
- Draw 20 mL of air into syringe.
- Aspirate approximately 10 mL of gastric contents.
- Check the contents and obtain pH level: pH below 4 means tube is in stomach; pH range of 6 to 7 means tube is in intestines.
- Assess the color of aspirate.
- If unable to aspirate contents or unsure of pH results, call prescribing practitioner for order to obtain x-ray verification.
- Wash hands/hand hygiene.
- Document results.

Do not administer the medication until placement in the stomach is verified.

▼ SAFETY FIRST ▼

RISK FOR ASPIRATION

Clients, especially those with an NG tube, are at risk for aspiration from esophageal reflux. Position the client as directed in the Nursing Checklist on instilling drugs into enteral tubes to minimize the risk of esophageal reflux and aspiration.

nurse must have knowledge of the special equipment, use manual dexterity and sterile technique, and follow Standard Precautions. An injection is an invasive procedure because it breaks the skin barrier. As such, it must be performed using proper aseptic technique to prevent risk of infection.

NURSING CHECKLIST

Instilling Drugs into Enteral Tubes

- Wash hands/hand hygiene, and don nonsterile gloves.
- Place the client in a high or semi-Fowler's position, as the client's condition allows; for an NG tube, unpin the tube from the client's gown to allow manipulation of the tube's free end. Place a linen saver over the bed linens to prevent soilage during administration of the medication.
- Dissolve crushed tablets, gelatin capsules, and powders in 15 to 30 mL of warm water. Dissolve each medication separately. Do not give whole or undissolved medications through the tube.
- Attach the syringe to the free end of the tube, pour the medication into the syringe barrel, and open the clamp; for NG tube instillation, hold the NG tube at the client's nose level.
- Hold the syringe barrel at a slight angle and allow the medication to flow at a steady, slow rate; add more medication before the syringe empties to prevent air from entering the stomach. If necessary, adjust the height of the NG tube to achieve a steady flow rate. Never push medications into the tube.
- Flush the tube with 15 to 30 mL of warm water, and add the next medication; repeat this process until all medications have been administered.
- As the syringe barrel begins to empty with the last of the medication, slowly add 30 to 60 mL of warm water into the syringe to clear the medication from the sides and distal end of the tube to prevent clogging.
- Before the syringe empties of water, clamp the tube, and detach and dispose of the syringe.
- Position the client as appropriate; clients with an NG tube should be placed on the right side with the head of the bed slightly elevated for at least 30 minutes after the instillation.
- Clean area, remove and dispose of gloves in the proper receptacle, and wash hands/hand hygiene.
- Document the instillation of the medication on the MAR, and record on the intake and output sheet the total amount of fluid instilled.

SPECIAL CONSIDERATIONS FOR ENTERAL TUBE MANAGEMENT

- When a client is receiving intermittent tube feedings, schedule the medications to prevent the two solutions from being given together.
- An adult client should not receive more than 400 mL of liquid at one time. If the administration of feedings and medication coincide, give the medication first to ensure that the client receives the prescribed dosage on time; the feeding may not be given in its entirety.
- When the client is receiving a continuous feeding, stop the feeding and aspirate the gastric contents. If the gastric contents are greater than 150 mL, withhold the medication and notify the prescribing practitioner.
- Never put tablets into tube feeding bags.
- For clients who have an NG tube for decompression (removal) of gastric contents, turn off the suction for 20 to 30 minutes after the instillation of the medication to allow time for the gastric contents to be emptied into the intestines, where most drugs are absorbed.
- For clients who have a nasogastric tube, never use the pigtail air vent for irrigation or administration of fluids.

The Centers for Disease Control and Prevention (CDC) issued revised Standard Precautions in 2007 that include new guidelines for safe injection practices. These guidelines address sterile technique and the need to use safe practice when preparing and administering medications, such as the following: Use each piece of sterile equipment once and discard, use single-dose vials for parenteral medications whenever possible, and do not use bags or bottles of IV solution as a common source of supply for multiple clients (CDC, 2007).

Equipment

Nurses use special equipment such as syringes, needles, ampules, and vials when administering parenteral medications.

SYRINGES A syringe has three basic parts: the hub, which connects with the needle; the barrel, or outside part, which contains measurement calibrations; and the plunger, which fits inside the barrel and has a rubber tip (see Figure 30-9 on page 777). The nurse must ensure that the hub, inside of the barrel, and shaft and rubber plunger tip are kept sterile. When handling the syringe, the nurse should touch only the outside of the barrel and the plunger's handle.

Most syringes are disposable, made of plastic, and individually packaged for sterility. There are several types of syringes, such as the hypodermic, insulin, and tuberculin syringes (see Figure 30-10 on page 777). When a medication

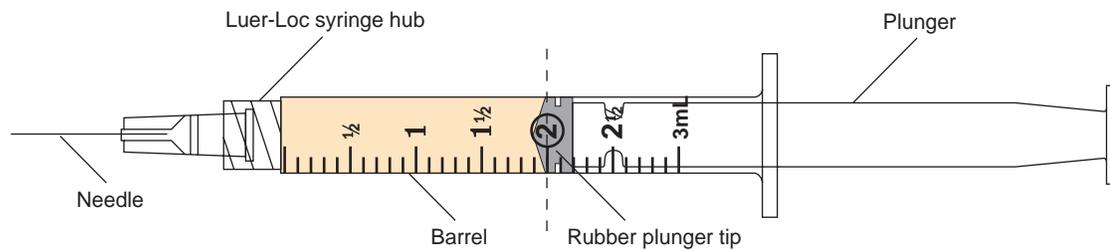

FIGURE 30-9 Parts of Syringe DELMAR/CENGAGE LEARNING

is incompatible with plastic, it is usually prefilled in a single-dose glass syringe. Syringes are often prepackaged with the commonly used needle size and gauge and are referred to as *disposable plastic syringes*.

The *hypodermic syringe* comes in 2-, 2.5-, 3-, 5-, 10-, and 12-mL sizes. The measurement calibrations (scales) are usually printed in milliliters and minims. Most syringes are marked in cubic centimeters (cc), and most drugs are ordered in milliliters; these are equivalent measurements (1 cc = 1 mL). The hypodermic syringe is used most often when a medication is ordered in milliliters. When the order is written in minims, it is safer to prepare the drug in a tuberculin syringe.

The *insulin syringe* is designed specially for use with the ordered dose of insulin. For example, if the prescribing practitioner writes the order for 30 units of U-100 insulin, the nurse will use an insulin syringe that is calibrated on the 100-unit scale. Insulin syringes are calibrated on the U-100 (100-unit) scale, which is based on 100 units of insulin contained in 1 mL of solution. Insulin syringes come in sizes that hold 0.5 mL (50 units) to 1.0 mL (100 units). Insulin syringes that hold 0.5 mL are the easiest to read and are therefore used for low dosages. There are other sizes of insulin syringes that complement the ordered dose, such as U-30 and U-50, although these dosages are seldom prescribed. The nurse should always compare the size of insulin syringe and the dose indicated on the insulin bottle with the prescribing practitioner's order; all three unit doses must be the same.

The *tuberculin syringe* is a narrow syringe, calibrated in tenths and hundredths of a milliliter (up to 1 mL) on one scale and in sixteenths of a minim (up to 1 minim) on the other scale. Originally this syringe was designed to administer the tuberculin drug, but it is commonly used today to administer small or precise doses, such as pediatric dosages. The tuberculin syringe should be used for doses 0.5 mL or less.

Prefilled single-dose syringes should not be confused with a unit dose. The nurse must be careful to check the prescribed dose against that in the prefilled syringe and discard excess medication. For example, if the prescribing practitioner orders diazepam (Valium) 5 mg IM as a preoperative sedative and the prefilled single-dose contains 10 mg/2 mL, the nurse must calculate dosage (5 mg/1 mL) and destroy 1 mL from the syringe before administration.

The Joint Commission requires labeling of all syringes. Not all medications are dispensed by the pharmacy in ready-to-administer injectable products in labeled syringes as prescribed for each client. Unlabeled syringes increase the risk for medication errors; see the accompanying Uncovering the Evidence display on page 778. Historically, nurses have used tape for labeling syringes, but this is not considered safe practice since the tape may obscure the contents and the graduations on the syringe barrel. Cohen (2008) suggests that providing commercially available syringe labels in all drug preparation areas and letting nurses choose a standard format can help reduce risks associated with unlabeled syringes.

FIGURE 30-10 Types of Syringes: A. 3-mL Syringe; B. Standard U-100 Insulin; C. 1-mL Tuberculin with Luer-Lok DELMAR/CENGAGE LEARNING

NEEDLES Most needles are disposable, made of stainless steel, and individually packaged for sterility. Reusable needles are seldom used, except in certain areas such as surgery and special procedure rooms; reusable needles require frequent inspection to ensure that the needle is sharp, and resterilization is necessary between uses.

The needle has four basic parts: the hub, which fits onto the syringe; the cannula, or shaft, which is attached to the hub; the bevel, which is the slanted part at the tip of the shaft; and the safety cap. Needles come in various sizes, from 1/4 inch to 5 inches, and with gauges that range from 28 to 14 (see Figure 30-11 on page 778).

The *gauge* of the needle refers to the diameter of the shaft; the larger the gauge number, the smaller the diameter of the shaft. Large-gauge needles produce less trauma to the body's tissue; however, the nurse has to consider the viscosity of a solution when selecting the gauge.

The *shaft of the needle* determines its length. The nurse selects the length of the needle on the basis of the client's

UNCOVERING THE

Evidence

TITLE

“2007 Study of Injectable Medication Errors”

AUTHOR

American Nurses Association

PURPOSE

To identify opinions, concerns, and experiences about challenges related to labeling on syringes.

METHODS

A nationwide online survey of nurses was conducted by the Atlanta-based Arketi Group and sponsored by the ANA and Inviro Medical Devices. Of the 1039 nurses, 22% of those surveyed had been a nurse for 1 to 5 years, 12% had been a nurse for 6 to 10 years, 15% had been a nurse for 11 to 15 years, and 51% had been a nurse for more than 15 years.

FINDINGS

Nearly all (97%) nurses worry about medication error, and two-thirds (68%) believe medication error could be reduced with more consistent syringe labeling.

IMPLICATIONS

The study indicates a need for the right safety equipment in regard to injectables in order to reduce the risk of medication errors and sharps-related injuries.

American Nurses Association. (2008). 2007 Study of Injectable Medication Errors. Retrieved September 29, 2008, from <http://psnet.ahrq.gov/resource.aspx?resourceID=5503>.

muscle development and weight and the type of injection, such as ID versus IM.

The needle may have a short or long *bevel*. The length of bevel selected is based on the type of injection. Long bevels are sharp and produce less pain when injected into the subcutaneous or muscle tissues; however, a short-bevel needle must be used for ID and IV injections to prevent occlusion of the bevel either by the tissue or by a blood vessel wall.

When the nurse removes a needle from its sterile wrapper, the hub of the needle should be immediately attached to the hub of the syringe to prevent contamination. Likewise, the protective cover should remain on the needle's shaft until the nurse is ready to use the needle.

After an injection, the nurse should not recap the needle; used needles should be disposed of in the proper receptacles, such as a sharps container, to prevent needlesticks. See Chapters 29 and 33 for details on how to prevent needlestick injuries. Most agencies have sharps containers in all client care areas. Chapter 33 provides a complete discussion of the needleless system.

AMPULES AND VIALS Drugs for parenteral injections are sterile preparations. Drugs that deteriorate in solution are dispensed as tablets or powders and dissolved in a solution immediately before injection. Drugs that remain stable in a solution are dispensed in ampules and vials in an aqueous or oily solution or suspension.

Ampules are glass containers of single-dose drugs (see Figure 30-12). The glass container has a constriction in the stem to facilitate opening the ampule. See Procedure 30-2 for removing a drug from an ampule. The medication is aspirated into a syringe with a filter needle to prevent small glass fragments from entering the syringe. Because many drugs are irritating to the subcutaneous tissue, the nurse should change the needle on the syringe after withdrawing a drug from an ampule.

Glass, single- or multiple-dose, rubber-capped drug containers are called vials (see Figure 30-13 on page 779). The vial is usually covered with a soft metal cap that can be easily removed. See Procedure 30-3 for removing a drug from a

FIGURE 30-12 Ampules DELMAR/CENGAGE LEARNING

FIGURE 30-13 Vials DELMAR/CENGAGE LEARNING

vial. The nurse should change the needle on the syringe after withdrawing a drug from a vial. Inserting the needle through the rubber cap of the vial can dull the needle or remove the needle coating that helps it glide through the skin.

Compatible medications can be mixed in the same syringe. Refer to compatibility charts or check with the pharmacist to determine if the medications can be mixed. If medications are going to be mixed, care must be exercised not to contaminate one medication with the other in their respective vials. See Procedure 30-4 for mixing insulins in one syringe. The nurse must calculate and measure carefully to be sure the final dose is accurate.

Angle of Injection

The angle of insertion depends on the type of injection. Figure 30-14 illustrates the angle of insertion for each type of parenteral injection.

Medication Administration: Intradermal

ID or intracutaneous injections are typically used to diagnose tuberculosis, identify allergens, and administer local anesthetics. The site below the epidermis is the location for administering ID injections; drugs are absorbed slowly from this site. The sites commonly used for ID injection are the inner aspect of the forearm (if it is not highly pigmented or covered with hair), upper chest, and upper back beneath the scapula (see Figure 30-15). Only small amounts of water-soluble medication should be used for subcutaneous injections.

The drug's dosage for an ID injection is usually contained in a small quantity of solution (0.01 to 0.1 mL). A 1-mL tuber-

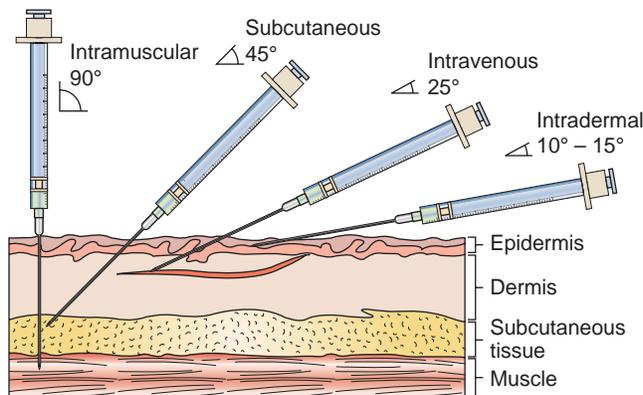

FIGURE 30-14 Angles of Insertion for Parenteral Injections DELMAR/CENGAGE LEARNING

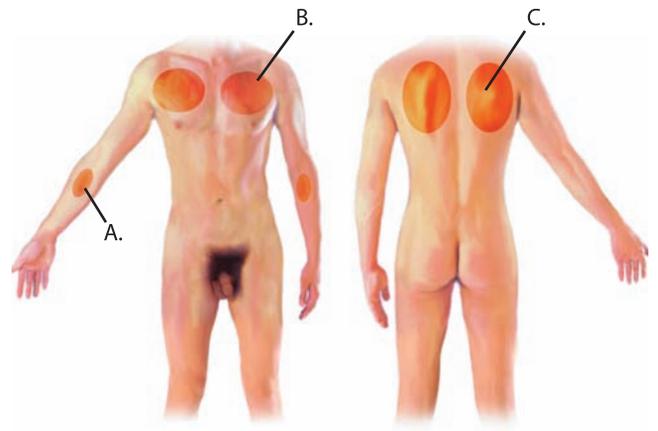

FIGURE 30-15 Intradermal Injection Sites: A. Inner Aspect of the Forearm; B. Upper Chest; C. Upper Back DELMAR/CENGAGE LEARNING

culin syringe with a short bevel, 25- to 27-gauge, 3/8- to 1/2-inch needle is used to provide accurate measurement. If repeated doses are ordered, the site should be rotated. ID injections are administered into the epidermis layer by angling the needle 10° to 15° to the skin. See Procedure 30-5 for administering ID injections.

Medication Administration: Subcutaneous

Subcutaneous injections are commonly used in the administration of medications such as insulin and heparin because these drugs are absorbed slowly, to produce a sustained effect. Subcutaneous injections place the medication into the subcutaneous tissue, between the dermis and the muscle. Clients who administer frequent subcutaneous injections should rotate sites regularly. An administration chart can help them keep track of the sites used. The amount of medication given varies but should not exceed 1.0 mL; if repeated drug doses are given, rotate the sites. Subcutaneous tissues are sensitive to irritating medications. Hard painful lumps can develop beneath the skin if the sites are not rotated.

Common sites for subcutaneous injections are the abdomen, the lateral and anterior aspects of the upper arm or thigh, the scapular area on the back, and upper ventrodorsal gluteal areas (see Figure 30-16 on page 780). The nurse should select a sterile 0.5- to 3-mL syringe with a 25- to 29-gauge, 3/8- to 1/2-inch needle. The medication is administered by angling the needle 45° or 90° to the skin. The client's body weight will influence the angle used for injection. As a general rule, to reach subcutaneous tissue, the nurse grasps 2 inches of tissue between two fingers and inserts the needle at a 90° angle. If only 1 inch of tissue can be grasped between the fingers, use a 45° angle to administer the medication.

The length of the needle may also vary with body weight. Normally for subcutaneous injections, a 25-gauge, 5/8-inch needle is used. A child will require a short needle, and an obese person may require a longer needle to ensure placing the medication in the subcutaneous tissue. The length of the needle should be approximately half the width of the

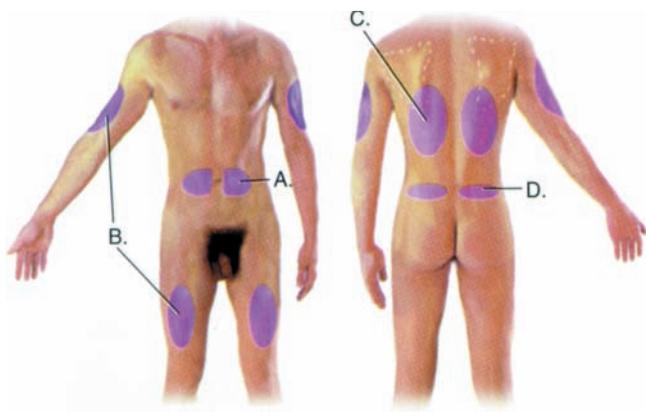

FIGURE 30-16 Subcutaneous Injection Sites: A. Abdomen; B. Lateral and Anterior Aspects of the Upper Arm and Thigh; C. Scapular Area on Back; D. Upper Ventrodorsal Gluteal Area

Anterolateral aspect of thigh	Vastus lateralis
Upper arm	Deltoid

pinched skinfold. See Procedure 30-6 for the technique used in administering a subcutaneous injection.

Medication Administration: Intramuscular

IM injections are used to promote rapid drug absorption and to provide an alternate route when the drug is irritating to subcutaneous tissue. The IM route enhances the absorption rate because there are more blood vessels in the muscles than in subcutaneous tissue; however, the absorption rate may be affected by the client's circulatory status.

Since the 1920s over 90 research studies related to IM injections have been reported in the literature (Beyea & Nicoll, 1995). Researchers have studied the medication volume and appropriate size of the syringe and needle for

administering an IM injection to a particular site. "Research on the maximum volume to be drawn up for a single injection is still inconclusive" (Beyea & Nicoll, 1996, p. 34). The nurse should determine the maximum volume to inject on the basis of the site and the client's muscle development:

- 3 mL for a large muscle (gluteus medius) in a well-developed adult
- 1 to 2 mL for less developed muscles in children and in older and thin clients
- 0.5 to 1.0 mL for the deltoid muscle

When more than 3 mL is ordered, the medication can be divided into two different sites.

There are three common sites for administering IM injections (see the accompanying display on common IM injection sites). Injection sites are identified by using appropriate anatomic landmarks (see Figure 30-17 on page 781).

The primary site for administering an IM injection in clients over 7 months old is the ventrogluteal (VG) site. The gluteus medius is a well-developed muscle, free of major nerves and large blood vessels. Research shows that injuries—including fibrosis, nerve damage, abscess, tissue necrosis, muscle contraction, gangrene, and pain—have been associated with all the common sites (e.g., dorsogluteal, deltoid, vastus lateralis) *except* the VG site (Beyea & Nicoll, 1996, p. 35). Recent research has suggested that the dorsogluteal muscle, which was once the first choice for adult IM injections, is no longer a safe site for IM injections (Hunt, 2008). These studies have demonstrated that the exact location of the sciatic nerve varies from one person to another. If the sciatic nerve is damaged by a needle, the person may experience adverse outcomes, such as pain or temporary or permanent paralysis of the lower extremities. Accidental injection into the superior gluteal artery may cause increased absorption or hemorrhage.

The nurse should avoid using the deltoid site in children. The deltoid muscle is not well developed in infants, children, and many adults. This site should be used only for small medication volumes.

The nurse will need to decide on the gauge and length of the needle on the basis of the consistency of the solution, the site, and how far the needle must be injected to reach the muscle. A 21- to 23-gauge needle will accommodate the consistency of most drugs and will minimize tissue injury and subcutaneous leakage. The needle's length is determined by the site:

- 1 1/2-inch needle, VG site for average-sized adults
- 1-inch needle, VG site for children
- 1-inch needle, deltoid or vastus lateralis

An obese client usually requires a 2-inch needle to ensure that the needle will reach a large muscle such as the gluteal muscle. For example, for a client weighing 100 pounds, use a needle 1 to 1 1/2 inches long; usually for a child, use only a 1-inch needle. It is important to consider the size of the client when determining the needle length; some children are large, and some adults are small. The nurse should administer an IM injection at a 90° angle. See Procedure 30-7 for administering an IM injection.

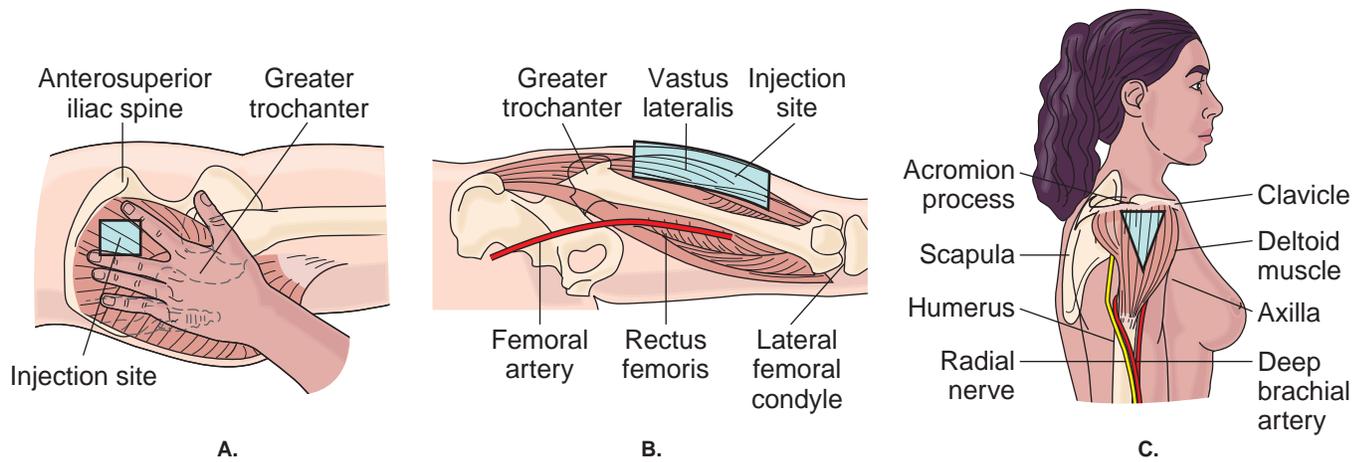

FIGURE 30-17 Intramuscular Injection Sites: **A.** Ventrogluteal: Place palm of left hand on right greater trochanter so index finger points toward anterosuperior iliac spine; spread first and middle fingers to form a V; the middle of the V is the injection site; **B.** Vastus lateralis: Identify greater trochanter; place hand at lateral femoral condyle; injection site is middle third of anterior lateral aspect. **C.** Deltoid: Locate the lateral side of the humerus from two to three finger widths below the acromion process in adults or one finger width below the acromion process in children. DELMAR/CENGAGE LEARNING

Z-TRACK INJECTION The **Z-track (zigzag) technique** refers to a method used in administering IM injections (see Procedure 30-7). This technique was traditionally used when administering Imferon, an iron preparation, which can cause permanent discoloration in the subcutaneous tissue. Today, the technique is used commonly when administering VG injections.

When administering a Z-track injection, the nurse should place the client in the prone position; then pull the skin to one side, insert the needle at a 90° angle, and administer the medication (see Figure 30-18). Spreading the skin, a common method formerly used for IM injections, increases the risk that medication will leak into the needle track and the subcutaneous tissue; this risk is virtually eliminated using the Z-track technique, making it the technique of choice (Beyea & Nicoll, 1996). The nurse waits 10 seconds and withdraws the needle at the same angle used for insertion; the site should not be massaged because massaging can cause tissue irritation.

Table 30-2 on page 782 summarizes the basics of ID, subcutaneous, and IM injections.

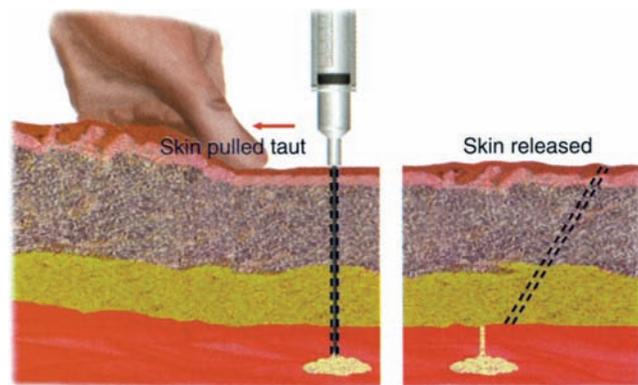

FIGURE 30-18 Administering Intramuscular Injection Using Z-Track Technique: Pulling skin taut and then releasing it after the needle is withdrawn seals the site. DELMAR/CENGAGE LEARNING

Medication Administration: Intravenous

The IV route is used when a rapid drug effect is desired or when the medication is irritating to tissue. IV administration provides immediate release of medication into the bloodstream; consequently, it can be dangerous. IV medications are administered by one of the following methods:

- IV fluid container (Figure 30-19 on page 782) and infusion pump
- Volume-control administration set
- Intermittent infusion by piggyback or partial fill
- Intravenous push (IVP or bolus)

See Chapter 33 for a discussion of other IV delivery systems.

When administering IV medications, regardless of the method used, the nurse should assess the patency of the infusion system and the condition of the injection site for signs of complications such as **infiltration** (swelling and discomfort at the IV site) and **phlebitis** (inflammation of a vein). See Chapter 33 for a complete discussion of these IV complications. Some IV medications or solutions with high or low pH or high osmolarity are irritating to veins and can cause phlebitis.

INFUSION PUMP An infusion pump is used to regulate fluids intravenously by exerting positive pressure on the tubing or on the fluid (see Figures 30-20 and 30-21 on pages 782 and 783). When the fluid flow is unrestricted, the pump pressure is comparable to that of gravity flow; however, if restrictions develop (increased venous resistance), the pump can maintain the fluid flow by increasing the pressure applied to the fluid. (See Chapter 33 for additional information.) Whenever electronic devices are used to regulate medication administration, nurses must avoid at-risk behaviors related to technology, such as overriding alerts on the infusion pumps.

TABLE 30-2 Summary of Intradermal, Subcutaneous, and Intramuscular Injections

TYPE OF INJECTION	PURPOSE	SITE	NEEDLE SIZE	MAXIMUM DOSE	ANGLE OF INSERTION
Intradermal	Injects medication below the epidermis; drugs are absorbed slowly; typically used for diagnosis of tuberculosis and allergens	Inner aspect of forearm; upper chest; upper back	Syringe with short bevel; 25- to 27-gauge; 3/8- to 1/2-inch	0.01–0.1 mL	10°–15°
Subcutaneous	Injects medication between dermis and muscle; absorbed slowly; typically used for insulin and anticoagulants	Abdomen; lateral and anterior aspects of upper arm and thigh; scapular area on back; ventrogluteal area	25-gauge, 5/8-inch needle (varies by size of person)	0.5–1.0 mL	45° or 90°
Intramuscular	Used to promote rapid drug absorption and to provide an alternate route when drug is irritating to subcutaneous tissue	Ventrogluteal; dorsogluteal; anterolateral aspect of thigh (vastus lateralis); upper arm (deltoid)	The gauge and length of needle are selected on the basis of medication volume and viscosity and client's body size	Well-developed adults: 4 mL in a large muscle; infants and small children: 0.5–1.0 mL; children and older adults: 1–2 mL; deltoid muscle: 0.5–1 mL	90°

ADDING DRUGS TO A VOLUME-CONTROL ADMINISTRATION SET

A volume-control set is used to administer small volumes of IV solution. These devices have various names as determined by the manufacturer, such as Soluset, Metriset, VoluTrol, or Buretrol. To administer a drug by this method, the nurse should:

- Withdraw the prescribed amount of medication into a syringe that is to be injected into the volume-control set.
- Cleanse the injection port of a partially filled volume-control set with an alcohol swab.
- Inject the prepared medication into the port of the volume-control set.
- Gently mix the solution in the volume-control chamber.

After injecting the medication into the volume-control chamber, the nurse should check the infusion rate and adjust as necessary to the prescribed rate of infusion.

ADMINISTERING MEDICATIONS BY INTERMITTENT INFUSION

A common method of administering IV medications is by using a secondary, or partial-fill, additive bag, often referred to as an IV piggyback (IVPB). A secondary line is a complete IV set (fluid container and tubing with either a microdrip or a macrodrip system) connected to a Y-port of a primary line (see Procedure 30-8). The primary line maintains venous access. The IVPB is used for medication administration. See Chapter 33 for a complete discussion of primary and secondary lines. When the IVPB medication is incompatible with the primary IV solution, the nurse must flush the primary IV tubing with normal saline before and after administering the medication.

INTERMITTENT INFUSION DEVICES When the client requires only the administration of IV medications without the infusion of solutions, an intermittent infusion device is

inserted into a peripheral needle or catheter in the client's vein (see Figure 30-22). This device is commonly referred to as a heparin or saline lock, depending on the agency's policy regarding the device's maintenance. A lock provides continuous access to venous circulation, eliminating the need for a continuous IV, and it increases the client's mobility.

The device can be used to infuse intermittent IVPB or IVP medications, or it can be converted to a primary IV. A major consideration for inserting a heparin lock device is that it provides venous access in case of an emergency. Lock devices are routinely used with cardiac clients.

Locks are generally flushed every 8 hours to maintain patency (patency refers to being freely opened). Some agencies require a diluted dose of heparin (100 units/mL) to be injected into the lock; other agencies use normal saline to keep the device patent. See Chapter 33 for a complete discussion of heparin and saline locks. When heparin is used, the device must be flushed with normal saline solution before and after administration of a medication.

ADMINISTERING IVP MEDICATIONS The method of medication administration by IV bolus or IVP injection is determined by the type of IV system. For example, an IVP medication can be injected into a saline or heparin lock (see Figure 30-23) or into a continuous infusion line. When giving an IVP medication into a continuous infusion line, the nurse must stop the fluids in the primary line; the nurse usually pinches the IV tubing closed to inject the drug (see Figure 30-24 on page 784). This technique is safe and prevents the nurse from having to recalculate the drip rate of the primary infusion line.

FIGURE 30-22 Heparin Locking Device DELMAR/CENGAGE LEARNING

FIGURE 30-23 Injecting a Bolus of Medication into a Peripheral Saline Lock DELMAR/CENGAGE LEARNING

FIGURE 30-24 Pinch the IV tubing of a primary infusion line to administer an IVP medication DELMAR/CEGAGE LEARNING

IVP medications can also be given into a central line or directly into the vessel by venipuncture. The five rights of medication administration are implemented when administering an IV bolus. The nurse must know the specific time interval to inject the medication and the specific reactions of the infused drug. The client must be monitored closely during and after injection for drug reactions.

MEDICATION ADMINISTRATION: TOPICAL

Topical medications may be administered to the skin, eyes, ears, nose, throat, rectum, and vagina. The medication generally provides a local effect but can also cause systemic effects. Drugs directly applied to the skin to produce a local effect include lotions, pastes, ointments, creams, powders, and aerosol sprays. The rate and degree of the drug's absorption are determined by the vascularity of the area.

Topical drugs are usually given to provide continuous absorption to produce different effects: to relieve pruritus (itching), to protect the skin, to prevent or treat an infection, to provide local anesthesia, or to create a systemic effect. Topical medications are usually ordered two or three times a day to achieve their therapeutic effect.

Before applying a topical preparation, the nurse should assess the condition of the skin for any open lesions, rashes, or areas of erythema and skin breakdown. Because secretions are produced by the skin and mucous membranes, the nurse should always implement Standard Precautions when applying a topical drug. The medication can be transferred to the nurse if gloves are not worn or an applicator, such as a sterile tongue depressor, is not used. The nurse should check with the client and the medical record for any known allergies.

Body oils may interfere with the adhesive properties of the patch, disk, or tape. The skin harbors microorganisms, and lesions can cause encrustation. The nurse should cleanse the area by washing with soap and warm water, unless contraindicated by a specific order. The skin should be thoroughly dry before a topical medication is applied. Open wounds require the nurse to use surgical asepsis.

When the skin is dry, the nurse can apply the medication. When applying a paste, a cream, or an ointment, the nurse should use a sterile tongue depressor to remove the medication

from the container; this method prevents cross-contamination. The medication is transferred from the tongue blade to a gloved hand for application. The medication should be applied in long, smooth strokes in the direction of the hair follicles to prevent the medication from entering the hair follicles. A new sterile tongue depressor should be used whenever more medication is removed from the container. Two to 4 hours after the application, the nurse should assess the area for signs of an allergic reaction.

Medication Administration: Eye

Eye medications, often referred to as ophthalmic medications, refer to drops, ointments, and disks. These drugs are used for diagnostic and therapeutic purposes—to lubricate the eye or socket for a prosthetic eye and to prevent or treat eye conditions such as glaucoma (elevated pressure within the eye) and infection. Diagnostically, eyedrops can be used to anesthetize the eye, dilate the pupil, and stain the cornea to identify abrasions and scars.

The nurse should review the abbreviations used in medication orders to ensure that the medication is instilled in the correct eye. Cross-contamination is a potential problem with eyedrops. The nurse should adhere to the following safety measures to prevent cross-contamination:

- Each client should have a bottle of eyedrops. Clients should never share eye medications.
- Discard any solution remaining in the dropper after instillation.
- Discard the dropper if the tip is accidentally contaminated, as by touching the bottle or any part of the client's eye. The risk of transferring infection from one eye to the other is increased if the tip touches any part of the client's eye.

See Procedure 30-9 for administering eye medications. The nurse should insert medication disks at bedtime because they usually cause blurring of the eyes on insertion. Standard Precautions are used when eye care and medications are being administered because of the potential contact with bodily secretions.

Medication Administration: Ear

Solutions ordered to treat the ear are often referred to as *otic* (pertaining to the ear) drops or irrigations. Eardrops may be instilled to soften ear wax, to produce anesthesia, to treat infection or inflammation, or to facilitate removal of a foreign body, such as an insect. External auditory canal irrigations are usually performed for cleaning purposes and less frequently for applying heat and antiseptic solutions. The internal ear is very sensitive to changes in temperature. Sudden changes can cause nausea and dizziness. Eardrops and irrigation fluids should be at room temperature.

Before instilling a solution into the ear, the nurse should inspect the ear for signs of drainage, an indication of a perforated tympanic membrane. Eardrops are usually contraindicated when the tympanic membrane is perforated. If the tympanic membrane is damaged, all procedures must be performed using sterile aseptic technique; otherwise, medical asepsis is used when instilling medications into the ear (see

Procedure 30-9). Medication should never be forced into the ear canal, especially if it is occluded (as by wax). Forcing medication into an occluded eardrum can injure the eardrum.

Certain conditions have contraindications for specific drugs; for example, hydrocortisone eardrops are contraindicated in clients with a fungal infection or a viral infection such as herpes.

Medication Administration: Nasal

Nasal instillations can be performed with different preparations: drops or nebulizers (atomizer or aerosol). Nasal drugs are administered to produce one or more of the following effects: to shrink swollen mucous membranes, to loosen secretions and facilitate drainage, and to treat infections of the nasal cavity or sinuses. Because many of these products are nonprescription drugs, clients should be taught their correct usage. For example, nasal decongestants are common over-the-counter drugs used to shrink swollen mucous membranes; however, when these drugs are used in excess, they may have a reverse or rebound effect by increasing nasal congestion.

The nasal sinuses (frontal, ethmoid, maxillary, and sphenoid sinuses) communicate with the nasal fossae and are lined with mucous membranes similar to those that line the nose. Nose drops can be instilled to remain in the nasal passage, to reach the ethmoid and sphenoid sinuses, or to reach the frontal or maxillary sinuses. Location is determined by the degree of hyperextension and position of the head during instillation (see Figure 30-25). Although the nose is considered a clean (not sterile) cavity, because of its connection with the sinuses, the nurse uses medical asepsis when performing nasal instillations. See Procedure 30-10 for administering nasal instillations.

Nebulizers (inhalers) are used to deliver a fine mist containing medication droplets. The nurse should administer or assist clients with the usage of atomizers and aerosols:

- Instruct the client to clear the nostrils by blowing the nose.
- Client should be in an upright position with head tilted back slightly.

SAFETY FIRST

SYSTEMIC EFFECTS OF EYEDROPS

The nurse should apply pressure to the inner canthus when instilling eyedrops that have potential systemic effects such as atropine and timolol maleate (Timoptic). Gentle pressure over the inner canthus prevents the medication from flowing into the tear duct, thereby decreasing the absorption rate of the drug.

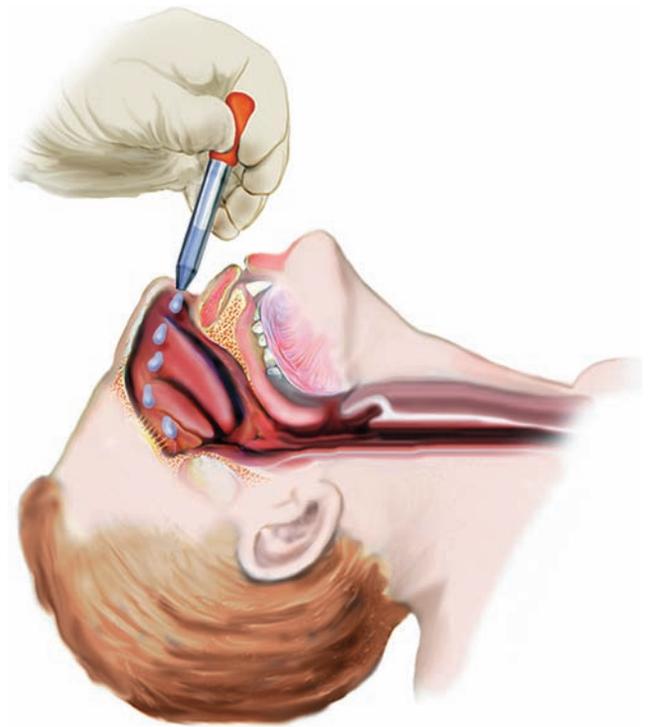

FIGURE 30-25 Positioning a Client for Nose Drop Instillation
DELMAR/CENGAGE LEARNING

Atomizer

- Occlude one nostril to prevent air from entering the nasal cavity and to allow the medication to flow freely in the open nostril.
- Insert the atomizer tip into the open nostril and instruct the client to inhale, then squeeze the atomizer once, and instruct the client to exhale.

Aerosol

- Shake the aerosol well before each use.
- Grasp between thumb and index finger and insert the adapter tip into one nostril while occluding the other nostril with a finger, then press the adapter cartridge firmly to release one measured dose of medication.
- Repeat the above steps as ordered for the other nostril.
- Instruct the client to keep head tilted backward for 2 to 3 minutes and to breathe through the nose while the medication is being absorbed.

When the client is discharged with a nasal inhaler, the nurse should teach the client how to store and use the device.

Respiratory inhalants are delivered by devices that produce fine droplets that are inhaled deep into the respiratory tract. A nebulizer is a device that is used to aerosolize medications into a mist for delivery directly into the lungs. These medication droplets are absorbed almost immediately through the alveolar epithelium into the bloodstream.

Oropharyngeal handheld inhalers deliver medications that produce both local and systemic effects, such as bronchodilators and mucolytics. Bronchodilators improve airway

patency and are used to prevent or treat bronchospasms, asthma, and allergic reactions. Mucolytics are used to liquify tenacious (thick) bronchial secretions. There are three types of oropharyngeal handheld inhalers: the metered-dose inhaler, the turbo-inhaler, and the nasal inhaler (previously discussed).

Clients must be able to form an airtight seal around the inhaling devices and be able to assemble the turbo-inhaler. This requirement prevents some clients, such as clients with visual or coordination impairments, from using these devices. Bronchodilators are contraindicated in clients who have a history of tachycardia.

The nurse should ensure that the client knows how to use the inhaler correctly so that the prescribed medication dose is delivered. See Procedure 30-11 for teaching a client how to use the nebulizer.

A metered-dose inhaler delivers a measured dose of the medication with each push of the canister. The nurse needs to evaluate the client's ability to adequately compress the inhaler to deliver a full dose and to inhale at the same time as the dose is expressed. Failure to do either could prevent the client from receiving the full benefit of the inhaler. The ability to compress the inhaler for dose delivery can be affected by hand strength (which diminishes with age), flexibility (as in arthritic changes), and disease related to weakness (such as chronic respiratory disease). Careful discharge instructions and observation of the client performing the task are important to continued therapeutic effect at home (see the accompanying Client Teaching Checklist for home care application).

Medication Administration: Rectal

Rectal instillations can be in the form of enemas, suppositories, and ointments. See Chapter 39 for a complete discussion of enema administration. Rectal ointments are used to treat local conditions and symptoms such as pain, inflammation, and itching caused by hemorrhoids. Rectal suppositories are cone-shaped masses of substances designed to melt at body temperature and to produce the intended effect at a slow and steady rate of absorption.

Suppositories provide a safe and convenient route for administering drugs that interact poorly with digestive enzymes or have a bad taste or odor. They are also used to provide temporary relief for clients who cannot tolerate oral preparations: for example, to relieve nausea and vomiting. Suppositories are also used to induce relaxation, relieve pain and local irritation, reduce fever, and stimulate peristalsis and defecation in clients who are constipated.

Rectal suppositories are contraindicated in cardiac clients because insertion may stimulate the vagus nerve, causing cardiac dysrhythmias (abnormal heart patterns). These drugs are also avoided in clients recovering from rectal or prostate surgery because they may cause pain on insertion and trauma to the tissues.

The nurse should assess the rectum for irritation or bleeding and check sphincter control. Some clients may

CLIENT TEACHING CHECKLIST

HOME CARE

Considerations for Use of Nasal Inhalers

- Provide the client with the manufacturer's directions for the specific type of inhaler, such as how to replace a medication cartridge for a nasal aerosol.
- Inhalers should be stored at room temperature.
- Aerosols are prepared under pressure and should not be punctured or placed in an incinerator.
- Instruct the client not to allow other people to use the inhaler.
- Caution the client about overuse that could cause a rebound effect, making the condition worse.
- Ensure that the client is knowledgeable about the expected and adverse effects of the drug. Some of these drugs do not produce therapeutic effects for several days, and some require 2 weeks of continuous use before the drug effects appear.
- Provide the client with a telephone number to call if assistance is needed.

experience problems in retaining the suppository. The nurse should instruct such a client to remain in the Sims' position for at least 15 minutes or should place the client on the abdomen, if the condition allows, and hold the buttocks closed. The prescribing practitioner should be notified when the client is unable to retain a suppository so that another route can be ordered.

Suppositories are often stored in the refrigerator to preserve the integrity of the drug form. A softened suppository is difficult to insert; to harden a suppository, place it under cold running water while it is still in its original wrapper. The nurse should follow the five rights of medication administration and Standard Precautions when administering rectal instillations. See Procedure 30-12 for the procedure on inserting a rectal suppository.

Medication Administration: Vaginal

Medications inserted into the vagina are in the form of suppositories, creams, gels, ointments, foams, or douches. These medications may be used to treat inflammation, infections, and discomfort, or as a contraceptive measure.

Vaginal creams, gels, and ointments usually come with a disposable tubular applicator with a plunger to insert the drug. Standard Precautions are always used by the nurse when inserting suppositories. Body temperature causes the suppository to melt and be absorbed. Suppositories are

usually inserted with the index finger of a gloved hand; however, small suppositories may come with an applicator, and the suppository is placed in the applicator's tip. Many clients prefer to insert their own vaginal suppository. In this case, provide privacy for the client. See Procedure 30-13 for the procedure on instilling a vaginal suppository. After insertion of these preparations, the client may notice drainage and should be informed that this is expected. If a suppository is given to treat infection, tell the client that the drainage may be foul smelling. The nurse should advise the client to wear a perineal pad to prevent soiling of the underpants. Clients

should be instructed not to use tampons after the insertion of vaginal medications because the tampon can absorb the medication and decrease the drug's effect.

Sterile technique is usually required by agency policy, especially if there is an open wound when administering a vaginal douche (irrigation). Douches are ordered to apply antimicrobial solutions, to remove offensive or irritating discharge, to reduce inflammation, and to prevent hemorrhage with warm or cold irrigations. The nurse should ensure that the client does not have an allergy to iodine because many vaginal preparations contain povidone-iodine.

NURSING CARE PLAN

The Client with Deep Vein Thrombosis

CASE PRESENTATION

Mrs. Landry, a 45-year-old, was admitted to your floor with a diagnosis of deep vein thrombosis. The client noticed swelling of her left leg about a week ago but decided to treat it at home. Four days later, the lower leg was very edematous, warm, and painful to move. After an office visit, the client was admitted to the hospital. This is Mrs. Landry's first hospitalization. On examination you find that the left leg is warmer than the right. The left thigh circumference is 3 inches larger than the right. The prescribing practitioner ordered a heparin IV drip after a loading dose bolus was given. The drip contained 10,000 units heparin in 500 mL of D5W at 10 mL/h (200 units/h). The prescribing practitioner anticipates that Mrs. Landry will be weaned off of the heparin drip and started on subcutaneous heparin within 5 days. At the time of discharge, she will be given Coumadin.

ASSESSMENT

- Edematous left thigh
- Left leg warmer to touch than right
- Left thigh circumference 3 inches larger than right

NURSING DIAGNOSIS 1: *Impaired tissue perfusion* related to the development of venous thrombi in the deep femoral vein.

NOC: Medication response

NIC: Maintenance of therapeutic blood levels of medication

EXPECTED OUTCOMES

The client will:

1. Report an absence of pain.
2. Demonstrate an absence of edema.
3. Experience the same degree of skin temperature in both legs.

INTERVENTIONS/RATIONALES

1. Maintain on bed rest. Reduces the possibility of embolus; may decrease the pain and swelling.
2. Elevate the legs above the heart. Elevation facilitates venous return and decreases the edema.

(Continues)

NURSING CARE PLAN (Continued)

3. Measure the circumference of the left thigh and compare with that of the right thigh. Measuring the circumference provides a quantitative reference point that can be used to evaluate the swelling.
4. Apply moist heat to the affected extremity. Heat provides an analgesic effect; it decreases venospasms and pain.
5. Administer the heparin as prescribed. Heparin prevents the conversion of fibrinogen to fibrin and prothrombin to thrombin, thereby limiting the extension of the thrombus.
6. Monitor the partial thromboplastin time (PTT). The PTT is used to monitor heparin therapy because heparin, a short-acting anticoagulant, increases the PTT.

NURSING DIAGNOSIS 2: *Injury, risk for*, bleeding related to the administration of an oral anticoagulant.

NOC: Medication response

NIC: Maintenance of therapeutic blood levels of medication

EXPECTED OUTCOMES

The client will:

1. Not demonstrate evidence of bleeding from gums or nose, in urine or stool, or under the skin.
2. Maintain the prothrombin time (PT) or international normalized ratio (INR) within **therapeutic range**.

INTERVENTIONS/RATIONALES

1. Advise the client to withhold the medication in the event that bleeding occurs and to notify the prescribing practitioner immediately. The dose may need to be adjusted.
2. Encourage the client to discontinue smoking. Smoking has a tendency to increase the metabolism of the medication, necessitating an increase in the dose.
3. Provide dietary education. Foods high in fat and foods rich in vitamin K can interfere with the PT.
4. Warn against taking oral contraceptive medication. There may be a decrease in anticoagulant effect due to the increased production of clotting factors with oral contraceptives.
5. Warn against taking aspirin and other over-the-counter medications. Aspirin may increase the risk of bleeding; it inhibits platelet formation.

EVALUATION

Resolution of the signs and symptoms of deep vein thrombus is a measurement of success. The client will be able to ambulate without difficulty, and the swelling, temperature difference, and pain will disappear. The client will be knowledgeable about taking the oral anticoagulant on discharge. Discharge follow-up will be needed to monitor the client's progress on the oral anticoagulant.

EVALUATION

The nurse is responsible for the ongoing evaluation of the client's response to medication. This evaluation requires knowledge of the therapeutic action of drugs and of the side effects and adverse reactions that can occur. Changes in a client's health status can change the way a client responds to medications. For example, clients who develop renal failure do not excrete medications well, and medications can build up within their system. Nurses need to assess for changes in clients' responses to medication. Nurses in the community setting need to evaluate their clients' ongoing ability to manage their own medication regimens. They can discuss the

regimen with the client and the family, observe client technique (as in self-administration of injections), and take physiological measures such as blood pressure readings. The nurse uses all information gathered through any source as a way of determining if the intended interventional outcomes are met.

The nurse who identifies a potential medication risk and initiates actions to prevent client injury is performing another form of evaluation. For example, if the client in the home setting cannot remember if the prescribed medications have been taken, providing the client with a daily or weekly pill box that is filled when the nurse is present prevents the client from taking too much medication or failing to take the dose as ordered.

PROCEDURE 30-1

Medication Administration: Oral, Sublingual, and Buccal

EQUIPMENT

- Prescribing practitioner's order for the medication
- Medication administration record (MAR)
- Medication cart or dispensing computer
- Medication tray
- Disposable medication cups
- Glass of water, juice, or other liquid
- Drinking straw
- Mortar and pestle, if needed
- Paper towels

ACTION

1. Wash hands/hand hygiene; put on clean gloves.
2. Arrange the medication tray and cups in the medication room or on the medication cart outside the client's room (see Figure 30-26). Most hospitals use a computerized, limited-access medication cart. Follow institutional protocol.

RATIONALE

1. Reduces the number of microorganisms.
2. Organizing medications and equipment saves time and reduces the possibility of error.

FIGURE 30-26 In some settings, medications are prepared at the medication cart. DELMAR/CENGAGE LEARNING

3. Unlock the medication cart, or log on to the computer.
4. Prepare the medication for one client at a time following the five rights. Select the correct drug from the medication drawer according to the MAR (see Figure 30-27 on page 790). Calculate the drug dosage if needed.
3. Medications need to be safeguarded.
4. The five rights are right client, right time, right medication, right dose, and right route. Comparing the MAR with the label reduces error. Double-checking reduces error in calculation.

(Continues)

PROCEDURE 30-1 Medication Administration: Oral, Sublingual, and Buccal (Continued)

ACTION

FIGURE 30-27 Select the correct drug from the medication drawer. DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 30-28 Scored tablets may be broken, if necessary. DELMAR/CENGAGE LEARNING

5. To prepare a tablet or capsule: Pour the required number of tablets or capsules into the bottle cap, and transfer the medication to a medication cup without touching them.
 - Scored tablets may be broken, if necessary, using gloved hands or with a pill-cutting device (see Figure 30-28).
 - A unit-dose tablet should be placed directly into the medicine cup *without* opening it until it is administered to the client.
 - For clients with difficulty in swallowing, some tablets may be crushed into a powder using a mortar and pestle or by being placed between two paper medication cups and ground with a blunt object, then mixed in a small amount of applesauce or custard. Be aware that time-released or specially coated medications must not be crushed. Check with the pharmacy if you are uncertain (see Figure 30-29 on page 791).
5. Avoids wasting expensive medications and avoids contamination of medication.
 - Tablets that are not scored are not meant to be broken. The medication's effectiveness would be diminished if the tablet were broken or crushed.
 - The wrapper maintains cleanliness and identification until it is administered.
 - A large tablet is usually easier to swallow if it is ground and mixed with soft food.

(Continues)

PROCEDURE 30-1 Medication Administration: Oral, Sublingual, and Buccal (Continued)

ACTION

RATIONALE

FIGURE 30-29 Some medications may be crushed and mixed with soft food, such as applesauce, for clients with difficulty in swallowing. DELMAR/CENGAGE LEARNING

6. To prepare a liquid medication: Remove the bottle cap from the container, and place cap upside down on the cart. Hold the bottle with the label up and the medication cup at eye level while pouring (see Figure 30-30). Fill the cup to the desired level using the surface or base of the meniscus as the scale, not the edge of the liquid on the cup. Wipe lip of bottle with paper towel.
7. To prepare a narcotic, obtain the key to the narcotic drawer and check the narcotic record for the drug count when signing out the dose (see Figure 30-31). If the drug count does not agree with records, report to charge nurse immediately. Institution may require an incident report be filed.

6. Placing the bottle cap upside down on the cart prevents contamination of the inside of the container. Holding the bottle with the label up keeps spilled liquid from obliterating the label. Holding the medication cup at eye level ensures an accurate dose. Wiping the lip of the bottle prevents the bottle cap from sticking.
7. Controlled substance laws require records of each dose dispensed. Early identification of errors assists in corrective action.

FIGURE 30-30 Measure oral medications at eye level. DELMAR/CENGAGE LEARNING

Ensures that the medication is absorbed and utilized correctly. • Nurse is responsible for ensuring that the client receives the dose and does not save it or discard it. • Maintains client's comfort. <p>10. Reduces transmission of microorganisms.</p> <p>11. Prevents administration error.</p> <p>12. Assists other staff in completing duties efficiently.</p>

delegation tip

The skill of medication administration and assessment of effects is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

Some medications require monitoring of blood levels to determine their effectiveness. When reviewing these laboratory values, notice if the levels are higher (toxic) or lower (subtherapeutic) than the recommended therapeutic range for that medication. Adjustments in the medication dose by the prescribing practitioner may be warranted to reach the recommended therapeutic level.

PROCEDURE
30-2

Withdrawing Medication from an Ampule

EQUIPMENT

- Medication ampule
- Sterile gauze pad or alcohol pad
- Syringe with filter needle
- Replacement needle
- Clean workspace
- Medication administration record (MAR)

|--|--|

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- Double-check the vial for the appropriate medication. Be certain that a medication error does not happen.
- Verify that the generic name on the vial is the same trade medication that is desired.
- Many new medications are coming on the market, often with similar names. Always verify that the medication you are about to use is the medication desired.

PROCEDURE 30-3

Withdrawing Medication from a Vial

EQUIPMENT

- Medication vial
- Syringe with needle
- Clean workspace
- Alcohol sponge pad
- Gloves (optional)
- Medication administration record (MAR)

(Continues)

PROCEDURE 30-3 Withdrawing Medication from a Vial (Continued)

ACTION	RATIONALE
<ol style="list-style-type: none"> 1. Wash hands/hand hygiene; secure supplies (see Figure 30-42). Apply gloves (optional). 2. Select the appropriate vial (see Figure 30-43). 3. Verify prescribing practitioner's orders. 4. Check expiration date. 	<ol style="list-style-type: none"> 1. Decreases transmission of microorganisms. 2. Prevents medication errors. 3. Prevents medication errors. 4. Avoids giving expired medication, which may have altered potency. 5. The route of medication delivery is essential to knowing what size syringe and needle will be needed. 6. Holding the syringe at eye level makes it easier to read the syringe calibrations and increases accuracy. 7. Ensures that the center of the rubber top is the cleanest area for needle entry. Reduces potential contamination with microorganisms. 8. Prevents spread of microorganisms.
<ol style="list-style-type: none"> 5. Determine the route of medication delivery, and select the appropriate size syringe and needle. 6. While holding the syringe at eye level, withdraw the plunger to the desired volume of medication. 7. Clean the rubber top of the vial with a 70% alcohol pad. Use a circular motion starting at the center and working out. 8. Using sterile technique, uncap the needle (see Figure 30-44). 9. Lay the needle cap on a clean surface. 	<ol style="list-style-type: none"> 9. Prevents spread of microorganisms.

FIGURE 30-42 Syringe, needle, vial of medication, and alcohol wipe are used to withdraw medication from a vial. DELMAR/CENGAGE LEARNING

FIGURE 30-43 Carefully select the medication ordered. DELMAR/CENGAGE LEARNING

FIGURE 30-44 Using sterile technique, uncap the needle. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-3 Withdrawing Medication from a Vial (Continued)

ACTION

FIGURE 30-45 Invert the vial and slowly withdraw the medication until the appropriate dosage has been reached. DELMAR/CENGAGE LEARNING

10. Placing the needle in the center of the vial, and inject the air slowly. Do not cause turbulence.
11. Invert the vial and slowly, using gentle negative pressure, withdraw the medication. Keep the needle tip in the liquid.
12. With the syringe at eye level, determine that the appropriate dose has been reached by volume (see Figure 30-45).
13. Slowly withdraw the needle from the vial. Follow the institution's policy regarding recapping and changing needles (see Figure 30-46).
14. Using ink, mark the current date and time and initials on the vial.
15. Label the syringe with drug, dose, date, and time.
16. Wash hands/hand hygiene.

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- Use the Z-track method routinely.
- Palpate your landmarks. Do not just visualize them.
- At times the medication itself causes pain for the client. Giving the medication slowly will decrease the client's discomfort.

RATIONALE

FIGURE 30-46 Follow the institutional policy regarding recapping needles. DELMAR/CENGAGE LEARNING

10. Adding air prevents the buildup of negative pressure in the vial. Injecting quickly may cause turbulence, which can result in air bubbles forming within the vial, which could affect the accuracy of the volume of liquid being withdrawn.
11. Decreases the number of air bubbles that tend to form with unsteady, fast, jerky motions. Keeping the needle tip in the liquid prevents drawing in air.
12. Ensures client receives the ordered dose of medication.
13. Avoids splatter of medication and potential contamination of nearby supplies. Keeps the needle sterile.
14. Prevents using a medication that has been opened too long per institutional protocol.
15. Prevents medication errors.
16. Decreases transmission of microorganisms.

PROCEDURE 30-4

Mixing Medications from Two Vials into One Syringe

EQUIPMENT

- Medication administration record (MAR)
- Medication vials
- Syringe
- Alcohol wipes

ACTION

1. Check MAR against the prescribing practitioner's written orders.
2. Check for drug allergies.
3. Wash hands/hand hygiene.
4. Gather the equipment needed (see Figure 30-47). Prepare the medication for one client at a time.
5. Check need for one medication to be drawn up before the other.
6. Determine the total medication volume (in milliliters) you will have in the syringe when you have finished drawing both medications into the syringe.
7. Swab the top of each vial with alcohol (see Figure 30-48).
8. Draw air into the syringe equal to the amount of medication to be drawn up from the second vial (see Figure 30-49 on page 800). Inject air into the second vial, and remove the syringe and needle from the vial (see Figure 30-50 on page 800). Some protocols require changing needles.

RATIONALE

1. Ensures accuracy in the administration of the medication.
2. Decreases risk of allergic reaction such as hives, urticaria, or anaphylactic shock.
3. Decreases transmission of microorganisms.
4. Promotes organization. Ensures that the right client receives the right medications.
5. Determines the order in which medications will be drawn up.
6. Determines how much of the second medication will need to be drawn into the syringe.
7. Decreases the transmission of microorganisms.
8. Avoids creating a vacuum in the second vial. When you draw medication from the second vial, you will not be able to inject air at that time because your syringe will already contain medication from the first vial. If you inject air, you will risk injecting medication and contaminating the second vial.

FIGURE 30-47 Syringe with needle, vials, and alcohol wipes are used to draw two medications into one syringe. DELMAR/CENGAGE LEARNING

FIGURE 30-48 Swab the top of each vial with alcohol. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-4 Mixing Medications from Two Vials into One Syringe (Continued)

ACTION

FIGURE 30-49 Draw air into the syringe equal to the amount of medication to be drawn up from the second vial. DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 30-50 Inject air into the second vial. DELMAR/CENGAGE LEARNING

9. Draw air into the syringe equal to the amount of medication to be drawn up from the first vial. Inject air into the first vial. Keep the needle and syringe in the vial (see Figure 30-51).
10. Pulling back on the plunger, withdraw the correct amount (in milliliters) of medication from the first vial (see Figure 30-52).
11. Remove the syringe from the first vial, and insert it into the second vial. Withdraw medication from the second vial to the volume (in milliliters) total of both medications summed together (see Figures 30-53 and 30-54 on page 801).

9. Avoids creating a vacuum in the first vial.
10. Draws up the first medication.
11. Draws up the second medication. Drawing up medication equal to the total of both medications ensures the correct amount of second medication is withdrawn.

FIGURE 30-51 Inject air into the first vial. DELMAR/CENGAGE LEARNING

FIGURE 30-52 Withdraw the correct amount of medication from the first vial. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-4 Mixing Medications from Two Vials into One Syringe (Continued)

ACTION

RATIONALE

FIGURE 30-53 Withdraw medication from the second vial to the volume of both medications summed together.

DELMAR/CENGAGE LEARNING

FIGURE 30-54 Double-check the syringe to make sure it contains medication equal to the total volume of both medications summed together.

DELMAR/CENGAGE LEARNING

12. Either leave the needle in the second vial until just prior to injecting the medication or follow the institution's policy regarding recapping needles.
13. Wash hands/hand hygiene.

MIXING INSULIN

Insulin solutions come premixed and in insulin pens; however, if these are not available, certain insulin solutions can be mixed. The clear insulin (regular, short-acting) is generally drawn up first, and then the cloudy solution (intermediate or long-acting). Mixing insulin can change time of action, absorption, and bioavailability; therefore, check the manufacturers' information regarding types of insulin, and carefully assess response of client. Before administering insulin, dosage must be double-checked by two professionals. An inaccurate dose of insulin can be life threatening.

14. Check client's most recent blood glucose level, dietary intake, oral intake status (e.g., NPO), and signs and symptoms related to glucose level.
15. Repeat Actions 1–4.
16. Remove caps from insulin vials (if necessary). Gently rotate (never shake) the suspension insulin (e.g., NPH, intermediate, or long-acting insulin) until no sediment is at the bottom of the vial.
17. Wipe off tops on insulin vials with alcohol sponge.

12. Prevents needlestick injuries.

13. Reduces transmission of microorganisms.

14. Prevents hypoglycemic episodes. May need to check with prescribing practitioner regarding insulin dosage. Prevents wasting of insulin if not to be given.
15. See Rationales 1–4.
16. Long-acting insulin is a cloudy suspension and needs to be completely and gently mixed to ensure that all particles are distributed equally in suspension.
17. Removes surface microorganisms.

(Continues)

PROCEDURE 30-4 Mixing Medications from Two Vials into One Syringe (Continued)

ACTION	RATIONALE
18. Draw back the amount of air into the syringe that equals the total dose of both insulin solutions. Insert the needle and syringe into the vial with the cloudy, suspension (intermediate or long-acting insulin), and inject air equal to the amount to be given of that insulin. Do not touch solution with needle.	18. Prevents negative pressure from pulling solution into vial for next use. Prevents contamination with different types of insulin.
19. Insert needle and syringe into vial of short-acting or regular insulin, and inject air equal to the amount to be given.	19. Prevents negative pressure in vial.
20. Keep needle and syringe in solution. Invert vial and withdraw medication slowly and accurately.	20. Slow withdrawal can help prevent air trapping and ensure accuracy.
21. Withdraw needle, expel any air bubbles, and check dose with another nurse.	21. Insulin must be double-checked for accuracy because of the dangers of administration of an inaccurate dose.
22. Invert the vial with longer-acting insulin, holding plunger carefully, and withdraw long-acting insulin, being careful not to inject any regular insulin into vial. Check dose with another nurse.	22. Prevents withdrawal of air and too much insulin. If too much insulin is withdrawn, the solution must be discarded and the procedure repeated. If regular insulin is accidentally injected into a vial of cloudy insulin, the vial must be discarded.
23. Store insulin properly according to manufacturer's specifications.	23. Ensures effective product.
24. Wash hands/hand hygiene; prepare to administer injection.	24. Prevents transmission of microorganisms.

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

Manufacturers are required by law to put the expiration date on all drugs. The nurse should check the expiration date to ensure that the drug is current. Outdated drugs should be returned to the pharmacy for proper disposal.

PROCEDURE 30-5

Medication Administration: Intradermal

EQUIPMENT

- Tuberculin syringe, 1 mL
- Needle (25- to 27-gauge, 1/4- to 5/8-inch)
- Antiseptic or alcohol swabs
- Medication ampule or vial
- Medication card or medication administration record (MAR)
- Disposable gloves

(Continues)

PROCEDURE 30-5 Medication Administration: Intradermal (Continued)

ACTION	RATIONALE
<ol style="list-style-type: none"> 1. Wash hands/hand hygiene; put on clean gloves. 2. In the inpatient setting, close door or curtains around bed and keep gown or sheet draped over body. In the outpatient setting, close door to exam or treatment room. Identify client. 3. Select injection site. <ul style="list-style-type: none"> • Inspect skin for bruises, inflammation, edema, masses, tenderness, and sites of previous injections. • Forearm site should be 3 to 4 finger widths below antecubital space and one hand width above wrists on inner aspect of forearm. 4. Select 1/4- to 5/8-inch, 25- to 27-gauge needle (see Figure 30-55). 5. Assist client into a comfortable position. Forearm site: Relax the arm with elbow and forearm extended on a flat surface. Distract client by talking about an interesting subject. 6. Use antiseptic swab in a circular motion to clean skin at site. 7. While holding the swab between fingers of nondominant hand, pull cap from needle. 8. Administer injection: <ul style="list-style-type: none"> • With nondominant hand, stretch skin over site with forefinger and thumb. • Insert needle slowly at a 10° to 15° angle, bevel up, until resistance is felt; then advance to no more than 1/8 inch below the skin. The needle tip should be seen through the skin. • Slowly inject the medication. Resistance will be felt. • Note a small bleb, like a mosquito bite, forming under the skin surface (see Figure 30-56). 	<ol style="list-style-type: none"> 1. Reduces transmission of microorganisms. 2. Provides privacy. Ensures medication is given to right client. 3. Injection site should be free of lesions. Repeated daily injections should be rotated. Ensures a clear site for interpreting results. 4. Ensures that needle will be injected into the intradermis. 5. Relaxation minimizes discomfort. Distraction reduces anxiety. 6. Circular motion and mechanical action of swab remove secretions containing microorganisms. 7. Swab remains accessible during procedure. Prevents contamination of needle. 8. <ul style="list-style-type: none"> • Needle penetrates tight skin easier than loose skin. • Ensures needle tip is in the dermis. • Dermal layer is tight and does not expand easily when fluid is injected. • Indicates the medication was deposited in the dermis.

FIGURE 30-55 Syringes come in many sizes. Select a 1-mL tuberculin safety syringe for intradermal injections. DELMAR/CENGAGE LEARNING

FIGURE 30-56 Note a small bleb, like a mosquito bite, forming under the skin surface as the medication is injected. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-5 Medication Administration: Intradermal (Continued)

ACTION	RATIONALE
9. Withdraw the needle while applying gentle pressure with the antiseptic swab.	9. Supporting tissue around injection site minimizes discomfort.
10. Do not massage the site.	10. Prevents medication from being dispersed into the tissue and altering test results.
11. Assist the client to a comfortable position.	11. Promotes comfort.
12. Discard the uncapped needle and syringe in a safe receptacle.	12. Decreases risk of needlestick.
13. Remove gloves; wash hands/hand hygiene.	13. Reduces transmission of microorganisms.

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- Remember to inject the needle with the bevel up so the medication is not injected into the subcutaneous tissue.
- Remember when documenting the site of the injection to indicate left or right arm, as markings often wash off.
- Mark sites with skin marking pen, if appropriate. This avoids confusion when evaluating results.
- If a bleb or wheal does not appear after an intradermal injection, select another site and repeat injection.

PROCEDURE 30-6

Medication Administration: Subcutaneous

EQUIPMENT

- Syringe appropriate for the medication being given
- Needle (25- to 27-gauge, 3/8- to 5/8-inch)
- Antiseptic or alcohol swabs
- Medication ampule or vial
- Medication administration record (MAR)
- Disposable gloves

ACTION	RATIONALE
1. Wash hands/hand hygiene; put on clean gloves. Select the appropriate syringe for the medication being given (see Figure 30-57 on page 805).	1. Reduces number of microorganisms.
2. Close door or curtains around bed, and keep gown or sheet draped over client. Identify client.	2. Provides privacy. Ensures medication is given to right client.
3. Select injection site. <ul style="list-style-type: none"> • Inspect skin for bruises, inflammation, edema, masses, tenderness, and sites of previous injections and avoid these areas. • Use subcutaneous tissue around the abdomen, lateral aspects of upper arm or thigh, or scapular area. 	3. Injection site should be free of lesions. <ul style="list-style-type: none"> • Repeated daily injections should be rotated. • Avoids injury to underlying nerves, bones, and blood vessels.

(Continues)

PROCEDURE 30-6 Medication Administration: Subcutaneous (Continued)

ACTION

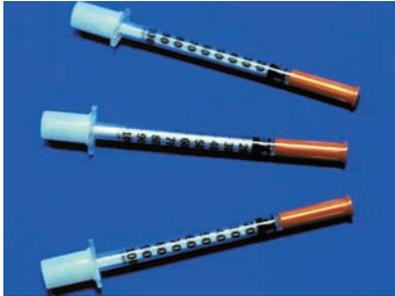

FIGURE 30-57 100-unit insulin syringes are used to administer insulin subcutaneously. DELMAR/CENGAGE LEARNING

4. Select needle size:
 - Measure skinfold by grasping skin between thumb and forefinger.
 - Be sure needle is one-half the length of the skinfold from top to bottom.
5. Assist client into a comfortable position:
 - Relax the arm, leg, or abdomen.
 - Distract client by talking about an interesting subject or explaining what you are doing step by step.
6. Use antiseptic swab to clean skin at site.
7. While holding swab between fingers of nondominant hand, pull cap from needle.
8. Administer injection:
 - Hold syringe between thumb and forefinger of dominant hand like a dart.
 - Pinch skin with nondominant hand (see Figure 30-58).
 - Inject needle quickly and firmly (like a dart) at a 45° to 90° angle (see Figure 30-59 on page 806).
 - Release the skin.
 - Grasp the lower end of the syringe with nondominant hand, and position dominant hand to the end of the plunger. Do not move the syringe.
 - Pull back on the plunger to ascertain that the needle is not in a vein. If no blood appears, slowly inject the medication. (Aspiration is contraindicated with some medications; check with the pharmacy if you are unclear.)

RATIONALE

FIGURE 30-58 Pinch the skin with the nondominant hand. DELMAR/CENGAGE LEARNING

4. Ensures that needle will be injected into subcutaneous tissue.
5. Relaxation minimizes discomfort. Distraction reduces anxiety.
6. Circular motion and mechanical action of swab remove microorganisms.
7. Swab remains accessible during procedure. Prevents contamination of needle.
8.
 - Quick, smooth injection is easier with proper position of syringe.
 - Needle penetrates tight skin easier than loose skin. Pinching skin elevates subcutaneous tissue.
 - Quick, firm injection minimizes discomfort. Angle depends on amount of subcutaneous tissue present and the site used.
 - Injection requires smooth manipulation of syringe parts. Movement of syringe may cause discomfort.
 - Aspiration of blood indicates intravenous placement of needle, so procedure may have to be abandoned.

(Continues)

PROCEDURE 30-6 Medication Administration: Subcutaneous (Continued)

ACTION

RATIONALE

FIGURE 30-59 When injecting at a 90° angle, hold the syringe like a dart and pierce the skin quickly and firmly. DELMAR/CENGAGE LEARNING

- | | |
|--|---|
| <p>9. Remove hand from injection site and quickly withdraw the needle. Apply pressure with the antiseptic swab. Do not push down on the needle with the swab while withdrawing it, as this will cause more pain.</p> <p>10. Apply pressure. Some medications should not be massaged. Ask the pharmacy if you are unclear.</p> <p>11. Assist the client to a comfortable position.</p> <p>12. Discard the uncapped needle and syringe in a disposable needle receptacle.</p> <p>13. Remove gloves; wash hands/hand hygiene.</p> | <p>9. Supporting tissue around injection site minimizes discomfort. Removing hand before withdrawing needle reduces chance of needlestick.</p> <p>10. Stimulates circulation and improves drug distribution and absorption.</p> <p>11. Promotes comfort and encourages client to remain still.</p> <p>12. Decreases risk of needlestick.</p> <p>13. Reduces transmission of microorganisms.</p> |
|--|---|

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- A simple rule to follow: If 2 inches of tissue can be grasped, the needle should be inserted at a 90° angle. If 1 inch of tissue can be grasped, the needle should be inserted at a 45° angle.
- Do not push a needle through the skin; insert it quickly and smoothly.
- Divert the client's attention by engaging in conversation.

PROCEDURE 30-7

Medication Administration: Intramuscular

EQUIPMENT

- Safety syringe (1- to 3-mL)
- Safety needle (19- to 23-gauge, 1 1/4 to 1 1/2 inches)
- Antiseptic or alcohol swabs
- Medication ampule or vial
- Medication administration record (MAR)
- Disposable gloves

ACTION

1. Wash hands/hand hygiene; put on clean gloves.
2. Close door or curtains around bed, and keep gown or sheet draped over client. Identify client.
3. Select injection site.
 - Inspect skin for bruises, inflammation, edema, masses, tenderness, and sites of previous injections.
 - Use anatomic landmarks.
4. Select needle size: Assess size and weight of client and site to be used. If appropriate, select prefilled syringe plunger, barrel, and needle cartridge (see Figures 30-60 and 30-61).
5. Assist client into a comfortable position:
 - For vastus lateralis, lying flat or supine with knee slightly flexed.
 - For ventrogluteal, lying on side or back with knee and hip slightly flexed.
 - For deltoid, standing with arm relaxed at side, sitting with lower arm relaxed on lap, or lying flat with lower arm relaxed across abdomen.
 - Distract client by talking about an interesting subject.
6. Use antiseptic swab to clean skin at site.
7. While holding swab between fingers of nondominant hand, pull cap from needle.

RATIONALE

1. Reduces number of microorganisms.
2. Provides privacy. Ensures medication is given to the right client.
3. Injection site should be free of lesions.
 - Repeated daily injections should be rotated.
 - Avoids injury to underlying nerves, bones, and blood vessels. Site should be selected based on muscle development, type and amount of medication, and comfortable access to site.
4. Ensures that needle will be injected into the muscle.
5. Relaxation minimizes discomfort. Distraction reduces anxiety.
6. Circular motion and mechanical action of swab remove secretions containing microorganisms.
7. Swab remains accessible during procedure. Prevents contamination of needle.

Remove gloves, and wash hands/hand hygiene.</p> | <p>8.</p> <ul style="list-style-type: none"> • Quick, smooth injection is easier with proper position of syringe. • Needle penetrates tight skin more easily than loose skin. • Quick, firm injection minimizes discomfort. • Injection requires smooth manipulation of syringe parts. Movement of syringe may cause discomfort. • Aspiration of blood indicates intravenous placement of needle, so procedure may have to be abandoned. <p>9. Supporting tissue around injection site minimizes discomfort. Removing hand prior to withdrawing needle prevents needlestick.</p> <p>10. Pressure prevents medication from leaking out of site. Gentle massage stimulates circulation and improves drug distribution and absorption.</p> <p>11. Promotes comfort.</p> <p>12. Decreases risk of needlestick.</p> <p>13. Reduces transmission of microorganisms.</p> |
|---|--|

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse affects are anticipated or are being monitored.

(Continues)

PROCEDURE 30-7 Medication Administration: Intramuscular (Continued)

nursing tips

The nurse should not draw an air bubble when using a plastic disposable syringe, as doing so can dramatically affect the medication dosage.

PROCEDURE 30-8

Medication Administration via Secondary Administration Sets (Piggyback)

EQUIPMENT

- Disposable gloves
- Medication prepared in a labeled infusion bag
- Short microdrip or macrodrip tubing set for piggyback (needleless system preferred); see Figure 30-63
- Safety sterile needles, 21- or 23-gauge, if needleless system not available
- Antiseptic swab
- Adhesive tape
- IV pole
- Medication administration record (MAR)

ACTION

1. Check prescribing practitioner's order.
2. Wash hands/hand hygiene. *Gloves are not necessary if you are adding fluids to an existing infusion line.* Secure IV tubing for piggyback administration (see Figure 30-63).
3. Check client's identification bracelet.
4. Explain procedure and reason drug is being given.

RATIONALE

1. Ensures accurate administration of medication.
2. Reduces transmission of microorganisms.
3. Ensures medication is given to correct client.
4. Information decreases anxiety.

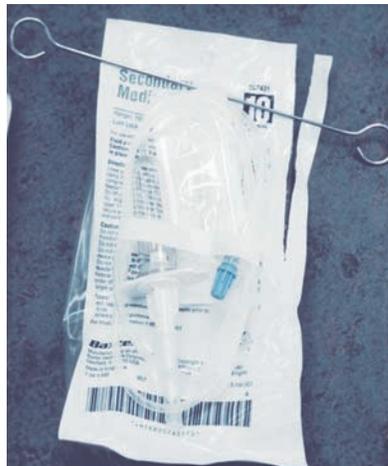

FIGURE 30-63 IV Tubing Set for Piggyback Administration. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-8 Medication Administration via Secondary Administration Sets (Piggyback) (Continued)

ACTION

RATIONALE

5. Prepare medication bag:
- Close clamp on tubing of infusion set.
 - Spike medication bag with infusion tubing (see Figure 30-64).
 - Open clamp (see Figure 30-65).
 - Allow tubing to be filled with solution to evacuate air from tubing (see Figure 30-66).

- 5.
- Prevents leakage of solution.
 - Provides a method of infusing the medication into the system.
 - Allows the solution to fill the tubing.
 - Prevents air embolus.

FIGURE 30-64 Spike the medication bag with the infusion tubing. DELMAR/CENGAGE LEARNING

FIGURE 30-65 Open the clamp on the IV tubing. DELMAR/CENGAGE LEARNING

FIGURE 30-66 Allow the tubing to fill with solution. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-8 Medication Administration via Secondary Administration Sets (Piggyback) (Continued)

ACTION

FIGURE 30-67 Hang the piggyback bag higher than the primary IV bag. DELMAR/CENGAGE LEARNING

6. Hang piggyback medication bag above level of primary IV bag. One way to do this is to lower the primary bag using an extender (found in the piggyback tubing package) (see Figure 30-67).
7. Connect piggyback tubing to primary tubing at Y-port:
 - For needleless system, remove cap on port and connect tubing (see Figure 30-68).
 - If a needle is used, clean port with antiseptic swab and insert small-gauge needle into center of port.
 - Secure tubing with adhesive tape.
8. Administer the medication:
 - Check the prescribed length of time for the infusion.
 - Regulate the flow rate of the piggyback by adjusting the regulator clamp (see Figure 30-69 on page 812).
 - Observe whether backflow valve on piggyback has stopped flow of primary infusion during drug administration.
9. Check primary infusion line when medication is finished:
 - Regulate primary infusion rate.
 - Leave secondary bag and tubing in place for next drug administration.
10. Dispose of all used materials, and place needles in needle biohazard sharps container.
11. Wash hands/hand hygiene.

RATIONALE

FIGURE 30-68 Remove cap on the needleless system port and connect the needleless system tubing. DELMAR/CENGAGE LEARNING

6. Relationship between height of the bags affects the flow rate to the client.
7. Ensures medication in piggyback bag is infused.
 - A needleless system is preferred to prevent accidental needlesticks.
 - A small-gauge needle does less damage to the rubber stopper on the port.
 - Prevents accidental removal of tubing.
8.
 - Each medication has a recommended rate for IV piggyback administration.
 - Medication infuses through primary line.
 - Prevents backup of medication into primary infusion line.
9.
 - Reestablishes primary infusion.
 - Reduces risk for entry of microorganisms by repeated changes of tubing.
10. Reduces transmission of microorganisms.
11. Reduces transmission of microorganisms.

(Continues)

PROCEDURE 30-8 Medication Administration via Secondary Administration Sets (Piggyback) (Continued)

FIGURE 30-69 Regulate the flow rate of the piggyback by adjusting the regulator clamp. DELMAR/CENGAGE LEARNING

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- Prepare medication and label in the medication room before approaching the client.
- Some IV solutions should be prepared by the pharmacist under the laminar air flow hood to ensure a sterile solution.
- Check with the pharmacist or drug text regarding drug compatibility.

PROCEDURE 30-9

Medication Administration: Eye and Ear

EQUIPMENT

EYE MEDICATION

- Medication administration record (MAR)
- Eye medication
- Tissue or cotton ball
- Nonsterile latex-free gloves (if needed)

EAR MEDICATION

- Medication administration record (MAR)
- Ear medication
- Nonsterile latex-free gloves
- Tissue

(Continues)

PROCEDURE 30-9 Medication Administration: Eye and Ear (Continued)

ACTION	RATIONALE
EYE MEDICATION	
<ol style="list-style-type: none"> 1. Check with the client and the chart for any known allergies or medical conditions that would contraindicate use of the drug. 2. Gather the necessary equipment. 3. Follow the five rights of drug administration. 4. Take the medication to the client's room and place on a clean surface. 5. Check client's identification armband. 6. Explain the procedure to the client; inquire if the client wants to instill medication. If so, assess the client's ability to do so. 7. Wash hands/hand hygiene; don nonsterile latex-free gloves if needed. 8. Place client in a supine position with the head slightly hyperextended. 	<ol style="list-style-type: none"> 1. Prevents occurrence of adverse reactions. 2. Promotes efficiency. 3. Promotes safety. 4. Decreases risk of contamination of bottle cap. 5. Accurately identifies client. 6. Reduces client's anxiety and enhances collaboration; some clients are used to instilling their own medication. 7. Decreases contact with bodily fluids. 8. Minimizes drainage of medication through the tear duct.
INSTILLING EYEDROPS	
<ol style="list-style-type: none"> 9. Remove cap from eye bottle, and place cap on its side. 10. Squeeze the prescribed amount of medication into the eyedropper. 11. Place a tissue below the lower lid. 12. With dominant hand, hold eyedropper 1/2–3/4 inch above the eyeball; rest hand on client's forehead to stabilize. 13. Place hand on cheekbone and expose lower conjunctival sac by pulling down on cheek. 14. Instruct the client to look up, and drop prescribed number of drops into center of conjunctival sac (see Figure 30-70 on page 814). 15. Instruct client to gently close eyes and move eyes. Briefly place fingers on either side of the client's nose to close the tear ducts and prevent the medication from draining out of the eye (see Figure 30-71 on page 814). 16. Remove gloves; wash hands/hand hygiene. 17. Record on the MAR the route, site (which eye), and time administered. 	<ol style="list-style-type: none"> 9. Prevents contamination of the bottle cap. 10. Ensures correct dose. 11. Absorbs the medication that flows from the eye. 12. Reduces risk of dropper touching eye structure and prevents injury to the eye. 13. Stabilizes hand and prevents systemic absorption of eye medication. 14. Reduces stimulation of the blink reflex; prevents injury to the cornea. 15. Distributes solution over conjunctival surface and anterior eyeball. 16. Reduces transmission of microorganisms. 17. Provides documentation that medication was given.
EYE OINTMENT APPLICATION	
<ol style="list-style-type: none"> 18. Repeat Actions 1–8. 19. Lower lid: <ul style="list-style-type: none"> • With nondominant hand, gently separate client's eyelids with thumb and finger and grasp lower lid near margin immediately below the lashes; exert pressure downward over the bony prominence of the cheek. 	<ol style="list-style-type: none"> 18. See Rationales 1–8. 19. <ul style="list-style-type: none"> • Provides access to the lower lid. • Reduces stimulation of the blink reflex and keeps cornea out of the way of the medication. • Ensures drug is applied to entire lid.

(Continues)

PROCEDURE 30-9 Medication Administration: Eye and Ear (Continued)

ACTION

FIGURE 30-70 Instruct the client to look up. Administer prescribed number of drops into the center of the conjunctival sac. DELMAR/CENGAGE LEARNING

- Instruct client to look up.
 - Apply eye ointment along inside edge of the entire lower eyelid, from inner to outer canthus.
20. Upper lid:
- Instruct client to look down.
 - With nondominant hand, gently grasp client's lashes near center of upper lid with thumb and index finger, and draw lid up and away from eyeball.
 - Squeeze ointment along upper lid starting at inner canthus.
21. Repeat Actions 16 and 17.

MEDICATION DISK

22. Repeat Actions 1–8.
23. Open sterile package and press dominant, sterile gloved finger against the oval disk so that it lies lengthwise across fingertip.
24. Instruct the client to look up.
25. With nondominant hand, gently pull the client's lower eyelid down and place the disk horizontally in the conjunctival sac.
- Then pull the lower eyelid out, up, and over the disk.
 - Instruct the client to blink several times.
 - If disk is still visible, repeat steps.
 - Once the disk is in place, instruct the client to gently press the fingers against the closed lids; do not rub eyes or move the disk across the cornea.
 - If the disk falls out, pick it up, rinse under cool water, and reinsert.

RATIONALE

FIGURE 30-71 Placing the fingers on the sides of the client's nose closes the tear ducts and prevents the medication from draining out of the eye. DELMAR/CENGAGE LEARNING

- 20.
- Keeps cornea out of the way of the medication.
 - Ensures medication is applied to entire length of lid.
21. See Rationales 16 and 17.
22. See Rationales 1–8.
23. Promotes sticking of disk to fingertip.
24. Reduces stimulation of the blink reflex and keeps cornea out of the way of the medication.
25. Allows the disk to automatically adhere to the eye.
- Secures the disk in the conjunctival sac.
 - Allows the disk to settle into place.
 - Ensures correct placement of the disk.
 - Secures disk placement. Prevents corneal scratches.
 - Preserves medication. This is not a sterile procedure. Health care provider must wear gloves to pick up disk.

(Continues)

PROCEDURE 30-9 Medication Administration: Eye and Ear (Continued)

ACTION	RATIONALE
26. If the disk is prescribed for both eyes, repeat Actions 23–25. 27. Repeat Actions 15–17.	26. Ensures both eyes are treated at the same time. 27. See Rationales 15–17.
REMOVING AN EYE MEDICATION DISK	
28. Repeat Actions 3 and 5–8. 29. Remove the disk: <ul style="list-style-type: none"> • With nondominant hand, invert the lower eyelid and identify the disk. • If the disk is located in the upper eye, instruct the client to close the eye, and place your finger on the closed eyelid. Apply gentle, long, circular strokes; instruct client to open the eye. Disk should be located in corner of eye. With your fingertip, slide the disk to the lower lid, and then proceed. • With dominant hand, use the forefinger to slide the disk onto the lid and out of the client's eye. 30. Remove gloves; wash hands/hand hygiene. 31. Record on the MAR the removal of the disk.	28. See Rationales 3 and 5–8. 29. <ul style="list-style-type: none"> • Exposes the disk for removal. • Safely moves the disk to the lower conjunctival sac. • Safely removes the disk without scratching the cornea. 30. Reduces transmission of microorganisms. 31. Provides documentation that the disk was removed.
EAR MEDICATION	
1. Check with client and chart for any known allergies. 2. Check the MAR against the prescribing practitioner's written orders. 3. Wash hands/hand hygiene. 4. Calculate the dose (see Figure 30-72). 5. Use the identification armband to properly identify the client.	1. Prevents the occurrence of hypersensitivity reactions. 2. Ensures accuracy in identification of the medication. 3. Reduces transmission of microorganisms. 4. Ensures administration of correct dose. 5. Ensures correct client.

FIGURE 30-72 Calculate the correct dose and draw medication into the ear dropper. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-9 Medication Administration: Eye and Ear (Continued)

ACTION

RATIONALE

FIGURE 30-73 Slowly instill the drops, holding the dropper at least 1/2 inch above the ear canal. DELMAR/CENGAGE LEARNING

- | | |
|--|--|
| <ul style="list-style-type: none"> 6. Explain the procedure to the client. 7. Place the client in a side-lying position with the affected ear facing up. 8. Straighten the ear canal by pulling the pinna down and back for children less than 3 years of age or upward and outward in adults and older children. 9. Slowly instill the drops into the ear canal by holding the dropper at least 1/2 inch above the ear canal (see Figure 30-73). 10. Ask the client to maintain the position for 2 to 3 minutes. 11. Place a cotton ball on the outermost part of the canal. 12. Wash hands/hand hygiene. 13. Document the drug, number of drops, time administered, and ear medicated. | <ul style="list-style-type: none"> 6. Enhances cooperation. 7. Facilitates administration of the medication. 8. Opens the canal and facilitates introduction of the medication. 9. Prevents injury to the ear canal. 10. Allows for distribution of the medication. 11. Prevents the medication from escaping when the client changes to a sitting or standing position. 12. Reduces transmission of microorganisms. 13. Documenting actions of the nurse will reduce the number of medication errors. |
|--|--|

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

It is a common error in household units to equate one drop to one minim. Because drops are variable, calibrated droppers should be used to administer medications by this method.

PROCEDURE 30-10

Medication Administration: Nasal

EQUIPMENT

- Medication in spray, drops, or aerosolized form
- Latex-free gloves
- Tissue as needed
- Dropper as needed

ACTION

1. Wash hands/hand hygiene. Wear a mask if the client is coughing or sneezing. Don latex-free gloves (see Figure 30-74).
2. Explain the purpose of the medication and the position desired for the client (see Figure 30-75).
3. Explain to the client the sensation of the local effects of the medications, such as burning, tingling, and effect on taste buds. If drops are used, explain to the client that a sensation of medications may be felt in the posterior oral pharynx.
4. If a nasal inhaler is prescribed, explain the manufacturer's directions and how inhalers work. Follow the five rights of drug administration (check identification and orders at five different stages of administration).

RATIONALE

1. Reduces transmission of microorganisms. Respiratory-related microorganisms are easily transferred by the hands and air droplets. Gloves prevent absorption of medication through the skin of health care worker.
2. Clients will be more compliant with medication if they understand the purpose and proper use of medication. Proper positioning is necessary with nose drops so the drops will reach the area of treatment by gravity with the client assuming a dependent position.
3. Some nasal medications cause undesirable tastes. If this occurs, the prescribing practitioner may order other medications or encourage mouthwashes after treatment. Warning of postnasal sensations of the medication will prepare the client. Some clients may feel a quick sensation of choking. This can be frightening if the client has not been alerted to this consequence.
4. Clients will be more compliant if they understand the use of the inhalers and that a fine cold mist will be released into the nasal passage via a pressurized container. Nasal medications that are prescribed must be considered to have the same safety precautions of administration as any medication.

FIGURE 30-74 Nasal medication spray. Wear latex-free gloves when administering nasal medication to a client. DELMAR/CENGAGE LEARNING

FIGURE 30-75 Explain the purpose of the medication to the client. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-10 Medication Administration: Nasal (Continued)

ACTION	RATIONALE
5. Have the client assume a comfortable position. If inhalers are to be used, this will generally be an upright position. If drops are to be instilled, the client should assume the appropriate position as mentioned earlier to medicate specific sinuses that need treatment. Before the instillation of drops or the use of an inhaler, ask the client to blow nose and clear nostrils of discharge as much as possible. Squeeze nose drops into dropper.	5. Nose drops are effective only if they reach the areas to be medicated. The client should be as comfortable as possible; otherwise, the client may not stay in desired position an adequate time. If the client is in a position with the neck hyperextended, a pillow or support by the nurse's hand under the neck may be necessary. Medications can be effective only if they are in contact with the mucous membranes. If large amounts of discharge are present, medications cannot be effective.
6. Have the client exhale and close one nostril.	6. The client will be asked to inhale with the use of nasal medications, so exhalation first is necessary.
7. Ask the client to inhale while the spray is pumped or sprayed into the first nostril (see Figure 30-76). If nose drops are used, insert nasal dropper only about 3/8 inch into the nostril, keeping the tip of the dropper away from the sides of the nostril. Insert the prescribed dosage of medication into the nostril. Discard any unused medication in dropper.	7. Nasal medications are more effective if instilled during inhalation as they will be carried and distributed farther into the nasal passages. Droppers should be kept away from the nostril to avoid inserting bacteria into the medication bottle. Excess medication is discarded for the same reason.
8. Ask the client to blot excess drainage from the nostril; however, do not have the client blow nose.	8. Blowing the nose will remove medication and therefore should not be done. However, excess medication should be removed from dripping out of the nostrils onto the facial areas in order to avoid discomfort.
9. Repeat the procedure on the other nostril.	9. Most often both nostrils contain congestion and therefore need to be treated.
10. Help the client resume a comfortable position. If nose drops are used, the client should stay in the appropriate position as indicated by manufacturer's suggestions, generally 5 minutes. Ask the client to breathe through the nose after the decongestion administration. It may be necessary to occlude one nostril at a time and breathe deeply.	10. Nose drops need positions that by gravity will allow medications to reach areas of desired treatment. (Note: If client will be self-administering medication, have client demonstrate administration; see Figure 30-77 on page 819.)

FIGURE 30-76 Ask the client to inhale while the spray is administered into the nostril.

DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-10 Medication Administration: Nasal (Continued)

ACTION

RATIONALE

FIGURE 30-77 If the client will be self-administering the medication, have the client demonstrate how to administer the medication. DELMAR/CENGAGE LEARNING

- | | |
|---|---|
| <ol style="list-style-type: none"> 11. Remove all soiled supplies and dispose according to Standard Precautions. Remove gloves. Wash hands/hand hygiene. 12. Evaluate the effect of the medication in 15 to 20 minutes. | <ol style="list-style-type: none"> 11. Use of gloves and proper disposal decreases the chance of transmission of microorganisms. Respiratory diseases are especially easily transmitted. 12. It is necessary to note if the medication is effective without adverse side effects; otherwise, other medications may be considered. If the client experiences bothersome or unpleasant symptoms, such as a bad taste, other medications may be considered. Clients generally will not comply with medications that have too many unpleasant side effects. |
|---|---|

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- If the nasal route of administration is used for medications with systemic effects, evaluate the patency of nasal passage before administration of the medication.
- Certain nasal medications may cause an unpleasant taste. Using a mouthwash after administration of the medications may aid in compliance with the prescribed regimen.
- Some clients may feel nauseated or even vomit after use of nasal medication, such as with nose drops or sprays that drip into the oral pharynx.

PROCEDURE 30-11

Medication Administration: Nebulizer

EQUIPMENT

HANDHELD NEBULIZER

- Medication administration record (MAR)
- Nebulizer set (cup, tubing, cap, T-shaped tube, mouthpiece, or mask) or prepackaged nebulizer and applicator
- Medication(s)
- Saline
- Air compressor, wall air, or wall oxygen

METERED-DOSE INHALER

- Metered-dose inhaler
- Aerochamber, if appropriate

ACTION

RATIONALE

HANDHELD NEBULIZER

- | | |
|--|--|
| <ol style="list-style-type: none"> 1. Assess client's ability to use the nebulizer. 2. Check the MAR against the prescribing practitioner orders. 3. Check for drug allergies and hypersensitivity. 4. Wash hands/hand hygiene before setting up the nebulizer; gather equipment (see Figure 30-78). 5. Set up the medication(s) for one client at a time. 6. Look at the medication at eye level if using droppers to dispense the solution into the nebulizer. | <ol style="list-style-type: none"> 1. Ensures client compliance. 2. Ensures accuracy in the administration of medication. (<i>Right drug</i>) 3. Decreases the risk of allergic reaction such as hives, urticaria, or anaphylactic shock. 4. Reduces transmission of microorganisms. 5. Ensures that client receives the right medication(s). (<i>Right drug</i>) 6. Increases accuracy. (<i>Right dose</i>) |
|--|--|

(Continues)

PROCEDURE 30-11 Medication Administration: Nebulizer (Continued)

ACTION	RATIONALE
7. Pour the entire amount of the drug(s) into the nebulizer cup carefully. <ul style="list-style-type: none"> • Avoid touching the drug while pouring into the nebulizer cup. 	7. Determines the correct amount of medicine and ensures accurate dosage. (<i>Right dose</i>) <ul style="list-style-type: none"> • Reduces transmission of microorganisms.
8. Cover the cup with the cap and fasten.	8. Prevents spillage of the medication.
9. Fasten the T-piece to the top of the cap.	9. Provides a connector for the mouthpiece.
10. Fasten a short length of tubing to one end of the T-piece.	10. Provides dead space to prevent room air from entering the system and medicated aerosol from escaping.
11. Fasten the mouthpiece or mask to the other end of the T-piece. <ul style="list-style-type: none"> • Avoid touching the nebulizer mouthpiece or the interior part of the mask. 	11. Provides a portal for the client to inhale the aerosolized medication. <ul style="list-style-type: none"> • Reduces transmission of microorganisms.
12. Identify the client prior to administration of medication(s).	12. Ensures the right client gets the medication. (<i>Right client</i>)
13. Identify the medication(s) to the client, and clearly explain the therapeutic purpose(s) of the medication.	13. Promotes client's cooperation and awareness of the medication's effects.
14. Advise the client to sit in an upright position.	14. Promotes better expansion of the lungs.
15. Attach tubing to the bottom of the nebulizer cup, and attach the other end to the air compressor or wall air. <ul style="list-style-type: none"> • Before turning it on, adjust the wall oxygen valve to 6 L/min (or less per prescribing practitioner's orders). • Leave the air on for about 6 to 7 minutes until the medications get used up. 	15. Provides a conduit for the compressed air. <ul style="list-style-type: none"> • Drives the medication into a mist or wet aerosol form. • Allows the client to receive the entire dose of medication.
16. Instruct the client to breathe in and out slowly and deeply through the mouthpiece or mask. <ul style="list-style-type: none"> • The client's lips should be sealed tightly around the mouthpiece. 	16. Promotes better deposition and efficacy of the medication in the airways.
17. Remain with the client long enough to observe the proper inhalation-exhalation technique.	17. Ensures the correct use of the nebulizer to get the full effects from the medications administered.
18. Wash hands/hand hygiene.	18. Reduces transmission of microorganisms.
19. Record the medications administered along with the date, time, and dosages on the chart.	19. Provides documentation of administration of drugs.
20. When the nebulizer cup is empty, turn off the compressor or wall air. <ul style="list-style-type: none"> • Detach the tubing from the compressor and the nebulizer cup. • If the nebulizer is disposable, dispose of the nebulizer in the appropriate container. • If the nebulizer is to be reused for this client, carefully wash, rinse, and dry the nebulizer components. 	20. Stops the aerosolization. <ul style="list-style-type: none"> • Prepares components for cleaning or disposal. • Prevents transmission of microorganisms. • Prevents transmission of microorganisms.

(Continues)

PROCEDURE 30-11 Medication Administration: Nebulizer (Continued)

ACTION	RATIONALE
21. Assess the client immediately following the treatment for results or adverse effects from the treatment.	21. Allows the nurse to determine the effectiveness of the treatment.
22. Reassess the client 5 to 10 minutes following the treatment.	22. Some effects may be delayed.
23. Wash hands/hand hygiene.	23. Reduces transmission of microorganisms.
METERED-DOSE NEBULIZER (SEE FIGURE 30-79)	
24. Assess the client for ability to use the metered-dose nebulizer.	24. Ensures client compliance.
25. Check the MAR against the prescribing practitioner's orders.	25. Ensures accuracy in the administration of medication.
26. Check for drug allergies and hypersensitivity.	26. Decreases the risk of allergic reaction, such as hives, urticaria, or anaphylactic shock.
27. Wash hands/hand hygiene before administering medication; don latex-free gloves.	27. Decreases risk of transmission of microorganisms and prevents reaction to latex.
28. Shake the prepackaged nebulizer.	28. Thoroughly mixes the medication.
29. Place the nebulizer into the applicator (see Figure 30-80).	29. Allows for proper administration of the medication.
30. Place the aerochamber onto the nebulizer if needed.	30. The aerochamber provides dead space for the medicated mist while the client inhales.
31. Have client place mouthpiece in mouth.	31. Delivers medication to lungs through the proper route.
32. Have the client press down on the prepackaged dispenser as the client simultaneously inhales.	32. Allows delivery of the medication to the lungs.
33. If there is an aerochamber attached to the nebulizer, have the client inhale slowly and deeply.	33. Allows proper delivery of the medication.
34. Observe the client for several minutes to assess for possible adverse effects from the medication.	34. Nebulized medication is delivered into the bloodstream almost immediately and reactions can occur right away.
35. Wash hands/hand hygiene.	35. Prevents transmission of microorganisms.
36. Record the medication administration and your observations.	36. Provides a record of care and ensures continuity of care.

FIGURE 30-79 Metered-Dose Nebulizer DELMAR/CENGAGE LEARNING

FIGURE 30-80 Preparation of a Metered-Dose Nebulizer and Medication DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-11
Medication Administration: Nebulizer (Continued)

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- Evaluate the client’s need for medication delivery. Some clients, such as young clients (usually less than 5 years old), clients with coordination problems, and clients with severe or acute asthma, will benefit more from using a nebulizer. Some clients, such as school-aged children, active adults, and clients with exercise-induced asthma, will benefit more from the ease and portability of a metered-dose inhaler.
- Be aware of the client’s ability to use the nebulizer device. Young children and clients with acute or severe exacerbation may not be able to use the mouthpiece for the nebulizer. A mask may provide better delivery of the medication(s).
- Measure the medication accurately by looking at the medicine dropper at eye level, and pour the exact amount of medication needed into the cup.
- Familiarize yourself with all the asthma medications in order to be aware of any outcomes the client may have from treatment. Some medications that the client might be taking can interact with each other. Beta blockers (propranolol, atenolol, and labetalol) can antagonize the beta agonists, increasing asthma symptoms. The nurse needs to be familiar with the medications in order to anticipate possible reactions.

PROCEDURE
30-12

Medication Administration: Rectal

EQUIPMENT

- Medication (suppository or medicated enema)
- Water-soluble lubricant
- Latex-free gloves
- Tissue or washcloth
- Bedpan if client physically immobile
- Medication administration record (MAR)
- Towels or pads (e.g., disposable “blue pads”)

ACTION

RATIONALE

1. Assess the client’s need for the medication.	1. Allows nurse to determine effectiveness of the medication.
2. Check prescribing practitioner’s written order.	2. Ensures safe and accurate administration of medication.
3. Check the MAR against the medication order, verifying correct client, medication, dose, route, and time.	3. Ensures accuracy and decreases chance of medication error.
4. Check for any drug allergies.	4. Decreases risk of allergic reaction.
5. Review the client’s history for any previous surgeries or bleeding.	5. Contraindications for rectal administration may be discovered.
6. Gather the equipment needed for the procedure before entering the client’s room (see Figure 30-81 on page 824).	6. Prevents numerous trips to gather supplies and helps the procedure flow smoothly.

(Continues)

PROCEDURE 30-12 Medication Administration: Rectal (Continued)

ACTION

FIGURE 30-81 Protective Pad, Latex-Free Gloves, Lubricant, and Rectal Medication DELMAR/CENGAGE LEARNING

7. Assess the client's readiness to receive the medication. Encourage visitors to leave until the procedure is completed, and close door or curtain.
8. Wash hands/hand hygiene.
9. Apply disposable gloves (see Figure 30-82).
10. Ask the client's name and check identification band.
11. Assist client into correct position: side-lying Sims' position, preferably the left side with upper leg drawn up toward chest. Provide protection under client such as towel or pad.
12. Visually assess the client's external anus.
13. Remove suppository from wrapper, and lubricate rounded end along with insertion finger. If a medicated enema is used, lubricate the enema tip if it is not prelubricated (see Figure 30-83).

RATIONALE

FIGURE 30-82 Don latex-free gloves before administering rectal medications. DELMAR/CENGAGE LEARNING

7. Promotes privacy and maintains self-image.
8. Reduces transmission of microorganisms.
9. Prevents contact with fecal material.
10. Ensures correct client.
11. The descending colon is on the left side; this is a more anatomically correct position. This position exposes the anus to identify placement. Pads can provide comfort to client who may fear soiling linen.
12. Determines presence of any active bleeding.
13. Lubrication decreases friction and decreases discomfort.

FIGURE 30-83 Lubricate the enema tip if necessary. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-12 Medication Administration: Rectal (Continued)

ACTION	RATIONALE
14. Tell client he or she will experience a cool sensation and pressure during administration. Encourage slow deep breaths.	14. Prepares client for administration. Relaxes the rectal sphincter.
15. Retract buttocks with nondominant hand, visualizing the anus (see Figure 30-84). Using the dominant index finger, slowly and gently insert the suppository through the anus, past the internal sphincter, and against the rectal wall. Depth of insertion will differ if client is a child or infant. If instilling a medicated enema, gently insert the enema tip past the internal sphincter and instill the contents by slowly squeezing (see Figure 30-85).	15. Slow insertion minimizes pain. Correct placement ensures adequate absorption and less chance for expulsion of medication.
16. Remove finger or enema tip, and wipe client's anal area with a washcloth or tissue.	16. Removes lubricant externally. Promotes cleanliness and comfort.
17. Discard gloves.	17. Reduces transmission of microorganisms.
18. Discuss with client a 10-minute time frame to remain in bed or on side.	18. Keeps suppository or medicated fluid in place for better absorption.
19. Place call light in client's reach if administering suppository containing laxative to assist once client has sensation to defecate.	19. Gives client control over situation and nurse response once sensation to defecate occurs.
20. Record administration of medication.	20. Provides documentation of administration of medication.
21. Document effectiveness or any side effects of treatment on nursing flow sheet or progress note if applicable.	21. Communicates with other caregivers the effectiveness of treatment.
22. Wash hands/hand hygiene.	22. Reduces transmission of microorganisms.

FIGURE 30-84 Retract the buttock and visualize the anus.

DELMAR/CENGAGE LEARNING

FIGURE 30-85 Gently insert the enema tip and instill the contents by slowly squeezing the bottle.

DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-12 Medication Administration: Rectal (Continued)

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- Adjust the height of the bed to decrease back strain during insertion.
- Communication helps decrease anxiety and promotes cooperation.
- Observe the client's nonverbal and verbal cues during the procedure.
- Provide for privacy: Close the door, pull the curtains, and ask visitors to leave until the procedure is complete.

PROCEDURE 30-13

Medication Administration: Vaginal

EQUIPMENT

- Vaginal medication: cream, foam, jelly, or suppository
- Applicator (if needed)
- Water-soluble lubricating jelly (for suppository)
- Nonsterile latex-free gloves
- Perineal pad
- Paper towel, toilet tissue, or tissue paper
- Washcloth and warm water (optional)

ACTION

RATIONALE

- | | |
|--|---|
| <ol style="list-style-type: none"> 1. Verify orders. 2. Ascertain if the client has ever had vaginal medications before and understands the procedure. 3. Ask the client to void. 4. Wash hands/hand hygiene. 5. Arrange equipment at client's bedside. 6. Provide complete privacy by closing door and curtains. 7. Assist the client into a dorsal-recumbent or Sims' position (see Figure 30-86 on page 827). 8. Drape the client as appropriate, such as over the client's abdomen and lower extremities. Provide towel or protective pad on bed. 9. Position lighting to illuminate vaginal orifice. 10. Don latex-free gloves and assess the perineal area for redness, inflammation, discharge, or foul odor. | <ol style="list-style-type: none"> 1. Prevents medication errors. 2. Enables client understanding and compliance. 3. Provides for client comfort during the procedure. 4. Reduces transmission of microorganisms. 5. Promotes organization. 6. This procedure can be embarrassing, and this protects the client's privacy. 7. Allows positioning for administration and for medication to remain in vagina. 8. Provides privacy. Prevents linen from becoming soiled. 9. Assists in visualization of vagina and proper administration of medication. 10. Decreases risk of transmission of microorganisms. Provides baseline data. Decreases risk of reaction to latex. |
|--|---|

(Continues)

PROCEDURE 30-13 Medication Administration: Vaginal (Continued)

ACTION

RATIONALE

FIGURE 30-86 This client is placed in Sims' position for administering vaginal medications. DELMAR/CENGAGE LEARNING

FIGURE 30-87 Place the suppository in the applicator. DELMAR/CENGAGE LEARNING

11. If using an applicator, fill with medication. If using a suppository, remove the suppository from the foil and position in the applicator (applicator is optional) (see Figure 30-87). An applicator may be used for suppositories, or a gloved finger may be used. The foil is discarded. Apply water-soluble lubricant to suppository or applicator (optional for applicator).
 12. For suppository, with nondominant hand, retract the labia (see Figure 30-88).
 13. With dominant hand, insert the applicator 2 to 3 inches into the vagina, sliding the applicator posteriorly (see Figure 30-89). Push the plunger to administer the medication (see Figure 30-90 on page 828). With a suppository, insert the tapered end first with the index finger or applicator along the posterior wall of the vagina (approximately 3 inches).
 14. Withdraw the applicator and place on a towel.
11. The medication is prepared for insertion. Lubricant provides comfort and ease of insertion.
 12. Allows visualization of the vaginal orifice and eases insertion of medication.
 13. Medication must be inserted completely to provide coverage of the entire vagina. When medication is deposited at the posterior end of the vagina, gravity will allow medication to move toward the orifice.
 14. Reduces transmission of microorganisms.

FIGURE 30-88 Retract the labia with the nondominant hand. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 30-13 Medication Administration: Vaginal (Continued)

ACTION	RATIONALE
20. Instruct the client to remain flat for at least 30 minutes.	20. Allows maximum contact between the medication and the vaginal mucous membranes.
21. Raise side rails and place the call light in reach.	21. Provides for client comfort and safety.
22. Wash hands/hand hygiene.	22. Reduces transmission of microorganisms.

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- Insert medication 2 to 3 inches.
- Clean client carefully after inserting medication to avoid perineal irritation.

KEY CONCEPTS

- The *United States Pharmacopeia* and *National Formulary* (USP and NF) outline drug standards for usage in the United States.
- The Food and Drug Administration (FDA) tests all drugs for toxicity before granting a company the right to market a drug.
- Drugs are usually referred to by their trade (company) or generic (nonproprietary) name.
- The oral administration route is the safest and least expensive administration route, although it is also the slowest to act.
- Parenteral drugs are injected through intradermal (ID), subcutaneous, intramuscular (IM), or intravenous (IV) routes and are typically fast-acting drugs.
- The pharmacokinetics of drugs includes absorption, distribution, metabolism, and excretion.
- Safe drug administration is facilitated by following the five rights: right drug, right dose, right client, right route, and right time.
- Nurses are both morally and legally responsible for correct administration of medications; this includes following institutional policy, considering clients' desires and abilities, fostering compliance, and correctly documenting all actions related to medication administration and medication errors.
- Drug abuse is a common problem, both in society and in the health care professions; nurses have a responsibility to report addicted colleagues so that they can find resources to help overcome their addictions.
- Before administering medications, the nurse must thoroughly assess the client's drug history, medical history, and psychosocial and cultural factors that may affect drug acceptance and compliance.
- Oral medications should be poured and measured at eye level to ensure accuracy.
- Although the prescribing practitioner will determine the dose and route of a parenteral drug, the nurse is responsible for choosing the correct gauge and length of the needle to be used.
- The nurse must always carefully monitor client reactions to medications and ensure that clients are appropriately educated as to the actions, side effects, and contraindications of all medications they are receiving.

REVIEW QUESTIONS

- The purpose of medication management is to produce the desired drug action by maintaining a constant drug level. The highest blood concentration of a single drug dose before the elimination rate equals the rate of absorption is called _____.
 - Onset of action
 - Peak plasma level
 - Half-life
 - Plateau
- The nurse cannot understand the prescribing practitioner's standing orders. What should she do?
 - Contact the unit manager to interpret the order.
 - Have the unit secretary call the prescribing practitioner.
 - Call the prescribing practitioner to have the order clarified.
 - Send the order to pharmacy, and let the pharmacist fill the order.
- The prescribing practitioner has order 2 teaspoonsful of Milk of Magnesia. The nurse converts this dose to the metric system and administers _____.
 - 5 mL
 - 10 mL
 - 15 mL
 - 30 mL
- What information should be obtained from the drug history?
 - Prescription drugs
 - Allergies
 - Herbal supplements
 - Over-the-counter drugs
 - Client's sensory and cognitive status
 - Lifestyles and beliefs
- What is the appropriate method to administer medications through a nasogastric tube?
 - Mix all medications together that are compatible, and flush with 20 to 30 mL warm water at the end.
 - Administer those medications that are compatible, and flush with 60 mL warm water at the end.
 - Administer each medication individually, and flush with 100 mL warm water at the end.
 - Administer each medication individually, flush with 15 to 30 mL warm water between each medication, and flush with 30 to 60 mL at the end.
- What is the usual dosage range for intradermal injections?
 - 0.01 to 0.1 mL
 - 0.1 to 0.15 mL
 - 1.15 to 0.2 mL
 - 0.2 to 0.25 mL
- The prescribing practitioner ordered 5 mL of a medication to be given deep IM for a 45-year-old female who weighs 140 pounds and is 5'7" tall. What is the most appropriate method to administer this injection?
 - A 5-mL syringe, 20–23-gauge, 1-inch needle
 - Two 3-mL syringes, 20–23-gauge, 1½-inch needle
 - Two 3-mL syringes, 23–25-gauge, 1-inch needle
 - Two 2-mL syringes, 20–23-gauge, 1½-inch needle
- The correct way to administer eardrops to an adult client is to _____.
 - Pull the pinna straight back
 - Pull the pinna down and back
 - Pull the pinna upward and outward
 - Pull the pinna straight down
- Which of the following is the correct way to administer eyedrops to an adult client?
 - Hold eye dropper in dominant hand, hold ½–¾ inch above the eyeball, and rest hand on client's forehead to stabilize. Use fingers of nondominant hand to separate the eyelids, instruct client to look up, and drop prescribed number of drops into center of the eye. Instruct the client to close eyes and move them around. Briefly place fingers on either side of the client's nose to close the tear ducts and prevent the medication from draining out of the eye.
 - Hold eye dropper in dominant hand, hold ½–1 inch above the eyeball, and rest hand on client's forehead to stabilize. Instruct the client to look up, and drop the prescribed number of drops into the center of the conjunctival sac. Instruct the client to gently close eyes and move eyes. Use a tissue to apply gentle pressure and absorb excess medication.
 - Hold eyedropper in dominant hand, hold ½–¾ inch above the eyeball, and rest hand on client's forehead to stabilize. Place nondominant hand on cheekbone, and expose lower conjunctival sac by pulling down on cheek. Instruct the client to look up, and drop the prescribed number of drops into the center of the conjunctival sac. Instruct client to gently close eyes and move eyes. Place fingers briefly on either side of the client's nose to close the tear ducts and prevent the medication from draining out of the eye.
 - Hold eyedropper in dominant hand; with nondominant hand, gently separate client's eyelids with thumb and finger, and grasp lower lid near margin immediately below lashes; exert pressure downward over the bony prominence of the cheek. Instruct the client to look up, and drop

the prescribed number of drops into the center of the conjunctival sac.

10. An RN has just received word of a new admission to the unit with the diagnosis of shortness of breath and indigestion-type pain. The RN needs to delegate procedures to other personnel and retain certain nursing functions. Which nursing functions can be delegated?
- Delegate to an LPN the administration of a prn IM injection for pain.
 - Delegate to an LPN the assessment of the new admission.
 - Delegate to an ancillary person the vital signs of the new admission.
 - Delegate to an ancillary person the observation of a client self-administering a metered-dose nebulizer.

CHAPTER 31

Complementary and Alternative Modalities

COMPETENCIES

1. Describe historical events influencing the use of complementary and alternative treatment modalities.
2. Discuss the effect of the mind-body relationship on a person's health.
3. Explain the concept of the nurse as an instrument of healing in holistic nursing practice.
4. Identify the various mind-body, body-movement, energetic-touch healing, spiritual, nutritional, and other modalities that can be used as complementary therapies in client care.
5. Discuss the use of complementary and alternative modalities throughout the life cycle.

KEY TERMS

acupressure
 acupuncture
 allopathic

Western society tends to think of healing in terms of medical, surgical, and other technological interventions. However, in many other cultures—both past and present—healing has been promoted by faith, magic, ritual, and other nonmedical approaches.

The use of **alternative therapies** (treatment approaches that are not accepted by mainstream medical practice) and **complementary therapies** (treatment approaches that can be used in conjunction with conventional medical therapies) is becoming more prevalent among the general public. This chapter discusses complementary and alternative medicine (CAM) treatment methods that are currently being used in holistic nursing practice. Nurses are encouraged to think critically before recommending or implementing these approaches and to also be open to the possibilities that are available to help people live to their fullest potential. It is important to remember that what is considered “alternative” to one culture may be viewed as “traditional” in another (e.g., traditional Chinese medicine and Ayurvedic medicine). The classification of CAM therapies changes according to research findings. “The list of what is considered to be CAM changes continually, as those therapies that are proven to be safe and effective become adopted into conventional health care and as new approaches to health care emerge” (National Center for Complementary and Alternative Medicine [NCCAM], 2007b).

HISTORICAL INFLUENCES ON CONTEMPORARY PRACTICES

For as long as history has been recorded, people have tried to cure ills and relieve pain. Early cave drawings depict healers practicing their art. Primitive healers attributed the cause of diseases to magic and superstition; as a result, religious beliefs and health practices became intertwined.

FROM ANCIENT TRADITION TO EARLY SCIENCE

Remedies and practices that are based in ancient traditions are being rediscovered and used by contemporary holistic

healers. This section discusses the impact of ancient healing practices on current use of CAM modalities.

Ancient Greece

The ancient Greek culture perceived health as maintenance of balance in all dimensions of life. In Greek mythology, Asclepius was the god of healing. Temples (called Asclepians) were beautiful places for people (regardless of ability to pay) to rest, restore themselves, and worship. The elaborate healing system consisted of myths, symbols, and rites administered by rigorously trained priest-healers.

The Far East

Healing systems of the Far East have traditionally integrated mind, body, and spirit into a system of balanced energy between the individual and the universe. The concept of a life force or life energy permeates Eastern philosophies. The accompanying Respecting Our Differences display lists the names of the life force in various cultures.

China

The traditional Chinese healing system is based on the belief in the oneness of all things in nature. Life energy (*chi*) flows through both the universe and the person, thus creating a

The Life Force in Various Cultures

Culture	Life Force
Chinese	Chi
Indian	Prana
Japanese	Qi
Native American	Flow of Spirit
Mystic Christianity	Holy Spirit
Greek	Pneuma

wholeness among all things and people. Chi provides warmth, protection from illness, and vitality. Chi flows along an invisible system of meridians (pathways) that link the organs together and connect them to the external environment and, therefore, to the universe. Illness and injury can alter the flow of this energy. The energy flow can be influenced by stimulating points along the meridians. Both acupuncture and acupressure are based on this concept of energy meridians.

Herbalism is an essential component of traditional Chinese healing practice. In seeking to promote balance, healers use herbs for dual purposes. For example, the herb *dong quai* relaxes the uterus when it is contracted and tightens it if it is too relaxed. A complete discussion of the use of herbs in contemporary health practices appears later in this chapter.

Many contemporary Western health care providers are studying and now using traditional Chinese medicine (TCM). These healing techniques have been used in various situations, such as with clients who are experiencing chronic pain associated with illness or injury. **Acupuncture**, one technique used in TCM, is the application of needles to various points on the body to alter the energy flow (see Figure 31-1).

India

Ayurveda, a healing system based on Hindu philosophy, embraces the concept of an energy force in the body that seeks to maintain balance or harmony. From the Ayurvedic perspective, the body and mind are filled with a vital energy (*prana*) that is the life force. The life energy (*prana*) is transported through the body by a “wind” or *vata*. *Vata* regulates every type of movement.

The Hindu concept of chakras refers to seven primary energy centers in the physical body. A **chakra** is a concentrated area of energy. The chakras are vertically aligned through the center of the body from the crown of the head to the pelvis. Chakras influence the physical body, emotions, mental patterns, and spiritual awareness. Each chakra has specific functions and a corresponding relationship to body structures and organs; see Figure 31-2.

FIGURE 31-1 Acupuncture Needles Inserted for Treatment of Depression COURTESY OF JACK STAR/PHOTOLINK/GETTY IMAGES

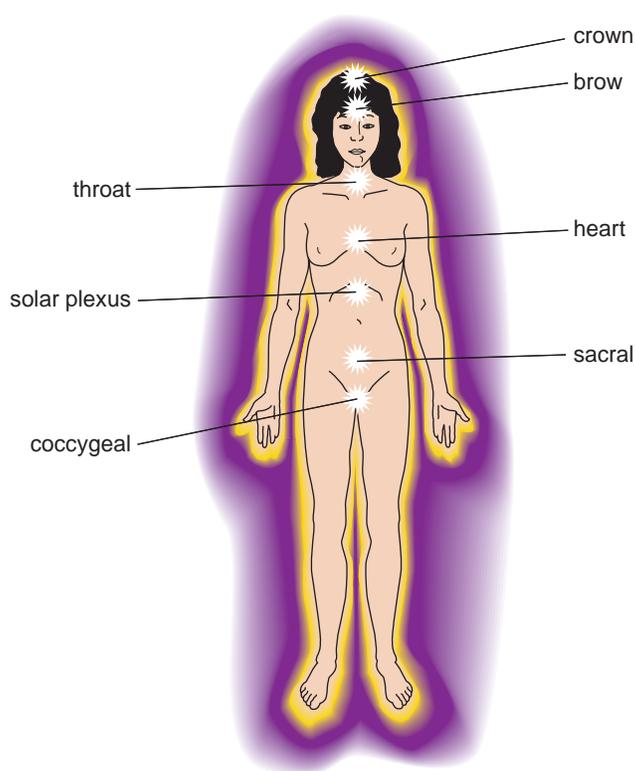

FIGURE 31-2 Locations of the Seven Major Chakras DELMAR/ CENGAGE LEARNING

Prevention of illness and restoration of health through introspection and spiritual growth are the primary goals in the Ayurvedic system. Union of the Divine and the Truth occurs through the physical and meditative practice of yoga. In contemporary practice, Ayurvedic intervention may consist of yoga, herbs, diet, exercise, steam baths, cathartics, and detoxifying massage.

SHAMANISTIC TRADITION

A need to understand and explain life processes (i.e., birth, health, illness, and death) is part of being human. Ritualized practices have been used to keep peace with the great spirits, to harness their power, to promote power, and to prevent death.

Shamanism refers to the practice of entering altered states of consciousness with the intent of helping others. The **shaman**, a folk healer-priest who uses natural and supernatural forces to help others, has an extensive knowledge of herbs, is skilled in many forms of healing, and serves as guardian of the spirits. Illness is considered to be the result of spirit loss. Shamans have the power to heal by working with the spirits to encourage their full return to the individual. The shaman functions as both healer and priest and one who has access to the supernatural.

Seeking wisdom about the universe, a relationship with the creator, and avoidance of death are all accomplished through ritualized processes that are performed by the shaman. The shaman's practice incorporates special objects such as power animals, totems, and fetishes as well as ritual songs, dances, food, and clothing. Sleep deprivation, ritual chants, isolation, imagery, drumming, and hallucinogenic drugs may

be used to create a trancelike state that is the vehicle through which the shaman contacts the spirit world.

ALLOPATHIC MEDICINE

Western medicine, referred to as **allopathic** medicine, is relatively new in that it was begun about 200 years ago. Its fundamental principle is that body and mind are separate entities. Allopathic medicine views the human as a collection of separate body parts. This conventional medical approach views health as the absence of disease and sees the goal of treatment as curing the disease or “fixing” the problem (e.g., trauma). The Western medical model focuses on ridding the body of symptoms induced by disease or injury.

The allopathic system is effective when aggressive treatment is needed for an emergency situation. State-of-the-art technology and advanced surgical techniques have become true lifesavers for many in modern Western societies. However, with its emphasis on curing symptoms, allopathic medicine overlooks the crucial role of energy, emotions, and thoughts. Allopathic medicine has been less effective in treating chronic conditions such as hypertension and arthritis. “The value of alternative medicine is especially effective for people with chronic, debilitating illnesses for which conventional medicine has few, if any, answers” (Fontaine, 2004, p. 10). See Table 31-1 for a comparison of allopathic and alternative perspectives.

CONTEMPORARY TRENDS

The public perception of CAM treatment methods has been changing over the past few decades. In the late 1960s and early 1970s, the “natural,” “new age,” and “self-help” movements began to attract adherents, first among consumers and later among health care practitioners. During that time, there was a growing trend toward rejection of traditional medicine because of its perceived invasiveness, painfulness, cost, and ineffectiveness. A rekindled interest in Eastern religions, lifestyle, and medicine has fueled the development of contemporary holistic, CAM modalities. CAM therapy has a major tenet—holism—that is, the connection among mind, body, and spirit.

Ever-increasing numbers of consumers who are seeking natural and safe approaches to health care are using CAM. The goals of CAM are numerous, including pain relief and treatment of chronic illness.

There is an increasing prevalence of the use of CAM in the United States. According to a nationwide, government-sponsored survey released in December 2008, approximately 38% of U.S. adults and 12% of children use some type of CAM. The use of CAM is greatest among individuals aged 30–69 years (NCCAM, 2008). Benson (2008) states that over 35 million U.S. adults use CAM therapies to improve health. The growing interest in complementary therapies is evidenced by the increased sale of natural substances, such as herbs and vitamins, which has become a multimillion dollar industry over the last decade.

Health care consumers who want to be more involved in their own healing view CAM as a way to promote their

TABLE 31-1 Comparison of Allopathic and Alternative Medicine

ALLOPATHIC PERSPECTIVE	ALTERNATIVE PERSPECTIVE
Health is absence of disease.	Health is a state of well-being characterized by mind/body balance.
Focus is on cure of disease.	Emphasis is on health maintenance and disease prevention through lifestyle choices.
Mind and body are treated as separate entities.	Mind and body are one; what affects one affects the other.
Disease results from causative agents, usually external.	Disease originates from within and is the result of imbalances that occur in response to an unhealthy lifestyle or inner disharmonies.
Healing depends on outside agents to cure the disease.	The body has a natural ability to heal itself.
Treatment consists of drugs, surgery, and radiation.	Treatment consists of diet, exercise, herbal medicines, social support, and stress management.
Healing is aggressive, quick, and seeks to destroy the invading agents.	Healing is a slow, natural process.
The physician plays the central role in healing.	The client has the most important role in healing (i.e., lifestyle choices).

Data from Fontaine, K. L. (2004). *Healing practices: Alternative therapies for nursing* (2nd ed.). Upper Saddle River, NJ: Prentice-Hall.

autonomy. Nurses are encouraged to teach clients to use the best of all systems in order to promote positive health outcomes. **Integrative therapy**, a clinical approach that combines Western technological medicine with techniques from Eastern medicine, is becoming more prevalent in the United States.

In 1992, the U.S. government established the Office of Alternative Medicine (OAM) at the National Institutes of Health (NIH) to study the efficacy of unconventional, alternative treatment methods. The OAM is now the NIH NCCAM. Its mission is to conduct and support research and training and to disseminate information on CAM to the public and health care practitioners.

MIND-BODY MEDICINE AND RESEARCH

The Western medical model is founded on the dualistic belief that the mind, body, and spirit are separate entities. However, **psychoneuroimmunology** (PNI), a relatively new field of science, is studying the complex relationship between the cognitive, affective, and physical aspects of humans. Psychoneuroimmunologists are investigating how the brain transmits signals along the nerves to enhance the body's normal immune functioning. PNI research supports the idea that the human mind can alter physiology. As stated by Briones:

The nervous system as well as the endocrine system maintain extensive communication with the immune system through the influence of hormones and neurotransmitters and also by way of the hardwiring of sympathetic and parasympathetic nerves to the lymphoid organs. There is now convincing evidence that the communication between these three body systems is bidirectional. (2007, p. 256)

All body cells have receptor sites for **neuropeptides** (amino acids produced in the brain and other sites in the body that act as chemical communicators) that are released when **neurotransmitters** (chemical substances produced by the body that facilitate nerve transmission) signal emotions in the brain. Thus, it is possible for cells to be directly affected by emotions. In other words, people can affect their health by what they think and feel. The intermeshed complex system of psyche and body chemistry is now referred to as the **bodymind**, an inseparable connection and operation of thoughts, feelings, and physiological functions.

HOLISM AND NURSING PRACTICE

The growth of the holistic health movement is based on the concept that body, mind, and spirit are interconnected. Holism refers to the concept that the whole is greater than the sum of its parts. Nursing in its broadest sense (theory, concept, and practice) is truly holistic in nature. Holism encompasses consideration of the physiological, psychological, sociocultural, intellectual, and spiritual aspects of each individual. Holistic nursing can be described as the art and science of caring for the whole person, knowing that each person is unique in all expressions of self. As holistic healers, nurses often employ CAM techniques to promote clients' well-being. The accompanying Spotlight On display lists concepts basic to a holistic philosophy of caring.

THE NATURE OF HEALING

The word *healing* is derived from the Anglo-Saxon word *hael*, which means to make whole, to move toward, or to become whole. It is important to establish that healing is not the same as curing (ridding one of disease) but rather is a process that activates the individual's healing forces from within. As a healing facilitator, the nurse enters into a relationship

SPOTLIGHT ON...

Caring

Holistic Concepts

- Mind and body are one, not separate.
- People are responsible for their own choices.
- People have the power to solve their own problems.
- Well-being is multifaceted—physical, emotional, mental, and spiritual.

with the client and can assist the client by offering to be a guide, change agent, or instrument of healing (a means by which healing can be achieved, performed, or enhanced).

COMPLEMENTARY AND ALTERNATIVE INTERVENTIONS

Many CAM interventions are used in holistic nursing practice. These interventions are categorized as mind-body, body-movement, energetic-touch, spiritual, nutritional, and other methodologies (see Table 31-2 on page 838). Although different in technique, many of the CAM therapies have common ideological threads, including:

- The whole system must be considered if the *parts* of the individual are to be helped to function.
- The person is integrated and related to his or her surroundings.
- There exists some life force or energy that can be used in the healing process.
- Ritual, prescribed practice, and skilled practitioners are integral parts of holistic healing interventions.

MIND-BODY: SELF-REGULATORY TECHNIQUES

Self-regulatory techniques are methods by which an individual can consciously control some functions of the sympathetic nervous system (e.g., heart rate, respiratory rate, and blood pressure). Self-regulatory techniques include relaxation, meditation, imagery, biofeedback, and hypnosis.

Relaxation

As a result of the flight-or-fight response (see Chapter 23 for details), the body releases epinephrine, speeds up metabolism, and increases heart and respiratory rates. Relaxation techniques offer a way for a person to reduce stress and return to a normal physiological state.

Cardiologist Herbert Benson (1975) studied the effects of meditation on individuals. He then incorporated the basic elements of meditation into the therapeutic process he called

TABLE 31-2 Categories of Complementary and Alternative Interventions

MIND-BODY	BODY-MOVEMENT	ENERGETIC-TOUCH	SPIRITUAL	NUTRITIONAL AND MEDICINAL	OTHER
<ul style="list-style-type: none"> • Hypnosis • Imagery • Biofeedback • Meditation • Relaxation 	<ul style="list-style-type: none"> • Chiropractic therapy • Yoga • Tai chi 	<ul style="list-style-type: none"> • Therapeutic touch • Healing touch • Massage • Acupuncture • Acupressure • Reflexology 	<ul style="list-style-type: none"> • Faith healing • Prayer • Laying on of hands • Shamanism: sand painting, sweat lodges, drumming 	<ul style="list-style-type: none"> • Herbs • Antioxidants • Macrobiotic diet 	<ul style="list-style-type: none"> • Humor • Pet therapy • Music • Aromatherapy

Delmar/Cengage Learning

the **relaxation response**, a state of increased arousal of the parasympathetic nervous system, which leads to a relaxed physiological state. Benson employed the relaxation response with individuals experiencing high blood pressure and heart disease. While initially trying to avoid a mystical flavor in his work, Benson later discovered that the techniques were more effective if individuals focused on an inspirational prayer or phrase.

One method for achieving relaxation is progressive muscle relaxation (PMR), which is the alternate tensing and relaxing of muscles (see Chapter 23 for a complete discussion of PMR). PMR is used to exert positive effects on heart rate and anxiety levels (Mayo Clinic, 2007). Aids to relaxation training include music or nature sounds, hypertonic saline relaxation tanks, isolation chambers, yoga, and imagery.

Nurses can use relaxation techniques in their work with clients to reduce pain and stress. Relaxation techniques are also an essential aspect of cognitive behavioral therapy when treating people with phobias, fear, and depression.

Meditation

The practice of **meditation**, quieting the mind by focusing one's attention, can bring about remarkable physiological changes. People who meditate strive for a sense of oneness within themselves and a sense of relatedness to a greater power and the universe. One form of meditation is mindfulness, in which individuals focus their complete attention on the present moment. This process temporarily stops negative thinking and related anxiety.

Some therapeutic benefits of meditation are:

- Stress relief
- Relaxation
- Reduced levels of lactic acid
- Decreased oxygen consumption
- Slowed heart rate
- Decreased blood pressure
- Improved functioning of immune system

As stated by Cuellar (2008), mindfulness meditation can be useful in improving health outcomes and quality of life.

To evoke the relaxation response through meditation, repeat a word or short phrase, preferably one that has special meaning to the individual. For example, some individuals repeat a short prayer or relaxing phrase.

Imagery

Imagery is a type of thinking without words in which the senses are used to evoke one's imagination. The practitioner encourages the client to use as many of the senses as possible in order to enhance the formation of vivid images. See Table 31-3, which presents examples of images that can be evoked by the five senses.

Imagery is not a new concept in nursing. In the mid-1800s, Nightingale wrote in *Notes on Nursing* (1860) about nurses helping the ill to alter their thoughts through images of nature, such as a bouquet of flowers.

Guided imagery can be used with clients who are capable of hearing and understanding the nurse's suggestions of

TABLE 31-3 Incorporating All Five Senses into Imagery

SENSORY CHANNEL	EXAMPLE
Visual	See the bright blue sky.
Auditory	Hear the babbling brook.
Kinesthetic	Feel the warm sand beneath your bare feet.
Gustatory	Taste the tartness of fresh lemonade.
Olfactory	Smell the salty air at the beach.

Delmar/Cengage Learning

meaningful and physiologically correct images. For example, a nurse can show a chart of the stages of bone healing to a client who has suffered a fracture and ask the client to imagine this activity occurring in his or her body.

In addition to being a tool for distraction when a person is confronting pain, discomfort, and fear, imagery is a powerful mechanism for making decisions and for altering behaviors. Imagery is also used to reduce pain and anxiety before and during procedures and to promote comfort. Imagery is described by Reed as being “time- and cost-effective, and creat[ing] a healing partnership between nurse and patient” (2007, p. 276). However, imagery is not suitable for use with every client; see the accompanying Safety First display. See Chapter 23 for directions on performing imagery and PMR exercises.

Biofeedback

Biofeedback is a measurement of physiological responses that yields information about the relationship between the mind and the body and helps clients change those responses through mental activity. Biofeedback allows a person to see the effect of the mind on the body. While attached to sensitive devices that measure such bodily responses as skin temperature, blood pressure, galvanic skin resistance, and electrical activity in the muscles, the individual imagines stressful experiences. The person’s physiological responses are then measured and recorded. Subsequent physiological responses to the relaxation response are also recorded. The individual receives an interpretation of these responses and is taught methods for practicing relaxation.

Biofeedback is used as a restorative method in rehabilitation settings to help clients who have lost sensation and function as the result of illness or injury. Biofeedback also enhances relaxation in tense muscles, relieves tension headaches, reduces bruxism (grinding of the teeth), reduces the pain of temporomandibular joint syndrome, and relieves backache. Temperature biofeedback is useful in training people to purposefully warm their hands to treat Raynaud’s disease (a circulatory disorder), to lower blood pressure, and to prevent or relieve migraine headaches.

Hypnosis

Misconceptions about the practice of hypnosis were once very common. Currently hypnosis is becoming more accepted as a therapeutic intervention. Therapeutic hypnosis induces altered states of consciousness or awareness (a trance) during which the person is more receptive to suggestion. It also enhances the client’s ability to form images. In 1955, the British Medical

Association approved hypnotherapy as a valid medical intervention. The American Medical Association did likewise in 1958. Therapeutic use of suggestion is the heart of hypnosis. Suggestions can be phrased directly (“You will feel more comfortable”) or indirectly (“You may feel different”). Hypnosis is a potentially effective and powerful tool for altering pain, anxiety, and some physiological processes. Although hypnosis is useful as an adjunct to treatment, it does not magically cure problems such as nicotine addiction, alcoholism, and eating disorders and should be used in conjunction with other modalities.

Nurses wishing to use hypnosis in their practice must be aware of the guidelines concerning this modality in the scope of practice as defined by the respective state boards of nursing. Advanced training in hypnosis is also necessary.

BODY-MOVEMENT: MANIPULATION STRATEGIES

As the name implies, body-movement therapies employ techniques for moving or manipulating various body parts to achieve therapeutic outcomes. Methods such as movement and exercise, yoga, tai chi, and chiropractic treatment are discussed in the following sections.

Movement and Exercise

Movement, as a therapeutic intervention and health-promoting activity, is associated with athletic exercise, dance, celebration, and healing rituals. Although the primary goal of exercise is fitness (muscle strength, flexibility, endurance, and cardiovascular and respiratory health), there are many other positive outcomes of exercise (see Chapter 23 for a complete discussion of the benefits of exercise).

Nurses can help clients use movement as therapy in a variety of ways, including range-of-motion exercises, water exercises, physical therapy, and stretching exercises. Physical activity is an effective method through which people of all ages can improve their level of functioning. Some of the therapeutic benefits of exercise are as follows:

- Improves circulation
- Enhances respiratory function
- Promotes elimination
- Stimulates the release of **endorphins** (brain chemicals that boost mood and help fight depression)
- Helps regulate metabolism
- Enhances immune function

YOGA Many cultures believe that particular forms of movement keep the body’s life forces in correct balance and flow. Yoga and tai chi are examples of ancient ritual movements that enhance overall health, including spiritual enlightenment and well-being. Both of these approaches require concentration, strength, flexibility, and use of symbolic movements. The three main elements of yoga are breathing, movement, and posture. Yoga involves completing a series of postures carried out in sequential order; see Figure 31-3 on page 840, which illustrates some basic yoga postures.

SAFETY FIRST

PRECAUTION FOR IMAGERY

Imagery is not recommended for clients who are emotionally unstable. The thoughts could become overwhelming and thus increase anxiety.

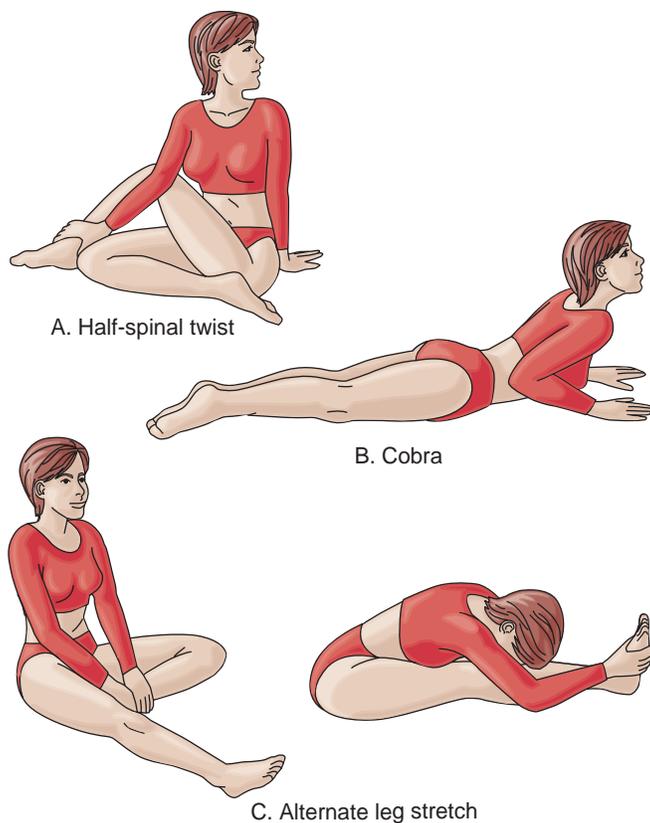

FIGURE 31-3 Yoga Postures DELMAR/CENGAGE LEARNING

Yoga rejuvenates, promotes longevity and self-realization, and speeds up the natural evolution of the person toward self-enlightenment. Yoga, a form of meditative exercise, originated in India and is an essential component of Ayurvedic healing.

TAI CHI Tai chi is based on the philosophy of the quest for harmony with nature and the universe through the laws of complementary (yin and yang) balance. When perfect harmony exists, the body functions effortlessly, spontaneously, perfectly, and in accordance with the laws of nature. If one moves to the right, then one must also move to the left. Tai chi consists of a series of sequential dancelike moves connected in a smooth, flowing process.

People who regularly perform tai chi believe it enhances stamina, agility, and balance and that it boosts energy and confers a sense of well-being. Tai chi has been shown to lower blood pressure and heart rate in people in cardiac rehabilitation programs, and it is also a method for improving balance and, thus, reducing falls, which is especially helpful for older adults (Leddy, 2006). Tai chi also helps reduce symptoms of individuals experiencing fibromyalgia, a musculoskeletal disorder associated with pain and functional impairment.

Chiropractic

The major principle underlying **chiropractic** therapy is that the brain sends vital energy to every organ in the body via the nerves originating in the spinal column. Disease

results from interferences along that pathway; therefore, manipulation of the spinal column is useful in alleviating a variety of ills. Removing the blocks with quick thrusts and adjustments allows the body to restore its innate recuperative power.

Chiropractic is widely accepted by the medical community. Chiropractors are staff members of some medical centers and hospitals. As with any CAM intervention, nurses should encourage clients considering the use of chiropractic services to undergo comprehensive health assessments first to rule out any contraindications. Many insurance companies pay for chiropractic services.

ENERGETIC-TOUCH HEALING

A category of CAM therapies that has been incorporated into nursing for decades is the **energetic-touch therapies**, a group of techniques that work with the body's energy field by the use of the hands to direct or redirect energy to enhance balance within the field. These modalities are effective interventions for many client problems and can be used to restore harmony in all aspects of a person's health. Energetic-touch therapies can be used with persons of all ages.

Energetic-touch therapies have their roots in traditional Chinese, ancient Eastern, and Native American philosophies. The fundamental concept is that individuals are composed of a life force, a source of energy that is not confined to physical skin boundaries. Another fundamental belief underlying energetic-touch therapies is that life depends on the movement of energy. Figure 31-4 on page 841 illustrates the energy field that extends beyond a person's physical body.

An individual's energy field consists of layers of energy that are in constant flux. The energy layers can be diminished or otherwise adversely affected by any type of illness, trauma, or distress. The energy system can also be positively affected by the intentionally directed use of the hands of a practitioner.

Holistic nurses were integral in helping the North American Nursing Diagnosis Association International (NANDA, 2009) to establish the diagnosis *Disturbed energy field*. NANDA considers this to be a disturbed energy field that leads to an imbalance of body, mind, or spirit.

There are many energetic-touch therapies being used by nurses today. These therapies are being effectively integrated into holistic practice. Massage, therapeutic touch, healing touch, Reiki, Jin Shin Jyutsu, and J Shin Do are some examples. Three of those therapies—massage, therapeutic touch, and healing touch—are discussed in more detail.

Touch

One of the most universal CAM modalities is touch. **Touch**, simply defined, is the means of perceiving or experiencing through tactile sensation. According to anthropologist Montague (1986), touch is the earliest sense to develop in humans and, thus, it provides a basic means of interacting with others and the environment. Tactile stimulation is necessary for survival and the healthy behavioral development of an individual (Bowlby, 1984). Touch has been used in all ancient cultures and shamanistic traditions for healing.

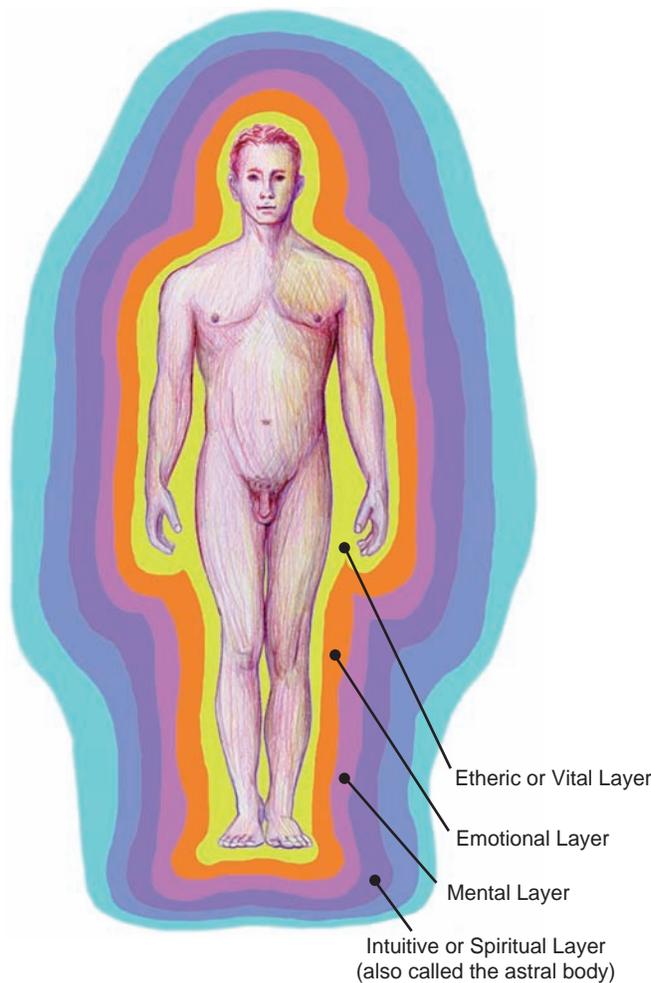

FIGURE 31-4 Layers of Human Energy Field Extending Beyond the Physical Boundaries DELMAR/CENGAGE LEARNING

The advent of scientific medicine and Puritanism led many healers away from the purposeful use of touch. Some cultures are very comfortable with physical touch; others specify that touch may be used only in certain situations within specified parameters. See Chapter 20 for a complete discussion about cultural aspects of touch.

Because touch involves personal contact, the nurse must be sure to convey positive intentions. When in doubt, the nurse should withhold touch until effective communication with the client has been established. Touch has several important uses in nursing practice in that it:

- Is an integral part of assessment
- Promotes bonding between nurse and client
- Is an important means of communication, especially when other senses are impaired
- Assists in soothing, calming, and comforting
- Helps keep the client oriented

See the Safety First Display on page 842.

Therapeutic Massage

Therapeutic massage is the application of pressure and motion by the hands with the intent of improving the

recipient’s well-being. It involves kneading, rubbing, and using friction. The primary techniques used to perform a massage are described in Table 31-4.

Many touch therapies have been assimilated into mainstream nursing practice. Massage therapy is now recognized as a highly beneficial modality and is prescribed by a number of health care practitioners. In addition, many states now have licensing requirements for massage practitioners.

Traditionally, back rubs have been administered by nurses to provide comfort to hospitalized clients. Massage techniques can be used with all age groups and are especially beneficial to those who are immobilized. A back rub or massage can achieve many results, including relaxation, increased circulation of the blood and lymph, and relief from musculoskeletal stiffness and pain. “Massage is an applicable, noninvasive, therapeutic modality that can be integrated safely as

TABLE 31-4 Basic Massage Techniques

TECHNIQUE	DESCRIPTION
Effleurage	The entire hand is used. Gliding and long rhythmic strokes are used. Firm, even-pressured strokes are directed toward the heart to assist blood return. Lighter pressure is used when moving away from the heart.
Petrissage	Pressing, squeezing, kneading, and rolling movements by both hands; entire hands are used. Deep circulation is enhanced. C-shaped motions stimulate muscle bodies. Promotes muscular relaxation.
Friction	Thumb pads, heel of hand, or fingertips are used. Focused, deep, circular motions are used. Penetrates deeper muscle layers. Is done after effleurage and petrissage.
Tapotement	Palm, fingertips, and knuckles are used. Brisk, vigorous, rhythmic, percussive movements are used. Hands alternately tap, cup, slap, and pummel muscles. Invigorates and stimulates tired muscles.
Vibration	Very fine, rapid, shaking movements are administered by entire hand. Stimulates or relaxes muscles.

Delmar/Cengage Learning

SAFETY FIRST

CONTRAINDICATIONS FOR TOUCH

It is important to know when not to touch. It may be difficult for persons who have been neglected, abused, or injured to accept touch therapy. Touching those who are distrustful or angry may escalate negative behaviors.

an adjunct intervention for managing side effects and psychological conditions associated with anticancer treatment in children. Massage may support immune function during periods of immunosuppression” (Hughes, Ladas, Rooney, & Kelly, 2008, p. 442).

Massage should be used with caution for people with heart disease, diabetes, hypertension, or kidney disease because increased circulation in these conditions may be harmful. Massage should never be attempted in areas of circulatory abnormalities such as aneurysm, varicose veins, necrosis, phlebitis, or thrombus or in areas of soft-tissue injury, open wounds, inflammation, joint or bone injury, dermatitis, recent surgery, or sciatica. See the Safety First display.

Procedure 31-1 describes the techniques involved in performing a massage. Almost half of all state boards of nursing recognize CAM as being within the scope of nursing practice (S. S. Kim, Erlen, Kim, & Sok, 2006). The National Association of Nurse Massage Therapists (NANMT) was established in 1990 to promote professional ethical standards for nurse massage therapists. The standards established by the NANMT reflect those of the American Nurses Association.

Therapeutic Touch

Therapeutic touch (TT), which is based on ancient healing practices (e.g., the laying on of hands), consists of assessing alterations in a person’s energy field and using the hands to direct energy to achieve a balanced state. The practice of TT was developed in the early 1970s by Dolores Krieger, PhD, RN, then professor of nursing at New York University, and Dora Kunz, a noted healer. TT is based on four concepts:

- A human being is an open energy system.
- Anatomically, a human being is bilaterally symmetrical.
- Illness is an imbalance in an individual’s energy field.

SAFETY FIRST

Do not massage areas with visible redness or edema, which may be indicators of a thrombus (blood clot). Rubbing such an area may release the thrombus into the bloodstream, resulting in a circulatory problem.

- Human beings have natural abilities to transform and transcend their conditions of living (Kunz & Krieger, 2004).

The TT process is readily learned in workshops, can be done with hands either on or off the body in the energy field, complements medical treatments, and has reasonably consistent and reliable results (see Figure 31-5). Table 31-5 on page 843 presents the five-phase process of TT.

The relaxation response may be apparent in the client as quickly as 2 to 5 minutes after a TT treatment has begun, and some clients may fall asleep or require less pain medication after a treatment. A clinical study indicates that TT reduces both pain and anxiety in clients with cancer (Jackson et al., 2008). Healing is enhanced when body energy is balanced.

Healing Touch

Healing touch (HT) is an energy-based therapeutic modality that alters the energy field through the use of touch. HT was developed by Janet Mentgen, a nurse, in the 1980s. In 1993, HT was established as a certification program of the American Holistic Nurses Association. Its curriculum includes varied techniques for use of HT in general balancing of the body’s energy field, relaxation, and specific problems such as headaches, spinal problems, and pain. One study indicates that the use of HT reduced anxiety and the length of hospital stay in clients with coronary artery bypass surgery (MacIntyre et al., 2008).

Table 31-6 on page 844 lists the five steps of HT. HT recognizes the need for follow-up or sequential treatments as well as discharge planning and referral to assist the client in adequately meeting goals.

In both TT and HT, the practitioner uses **centering**, a process of bringing oneself to an inward focus of serenity, before initiating treatment. Centering is a useful tool to employ before performing any treatment or before any situation that may be stressful or difficult (e.g., an important school examination).

In addition to therapeutic massage, TT, and HT, there are many other touch modalities that can be integrated into

FIGURE 31-5 A nurse administers therapeutic touch to a client. Is there a relationship between the use of TT as a therapeutic modality and the healing systems that can be traced to Far Eastern cultures? DELMAR/CENGAGE LEARNING

TABLE 31-5 Phases of Therapeutic Touch

PHASE	DEFINITION	TECHNIQUES
Centering	<ul style="list-style-type: none"> Bringing body, mind, and emotions to a quiet, focused state of consciousness Being still Being nonjudgmental 	Become centered by use of: <ul style="list-style-type: none"> Controlled breathing Imagery Meditation
Assessment (“scanning”)	<ul style="list-style-type: none"> Using the hands to determine the nature of the client’s energy field Being attuned to sensory cues (e.g., warmth, coolness, static, pressure, tingling) to detect changes in client’s energy 	<ul style="list-style-type: none"> Hold hands 2 to 6 inches away from person’s energy field while moving the hands from the head to the feet in a rhythmic, symmetrical manner.
Unruffling (“clearing”)	<ul style="list-style-type: none"> Facilitating the symmetrical and rhythmic flow of energy through the field 	<ul style="list-style-type: none"> Use slightly more vigorous hand movements from midline while continuing to move in a rhythmic and symmetrical manner from the head to the feet.
Treatment (“balancing,” “rebalancing,” or “intervention”)	<ul style="list-style-type: none"> Projecting, directing, and modulating energy on the basis of the nature of the living energy field Assisting to reestablish order in the system 	<ul style="list-style-type: none"> Because each practitioner experiences the living energy field uniquely, the law of opposites serves as a guideline for intervening (e.g., if a pulling or drawing sensation is detected, then direct energy to the depleted area until it feels replenished). Continue to assess, clear, and balance the field while remaining centered.
Evaluation	<ul style="list-style-type: none"> Using professional, informed, and intuitive judgment to determine when to end the session 	<ul style="list-style-type: none"> Reassess the field. Elicit feedback from the client. Give the client an opportunity to rest and integrate the process.

Note: The phases, although learned sequentially by beginners, are dynamic and often are performed concurrently and repetitively by experienced practitioners. Data from Macrae, J. (2005). *Therapeutic touch: A practical guide*. New York: Alfred A. Knopf.

nursing practice. Some of the more common types of touch therapies are reflexology and acupressure with its many variations. These techniques involve deep-tissue bodywork and require advanced training for practitioners.

Shiatsu Acupressure

Shiatsu **acupressure** is based on East Asian philosophy and Japanese methodology. *Shiatsu*, from the word meaning “finger pressure,” differs from acupuncture, a procedure that uses needles and heat to deliver treatment. In Shiatsu, blocked energy within the client is released by application of the practitioner’s fingers, thumbs, and heels of the hands along certain pressure points (meridians). Acupressure, which is a noninvasive technique, has been used to successfully treat nausea and vomiting associated with pregnancy (Can Gurkan & Arslan, 2008; Shin, Song, & Seo, 2007). Acupressure is also recommended as an effective, noninvasive method for decreasing agitated behavior in people with dementia (Yang, Wu, Lin, & Lin, 2007). When practicing shiatsu, nurses need to be self-aware and grounded—that is, focused on their

inner energy. This focus enables the practitioner to concentrate completely on promoting the client’s comfort.

Acupuncture

Acupuncture is the use of needles inserted at specific points on the body (energy pathways) to promote healing. Acupuncture is done to manipulate the energy flow throughout the body; treatment focuses on correcting the flow of *chi* (energy) when imbalances (blockages) occur. TCM practitioners believe that meridians conduct chi between the body’s surface and internal organs. Acupuncture points are believed to stimulate the central nervous system to release chemicals into the muscles, spinal cord, and brain. These chemicals either alter the experience of pain or produce other chemicals that lessen pain.

Acupuncture is one of the oldest, most commonly used medical procedures in the world. It originated in China over 2,000 years ago and is effective in treating a variety of health problems. Extensive research is currently being done to determine the efficacy of acupuncture. This CAM method

TABLE 31-6 Steps of Healing Touch

STEP	DESCRIPTION	NURSING GUIDELINES
Initial interview	<ul style="list-style-type: none"> Provides the working base for energetic interventions and functions as an intake assessment. 	<ul style="list-style-type: none"> Introduce yourself. Explain the HT modality so that a feeling of confidence can begin to develop. Determine the main problem or reason for treatment. Identify relevant health history: hospitalizations, diseases, injuries, diagnoses, medications (past and present) including use of recreational drugs, nicotine, alcohol, caffeine, vitamins, and herbs. All these factors can influence the energy field.
Assessment	<ul style="list-style-type: none"> In wellness, the energy flows evenly from head to toe without blocks, breaks, unevenness, or temperature variations. Any disruption of the flow reflects disharmony in that area. 	<ul style="list-style-type: none"> Approach the client from a centered state. Begin by determining the shape of the energy field by slowly scanning its outer edges. Start 3 to 4 feet away from the body and move toward it using the palms until you can determine the actual outline of the energy field. Continue the assessment by feeling the vital layer 1 to 6 inches off the skin. Identify areas in relation to the physical body where the field is different, perhaps not as vibrant or as smooth as in other areas.
Documentation	<ul style="list-style-type: none"> Begins with the initial client contact. 	<ul style="list-style-type: none"> Mentally take note of all sensations, even subtle ones. A picture of the energy pattern is usually easy to execute by drawing the perceived pattern on a simple outline of the body. Areas of energetic differences can be drawn in, as can injuries, swelling, scars, or the track of a pain ridge.
Intervention	<ul style="list-style-type: none"> The healer can choose many healing interventions in this sequence: therapeutic touch, full-body techniques, and localized and specific techniques. 	<ul style="list-style-type: none"> During the intervention, which may last 20 to 30 minutes, all of the healer's skill and experience are used.
Completion and grounding	<ul style="list-style-type: none"> After completion of the interventions, carefully ground the client to help restore balance and promote integration. Determine that the client is fully alert if the client will leave after the session. 	<p>Grounding can be done in a variety of ways, including:</p> <ul style="list-style-type: none"> Hold the feet until you sense a flow and a connection with the client and sense that the client's energy is back in the feet. Brush down the body from head to toe and down the arms toward the ground. Repeat briskly several times. Give a suggestion: "Feel your fingers and your toes; now gently move them until you return to full awareness in this room." Reassess the energy field at this time and document the changes. Spend some time with the client to obtain feedback. Focus on what the client experienced. Talking helps the client to feel grounded.

has been shown to be effective for management of symptoms (i.e., pain, dyspnea, nausea, and vomiting) in clients receiving palliative and hospice care (Standish, Kozak, & Congdon, 2008). Other studies indicate the efficacy of acupuncture in pain reduction, in children with cancer (Rheingans, 2007), and in adults with pain resulting from osteoarthritis of the knee (Maa, Sun, & Wu, 2008). The use of acupuncture in effectively treating insomnia is documented in other research studies (Kalavapalli & Singareddy, 2007; K. B. Kim & Sok, 2007). Findings of another study indicate that acupuncture is helpful in reducing hot flashes for women receiving hormonal treatment for breast cancer (Walker, de Valois, Davies, Young, & Maher, 2007).

Reflexology

Reflexology is rooted in ancient healing arts. Egyptian wall paintings from approximately 2300 BC show the use of reflexology. Contemporary use of reflexology is credited to the work of William H. Fitzgerald, an American physician who, in the early 1900s, discovered that applying pressure to certain parts of the fingers could relieve pain in other body parts. In the 1930s, Eunice Ingham discovered that certain points on the feet were more responsive to pressure and provided better pain relief than points on the hand.

The fundamental concept of reflexology is that the body is divided into 10 equal, longitudinal zones that run the length of the body from the top of the head to the tip of the toes. These 10 zones are correlated with the 10 fingers and toes. The foot is viewed as a microcosm of the entire body. Reflexology theory posits that illness manifests itself in calcium deposits and acids in the corresponding part of the person's foot. Pressing specific points on the foot stimulates energy movement and produces relaxation, reduces stress, and promotes health by relieving pressures and accumulation of toxins in the corresponding body part (see Figure 31-6).

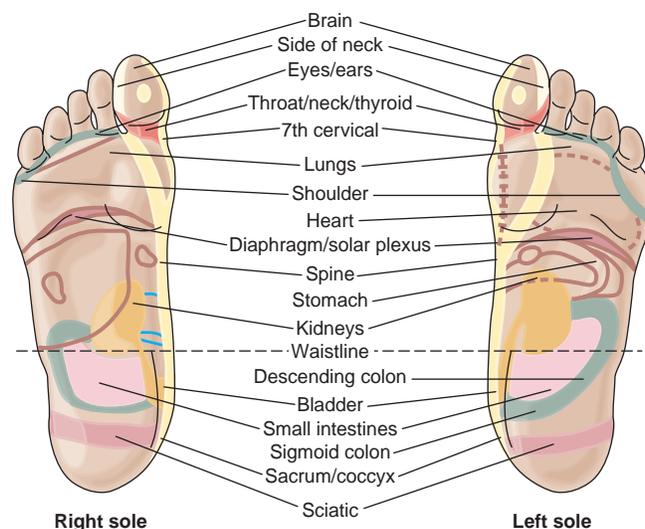

FIGURE 31-6 Foot Reflexology Charts REPRODUCED WITH PERMISSION FROM BETTER HEALTH WITH FOOT REFLEXOLOGY; COPYRIGHT © 1983 BY DWIGHT C. BYERS. INGHAM PUBLISHING, INC., POB 12642, ST. PETERSBURG, FL 33733-2642. WWW.REFLEXOLOGY-USA.NET

Reflexology can be used as a complementary method for managing chronic conditions such as asthma, sinus infections, migraines, irritable bowel syndrome, kidney stones, and constipation. Other symptoms that have responded well to reflexology sessions are phantom limb pain (experienced by individuals with amputated limbs) and anxiety (Brown & Lido, 2008; McVicar et al., 2007). Once the pressure points are learned, the nurse can massage the areas of the client's foot to relieve pain and produce relaxation. See the Community Considerations display.

SPIRITUAL THERAPIES

A state of wholeness or health is dependent not only on one's relationship to the physical and interpersonal environment but also to the spiritual aspects of self. The idea that there is a relationship between spirituality and health is not new. Spirituality is the core of many holistic modalities.

The role of the spirit in healing is witnessed in all cultures. The inseparable link between the state of one's soul (life energy or spirit) and the state of one's health is accepted by many cultures. Psychoneuroimmunologists are validating that there are inner mechanisms of healing within individuals. Many of the major religions have ideologies relating to health, illness, and healing. Health maintenance implies having a balanced spiritual life. Refer to Chapter 24 for more information on spirituality.

Faith Healing

At the heart of spiritual or faith healing is the practitioner's belief that one has to purify one's self and reach a state of unity with God or a Higher Power. This process, based on religious belief, is usually done through prayer. During preparation for healing, the practitioner adapts a passive and receptive mood in order to be a channel for divine power. To benefit from the healer's intervention, the ill person's belief enhances, but is not crucial to, the success of healing.

Individuals with strong spiritual beliefs rely on faith for support, comfort, and assistance. For example, "in contemporary Navajo society, traditional Navajo ceremonies, Native American Church prayer meetings, and Navajo Christian

COMMUNITY CONSIDERATIONS

Application of Touch

Is there a group of people whom you can identify as being socially isolated or in distress who could benefit from one or more of the touch therapies? Consider residents of extended care facilities, caregivers of chronically ill children or elderly parents, and hospice clients. Do you think that touch therapies can be used as routine preventive care for healthy populations?

faith healing are all highly sought-after resources in the everyday pursuit of health and well-being” (Csordas, Storck, & Strauss, 2008, p. 595). According to Mehl-Madrona (2008), people with cancer who sought out aboriginal healers perceived a sense of forgiveness, release of anger and blame, and refusal to accept death as imminent. A study by Tanyi and Werner (2007) indicates that African American women with end-stage renal disease had several sources of spiritual support, including perceptions of God’s concern for them, a sense of life’s purpose, and satisfaction with life.

Healing Prayer

When individuals pray, they believe they are communicating directly with God or a Higher Power. Prayer is an integral part of a person’s spiritual life and, as such, can affect well-being. Florence Nightingale (1860) recognized that prayer helps connect individuals to nature and the environment. Many religions adhere to established rituals for organized prayer. For example, Tibetan Buddhists use prayer wheels—wooden and metal cylinders with prayers written on them. Islam has five periods of prayer scheduled daily. Some religious groups, such as Christian Scientists, rely on prayer in lieu of conventional medical therapy due to the belief that prayer alone can heal disease. “Chronic illnesses such as cancer are very stressful events and prayer is a valuable coping strategy for Muslim cancer patients” (Rezaei, Adib-Hajbaghery, Seyedfatemi, & Hoseini, 2008, p. 96). Results from another study indicate that prayer was preferred by the majority of older home care clients experiencing depression (Fyffe, Brown, Sirey, Hill, & Bruce, 2008).

NCCAM (2007a) is currently investigating the effects of prayer on physical health. The exact mechanism for the effect of prayer on healing is not known; see Figure 31-7. “Prayer has been used for persons with every type of illness, of all age groups, and from all cultures” (Snyder, 2006, p. 149). Prayer provides comfort and support to many individuals experiencing pain and anxiety as a result of illness and/or treatment procedures.

FIGURE 31-7 Prayer brings a sense of peace and healing to many individuals. DELMAR/CENGAGE LEARNING

NUTRITIONAL THERAPIES

In the last 40 years, nutritional interventions for prevention and treatment of disease have received increased interest from consumers and health care providers. This section addresses the CAM nutritional approaches.

Nutraceuticals

Currently, many foods are being studied for their medicinal value. The term **nutraceuticals** refers to any natural substances found in plant or animal foods that act as protective or healing agents. **Phytonutrients** are those chemicals found in plants; see Table 31-7 on page 847 for a listing of the major phytonutrients and their actions.

The best source of nutrients is fresh whole foods, preferably eaten in their natural form. The standard Western diet lacks many essential nutrients and contains many harmful additives due to processing. In contrast, the TCM diet contains fresh, semiraw, and slightly cooked ingredients. Foods that are being investigated by the National Cancer Institute (2007) for possible cancer preventive qualities include carrots, celery, citrus fruits, flaxseed, garlic, licorice root, parsley, and soybeans.

Antioxidants and Free Radicals

Antioxidants exert several beneficial effects, including prevention of cancer, reduction of heart disease, and decreased allergy symptoms (Lukan, Racz, Mocnejova, & Tkac, 2008). Antioxidants react with free radicals, preventing them from damaging cells and from altering DNA. Dietary antioxidants have been shown to be effective in protecting the body from free radicals. The antioxidants devour free radicals (unstable molecules that alter genetic codes and trigger the development of cancer growth in cells).

Sources for dietary antioxidants include vitamin C (in fruits and vegetables), beta-carotene (yellow-orange pigment in fruits and vegetables), and vitamin E (in polyunsaturated oils, butter, and eggs). Other vitamins, minerals, trace elements, and enzymes are being investigated for possible therapeutic value. See Chapter 34 for a thorough discussion of the essential vitamins, their functions, and major sources.

Macrobiotic Diet

In the 1960s, macrobiotic diets (from the Greek *makro*, meaning long, and *bios*, meaning life) became popular because of the heightened interest in “natural” and more spiritual approaches to managing health and illness. The basis for macrobiotics is the Taoist concept of balance between opposites that is achieved through food intake. Food has the qualities of *yin* (associated with death, cold, and darkness) and *yang* (associated with immortality, heat, and light). For example, tropical and sweet foods are yin, and meat and eggs are yang. Overindulgence in either type causes difficulties; too much yin yields worry and resentment whereas too much yang leads to hostility and aggression. People need balance and, therefore, should consume foods that are neither too yin nor too yang.

Because brown rice and whole grains are categorized as balanced foods, they are major staples in a macrobiotic diet.

The diet should be flexible and related to the season; it should consist of foods indigenous to the area in which the individual lives. Foods to be avoided include processed and treated foods, red meat, sugar, dairy products, eggs, and caffeine. See the Safety First display.

Herbal Therapy

Herbal medicine has been a powerful tool in folk healing for centuries. Medicinal herbs have been catalogued for thousands of years and have probably existed in every culture. Many drugs commonly used today were once folk remedies derived from plants. For example, salicin, the active chemical

ingredient found in white willow bark, has been used by TCM practitioners and Native Americans for pain relief. This same salicin is a precursor to salicylic acid, an ingredient in aspirin. Herbal medicine, also known as botanical medicine or phytotherapy, uses plant extracts for therapeutic outcomes. Many holistic practitioners incorporate the use of herbs into their practice.

Learning about herbal treatment is similar to learning pharmacology. Herbs work because of their chemical composition. Different herbs contain different compounds that can strengthen the immune system, alter the blood chemistry, or protect specific organs against disease. For example, peppermint oil may help relieve the symptoms of irritable bowel syndrome by exerting a relaxant effect on the muscles of the gastrointestinal tract. Echinacea is frequently used for its immune-enhancing properties. However, it should not be taken longer than 8 to 10 consecutive weeks due to the potential for liver toxicity.

Herbs are not cure-alls, and many take time to exert their healing properties. Generally, it is wise to use herbs for treating conditions one would ordinarily self-treat; see the Safety First display on page 848. Conditions that generally respond well to herbal therapy are:

SAFETY FIRST

MACROBIOTIC DIETS

Children and pregnant women should use the macrobiotic diet with caution. It may not have sufficient variety and, therefore, could be deficient in vitamins D and B₁₂.

TABLE 31-7 Actions and Sources of Major Phytonutrients

PHYTONUTRIENT	SOURCES	ACTIONS
Ascorbic acid	Citrus fruits, broccoli, most fruits and vegetables	Binds iron, preventing it from becoming a cancer-causing prooxidant
Capsaicin	Red chili peppers	Helps prevent carcinogens from binding with DNA at the cellular level
Catechins	Green tea, black tea	Reduces the risk of gastrointestinal cancers
Fiber lignans	Soybeans, flaxseed, nuts	Inhibits growth of tumors
Fiber pectins	Apples, pears, plums, prunes	Improves colon health; encourages growth of beneficial intestinal flora
Lycopene	Tomatoes, tomato sauce	Protects against prostate cancer; helps block UVA and UVB rays
Phytoestrogens	Soy products, alfalfa sprouts	Helps reduce menopausal symptoms; may block some cancers (e.g., breast, prostate)
Phytosterols	Plant oils, corn, sesame, soy, safflower, pumpkin, wheat	Inhibits uptake of cholesterol from foods; blocks hormonal role in cancer production
Protease inhibitors	Soybeans and soy products, eggs, cereals, potatoes	Protects against negative effects of radiation and free radical damage; prevents activation of certain genes that cause cancer
Sulfur compounds	Onions, garlic	Lowers blood pressure; improves immune system response; fights infections; has antimicrobial effect; lowers cholesterol; reduces triglycerides

Data from Balch, P. (2008). *Prescription for nutritional healing: The A-to-Z guide to supplements*. New York: Penguin; Weil, A. (2007). *8 weeks to optimum health: A proven program for taking full advantage of your body's natural healing power* (rev. ed.). New York: Random House.

SAFETY FIRST

USE OF MEDICINAL PLANTS

Avoid casual treatment of self or others with plants. Just because the substance is “natural” does not mean it is harmless. If not processed properly, many plants (including some herbs) can be poisonous.

- Allergies
- Arthritis
- Digestive problems (indigestion, diarrhea)
- Headache
- Insomnia
- Kidney and urinary tract infections
- Menopausal symptoms
- Menstrual problems
- High or low blood pressure
- Skin disorders

Table 31-8 on page 849 lists medicinal uses of commonly used herbs.

In the past decade, several thousand natural products were tested by the National Cancer Institute. Many contemporary cancer therapies are derived from natural sources.

Herbs are not to be used indiscriminately, as their use may result in some negative outcomes. Some individuals may experience allergic reactions to certain botanicals; see Table 31-9 on page 850 for possible allergic reactions to herbs. Consumers need to be taught the following regarding herbs and allergies: to recognize the potential for developing allergic reactions to herbs, to identify the indicators of such reactions, and to immediately stop using the herb if allergic symptoms occur.

Individuals using herbs need to understand that problems can occur when taking herbal products and medications concurrently. The chemical constituents of herbs may alter the effects of some medications; see Table 31-10 on page 850. To ensure client safety, nurses should:

- Ask clients about their use of herbals in a nonjudgmental manner.
- Discuss the risks and benefits of the herbs taken.
- Suggest that clients purchase and use only herbal products labeled “standardized” for quality checks.

OTHER CAM METHODOLOGIES

The mind-body, body-movement manipulation, energetic-touch, spiritual, and nutritional treatment modalities are not the only available CAM therapies. Others, such as aromatherapy, humor, pet therapy, and music therapy, are also being used as methods to improve health status.

Aromatherapy

Aromatherapy is the therapeutic use of concentrated essences or essential oils that have been extracted from plants and flowers. When diluted in a carrier oil for massage or in warm

water for inhalation, essences may be stimulating, uplifting, relaxing, or soothing. Essential oils help relax the mind and the body by promoting balance between the sympathetic and parasympathetic nervous systems. Oils can be absorbed through the skin or enter the body through inhalation.

Aromatherapists use concentrated oils derived from roots, bark, or flowers of herbs and other plants to treat specific ailments. The aromas cause physical and emotional responses within a person. Aromatherapy is used to treat a variety of conditions and promote a sense of well-being, including:

- Stress and anxiety-related problems
- Muscular and rheumatic pains
- Digestive disorders (e.g., nausea)
- Female sexual health conditions (e.g., PMS, postpartal problems, and menopausal symptoms)
- Dermatological conditions

According to a literature review by Buckle (2007), numerous pilot studies have indicated the efficacy of aromatherapy on radiation burns, slow-healing wounds, Alzheimer’s disease, and end-of-life agitation.

Some essential oils have antibacterial properties and are found in a wide variety of pharmaceutical preparations. Essential oils should be used intelligently and with caution; see the Nursing Checklist and the accompanying Safety First display.

Humor

Of all the complementary interventions presented in this chapter, humor is the one that can be used most often to

NURSING CHECKLIST

Guidelines for Using Aromatherapy

- Always dilute essential oils in a carrier oil.
- Do a skin patch test for sensitivity before applying essential oils to the skin.
- Avoid contact with the eyes.
- Inhale essential oils only for short periods of time.
- Store in dark glass bottles, tightly capped and away from heat and sunlight.
- Store only in glass containers, not plastic.
- Use only pure essential oils, not synthetics.

SAFETY FIRST

PRECAUTIONS WITH ESSENTIAL OILS

Some essential oils can trigger asthma attacks or epileptic seizures, cause harm to people with cancer, or elevate or depress blood pressure. Instruct clients with asthma, cancer, epilepsy, or hypertension and those who are pregnant to avoid the use of essential oils.

TABLE 31-8 Medicinal Value of Herbs

HERB	MEDICINAL USES (SEE NOTE)	HERB	MEDICINAL USES (SEE NOTE)
Aloe vera (<i>Aloe vera</i>)	<ul style="list-style-type: none"> Promotes wound healing Minor cuts and abrasions Burns 		<ul style="list-style-type: none"> sickness associated with pregnancy Stimulates circulation in feet and hands

promote wellness. Humor is a frequently used modality with clients of all ages in a variety of health care settings. Humor has many therapeutic outcomes, including:

- Increased ability to cope with pain
- Enhanced immune functioning
- Reduced preprocedural anxiety

Former chair of the Task Force in Psychoneuroimmunology at the School of Medicine at UCLA, Norman Cousins (1979), related how he enhanced his recovery from an incurable connective tissue disorder, ankylosing spondylitis, by the daily watching of films and movies that made him laugh. Humor can be used effectively to relieve anxiety and promote relaxation, improve respiratory function, enhance immunological function, and decrease pain by stimulating the production of endorphins.

It is important to determine the client's perception of what is humorous in order to avoid offending. Differentiation between humorous and offensive situations varies greatly from culture to culture and person to person. Nurses can use humor with clients in a variety of ways. A humor cart (portable cart

TABLE 31-10 Interactions between Herbs and Medications

HERBAL PRODUCT	DRUG	EFFECT WHEN COMBINED
Aloe	Thiazide diuretics and corticosteroids Cardiac glycosides and antiarrhythmic agents	Enhanced potassium loss Potentiated by potassium loss
Belladonna	Tricyclic antidepressants, amantadine, quinidine	Increased anticholinergic effect
Brewer's yeast	MAO inhibitor antidepressants	Increased blood pressure
Dan Shen	Warfarin	Increased warfarin bioavailability; increased prothrombin time
Ginkgo	Warfarin, heparin	Increased risk of bleeding
Licorice root	Acetaminophen Antihypertensives Estrogens Fludrocortisone Thiazide diuretics and corticosteroids	Speeds acetaminophen excretion Decreased antihypertensive effect Increased estrogenic effect Increased blood pressure Enhanced potassium loss

Data from Gladstar, R. (2008). *Rosemary Gladstar's herbal recipes for vibrant health*. North Adams, MA: Storey Books; Skidmore-Roth, L. (2009). *Mosby's handbook of herbs and natural supplements* (4th ed.). St. Louis, MO: Elsevier.

or carrier filled with joke books, magic tricks, and funny videos) is easy to use and allows clients to select their own humor tools for health. The type of humor should be age appropriate and culturally sensitive. See the Nursing Checklist on this page.

Pet Therapy

The use of animals to enhance health status has a long history. In Britain in the eighteenth and nineteenth centuries, pets were used in institutions to give a sense of meaning and purpose to people institutionalized due to developmental delays (mental retardation). Florence Nightingale (1860) noted the value of pets as companions for individuals with chronic illness.

NURSING CHECKLIST

Using Humor as a Therapeutic Intervention

- Establish a trusting nurse-client relationship.
- Conduct a humor assessment to determine the type of humor appreciated by the client and the client's usual response to humor.
- Follow the client's lead in the type of humorous strategies used (e.g., jokes, satire, puns).
- Involve the family and significant others in the humor.
- Use humor as an adjunct, not a substitute, for pain medication.
- Continually evaluate the humor strategy for its effectiveness.

The therapeutic use of pets may be particularly helpful with older adults. Playing with and petting animals can help people feel less isolated; see Figure 31-8. Pet therapy is currently used as adjunctive treatment for people in both acute and long-term care settings. There are many uses for pet therapy. It can be implemented to help cope with physical limitations, improve mood, decrease blood pressure, and improve socialization skills and self-esteem.

Music

Music enters the bodymind through the auditory sense. Therapeutic use of music consists of playing music to elicit positive changes in behavior, emotions, or physiological response. Music complements other treatment modalities and encourages clients to become active participants in their health care and recovery.

Music is a good adjunct to use with imagery as it can add to the relaxation response and, therefore, heighten images; see Figure 31-9. Music can be used to relax or stimulate. Music is used for celebrations, spiritual ceremonies, entertainment, and recreation.

The basic elements of music—rhythm, pitch, and intensity—are transmitted by sensory impulses from the cochlea to the thalamus, and then to the cerebral cortex, affecting the autonomic nervous system. Here are some ways in which music has been used as a therapeutic intervention:

- Music can reduce postoperative pain in women following gynecologic surgery (Good & Ahn, 2008).
- As a group intervention, music can improve depression, anxiety, and relationships in clients with mental illness (Choi, Lee, & Lim, 2008).

FIGURE 31-8 Interacting with pets can lead to therapeutic benefits. DELMAR/CENGAGE LEARNING

FIGURE 31-9 This individual is experiencing the combined effects of music and imagery, which potentiate the relaxing effects of each modality. DELMAR/CENGAGE LEARNING

- When used with clients experiencing moderate to severe dementia, music had a positive effect on anxiety, agitation, irritability, and nighttime disturbances (Raglio et al., 2008).
- Music improved intraoperative relaxation and postoperative relaxation for clients who had cardiac surgery (Ikedo, Gangahar, Quader, & Smith, 2007).

Music can be a very useful tool for clients who may be immobilized, who must wait for diagnostic tests, or who undergo the perioperative experience. Pleasurable sounds and music can reduce stress, perception of pain, anxiety, and feelings of isolation. To promote relaxation, select music that is repetitive and low-pitched. Rhythm is most soothing when it has a 3/4 beat. Relaxation is induced by repetition of music, such as lullabies and chants. Music can also be especially useful in helping adolescent clients relax.

Although music is therapeutic for people at all stages of the life cycle, **music-thanatology** is a holistic and palliative method for use of music with dying clients. Music-thanatology is used to help dissipate obstacles to the client's peaceful transition to death. When used with clients who have advanced-stage cancer, music helps reduce anxiety, pain, and isolation and provides the potential for a more peaceful dying experience (Magill & Berenson, 2008).

NURSING AND COMPLEMENTARY/ALTERNATIVE APPROACHES

Nurses play an important role in educating consumers about unconventional interventions by providing information about the safety and efficacy of such methods. Working as advocates and educators, nurses help clients to integrate CAM modalities with conventional treatment methods (Eliopoulos, 2009).

Education is a major function of nursing and is greatly needed as consumers try to determine which CAM methods to use. Consumers should be taught to recognize the signals of fraudulent practice and to avoid healers who:

- Promise immediate relief or success
- State that their way is the only sure therapy
- Refuse to work with other health care providers
- Claim to have all the answers
- Use testimonials that claim amazing results

Other nursing interventions are to provide clients with information about the appropriate use of CAM, to protect clients from unsafe practices and practitioners, and to assist colleagues in being informed of the ever-changing knowledge base about CAM. Many clients and family members obtain health care information from the World Wide Web. See the accompanying Client Teaching Checklist for information on helping clients evaluate Web resources.

Holistic nurses individualize every intervention on the basis of the client's unique needs. From the time before birth until the moment of death, people of all ages experience trauma, stress, and life challenges and have needs in all dimensions. Nurses are challenged to discover and meet those needs. Table 31-11 on page 853 provides suggestions for the use of CAM modalities throughout the life cycle. See the accompanying Respecting Our Differences displays.

CLIENT TEACHING CHECKLIST

Evaluating Health Resources on the Web

Encourage clients to answer these questions:

- Who runs the site?
- Who pays for the site?
- What is the purpose of the site?
- Where does the information come from?
- How is the information selected?
- How current is the information?
- How does the site choose links to other sites?
- What information about you does the site collect, and why?

Data from National Center for Complementary and Alternative Medicine. (2006). *Get the facts: 10 things to know about evaluating medical resources on the Web*. Retrieved August 12, 2009, from <http://nccam.nih.gov/health/webresources>

RESPECTING OUR DIFFERENCES

You are assigned to care for a 6-year-old boy who does not speak your language, who is confined to bed, and whose parents must leave him for periods of time because of work obligations. During these periods he cries and is uncooperative with staff. The parents feel guilty, and everyone on your unit finds his behavior unsettling. Your nurse manager asks you to devise a care plan to meet the child's needs and help him cope. What CAM treatment modalities can you employ to deal with his anxieties? Do you need a prescribing practitioner's order to use them?

RESPECTING OUR DIFFERENCES

Complementary and Alternative Treatment: To Seek It or Not?

Your close friend has AIDS and is experiencing a great deal of pain and discouragement. She wants to find alternative methods to ease the pain. She confides in you that she believes there may be a cure available at the holistic health center. How do you best help your friend with this situation? What do you advise? Evaluate the same scenario by changing the friend to a client. Is your approach different? Do you give the same advice?

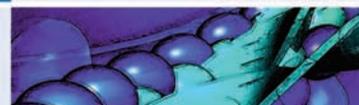

NURSE AS INSTRUMENT OF HEALING

When nurses serve as instruments of healing, the objective is to help clients call forth their inner resources for healing. In order to accomplish this goal, nurses must develop the following attributes:

- Knowledge base: Initially established in nursing school and then continuously expanded through lifelong learning
- Intentionality: A conscious direction of goals that is essential in helping the healer to focus
- Respect for differences: Demonstrated by honoring clients' culturally based health beliefs
- Ability to model wellness: Tending to one's own needs and attempting to stay as healthy and balanced as possible

In order to assist client healing, it is imperative that nurses take care of themselves. Self-nurturing enables nurses to be effective in caring for others because they have met their own needs. See the Uncovering the Evidence display on page 853.

UNCOVERING THE

Evidence

TITLE OF STUDY

“The Effect of Aromatherapy Massage with Music on the Stress and Anxiety Levels of Emergency Nurses: Comparison between Summer and Winter”

AUTHORS

M. Cooke, K. Holzhauser, M. Jones, C. Davis, and J. Finucane

(Continues)

UNCOVERING THE (Continued)

Evidence

PURPOSES

(1) To evaluate the use of aromatherapy massage and music as interventions to cope with the occupational stress and anxiety experienced by emergency department nurses and (2) to compare any difference in results between massage sessions performed in the summer and the winter.

METHODS

The study used a one-group, pretest-posttest, quasi-experimental design with random assignment of participants. Nursing occupational stress was assessed before and after 12 weeks of aromatherapy massage with music. Anxiety was measured before and after each massage session.

FINDINGS

Emergency nurses were significantly more anxious in winter than in summer. Aromatherapy massage with music significantly reduced emergency nurses' anxiety.

IMPLICATIONS

High stress levels can be detrimental to the health of emergency nurses. The provision of a support mechanism such as on-site massage may be used as an effective strategy for reducing anxiety experienced by emergency nurses.

Cooke, M., Holzhauser, K., Jones, M., Davis, C., & Finucane, J. (2007). The effect of aromatherapy massage with music on the stress and anxiety levels of emergency nurses: Comparison between summer and winter. *Journal of Clinical Nursing, 16*(9), 695–703.

PROCEDURE 31-1

Administering Therapeutic Massage

EQUIPMENT

- Flat sheet
- 1 or 2 pillows
- Bath blanket or light coverlet
- Towel
- Lotion or oil

ACTION

RATIONALE

- | ACTION | RATIONALE |
|--|--|
| 1. Set room temperature at approximately 75°F. Provide low or indirect lighting, privacy, and background music. | 1. Maintains client's body heat, protects privacy, and promotes relaxation. |
| 2. Prepare the massage table or hospital bed by placing a clean sheet on the surface. Adjust the surface height. | 2. Both the massage table and hospital bed are adjustable so that the height of the work surface can be raised or lowered as necessary to prevent back strain. |
| 3. Remove rings and watch. Wash hands/hand hygiene. | 3. Avoids scratching the client and prevents transmission of microorganisms. |
| 4. Explain the procedure to the client. | 4. Prepares the client for the treatment. |
| 5. Assist the client to assume either a prone, Sims', supine, or sitting position, depending on client's condition. | 5. Appropriate position enables the nurse to apply the necessary amount of pressure without causing discomfort for the client. |
| 6. Loosen or remove clothing from the client's back and arms. Drape the client with a sheet to cover areas not being treated directly. | 6. Exposes parts of the back on which the massage will be performed. Draping untreated parts of the back helps keep the client warm and provides privacy. |
| 7. Squeeze a small amount of lotion or oil into the palm of the hand to warm before applying to the client. | 7. Cold lotion or oil can cause discomfort to the client. |

(Continues)

PROCEDURE 31-1 Administering Therapeutic Massage (Continued)

ACTION	RATIONALE
8. Begin with light to medium effleurage (see explanation in text) at lower back and continue upward following muscle groups, being careful to avoid the spine and spinal processes (see Figure 31-10). Move hands up toward the base of the neck and continue outward over the trapezius muscles with circular motions, over and around shoulders and upper arms, and return with lighter downward strokes laterally over the latissimus dorsi to the upper gluteals. Use slow rhythmical movements, keeping in contact with the skin at all times. Check pressure. Continue the effleurage for approximately 3 minutes.	8. Prevents damage to internal structures, stimulates circulation, and promotes relaxation.
9. Continue treatment if appropriate with gentle petrissage (see explanation in text) to major muscle groups in the back, shoulders, and upper arms (see Figure 31-11).	9. Enhances circulation, stimulates muscles, and promotes relaxation.
10. Use friction (see explanation in text) to particular muscle groups where tension is being held.	10. Penetrates deeper muscle layers, thus promoting further relaxation.
11. Use tapotement (see explanation in text) to stimulate any muscle groups that may be fatigued.	11. Invigorates and stimulates tired muscles.
12. Finish treatment with effleurage.	12. Assists with relaxation and provides a sense of completion.
13. Wipe any excess lotion or oil from skin with towel, or use small amount of warm soap and water to clean client's skin, taking care to dry completely.	13. Promotes and maintains skin integrity.
14. Assist client into comfortable position for a period of rest or sleep.	14. Allows client to fully experience therapeutic benefit of massage.
15. Document treatment, client's response, and skin assessment data.	15. Communicates pertinent data to other members of treatment team; promotes continuity of care.
16. Wash hands/hand hygiene.	16. Reduces transmission of microorganisms.

PROCEDURE 31-1 Administering Therapeutic Massage (Continued)

delegation tip

Therapeutic massage may be delegated to any individual properly trained in performing the techniques.

nursing tips

- *Keep the client covered as much as possible to provide privacy and promote comfort.*
- *Be sure to determine client preference when using lotions or oils. Some fragrances may be unpleasant to a client.*
- *Ask client for input regarding the use of music during massage.*
- *Use this time as an opportunity to assess the client's skin integrity and psychological comfort level.*

KEY CONCEPTS

- Ever-increasing numbers of health care consumers are using CAM modalities.
- Psychoneuroimmunology is the study of how the body and mind are connected and how beliefs, thoughts, and emotions affect health.
- Holistic nursing practice encompasses consideration of each client as a unique and whole being with many aspects: physiological, psychological, sociocultural, intellectual, and spiritual.
- Healing is not curing but rather is regaining balance and finding harmony and wholeness as changes take place from within the individual.
- No one person can heal another, but a nurse can act as a guide, support system, or instrument of healing for a client.
- Some of the mind-body modalities that nurses use are meditation, relaxation, imagery, biofeedback, and hypnosis.
- Body-movement modalities include movement, exercise, and chiropractic therapy.
- Energetic-touch therapies can be used with persons of all ages and in various stages of illness and wellness.
- Energetic-touch therapies include massage, therapeutic touch (TT), healing touch (HT), shiatsu acupressure, and reflexology.
- Spiritual therapies such as faith healing, healing prayer, and laying on of hands are helpful modalities.
- Nutritional therapies include antioxidants, macrobiotic diets, and herbal therapy.
- Other modalities, such as aromatherapy, humor, pet therapy, and music therapy, are valuable adjuncts to conventional treatment.

REVIEW QUESTIONS

- Which of the following CAM interventions should be avoided when working with toddlers?
 - Art/drawing
 - Hypnosis
 - Massage
 - Music
- A nurse is working with a client who uses herbs to promote health. Which of the following herbs is useful in treating nausea?
 - Aloe vera
 - Calendula
 - Ginger
 - Sage
- Native American healing practices are strongly rooted in which of the following?
 - Allopathic medicine
 - New Age concepts
 - Spiritual beliefs
 - Yoga techniques
- Which of the following nursing responses is most therapeutic for a client who expresses interest in using herbal remedies?

- a. "I use lavender and valerian to help me relax at night."
 - b. "My herbalist recommends the use of St. John's wort to promote healing."
 - c. "Since they are natural, herbs are completely safe."
 - d. "What have you been doing to promote your health?"
5. When planning care for a client with chronic pain, the nurse establishes a diagnosis of *Disturbed energy field*. Which of the following CAM approaches would be of most use for this client?
 - a. Aromatherapy
 - b. Healing touch
 - c. Herbals
 - d. Humor
 6. Which of the following foods are dietary sources of antioxidants? Select all that apply.
 - a. Butter
 - b. Carrots
 - c. Flaxseed
 - d. Garlic
 - e. Parsley
 - f. Red meat
 7. Which of the following is a reason why many people seek out and use CAM therapies?
 - a. CAM therapies are cost-effective.
 - b. Cultural beliefs usually prohibit the use of "folk remedies."
 - c. Insurance companies reimburse for most CAM therapies.
 - d. They are satisfied with allopathic treatment methods.
 8. Which of the following best describes the Ayurvedic perspective of health?
 - a. Absence of disease equals health.
 - b. Harmony is maintained through use of natural and supernatural forces.
 - c. Prana in the body maintains a state of balance.
 - d. Use of totems, fetishes, dance, and chanting promotes health.
 9. A nurse is caring for a Buddhist client who asks that his priest be allowed to conduct chanting and healing prayers in his hospital room. Which of the following nursing actions is most appropriate?
 - a. Check with the nursing supervisor about the client's request.
 - b. Explain that the client may go to the hospital chapel for prayer and chanting.
 - c. Provide privacy for the client and priest to pray and chant.
 - d. Tell the client that chanting is not allowed because it will disturb other clients.
 10. Which of the following statements accurately describes CAM? Select all that apply.
 - a. CAM considers the whole person through use of body-mind interventions.
 - b. CAM is most effective in treating acute, emergency situations.
 - c. The American public has a negative view of CAM approaches.
 - d. The U.S. federal government supports research into the efficacy of CAM modalities.
 - e. There has been little scientific research to support the use of CAM modalities.
 - f. Use of CAM modalities is increasing in the United States.

“And what nursing has to do in either case, is to put the patient in the best condition for nature to act upon him.”

—FLORENCE NIGHTINGALE (IN SKRETKOWICZ, 1992)

CHAPTER 32

Oxygenation

COMPETENCIES

1. Describe the basic physiological mechanisms of ventilation, circulation, and oxygenation.
2. Assess the client's ventilatory, circulatory, and oxygenation status.
3. Explain potential client outcomes when oxygenation is impaired.
4. State common client knowledge deficits related to oxygenation impairment.
5. Develop nursing interventions that promote oxygenation.
6. Describe actions for emergency support of airway, ventilation, and circulation.

KEY TERMS

aerobic metabolism	deadspace	oxygen uptake
anaerobic metabolism	diastole	oxyhemoglobin dissociation curve
anemia	diffusion defect	paroxysmal nocturnal dyspnea
angina pectoris	external respiration	postural drainage
atelectasis	gallops	precapillary sphincters
atherosclerosis	heart failure	restrictive pulmonary disease
autoregulation	Heimlich maneuver	shunting
cardiac conduction system	hypercapnia	sleep apnea
cardiac cycle	hypoxemia	surfactant
cardiac output	hypoxia	systole
cardiopulmonary resuscitation (CPR)	infarction	tachypnea
chest physiotherapy (CPT)	intermittent claudication	tracheotomy
chronic obstructive pulmonary disease (COPD)	internal respiration	ventilation
cyanosis	ischemia	ventilation-perfusion (V/Q) mismatching
	murmurs	work of breathing
	obstructive pulmonary disease	

Oxygenation, the delivery of oxygen to the body's tissues and cells, is necessary to maintain life and health. Clients with compromised oxygenation status need careful assessment and thoughtful nursing care to achieve an adequate and comfortable level of oxygenation function. The purpose of this chapter is to explore the elements of the process of oxygenation, common mechanisms by which it may be impaired, and interventions that are aimed at improving oxygen delivery to the cells.

PHYSIOLOGY OF OXYGENATION

The delivery of oxygen to the body's cells is a process that depends upon the interplay of the pulmonary, hematologic, and cardiovascular systems. Specifically, the processes involved include ventilation, alveolar gas exchange, oxygen transport and delivery, and cellular respiration. The basic anatomy of the lungs is shown in Figure 32-1.

VENTILATION

The first step in the process of oxygenation is **ventilation**, which is the movement of air into and out of the lungs for the purpose of delivering fresh air into the lung's alveoli (see Figure 32-2 on page 861). Ventilation is regulated by respiratory control centers in the pons and medulla oblongata, which are located in the brain stem. The rate and depth of ventilation are constantly adjusted in response to changes in the concentrations of hydrogen ion (pH) and carbon dioxide (CO₂) in the body's fluids. For instance, an increase in carbon dioxide in the blood or a decrease in pH in the body's fluids will stimulate faster and deeper ventilation. A decrease

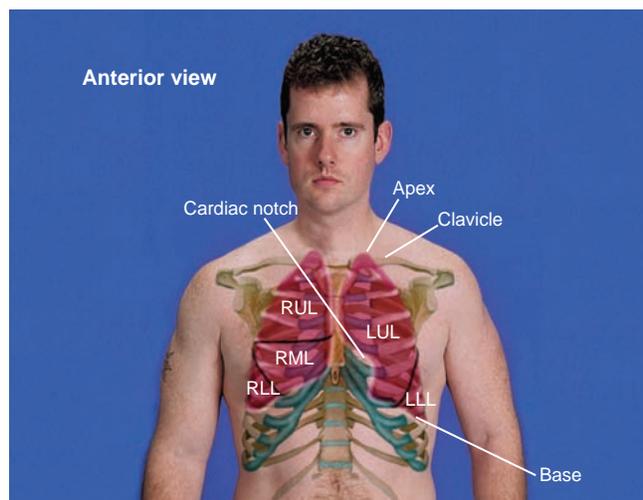

FIGURE 32-1 Lungs. RUL = right upper lobe, RML = right middle lobe, RLL = right lower lobe, LUL = left upper lobe, LLL = left lower lobe. DELMAR/CENGAGE LEARNING

in blood oxygen concentration (**hypoxemia**) will also stimulate ventilation, but to a lesser degree.

Inhalation of air is initiated when the diaphragm contracts, pulling it downward and thus increasing the size of the intrathoracic space (see Figure 32-3 on page 861). This space is also increased by contraction of the external intercostal muscles, which elevate and separate the ribs and move the sternum forward. The effect of increasing the space inside the thorax is to decrease the intrathoracic pressure so that air will be drawn in from the atmosphere. Stretch receptors in the lung tissue send signals back to the brain to cause cessation of inhalation, preventing overdistension of the lungs. Exhalation

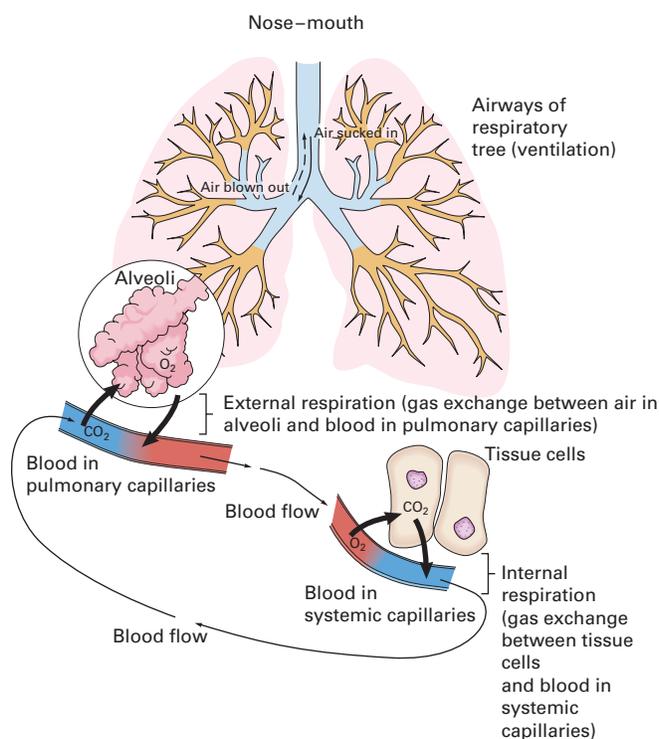

FIGURE 32-2 Elements of Oxygenation of the Pulmonary and Hematologic Systems DELMAR/CENGAGE LEARNING

occurs when the respiratory muscles relax, thus reducing the size of the intrathoracic space, increasing the intrathoracic pressure, and forcing air to exit the lungs. Under normal conditions, exhalation is a passive process.

When the movement of air is impeded, additional muscles may be used to increase the ventilatory ability. These accessory muscles of ventilation include the sternocleidomastoid muscle, the abdominal muscles, and the internal intercostal muscles. In some disease states, exhalation is impaired, requiring that the individual actively force air out of the lungs rather than passively exhaling. Forced expiration is aided by the intercostal muscles and the abdominal recti. When additional muscular force is required for breathing, the **work of breathing** is said to be increased.

Several mechanisms exist to keep the airways clear of microorganisms and debris. As air is inhaled through the nose, the larger particles are filtered out through hairs lining the nasal passages. The mucous membranes of the nasopharynx and sinuses warm and humidify the inspired air, and the film of mucus lining these membranes traps smaller particles. Closure of the glottis protects the airway from aspiration of food and fluids during swallowing. In the trachea and larger bronchi, tiny hairlike cilia continually produce wavelike movements to propel mucus and particles upward, where they can be coughed out. If any invaders manage to reach the alveoli, specialized alveolar macrophages will engulf and destroy the offending organism. Disease processes can interfere with any of these protective mechanisms, increasing the individual's vulnerability to infection and injury.

ALVEOLAR GAS EXCHANGE

Once fresh air reaches the lung's alveoli, the next step in the process of oxygenation begins. The exchange of oxygen from the alveolar space into the pulmonary capillary blood is

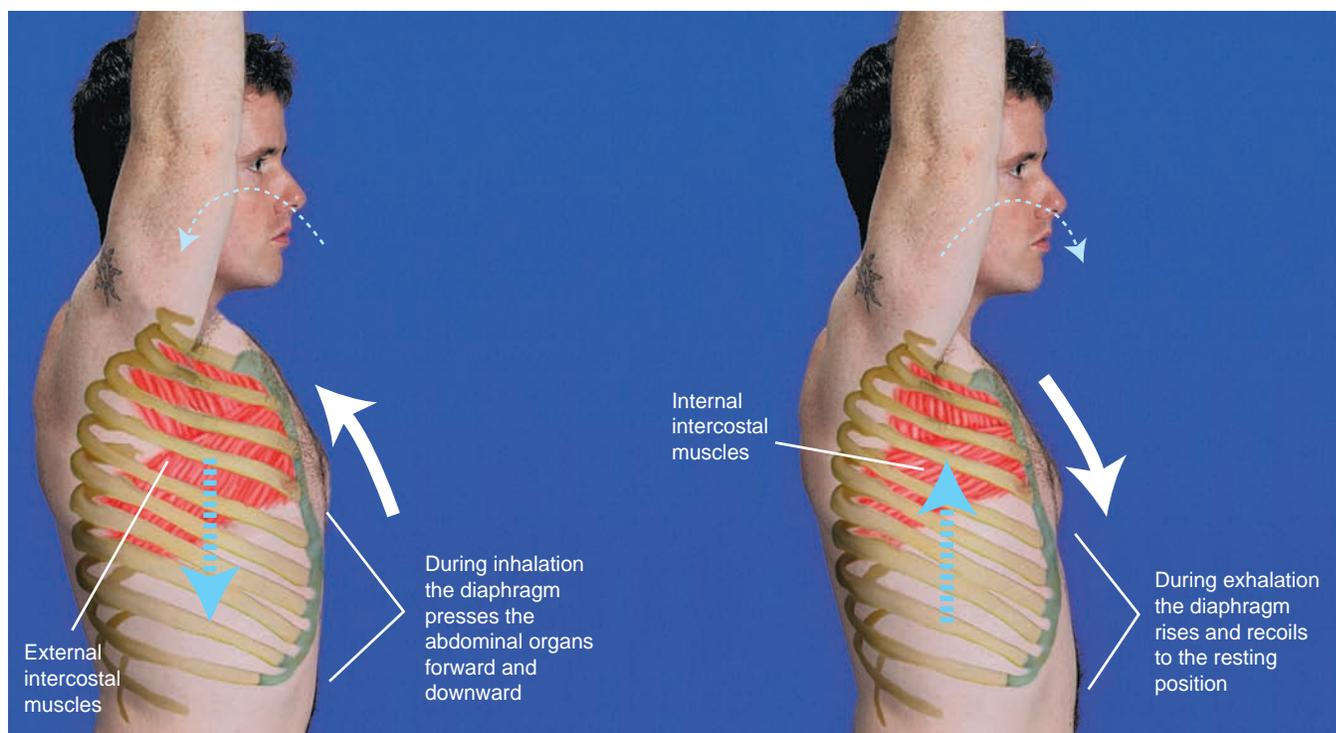

FIGURE 32-3 Mechanics of breathing. Inhalation increases the volume of the thorax by diaphragmatic excursion and elevation of the sternum. Exhalation is normally accomplished by passive elastic recoil. DELMAR/CENGAGE LEARNING

referred to as **oxygen uptake**; it may also be called **external respiration**. Oxygen diffuses across the alveolar membrane in response to a concentration gradient; that is, it moves from an area of higher concentration (the alveoli) to an area of lower concentration (the pulmonary capillary blood), seeking equilibrium. At the same time, carbon dioxide diffuses from the blood to the alveolar space, also in response to a concentration gradient (see Figure 32-4).

OXYGEN TRANSPORT AND DELIVERY

Oxygen Transport in the Blood

Once the diffusion of oxygen across the alveolar-capillary membrane occurs, the oxygen molecules are dissolved in the blood plasma. Three factors influence the capacity of the blood to carry oxygen: the amount of dissolved oxygen in the plasma, the amount of hemoglobin, and the tendency of the hemoglobin to bind with oxygen. However, the plasma is not able to carry nearly enough dissolved oxygen to meet the metabolic needs of the body. The oxygen-carrying capacity of the blood is greatly enhanced by the presence of hemoglobin in the erythrocytes.

The amount of oxygen carried in a sample of blood is measured in two ways. Oxygen dissolved in plasma is expressed as the partial pressure of oxygen (P_{aO_2}). The normal P_{aO_2} in arterial blood is about 80 to 100 mm Hg. The oxygen dissolved in plasma, however, represents only about 1% to 5% of the total oxygen content of the blood. The vast majority of oxygen

in the blood is carried bound to the hemoglobin molecule. The amount of oxygen bound to hemoglobin is expressed as the percentage of hemoglobin that is saturated with oxygen (S_{aO_2}), with 100% being fully saturated. Since the S_{aO_2} is a percentage indicating the relationship between oxygen and hemoglobin, the nurse should interpret the client's S_{aO_2} measurement with the hemoglobin level. Normal saturation of arterial blood (S_{aO_2}) is about 96% to 98%.

Hemoglobin molecules have the ability to form a reversible bond with oxygen molecules, so that the hemoglobin readily takes up oxygen in the lungs, while it also readily releases oxygen to the body's cells in the systemic capillary beds. This seemingly paradoxical shift in hemoglobin's affinity for oxygen is represented by the **oxyhemoglobin dissociation curve**, which is a graphic representation of the relationship between the P_{aO_2} and oxygen saturation.

The affinity of hemoglobin for oxygen is highest when the P_{aO_2} , the measure of oxygen dissolved in the arterial blood plasma, is 70 mm Hg or higher; in this portion of the curve, further increases in P_{aO_2} result in very little change in S_{aO_2} (see Figure 32-5A on page 863). This characteristic of the oxyhemoglobin dissociation curve accounts for the rapid uptake of oxygen by hemoglobin in the pulmonary circulation and allows for some decrease in P_{aO_2} , such as might occur with disease or in high altitudes, without significantly sacrificing S_{aO_2} .

As the oxygen-saturated blood is circulated to the peripheral capillary beds, dissolved oxygen diffuses out of blood. This decrease in dissolved oxygen causes hemoglobin to lose its affinity for oxygen, so the oxygen is then released to the body's cells. Once the P_{aO_2} in the blood drops below 60 mm Hg, hemoglobin releases oxygen very easily. This release is represented in the lower left portion of the curve, also known as the venous portion, and permits rapid unloading of oxygen to the cells (see Figure 32-5B on page 863).

Several physiological factors may alter the affinity of hemoglobin for oxygen, and these shifts can be represented on the oxyhemoglobin dissociation curve. A shift to the left occurs when affinity is increased so that for a given P_{aO_2} , the associated S_{aO_2} will be higher. This means that although the arterial blood may be carrying adequate oxygen, little of it is being released to the tissues. A shift to the left may be caused by increased pH (alkalosis), hypothermia, or a decrease in the red blood cell enzyme 2,3-diphosphoglycerate (2,3-DPG), which may occur after massive transfusions of banked blood.

A shift to the right of the oxyhemoglobin dissociation curve means that for a given P_{aO_2} , the S_{aO_2} will be lower. This phenomenon represents a decreased affinity of hemoglobin for oxygen so that oxygen is more readily released to the tissues. This shift occurs in response to acidosis, hyperthermia, and hypoxia (which induces increased production of 2,3-DPG) and results in improved delivery of oxygen to the tissues.

Circulation

Once oxygen is bound to hemoglobin, the oxygen is delivered to the cells of the body by the process of circulation. Circulation of the blood is the function of the heart and blood vessels.

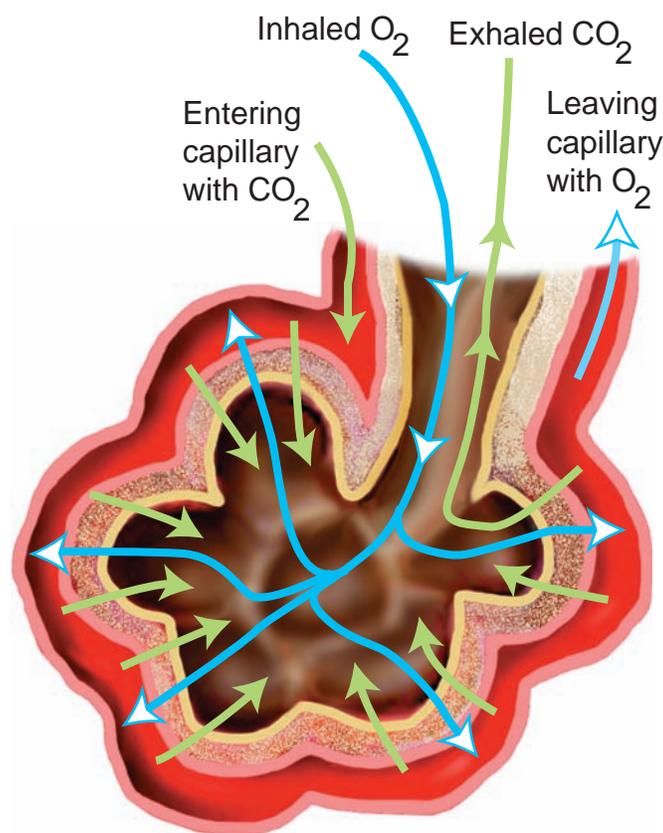

FIGURE 32-4 Alveolar Gas Exchange DELMAR/CENGAGE LEARNING

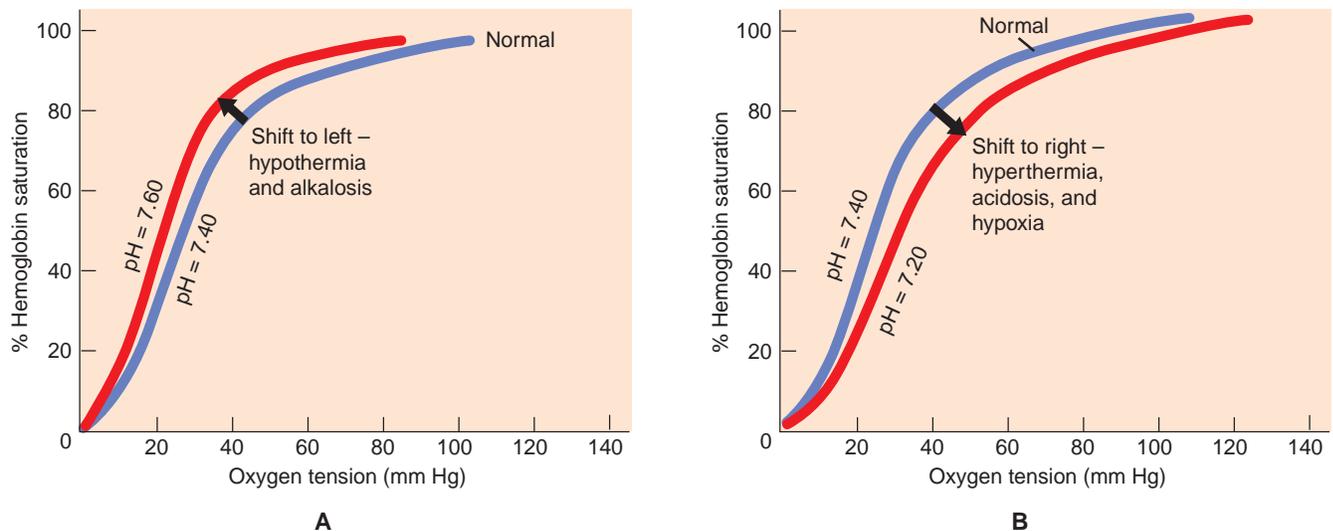

FIGURE 32-5 Oxyhemoglobin Dissociation Curve: A. Effect of increase in pH; B. Effect of decrease in pH. DELMAR/CENGAGE LEARNING

The heart is a muscular pump that is divided into four chambers: the right and left atria and the right and left ventricles (see Figure 32-6 on page 864). A series of valves allows for unidirectional blood flow through the chambers, which is driven by the sequential contraction and relaxation of the heart muscle.

A single cycle of atrial and ventricular contraction and relaxation is referred to as a **cardiac cycle**, which is the product of the interplay of electrical and mechanical events. The electrical activity of the heart involves the generation and transmission of electrical current by specialized cardiac cells known as the **cardiac conduction system** (see Figure 32-7 on page 864). A small mass of cells in the right atrium, the *sinoatrial node*, or *SA node*, normally controls the heart rate by rhythmically generating electrical impulses. For this reason, the SA node is often referred to as the heart's "pacemaker." The impulses created by the SA node travel along specialized internodal pathways to spread throughout the atria, resulting in mechanical muscular contraction. The electrical activity is then transmitted down to the ventricles via the *atrioventricular (AV) node* and spreads through the ventricular tissue along the *bundle of His*, *right and left bundle branches*, and *Purkinje fibers*. Again, the result is muscular contraction. The sequential contraction and relaxation of the atria and ventricles are essential factors in the cyclical filling and emptying of the chambers, which produce circulation.

The process of a chamber filling is referred to as **diastole**, and the process of a chamber emptying is **systole**. Atrial diastole occurs as the right and left atria relax and blood flows into the right and left atrial chambers from the venae cavae and pulmonary veins, respectively. As pressure rises in the atria, the atrioventricular valves (the mitral and tricuspid) open, permitting the blood to begin flowing into the ventricles. Ventricular filling is further augmented by contraction of the atrial muscle (atrial systole), forcing additional blood into the ventricles. This contribution to ventricular filling is sometimes called "atrial kick."

Filling of the ventricles causes the intraventricular pressure to rise. When the intraventricular pressure exceeds the pressure in the atria, the atrioventricular valves close. The ventricular muscle then begins to contract, further increasing intraventricular pressure until it is sufficient to force open the two semilunar valves (the pulmonic and aortic valves). As contraction of the ventricular walls proceeds, blood is forced out of the ventricles and into the circulation (ventricular systole).

Blood leaving the right ventricle is pumped into the pulmonary artery, which quickly branches into the right and left pulmonary arteries. Further division of the pulmonary arterial tree culminates in the pulmonary capillary bed. Blood in the pulmonary capillaries is in very close contact with the alveolar air; it is here that alveolar-capillary gas exchanges take place. From the pulmonary capillaries, the freshly oxygenated blood flows into the pulmonary veins and to the left atrium, which delivers it to the left ventricle (see Figure 32-8 on page 865).

Blood leaving the left ventricle enters the aorta. The aorta serves as the "trunk" of the arterial tree, with branches leading to every organ and tissue group in the body. Blood flow through the arterial system is driven by the pressure generated during ventricular systole and is influenced by the volume and viscosity of the blood and the amount of resistance within the arterial system. Blood flow to specific organs and tissues may be increased or reduced by the relaxation or contraction of **precapillary sphincters**, which are rings of smooth muscle surrounding the arterioles. This mechanism allows for redistribution of blood flow to the areas of greatest need, a process known as **autoregulation**.

Blood return through the venous system is also driven by pressure gradients, although the venous system operates under lower pressure than the arterial system does. In order to boost venous return, many veins (particularly in the lower extremities) are equipped with valves that prevent backward flow of blood (regurgitation); as the veins are compressed by their surrounding skeletal muscles, blood is forced along toward the vena cava and ultimately to the right atrium.

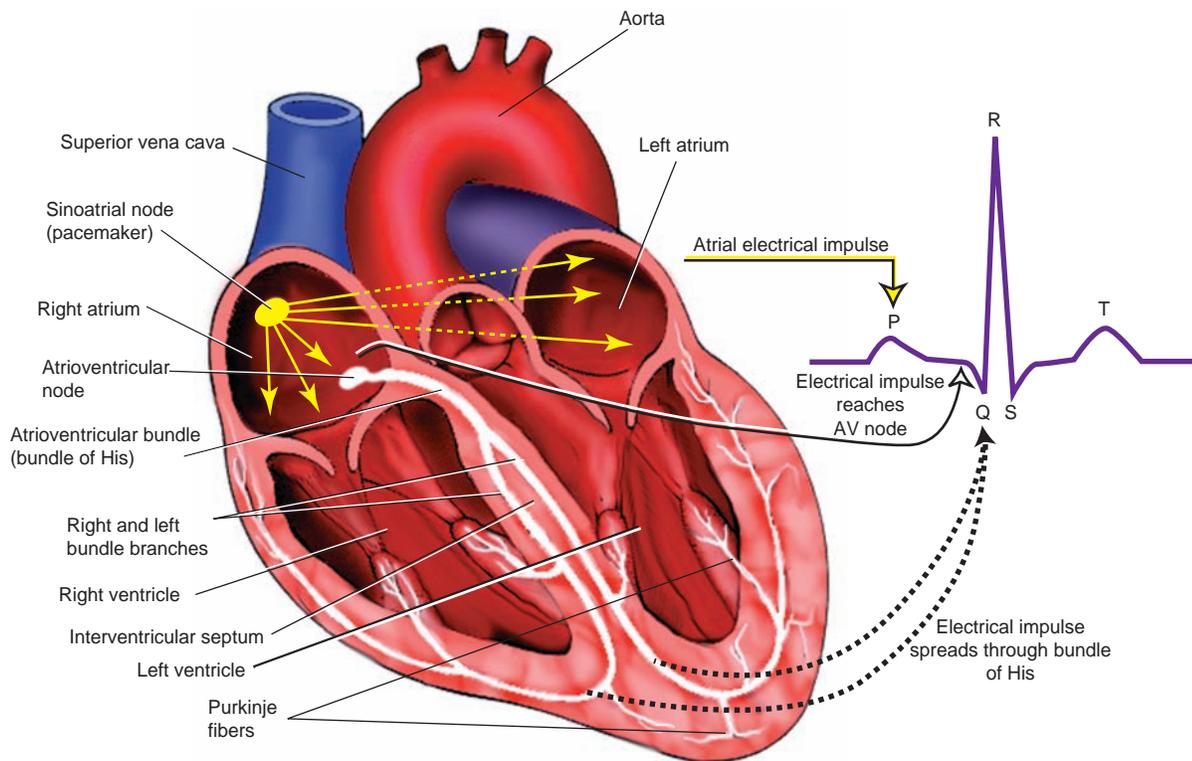

FIGURE 32-7 Cardiac Conduction System DELMAR/CENGAGE LEARNING

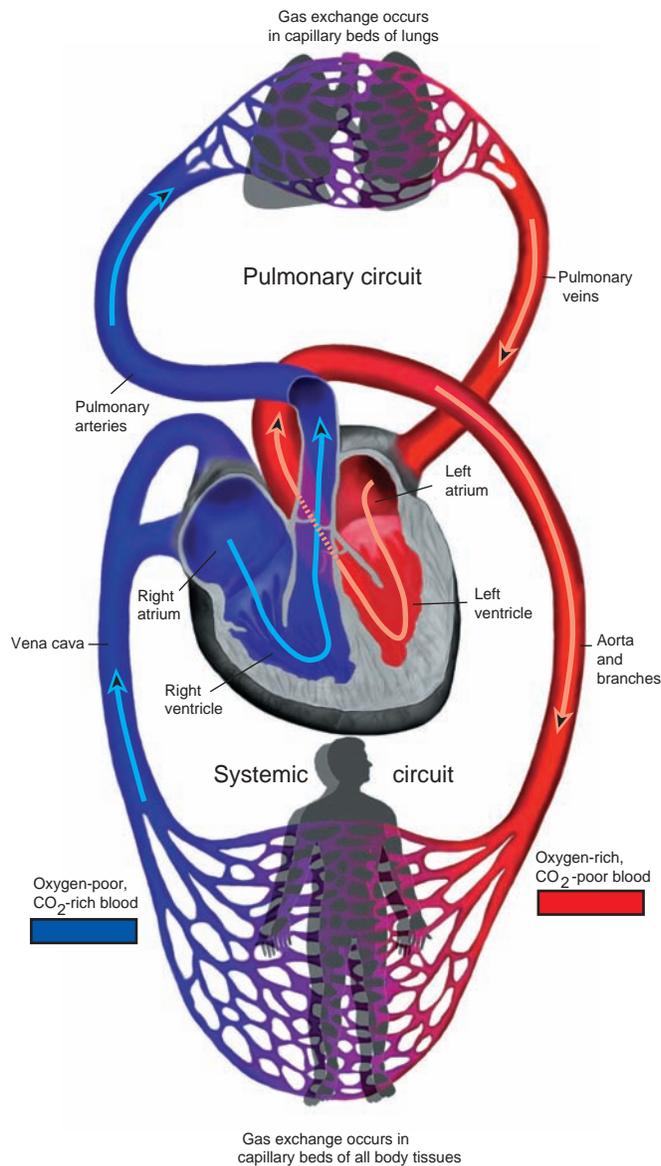

FIGURE 32-8 Systemic and Pulmonary Circuits DELMAR/CENGAGE
LEARNING

CELLULAR RESPIRATION

Gas exchange at the cellular level, like that at the alveolar level, takes place via diffusion in response to concentration gradients. Oxygen diffuses from the blood to the tissues, while carbon dioxide moves from the tissues to the blood; the blood is then reoxygenated by the lungs. This process is referred to as **internal respiration**.

FACTORS AFFECTING OXYGENATION

Adequate oxygenation is influenced by many factors, including age, environmental and lifestyle factors, and disease processes.

AGE

Oxygenation status can be influenced by age. Older adults may exhibit a barrel chest and require increased effort to expand the lungs. Loss of alveolar gas exchange is accompanied by a decrease in the PaO_2 . Older adults are also more susceptible to respiratory infection because of decreased activity in the cilia, which normally are an effective defense mechanism.

ENVIRONMENTAL AND LIFESTYLE FACTORS

Environmental and lifestyle factors can significantly affect a client's oxygenation status. Clients who are exposed to dust, animal dander, asbestos, or toxic chemicals in the home or workplace are at increased risk for alterations in oxygenation. Individuals who experience significant physical or emotional stress or who are obese or underweight are also subject to changes in oxygenation status; see the accompanying Uncovering the Evidence display on page 866. Smokers and those exposed to secondhand smoke should be questioned as to the type and amount of tobacco and number of years of exposure.

DISEASE PROCESSES

Oxygenation alterations can often be traced to disease states related to alterations in ventilation, alveolar gas exchange, oxygen uptake, or circulation. There are many disease states that may affect oxygenation, including obstructive pulmonary disease, restrictive pulmonary disease, diffusion defects, ventilation-perfusion mismatching, atherosclerosis, heart failure, anemia, and alterations in oxygen uptake.

Obstructive Pulmonary Disease

Alterations in ventilation may be related to obstructive or restrictive pulmonary disease. **Obstructive pulmonary disease** occurs when the airways become partially or completely blocked, diminishing airflow, or the lungs lose some of their elastic recoil, trapping stale air, which should be exhaled. In both cases, the end result is impaired exhalation, air trapping, and difficulty bringing fresh air into the alveoli (see Figure 32-9 on page 867). The most common obstructive pulmonary diseases are asthma, emphysema, and chronic bronchitis, collectively known as **chronic obstructive pulmonary disease (COPD)**.

Restrictive Pulmonary Disease

Restrictive pulmonary disease represents pathologies that impair the ability of the chest wall and lungs to expand during the inspiratory phase of ventilation. This impairment increases the work of breathing and also reduces airflow to the alveoli. A wide variety of disorders causes restrictive lung disease, including pneumonia and pulmonary fibrosis (scarring). The following compromise a client's respiratory health, increasing the susceptibility to pneumonia:

- Smoking
- Emphysema
- Intoxication
- Weak cough reflex

UNCOVERING THE

Evidence

TITLE OF STUDY

“Importance of Aerobic Fitness in Cardiovascular Risks in Sedentary Overweight and Obese African-American Women”

AUTHOR

T. Gaillard

PURPOSE

To examine the clinical and metabolic risk factors of cardiovascular disease (CVD) in nondiabetic, sedentary, overweight or obese African American women with varying degrees of aerobic fitness.

METHODS

Forty-eight African American women, with mean age of 43 years and body mass index of 32.3, participated in the study. Fasting and 2-hour postprandial serum glucose, insulin, and C-peptide levels were obtained during an oral glucose tolerance test. Insulin sensitivity was calculated by homeostasis model assessment of insulin resistance (HOMA-IR). Aerobic fitness was categorized empirically as very low aerobic fitness (VLAF; $n = 17$, $V_{O_{2max}} < 21$ mL/kg/min), low aerobic fitness (LAF; $n = 12$, $V_{O_{2max}} 21-24.4$ mL/kg/min), and moderate aerobic fitness (MAF; $n = 19$, $V_{O_{2max}} > 24.4$ mL/kg/min).

FINDINGS

Significant differences were found in serum glucose, insulin, and C-peptide levels as well as the HOMA-IR in the VLAF versus LAF and MAF groups. Mean HOMA-IR was statistically greater in the VLAF and LAF groups when compared to the MAF group.

IMPLICATIONS

Modest aerobic fitness has a significant impact on insulin sensitivity, atherogenic lipids, lipoprotein parameters, and the overall risks for CVD in sedentary overweight or obese African American women. Whether modest physical fitness translates into prevention of type 2 diabetes and CVD in African American women remains to be determined by additional research.

Gaillard, T. (2007). Importance of aerobic fitness in cardiovascular risks in sedentary overweight and obese African-American women. *Nursing Research*, 56(6), 407-415.

- Immunosuppressed status
- Medicated or unconscious status

Traumatic injury to the thorax or a break in the pleural membrane that surrounds the lungs may also produce restrictive pulmonary dysfunction. The stability of the chest depends upon the rib cage; multiple rib fractures may produce a type

of paradoxical chest wall movement called “flail chest” that impedes normal airflow. The dual-layer pleural membrane also has an important structural function; it helps maintain a negative pressure between its two layers that keeps the lungs from collapsing upon themselves. A break in either layer of the membrane or an abnormal collection of fluid between them interferes with this function, permits alveoli to collapse, and increases the work of breathing. Common pleural defects are described in Table 32-1 on page 867.

Alveolar collapse, known as **atelectasis**, can be caused by pleural defects as described above, by compression from a mass such as a tumor, or by occlusion of the small airways by secretions, which prevents air movement into the associated alveoli. Failure of a client to breathe deeply after abdominal surgery may result in atelectasis. Regardless of the cause, atelectasis results in restrictive pulmonary dysfunction and reduces the amount of alveolar-capillary surface area engaged in gas exchange.

Diffusion Defects

Another mechanism of oxygenation impairment is a decrease in the efficiency of gas diffusion from the alveolar space into the pulmonary capillary blood, known as a **diffusion defect**. This may be caused by thickening of the alveolar-capillary basement membrane or by marked increases in the speed of blood flow through the pulmonary capillary beds, which reduce contact time with the alveoli. Diffusion defects by themselves are uncommon but may coexist with obstructive or restrictive pulmonary disease such as emphysema, pulmonary edema, or fibrosis.

Ventilation-Perfusion Mismatching

Gas exchange across the alveolar-capillary membrane is also influenced by **ventilation-perfusion (V/Q) mismatching**, or the balance between ventilation and perfusion. The amount of fresh air entering the alveoli (alveolar ventilation) and the amount of blood flow to various regions of the pulmonary capillary network (perfusion) are not uniform throughout the lungs. Due to alterations in position and the effect of gravity, certain zones of lung tissue may have better ventilation or perfusion than others at any given time.

An important mechanism of compensation in healthy lung tissue is to produce vasoconstriction or bronchoconstriction as needed to better match ventilation to perfusion or vice versa. Many disease states, however, produce areas of V/Q mismatching that cannot be overcome by compensatory responses. When mismatching occurs, some alveolar regions will be well ventilated but poorly perfused (a condition known as **deadspace**), while others may be well perfused but poorly ventilated (known as **shunting**). This phenomenon is illustrated in Figure 32-10 on page 868.

Alterations in circulation may occur in either the pulmonary or the systemic vasculature and may be localized or generalized. Generalized decreases in pulmonary circulation may be caused by right-sided heart failure or by pathologies in the pulmonary vascular system such as pulmonary hypertension and the resultant pulmonary artery sclerosis. Regional

FIGURE 32-9 One mechanism of air trapping in COPD. During inspiration, the airway widens and opens. During exhalation, the airway closes, trapping air distal to the obstruction and preventing fresh air from entering the alveoli. DELMAR/CENGAGE LEARNING

TABLE 32-1 Common Pleural Defects

PLEURAL DEFECT	DESCRIPTION
Pleural effusion	Collection of fluid between the pleural layers. May consist of serous fluid (hydrothorax), purulent fluid (empyema), or chyle (chylothorax).
Hemothorax	Collection of blood between the pleural layers.
Pneumothorax	A collection of air between the pleural layers caused by a hole in one or both layers of the pleural membrane. May be classified as open (communicating with a chest wall wound) or closed (no exterior wound).
Tension pneumothorax	A pneumothorax that rapidly expands with each respiratory cycle, compressing the lungs and heart and pushing the great vessels and trachea toward the opposite side of the chest. A tension pneumothorax is a medical emergency requiring immediate intervention.

Delmar/Cengage Learning

decreases in pulmonary circulation may be related to blockage of a pulmonary artery by an embolus or by regional vasoconstriction.

Atherosclerosis

Alterations in systemic circulation may also be generalized or localized. A common cause of altered arterial circulation is **atherosclerosis**. This disease is characterized by narrowing and eventual occlusion of the lumen (opening of the arteries) by deposits of lipids, fibrin, and calcium on the interior walls of the arteries (see Figure 32-11 on page 868). The reduction in blood flow with accompanying oxygen deprivation leads to **ischemia** (deprivation of blood flow) and even-

tual **infarction** (necrosis or death) of the affected tissue. Atherosclerosis in the coronary arteries (coronary heart disease) and the arteries of the brain (cerebral vascular disease) causes myocardial infarction and stroke, respectively, two of the leading causes of death in our society.

Heart Failure

Generalized decreases in tissue perfusion may be caused by left-sided heart failure or by loss of circulating blood volume as may occur with shock or hemorrhage. **Heart failure** is a condition in which the heart is unable to pump enough blood to meet the metabolic needs of the body; typically, this is accompanied by a backup of blood in the venous circuits

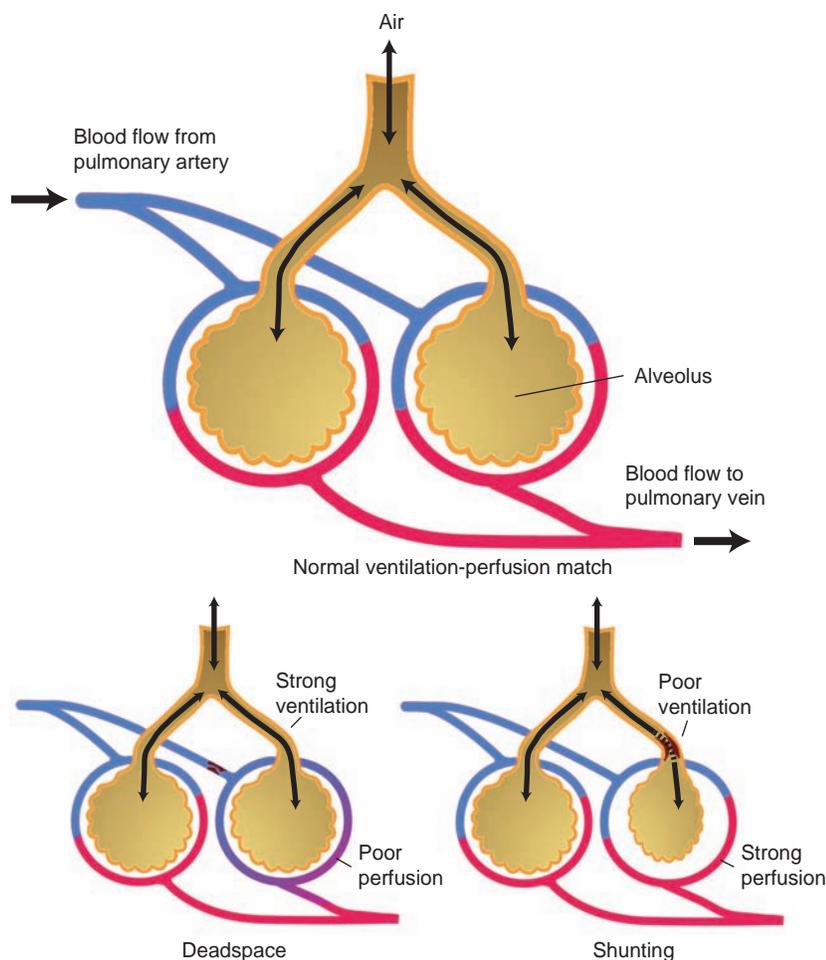

FIGURE 32-10 Types of Ventilation-Perfusion Abnormalities DELMAR/CENGAGE LEARNING

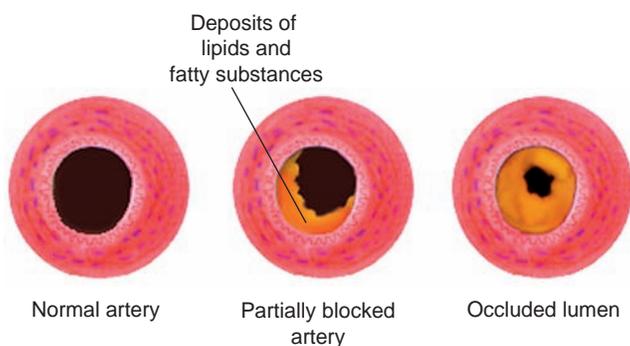

FIGURE 32-11 Progression of Atherosclerosis DELMAR/CENGAGE LEARNING

(pulmonary and systemic veins), leading to the condition known as congestive heart failure. The increased pressure of the blood in the engorged veins causes fluid to leak out of the associated capillary beds, causing edema in the tissue, including the lungs (pulmonary edema). See the accompanying Client Teaching display on page 869 for special considerations regarding sexual activity.

Congestive heart failure results in poor arterial perfusion to the body's tissues. This reduction in **cardiac output**

(amount of blood pumped by the heart) may be mild, causing only vague symptoms, or may be profound enough to cause death. Causes of congestive heart failure include myocardial infarction, hypertensive heart disease, and valvular disorders, among others.

Loss of circulating blood volume (hypovolemia) may result from massive bleeding, loss of fluid through a wound (such as an extensive burn injury), or severe dehydration.

Anemia

Another factor that influences oxygenation is the amount of hemoglobin in the blood available to bind with oxygen. A deficiency of hemoglobin (**anemia**) may decrease the oxygen-carrying capacity of the blood. A person who is anemic may have normal SaO_2 levels but still continue to experience inadequate tissue oxygenation at the cellular level. Certain poisoning syndromes, most notably carbon monoxide poisoning, mimic anemia in that they reduce oxygenation by competing with oxygen for binding sites on the hemoglobin molecule.

Alterations in Oxygen Uptake

A final factor to consider in the process of oxygenation involves the uptake of oxygen by the body's cells. Certain conditions may impair the cells' ability to take up and utilize

CLIENT TEACHING CHECKLIST

Special Considerations regarding Sexual Activity

Clients recovering from acute cardiac compromise, such as congestive heart failure or myocardial infarction, need sensitive nursing care and education regarding sexual activity. Help alleviate their concerns by sharing the following American Heart Association recommendations:

- Check with your health care provider.
- Resume sexual activity when you feel ready; most cardiac-compromised clients can safely resume sexual activity within 2 to 4 weeks.
- Take it slow and establish your comfort level; begin with lower energy forms of sexual expression, such as touching and holding.
- Continue taking prescribed cardiac medications; report to your health care provider any impact of these medications on sexual desire and performance.
- Experiencing an increased awareness of breathing, heartbeat, and muscle tightening during sexual activity is normal.

oxygen, particularly when the mitochondria are damaged. Cyanide poisoning and severe sepsis impair mitochondrial functioning, rendering the oxygen in arterial blood useless to the cells.

PHYSIOLOGICAL RESPONSES TO REDUCED OXYGENATION

When oxygen delivery is inadequate to meet the metabolic needs of the body, various responses to this deficit can be expected, including changes in metabolic pathways and efforts to increase the extraction of available oxygen. If these efforts fail, cells will be damaged and ultimately die.

Increased Oxygen Extraction

Under normal conditions, the cells of the body do not extract all of the oxygen carried in the arterial blood. In fact, blood returning to the heart via the venous circulation is typically about 75% saturated with oxygen. In response to poor oxygen delivery or increased oxygen need, the cells can extract more oxygen from the arterial blood.

Anaerobic Metabolism

The utilization of food (glucose) for cellular energy occurs via metabolic pathways that use oxygen; this is known as **aerobic metabolism**. Many cells are also capable of utilizing

alternate metabolic pathways in the absence of oxygen for short periods of time; this is referred to as **anaerobic metabolism**. Anaerobic metabolism is limited by several factors:

1. Not all cells are capable of significant anaerobic metabolism (most notably brain cells).
2. Anaerobic metabolism yields less energy per unit of fuel than does aerobic metabolism.
3. Anaerobic metabolism results in the accumulation of acid by-products, such as lactate, which upset the chemical environment of the cell and induce the release of cell-damaging (lysosomal) enzymes.

Tissue Ischemia and Cell Death

Prolonged oxygen deprivation (**hypoxia**) will lead to a syndrome ending in cellular death. The decreased production of adenosine triphosphate (ATP) resulting from anaerobic metabolism reduces the amount of energy available for cellular metabolic functions and results in a breakdown in all cellular functions. The integrity of the cell membrane becomes impaired, and the cell begins to swell. Cellular organelles may become damaged and lysosomal enzymes released, killing the cell. The destruction of tissues or organs as a result of oxygen deprivation is known as an infarction. Widespread cellular death resulting from oxygenation disturbances is the underlying characteristic of a devastating syndrome known as *multiple organ dysfunction syndrome* (MODS).

Carbon Dioxide Transport and Excretion

Carbon dioxide is a natural by-product of glucose metabolism. Like oxygen, it exists normally as a gas and can be dissolved in the plasma as well as loosely bound to the hemoglobin molecule, although carbon dioxide attaches to a different binding site on the hemoglobin molecule than does oxygen. In the lungs, carbon dioxide is released into the alveoli by diffusion, and when the individual exhales, the carbon dioxide exits to the atmosphere.

In the body fluids, carbon dioxide functions as an acid because, combined with water, it produces carbonic acid. The hydrogen ions that are liberated in this process stimulate the respiratory control centers in the pons and medulla to increase the rate and depth of breathing; more carbon dioxide is then released by the lungs, and the pH of the body is brought back to normal. Likewise, increased production of carbon dioxide, as may be associated with fever or exercise, is often a cause of increased ventilatory rate (**tachypnea**) and depth. Elevated blood levels of carbon dioxide (**hypercapnia**) indicate inadequate alveolar ventilation.

ASSESSMENT

HEALTH HISTORY

The health history of the individual experiencing oxygenation deficits is important in the development of the plan of care. The health history should begin with a thorough exploration

of the presenting problem (see Table 32-2), including how long it has been present and whether it has recently gotten worse, then should proceed to explore the medical history, impact of the illness on activities of daily living (ADL), and the client's knowledge level and coping abilities.

PHYSICAL EXAMINATION

Inspection will begin when the nurse first encounters the client. This is a time to make general notes of the client's efforts at ventilation, especially anxious or distressed appearance, flaring of nostrils, position preferences, and general chest configuration (see Figure 32-12). While counting the respiratory rate, also note the rhythm or pattern of the breathing for regularity or irregularity (see Figure 32-13). The signs and symptoms of hypoxia are relative to the onset. Early clinical manifestations of hypoxia include restlessness,

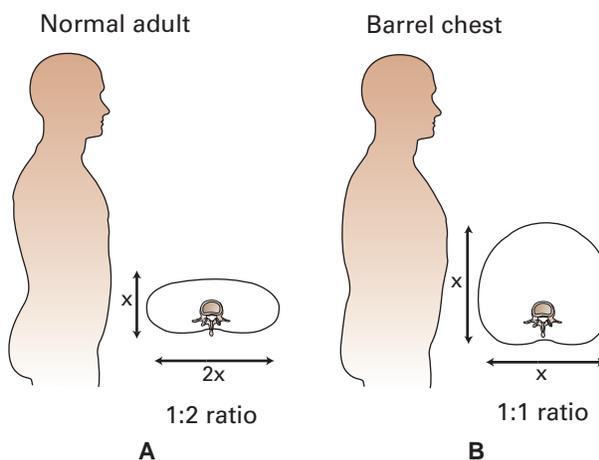

FIGURE 32-12 Changes in chest configuration and posture. **A.** The normal ratio of the anterior-posterior diameter to the lateral diameter is 1:2. **B.** With a barrel chest, the ratio between the diameters is 1:1. DELMAR/CENGAGE LEARNING

TABLE 32-2 Health History Related to Oxygenation	
PRESENTING PROBLEM	QUALIFIERS
Cough	<ul style="list-style-type: none"> Onset: sudden or gradual, how long ago Nature: dry, moist, barking, hacking, productive, nonproductive Pattern: continuous, occasional, related to time of day, position or activity, weather Severity Associated symptoms: pain, shortness of breath, wheezing Alleviating factors: vaporizers, OTC medications
Sputum	<ul style="list-style-type: none"> Amount, color, odor Presence of blood in sputum
Shortness of breath	<ul style="list-style-type: none"> Onset: sudden or gradual Nature: precipitated by choking or gagging Pattern: associated with activity or position; continuous or intermittent Associated symptoms: pain, cough, diaphoresis Alleviating factors
Pain	<ul style="list-style-type: none"> Location and radiation Nature: stabbing, dull, aching, burning, squeezing, crushing Associated symptoms: dizziness, nausea, diaphoresis, palpitations Aggravating factors Alleviating factors

Delmar/Cengage Learning

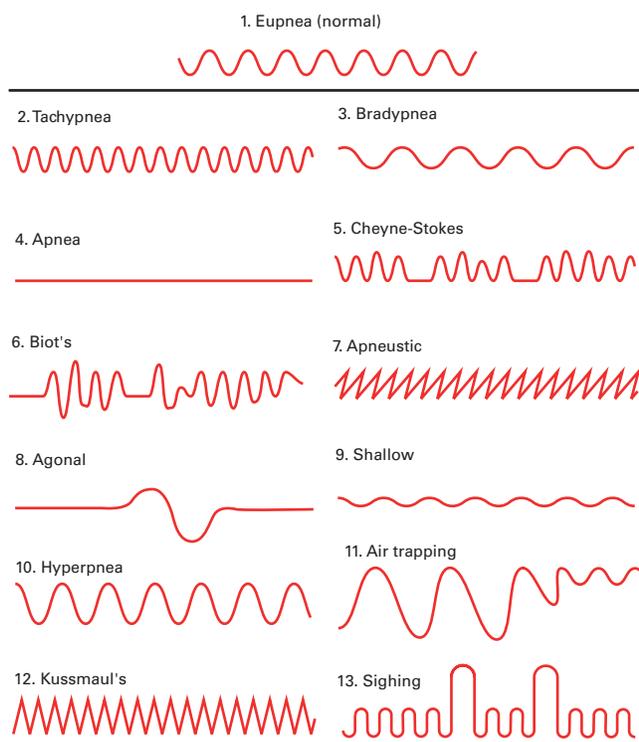

FIGURE 32-13 Respiratory Patterns DELMAR/CENGAGE LEARNING

apprehension, anxiety, dizziness, inability to concentrate, confusion, agitation, increased pulse rate, increased rate and depth of respiration, and elevated blood pressure (unless the hypoxia is caused by shock). If the hypoxia goes untreated, the respiratory rate may decline and changes in the level of consciousness progress to stupor or coma, indicating ischemia of neuronal cells resulting from oxygen deprivation. Perfusion deficits resulting in poor circulation can be visually noted in mottled skin, **cyanosis** (bluish coloration of the skin), and edema. The bluish discoloration of cyanosis is the result of the presence of desaturated hemoglobin in capillaries that may occur from either hypoxia or stagnant blood flow. When

cyanosis is observed in the tongue, soft palate, and conjunctiva of the eye, it indicates hypoxemia, whereas cyanosis of the extremities, nail beds, and earlobes is often a result of vasoconstriction and stagnant blood flow. Clubbing of the fingers, which manifests as a flattened angle of the nailbed and a rounding of the fingertips, is a sign of chronic hypoxia (see Figure 32-14). Regardless of the mechanism behind it, it is important to remember that cyanosis is often a late development in clients with poor oxygenation and may be further delayed in those with dark skin pigmentation or low blood hemoglobin (anemia). Therefore, the absence of cyanosis should not be taken as an assurance that oxygenation is adequate. However, the presence of cyanosis, especially central cyanosis, should be considered an indicator of a hypoxic emergency.

Common palpation findings related to compromised ventilation include vocal fremitus and displacement of the

trachea. Perfusion deficits are noted in changes in pulse rate or character, clammy skin, and ulcers in the lower extremities.

Percussion may reveal hyperresonance, dull percussion tone, or changes in the density of the lungs and surrounding tissues.

Auscultation may reveal adventitious breath sounds (e.g., crackles [rales], wheezes, rhonchi, pleural friction rub, or stridor), all indicators of alterations in ventilation (see Table 32-3). Circulation deficits will be noted upon auscultation by **gallops**, or extra heart sounds, and **murmurs**, or sounds produced by blood flowing through a malfunctioning valve.

DIAGNOSTIC AND LABORATORY DATA

There are many tests to measure oxygenation status. Pulse oximetry uses light waves to measure oxygen saturation (SaO₂) noninvasively (see Figure 32-15 on page 872). See Chapter 40, Procedure 40-2: Pulse Oximetry. Arterial blood gases (ABGs) measure a number of indicators that can affect oxygenation status; these factors and their values are listed in Table 32-4 on page 872. Sputum collection is another valuable tool in assessing a client's oxygenation functioning; this procedure is outlined in Table 32-5 on page 873, and common findings and their indications are listed in Table 32-6 on page 873. Measurements of lactic acid, hemoglobin, and hematocrit are also useful in determining the effectiveness of the body's oxygen delivery to tissues.

FIGURE 32-14 Clubbing of the Fingers as a Result of Chronic Hypoxia COURTESY OF ROBERT A. SILVERMAN, MD, PEDIATRIC DERMATOLOGY, GEORGETOWN UNIVERSITY

TABLE 32-3 Characteristics of Adventitious Breath Sounds

BREATH SOUND	RESPIRATORY PHASE	DESCRIPTION	CONDITIONS
Fine crackle	Predominantly inspiration	Dry, high-pitched crackling, popping; short duration; roll hair by ears between your fingers to simulate this sound	Chronic obstructive pulmonary disease, congestive heart failure, pneumonia, pulmonary fibrosis, atelectasis
Coarse crackle	Predominantly inspiration	Moist, low-pitched crackling, gurgling; long duration	Pneumonia, pulmonary edema, bronchitis, atelectasis
Sonorous wheeze	Predominantly expiration	Low-pitched; snoring	Asthma, bronchitis, airway edema, tumor, bronchiolar spasm, foreign body obstruction
Sibilant wheeze	Predominantly expiration	High-pitched; musical	Asthma, chronic bronchitis, emphysema, tumor, foreign body obstruction
Pleural friction rub	Inspiration and expiration	Creaking, grating	Pleurisy, tuberculosis, pulmonary infarction, pneumonia, lung abscess
Stridor	Predominantly inspiration	Crowing	Croup, foreign body obstruction, large airway tumor

Delmar/Cengage Learning

FIGURE 32-15 Client with Pulse Oximeter DELMAR/CENGAGE LEARNING

Selected tests to determine oxygenation status are discussed in Table 32-7 on page 874. (See Figure 32-16 for ventilatory function.) Clients undergoing these tests are often apprehensive and need nursing care and education directed at their knowledge levels. Refer to Chapter 28 for further diagnostic information.

NURSING DIAGNOSIS

Nursing care of the client experiencing oxygenation problems should be prioritized on the basis of the A-B-C format used in basic life support; that is, consider the *airway*, *breathing*, and *circulation* first and foremost. The primary nursing diagnoses are related to these priorities. Pertinent North American Nursing Diagnosis Association–approved nursing diagnoses regarding oxygenation are discussed in the sections that follow.

INEFFECTIVE AIRWAY CLEARANCE

Ineffective airway clearance exists when the client has difficulty maintaining a patent (open) airway at any point

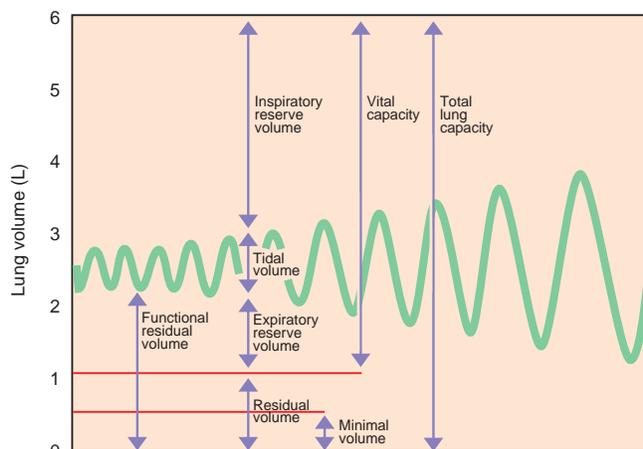

FIGURE 32-16 Graphic Representation of Lung Volumes and Capacities DELMAR/CENGAGE LEARNING

along the airway. This occlusion of the airway may be partial or complete. Causes of ineffective airway clearance include:

- Obstruction of the airway by the tongue (as may occur in the comatose or anesthetized client)
- Obstruction of airway by secretion (as may occur with excessive sputum production and ineffective or absent cough)
- Upper airway obstruction caused by edema of the larynx or glottis
- Obstruction of the trachea or a bronchus by foreign body aspiration
- Partial occlusion of the bronchi and bronchioles by infection (bronchitis, bronchiolitis), inflammation and smooth muscle spasm (asthma), or occlusion or compression by a tumor mass
- Occlusion of the more distal airways by the changes associated with emphysema

Assessment findings in the client with ineffective airway clearance include a complaint of feeling short of breath or

TABLE 32-4 Arterial Blood Gases

MEASUREMENT	NORMAL ARTERIAL VALUES	CLINICAL SIGNIFICANCE
pH	7.35–7.45	Indicates acid-base balance
P _{CO₂}	35–45 mm Hg	Partial pressure of carbon dioxide; indicates adequacy of alveolar ventilation; represents respiratory component of acid-base balance
HCO ₃ ⁻	22–26 mEq/L	Bicarbonate level; indicates metabolic component of acid-base balance
Pa _{O₂}	80–100 mm Hg	Partial pressure of oxygen; represents oxygen dissolved in plasma
Sa _{O₂}	96%–98%	Saturation of hemoglobin with oxygen

Delmar/Cengage Learning

TABLE 32-5 Protocol: Assisting a Client with Sputum Collection

Purpose	<ul style="list-style-type: none"> To collect an adequate sample of sputum for laboratory analysis or culture To minimize contamination of the sample with oral or other secretions
Level	<ul style="list-style-type: none"> Independent
Supportive data	<ul style="list-style-type: none"> Increasing the client's knowledge promotes cooperation and increases the diagnostic value of the sample obtained.
Assessment	<ul style="list-style-type: none"> Verify the type of test to be performed: Cytology studies should be collected into a cup containing a preservative solution; cultures must be collected into a sterile container. Assess the client's level of consciousness and ability to follow instructions. Assess the client's breath sounds; coarse rales indicate the presence of sputum in the airways.
Interventions	<ul style="list-style-type: none"> Obtain correct specimen container. Wash hands and don clean gloves. Assist the client to rinse the mouth with water (not mouthwash). Instruct client to raise sputum from the lungs, not the throat or nose. Instruct client to expectorate sputum into the cup without touching the inside of the container. Replace cap on container as soon as sample is obtained. Label container and wash the outside if indicated. Place in a bag with a biohazard label for transport. Provide mouth care for the client and assist to a comfortable position. Remove gloves and wash hands. Send specimen to lab immediately.
Documentation	<ul style="list-style-type: none"> Document amount, color, character, and odor of sputum obtained and time the specimen was sent to the lab.

Delmar/Cengage Learning

suffocating, a condition sometimes referred to as “air hunger.” The use of accessory muscles of ventilation may be noted, and the client may complain of fatigue. Shortness of

breath may be noted on observation, and the client may have difficulty speaking because of it.

A cough may be noted, and on auscultation crackles and rhonchi may be heard. Poor aeration of the alveoli, as can occur with emphysema and severe asthma, will cause diminished breath sounds over the peripheral lung fields. Complete obstruction of a large or medium-sized airway will result in a loss of breath sounds over the affected lung segment.

INEFFECTIVE BREATHING PATTERNS

Ineffective breathing pattern is commonly a problem for clients with restrictive pulmonary disease or central nervous system disorders that affect breathing. Those with restrictive pulmonary disease, in an effort to decrease their work of breathing, tend to adopt a pattern of rapid, shallow respirations. This respiratory pattern does not deliver adequate fresh air to the alveoli, resulting in chronic air hunger while contributing to muscle fatigue. Central nervous system disorders, including the effects of anesthetics and narcotics, may reduce both the rate and the depth of ventilation. Lesions affecting the brain stem in particular may reduce ventilation to dangerous levels.

Another group of clients at risk for ineffective breathing patterns are those who have had major abdominal or thoracic surgery or whose mobility is restricted. These individuals

Delmar/Cengage Learning	

have a tendency to take shallow breaths and to avoid sighing and coughing, both necessary to maintain airway integrity.

Neuromuscular diseases that weaken the respiratory muscles may also result in ineffective breathing patterns as well as impaired airway clearance. Examples of such disorders include Guillain-Barré syndrome and myasthenia gravis. Alterations in thoracic structures that interfere with breathing patterns include abnormal curvatures of the spine (scoliosis, kyphosis), chest wall injury, and pleural defects.

IMPAIRED GAS EXCHANGE

Impaired gas exchange occurs when, despite the delivery of fresh air to the alveoli, adequate oxygen does not enter the

arterial blood or carbon dioxide is not removed from the venous blood. Often this condition is the result of V/Q mismatching or overall decreases in the amount of alveolar-capillary surface area available for gas exchange, a characteristic of emphysema. Another cause of impaired gas exchange is widespread shunting, as may occur with atelectasis (alveolar collapse) and pneumonia. Impaired gas exchange is assessed by measuring the oxygen and carbon dioxide content in the arterial blood via ABG analysis, pulse oximetry, or both.

DECREASED CARDIAC OUTPUT

Decreased cardiac output impairs oxygen delivery to the tissues and may also be a factor in impaired gas exchange, as

when congestive heart failure causes pulmonary edema. Causes of decreased cardiac output include heart failure and various types of shock. The assessment findings associated with decreased cardiac output may include low blood pressure; cool, clammy skin; weak, thready pulses; low urine output; and a diminished level of consciousness. If pulmonary edema is present, crackles will be heard over the lung bases and the client may produce frothy pink or white sputum.

INEFFECTIVE TISSUE PERFUSION

Ineffective (decreased) tissue perfusion may be widespread, as in the case of decreased cardiac output, or it may be confined to one or more tissues or organs of the body. A common cause of regional decreases in tissue perfusion is atherosclerosis, which may impair perfusion to the heart, brain, kidneys, or extremities. Assessment findings depend upon the organ or tissue involved, but one common finding is pain. The tissue that is deprived of oxygen will in many cases be painful, as the accumulation of lactic acid and the chemical mediators of the inflammatory response stimulate local pain receptors.

OTHER NURSING DIAGNOSES

The relationship between the primary nursing diagnoses discussed earlier and the secondary nursing diagnoses in the client with oxygenation problems is reciprocal; that is, the primary diagnoses both influence and are influenced by the secondary diagnoses. A holistic approach to nursing care requires that all diagnoses affecting the client be considered and prioritized in developing the plan of care.

Deficient Knowledge

Deficient knowledge may exist to varying degrees in the client with either acute or chronic oxygenation problems. Involving the client in the plan of care requires that the client be informed regarding the disease process, diagnostic procedures, and treatment modalities. Assessment for deficient knowledge involves questioning the client and family with regard to their understanding and perceptions of these subjects. It is a mistake to assume that a client with a long-standing chronic illness has a good understanding of that illness.

Activity Intolerance

Activity intolerance reflects the impact of the illness on the client's ability to perform ADL; the degree of this impairment may range from mild to severe, but it is important that this judgment be based on the client's, not the nurse's, perception of the activity intolerance. Activity restrictions that may be a mere annoyance for one individual can be viewed as catastrophic by another.

To assess activity intolerance, both interview and observation are useful. Ask the client to compare the current level of activity with the previous level and desired level. In addition, observe the client performing activities such as moving about in bed, ambulating, and performing personal care activ-

ities; note the point at which fatigue or dyspnea occurs and the amount of rest required. Objective tests of exercise tolerance, such as stress tests, may be performed in certain cases.

Insomnia

Insomnia is common in people with both cardiac and pulmonary disease. As mentioned earlier, many people with restrictive and obstructive pulmonary diseases find that breathing is easiest in an upright position; this position is also more comfortable for those with congestive heart failure. Sudden attacks of dyspnea during sleep, called **paroxysmal nocturnal dyspnea**, may interrupt the sleep of these clients, resulting in chronic fatigue. Complaints of poor sleep, along with daytime sleepiness and fatigue, are common assessment findings. Insomnia can result in personality changes, hallucinations, and delusions.

A particular sleep problem associated with airway obstruction is **sleep apnea**. It is often seen in males who are overweight and have short, thick necks and is commonly associated with loud, heavy snoring. The soft tissues of the upper airways collapse during sleep, resulting in periods of absence of breathing (apnea). The individual then rouses enough to resume breathing, interrupting the normal sleep cycle. These individuals may complain of persistent daytime fatigue despite what seems to be adequate nighttime sleep.

Imbalanced Nutrition

Nutritional alterations are also commonly associated with both cardiac and pulmonary disease. The client with dyspnea may have difficulty consuming adequate food because of the effort involved; in turn, the malnutrition contributes to respiratory muscle weakness. The client with a productive cough may have an unpleasant taste in the mouth, interfering with appetite. Congestive heart failure may cause a poor appetite (anorexia) because of decreased perfusion to the gut. On the other hand, obesity can affect oxygenation by increasing the work of breathing as well as the cardiac workload.

Acute Pain

Acute pain may be present in the client with ischemia to the heart or to the extremities due to inadequate perfusion; chest wall or pleuritic pain may also be a feature of many pulmonary disorders. Adequate pain control can influence the effectiveness of breathing patterns and coughing, making pain control a priority in these cases. Pain assessment should address the nature of the pain, its intensity, its location and radiation, factors that make it better or worse, and any associated symptoms. For instance, pain caused by myocardial ischemia is called **angina pectoris** and is often described as crushing or squeezing in nature; it may be confined to the chest or it may radiate to the neck, shoulder, jaw, arm, or hand. Ischemia to the extremities (most often the legs) produces a pain known as **intermittent claudication**, which is typically brought on by exercise and relieved by rest. See Chapter 35 for further discussion of pain assessment.

Anxiety

Anxiety is often a prominent finding in individuals who are experiencing breathing difficulties or acute cardiac problems, such as chest pain. The anxious client may have difficulty answering questions and focusing on the instructions being given and may expend excessive amounts of precious energy in the process. Therefore, recognition and control of anxiety bring both psychological and physiological benefits.

PLANNING AND OUTCOMES

In identifying goals and planning nursing care for the client with oxygenation disorders, carefully consider individual goals for each nursing diagnosis and each client; the goals should be individualized to reflect the client's capabilities and limitations. In many cases, identifying desired outcomes of care is best accomplished in small steps, progressing from one level of functioning to the next until the ultimate objective is attained. Such an approach prevents the client from feeling overwhelmed with the magnitude of the task at hand while allowing for the satisfaction of reaching intermediate outcomes. Outcomes may be based on physiological parameters such as respiratory rate or ABG values, on activity tolerance and client comfort levels, or on identified learning needs.

The outcomes for a particular client should be based upon the assessment findings that led to the nursing diagnoses at hand. For example, if a respiratory rate of 30 breaths per minute with a shallow breathing pattern and suprasternal retraction led to a diagnosis of ineffective breathing pattern, then the desired outcome of intervention might be a respiratory rate of 20 breaths per minute or less and the absence of retractions. Achievement of the outcome indicates resolution of the problem.

COLLABORATION

The management of care for a client with impaired oxygenation requires a dynamic and systematic collaborative approach to providing and coordinating health care services. It is the participative process of a multidisciplinary team that facilitates options and services for meeting the client's health needs in a way that decreases fragmentation and duplication of care and enhances quality, cost-effective outcomes. Refer to the clinical pathway for a client with pneumonia in the Nursing Care Plan at the end of this chapter for an example of collaborative practice among various disciplines.

IMPLEMENTATION

Interventions for promoting and maintaining adequate oxygenation include airway clearance, breathing patterns, oxygen update and delivery, cardiac output and tissue perfusion, and emergency interventions. Other interventions address the associated nursing diagnoses for maintaining the client's

optimal level of health. The interventions for acid-base management are discussed in Chapter 33.

INTERVENTIONS TO PROMOTE AIRWAY CLEARANCE

Interventions to promote airway clearance focus on clearing the airways of secretions, relieving bronchospasm, and, when necessary, bypassing the natural airway structures with an artificial airway. All of these procedures are facilitated when the client has been well informed of the purpose for the interventions and knows what to expect.

Teach Effective Coughing

Effective coughing techniques may need to be taught to the client experiencing either short-term or chronic airway obstruction. Coughing is an important element of postoperative care in order to prevent pulmonary complications. Effective coughing should be preceded by a series of slow, deep breaths. One technique that may be useful is "huffing," or delivering a series of short, forceful exhalations, prior to actual coughing. The intent is to raise the sputum to the level where it can then be coughed out. If the client is recovering from thoracic or abdominal surgery, splinting the incision by holding a pillow firmly against it will reduce the pain caused by coughing. In most cases, assisting the client to a sitting position will increase the effectiveness of the cough. Assess the sputum produced by coughing, noting the amount, color, and odor. Recognize that the client may become fatigued after coughing and need a rest period; also offer oral care such as a mouth rinse after sputum has been expectorated.

Initiate Postural Drainage and Chest Physiotherapy

Postural drainage and **chest physiotherapy (CPT)** are techniques intended to promote the drainage of secretions from the lungs. Positioning for drainage of each of the lung lobes is accompanied by percussion or vibration applied to the chest wall to loosen secretions (see Figure 32-17 on page 877). Percussion involves using a cupped hand to beat firmly on the chest wall (see Figure 32-18 on page 877); a firm rubber cup of a size appropriate to the client's body size may also be used. Vibration is done using a special vibrator applied to the chest wall. Inhalation treatments containing bronchodilator or mucolytic drugs may be administered before CPT and postural drainage.

Measures should be taken to minimize the client's anxiety and discomfort during these procedures. Pain medications, if indicated, should be timed so that their effectiveness peaks at the time of the treatment. Also, the nurse must recognize that some clients may be unable to tolerate certain postural drainage positions, and the treatment must be modified. Those with congestive heart failure or increased intracranial pressure particularly will not be able to tolerate a head-down position.

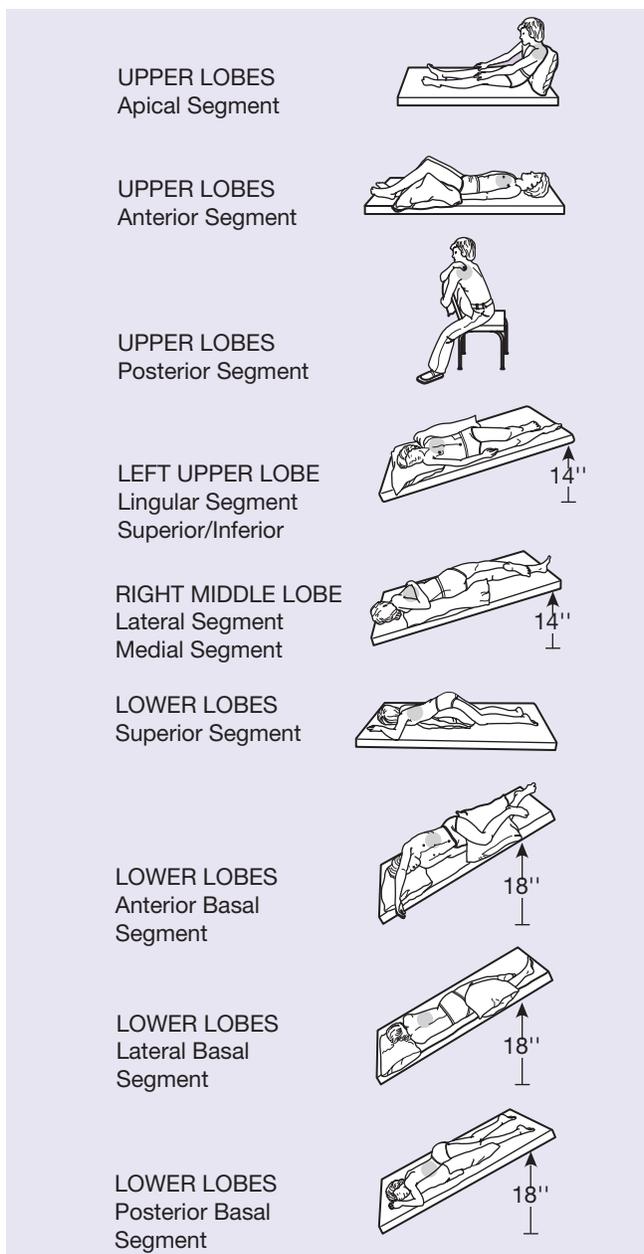

FIGURE 32-17 Postural Drainage Positions DELMAR/CENGAGE LEARNING

Monitor Hydration

Hydration, that is, the provision of adequate fluid intake, is important in thinning the pulmonary secretions so that they may be more easily expectorated. This may be beneficial in cases of pneumonia, bronchitis, and asthma. Clients experiencing congestive heart failure, on the other hand, may require limitation of fluid intake to reduce pulmonary congestion due to fluid volume overload.

Each exhalation contains not only carbon dioxide and other gases but also water vapor. This “insensible fluid loss” will be increased in those who are tachypneic as well as in clients receiving supplemental oxygen if the oxygen is not adequately humidified. Artificial airways that bypass the natural humidification processes of the nose and oropharynx also

FIGURE 32-18 Chest Wall Percussion: Positions of Hands to Strike DELMAR/CENGAGE LEARNING

contribute to increased insensible fluid losses. Drying and inflammation of the respiratory mucosa may result. For this reason, humidification of inspired oxygen, especially that which is delivered through an artificial airway, is very important.

Administer Medications

Medications that assist in airway clearance include expectorants, mucolytics, and bronchodilators. It may be beneficial to administer the medications before CPT or postural drainage treatments in order to maximize the treatment’s effectiveness. Clients must be taught the name of the medication they are receiving, the purpose of the medication, the dose, and how it is to be taken. The most common and most significant side effects should also be reviewed with the client. A summary of medications used for airway clearance is presented in Table 32-8 on page 878.

Monitor Environmental and Lifestyle Conditions

Environmental and lifestyle conditions may greatly influence the client’s long-term recovery. Allergic conditions such as asthma may improve dramatically if the allergens to which the client is sensitive are identified and removed from the client’s environment. Certain allergens such as animal dander

TABLE 32-8 Medications Used for Airway Clearance

DRUG TYPE	COMMON EXAMPLES	ACTIONS
Beta-adrenergic sympathomimetic	Epinephrine, isoproterenol, albuterol, metaproterenol, terbutaline	Causes bronchial smooth muscle relaxation (dilates bronchi)
Corticosteroid	Beclomethasone, prednisone, prednisolone, hydrocortisone	Elicits anti-inflammatory action
Mast cell stabilizer	Cromolyn sodium	Prevents histamine release from mast cells
Methylxanthine	Aminophylline, theophylline	Dilates bronchi and increases ciliary movement
Mucolytic/expectorant	Mucomyst (acetylcysteine), guaifenesin	Thins respiratory secretions by increasing the amount of fluid produced

Delmar/Cengage Learning

or feather pillows may be relatively easy to eliminate; others, such as house dust and pollen, may be impossible to eliminate but can be reduced using devices such as air filters.

Smoking is a significant contributing factor in both heart and lung disease. Smoking cessation may not reverse advanced disease but will often reduce the client's symptoms and improve the quality of life. Smoking cessation programs and support groups, along with nicotine replacements such as transdermal patches, may help the client succeed in quitting smoking.

Introduce Artificial Airways

Artificial airways (see Figure 32-19A–D) may be used for clients with significant airway obstruction that cannot be relieved by more conservative means or who require mechanical ventilatory support. Nasal airways, also known as nasal trumpets, may be placed in conscious adults who have adequate breathing ability but require assistance in keeping their upper airways open. These airways are usually fairly well

A

B

C

D

FIGURE 32-19 Types of Artificial Airways: A. Oral airway and endotracheal tube; B. Nasal trumpet; C. Tracheostomy tube; D. Pediatric tracheostomy tube. DELMAR/CENGAGE LEARNING

tolerated and can provide a conduit for frequent nasotracheal suctioning while minimizing trauma to the nasal mucosa.

The oral airway is used to maintain the tongue away from the posterior oropharynx in the unconscious client. It is essential to choose the correct size, since an airway that is too large may actually cause occlusion, while one that is too small may compress the tongue, stimulating the vomiting center. Oral airways are not well tolerated in conscious individuals, who may gag and vomit if an oral airway is in place.

Endotracheal tubes bypass the upper airway structures altogether; they may be inserted via the nose or mouth and are passed beyond the vocal cords into the trachea. An inflatable cuff near the distal end of the tube serves to seal off the airway, allowing for mechanical ventilatory assistance and protecting the airway from aspiration.

Since endotracheal tubes bypass the filtration and humidification normally provided by the nose and oropharynx, care must be taken to humidify the inspired air and to prevent introduction of pathogenic organisms into the lungs. Meticulous attention to aseptic technique when caring for clients with endotracheal tube and ventilator circuits is mandatory.

Mouth care must be provided for the client with an endotracheal tube. The tube prevents adequate swallowing, so the client will be unable to eat. Frequent cleansing and suctioning of the oral cavity (every 2 hours) reduces discomfort and the risk of breakdown and infection of the oral mucosa.

Nutritional needs for the client with an endotracheal tube must be addressed by providing enteral feeding (via nasogastric or gastrostomy tube) or total parenteral nutrition (hyperalimentation). Whatever the means, adequate nutrition is necessary to maintain and improve respiratory muscle strength.

A **tracheotomy** is a surgical procedure done to provide long-term airway support or as an emergency procedure when an endotracheal tube cannot be passed successfully. An opening (stoma) is made in the trachea below the cricoid cartilage, and a semirigid plastic tube (tracheostomy tube) is passed through the opening and into the trachea. A cuff, similar to that in an endotracheal tube, is inflated near the distal airway. The cuff of an endotracheal tube or tracheostomy tube must be deflated before removing the tube; removal of a tube with an inflated cuff may cause laryngeal edema and damage to the vocal cords. For this reason, the tube must be taped securely in place, and confused or agitated clients may require sedation or wrist restraints to prevent them from pulling at the tube.

Many tracheostomy tubes consist of two tubes or *cannulae*: an outer cannula that stays in place and an inner cannula that can be removed to be cleaned or replaced. This permits thorough removal of encrusted secretions to prevent occlusion of the airway. The outer cannula is connected to a flange that permits the tubes to be secured around the neck with twill tape or a cloth strap. See Procedure 32-1 for tracheostomy care.

Like an endotracheal tube, a tracheostomy tube bypasses the upper airways, so humidification and prevention of infection must be considered. Because both types of airways prevent the movement of air through the vocal cords, which produce speech, the client will not be able to talk while these tubes are in place (some long-term tracheostomy clients may

be outfitted with a tracheostomy tube that has slits, or “fenestrations,” that permit speech). If possible, reviewing an alternate method of communication prior to tube insertion can reduce the anxiety and isolation that may be felt by the intubated client. Writing of messages and use of an alphabet board are two possible methods of communication. Significant others should also be advised that the intubated client will not be able to speak but can hear and understand what is being said.

Suction the Airway

Suctioning of the airway, whether a natural or artificial airway, may be necessary to clear secretions the client cannot remove by coughing. Suctioning becomes especially important when an endotracheal tube or tracheostomy tube is present because coughing is significantly impaired by these devices.

Nasotracheal suctioning involves passing a suction catheter or nasal trumpet through the naris and into the oropharynx. See Procedures 32-2 and 32-3 regarding suctioning. Once the tip is in the oropharynx, a strong cough reflex may be elicited. At this time suction is applied to the catheter, and it is withdrawn while a twisting motion is applied to the catheter.

Endotracheal suctioning involves passing the suction catheter through the endotracheal tube or tracheostomy into the trachea and applying suction as the catheter is withdrawn.

INTERVENTIONS TO IMPROVE BREATHING PATTERNS

Properly Position Client

Client positioning to improve breathing patterns may begin by taking cues from the client. If the client finds that breathing is easier in an upright or sitting position, the nurse should allow that position to be maintained. Supporting the client with elevation of the head of the bed or with pillows can reduce the client’s workload and minimize fatigue. Maintaining proper body alignment and preventing slouching or slumping in the bed increase the efficiency of ventilatory efforts.

As previously stated, clients with obstructive respiratory disease may find that leaning forward, with the clavicles elevated, is most comfortable. Providing an overbed table for the client on which to rest the elbows may facilitate this position, *provided the wheels are locked or removed to prevent the table from rolling away and placing the client at risk for a fall.*

Teach Controlled Breathing Exercises

Controlled breathing exercises may also improve breathing efficiency for the client with obstructive respiratory disease. One technique that is especially useful is *pursed-lip breathing*. This technique involves forced exhalation against pursed (partially closed) lips, which maintains positive pressure in the lungs during the expiratory phase and prevents collapse of the smaller airways. This in turn reduces the amount of air trapping characteristic of obstructive disease.

Deep-breathing exercises encourage the client to take slow, deep breaths instead of the rapid, shallow breathing pattern that may be present in restrictive lung disease and in

those who are anxious. Abdominal breathing involves the use of the abdominal muscles to pull the diaphragm downward. Placing one's hand on the client's abdomen and instructing the client to watch it rise give a visual aid to teaching the technique.

Apical and basal expansion exercises direct the client to focus on achieving maximal expansion of the upper lung lobes (apices) and lower lobes (bases), respectively. To perform these techniques, place one's hands flat against the chest wall just below the clavicles for apical exercises or over the lower ribs along the midaxillary lines for basal exercises and apply gentle pressure. Instruct the client to push the nurse's hands away with the chest wall by breathing. These exercises should be repeated several times a day.

Incentive spirometry is another technique used to encourage deep breathing. The client draws air through the spirometry device, which measures the volume of air displaced by moving a float ball or similar device up a column. Goals (incentives) can be marked on the spirometer, and clients can compare their progress with the desired goal. Instruct the client to hold the inspired breath for 2–3 seconds before exhaling. Incentive spirometry is often performed in the care of postoperative clients and is usually done every 1 to 2 hours while awake.

Deep breathing may also be augmented using intermittent positive-pressure breathing (IPPB). An IPPB machine delivers a volume of air under pressure through a mouthpiece when the client draws air through the mouthpiece. IPPB requires the client's cooperation, so preparatory teaching is essential. IPPB may include the administration of aerosolized medications and may be followed by coughing exercises, CPT, and postural drainage.

Introduce Chest Drainage Systems

Chest drainage systems (chest tubes) improve breathing patterns by removing accumulations of air and fluid from the pleural space, permitting the lungs to return to normal expansion. The tubes are inserted through the chest wall via a stab wound; multiple holes in the tip of the tube collect drainage from the pleural space. This drainage is then collected into a drainage system by either suction control or gravity. A special feature called a water seal prevents the reintroduction of air into the pleural space through the chest tube.

INTERVENTIONS TO IMPROVE OXYGEN UPTAKE AND DELIVERY

Administer Oxygen

Oxygen uptake in the pulmonary capillary beds can be improved by increasing the concentration of oxygen in the alveolar air; this increase in the P_{aO_2} in the alveoli increases the driving pressure for gas diffusion across the alveolar-capillary membrane.

The percentage of oxygen in the inspired air is referred to as the fraction of inspired oxygen, or F_{IO_2} , expressed as a percentage; normal atmospheric air has an F_{IO_2} of 21%. Supplemental oxygen delivery systems are capable of increasing

the F_{IO_2} to anywhere from 24% to nearly 100% oxygen (see Figures 32-20 on page 881 and 32-21 on page 882 and Procedure 32-4).

Oxygen administration, like the administration of any drug, is not without hazards. Clients who have chronic pulmonary disease associated with carbon dioxide retention (hypercapnia) may become insensitive to carbon dioxide levels to drive their respiratory rate. Instead, these clients may depend upon a chronic low oxygen level in the blood (hypoxemia) to stimulate their respiratory drive. While low-flow oxygen may be beneficial to these clients, excessive oxygen administration may obliterate that hypoxic drive, resulting in apnea.

Another possible hazard of oxygen administration is oxygen toxicity. Prolonged administration of high F_{IO_2} (greater than 50% for more than 24 hours) may actually damage lung tissue and produce severe respiratory difficulties. The mechanisms by which oxygen toxicity occurs are twofold. First, it should be understood that 78% of the inspired air consists of the gas nitrogen. Although nitrogen is (under normal conditions) physiologically inert, it does serve an important function in the lung: It keeps the alveoli open simply by occupying space. High concentrations of oxygen displace nitrogen from the alveoli; as this oxygen is absorbed by the alveolar capillary blood, the volume of gas in the alveolar space is reduced and the alveoli collapse. Once the alveoli have collapsed (atelectasis), no airflow occurs and the work of breathing increases dramatically.

Second, oxygen in high concentrations is toxic to the type II alveolar cells, which are responsible for the production of **surfactant**. Surfactant is a substance that assists in keeping the alveoli open by reducing the alveolar surface tension (the tendency of the alveolar walls to collapse upon themselves). Atelectasis results when surfactant is insufficient.

Widespread atelectasis due to oxygen toxicity may result in a syndrome known as the adult respiratory distress syndrome (ARDS), which is characterized by diffuse pulmonary edema, severe stiffness of the lung tissue, and profound hypoxemia.

Oxygen increases the risk of fire. Although oxygen itself is not a flammable gas, it is a necessary catalyst for fire to occur. The presence of any fuel (bed linens, paper) along with any source of ignition (a lighted cigarette, an electrical spark) will lead to fire more rapidly, and the fire will burn more vigorously, in an oxygen-rich environment. Instruct clients on oxygen administration to caution all family members and visitors to the home to avoid lighting matches, cigarettes, or any other substances in the presence of the oxygenation equipment. Also advise clients receiving therapy in the home to inspect all electrical equipment prior to use.

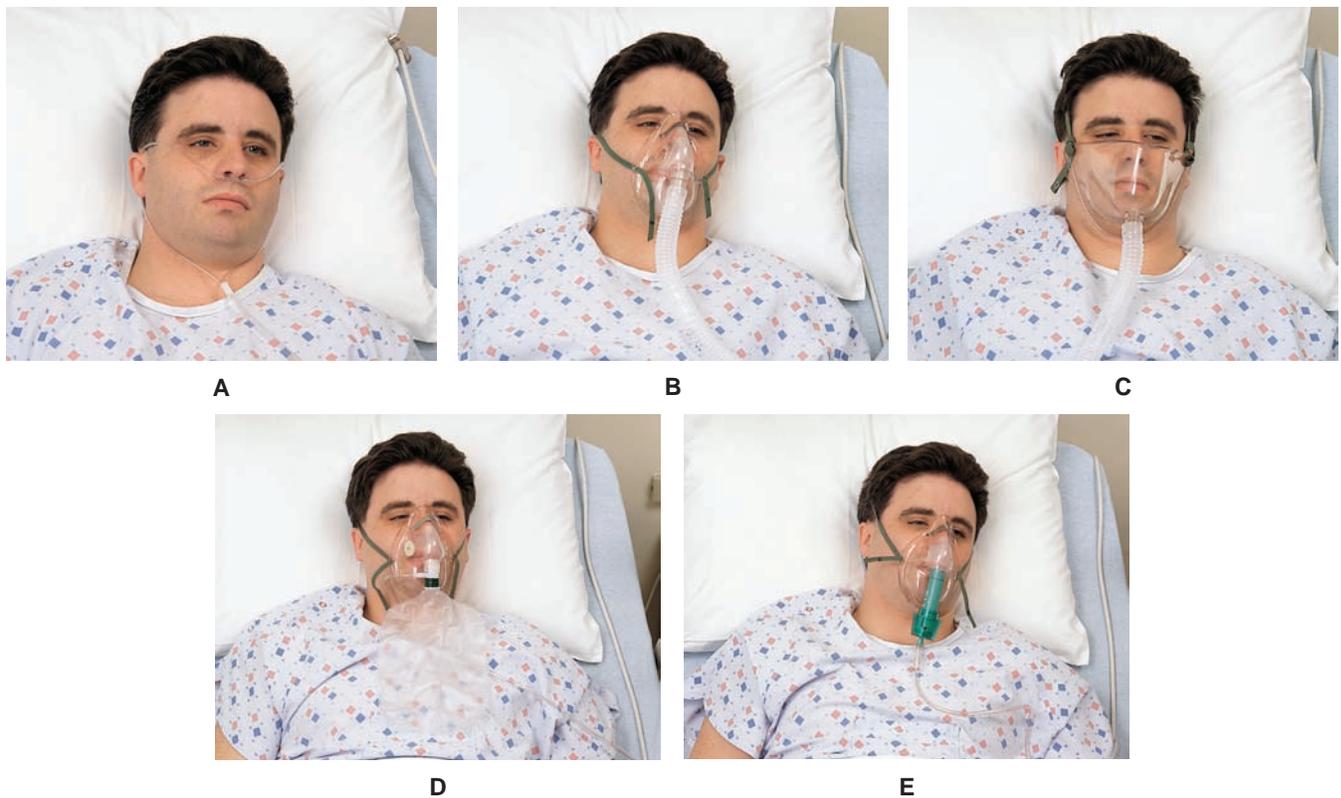

FIGURE 32-20 Oxygen Delivery Systems: A. Nasal cannula; B. Single face mask; C. Open face tent; D. Reservoir mask; E. Venturi mask.
DELMAR/CENGAGE LEARNING

Administer Blood Components

Blood component administration is indicated when the client's oxygenation is impaired because of decreased circulating blood volume, decreased hemoglobin concentration in the blood (anemia), or hemorrhage. Red blood cells may be administered. Since a blood transfusion is really a type of tissue transplant, extreme care must be taken to decrease the possibility of an immune system rejection response known as a transfusion reaction.

INTERVENTIONS TO INCREASE CARDIAC OUTPUT AND TISSUE PERFUSION

The client with impaired cardiac output and tissue perfusion is likely to be experiencing edema of the lower extremities and the lungs, fatigue, activity intolerance related to poor tissue oxygenation, and possibly angina and intermittent claudication. Interventions are aimed at reducing symptom severity while optimizing cardiac performance.

Manage Fluid Balance

Management of fluid balance is a cornerstone in the care of the client with reduced cardiac output. If congestive heart failure is present, fluid intake may be restricted to prevent edema and circulatory overload. Often, sodium intake is also limited because sodium promotes fluid retention. Diuretics may also be given to increase fluid excretion by the kidneys.

SAFETY FIRST

BLOOD ADMINISTRATION

To minimize the risk of a serious transfusion reaction when administering blood components, be sure to:

- Follow institutional policy regarding client identification for each transfusion.
- Assess and record client vital signs (temperature, pulse, blood pressure, respirations) before initiating the transfusion and within 1 hour of completing the transfusion.
- Instruct the client to report any unusual feelings, including flushing, itching, headache, or back pain.
- Reassess vital signs after the first 10 to 15 minutes of slowly infusing the blood component. Stop the transfusion immediately if fever, tachycardia, hypotension, dyspnea, or any reports of the previously listed symptoms occur. Notify the client's prescribing practitioner and the blood bank for further instructions.

FIGURE 32-21 Oxygen Flow Meter Attached to Wall DELMAR/
CENGAGE LEARNING

Monitoring of fluid balance by the nurse may involve the measurement of fluid intake and output (I&O) and measurement of daily weights. I&O measurement involves teaching the client the importance of accounting for all I&O and providing a container for the measurement of urine. Daily weights should be performed at the same time each day (usually early in the morning), with the same amount of clothing on, and on the same scale to maximize accuracy.

Clients receiving diuretics may also require monitoring for electrolyte imbalances. Potassium, particularly, may become depleted in the client receiving loop diuretics such as furosemide. Encouraging the consumption of potassium-rich foods such as bananas, and perhaps potassium supplementation, is often required.

Suggest Activity Restrictions and Assistance with Activities of Daily Living

Activity restrictions and assistance with ADL should be based upon the client's activity tolerance. The purpose of activity assistance is to decrease the oxygen demands of the body. The client's activity tolerance may be gradually increased through a sequence of exercise protocols as part of a cardiac rehabilitation

program. Such a program incorporates careful monitoring of the client as the exercise level increases over time.

Position Client Properly

Positioning of the client with decreased cardiac output is done to decrease the fluid load to the heart and to decrease the development of pulmonary edema. The venous system is able to pool blood when aided by gravity; this "venous capacitance" is increased when the client's head and upper body are elevated and the legs are in a dependent position. Although it is customary in the hospital environment to place clients in a supine position, this position may be detrimental for the client with congestive heart failure, as evidenced by worsening dyspnea, tachycardia and tachypnea, and decreased arterial oxygen saturation.

Administer Medications

Medications to improve cardiac output and perfusion include diuretics as mentioned earlier, cardiac glycosides, and other inotropic agents. Antihypertensives, nitrates, and vasodilators may also be given to increase cardiac oxygen supply and reduce the myocardium's demand for oxygen. Table 32-9 on page 883 lists the drugs most commonly used.

EMERGENCY INTERVENTIONS

Complete airway obstruction, cardiac arrest, and respiratory arrest are emergency situations that will result in death if not immediately rectified. Nurses receive regular training in the basic life support techniques described in the following text; hands-on practice is an essential component of that training, and this text is not intended to serve as a substitute.

Remove Airway Obstruction

Complete airway obstruction is often the result of aspiration of food or some other foreign object into the trachea. The presence of a complete airway obstruction is characterized by an inability to speak or cough; the victim may also raise the hands to the throat and will likely appear very anxious. The rescuer should verify that obstruction is present by asking the victim, "Are you choking?"

Relief of the obstruction is attempted by way of the **Heimlich maneuver**, which is described in Procedure 32-5.

Initiate Cardiopulmonary Resuscitation

Cardiac and respiratory arrest require artificial support of circulation and ventilation if the victim is to survive. **Cardiopulmonary resuscitation (CPR)** is the accepted technique of basic life support, as described in Procedure 32-6. The technique described is used for adult victims; different techniques are applied for children and infants and can be learned through courses such as those offered by the American Heart Association or the American Red Cross.

TABLE 32-9 Medications Used to Improve Cardiac Function

DRUG TYPE	COMMON EXAMPLES	ACTIONS
Diuretic	Furosemide (Lasix), bumetanide (Bumex), hydrochlorothiazide (HydroDIURIL, HCTZ), spironolactone (Aldactone)	Affects renal tubules, resulting in increased excretion of water and certain electrolytes; lowers blood pressure and decreases cardiac workload
Cardiac glycoside	Digoxin (Lanoxin)	Increases force of cardiac contraction and slows heart rate
Inotropic agent	Dobutamine (Dobutrex), amrinone (Inocor), dopamine (Intropin), isoproterenol (Isuprel)	Increases force of cardiac contraction
Antihypertensive	ACE inhibitors (captopril, enalapril), beta-adrenergic blockers (labetalol, propranolol, atenolol), calcium channel blockers (nicardipine, diltiazem), centrally acting alpha-adrenergics (clonidine, methyldopa), ganglionic blockers (trimethaphan), peripherally acting antiadrenergics (guanethidine, prazosin), vasodilators (minoxidil, hydralazine)	Lowers blood pressure by various mechanisms, decreasing the heart's workload
Nitrate	Nitroglycerin, isosorbide dinitrate (Isordil)	Dilates the coronary arteries and peripheral vessels, increasing cardiac oxygen supply while decreasing cardiac workload

Delmar/Cengage Learning

INTERVENTIONS TO ADDRESS ASSOCIATED NURSING DIAGNOSES

Explore Lifestyle and Activity Adaptations

Lifestyle and activity adaptations may be necessary for the client with chronic alterations in oxygenation. Interventions related to lifestyle and activity have three general purposes:

- To minimize energy and oxygen consumption
- To reduce factors that contribute to the disease process
- To systematically increase activity tolerance

Measures to reduce energy and oxygen consumption are chosen after a careful assessment of the client's activity tolerance. Clients may need assistance with ADL, including hygiene and toileting; however, it should be noted that complete bed rest is not always the best option. Many clients find that using a bedside commode or toilet is less physically taxing than using a bedpan, especially for bowel movements.

Occupational roles may also need to be modified. If the client is not able to continue working in the old job, it may be possible to take on a new job that is less taxing or to reduce the number of hours worked. If such changes are not possible, the client may have to quit working altogether. All of these possibilities may cause much distress to the client and family, who must grapple with role issues, authority and autonomy issues, and possibly financial concerns. Signs of inadequate family coping, such as marital discord, anger or

SPOTLIGHT ON...

Professionalism

Mouth-to-Mouth Breathing

In recent years, increased concern over the possibility of disease transmission during mouth-to-mouth breathing has led to the development of newer variations on this technique. Several styles of masks that fit over the victim's mouth and contain a one-way valve through which the rescuer breathes are available for both in-hospital and community use. Have you ever performed mouth-to-mouth breathing through one of these masks? Knowing that there is a possibility of disease transfer, would you be willing to administer mouth-to-mouth breathing without a mask?

hostility, sleep disturbances, and depression, should be noted and appropriate interventions, such as a referral for counseling, should be instituted.

Lifestyle adaptations aimed at reducing factors that contribute to the disease process include removal of allergens

Activity adaptations in the home setting may involve alterations in the physical environment of the home, changes in family roles, or changes in work roles. The client who cannot climb stairs may need to have sleeping quarters moved to the first floor of the house. Clients may also need to give up household chores that cause distress and perhaps take on other, less physically taxing roles. Changes such as these can be trying for the entire family, and they will need support during the period of transition. Home health nurses are a tremendous resource for families facing role changes related to illness.

from the environment, smoking cessation, and control of modifiable risk factors for heart disease. Allergen control and smoking cessation were discussed in the section Interventions to Promote Airway Clearance. Modification of cardiac risk factors includes smoking cessation as well as dietary alterations and weight control, control of diabetes and hypertension if present, exercise, and stress management. A comprehensive cardiac rehabilitation program addresses all of these issues while monitoring the client's progress toward individualized goals.

Encourage Dietary and Nutritional Modifications

Dietary modifications for cardiovascular disease may include reduction of sodium intake and reduction of total fat, saturated fat, and cholesterol intake. Sodium consumption may be reduced by decreasing or eliminating salt used in cooking and added at the table and avoiding highly processed foods such as prepared meats, canned meat or fish, and many prepared sauces. The client should be taught to examine food labels for sodium content per serving; see the Client Checklists on this page and page 883 regarding a healthy diet and general reminders.

The client who is not receiving adequate nutrient intake because of poor appetite or severe dyspnea will need assistance in finding ways to increase intake of calories and essential nutrients. Eating small, frequent meals of high nutritional value and using dietary supplements are often helpful.

Promote Comfort

Promoting comfort for the client with oxygenation disturbances can be a challenge but is extremely important. Comfort influences the client's ability to eat, sleep, learn, and cope with the illness and the care being provided.

Altered comfort related to pain is best approached by removing or modifying the cause of the pain if possible and administering analgesics if indicated. The use of analgesics in the postoperative client is particularly important in allowing the

CLIENT TEACHING CHECKLIST

Following a Healthy Diet

Reduction of total dietary fat, saturated fat, and cholesterol can be a challenge and requires careful client teaching. Use food labels and reference charts to help clients follow these dietary outlines:

- Reduce fat intake to no more than 30% of the total caloric intake.
- Keep saturated fats down to no more than 10% of the total caloric intake. Saturated fats include those from animal sources such as milk and dairy products. Palm and coconut oils, although from vegetable sources, have the same effect as animal fats in terms of raising serum cholesterol.
- Limit cholesterol intake to no more than 300 mg per day.
- Eat less meat and dairy products and more fresh fruits, vegetables, and whole grains.
- Avoid processed foods, especially those with sauces or fillings. When eating out, choose baked or grilled dishes rather than fried, sautéed, or stewed.
- Enjoy treats such as rich desserts only occasionally; choose low-fat desserts such as low-fat frozen yogurt, fruit sorbets, or angel food cake whenever possible.

client to participate fully in deep-breathing and coughing exercises. See Chapter 35 for more discussion of pain management.

Pain related to tissue ischemia is best relieved by improving the oxygen delivery to the tissues while reducing the oxygen demand. The first response to ischemic pain should be to rest the affected tissue. If the pain is in the legs, for example, the client should sit down. Improving delivery of oxygen to the legs in the client with peripheral vascular disease may involve positioning the legs lower than heart level (elevating the legs will often make the pain worse).

Heart pain related to ischemia (angina pectoris) should also be dealt with first and foremost by resting. Resting will decrease the heart's workload and in some cases is sufficient to relieve the pain. Improving oxygen delivery to the heart may be accomplished by providing supplemental oxygen or by using medications, such as nitrates, that improve coronary blood flow. In some cases, narcotic analgesics such as morphine are necessary.

COMPLEMENTARY THERAPIES

Many complementary therapies that enhance oxygenation originate in ancient healing traditions of China and India. For example, the practice of meditation and yoga produces a

CLIENT TEACHING CHECKLIST

General Reminders

- Assess the client's and family's level of knowledge.
- Focus on identifying misconceptions that need to be clarified.
- Ask open-ended questions, such as "Tell me what your medications are for," instead of simple yes-or-no questions.
- Set goals with the client's input; base goals upon realistic expectations.
- State goals clearly: For example, "Mr. Jones will be able to name all of his medications, the dose, and frequency they are taken and list one major side effect of each."
- Individualize teaching methods, taking into account the client's particular needs and abilities.
- Involve the family in teaching sessions.

sense of serenity and relaxation and other positive physiologic benefits. Harvard Medical School professor Herbert Benson studied the effects of people who practiced transcendental meditation in the 1970s and showed that meditation decreases oxygen consumption and metabolism; lowers blood pressure, heart rate, and respiratory rate; increases the production of alpha brain waves; and relieves stress and enhances overall well-being. Dean Ornish, MD, has successfully reversed coronary artery disease by using yoga with dietary changes, moderate exercise, and support groups.

Herbs

Herbs are often used with relaxation techniques, exercise, and diet to prevent diseases of the cardiovascular and respiratory systems; see the accompanying display for commonly used herbs for these systems. Respiratory stimulants are expectorants that loosen mucus from the respiratory system. *Lobelia*

HERBS

HERBS FOR THE CIRCULATORY SYSTEM

Broom	Buckwheat	Cayenne
Dandelion	Ginger	Hawthorn
Horse chestnut	Lime blossom	Mistletoe
Yarrow		

HERBS FOR THE RESPIRATORY SYSTEM

Stimulants (expectorants):

Bittersweet	Cowslip	Daisy
Senega	Soapwort	Squill
Thuja		

Relaxants (promote expectoration):

Angelica	Aniseed	Coltsfoot
Elecampane	Flaxseed	Grindelia
Hyssop	Plantain	Thyme
Wild cherry bark	Wild lettuce	

Demulcents (mucilaginous):

Lungwort root	Coltsfoot	Flaxseed
Licorice	Comfrey	Marshmallow
Mullein		leaf

Adapted from Hoffmann, D. (1998). *The new holistic herbal* (3rd ed.). Boston: Element.

(Indian tobacco) contains lobeline, a nonaddicting substance similar to nicotine, and is often used to quit smoking.

Arnold, Clark, Lasserson, and Wu (2008) assessed the efficacy and safety of herb and plant extracts in the management of chronic asthma. The evidence base for the effects of herbal treatment was hampered by the variety of treatments assessed, poor reporting quality of the studies, and lack of available data. The researchers determined that positive review findings warrant additional well-designed trials in this area.

NURSING CARE PLAN

The Client with Pneumonia

CASE PRESENTATION

Mrs. Johnson is a 72-year-old woman hospitalized for left lower lobe pneumonia. She complains of a persistent cough and occasional pain in her left chest associated with coughing, fever, and shortness of breath. Prior to this admission, she has been healthy and independent. Upon assessment, you find her mildly dyspneic, occasionally pausing in the middle of a sentence to breathe. Her respiratory rate is 28 breaths per minute. Her pulse is 100 per minute and regular; blood pressure is 140/90 mm Hg. Her skin is warm, dry, and pale pink with brisk capillary refill. You do not note any edema. She is receiving oxygen by nasal cannula at 6 L/min.

(Continues)

NURSING CARE PLAN (Continued)

ASSESSMENT

- Dyspnea, tachypnea, and tachycardia
- Cough, chest pain, fever

NURSING DIAGNOSIS 1: *Impaired gas exchange* related to presence of infectious exudate in the left lower lobe of the lung

NOC: Respiratory status: gas exchange

NIC: Airway management: facilitation of patency of air passages

EXPECTED OUTCOMES

The client will:

1. Report relief of dyspnea.
2. Demonstrate return of respiratory rate to 20/min or less and heart rate to 100/min or less.
3. Be able to speak comfortably.

INTERVENTIONS/RATIONALES

1. Teach client effective techniques for coughing, such as sustained maximal inspiration and “huffing.”
Increases the clearance of exudate.
2. Assist with chest physiotherapy and postural drainage as indicated. Promotes the clearance of exudate by using gravity, percussion, and vibration of the chest wall.
3. Humidify inspired oxygen, and encourage oral fluid intake. Promotes liquefaction of pulmonary secretions, which facilitates expectoration.
4. Encourage client to lie on right side while in bed. Positioning with the unaffected lung down provides the best match of ventilation and perfusion.
5. When assessing for dyspnea, do so not only with the client at rest but also during activities such as talking, eating, and moving. Clients who appear to be breathing comfortably at rest may become dyspneic with minimal activity.

NURSING DIAGNOSIS 2: *Imbalanced nutrition: less than body requirements* related to decreased oral intake and increased metabolic requirements

NOC: Nutritional status: food and fluid intake

NIC: Nutritional management

EXPECTED OUTCOMES

The client will:

1. Maintain usual body weight
2. Consume at least 50% of food provided

INTERVENTIONS/RATIONALES

1. Provide oral care after coughing, after respiratory treatments, and before meals. Coughing and the expectoration of secretions can create an unpleasant taste in the mouth, which interferes with appetite.
2. Assess food intake and provide supplements if intake is insufficient to meet caloric needs. Dietary supplements may provide increased calories and nutrients.
3. Encourage liberal fluid intake. Clients with fever and dyspnea lose excess body fluids through the skin and lungs. Adequate hydration will help liquefy pulmonary secretions and prevent decreases in circulating blood volume. Always check for contraindications such as heart failure, kidney disease, or a prescribing practitioner–ordered fluid restriction before encouraging increased fluids.
4. Weigh daily. Monitors progress to goal so that plan can be modified as needed. Daily gains or losses in excess of 1 pound are often due to fluid balance alterations. Slower gains or losses may be due to nutritional alterations.

(Continues)

NURSING CARE PLAN (Continued)

EVALUATION

Success of the nursing interventions can be measured by a visible increase in the client's comfort and ease of speaking and a decreased effort at the work of breathing. The client will report that dyspnea has been relieved and will have respiratory and heart rates within the normal range. Ongoing evaluation will be needed to monitor client's weight to ensure that intake is adequate to meet client's caloric requirements.

EVALUATION

Clients with compromised oxygenation status need careful nursing care to address both their physical and psychological needs. Evaluation will be based on the outcomes and goals that the nurse and client have established together. In many instances, the evaluation of the success of the specific inter-

ventions will be a matter of degree, that is, the degree to which the client is or can be returned to a satisfactory state of respiratory functioning. It is important when evaluating progress to revisit the initial plan of care to determine if each expected outcome was within reasonable expectations and then to revise the goals, interventions, and plan of care to reflect truly reasonable expectations.

PROCEDURE 32-1

Maintaining and Cleaning the Tracheostomy Tube

EQUIPMENT

- Gloves
- Sterile water or saline
- Tracheostomy dressing (4 × 4 gauze *without* cotton lining)
- Hydrogen peroxide
- Cotton-tip applicators
- Tracheostomy ties (twill tape, intravenous tubing, or commercially available Velcro ties)

ACTION

RATIONALE

CLEANING TRACH TUBE SITE

- | | |
|---|--|
| <ol style="list-style-type: none"> 1. Wash hands/hand hygiene, apply gloves, and assemble equipment (see Figure 32-22 on page 888). 2. Remove soiled dressing and discard. 3. Cleanse neck plate of tracheostomy tube with cotton applicators moistened with hydrogen peroxide. 4. Rinse neck plate of tracheostomy tube with applicators moistened with sterile water or saline. 5. Cleanse skin under neck plate of tube with cotton applicator moistened with hydrogen peroxide (see Figure 32-23 on page 888). | <ol style="list-style-type: none"> 1. Reduces the transmission of microorganisms. 2. Prevents contamination of other areas. 3. Removes crusted secretions from neck plate of tracheostomy tube. 4. Removes hydrogen peroxide. 5. Removes dried and crusted secretions from under neck plate of tracheostomy tube. |
|---|--|

(Continues)

PROCEDURE 32-1 Maintaining and Cleaning the Tracheostomy Tube (Continued)

ACTION

RATIONALE

FIGURE 32-22 Tracheostomy care tray, hydrogen peroxide, tape, dressing, sterile and clean gloves. DELMAR/CENGAGE LEARNING

FIGURE 32-23 Clean stoma under faceplate. DELMAR/CENGAGE LEARNING

- | | |
|--|--|
| <ol style="list-style-type: none"> 6. Rinse skin under neck plate with applicators moistened with sterile water or saline. 7. Dry skin under neck plate with cotton applicators. 8. <i>Using your clean hand</i>, gently loosen the inner cannula of the tracheostomy tube by twisting the outer ring counterclockwise; then withdraw the inner cannula in a smooth motion. Place the inner cannula into the basin of peroxide.
<i>Note:</i> Some tracheostomy tubes use disposable inner cannulae that would be replaced at this point in the procedure. If replacing a disposable inner cannula, skip to Action 12. 9. <i>Using your sterile hand</i>, pick up the cannula. Using your clean hand, pick up the nylon brush and scrub to remove any visible crusts or secretions from inside and outside the cannula (see Figure 32-24 on page 889). 10. Place the cannula into the container of sterile saline. Agitate so that all surfaces are bathed in saline. 11. Inspect the inner cannula again to be sure it is clean; then remove excess saline from the lumen by tapping the cannula against a sterile surface. 12. Gently replace the inner cannula, following the curve of the tube. When fully inserted, lock the inner cannula in place by rotating the external ring clockwise until it clicks into place. | <ol style="list-style-type: none"> 6. Removes hydrogen peroxide. 7. Removes moisture, which can result in skin irritation. 8. Minimizes trauma to the client's tracheal tissues and reduces reflexive coughing. The hydrogen peroxide serves to dissolve crusted secretions. 9. Any secretions retained on the inner cannula may be aspirated into the client's lungs, causing infection and possible airway obstruction. In some cases, the pipe cleaners may be needed to gain access to the inner surface of the cannula. 10. Rinses the peroxide off the cannula before it is returned to the client. 11. Fluid trapped in the lumen of the cannula can be aspirated by the client. 12. Minimizes tissue trauma and unintentional displacement. |
|--|--|

(Continues)

PROCEDURE 32-1 Maintaining and Cleaning the Tracheostomy Tube (Continued)

ACTION

RATIONALE

FIGURE 32-24 Clean lumen and inner cannula. DELMAR/CENGAGE LEARNING

FIGURE 32-25 Change tracheostomy ties. DELMAR/CENGAGE LEARNING

ONE-PERSON TECHNIQUE OF CHANGING TRACHEOSTOMY TIES

13. Prepare clean tracheostomy ties.
 - Cut a length of twill tape that will fit around the client's neck plus 6 inches. Cut the ends of the twill tape on the diagonal.
 - Open Velcro ties on continuous neck band.
14. Leaving the old tracheostomy ties in place, insert one end of the new tracheostomy tie through the hole in the tracheostomy neck plate from back to front (see Figure 32-25). Pull the ends even, and slide both ends of the tape around the back of the head to the other side.
15. Insert one end of tape through the opening on the other side of the tracheostomy tube neck plate from back to front.
16. Tie the two ends of the new tape with a square knot at side of neck. Keep two fingers under the tape as the knot is tied. Without putting pressure on the neck plate or the tape, pull on the knot to make sure it will stay tied.
17. Untie and remove old tracheostomy tapes and discard. Hold the neck plate firmly with one hand while untying the old tapes.
18. Place one finger under tracheostomy ties.

13. Ensures that all equipment is prepared prior to beginning procedure. A diagonal cut will make the tape easier to thread.
14. Maintains tube security while tapes are changed.
15. Secures tracheostomy tube.
16. Secures tracheostomy tube. Fingers under tape prevent the tape from being tied too tightly.
17. Old tapes can be removed once the tracheostomy tube has been secured. Holding the plate firmly prevents dislodgment if the new tie is accidentally cut.
18. Checks for tightness and security.

TWO-PERSON TECHNIQUE OF CHANGING TRACHEOSTOMY TIES

19. Cut two pieces of twill tape about 12 to 14 inches in length.
20. Make a fold about 1 inch below the end of each piece of twill tape, and cut a half-inch slit lengthwise in the center of the fold.

(Continues)

PROCEDURE 32-1 Maintaining and Cleaning the Tracheostomy Tube (Continued)

ACTION	RATIONALE
21. Have a second person gently hold the tracheostomy tube in place with fingers on both sides of the neck plate.	21. Prevents accidental movement of the tracheostomy tube that could result in coughing and accidental decannulation.
22. Untie old tracheostomy ties and discard.	22. Removes tracheostomy ties.
23. Insert the split end of the tracheostomy tape through the opening on one side of the tracheostomy tube neck plate. Pull the distal end of the tracheostomy tie through the cut end and pull tightly.	23. Secures tracheostomy tie within neck plate.
24. Repeat procedure with second piece of twill tape.	24. Secures tracheostomy tube.
25. Tie tracheostomy tapes with a double knot at the side of the neck.	25. Secures tracheostomy tube.
26. Insert one finger under tracheostomy tapes.	26. Ensures that tube has been tied securely.
27. Insert tracheostomy gauze under neck plate of tube.	27. Prevents irritation of skin from secretions and rubbing of tracheostomy tube.
28. Discard all used materials; wash hands/hand hygiene.	28. Reduces transmission of microorganisms.

delegation tip

The maintenance and cleaning of tracheal tubes cannot be delegated by the nurse. Ancillary personnel may assist the nurse in providing care to clients receiving this treatment and should be instructed to report a client experiencing increased secretions, dyspnea, or the need for suctioning to the nurse.

nursing tips

Use sterile equipment and careful technique while performing the procedure to prevent microorganisms from contaminating a new trach wound.

PROCEDURE 32-2

Performing Nasopharyngeal and Oropharyngeal Suctioning

EQUIPMENT

- Suction source (wall suction regulator with collection bottle or portable suction machine)
- Sterile suction kit (contains suction catheter, sterile gloves, sterile solution container; may contain a small container of sterile normal saline)
- Sterile water-soluble lubricant
- Extension tubing connected to suction device
- Small bottle of sterile water or normal saline if not included in kit
- Personal protective devices: gown, mask, and goggles or face shield if splattering is likely (e.g., a client with a vigorous productive cough)

(Continues)

PROCEDURE 32-2 Performing Nasopharyngeal and Oropharyngeal Suctioning (Continued)

ACTION	RATIONALE
1. Assess the client's need for suctioning: inability to effectively clear the airway by coughing and expectoration; coarse bubbling or gurgling noises with respiration.	1. Suctioning is an uncomfortable and traumatic procedure and should be used only when needed.
2. Choose the most appropriate route (nasopharyngeal or oropharyngeal) for your client. If nasopharyngeal approach is considered, inspect the nares with a penlight to determine patency. Alternatively, you may assess patency by occluding each naris in turn with finger pressure while asking the client to breathe through the remaining naris.	2. The oropharyngeal approach is easier but requires that the client cooperate; it may also produce gagging more readily in some persons. The nasopharyngeal route is more effective for reaching the posterior oropharynx but is contraindicated in clients with a deviated nasal septum, nasal polyps, or any tendency toward excessive bleeding (low platelet count, use of anticoagulants, recent history of epistaxis or nasal trauma).
3. Explain the procedure to the client. Advise that suctioning may cause coughing or gagging but emphasize the importance of clearing the airway.	3. Promotes cooperation and reduces anxiety.
4. Wash hands/hand hygiene.	4. Reduces the transmission of microorganisms.
5. Position the client in a high Fowler's or semi-Fowler's position.	5. Maximizes lung expansion and effective coughing.
6. If the client is unconscious or otherwise unable to protect airway, place in a side-lying position.	6. Protects the client from aspiration in the event of vomiting.
7. Connect extension tubing to suction device if not already in place, and adjust suction control to between 80 and 100 mm Hg.	7. Excessive negative pressure can cause tissue trauma, whereas insufficient pressure will be ineffective.
8. Put on gown and mask as well as goggles or face shield if indicated.	8. Protects from splattering with body fluids.
9. Using sterile technique (see Figure 32-26), open the suction kit. Consider the inside wrapper of the kit to be sterile, and spread the wrapper out carefully to create a small sterile field.	9. Produces an area in which to place sterile items without contaminating them.

FIGURE 32-26 Sterile Technique DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 32-2 Performing Nasopharyngeal and Oropharyngeal Suctioning (Continued)

ACTION	RATIONALE
10. Open a packet of sterile water-soluble lubricant, and squeeze out the contents of the packet onto the sterile field.	10. Lubricant will be used to further lubricate the catheter tip if the nasopharyngeal route is used.
11. If sterile solution (water or saline) is not included in the kit, pour about 100 mL of solution into the sterile container provided in the kit.	11. This solution will be used to lubricate the catheter and to rinse the inside of the catheter to clear secretions.
12. Carefully lift the wrapped gloves from the kit without touching the inside of the kit or the gloves themselves. Lay the wrapped gloves down next to the suction kit, and open the wrapper. Put on the gloves using sterile gloving technique.	12. The gloves should be kept sterile for handling the sterile suction catheter to avoid introducing pathogens into the client's airway.
13. If a cup of sterile solution is included in the suction kit, open it.	13. This solution will be used to lubricate the catheter and to rinse the inside of the catheter to clear secretions.
14. Designate one hand as <i>sterile</i> (able to touch only sterile items) and the other as <i>clean</i> (able to touch only nonsterile items).	14. Usually, the dominant hand is the sterile hand, while the nondominant hand is clean. This prevents contamination of sterile supplies while allowing you to handle unsterile items.
15. <i>Using your sterile hand</i> , pick up the suction catheter. Grasp the plastic connector end between your thumb and forefinger, and coil the tip around your remaining fingers.	15. Prevents accidental contamination of the catheter tip.
16. Pick up the extension tubing <i>with your clean hand</i> . Connect the suction catheter to the extension tubing, taking care not to contaminate the catheter (see Figure 32-27).	16. The extension tubing is not sterile.
17. Position your clean hand with the thumb over the catheter's suction port.	17. Suction is activated by occluding this port with the thumb. Releasing the port deactivates the suction.
18. Dip the catheter tip into the sterile solution, and activate the suction. Observe as the solution is drawn into the catheter.	18. Tests the suction device as well as lubricates the interior of the catheter to enhance clearance of secretions.

FIGURE 32-27 Attach catheter to tubing. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 32-2 Performing Nasopharyngeal and Oropharyngeal Suctioning (Continued)

ACTION	RATIONALE
19. For oropharyngeal suctioning, ask the client to open mouth. Without activating the suction, gently insert the catheter and advance it until you reach the pool of secretions or until the client coughs.	19. To minimize trauma, do not apply suction while the catheter is being advanced.
20. For nasopharyngeal suctioning, estimate the distance from the tip of the client's nose to the earlobe and grasp the catheter between your thumb and forefinger at a point equal to this distance from the catheter's tip.	20. Ensures placement of the catheter tip in the oropharynx and not in the trachea.
21. Dip the tip of the suction catheter into the water-soluble lubricant to coat the catheter tip liberally.	21. Promotes the client's comfort and minimizes trauma to nasal mucosa.
22. Insert the catheter tip into the naris with the suction control port uncovered. Advance the catheter gently with a slight downward slant. Slight rotation of the catheter may be used to ease insertion. Advance the catheter to the point marked by your thumb and forefinger (see Figure 32-28).	22. Guides the catheter toward the posterior oropharynx along the floor of the nasal cavity.
23. If resistance is met, <i>do not force the catheter</i> . Withdraw it and attempt insertion via the opposite naris.	23. Forceful insertion may cause tissue damage and bleeding.
24. Apply suction intermittently by occluding the suction control port with your thumb; at the same time, slowly rotate the catheter by rolling it between your thumb and fingers while slowly withdrawing it. Apply suction for no longer than 15 seconds at a time.	24. Prolonged suction applied to a single area of tissue can cause tissue damage.
25. Repeat Action 24 until all secretions have been cleared, allowing brief rest periods between suctioning episodes.	25. Promotes complete clearance of the airway.
26. Withdraw the catheter by looping it around your fingers as you pull it out.	26. Allows you to maintain control over the catheter tip as it is withdrawn.
27. Dip the catheter tip into the sterile solution and apply suction.	27. Clears the extension tubing of secretions that would promote bacterial growth.

FIGURE 32-28 Insert catheter into nostril. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 32-2 Performing Nasopharyngeal and Oropharyngeal Suctioning (Continued)

ACTION	RATIONALE
28. Disconnect the catheter from the extension tubing. Holding the coiled catheter in your gloved hand, remove the glove by pulling it over the catheter. Discard catheter and gloves in an appropriate container.	28. Contains the catheter and secretions in the glove for disposal.
29. Discard remaining supplies in the appropriate container.	29. Follow institutional policy regarding the disposal of client care supplies.
30. Wash hands/hand hygiene.	30. Prevents the transmission of microorganisms.
31. Provide the client with oral hygiene if indicated or desired.	31. Suctioning and coughing may produce an unpleasant taste.
32. Document the procedure, noting the amount, color, and odor of secretions and the client's response to the procedure.	32. Changes in the amount, color, or odor of pulmonary secretions may indicate infection.

delegation tip

Nasopharyngeal and oropharyngeal suctioning are not delegated by the nurse. Ancillary personnel may assist in providing care to clients receiving these treatments and should be instructed to report a client experiencing a nonproductive cough, dyspnea, or the need for suctioning to the nurse.

nursing tips

Clients with oxygenation impairment may be confused or agitated, making safety a vital concern of the nurse.

PROCEDURE 32-3

Suctioning Endotracheal and Tracheal Tubes

EQUIPMENT

- Sterile gloves
- Mask, eye protection, and gown if appropriate
- Source of negative pressure (suction machine or wall suction)
- Sterile suction catheter
- Oxygen or Ambu bag
- Equipment for tracheostomy care or tracheostomy care tray

ACTION

RATIONALE

SUCTIONING A TRACHEAL TUBE

- | | |
|---|------------------------------------|
| 1. Assess depth and rate of respirations; auscultate breath sounds. | 1. Determines need for suctioning. |
| 2. Assemble supplies on bedside table (see Figure 32-29A and 32-29B on page 895). | 2. Organizes work. |

PROCEDURE 32-3 Suctioning Endotracheal and Tracheal Tubes (Continued)

ACTION

RATIONALE

A

B

FIGURE 32-29 A. Protective gear, dressing, and a tracheostomy care tray. B. Protective gear and suction equipment.
DELMAR/CENGAGE LEARNING

3. Wash hands/hand hygiene.
 4. Connect suction tube to source of negative pressure. Set suction control to between 80 and 100 mm Hg.
 5. Administer oxygen or use Ambu bag before beginning procedure.
 6. Remove inner cannula and place in basin of hydrogen peroxide to loosen secretions, if reusable, or set aside if disposable. Do not dispose of disposable cannula until new inner cannula is securely in place.
 7. Apply sterile glove to dominant hand.
 8. Open sterile suction catheter or use the reusable closed system catheter. The sterile suction catheter is removed from the package with the dominant, sterile hand. Wrap the catheter tubing around hand from the tip of the catheter down to the port end. Attach catheter to suction.
 9. Quickly and gently insert the catheter during inspiration until resistance is met or the client coughs; then pull back 1 cm (1/2 inch).
 10. Apply suction intermittently while gently rotating the catheter and removing it (see Figure 32-30 on page 896).
 - In a disposable catheter, suction is applied by placing the thumb of dominant hand over the open port of the catheter connector.
 - In a closed system catheter, suction is applied by depressing the white button at the connector end of the catheter.
3. Reduces transmission of microorganisms.
 4. Prepares for suctioning procedure.
 5. Hyperoxygenates client and prevents hypoxia during suctioning.
 6. Suctioning should be performed after inner cannula has been removed to allow easier passage of the suction catheter. Retain the old cannula until you are sure the new cannula fits correctly.
 7. Ensures sterile technique.
 8. Maintains catheter sterility and prevents accidental contamination.
 9. Minimizes removal of oxygen and trauma to the tracheal mucosa.
 10. Increases removal of mucus while minimizing irritation to tracheal mucosa.

(Continues)

PROCEDURE 32-3 Suctioning Endotracheal and Tracheal Tubes (Continued)

ACTION

FIGURE 32-30 Suction tracheostomy. DELMAR/CENGAGE LEARNING

11. Wrap the disposable suction catheter around sterile, dominant hand while withdrawing it from the endotracheal tube.
12. Suction for no more than 10 seconds.
13. Administer oxygen using the sigh function on the ventilator or using an Ambu bag.
14. Assess airway and repeat suctioning as necessary.
15. Clean inner cannula using tracheostomy brush and rinse well in sterile water or sterile saline. Dry (or open new disposable inner cannula).
16. Reinsert inner cannula and lock into place.
17. Apply humidified oxygen or compressed air.
18. Remove gloves and discard.
19. Wash hands/hand hygiene.
20. Record the procedure and client's tolerance of the procedure, including amount and consistency of secretions.

SUCTIONING AN ENDOTRACHEAL TUBE

21. Repeat Actions 1–14 (see Figure 32-31 and Figure 32-32 on page 897).
22. Remove gloves and discard.
23. Wash hands/hand hygiene.
24. Record the procedure and client's tolerance of the procedure, including amount and consistency of secretions.

RATIONALE

FIGURE 32-31 Assess for respiratory rate and lung sounds. Repeat suctioning if needed. DELMAR/CENGAGE LEARNING

11. Prevents accidental contamination of the catheter.
12. Prevents hypoxia.
13. Reoxygenates the client.
14. Determines need to continue suctioning.
15. Removes secretions and maintains patent inner cannula.
16. Prevents secretions from obstructing outer cannula.
17. Thins secretions.
18. Prevents transmission of microorganisms to other clients.
19. Reduces the transmission of microorganisms.
20. Provides documentation of the procedure.
21. See Rationales 1–14.
22. Prevents transmission of microorganisms to other clients.
23. Reduces the transmission of microorganisms.
24. Provides documentation of the procedure.

(Continues)

PROCEDURE 32-3
Suctioning Endotracheal and Tracheal Tubes (Continued)

FIGURE 32-32 Endotracheal suctioning. Apply suction while gently rotating the catheter and removing it. Do not suction for more than 10 seconds. DELMAR/CEGAGE LEARNING

delegation tip

The suctioning of endotracheal and tracheal tubes is not delegated by the nurse. Ancillary personnel may assist the nurse in providing care to clients receiving this treatment and should be instructed to report a client experiencing increased secretions, dyspnea, or the need for suctioning to the nurse.

nursing tips

- Because suctioning removes air (and oxygen) from the client’s airways as well as secretions, care must be taken to avoid excessive suctioning and prevent severe oxygen desaturation.
- After suctioning, provide mouth care and suction the oropharynx if indicated. Assist the client to a comfortable position and allow for a rest period.

PROCEDURE
32-4

Administering Oxygen Therapy

EQUIPMENT

- Stethoscope
- Oxygen source—portable or in-line
- Oxygen flow meter
- Oxygen delivery device: nasal cannula, mask, tent, or T-tube with adapter for artificial airway
- Oxygen tubing
- Pulse oximetry
- Humidifier and distilled or sterile water (not needed with low flow rates per nasal cannula)

ACTION

RATIONALE

NASAL CANNULA (SEE FIGURE 32-33 ON PAGE 898)

- | | |
|--|--|
| <ol style="list-style-type: none"> 1. Wash hands/hand hygiene. 2. Verify the prescribing practitioner’s order. | <ol style="list-style-type: none"> 1. Reduces the transmission of microorganisms. 2. Ensures correct dosage and route. |
|--|--|

(Continues)

PROCEDURE 32-4 Administering Oxygen Therapy (Continued)

ACTION

FIGURE 32-33 Nasal cannula and oxygen tubing attached to a flow meter. DELMAR/CENGAGE LEARNING

3. Explain procedure and hazards to the client. Remind clients who smoke of the reasons for not smoking while O₂ is in use.
4. If using humidity, fill humidifier to fill line with distilled water and close container.
5. Attach humidifier to oxygen flow meter.
6. Insert humidifier and flow meter into oxygen source in wall or portable unit.
7. Attach the oxygen tubing and nasal cannula to the flow meter and turn it on to the prescribed flow rate (1–5 L/min). Use extension tubing for ambulatory clients so they can get up to go to the bathroom.
8. Check for bubbling in the humidifier.
9. Place the nasal prongs in the client's nostrils (see Figure 32-34). Secure the cannula in place by adjusting the tubing around the client's ears and using the slip ring to stabilize it under the client's chin.

RATIONALE

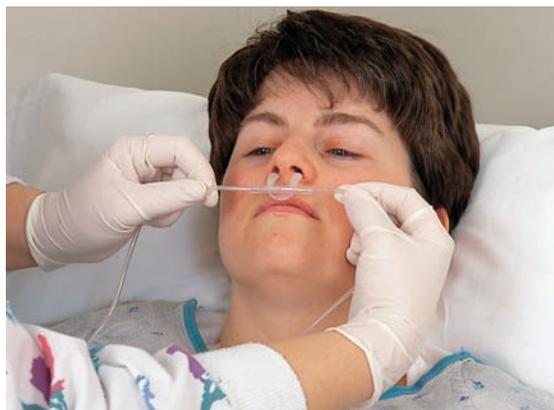

FIGURE 32-34 Insert cannula prong into nostrils. DELMAR/CENGAGE LEARNING

3. Increases compliance with procedures. Oxygen supports combustion.
4. Prevents drying of the client's airway and thins any secretions.
5. Allows the oxygen to pass through the water and become humidified.
6. For access to oxygen. Many institutions also have compressed air available from outlets very similar in appearance to oxygen outlets. Green always stands for oxygen. Be sure to plug the flow meter into the green outlet.
7. Rates above 6 L/min are not efficacious and can dry the nasal mucosa.
8. Ensures proper functioning.
9. Keeps delivery system in place so client receives the amount of oxygen ordered.

(Continues)

PROCEDURE 32-4 Administering Oxygen Therapy (Continued)

ACTION	RATIONALE
10. Check for proper flow rate every 4 hours and when the client returns from procedures.	10. Ensures that client receives proper dose. The nasal cannula is a low-flow system because it administers oxygen while the client also inspires room air. The actual dose of oxygen received by the client will vary depending on the client's respiratory pattern. The delivery rate may be changed during procedures.
11. Assess client's nostrils every 8 hours. If the client complains of dryness or has signs of irritation, use sterile lubricant to keep mucous membranes moist. Add humidifier if not already in place.	11. Dry membranes are more prone to breakdown by friction or pressure from nasal cannula.
12. Monitor vital signs, oxygen saturation, and client condition every 4–8 hours (or as indicated or ordered) for signs and symptoms of hypoxia.	12. Detects any untoward effects from therapy.
13. Wean client from oxygen as soon as possible using standard protocols.	13. Oxygen is not without side effects and should be used only as long as needed. Problems with reimbursement may develop if criteria for therapy are not met.

MASK: VENTURI (HIGH-FLOW DEVICE), SIMPLE MASK (LOW FLOW), PARTIAL REBREATHER MASK, NONREBREATHER MASK, AND FACE TENT

14. Wash hands/hand hygiene.	14. Reduces the transmission of microorganisms.
15. Repeat Actions 2–6.	15. See Rationales 2–6.
16. Attach appropriately sized mask (see Figure 32-35 on page 900) or face tent to oxygen tubing, and turn on flow meter to prescribed flow rate. The Venturi mask will have color-coded inserts that list the flow rate necessary to obtain the desired percentage of oxygen. Allow the reservoir bag of the nonrebreathing or partial rebreathing mask to fill completely. Figure 32-36 on page 900 shows several types of oxygen masks.	16. Ensures proper fit; size needed is based on the client's size. Checks the oxygen source and primes the tubing and mask or tent.
17. Check for bubbling in the humidifier.	17. Ensures proper functioning.
18. Place the mask or tent on the client's face, fasten the elastic band around the client's ears, and tighten until the mask fits snugly.	18. Prevents loss of oxygen from the sides of the mask.
19. Check for proper flow rate every 4 hours.	19. Ensures that client is receiving the proper dose.
20. Ensure that the ports of the Venturi mask are not under covers or impeded by any other source.	20. Air must be entrained to mix room air and oxygen coming from source to ensure proper oxygen percentage (F_{IO_2}).
21. Assess client's face and ears for pressure from the mask, and use padding as needed.	21. Provides client comfort and prevents skin breakdown.
22. Wean client to nasal cannula and then wean off oxygen per protocol.	22. Oxygen is not without side effects and should be used only as long as needed. The nasal cannula provides a lower F_{IO_2} than the mask. Problems with reimbursement may develop if criteria for therapy are not met.

(Continues)

**PROCEDURE 32-4
Administering Oxygen Therapy (Continued)**

ACTION

RATIONALE

FIGURE 32-35 Make sure the mask used is the appropriate size for the client. DELMAR/CENGAGE LEARNING

OXYGEN VIA AN ARTIFICIAL AIRWAY (TRACHEOSTOMY OR ENDOTRACHEAL TUBE)

- | | |
|---|---|
| <ul style="list-style-type: none"> 23. Wash hands/hand hygiene. 24. Verify the prescribing practitioner's order. 25. Fill the humidifier with sterile water, and close the container. 26. Attach humidifier and warmer to the oxygen flow meter (see Figure 32-37). 27. Attach the wide-bore oxygen tubing and T-tube adapter or tracheostomy mask to the flow meter, and turn the meter to the flow rate needed to achieve the prescribed oxygen concentration. An oxygen analyzer may be used to check the actual oxygen percentage being delivered. | <ul style="list-style-type: none"> 23. Reduces the transmission of microorganisms. 24. Ensures correct dosage and time. 25. Avoids contamination of the water. 26. Humidification and warming of the air are essential with an artificial airway because the upper airway is bypassed by the tube. 27. Checks the oxygen source and primes the tubing and adapter. |
|---|---|

FIGURE 32-37 Oxygen Humidifier and Warmer DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 32-4 Administering Oxygen Therapy (Continued)

ACTION	RATIONALE
28. Check for bubbling in the humidifier and a fine mist from the adapter.	28. Ensures proper functioning.
29. Attach the T-piece to the client's artificial airway, or place the mask over the client's airway. Be sure the T-piece is firmly attached to the airway (see Figure 32-38).	29. Ensures that client will not develop complications related to an interrupted oxygen supply.
30. Position tubing so that it is not pulling client's airway.	30. Provides for client comfort and prevents dislodgment of the artificial airway.
31. Check for proper flow rate and patency of the system every 1–2 hours, depending on the acuity of the client. Suction as needed to maintain a patent airway.	31. Ensures that client is receiving proper dose.
32. Monitor airway patency, vital signs, oxygen saturation, and signs and symptoms of hypoxia every 2 hours, or more frequently as necessary or as ordered. Additionally, monitor breath sounds and tube position every 4 hours.	32. Detects response to or any untoward effects from therapy. Determines whether tube is in place.

FIGURE 32-38 Attach the T-piece to the oxygen tubing. DELMAR/CENGAGE LEARNING

delegation tip

The initiation of oxygen therapy requires assessment by a nurse or respiratory care practitioner. All personnel are responsible for maintaining fire and safety precautions when oxygen is in use. Ancillary personnel should be instructed to report dyspnea, tachycardia, any changes in the client's activity tolerance, a respiratory rate less than 12 or greater than 20 breaths per minute in the adult client, or changes in mental status. Ancillary personnel should be instructed how to properly reapply respiratory therapy equipment, how to initiate assistance with activities of daily living for the client requiring oxygen therapy, and to report any abnormal client responses.

nursing tips

Promote client comfort by adjusting tubing or padding so that clients are more likely to leave oxygen therapy equipment on.

PROCEDURE 32-5

Performing the Heimlich Maneuver

EQUIPMENT

- An individual with the training to perform this procedure

ACTION

RATIONALE

FOREIGN BODY OBSTRUCTION—ALL CLIENTS

1. Assess airway for complete or partial blockage (see Figure 32-39).

1. If there is good air exchange and the client is able to forcefully cough, you should not intervene or interfere with the client's attempts to expel the foreign body. Encourage attempts to cough and breathe, as attempts to cough will provide a more forceful effort. If complete airway obstruction is apparent, the Heimlich maneuver or alternative method of subdiaphragmatic thrust should be performed immediately.
2. Provides follow-up care by professionally trained personnel.

2. Activate emergency response assistance if respiratory distress or complete blockage; for example, ask bystander to call 911.

CONSCIOUS ADULT CLIENT—SITTING OR STANDING (HEIMLICH MANEUVER)

3. Stand behind the client (see Figure 32-40).
4. Wrap both arms around the client's waist (see Figure 32-41 on page 903).
5. Make a fist with one hand, and grasp the fist with your other hand, placing the thumb side of the fist against the client's abdomen. The fist should be placed midline, below the xiphoid process and lower margins of the rib cage and above the navel (see Figure 32-42 on page 903).

3. Proper positioning is necessary to provide an effective subdiaphragmatic thrust.
4. Proper positioning is necessary to provide an effective subdiaphragmatic thrust.
5. Correct hand placement is important to prevent internal organ damage.

FIGURE 32-39 Assess the client. Assess the airway for blockage. DELMAR/CENGAGE LEARNING

FIGURE 32-40 Stand behind the client. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 32-5 Performing the Heimlich Maneuver (Continued)

ACTION

FIGURE 32-41 Wrap both arms around the client's waist.
DELMAR/CENGAGE LEARNING

6. Perform a quick upward thrust into the client's abdomen; each thrust should be separate and distinct.
7. Repeat this process 6 to 10 times until the client either expels the foreign body or loses consciousness.

UNCONSCIOUS ADULT CLIENT OR ADULT CLIENT WHO BECOMES UNCONSCIOUS

8. Repeat Actions 1 and 2.
9. Position the client supine; kneel astride the client's abdomen.
10. Place the heel of one hand midline, below the xiphoid process and lower margin of the rib cage and above the navel. Place the second hand directly on top of the first hand.
11. Perform a quick upward thrust into the diaphragm, repeating 6 to 10 times.
12. Perform a finger sweep:
 - a. Use one hand to grasp the lower jaw and tongue between your thumb and fingers and lift. This will open the mouth and pull the tongue away from the back of the throat.
 - b. Using the index finger of the other hand, insert the finger into the client's mouth next to the cheek and, using a hooking motion, dislodge any foreign body. Caution must be used to prevent pushing the foreign body farther down into the airway (see Figure 32-43 on page 904).

RATIONALE

FIGURE 32-42 Make a fist. Place the fist below the xiphoid process, above the client's navel.
DELMAR/CENGAGE LEARNING

6. This subdiaphragmatic thrust can produce an artificial cough by forcing air from the lungs.
7. Attempts to dislodge food or a foreign body to relieve airway obstruction should be continued as long as necessary because of the serious consequences of hypoxia.
8. Determines the need for intervention and summons essential help.
9. Proper positioning is necessary to provide an effective subdiaphragmatic thrust.
10. Proper positioning is necessary to provide an effective subdiaphragmatic thrust.
11. A client who becomes unconscious may become more relaxed so that the previously unsuccessful Heimlich maneuver may be successful.
12. Should only be used on the unconscious client, who will not fight the action.
 - a. Draw the tongue away from any foreign body lodged in the back of the throat.

(Continues)

PROCEDURE 32-5 Performing the Heimlich Maneuver (Continued)

ACTION

RATIONALE

FIGURE 32-43 Use a sweeping, hooking motion to dislodge and remove obstruction. DELMAR/CENGAGE LEARNING

13. Open the client's airway, and attempt ventilation.
14. Continue sequence of Heimlich maneuver, finger sweep, and rescue breathing as long as necessary.

CONSCIOUS ADULT SITTING OR STANDING—CHEST THRUSTS

15. Repeat Actions 1 and 2.
16. Stand behind the client, and wrap your arms around the client's waist.
17. Make a fist, and place the thumb side of the fist against the client's abdomen. Grasp fist with other hand upward.
18. Perform backward thrusts until either the client becomes unconscious or the foreign body is expelled.

UNCONSCIOUS ADULT—CHEST THRUSTS

19. Repeat Actions 1 and 2.
20. Place client in the supine position, and kneel astride the client's thighs.
21. Place the heel of one hand against the client's abdomen. This should be slightly above the navel but below the xiphoid process.
22. Perform each thrust in a slow, separate, and distinct manner.
23. Follow Actions 9–12 for the adult Heimlich maneuver, unconscious client.

13. The brain can suffer irreversible damage if it is without oxygen for over 4–6 minutes.
14. Life-saving efforts must continue until they are successful or until the rescuer becomes exhausted and cannot go on.

15. Determines the need for intervention and summons essential help.
16. Proper hand placement should avoid the xiphoid process and rib cage margins to minimize internal organ damage.
17. Proper hand placement should avoid the xiphoid process and rib cage margins to minimize internal organ damage.
18. Thrusts may not be effective on the first tries. Keep trying. Chest thrusts should be used only for very obese people and women in the late stages of pregnancy.

19. Determines the need for intervention and summons essential help.
20. Places the client and the rescuer in the most effective position to apply interventions.
21. This is the most effective position for thrust.
22. Each thrust should be delivered with intention of relieving the airway obstruction.
23. Performs the life-saving procedure.

(Continues)

PROCEDURE 32-5 Performing the Heimlich Maneuver (Continued)

ACTION	RATIONALE
AIRWAY OBSTRUCTION—INFANTS AND SMALL CHILDREN	
24. Differentiate between infection and airway obstruction.	24. Infectious complications that lead to airway obstruction require immediate medical attention, establishment of a patent airway (intubation or emergency tracheotomy), and treatment of the underlying infection. Food or foreign body airway obstruction also needs immediate attention; however, airway management differs between each scenario.
Infant Airway Obstruction	
25. Straddle infant over forearm in the prone position with the head lower than the trunk. Support the infant's head, positioning a hand around the jaws and chest.	25. Proper positioning is essential for success of the maneuver and prevention of other organ damage.
26. Deliver five back blows between the infant's shoulder blades.	26. Technique for dislodging the obstruction.
27. Keeping the infant's head down, place the free hand on the infant's back and turn the infant over, supporting the back of the child with hand and thigh.	27. Safely rotates the infant's position to continue life-saving procedures.
28. With free hand, deliver five thrusts in the same manner as infant external cardiac compressions.	28. Technique for dislodging the obstruction.
29. Assess for a foreign body in the mouth of an unconscious infant, and utilize the finger sweep <i>only</i> if a foreign body is visualized.	29. A blind finger sweep is avoided in infants and children as a foreign object can be pushed back farther into the airway, increasing obstruction.
30. Open airway and assess for respiration. If respirations are absent, attempt rescue breathing. Assess for the rise and fall of the chest; if not seen, reposition infant and attempt rescue breathing again.	30. Many times some air can get around the foreign body causing the airway obstruction. This allows for some oxygenation of the client. Without oxygen, irreversible brain damage can occur within 4–6 minutes.
31. Repeat the entire sequence again: five back blows, five chest thrusts, assessment for foreign body in oral cavity, and rescue breathing as long as necessary.	31. Life-saving efforts must continue until they are successful or until the rescuer becomes exhausted and cannot go on.
Small Child Airway Obstruction (Conscious, Standing, or Sitting)	
32. Assess air exchange, and encourage coughing and breathing. Provide reassurance to the child that you are there to help.	32. Inability to breathe is a distressing event for anyone, especially a small child who may not fully understand the circumstance. Reassurance is important to gain the child's trust and cooperation with the maneuvers necessary to help him or her, especially if the child is conscious.

(Continues)

PROCEDURE 32-5 Performing the Heimlich Maneuver (Continued)

ACTION	RATIONALE
<p>33. Ask the child if he or she is choking. If the response is affirmative, follow the steps outlined below. In addition, if the child has poor air exchange (and infection has been ruled out), initiate the following steps:</p> <ol style="list-style-type: none"> Stand behind the child with arms wrapped around child's waist and administer 6–10 subdiaphragmatic abdominal thrusts. Continue until foreign object is expelled or the child becomes unconscious. 	<p>33. Many small children are capable of responding to simple questions such as "Are you choking?"</p> <ol style="list-style-type: none"> Proper positioning is essential for success of the maneuver and prevention of other organ damage. Life-saving efforts must continue until they are successful or until the rescuer becomes exhausted and cannot go on.
<p>Small Child Airway Obstruction (Unconscious)</p>	
<p>34. Position the child supine, kneel at the child's feet, and gently deliver five subdiaphragmatic abdominal thrusts. The subdiaphragmatic thrusts are delivered in the same manner as for an adult but more gently.</p>	<p>34. This is the recommended position for small children; the astride position may be used for larger children. Proper positioning is essential for success of the maneuver and prevention of other organ damage.</p>
<p>35. Open airway by lifting the lower jaw and tongue forward. Perform a finger sweep only if a foreign body is visualized.</p>	<p>35. Opens the airway and allows visualization of the oral cavity. A blind finger sweep can cause increased obstruction by pushing a foreign object farther back into the airway.</p>
<p>36. If breathing is absent, begin rescue breathing. If the chest does not rise, reposition the child and attempt rescue breathing again.</p>	<p>36. Many times some air can get around the foreign body causing the airway obstruction. This allows for some oxygenation of the client. Without oxygen, irreversible brain damage can occur within 4–6 minutes.</p>
<p>37. Repeat this sequence as long as necessary.</p>	<p>37. Life-saving efforts must continue until they are successful or until the rescuer becomes exhausted and cannot go on.</p>
<p>38. Wash hands/hand hygiene.</p>	<p>38. Reduces transmission of microorganisms.</p>

delegation tip

The Heimlich maneuver may be performed by any trained individual. A technique adjustment may need to be demonstrated in pregnant women.

nursing tips

Approach clients with confidence, and reassure clients that you will remain with them throughout the procedure.

PROCEDURE
32-6
Administering Cardiopulmonary Resuscitation (CPR)
EQUIPMENT
Hospital or Clinical Setting

- Hard, flat surface (e.g., chest compression board)
- Body substance isolation items
 - Gloves
 - Face shield
 - Mask/CPR oral barrier device
- Ambu bag
- Oral airway
- Emergency resuscitation cart (including defibrillator)
- Documentation forms

Outside: Public Environment

- Hard, flat surface (e.g., floor)
- Body substance isolation items, if available
 - Gloves
 - Face shield
 - Mask/CPR oral barrier device

ACTION
RATIONALE
CPR: ONE RESCUER—ADULT, ADOLESCENT

- | | |
|---|---|
| <ol style="list-style-type: none"> 1. Assess responsiveness by tapping or gently shaking client while shouting, "Are you OK?" (see Figure 32-44). 2. Activate emergency medical system (EMS). In the hospital or clinical setting, follow institutional protocol. In the community or home environment, activate the local emergency response system (e.g., 911). According to the CPR guideline for 2005 (American Heart Association, 2005), rescuers should notify the EMS or phone 911 for unresponsive adults before beginning CPR. | <ol style="list-style-type: none"> 1. Prevents injury to a client who is not experiencing cardiac or respiratory arrest. Also assists in assessing level of consciousness and possible etiology of crisis. 2. Activates assistance from personnel trained in advanced life support. |
|---|---|

FIGURE 32-44 Assess the client's responsiveness. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 32-6 Administering Cardiopulmonary Resuscitation (CPR) (Continued)

ACTION	RATIONALE
<ol style="list-style-type: none"> 3. Position client in a supine position on a hard, flat surface (e.g., floor or cardiac board). Use caution when positioning a client with a possible head or neck injury. 4. Apply appropriate body substance isolation items (e.g., gloves, face shield) if available. 5. Position self. Face the client on your knees parallel to the client, next to the head, to begin to assess the airway and breathing status. 6. Open airway. The most commonly used method is the head-tilt/chin-lift method. This is accomplished by placing one hand on the client's forehead and applying a steady backward pressure to tilt the head back while placing the fingers of the other hand below the jaw at the location of the chin and lifting the chin (see Figure 32-45). In the event of a suspected head or neck injury, this lift is modified and the jaw thrust is used. To perform the jaw thrust, place hands at the angles of the lower jaw and lift, displacing the mandible forward while tilting the head backward (see Figure 32-46). Additionally, if available, insert oral airway. 7. Assess for respirations. Look, listen, and feel for air movement (3–5 seconds). 	<ol style="list-style-type: none"> 3. Proper positioning facilitates assessment of the cardiac and respiratory status and successful external cardiac massage. Care must be taken in positioning a client with a potential head or neck injury to prevent further damage. 4. Prevents transmission of disease. 5. Proper positioning prevents rescuer fatigue and facilitates CPR by allowing the rescuer to move from chest compressions to artificial breathing with minimal movement. 6. A patent airway is essential for successful artificial respirations. The head-tilt/chin-lift assists in preventing the tongue from obstructing the airway. The jaw thrust is used when a head or neck injury is suspected because it prevents extension of the neck and decreases the potential of further injury. 7. Cardiopulmonary resuscitation should not be administered to a client with spontaneous respirations or pulse because of the potential risk of injury.

FIGURE 32-45 Use the head-tilt/chin-lift method to open airway. DELMAR/CENGAGE LEARNING

FIGURE 32-46 The jaw-thrust method is used to open the airway if a neck injury is suspected. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 32-6 Administering Cardiopulmonary Resuscitation (CPR) (Continued)

ACTION	RATIONALE
<p>8. If respirations are absent:</p> <ul style="list-style-type: none"> • Occlude nostrils with the thumb and index finger of the hand on the forehead that is tilting the head back (see Figure 32-47). • Form a seal over the client's mouth using either your mouth or the appropriate respiratory assist device (e.g., Ambu bag and mask) and give two full breaths of 1 second, allowing time for both inspiration and expiration (see Figure 32-48). • In the event of a serious mouth or jaw injury that prevents mouth-to-mouth ventilation, mouth-to-nose ventilation may be used by tilting the head as described earlier with one hand and using the other hand to lift the jaw and close the mouth. <p>9. Assess for the rise and fall of the chest:</p> <ul style="list-style-type: none"> • If the chest rises and falls, continue to Action 10. • If the chest does not move, assess for excessive oral secretions, vomit, airway obstruction, or improper positioning. <p>10. Palpate the carotid pulse (5–10 seconds) (see Figure 32-49 on page 910):</p> <ul style="list-style-type: none"> • If present, continue rescue breathing at the rate of 12 breaths/min. Each rescue breath should be given for 1 second. • If absent, begin external cardiac compressions. 	<p>8. Occluding the nostrils and forming a seal over the client's mouth will prevent air leakage and provide full inflation of the lungs. Excessive air volume and rapid inspiratory flow rates can create pharyngeal pressures that are greater than esophageal opening pressures. This will allow air into the stomach, resulting in gastric distention and increased risk of vomiting.</p> <p>9. Visual assessment of chest movement helps confirm an open airway. A volume of 800–1200 mL is usually sufficient to make the chest rise in most adults.</p> <p>10. Performing chest compressions on an individual with a pulse could result in injury. Additionally, the carotid pulse may persist when peripheral pulses are no longer palpable. Hyperventilation assists in maintaining blood oxygen levels. Additionally, a pulse may be present for 6 minutes after respirations have ceased.</p>

FIGURE 32-47 Occlude both nostrils with fingers. DELMAR/
CENGAGE LEARNING

FIGURE 32-48 Give two full breaths. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 32-6 Administering Cardiopulmonary Resuscitation (CPR) (Continued)

ACTION

FIGURE 32-49 Palpate for a carotid pulse. DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 32-50 Place the heel of one hand next to the index finger on the client's sternum. DELMAR/CENGAGE LEARNING

11. Cardiac compressions are performed as follows:

- Maintain a position on knees parallel to sternum.
- Position the hands for compressions:
 - a. Using the hand nearest to the legs, use the index finger to locate the lower rib margin and quickly move the fingers up to the location where the ribs connect to the sternum.
 - b. Place the middle finger of this hand on the notch where the ribs meet the sternum and the index finger next to it.
 - c. Place the heel of the opposite hand next to the index finger on the sternum (see Figure 32-50).
 - d. Remove the first hand from the notch, and place it on top of the hand that is on the sternum so that they are on top of each other.
 - e. Extend or interlace fingers, and do not allow them to touch the chest (see Figure 32-51 on page 911).
 - f. Keep arms straight with shoulders directly over hands on sternum, and lock elbows (see Figure 32-52 on page 911).
 - g. Compress the adult chest 3.8–5.0 cm (1½–2 inches) at the rate of approximately 100 compressions per minute.

11. Irreversible brain and tissue damage can occur if a client is hypoxic for over 4–6 minutes. Proper positioning is essential for the following reasons:

- Allows for maximum compression of the heart between the sternum and vertebrae.
- Compressions over the xiphoid process can lacerate the liver.
- Keeping fingers off the chest during compressions reduces the risk of rib fracture.

(Continues)

PROCEDURE 32-6 Administering Cardiopulmonary Resuscitation (CPR) (Continued)

ACTION

FIGURE 32-51 Extend or interlace the fingers. DELMAR/CENGAGE LEARNING

- h. The heel of the hand must completely release the pressure between compressions, but it should remain in constant contact with the client's skin.
 - i. Use the mnemonic "one and, two and, three and . . ." to keep rhythm and timing.
 - j. Ventilate client as described in Action 8.
12. Maintain a hard and fast compression rate for approximately 100 times/min, interjecting 2 ventilations after every 30 compressions (compression:ventilation rate of 30:2). Each rescue breath should be given for 1 second.
 13. Reassess the client after four cycles.

CPR: TWO RESCUERS—ADULT, ADOLESCENT

14. Follow the previous steps with the following changes:
 - One rescuer is positioned facing the client parallel to the head while the other rescuer is positioned on the opposite side facing the client parallel to the sternum next to the trunk (see Figure 32-53 on page 912).
 - The rescuer positioned at the client's trunk is responsible for performing cardiac compressions and maintaining the verbal mnemonic count. This is Rescuer 1.

RATIONALE

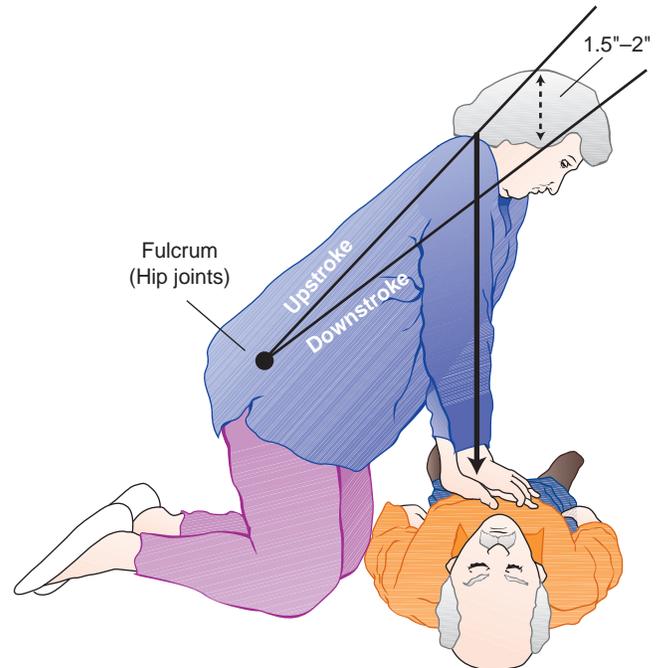

FIGURE 32-52 Proper Position of Rescuer DELMAR/CENGAGE LEARNING

12. Faster rate increases blood flow to key organ tissues. Minimizes interruptions in chest compressions. Large and forceful breaths may cause gastric inflation.
13. Determines return of spontaneous pulse and respirations and need to continue CPR.
14. Proper positioning allows one rescuer to perform artificial respirations while the other administers chest compressions without getting in each other's way. In addition, this facilitates ease in changing positions when one of the rescuers becomes fatigued. Palpating the carotid pulse with each chest compression during the first full minute ensures that adequate stroke volume is being delivered with each compression.

(Continues)

PROCEDURE 32-6 Administering Cardiopulmonary Resuscitation (CPR) (Continued)

ACTION

RATIONALE

FIGURE 32-53 Two-rescuer positioning. One person kneels on each side of the client. DELMAR/CENGAGE LEARNING

- The rescuer positioned at the client's head is responsible for monitoring respirations, assessing the carotid pulse, establishing an open airway, and performing rescue breathing. This is Rescuer 2.
- Maintain the compression rate at approximately 100 times/min, interjecting 2 ventilations after every 30 compressions (compression:ventilation rate of 30:2).
- Rescuer 2 palpates the carotid pulse with each chest compression during the first full minute.
- Rescuer 2 is responsible for calling for a change when fatigued, following this protocol.
- Rescuer 1 calls for a change and completes the 30 chest compressions.
- Rescuer 2 administers 2 breaths and then moves to a position parallel to the client's sternum and assumes the proper hand position.
- Rescuer 1 moves to the rescue breathing position and checks the carotid pulse for 5 seconds. If cardiac arrest persists, Rescuer 1 says, "continue CPR" and delivers 1 breath. Rescuer 2 resumes cardiac compressions immediately after the breath.

Two rescuers are needed because one person cannot maintain CPR indefinitely. When a rescuer becomes fatigued, chest compressions can become ineffective, decreasing the volume of oxygenated blood circulated to key organs and tissue.

(Continues)

PROCEDURE 32-6 Administering Cardiopulmonary Resuscitation (CPR) (Continued)

ACTION	RATIONALE
CPR: ONE RESCUER—CHILD (1–7 YEARS)	
15. Assess responsiveness, activate EMS, position the child, apply appropriate body substance isolation, position self, open airway, and assess for respirations as described in Actions 1–7. Remember respiratory arrest is more common in the pediatric population.	15. See Rationales 1–7.
16. If respirations are absent, begin rescue breathing: <ul style="list-style-type: none"> • Give two slow breaths (1 sec/breath), pausing to take a breath in between. • Use only the amount of air needed to make the chest rise. When you see the chest rise and fall, you are using the right volume of air. 	16. Hypoxia can cause irreversible brain and tissue damage after 4–6 minutes. <ul style="list-style-type: none"> • The volume of air in a small child’s lungs is less than an adult’s. Excessive air volume and rapid inspiratory rates can increase pharyngeal pressures that exceed esophageal opening pressures. This allows air to enter the stomach, causing gastric distention, increasing the risk of vomiting, and further compromising the client’s respiratory status.
17. Palpate the carotid pulse (5–10 seconds). If present, ventilate at a rate of once every 4 seconds or 15 times/min. If absent, begin cardiac compressions.	17. Performing chest compressions on a child with a pulse could result in injury. Additionally, the carotid pulse may persist when peripheral pulses are no longer palpable. Hyperventilation assists in maintaining blood oxygen levels. Additionally, a pulse may be present for 6 minutes after respirations have ceased.
18. Cardiac compressions (child 1–7 years): <ul style="list-style-type: none"> • Maintain a position on knees parallel to child’s sternum. • Position the hands for compressions: <ol style="list-style-type: none"> a. Locate the lower margin of the rib cage using the hand closest to the feet, and find the notch where the ribs and sternum meet. b. Place the middle finger of this hand on the notch, and then place the index finger next to the middle finger. c. Place the heel of the other hand next to the index finger of the first hand on the sternum with the heel parallel to the sternum (1 cm above the xiphoid process). d. Keeping the elbows locked and the shoulders over the child, compress the sternum 2.5–3.8 cm (1–1½ inches) at the approximate rate of 100 times/min. e. Keep the other hand on the child’s forehead. 	18. Irreversible brain and tissue damage can occur if a client is hypoxic for over 4–6 minutes. Proper positioning is essential for the following reasons: <ul style="list-style-type: none"> • Allows for maximum compression of the heart between the sternum and vertebrae. • The backward tilt of the head lifts the back of small children. • Compressions over the xiphoid process can lacerate the liver. • Keeping fingers off the chest during compressions reduces the risk of rib fracture. • Keeping one hand on the child’s forehead helps maintain an open airway.

(Continues)

PROCEDURE 32-6 Administering Cardiopulmonary Resuscitation (CPR) (Continued)

ACTION	RATIONALE
<p>f. Use a compression:ventilation ration of 30:2. Administer a ventilation of 1 second for each breath.</p> <p>g. Reevaluate the child after 20 cycles.</p> <p>h. According to the guideline published by the American Heart Association (2005), it is recommended that a 1-minute CPR be performed for infants and children up to age 8 before calling 911. In institutions, follow hospital protocol (American Heart Association, 2005).</p>	
CPR: ONE RESCUER—INFANT (1–12 MONTHS)	
<p>19. Assess responsiveness, activate EMS, position the child, apply appropriate body substance isolation, position self, open airway, and assess for respirations as described in Actions 1–7. Remember, respiratory arrest is more common in the pediatric population.</p>	<p>19. See Rationales 1–7.</p>
<p>20. If respirations are absent, begin rescue breathing:</p> <ul style="list-style-type: none"> • Avoid overextension of the infant’s neck. • Place a small towel or diaper under the infant’s shoulders, or use a hand to support the neck. • Make a tight seal over both the infant’s nose and mouth, and gently administer artificial respirations. • Give two slow breaths (1–1 1/2 sec/breath), pausing to take a breath in between. • Use only the amount of air needed to make the chest rise. 	<p>20. Irreversible brain and tissue damage can occur if a client is hypoxic for over 4–6 minutes. Proper positioning is essential for the following reasons:</p> <ul style="list-style-type: none"> • It is believed that overextension of an infant’s head can cause a closing or narrowing of the airway. • Proper positioning with support allows maximum compression of the heart between the sternum and vertebrae. • Making a complete seal over the infant’s mouth and nose prevents air leakage. • The volume of air in a small child’s lungs is less than an adult’s. Excessive air volume and rapid inspiratory rates can increase pharyngeal pressures that exceed esophageal opening pressures. This allows air to enter the stomach, causing gastric distention, increasing the risk of vomiting, and further compromising the client’s respiratory status.
<p>21. Assess circulatory status using the brachial pulse:</p> <ul style="list-style-type: none"> • Locate the brachial pulse on the inside of the upper arm between the elbow and shoulder by placing your thumb on the outside of the arm and palpating the proximal 	<p>21. The carotid pulse is often difficult to locate in the infant; therefore, the brachial artery is the recommended site.</p>

PROCEDURE 32-6 Administering Cardiopulmonary Resuscitation (CPR) (Continued)

ACTION	RATIONALE
<p>side of the arm with the index finger and middle fingers.</p> <ul style="list-style-type: none"> • If a pulse is palpated, continue rescue breathing 20 times/min or once every 3 seconds. • If a pulse is absent, begin cardiac compressions. <p>22. Cardiac compressions (infant 1–12 months):</p> <ul style="list-style-type: none"> • Maintain a position parallel to the infant. Infants can easily be placed on a table or other hard surface. • Place a small towel or other support under the infant’s shoulders and neck. • Position the hands for compressions: <ol style="list-style-type: none"> a. Using the hand closest to the infant’s feet, locate the intermammary line where it intersects the sternum. b. Place the index finger 1 cm below this location on the sternum, and place the middle finger next to the index finger. c. Using these two fingers, compress in a downward motion 1.3–2.5 cm (1/2–1 inch) at the rate of 100 times/min. d. Keep the other hand on the infant’s forehead. e. At the end of every fifth compression, administer a ventilation (1–1 1/2 seconds). f. Reevaluate infant after 20 cycles. g. According to the guideline published by the American Heart Association (2005), it is recommended that a 1-minute CPR be performed for infants and children up to age 8 before calling 911. In institutions, follow hospital protocol (American Heart Association, 2005). 	<p>22. Irreversible brain and tissue damage can occur if a client is hypoxic for over 4–6 minutes. Proper positioning is essential for the following reasons:</p> <ul style="list-style-type: none"> • Allows for maximum compression of the heart between the sternum and vertebrae. • A small towel, diaper roll, or some other type of support is necessary for effective cardiac compressions. • Compressions over the xiphoid process can lacerate the liver. • Keeping other fingers and hands off the chest during compressions reduces risk of rib fracture. • Keeping one hand on the infant’s forehead helps maintain an open airway.

CPR: TWO RESCUERS—CHILD (1–7 YEARS) AND INFANT (1–12 MONTHS)

- | | |
|--|--|
| <p>23. Follow Action 14 for two-rescuer CPR for adults with the following changes:</p> <ul style="list-style-type: none"> • Utilize the child or infant procedure for chest compressions. • Change the ratio of compressions to ventilation to 5:1 (5 chest compressions to 1 ventilation). • Deliver the ventilation on the upstroke of the third compression. | <p>23. Improper hand placement can cause internal organ damage or other medical complications in infants or children. Increased rate of ventilation allows for maximum oxygen delivery to prevent tissue hypoxia. Delivering compressions during the upstroke phase allows for full lung expansion during inspiration.</p> |
|--|--|

(Continues)

PROCEDURE 32-6 Administering Cardiopulmonary Resuscitation (CPR) (Continued)

CPR—NEONATE OR PREMATURE INFANT

24. Follow the infant guidelines with the following changes for chest compressions:
 - Encircle the chest with both hands.
 - Position thumbs over the midsternum.
 - Compress the midsternum with both thumbs.
 - Compress 1.3–1.8 cm (1/2–3/4 inch) at a rate of 100–120 times/min.
25. If properly trained, use an automated external defibrillator (AED). AEDs are not recommended for children under 8 years of age.

In hospital setting, use defibrillator as specified by institution protocol. Defibrillator should be placed only by properly trained personnel.
24. Improper hand placement can cause internal organ damage or other medical complications in infants or children.
25. The use of an AED can increase the client's chances for survival by restoring rhythm and circulation. AEDs have not been adequately tested in children, and excessive joules may cause injury.

Protocol in hospital settings includes the use of defibrillator with codes and can increase survival. Injury to self, staff, or the client may occur with untrained personnel.

delegation tip

The administration of CPR to adults and children is a skill that may be delegated to ancillary personnel and caregivers after proper instruction and CPR certification.

nursing tips

Maintain an ongoing assessment of the cardiac and respiratory status throughout emergency resuscitation efforts.

KEY CONCEPTS

- Adequate tissue oxygenation is essential to survival and may be threatened by deficits in air movement through the lungs to deliver fresh air to the alveoli (ventilation), the exchange of oxygen and carbon dioxide across the alveolar-capillary membrane (diffusion or external respiration), oxygen transport in the blood, the delivery of oxygen to the tissues (circulation), or the uptake of oxygen by the cells (internal respiration).
- Impairment of oxygen delivery to the tissues results first in compensatory efforts such as anaerobic metabolism and increased oxygen extraction; when these efforts fail, tissue ischemia and infarction will ensue.
- Client teaching related to oxygenation impairment involves teaching about the disease process, treatments, and lifestyle alterations that may be indicated; teaching should involve not only the client but also the family.
- Nursing care related to oxygenation focuses on maintaining a patent airway, promoting effective ventilation, promoting optimal circulation and perfusion, and meeting the client's learning, nutritional, activity, and sleep needs.
- A holistic approach to care recognizes that each of the problems experienced by the client with oxygenation deficits is interrelated.

- Emergency support of airway, ventilation, and circulation is achieved by instituting the Heimlich

maneuver for airway obstruction and cardiopulmonary resuscitation for cardiopulmonary arrest.

REVIEW QUESTIONS

1. Normal breath sounds heard over both lungs are described as being:
 - a. Loud
 - b. Intermediate
 - c. Soft
 - d. Adventitious
2. What is the classic sign of chronic hypoxia?
 - a. Cyanosis
 - b. Decreased level of consciousness
 - c. Clubbing of the fingers
 - d. Loss of appetite
3. The breath sound “fine crackle” is indicative of which condition?
 - a. Asthma
 - b. Bronchitis
 - c. Chronic obstructive pulmonary disease
 - d. Foreign body obstruction
4. Yellowish-green sputum is indicative of:
 - a. Asthma
 - b. Bacterial infection
 - c. Pneumonia
 - d. Pulmonary edema
5. Which client is most prone to problems while receiving oxygen?
 - a. Postoperative
 - b. Asthmatic
 - c. Myocardial infarction
 - d. Chronic pulmonary disease
6. Hydration should be restricted in clients experiencing:
 - a. Pneumonia
 - b. Bronchitis
 - c. Asthma
 - d. Congestive heart failure
7. Which indicates partial obstruction of the larynx or trachea and demands immediate attention?
 - a. Mediastinal crunch
 - b. Pleural rub
 - c. Rhonchi
 - d. Stridor
8. Which should the nurse include when suctioning a client’s tracheostomy?
 - a. Instill sterile saline down the trachea to stimulate cough, then suction with continuous suctioning.
 - b. Insert the catheter until a cough reflex is obtained or until resistance is felt.
 - c. Adjust the wall suction to 150 mm Hg for the procedure.
 - d. Suction the client’s mouth before entering the trachea.
9. Which nursing intervention may not be delegated to ancillary personnel?
 - a. Adjusting the rate of oxygen flow
 - b. Reapplying a nasal cannula
 - c. Providing comfort measures
 - d. Reporting a change in the client’s condition

“The most important practical lesson that can be given to nurses is to teach them what to observe—how to observe—what are of importance.”

—NIGHTINGALE (IN SKRETKOWICZ, 1992)

CHAPTER 33

Fluids and Electrolytes

COMPETENCIES

1. Review the physiological processes and core concepts relative to body fluid and acid-base balance and imbalances.
2. Relate the common disturbances in body fluid and acid-base balance to their clinical manifestations and nursing interventions.
3. Identify the key elements for assessing clients with body fluid and acid-base alterations.
4. Describe the nursing data that support the common nursing diagnoses and goals for clients with body fluid and acid-base disturbances.
5. Describe the common nursing interventions for clients with alterations in body fluid and acid-base balance.
6. Identify the key indicators to evaluate client achievement of expected outcomes to restore and to maintain body fluid and acid-base balance.

KEY TERMS

acid	homeostasis	infiltration
acid-base balance	hydrostatic pressure	intracath
acid-base buffer system	hypercalcemia	intravenous (IV) therapy
acidosis	hyperchloremia	isotonic
alkalosis	hyperkalemia	osmolality
angiocatheter	hypermagnesemia	osmolarity
arterial blood gases (ABGs)	hypernatremia	osmole
base	hyperphosphatemia	osmosis
butterfly (scalp vein or wing-tipped) needles	hypertonic	osmotic pressure
colloids	hypervolemia	permeability
crystalloids	hypocalcemia	phlebitis
cytomegalovirus (CMV)	hypochloremia	piggybacked
diffusion	hypokalemia	semipermeable
edema	hypomagnesemia	skin turgor
electrochemical gradient	hyponatremia	solute
electrolyte	hypophosphatemia	solvent
flashback	hypotonic	vesicant
flow rate	hypoxemia	
	implantable port	

The physiological functions and alterations of body fluid and acid-base balance are presented in this chapter. The term *body fluid* is used to denote both water and electrolytes, whereas the term *body water* refers to water alone. **Homeostasis**, or equilibrium of the internal environment, refers to the state of balance of body fluid.

PHYSIOLOGY OF FLUID AND ACID-BASE BALANCE

The body normally maintains a balance between the amount of fluid taken in and the amount excreted. Health promotion requires a maintenance of body fluid and acid-base balance.

FLUID COMPARTMENTS

The body's fluid is contained within three compartments: cells, blood vessels, and the tissue space (space between the cells and blood vessels). To understand this concept, visualize cars on a freeway. The cars represent cells; the lanes represent the blood vessels, and the space between the cars in the lanes represents the tissue space. The freeway itself is the body.

Just as traffic is ongoing and continuous, fluids move constantly from one compartment to another to accommodate the cell's metabolic needs (see Figure 33-1). Specific terms are used in describing compartmentalized body fluid. The prefixes (see the accompanying display) used with the root words for the compartments that contain the body fluid give meaning to the following terms:

- **Intracellular fluid:** *within* the cell
- **Intravascular fluid:** *within* blood vessels
- **Interstitial fluid:** *between* cells; fluid that surrounds cells

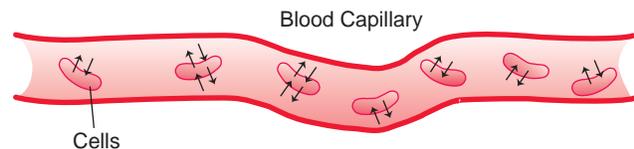

FIGURE 33-1 Movement of Fluid between the Intracellular and Extracellular Compartments DELMAR/CENGAGE LEARNING

There are two types of body fluid: intracellular fluid (ICF) and extracellular fluid (ECF). Because intravascular and interstitial fluids are outside the cells, these fluids are extracellular. Key terms used in explaining the movement of molecules in body fluids are:

- **Solute:** Substance dissolved in a solution
- **Solvent:** Liquid that contains a substance in solution
- **Permeability:** Capability of a substance, molecule, or ion to diffuse through a membrane (covering of tissue over a surface, organ, or separating spaces)
- **Semipermeable:** Selectively permeable (All membranes in the body allow some solutes to pass through the membrane without restriction but will prevent the passage of other solutes.)

PREFIXES

<i>Inter-</i>	Between
<i>Intra-</i>	Within
<i>Extra-</i>	Outside
<i>Hypo-</i>	Under, beneath, deficient
<i>Hyper-</i>	Above, beyond, excessive

Cells have permeable membranes that allow fluid and solutes to pass into and out of the cell. Permeability allows the cell to acquire the nutrients it needs from ECF to carry on metabolism and to eliminate metabolic waste products.

Blood vessels have permeable membranes that bathe and feed the cells. The intravascular fluid of arterioles carries oxygen and nutrients to the cells. The venules take in the waste products from the cells' metabolic activity.

Cells and capillaries form a meshlike structure that creates a tissue space between cells and the vascular system to allow cellular access to the vascular system. Interstitial space promotes access of the cells to the arterioles and venules.

BODY WATER DISTRIBUTION

Water is the largest single constituent of the body, representing 45% to 75% of the body's total weight. About two-thirds of the body fluid is intracellular. The remaining one-third is extracellular, with one-fourth of this fluid being intravascular and three-fourths being interstitial fluid. Bones are made up of nearly one-third water, while the muscles and brain cells contain 70% water. Body fat is essentially free of water; therefore, the ratio of water to body weight is greater in leaner people than in obese people.

Water is present in all body tissues and cells and serves two main functions: (1) to act as a solvent for the essential nutrients so that they can be used by the body and (2) to transport nutrients and oxygen from the blood to the cells and remove waste material and other substances from the cells back to the blood so they can be excreted by the body. Water is also needed by the body to:

- Give shape and form to the cells
- Regulate body temperature
- Act as a lubricant in joints
- Cushion body organs
- Maintain peak physical performance

Water loss has a negative effect on the body's ability to function because every 2% to 5% of water loss results in a 30% decrease in work performance (Tierra & Lust, 2008).

ELECTROLYTES

An **electrolyte** is a compound that when dissolved in water or another solvent, forms or dissociates into ions (electrically charged particles) (see Figure 33-2). The electrolytes provide inorganic chemicals for cellular reactions and control mechanisms. Electrolytes have special physiological functions in the body that promote neuromuscular irritability, maintain body fluid osmolarity, regulate acid-base balance, and distribute body fluids between the fluid compartments.

Electrolytes are measured in terms of their electrical combining power, the quantities of cations and anions in a solution, expressed as milliequivalents per liter (mEq/L). Because electrolytes produce either positively charged ions (cations) or negatively charged ions (anions), they are critical regulators in the distribution of body fluid. The main electrolytes in body fluid are sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), and magnesium (Mg^{2+}).

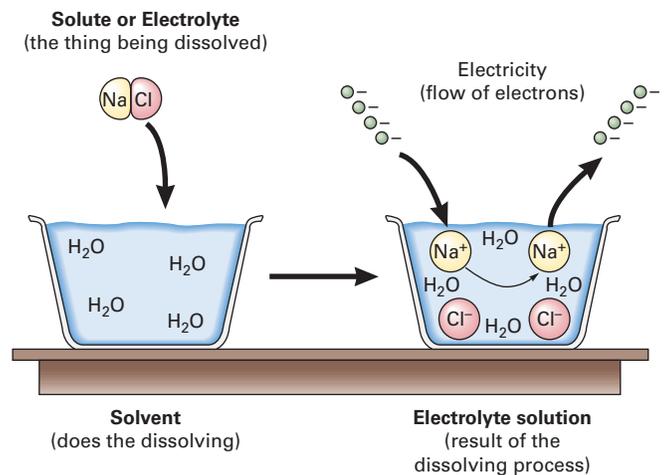

FIGURE 33-2 Dissolution of Electrolytes DELMAR/CENGAGE LEARNING

Table 33-1 on page 922 discusses the distribution of electrolytes in body fluid, their regulatory functions, and dietary sources. As shown in Table 33-1, the ECF contains the largest quantities of sodium, chloride, and bicarbonate ions, but only small quantities of potassium, calcium, magnesium, phosphate, sulfate, and organic acid ions. The ICF contains only small quantities of sodium and chloride ions and almost no calcium ions. Large quantities of potassium and phosphate ions with moderate quantities of magnesium and sulfate ions are contained within ICF (see Table 33-2 on page 923).

MOVEMENT OF BODY FLUIDS

The physiological forces that affect the movement of body fluids through cell walls and capillaries can be perceived as a mass transportation system that carries traffic between the compartments. These forces transport molecules of water, foods, gases, wastes, and ions to maintain a physiological balance between ECF and ICF volumes. These transport processes account for fluid shifts between the compartments (see Table 33-3 on page 924).

REGULATORS OF FLUID BALANCE

The body has many regulators that maintain fluid balance, including fluid and food intake, skin, lungs, gastrointestinal (GI) tract, and kidneys. When all organs are functioning normally, the body is able to maintain homeostasis.

Fluid and Food Intake and Loss

There are three natural sources by which water enters the body: oral liquids, water in foods, and water formed by oxidation of foods. A normal diet provides the electrolytes required by the body. For example, the typical daily amount of body fluid intake for an adult is:

Ingested liquids	1500 mL
Water in foods	700 mL
Water from oxidation	200 mL
TOTAL	2400 mL

TABLE 33-1 Common Electrolytes

ELECTROLYTE ION	DISTRIBUTION IN BODY FLUID		BASIC FUNCTIONS	DIETARY SOURCES
	EXTRACELLULAR (mEq/L)	INTRACELLULAR (mEq/L)		
Sodium (Na ⁺)	135–145	15–20	Regulates fluid volume within extracellular fluid (ECF) compartment. Increases cell membrane permeability. Regulates vascular osmotic pressure. Controls water distribution between ECF and intracellular fluid (ICF) compartments. Stimulates conduction of nerve impulses. Maintains neuromuscular irritability.	Table salt (NaCl), 40% of which is sodium; cheese, milk, processed meat, poultry, shellfish, fish, eggs, and foods preserved with salt (e.g., ham and bacon)
Potassium (K ⁺)	3.5–5	150–155	Regulates osmolality of ICF. Promotes transmission of nerve impulses. Promotes contraction of skeletal and smooth muscles. Promotes enzymatic action for cellular energy production by transforming carbohydrates into energy and restructuring amino acids into proteins. Regulates acid-base balance by cellular exchange of hydrogen ions.	Fruits, especially bananas, oranges, and dried fruits; vegetables, meats, and nuts
Calcium (Ca ²⁺)	4.5–5.5	1–2	Provides strength and durability to bones and teeth. Establishes thickness and strength of cell membranes. Promotes transmission of nerve impulses. Decreases neuromuscular excitability. Is essential for blood coagulation. Promotes absorption and utilization of vitamin B ₁₂ . Activates enzyme reactions and hormone secretions.	Dairy products (milk, cheese, and yogurt), sardines, whole grains, and green leafy vegetables
Magnesium (Mg ²⁺)	1.5–2.5	27–29	Activates enzyme systems, mainly those associated with vitamin B metabolism and the utilization of potassium, calcium, and protein. Promotes regulation of serum calcium, phosphorus, and potassium levels. Promotes neuromuscular activity.	Green leafy vegetables, whole grains, fish, and nuts

TABLE 33-2 Distribution of Chloride, Bicarbonate, Phosphate, and Sulfate in Body Fluid

ELECTROLYTE	EXTRACELLULAR INTRACELLULAR	
	(mEq/L)	(mEq/L)
Chloride (Cl ⁻)	98–106	1–4
Bicarbonate (HCO ₃ ⁻)	25–27	10–12
Phosphate (HPO ₄ ⁻)	1.7–4.6	100–104
Sulfate (SO ₄ ⁻)	1	2

Fischbach, F. (2008). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott Williams & Wilkins.

Body fluid is replenished by the ingestion of liquids and food products such as meats and vegetables, which contain 65% to 97% water. The third source of body fluid is the metabolism of foods, which yields water of oxidation. The kidneys excrete the largest quantity of fluid; other avenues for water loss are the lungs, skin, and GI tract.

Skin

An estimated water loss of 300 to 400 mL per day occurs by diffusion through the skin of an adult. Because the person is not aware of this water loss, it is called *insensible loss*. Water is also lost through the skin by perspiration; however, the total amount of water lost by perspiration can vary from 1.5 to 3.5 L per hour, depending on environmental factors and body temperature.

Lungs

An estimated insensible water loss of 300 to 400 mL per day occurs in an adult through expired air, which is saturated with water vapor. This amount may vary with the rate and depth of respirations.

Gastrointestinal Tract

Although a large amount of fluid—about 8000 mL per day in the adult—is secreted into the GI tract, almost all of this fluid is reabsorbed by the body. In adults, about 200 mL of water is lost per day in feces. Severe diarrhea can cause a fluid and electrolyte deficit because the GI fluids contain a large amount of electrolytes.

Kidneys

The kidneys play a major role in maintaining fluid balance by excreting 1200 to 1500 mL/day in the adult. The excretion of water by healthy kidneys is proportional to the fluid ingested and the amount of waste or solutes excreted.

When an ECF volume deficit occurs, hormones play a key role in restoring the ECF volume. The release of the

following hormones into circulation causes the kidneys to conserve water:

- Antidiuretic hormone (ADH) from the posterior pituitary gland acts on the distal tubules of the kidneys to reabsorb water.
- Aldosterone (produced in the adrenal cortex) causes the reabsorption of sodium from the renal tubules. The increased reabsorption of sodium causes water retention in the ECF, increasing its volume.
- Renin, which is released from the juxtaglomerular cells of the kidneys, promotes vasoconstriction and the release of aldosterone.

The interaction of these hormones with regard to renal functions serves as the body's compensatory mechanism to maintain homeostasis.

Sodium is the main electrolyte that promotes the retention of water. An intravascular water deficit causes the renal tubules to reabsorb more sodium into circulation. Because water molecules go with the sodium ions, the intravascular water deficit is corrected by this action of the renal tubules.

ACID-BASE BALANCE

Acid-base balance refers to the homeostasis of the hydrogen ion concentration in ECF. The slightest variation in the hydrogen ion concentration causes marked alterations in the rate of cellular chemical reactions. The pH symbol is used to indicate the hydrogen ion concentration of body fluids; 7.35 to 7.45 is the normal pH range of ECF. Hydrogen ions (H⁺), which carry a positive charge, are protons. Depending on the number of hydrogen ions present, a solution can be either acidic, neutral, or alkaline.

As the number of hydrogen ions increases, the fluid becomes acidic. *Acidity of a solution increases as the pH value decreases.* An **acid** is a substance that donates hydrogen ions. For example, hydrochloric acid (HCl) ionizes in water (a solution) to form hydrogen ions and chloride ions. HCl, which is found in gastric juices, has a strong tendency to form ions, discharging hydrogen ions into the solution; carbonic and acetic acids are considered weak acids because in a solution they provide a low concentration of hydrogen ions.

As the number of hydrogen ions decreases, the fluid becomes alkaline. *Alkalinity of a solution increases as the pH value increases.* A **base** is a substance that accepts hydrogen ions (proton acceptor).

A neutral solution has a pH of 7. In such a solution there are equal numbers of hydrogen ions (H⁺) and hydroxyl ions (OH⁻), which can combine to form water (H₂O). When the number of hydrogen ions is increased, the solution becomes acidic (pH value below 7); a decrease in the number of hydrogen ions causes the solution to become alkaline (pH value above 7). When the number of free hydrogen ions in a solution increases to the point that the pH value becomes less than 7.35, the body is in a state of **acidosis**. The opposite occurs with **alkalosis**, in which a pH value higher than 7.45 results from a low hydrogen ion concentration.

TABLE 33-3 Movement of Body Fluid

PHYSIOLOGICAL FORCE	PROCESS	RELATED FACTORS
<p>Diffusion Rate of diffusion (continual movement of molecules in a solution or a gas) is influenced by:</p> <ul style="list-style-type: none"> • Size of the molecule (smaller molecules diffuse faster than larger molecules) • Concentration of the molecules (molecules move from an area of greater concentration to an area of lesser concentration) • Temperature of the solution (higher temperatures increase the rate of diffusion) 	<p>Particles move across a permeable membrane and disperse in all directions through a solution or a gas (see Figure 33-3 on page 925).</p>	<p>Particle's electrical charge can also affect the process of diffusion because ions with opposite charges are pulled toward other ions.</p>
<p>Osmosis Process of osmosis, the passage of a solvent from an area of lesser concentration to an area of greater concentration, is influenced by:</p> <ul style="list-style-type: none"> • Net movement of water • Semipermeability of the membrane 	<p>Solvent molecules move across a membrane to an area where there is a higher concentration of solute that cannot pass through the membrane (see Figure 33-4 on page 925).</p>	<p>Osmotic pressure is the force created when two solutions of different concentrations are separated by a selectively permeable membrane. An osmole is the unit of measure of osmotic pressure.</p>
<p>Active transport An electrochemical gradient (sum of all the diffusion forces acting on the membrane, from either a concentration gradient or an electrical or a pressure gradient) exists when there is active transport.</p>	<p>Occurs when a cell membrane moves molecules or ions against an electrochemical gradient from an area of lesser concentration to an area of greater concentration.</p>	<p>For active transport to occur, there must be a carrier and adenosine triphosphate (ATP) molecules inside the cell membrane (see Figure 33-5 on page 925).</p>
<p>Hydrostatic pressure Hydrostatic pressure, the force a liquid exerts on the sides of the container that holds it, is governed by:</p> <ul style="list-style-type: none"> • Force by which the heart pumps • Rate of blood flow • Arterial blood pressure • Venous blood pressure 	<p>The force of fluid presses outward against the blood vessel wall.</p>	<p>Hydrostatic pressure is twice as great at the arterial end than at the venous end, causing fluid and solutes to go from the arterial end of the capillary into the interstitial space.</p>
<p>Filtration Filtration is governed by the presence of a greater hydrostatic pressure in the arterial end capillaries than in the interstitial spaces.</p>	<p>Movement of fluid through a semipermeable membrane from an area with higher hydrostatic pressure to an area with lower hydrostatic pressure creates an outward gain of fluid in the interstitial spaces.</p>	<p>The body achieves total fluid balance when the excess fluid and solutes remaining in the interstitial spaces are returned to the intravascular compartment by the lymphatic system.</p>
<p>Colloid osmotic pressure Created by solutes or colloids (proteins or nondiffusible substances) in the plasma</p>	<p>Movement of fluid between the intravascular and interstitial compartments, based on the number of solute particles on the concentrated side and the presence of a semipermeable membrane.</p>	<p>Because the protein content of intravascular fluid is 16 times as great as that of interstitial fluid, the fluids move into the capillary or intravascular compartment when the heart pumps effectively.</p>

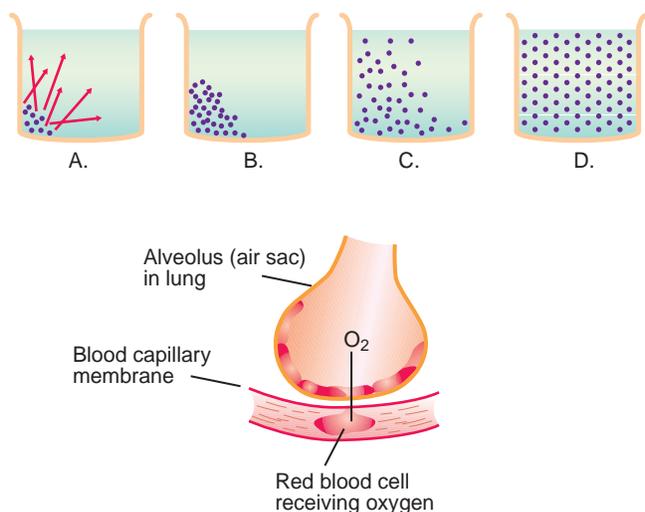

FIGURE 33-3 Process of diffusion. **A.** A small lump of sugar is placed in a beaker of water; its molecules dissolve and begin to diffuse outward. **B., C.** The sugar molecules continue to diffuse through the water from an area of greater concentration to an area of lesser concentration. **D.** Over a long period of time, the sugar molecules are evenly distributed throughout the water, reaching a state of equilibrium. Example of diffusion in the human body: Oxygen diffuses from an alveolus in a lung, where it is in greater concentration, across the capillary membrane, into a red blood cell, where it is in lesser concentration. DELMAR/CENGAGE LEARNING

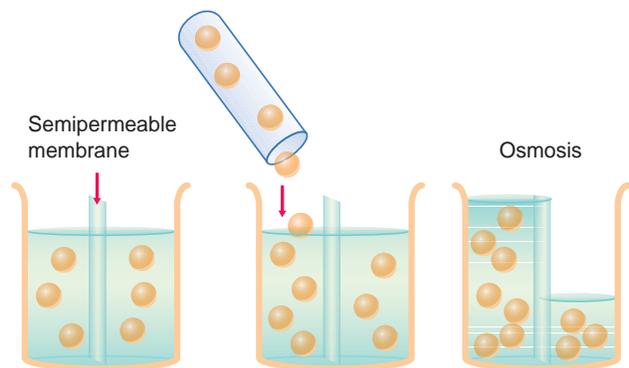

FIGURE 33-4 Process of Osmosis DELMAR/CENGAGE LEARNING

REGULATORS OF ACID-BASE BALANCE

The body has three main control systems that regulate acid-base balance to counter acidosis or alkalosis: the buffer systems, respiration, and renal control of hydrogen ion concentration. These systems vary in their reaction time in regulating and restoring balance to the hydrogen ion concentration of a solution.

Buffer Systems

All body fluids are supplied with an **acid-base buffer system**, a solution containing two or more chemical compounds that prevents marked changes in hydrogen ion concentration when either an acid or a base is added to a solution. The buffer system reacts within a fraction of a second to prevent excessive changes in the hydrogen ion concentration.

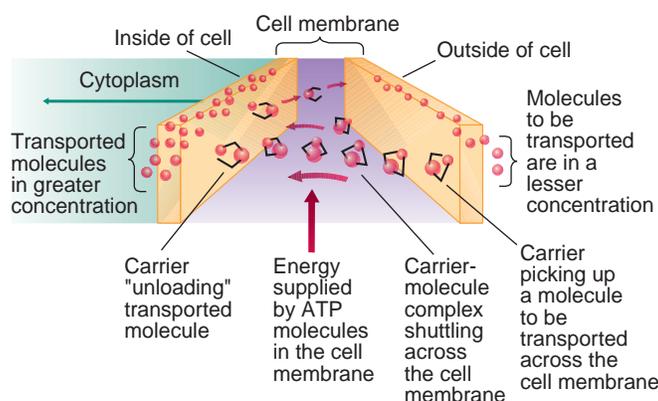

FIGURE 33-5 Active Transport of Molecules from an Area of Lesser Concentration to an Area of Greater Concentration

DELMAR/CENGAGE LEARNING

There are several *chemical* buffer systems of body fluids, which are activated under different conditions; however, the bicarbonate-carbonic acid system (carbonate system) is the body's primary buffer system. The carbonate system consists of a mixture of carbonic acid (H_2CO_3) and sodium bicarbonate (NaHCO_3). The pH of the ECF can be returned to normal limits by this system because carbonic acid is a weak acid, which ionizes to a limited extent, and bicarbonate is a weak base, which yields the hydroxyl ion.

Bicarbonate helps to stabilize pH by combining reversibly with hydrogen ions. Most of the body's bicarbonate is produced in red blood cells (RBCs), where the enzyme carbonic anhydrase accelerates the conversion of carbon dioxide to carbonic acid. The production of bicarbonate is illustrated in the following reversible equation:

When the hydrogen ion concentration increases in the extracellular space, the reaction shifts toward the left; a decreased concentration of hydrogen ion drives the reaction to the right.

Respiratory Regulation of Acid-Base Balance

The respiratory buffering system helps to maintain acid-base balance by controlling the content of carbon dioxide in ECF. The *rate of metabolism* determines the formation of carbon dioxide. Carbon dioxide is continually being formed in the body by different intracellular metabolic processes. The carbon in foods is oxidized by oxygen to form carbon dioxide.

It takes the respiratory regulatory mechanism several minutes to respond to changes in the carbon dioxide concentration of ECF. With the increase of carbon dioxide in ECFs, respirations are increased in rate and depth so that more carbon dioxide is exhaled. As the respiratory system removes carbon dioxide, there is less carbon dioxide in the blood to combine with water to form carbonic acid. Likewise, if the blood level of carbon dioxide is low, respirations are depressed to maintain a normal ratio between carbonic acid and basic bicarbonate.

Renal Control of Hydrogen Ion Concentration

The kidneys control ECF pH by eliminating either hydrogen ions or bicarbonate ions from body fluids. If the bicarbonate concentration in the ECF is greater than normal, the kidneys excrete more bicarbonate ions, making the urine more alkaline. Conversely, if more hydrogen ions are excreted in the urine, the urine becomes more acidic. The renal mechanism for regulating acid-base balance cannot readjust the pH within seconds, as can the ECF buffer system, nor within minutes, as can the respiratory compensatory mechanism, but it can function over a period of several hours or days to correct an acid-base imbalance.

FACTORS AFFECTING FLUID AND ELECTROLYTE BALANCE

The balance of fluids and electrolytes in the body is dependent on many factors and will vary with such elements as age and lifestyle.

AGE

Body water distribution is relative to body size. The smaller the body, the larger the fluid content:

- Adult, 60% water
- Child, 60%–77% water
- Infant, 77% water
- Embryo, 97% water

In older adults, body water diminishes because of tissue loss; the percentage of total body weight that is fluid may be reduced to 45% to 50% in persons over age 65. Caution must be used when administering diuretics, especially thiazide diuretics, to older adults to prevent diuretic-induced electrolyte disturbances.

LIFESTYLE

Loss of body fluids can result from stress, exercise, or a warm or humid environment. Stress leads to increased blood volume and decreased urine production, with a subsequent intensification of ADH levels. Sweating and exercise cause the body to lose water and sodium, thus necessitating electrolyte replacement and intensifying the thirst response. Warm climates can exert a similar effect.

An individual's diet will also determine fluid and electrolyte levels. Adequate intake of fluids, carbohydrates, potassium, calcium, sodium, fats, and protein is essential in helping the body maintain homeostasis and function properly. Dehydration is one of the most common yet most serious fluid imbalances that can occur from poor monitoring of diet. One nursing goal is to ensure that all clients understand the role water plays in health and to see that clients understand how to maintain adequate hydration status.

DISTURBANCES IN ELECTROLYTE AND ACID-BASE BALANCE

The clinical management of clients experiencing disturbances in sodium, potassium, calcium, magnesium, and phosphate is presented using the functional health pattern model. See Table 33-4 on page 927 for the causes, clinical manifestations, and nursing interventions for these electrolyte disturbances. Because chloride has several characteristics similar to other ions, a brief discussion of chloride imbalance is also presented. Acid-base imbalances caused by a disturbance in the level of either carbonic acid or bicarbonate are also presented using the functional health pattern model.

ELECTROLYTE DISTURBANCES

In health, normal homeostatic mechanisms function to maintain electrolyte and acid-base balance. In illness, one or more of the regulating mechanisms may be affected, or the imbalance may become too great for the body to correct without treatment. Refer to Chapter 28, Table 28-7, for the normal laboratory values of electrolytes.

Sodium

Sodium is the primary determinant of ECF concentration because of its high concentration and inability to cross the cell membrane easily. As discussed in Table 33-4, alterations in sodium concentration can produce profound central nervous system effects on cognition and sensory perception and on the circulating blood volume. When the kidneys reabsorb sodium ions, chloride and water are reabsorbed with the sodium to maintain the body's fluid volume.

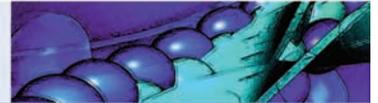

HYPONATREMIA *Hyponatremia* is a deficit in the extracellular level of sodium. With hyponatremia, there is either a sodium deficit or a water excess; a hypo-osmolar state exists because the ratio of water to sodium is too high. The water moves out of the vascular space into the interstitial space and then into the intracellular space, causing edema. The low extracellular serum sodium causes water to enter the cells in the brain, thereby producing cerebral edema as manifested by the cognitive and sensory changes listed in Table 33-4.

HYPERNATREMIA *Hypernatremia* is an excess in the extracellular level of sodium. With an excess of sodium or a loss of water, a hyperosmolar state exists because the ratio of sodium to water is too high. This ratio causes an increase in the extracellular osmotic pressure, which pulls fluid out of the cells into the extracellular space. The symptoms of this increase depend on the cause and the location of the edema (see Table 33-4).

Potassium

The normal range of extracellular potassium is narrow (3.5–5.0 mEq/L). The slightest decrease or increase can cause serious or life-threatening effects on physiological

Delmar/Cengage Learning		

functions. A reciprocal relationship exists between sodium and potassium; large sodium intake results in an increased loss of potassium, and vice versa. When potassium is lost from the cells, sodium enters the cells. An intracellular potassium deficit may coexist with an excess of extracellular potassium. There are two main categories of diuretics that can cause hypokalemia: potassium-wasting and potassium-sparing diuretics.

HYPOKALEMIA *Hypokalemia* is a decrease in the extracellular level of potassium. GI tract disturbances and the use of diuretics can place the client at risk for hypokalemia and

an acid-base imbalance (metabolic alkalosis). Potassium-wasting diuretics can cause hypokalemia. Besides diuretics, other major drug groups that can cause hypokalemia are laxatives, corticosteroids, and antibiotics.

HYPERKALEMIA *Hyperkalemia* is an increase in the extracellular level of potassium. There are major drug groups that may cause hyperkalemia:

- Potassium-sparing diuretics
- Central nervous system agents
- Oral and intravenous (IV) replacement potassium salts

Hyperkalemia can also inhibit the action of digitalis.

SAFETY FIRST

HYPOKALEMIA

Hypokalemia can cause a cardiac arrest when:

- The potassium level is less than 2.5 mEq/L.
- The client is taking digitalis (a drug that strengthens the contraction of the myocardium and slows down the rate of the heart). *Hypokalemia enhances the action of the drug, causing toxicity.*

Calcium

Most of the body's calcium (99%) is deposited in bone as phosphate and carbonate. The remaining 1% is in the blood plasma (serum). Normally, 50% of the serum calcium is ionized (physiologically active), with the remaining 50% bound to protein. Free, ionized calcium is needed for cell membrane permeability. The calcium that is bound to plasma protein cannot pass through the capillary wall and therefore cannot leave the intravascular compartment. Approximately 50% of the serum calcium level is bound to protein. Correlate the serum calcium level with the serum albumin level when evaluating the laboratory results. *Any change in serum protein will result in a change in the total serum calcium.*

A stable blood level of calcium is maintained by a negative-feedback system controlled by vitamin D, parathyroid hormone, calcitonin (thyrocalcitonin), and the serum concentrations of calcium and phosphate ions. A decreased blood level stimulates the parathyroid gland to secrete parathyroid hormone, which in turn mobilizes the release of calcium from the bone, increases renal reabsorption, and increases intestinal absorption in the presence of vitamin D. Likewise, calcitonin, secreted by the thyroid gland, reduces the blood calcium concentration.

Calcium ions are never completely absorbed from the GI tract. Dietary calcium absorption and utilization require an adequate amount of protein and vitamin D. Besides being needed by the body for bone and tooth formation, calcium is an important ion in the blood-clotting mechanism and for maintaining the integrity of the neuromuscular system.

HYPOCALCEMIA *Hypocalcemia* is a decrease in the extracellular level of calcium. The rapid administration of citrated blood, alkalosis, and elevated levels of serum albumin

increase the activity of calcium binders, thereby decreasing the amount of free calcium.

HYPERCALCEMIA *Hypercalcemia* is an increase in the extracellular level of calcium. The clinical symptoms result from a decrease in neuromuscular activity, reabsorption of calcium from bone, and the kidney's response to a high serum calcium concentration. A rapid increase in the extracellular level of calcium (above 8–9 mEq/L) can trigger a hypercalcemic crisis. To prevent a hypercalcemic crisis, provide adequate hydration and administer diuretics, phosphate, or both as prescribed by the prescribing practitioner.

Magnesium

Magnesium plays an important role as a coenzyme in the metabolism of carbohydrates and proteins and as a mediator in neuromuscular activity. Magnesium has the unique characteristic of being the only cation that has a higher concentration in cerebrospinal fluid than in ECF.

HYPOMAGNESEMIA *Hypomagnesemia* is a decrease in the extracellular level of magnesium and usually occurs with hypokalemia and hypocalcemia. It is probably the most undiagnosed electrolyte deficit because it is asymptomatic until the serum level approaches 1.0 mEq/L; the normal range is 1.5–2.5 mEq/L (Kee, Paulanka, & Polek, 2010).

Drugs that may cause hypomagnesemia include digitalis, potassium-wasting diuretics, cortisone, aminoglycosides, and amphotericin B; the chronic use of laxatives may also cause the condition. The continuous use of total parenteral nutrition (TPN, hyperalimentation) without a magnesium supplement can cause hypomagnesemia. Clinical manifestations are related to the neuromuscular, neurologic, or cardiovascular system (see Table 33-4).

HYPERMAGNESEMIA *Hypermagnesemia* refers to an increase in the extracellular level of magnesium. It rarely occurs from excessive dietary ingestion; however, overuse of magnesium-containing drugs (antacids, laxatives, and IV magnesium sulfate) can cause hypermagnesemia. The clinical manifestations of hypermagnesemia are nonspecific (see Table 33-4).

Phosphate

Phosphate is the main intracellular anion; it appears as phosphorus in the serum. Phosphorus is similar to calcium in that vitamin D is needed for its reabsorption from the renal tubules.

COMMUNITY CONSIDERATIONS

Intake of Phosphorus

When the dietary intake of calcium from milk is sufficient to meet minimal requirements, phosphorus needs will also be met. How will you educate clients who either cannot or will not consume an adequate daily intake of milk to meet their calcium and phosphorus needs?

SAFETY FIRST

POTASSIUM CHLORIDE

Never administer more than 10 mEq of intravenous potassium chloride (KCl) per hour; the normal dose of intravenous KCl is 20–40 mEq/L to infuse over an 8-hour period.

HYPOPHOSPHATEMIA *Hypophosphatemia* is a decreased extracellular level of phosphorus. An increase in parathyroid hormone causes decreased renal reabsorption and increased excretion of phosphates. The aim of nursing care is to protect the client from injury and to correct the deficit (see Table 33-4).

HYPERPHOSPHATEMIA *Hyperphosphatemia* is an increased extracellular level of phosphorus. Excessive administration (oral or IV) of phosphate-containing substances can cause hyperphosphatemia. Other causes of hyperphosphatemia are hypoparathyroidism, renal insufficiency, and laxatives containing phosphate.

Chloride

As previously stated, chloride and water move in the same direction as sodium ions, influencing the osmolality of ECF. Although chloride losses usually follow sodium losses, the proportion will differ because a loss of chloride can be compensated for by an increase in bicarbonate. Therefore, signs and symptoms of a chloride imbalance will be similar to those of a metabolic acid-base imbalance, discussed later in this chapter. A deficit of either chloride or potassium will lead to a deficiency of the other electrolyte.

HYPCHLOREMIA *Hypochloremia* is a decrease in the extracellular level of chloride. GI tract losses may cause a decrease in chloride because of the acid content of gastric juices, mainly hydrogen chloride. Because the bicarbonate ion compensates for the loss of chloride, the client is at risk for developing metabolic alkalosis. The signs and symptoms of hypochloremia are muscle twitching and slow, shallow breathing. With a severe loss of chloride and ECF volume, there may be a drop in blood pressure.

HYPERCHLOREMIA *Hyperchloremia* is an increase in the extracellular level of chloride. It usually occurs with dehydration, hypernatremia, and metabolic acidosis. The signs and symptoms of hyperchloremia are muscle weakness; deep, rapid breathing; and lethargy progressing to unconsciousness if untreated.

ACID-BASE DISTURBANCES

The common types of acid-base imbalances are respiratory acidosis and alkalosis and metabolic acidosis and alkalosis.

Laboratory Data

The biochemical indicators of acid-base imbalance are assessed by measurement of **arterial blood gases (ABGs)**. ABGs measure the levels of oxygen and carbon dioxide in arterial blood. The levels of blood pH, bicarbonate ion, sodium, potassium, and chloride are also important in the assessment of acid-base imbalance.

In the determination of whether the acid-base imbalance is caused by a respiratory or a metabolic alteration, the key indicators are bicarbonate and carbonic acid levels (see Figure 33-6).

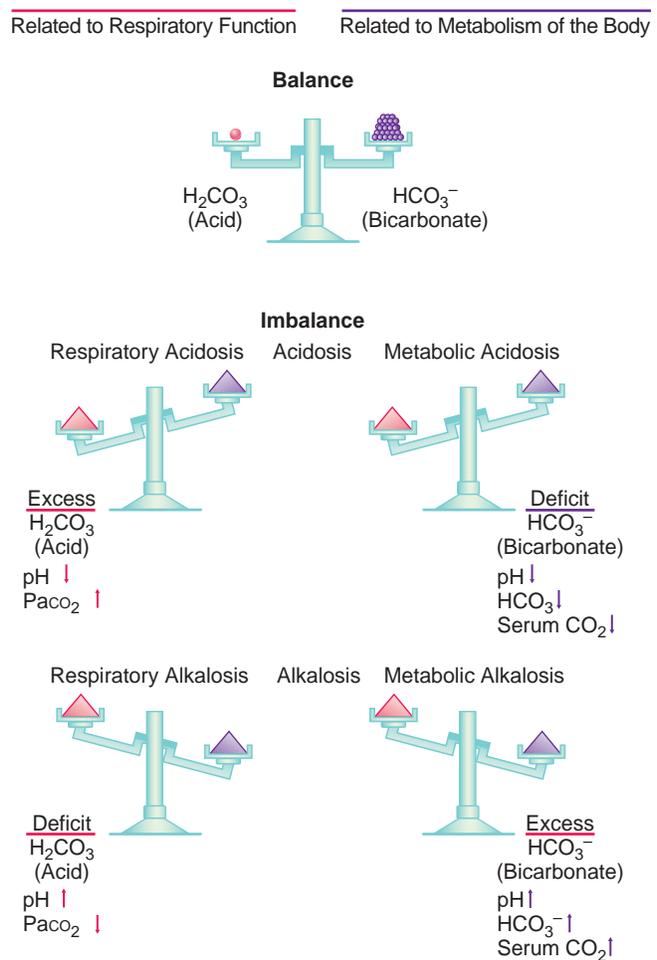

FIGURE 33-6 Acid-Base Balance and Imbalance. DELMAR/CENGAGE LEARNING

With respiratory acidosis and alkalosis, the bicarbonate level is normal and carbonic acid is either increased (acidosis) or decreased (alkalosis). With metabolic acidosis and alkalosis, the carbonic acid is normal and the bicarbonate level is either decreased (acidosis) or increased (alkalosis). Refer to Chapter 28 for a complete discussion of ABG analysis and to Chapter 32, Table 32-4, for normal values for ABGs.

Respiratory Acidosis (Carbonic Acid Excess)

Respiratory acidosis is characterized by an increased hydrogen ion concentration (a blood pH below 7.35), an increased arterial carbon dioxide pressure (greater than 45 mm Hg), and an excess of carbonic acid. Respiratory acidosis is caused by hypoventilation or any condition that depresses ventilation (see the accompanying display on common causes of respiratory acidosis on page 935).

Hypoventilation can begin in the respiratory system, as occurs with respiratory failure, or outside the respiratory system, as occurs with drug overdose. Common drugs that can cause central nervous system depression and place the client at risk for respiratory acidosis are narcotics, barbiturates, and anesthetic agents.

COMMON CAUSES OF ACUTE AND CHRONIC RESPIRATORY ACIDOSIS

Acute

Drug-induced CNS depression
Pneumonia and atelectasis
Pulmonary edema
Respiratory distress syndrome
Pneumothorax
Hypoventilation
Poliomyelitis
Chest trauma
Brain and spinal cord injury

Chronic

Asthma
Cystic fibrosis
Emphysema

Clients with respiratory acidosis experience neurologic changes resulting from the acidity of the cerebrospinal fluid and brain cells. Hypoventilation causes hypoxemia (decreased oxygen levels), which causes further neurologic impairments; refer to Chapter 32 for a complete discussion of **hypoxemia**. Hyperkalemia may accompany acidosis. See Table 33-5 on page 936 for the clinical manifestations and nursing interventions used to treat respiratory acidosis.

Respiratory Alkalosis (Carbonic Acid Deficit)

Respiratory alkalosis is characterized by a decreased hydrogen ion concentration (a blood pH above 7.45) and a decreased arterial carbon dioxide pressure (less than 35 mm Hg). Respiratory alkalosis is caused by hyperventilation (excessive exhalation of carbon dioxide) resulting in hypocapnia (decreased arterial carbon dioxide concentration). Hyperventilation can be triggered by hypoxia at high altitudes, anxiety, fear, pain, fever, and rapid mechanical ventilation. Other causes of hyperventilation, which involve overstimulation of the respiratory center, include salicylate poisoning, hyperthyroidism, pneumonia, atelectasis, asthma, adult respiratory distress syndrome, congestive heart failure, pulmonary edema and embolus, brain tumors, meningitis, and encephalitis; see Table 33-5 for the clinical manifestations and treatment.

Metabolic Acidosis (Bicarbonate Deficit)

Metabolic acidosis is characterized by a decrease in hydrogen ion concentration (blood pH below 7.35) or a decrease in bicarbonate concentration. Causes of metabolic acidosis can be divided into two categories: loss of base and gain in metabolic acids. Chronic diarrhea causes an excessive loss of bicarbonate and sodium ions from the small intestines. With the loss of sodium ions, chloride ions are in excess and combine with hydrogen to produce a strong acid (hydrochloric acid).

Clients with certain medical diagnoses are at risk for metabolic acidosis. Such conditions include:

1. Diabetic ketoacidosis: The cells are deprived of glucose (decrease or absence of insulin) for metabolism; the

liver, in response to the needs of the cells, increases the metabolism of fatty acids, which causes an increase in ketone bodies, making the ECF more acidic.

2. Renal failure: The normal mechanism of the kidneys to conserve sodium and water and excrete hydrogen is compromised.
3. Anaerobic metabolism: Cellular catabolism and acid accumulation occur with starvation, severe malnutrition, infection, fever, trauma, shock, and excessive exercise.
4. Drug overdose: Acid accumulation results from excessive ingestion of salicylate, paraldehyde, and methanol.

In response to metabolic acidosis, the respiratory center is stimulated, causing an increase in the rate and depth of respirations (Kussmaul breathing), to lower the acid concentration in ECF by increasing the exhalation of carbon dioxide. The respiratory compensatory mechanism is usually ineffective in decreasing acids, especially if the client has chronic obstructive pulmonary disease or is in ketoacidosis. Metabolic acidosis causes an electrolyte shift: Hydrogen and sodium ions move into the cell, and potassium moves into the ECF. Hyperkalemia may cause ventricular fibrillation and death. Refer to Chapter 32 for additional information on these diagnoses. The renal compensatory mechanism tries to increase the pH by exchanging sodium ions with hydrogen ions to increase the excretion of hydrogen; refer to Table 33-5 for the clinical manifestations and treatment of metabolic acidosis.

Metabolic Alkalosis (Bicarbonate Excess)

Metabolic alkalosis is characterized by an increased loss of acid from the body or a gain in base (increased levels of bicarbonate). The blood pH is above 7.45. A gain in base may result from excessive ingestion of antacids. These substances neutralize acids, producing alkalosis and hypercalcemia. The excessive oral or parenteral administration of sodium bicarbonate or other alkaline salts (e.g., sodium or potassium acetate, lactate, or citrate) increases the amount of base in ECFs.

The following clinical conditions can place clients at risk for metabolic alkalosis:

1. Vomiting and nasogastric suctioning or lavage cause a loss in hydrochloric acid and chloride; with the loss of the hydrogen and chloride ions, bicarbonate ions are absorbed, unneutralized, into the bloodstream and the pH of the ECF rises (alkalosis).
2. Diarrhea and steroid or diuretic therapy can cause excessive loss of potassium, chloride, and other electrolytes; the potassium deficit causes the kidneys to exchange hydrogen ions (instead of potassium ions) for sodium ions, which promotes the loss of hydrogen, thereby increasing bicarbonate level. Hydrochlorothiazide, a thiazide diuretic, blocks the reabsorption of sodium in the cortex in the distal tubule, causing sodium to be excreted in greater amounts than water (hyponatremia). Thiazides also cause hypokalemia because of the loss of urinary potassium. The secondary effects of thiazides lead to metabolic alkalosis because of a depletion in volume, chloride, potassium, and hydrogen ions (Smeltzer, Bare, Hinkle, & Cheevee, 2008).

Kee, J., Paulanka, B., & Polek, C. (2010). *Fluids and electrolytes with clinical applications: A programmed approach* (8th ed.). Clifton Park, NY: Delmar/Cengage Learning.

The respiratory and renal compensatory mechanisms respond to an increased bicarbonate–carbonic acid ratio. The rate and depth of respirations are decreased in an effort to retain carbon dioxide. The arterial carbon dioxide concentration rises, creating respiratory acidosis, to counter the pH imbalance of metabolic alkalosis.

A normal serum potassium level is a prerequisite to renal compensation. In alkalosis, potassium ions enter the cells in exchange for hydrogen ions, causing hypokalemia. Hypokalemia further potentiates metabolic alkalosis because the kidneys conserve hydrogen ions by excreting potassium ions in

exchange for sodium ions. When hypokalemia is present, the kidneys cannot function as a compensatory mechanism; therefore, they continue to excrete hydrogen, and bicarbonate excess continues. See Table 33-5 for the clinical manifestations and treatment of metabolic alkalosis.

ASSESSMENT

Assessment data are used to identify clients who have potential or actual alterations in fluid volume. Clients receiving certain treatments, such as medications and IV therapy, are at

risk for developing imbalances. The key nursing assessment indicators that identify imbalances are daily weights, vital signs, intake and output, and the physical findings of the skin, oral cavity, eyes, venous filling, and neuromuscular system.

HEALTH HISTORY

The nursing history should elicit data specific to fluids:

- Lifestyle (sociocultural and economic factors, stress, exercise)
- Dietary intake (recent changes in the amount and types of fluid and food, increased thirst)
- Religion (whether illness has had an effect on beliefs or religion; query whether the client would like a visit from a religious counselor)
- Weight (sudden gain or loss)
- Fluid output (recent changes in the frequency or amount of urine output)
- GI disturbances (prolonged vomiting, diarrhea, anorexia, ulcers, hemorrhage)
- Fever and diaphoresis
- Draining wounds, burns, trauma
- Disease conditions that could upset homeostasis (renal disease, endocrine disorders, neural malfunction, pulmonary disease)
- Therapeutic programs that can produce imbalances (special diets, medications, chemotherapy, administration of IV fluid or TPN, gastric or intestinal suction)

PHYSICAL EXAMINATION

The nurse performs a complete physical examination and identifies all abnormalities because fluid alterations may affect any body system. The physical assessment of clients with altered fluid status is discussed in this section. Refer to Chapter 26 for procedures on weight and vital sign measurement.

Daily Weight

Changes in the body's total fluid volume are indicated by weight; for instance, each kilogram (2.2 lb) of weight gained or lost is equivalent to 1 L (1000 mL) of fluid gained or lost. Accurate measurement of daily weight requires the nurse to implement the agency's protocol to control certain variables. For example, the nurse should obtain the measurement at the same time each day, using the same scale.

Vital Signs

Measurement of vital signs provides the nurse with information regarding the client's fluid, electrolyte, and acid-base status and the body's compensatory response for maintaining balance. An elevated temperature places the client at risk for dehydration caused by an increased loss of body fluid.

Changes in the pulse rate, strength, and rhythm are indicative of fluid alterations. Fluid volume alterations may cause the following pulse changes:

- Fluid volume deficit (FVD): increased pulse rate and weak pulse volume
- Fluid volume excess (FVE): increased pulse volume and third heart sound

Respiratory changes are assessed by inspecting the movement of the chest wall, counting the rate, and auscultating the lungs. Changes in the rate and depth may cause respiratory acid-base imbalances or may be indicative of a compensatory response in metabolic acidosis or alkalosis, as previously discussed in Table 33-5.

Blood pressure measurements can be used to assess the degree of FVD. FVD can lower the blood pressure with or without orthostatic hypotension. A narrow pulse pressure (less than 20 mm Hg) may indicate FVD that occurs with severe hypovolemia.

Intake and Output

Measure and record the client's intake and output for a 24-hour period to assess for an actual or potential imbalance. A minimum intake of 1500 mL is essential to balance urinary output and the body's insensible water loss. Intake includes all liquids (e.g., ice cream, soup, gelatin, juice, and water) taken by mouth and liquids administered through tube feedings (nasogastric or jejunostomy) and parenterally (IV fluids and blood or its components). Output includes urine, diarrhea, vomitus, and drainage from tubes such as through gastric suction. The recording of intake and output data is usually referred to as the I&O.

THIRST The most common indicator of FVD is thirst. With a decrease in ECF volume or an increase in the plasma osmolality, the hypothalamus triggers a thirst response. Older adults are prone to a FVD (dehydration) because the thirst mechanism in the medulla becomes less responsive with aging.

FOOD INTAKE The intake of food also contributes to maintaining ECF volume. One-third of the body's fluid needs are met by ingested food. Food also provides the body with necessary electrolytes. See Chapter 34 for a complete discussion of metabolism.

Edema

Edema, the detectable accumulation of increased interstitial fluid, is the main symptom of FVE. Edema may be localized (confined to a specific area) or generalized (occurring throughout the body's tissue). Localized edema is characterized by taut, smooth, shiny, pale skin. The body may retain 5 to 10 lb of fluid before edema is noticeable. Inspect the dependent body parts—sacrum, back, and legs—to assess peripheral edema. Pitting edema is rated on a 4-point scale:

- +0, no pitting
- +1, 0''–1/4'' pitting (mild)
- +2, 1/4''–1/2'' pitting (moderate)
- +3, 1/2''–1'' pitting (severe)
- +4, greater than 1'' pitting (severe)

Skin Turgor

Skin turgor is the normal resiliency of the skin. When the skin is pinched and released, it springs back to a normal position because of the outward pressure exerted by the cells and interstitial fluid. To measure the client's skin turgor, grasp and raise the skin with two fingers as follows:

- Adults: over the sternum, forehead, or inner aspect of the thigh. With aging, there are fewer elastic fibers in the skin, resulting in reduced skin turgor. Assess the tongue for creases or furrows to monitor dehydration in older adults.
- Children: over the abdominal area or medial aspect of the thigh.

With dehydration there is a decreased skin turgor, as manifested by lax skin that returns slowly to the normal position. Increased skin turgor, which occurs with edema, is manifested by smooth, taut, shiny skin that cannot be grasped and raised.

Buccal (Oral) Cavity

Inspect the buccal cavity. With FVD, there is a decrease in saliva, which causes sticky, dry mucous membranes and dry cracked lips. The tongue has longitudinal furrows.

Eyes

Inspect the eyes. FVD causes sunken eyes, dry conjunctiva, and decreased or absent tearing. Puffy eyelids (periorbital edema, or papilledema) are characteristic of FVE; the client may also have a history of blurred vision.

Jugular and Hand Veins

Circulatory volume is assessed by measuring venous filling of the jugular and hand veins. Place the client in a low Fowler's position. Then:

1. Palpate the jugular (neck) veins: FVE causes a distention in the jugular veins (see Figure 33-7).
2. Place the client's hand below the heart level, and palpate the jugular veins; with FVD there is decreased venous filling (flat neck veins).

FIGURE 33-7 Positioning the Client to Assess Jugular Vein Distention DELMAR/CENGAGE LEARNING

Neuromuscular System

Fluid and electrolyte imbalances may cause neuromuscular alterations: The muscles lose their tone and become soft and underdeveloped, and reflexes are diminished. Calcium and magnesium imbalances cause an increase in neuromuscular irritability. To assess for neuromuscular irritability, perform the following tests:

1. Chvostek's sign: Tap the facial nerve 2 cm anterior to the earlobe; unilateral twitching of the facial muscles (inclusive of the eyelids and lips) indicates a positive response (see Figure 33-8).
2. Trousseau's sign: Place a blood pressure cuff on the arm, inflate the cuff slightly above the systolic pressure, leave the cuff inflated 2–3 minutes, and deflate; carpal spasm or tetany indicates a positive response.

A positive Chvostek's sign and Trousseau's sign may occur with hypocalcemia and hypomagnesemia.

Other neurologic signs include inability to concentrate, confusion, and emotional lability, as previously discussed in Tables 5-4 and 5-5.

DIAGNOSTIC AND LABORATORY DATA

Biochemical assessment is another essential source of objective data. Laboratory results can be used to detect imbalances before clinical symptoms are assessed in the physical examination. Laboratory tests used in assessing clients with common alterations in ECF volume are discussed next; refer to Chapter 28 for the normal values presented in this section.

Hemoglobin and Hematocrit Indices

The hematocrit is affected by changes in plasma volume. For instance, with severe dehydration and hypovolemic shock,

FIGURE 33-8 Assessing for Chvostek's Sign DELMAR/CENGAGE LEARNING

the hematocrit is increased, whereas overhydration decreases the hematocrit. Hemoglobin levels are decreased with severe hemorrhage.

Osmolality

Osmolality is a measurement of the total concentration of dissolved particles (solutes) per kilogram of water. Osmolality measurements are performed on both serum and urine samples to determine alterations in fluid and electrolyte balance. Osmolality can also be explained in relation to the specific gravity of body fluids. Specific gravity expresses the weight of the solution when compared with an equal volume of distilled water; the osmolality of a solution can be estimated by the specific gravity.

SERUM OSMOLALITY Serum osmolality is a measurement of the total concentration of dissolved particles per kilogram of water in serum, recorded in milliosmoles per kilogram (mOsm/kg). The particles measured in serum osmolality include electrolyte ions, such as sodium and potassium, and electrically inactive substances dissolved in serum, such as glucose and urea. Water and sodium are the main entities that control the osmolality of body fluids. Serum sodium is responsible for 85% to 90% of the serum osmolality.

The normal serum osmolality is 275 to 295 mOsm/kg (Fischbach, 2008). It can increase with dehydration and loss of body water and decrease with water excess.

In clinical practice, the terms *osmolality* and **osmolarity**, the concentration of solutes per liter of cellular fluid, are often used interchangeably to refer to the concentration of body fluid. However, these terms are actually different: Osmolality refers to the concentration of solutes in the total body water (solutes per kilogram of body weight) rather than in cellular fluid. Figure 33-9 relates osmosis to the osmolality of a solution. The appropriate term to use in IV fluid therapy is *osmolarity* (Smeltzer et al., 2008). An osmolar solution is described as:

- **Hypotonic** (hypo-osmolar) when there are fewer solutes in proportion to the volume of water than is the case in the body
- **Isotonic** (iso-osmolar) when body water and solutes (sodium) are in amounts equal to those in the body
- **Hypertonic** (hyperosmolar) when there are more solutes in proportion to the volume of water than is the case in the body

URINE OSMOLALITY Urine osmolality is a measurement of the total concentration of dissolved particles per kilogram of water in urine, recorded in milliosmoles per kilogram (mOsm/kg). The particles measured in urine osmolality come from nitrogenous waste (creatinine, urea, and uric acid), with urea contributing most. Urine osmolality is a more accurate indicator of hydration than is the specific gravity of urine. Urine osmolality varies greatly with diet and fluid intake and reflects the ability of the kidneys to adjust the concentration of urine in order to maintain fluid balance. Some medications and the presence of protein and glucose

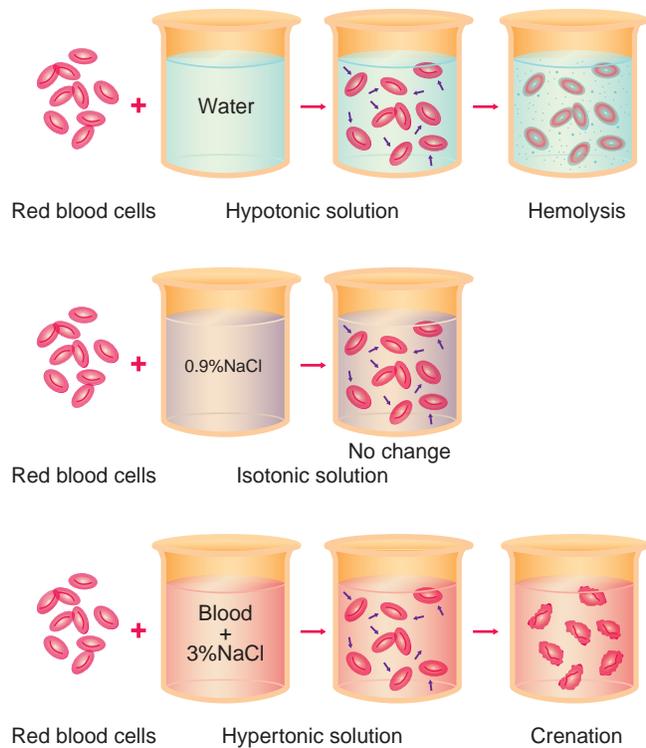

FIGURE 33-9 Osmosis as it relates to the osmolality of a solution. The movement of water through a membrane from a lower concentration to a higher concentration is called osmosis. In a hypotonic solution, the water moves into the cells, causing them to swell and burst. The cells in the isotonic solution are normal in size and shape because the same amount of water is entering and leaving the cells. Cells in the hypertonic solution are losing water because water moves from a weaker concentration inside the cell to a greater concentration outside the cell membrane.

DELMAR/CENGAGE LEARNING

solutes in the urine can give a false high specific gravity reading. With normal kidney function, a dehydrated client will have an elevated urine osmolality, whereas clients with shock, hyperglycemia, hemoconcentration, and acidosis will have elevations in both urine and serum osmolality.

Urine pH

The measurement of the pH of urine reveals the hydrogen ion concentration of the urine to determine its acid or alkaline status. When the kidney buffering system is compensating for either metabolic acidosis or alkalosis, the pH of the urine should be within normal range (4.6–8.0). This is considered a sign of normal function. However, when the renal compensatory function fails to respond to the pH of the blood, the urine pH will increase with acidosis and decrease in alkalosis.

Serum Albumin

Albumin is synthesized in the liver from amino acids. Serum albumin plays an important role in fluid and electrolyte balance by maintaining the colloid osmotic pressure of blood, which prevents the accumulation of fluid (edema) in the tissues. However, serum albumin has a half-life of 21 days and fluctuates according to the level of hydration; therefore, it is

not a good indicator of acute alterations in protein depletion. Clinically, this blood test is used to measure prolonged protein depletion, which occurs in chronic malnutrition. Refer to Chapter 34 for a discussion of serum albumin and prealbumin.

NURSING DIAGNOSIS

“Fluid volume, pressure, and levels of sodium and albumin are keys to maintaining fluid balances between the intracellular and extracellular (intravascular and interstitial) spaces. Capillary permeability and the lymphatic system also play a role” (Holcomb, 2008, p. 50). In order to make a nursing diagnosis, the nurse must be able to interpret assessment and biochemical data and draw conclusions relative to the client’s imbalance. The primary nursing diagnoses for clients with fluid imbalances are presented in the accompanying display on nursing diagnoses for fluid alterations.

EXCESS FLUID VOLUME

Excess fluid volume (EFV) exists when the client has increased interstitial and intravascular fluid retention and edema. EFV is related to the excess fluid either in tissues of the extremities (peripheral edema) or in lung tissues (pulmonary edema). Factors that put the client at risk for EFV are:

- Excessive intake of fluids (e.g., IV therapy, sodium)
- Increased loss or decreased intake of protein (chronic diarrhea, burns, kidney disease, malnutrition)
- Compromised regulatory mechanisms (kidney failure)
- Decreased intravascular movement (impaired myocardial contractility)
- Lymphatic obstruction (cancer, surgical removal of lymph nodes, obesity)
- Medications (steroid excess)
- Allergic reaction

Assessment findings in the client with FVE include acute weight gain; decreased serum osmolality (less than 275 mOsm/kg), protein and albumin, blood urea nitrogen (BUN), hemoglobin (hgb), and hematocrit (HCT); increased central venous pressure (greater than 12–15 cm H₂O); and signs and symptoms of edema. The clinical manifestations of edema are relative to the area of involvement, either pulmonary or peripheral (see the accompanying display on clinical manifestations of edema).

CLINICAL MANIFESTATIONS OF EDEMA

Pulmonary Edema

Constant cough
Dyspnea
Engorged neck and hand veins
Moist crackles in lungs
Bounding pulse

Peripheral Edema

Pitting edema in extremities
Edematous area: tight, smooth, shiny, pale, cool skin
Puffy eyelids
Weight gain

DEFICIENT FLUID VOLUME

Deficient fluid volume (DFV) exists when the client experiences vascular, interstitial, or intracellular dehydration. The degree of dehydration is classified as mild, marked, severe, or fatal on the basis of the percentage of body weight lost. There are three types of dehydration based on the proportion of fluid and particles in the intracellular and extracellular spaces:

- *Isotonic dehydration* (hypovolemia) refers to the loss of both fluid and particles in the vascular space that occurs with vomiting, diarrhea, and bleeding; it is the most common form of dehydration, especially in infants and children.
- *Hypertonic dehydration* refers to a greater loss of fluid than particles in the vascular space when the body tries to maintain a normalized isotonic state by pulling fluids from the intracellular space into the vascular space; it occurs in diabetic ketoacidosis, renal insufficiency, and the administration of hypertonic solutions.
- *Hypotonic dehydration* refers to a greater loss of particles than fluid in the vascular space when the body tries to maintain a normal isotonic state by pushing fluids from the vascular space into the intracellular space, causing the cells to swell; it occurs in chronic disease states and with the administration of hypotonic solutions.

Assessment findings in the client with DFV include thirst and weight loss, with the amount varying with the degree of dehydration. With marked dehydration, the mucous membranes and skin are dry. There is poor skin turgor; low-grade temperature elevation; tachycardia; respirations 28 or greater; a decrease (10–15 mm Hg) in systolic blood pressure; slowing in venous filling; a decrease in urine (less than 25 mL per hour); concentrated urine; elevated HCT, hgb, and BUN; and an acid blood pH (less than 7.4).

Severe dehydration is characterized by the symptoms of marked dehydration. Also, the skin becomes flushed. The systolic blood pressure continues to drop (60 mm Hg or below). There are behavioral changes (restlessness, irritability, disorientation, and delirium). The signs of fatal dehydration are anuria and coma that leads to death.

RISK FOR DEFICIENT FLUID VOLUME

Risk for FVD exists when the client is at high risk of developing vascular, interstitial, or intracellular dehydration resulting from active or regulatory losses of body water in excess of needs. Clients who lose excessive amounts of gastric juices, either through vomiting or suctioning, are prone to develop not only DFV but also metabolic alkalosis, hypokalemia, and hyponatremia; gastric juices contain hydrochloric acid, pepsinogen, potassium, and sodium. The multiple factors that can place the client at risk for FVD are listed in the preceding accompanying display, Nursing Diagnoses for Fluid Alterations.

OTHER NURSING DIAGNOSES

The relationship between the primary nursing diagnoses just discussed and the secondary diagnoses in clients with fluid

NURSING DIAGNOSES FOR FLUID ALTERATIONS

Excess Fluid Volume Related to:

- Excessive fluid intake secondary to excess sodium intake
- Compromised regulatory mechanism (renal and cardiac dysfunction)
- Inaccurate intravenous infusion rate

Deficient Fluid Volume Related to:

- Excessive fluid loss secondary to vomiting, blood loss, surgical drains and tubes, diarrhea, and diuretics

Risk for Deficient Fluid Volume Related to:

- Extremes of age (very young or old) and weight
- NPO and fluid restrictions
- Increased fluid output from normal routes: vomiting, diarrhea, urine
- Increased fluid losses from drainage or suction routes: wounds, drains, indwelling tubes (e.g., urine catheter, nasogastric suction)
- Loss of plasma associated with severe trauma and burns
- Disorders that impair fluid intake or absorption (immobility, unconsciousness)
- Chronic disorders: congestive heart failure, pulmonary edema, chronic obstructive lung disease, renal failure, diabetes, cancer, transplant candidates
- Deficient knowledge related to factors influencing fluid requirements (hypermetabolic states, hyperthermia, and dry, hot environment)
- Medications (e.g., diuretics)

imbalances is reciprocal: The primary diagnoses influence and are influenced by the secondary diagnoses. Holistic nursing requires that all diagnoses relative to a client be considered when developing a client's plan of care.

Impaired Gas Exchange

Impaired gas exchange related to a ventilation perfusion imbalance occurs when clients experience a decreased passage of oxygen or carbon dioxide between the alveoli of the lungs and the vascular system. This alteration is assessed by measuring the oxygen and carbon dioxide content through ABG analysis, pulse oximetry, or both. Refer to Chapter 32 for further discussion of oxygenation.

Decreased Cardiac Output

Decreased cardiac output occurs when the blood pumped by a client's heart is reduced so much that it is inadequate to meet the needs of the body's tissue. This alteration may be caused by heart failure and various types of shock. Assessment findings may include low blood pressure; cool, clammy skin; weak, thready pulses; decreased urinary output; and a diminished level of consciousness.

Risk for Infection

Many disorders may place the client at risk for invasion by pathogenic organisms. Clients receiving IV therapy are at risk for an infection because their primary defense, the skin, is broken at the puncture site. Assessment findings indicative of IV site infection are client complaints of soreness around the site, erythema, swelling at the site, and foul-smelling discharge.

Impaired Oral Mucous Membrane

Altered oral mucous membrane occurs when a client experiences disruption in the tissue layers of the oral cavity. It is frequently related to dehydration. Assessment findings may include oral pain or discomfort, stomatitis, and decreased salivation.

Deficient Knowledge

A knowledge deficit may exist to varying degrees in clients with fluid imbalances. Information obtained from a client's health history may indicate the client's level of understanding and perception of these alterations and direct teaching. Clients need to participate actively in their plans of care.

PLANNING AND OUTCOMES

Holistic nursing care for clients experiencing fluid imbalances requires that the nurse, in collaboration with each client, identify specific goals for the nursing diagnosis. These goals should be individualized to reflect the client's capabilities and limitations and should be appropriate to the diagnosis as determined by the assessment data.

The *Nursing Outcomes Classification* (NOC) (Moorhead, Johnson, Swanson, & Maas, 2008) has five outcome classifications in the physiologic health (II) domain regarding fluid and electrolytes:

1. Nutritional Status: Food and Fluid Intake (1008). The rating scale is from not adequate to totally adequate, and the indicators that monitor food and fluid intake (oral, tube feeding, infusions) (p. 413).
2. Electrolyte and Acid/Base Balance (0600). The rating scale is from severely compromised to not compromised, and the indicators that monitor vital signs; serum electrolytes, urine pH, and specific gravity; and cognitive and neuromuscular response (p. 265).
3. Fluid Balance (0601). The rating scale is from severely compromised to not compromised, and the indicators that monitor I&O, weight, pressures, pulses, and serum electrolytes (p. 295).

4. Fluid Overload Severity (0603). The rating scale is from severe to none, and the indicators that monitor for edema, increased blood pressure and weight, and changes in cognition function and serum sodium (p. 297).
5. Hydration (0602). The rating scale is from severely compromised to not compromised, and the indicators that monitor adequate fluid intake, skin turgor, moist mucous membranes, output, serum sodium, and cognitive function (p. 314).

During the planning phase, the nurse also selects and prioritizes nursing interventions to support the client's achievement of expected outcomes based on the goals. For example, if vomiting and diarrhea, with a weight loss of 5% and dry mucous membranes, led to a diagnosis of *Deficient fluid volume*, then goals might include relief from vomiting and diarrhea and achievement of the proper fluid balance of I&O.

COLLABORATION

Infusion therapy in the hospital and other health care facilities usually follows the same format. The prescribing practitioner orders the solution or drug, the pharmacy compounds and dispenses it, and nurses administer it. However, home infusion therapy requires collaborative efforts between pharmacy services and nursing services because many of the responsibilities are shared jointly between pharmacy and nursing. Registered nurses in the home setting administer a wide variety of therapies such as chemotherapy, antibiotics, pain management, and hydration. Oseland and Querciagrossa (2003) address the need for effective communication between pharmacy and nursing and identify the overlapping responsibilities of pharmacy and nursing (see the accompanying display on home infusion therapy).

IMPLEMENTATION

Nurses have the responsibility to collaborate with and advocate for clients to ensure that they receive care that is appropriate, ethical, and based on practice standards. Nurses rely heavily on the data obtained from the history in formulating expected outcomes and selecting appropriate nursing interventions to support the clients' natural patterns as revealed in their histories.

The rationale for interventions related to alterations in either body fluid or electrolytes is based on the goal of maintaining homeostasis and regulating and maintaining essential fluids and nutrients. The nurse capitalizes on clients' adaptive capabilities by selecting interventions based on clients' perceptions of their support, strengths, and options.

The *Nursing Interventions Classification* (NIC) (Bulechek, Butcher, & Dochterman, 2008) has classifications that address three major categories (i.e., Acid-Base Management, Electrolyte Management, and Fluid Management) and a specific classification for the management of each type of alteration (e.g., metabolic acidosis, hypokalemia, hypervolemia). Although the nursing activities are specific for each intervention set, most of these interventions contain the activities of

HOME INFUSION THERAPY

Overlapping Responsibilities of Pharmacy and Nursing

- Interdisciplinary communication
- Review of medical record
- Nutritional assessment
- Assessment of medication history
- Developing a plan of care
- Review of lab data
- Monitoring therapeutic response
- Supply management
- 24-hour on-call support
- Prescribing practitioner follow-up

Oseland, S., & Querciagrossa, A. (2003). Collaboration of nursing and pharmacy in home infusion therapy. *Home Healthcare Nurse, 21*(12), 819.

monitoring daily weight, measuring vital signs and I&O, and maintaining patent IV access. The nursing activities relative to assessment and implementation, for example, often require weight and vital sign measurements. Common interventions that promote attainment of expected outcomes to restore and maintain homeostasis are discussed next.

MONITOR DAILY WEIGHT

Daily weight is one of the main indicators of water and electrolyte balance. The nurse is responsible for the accurate measurement and recording of daily weights; the prescribing practitioner uses these data with other clinical findings in determining the client's fluid therapy.

MEASURE VITAL SIGNS

The frequency of measuring the vital signs is dependent upon the client's acuity level and clinical situation. For example, the vital signs of the typical postoperative client might be taken every 15 minutes until stable, whereas a client experiencing shock or hemorrhage should have vital signs monitored continuously. Vital sign measurements and other clinical data are used to determine the type and amount of fluid therapy.

MEASURE INTAKE AND OUTPUT

I&O measurements are initiated to monitor the client's fluid status over a 24-hour period (see Procedure 33-1 for information on how to measure the I&O). Agency policy relative to I&O may vary with regard to:

- The time frames for charting (e.g., every 8 hours versus every 12 hours)
- The time at which the 24-hour totals are calculated
- The definition of "strict" I&O

APPLICATION: HOME CARE**Considerations for Measuring I&O in the Home Care Environment**

- Elicit client and family member input when selecting household items to be used for intake measurement.
- Provide containers for measuring output; adapt the urinary container to home facilities, and include teaching relative to proper washing and storage.
- Teach handwashing technique.
- Provide written instructions on what is to be measured.
- Provide sufficient I&O forms to last between the nurse's visits.
- Identify the parameters for evaluating a discrepancy between the I&O and for notifying the nurse or prescribing practitioner.

Strict I&O measurement usually involves accounting for incontinent urine, emesis, and diaphoresis and might require weighing soiled bed linens. *Don gloves before handling soiled linen.*

The nurse reviews the client's 24-hour I&O calculations to evaluate fluid status. Intake should exceed the output by 500 mL to account for insensible body losses. I&O and daily weights are critical components of intervention because these measurements are also used to evaluate the effectiveness of diuretic or rehydration therapy. Remove gloves and perform hand hygiene before recording the amount of drainage on the I&O form to prevent the transfer of microorganisms when the form is removed from the client's room.

Securing an accurate I&O requires the full support of the client and the client's family. The client and family members should be taught how to measure and record the I&O (see the accompanying Application display for special home health care considerations).

PROVIDE ORAL HYGIENE

The nurse is responsible for providing oral hygiene to promote client comfort and integrity of the buccal cavity. Refer to Chapter 29 for the procedure on oral hygiene. The frequency of oral hygiene depends on the condition of the client's buccal cavity and the type of fluid imbalance. A client who is dehydrated or NPO for more than 24 hours may have decreased or absent salivation, coated tongue, and furrows on the tongue. These clients are at risk for developing oral diseases such as stomatitis, oral lesions or ulcers, and gingivitis. Avoid the use of alcohol and glycerin mouthwashes and glycerin swabs. These ingredients may feel refreshing, but they have a drying effect on the mucous membranes.

**SPOTLIGHT ON...****Oral Hygiene**

When you wake up in the morning, do you drink or eat anything before brushing your teeth? If you were sick, hospitalized, and without family or significant other support, would you want to drink or eat if your mouth tasted sour? Many of your clients will feel the same way and will need supportive nursing care to maintain oral hygiene. Muscular weakness and difficulty swallowing are other problems that could compound the client's dependency on you for oral hygiene.

INITIATE ORAL FLUID THERAPY

Oral fluids may be totally restricted—a situation commonly referred to as *nothing by mouth* (NPO, which is from the Latin *non per os*)—or they may be restricted or forced, depending on the client's clinical situation. For example, oral replacement therapy is often used for clients with mild dehydration. According to Hockenberry and Wong (2007), oral rehydration therapy has a very high success rate in the treatment of childhood diarrhea with mild to moderate dehydration, and it has fewer complications when compared to IV replacement therapy. Severe dehydration in children is a medical emergency and must be treated with IV replacement therapy.

Nothing by Mouth

Clients are placed on NPO status as prescribed by the prescribing practitioner. On the basis of agency policy and clarification with the prescribing practitioner, the client may be allowed small amounts of ice chips or medications with a sip of water when NPO. Common clinical situations that may require NPO status include the need to:

- Avoid aspiration in unconscious, perioperative, and preprocedural clients who will receive anesthesia or conscious sedation
- Rest and heal the GI tract in clients with severe vomiting or diarrhea or when the client has a GI disorder (inflammation or obstruction)
- Prevent the further loss of gastric juices in clients with nasogastric suctioning

NPO clients should receive oral hygiene every 1 to 2 hours or as needed for comfort and to prevent alterations of the mucous membranes.

Restricted Fluids

Intake may be restricted to 200 mL over a 24-hour period; intake is commonly restricted in the treatment of EFV related to heart and renal failure. Client and family teaching and collaboration are the main nursing interventions in implementing this measure.

How the nurse limits the fluids should be determined in collaboration with the client. For example:

- Fifty percent of the allowed fluids might be taken at breakfast and lunch.
- The remaining 50% might be taken with the evening meal and before bedtime, unless the client has to be awakened during the night for a medication.

Forced Fluids

Forcing or encouraging the intake of oral fluids, mainly water, may be done when treating older adult clients who are at risk for dehydration and clients with renal and urinary problems (e.g., kidney stones). Compliance is obtained by client education and preference relative to timing and the type of liquids.

A client might, for example, be requested to consume 2000 mL over a 24-hour time period. If the client is intimidated on hearing this amount, which may sound very large, explain that the number of glasses to which this volume equates is only eight. Follow a similar time frame as set forth for restricted fluids, with the largest quantity of fluids administered with meals. Ice, gelatin, and ice cream count as liquid intake.

MAINTAIN TUBE FEEDING

When the client cannot ingest oral fluids and has a normal GI tract, fluids and nutrients can be administered through a feeding tube as prescribed by a prescribing practitioner. Refer to Chapter 34 for a complete discussion of feeding tubes.

MONITOR INTRAVENOUS THERAPY

When fluid losses are severe or the client cannot tolerate oral or tube feedings, fluid volume is replaced parenterally through the IV route. **Intravenous (IV) therapy** is the administration of fluids, electrolytes, nutrients, or medications by the venous route. The prescribing practitioner prescribes IV therapy to treat or prevent fluid and electrolyte or nutritional imbalances. Prescribing practitioners do not write an order to perform venipuncture. Instead, the order may read “Start IV” and should specify the exact IV therapy ordered; the order to perform the venipuncture is implied. All orders should be questioned if they are not clear. The nurse has specific responsibilities relative to IV therapy (see the accompanying Nursing Process Highlight).

The Infusion Nurses Society (INS, 2006) is the professional organization that establishes standards of practice to promote excellence in IV nursing to ensure the highest quality, cost-effective care for all individuals requiring infusion therapies. Infusion nursing standards of practice direct the development of agency policy and protocols in accordance with state and federal regulations and should complement the manufacturer’s direction for usage. The nurse should review the agency’s procedures before gathering the equipment. IV therapy requires parenteral fluids (solutions) and special equipment: administration set, IV pole, filter, infusion control device to regulate IV flow rate, and an established venous route.

NURSING PROCESS HIGHLIGHT

Implementation

IV Therapy

- Know why the therapy is prescribed.
- Document client understanding.
- Select the appropriate equipment in accordance with agency policy.
- Obtain the correct solution as prescribed.
- Assess the client for allergies: tape, iodine, latex, ointment, or antibiotic preparations to be used for skin preparation of the venipuncture site.
- Administer the fluid at the prescribed rate.
- Observe for signs of **infiltration**, the seepage of substances into the interstitial tissue that occurs as a result of accidental dislodgment of the needle from the vein, and other complications that are fluid specific.
- Document implementation of prescribed IV therapy in the client’s medical record.

Parenteral Fluids

The nurse confirms the type and amount of IV solution by reading the prescribing practitioner’s order in the medical record. IV solutions are sterile and packaged in plastic bags or glass containers. Solutions that are incompatible with plastic are dispensed in glass containers.

Plastic IV solution bags collapse under atmospheric pressure to allow the solution to enter the infusion set. Plastic solution bags are packaged with an outer plastic bag, which should remain intact until the nurse prepares the solution for administration. When the plastic solution bag is removed from its outer wrapper, the solution bag should be dry. If the solution bag is wet, the nurse should not use the solution. The moisture on the bag indicates that the integrity of the bag has been compromised and that the solution cannot be considered sterile. The bag should be returned to the dispensing department that issued the solution. Glass containers are discussed in the section on equipment.

IV solutions are usually packaged in quantities ranging from 50 to 1000 mL. The nurse should select a container that has the prescribed amount of solution closest to the prescribed volume. **Crystalloids**, electrolyte solutions with the potential to form crystals, are used to replace concurrent losses of water, carbohydrates, and electrolytes. Sodium chloride and Ringer’s lactate are commonly used crystalloid solutions.

There are three types of parenteral fluids that are classified in accord with the tonicity of the fluid relative to normal blood plasma. As previously discussed, an osmolar solution can be hypotonic, isotonic, or hypertonic. The type of solution is prescribed on the basis of the client’s diagnosis and

the goal of therapy. The normal osmolarity of blood is between 280 and 295 mOsm/L, so the desired effect of the tonicity of the fluid is determined as follows:

1. Hypotonic fluid (hypo-osmolar, less than 290 mOsm/L) lowers the osmotic pressure and causes fluid to move into the cells; if fluid is infused beyond the client's tolerance, water intoxication may result.
2. Isotonic fluid (iso-osmolar, 290 mOsm/L) increases ECF volume; if fluid is infused beyond the client's tolerance, cardiac overload may result.
3. Hypertonic fluid (hyperosmolar, greater than 290 mOsm/L) increases the osmotic pressure of the blood plasma, drawing fluid from the cells; if fluid is infused beyond the client's tolerance, cellular dehydration may result (Smeltzer et al., 2008).

Table 33-6 on page 947 discusses the common types of IV solutions in terms of their tonicity, contents, and clinical usage.

Crystalloid solutions can be isotonic (equal to the sodium chloride concentration of blood, 0.9%), hypotonic (less than the sodium chloride concentration of blood), or hypertonic (greater than the sodium chloride concentration of blood) (Kee et al., 2010).

Colloids (nondiffusible substances) function like plasma proteins in blood by exerting a colloidal pressure to replace intravascular volume only. Examples of colloidal solutions are albumin, dextran, Plasmanate, and hetastarch (artificial blood substitute). During the administration of these solutions, the nurse should monitor the client for hypotension and allergic reactions (Kee et al., 2010). Blood transfusions are discussed later in this chapter.

Equipment

IV equipment is sterile, disposable, and prepackaged with user instructions. The user instructions are usually placed on the outside of the package, with a schematic that labels the parts, allowing the user to read the package prior to opening. The following discussion regarding IV equipment, inclusive of the frequency of when to change disposal IV therapy equipment, is based on the revised 2000 *Infusion Nursing Standards of Practice* developed by the INS. All IV equipment must be inspected by the nurse to determine the integrity of the IV product before, during, and after use. Product integrity refers to the sterility of the equipment. Products are assessed for integrity by visual examination of the product and checking the expiration date on the equipment. All products identified with a defect must be returned to the appropriate department within the agency with a written report identifying the defect.

Since IV therapy provides a direct access into the vascular system, the nurse must understand the basic epidemiology principles and common organisms that may cause an infection and implement infection control measures to minimize the potential for infectious complications. The nurse uses aseptic technique and Standard Precautions when assembling and changing IV equipment. To decrease the risk of pathogen transmission, hand hygiene is required before and immediately after all IV procedures and upon removal of

gloves. The frequency of changing sterile IV equipment reflects not only the national standards of practice but also the agency's established infection control policies. Infection control data may allow the agency to increase the time interval beyond the recommended standard provided the data verify low infection rates. The INS (2006) recommends that an organization that exhibits an increased rate of catheter-related bloodstream infection with the practice of 72-hour administration set changes should return to a 48-hour administration set change interval.

ADMINISTRATION SET The administration set (infusion set) refers to the plastic disposal tubing that provides for the infusion of a solution. There are several types of infusion sets to accommodate the solution and the mode of administration: primary continuous, secondary, primary intermittent, and special tubing for certain solutions such as blood and blood components. There are several add-on devices (e.g., extension sets, filters, stopcocks, PRN adaptor, needleless devices) that are used in conjunction with the administration set and changed whenever the set is changed.

Administration sets are changed at established time intervals and immediately upon suspected contamination or when the integrity of the set has been compromised. The administration set contains an insertion spike with a protective cap, a drip chamber, tubing with a slide clamp and regulating (roller) clamp, a rubber injection port, and a protective cap over the needle adapter (see Figure 33-10 on page 948). The protective caps keep both ends of the infusion set sterile and are removed only just before usage. The insertion spike is inserted into the port of the IV solution container.

Infusion sets can be vented or nonvented. The nonvented type is used with plastic bags of IV solutions and vented bottles. The vented set is used for glass containers that are not vented (see Figure 33-11 on page 948).

Glass containers require an air vent so that air can displace fluid from the container into the IV tubing. Some glass bottles are vented with an inside tube that exits the bottle into a rubber stopper in the neck of the bottle; if the bottle is not vented, then the nurse needs to select a vented infusion set.

The drip chamber is calibrated to allow a predictable amount of fluid to be delivered. There are two types of drip chambers: a macrodrip, which delivers 10 to 20 drops per milliliter of solution, and a microdrip, which delivers 60 drops per milliliter. The drip rate varies with the manufacturer as indicated on the package.

The administration set has a manual flow-control device such as a slide clamp (Figure 33-10), a roller clamp, or a screw to regulate a prescribed infusion rate. Follow the manufacturer's guidelines when using the manual flow-control device to regulate the prescribed infusion rate. The end of the IV tubing contains a needle adapter that attaches to the sterile device inserted in the client's vein. Extension tubing may be used to lengthen the primary tubing.

A primary continuous administration set is used to administer routine solutions prescribed to infuse continuously over a 24-hour period. The primary administration set, inclusive of the add-on devices, is changed every 72 to

TABLE 33-6 Common Intravenous Solutions

TONICITY	SOLUTION	CONTENTS (MEQ/L)	CLINICAL IMPLICATIONS
Hypotonic	Sodium chloride 0.45%	77 Na ⁺ , 77 Cl ⁻	Daily maintenance of body fluid and establishment of renal function.
Isotonic	Dextrose 2.5% in 0.45% saline	77 Na ⁺ , 77 Cl ⁻	Promotes renal function and urine output.
	Dextrose 5% in 0.2% saline	38 Na ⁺ , 38 Cl ⁻	Daily maintenance of body fluids when less Na ⁺ and Cl ⁻ are required.
	Dextrose 5% in water (D5W)		Promotes rehydration and elimination; may cause urinary Na ⁺ loss; good vehicle for K ⁺ .
	Ringer's lactate	130 Na ⁺ , 4 K ⁺ , Ca ²⁺ , 109 Cl ⁻ , 28 lactate	Resembles the normal composition of blood serum and plasma; K ⁺ level below body's daily requirement.
	Normal saline (NS), 0.9%	154 Na ⁺ , 154 Cl ⁻	Restores sodium chloride deficit and extracellular fluid volume.
	Dextran 40 10% in NS (0.9%) or D5W		A colloidal solution used to increase plasma volume of clients in early shock; it should not be given to severely dehydrated clients and clients with renal disease, thrombocytopenia, or active hemorrhaging.
	Dextran 70% in NS		A long-lived (20 hours) plasma volume expander; used to treat shock or impending shock due to hemorrhage, surgery, or burns. It can prolong bleeding and coats the RBCs (draw type and cross-match prior to administering).
Hypertonic	Dextrose 5% in 0.45% saline	77 Na ⁺ , 77 Cl ⁻	Daily maintenance of body fluid and nutrition; treatment of FVD.
	Dextrose 5% in saline 0.9%	154 Na ⁺ , 154 Cl ⁻	Fluid replacement of sodium, chloride, and calories (170).
	Dextrose 10% in saline 0.9%	154 Na ⁺ , 154 Cl ⁻	Fluid replacement of sodium, chloride, and calories (340).
	Dextrose 5% in lactated Ringer's	130 Na ⁺ , 4 K ⁺ , 3 Ca ²⁺ , 109 Cl ⁻ , 28 lactate	Resembles the normal composition of blood serum and plasma; K ⁺ level below body's daily requirement; caloric value 180.
	Hyperosmolar saline 3% and 5% NaCl	856 Na ⁺ , 865 Cl ⁻	Treatment of hyponatremia; raises the Na ⁺ osmolarity of the blood and reduces intracellular fluid excess.
	Ionosol B with dextrose 5%	57 Na ⁺ , 25 K ⁺ , 49 Cl ⁻ , 25 lact., 5 Mg ²⁺ , 7 PO ₄ ⁻	Treatment of polyionic parenteral replacement caused by vomiting-induced alkalosis, diabetic acidosis, fluid loss from burns, and postoperative FVD.
	Ionosol D-CM with dextrose 5%	138 Na ⁺ , 12 K ⁺ , 5 Ca ²⁺ , 108 Cl ⁻ , 50 lactate, 3 Mg ²⁺	Treatment of electrolyte losses of duodenal fluids caused by intestinal suction or biliary or pancreatic drainage; treatment of mild acidosis.
	Aminosyn-RF 5.2%	5.4 K ⁺	Restores fluid and protein and promotes wound healing.
	Aminosyn II 3.5%	18 Na ⁺	Treatment of malnourished older adult clients and hypoproteinemia; it is not to be given to clients with severe liver damage.

Kee, J. L., Paulanka, B. J., & Polek, C. (2010). *Fluids and electrolytes with clinical applications: A programmed approach* (8th ed.). Clifton Park, NY: Delmar/Cengage Learning.

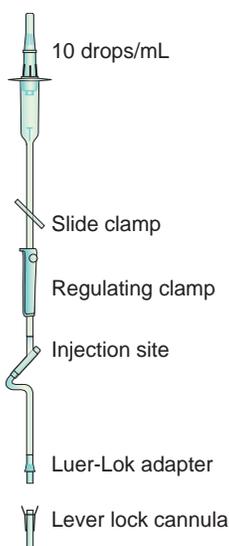

FIGURE 33-10 Basic Administration Set DELMAR/CENGAGE LEARNING

96 hours in conjunction with the peripheral cannula change. A bag of IV solution should not hang longer than 24 hours.

Secondary administration sets are often referred to as “piggyback” administration sets. The secondary tubing is connected into the primary tubing at an injection site (see Figure 33-11) and allows for the administration of a second solution (e.g., medication). Secondary administration sets are also changed every 72 to 96 hours.

Primary intermittent administration sets are used to deliver medications at prescribed intervals through an injection or

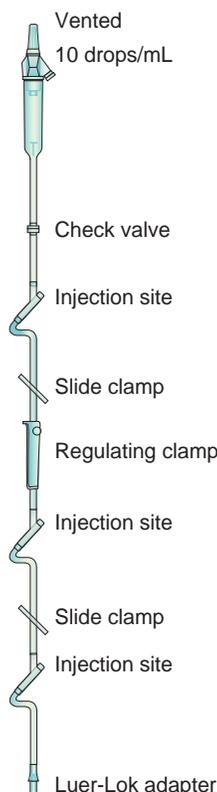

FIGURE 33-11 Vented Administration Set DELMAR/CENGAGE LEARNING

access port and are changed every 72 to 96 hours; all add-on devices such as extension sets, filters, PRN adaptors, and stop-cocks are changed with the intermittent administration set. A sterile needle or needleless device should be aseptically attached to the intermittent administration set prior to administering the medication and removed immediately after each use.

Neonates, infants, and children are at risk for *Altered fluid balance: Overload, related to rehydration*. IV tubing with a microdrip and special volume-control chambers are used to regulate the amount of fluid to be administered over a specific time interval. Armboards and soft restraints are used to stabilize peripheral infusions by immobilizing the extremity to prevent accidental removal of infusion devices.

Health Hazard A *Health Alert* from Health Care Without Harm (HCWH) (1999) cautioned the public about the potential risks of exposure to diethylhexyl phthalates (DEHP) from medical products such as IV bags and tubing. More than 500 million IV bags are used in the United States every year to deliver blood, medication, and other essential solutions to clients (HCWH, 1999). Eighty percent of the IV bags are made with polyvinyl chloride (PVC), which requires a plasticizer to make the bags soft and flexible. DEHP is the softener used in PVC products. DEHP has been shown to leach from IV bags into the solutions they contain and directly into the client’s bloodstream.

The Environmental Protection Agency has classified DEHP as a probable human carcinogen, and HCWH claims that studies have shown that DEHP can damage the heart, liver, testes, and kidneys and interfere with sperm production. Certain drugs such as Taxol (used to treat breast cancer) and Taxotere (used to treat ovarian and breast cancer and AIDS-related Kaposi’s sarcoma) have been shown to increase the leaching of DEHP from PVC plastics into the solution; see the accompanying display (on page 949) for additional drugs that can increase leaching of DEHP from PVC IV products. Although one leading producer of vinyl IV bags containing DEHP plans to develop an alternative to PVC for their products, no time frames were given to totally remove these products from the market.

A second health hazard is inherent in the use of DEHP. The disposal of medical products containing DEHP releases highly toxic and endocrine-disrupting dioxins. PVC is the only plastic linked both to phthalate chemical leaching and to the production of dioxin.

INTRAVENOUS FILTERS IV filters prevent the passage of undesirable substances such as particulate matter and air from entering the vascular system. Particulate matter filters are utilized when preparing infusion medications for administration to prevent obstruction in the vascular and pulmonary systems, irritation, and **phlebitis** (inflammation of a vein). Air-eliminating filters are used for the delivery of infusion therapy to decrease the potential of air emboli; the filter should be located as close as possible to the cannula site. IV filters come in various sizes; the finer the filter, the greater is the degree of solution filtration. Although studies have shown that IV filters

DRUGS THAT INCREASE LEACHING OF DEHP FROM PVC PLASTICS

- Chemotherapeutic agents: etoposide (VePesid) and teniposide (Vumon)
- Antianxiety agents: chlordiazepoxide HCl (Librium)
- Antifungal agents: miconazole (Monistat IV)
- Immunosuppressive agents: cyclosporine (Sandimmune) and tacrolimus (Prograf)
- Nutritional solutions: fat emulsions and vitamin A

Stewart, M. (1999, March/April). IV bags pose patient risk. *American Nurse*, 31(2), 12.

reduce the risk of bacteremia and phlebitis as much as 40%, many agencies do not use IV filters because of cost.

NEEDLES AND VENOUS PERIPHERAL-SHORT CATHETERS Needles and peripheral-short catheters provide access to the venous system. A variety of devices are available in different sizes to complement the age of the client and the type and duration of the therapy and to protect the user from injury (see Figure 33-12).

As with any gauge needle, the larger the number, the smaller the lumen. The nurse considers the client's age, body size, purpose of the infusion, and type of solution to be administered when selecting the gauge of the needle or catheter:

- Infants and small children, 24-gauge
- Preschool through preteen, 24- or 22-gauge
- Teenagers and adults, 22- or 20-gauge
- Geriatric, 22- or 24-gauge

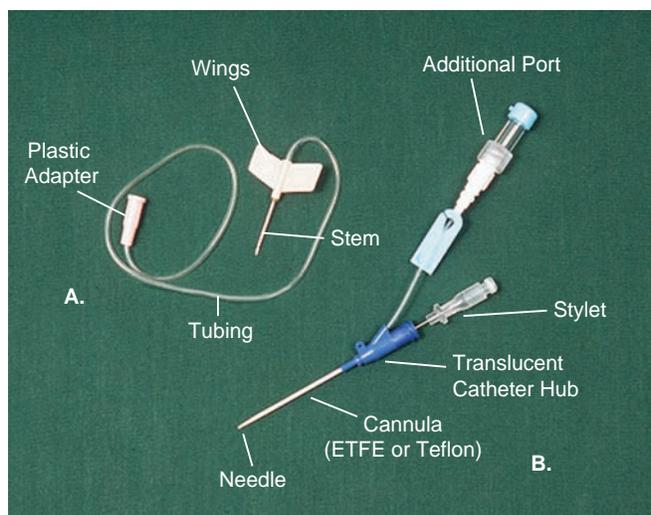

FIGURE 33-12 Peripheral IV Devices: A. Butterfly; B. Angiocatheter DELMAR/CENGAGE LEARNING

Butterfly (scalp vein or wing-tipped) needles are short, beveled needles with plastic flaps attached to the shaft. The flaps, which are flexible, are held tightly together to facilitate ease of insertion and then flattened against the skin to prevent dislodgment during infusion. These needles are commonly used for short-term or intermittent therapy and for infants and children.

There are several types of short catheters used to access peripheral veins. Short peripheral venous catheters vary in length from 3/4 to 11/4 inches. During insertion, some of these catheters are threaded over a needle, and others are threaded inside a needle. **Intracath** is a term used to refer to a plastic tube inserted into a vein. An **angiocatheter** is a type of intracath with a metal stylet to pierce the skin and vein, after which the plastic catheter is threaded into the vein and the metal stylet is removed, leaving only the plastic catheter in the vein. Short venous catheters have a safety mechanism to reduce the risk of accidental needlesticks. These devices are designed to allow for easy insertion of the catheter while providing a built-in safety feature to reduce the potential for exposure to bloodborne pathogens.

PERIPHERAL INTRAVENOUS AND SALINE/HEPARIN LOCKS Peripheral intravenous (PI) and saline/heparin locks are devices that establish a venous route as a precautionary measure for clients whose condition may change rapidly or who may require intermittent infusion therapy. A peripheral catheter is inserted into a vein, and the hub is capped with a Luer-Lok injection or access port (see Figure 33-13).

NEEDLE-FREE SYSTEM Safety is a concern associated with IV therapy; refer to Chapter 29. Accidental needlestick injuries and puncture wounds with contaminated devices increase the employee's risk for infectious diseases such as AIDS, hepatitis (B and C), and other viral, rickettsial, bacterial, fungal, and parasitic infections. Health care agencies now use totally needle-free IV systems (see Figure 33-14 on page 950) to decrease the risk of employee injuries.

VASCULAR ACCESS DEVICES Vascular access devices (VADs) include various catheters and implanted ports that allow for long-term IV therapy or repeated access to the central venous system. The kind of VAD used depends on the client's diagnosis and the type and length of treatment (see Table 33-7 on page 950). Site selection and insertion of central catheters, other than peripherally inserted central catheters, are medical acts performed by a prescribing practitioner. Although there are many types of catheter materials, insertion techniques, and kinds of central catheters, *all central catheters*

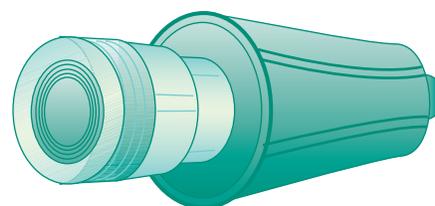

FIGURE 33-13 Luer-Lok Injection Device DELMAR/CENGAGE LEARNING

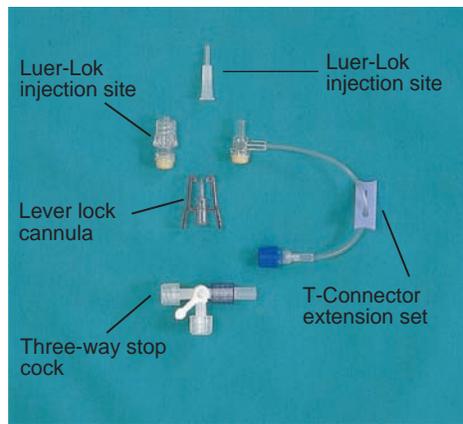

FIGURE 33-14 Needle-Free System DELMAR/CENGAGE LEARNING

must be radiopaque to allow for radiographic verification of placement of the catheter and its tip prior to the administration of any solution.

Central catheters are usually inserted into an upper extremity, the internal jugular veins, and subclavian veins with the tip located in the distal superior vena cava to minimize vessel irritation and sclerosis. The femoral vein can be used for central venous access when there is thrombosis of the internal jugular or subclavian veins; correct tip location should be in the inferior vena cava. Insertion of a central catheter can be performed either percutaneously or surgically. Surgically, either a central catheter is placed entirely under the skin (implanted) or the catheter partially exits the skin (tunneled).

A tunneled catheter is inserted through the subcutaneous tissue, usually between the nipple and clavicle, with the catheter tip inserted through the cephalic or external jugular vein and threaded to the superior vena cava.

An **implantable port** is a device made of a radiopaque silicone catheter and a plastic or stainless steel injection port with a self-sealing silicone-rubber septum. The prescribing practitioner inserts the device into a subcutaneous pocket, usually over the third or fourth rib, lateral to the sternum. The distal tip of the catheter is surgically tunneled in the cephalic or external jugular vein, with the proximal end of the catheter tunneled through the subcutaneous tissue into the injection port of the device.

Implanted ports and pumps are VADs that provide for the delivery of prescribed parenteral therapies. Accessing these devices requires the use of aseptic technique. Noncoring needles such as a Huber needle are used to access an implanted port or pump and should be changed at least every 7 days. The smallest gauge noncoring needle that can deliver the prescribed therapy should be used when accessing the port or pump. Nurses caring for clients with implanted ports or pumps must have a thorough knowledge of the design features of the device, as explained in the manufacturer’s guidelines, to ensure correct access, administration techniques, and maintenance and to avoid potential complications.

Implanted pumps have a reservoir designed to continuously infuse a specific volume of solution over a preset period of time; the pump must be routinely emptied and refilled at established intervals. Some pumps have an additional feature, a side port designed for administration of intermittent medication. The flow rate of some pumps is sensitive to changes in atmospheric pressure, body temperature, blood pressure, and the viscosity of the medications. Clients are instructed to report changes in their lifestyle and physical condition that may affect the pump’s flow rate. *Only nurses who have been specially trained are allowed to access an implanted port or pump because of the risk of infiltration into the tissue if needle placement is incorrect.*

TABLE 33-7 Vascular Access Devices

TYPE	BRAND NAME	USE
Nontunneled central venous catheter (single-, dual-, or triple-lumen)	Hohn, Arrow	Short-term fluid or blood administration, obtaining blood specimens, and administering medications
Tunneled central venous catheter (single-, dual-, or triple-lumen)	Hickman, Broviac, Groshong	Long-term (months to years) fluid replacement therapy, medication administration, nutritional supplement, and blood specimen withdrawal
Implanted infusion port (single, dual)	Chemo-Port, Infuse-a-Port, Mediport, Port-a-Cath	Long-term (months to years) fluid replacement therapy, medication administration (especially chemotherapy), blood or blood product administration, and blood specimen withdrawal
Peripherally inserted central catheter (PICC) (single, dual)	PICC, Groshong PICC, Pee-a-Cath, Arrow PICC	Long-term fluid replacement therapy, medication administration (chemotherapy, antibiotics, controlled narcotics), blood or blood product administration, and blood specimen withdrawal

Delmar/Cengage Learning

SAFETY FIRST

INSERTING A CVC

When assisting with the insertion of a central venous catheter, observe the client for symptoms of a pneumothorax: sudden shortness of breath or sharp chest pain; increased anxiety; a weak, rapid pulse; hypotension; pallor; or cyanosis. These symptoms indicate accidental puncture of the pleural membrane.

A peripherally inserted central catheter (PICC) is a silicone or polyurethane catheter inserted into one of the major veins in the antecubital fossa or upper extremity with the distal tip terminating in the lower-third section of the superior vena cava. A PICC can be trimmed at the time of insertion to a specific length that is determined by the approximate distance between the insertion site and the superior vena cava. State boards of registered nurses allow specially trained nurses to insert PICCs. Placement of the catheter's tip is confirmed by x-ray prior to the administration of any solution. The registered nurse who inserts the PICC must document the type of PICC inserted and the total length of the inserted catheter and record if the length of the catheter was trimmed prior to insertion.

The recommended way to secure a VAD is with a manufactured catheter stabilization device. These devices contain an adhesive anchoring pad to help reduce catheter dislodgment and the need for removal and reinsertion (Hadaway, 2008). Sterile tape and surgical strips are still acceptable methods of catheter stabilization. The INS (2006) no longer considers dressings as stabilization devices. Although dressings protect the insertion site and skin, there is no evidence that they enhance catheter stabilization (Hadaway, 2008). At each dressing change, document the external catheter length. If the length has changed, the internal tip location has also changed; the altered tip location could increase the risk of complications such as vein thrombosis and dysrhythmias. See Procedure 33-8 on changing the central venous dressing.

Preparing an Intravenous Solution

To prepare an IV solution, read the agency's policy and procedures and gather the necessary equipment. Because IV equipment and solutions are sterile, check the expiration date on the package prior to usage. The solution can be prepared at the nurses' work area or in the client's room (Procedure 33-2 and Procedure 33-3).

The nurse prepares and applies a time strip to the IV solution bag to facilitate monitoring of the infusion rate as ordered by the prescribing practitioner (see Figure 33-15). Use only labels appropriate for IV bags. Do not use a felt-tipped pen to mark an IV bag; the ink from the pen can leak through the plastic and contaminate the solution. Do not label a bag with a time strip made of adhesive silk or paper

FIGURE 33-15 Apply a time strip to the IV container. DELMAR/CENGAGE LEARNING

tape, as the adhesive will leach into the bag. The IV tubing is tagged with the date and time to indicate when the tubing replacement is necessary. IV tubing is changed every 72 to 96 hours in accordance with the agency's policy. The nurse initials the time strip and IV tubing tag.

Initiating IV Therapy

When initiating IV therapy, the nurse should assess for a venipuncture site. Figure 33-16 on page 952 presents the common peripheral sites for starting IV therapy in pediatric, adult, and geriatric clients (see Chapter 28, Procedure 28-1, Venipuncture).

When assessing clients for potential sites, consider their age, body size, clinical status and impairments, and skin condition (see the accompanying display for contraindications when selecting a site on page 952). Lower-extremity veins (e.g., the foot) are common IV sites with children but are avoided in adults because of the danger of thrombophlebitis (INS, 2006). The median vein (see Figure 33-16), usually located between two branches of the median nerve, is difficult to palpate or visualize; venipuncture in this area can be painful and should be avoided whenever possible. Because contact with blood is likely, venipuncture requires the implementation of Standard Precautions. Refer to Chapter 29 for a complete discussion of Standard Precautions.

Select a vein for puncture at its most distal end to maintain the integrity of the vein because venous blood flows with an upward movement toward the heart. The accessory cephalic vein (see Figure 33-16) is a medium- to large-sized vein that is easy to stabilize and palpate and readily accepts large needles; however, valves at the junction with the cephalic vein may prohibit the advancement of a cannula. When

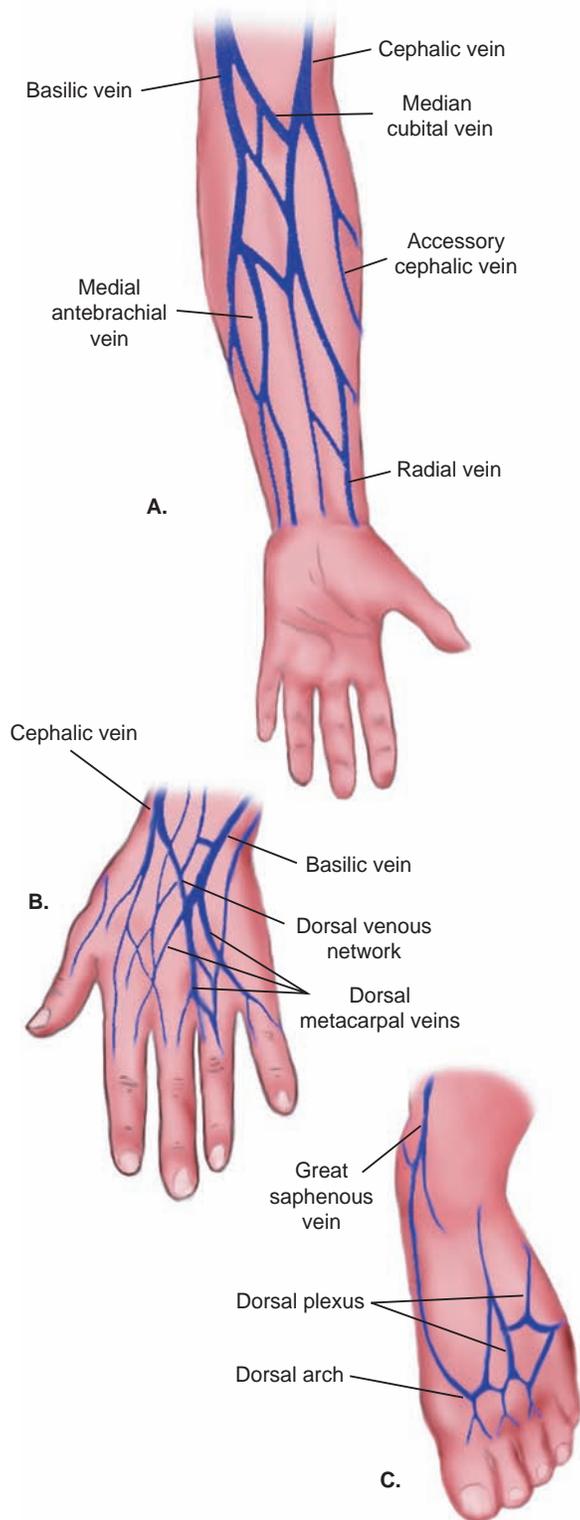

FIGURE 33-16 Peripheral Veins Used in Intravenous Therapy: A. Arm and Forearm; B. Dorsum of the Hand; C. Dorsal Plexus of the Foot DELMAR/CENGAGE LEARNING

a vein is punctured with an instrument, such as a needle, fluids can infiltrate (leak from the vein into the tissue at the site of puncture). If IV therapy has to be discontinued for any reason, such as infiltration, it can be restarted above the initial puncture site only. No more than two attempts at inserting an IV should be made by a single nurse (INS, 2006).

VENIPUNCTURE SITE CONTRAINDICATIONS

- Signs of infection, infiltration, or thrombosis
- Affected arm of a postmastectomy client
- Arm with a functioning arteriovenous fistula
- Affected arm of a paralyzed client
- Any arm that has circulatory or neurologic impairments

In the 1990s nurses began using ultrasound for PICC insertion, and the technique is now endorsed by the Agency for Healthcare Research and Quality and the Centers for Disease Control and Prevention (CDC). Using ultrasound for PICC insertion raises the rate of successful insertions to more than 90%, compared to about 80% with traditional, non-ultrasound-guided PICC insertion (Moureau, 2008). Ultrasounds not only allow the nurse to easily and accurately locate and identify veins, arteries, and nerve bundles of the upper arm but also let the nurse assess vein characteristics before determining whether the vein is suitable for catheter placement.

When prepping the client's skin for a venipuncture, cleanse the skin with 2% to 3% aqueous chlorhexidine (preferred), tincture of iodine 2%, 10% povidone-iodine, or 70% isopropyl alcohol and wait for it to dry. Do not apply alcohol after the skin has been prepped with povidone-iodine. Allow povidone-iodine to remain on the skin for at least 2 minutes. Chlorhexidine is not approved for use with infants less than 2 months of age. Antiseptic solutions should be allowed to air-dry completely to effectively reduce microbial count (INS, 2006).

Administering IV Therapy

Once the solution is prepared for administration, the nurse calculates the rate and explains the procedure to the client (see Procedure 33-4 for assessing and maintaining an IV insertion site). There are three ways to administer solutions:

1. Initiate the infusion by performing a venipuncture.
2. Use an existing IV system: catheter, saline/heparin or PI lock, central line, or implanted port.
3. Add a solution to a continuous-infusion line (see Procedure 33-35).

Fluid administration can be continuous, ongoing over a 24-hour period, or intermittent (1000 mL ordered once in a 24-hour period). Although fluids may be continuous, the type of fluids can alternate over a 24-hour period; for example, an order might be *add 40 mEq of KCl to first bag of 1000 mL of normal saline*.

The aging process causes physiological changes in the skin, muscles, and veins. The skin loses its durability, making it prone to tears and abrasions. Decrease in muscle mass may

cause the vein to roll during puncture. The veins themselves are also more fragile in older adults. When first infusing fluid into the vein, administer it slowly and observe carefully for any sign of infiltration.

IV medications may be **piggybacked**, added to an existing IV solution to infuse concurrently. IV solutions and medications that have been refrigerated should be warmed to room temperature before administration (usually 30 minutes) to increase the client's comfort.

Instead of setting the total volume to be infused (e.g., 1000 mL), set the volume slightly lower (e.g., at 950 mL) so that the alarm will go off before the fluids are absorbed completely. This method will give you time to have the next bag of fluids ready when all 1000 mL have been absorbed. This is especially helpful when dealing with refrigerated fluids that must be warmed to room temperature before administering. If you will be off duty when the volume will be absorbed and you have set the alarm to go off early, tell the oncoming nurse during report.

Flushing

Flushing refers to the instillation of a solution into an IV cannula. Flushing is performed to assess and maintain cannula patency and prevent the mixing of incompatible medications and solutions, following the conversion of continuous IV therapy to intermittent IV therapy, and to maintain intermittent cannula patency following IV medication administration and blood sampling (see Procedure 33-6).

The type of solution and frequency of flushing an intermittent IV cannula are determined by the agency's policy. According to the INS (2006), flushing a cannula at established intervals with saline (0.9% sodium chloride injection) is the accepted solution to ensure and maintain patency of an intermittent PI cannula, while a heparin flush solution is the accepted solution to maintain patency of intermittent central venous devices. The volume of flush is equal to the volume capacity of the cannula and add-on devices times two (INS, 2006). Consideration is also given to the volume and frequency of heparin flush in order to prevent an alteration in the client's clotting factors.

When flushing a cannula, positive pressure within the lumen of the catheter must be maintained to prevent the reflux of blood into the cannula lumen. Use the manufacturer-recommended maximum pressure limits (pounds per square inch) when selecting the size of the syringe to use for flushing, since the smaller the syringe, the greater the pressure generated; excessive internal pressures in the device increase the potential for cannula damage and progressive internal cannula weakening over the life of the device (INS, 2006). If resistance is met when flushing a cannula, do not exert pressure in an attempt to restore patency of an occluded cannula since this action may result in the dislodgment of a clot into the vascular system or rupture of the catheter.

Regulating IV Solution Flow Rates

Infusion sets with macrodrip chambers are often used for adult clients, whereas microdrip chambers are used for volume-sensitive clients, such as geriatric or pediatric clients.

Pediatric and geriatric clients usually require some type of device to regulate the fluids as a safety factor to prevent overload. Devices such as controllers and pumps are commonly used to regulate the rate of infusion.

Calculation of Flow Rate

The **flow rate** is the volume of fluid to infuse over a set period of time as ordered by the prescribing practitioner. The prescribing practitioner will identify either the amount to infuse per hour (such as 125 mL per hour or 1000 mL over an 8-hour period). Calculate the hourly infusion rate as follows:

$$\frac{\text{Total volume}}{\text{Number of hours to infuse}} = \text{mL/hour infusion rate}$$

For example, if 1000 mL is to infuse over 8 hours:

$$\frac{1000}{8} = 125 \text{ mL/hour}$$

Calculate the actual infusion rate (drops per minute) as follows:

$$\frac{\text{Total volume}}{\text{Total time (minutes)}} \times \text{drop factor} = \text{drops per minute}$$

For example, if 1000 mL is to infuse over 8 hours with a tubing drop factor of 10 drops per milliliter:

$$\begin{aligned} \frac{1000 \text{ mL}}{8(60) \text{ min}} \times 10 \text{ drops/mL} \\ = \frac{10,000 \text{ mL}}{480 \text{ min}} = 20.8 \text{ or } 21 \text{ drops/min} \end{aligned}$$

Another way to calculate the actual infusion rate is to use the hourly infusion rate; for the example just given:

$$\frac{125 \text{ mL} \times 10 \text{ drops/mL}}{60 \text{ min}} = 20.8 \text{ or } 21 \text{ drops/min}$$

See Procedure 33-7.

Flow-Control Devices

Flow-control devices are used to regulate the infusion at the prescribed administration rate. Safety factors such as the client's age and condition, prescribed therapy, and setting are considered when selecting a flow-control device. There are two basic types of flow-control devices: manual flow-control devices and electronic infusion devices. Manual flow-control devices include roller, screw, and slide clamps and may include volume-control devices such as a buretrol. These devices are used routinely to regulate the accurate delivery of most prescribed IV therapies.

Electronic infusion devices, which are operated either by electricity or battery, are used to administer IV fluids and medications and should be considered on all central access devices (INS, 2006). Electronic infusion pumps have audible

alarms that sound when the solution has infused, the infusion tubing contains air or is kinked, or the cannula is clotted. There are two types of electronic infusion devices: controllers and pumps. Controller infusion devices generate flow by gravity and are capable of maintaining a constant preset flow rate either by drop counting or volumetric delivery. The nurse sets the flow rate, and the specific gravity of the solution and the height of the bag determine the maximum delivery pressure. Fluids with low viscosity are usually infused by electronic controllers.

Infusion pumps maintain the flow rate under positive pressure. Pumps counter the effects of resistance in the delivery system and pressure fluctuations at the infusion site. Positive pressure infusion devices are classified as either volumetric or syringe pumps and are used to deliver viscous fluids or large volumes of fluids. Volumetric pumps use either a peristaltic pumping action or a pumping cassette or chamber to deliver a fixed volume over a specified period of time. Syringe infusion pumps rely on a syringe or cartridge to deliver the fluid at a specific set rate.

MANAGING IV THERAPY

IV therapy requires frequent client monitoring by the nurse to ensure an accurate flow rate and other critical nursing actions. These other actions include ensuring client comfort and positioning; checking IV solution for correct solution, amount, and timing; monitoring expiration dates of the IV system (tubing, venipuncture site, dressing) and changing as necessary; and being aware of safety factors.

Coordinate client care with the maintenance of IV lines. Clients with IV therapy usually require assistance with hygienic measures, such as changing a gown. Change IV tubing when doing site care to decrease the number of times the access device is manipulated, thereby decreasing the risk for infiltration and phlebitis. PI devices are changed every 72 to 96 hours as directed by CDC guidelines.

Hypervolemia

Hypervolemia, increased circulating fluid volume, may result from rapid IV infusion of solutions. This causes cardiac overload, which may lead to pulmonary edema and cardiac failure. Monitor the infusion rate hourly, and refer to the Nursing Care Plan “The Client with Excess Fluid Volume” for the assessment and interventions for a client experiencing FVE.

If a solution infuses at a rate greater than prescribed, decrease the rate to *keep vein open* (KVO) and immediately notify the prescribing practitioner. Report the amount and type of solution that infused over the exact time period and the client’s response.

Infiltration

Infiltration may be caused by inserting the wrong type of device, using the wrong-gauge needle, or dislodgment of the device from the vein. When a drug or solution is administered under high pressure by a pump, it may also cause infiltration or vein irritation.

SAFETY FIRST

IVS AND THE CRITICALLY ILL

Never remove a functioning IV device from a critically ill client until another successful venipuncture has been performed; an established IV route may be needed for the administration of solutions, medications, or blood components.

Infiltration results in the leaking of fluids or medications into the surrounding tissue. The client usually complains of discomfort at the IV site. Inspect the site by palpating for swelling, and feel the temperature of the skin (coolness and paleness of skin are indications of infiltration).

The nurse confirms that the needle is still in the vein by pinching the IV tubing; this action should cause a **flashback**: Blood should rush into the tubing if the needle is still in the vein. If a flashback does not occur, aspirate the injection port nearest the device as explained in Procedure 33-4. Discontinue the needle or catheter if it cannot be aspirated, and apply a sterile dressing to the puncture site.

After the IV has been removed, the puncture site may ooze or bleed, especially in clients receiving anticoagulants. If oozing or bleeding occurs, apply pressure and reapply a sterile dressing until it stops. Accurately assess and document the degree of edema.

Clients may be injured by infiltration. If the IV site becomes grossly infiltrated, the edema in the soft tissue may cause a nerve compression injury with permanent loss of function to the extremity. If a **vesicant** (medication that causes blistering and tissue injury when it escapes into surrounding tissue) infiltrates, it may cause significant tissue loss with permanent disfigurement and loss of function.

Phlebitis

Phlebitis may result from either mechanical or chemical trauma. Mechanical trauma may be caused by inserting a device with too large a gauge, using a vein that is too small or fragile, or leaving the device in place for too long. Chemical trauma may result from infusing too rapidly or from an acidic solution, a hypertonic solution, a solution that contains electrolytes (especially potassium and magnesium), or other medications.

Phlebitis may be a precursor of sepsis. Listen for client complaints of tenderness, the first indication of an inflammation. Inspect the IV site for changes in skin color and temperature (a reddened area or pink or red stripe along the vein, warmth, and swelling are indications of phlebitis). Tenderness, not redness, is the earliest sign of PI-site phlebitis.

If phlebitis is present, discontinue the IV infusion. Before removing and discarding the venous device, check the agency’s policy to see whether the tip of the device needs to be cultured and sent to the laboratory for a culture and sensitivity test. After removing the device, apply a sterile dressing

to the site and moist, warm compresses to the affected area. Document in the nurses' notes the time, symptoms, and nursing interventions.

Hypertonic solutions may cause irritation necessitating frequent IV site changes. Observe the site for symptoms of postinfusion phlebitis following IV removal. This may occur in response to either chemical or mechanical factors of the preexisting IV. Postinfusion phlebitis is treated with warm, moist compresses to the site and elevation of the extremity.

Catheter Sepsis

If the client complains of chills and fever, check the length of time that this IV solution has been hanging and the needle or catheter has been in place; assess the client's vital signs, and assess for other symptoms of pyrogenic reactions, such as backache, headache, malaise, nausea, and vomiting. Unexplained fever may be related to catheter sepsis. Pulse rate increases and temperature is usually above 100°F if IV-related sepsis occurs. Stop infusion, notify the prescribing practitioner, and obtain blood specimens if prescribed.

Intravenous Dressing Change

IV dressing changes require the use of Standard Precautions and aseptic technique; refer to Procedure 33-8. Institutional policy and the type of IV access device and dressing determine the frequency of care:

1. Nontransparent (gauze) dressing may be used for a PI. It is changed every 48 hours.
2. Transparent dressings (Bioclusive, OpSite, Tegaderm) allow visualization of the IV site; these dressings are changed every 3 to 7 days.

Discontinuation of Intravenous Therapy

IV therapy is discontinued on the prescribing practitioner's order as determined by the client's need or response to therapy (Procedure 33-9). The removal of a short peripheral catheter is a nursing intervention to minimize the complication risks related to infusion therapy or to implement the prescribing practitioner's order. Peripheral catheters are removed every 72 to 96 hours and immediately upon suspected contamination or complications. Pressure and a dry sterile dressing are applied to the site upon removal of the catheter; refer to Procedure 33-9. The integrity of the catheter and insertion site should be assessed, with observations and actions documented to the client's medical record.

The removal of a PICC is usually a simple procedure; however, research suggests that in 7% to 12% of PICC removals, difficulties can arise (Macklin, 2000). Only nurses who have been trained in the insertion of a PICC line should remove the catheter. Since the catheter is completely inserted in the vascular system and invisible, the nurse must feel for resistance during removal. If resistance is felt, the nurse stops and assesses for certain complicating factors: venous spasm, vagal reaction, phlebitis, thrombosis, and knotting of the catheter. Prior to removal, the nurse must verify in the client's medical record the type and specific length of the inserted PICC.

UNCOVERING THE

Evidence

TITLE OF STUDY

“The Determination of Record-Keeping Behavior of Nurses Regarding Intravenous Fluid Treatment: The Case of Turkey”

AUTHORS

S. Arslan and A. Karadag

PURPOSE

To determine the record-keeping behavior of nurses regarding intravenous fluid treatment (IVFT).

METHODS

The study was conducted with 150 nurses working in adult clinics of a 936-bed university hospital.

FINDINGS

The most frequently fulfilled record-keeping behaviors were solution type, total solution amount, and date of treatment. The least frequently fulfilled behaviors were the diagnoses of clients and the time of passage for medication added to the solution. The nurses never recorded type of IVFT, complications, and discontinuation of therapy.

IMPLICATIONS

According to the findings of this study, the record-keeping behavior of nurses regarding IVFT is not at the desired level.

Arslan, S., & Karadag, A. (2008). The determination of record-keeping behavior of nurses regarding intravenous fluid treatment: The case of Turkey. *Journal of Infusion Nursing*, 31(5), 287–294.

Blood Transfusion

The purpose of a blood transfusion is to replace blood loss (deficit) with whole blood or blood components. On the basis of the client's unique needs, the prescribing practitioner determines the type of transfusion to administer, either whole blood or a component of whole blood, such as packed RBCs.

WHOLE BLOOD AND BLOOD PRODUCTS Clients with a demonstrated deficiency in either whole blood or a specific component of blood are given a blood transfusion. Whole blood contains RBCs and plasma components of blood. It is used when the client needs all the components of blood to restore blood volume after severe hemorrhage and to restore the capacity of the blood to carry oxygen. Various types of blood components are used in the clinical setting (see Table 33-8 on page 956). Packed RBCs are more commonly prescribed than whole blood.

TABLE 33-8 Blood-Component Therapy

TYPE	USES	SPECIAL CONSIDERATIONS
Fresh or frozen plasma	<ul style="list-style-type: none"> Replaces deficient coagulation factors Increases intravascular compartment 	<ul style="list-style-type: none"> Use within 6 hours with any straight-line administration set. Client is at risk for hepatitis.
Platelet	<ul style="list-style-type: none"> Corrects bleeding disorders (e.g., thrombocytopenia) Replaces platelets 	<ul style="list-style-type: none"> Infuse at rate of 10 minutes a unit with special platelet administration set.
Albumin	<ul style="list-style-type: none"> Restores intravascular volume Treats shock and hypoproteinemia 	<ul style="list-style-type: none"> Available in 5% and 25% solution. Infuse slowly with special tubing that accompanies solution.
Granulocyte (white blood cell)	<ul style="list-style-type: none"> Restores the leukocyte count, usually depressed in clients receiving radiation or chemotherapy 	<ul style="list-style-type: none"> Infuse slowly, over 2- to 4-hour interval with Y-type blood filters, and prime with normal saline.
Cryoprecipitate	<ul style="list-style-type: none"> Restores factor VIII and fibrinogen in treating hemophilia A 	<ul style="list-style-type: none"> Infuse with a straight-line administration set. Observe for febrile reactions.

Delmar/Cengage Learning

Plasma or fresh frozen plasma is separated and frozen within 8 hours after blood collection. Albumin (protein colloid) is a volume expander that maintains the colloid osmotic pressure of the blood. Albumin, hetastarch, and dextran (nonprotein colloids) are agents that increase intravascular volume in order to maintain hemodynamic stability and to provide adequate tissue perfusion. Cryoprecipitate is the most expensive of all blood components because it is constituted from many units of whole blood.

When the prescribing practitioner orders the administration of whole blood or a blood product, the client's blood is typed and cross-matched; refer to Chapter 28 for a complete discussion of blood groups and Rhesus (Rh) factor. Check with the family for donors if time and the client's condition permit. The blood is stored in the blood bank after typing and cross-matching until the nurse is ready to administer it.

Although whole blood has a refrigerated shelf life of 35 days, platelets must be administered within 3 days after they have been extracted from whole blood. If the RBCs and plasma are frozen, their shelf life can be extended up to 3 years (Kee et al., 2010).

INITIAL ASSESSMENT AND PREPARATION The nurse must perform an initial assessment before administering blood (see the accompanying display on page 957). The viscosity of whole blood usually requires the use of an 18- or 19-gauge needle or catheter to prevent damage to the red cells.

Scheduled IV medications should be infused before blood administration. This sequence prevents a reaction to a medication while blood is infusing; if a reaction were to

occur, the nurse would not be able to discern which infusate was causing the reaction.

ADMINISTERING WHOLE BLOOD OR A BLOOD COMPONENT The agency's blood protocol may require that a licensed person sign a form to release the blood from the blood bank and that a blood product be checked by two licensed personnel prior to infusion. The following information must be on the blood bag label and verified for accuracy: the client's name and identification number, ABO group and Rh factor, donor number, type of product ordered by the practitioner, and the expiration date.

Observe the blood bag for any signs of puncture, gas bubbles, color, and consistency (RBCs clumping). When the information has been verified, both licensed personnel sign the appropriate form. If any of the information does not match exactly or if the product has expired, return the product immediately to the blood bank.

Blood should be administered within 30 minutes after it has been received from the bank to maintain RBC integrity and to decrease the chance of infection. Whole blood should not go unrefrigerated for more than 4 hours. Room temperature will cause RBC lysis, releasing potassium and causing hyperkalemia (see Procedure 33-10).

SAFETY MEASURES As discussed in Procedure 33-10, the client should be observed for the initial 15 minutes for a transfusion reaction. Vital signs are usually taken every 15 minutes for the first hour, then every hour while the blood is transfusing.

BLOOD TRANSFUSION, INITIAL ASSESSMENT

- Verify that client has signed a blood administration consent form and that this consent matches what the prescribing practitioner has ordered.
- Verify whether the client has an 18- or 19-gauge needle or catheter in the vein; if the blood is to be infused quickly, a 14- or 15-gauge device must be used. Pediatric and older adult clients may require a 23-gauge device because of smaller or thin-walled veins.
- Ensure patency of the existing IV site.
- Establish baseline data for vital signs, especially temperature, and assess skin for eruptions or rashes.
- Check client's blood type against the label on the whole blood or blood component prior to administration, to ensure compatibility.
- Assess client's age. If the client is at risk for circulatory overload (pediatric, older adult, and malnourished clients), notify the blood bank to divide the 500-mL bag of blood into two 250-mL bags or discuss with the prescribing practitioner other alternatives, such as packed RBCs rather than whole blood.

To prevent blood contamination, change the blood tubing and filter every 4 hours or after each unit of blood. Transfuse each unit of blood over a 2- to 4-hour interval.

As a precaution against a blood transfusion reaction, prepare a bag of 0.9% sodium chloride, as directed by policy. The 0.9% sodium chloride is prepared as a secondary infusion system; it should not be connected to the Y-set tubing that is transfusing blood. If the client has a reaction and the blood is discontinued, the secondary bag of 0.9% sodium chloride should be connected and infused. This action prevents the client from receiving all the blood that is in the Y-set tubing, approximately 20 to 30 mL. Even though the procedure for infusing packed cells requires a Y-set for coadministering 0.9%

SAFETY FIRST

BLOOD TRANSFUSION INCOMPATIBILITY

Use only normal saline with a blood product. Blood transfusions are incompatible with dextrose and with Ringer's solution. Together, they cause hemolysis, clumping of RBCs.

sodium chloride, the secondary bag of 0.9% sodium chloride is a precautionary measure for transfusion reactions.

There are three basic types of transfusion reactions: allergic, febrile, and hemolytic. Other complications include sepsis, hypervolemia, and hypothermia. An allergic reaction may be mild or severe, depending on the cause. Hemolytic reactions may be immediate or delayed up to 96 hours, depending on the cause of the reaction. The classic symptoms of a reaction and sepsis are fever and chills.

The immediate nursing actions for all types of reactions and complications are to stop the transfusion, keep the vein open with 0.9% sodium chloride, and notify the prescribing practitioner. Other measures include sending the IV tubing and bag of blood back to the blood bank, obtaining a blood and urine specimen, labeling the specimen "Blood Transfusion Reaction," processing a transfusion reaction report, monitoring vital signs every 15 minutes for 4 hours or until stable, and monitoring the I&O.

A delayed hemolytic reaction results when donor and client anti-A or anti-B agglutinins are mismatched or when there has been improper storage of the blood unit. This reaction causes the cells to clump and form plugs in small blood vessels. Within a few hours or days, the phagocytic white blood cells (WBCs) and the reticuloendothelial system destroy agglutinated cells, releasing hemoglobin into the plasma. The client is monitored for jaundice, persistent anemia or fever, oliguria, flank pain, and abnormal bleeding.

An immediate hemolytic reaction is a rare occurrence. It results from a mismatch of the donor's and client's blood, causing immediate hemolysis of RBCs. The antibodies cause lysis of RBCs, which release proteolytic enzymes that rupture the cell membranes. The clinical manifestations are headache, dyspnea, cyanosis, chest pain, and tachycardia.

Febrile reactions are common and result from the client's sensitivity to WBCs, platelets, or plasma proteins. Warm, flushed skin; headache; muscle pain; and anxiety are the symptoms of a febrile reaction. It is treated with antipyretic medication.

To help prevent a febrile reaction, keep the client warm during the transfusion. Make sure that the tubing has a leukocyte-reduction filter. The leukocyte-reduction filter also reduces the risk of transmitting **cytomegalovirus (CMV)**, a DNA virus that causes intranuclear and intracytoplasmic changes in infected cells. Approximately 10% of seropositive donors are capable of transmitting CMV infection.

SAFETY FIRST

TRANSFUSION REACTION

The severity of a transfusion reaction is relative to its onset. Severe reactions may occur shortly after the blood starts to infuse. At the first sign of a reaction, stop the blood infusion immediately.

Mild allergic reactions are common, resulting from a sensitivity to infusing plasma proteins. Allergic reactions cause a rash, itching, hives (urticaria), and wheezing. Clients with these symptoms should be monitored for anaphylactic shock. Antihistamines may be prescribed to counter the allergic response.

Severe allergic reaction results from an antibody-antigen response as demonstrated by shortness of breath and chest pain; if untreated, it may cause circulatory collapse and cardiac arrest. If this occurs, initiate CPR after the blood has been discontinued.

Sepsis results from the administration of contaminated blood (containing gram-negative bacteria). It is a serious complication. Clinical manifestations include chills and fever, vomiting, abdominal cramping, diarrhea, shock, and renal failure. It is treated with broad-spectrum antibiotics and steroids. Nursing measures are directed toward maintaining hydration and monitoring I&O to evaluate renal function.

Hypervolemia from fluid overload is a preventable complication. Clients at risk for fluid overload are placed in a sitting position. The blood is transfused at a reduced flow rate; request the blood laboratory to divide the unit into two containers of blood so that none of it is unrefrigerated for more than 2 hours during transfusion. Clinical manifestations of hypervolemia are similar to those of fluid overload: dyspnea, cough and rales, distended neck veins, hypertension, tachycardia, and pulmonary edema. Administer oxygen and IV diuretics as prescribed to treat circulatory overload.

Clients needing rapid transfusions are at risk for transfusion-induced hypothermia. Such clients may include neonates needing exchange transfusions and trauma victims who require large volumes of whole blood. A blood-warming device may be prescribed to prevent transfusion-induced hypothermia. The symptoms of transfusion-induced hypothermia result from the rapid transfusion of large amounts of cold blood. If the infusing blood temperature is below 30°C (86°F), the myocardial temperature decreases, causing hypotension and myocardial irritability that may progress to ventricular fibrillation and cardiac arrest. Nursing interventions are directed toward warming the client with temperature-regulating blankets after the transfusion has been stopped. Obtain an electrocardiogram (ECG) to assess for cardiac arrhythmias.

COMPLEMENTARY THERAPY

Herbs and certain foods are used to maintain health and prevent the onset of chronic debilitating diseases such as diabetes mellitus and renal failure. Naturopathic health care practitioners (NDs) use herbs as medicine, and although herbs are the main ingredient of some of the drugs used in conventional medicine, NDs use herbs differently than MDs. MDs prescribe drugs to treat symptoms. For example, in hypertension, the prescribed drug controls the blood pressure but does not correct the reason why the body has increased the pressure in the first place; an ND uses herbs to correct the underlying problem. The following discussion will explain how herbs and foods can be used to treat certain conditions that create disturbances in body fluids and pH.

Traditional Chinese medicine relies on nutrition and dietetic principles to treat certain illnesses and imbalances. Foods are recommended based on their energetic properties such as toxifying, dispersing, heating, cooling, moistening, and drying and eating in tune with seasonal changes. Cooling foods such as watermelon, celery, and cucumber are recommended during the warmer months of spring and summer because they contain a higher percentage of water than warming foods such as meats, garlic, and spices, which are eaten during the cooler months of autumn and winter.

Many plants have a hypoglycemic action; they lower blood sugar levels. Such plants include dandelion root, garlic, ginseng, and nettles. Other plants have also been identified as possessing hypoglycemic action such as allspice, artichoke, banana, barley, bugleweed, lettuce, oats, onion, and spinach, to name a few. When herbs and diet are used in a tailor-made combination for the individual, the amount of glucose entering the blood is kept at a constant level. Tierra and Lust (2008) recommend dandelion root in combination with other tonic herbs such as ginseng and a little ginger for maximum benefit, along with a balanced diet for hypoglycemia.

Herbs such as dandelion and cleavers, which aid the kidneys, not only are useful for renal problems but may aid the cleansing mechanism in treating the whole body, no matter what the problem. The main benefits of dandelion are exerted upon the functions of the liver by clearing obstructions and stimulating and aiding the liver to eliminate toxins from the blood. Dandelion root is helpful in treating hypertension, thus aiding the action of the heart. Dandelion (root and leaf) acts as a diuretic and can be taken for fluid retention, cystitis, and nephritis. Dandelion also contains a high percentage of potassium and actually increases the potassium level, thereby avoiding the loss of potassium caused by synthetic diuretics.

Caution should be used when taking licorice since this herb contains a variety of active ingredients. Glycyrrhizin, an active ingredient of licorice, can produce effects similar to aldosterone. Due to the aldosterone-like effects, whole licorice can cause fluid retention, high blood pressure, and potassium loss in doses that exceed 3 g daily for more than 6 weeks. Clients who take digitalis or a thiazide diuretic or who have hypertension, heart disease, diabetes, or kidney disease should avoid the use of licorice.

EVALUATION

Evaluation is an ongoing process for clients with fluid, electrolyte, and acid-base imbalances. Focus on the client's responses when evaluating whether the time frames and expected outcomes are realistic (such as whether the I&O are within 200 to 300 mL of each other). The client's vital signs should be within normal limits. The IV infusion rate is accurately calculated and reassessed throughout therapy to maintain the client's hydration. The IV site should remain free from erythema, edema, and purulent drainage. The nursing care plan is modified as necessary to support the client's expected outcomes.

NURSING CARE PLAN

The Client with Deficient Fluid Volume**CASE PRESENTATION**

Mrs. Gray is a 75-year-old woman with diabetes who has been experiencing flulike symptoms of vomiting and diarrhea for 5 days. She lives alone and does not like to cook. When she got up this morning, she felt weak and dizzy; she called 911 to take her to the clinic. The EMS providers called the practitioner en route, and Mrs. Gray was taken directly to the infusion center.

ASSESSMENT

- Marked thirst
- Temperature 37.2°C
- BP 94/74
- Wt 157 lb (5% loss from 165)
- Dry mucous membranes
- Respirations 30
- Apical pulse 108/min
- ↑ HCT, ↑ hgb, ↑ BUN

NURSING DIAGNOSIS 1: *Deficient fluid volume* related to vomiting and diarrhea

NOC: Hydration

NIC: Fluid/electrolyte management

EXPECTED OUTCOMES

1. The client will
 - Experience relief from vomiting and diarrhea in 2–4 hours.
 - Demonstrate clinical signs of adequate hydration prior to discharge.
 - Understand the reasons for the deficient fluid and the amounts and types of foods and fluids to consume to prevent a recurrence.
2. The client's fluid intake and output will be balanced in 12–24 hours.
3. The client's weight will be stable, and lab values will be within normal limits prior to discharge.

INTERVENTIONS/RATIONALES

1. Assess and document amount, color, and characteristics of vomitus and diarrhea.
Determines fluid replacement.
2. Maintain NPO status. Allows the GI tract to heal.
3. Measure vital signs qh. Monitors client status.
4. Assess skin turgor. Indicates hydration status.
5. Administer antiemetics and antidiarrheals. Prevents further fluid loss.
6. Measure and document qh. Assesses fluid balance.
7. Report and document output < 30 mL/h. Alerts to severe fluid imbalance.
8. Administer PO fluids as tolerated 2 hours postvomiting/diarrhea. Gradually reintroduces oral intake.
9. Administer IV lactated Ringer's solution with flow rate as prescribed. Prevents overhydration.
10. Assess and document skin and mucous membrane moisture, skin color and hydration, urine for sugar or acetone, and mental status. Indicates hydration status.
11. Weigh the client on the same scale, in the same clothes, after voiding. Monitor serum glucose, osmolality, HCT, hgb, and BUN. Monitors weight changes and fluid and electrolyte status.

(Continues)

NURSING CARE PLAN (Continued)

12. Assess the client's knowledge level; provide information about causes and why interventions are being performed, and explain actions to take to prevent a recurrence. Educates client as to causes and remedies for fluid volume deficit.

EVALUATION

- Client free from vomiting 2 hours postadmission; diarrhea stopped within 5 hours after being placed NPO.
- Hourly urinary output 30 mL/h; tolerated 4 oz of Gatorade 6 hours postadmission, progressed to clear liquid diet; I&O balanced 20 hours postadmission.
- Mucous membranes moist; good skin turgor and color; absence of thirst; urine was free from sugar and acetone; alert client prior to discharge.
- Client's weight and lab values were within normal limits prior to discharge.
- Client verbalizes knowledge of causes and methods of monitoring fluid status.

NURSING CARE PLAN

The Client with Excess Fluid Volume

CASE PRESENTATION

Mr. Hill, a 68-year-old widower, was taken to the emergency department by his granddaughter and stated, "I can't breathe." He has a history of hypertension and heart disease. He is obese. The practitioner ordered a stat chest x-ray, complete blood cell count (CBC), and electrolytes.

ASSESSMENT

- Shortness of breath (SOB), rales
- Constant cough
- Wt 161.8 lb
- Pitting edema, ankles
- 36.4°C; 186/114; 98; 30 and labored
- Engorged neck veins
- Pulmonary congestion (x-ray)
- ↓ HCT; ↓ hgb

NURSING DIAGNOSIS 1: *Excess fluid volume* related to body fluid overload secondary to heart dysfunction

NOC: Fluid overload severity

NIC: Fluid monitoring

EXPECTED OUTCOMES

1. The client will
 - Have a balanced fluid intake and output (est. 2500 mL/day) for 2 days.
 - Identify a specific amount of weight to lose over the next 6 months.
 - Manifest normal hydration status prior to discharge.
 - Demonstrate understanding of the causes of excess fluid and the role of heart medications, foods, and exercise to assist with weight reduction.
2. The client's skin integrity will be maintained over the edematous areas.

(Continues)

NURSING CARE PLAN (Continued)

INTERVENTIONS/RATIONALES

1. Measure and document hourly I&O; restrict fluids as ordered. Monitors fluid status.
2. Administer diuretics as ordered; document the response. Increases excretion of electrolytes.
3. Weigh daily at the same time with the same clothing. Monitors overall client status.
4. Measure and document vital signs qh until SOB subsides, then q2h. Hourly assessments: Auscultate for third heart sound, breath sounds; assess rate, rhythm, depth of respirations, and the position the client takes to relieve SOB; report changes in respiratory pattern. Monitors client response to therapy and diuretics; gives information to modify plan of care.
5. Inspect and palpate areas of edema. Determines whether edema is localized or generalized and reveals extent.
6. Institute preventive skin measures: Elevate extremities on pillows to ↓ pressure and promote venous circulation; avoid rubbing the skin, apply lotion, pat dry; avoid soap on the area; inspect for redness or blanching. Maintains skin integrity, promotes circulation, and promotes client comfort.
7. Assess client's knowledge of hypertension and decreased cardiac output; digitalis; the effects of a large abdominal girth on breathing; and foods low in sodium, fats, and carbohydrates. Educating client about causes, aggravating and alleviating factors, and effects of fluid excess is the first step in encouraging client in proper self-care.

EVALUATION

- Output for the first 2 hours 2020 mL; Day 2, I&O measurements indicative of fluid balance.
- Client identified need to lose 30 lb over the next 6 months.
- The client's hemodynamic status is within normal levels as demonstrated by HCT, hgb, and BP 156/92 and by the absence of SOB, abnormal breath sounds, jugular engorgement, or peripheral edema.
- The client's skin integrity was maintained.
- The client was unable to verbalize knowledge of how his weight, high-sodium diet, failure to take his heart medications, and chronic alterations caused the fluid excess. Referred to home health for client teaching.

NURSING PROCESS HIGHLIGHT

Implementation

Fluid Replacement

Fluid replacement is based on weight loss. A 2.2-lb (1 kg) loss is equivalent to 1 L (1000 mL) of fluid loss. First, convert Mrs. Gray's weight from pounds to kilograms. Then determine the fluid intake replacement needed on the basis of the weight loss: Include the IV lactated Ringer's solution and PO Gatorade in milliliters. On the basis of the intake, what should have been her output prior to discharge?

NURSING PROCESS HIGHLIGHT

Nursing Diagnosis

Secondary Diagnoses

The nursing diagnosis *EFV: Edema* usually has many accompanying secondary nursing diagnoses: *Breathing pattern: Ineffective*, related to increased capillary permeability causing fluid overload in the lung tissue (pulmonary edema); *Skin integrity: Impaired*, related to edematous tissues (peripheral edema); *Ineffective tissue perfusion* related to hypervolemia as manifested by peripheral (tissue) edema; and *Deficient knowledge: EFV*, related to chronic alterations.

PROCEDURE 33-1

Measuring Intake and Output

EQUIPMENT

- Intake and output (I&O) form at bedside
- I&O graphic record in chart
- Glass or cup
- Bedpan or urinal bedside commode
- Graduated container for output
- Nonsterile gloves
- Sign at bedside stating client is on I&O

ACTION

RATIONALE

1. Wash hands/hand hygiene.
 2. Explain the rules of I&O record. All fluids taken orally must be recorded on the client's I&O form (sometimes called a fluid balance flow sheet).
 - Client must void into bedpan or urinal, not into toilet (see Figure 33-17).
 - Toilet tissue should be disposed of in plastic-lined container, not in bedpan.
 3. Measure all oral fluids in accord with institution policy; for example, cup 150 mL, glass 240 mL. Record all IV fluids as they are infused (see Figure 33-18).
 4. Record time and amount of all fluid intake in the designated space on bedside form (oral, tube feedings, IV fluids).
 5. Transfer 8-hour total fluid intake from bedside I&O record to graphic sheet or 24-hour I&O record on client's chart.
1. Reduces transmission of microorganisms.
 2. Elicits client support.
 - Fluid voided into the toilet cannot be measured.
 - Liquids absorbed into toilet tissue cannot be measured by volume.
 3. Provides for consistency of measurement.
 4. Documents fluids.
 5. Provides for data analysis of the client's fluid status.

FIGURE 33-17 Graduated specimen container is used to measure urine, drainage, or other output. DELMAR/CENGAGE LEARNING

FIGURE 33-18 All IV infused fluids must be measured. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 33-1
Measuring Intake and Output (Continued)

ACTION	RATIONALE
6. Record all fluid intake in the appropriate column of the 24-hour record.	6. Documents intake by type and amount.
7. Complete 24-hour intake record by adding all 8-hour totals.	7. Provides consistent data for analysis of the client's fluid status over a 24-hour period.
OUTPUT	
8. Apply nonsterile gloves.	8. Reduces potential for transmission of pathogens.
9. Empty urinal, bedpan, or Foley drainage bag (see Figure 33-19) into graduated container or commode "hat" (see Figure 33-20).	9. Provides accurate measurement of urine.
10. Remove gloves. Wash hands/hand hygiene.	10. Prevents cross-contamination.
11. Record time and amount of output (urine, drainage from nasogastric tube, drainage tube) on I&O record.	11. Documents output.
12. Transfer 8-hour output totals to graphic sheet or 24-hour I&O record on the client's chart.	12. Provides for data analysis of the client's fluid status.
13. Complete 24-hour output record by totaling all 8-hour totals.	13. Provides consistent data for analysis of the client's fluid status over a 24-hour period.
14. Wash hands/hand hygiene.	14. Reduces transmission of microorganisms.

FIGURE 33-19 Urine in Foley drainage bag must be measured. DELMAR/CENGAGE LEARNING

FIGURE 33-20 Empty urine into a graduated container to measure. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 33-1 Measuring Intake and Output (Continued)

delegation tip

I&O measurement may be delegated to ancillary personnel knowledgeable about the following:

- Obtaining accurate measurements and reporting incontinence
- Observing the amount, color, and any odor from the output
- Recording measurements on proper clinical records
- Protecting themselves from contamination from a body fluid and storing collection containers in designated areas

nursing tips

- Keep I&O flow sheet close to the bedside.
- Teach clients about the necessity of keeping accurate I&O records.
- Keep water fresh, and encourage beverages as allowed.
- Record measurements immediately instead of waiting until the end of the shift.
- 240 cc ice chips equal 120 cc fluid.
- Pureed food is not considered to be fluid intake.
- Bottled nutrient tube feedings are liquid and must be considered in I&O.
- All postoperative clients are at risk for fluid loss through blood or plasma from their incision sites. Monitor the dressings.
- Remember that fluids taken to swallow pills must be recorded as intake.
- Do not have visitors or family members empty bedpans, urinals, or catheter bags.

PROCEDURE 33-2

Preparing an IV Solution

EQUIPMENT

- IV solution in a bag
- Medication administration record (MAR)
- IV flow sheet
- IV tubing, if needed

ACTION

RATIONALE

- | | |
|---|---|
| <ol style="list-style-type: none"> 1. Check prescribing practitioner's order for the IV solution (see Figure 33-21 on page 965). 2. Wash hands/hand hygiene. Apply gloves if required by institutional policy. 3. Prepare new bag by removing protective cover from bag. 4. Inspect the bag for leaks, tears, or cracks. Inspect the fluid for clarity, particulate matter, and color. Check expiration date. | <ol style="list-style-type: none"> 1. Ensures accurate administration of the solution. 2. Reduces the transmission of microorganisms. 3. Allows for access to the solution container. 4. Prevents infusing contaminated or outdated solution. |
|---|---|

PROCEDURE 33-2 Preparing an IV Solution (Continued)

A

B

FIGURE 33-24 A. Priming the IV tubing. B. Open the roller clamp on the tubing to allow the fluid to enter the tube and expel the air. DELMAR/CENGAGE LEARNING

delegation tip

The skill of IV solution administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- Anticipate the need for the next bag of IV solution to avoid the risk of an IV clotting caused by the solution running out.
- Hold the bag up against both a light and dark solid background to check for discoloration.

PROCEDURE 33-3

Preparing the IV Bag and Tubing

EQUIPMENT

- Disposable gloves
- IV solution in a bag
- IV tubing as ordered
- Sterile 2 × 2 gauze

(Continues)

PROCEDURE 33-3
Preparing the IV Bag and Tubing (Continued)

ACTION	RATIONALE
1. Check prescribing practitioner’s order for the IV solution.	1. Ensures accurate administration of the solution.
2. Wash hands/hand hygiene.	2. Reduces transmission of microorganisms.
3. Check client’s identification bracelet. Gather equipment (see Figure 33-25).	3. Ensures medication is given to the correct client.
4. Prepare new bag by removing protective cover. Check the expiration date on the bag and assess for cloudiness or leakage.	4. Allows for quick, smooth preparation. Ensures that the solution is sterile.
5. Open new infusion set. Unroll tubing and close roller clamp.	5. Prevents fluid from leaking after IV bag is spiked.
6. Spike bag with tip of new tubing and compress drip chamber to fill halfway (see Figures 33-26 to 33-28).	6. Promotes rapid flow of solution through new tubing without air bubbles.
7. Open roller clamp, remove protective cap from the end of the tubing, and slowly flush solution completely through tubing.	7. Removes air from tubing. Prevents entry of air into the venous system, a cause of air embolus. If fluid enters tubing too rapidly, air bubbles occur.
8. Close roller clamp and replace cap protector.	8. Prevents fluid from leaking and maintains sterility of tubing.

FIGURE 33-25 Gloves, alcohol pad, IV solution, and tubing. DELMAR/CENGAGE LEARNING

FIGURE 33-26 Remove the protective cap from the end of the IV tubing. DELMAR/CENGAGE LEARNING

FIGURE 33-27 Spike the bag with the sharp tip of the new tubing. DELMAR/CENGAGE LEARNING

FIGURE 33-28 Compress the drip chamber and allow it to fill halfway with fluid. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 33-3 Preparing the IV Bag and Tubing (Continued)

ACTION	RATIONALE
9. Apply clean gloves. 10. Remove old tubing and replace with new tubing: <ul style="list-style-type: none"> • Place sterile 2 × 2 gauze under IV catheter or heparin lock. • Stabilize hub of catheter or needle and gently pull out old tubing. • Quickly insert new tubing into hub of catheter or needle. • Open roller clamp to establish flow of IV solution. • Reestablish drip rate (see Figure 33-29). • Apply new dressing to IV site. 	9. Reduces transmission of microorganisms. 10. <ul style="list-style-type: none"> • Absorbs fluids that may drip during the procedure, preventing contamination of surrounding areas. • Prevents accidental dislodging of catheter or needle. • Prevents backflow of blood or the entrance of air into the vein. • Prevents catheter occlusion and maintains IV flow at prescribed rate. • Maintains IV flow at prescribed rate. • Provides protection from infection and accidental dislodgment.
11. Discard old tubing and IV bag.	11. Prevents accidental transmission of microorganisms.
12. Remove gloves and dispose of all used materials.	12. Reduces transmission of microorganisms.
13. Apply a label with date and time of change to tubing. Calculate IV drip rates and begin infusion at prescribed rate.	13. Indicates when tubing replacement is due (every 72–96 hours), in accordance with agency policy. Ensures administration at prescribed rate.
14. Wash hands/hand hygiene.	14. Reduces transmission of microorganisms.

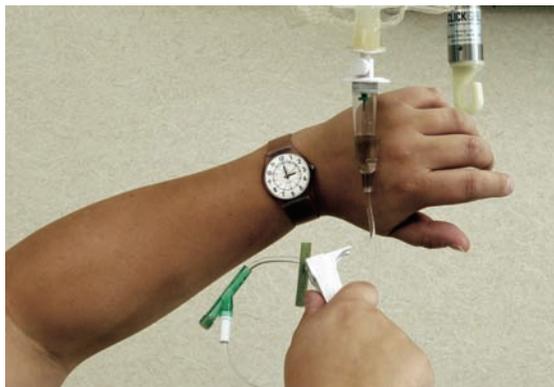

FIGURE 33-29 Establish the drip rate. DELMAR/CENGAGE LEARNING

delegation tip

Initiating IV therapy via IV bag and tubing preparation is a skill involving assessment and the use of medical asepsis. It is a procedure not delegated by the nurse unless other licensed personnel have been trained and certified to perform the procedure.

nursing tips

- Be sure the tape at the IV site is loosened so it is easier to change the tubing.
- Place a towel under the arm of the IV site where the tubing will be changed in order to keep the linen clean in case of blood leaking from the needle during IV tubing change.

PROCEDURE 33-4

Assessing and Maintaining an IV Insertion Site

EQUIPMENT

- Clean gloves
- Gauze dressing
- Tape
- Nursing documentation record

ACTION

RATIONALE

- | | |
|---|--|
| <ol style="list-style-type: none"> 1. Review prescribing practitioner's order for IV therapy. 2. Review client's history for medical conditions or allergies. 3. Review client's IV site record and intake and output (I&O) record. 4. Wash hands/hand hygiene. 5. Assemble equipment and obtain client's vital signs (see Figure 33-30). 6. Check IV fluid for correct fluid, additives, rate, and volume at the beginning of the shift (see Figure 33-31). 7. Check IV tubing for tight connections every 4 hours. 8. Check gauze IV dressing hourly to be sure it is dry and intact (see Figure 33-32 on page 971). 9. If the gauze is not dry and intact, remove the dressing and observe site for redness, swelling, or drainage. 10. If an occlusive dressing is used, do not remove the dressing when assessing the site. 11. Observe vein track for redness, swelling, warmth, or pain hourly. 12. Document IV site findings in the nursing record or flow sheet. 13. Wash hands/hand hygiene. | <ol style="list-style-type: none"> 1. Ensures accuracy in the administration of IV therapy. 2. Decreases risk of fluid overload and allergic reactions. 3. Assesses for potential problems with fragile IV sites and fluid balance. 4. Decreases transmission of microorganisms. 5. Assesses for changes in cardiovascular system. 6. Ensures client is receiving correct therapy. 7. Ensures that no fluid leaks from tubing and connections. 8. Ensures there is no sign of infiltration or infection at IV insertion site. 9. Ensures there is no sign of inflammation or infection at IV site. 10. Ensures there is no sign of inflammation or infection at IV site. Transparent dressings can be left in place up to a week if they remain clean, dry, and intact (Hadaway, 2008). 11. These are early signs of phlebitis or infiltration. 12. Provides documentation of frequent IV site observation. 13. Decreases transmission of microorganisms. |
|---|--|

FIGURE 33-30 Transparent dressing, nonsterile gloves, tape, gauze sponges, and topical iodine ointment. DELMAR/ CENGAGE LEARNING

FIGURE 33-31 Check the IV fluid rate, volume, tubing, and additives at the beginning of the shift. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 33-4 Assessing and Maintaining an IV Insertion Site (Continued)

FIGURE 33-32 Check the IV dressing site every hour. DELMAR/CENGAGE LEARNING

delegation tip

Assessing and maintaining the IV after establishing the infusion is the responsibility of the nurse. It is a procedure not delegated unless other licensed personnel have been trained and certified to perform the procedure. Ancillary personnel may be instructed to report an infusion that is dripping too fast or an IV bag that is almost empty. It is the nurse's responsibility to monitor the infusion, but ancillary personnel may also be instructed to report any observations such as swelling, leaking, client concerns about pain, numbness, or tingling at the site or in the extremity used for the infusion. Ancillary personnel may also be involved in monitoring the client's daily weight, if ordered, along with I&O. They should be instructed not to obtain vital signs on an extremity with solutions infusing.

nursing tips

- Be organized. Review the orders before examining the client's IV so you do not have to go back and check.
- Bring supplies with you for the assessment: gauze, tape, scissors, gloves.
- As you complete your assessment of the client's IV, incorporate teaching the client the signs and symptoms to report.

PROCEDURE 33-5

Changing the IV Solution

EQUIPMENT

- Disposable gloves
- Additives as ordered
- Alcohol swab (if needed)
- IV solution in a bag
- IV tubing

(Continues)

PROCEDURE 33-5 Changing the IV Solution (Continued)

ACTION	RATIONALE
<ol style="list-style-type: none"> 1. Check prescribing practitioner's order for the IV solution. 2. Wash hands/hand hygiene. Don clean gloves. 3. Check client's identification bracelet. 4. Prepare new bag with additives as ordered by prescribing practitioner (see Figure 33-33). <ul style="list-style-type: none"> • Plan for new bag to be hung at least 1 hour before it is needed. • Change solution when the IV bag is empty but there is still solution in the drip chamber (see Figure 33-34). 5. Be sure drip chamber is at least half full (see Figure 33-35 on page 973). 6. Change IV solution: <ul style="list-style-type: none"> • Move roller clamp to stop flow of fluid. • Remove old IV bag from IV pole and hang new bag. • Spike new bag with tubing (see Figure 33-36 on page 973). • Reestablish prescribed flow rate. 	<ol style="list-style-type: none"> 1. Ensures accurate administration of the solution. 2. Reduces transmission of microorganisms. 3. Ensures IV solution is given to the correct client. 4. Laboratory tests may reveal a need for potassium, insulin, or magnesium. <ul style="list-style-type: none"> • Reduces clot formation in vein caused by empty IV bag. • Prevents air from entering tubing and vein from clotting from lack of flow of fluid. 5. Prevents entry of air into IV tubing while bag is being changed. 6. <ul style="list-style-type: none"> • Prevents fluid in drip chamber from emptying while changing solutions. • Prepares equipment. • Maintains sterility of solution. • Prevents clotting of vein.

FIGURE 33-33 Prepare new bag. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 33-5 Changing the IV Solution (Continued)

ACTION

FIGURE 33-35 Make sure the drip chamber is at least half full of fluid. DELMAR/CENGAGE LEARNING

7. Check for air in tubing.
 - If air bubbles are present, close the roller clamp. While stretching the tubing, flick the tubing with the finger and watch the bubbles rise to the drip chamber.
 - If a large amount of air is in the tubing, insert a needle with an empty syringe into a port below the air (see Figure 33-37 on page 974) and allow the air to enter the syringe as it flows to the client (see Figure 33-38 on page 974).
8. Empty remaining fluid from old IV if needed (see Figure 33-39 on page 974).
9. Remove gloves and dispose of all used materials.
10. Apply a label with date, time, and type of solution.
11. Wash hands/hand hygiene.

RATIONALE

FIGURE 33-36 Spike the new bag with the sharp end of the tubing. DELMAR/CENGAGE LEARNING

7. Reduces risk of air embolus.
8. Disposes of excess fluid. Reduces risk of spilling large amounts of fluid in waste can.
9. Reduces transmission of microorganisms.
10. Allows for planning of next change.
11. Reduces transmission of microorganisms.

(Continues)

PROCEDURE 33-5 Changing the IV Solution (Continued)

FIGURE 33-37 If there is a large amount of air in the tubing, insert a syringe into a port between the air and the client. DELMAR/CENGAGE LEARNING

FIGURE 33-38 Allow the air to flow into the syringe. DELMAR/CENGAGE LEARNING

FIGURE 33-39 Drain the remaining fluid from the old IV bag. DELMAR/CENGAGE LEARNING

delegation tip

Changing the IV solution after establishing the infusion is the responsibility of the nurse. It is a procedure not delegated unless other licensed personnel have been trained and certified to perform the procedure. Ancillary personnel may be instructed to report an infusion that is dripping too fast or an IV bag that is almost empty.

nursing tips

- Anticipate the need for the next bag of IV solution to avoid the risk of an IV clotting because of the solution running out.
- Keep in mind the client's laboratory results and need for fluid to be sure the correct solution is given.

PROCEDURE 33-6

Flushing a Central Venous Catheter

EQUIPMENT

- Chlorhexidine 2% and alcohol swabs
- Syringes (10-mL)
- Vial or ampule of normal saline solution
- Vial of heparin solution (heparin flush or heparin 100 units/mL in saline) (check institution policy on heparin solution use)
- Plastic clamp or metal bull-dog clamp
- Sterile needle (20- to 22-gauge)
- Sterile gloves, gown, and mask

ACTION

1. Wash hands/hand hygiene. Apply gloves, gown, and other protective equipment as needed.
2. Prepare two syringes (see Figure 33-40): one with 10 mL normal saline and one with 5 mL heparin solution.
3. Swab injection cap or catheter hub with alcohol or chlorhexidine 2%.
4. Clamp catheter and remove cap.
5. Check catheter for patency:
 - Attach syringe with normal saline.
 - Release clamp.
 - Aspirate heparin solution from catheter (see Figure 33-41).
 - Observe blood return.
 - Flush quickly with normal saline (see Figure 33-42 on page 976).
 - Reclamp.
 - Remove empty syringe.
 - Attach syringe filled with 5 mL heparin solution to catheter.
 - Release clamp.
 - Flush quickly.
 - Reclamp.

RATIONALE

1. Reduces transmission of microorganisms.
2. Preparing equipment in advance allows for a smooth procedure.
3. Prevents introduction of microorganisms into catheter.
4. Prevents entrance of air into catheter.
5. Ensures patency of catheter.
 - Connects syringe to catheter.
 - Opens catheter lumen.
 - Removes old heparin solution.
 - Verifies patency of catheter.
 - Ensures that catheter will be cleared of any blood so it will not clot.
 - Clamping catheter during changes of syringes prevents air from entering catheter.
 - Continues procedure.
 - Connects syringe to catheter.
 - Opens catheter lumen.
 - Injects heparin solution into catheter.
 - Closes catheter lumen.

FIGURE 33-40 Prepare two syringes. DELMAR/CENGAGE LEARNING

|---|--|

delegation tip

Flushing a central venous line is a complex skill requiring assessment and proper technique. It is a procedure not delegated unless other licensed personnel have been trained and certified to perform the procedure.

nursing tips

- | | |
|---|---|
| <ul style="list-style-type: none"> • Have all the equipment available for the procedure. • Take advantage of this procedure to assess the client and provide emotional support. • Different catheters require different amounts of heparin or no heparin at all. | <ul style="list-style-type: none"> • Some catheters do not require clamps. • If maneuvers to aspirate blood are not successful, the prescribing practitioner should be notified so fibrinolytic therapy (urokinase) can be ordered and given according to institutional policy. |
|---|---|

PROCEDURE
33-7

Setting the IV Flow Rate

EQUIPMENT

- | | |
|---|---|
| <ul style="list-style-type: none"> • Watch with a second hand • IV solution in a bag • IV tubing | <ul style="list-style-type: none"> • IV infusion pump • Volume-control device • Paper and pencil |
|---|---|

ACTION

RATIONALE

- | | |
|--|---|
| <ul style="list-style-type: none"> 1. Check prescribing practitioner's order for the IV solution and rate of infusion. 2. Wash hands/hand hygiene. | <ul style="list-style-type: none"> 1. Ensures accurate administration of the solution. 2. Reduces transmission of microorganisms. |
|--|---|

(Continues)

PROCEDURE 33-7 Setting the IV Flow Rate (Continued)

ACTION	RATIONALE
3. Check client's identification bracelet.	3. Ensures medication is given to the correct client.
4. Prepare to set flow rate: <ul style="list-style-type: none"> • Have paper and pencil ready to calculate flow rate. • Review calibration in drops per milliliter (gtt/mL) of each infusion set. 	4. <ul style="list-style-type: none"> • A nurse unfamiliar with IV fluid rates should calculate the rate at first. • Drops per milliliter vary with manufacturer and tubing type. Macrodrop tubing varies from 10–15 gtt/mL. Microdrop tubing generally delivers 60 gtt/mL.
5. Determine hourly rate by dividing total volume by total hours.	5. Provides a prescribed hourly rate with no sudden increases or decreases. The formula for calculation is:
Example 1: The order reads 1000 mL D5W with 20 mEq KCl over 8 hours:	$\frac{\text{m/h}}{60 \text{ min}} = \text{mL/min}$
$\frac{1000 \text{ mL}}{8 \text{ h}} = 125 \text{ mL/h}$	
Example 2: Three liters are ordered for 24 hours:	
$\frac{3000 \text{ mL}}{24 \text{ h}} = 125 \text{ mL/h}$	
6. Apply a time label to the IV bag with the hourly time periods according to the rate. 7. Calculate the minute rate based on the drop factor of the infusion set:	6. Provides a visual check of the fluid infused to be sure the rate is correct. 7. The nurse can use the formulas to calculate how many drops per minute will be infused and can adjust the rate for a change in tubing (macrodrop, microdrop).
$\text{Drop factor} \times \text{mL/min} = \text{gtt/min}$	
$\frac{\text{mL/h} \times \text{drop factor}}{60 \text{ min}} = \text{gtt/min}$	
$\frac{\text{hourly rate} \times \text{drop factor}}{\text{infusion time in minutes}} = \text{gtt/min}$	
<ul style="list-style-type: none"> • Microdrop example: $\frac{125 \text{ mL} \times 60 \text{ gtt/mL}}{60 \text{ min}} = \frac{7500 \text{ gtt}}{60 \text{ min}} = 125 \text{ gtt/min}$ 	
<ul style="list-style-type: none"> • Macrodrop example: $\frac{125 \text{ mL} \times 15 \text{ gtt/mL}}{60 \text{ min}} = 31 \text{ gtt/min}$ 	
8. Set flow rate using the appropriate device (see Figures 33-43 and 33-44 on page 978). <ul style="list-style-type: none"> • For regular tubing without a device: Count drops in drip chamber for 1 minute while 	8. <ul style="list-style-type: none"> • Ensures that infusion is administered as ordered. • Pumps the solution through the tubing at the rate set.

(Continues)

PROCEDURE 33-7 Setting the IV Flow Rate (Continued)

ACTION

RATIONALE

FIGURE 33-43 There are many types of IV pumps available. DELMAR/CENGAGE LEARNING

A

B

FIGURE 33-44 A. IV Tubing and Drip Chamber with a Dial-A-Flo; B. Volume-Control Infusion Chamber DELMAR/CENGAGE LEARNING

watching second hand of watch and adjust the roller clamp as necessary (see Figure 33-45 on page 979).

- For an infusion pump: Insert the tubing into the flow-control chamber, select the desired rate (generally calibrated in cc/min), open the roller clamp, and push the start button.
- For a controller: Place IV bag 36 inches above the IV site, select the desired drops per minute, open the roller clamp, and count drops for 1 minute to verify rate.

- The controller works by gravity.
- The amount of fluid in the volume-control chamber depends on the amount of fluid to be infused per hour:

$$50 \text{ cc/hour} = 50 - 100 \text{ cc of fluid}$$

$$100 \text{ cc/hour} = 100 - 200 \text{ cc of fluid}$$

(Continues)

PROCEDURE 33-7 Setting the IV Flow Rate (Continued)

ACTION	RATIONALE
<ul style="list-style-type: none"> For volume-control device: Place device between IV bag and insertion spike of IV tubing, fill with 1–2 hours amount of IV fluid, and count drops for 1 minute (see Figure 33-46). <ol style="list-style-type: none"> Monitor infusion rates and IV site for infiltration. Assess infusion when alarm sounds. Wash hands/hand hygiene. 	<ol style="list-style-type: none"> Infusion devices may fail. Alarms on infusion devices signal when a drip has not been sensed. It can be caused by an empty IV bag, a kink in the tubing, a clotted needle, an infiltrated IV, or another malfunction of the device. Reduces transmission of microorganisms.

FIGURE 33-45 Count the drips in the drip chamber for 1 minute. DELMAR/CENGAGE LEARNING

FIGURE 33-46 The controller is placed between the IV bag and the client. It is filled with 1 to 2 hours worth of IV fluid. DELMAR/CENGAGE LEARNING

delegation tip

Setting the rate of the IV after establishing the infusion is the responsibility of the nurse. It is a procedure not delegated unless other licensed personnel have been trained and certified to perform the procedure. Ancillary personnel may be instructed to report an infusion that is dripping too fast or an IV bag that is almost empty. It is the nurse's responsibility to monitor the infusion, but ancillary personnel may also be instructed to report observations such as swelling, leaking, or client concerns about pain, numbness, or tingling at the site or in the extremity used for the infusion.

nursing tips

- Anticipate the client's need for IV fluid so the next bag is ready to hang before the current one is finished.
- Watch for kinks in the IV tubing or other impediments to the infusion of the fluid.
- Remember not to depend entirely on an infusion pump or controller as they can fail.

PROCEDURE 33-8

Changing the Central Venous Dressing

EQUIPMENT

- Chlorhexidine 2% or agency-approved antiseptic solution
- Skin protectant solution
- Sterile gauze, tape, or transparent semipermeable membrane (TSA) dressing
- Label with date and time of dressing change
- Latex-free gloves

ACTION

1. Wash hands/hand hygiene; don clean gloves. Open dressing tray (see Figure 33-47).
2. Remove old dressing carefully by pulling up a small section on each side and pulling laterally (see Figures 33-48 and 33-49), being careful not to dislodge the central catheter.
3. Note drainage on dressing.
4. Inspect skin at insertion site for redness, tenderness, or swelling (see Figure 33-50).

RATIONALE

1. Reduces the number of microorganisms.
2. Skin integrity may be impaired. The dressing should release from the skin and catheter.
3. Potential for bleeding or infectious material.
4. Assesses for infection.

FIGURE 33-47 Central venous catheter dressing change tray, mask, clamp, and nonsterile gloves. DELMAR/CENGAGE LEARNING

FIGURE 33-48 Inspect the dressing. DELMAR/CENGAGE LEARNING

FIGURE 33-49 Remove the old dressing. Be careful not to dislodge the catheter. DELMAR/CENGAGE LEARNING

PROCEDURE 33-8 Changing the Central Venous Dressing (Continued)

ACTION

RATIONALE

FIGURE 33-51 Clean the site with povidone-iodine swab. DELMAR/CENGAGE LEARNING

- | | |
|---|--|
| <ol style="list-style-type: none"> 5. Palpate tunneled catheter for presence of Dacron cuff, using care not to palpate close to the exit site. 6. Visually inspect catheter from hub to skin. 7. Remove gloves and put on sterile gloves. 8. Clean exit site according to institution protocol. Most use chlorhexidine 2% beginning at the catheter and moving out in a circular manner for 3 cm to maintain aseptic technique (see Figure 33-51). 9. Apply a skin protectant solution (check agency policy). 10. Apply transparent dressing (see Figures 33-52, 33-53, and 33-54 on page 982). Some institutions prefer to omit the gauze dressing to allow visualization of the site. In this case, only the TSM dressing is applied. 11. Label with date and time of dressing change (see Figure 33-55 on page 982). Gauze dressings are changed every 48 hours on peripheral and central catheters. TSM dressings are changed at the time of access site rotation or every 3–7 days, whichever occurs first. | <ol style="list-style-type: none"> 5. Documents proper placement of catheter. 6. Checks whether catheter has a crack or is split or cut. 7. Prevents transmission of microorganisms from skin to exit site. 8. Eliminates microorganisms by chemical and mechanical means. Clinical evidence points to a lower risk of catheter-related bloodstream infections when chlorhexidine gluconate is used to clean the skin during dressing change (Hadaway, 2008). 9. Prevents skin irritation and prolongs dressing integrity. Do not apply antiseptic or antimicrobial ointment to the insertion site unless it is a hemodialysis catheter. According to the CDC, povidone-iodine antiseptic ointment should be applied to a hemodialysis site after catheter insertion and at the end of each dialysis session as long as the ointment does not interact with the catheter material. Check the manufacturer's directions to see if povidone-iodine ointment can be safely used with the client's type of catheter. 10. Prevents bacteria from entering exit site. 11. Documents time to plan for next change. |
|---|--|

(Continues)

PROCEDURE 33-8 Changing the Central Venous Dressing (Continued)

ACTION

12. Secure tubing to client's clothing.
13. Remove gloves and dispose of all used materials.
14. Wash hands/hand hygiene.

RATIONALE

12. Prevents accidental displacement.
13. Reduces transmission of microorganisms.
14. Reduces transmission of microorganisms.

FIGURE 33-52 Slide the first piece of gauze directly over and under the catheter. DELMAR/CENGAGE LEARNING

FIGURE 33-53 Place the next piece of gauze directly over the insertion site. DELMAR/CENGAGE LEARNING

FIGURE 33-54 Place a larger piece of gauze over the area and secure with tape or transparent dressing. DELMAR/CENGAGE LEARNING

FIGURE 33-55 Write the date and time of the dressing change on the label. DELMAR/CENGAGE LEARNING

delegation tip

Changing the central venous catheter dressing is a skill involving assessment and the use of sterile technique. It is a procedure not delegated by the nurse unless other licensed personnel have been trained and certified to assist with the procedure. Ancillary personnel who will be caring for the client need to be instructed to report any disruption of the closed dressing, along with complaints of pain, redness, or swelling at the insertion site.

(Continues)

PROCEDURE 33-8
Changing the Central Venous Dressing (Continued)

nursing tips

- A cotton-tipped applicator dipped in normal saline may help loosen exudate on a catheter.
- Have a catheter repair kit available if a leak or hole is seen during the dressing change.
- In general, never apply alcohol-containing agents directly to the VAD's external portion unless you know it is in accordance with the agency's policy for that specific brand of catheter.

PROCEDURE
33-9

Discontinuing the IV and Changing to a Saline or Heparin Lock

EQUIPMENT

- Disposable gloves
- Syringe, 3 to 5 mL
- Sterile needles, 25-gauge
- Antiseptic swab (usually alcohol unless control line)
- Syringe with saline flush solution
- Intermittent infusion device
- Transparent dressing, if required

ACTION

RATIONALE

- | | |
|---|--|
| <ol style="list-style-type: none"> 1. Check prescribing practitioner's order to discontinue IV and to insert a saline lock. 2. Wash hands/hand hygiene; don clean gloves. 3. Check client's identification bracelet. 4. Explain procedure and reason for discontinuing IV to client. 5. Prepare supplies at bedside: <ul style="list-style-type: none"> • Syringe with saline • Syringe with heparin • Saline lock (see Figure 33-56 on page 984) 6. If inserting a new saline lock: Prime the extension tubing with saline and place the saline lock on it. Follow the procedures for starting an IV, including assessing and preparing the site, inserting the over-the-needle-catheter (ONC) (see Figure 33-57 on page 984) or butterfly needle, and obtaining a blood return. Do not attach the needle or ONC to the IV tubing. Instead, attach the ONC to the extension tubing. Dress the site (see Figure 33-58 on page 984) per policy. If inserting a new saline lock, prime extension tubing with solution and place connector in the hub of the angi catheter. For needleless | <ol style="list-style-type: none"> 1. Ensures accurate placement of saline lock. 2. Reduces transmission of microorganisms. 3. Ensures correct procedure is performed for the client. 4. Information decreases anxiety. 5. Ensures smooth procedure. 6. Priming the extension tubing prevents air from being forced into the vein. |
|---|--|

(Continues)

PROCEDURE 33-9 Discontinuing the IV and Changing to a Saline or Heparin Lock (Continued)

ACTION

DELMAR/CENGAGE LEARNING

systems, follow steps of manufacturer. In a spring-loaded, retractable needle system, press the button after a flashback of blood is observed. To ensure needle separation, turn angiocatheter 360° at the hub before inserting the catheter into the vein. Advance the catheter and attach to extension tubing with the addition of a one-way needleless safety valve that has been flushed with solution. Secure with dressing as per institution protocol.

7. If discontinuing an IV and converting to a saline lock: Stop IV infusion.
 - For IV tubing, roll clamp to close IV tubing.
 - For infusion pump, turn switch to off.
8. Place saline lock:
 - Open sterile package with needleless adapter saline lock.
 - For existing IV, loosen IV tubing and remove.
 - Screw saline lock into hub of tubing (see Figure 33-59).

7. Stops the flow of the fluid in the IV tubing.

8. Places the saline lock.

(Continues)

PROCEDURE 33-9 Discontinuing the IV and Changing to a Saline or Heparin Lock (Continued)

ACTION	RATIONALE
<ul style="list-style-type: none"> • To check for patency, remove cap from one-way valve following vigorous scrubbing with alcohol at the connection site. Connect needleless Luer-Lok syringe to the valve. Inject solution into IV site per protocol, using gentle pulsating motions to create turbulence. Remove syringe and replace sterile cap at end of tubing. <ol style="list-style-type: none"> 9. Check for patency of IV: <ul style="list-style-type: none"> • Clean saline lock with antiseptic solution (usually alcohol wipe). • Insert saline syringe with 25-gauge needle into center of diaphragm. (Needleless system will not require needle.) • Pull back gently on syringe and watch for blood return. • Inject saline <i>slowly</i> into lock (see Figure 33-60). • Assess client's pain at site. 10. Keep lock patent with normal saline or heparin. Every 8 hours: <ul style="list-style-type: none"> • Clean the rubber diaphragm with an antiseptic swab (not applicable if needleless system). • Insert the syringe or needleless adapter with saline or heparin into the diaphragm. • Inject saline or heparin slowly into lock (see Figure 33-61). 11. Remove the syringe or needleless adapter from the diaphragm and swab it with an antiseptic swab. Discard needle or adapter in sharps container. 12. Assess the site for any signs of leakage, irritation, or infiltration (see Figure 33-62 on page 986). 	<ol style="list-style-type: none"> 9. Ensures the IV is patent so that the saline lock will function. Flushing with saline clears the lock. <ul style="list-style-type: none"> • Flushing should be done slowly. • Assess for pain to ensure site is patent. 10. Ensures patency of saline lock. Only use heparin if prescribed as “flush with heparin” or if institutional policy requires it. Because of the potential for heparin-induced thrombocytopenia, the use of heparin to lock the catheter is becoming more controversial (Hadaway, 2008). The needleless system reduces risk of needlesticks. 11. Reduces transmission of microorganisms. Reduces risk of needlesticks. 12. Detects problems with the site that need additional assessment and intervention.

FIGURE 33-60 Inject saline slowly into the lock and extension tubing. DELMAR/CENGAGE LEARNING

FIGURE 33-61 Maintain the saline lock by injecting saline slowly into the lock, every 8 hours. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 33-9 Discontinuing the IV and Changing to a Saline or Heparin Lock (Continued)

ACTION	RATIONALE
13. Remove gloves and dispose of all used materials.	13. Reduces transmission of microorganisms.
14. Wash hands/hand hygiene.	14. Reduces transmission of microorganisms.

FIGURE 33-62 Assess the site for leakage, irritation, inflammation, or infection. Clean up and dispose of all materials. DELMAR/CENGAGE LEARNING

delegation tip

Discontinuing or changing the IV to a saline lock is the responsibility of the nurse. It is a procedure not delegated unless other licensed personnel have been trained and certified to perform the procedure. Ancillary personnel may be instructed to report any bleeding, leaking, or client concerns after the procedure.

nursing tips

- Sometimes no blood will return from a saline lock even though it is patent. Removing the screw-on cap, using sterile technique, may result in a blood return if the saline lock is patent. If in doubt, restart the saline lock at a new site.
- Be sure the IV site is visible and free of tape or dressing while checking for patency.
- Remember, a saline flush must inject enough saline to fill the entire set from the injection port to the needle tip.
- In some situations, such as with certain central lines, heparin may be used. Use heparin solution designated for flush, and follow institution protocol.

PROCEDURE 33-10

Administering a Blood Transfusion

EQUIPMENT

- Blood administration set and filter
- IV solution of 0.9% sodium chloride (normal saline)
- Disposable gloves
- Infusion pump if compatible with the specific blood product
- Tape
- Leukocyte-depleting filter, if ordered
- Pressure bag, if needed
- Blood warmer, if needed

(Continues)

PROCEDURE 33-10 Administering a Blood Transfusion (Continued)

ACTION	RATIONALE
<ol style="list-style-type: none"> 1. Verify the prescribing practitioner's order for the transfusion. 2. If a venipuncture is necessary, see Chapter 28, Procedure 28-1. 3. Explain procedure to the client. 4. Review side effects (dyspnea, chills, headache, chest pain, itching) with client and ask client to report these to the nurse. 5. Have the client sign consent forms. 6. Obtain baseline vital signs. 7. Obtain the blood product from the blood bank within 30 minutes of initiation. 8. Verify and record the blood product and identify the client with another nurse (see Figure 33-63): <ul style="list-style-type: none"> • Client's name, blood group, Rh type • Cross-match compatibility • Donor blood group and Rh type • Unit and hospital number • Expiration date and time on blood bag • Type of blood product compared with prescribing practitioner's order • Presence of clots in blood 9. Instruct client to empty the bladder. 10. Wash hands/hand hygiene; put on gloves. 11. Open blood administration kit and move roller clamps to "off" position. 	<ol style="list-style-type: none"> 1. Blood must be ordered by a health care provider. 2. Ensures a patent and adequate IV for infusion of blood. 3. Ensures that client understands procedure and decreases anxiety. 4. Prompt reporting of a side effect will lead to earlier discontinuation of transfusion and minimize the reaction. 5. Most institutions require the client to sign a consent form. 6. Allows detection of a reaction by any change in vital signs during the transfusion. 7. Prevents bacterial growth and destruction of red blood cells. 8. Strict verification procedures will reduce the risk of administering blood products to the wrong client. If there is an error during this procedure, notify the blood bank and do not administer the product. 9. A urine specimen after initiation of the transfusion will be needed if a transfusion reaction occurs. 10. Reduces transmission of microorganisms and, therefore, risk of transmission of human immunodeficiency virus (HIV), hepatitis, or bloodborne bacteria. 11. Closing the roller clamps prevents accidental spilling of blood.

FIGURE 33-63 Verify the blood product with another nurse. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 33-10 Administering a Blood Transfusion (Continued)

ACTION

12. For Y-tubing set:
- Spike the 0.9% sodium chloride bag and open the roller clamp on the Y-tubing connected to the bag and the roller clamp on the unused inlet tube until tubing from the 0.9% sodium chloride bag is filled. Close clamp on unused tubing.
 - Squeeze sides of drip chamber and allow filter to partially fill (see Figure 33-64).
 - Open lower roller clamp and allow tubing to fill with 0.9% sodium chloride to the hub.
 - Close lower clamp.
 - Invert blood bag once or twice. Spike blood bag and open clamps on inlet tube to allow blood to cover the filter completely (see Figures 33-65 and 33-66 on page 989).
 - Close lower clamp.
13. For single-tubing set:
- Spike blood unit.
 - Squeeze drip chamber and allow the filter to fill with blood (see Figure 33-67 on page 989).
 - Open roller clamp and allow tubing to fill with blood to the hub.
 - Prime another IV tubing with 0.9% sodium chloride and piggyback it to the blood administration set with a needle; secure all connections with tape.

FIGURE 33-64 Close the roller clamp on the administration set and priming drip chamber. DELMAR/CENGAGE LEARNING

RATIONALE

- 12.
- The Y-tubing allows the nurse to switch from infusing 0.9% sodium chloride to blood. This is especially helpful when multiple transfusions are given. Follow institutional guidelines for the number of units that can be given before tubing needs to be changed. Dextrose solutions are not used with blood transfusions as they can clot the donor blood.
 - A correctly filled drip chamber enables an accurate drip count.
 - Removes all air from tubing system.
 - Prevents waste of IV fluid.
 - Equal distribution of cells prevents clumping, which can lead to clotting of cells. Fragile blood cells may be damaged if they drop on an uncovered filter.
 - Prevents blood from flowing until tubing is attached to venous catheter.
- 13.
- Attaches tubing to blood unit.
 - A correctly filled drip chamber enables an accurate drip count.
 - Prevents air from being forced into the vein.
 - The blood product should not be piggybacked into the 0.9% sodium chloride line to avoid forcing blood cells through both a needle and a venous catheter.

FIGURE 33-65 Blood and 0.9% Sodium Chloride DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 33-10 Administering a Blood Transfusion (Continued)

ACTION

FIGURE 33-66 Close the saline roller clamp and open the blood roller clamp. DELMAR/CENGAGE LEARNING

14. Attach tubing to venous catheter using sterile precautions, and open lower clamp.
15. Infuse the blood at a rate of 2–5 mL/min according to the prescribing practitioner's order.
16. Remain with client for first 15–30 minutes, monitoring vital signs every 5 minutes for 15 minutes, then every 15 minutes for 1 hour, then hourly until 1 hour after the infusion is completed, or per institution policy.
17. After blood has infused, allow the tubing to clear with 0.9% sodium chloride.
18. Appropriately dispose of blood bag in a biohazard bag, tubing, and gloves, and follow policy regarding disposition. Wash hands/hand hygiene.
19. Document the procedure.

delegation tip

Initiating a blood transfusion is a skill involving assessment and knowledge regarding blood replacement techniques. It is an invasive procedure not delegated unless other licensed personnel have been trained and certified to perform the procedure. Ancillary personnel who will be caring for the client need to be instructed to handle the transfusion extremity gently and to take vital signs on another extremity. Vital signs should be recorded according to institution policy and the results reported promptly to the nurse. Any client complaints about chills, fever, itching, or the appearance of hives, chest pain, dyspnea, or swelling at the IV site should be immediately reported to the nurse.

RATIONALE

FIGURE 33-67 Allow the filter to fill with blood. DELMAR/CENGAGE LEARNING

14. Allows the blood product to be infused into the client's vein.
15. Packed red blood cells usually run over 1 1/2–2 hours; whole blood runs over 2–3 hours.
16. If a reaction occurs, it generally happens during the first 15–30 minutes. Changes in vital signs can warn of a transfusion reaction.
17. The client will receive all the blood that is left in the tubing.
18. Reduces transmission of microorganisms.
19. Ensures accurate records.

(Continues)

PROCEDURE 33-10 Administering a Blood Transfusion (Continued)

nursing tips

Blood components are prescribed to infuse at different rates:

- Red blood cells: 1 unit over 2–3 hours (<4 hours)
- Platelets: 30–60 minutes or more slowly (<4 hours)
- Fresh frozen plasma: 200 mL/h or more slowly
- Cryoprecipitate: 1–2 mL/min

KEY CONCEPTS

- Health promotion requires a maintenance of body fluid and acid-base balance.
- There are two types of body fluid: intracellular and extracellular. Because intravascular and interstitial fluids are outside the cells, these fluids are called extracellular fluids (ECFs).
- Water is the largest single constituent of the body, representing 45% to 75% of the body's total weight.
- Electrolytes have special physiological functions in the body that promote neuromuscular irritability, maintain body fluid osmolarity, regulate acid-base balance, and distribute body fluids between the fluid compartments. The body has many regulators that maintain fluid balance: fluid and food intake, skin, lungs, gastrointestinal tract, and kidneys.
- When an ECF volume deficit occurs, hormones play a key role in restoring the ECF volume.
- Sodium is the main electrolyte that promotes the retention of water.
- Acid-base balance refers to the homeostasis of the hydrogen ion concentration in body fluids.
- When the number of free hydrogen ions in a solution increases to lower the pH value below 7.35, the body is in a state of acidosis. The opposite occurs with alkalosis; a pH value higher than 7.45 results from a low hydrogen ion concentration.
- The body has three main control systems to regulate acid-base balance: buffer systems, respiratory regulation, and renal control of hydrogen ion concentration.
- In health, normal homeostatic mechanisms function to maintain electrolyte and acid-base balance; in illness, one or more of the regulating mechanisms may be affected, or the imbalance may become too great for the body to correct without treatment.
- Disturbances in one of the body's electrolytes usually cause changes in other electrolytes and can alter the pH of the blood.
- The slightest decrease or increase in extracellular potassium can cause serious, adverse, or life-threatening effects on physiological functions.
- The client's health history, physical assessment, and biochemical data are used by the nurse in formulating nursing goals, expected outcomes, diagnoses, and interventions.
- Nursing interventions that promote the resolution of alterations in fluid balance are based on the principles of client safety and standards of care.
- Following institutional protocol and established procedures for IV therapy helps ensure client safety.
- Hospitalized clients, especially older adults, are at risk for developing dehydration.
- Clients receiving intravenous therapy and blood transfusions require constant monitoring for complications.
- Evaluation of the achievement of client expected outcomes requires the interrelational analysis of weight, intake and output, vital signs, and biochemical results.

REVIEW QUESTIONS

- Which client is most at risk for fluid volume deficit?
 - A 30-year-old woman with a fractured tibia
 - An 82-year-old woman with a fractured hip
 - A 58-year-old man with a myocardial infarction
 - A 35-year-old woman who just delivered a baby
- The priority nursing action for a client with a serum sodium level of 115 mEq/L is _____.
 - Frequent oral hygiene
 - Monitor vital signs every 2 hours
 - Seizure precautions
 - Cardiac rhythm monitoring
- A client receiving D5W at 100 mL/h is most at risk for developing _____.
 - Hyponatremia
 - Hypernatremia
 - Fluid volume deficit
 - Fluid volume excess
- The priority nursing assessment for a client with hypokalemia is _____.
 - Blood pressure
 - Chvostek's sign
 - Edema
 - Heart rhythm
- The priority nursing action for a client with a serum potassium level of 5.5 mEq/L who has received an oral dose of Kayexalate is to monitor _____.
 - Urine output
 - Blood pressure
 - Bowel movement
 - Seizure activity
- The priority nursing action for a bedridden client with a serum calcium level of 13 mg/dL is to _____.
 - Provide passive range-of-motion (ROM) exercises and encourage fluids
 - Teach the client to increase intake of whole grains and nuts
 - Place a tracheostomy tray at the bedside
 - Administer calcium gluconate IM as prescribed
- A client is admitted to the hospital with a history of vomiting for 3 days and decreased oral intake. Which set of arterial blood gases would indicate that the client is in a state of metabolic acidosis?
 - pH of 7.43, PaCO₂ of 36 mm Hg, HCO₃ of 26
 - pH of 7.41, PaCO₂ of 49 mm Hg, HCO₃ of 30
 - pH of 7.33, PaCO₂ of 35 mm Hg, HCO₃ of 17
 - pH of 7.25, PaCO₂ of 56 mm Hg, HCO₃ of 28
- A client with a small bowel obstruction and a nasogastric tube connected to low intermittent suction for 2 days should be monitored for which acid-base disorder?
 - Respiratory alkalosis
 - Respiratory acidosis
 - Metabolic alkalosis
 - Metabolic acidosis
- Which statement about VAD placement reflects best practice?
 - To maintain patency, infuse 0.9% sodium chloride solution immediately after VAD insertion.
 - Document the total length of the catheter prior to infusing any solution.
 - Confirm and document the tip's correct anatomic location from the radiology department before using the VAD.
 - If the client's VAD was placed at another facility, you don't need to confirm tip location.
- When priming the IV tubing for a blood transfusion, which type of IV solution should the nurse use?
 - Dextrose 5% in 0.2% saline
 - Dextrose 5% in water
 - Ringer's lactate
 - Normal saline 0.9%

“The human body is a complex organism with the ability to heal itself—if only you listen to it and respond with proper nourishment and care.”

—BALCH (2006)

CHAPTER 34

Nutrition

COMPETENCIES

1. Identify the physiological value of nutrients.
2. Describe the processes of digestion, absorption, and metabolism.
3. Describe how diet guidelines and menu planning promote nutrition and health.
4. Explain how culture influences food preferences and eating habits.
5. Explain the impact of age-related changes on nutritional status.
6. Describe the process of assessing a client's nutritional status.
7. Identify common knowledge deficits related to nutrition.
8. Describe the expected outcomes of nursing interventions that promote optimum nutritional status.
9. Describe the role of nutritional support teams in managing the care of clients with nutritional deficits.
10. Identify common nursing interventions for clients experiencing nutritional deficits.

KEY TERMS

absorption	fatty acids	monounsaturated fatty acids
aerobic metabolism	free radical scavengers	negative nitrogen balance
anabolism	free radicals	nitrogen balance
anaerobic metabolism	gluconeogenesis	nonessential amino acids
anorexia nervosa	glycolysis	nutrition
anthropometric measurements	high-biological-value proteins (complete proteins)	obligatory loss of proteins
antioxidants	hyperglycemia	parenteral nutrition
appetite	hyperthyroidism	peristalsis
atherosclerosis	hypoglycemia	phospholipids
basal metabolic rate (BMR)	hypothyroidism	polysaccharides
body mass index (BMI)	insulin	polyunsaturated fatty acids
bulimia nervosa	ketogenesis	positive nitrogen balance
calorie	ketones	prealbumin
carbohydrates	kilocalories	proteins
catabolism	lipids	recommended dietary allowances (RDAs)
cholesterol	low-biological-value proteins (incomplete proteins)	saccharides
chylomicrons	malnutrition	satiety
deamination	mastication	saturated fatty acids
deglutition	metabolic rate	skinfold measurement
diabetes mellitus	metabolism	total parenteral nutrition (TPN)
dietary fiber	mid-upper-arm circumference (MAC)	transferrin
digestion	minerals	triglycerides
disaccharides	monosaccharides	unsaturated fatty acids
enteral nutrition		vitamins
essential amino acids		water-soluble vitamins
fat-soluble vitamins		

The body requires the consumption of nutrients to support physiological activities of digestion, absorption, and metabolism to maintain homeostasis. The metabolism of nutrients (carbohydrates, proteins, fats, vitamins, and minerals) plays an essential role in providing the body with the necessary substances to maintain internal homeostasis.

PHYSIOLOGY OF NUTRITION

Nutrition is the process by which the body metabolizes and utilizes nutrients. Nutrients are classified as energy nutrients, organic nutrients, and inorganic nutrients; see the accompanying display on classes of nutrients. Energy nutrients release energy for maintenance of homeostasis. Organic nutrients build and maintain body tissues and regulate body processes. Inorganic nutrients provide a medium for chemical reactions, transport materials, maintain body temperature, promote bone formation, and conduct nerve impulses.

In the body, essentially all carbohydrates are converted into glucose before they reach the cells, proteins are converted into amino acids, and fats are converted into fatty acids. These nutrients are digested, absorbed by the blood or

CLASSES OF NUTRIENTS

DESCRIPTION	CLASSES
Energy nutrients	Carbohydrates Proteins Fats
Organic nutrients	Carbohydrates Proteins Fats Vitamins
Inorganic nutrients	Water Minerals

lymphatic system, and transported to the body's cells. Inside the cells' mitochondria, the nutrients react chemically with oxygen and various enzymes to produce energy.

DIGESTION

Digestion refers to the mechanical and chemical processes that convert nutrients into a physically absorbable state.

Figure 34-1 shows the anatomical structures of the gastrointestinal (GI) tract (digestive tract). Figure 34-2 explains the physiological mechanisms that support the digestive process in each anatomical structure.

The mouth prepares foodstuffs for digestion by **mastication**, the chewing, tearing, or grinding of food by the teeth into fine particles and mixing with enzymes in saliva. The salivary glands release lubricating secretions that bind with food particles to facilitate swallowing.

Deglutition, the swallowing of food, begins in the mouth and continues in the pharynx and esophagus. Peristaltic waves and mucous secretions move food down the esophagus. Relaxation of the lower esophageal sphincter (gastroesophageal constrictor muscle) allows food to enter the stomach; contraction of this sphincter muscle prevents regurgitation (reflux) of stomach contents.

Digestion begins in the stomach and is completed in the small intestine. This is accomplished by specific substances entering the duodenum: pancreatic enzymes through the pancreatic duct, bile through the common bile duct, and intestinal enzymes produced in the jejunum. **Peristalsis** (coordinated, rhythmic, serial contraction of the smooth muscle lining of the intestines) forces chyme (an acidic, semifluid paste) through the small intestine to the large intestine and promotes the absorption of vitamins, minerals, and water.

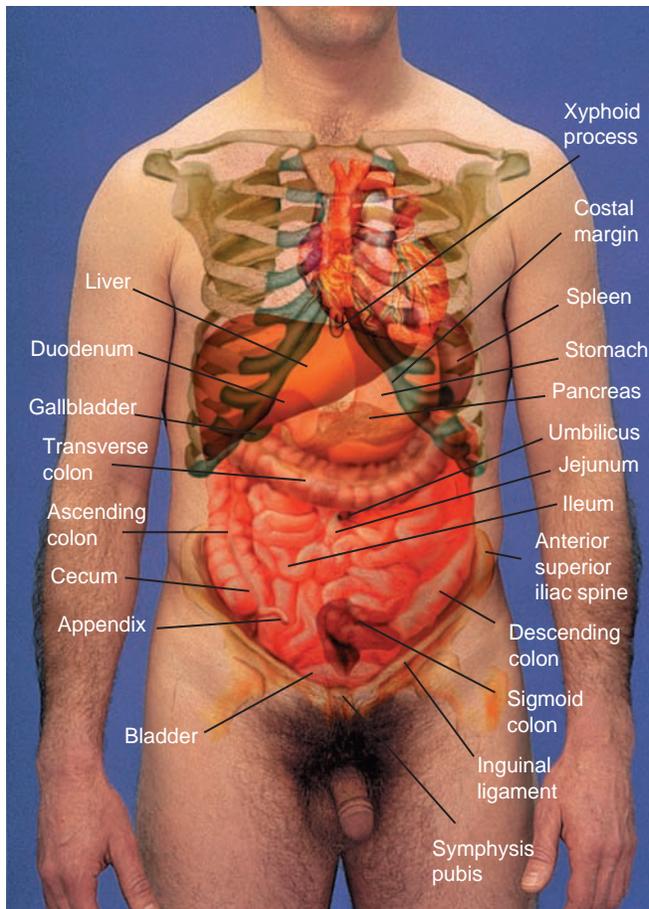

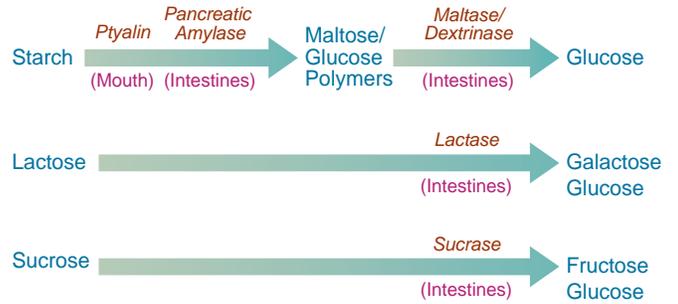

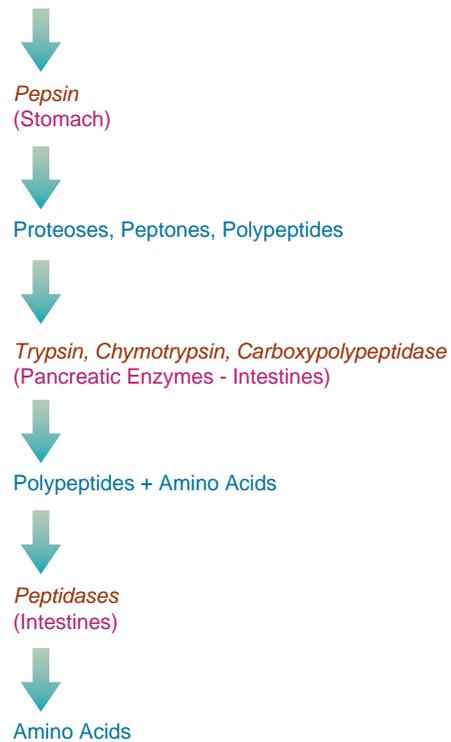

FIGURE 34-1 Gastrointestinal Tract DELMAR/CENGAGE LEARNING

A. Carbohydrates

B. Proteins

C. Fats

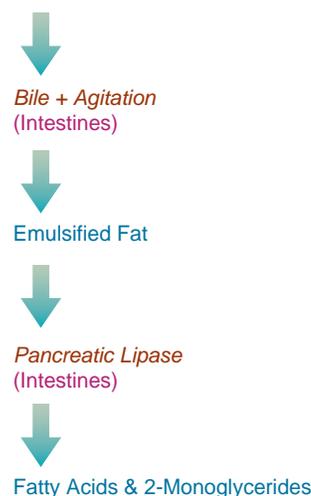

FIGURE 34-2 Digestion of Proteins, Carbohydrates, and Fats DELMAR/CENGAGE LEARNING

Only carbohydrates, proteins, and fats require chemical digestion by enzymatic activity for absorption.

ABSORPTION

Absorption is the process by which the end products of digestion—**monosaccharides** (simple sugars), amino acids, glycerol, fatty acid chains, vitamins, minerals, and water—pass through the epithelial membranes in the small and large intestines into the blood or lymph systems. Most absorption occurs in the small intestine through the processes of osmosis, diffusion, and active transport (see Figure 34-3). Water absorption occurs throughout the digestive tract.

The main function of the large intestine is to absorb water and collect food residue (dietary fiber). **Dietary fiber** is the part of food that body enzymes cannot digest and absorb, such as the outer hulls of corn kernels, grains of wheat, celery strings, and apple skins. Dietary fiber absorbs water in the large intestine, promoting the formation of a soft, bulky stool that moves quickly through the large intestine; some fiber is believed to bind cholesterol in the colon, thus reducing the risk of heart attack (Roth, 2007). In healthy individuals, most of the end products of digestion are absorbed (99% of carbohydrates, 95% of fat, and 92% of protein) and used by the body (Roth, 2007).

METABOLISM

Metabolism is the aggregate of all chemical reactions and processes in every body cell, such as growth, generation of energy, elimination of wastes, and other bodily functions as they relate to the distribution of nutrients in the blood after digestion.

The liver prepares nutrients for their role in energy production. It converts all monosaccharides to glucose and

excess amino acids to urea, carbohydrates, or fats. Excess fats are converted in the liver to glycerol and fatty acids, then to acetylcoenzyme A (acetyl CoA).

Glycolysis refers to the breakdown of glucose by enzymes located inside the cell's cytoplasm. This process produces adenosine triphosphate (ATP) and pyruvate, which provide the cell with energy. Pyruvate may be used in two different metabolic functions. In **aerobic metabolism**, pyruvate enters the cell's mitochondria and in the presence of oxygen is converted to acetyl CoA. In **anaerobic metabolism** (metabolism without the presence of oxygen) lactate is produced in the cytoplasm by an enzyme (lactate dehydrogenase); this type of metabolism takes place when the oxygen supply is limited, as in the muscles and red blood cells, which lack mitochondria.

When pyruvic acid is formed by glycolysis, it is then converted into acetyl CoA. This conversion begins a cyclic metabolic pathway called the Krebs cycle (citric acid cycle or tricarboxylic acid cycle). The Krebs cycle extracts energy through oxidation of acetyl CoA within the mitochondria of body cells. The Krebs cycle is a pathway common to all energy nutrients because acetyl CoA may be formed from carbohydrates, proteins, and fats (see Figure 34-4).

Built into the inner mitochondrial membrane is a series of molecules to assist in electron transport during aerobic metabolism. The electron transport system converts energy released from the Krebs cycle into ATP for use by cells in anabolism and catabolism. **Anabolism** refers to the constructive phase of metabolism, in which smaller molecules, such as amino acids, are converted to larger molecules, such as proteins. **Catabolism** is the destructive phase, in which larger molecules, such as glycogen, are converted to smaller molecules, such as pyruvic acid.

The rate of metabolism is governed primarily by the hormones triiodothyronine (T_3) and thyroxine (T_4) secreted by

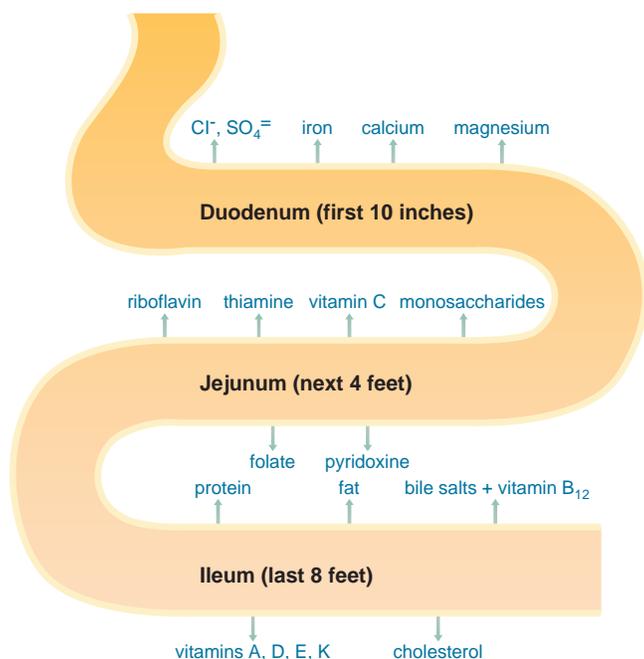

FIGURE 34-3 Nutrient Absorption in the Small Intestine

DELMAR/CENGAGE LEARNING

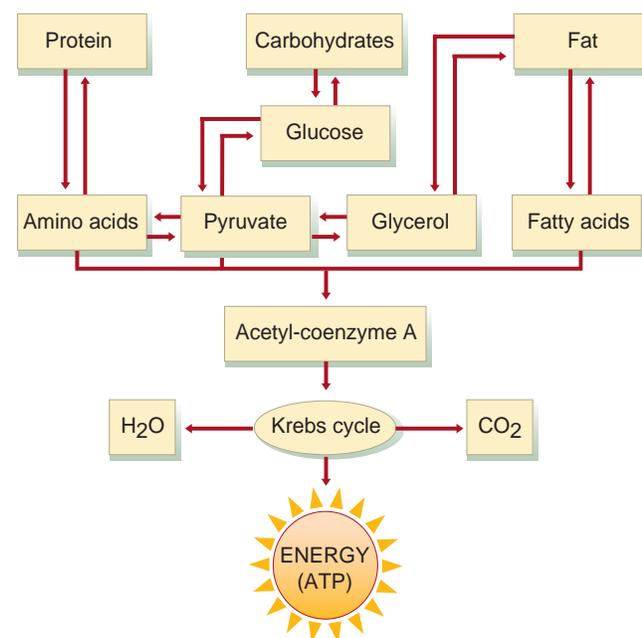

FIGURE 34-4 Energy Nutrients and the Krebs Cycle

DELMAR/CENGAGE LEARNING

the thyroid gland. **Hyperthyroidism** refers to the increased secretion of these thyroid hormones, which increases the rate of metabolism. With **hypothyroidism**, a decrease in the secretion of thyroid hormones, the metabolic rate is decreased.

ENERGY

Metabolic rate refers to the rate of heat liberation during chemical reactions; it is expressed in units called calories. A **calorie** is the quantity of heat required to raise the temperature of 1 gram of water 1°C; it is used to express the quantity of energy released from different foods or expended by different functional processes of the body. Because a large quantity of energy is released during metabolism, the energy is expressed in terms of **kilocalories** (kcal), each of which is equivalent to 1000 calories. The **basal metabolic rate (BMR)** refers to the energy needed to maintain essential physiological functions, such as respiration, circulation, and muscle tone, when a person is at complete rest both physically and mentally.

EXCRETION

Digestive and metabolic waste products are excreted through the intestines and rectum. Other excretory organs are the kidneys, sweat glands, skin, and lungs; see Chapter 39 for a complete discussion of elimination. The skin and sweat glands remove water, toxins, salts, and nitrogen wastes; the lungs remove carbon dioxide and water.

NUTRIENTS

Understanding the role of basic nutrients provides the foundation for selecting foods that promote health. The six categories of nutrients are water, vitamins, minerals, carbohydrates, proteins, and lipids (fats). Selecting the healthiest forms of each of these nutrients and eating them in the proper balance will enable the body to function at its optimal level of health. Nutrients work synergistically; for example, there is a cooperative action between certain vitamins and minerals that work as catalysts, promoting the absorption and assimilation of other vitamins and minerals.

WATER

Water is the most abundant nutrient in the body and accounts for 60% to 70% of an adult's total body weight and 77% of an infant's weight. It is a major component of body fluids, secretions, and excretions. Body water decreases as body fat increases and with aging.

Water and electrolytes are substances that must be acquired from the diet. In the United States, much of water consumption is in the form of beverages (milk, coffee, tea, and soft drinks). The estimated water requirement for infants, children, and adults is 1.5 mL/kcal of energy expenditure. The water and electrolyte requirements for infants correspond to the water-to-energy ratio and the electrolyte

composition in human milk and common formulas. Although pregnancy and lactation increase bodily demands for water and electrolytes, these demands are usually met with normal ingested amounts; the one exception is in a lactating woman, who requires, on average, an additional 750 mL/day of water during the first 6 months to match the amount of milk secreted.

Normally the body maintains a balance between the amount of fluid taken in and the amount excreted. The requirements for body water are met through the consumption of liquids and foods and the oxidation of food. Solid foods, especially fruits and vegetables, contain 85% to 95% water. The normal daily turnover of water is 4% of an adult's total body weight and 15% of an infant's total body weight; refer to Chapter 33 for a complete discussion of water's role in maintaining homeostasis.

VITAMINS

Vitamins are organic compounds that regulate cellular metabolism, assisting the biochemical processes that release energy from digested food. Vitamins are called micronutrients because they are needed in small quantities when compared with other nutrients (water, carbohydrates, proteins, and fats). Vitamin requirements are dependent on many factors, such as body size, amount of exercise, rate of growth, and pregnancy.

Of the major vitamins, some are classified as either fat soluble or water soluble. **Fat-soluble vitamins** (vitamins A, D, E, and K) require the presence of fats for their absorption from the GI tract and for cellular metabolism and can be stored for longer periods of time in the body's fatty tissue and the liver. **Water-soluble vitamins** (vitamin C and B complex vitamins) require daily ingestion in normal quantities because these vitamins are not stored in the body.

Certain vitamins, minerals, and enzymes are classified as **antioxidants**, a substance that blocks or inhibits destructive oxidation reactions, such as vitamins C and E, the minerals selenium and germanium, and the enzymes catalase and superoxide dismutase, coenzyme Q₁₀, and some amino acids. Antioxidants help protect the body from the formation of **free radicals**, atoms or groups of atoms that can cause damage to cells. Free radicals can impair the immune system and lead to infections and certain degenerative diseases, such as heart disease and cancer. Free radicals are normally controlled by **free radical scavengers**, substances that remove or neutralize free radicals. Certain enzymes (superoxide dismutase, methionine reductase, catalase, and glutathione peroxidase) are free radical scavengers that are produced by the body. Besides vitamins C, E, A, and beta-carotene, certain herbs also act as antioxidants, such as bilberry, ginkgo, grape seed extract, green tea, and flavonoids. To maintain an effective level of antioxidants, clients should ingest five to nine daily servings of fresh, whole fruits and vegetables. Antioxidants seem to be more effective when obtained from food sources rather than from supplements. Morris (2004) reviewed three prospective studies regarding dietary influences on Alzheimer's disease. The strongest evidence for antioxidant protection

against this disease was for ingesting foods high in vitamin E. None of the studies, however, found that vitamin E and vitamin C supplements were associated with less risk of Alzheimer's. The functions, clinical significance, and dietary sources of fat-soluble and water-soluble vitamins are presented in Table 34-1. Megadoses of both types of vitamins (fat and water soluble) can cause toxicity. Once the catalytic demands have been met by these vitamins, the remaining vitamins act as free chemicals that may be toxic to the body.

MINERALS

Minerals (inorganic elements) serve as catalysts in biochemical reactions. They are classified according to their daily requirement: macrominerals (quantities of 100 mg or greater)

and microminerals (trace elements, quantities less than 100 mg). The major macrominerals required by the body are calcium, phosphorus, and magnesium; see Chapter 33 for a complete discussion of these minerals (electrolytes).

Microminerals such as copper, fluoride, iodine, iron, selenium, and zinc play essential roles in metabolism. For example:

- Copper and iron are needed for hemoglobin formation.
- Copper is needed for the synthesis of phospholipids and prostaglandin and for the formation of some enzymes.
- Iron is needed for the synthesis of vitamins, purines, and antibodies.
- Fluoride is required for teeth formation and the prevention of dental caries.
- Iodine is the basic component of thyroid hormones.

TABLE 34-1 Fat-Soluble and Water-Soluble Vitamins

VITAMIN	FUNCTIONS	CLINICAL SIGNIFICANCE	DIETARY SOURCES
Fat-Soluble			
Vitamin A (retinol, retinal, retinoic acid)	Epithelial tissue proliferation Retinal pigmentation Immune system (antigen recognition) Antioxidant	Scaly skin, dry mucous membranes Night blindness Increased risk for infections Cancer and other diseases	Whole milk and whole milk products, eggs, fruits and vegetables (green leafy and yellow), fish, animal liver, fish liver oil. Caution: Do not exceed a daily dose of over 10,000 international units if pregnant or history of liver disease
Vitamin D (cholecalciferol, ergosterol)	Bone and tooth development Enhances immunity	Children: rickets and delayed dentition Adults: osteomalacia	Fortified milk, margarine, eggs, fish, cod liver oil, oatmeal, sweet potatoes, vegetable oils
Vitamin E (tocopherol)	Synthesis of heme Antioxidant, prevents oxidation of polyunsaturated fatty acids and of vitamins A and C	Premature infants: macrocytic anemia and hemolysis of RBCs Damage to RBCs, destruction to nerves	Cold-pressed vegetable oils, dark green leafy vegetables, milk, eggs, meats, legumes, nuts, seeds, whole grains
Vitamin K	Formation of prothrombin, blood clotting Bone formation and repair; synthesis of osteocalcin	Newborn: hemorrhagic disease Adults: prolonged clotting times Osteoporosis	Dark green leafy vegetables, asparagus, broccoli, Brussels sprouts, cabbage, cauliflower, egg yolks, liver, oatmeal, oats, rye, safflower oil, soy beans, wheat
Water-Soluble			
B complex Vitamin B ₁ (thiamine)	Metabolism of carbohydrates and some amino acids (energy), production of hydrochloric acid, enhances circulation and assists in blood formation	Degeneration of myelin sheath in central nervous system (CNS) (paralysis) and in peripheral nerves (polyneuritis) Weakness of cardiac muscle: heart failure, peripheral vasodilation, and edema GI: indigestion, severe constipation, anorexia, gastric atony,	Pork, fish, eggs, poultry, dried beans, whole grains, wheat germ, oatmeal, bread, pasta, brown rice, legumes, rice bran, peanuts

(Continues)

TABLE 34-1 (Continued)

VITAMIN	FUNCTIONS	CLINICAL SIGNIFICANCE	DIETARY SOURCES
		hypochlorhydria (referred to as beriberi—all above systems involved)	
Vitamin B ₂ (riboflavin)	Oxidation and reduction of carbohydrates, fats, and proteins Red blood cell (RBC) formation, antibody production	Digestive disturbances, burning sensations in eyes and skin, headaches, mental depression, forgetfulness (frequently occurs with thiamine or niacin deficiency), skin lesions, eye disorders (cataracts)	Milk, whole grains, green vegetables, liver, cheese, egg yolks, fish, legumes, meat, poultry, yogurt
Vitamin B ₆ (pyridoxine)	Functions as coenzyme to protein and amino acid metabolism, absorption of fats and protein	Convulsions, dermatitis, nausea and vomiting, anemia, flaky skin	Whole grains, liver, fish, poultry, green beans, meats, nuts, potatoes, eggs, brewer's yeast
Vitamin B ₁₂ (cobalamin compounds)	Metabolically functions as a coenzyme: hydrogen acceptor and replication of genes	Demyelination of large spinal cord nerves: loss of peripheral sensation and paralysis (usually the result of intrinsic factor deficiency)	Milk, eggs, cheese, meat, fish, poultry, brewer's yeast
Biotin	Synthesis of fatty acids Protein metabolism Utilization of glucose	Infants: seborrheic dermatitis (cradle cap) Adults: rare	Liver, kidneys, dark green vegetables, egg yolk, green beans, brewer's yeast, milk, poultry, saltwater fish, whole grains
Vitamin C (ascorbic acid)	Formation of RBCs Production of collagen (capillary wall integrity) enzyme Metabolism of amino acids Prevention of oxidation of vitamins	Bleeding gums, bruising Poor wound healing, retardation of bone growth, fragile blood vessel walls, gum lesions (referred to as scurvy)	Citrus fruits, strawberries, cantaloupe, fresh vegetables: potatoes, cabbage, tomatoes, broccoli, green peppers
Folic acid (pteroylglutamic acid)	Synthesis of purines and thymine (DNA formation) Maturation of RBCs Functions as coenzyme in DNA and RNA synthesis	Retarded growth Sore red tongue Macrocytic anemia	Liver, green leafy vegetables, meat, fish, poultry, whole grains, barley, bran, brewer's yeast, brown rice
Niacin (nicotinic acid)	Coenzyme in energy metabolism	Muscular weakness, CNS lesions, dementia Skin: cracked, pigmented scalliness Irritation and inflammation of the mucous membranes of GI tract, producing GI hemorrhage (referred to as pellagra)	Meats, dairy products, whole grains, cereals, tuna, broccoli, carrots, cheese, corn flour
Pantothenic acid	Metabolism of carbohydrates and fats	None known	Meats, whole grain cereals, legumes

Delmar/Cengage Learning

- Selenium enhances vitamin E absorption and stimulates antibody response to infection.
- Zinc plays a major role in wound healing, maintains connective tissue integrity, assists with the formation of enzymes and insulin, boosts the immune response, and maintains normal blood concentrations of vitamin E. It also aids in the absorption of vitamin A, has antioxidant properties, and is a constituent of the antioxidant enzyme superoxide dismutase.

Other microminerals are arsenic, cadmium, nickel, silicon, tin, and vanadium; however, the specific roles that these microminerals play in metabolism have not been identified.

CARBOHYDRATES

Carbohydrates are organic compounds composed of carbon, hydrogen, and oxygen. They play a significant role in providing cells with energy and supporting the normal functioning of the body. Table 34-2 on page 1001 identifies the functions of carbohydrates and the problems that result from insufficient intake.

Carbohydrates are classified according to the number of **saccharides** (sugar units):

- **Monosaccharides** (simple sugars) include glucose, galactose, and fructose.
- **Disaccharides** (double sugars) include sucrose, lactose, and maltose.
- **Polysaccharides** (complex sugars) include glycogen, cellulose (fiber), and starch.

Glucose supplies the major source of energy needed for cellular activity, such as muscle contractions and nerve impulse transmission. When metabolized, every gram of glucose yields 4 kcal. Glucose is also needed for the synthesis of fatty acids and amino acids.

Carbohydrates have a protein-sparing action, based on a minimum daily ingestion of 50 to 100 grams (200–400 kcal) to spare the metabolism of protein. When dietary intake is below the minimum requirement, **triglycerides** (lipid compounds consisting of three fatty acids and a glycerol molecule) and proteins are metabolized to produce energy.

The three major sources of dietary carbohydrates are starches (nonanimal foods, primarily grains), lactose (milk), and sucrose (cane sugar). The ordinary diet contains far more starches than either lactose or sucrose. See Figure 34-2A for information on the digestion of these sugars.

Cells are unable to store large quantities of carbohydrates. The liver converts excess galactose and fructose into glucose and stores it in the form of glycogen. **Insulin** (pancreatic hormone) aids in the diffusion of glucose into the liver and muscle cells and in the synthesis of glycogen. Glucose metabolism is dependent on the availability of insulin (see Figure 34-5 on page 1002).

An increase in blood glucose levels can cause **hyperglycemia**, a blood glucose level greater than 110 mg/dL. This occurs in **diabetes mellitus**, a disease in which the pancreas fails to secrete adequate levels of insulin to accommodate

blood glucose levels. When hyperglycemia occurs, **ketones** (the end product of incomplete fat metabolism) build up in the bloodstream, causing metabolic acidosis.

In **hypoglycemia**, the blood glucose level is below normal (less than 80 mg/dL) because the supply of insulin is so high that most of the glucose moves from the blood into the cells. Because brain tissue requires a constant source of glucose for energy, hypoglycemia can alter the normal functions of the brain.

Glucose (dextrose) is a common substance in intravenous therapy (dextrose 5% in water) because it is readily absorbed into the body's cells. This solution provides 170 kcal/L; refer to Chapter 33 for a complete discussion of intravenous replacement therapy.

PROTEINS

Proteins are organic compounds that contain carbon, hydrogen, oxygen, and nitrogen atoms; some proteins also contain sulfur.

After water, proteins are the most abundant intracellular substance. Proteins are essential for almost every bodily function, beginning with the genetic control of protein synthesis, cell function, and cell reproduction (see Table 34-2). The end products of protein digestion are amino acids.

The normal blood concentration of amino acids is between 35 and 65 mg/dL. There are 20 identified amino acids, which are categorized as either essential or nonessential:

- **Nonessential amino acids** can be synthesized (manufactured) in the cells; see the accompanying display on amino acids on page 1002.
- **Essential amino acids** must be ingested in the diet because they cannot be synthesized in the body; see the accompanying display on amino acids.

Proteins are also classified as complete or incomplete. **High-biological-value proteins (complete proteins)** contain all of the essential amino acids. Complete proteins are primarily animal proteins, such as those in meat, poultry, fish, dairy products, and eggs.

Low-biological-value proteins (incomplete proteins) lack one or more of the essential amino acids, usually lysine, methionine, and tryptophan. Most vegetables are incomplete proteins. By properly mixing complementary proteins in the diet, such as corn and beans, one can produce a complete protein.

All essential amino acids are needed by cells for anabolism and repair. The surplus amino acids are sent back to the liver, where they are degraded (nitrogen is split from the amino acid); the remaining parts are used for energy or converted to carbohydrate or fat and stored as glycogen or adipose tissue. Carbon dioxide, water, and nitrogen are the end products of amino acid metabolism.

The degradation of amino acids begins the process of **deamination**, the removal of the amino groups from the amino acids. During protein deamination, several other physiological processes of clinical significance occur:

1. **Gluconeogenesis**, the conversion of amino acids into glucose or glycogen

TABLE 34-2 Normal Function and Deficiencies of Selected Nutrients

NUTRIENT	FUNCTIONS	DEFICIENCIES
Proteins	Growth and replacement: clotting factor production, collagen synthesis, epithelial cell proliferation, fibroblast proliferation	Increased risk of bruising and hemorrhage; muscular wasting; depigmentation of hair and skin; poor wound healing; decreased enzyme production
	Immunity: antibodies, white blood cell production and migration, cell-mediated phagocytosis	Lymphopenia; impaired cellular immunity
	Fluid balance: intracellular osmotic pressure, albumin, maintenance of blood volume	Edema; hypoalbuminemia
	Sodium and potassium balance	Impaired nerve impulse transmission and muscle function
	Buffer action	pH imbalances
	Energy source	Negative nitrogen balance
Carbohydrates	Primary source of energy; sparing of protein	Impaired brain functions; increased ketone bodies, producing acidosis; poor wound healing
Fats	Source of concentrated energy and essential fatty acids	Inhibited tissue repair
	Cell membrane integrity	Irritated and reddened skin
	Promotes absorption of fat-soluble vitamins; maintains body temperature	Deficit in fat-soluble vitamins; impaired fat digestion
	Synthesis of bile salts, steroid hormones, and vitamin D	Electrolyte depletion
Vitamin A	Collagen synthesis	Poor wound healing
	Epithelialization	Dry, scaly skin
Vitamin C	Collagen synthesis	Poor wound healing
	Maintains capillary integrity	Increased risk of bruising and hemorrhage
Vitamin K	Coagulation	Increased risk of bruising and hemorrhage
Pyridoxine, riboflavin, and thiamine	Cofactors in cellular development	Irritated and reddened skin
	Red blood cell formation	Nerve and muscular weakness; anemia
	Immunity: antibodies and white blood cell formation	Increased risk of infection
Copper	Red blood cell and connective tissue formation	Decreased collagen synthesis; poor wound healing from local tissue ischemia (anemia)
Iron	Collagen synthesis	Impaired collagen cross-linkage
	Enhancement of leukocytic activity	Increased risk of infection
	Hemoglobin synthesis	Anemia
Zinc	Cell proliferation	Poor wound healing
	Cofactor in enzymes	Increased risk of infection; alteration in taste

asparagine		

ESSENTIAL AMINO ACIDS

threonine	methionine	valine
leucine	isoleucine	lysine
arginine	phenylalanine	tryptophan
histidine		

- Ketogenesis**, the conversion of amino acids into keto acids or fatty acids
- Nitrogen balance**, the net result of intake and loss of nitrogen that measures protein anabolism and catabolism
- Positive nitrogen balance**, the condition that exists when nitrogen intake exceeds output (protein anabolism exceeds catabolism)
- Negative nitrogen balance**, the condition that exists when nitrogen output exceeds intake (protein catabolism exceeds anabolism)
- Obligatory loss of proteins**, the degrading of the body's own proteins into amino acids, which are then deaminated and oxidized (occurs when a person fails to ingest adequate amounts of proteins)

Nitrogen balance measures protein equilibrium and is used to evaluate the client's nutritional status. Clients on bed rest or with a fever are in a catabolic state that produces a negative nitrogen balance. The muscle wasting that occurs with immobility causes negative nitrogen balance. Massive trauma and burns are other common examples of catabolic states that produce a negative nitrogen balance initially upon injury. Diet therapy is directed toward providing adequate amounts of proteins and kilocalories so that the body does not use its own protein as an energy source. A person must ingest a minimum of 20 to 30 grams of protein each day to prevent a net loss of body proteins.

LIPIDS

Lipids (fats) are organic compounds that are insoluble in water but soluble in organic solvents such as ether and alcohol. They are composed of the same elements as carbohydrates (carbon, hydrogen, and oxygen) but have a higher hydrogen concentration. Refer to Table 34-2 for a discussion of the normal functions of fats and the problems that arise from insufficient intake.

Fatty acids are the basic structural units of most lipids. They contain carbon chains and hydrogen. **Saturated fatty acids** form fats, glycerol esters of organic acids whose carbon atoms are joined by single bonds (all of the carbon atoms are saturated with hydrogen). Diets high in saturated fats are associated with a high incidence of coronary heart disease. Foods high in such fats are animal meats (especially beef), whole-milk products, butter, most cheeses, and some plant fats, such as chocolate, coconut, and palm oils.

Unsaturated fatty acids form glycerol esters of organic acids whose carbon atoms are joined by double or triple bonds (at least two carbon atoms in the fatty acid chains in the esters are unattached to hydrogen atoms). **Monounsaturated fatty acids** are fatty acids that form esters with one double or triple bond; foods in this category include nuts, fowl, and olive oil. **Polyunsaturated fatty acids** form esters that have many carbons unbonded to hydrogen atoms. Foods such as fish, corn, sunflower seeds, soybeans, cottonseeds, and safflower oil contain such esters.

The most important lipids follow:

- Triglycerides are lipid compounds composed of three fatty acid molecules attached to a glycerol molecule.
- Phospholipids** are composed of one or more fatty acid molecules and one phosphoric acid radical and usually contain a nitrogenous base.
- Cholesterol**, a lipid that is produced by the body and used in the synthesis of steroid hormones and excreted in bile, is considered a fat and is found in whole milk and egg yolk.

Phospholipids and cholesterol lipids constitute 2% of the total cell mass; they are basically insoluble in water and are used to form membranous barriers that separate the different intracellular compartments. The cell membrane is composed almost entirely of proteins and lipids (phospholipids and cholesterol).

Besides phospholipids and cholesterol, some cells contain triglycerides, which account for 95% of the fat cell mass. Triglycerides are the body's main storehouse of energy-giving nutrients; when dissolved, they can be used for energy as needed.

Most dietary fats are triglycerides, found primarily in animal food. Most plant foods contain trace elements of triglycerides. Other than butter fat, which is digested by gastric lipase (tributyrase), essentially all fat digestion occurs in the small intestine in the presence of pancreatic juices (see Figure 34-2C).

When free fatty acids, monoglycerides, free cholesterol, and phospholipids are absorbed by the blood and lymph system, they are resynthesized into minute molecules called **chylomicrons** (lipoproteins, synthesized in the intestines, that transport triglycerides to the liver).

SPOTLIGHT ON...

A Fatty Meal

What impact would it have on a person, especially a teenager, if he or she could see a blood sample drawn 30 minutes after eating a large quantity of fast food? Do you think seeing the blood turn turbid or yellowish after a fatty meal would alter that person's eating habits?

Low-density lipoproteins are responsible for the formation of **atherosclerosis**, a disease of the arteries in which fatty lesions called atheromatous plaques develop inside the walls of the arteries. A diet high in saturated fats and cholesterol causes the formation of atherosclerosis. Almost half of the deaths in the United States and Europe are attributed to atherosclerosis, usually the result of coronary artery thrombosis.

PROMOTING PROPER NUTRITION

Hunger means a craving for food and is a subjective sensation. For example, when a person has not eaten for hours, the stomach undergoes intense rhythmic contractions called hunger contractions. These contractions sometimes cause pain, in the form of hunger pangs. Hunger not only is a physiological response but also involves psychological sensations. For instance, after a total gastrectomy (surgical removal of the stomach), clients still report a craving for food.

Appetite means the desire for specific types of food instead of food in general. A person's appetite determines the type of foods he or she eats. **Satiety** means a feeling of fulfillment from food. It is the opposite of hunger and occurs when a person's nutritional stores have been replenished and psychological cravings have been met.

RESPECTING OUR DIFFERENCES

Satiety

How does one know when enough food has been eaten? How do the oral factors of chewing, salivation, swallowing, and tasting contribute to satiety? How true is the saying that healthy eating habits require three meals a day and that each of those meals should be filling? How are lifelong eating habits developed in early childhood?

Daily food guides have been developed by various organizations to establish standards that promote nutrition and health. These guides assist healthy persons in meal planning; however, the guides do not take into account the nutritional needs arising from metabolic and other medical disorders. Besides the American food guides, guidelines have been developed by other countries—for instance, Canada's *Food Guide to Healthy Eating*—and the World Health Organization.

DIETARY REFERENCE INTAKES AND RECOMMENDED DAILY ALLOWANCES

The **recommended dietary allowances (RDAs)** are recommended allowances of essential nutrients (protein, fat-soluble and water-soluble vitamins, and minerals) by age category, inclusive of weight and height. RDAs are established by the National Nutrition Board of the National Academy of Sciences–National Research Council. RDAs represent the normal nutritional needs of 97% to 98% of the people in each specific category; the RDAs do not take into consideration an individual's specific needs or physiological disorders.

Although RDAs have been in existence for the past 20 years as a nutritional guide to support healthy persons, the Food and Nutrition Board, in partnership with Health Canada, has initiated an effort to define new nutrient reference values. The Dietary Reference Intake (DRI) is a generic term that refers to at least three types of reference values: Estimated Average Requirement (EAR), RDA, and Tolerable Upper Intake Level (UL). EAR is the intake value that is estimated to meet the requirement defined by a specific indicator of adequacy in 50% of an age-specific and a gender-specific group. UL is the maximum level of daily nutrient intake that is unlikely to pose risks of adverse health effects to almost all of the individuals in the group for whom it is designed. The goal of DRI is to set nutrient reference values for all of the nutrients; see the accompanying display on DRIs on page 1004 for the first seven nutrient groups studied.

The Evidence-Based Guidelines issued by the National Institutes of Health call for weight loss by restricting caloric intake and increasing physical activity. Every 5 years the U.S. Department of Agriculture (USDA) and the Department of Health and Human Services are responsible for updating and publishing the *Dietary Guidelines for Americans* (DGA). These guidelines are based on the latest scientific and medical knowledge regarding ways to improve overall health through proper nutrition. The DGA 2005 stresses the need to balance caloric intake with daily physical activity and to choose nutrient-dense foods and beverages from the five major food groups while selecting those foods that limit the intake of saturated and trans fats, cholesterol, added sugar, salt, and alcohol and increasing intake of fruits and vegetables to achieve a healthy weight and prevent certain conditions such as obesity, diabetes, and cardiovascular disease. The DGA is a federal nutrition policy that offers guidelines for federally funded nutrition programs such as school lunch programs. See Figure 34-6 on page 1004 for key recommendations for the general population, as addressed in the DGA 2005.

EVALUATION OF DIETARY REFERENCE INTAKES

The seven nutrient groups are as follows:

1. Calcium, vitamin D, phosphorus, magnesium, and fluoride
2. Folate and other B vitamins
3. Antioxidants (e.g., vitamins C and E and selenium)
4. Macronutrients (e.g., protein, fat, and carbohydrates)
5. Trace elements (e.g., iron, zinc)
6. Electrolytes and water
7. Other food components (e.g., fiber, phytoestrogens)

pyramid, the Spanish daily food guide flyer, the Mediterranean diet pyramid, the Asian diet pyramid, and Canada's Food Guide to Healthy Eating (see Figure 34-7 on page 1005).

SOCIETAL CONCERNS

Modern society has turned from a diet of whole grains, fruits, and vegetables to one of processed foods, fast foods, additives, preservatives, and hydrogenated oils that can have a damaging effect on a person's health. Processed foods usually contain excessive amounts of sodium that can cause fluid retention and lead to hypertension, aggravating many medical disorders such as congestive heart failure, certain forms of kidney disorders, and premenstrual syndrome (PMS). Additives are placed in foods for one or more of the following reasons: to lengthen shelf life; to make a food more appealing by enhancing color, texture, or flavor; to facilitate food preparation; or to otherwise make the product more marketable. Some additives are derived from natural sources such as sugar, while others are made synthetically, such as aspartame (NutraSweet). Although additives are usually identified on the "ingredient label" of a product, they are initially used without health warnings. For example, monosodium glutamate (MSG) and the artificial sweeteners cyclamate, saccharin, and aspartame are used without warning but have been known to cause headaches, diarrhea, confusion, memory loss, and seizures.

THE FOOD GUIDE PYRAMID

The Food Guide Pyramid was first developed by the USDA in 1992 to meet the dietary needs of healthy persons over 2 years of age; it was changed in 2005 to complement the revised DGA and DRI. The pyramid is an educational tool that suggests the number of daily servings from each of the five basic food groups (see Figure 34-6). In addition to the Food Guide Pyramid, pyramids for other cultures include the Native American food

GRAINS

Make half your grains whole

- Eat at least 3 ounces of whole grain bread, cereal, crackers, rice, or pasta every day
- Look for "whole" before the grain name on the list of ingredients

MILK

Get your calcium-rich foods

- Go low-fat or fat-free
- If you don't or can't consume milk, choose lactose-free products or other calcium sources

MEAT AND BEANS

Go lean on protein

- Choose low-fat or lean meats and poultry
- Bake it, broil it, or grill it
- Vary your choices—with more fish, beans, peas, nuts, and seeds

VEGETABLES

Vary your vegetables

- Eat more dark green veggies
- Eat more orange veggies
- Eat more dry beans and peas

FRUITS

Focus on fruits

- Eat a variety of fruit
- Choose fresh, frozen, canned, or dried fruit
- Go easy on fruit juices

OILS

Know your fats

- Make most of your fat sources from fish, nuts, and vegetable oils
- Limit solid fats like butter, stick margarine, shortening, and lard

FIGURE 34-6 Steps to a Healthier You: MyPyramid FROM *INSIDE MYPYRAMID*, BY THE U.S. DEPARTMENT OF AGRICULTURE, 2005, RETRIEVED APRIL 21, 2005, FROM [HTTP://WWW.MYPYRAMID.GOV/PYRAMID](http://www.mypyramid.gov/pyramid).

Text not available due to copyright restrictions

Genetically altering the world's food supply has caused many persons to question the essential ingredients of nutrients and the role of the U.S. Food and Drug Administration (FDA) in regulating safe, healthy food products. Although the FDA in 1993 approved the use of rBGH, a genetically engineered bovine growth hormone that enables dairy cows to produce 100% more milk than normal, Canadian health officials rejected a major U.S. corporation's request for approval of rBGH because the product label acknowledges that it can cause udder infections; painful, debilitating foot disorders; and reduced life span in treated cows. Humans who drink the milk from cows treated with rBGH can develop breast or prostate cancer as well as other reproductive disorders and diseases.

The European Union's Scientific Committee on Veterinary Measures reported that 17 beta-oestradiol, one of the six growth hormones that are used in 90% of all nonorganic beef raised in the United States, is "a complete carcinogen." American beef is banned in Europe because these hormones "may cause a variety of health problems, including cancer, developmental problems, harm to the immune system and brain disease" (Campaign for Food Safety, 1999).

In 1995, no genetically modified crops were grown for commercial sale; however, these statistics have changed rapidly in the past 3 years: By 1998, 73 million acres of genetically modified crops were being grown worldwide, more than 50 million acres of them in the United States; in 1999, an estimated 30,000 genetically modified products were in U.S.

grocery stores; and in 2000, 100% of a major U.S. corporation's soybeans (60 million acres) was genetically modified (Genetically Altering the World's Food, 1999). The FDA's position is that genetically modified foods do not need to be labeled; therefore, the consumer is deprived of the opportunity to make an informed choice in the grocery store.

"Consumers are increasingly choosing organic products out of concern for the purity of their food and the health of the environment" (Long, 1999, p. 44). In 2000, new organic certification rules were passed in the United States. These new regulations prohibit organic farmers from using toxic synthetic pesticides and fertilizers, genetically engineered seeds or other materials, irradiation, and sewage sludge. Organic farmers must adhere to strict standards regarding the use of fresh manure, animal confinement, and antibiotics and hormones. For a product to be labeled "certified organic" on the front of the package, 95% or more of the ingredients must be organically grown. To indicate on the label "made with organic ingredients," the product must contain at least 50% organic ingredients.

WEIGHT MANAGEMENT

Maintaining homeostasis requires a balance between intake of nutrients and energy expenditure. Average weight is relative to energy balance, the situation in which energy intake equals energy output.

Overweight

Overweight is an energy imbalance in which more food is consumed than is needed, causing a storage of fat. Overweight indicates a positive energy balance and is defined as weight 10% to 20% above average; obesity refers to weight 20% above average. Overweight may result from one or more factors: genetic, psychological, social, cultural, economic, or physiological. Genetically linked factors, such as a low BMR, excess fat distribution, and obese parents, place a person at risk for obesity. Some people overeat in response to emotional stress or whenever food is available rather than in response to hunger. Sociocultural norms influence eating habits; some cultures place a high value on excess weight. Hormonal imbalances, such as decreased thyroxin levels, can lower the BMR, causing weight gain if food intake remains constant. Other conditions that may contribute to obesity include some cancers, menopause, smoking cessation, impaired mobility, and some drugs such as antidepressants and glucocorticoids (James & Kohlbray, 2004). The degree of obesity is determined by calculating the body mass index, discussed later in this chapter.

Adult, teenage, and childhood obesity is an epidemic in the United States. Studies of ethnic groups indicate that physical inactivity is a risk factor associated with non-insulin-dependent diabetes (type 2), which is more prevalent in the United States in blacks and Native Americans (Gillespie, 2006). Although these populations have a disproportionate number of poor, unemployed, and disadvantaged individuals who lack access to health care, prevention and treatment programs need to focus heavily on exercise that is tailored to the

RESPECTING OUR DIFFERENCES

Vulnerability to Obesity

Cultural practices may encourage a calorie-dense diet. Some ethnic groups consider overweight and obesity acceptable or even desirable. An individual's emotional status also affects eating. What implications do these factors have in teaching clients about weight in relation to health?

activity tolerance of each individual. An estimated 80% of adults with type 2 diabetes are overweight or obese (James & Kohlbray, 2004).

Underweight

An underweight person expends more calories than are consumed. Underweight, a negative energy balance, is weight at least 10% to 15% below average. Being underweight decreases the individual's resistance to infection and increases susceptibility to fatigue and sensitivity to cold environments.

Family dynamics and a fear of overweight are psychological conditions that can contribute to eating disorders. **Anorexia nervosa** (self-starvation) disrupts metabolism because of inadequate caloric intake and results in hair loss, low blood pressure, weakness, amenorrhea, brain damage, and even death (Roth, 2007). **Bulimia nervosa** refers to food-gorging binges followed by purging of food, usually through self-induced vomiting or laxative abuse.

Underweight can also be caused by long-term conditions that deplete the body's resources, such as fever, infection, and cancer, or that prevent nutrient absorption, as occurs with diarrhea, metabolic or GI disorders, and laxative abuse. Other causes of underweight are hyperthyroidism and poverty.

FACTORS AFFECTING NUTRITION

Understanding the factors that may influence nutrition is essential in eliciting client and family cooperation in providing optimal nutritional care.

AGE

Infants and children vary in weight and energy requirements. The infant's physiological development has implications for fluid, electrolyte, and food intake that can predispose this age group to various imbalances. These factors are directly related to the infant's total body surface area, immature physiologic development, and the rate of growth and development during the first year of life; refer to Chapter 18 for a complete discussion of growth and development.

CLIENT TEACHING CHECKLIST

Tips to Reduce Dietary Fat

- Read the nutritional labels for fat content on products before buying.
- Substitute plant proteins for meat, and avoid chocolate.
- Use low-fat dairy products such as skim milk instead of whole milk and low-fat yogurt instead of sour cream.
- Use 1/4 cup of egg substitute or two egg whites for one whole egg.
- Substitute margarine that is low in saturated fat for butter on breads, and use low-fat dressings for salads.
- Trim fats from meats and skin from poultry before cooking, and drain fat from meat after cooking.
- Include more fish and less red meat in the diet.
- Use herbs and spices instead of margarine, oil, and salt when cooking to bring out the flavor in foods.
- Cook foods by baking, broiling, boiling, roasting, or stewing to avoid additional fat from frying.
- Avoid adding flour, bread crumbs, and coating mixes when preparing foods.
- Use vegetable oils and sprays instead of shortening, lard, or butter when cooking and baking.
- Eat fresh fruits and vegetables instead of desserts high in fat.

From ages 1 to 6 years, nutritional intake varies in relation to growth rate, making the child's eating habits erratic. The child will usually select foods based on developmental nutritional needs in accordance with:

- High kilocaloric intake to maintain energy requirements
- Adequate levels of protein, vitamin D, calcium, and phosphate to complement teeth eruption and an increase in muscle mass and bone density

School-age children can eat larger meals less frequently because of the digestive system's maturation and the presence of permanent teeth. A diet that supplies the RDAs will promote optimal development and health and at the same time avoid weight gain during the preadolescent period.

Adolescence, a period of rapid growth and sexual maturation, requires guidance in dietary choices. Hormonal changes associated with menstruation make girls prone to fluid imbalance. Teenagers eat many of their meals away from home—for example, in fast-food restaurants.

Peer groups influence a teenager's choices, such as what, when, and where to eat (see Figure 34-8). At the same time, body image is of critical importance for teenagers. The social pressures and other emotional stressors of adolescence may have a negative effect on eating habits, leading to obesity, the use of fad diets, and eating disorders such as anorexia nervosa

FIGURE 34-8 Adolescents are vulnerable to peer influence

DELMAR/CENGAGE LEARNING

and bulimia. See the accompanying Spotlight On display for some points on food-related behaviors.

During adulthood, growth stops and metabolism declines, thereby decreasing the need for kilocaloric intake. With pregnancy and lactation, the nutritional needs once again increase. During pregnancy, changes occur that may result in fluid retention (dependent edema), for example, hormonal changes, pressure of the fetus on the inferior vena cava, vascular congestion, and increased capillary filtration pressure.

The aging process brings about structural and functional changes that may put older adults at risk. The older population cannot be classified as a homogeneous group because people do not age physically at the same rate they do chronologically; see the Client Teaching Checklist on page 1008 for dietary guidelines for older clients.

Socioeconomic factors, access to a grocery store, and lifestyle may affect the nutritional status of older adults. Having to prepare their own food and eat alone are other challenges they face. Refer to Chapter 19 for additional information on older adults.

LIFESTYLE

Eating is a social activity in most cultures. A person's lifestyle may have a major impact on food-related behaviors. Families with both parents working or with children involved in

SPOTLIGHT ON...

Food-Related Behaviors

How are food fads developed? What lasting impact do these fads have on health? What role does the media play in forming an individual's food beliefs? Is the statement "Yogurt and vitamin E retard aging" related to a fad or a misconception, or is it a fact based on research? To answer this last question, refer to Table 34-1.

sports and other activities might find it difficult to sit down at the dinner table together for a home-cooked meal. When meals are eaten on the run, they tend to be high in fat and carbohydrates and the family misses the opportunity to come together to share important events of the day.

Food preferences are usually developed in childhood and modified throughout the life span. Lifestyle nutritional behaviors often come from traditional family practices. These practices affect not only food-related behaviors but also an individual's

CLIENT TEACHING CHECKLIST

Special Dietary Considerations for Older Clients

- Special attention must be given to water needs, regardless of physical activity, because the thirst mechanism is less responsive than in younger people.
- Decrease the kilocaloric requirements in relation to activity: 10% for ages 51–75 and 20% to 25% for ages 75 and older. Bedridden and immobilized persons need a further reduction in kilocalories. Limit the quantities of empty kilocaloric foods (sugars, sweets, fats, oils, and alcohol).
- Maintain protein requirements, with 12% to 14% of the kilocalories derived from protein foods (meat, fish, eggs, poultry, milk, and cheese).
- Ensure adequate consumption of fats, especially unsaturated fats, to provide a source of energy, provide the essential amino acids, utilize the fat-soluble vitamins, and serve as a lubricating agent.
- Select carbohydrates as follows: Limit concentrated sweets; use moderate amounts of simple sugars (candy, sugar, jams, jellies, preserves, and syrups); the main source should be complex carbohydrates (fruits, vegetables, cereals, and breads).
- Ensure adequate amounts of vitamin D, calcium, and phosphorus to maintain bone integrity (fortified milk is a good source).
- Ensure high-fiber foods (dried fruits, whole grain cereals, nuts, fresh fruits, and vegetables) to increase satiety and maintain intestinal mobility to avoid constipation.
- Ensure a safe, adequate intake of sodium, avoiding canned foods and salted or cured meats high in sodium content for those with cardiac problems and hypertension.
- Include foods from the food guide pyramid in the amounts that meet the RDAs for ages 51 and older.

NUTRITIONAL BEHAVIORS OF SELECTED ETHNIC GROUPS

- Asians' main food types are rice, green tea, vegetables, and fish. A rice-and-water soup is often fed to the sick.
- The Islamic (Muslim) law does not permit the consumption of pork, alcohol, or meat that has not been slaughtered according to the Islamic code. The main meal is at midday.
- Orthodox Jews are not permitted to eat pig, rabbit, and shellfish; milk and meat are not taken at the same meal. A vegetarian diet is acceptable when kosher meat is not available. Strict guidelines dictate food preparation.

beliefs regarding health and wellness. Lifestyle behaviors can be changed. When understood, people can learn to make healthy nutritional choices. If a person gets sufficient rest, has the self-awareness to recognize stress, exercises regularly, and avoids addictive behaviors such as smoking and alcohol, then he or she will usually make healthy nutritional decisions.

ETHNICITY, CULTURE, AND RELIGIOUS PRACTICES

Dietary customs reflect the socialization and cultural patterns of ethnic groups (see Figure 34-9). Culture is evidenced by patterns of values and behaviors that are characteristic of a particular group. Religious beliefs often dictate which types of foods may be eaten and how they should be prepared.

Although it is not possible to learn the nutritional behaviors for all ethnic groups, recognize the need to comply with the client's routine patterns (see the accompanying display on the nutritional behaviors of selected ethnic groups). Refer to Chapter 20 for additional cultural factors that are evidenced in food behaviors.

FIGURE 34-9 Family and cultural values often affect diet DELMAR/ CENGAGE LEARNING

OTHER FACTORS

Other factors influence the types of foods selected and their nutritional value. Economics is a major influence on food selection; fresh fruits and vegetables and lean meats are expensive and are often substituted with products that tend to be low in protein and high in starch.

Food preferences are an expression of an individual's likes and dislikes. They may be related to the texture of food, how it is prepared, or what was served during childhood. However, preferences can also be an expression of a person's economic, ecological, ethical, or religious beliefs. Vegetarians, for example, follow a diet of plant foods and may include eggs or milk, depending on preference. A vegetarian diet is healthy when it includes a wide variety of foods to ensure adequate amounts of protein, vitamins, and minerals.

Gender may play a role in food selection, owing mainly to stereotyping (for example, the idea that males eat meat and potatoes and females eat salads). Peer pressure often dictates what teenagers eat. Stress, depression, and alcohol abuse alter the appetite. Medications can alter food absorption and excretion and affect the taste of food. GI disorders can cause anorexia, nausea, vomiting, diarrhea, constipation, discomfort, and pain, all of which may influence eating habits and food preferences.

ASSESSMENT

The goals of a nursing assessment are to collect subjective and objective data regarding the client's nutritional status and to determine which type of nutritional support is needed. Nurses are in a unique position to recognize **malnutrition**, or alterations related to inadequate intake, disorders of digestion or absorption, and overeating. Assessment must be performed in a logical fashion and should include three basic components: nutritional history, physical examination with anthropometric measurements, and diagnostic and laboratory data.

NUTRITIONAL HISTORY

The nutritional history of clients experiencing alterations in nutrition and metabolism is of critical importance in the development of the plan of care. Several methods can be used in collecting these subjective data: 24-hour recall, food-frequency questionnaire, food record, and diet history; see Table 34-3 on page 1010 for an example of a nutritional history. Begin the history with a thorough exploration of the client's presenting problems as they relate to onset, duration, nature, pattern, severity, associated symptoms, and efforts made to relieve the symptoms.

24-Hour Recall

The 24-hour recall requires client identification of everything consumed in the previous 24 hours. It is performed easily and quickly by asking pertinent questions. However, clients may be unable to recall their intake accurately or anything

SPOTLIGHT ON...

Caring and Compassion

Personal Biases

Performing a nutritional history requires a questioning, nonjudgmental attitude. Examine your biases to treat the viewpoints of all clients equally. To gain a sincere understanding of clients' perspectives, develop an open mind, and listen with empathy.

atypical for their diet. Family members can often assist with these data, if necessary.

Food-Frequency Questionnaire

The food-frequency method gathers data relative to the number of times per day, week, or month the client eats particular foods. The nurse can tailor the questions to particular nutrients, such as cholesterol and saturated fat. This method helps validate the accuracy of the 24-hour recall and provides a more complete picture of foods consumed.

Food Record

The food record provides quantitative information regarding all foods consumed, with portions weighed and measured for 3 consecutive days. This method requires full client or family member cooperation.

Diet History

The diet history elicits detailed information regarding the client's nutritional status, general health pattern, socioeconomic status, and cultural factors (see Table 34-3). This method incorporates information similar to that collected by the 24-hour recall and food-frequency questionnaire. Inform the client that the history might require more than one interview because of the amount of data to be collected.

Although the history data may indicate adequate nutrition, clients must be reassessed periodically to prevent nutritional problems from occurring. Fear, anxiety, or depression before or during hospitalization may lead to poor food intake, which is the leading cause of malnutrition.

PHYSICAL EXAMINATION

A physical assessment requires decision making, problem solving, and organization; refer to Chapter 27 for a complete discussion of physical assessment. This section presents the physical assessment findings that suggest nutrient imbalance. "The nurse should be aware of rapidly proliferating tissues such as hair, skin, eyes, lips, and tongue that usually show nutrient deficiencies sooner than other tissues" (Hammond, 1999, p. 355). (Refer to Table 34-4 on page 1012 for the assessment findings of clients with nutrient imbalances.) Essential components of anthropometric measurements (height, weight, and skinfolds) are also discussed.

TABLE 34-3 Health History Related to Nutrition and Metabolism

ENVIRONMENT AND LIFESTYLE	POSSIBLE FINDINGS
Employment	<ul style="list-style-type: none"> • Exposure to heat, toxic chemicals • Extent of physical exertion • Degree of stress
Home environment	<ul style="list-style-type: none"> • Central air/heat; lives alone or with other family members; ability to shop/cook
Tobacco use	<ul style="list-style-type: none"> • Use of smokeless tobacco; cigarettes: number of years; packs per day; if quit, how long
Nutritional status	<ul style="list-style-type: none"> • Weight changes: loss or gain • Fluid consumption for 24 hours: number of glasses of water, cups of coffee or tea, soft drinks; amount of alcohol consumed • Food preferences and restrictions • Dietary restrictions (sodium) • Use of supplements: vitamins, minerals, commercial liquids, herbs
Presenting Problem	Possible Findings
Weight loss	<ul style="list-style-type: none"> • Onset: sudden or gradual duration • Pattern: decreased intake, increased activity • Severity: how much, specific time frame • Associated symptoms: anorexia, nausea, vomiting, diarrhea, dysphagia (difficulty in swallowing), odynophagia (pain in swallowing), polyuria (passage of excessive urine), fatigue, dyspnea, depression, cognitive impairment, motor weakness or paralysis • Efforts to relieve weight loss: increased intake, decreased activity
Anorexia	<ul style="list-style-type: none"> • Onset: sudden, gradual duration • Pattern: continuous, occasional, related to food intake—specific foods, time of day, activity, drugs, radiation or chemotherapy • Severity: intake for 24 hours • Associated symptoms: weight loss, nausea, vomiting, diarrhea, dysgeusia (distortion of sense of taste), fatigue, depression • Efforts to relieve anorexia: dietary changes—types of foods and preparation, time of day, eating with others or alone
Nausea and vomiting	<ul style="list-style-type: none"> • Onset: sudden, gradual duration • Nature of emesis: color, consistency, amount • Pattern: continuous, occasional, related to food intake—specific foods, time of day, position or activity • Severity: specific amount in a 24-hour period • Associated symptoms: weight loss, anorexia, dysphagia, diarrhea, fatigue, motor weakness, pain • Efforts to relieve nausea and vomiting: eliminating odors, certain foods, medications; changing position or activity after meals
Diarrhea	<ul style="list-style-type: none"> • Onset: sudden or gradual duration • Nature of feces: color, consistency, amount • Pattern: frequency, related to food intake • Severity: number of times in 24 hours • Associated symptoms: nausea, vomiting, pain, fatigue, motor weakness, weight loss • Efforts to relieve: decrease fluid intake with meals; identify foods, medications, and other stressors that trigger diarrhea

Delmar/Cengage Learning

Intake and Output (I&O)

I&O measurements and daily weights are critical components of a nutritional assessment; refer to Chapter 33, Procedure 34-1, I&O measurements, and Chapter 26 for a complete discussion of weight measurement.

Anthropometric Measurements

Anthropometric measurements (measurements of the size, weight, and proportions of the body) evaluate the client's calorie-energy expenditure balance, muscle mass, body fat, and protein reserves based on height, weight, skinfolds, and limb and girth circumferences. Chapter 26 discusses the assessment of height and weight; refer to Chapter 33 for additional nursing measures relative to daily weights.

The **body mass index (BMI)** determines whether a person's weight is appropriate for height and is calculated using a simple formula:

$$\text{BMI} = \frac{\text{weight (kg)}}{[\text{height (m)}]^2}$$

For example, a person who weighs 65 kg and is 1.6 m tall would have a BMI of $65 \text{ kg}/(1.6 \text{ m})^2$, or 25.4. According to the Centers for Disease Control and Prevention, a healthy BMI for adults is between 18.5 and 24.9. Specific ranges have

been established as follows: underweight—BMI less than 18.5; overweight—BMI of 25 to 29; obese—BMI of 30 or more. Height and weight tables are available in most health care settings.

SKINFOLD MEASUREMENTS **Skinfold measurement**

indicates the amount of body fat. This information is beneficial in promoting health and determining risks and treatment modalities associated with chronic illness and surgery. This assessment is usually performed in an outpatient setting when the nurse develops a client's profile.

A special caliper is used to measure skinfolds. The caliper should grasp only the subcutaneous tissue, not the underlying muscle. Measurements can be taken of the triceps, subscapular, biceps, and suprailiac skinfolds.

- To measure the triceps fold, locate the midpoint of the upper arm. Grasping the skin on the back of the upper arm, place the calipers 1 cm below fingers (see Figure 34-10 on page 1013), and measure the thickness to the nearest millimeter.
- For a subscapular skinfold measurement, grasp the skin below the scapula with three fingers, angle the fold about 45° laterally to the scapula (see Figure 34-11 on page 1013), place the caliper 1 cm above fingers, and read the measurement.

It is essential to document the skinfold sites, the type of caliper used, and the measurement in millimeters.

TABLE 34-4 Adult Physical Assessment Findings: Nutrient Imbalance

ASSESSMENT FINDINGS	NUTRIENT DEFICIENCIES AND EXCESSES	ASSESSMENT FINDINGS	NUTRIENT DEFICIENCIES AND EXCESSES
Hair			
Dull, dry brittle	Protein deficiency	Petechiae and ecchymoses	Vit C and vit K deficiency
Hair loss	Protein, zinc, and biotin deficiency or vit A excess	Darkening and peeling of sun-exposed areas	Niacin deficiency
Loss of pigment in strips around hair line	Protein and copper deficiency	Poor wound healing	Protein, zinc, and vit C deficiency
Head and neck		Nails	
Headache	Vit A and D excess	Koilonychia (spoon-shaped nails)	Iron deficiency
Epistaxis (nosebleed)	Vit K deficiency	Brittle, fragile	Protein deficiency
Thyroid enlargement	Iodine deficiency	Heart	
Eyes		Tachycardia	Vit B ₁ deficiency
Pale conjunctiva	Iron deficiency	Hypertension	Calcium and potassium deficiency or sodium excess
Blue sclerae	Iron deficiency	Abdomen

Corneal vascularization	Vit B ₂ deficiency	Musculoskeletal	
Mouth		Muscle wasting	Protein and vit B ₁ , B ₆ , and B ₁₂ deficiency
Lesions at corners of mouth	Vit B ₂ deficiency	Edema	Protein and vit B ₁ deficiency
Glossitis (red, sore tongue)	Niacin, folate, vit B ₁₂ , and other vit B deficiencies	Calf tenderness	Vit B ₁ and C, biotin, and selenium deficiency
Gingivitis (inflamed gums)	Vit C deficiency	Bone tenderness	Vit D, calcium, and phosphorus deficiency or vit A excess
Hypogeusia (poor sense of taste)	Zinc deficiency	Knock-knees, bowed legs, and fragile bones	Vit D, calcium, phosphorus, and copper deficiency
Dysgeusia (bad taste)	Zinc deficiency	Neurologic	
Dental caries	Fluoride deficiency	Paresthesia	Vit B ₁ , B ₆ , and B ₁₂ , and biotin deficiency
Mottling of teeth	Fluoride excess	Weakness	Vit C, B ₁ , B ₆ , and B ₁₂ deficiency
Atrophy of papillae on tongue	Iron and vit B deficiency	Ataxia	Vit B ₁ and B ₁₂ deficiency
Skin		Tremor	Magnesium deficiency
Dry, scaly	Vit A, zinc, and essential fatty acids deficiency or vit A excess	Decreased tendon reflexes	Vit B ₁ deficiency
Eczematous lesions	Zinc deficiency	Disorientation	Vit B ₁ deficiency
		Drowsiness, lethargy	Vit B ₁ deficiency or vit A and D excess
		Depression	Vit B ₁ and biotin deficiency

Delmar/Cengage Learning

MID-UPPER-ARM CIRCUMFERENCE The measurement of **mid-upper-arm circumference (MAC)** serves as an index for skeletal muscle mass and protein reserve. Instruct the client to relax and flex the forearm; with a measuring tape, measure the circumference at the midpoint of the upper arm (see Figure 34-12 on page 1013).

ABDOMINAL-GIRTH MEASUREMENT When made repeatedly over a span of time, an abdominal girth measurement serves as an index as to whether abdominal distention is increasing, decreasing, or remaining the same. With an indelible pen, place an X on the client's abdomen at the point of greatest distention. Using a measuring tape, measure the abdomen's circumference.

FIGURE 34-10 Measuring Triceps Skinfold, at Midpoint of the Upper Arm DELMAR/CENGAGE LEARNING

FIGURE 34-12 Measuring the Mid-Upper-Arm Circumference DELMAR/CENGAGE LEARNING

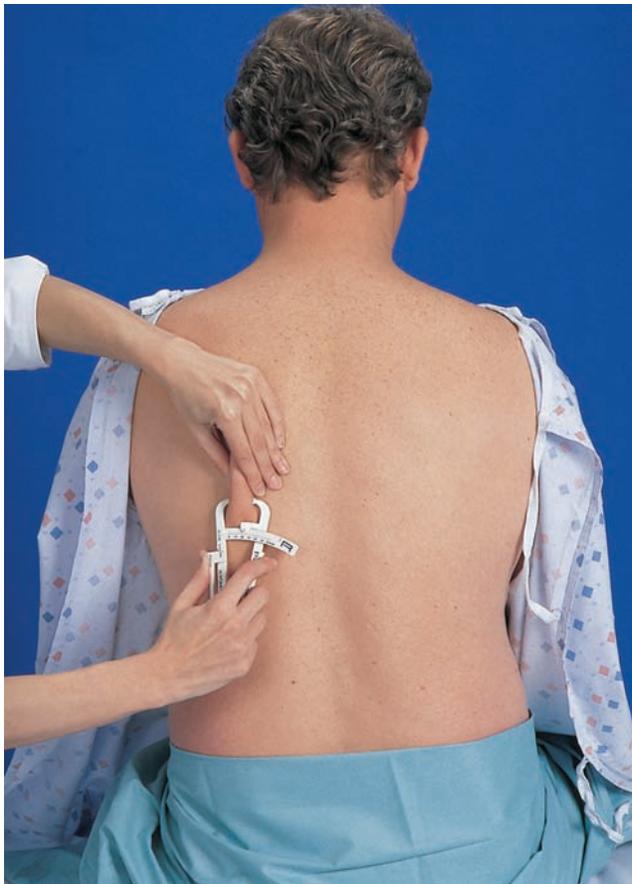

FIGURE 34-11 Measuring the Subscapular Skinfold DELMAR/CENGAGE LEARNING

This measurement should be performed at the same time each day and consistently recorded in either inches or centimeters.

DIAGNOSTIC AND LABORATORY DATA

Biochemical data assessment is another essential source of objective data. Trends revealed in laboratory results can be used to detect alterations in nutrition and metabolism before clinical symptoms are assessed in the examination. Refer to Chapter 28 for a detailed discussion of laboratory testing. No single laboratory test is diagnostic of malnutrition.

Protein Indices

Several tests that reflect protein synthesis can also reflect nutritional status. Serum levels of albumin and transferrin are used to identify protein-calorie malnutrition.

SERUM ALBUMIN Albumin is synthesized in the liver from amino acids. Serum albumin plays an important role in fluid and electrolyte balance and the transport of nutrients, hormones, and drugs. However, serum albumin has a half-life of 21 days and fluctuates according to the level of hydration; therefore, it is not a good indicator of acute alterations in protein status. Clinically, this blood test is used to measure prolonged protein depletion that occurs in chronic malnutrition, liver disease, and nephrosis. Albumin levels below 3.5 g/dL may indicate some degree of malnutrition.

PREALBUMIN Research has provided a newer, more accurate test to evaluate protein status. **Prealbumin** (a precursor

of albumin) has a half-life of 2–3 days; it is used to determine protein depletion in acute conditions, such as trauma and inflammation, and serves as a guide for nutritional therapy. Prealbumin levels between 15 mg/dL and 5 mg/dL reflect mild to moderate protein depletion, while levels below 5 mg/dL indicate severe protein depletion.

SERUM TRANSFERRIN **Transferrin** (nonheme iron) is a blood protein in combination with iron; it is used to transport iron throughout the body to all cells. It is responsive to iron stores, increasing when they are low and decreasing when they are high. This test is considered a sensitive indicator of protein deficiency because it responds promptly to changes in protein intake. Levels below 200 mg/dL may indicate mild to moderate protein depletion, and levels below 100 mg/dL may indicate severe depletion.

Hemoglobin Level

The hemoglobin test measures the oxygen and iron-carrying capacity of the blood; the normal level is 12 to 15 g/100 mL. A decreased hemoglobin may indicate some form of anemia, such as microcytic iron deficiency anemia or blood loss.

Total Lymphocyte Count

Another test that may be used to measure protein depletion is total lymphocyte count. Protein deficiency may cause a depression in the immune system, with a resultant decrease in the total lymphocyte count; this can occur with severe debilitating diseases, such as cancer or renal disease.

Nitrogen Balance

Nitrogen balance studies indicate the degree to which protein is being depleted or replaced in the body. The blood urea nitrogen (BUN) is increased with severe dehydration, malnutrition, starvation, excessive protein intake, and most commonly kidney disease (the kidneys fail to excrete urea). A decreased BUN results from a diet low in protein-rich foods.

Urine Creatinine Excretion

During skeletal muscle metabolism, creatinine is released at a rate in proportion to the total body mass. A 24-hour urine test is done to measure the total amount of creatinine excreted by the kidneys. In malnutrition, the creatinine level is decreased as a result of muscle atrophy.

NURSING DIAGNOSIS

In order to make a nursing diagnosis, the nurse must interpret the subjective and objective data and draw conclusions from the client's assessment data obtained during a comprehensive health history and physical examination. The approved nursing diagnoses are discussed to assist with the appropriate selection of primary and secondary nursing diagnoses for clients with nutritional alterations.

IMBALANCED NUTRITION: LESS THAN BODY REQUIREMENTS

An estimated 30% to 50% of hospitalized clients are at risk for malnutrition; increased morbidity and mortality rates are associated with malnutrition (Bulechek, Butcher, & Dochterman, 2008). The diagnosis *Imbalanced nutrition: less than body requirements* exists when the client fails to ingest or digest food or absorb nutrients. The Nursing Process Highlight lists some possible causes of this nursing diagnosis.

Such clients may experience a weight loss of 20% or more from their ideal weight. The dietary history may reveal inadequate food intake based on the RDAs, a lack of interest in or an aversion to eating, a perceived inability to ingest food, and reduced energy level. Clients have poor muscle tone, with skinfolds less than 60% of standard measurement, and they may experience difficulty in swallowing or masticating food because of muscular weakness. The conjunctive and mucous membranes are usually pale, and the buccal cavity is sore and inflamed.

IMBALANCED NUTRITION: MORE THAN BODY REQUIREMENTS OR RISK FOR IMBALANCED NUTRITION: MORE THAN BODY REQUIREMENTS

Imbalanced nutrition: more than body requirements exists when clients experience or are at risk for an intake of nutrients that exceeds metabolic needs. Clients may be at risk because of one or more of the following factors: hereditary predisposition or obesity in one or both parents; dysfunctional psychological conditioning in relationship to

NURSING PROCESS HIGHLIGHT

Diagnosis

Factors Causing Nutritional Imbalance

Multiple factors can cause *imbalanced nutrition: less than body requirements*:

- **Biological:** Buccal cavity discomfort, pain; difficulty in swallowing; stomach strictures, ulcers; inflammation, obstruction of the biliary or intestinal system; chronic diarrhea; pulmonary disorders; postoperative status; transplantation candidate, pre- and postsurgery; cancer and radiation therapy; immunosuppression
- **Psychological:** Anorexia nervosa; bulimia; severe stress, anxiety, fatigue, or depression; prolonged grieving; lack of knowledge; extreme food fad and dieting practices
- **Economic:** Inadequate finances to purchase protein-rich foods

Text not available due copyright restrictions

food, such as using food as a reward or comfort measure; and age-related factors, most notably early infancy, adolescence, and aging.

Clients with more than body requirements experience a weight gain of 10% to 20% over the ideal for height and frame and triceps skinfolds greater than 15 mm in men and 23 mm in women. The client's dietary history may reveal a sedentary activity level and one or more dysfunctional eating patterns: pairing food with other activities, such as watching TV; concentrating the intake of food at night; and eating in response to internal cues (anxiety) or external cues (such as a social event) instead of in response to hunger.

OTHER NURSING DIAGNOSES

The client who is protein-depleted may also experience deficiencies in vitamins (especially A and C) and minerals (especially zinc, magnesium, and iron). Refer to the accompanying display for a list of common secondary nursing diagnoses related to nutritional and metabolic problems. Because the secondary diagnosis is related to the nutritional/metabolic problem, it is written in terms of the etiology of the primary diagnosis, for example, *risk for impaired skin integrity* related to inadequate intake of proteins, vitamins, and minerals.

PLANNING AND OUTCOME IDENTIFICATION

The nurse relies heavily on the data obtained from the nutritional history and collaborates with the client and other health team members in formulating goals and expected outcomes to promote optimal nutritional care. Nursing diagnoses of life-threatening conditions, such as *impaired swallowing* related to decreased or absent gag reflex, are given first priority. Other diagnoses that are actual problems take priority over high-risk problems.

In the planning phase, the nurse identifies and explains to the client the need for and basis of the therapy. The nurse takes into consideration the client's dietary habits, likes, dislikes, needs, readiness for learning, and nutritional assessment data in defining goals and developing outcomes in collaboration with the client. Refer to the accompanying display for samples of NOC nutrition outcomes.

The nurse selects appropriate nursing interventions to match the client's routine patterns, as obtained in the health history, and to support achievement of the goals and outcomes. Proceeding in this fashion facilitates the client's adaptive capabilities through skillful interventions.

COLLABORATION

The management of nutritional problems is usually a long-term process that requires a multidisciplinary approach. For example, obesity management programs often involve clinicians, dietitians, exercise physiologists, health educators, and social workers or psychologists. Family involvement is an essential component in managing obesity.

NURSING OUTCOMES CLASSIFICATION (NOC): NUTRITION

- Nutritional Status (1004)
- Nutritional Status: Biochemical Measures (1005)
- Nutritional Status: Energy (1007)
- Nutritional Status: Food & Fluid Intake (1008)
- Nutritional Status: Nutritional Intake (1009)

Moorhead, S., Johnson, M., Swanson, M., & Maas, M. (2008). *Nursing outcomes classification (NOC)* (4th ed.). St. Louis, MO: Mosby.

Since the early 1980s, nutrition support teams (NSTs) were established to reduce the complications of parenteral nutrition (PN). To achieve the expertise required for a consulting service, the teams have become multidisciplinary. The clinical functions of NSTs are:

- Identification of clients who are nutrition impaired or at risk for malnutrition
- Performance of a nutritional assessment to guide nutritional therapy
- Provision of nutritional support that is safe and effective

The nurse is seen as the vital link between the client and other team members to include a prescribing practitioner, nurse, pharmacist, and dietitian. The nurse's role is critical, both for the implementation of nutritional support and for ongoing assessment, because the nurse administers and monitors nutritional therapies.

IMPLEMENTATION

The nurse is responsible for understanding the client's nutritional needs and for making clinical judgments relative to outcomes of therapy. This responsibility includes intervening to prevent the rapid depletion of the body's protein and energy reserves. Performance of nursing interventions to accomplish goals and outcomes includes monitoring the client's weight and intake, diet therapy, and feeding. Client teaching occurs with each intervention to maximize the effectiveness of nutritional therapy.

The Nursing Interventions Classification (NIC) consists of specific interventions for clients with impaired nutrition, such as Behavior Management: Overactivity/Inattention, Eating Disorders Management, Enteral Tube Feeding, Nausea Management, and Nutrition Management. These interventions identify the specific nursing activities for each classification.

MONITORING WEIGHT AND INTAKE

Weight and intake measurements are used to assess the client's nutritional status and to monitor the effectiveness of therapy. Refer to Chapters 26 and 33 for nursing actions relative to daily weights and I&O considerations.

INITIATING DIET THERAPY

Nutritional problems often require dietary modification. Therapeutic nutrition requires consideration of the client's total needs: cultural, socioeconomic, psychological, and physiological. Modified diets should promote effective nutrition within the client's lifestyle; this often requires client teaching regarding the avoidance of certain foods or adding food items to the diet, given the client's sociocultural context, economic restraints, and religious beliefs. See Table 34-5 on page 1017 for the various types of therapeutic diets and examples of food items for each diet; dietary restrictions vary among agencies and in accordance with the client's tolerance. A *diet as tolerated* is prescribed to allow the

client to eat whatever foods the client can chew, swallow, and digest and may progress to a *regular diet* without any restrictions. Recent research has changed the nutritional management of clients by introducing dietary support early after surgery, trauma, or acute illness; this change stresses the need for positive nitrogen balance and its role in healing and recovery.

ASSISTANCE WITH FEEDING

Assessment data provide direction regarding how to assist the client with eating. Clients with difficulty in self-feeding, chewing, or swallowing will require assistance to promote safety and adequate intake of nutrients; see the accompanying Nursing Process Highlight on page 1018.

Clients with a neurologic disease such as an acute stroke, Parkinson's disease, or dementia or with a history of prolonged or multiple endotracheal intubations or tracheostomy may need a bedside swallow screen to identify dysphagia and aspiration risk until further studies can be done by a speech-language pathologist (Grams & Spremulli, 2008). If the client is managing oral secretion, offer small pieces of ice or sips of water and observe for cough, drooling, voice change (especially a wet or gurgling quality), and swallowing difficulty. Stop the screen immediately if any of these symptoms occur, and notify the prescribing practitioner.

Because eating is a social activity (see Figure 34-13 on page 1017), it is important to encourage a family member or friend to be present at meals. If this is not possible, assess the availability of other resources to provide social stimulation during meals, such as watching TV, listening to music, or having a staff member remain with the client.

PROVIDING NUTRITION SUPPORT

Proper nutrition in hospitalized clients is necessary for wound healing, recovery, reduction in morbidity, and consequent reductions in length of stay and mortality. The most common nutritional deficiency in hospitalized clients is protein-energy malnutrition. This type of malnutrition depletes body cell mass and impairs tissue and organ function. When protein-energy malnutrition is left untreated, the following client negative outcomes may occur:

- Weakness
- Compromised immunity
- Decreased wound healing
- Increased risk for complications

Nutrition support (NS) is prescribed for those clients at risk for protein-energy malnutrition.

There are two routes for delivery of NS in adult clients: enteral nutrition (EN) and PN. **Enteral nutrition** includes both the ingestion of food orally and the delivery of nutrients through a GI tube. **Parenteral nutrition** refers to nutrients bypassing the small intestine and entering the blood directly. EN is preferred over PN because of decreased bacterial translocation and reduced expense and is usually delivered through a feeding tube (see Figure 34-14 on page 1018).

TABLE 34-5 Therapeutic Diets

TYPE	DESCRIPTION
Clear liquid	Prescribed primarily for surgical clients: water, broth/bouillon, clear fruit juices, gelatin, carbonated beverages, coffee, tea, popsicles
Full liquid	Prescribed mainly for postoperative clients: clear liquids, plus all fruit and vegetable juices, smooth-textured dairy products, custard and pudding
Pureed	Prescribed for clients with dysphagia: full liquids, plus pureed fruits, vegetables, and meats, scrambled eggs
Mechanical soft	Prescribed for clients having difficulty chewing/swallowing: pureed foods that are finely diced or ground, plus cheese, barley, rice, pancakes, and breads
Soft	Prescribed for clients having difficulty chewing/swallowing: mechanical soft foods, plus enriched pasta, broiled seafood, and desserts without nuts and dried fruits
Liberal bland	Prescribed for clients with excessive digestive enzymes: eliminates chemical and mechanical food irritants such as fried foods, alcohol, and caffeine
Low residue	Prescribed for client with mucosal irritation existing with diverticulitis, ulcerative colitis, and Crohn's disease: eliminates raw fruits (except bananas), vegetables, seeds, plant fiber, and whole grains and limits dairy products to two servings a day
High fiber	Prescribed for clients with diverticulosis: raw fruits and vegetables, seeds, plant fiber and whole grains; the opposite of low residue
Fat controlled	Prescribed for clients with atherosclerosis, heart disease, and obesity: decreases saturated fats by restricting animal fats, gravies, sauces, chocolate, and whole-milk products
Sodium restricted	Prescribed for clients with excess fluid volume, hypertension, heart failure, myocardial infarction, and renal failure: restrictions for mild, 2 to 3 g; moderate, 1000 mg; strict, 500 mg; and severe, 250 mg
Lactose intolerant	Prescribed for client who lacks or is deficient in lactase, an enzyme that splits lactose into glucose and galactose: eliminates milk and dairy products, except yogurt
Candidiasis	Prescribed for client with <i>Candida albicans</i> , a normal, parasitic yeastlike fungus that may multiply with certain conditions or therapies, such as antibiotics or chemotherapy: eliminates all fruits, sugar, yeast, and fermented foods

Delmar/Cengage Learning

Critical indicators for determining the feeding route and NS formula include GI function, expected duration of therapy, aspiration risk, and the potential for or the actual development of organ dysfunction. For example, the decision to initiate PN or EN support is based on evidence that the client is unable to meet his or her own nutritional needs by oral intake and will therefore experience malnutrition. Refer to Figure 34-15 on page 1019 for a clinical decision algorithm that outlines the selection process for choosing the route of nutritional support in adult clients. The client's NS may be determined by an NST in accordance with American Society for Parenteral and Enteral Nutrition (ASPEN) guidelines.

The nurse is responsible for eliciting the client's or family's continued consent and collaboration with the therapy.

FIGURE 34-13 Eating is a social activity DELMAR/CENGAGE LEARNING

NURSING PROCESS HIGHLIGHT

Implementation

Nursing Measures That Promote Client Feeding

- Before bringing the meal tray into the room, ask whether the client needs to void or have a bowel movement.
- Provide hygiene measures before serving the meal tray.
- Position the client in a comfortable position, preferably in a chair, if not contraindicated.
- Ask about the client's eating habits and the foods he or she prefers to eat first. Ask what help is needed. For instance, older adults may want scrambled eggs placed in a sandwich to make them easier to handle.
- Make sure the foods are being served at the correct temperature.
- Provide assistance if the client is unable to handle eating utensils or to open containers and packages.
- Provide adequate time for the client who has difficulty chewing or swallowing. Make sure that someone is in the room while the client is eating.
- Document the type and amount of food taken at each meal.
- Remove the tray after the meal, and provide hygiene measures.

The prescribing practitioner obtains the client's informed consent for starting the therapy. The nurse teaches the client and family about the nutritional support to restore a sense of independence and self-esteem. Many staff nurses are board certified in NS by the ASPEN.

ENTERAL TUBE FEEDING

Candidates for enteral tube feeding are clients who have a functional GI tract and will not, should not, or cannot eat. Therefore, tube feedings are used for clients who are (or may become) malnourished and in whom oral feedings are insufficient to maintain adequate nutritional status.

Enteral tube feedings maintain the structural and functional integrity of the GI tract, enhance the utilization of nutrients, and provide a safe and an economical method of feeding. Enteral tube feedings are contraindicated in clients with the following:

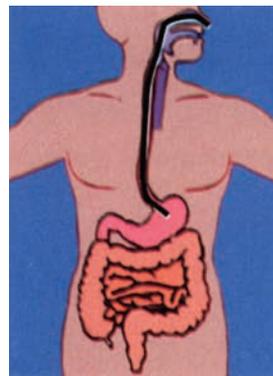

- Diffused peritonitis
- Intestinal obstruction that prohibits normal bowel functioning
- Intractable vomiting; paralytic ileus
- Severe diarrhea

Feeding Tubes

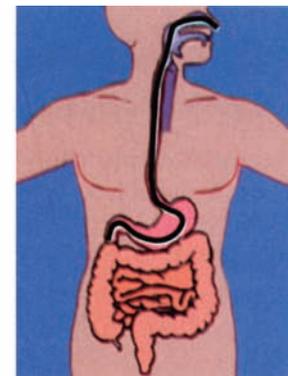

Most feeding tubes are made of silicone or polyurethane, which are durable and biocompatible with formulas. They vary in diameter (8 to 12 French) and length in accordance with the route and formula. The prescribing practitioner selects the route (see Figure 34-14) and type of feeding tube on the basis of the anticipated duration of feeding, the condition of the GI tract, and the potential for aspiration.

Insertion of Enteral Feeding Tubes

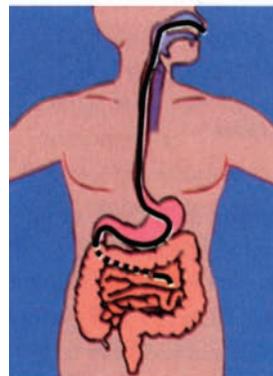

Nasoenteral insertion of a gastric feeding tube is the simplest and most often used method of tube feeding. It is used as a

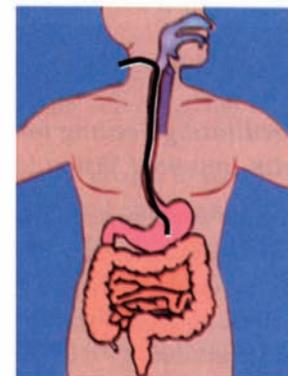

Nasogastric Route

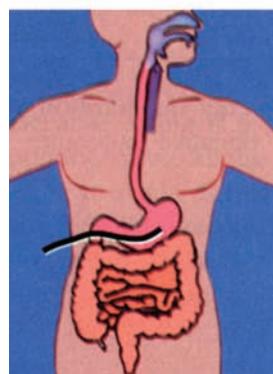

Nasoduodenal Route

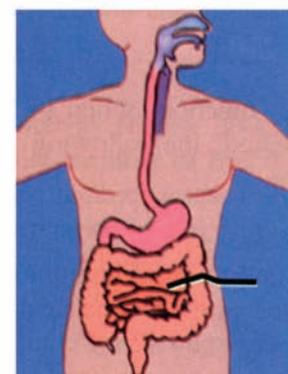

Nasojejunal Route

Esophagostomy Route

Gastrostomy Route

Jejunostomy Route

FIGURE 34-14 Enteral Feeding Routes DELMAR/CENGAGE LEARNING

accepted technique to provide enteral access for both children and adults.

Enteral Formulas

Nutrients administered through tubes are liquefied so they can be easily digested and absorbed. Commercially prepared formulas are available and used in most health care settings. Enteral tube feeding is used with caution in clients with severe pancreatitis, enterocutaneous fistulae, and GI ischemia. These feedings are not recommended during the early stages of short-bowel syndrome or in the presence of severe malabsorption. There are three basic types of formulas, which differ in osmolality, digestibility, kilocalories, lactose content, viscosity, and fat content:

- *Isotonic formula* contains proteins, fats, and carbohydrates with a high molecular weight and an osmolality equal to that of the body (300 mOsm). Isocal and Osmolite are isotonic formulas that supply 1 kcal/mL and are lactose free.
- *Elemental (monomeric) formula* contains monosaccharides and amino acids with minimal triglyceride content in hypertonic concentrations. Vivonex and Vivonex HN are elemental formulas that supply 1 kcal/mL; they are started at half strength or less and gradually increased to full strength due to their hypertonic concentration.
- *Fluid restriction formula* contains a highly concentrated source of kilocalories (2 kcal/mL). Magnacal is a fluid restriction formula that is started at half strength or less and gradually increased to full strength due to the hypertonic concentration.

Administration of Enteral Feedings

Once the feeding tube's position has been radiographically verified, the formula can be administered as prescribed (see Procedure 34-2). Most clients with a small-bore tube receive continuous feeding with a formula pump to regulate the rate. One of the advantages of continuous feeding is that it keeps gastric volume small, minimizing residual volume and reducing the risk of aspiration pneumonia; the client is less likely to experience bloating, nausea, abdominal distention, and diarrhea.

Safety Considerations

Clients receiving EN through a feeding tube are at risk for aspiration. Tube feeding aspiration can result from several

Text not available due to copyright restrictions

temporary measure for clients who are expected to resume oral feeding. Nasogastric intubation refers to insertion of a tube through the nostril into the stomach (see Procedure 34-1). Nasoduodenal or nasojejunal intubation allows nasal access to the duodenum and jejunum; it is done with a longer tube and decreases the client's risk of vomiting and aspiration. Radiographic visualization is used to confirm tube placement prior to feeding.

Enterostomy is the surgical creation of an artificial fistula (gastrostomy, jejunostomy) in the intestines by an incision through the abdominal wall. Tube enterostomies can be placed at various points along the GI tract and are performed when long-term tube feeding is anticipated or when obstruction makes nasal intubation impossible.

Percutaneous endoscopic gastrostomy (PEG) tube placement is usually performed by the prescribing practitioner at the bedside or in the endoscopy room; *insertion of a PEG tube does not require surgery*. Endoscopy nurses are often trained to assist with PEG placement. PEG has become an

SAFETY FIRST

SMALL-BORE FEEDING TUBE

When inserting a small-bore feeding tube with a guide wire or stylet, never attempt to reinsert the guide wire or stylet while the tube is in the client. The guide wire or stylet may perforate the GI mucosa, especially the esophagus, and injure the client.

SAFETY FIRST

ALLERGIES

Before administering a tube feeding, determine whether the client has any food allergies. Clients may be lactose intolerant or may have an allergy to the formula.

factors: displacement of the tube into the esophagus, large amounts of gastric residue, and lowered intestinal motility and delayed gastric emptying, which may occur in clients who are on bed rest or receiving narcotics for pain relief. Auscultate for bowel sounds to determine gastric motility. If the bowel sounds are hypoactive or absent, stop or withhold additional feeding and notify the prescribing practitioner.

Always assess placement of the feeding tube before administering any liquids. Clients who are receiving continuous gastric feeding should be assessed every 4 hours for tube placement and residual gastric contents. Aspirate gastric contents with a syringe. This is done more easily with a large-bore tube rather than a small-bore one. The lumen of a small-bore tube collapses easily, making aspiration difficult and sometimes impossible. Observe and check the pH of the aspirate as explained in Procedure 34-1. Replace stomach contents after checking the residue to prevent fluid and electrolyte imbalance.

Although the literature documents the numerous research studies regarding the various methods to verify feeding tube position, there is no evidence to document 100% accuracy of any one nonradiographic method to verify tube placement. Huffman, Pieper, Jarczok, Bayne, and O'Brien (2004) reviewed the research literature on methods that document proper position of orally or nasally placed feeding tubes and determined that pH testing, combined with visual inspection of the aspirate, is the most reliable bedside method of verifying feeding tube position. Caution should be used when testing the pH aspirate of clients receiving certain drugs that may alter the pH, such as acid-suppressing medications or continuous feedings. The best practice for feeding tube verification is as follows:

- Document pH of aspirate with initial placement. Radiographic confirmation should be obtained for nasointestinal feeding tubes after initial placement.
- Document insertion distance with initial placement and record the external length of the tube in the nursing notes.
- Check the pH of aspirate before administering any medication or feeding.

A pH of 4 or less in adults (5 or less in children) suggests that the tip of the tube is in a gastric location, and the appearance of the aspirate can verify this. The characteristics of aspirates are:

- *Gastric aspirates:* Cloudy and green, tan or off-white, or bloody or brown (fresh or old blood)
- *Intestinal aspirates:* Basically clear and yellow to bile-colored

SAFETY FIRST

GASTRIC RESECTION

Never insert, manipulate, or remove a nasogastric tube on gastric resection clients: The suture line could easily be interrupted, causing hemorrhage.

- *Pleural aspirates:* Tan or off-white mucus, may be pale yellow and serous (indicating blood)

When the nurse has any question regarding proper position, elective replacement and reassessment and/or radiographic confirmation should be considered before the administration of medications or feeding.

Client safety and comfort require daily cleansing of the feeding tube's exit site. Cleanse the skin with a clean washcloth, soap, and water. Nasal feeding tubes require daily removal of the tape from the nose and cleansing and inspection of the skin for irritation, inflammation, and infection and of the nares for erosions, ulcers, or abscesses.

Enterostomy tubes require surgical asepsis of the exit site until the incision heals; rotate the tubes within the stoma to promote healing. Report any observations of redness, irritation, or gastric leakage at the site. Once the stoma has healed, the tube can be removed and reinserted for each feeding. Between feedings, a prosthetic device may be used to cover the ostomy opening.

PEG tubes require daily rotation to relieve pressure on the skin. Notify the prescribing practitioner if the nurse is unable to rotate the PEG; it may be an indication of internal embedding of the tube into the gastric wall. When the tube is internally embedded, it can cause gastric acid reflux, which results in skin breakdown, sepsis, and cellulitis. Care must be taken to avoid dislodgment of the tube. Keep it secured to the client's abdomen with tape, being careful not to use excessive tension. PEG tubes require frequent flushing to prevent clogging. These tubes have small lumens. If a tube becomes clogged, flush it with 60 mL of lukewarm tap water.

Potential Complications

Clients receiving EN need to be monitored closely to prevent complications. The nurse should perform the following actions:

1. Assess the client for signs of gastric retention: nausea, vomiting, and cramping. Palpate the abdomen for distention, auscultate for bowel sounds with a stethoscope, and aspirate the gastric contents every 4 hours. If the aspirate exceeds 100 mL in a 4-hour period or if bowel sounds are absent (indicating an ileus), discontinue the feeding and notify the prescribing practitioner. *Do not remove the feeding tube.*
2. Monitor the feeding tube placement every 4 hours by checking for any coils or kinks in the back of the throat and measuring the length of tubing outside of the body.
3. Assess the client for pulmonary aspiration by checking the gag reflex. If the reflex is absent, suction the client.

Discontinue the feeding and remove the tube if signs of respiratory distress are present, and notify the prescribing practitioner.

4. Keep the client in a high Fowler's position to prevent aspiration if vomiting should occur. If vomiting does occur, suction client immediately and assess the formula amount and rate at which it was given.
5. Dilute feedings to half strength, and slow the feeding time to prevent diarrhea.
6. To maintain or achieve patency of gastric and/or jejunostomy feeding tubes, a medical device called a DeClogger may be used as prescribed by the client's prescribing practitioner to maintain the patency of these tubes (see the accompanying Nursing Checklist).

Teach the client and caregiver how to monitor for complications prior to discharge for home treatment. The client and caregiver should be given the opportunity to practice these assessment measures and demonstrate competency in performing the actual procedures.

Clients with feeding tubes may be discharged to the home. The NST evaluates these clients to determine:

- Ability to meet nutrient requirements orally
- Clinical status relative to home discharge
- Tolerance of prescribed nutritional therapy
- Willingness and ability to perform the necessary tasks of tube feeding
- Benefits of continuing therapy at home

The NST works with the client and caregiver to secure the necessary supplies prior to discharge from the hospital. Clients on home feedings require monitoring by nurses and nutritional support specialists who are familiar with the procedure and complications of enteral tube feeding.

Removal of a Nasogastric Tube

When the prescribing practitioner determines that the client's nutritional status no longer warrants EN therapy or the need to provide decompression of the gastric contents, the nasogastric tube is removed; refer to the accompanying Nursing Checklist on page 1022. If the client is connected to suction for decompression, the prescribing practitioner may prescribe clamping the tubing for several hours prior to removal to ensure a functioning GI tract.

PARENTERAL NUTRITION

PN is the infusion of a solution directly into a vein to meet the client's daily nutritional requirements. Formerly called hyperalimentation, it is frequently referred to as **total parenteral nutrition (TPN)**, the intravenous infusion of a solution containing dextrose, amino acids, fats, essential fatty acids, vitamins, and minerals. Other terms used interchangeably with TPN are 3 in 1 (dextrose, amino acids, and fats) and total nutrient admixtures (TNAs).

PN is used to treat malnourished clients or clients who have the potential for becoming malnourished and who are not candidates for enteral support. PN can be prescribed for either short-term or long-term use, as previously discussed in the decision algorithm (see Figure 34-15).

NURSING CHECKLIST

Use of a DeClogger

1. Gather equipment: towel, receptacle for used items, nonsterile gloves, and appropriate size DeClogger that corresponds to the size of the feeding tube as prescribed by the prescribing practitioner.
2. Verify the prescribing practitioner's prescription.
3. Review the agency's policy.
4. Check the client's armband, and explain the procedure.
5. Provide for privacy.
6. Wash hands.
7. Turn the enteral feeding pump to the pause mode; if feeding to gravity, clamp the tubing.
8. Don nonsterile gloves.
9. Place the clean towel under the tube to protect the bed linens.
10. Disconnect tubing, and place cap on delivery tube to prevent contamination.
11. Attempt to flush tube with 30–60 cc of water.
12. Gently insert the appropriate size DeClogger into the opening of the tube.
13. Slowly rotate the DeClogger in a clockwise fashion until the stop disc meets the opening of the tube.
14. To remove, slowly rotate the DeClogger in a counter-clockwise fashion as you pull back on the device.
15. Flush the feeding tube with 30–60 cc of water.
16. Reconnect the delivery tube, and restart enteral feedings.
17. Discard the DeClogger into the receptacle, remove gloves, place in receptacle, and dispose of receptacle in accordance with agency policy.
18. Wash hands, and document procedure in the client's medical record.

The type of device used for PN therapy is determined by the duration of the therapy and the osmolality of the solution. Peripheral parenteral nutrition (PPN) is used for short-term treatment to deliver isotonic or mildly hypertonic solutions into a peripheral vein; the volume is usually limited to between 2000 and 3000 mL/day, providing a caloric value of about 2000 kcal/day.

Central parenteral nutrition (CPN) is used for long-term therapy to infuse highly hypertonic solutions directly into the superior vena cava. The delivery of highly hypertonic solutions into peripheral veins can cause sclerosis, phlebitis, or swelling; refer to Chapter 33 for a complete discussion of intravenous therapy complications. Malnourished clients are prone to infections because their immune systems have been

**NURSING CHECKLIST****Removal of a Nasogastric Tube**

1. Gather equipment: tube plug or clamp, towel, washcloth, paper towel, receptacle for contaminated items, and nonsterile gloves.
2. Verify the prescribing practitioner's prescription.
3. Check the client's armband, and explain the procedure.
4. Provide for privacy.
5. Wash hands and don gloves.
6. Place the client in a high Fowler's position, and adjust the height of the bed to a comfortable working position.
7. Place the towel across the client's chest.
8. Clamp or plug the tube, and unpin the tube from the client's gown.
9. Remove the tape securing the tube from the client's nose.
10. Hold the paper towel open in nondominant hand under the client's chin; with dominant hand, grasp and pinch the tube near the nostril, and remove the tube with a steady, continuous pull, allowing the tube to fall into the paper towel.
11. Dispose of the tube and paper towel in the receptacle.
12. Clean the client's nares, and provide oral hygiene.
13. Position the client comfortably, place call light within easy reach, and return bed to a low position.
14. Remove gloves, place in receptacle, and dispose of receptacle in accordance with agency policy.
15. Wash hands, and document procedure in the client's medical record.

compromised. EN and PN provide a positive medium for the potential growth of microorganisms. To decrease the risk of infection, institute the following nursing measures:

1. Verify placement of feeding line prior to administration of liquids.
2. Administer nutrients in accordance with the prescribed time interval.
3. Add small quantities of enteral formula to the bag.
4. Wash reusable EN feeding bag with warm water and soap after each use, at least every 24 hours.
5. Keep PN refrigerated; remove from refrigerator 30 minutes prior to administration.
6. Change EN and PN tubing every 24 hours.

Specific client populations that benefit from PPN or CPN are described in the accompanying display.

Components of Parenteral Nutrition

PN solutions are predigested or chemically prepared nutrients that can be administered singly or as admixtures. The basic components of PN are:

1. Carbohydrates, primarily in the form of monohydrous glucose, ranging from 5% solution for PPN to 50% to 70% hypertonic solution for CPN; provides client with 60% to 70% of caloric (energy) needs
2. Amino acids, in the form of synthetic crystalline amino acid solutions; provides 5% to 15% of the total calories (CPN solutions contain sufficient amino acids for tissue synthesis)
3. Lipids (fat emulsions), prepared from safflower and soybean oil with egg phospholipids; supply up to 30% of client's caloric (energy) intake; additional lipid emulsions and glucose or amino acids provide for a TNA isotonic solution. Clients with a known egg allergy should not receive TPN with lipid emulsions.

Other ingredients, called admixtures, provide for the client's biochemical needs (electrolytes, vitamins, and trace elements such as zinc, selenium, chromium, magnesium, iodine, copper, iron, and molybdenum).

Medications, such as heparin, may also be added to the TPN solution. Heparin is commonly added to reduce the buildup of a fibrinous clot at the catheter's tip. When the TPN catheter is the only available venous access, TPN may be used to

CANDIDATES FOR PPN OR CPN THERAPY**SHORT-TERM (UP TO 2 WEEKS) PPN**

1. Preoperative for severely depleted clients
2. Postoperative for abdominal surgery clients who have been NPO for several days because of an ileus
3. Inflamed or ulcerated bowel needing 1 or more weeks of rest: acute exacerbations of Crohn's disease and colitis, radiation enteritis, acute or necrotizing pancreatitis, or an enterocutaneous or a high-output fistula
4. Congenital anomalies before surgical repair: intestinal obstruction, tracheoesophageal fistula, midgut malrotation, volvulus, and omphalocele
5. Short-bowel syndrome: small-bowel resection of 75% or more to control diarrhea and prevent dehydration and malnutrition
6. Cancer clients receiving chemotherapy or radiation therapy

LONG-TERM (GREATER THAN 2 WEEKS) CPN

1. Hyperemesis gravidarum
2. Low-birth-weight neonates
3. Failure to thrive
4. Intractable diarrhea
5. Severely burned clients

deliver antibiotics. The TPN solution should be prepared only by a pharmacist using sterile technique and a laminar flow hood to reduce the risk of contamination. See the Nursing Checklist on page 1024 on interventions for a client receiving TPN.

Client assessment for home parenteral nutrition (HPN) should consider the physical, psychosocial, and financial resources of the client and the caregiver. Maintaining a client on HPN is challenging because of the expense, technology, and required changes in lifestyle. When the PN is prescribed daily, it is usually administered overnight to minimize disruption to the client's lifestyle. Home health nurses should visit the client daily until the client and caregiver demonstrate proficiency in handling the equipment and maintaining aseptic technique.

Clients receiving PN in the home environment require close monitoring to prevent catheter sepsis and cardiac overload. The PN solution should be administered with a volumetric infusion pump. If the home does not have air conditioning to maintain the proper temperature of the solution during infusion, the solution can be divided into two bags. The second bag can be refrigerated while the first bag is infusing. The same schedule is followed for monitoring the biochemical effectiveness of PN, as discussed earlier for the hospitalized client.

Refeeding Syndrome

Refeeding syndrome is a complication that can occur during the initial phase of EN or PN therapy, oral intake, or dextrose-containing IV fluids. It occurs in severely malnourished clients who experience significant fluid and electrolyte imbalances after aggressive nutritional support is initiated. Malnourished clients adapt to nutritional deprivation and compensate by decreasing basal energy requirements. The initiation of replacement therapy, especially if the PN is undertaken too aggressively, can result in an electrolyte shift from plasma to the intracellular fluid.

Electrolyte disturbances, mainly decreased levels of phosphorus, magnesium, or potassium, occur immediately after the rapid initiation of refeeding, usually within 12 to 72 hours, and can continue for the next 2 to 7 days. Cardiac complications can develop within the first week, often within the first 12 to 48 hours, with neurologic signs and symptoms developing more slowly (Yantis & Velander, 2008). The clinical manifestations include edema, hypernatremia, hypokalemia, hypomagnesemia, and hypophosphatemia. Nursing measures are directed at prevention by initiating EN and PN therapy slowly and monitoring the client's electrolytes to prevent cardiac complications.

ADMINISTERING MEDICATION THROUGH A FEEDING TUBE

Refer to agency protocol regarding medication administration and contraindications. Feeding tubes with a double lumen have two separate ports; read the manufacturer's instructions to determine which port to use to administer the medication. Administering medications through the wrong port may cause the tube to clog.

Check for tube placement, clear the tubing of formula, and check the patency of the tube by flushing it with warm water before administering the medication. It is advisable to

use the liquid form of any medications whenever possible. After administering each medication, flush the port to prevent clogging. Measure the aspirates removed, all liquids instilled into the tube, and the water used for flushing and medications, and record on the client's I&O record. Refer to Chapter 30 for additional information on administering medication through a feeding tube.

COMPLEMENTARY AND ALTERNATIVE THERAPY

Holistic nursing recognizes wellness as a state of harmony among mind, body, and spirit. To nourish means to provide that which is necessary for life, health, and growth; to nourish also means to cherish, to strengthen, and to promote. Nourishment encourages expansion and growth, supporting each being as unique, whole, and individual. The following discussion provides a broad perspective regarding the use of nutrients in complementary therapies and how herbal medicine incorporates certain plants for their specific properties in order to treat digestive symptoms and diseases.

Although there are numerous types of complementary therapies, they all integrate, to some degree, nutrition as part of their therapeutic regimen. Diet and nutrition are used by many alternative modalities for the prevention and treatment of chronic diseases:

1. *Ayurvedic medicine*, India's ancient system of healing, treats the whole person with diet, nutrition, and lifestyle recommendations to promote health and spiritual development. For example, diabetes is a complex condition with a multitude of metabolic imbalances involving the regulation of insulin and glucose in the body. Clients with type 2 diabetes mellitus die of cardiovascular disease at rates two to four times higher than nondiabetic populations of similar demographic characteristics; they also experience increased rates of nonfatal myocardial infarction and stroke (ACCORD, 2008). With the growing prevalence of obesity in the United States, diabetes is currently considered an epidemic disease that is largely preventable and treatable through yoga. Yoga's effectiveness at preventing and treating diabetes is due to its emphasis on a healthy diet and lifestyle as well as its ability to balance the endocrine system, massage and tone the abdominal organs, stimulate the nervous and circulatory systems, and reduce stress (Upadhyay, Balkrishna, & Upadhyay, 2008).
2. *Traditional Chinese medicine*, one of the oldest systems of healing, incorporates acupuncture, Chinese herbs, massage, food therapy, exercise, and lifestyle changes into prevention and treatment.
3. *Chiropractic medicine*, an American heritage, relies on a sound nutritional program as adjunct therapy to support the body's inherent ability to heal itself by reestablishing an unobstructed flow of nerve impulses between the brain and the rest of the body.
4. *Naturopathic medicine*, an ancient form of healing that was formalized in America into a system of preventive and restorative treatments around the early 1900s, uses

**NURSING CHECKLIST****Interventions for Client Receiving TPN**

1. Monitor weight: baseline and daily weight for 1 week and twice a week thereafter. The ideal weight gain for a client is 1 pound per week. Rapid weight gain may be indicative of fluid overload; monitor such a client for peripheral and pulmonary edema.
2. Monitor I&O: Record daily I&O and compare these data with the client's weight. Closely monitor the infusion rate with an infusion pump (preferably a volumetric pump for the greatest accuracy).
3. Monitor biochemical lab values:
 - Electrolytes, especially magnesium and calcium, if these have been added to the PN solution, on Day 1 and once a week thereafter while on PN. With severely malnourished clients, observe for "refeeding syndrome" (a rapid drop in potassium, magnesium, and phosphate serum levels). Initiate feeding slowly to avoid cardiac overload.
 - Prealbumin serum levels: Check on Day 1 and once a week while on PN. In clients who are severely dehydrated, the albumin levels may drop initially as treatment restores hydration.
 - Glucose (capillary): Check every 6 hours for the first week, then once daily while on PN. Monitor for signs of hyperglycemia (thirst and oliguria), and confirm weekly blood glucose meter levels with laboratory tests.
 - Bleeding indices (prothrombin time [PT]) on Day 1 and once a week while on PN; indicated for clients receiving heparin therapy.
 - Liver function tests, especially enzymes, bilirubin, triglycerides, and cholesterol on Day 1 and once a week for clients on PN with lipids; abnormal values may indicate an intolerance to or an excess in lipid emulsions or problems with the metabolism with glucose and protein.
 - Renal function tests, especially blood urea nitrogen, creatinine, and 24-hour urinary urea nitrogen, on Days 2–5; abnormal values indicate an excess of amino acids.
 - Transferrin should be measured on Day 1 and every 2 weeks thereafter.
4. Administer solution with an IV tubing filter to remove crystals from the solution, vent air, and trap microorganisms.
5. Change IV tubing, using aseptic technique, as indicated by the agency's protocol; most infection control guidelines recommend changing the tubing every 24 hours.
6. Use a volumetric pump to ensure accurate infusion rates.
7. Monitor for common complications of PN therapy:
 - Phlebitis or thrombosis at the IV site, as indicated by tenderness and redness
 - Catheter tip sepsis, as indicated by fever and other signs and symptoms of sepsis
 - Liver, renal, and metabolic complications (as discussed in monitoring the biochemical laboratory values)
8. Wean the client from PN, documenting the dietary intake of total calories and protein.
9. Teach the client and the caregiver about the management of PN therapy, and arrange for a home health care consult; if possible, have the home health nurse consult with the client while the client is still in the hospital to promote continuity of care.

clinical nutrition as a main cornerstone of therapy to achieve and maintain health.

5. *Osteopathic medicine*, founded by Dr. Andrew Taylor Still, a medical surgeon for the Union Army during the Civil War, integrates into conventional medicine nutritional recommendations for prevention. For example, to prevent coronary heart disease, a diet low in saturated fats is combined with antioxidants (vitamins C, A, and E) to help prevent free radical formation, thus preventing tissue breakdown as well as the accumulation of plaque in the arteries.
6. *Herbal medicine* recognizes food as medicine, ensuring that the unique healing properties of specific herbs have a direct effect upon tissue. The healing effect is through direct contact with the tissue and the effects

caused by the metabolism and absorption of the chemicals present in the various plants. Based on a holistic context, herbal medicine recognizes that true healing must involve all dimensions of the person to change whatever dietary indiscretions exist as well as to make other adjustments in the person's lifestyle.

Many herbal products are available in various forms such as teas, extracts, capsules, and tablets to provide nutrients that nourish our bodies and relieve digestive symptoms. The following discussion addresses the digestive and nondigestive actions of certain herbs: bitters, chamomile, dandelion, peppermint, rosemary, and slippery elm.

Bitters is a term used to describe a group of herbs that have a bitter taste. The taste of bitterness on the tongue sends a message to the brain through the nervous system to

SPOTLIGHT ON...

Legal and Ethical

Withholding Nutritional Support

The obligation to promote the good of the client is basic to being a health care provider and is part of each professional's duty to the client. This obligation underlies the requirement to evaluate the benefits and burdens of a treatment from the client's perspective.

When and by whom should a decision be made to withhold or withdraw nutritional support in the absence of an advance directive? Consider the benefits to the client and the burden that nutritional support places on the client, family, and caregiver.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Percutaneous Endoscopic Gastrostomy Feeding in Nursing Homes”

AUTHORS

A. M. Brotherton and B. Carter

PURPOSE

To explore the experiences of relatives of nursing home residents receiving percutaneous endoscopic gastrostomy (PEG) feeding.

METHOD

Qualitative methodology using semistructured interviews explores the experiences and perceptions of eight relatives.

FINDINGS

The relatives expressed four themes: dependence and resulting disempowerment, having minimal or no involvement in the decision-making process for PEG placement, betrayal, and the losses associated with the social aspects of eating.

IMPLICATIONS

There is a need for professional education about the psychosocial implications of feeding and an increased level of support for relatives to assist them to develop coping strategies.

Brotherton, A., & Carter, B. (2007). Percutaneous endoscopic gastrostomy feeding in nursing homes. *Clinical Nursing Research, 16*(4), 350–369.

stimulate the secretion and activity of the esophagus, and the secretions of the stomach, duodenum, and gallbladder, and to stimulate the production of insulin by the pancreas. The bitterness promotes appetite and in a complex way aids digestion. Bitter herbs are considered digestive stimulants because they stimulate various parts of the digestive system to increase or improve digestive activity. The most valuable bitter herbs are barberry, centaury, gentian root, goldenseal, mugwort, white horehound, and wormwood.

Chamomile contains calcium, essential oils, iron, magnesium, manganese, potassium, tannic acid, vitamin A, apigenin (a sedative compound), and other nutritive ingredients. It possesses the following actions: antiinflammatory, appetite stimulant, digestive aid, diuretic, nerve tonic, and sleep aid. Traditionally, chamomile is used for stress and anxiety, indigestion, and insomnia, and it is often used to treat colitis, diverticulosis, fever, headaches, and pain. It is effective as a gargle or mouthwash for treating gingivitis. *Caution:* This herb should not be taken over long periods of time, as it may cause an allergy to ragweed; it should not be used by persons who are allergic to ragweed (Balch, 2006).

Dandelion leaves and roots are high in iron, manganese, phosphorus, protein, aluminum, and vitamin A, with trace amounts of calcium, chromium, niacin, riboflavin, silicon, zinc, and vitamin C. It is a potent digestive tonic that may be used in conditions that affect the GI tract, such as heartburn, gas, gastroesophageal reflux, and constipation. Dandelion has a toning effect on the liver, gallbladder, and pancreas, providing relief from gallstones or gallbladder attacks as well as diabetes and hypoglycemia. Dandelion is considered safe and may be taken as often as needed. *Caution:* Due to its laxative effects, large sudden intake may result in diarrhea; start with smaller doses, and gradually increase over time.

Peppermint contains essential oils, tannic acid, vitamin C, and other ingredients. It is one of the best carminative agents (stimulates and soothes the digestive system, removes gas), and it enhances digestion by increasing stomach acidity. It is

NURSING PROCESS HIGHLIGHT

Implementation

Collaborative Measures to Support Behavioral Change

Planning interventions to assist clients with their nutritional problems requires consideration of the specific contributing factors, food preferences and beliefs, and chronic conditions related to the problem. Changing eating patterns requires client motivation and desire to change. No one can make another person change his or her behavior, but nurses can assist their clients with the “why” and “how” regarding change. Reinforce all positive changes.

often recommended for chills, colic, diarrhea, headache, heart trouble, indigestion, nausea, poor appetite, rheumatism, and spasms. *Caution:* This herb may interfere with iron absorption.

Rosemary is often used as a natural food preservative because of its chemical and nutritive content. It is considered a circulatory and digestive bitter; it fights bacteria, relaxes the stomach, and acts as a decongestant; it also helps prevent liver toxicity, and it has anticancer and antitumor properties. It relieves intestinal colic, flatulent dyspepsia, headaches, high and low blood pressure, circulatory problems, and menstrual cramps, and it is used to treat ulcerative colitis, Crohn's disease, and fevers, especially colds and influenza (Balch, 2006).

Slippery elm bark contains calcium, phosphorus, polysaccharides, starch, tannins, and vitamin K. It soothes inflamed mucous membranes of the stomach, bowels, and urinary tract. It may be used to treat gastritis, gastric or duodenal ulcer, enteritis, colitis, diarrhea, and colds, flu, and sore throat.

Garlic (*Allium sativum*), the second most utilized supplement, has shown antiviral, antibacterial, antifungal, and antioxidant abilities. Garlic's medicinal actions may help or prevent certain diseases such as Alzheimer's disease, cancer, cardiovascular disease, children's conditions, dermatologic

applications, stress, and infections (Bongiorno, Fratellone, & LoGiudice, 2008). Some studies indicate possible benefits in diabetes, drug toxicity, and osteoporosis.

EVALUATION

Evaluation of nutritional therapy is ongoing. The nurse uses current data to measure the achievement of goals and outcomes; once they are achieved, the plan of care is revised accordingly. If goals are not met, the nurse should determine whether the nursing diagnosis was accurate or whether the nursing interventions were appropriate and the outcomes achievable.

The plan of care should be modified to maximize the client's response to therapy. For example, if the home health client states compliance with diet therapy to maintain the HDL, LDL, and cholesterol levels within normal limits, but the values are not within normal limits, then institute a food record to monitor cholesterol and fat intake for 3 consecutive days. Visit the client on the fourth day and review the record. Provide teaching as necessary to assist the client in changing eating patterns.

NURSING CARE PLAN

Client with Imbalanced Nutrition: More Than Body Requirements

CASE PRESENTATION

Mrs. Jones, age 55, was diagnosed 2 years ago with type 2 (non-insulin-dependent) diabetes. She is being seen in the clinic for her 6-month visit. She says, "I hardly have the energy to get up and dress in the morning. I am thirsty all day and awaken several times during the night, having to go to the bathroom." She does not work and hasn't been involved in community activities for the past 5 years since her youngest child graduated from high school. Her daily routine involves cooking for her husband and brother, reading, and watching TV for 6–8 hours. She loves to bake fresh breads and pastry. She has a history of obesity and does not exercise. She says, "I eat because I have nothing else to do."

ASSESSMENT

- Weight, 80.6 kg
- Height, 5'4"
- Triceps skinfold, 28 mm
- Elevated blood glucose
- Weight gain, 3.6 kg
- Sedentary lifestyle
- Eats in response to boredom

NURSING DIAGNOSIS: *Imbalanced nutrition: more than body requirements* related to excess intake of high-calorie foods, eating in response to boredom, and sedentary lifestyle

NOC: Motivation, weight control

NIC: Weight management

(Continues)

NURSING CARE PLAN (Continued)

EXPECTED OUTCOMES

The client will

1. Verbalize factors contributing to excess weight.
2. Lose 1–2 lb/week while eating well-balanced meals.
3. Engage in 20–30 minutes of exercise 3 times a week.
4. Explore outside interests to decrease boredom and increase feelings of self-worth.

INTERVENTIONS/RATIONALES

1. Conduct a dietary history, using open-ended statements to assist client in exploring psychological factors that may contribute to eating. Nonjudgmental approach to acquiring information will encourage client trust and honesty.
2. Adapt eating habits to decrease amount of intake (having smaller servings, taking small bites and chewing each bite 12 times, putting the fork on the plate between bites, drinking water with meals, eating only at mealtime, chewing sugar-free gum when watching TV). Healthy eating habits and tips on recognizing fullness during a meal will help the client eat to satisfy hunger, not boredom.
3. Assess client's motivation to lose weight. Having client's support for care plan will influence success.
4. Discuss risk factors and symptoms (thirst and urination) of diabetes. Client's understanding of her disease may increase motivation to manage it.
5. Instruct client to maintain a daily dietary intake log: time, type, and amount. Helps client recognize her eating patterns and note healthy and unhealthy behaviors.
6. Provide client with dietary materials: Review the food pyramid and diabetic exchange list; plan with client an 1800-kilocalorie diet for a week, taking into consideration food preferences. Ensures client has information necessary to plan healthy meals within recommended guidelines.
7. Return visit with nurse in 1 week. Monitor progress and assess plan of care. Review with client age-appropriate exercises; emphasize need for daily walking. Changing sedentary lifestyle will increase self-esteem, burn calories, and increase energy level.
8. Review with client community and church interests outside the home, unrelated to cooking and eating. Helps client focus on activities not involving food to decrease boredom and to increase self-esteem.

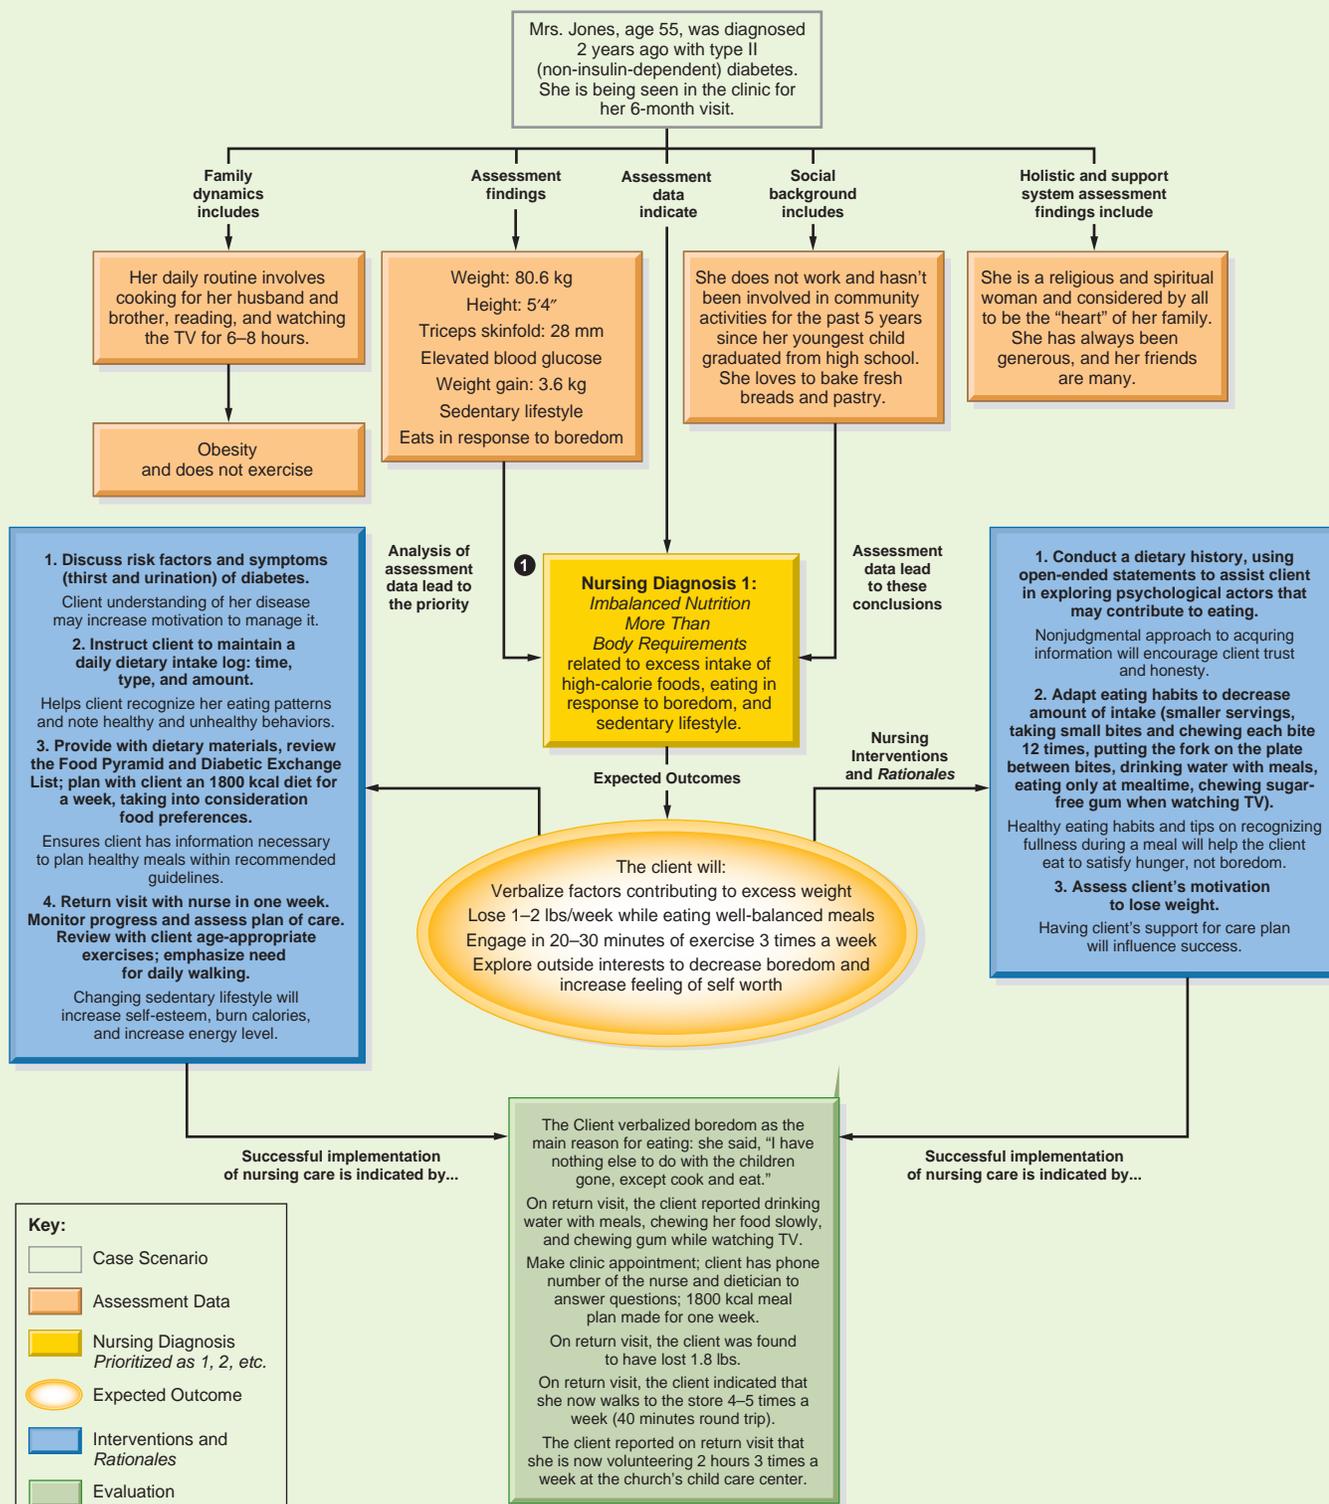

EVALUATION

1. The client verbalized boredom as the main reason for eating; she said, "I have nothing else to do with the children gone, except cook and eat."
2. On return visit, the client reported drinking water with meals, chewing her food slowly, and chewing gum while watching TV.
3. Make clinic appointment; client has phone number of the nurse and dietitian to answer questions; 1800-kilocalorie meal plan made for 1 week.
4. On return visit, the client was found to have lost 1.8 lb.
5. On return visit, the client indicated that she now walks to the store 4–5 times a week (40 minutes round trip).
6. The client reported on return visit that she is now volunteering 2 hours three times a week at the church's child care center.

CONCEPT MAP

THE CLIENT WITH IMBALANCED NUTRITION: MORE THAN BODY REQUIREMENTS

Client with Imbalanced Nutrition: Less Than Body Requirements

CASE PRESENTATION

Jim, age 28, has been HIV-positive for 4.5 years. He arrives at the clinic complaining of diarrhea and cramping for 3 weeks and a burn wound on his right forearm that will not heal. He states, "I do not have the energy to eat or get dressed." The past month, he has eaten mainly bread, cereal, milk, and potatoes.

ASSESSMENT

- Weight loss
- Dry, scaly skin
- Pale conjunctiva
- Decreased hgb, HCT, MCV
- Triceps skinfold, 7.2 mm
- Gingivitis
- Decreased Na, K, Fe, zinc
- Decreased serum albumin, prealbumin, transferrin, nitrogen balance, zinc, and total lymphocyte count (TLC); urine creatinine excretion

NURSING DIAGNOSIS: *Imbalanced nutrition: less than body requirements* related to inability to absorb nutrients because of HIV enteropathy

NOC: Nutrient intake.

NIC: Nutrition management.

EXPECTED OUTCOMES

The client will

1. Receive adequate nutrients to meet metabolic needs.
2. Stabilize weight within 24–48 hours after initiation of TPN.
3. Gain 0.25–0.5 kg/wk.
4. Select a diet high in calcium, iron, protein, and calories.

INTERVENTIONS/RATIONALES

1. Weigh in daily; record hourly I&O; monitor qh BP, P, R rate, breath sounds, edema.
Monitors overall health status for changes, balance of fluid intake and output, and signs of deterioration.
2. NPO until diarrhea subsides; record frequency and consistency of stools (weight and measure).
As prescribed; monitors progression of diarrhea.
3. Administer TPN as ordered; implement TPN protocol. Maintains caloric intake needs safely.
4. Monitor daily laboratory data: glucose, vitamins, minerals, trace elements, electrolytes; monitor prealbumin and BUN every other day. Assesses nutritional effect of TPN.
5. Mouth care every 2–4 hours to keep mucous membranes moist. Provides for client comfort.
6. Collaborate with the nutritional support team for a progressive diet postdiarrhea, taking into consideration client's food preferences. Outlines appropriate diet; client is most likely to eat foods he prefers.
7. Offer small, frequent feedings. Facilitates digestion and maintains constant energy levels.
8. Provide oral hygiene before and after meals. Enhances taste sensation.
9. Assist the client with meals as needed. Provide rest periods 1 hour before and after meals. Surrounds eating with quiet time to focus; improves digestion.
10. Gradually wean the client off TPN as ordered. Begin return to oral nutrition intake.
11. Monitor daily calorie count for 3 days and stool counts daily. Gives indication of amount eaten versus amount excreted; monitors diarrhea.
12. Allow client to select food high in protein and calories. Involvement in diet planning increases compliance.
13. Administer drugs between meals. Helps avoid nausea at mealtime.
14. Provide positive reinforcement for increased food intake and weight gain. Helps client acknowledge progress; shows support for plan of care.
15. Assess the client's knowledge of the RDAs. Current knowledge levels will determine learning needs.
16. Instruct the client on dietary planning based on the Food Guide Pyramid, as directed by the nutritional support team. Client involvement in dietary planning increases likelihood of success.

(Continues)

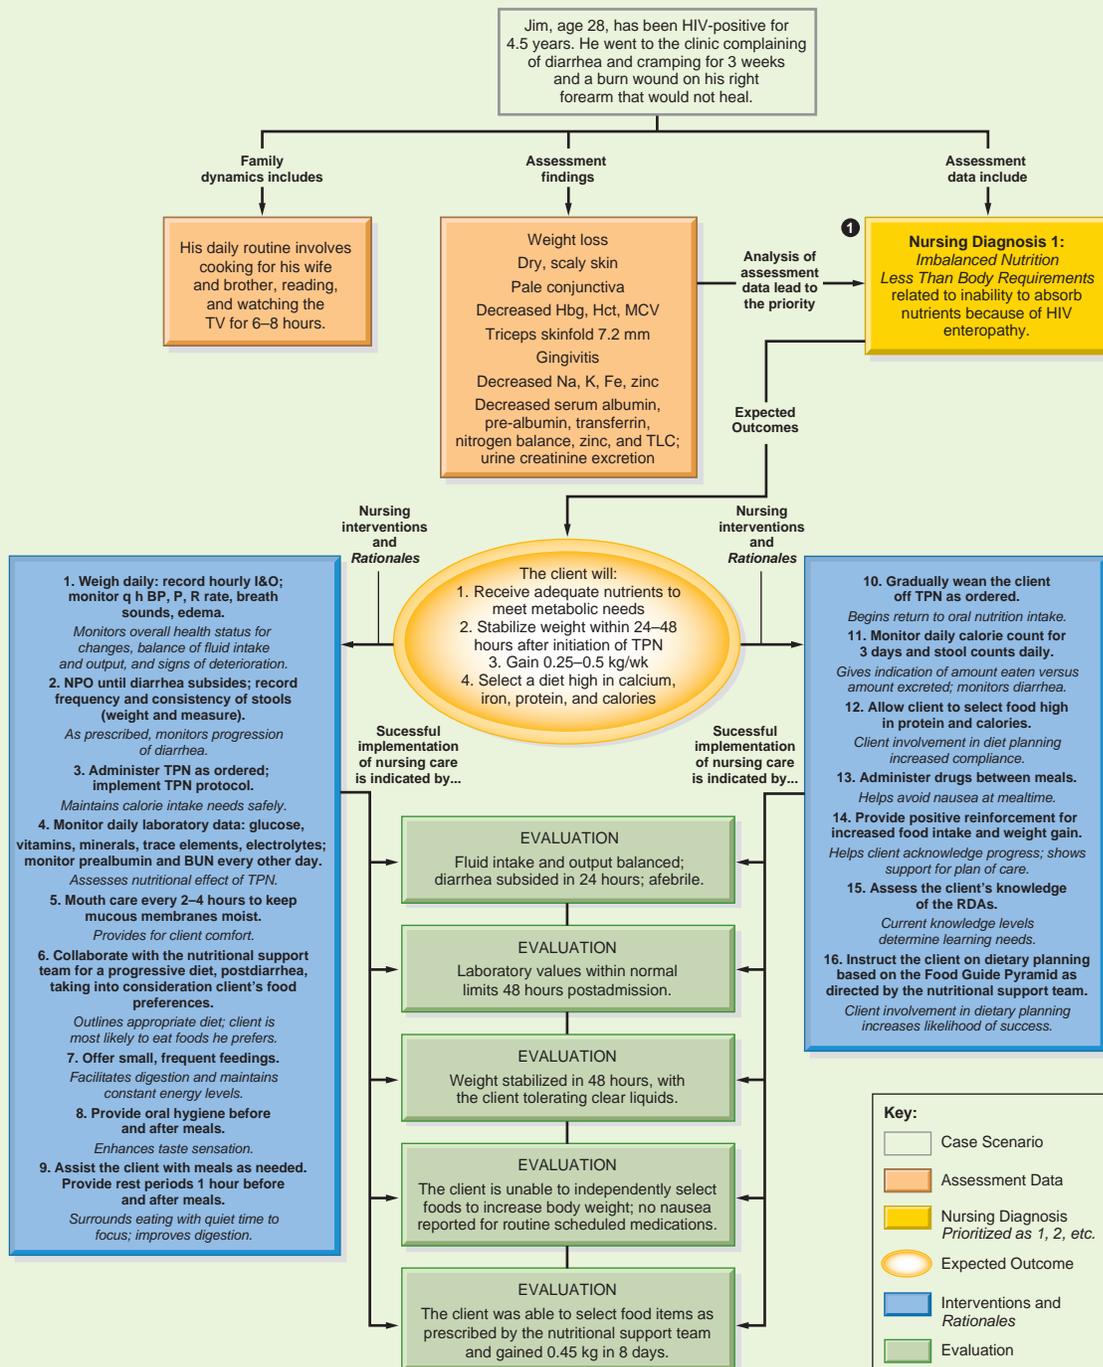

NURSING CARE PLAN (Continued)

EVALUATION

1. Fluid intake and output balanced; diarrhea subsided in 24 hours; afebrile.
2. Laboratory values within normal limits 48 hours postadmission.
3. Weight stabilized in 48 hours, with the client tolerating clear liquids.
4. The client is unable to independently select foods to increase body weight; no nausea reported for routine scheduled medications.
5. The client was able to select food items as prescribed by the nutritional support team and gained 0.45 kg in 8 days.

CONCEPT MAP

THE CLIENT WITH IMBALANCED NUTRITION: LESS THAN BODY REQUIREMENTS

PROCEDURE
34-1
Inserting a Nasogastric or Nasointestinal Tube for Suction and Enteral Feedings
EQUIPMENT

- Nonsterile gloves
- Cup of ice or water and straw
- Towel and tissues
- Flashlight or penlight
- Hypoallergenic tape, rubber band, safety pin
- 20-mL syringe or Asepto syringe, 30 mL or larger with small-bore tube
- Disposable irrigation set (optional)
- Wall mount or portable suction equipment as available
- Ice chips in an emesis basin
- Water-soluble lubricant
- Tongue blade
- pH chemstrip
- Number 6, 8, or 12 French tube for gastric suction (Levine, Salem sump, or Anderson) or a small-bore feeding tube, 8 or 12 French tube (Keofeed, Dobbhoff, Moss)
- Administration set with pump or controller for feeding tube

ACTION
RATIONALE

- | | |
|--|--|
| <ol style="list-style-type: none"> 1. Review client's medical record. 2. Gather equipment. Wash hands/hand hygiene. 3. Check client's armband; explain procedure, showing items. 4. Place client in Fowler's position, at least a 45° angle or higher, with a pillow behind client's shoulders; provide for privacy. <i>Place comatose clients in semi-Fowler's position.</i> 5. Place towel over chest, with tissues in reach. Don gloves. 6. Examine nostrils and assess as client breathes through each nostril. 7. Measure length of tubing needed by using tube as a tape measure: <ul style="list-style-type: none"> • Measure from bridge of client's nose to earlobe to xiphoid process of sternum (see Figure 34-16A on page 1032). • If tube is to go below stomach (nasoduodenal or nasojejunal), add an additional 15 to 20 cm (see Figure 34-16B). • Place a small piece of tape on tube to mark length. | <ol style="list-style-type: none"> 1. Confirms prescribing practitioner's prescription for inserting a nasogastric tube; history of nasal or sinus problems. 2. Promotes efficiency. Prevents the spread of microorganisms. 3. Verifies correct client; reduces anxiety and increases client cooperation. 4. Facilitates passage of the tube into the esophagus and swallowing. 5. Prevents soiling of gown and bedding and protects nurse from contamination with bodily fluids; lacrimation can occur during insertion through nasal passages. 6. Determines the most patent nostril to facilitate insertion. 7. Approximates length of tube needed to reach stomach. |

delegation tip

Inserting and maintaining a nasogastric tube is the responsibility of the nurse. Oral hygiene for the client may be delegated.

nursing tips

Prepare the split tape before putting on gloves.

PROCEDURE
34-2
Administering Enteral Tube Feedings
EQUIPMENT

- Asepto syringe or 20- to 50-mL syringe
- Emesis basin
- Clean towel
- Disposable gavage bag and tubing
- Formula
- Infusion pump for feeding tube
- Water to follow feeding
- Nonsterile gloves

ACTION
RATIONALE

- | | |
|--|---|
| <ol style="list-style-type: none"> 1. Identify client and review medical record for formula, amount, and time. 2. Wash hands/hand hygiene. 3. Check client's armband. 4. Explain procedure to client. 5. Assemble equipment. Add color to formula per institutional policy. If using a bag, fill with prescribed amount of formula. 6. Place client on right side in high Fowler's position. 7. Wash hands/hand hygiene, and don nonsterile gloves. 8. Provide privacy. 9. Observe for abdominal distention; auscultate for bowel sounds. 10. Check feeding tube (see Figure 34-20 on page 1037). Insert syringe into adapter port, aspirate stomach contents, and determine amount of gastric residue. If residue is greater than 50 to 100 mL (or in accordance with agency protocol), hold feeding until residue diminishes. Instill aspirated contents back into feeding tube. 11. Administer tube feeding. | <ol style="list-style-type: none"> 1. Verifies health care provider's prescription for appropriate formula and amount. 2. Prevents the spread of microorganisms. 3. Verifies correct client. 4. Reduces anxiety and increases client cooperation. 5. Ensures efficiency when initiating feeding. Color will distinguish formula aspirate. 6. Reduces risk of pulmonary aspiration in the event that the client vomits or regurgitates formula. 7. Reduces transmission of pathogens from gastric contents. 8. Puts the client at ease. 9. Assesses for delayed gastric emptying; indicates presence of peristalsis and ability of GI tract to digest nutrients. 10. Indicates whether gastric emptying is delayed. Reduces risk of regurgitation and pulmonary aspiration related to gastric distention. Prevents electrolyte imbalance. 11. Provides nutrients as prescribed. |
| INTERMITTENT BOLUS | |
| <ol style="list-style-type: none"> 12. Pinch the tubing. 13. Remove plunger from barrel of syringe and attach to adapter. 14. Fill syringe with formula (see Figure 34-21 on page 1037). 15. Allow formula to infuse slowly; continue adding formula to syringe until prescribed amount has been administered. | <ol style="list-style-type: none"> 12. Prevents air from entering tubing. 13. Provides system to deliver feeding. 14. Allows gravity to control flow rate, reducing risk of diarrhea from bolus feeding. 15. Prevents air from entering stomach. Decreases risk of diarrhea. |

PROCEDURE 34-2 Administering Enteral Tube Feedings (Continued)

ACTION	RATIONALE
19. Attach distal end of tubing to feeding tube adapter, and adjust drip to infuse over prescribed time.	19. Allows gravity to control flow rate, reducing risk of diarrhea from bolus feeding.
20. When bag empties of formula, add 30 to 60 mL or prescribed amount of water; close clamp.	20. Prevents air from entering stomach and reduces risk for gas accumulation. Maintains patency of feeding tube.
21. Change bags every 24 hours.	21. Decreases risk of multiplication of microorganisms in bag and tubing.
CONTINUOUS GAVAGE	
22. Check tube placement at least every 4 hours.	22. Ensures that feeding tube remains in stomach.
23. Check residual at least every 8 hours.	23. Indicates ability of GI tract to digest and absorb nutrients.
24. If residual is above 100 mL, stop feeding.	24. Reduces risk of regurgitation and pulmonary aspiration related to gastric distention.
25. Add prescribed amount of formula to bag for a 4-hour period; dilute with water if prescribed.	25. Provides client with prescribed nutrients and prevents bacterial growth (formula is easily contaminated).
26. Hang gavage bag on IV pole. Prime tubing.	26. Removes air from tubing.
27. Thread tubing through feeding pump (see Figure 34-23), and attach distal end of tubing to feeding tube adapter; keep tubing straight between bag and pump.	27. Provides for controlled flow rate; prevents loops in tubing.

FIGURE 34-23 Thread the gavage bag tubing through the feeding pump DELMAR/CENGAGE LEARNING

|---|---|
| 28. Adjust drip rate. | 28. Infuses formula over prescribed time. |
| 29. Monitor infusion rate and signs of respiratory distress or diarrhea. | 29. Prevents complications associated with continuous gavage. |
| 30. Flush tube with water every 4 hours as prescribed or following administration of medications. | 30. Maintains patency of tube. |

(Continues)

PROCEDURE 34-2 Administering Enteral Tube Feedings (Continued)

ACTION	RATIONALE
31. Replace disposable feeding bag at least every 24 hours, in accordance with institution's protocol.	31. Prevents the spread of microorganisms.
32. Elevate head of bed at least 30° at all times, and turn client every 2 hours.	32. Prevents aspiration, promotes digestion, and reduces skin breakdown.
33. Provide oral hygiene every 2–4 hours.	33. Provides comfort and maintains the integrity of buccal cavity.
34. Administer water as prescribed, with and between feedings.	34. Ensures adequate hydration.
35. Remove gloves and wash hands/hand hygiene.	35. Prevents the spread of microorganisms.
36. Record total amount of formula and water administered on intake and output (I&O) form and client's response to feeding.	36. Documents administration of feeding and achievement of expected outcome; for example, client tolerates feeding and weight is maintained or increased.

delegation tip

Feedings via gastrostomy tubes may be given by LPNs/LVNs if the facility and the state permit. They must be properly trained in assessing tube placement, proper positioning of the client, and administration of the correct type and rate of feeding. All medications must be administered by the nurse.

nursing tips

Formulas can spoil. This is especially true in non-air-conditioned areas in hot, humid weather. Discard them if they have been opened and unused per manufacturers' specifications.

It is the responsibility of the nurse to perform daily equipment quality controls to ensure that the volume is being delivered as indicated by the setting on the infusion pump. If the pump fails and delivers the wrong amount of fluid, the nurse is responsible.

KEY CONCEPTS

- The metabolism of nutrients (carbohydrates, proteins, fats, vitamins, and minerals) plays an essential role in providing the body with the substances necessary for maintaining homeostasis.
- Most nutrients are absorbed in the small intestine through the processes of osmosis, diffusion, and active transport.
- The intracellular productions of energy from carbohydrates, proteins, and fats are interrelated and depend on other physiological processes, such as conversions that take place in the liver, glycolysis, Krebs cycle, and electron transport system.
- A calorie is the quantity of heat required to raise the temperature of 1 gram of water 1°C.
- There are six categories of nutrients: water, carbohydrates, proteins, fats, vitamins, and minerals.
- Carbohydrates have a protein-sparing action, based on a minimum daily ingestion of 50 to 100 grams (200–400 kcal).
- Proteins are essential for almost every bodily function, beginning with the genetic control of protein synthesis, cell function, and cell reproduction.
- Diets high in saturated fats are associated with an increased incidence of coronary heart disease.
- Low-density lipoproteins are responsible for the formation of atherosclerosis, which develops from a high blood plasma level of cholesterol and usually results from a diet high in saturated fats.

- Daily food guides assist healthy persons in meal planning.
- The recommended dietary allowance represents the dietary intake of essential nutrients by age category, inclusive of weight and height.
- The *Dietary Guidelines for Americans 2005* promotes weight management by balancing calories from foods and beverages with calories expended.
- The Food Guide Pyramid outlines the number of servings in each of the six food groups needed to maintain a healthy weight.
- Peer-group influence, social pressures, and other emotional stressors of adolescence may have a negative effect on eating habits, leading to obesity, fad diets, anorexia nervosa, and bulimia.
- Food preferences are usually developed in childhood, are modified throughout the life span, and are an expression of an individual's likes and dislikes.
- Malnutrition refers to alterations relative to inadequate intake, disorders of digestion or absorption, and overeating.
- Assessment includes three basic components: nutritional history, physical examination with anthropometric measurements, and diagnostic and laboratory data.
- Anthropometric measurements evaluate the client's calorie-energy expenditure balance, muscle mass, body fat, and protein reserves based on height, weight, skinfold, and limb and girth circumferences.
- The blood urea nitrogen (BUN) is increased with severe dehydration, malnutrition, starvation, excessive protein intake, and, most commonly, kidney disease.
- The nurse is responsible for understanding the client's metabolic needs and for making clinical judgments relative to nutritional outcomes.
- Therapeutic nutrition requires consideration of the client's total needs: cultural, socioeconomic, psychological, and physiological.
- Protein-energy malnutrition is the most common nutritional deficiency in hospitalized clients.
- Enteral and parenteral nutrition are two methods of delivering nutrition support in adult clients.
- Clients receiving PN in the home environment require close monitoring to prevent catheter sepsis and cardiac overload.
- Refeeding syndrome occurs during the initial phase of EN or PN and can be averted by starting the therapy gradually and slowly increasing the rate.

REVIEW QUESTIONS

- Which are considered basic nutrients in the body? Select all that apply.
 - Water
 - Vitamins
 - Minerals
 - Carbohydrates
 - Proteins
 - Lipids
- The evidence-based guidelines issued by the National Institutes of Health call for weight loss by restricting intake and increasing physical activity. Which food items should be eliminated from a client's diet to achieve these guidelines? Select all that apply.
 - Saturated fats
 - Animal fats
 - Added sugar and salt
 - Alcohol
 - Green leafy vegetables
 - Dark fruits
- Diet teaching for a postoperative client should include the increase of which nutrient to assist with tissue repair?
 - Vitamin
 - Carbohydrate
 - Protein
 - Fat
- Which subjective assessment should the nurse include when assessing a client's gastrointestinal tract?
 - Rebound tenderness
 - Diarrhea
 - Generalized red abdominal rash
 - Hematuria
- During an inspection of the abdomen, which abdominal findings should the nurse report as abnormal?
 - Bilateral symmetrical abdomen
 - Flat abdominal contour
 - Strong abdominal pulsations
 - Depressed umbilicus beneath the abdominal surface
- Which anthropometric measurement indicates the amount of body fat?
 - Height
 - Weight
 - Body mass index
 - Skinfold
- The nurse obtains a pH of 8.0 when aspirating for gastric contents when assessing correct tube placement. The nurse evaluates a pH of 8.0 to be _____.
 - Alkaline, indicating respiratory secretions
 - A neutral pH

- c. Acidic, confirming gastric secretions
 - d. Indicative of intestinal secretions
8. When assessing a client with a nasogastric tube, the nurse discovers it is set on continuous high suction. Which nursing intervention should the nurse implement?
- a. Clamp the tube for 30 minutes, then reconnect it to continuous high suction.
 - b. Call the prescribing practitioner and remove the tube.
 - c. Irrigate the tube with 30 mL of warm water and record the drainage characteristics.
 - d. Change the suction to low intermittent suction.
9. The type of malnutrition that most commonly occurs in the acutely ill hospitalized client is _____.
- a. Anorexia nervosa
 - b. Mixed malnutrition
 - c. Marasmus
 - d. Protein-energy malnutrition
10. Which of the following are the three essential nutrients included in PN required for anabolism and tissue synthesis?
- a. Trace elements, protein, and fats
 - b. Protein, carbohydrates, and fats
 - c. Fats, electrolytes, and carbohydrates
 - d. Vitamins, electrolytes, and protein

CHAPTER 35

Comfort and Sleep

COMPETENCIES

1. Describe types of pain.
2. Assess the nature of pain as it relates to onset, intensity, and duration.
3. Discuss the physiology of pain.
4. Describe nonpharmacologic interventions in pain control.
5. Discuss the use of pharmacologic interventions in pain control.
6. Describe the stages of sleep.
7. Discuss age-related sleep variations.
8. Explain how sleep deprivation affects an individual.
9. Discuss nursing interventions that promote comfort, rest, and sleep.

KEY TERMS

acute pain	gate control pain theory	perception
addiction	hyperalgesia	phantom limb pain
adjuvant medications	hypersomnia	physical dependence
afferent (ascending) pain pathway	imagery	progressive muscle relaxation
allodynia	insomnia	recurrent acute pain
biofeedback	ischemic pain	referred pain
biological clock	lancinating	reframing
bruxism	mixed agonist-antagonists	relaxation techniques
ceiling effect	modulation	rest
chronic acute pain	myofascial pain syndromes	sleep
chronic nonmalignant pain	narcolepsy	sleep apnea
chronic persistent pain	neuralgia	sleep cycle
chronobiology	neuropathic pain	sleep deprivation
circadian rhythms	nociception	somatic pain
colic	nociceptors	somnambulism
counterstimulation	pain	tolerance
cutaneous pain	pain threshold	transcutaneous electrical nerve stimulation (TENS)
distraction	pain tolerance	transduction
efferent (descending) pain pathway	parasomnia	transmission
endorphins	paresthesia	trigger point
	patient-controlled analgesia (PCA)	visceral pain

The experience of pain and the quality of rest and sleep are both factors that can have a significant impact on a client's health. Both are personal experiences that can affect all other aspects of an individual's health, including physical well-being, mental status, and effectiveness of coping mechanisms. Pain is the most common reason that people seek health-related treatment (Jeong & Holden, 2008). This chapter explores the nature of pain, the importance of rest and sleep, and nursing care to help clients maintain their optimal health when the presence of pain or a rest or sleep disturbance threatens to compromise their health status.

PAIN

Pain is a universal human experience; it is defined as “the state in which a person experiences and reports the presence of severe discomfort or an uncomfortable sensation” (Carpenito-Moyet, 2008, p. 126). Pain is a subjective experience that is often difficult for clients to describe and nurses to understand, yet it is among the most common complaints that cause individuals to seek health care. The International Association for the Study of Pain (IASP) (2007) states that pain may be accompanied by sensory and emotional experiences as a result of actual or potential tissue damage. Until recently, pain was viewed as a symptom that required diagnosis and treatment of

the underlying cause. It is now clear that pain itself can be detrimental to the health and healing of clients. Pain is a stressor that can trigger both physiological and psychological discomfort. Untreated pain can lead to physical disorders related to undernutrition, immobility, and immune suppression.

Because of a growing national awareness of the under-treatment of pain, clients are regularly being assessed for pain. The Joint Commission offers guidelines regarding clients' rights and standards of care for pain management. The Joint Commission's pain standards mandate pain assessment and management as a priority in daily clinical practice; pain intensity is considered the *fifth vital sign*, along with temperature, pulse, respiration, and blood pressure, and the client has the right to a full pain workup when pain is not easily characterized or treated. These guidelines rely on pain rating scales, discussed later in this chapter, and they are most applicable to acute or postoperative pain.

NATURE OF PAIN

Pain, a response to noxious stimuli, can be a protective mechanism to prevent further injury, as seen in clients who guard or protect an injured body part. The sensation of pain as the warning of potential tissue damage may be absent in people with nerve or spinal cord abnormalities, diabetic neuropathy, multiple sclerosis, and nerve or spinal cord injury.

Common Myths about Pain

Because pain is subjective (dependent on a client's perception) and cannot be objectively measured by another individual through a laboratory test or diagnostic data, it is often misunderstood and misjudged. A client's report about level of pain will vary on the basis of cultural and experiential backgrounds, and the nurse's interpretations of a client's pain will be filtered through the nurse's own biases and expectations. Incongruence between the nurse's view and the client's perception of pain can often lead to undermedication and unnecessary suffering on the client's part. The accompanying Spotlight On display outlines some of the common myths about pain, along with factual statements countering those beliefs.

SPOTLIGHT ON...

Compassion

Common Myths about Pain

Myth	Fact
<ul style="list-style-type: none"> The nurse is the best judge of a client's pain. 	<ul style="list-style-type: none"> Pain is a subjective experience; only the client can judge the level and severity of pain.
<ul style="list-style-type: none"> If pain is ignored, it will go away. 	<ul style="list-style-type: none"> Pain is a real experience that can be appropriately treated.
<ul style="list-style-type: none"> Clients should not take any measures to relieve their pain until it is unbearable. 	<ul style="list-style-type: none"> Pain control and relief measures are effective in lowering pain levels and help clients function more normally and comfortably.
<ul style="list-style-type: none"> Most complaints of pain are purely psychological (e.g., "it's all in your head"); only "real" pain manifests in obvious physical signs such as moaning or grimacing. 	<ul style="list-style-type: none"> Most clients honestly report their perception of pain. Physical responses to pain vary greatly depending on experience and cultural norms. Visible expressions of pain are not always reliable indicators of its severity.
<ul style="list-style-type: none"> Clients with severe tissue damage experience significant pain; those with lesser damage feel less pain. 	<ul style="list-style-type: none"> Individuals' perceptions of pain are subjective; the extent of tissue damage is not necessarily proportional to the extent of pain experienced.
<ul style="list-style-type: none"> Clients taking pain medications will become addicted to the drug. 	<ul style="list-style-type: none"> Addiction is unlikely when analgesics are carefully administered and closely monitored.

Types of Pain

Pain can be qualified in two basic ways: by its cause or origin and by its description or nature. Pain categorized by its origin is either cutaneous, somatic, or visceral. **Cutaneous pain** is caused by stimulation of the cutaneous nerve endings in the skin and results in a well-localized "burning" or "prickling" sensation; getting a knot in the hair that is pulled out during combing may cause cutaneous pain. **Somatic pain** is nonlocalized and originates in support structures such as tendons, ligaments, and nerves or may be deep pain; jamming a knee or finger will result in somatic pain. **Visceral pain** is discomfort in the internal organs and is less localized and more slowly transmitted than cutaneous pain. Visceral pain is often difficult to assess because the location may not be directly related to the cause. Pain originating from the abdominal organs is often called **referred pain** because the sensation of pain is not felt in the organ itself but instead is perceived at the spot where the organs were located during fetal development. Figure 35-1 on page 1046 shows the cutaneous areas where visceral pain is often referred.

Acute pain is most frequently identified by its sudden onset and relatively short duration, mild to severe intensity, and a steady decrease in intensity over a period of days to weeks. Some forms of acute pain may have a slower onset. Once the noxious stimulus is resolved, the pain usually decreases. Examples of noxious stimuli are needlesticks, surgical incisions, burns, and fractures.

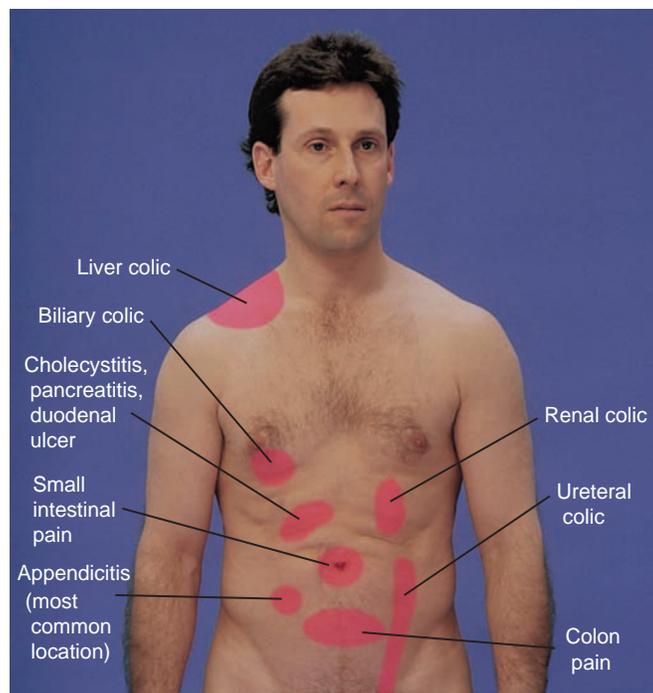

Recurrent acute pain is identified by repetitive painful episodes that may recur over a prolonged period or throughout the client's lifetime. These painful episodes alternate with pain-free intervals. Examples of recurrent pain include migraine headaches, sickle cell pain crises, and the pain of angina pectoris due to myocardial hypoxia.

Chronic persistent pain is identified as long-term (lasting 6 months or longer) nearly constant, or recurrent pain that produces significant negative changes in the client's life. Unlike acute pain, chronic pain may last long after the pathology is resolved. According to the National Center for Health Statistics (2006), more than 76 million Americans have chronic pain; that is more than all Americans with diabetes, heart disease, and cancer combined.

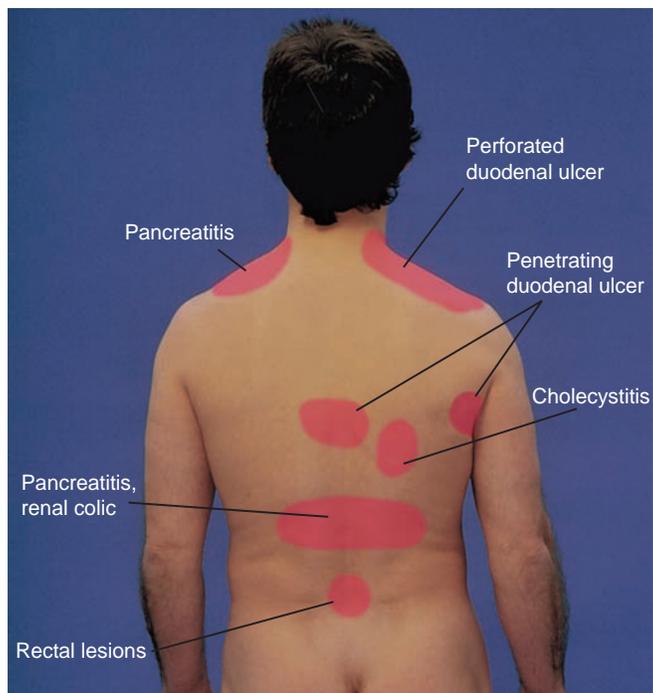

The American Geriatrics Society (AGS, 2009) describes persistent pain as pain that may or may not be associated with disease and states that it is prevalent in older persons. The AGS recommends use of *persistent pain* rather than *chronic pain* because the term *persistent* has a more positive connotation. Many individuals equate the word *chronic* with untreatable and, thus, expect to have no relief from long-term pain.

Chronic acute pain occurs almost daily over a long period, has the potential for lasting months or years, and has a high probability of ending. Severe burn injuries and cancer are examples of pathophysiology leading to chronic acute pain, which may last for long periods before the condition is cured or controlled.

Chronic nonmalignant pain (CNP) occurs almost daily and lasts for at least 6 months, with intensity ranging from mild to severe. Chronic pain, a primary motivator for

A

B

FIGURE 35-1 Areas of Referred Pain. A. Anterior View; B. Posterior View DELMAR/CENGAGE LEARNING

individuals to seek health care intervention, can greatly influence a client's quality of life, including emotional, social, vocational, and financial areas. Examples of pathophysiology leading to CNP include:

- Many forms of **neuralgia** (paroxysmal pain that extends along the course of one or more nerves)

- Low back pain
- Rheumatoid arthritis
- Ankylosing spondylitis
- **Phantom limb pain** (a form of neuropathic pain that occurs after amputation, with pain sensations referred to an area in the missing portion of the limb)
- **Myofascial pain syndromes** (a group of muscle disorders characterized by pain, muscle spasm, tenderness, stiffness, and limited motion)

CNP may be associated with several problems, including:

- Activity intolerance, which leads to physical deconditioning
- Functional impairment with resultant changes in role performance (parent, breadwinner)
- Social isolation, which alters relationships
- Sleep deprivation
- Frustration, anxiety, anger, and depression

When CNP is severe enough to disable the client, nurses understand that pain management becomes a priority in order to improve the client's quality of life.

PHYSIOLOGY OF PAIN

Noxious stimuli activate **nociceptors** (receptive neurons for painful sensations) that, together with the axons of neurons, convey information to the spinal cord where reflexes are activated. The information is simultaneously transmitted to the brain supraspinally. Long-lasting changes in cells within the spinal cord's **afferent (ascending)** and **efferent (descending) pain pathways** may occur after a brief noxious stimulus.

Physiological responses (such as elevated blood pressure, pulse rate, and respiratory rate; dilated pupils; pallor; and perspiration) to even a brief acute pain episode will begin showing adaptation within a short period, possibly minutes to a few hours. Physiologically, the body cannot sustain the extreme stress response for anything other than short periods of time. The body conserves its resources by physiological adaptation (returning to normal or near-normal blood pressure, pulse rate, and respiratory rate; normal pupil size; and dry skin) even in the face of continuing pain of the same intensity. Pain can be categorized into two types, according to its pathophysiology (see Table 35-1 on page 1047).

Nociceptive Pain

The four fundamental processes involved in **nociception**, the process by which an individual becomes consciously aware of pain, are as follows:

- **Transduction**—the changing of noxious stimuli in sensory nerve endings to energy impulses
- **Transmission**—movement of impulses from the site of origin to the brain
- **Perception**—developing conscious awareness of pain
- **Modulation**—the changing of pain impulses

TRANSDUCTION OF PAIN When noxious stimuli occur, tissues are damaged. Cell damage releases the following sensitizing substances:

TABLE 35-1 Pathology-Based Pain Classification

	NOCICEPTIVE PAIN	NEUROPATHIC PAIN
Description	Normal processing of noxious stimuli; may damage tissue if prolonged	Abnormal processing of stimuli by peripheral nervous system (PNS) or central nervous system (CNS)
Examples	Somatic pain, visceral pain	Centrally generated pain: <ul style="list-style-type: none"> • Phantom pain • Spinal cord injury Peripherally generated pain: <ul style="list-style-type: none"> • Diabetic neuropathy • Trigeminal neuralgia

Data from Boswell, M. V., & Cole, B. C. (2006). *Weiner's pain management: a practical guide for clinicians* (7th ed.). Boca Raton, FL: CRC Press; McGuire, L. (2010). Pain: the fifth vital sign. In D. D. Ignatavicius & M. L. Workman (Eds.), *Medical-surgical nursing: patient-centered collaborative care* (6th ed.). St. Louis, MO: Elsevier, p. 39.

- Prostaglandins (PG)
- Bradykinin (BK)
- Serotonin (5-HT)
- Substance P (SP)
- Histamine (H)

Release of these substances alters the electrical charge on the neuronal membrane. This change in electrical charge is a result of movement of calcium, sodium, potassium, and chloride ions across cell membranes. The impulse is then ready to be transmitted along the nociceptor fibers (Straud & Spaeth, 2008).

TRANSMISSION OF PAIN The specific action of pain varies depending on the type of pain. In cutaneous pain, cutaneous nerve transmissions travel through a reflex arc from the nerve ending (point of pain) to the brain at a speed of approximately 300 feet per second, with a reflex response causing an almost immediate reaction. This explains why when a hot stove is touched the person's hand jerks back *before* there is conscious awareness that damage is occurring (see Figure 35-2 on page 1048). After a hot stove is touched, a sensory nerve ending in the skin of the finger initiates nerve transmission that travels through the dorsal root ganglion to the dorsal horn in the gray matter of the spinal cord. From there, the impulse travels through an interneuron that synapses with a motor neuron, which exits the spinal cord at the same level. This motor neuron, and the stimulation of the muscle it innervates, is responsible for the swift movement of the hand away from the hot stove.

In the case of the hot stove, the sensory neuron synapses not only with an interneuron but also with an afferent sensory neuron. The impulse travels up the spinal cord to the thalamus, where a final synapse conducts the impulse to the cortex of the brain. The efferent or descending motor neuron response is conducted from the brain through the spinal

cord, where it synapses with a motor neuron that exits the spinal cord and innervates the muscle.

In visceral pain, transmission of pain impulses is slower and less localized than in cutaneous pain. The internal organs (including the gastrointestinal [GI] tract) have a minimal number of nociceptors, which explains why visceral pain is poorly localized and is felt as a dull aching or throbbing sensation. However, internal organs have extreme sensitivity to distension. The cramping pain of **colic** (acute abdominal pain), for example, results when:

- Flatus or constipation causes distension of the stomach or intestines.
- There is hyperperistalsis, as in gastroenteritis.
- A substance tries to pass through a lumen (an opening) that is too small.

The physiology of **ischemic pain**, or pain occurring when the blood supply of an area is restricted or cut off completely, also differs from that of cutaneous pain. The restriction of blood flow causes inadequate oxygenation of the tissue supplied by those vessels as well as inadequate metabolic waste product removal. Ischemic pain has the most rapid onset in an active muscle and a much slower onset in a passive muscle. Examples of ischemic pain are muscle cramps, sickle cell pain crisis, angina pectoris, and myocardial infarction. When ischemic pain occurs in a muscle that continues to work, a muscle spasm (cramp) is the outcome. If the blood supply to the heart is severely restricted or completely cut off and is not restored quickly, a myocardial infarction will occur. See the Safety First display on page 1048.

In acute pain episodes, substances released from injured tissue lead to stress hormone responses in the client. This causes an increased metabolic rate, enhanced breakdown of body tissue, impaired immune function, increased blood clotting, and water retention, and it triggers the fight-or-flight reaction, leading to tachycardia and negative emotions.

SAFETY FIRST

ISCHEMIC PAIN

Supplemental oxygen and pain medication must be administered quickly to clients with ischemic pain to minimize oxygen deprivation and prevent infarction (tissue death).

PAIN PERCEPTION When the impulse has been transmitted to the cortex and is interpreted by the brain, the information is available on a conscious level. It is then that the person becomes aware of the intensity, location, and quality of pain. This information is interpreted in light of previous experience, adding the affective component to the pain experience.

MODULATION Modulation refers to activation of descending neural pathways that inhibit transmission of pain. Descending

neurons originate in the brain stem and descend to the dorsal horn of the spinal cord. The descending fibers release substances that produce analgesia by blocking the transmission of noxious stimuli. Pain modulation is a result of the effects of endogenous opioids, also called enkephalins and **endorphins**.

Neuropathic pain arises from damage to portions of the peripheral or central nervous system (CNS). This pain is *not* nociceptive pain, nor that which is due to ongoing tissue injury or inflammation. It is important to differentiate neuropathic pain from other types of pain because the treatment differs significantly. Table 35-2 on page 1049 identifies some of the differences between nociceptive and neuropathic pain.

Neuropathic pain is a result of abnormal processing of sensory input by either the peripheral or CNS. Two types of neuropathic pain are **allodynia** (a nonpainful stimulus is felt as painful in spite of the tissue appearing normal) and **pares-thesia** (an abnormal sensation such as burning, prickling, or tingling).

Myofascial pain was first described by Travell and Rinzler (1952) as pain that occurs as a result of a small, hypersensitive region in a muscle ligament, fascia, or joint

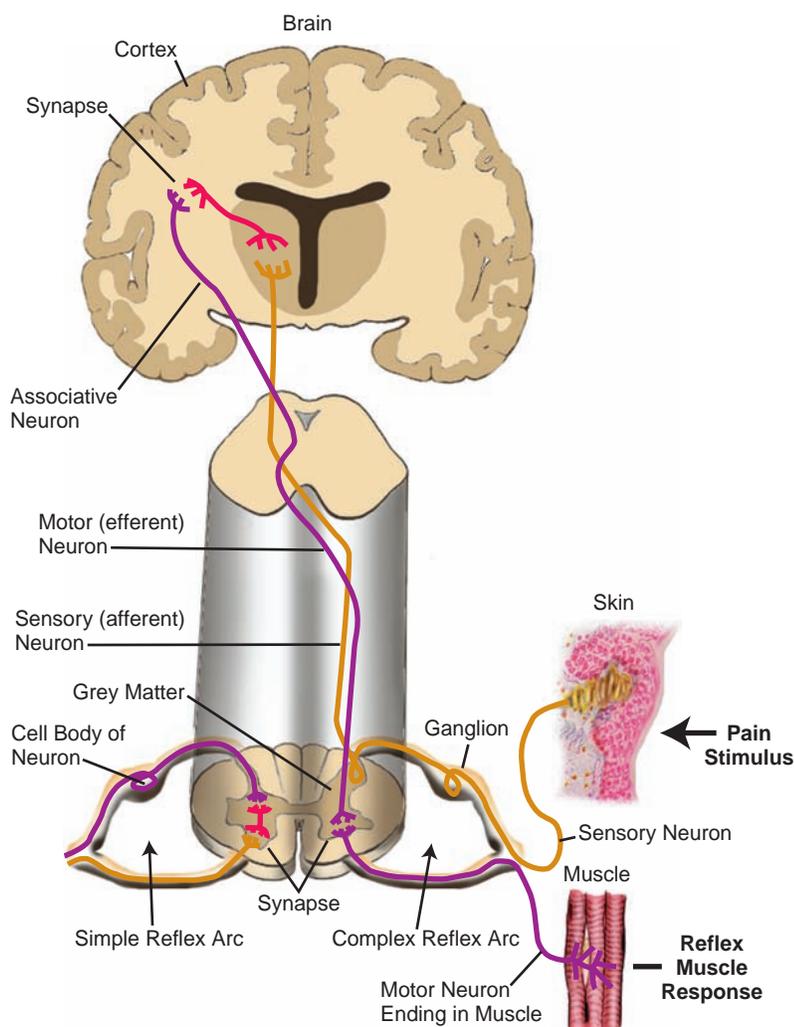

FIGURE 35-2 Reflex Arcs DELMAR/CENGAGE LEARNING

TABLE 35-2 Differences between Nociceptive Pain and Neuropathic Pain

	NOCICEPTIVE PAIN	NEUROPATHIC PAIN
Pain descriptors	Varied	Sharp, shooting, lancinating, tingling, pins and needles, strange or dull, aching, burning
Pain pattern	Pain intensity decreases steadily over period of days to weeks in the absence of repeated injury or inflammation	Pain persists or even intensifies during weeks or months after injury
Response to opioids	Generally relieves pain with acceptable margin between comfort and sedation	“Resistant” to opioids, with significant pain remaining even when opioid doses lead to severe sedation
Response to NSAIDs	Generally effective at partial reduction of pain intensity	Rarely relieved by NSAIDs
Response to tricyclic antidepressants, anticonvulsants, local anesthetics	Generally ineffective	Often decreased significantly or relieved

Data from Allen, S. (2005). Pharmacotherapy of neuropathic pain. *Continuing Education in Anaesthesia, Critical Care & Pain*, 5(4): 134–137; Daniel, H. C., Narewska, J., Sherpell, M., Hoggart, B., Johnson, R.I., & Rice, A. S. (2008). Comparison of psychological and physical function in neuropathic and nociceptive pain: implications for cognitive behavioral pain management programs. *European Journal of Pain*, 12(6):734–741.

capsule called a **trigger point**. The trigger point is a hyper-sensitive point that when stimulated causes a local twitch or “jump” response. Myofascial pain is often accompanied by a localized, deep ache that is surrounded by a referred area of **hyperalgesia**, or extreme sensitivity to pain.

Gate Control Theory of Pain

Theories of pain transmission and interpretation attempt to describe and explain the pain experience. In 1965, Melzack and Wall proposed the **gate control pain theory**, which was the first to recognize that the psychological aspects of pain are as important as the physiological aspects. The gate control theory combines cognitive, sensory, and emotional components—in addition to the physiological aspects—and

proposes that they can act on a gate control system to block the individual’s perception of pain. Pain perception is regulated through a gating mechanism at the dorsal horn of the spinal cord. The gating mechanism causes vasoconstriction and decreased nerve conduction velocity, thereby reducing the transmission of noxious stimuli. As a result, the level of conscious awareness of painful sensation is altered.

The gate control theory is based on the premise that pain impulses travel through either small-diameter or large-diameter nerve cells, both of which pass through the same gate. The large-diameter cells have the ability, when properly stimulated, to “close the gate” and thus block transmission of the pain impulse to the brain (see Figure 35-3). Stimulants such as cutaneous massage, opioid release, and

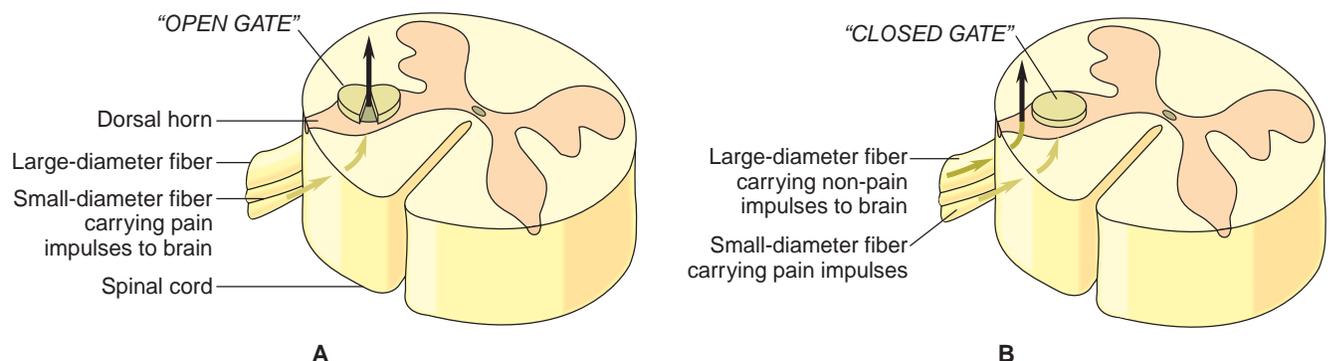

FIGURE 35-3 Gate Control Theory: Blocking Transmission of Pain DELMAR/CENGAGE LEARNING

excessive stimulation all activate the large-diameter cells to close the gate. Clinically, the effectiveness of several non-pharmacologic modalities, such as massage, acupuncture, and acupressure, supports the gate control theory.

FACTORS AFFECTING THE PAIN EXPERIENCE

The subjective nature of pain varies from person to person and is influenced by several variables. Many factors account for the differences in a client's individual response to pain, including age, previous experience with pain, and cultural factors.

Age

Age can greatly influence a client's perception of the pain experience. Infants are sensitive to pain and typically exhibit discomfort through crying or physical movement. Toddlers also use crying and physical movement to indicate pain, and they begin to develop the skills needed to verbally describe pain or point to the area that is hurting. Children often do not understand why pain occurs and can therefore be frightened or resentful of the pain experience; in some cases, children revert to habits of their younger years (regression) as a coping mechanism when faced with pain they cannot otherwise manage.

Adolescents often sense great peer pressure and may be reluctant to admit having pain for fear of being called weak or sensitive. Adults may continue pain behaviors they learned as children and may also be reluctant to admit pain or seek medical care because of fear of the unknown or fear of the impact that treatment may have on their lifestyle.

Older adults may often ignore their pain, viewing it as an unavoidable consequence of aging; family and health care members may inadvertently support this stereotype and be less than responsive to an older client's complaints of pain. Pain may be manifested differently by older individuals. For example, pain may be referred (e.g., gallbladder pain is felt in the shoulder). Also, the intensity of pain in some older clients may not accurately reflect the severity of the underlying pathology (e.g., a myocardial infarction may be felt as a fluttering sensation).

Pain related to chronic disease is prevalent among the elderly population, even those who live in the community (Martinez, 2009). Persistent pain is common in older persons and among nursing home residents (Zwakhalen, Hamers, Abu-Saad, & Berger, 2006). According to Martinez (2009), 73% to 80% of the elderly population have reported pain symptoms. However pain in many elders is not reported and, therefore, is untreated. The undertreatment of pain in the older client often is the result of underreporting and underdetection. Some outcomes of untreated pain in older adults include the following:

- Sleep alterations
- Nutrition problems
- Impaired gait
- Cognitive impairments
- Decreased socialization
- Increased incidence of falls
- Decreased ability to function independently

Previous Experience with Pain

Clients' previous experiences with pain will often influence their reactions. Coping mechanisms that were used in the past may affect clients' judgment as to how the pain will affect their lives and what measures they can use to successfully manage the pain on their own. Client teaching about pain expectations and management methods can often allay clients' fears and lead to more successful pain management, especially in those clients who do not have previous pain experience or who have memories of a previous devastating pain experience that they do not wish to repeat.

Cultural Norms and Attitudes

Cultural diversity in pain responses can easily lead to problems in pain management. There are no significant differences among groups in the level of intensity at which pain becomes appreciable or perceptible. However, cultural values regarding pain can affect the client's beliefs about pain as well as responses to pain, and the level of intensity or duration of pain the client is willing to endure is culturally determined.

Expression of pain is also governed by cultural values. In some cultures, tolerance of pain, and therefore "suffering in silence," is expected; in others, full expression of pain may include animated physical and emotional responses. The nurse must be careful not to equate the level of expression of pain with the level of actual pain experienced but instead to consider cultural influences that affect the expression of pain.

ASSESSMENT

In order for pain to be treated effectively, it must first be assessed accurately. The client's self-report of the existence and intensity of the pain is the most accurate and reliable evidence of the nature of the pain. Assessment of pain includes the collection of subjective and objective data through the use of various assessment tools and the construction of a database to use in developing a pain management plan. Pain assessment should be performed for every client, as recommended by the Joint Commission.

Data Collection

As pain intensity is considered the fifth vital sign, nurses need to assess all clients for pain on admission for any health care service. The client's perception of the pain should cover a description of several qualifiers, including:

- Intensity
- Location
- Quality (radiating, burning, diffuse)
- Associated manifestations (factors that often accompany the pain, such as nausea, constipation, or dizziness)
- Aggravating factors (variables that worsen the pain, such as exercise, certain foods, or stress)
- Alleviating factors (measures the client can take to lessen the effect of the pain, such as lying down, avoiding certain foods, or taking medication)

Nurses must look for nonverbal signs of pain, such as changes in motor activity or facial expression. It is also important to ask family members to share their observations; they may be the first ones to note subtle behavior changes indicative of pain. When assessing a client's report of pain, the nurse should also determine a client's pain threshold and pain tolerance level. **Pain threshold** is the level of intensity at which pain becomes appreciable or perceptible and will vary with each individual and type of pain. **Pain tolerance** is the level of intensity or duration of pain the client is willing or able to endure. A client's perceptions and attitudes about pain are dramatically influenced by many factors, including previous experiences and cultural background.

Clients' behavioral adaptation may yield no report of pain unless questioned specifically. **Distraction** (focusing attention on stimuli other than pain) may also be used by clients. Clients often minimize the pain behaviors they are able to control for a number of reasons, including:

- To be a "good" client and avoid making demands
- To maintain a positive self-image by not appearing to be weak
- By using distraction as a method of making pain more bearable (young children are particularly adept at this)
- Exhaustion

Pain is fatiguing, as a significant amount of energy is used to deal with it. The longer a person suffers pain, the greater the level of fatigue. Although there is no conscious awareness of pain during sleep, there may be a dream-state awareness; see the accompanying Nursing Process Highlight. The stress response continues, and the body, physiologically, pays the price. Clients also wake up with considerably more pain than they had before going to sleep, thereby requiring even more intervention (pharmacologic and nonpharmacologic) to reduce the pain.

Occasionally there is a discrepancy between pain behaviors observed by the nurse and the client's self-report of pain. Client pain behaviors include splinting of the painful area,

distorted posture, impaired mobility, insomnia, anxiety, attention seeking, and depression. Discrepancies between behaviors and the client's self-report can be due to coping skills (e.g., relaxation techniques or distraction), stoicism, anxiety, or cultural differences in expected pain behaviors. Whenever these discrepancies occur, they should be addressed with the client, and the pain management plan should be altered accordingly.

Assessment Tools

Pain assessment tools are the single most effective method of identifying the presence and intensity of pain in clients. Tools used for assessing pain should be appropriate to the client's age and cultural context. When assessing pain, health care professionals should avoid making value judgments. For example, clients who watch the clock for the next pain medication or wake up from sleep requesting the medication should not be labeled as "drug seekers." Research has shown that clients may rest and sleep despite moderate to severe pain, and distractions, especially laughter, is an effective way of coping with pain (Ufema, 2008). See Table 35-3 on page 1052 for sample questions used in pain assessment.

INITIAL PAIN ASSESSMENT TOOL Figure 35-4 on page 1053 is a tool that may be used for initial pain assessment for clients who have complex or persistent pain. The tool assesses location, intensity, and quality, precipitating and alleviating factors, and how the pain affects function and quality of life. Once this tool is completed, another less detailed tool can be used for the ongoing monitoring of the client's pain level; see the accompanying Nursing Process Highlight.

PAIN INTENSITY SCALES Pain intensity scales are another quick, effective method for clients to rate the intensity of their pain (see Figure 35-5 on page 1054). The verbal rating scale (VRS) and the numeric rating scale (NRS) are often used together to collect more accurate client input. The VRS uses adjectives ranging from "no pain" to "excruciating pain"

NURSING PROCESS HIGHLIGHT

Assessment

Assessing the Effect of Pain on Sleep

Questioning clients about the effect that pain has on their sleep habits will help clarify the intensity of the pain and its effect on clients' patterns of daily living.

Ask: Does the pain:

- Prevent you from falling asleep?
- Make finding a comfortable sleeping position difficult?
- Wake you up from a sound sleep?
- Keep you from falling back asleep once awakened?
- Leave you feeling tired and unrefreshed after a sleeping session?

NURSING PROCESS HIGHLIGHT

Assessment

The client may exhibit any or all of the following indicators of pain:

- Reporting or complaining of pain
- Focusing on pain
- Crying or moaning
- Frowning or grimacing
- Rubbing or protecting painful areas
- Altering posture or movements to lessen pain
- Splinting painful areas by increasing muscle tension
- Reporting insomnia, fatigue, or depression

TABLE 35-3 Pain Assessment Questions

CHARACTERISTIC	QUESTION	EXPLANATION
Quality	“How do you feel?”	Common descriptors include aching, burning, dull, numb, sharp, and throbbing.
Intensity	“Using this scale, what number best describes your pain?” “Which picture best describes your pain?”	Use the verbal rating scale (VRS) and the numeric rating scale (NRS) in combination. Use the Wong-Baker faces scale.
Location	“Where does it hurt?” “What part of your body is painful?”	Encourage client to point to the affected area. On a printed body outline, have client shade in the areas that correspond to painful areas of his or her body.
Duration	“Is the pain constant?” “Does the pain come and go?”	Instruct client to time painful episodes.
Triggers	“What makes the pain worse?” “What lessens the pain?”	Have client focus on triggers such as positions, activities, or situations.
Effects	“How has the pain affected your life?” “Do you have any symptoms in addition to pain?”	Include effects on work, school, relationships, eating, sleep, energy level, recreation/leisure, and moods. Ask client about presence of confusion, constipation, itching, nausea or vomiting, problems with urination, and sleepiness or drowsiness.
Knowledge level	“What do you understand about your pain and its causes?” “What have you been taught about your pain?” “Have you taken any medicine for pain? If so, what?”	Document the client’s responses.

Data adapted from Macintyre, P., Rowbotham, D. & Walker, S. (2008). *Clinical pain management acute pain* (2nd ed.). New York: Oxford University Press, USA; Spies, K., Rehberg, Bl., Schug, S., Jaehnicen, G., & Harper, S, (2008). *Pocket guide pain management*. Warren, IL: Springer.

to describe intensity. Frequent use of these tools will increase understanding of pain severity. When using the NRS, clients are asked to assign their pain a number, with 0 meaning no pain and 10 representing the worst possible pain. “On a scale of 0 to 10, with 0 being no pain at all and 10 being the worst pain you could ever have, how much do you hurt right now?” If there are multiple painful areas, this question can be asked regarding each area.

With the Joint Commission requiring pain assessments for all clients, using behavioral pain scales for clients who cannot self-report has become common practice (D’Arcy, 2008). The assessment tools designed for use by the non-self-reporting client include the Pain Assessment in Advanced Dementia Scale for clients with dementia and the Payen Behavioral Pain Scale for critically ill, sedated, and mechanically ventilated clients. These tools are effective when used consistently by nurses to assess pain in nonverbal clients (D’Arcy, 2008).

PAIN DIARY Client input is essential if accurate assessment data are to be collected. Self-monitoring of symptoms

can be promoted by having clients complete a pain diary. The pain diary should include:

- Date and time
- Intensity
- Situation (What were you doing?)
- How did you feel?
- What were you thinking?
- What did you do to ease the pain?
- How effective was the pain control strategy?

PSYCHOSOCIAL PAIN ASSESSMENT A psychosocial assessment is performed to identify the client’s attitudes and beliefs regarding pain and social support. The initial assessment should include an evaluation of the client’s mood (depression or anxiety), self-efficacy, coping skills, and concerns. Concerns regarding pain may include feelings of helplessness and fears about using certain types of drugs and addiction. An initial evaluation should include assessment of social support, family or caregiver relationships, work history, cultural environment, spirituality, and accessibility to health care services.

Developmental Considerations

Because pain experiences and reports can be influenced by age and developmental level, special consideration should be used to factor in those influences. Infants, children, and adolescents provide a special challenge in pain assessment because their pain behaviors often differ from those considered normal in the adult population. Certain myths hinder the accurate assessment and management of pain in children; see Table 35-4.

Two useful tools for assessing pain in children are the Wong-Baker Faces Rating Scale and the Poker Chip Tool. The Wong-Baker Faces Rating Scale can be used with children as young as 3 years, as it helps them express their level of pain by pointing to a cartoon face that most closely resembles how they are feeling (see Figure 35-6).

The Poker Chip Tool consists of four red poker chips that can easily be carried in a pocket and available when needed. The chips are aligned horizontally on a hard surface in front of the child, and they are described as “pieces of hurt.” The chips are described from left to right as just a little bit of hurt, a little more hurt, more hurt, and the most hurt you could ever have. The child is then asked, “How many pieces of hurt do you have right now?” This tool can be used with children 4 to 13 years old.

The verbal 0 to 10 scale is also frequently used for school-age and adolescent clients in a number of settings. It is important to remember that any child under stress or with anxiety will regress, and regression may make use of the verbal 0 to 10 scale in children under 8 to 10 years of age of questionable value. See the accompanying Spotlight On display on page 1055 for developmental considerations.

NURSING DIAGNOSIS

The two primary nursing diagnoses used to describe pain are *acute pain* and *chronic pain*. According to NANDA (2009),

TABLE 35-4 Myths about Pain and Children

MISCONCEPTION	FACT
Infants do not feel pain.	Anatomic structures for pain processing reach adult maturity at 36 weeks after conception.
Children tolerate pain better than adults.	Even though children may not express pain as adults do, there are behavioral indicators of pain in children. Children as young as age 3 can use pain scales to communicate the level of pain experienced.
Children become accustomed to pain or painful procedures.	Some children show increased signs of discomfort with repeated painful procedures. Anxiety over impending procedures only exacerbates pain.
Narcotics are more dangerous for children than for adults.	When used appropriately, opioids are not more dangerous for children than for adults.

Delmar/Cengage Learning

Text not available due to copyright restrictions

acute pain is defined as an uncomfortable experience that occurs as a result of actual or potential tissue damage. The onset may be sudden or slow. *Chronic pain* and acute pain are differentiated by the length of time that the unpleasant experiences last; acute pain has lasted less than six months, whereas, chronic pain has a duration of greater than six months. Presenting characteristics of *acute pain* and *chronic pain* are listed in the Nursing Process Highlight on page 1055.

If the client presents with problems in addition to pain, the nurse must be alert to the possibility that the pain may be the *cause* (not the effect) of another problem. For example, a client may be experiencing *impaired physical mobility* or *activity intolerance* related to pain caused by a broken leg, as evidenced by verbal complaint, fatigue, and guarding the affected leg.

SPOTLIGHT ON...

Professionalism

Pain Assessment Tools

After reviewing these brief case presentations, determine the type of pain assessment tool most appropriate for each:

1. A developmentally normal 42-year-old man during an overnight hospital stay after orthopedic surgery on the ankle
2. A developmentally normal 12-year-old oncology client with severe mucositis (inflammation of the mucous membrane) after chemotherapy for recurrent osteosarcoma (following an above-the-knee amputation) with metastases to multiple ribs and severe phantom limb pain

PLANNING AND OUTCOMES

When planning care for the client experiencing pain, mutual goal setting is of utmost importance. After assessing the client's perception of the problem, work with the client in developing realistic outcomes. Be sure to use both nonpharmacologic and pharmacologic interventions in planning strategies to help the client achieve desired levels of functioning and pain control.

When asking about the client's goal for pain relief, the nurse often has to state, "We can't usually get rid of all your pain, but if we could get it down to a place that it didn't bother you so much, what would that be?" Thus, the family and health care professionals involved will all be aware of a realistic goal for pain relief.

The goal of palliative care is to provide interventions that support the achievement of quality of life for clients and their families. The Hospice and Palliative Nurses Association's (HPNA) position statement on pain addresses "unrelieved pain" as the most feared symptom of those at the end of life. "Unrelieved pain can contribute to unnecessary suffering, as evidenced by sleep disturbances, hopelessness, loss of control, and impaired social interactions. Pain may actually hasten death by increasing physiological stress, decreasing mobility, [and] contributing to pneumonia and thromboemboli" (HPNA, 2008, p. 1). See the accompanying display on page 1056 for the HPNA position statement on pain.

Collaboration

In order to identify all of the potentially treatable contributing factors to pain, management of pain often requires an interdisciplinary team. This is especially true for persistent (chronic) pain that is a multifaceted problem, involving physiological, psychological, and social factors. The treatment of pain requires collaboration between interdisciplinary team members and may require the services of a *pain manager/specialist*, such as a physician or nurse practitioner. Almost all

Text not available due to
copyright restrictions

health care providers, such as psychologists, pharmacists, spiritual counselors, social workers, and rehabilitation specialists, participate in the management of persistent pain and palliative care.

IMPLEMENTATION

The Nursing Interventions Classification (NIC) system defines those nursing actions regarding pain management, identifies certain measures to relieve pain (e.g., patient-controlled analgesia assistance), and addresses specific pain relief actions within other related intervention sets, such as *client rights protection* and *dying care*. The NIC activities clearly emphasize the need for nurses to listen to clients' description of pain and to respect their right to obtain effective pain management. See the accompanying display on page 1057 for a

sample of NIC-defined activities for pain management. Managing pain presents the nurse with many challenges and requires the collaborative efforts of other health care professionals. The NIC system also presents specific interventions for various pharmacological, nonpharmacological, and interpersonal strategies for pain management. These strategies are discussed later in this section.

Nurse-Client Relationship

Pain is a subjective symptom, it is not visible, and only the client knows how it feels. The client's self-report of pain is the most valid assessment data to direct nursing care. Nurses need to assist clients in using the proper language to report pain symptoms.

Establishment of a therapeutic relationship is the foundation for effective nursing care of the client experiencing pain. Clients who trust their nurses to be there, to listen, and to act are the ones who are most likely to be comfortable. See the Uncovering the Evidence display on page 1057.

CLIENT EDUCATION Client education regarding pain management begins with defining pain, identifying the probable causes, introducing clients to pain assessment tools, and allowing clients to choose the tool they would like to use. The importance of talking to health care providers about the client's pain and using a preventive approach to pain management must also be emphasized. Provide written information to reinforce verbal explanations. Teach the importance of around-the-clock dosing instead of prn administration of analgesic medications. Refer to the Client Teaching checklist on page 1058.

When a client is to be discharged from a health care facility, discharge teaching should include pain management information with specific guidelines:

General overview of pain

- Definition
- Cause and contributing factors
- Pain assessment, including use of assessment tools
- Importance of preventive approach
- Family involvement

Pharmacologic pain management

- Overview of drug management
- Addiction, dependence, and tolerance
- Respiratory depression
- Communicating with health care providers about pain
- Controlling accompanying symptoms (e.g., constipation, nausea)

Nonpharmacologic pain management

- Importance of strategies
- Review of past experience with nonpharmacologic methods
- Demonstration of specific techniques

Both nonpharmacologic and pharmacologic interventions can be effective in caring for clients with pain. In some cases of mild pain, nonpharmacologic techniques may be the primary intervention, with medication available as "backup." In cases of moderate to severe pain, nonpharmacologic techniques can be an effective adjunctive or complementary treatment.

HPNA POSITION STATEMENT ON PAIN

The HPNA supports the provision of appropriate pain management for patients in all clinical settings. It is the position of the HPNA board of directors that:

- All people, including vulnerable populations such as cognitively impaired, infants, children, and the elderly, facing progressive, life-limiting illness have the right to optimal pain relief.
- All health care providers have an obligation to believe the patient's report of pain.
- Pain assessment and management should incorporate principles of cultural sensitivity as well as patients' values and beliefs.
- All health care professionals caring for patients with progressive, life-threatening illnesses need to acquire and utilize current knowledge and skills to implement appropriate pain management.
- Health care organizations need to adopt policies and procedures that address the assessment and pharmacologic and nonpharmacologic management of pain.
- Pain management should include, as appropriate, advanced technology.
- Pain assessments and management should be aligned with evidenced-based practice.
- The need for regulatory control of opioids must be balanced with access to opioids for all patients who need them.
- Pain management should be part of the education for all health care providers who are caring for patients with advanced, life-limiting illnesses.
- Health care professionals must advocate for their patients to ensure adequate pain relief.
- Uncontrolled pain should be considered an emergency, with all health care professionals taking responsibility to provide relief.
- Patients have the right to participate actively in decisions about their pain management.
- Families should be supported in their efforts to observe and relieve pain when appropriate.
- Hospice and palliative care programs should share their knowledge of pain management concepts with others in their communities.
- Use of placebos for pain management is inappropriate and unethical.

UNCOVERING THE

Evidence

TITLE OF STUDY

“The Quality of Postoperative Pain Management from the Perspectives of Patients, Nurses and Patient Records”

AUTHORS

L. Gunningberg and E. Idvall

PURPOSE

To study the quality of postoperative pain management in a university hospital.

METHOD

This study compared client and nurse data using the Strategic and Clinical Quality Indicators in Postoperative Pain Management questionnaire in two nursing departments.

FINDINGS

Clients in general surgery experienced more pain than clients in thoracic surgery. In general surgery, the clients assessed their worst pain significantly higher than the nurse did. The clients who experienced more pain were less satisfied with the quality of their care and experienced higher pain intensity levels.

IMPLICATIONS

In both departments, areas identified as needing improvement were communication, action, trust, and environment. It is important to discuss what information the client needs as well as how and when it should be given.

Gunningberg, L., & Idvall, E. (2007). The quality of postoperative pain management from the perspectives of patients, nurses and patient records. *Journal of Nursing Management*, 15(7), 756–766.

SAMPLE OF THE NIC SYSTEM'S PAIN MANAGEMENT ACTIVITIES

- Use therapeutic communication strategies to acknowledge the pain experience and to convey acceptance of the client's response to pain.
- Determine the impact of the pain experience on quality of life (e.g., sleep, appetite, activity, cognition, mood, relationships, performance of job, and role responsibilities).
- Evaluate, with the client and the health care team, the effectiveness of past pain control measures that have been used.
- Utilize a developmentally appropriate assessment method that allows monitoring change in pain and assists in identifying actual and potential precipitating factors (e.g., flow sheet, daily diary).
- Consider the client's willingness to participate, ability to participate, preferences, support of significant others for method, and contraindications when selecting a pain relief strategy.
- Select and implement a variety of measures (e.g., pharmacologic; nonpharmacologic, such as biofeedback, TENS, hypnosis, relaxation, guided imagery, music therapy, distraction, play therapy, activity therapy, acupressure, hot and cold application, and massage; and interpersonal) to facilitate pain relief, as appropriate.
- Teach principles of pain management.
- Evaluate the effectiveness of the pain control measures used through ongoing assessment of the pain experience.
- Promote adequate rest and sleep to facilitate pain relief
- Utilize a multidisciplinary approach to pain management, when appropriate.

Bulechek, G., Butcher, H., & Dochterman, J. (2008). *Nursing interventions classification (NIC)* (5th ed.). St. Louis, MO: Elsevier.

Pharmacologic Pain Management

Principles for the care of clients experiencing pain follow:

- Assess the pain.
- Treat the contributing factors (pathology).
- Individualize the client's analgesic therapy.
- Choose the least invasive route of administration.
- Administer analgesics at regularly scheduled intervals (around-the-clock dosing) rather than on an as-needed (prn) basis.
- Keep clients in control of their own analgesia as much as possible.
- Titrate doses to provide maximum pain relief and minimum side effects.

Other general principles that guide practice are discussed in the following sections.

COMBINE ANALGESICS Combining analgesics on the basis of the World Health Organization's three-step analgesic ladder is imperative to provide effective pharmacologic intervention for clients with all types of pain. The use of adjuvant medication is recommended (Management of Cancer Pain Guideline Panel, 1994). **Adjuvant medications** are those drugs used to enhance the analgesic efficacy of opioids, to treat concurrent symptoms that exacerbate pain, and to provide independent analgesia for specific types of pain. Adjuvant medication (medication without intrinsic analgesic properties) is often helpful in treating chronic pain. Adjuvant drugs include anticonvulsants, antidepressants, and sedatives.

**CLIENT TEACHING CHECKLIST****Pain Management Information**

- Help clients understand the importance of effective pain management. Explain the outcomes of unrelieved pain.
- Teach at the client's level of comprehension. Assess literacy level.
- Respect the client's cultural beliefs related to pain.
- Correct any misconceptions about the use of opioid analgesics. Instruct the client about the low risk for addiction when these medications are used for pain relief.
- Instruct the client on the use of complementary methods for relieving pain, including massage, application of heat and cold, and imagery.

For example, gabapentin (Neurontin) is one anticonvulsant useful in treating older clients experiencing chronic pain (Boswell & Cole, 2006). Education for clients taking adjuvant medication must explain the need to continue to take the analgesic drug with the adjuvant medication. Table 35-5 lists some common adjuvant medications used in pain management.

MAINTAIN THERAPEUTIC SERUM LEVELS Currently, many prescribing practitioners use “as needed” or “prn” range orders for opioid analgesics for the management of acute pain (Boswell & Cole, 2006). Range orders provide safe and flexible dosing adjustments based on the client's response to treatment. Historically, the use of as-needed orders for pain management has caused the undertreatment of pain because prescribers have failed to order adequate doses at frequent intervals, and nurses administer inadequate doses. In an effort to provide clinical guidelines that address the use of as-needed orders, the American Society for Pain Management Nursing (ASPMN) and the APS (2004) issued

TABLE 35-5 Adjuvant Medications for Pain Management

MEDICATION	TYPE OF PAIN	EFFECTS
Tricyclic antidepressants (amitriptyline, doxepin, imipramine, trazodone)	Neuropathic pain frequently described as dull, aching, or throbbing	<ul style="list-style-type: none"> • Mood elevation, enhancement of opioid analgesia, direct analgesic effects • Anticholinergic side effects: dry mouth, constipation, urinary retention
Anticonvulsants (carbamazepine, clonazepam, phenytoin)	Neuropathic pain frequently described as sharp shooting, burning, or lancinating	<ul style="list-style-type: none"> • Suppresses the spontaneous neuronal firing, which causes this type of pain
Corticosteroids (dexamethasone, prednisone)	Pain due to cerebral or spinal cord edema or pain in peripheral nerves caused by perineural edema	<ul style="list-style-type: none"> • Mood elevation, strong anti-inflammatory activity, appetite stimulation
Antihistamine (hydroxyzine)	Pain or nausea in the anxious client	<ul style="list-style-type: none"> • Relief of complicating symptoms, including anxiety, insomnia, nausea, and pruritus
Neuroleptic (methotrimeprazine)	Alternative analgesic for clients who are opioid-tolerant or have opioid-limiting side effects, especially constipation	<ul style="list-style-type: none"> • Antiemetic and anxiolytic • This is the one phenothiazine to date that has demonstrated analgesic properties: methotrimeprazine 15 mg IM was found to be equivalent to morphine 10 mg IM
Psychostimulants (dextroamphetamine, methylphenidate)	Continued pain with opioid-induced sedation	<ul style="list-style-type: none"> • Improves opioid analgesia and decreases sedation

Data from Macintyre, P., & Shug, S. (2007). *Acute pain management: a practical guide* (3rd ed.). St. Louis, MO: Elsevier.

SAFETY FIRST

Placebos should not be used by any route of administration in the assessment and management of pain in any client regardless of age or diagnosis.

a consensus statement regarding support for safe medication practice and the appropriate use of prn range opioid analgesic orders in pain management. “Evidence-based clinical practice guidelines support the need for individual titration of the dose of opioid analgesics” (ASPMN & APS, 2004, p. 1); see the Safety First display.

Nurses should base their decisions regarding implementation of range orders on client assessment and knowledge of the prescribed drug, such as time of onset, peak effect, duration of action, and side effects. The client’s response to the analgesic dose interval should be evaluated, documented, and communicated by the nurse. An appropriate use of opioids should be individually tailored based on a sound working knowledge of analgesic pharmacology, appropriately timed reassessments and adjustments, and client response.

CHOOSE APPROPRIATE ROUTES OF ADMINISTRATION

Available routes of administration play an important role in the choice of pain management technique. In general, the oral route (PO) of administration is preferred because it is the most convenient and cost-effective. When the oral route is not feasible, other routes (such as rectal or transdermal) can be used to administer analgesics.

The rectal route is effective when clients are nauseated and vomiting or when they are NPO. Suppositories of morphine, hydromorphone, and oxycodone are available. Contraindications to rectal administration include diarrhea, lesions of the rectum or anus, or an immunosuppressed status. The transdermal route bypasses GI absorption but has a slow onset and a slow decline in blood level after the patch is removed.

With continuing documentation of unreliable absorption of intramuscular (IM) injections of opioids, the prudent approach is to switch to subcutaneous or intravascular administration. Continuous infusions are possible by either intravenous (IV) or subcutaneous methods. See Table 35-6 on page 1060 for an overview of administration routes; see Chapter 30 for a complete discussion of medication administration routes.

NONSTEROIDAL ANTI-INFLAMMATORY DRUGS The nonopioid class of pharmacologic agents consists of a group of medications classified as nonsteroidal anti-inflammatory drugs (NSAIDs). NSAIDs attenuate prostaglandin production by inhibiting cyclooxygenase (COX) enzymes. Prostaglandin, a chemical present in most body tissue, is released with cell trauma, causing edema and erythema. NSAIDs block COX, an enzyme with two isoforms (COX-1 and COX-2), and prevent the production of prostaglandin and other substances, provid-

ing analgesia, antipyresis, and anti-inflammation. COX-1 is normally present in the GI tract, kidneys, and platelets, and it catalyzes the synthesis of prostaglandins in the GI mucosa and platelets. The GI side effects of oral NSAIDs, addressed in Table 35-6, probably result from the drugs’ inhibition of COX-1 activity and the subsequent protective effects of prostaglandins on GI mucosa. NSAIDs are useful in treating mild to moderate pain, especially painful conditions involving inflammation. NSAIDs are usually classified by their chemical structure. See the accompanying display on classes of NSAIDs.

The widespread use of NSAIDs makes them the culprit in many adverse drug effects. Aspirin, an over-the-counter NSAID, is used frequently to treat mild pain; however, some clients such as asthmatics may have aspirin hypersensitivity. Hypertensive clients also may experience adverse effects with some NSAIDs; for example, ibuprofen may cause an intermediate elevation in blood pressure, naproxen may cause a significant elevation in blood pressure, and celecoxib may hamper the healing of broken bones.

NSAIDs are also subject to the **ceiling effect** (as the dose of medication is increased above a certain level, the analgesic effect remains the same), and only the adverse effects continue to increase. For example, acetaminophen is relatively easy on the GI tract and does not affect platelet aggregation, but large doses over time have caused liver damage, with extreme overdoses causing liver failure.

Educate clients and their families regarding the ceiling effect because they may feel that “If a little helps some, then more is better.” The risk for significant side effects and adverse reactions is increased by this misunderstanding.

OPIOID ANALGESICS Opioids remain the gold standard for managing moderate to severe pain (Patterson, 2008). The opioids and NSAIDs offer pain relief through different mechanisms. For example, the opioids act on several sites in the CNS rather than on the peripheral nervous system, as do the NSAIDs. Opioids alter the release of neurotransmitters; therefore, pain transmission is interrupted at several sites in the CNS. The result is an altered perception of and response to pain.

The opioid analgesics fall into three classes: pure opioid agonists, partial agonists, and **mixed agonist-antagonists** (compounds that block opioid effects on one receptor type while producing opioid effects on a second receptor type). Pure agonists are those that produce a maximal response

CLASSES OF NSAIDS

- Propionic: Ibuprofen, naproxen, ketoprofen
- Acetic: Indomethacin, sulindac, tolmetin
- Salicylic: Aspirin, sodium salicylate, salicylamide
- Anthranilic: Phenylbutazone, piroxicam
- Pyrrolopyrroles: Ketorolac, etodolac
- COX-2 inhibitors: Celecoxib, valdecoxib

TABLE 35-6 Advantages and Disadvantages of Selected Medication Administration Routes

INTERVENTION	ADVANTAGES	DISADVANTAGES
Oral NSAIDs	<ul style="list-style-type: none"> Useful for a wide variety of mild to moderate pain. Widely available, some over the counter. Additive analgesia when combined with opioids and other modalities. Can be administered by client or family. Some are inexpensive. 	<ul style="list-style-type: none"> Ceiling effect to analgesia. Side effects, especially gastritis and renal toxicity, can be serious. May risk bleeding in severely thrombocytopenic clients. Only one NSAID (ketorolac) is available now for parenteral administration. Many are expensive. Contraindicated in high-risk clients with congestive heart failure and coronary artery disease. Drug interactions: β-blockers, loop diuretics, angiotensin-converting enzyme (ACE) inhibitors, anticoagulants.
Oral opioids	<ul style="list-style-type: none"> Effective for both localized and generalized pain. Ceiling to analgesic effectiveness imposed only by side effects. Multiple drug choices in the class. Sedative and anxiolytic properties useful in some acute treatment settings. Can be administered by client or family. Some are inexpensive. Long-acting, controlled-release forms are available. 	<ul style="list-style-type: none"> Side effects may limit analgesic effectiveness. Prescription of these substances is regulated. Stigma or fears associated with use.
Transdermal opioids (fentanyl)	<ul style="list-style-type: none"> Long duration of action (48–72 h) from single patch. Allows use of a strong opioid (fentanyl) in outpatient settings for some clients who have not tolerated morphine and related drugs. Many clients find them easy to use. Provides continuous administration of an opioid without use of needles or pumps. Can be administered by client or family. 	<ul style="list-style-type: none"> Side effects may not be as quickly reversible as in oral administration. Mild erythema at site. Difficult to modify dosage rapidly. Relatively slow onset of action. Requires additional short-acting medicine for breakthrough pain. Expensive.
Rectal opioids	<ul style="list-style-type: none"> Relatively easy-to-use alternative route when the oral route is unavailable. Other opioid suppositories available for morphine-intolerant clients. Can be administered by client or family. Less expensive than subcutaneous or intravenous (IV) infusions. 	<ul style="list-style-type: none"> Not widely accepted by clients or families. Side effects may limit analgesic effectiveness. Relatively slow onset of action. Contraindicated if low white blood cell or platelet count (risks of infection, bleeding).
Subcutaneous infusion	<ul style="list-style-type: none"> Can provide rapid pain relief without IV access. Morphine and hydromorphone are the preferred drugs for this route when administered in the home. 	<ul style="list-style-type: none"> Only a limited volume of infusate can be administered (e.g., 2–4 mL/h). Induration or irritation at infusion site may be a complication. Requires skilled nursing and pharmacy support.

(Continues)

TABLE 35-6 (Continued)

INTERVENTION	ADVANTAGES	DISADVANTAGES
	<ul style="list-style-type: none"> When used in patient-controlled analgesia (PCA) mode, allows for rapid individual dose titration and provides sense of control for client. 	<ul style="list-style-type: none"> Often requires expensive drug infusion pump and recurring charges for disposables.
IV infusion	<ul style="list-style-type: none"> Can provide rapid pain relief. Almost all opioids can be given by this route. Not limited to infusate volumes. When used in PCA mode, allows for rapid individual dose titration and provides sense of control for client. 	<ul style="list-style-type: none"> Infection and infiltration of IV lines are potential complications. Requires skilled nursing and pharmacy support. Often requires expensive drug infusion pump and recurring charges for disposables.
Epidural, intrathecal, and intracerebral ventricular routes	<ul style="list-style-type: none"> Effective for moderate-to-severe acute pain expected to last 24 hours (e.g., acute post-operative pain). Usually requires less analgesia and promotes early ambulation following surgery. Postoperatively better pain relief at rest and after coughing, less nausea and vomiting, and improved bowel function and mental status. 	<ul style="list-style-type: none"> Tolerance may occur sooner than with oral or rectal administration. Infection at catheter site can produce meningitis and/or epidural abscess. Contraindicated in presence of acute spinal cord compression. Requires careful monitoring, especially when therapy begins and when doses are increased.
Regional neurolytic blocks	<ul style="list-style-type: none"> Effective for pain relief with certain diagnoses (e.g., pancreatic cancer). May be useful for movement-related and abdominal visceral pain that is refractory to drug therapy. Can allow dosage (and side effect) reduction of systemic drugs for localized pain. 	<ul style="list-style-type: none"> Risk of postural hypotension, bowel and bladder incontinence, and limb weakness. Procedure is irreversible. Requires special expertise. Expenses for specialized care and operating room costs.

Data from Boswell, M. V., & Cole, B. C. (2006). *Weiner's pain management: a practical guide for clinicians* (7th ed.). Boca Raton, FL: CRC Press; Campbell, W., Nicholas, M., & Breivik, H. (2008). *Clinical pain management practice & procedures* (2nd ed.). New York: Oxford University Press, USA; Spies, K., Rehberg, Bl., Schug, S., Jaehnicen, G., & Harper, S. (2008). *Pocket guide pain management*. Warren, IL: Springer; Stanton-Hicks, M. (2009). *The Cleveland Clinic guide to pain management*. New York: Kaplan.

from cells when they bind to the cells' opioid receptor sites. Morphine (the gold standard against which all other opioids are measured), fentanyl, methadone, hydromorphone, and codeine are pure agonists. Meperidine, although classified as a pure agonist, is not recommended except in clients with a true allergy to all other narcotics, because of its neurotoxicity. Meperidine produces clinical analgesia for only 2.5 to 3.5 hours when given intramuscularly in adults. In pediatric clients receiving intravenous meperidine, analgesia may last for only 1.5 to 2.0 hours. Opioids can be safely administered to an elderly client by starting with a lower dose, monitoring for drug-drug interactions, and titrating doses upward cautiously, depending on the client's response (Patterson, 2008). Caution should be used when administering opioids to elderly clients with decreased blood volume or with renal impairment.

Meperidine should be reserved for very brief courses in otherwise healthy clients who have demonstrated an unusual

reaction (e.g., local histamine release at the infusion site) or allergic response during treatment with other opioids such as morphine or hydromorphone (Macintyre & Shug, 2007).

Unlike the NSAIDs, pure agonist opioids are not subject to the ceiling effect. As the dosage is increased, there is increasing pain relief, with the only limiting factor being the degree of side effects, particularly respiratory depression and constipation. Many of the analgesic medications (especially opioids) can cause the unwanted effect of constipation. See the accompanying Client Teaching Checklist on page 1062.

Other side effects that occur frequently in clients on opioid medications are pruritus and nausea, but the degree to which they are present from each medication varies among individuals. Clients must be instructed regarding these *normal* responses to opioids and informed that it does not mean that they are allergic to them. A true allergy to opioids would be indicated by a rash or hives that start after receiving the opioid, a local histamine release at the site of

**CLIENT TEACHING CHECKLIST****Preventing Opioid-Induced Constipation**

- Eat high-fiber foods.
- Drink 8–10 glasses of fluid per day.
- Eat foods that previously helped relieve constipation.
- Increase physical activity, such as walking.
- Consume a hot beverage about 30 minutes prior to the planned time for a bowel movement.
- Use laxatives or stool softeners only as advised by the health care provider.

infusion, or anaphylaxis. Clients also need to know that the pruritus and nausea generally subside after 4 to 5 days of opioid therapy. In the meantime, an antihistamine such as diphenhydramine or hydroxyzine may be used for pruritus, and an antiemetic such as metoclopramide or trimethobenzamide can be used to treat the nausea. Almost all medications used to treat side effects have their own side effect of sedation; thus, there is the possibility of a cumulative effect of severe sedation.

Mixed agonist-antagonist opioids are believed to be subject to the ceiling effect for pain relief as well as a ceiling effect for respiratory depression. Mixed agonist-antagonist opioids activate one opioid receptor type while simultaneously blocking another type. Butorphanol, pentazocine, and nalbuphine are the most frequently used in pain management.

PATIENT-CONTROLLED ANALGESIA (PCA) **Patient-controlled analgesia (PCA)** is a method to relieve pain through self-administration of analgesics (usually opioids, e.g., morphine) by a client using a programmable pump connected to a subcutaneous, intravenous, or epidural catheter. The Joint Commission and the Institute for Safe Medication Practices recommend safe practices for PCA use that include standardized client education on PCA usage; standardized order sets, drugs, and drug concentrations used for PCA; annual competency assessment for nurses; and signatures of two nurses when therapy is initiated and with all dosing changes. See the accompanying display on page 1063 for a sample of NIC activities related to the use of PCA. PCA is used in health care facilities and in the home to manage postoperative or cancer pain. The client is taught how to operate the PCA by pressing the button of the PCA pump to administer the proper bolus (amount of analgesic received when pressing the button) dose of the prescribed analgesic as demanded. A recent study evaluated the effects of analgesic quality provided by a PCA intervention on pain management; the results showed a significant correlation between pain cognition and analgesic quality (Yeh, Yang, Chen, & Tsou, 2007).

The PCA system is designed for client initiation. Although PCA is contraindicated in sedated and confused clients, nurse-activated PCA or PCA by proxy such as a family member or friend is a controversial practice because of the possibility of oversedation. The ASPMN, the Joint Commission, and the Institute for Safe Medication Practices do not support the practice of PCA by proxy; however, the ASPMN does support the practice of authorized agent-controlled analgesia in a variety of client settings when the agency has in place clear guidelines that ensure safe use of the therapy (Wuhrman et al., 2007). The Joint Commission has guidelines that require those health care agencies that allow nurse-activated PCA or PCA by proxy to maintain strict policies, with documented education of family members and other caregivers who administer the PCA by proxy.

Nurses collaborate with the prescribing practitioner, the client, and the client's family members to ensure that PCA orders are clear and complete. Each order must address the analgesic to be used, route of administration, bolus dose, lockout interval, maximum dose limit, the loading dose (first bolus dose), and the basal infusion rate (continuous infusion rate). The lockout interval is the time period during which pressing the button more than once results in only one dose of analgesic received. The maximum dose limit is the amount of analgesic that can be received within a certain period of time (e.g., 1 hour). To safely administer PCA, nurses should maintain a patent catheter, instill the analgesic solution into the PCA chamber, and program the PCA pump according to the prescribed parameters; see Procedure 35-1.

EPIDURAL ANALGESIA Epidural analgesia has been used traditionally for the administration of opioid analgesics for chronic intractable pain and for chemotherapy. Epidural catheters are placed by anesthesia providers into the epidural space. The epidural space is a *potential* space, without free-flowing fluid, between the walls of the vertebral canal and the dura mater of the spinal cord, and it contains vessels, fat, and nerves. Analgesics are administered through a needle that has been placed into the epidural space; a catheter may be threaded through the needle and taped into place for continuous use to manage acute pain, usually 2 to 4 days (Macintyre, Rowbotham, & Walker, 2008). Epidural analgesic may be administered by bolus, continuous infusion, and patient-controlled epidural analgesia (PCEA).

Nursing management of epidural infusions requires strict aseptic technique to prevent infection; check the external dressing around the catheter site for dampness or discharge and the catheter for breaks. An epidural catheter should be secured carefully to the outside skin (if it is not connected to an implanted reservoir) to prevent displacement of the catheter. To initiate an infusion, connect the catheter to an infusion pump, a port, or a reservoir, or cap it off for bolus injections. Epidural infusions are always administered through electronic infusion devices for proper rate control; the epidural catheter should be clearly labeled to reduce the risk of accidental IV injections, and the infusion tubing should be changed every 24 hours or according to agency policy. Monitor the client for signs of respiratory

NIC SAMPLE ACTIVITIES FOR PATIENT-CONTROLLED ANALGESIA (PCA) ASSISTANCE

- Ensure that the client is not allergic to the analgesic to be administered.
- Teach client and family to monitor pain intensity, quality, and duration; respiration rate; and blood pressure.
- Validate that the client can use a PCA device and is able to communicate, comprehend explanations, and follow directions.
- Teach client and family members how to use the PCA device, to administer an appropriate bolus loading dose of analgesic, and to set an appropriate basal infusion rate on the PCA device.
- Assist the client and family member to set the appropriate lockout interval on the PCA device and demand doses on the PCA device.
- Consult with client, family members, and prescribing practitioner to adjust lockout interval, basal rate, and demand dosage, according to the client's responsiveness.
- Teach client how to titrate doses up or down, depending on the respiratory rate, pain intensity, and pain quality.
- Teach client and family members the action and side effects of pain-relieving agents.
- Document client's pain, amount and frequency of drug dosing, and response to pain treatment on a pain flow sheet.
- Consult with clinical pain experts for a client who is having difficulty achieving pain control.

Bulechek, G., Butcher, H., & Dochterman, J. (2008). *Nursing interventions classification (NIC)* (5th ed.). St. Louis, MO: Elsevier.

depression (see the accompanying display on page 1064) and untoward reactions such as pruritus, nausea, and vomiting. Notify the prescribing practitioner of any signs or symptoms of infection or pain at the insertion site.

Epidural pain management is used for oncology clients when other methods of pain control are insufficient or poorly tolerated (D'Arcy, 2008). An epidural solution usually contains a combination of drugs such as a local anesthetic (bupivacaine) and an opioid (fentanyl or morphine). All drugs administered epidurally should be preservative-free to avoid damage to neural tissue and fluids.

ADDICTION, TOLERANCE, AND PHYSICAL DEPENDENCE As a result of fears of addiction, family caregivers tend to undermedicate their relative's pain. Family and client

education about addiction and pain medication should be a priority for those receiving opioid therapy. **Addiction** is a biological and psychosocial dependence on a substance. It is a chronic neurobiologic disease characterized by a craving for the substance, compulsive use, lack of control over the drug, and continued use despite harm (D'Arcy, 2008). **Tolerance** can occur after repeated administration of an opioid analgesic, when a specific dose loses its effectiveness and the client requires larger and larger doses to produce the same level of analgesia. The first indication of tolerance is decreased duration of action, then decreased analgesia. If this pattern is noted in clients with continuing opioid needs, the analgesic dose needs to be titrated higher immediately. **Physical dependence** is the reaction of the body, commonly known as withdrawal syndrome, to abrupt discontinuation of an opioid after repeated use.

RESPIRATORY DEPRESSION Titrating opioid analgesics to obtain optimal pain management with minimal side effects is a difficult task. See the accompanying display for a list of risk factors predisposing to respiratory depression in clients receiving appropriate dosages of sedatives or opioid analgesics. This list should be used to identify clients of all ages who require increased vigilance, possible cardiac and pulse oximetry (determination of oxygen saturation of arterial blood) monitoring, and frequent assessment when taking opioid analgesics. It is not to be construed as a reason for denying the client adequate pain management. When caring for clients receiving opioid analgesics, the nurse should periodically identify the presence and intensity of risk factors.

LOCAL ANESTHESIA Local anesthetics are effective for pain management in a variety of settings. Topical analgesics produce effective analgesia with reduced systemic drug levels, a factor particularly beneficial to young and older clients. Topical analgesics differ from transdermal delivery systems (see Table 35-6) in that transdermals deliver systemic rather than local effects. Commonly used topical analgesics include capsaicin cream 0.75%, lidocaine/prilocaine (EMLA), and the 5% lidocaine patch. Topical anesthetics are available for teething, sore throats, denture pain, laceration repair, and intravenous catheter insertions. EMLA cream is a mixture of local anesthetics, combining prilocaine and lidocaine. It produces complete anesthesia for at least 60 minutes when topically applied to intact skin.

Another topical anesthetic, TAC, is available for anesthesia during closure of lacerations. It is a combination of tetracaine 0.5%, adrenaline 1:2000, and cocaine 11.8% in a normal saline solution that can be applied directly to the open wound surface in place of local anesthetic infiltration with a needle. This allows pain-free cleansing of the laceration as well as suturing. Because both adrenaline (epinephrine) and cocaine cause vasoconstriction, TAC cannot be used in areas supplied by end-arteriolar blood supply such as digits, the ears, or the nose. It also is contraindicated on burned or abraded skin because this could lead to increased systemic absorption of cocaine and tetracaine, thus placing

RISK FACTORS PREDISPOSING TO RESPIRATORY DEPRESSION WITH USE OF SEDATIVES OR OPIOID ANALGESICS

NEUROLOGICAL IMPAIRMENT

- Cerebral palsy
- Altered level of consciousness

RESPIRATORY COMPROMISE

- Thoracic skeletal deformities (e.g., scoliosis, kyphosis, contracture)
- Neurodegenerative disorders (e.g., muscular dystrophy, tuberous sclerosis, Werdnig-Hoffman disease, myasthenia gravis)
- Pulmonary disease (e.g., cystic fibrosis, reactive airway disease, bronchopulmonary dysplasia, chronic obstructive lung disease)
- Thoracic or high abdominal incision
- Abdominal distension

METABOLIC ALTERATION

- Liver dysfunction or failure
- Metabolic disease
- Sepsis

RENAL COMPROMISE

- Kidney dysfunction or failure
- Single kidney

- Hypovolemia
- Urine output 1 mL/kg/h in children, 30 mL/h in adults, or elevated blood urea nitrogen (BUN) or creatinine

OTHER

- Obesity (when drug is ordered on actual weight rather than estimated lean body weight)
- Increasing sedation
- Agitation
- Preverbal or nonverbal client

CONCURRENT ADMINISTRATION OF OTHER NARCOTICS OR SEDATIVES

- Opioid analgesics
- Sedatives, hypnotics, and tranquilizers
- Anticonvulsants
- Antihistamines
- Psychotropics

the client at risk for seizures. The 5% lidocaine patch reduces pain and may allow tapering of concomitant analgesic therapy in clients with neuropathic pain, such as diabetic polyneuropathy.

Treatment of Neuropathic Pain

Neuropathic pain is often refractory to treatment with NSAIDs and opioids. When increasing doses of opioids are ineffective in controlling postoperative pain, an immediate search for the underlying cause should begin, and the diagnosis of neuropathic pain should be considered. Once diagnosed, the focus of treatment is optimizing functional abilities.

A trial of a tricyclic antidepressant is frequently the first step for a client who describes dull, aching, or throbbing pain. Amitriptyline is often the drug of choice because it has been the most widely studied (Spies et al., 2008). This class of medications is useful in pain management as a result of:

- Mood elevation
- Potentiation of opioid analgesia
- Direct analgesic effects

Clients with neuropathic pain often have significant sleep deprivation. Amitriptyline's action and the side effect of

drowsiness improve the client's ability to fall asleep and to sleep for longer periods. Amitriptyline must be started at very low doses, especially in children, the debilitated, or elderly clients, then increased slowly. It should be administered at bedtime to promote sleep and to minimize falls resulting from orthostatic hypotension. The onset of analgesic effects occurs within 1 to 2 weeks, and maximal effect can be seen in 4 to 6 weeks.

Anticonvulsants are often tried first for clients with burning, sharp, shocking, shooting, or **lancinating** (piercing or stabbing) pain. Carbamazepine is often the drug of choice, with other possibilities being clonazepam or phenytoin. These medications suppress spontaneous neuronal firing that leads to the lancinating pain of nerve injury. Carbamazepine may cause transient bone marrow suppression and requires regular monitoring of serum drug levels, blood counts, and liver function. It should be avoided if possible in clients with any form of bone marrow suppression (e.g., those undergoing chemotherapy, radiation therapy, or taking immunosuppressants posttransplantation).

Corticosteroid effects include mood elevation, anti-inflammatory effects, and appetite stimulation. Corticosteroids are effective in reducing the neuropathic pain caused by pressure on nerves both centrally and peripherally.

The two corticosteroids most frequently used in pain management are dexamethasone and prednisone.

If muscle spasms are a major contributor to the client's discomfort, then baclofen can be tried for its antispasmodic effect. This is particularly effective for clients with spinal cord injuries or upper motor neuron dysfunction, including cerebral palsy.

For many individuals, the use of nonpharmacologic methods enhances pain relief. These nonpharmacologic strategies are often used in combination with medication. Complementary and alternative methods are being used with increasing frequency to treat pain. The use of such strategies is often influenced by the client's culture. The accompanying Respecting Our Differences display lists some commonly used complementary and alternative treatment approaches.

In some cases of mild pain, nonpharmacologic techniques may be the primary intervention, with medication available as a backup. In cases of moderate to severe pain, nonpharmacologic techniques can be an effective adjunctive or complementary treatment.

Cognitive-Behavioral Interventions

An effective approach to pain management combines both pharmacologic and nonpharmacologic methods (Zwakhalen et al., 2006). Cognitive-behavioral interventions are designed to educate clients and to modify clients' attitudes and behaviors. These nonpharmacologic approaches are an important part of the multimodal approach to pain management and can be used in conjunction with appropriate analgesics. A major goal of these interventions is to help the client gain a sense of control over the pain. The effectiveness of selected therapies is outlined in Table 35-7 on page 1066.

DISTRACTION Distraction is a pain management strategy that focuses the client's attention on something other than

the pain and associated negative emotions. Children and adolescents seem to be particularly adept at using distraction. As many parents know, interactive games or listening to music can be powerful distraction techniques for children; they can also be effective for adults experiencing pain.

REFRAMING **Reframing** is a technique that teaches clients to monitor their negative thoughts and replace them with ones that are more positive. Teaching a client to view pain by expressing not "I can't stand this pain, it's never going away" but instead "I've had similar pain before, and it's gotten better" is an example of effective reframing.

RELAXATION TECHNIQUES **Relaxation techniques** (a variety of methods used to decrease anxiety and muscle tension), **imagery** (a strategy that uses mental images to assist with relaxation), and **progressive muscle relaxation** (a strategy in which muscles are alternately tensed and relaxed) are used to achieve both mental and physical relaxation. Physical relaxation leads to reduction of skeletal muscle tension; mental relaxation is used to alleviate anxiety.

BIOFEEDBACK Biofeedback training is another method that may be helpful for the client in pain, especially one who has difficulty relaxing muscles. **Biofeedback** is a process through which individuals learn to influence their physiological responses. Through biofeedback, clients can alter their pain experience.

CUTANEOUS STIMULATION **Counterstimulation** is the term used to identify techniques believed to activate the endogenous opioid and monoamine analgesia systems. These interventions are effective by decreasing swelling through cryotherapy (or cold applications), decreasing stiffness (heat applications), and increasing large-diameter nerve fiber input to block small-diameter pain fiber messages (cold, heat, pressure, vibration, or massage). Therapeutic heat and cold are effective pain management tools; they are readily available and easy to use. Both heat and cold can produce analgesia for pain. Heat therapy increases blood flow, increases tissue metabolism, decreases vasomotor tone, and increases the viscoelasticity of connective tissue, making it particularly effective in easing joint stiffness and pain. The use of heat as therapy should be closely monitored, as it can produce increased inflammation and edema.

Cold therapy exerts many benefits, including the following:

- Alleviates edema by reducing vascular flow
- Counteracts inflammation
- Reduces fever
- Diminishes muscle spasms
- Elevates pain threshold as a result of decreasing the velocity of nerve conduction

Application of cold is inappropriate for clients with cold intolerance, vascular insufficiency, and conditions aggravated by cold (e.g., Raynaud's phenomenon).

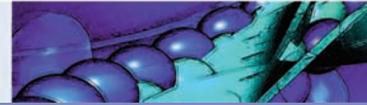

TRANSCUTANEOUS STIMULATION Transcutaneous stimulation is achieved through the use of transcutaneous

RESPECTING OUR DIFFERENCES

Complementary/Alternative Therapy

- Acupuncture or acupressure
- Application of heat or cold
- Focused breathing
- Herbal remedies
- Humor
- Hypnosis
- Imagery
- Massage
- Meditation
- Music
- Progressive muscle relaxation
- Tai chi
- Therapeutic touch
- Yoga

TABLE 35-7 Advantages and Disadvantages of Nonpharmacologic Therapies

INTERVENTION	ADVANTAGES	DISADVANTAGES
Relaxation, imagery, biofeedback, distraction, and reframing	<ul style="list-style-type: none"> • May decrease pain and anxiety without drug-related side effects. • Can be used as adjuvant therapy with most other modalities. • Can increase client's sense of control. • Most are inexpensive, require no special equipment, and are easily administered. 	<ul style="list-style-type: none"> • Client must be motivated to use self-management strategies. • Requires professional time to teach interventions.
Client education	<ul style="list-style-type: none"> • Effective in improving ability to follow medical regimen and in decreasing pain. • Multiple teaching aids available. • Promotes self-care in pain treatment and management of side effects. 	<ul style="list-style-type: none"> • Requires professional time to teach pain management regimens.
Psychotherapy, structured support, and hypnosis	<ul style="list-style-type: none"> • May decrease pain and anxiety for clients who have pain that is difficult to manage. • May increase client's coping skills. 	<ul style="list-style-type: none"> • Requires skilled therapist.
Cutaneous stimulation (superficial heat, cold, and massage)	<ul style="list-style-type: none"> • May reduce pain, inflammation, or muscle spasm. • Can be used as adjuvant therapy with most other modalities. • Relatively easy to use. • Can be administered by clients or families. • Relatively low cost. 	<ul style="list-style-type: none"> • Heat may increase bleeding and edema after acute injury. • Cold is contraindicated for use over ischemic tissues.
Transcutaneous electrical nerve stimulation (TENS)	<ul style="list-style-type: none"> • May provide pain relief without drug-related side effects. • Can be used as adjuvant therapy with most other modalities. • Gives client sense of control over pain. 	<ul style="list-style-type: none"> • Requires skilled therapist to initiate therapy. • Potential risk of infection, bleeding.
Acupuncture	<ul style="list-style-type: none"> • May provide pain relief without side effects. • Can be used as adjuvant therapy with most other modalities. 	<ul style="list-style-type: none"> • Requires skilled therapist.

electrical nerve stimulation, acupuncture, and acupressure. **Transcutaneous electrical nerve stimulation (TENS)** is a method of applying minute amounts of electrical stimulation to large-diameter nerve fibers via electrodes placed on the skin. Placement of the electrodes is determined by identifying which nerve innervates the painful area, then determining where that nerve is superficial, or where an anesthetic block would be placed to numb that nerve. Other modalities of pain management should *not* be abandoned while a trial of

TENS occurs. Although TENS can be successful, there are two major contraindications:

1. No electrodes should be placed in the area over or surrounding demand cardiac pacemakers.
2. No electrodes can be placed over the uterus of a pregnant woman.

Meissner (2009) tested the effectiveness of episodic TENS with clients experiencing postoperative pain.

The study suggests that TENS could be used for postoperative clients whose pain does not respond to conventional therapies or who experience adverse reactions to analgesic medications. Refer to Chapter 40 for an additional discussion of the use of TENS.

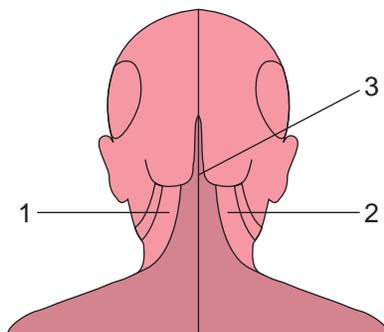

Acupuncture is another counterstimulation technique; it is performed by a specialist and accomplished by insertion of small solid needles into the skin and musculature at specific sites and at various depths. Acupressure accomplishes the same stimulation through cutaneous pressure over the selected site. Acupressure has been used in traditional Chinese medicine (TCM) since the fifth century BC. Firm pressure is applied by the fingers to specific acupuncture points on the body to unblock the *chi* (energy) (see Figure 35-7). When the client seeks acupressure, acupuncture, or TENS treatment, it is important to determine the efficacy of the present treatment regime.

ENCOURAGE EXERCISE Exercise is an important treatment for chronic pain because it strengthens weak muscles, helps mobilize joints, and helps restore balance and coordi-

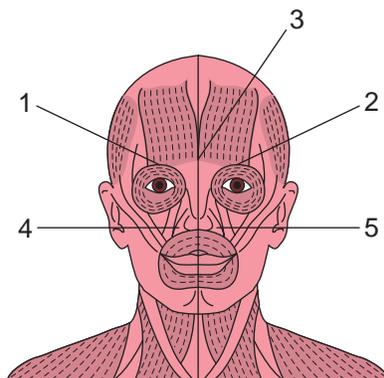

nation. Passive range of motion should not be used if it increases pain or discomfort. Immobilization is frequently used for clients with episodes of acute pain or to stabilize fractures; however, prolonged immobilization should be avoided whenever possible because it can lead to muscle atrophy and cardiovascular deconditioning. Researchers found that mobilization reduced pain, swelling, and stiffness; allowed clients to return to work sooner; and preserved range of joint motion better than rest (Gevirtz, 2008).

NUTRITION Dietary practices may affect pain by inhibiting biochemical events—associated inflammation. Some foods may actually trigger a painful episode, for example, red wine, cheese, citrus fruits, and cured meats often contribute to the onset of migraine headaches.

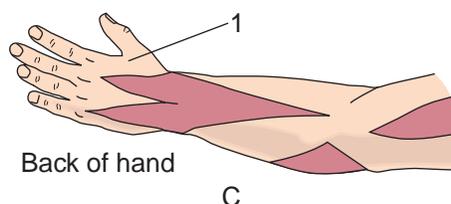

Other foods may help alleviate the pain associated with chronic diseases. For example, cherries and berries with red, blue, or black skins have high amounts of bioflavonoids, substances with anti-inflammatory properties. Table 35-8 on page 1068 lists foods with properties that produce a pain-reducing effect.

TABLE 35-8 Nutrition and Therapeutic Outcomes

NUTRIENTS	THERAPEUTIC EFFECT
Cherries and berries with black or red-blue skins (raspberries, blackberries)	Rich in bioflavonoids (anti-inflammatory substances); used in pain associated with arthritis and gout
Calcium, magnesium, zinc, and vitamins A, B-complex, C, D, and E (found in fruits, vegetables, legumes, whole grains, sunflower seeds, nuts)	Enhances the effects of analgesics
Fatty acid eicosapentaenoic acid (EPA), a component of certain fish oils (found in cold-water fish)	Inhibits formation of substances associated with inflammation
Amino acids (found in whole grains, starchy vegetables, dairy products, turkey)	Produces mild analgesia

Data from Balch, P. (2008). *Prescription for nutritional healing: The A-to-Z guide to supplements*. New York: Penguin; Nix, S. (2008). *Williams' basic nutrition & diet therapy* (12th ed.). St. Louis: Elsevier. Delmar/Cengage Learning

HERBALS Many herbs may be useful in mediating pain; see Table 35-9 on page 1069. Libster (2002) reports that the topical application of capsaicin cream (0.025%) four times a day for 4 weeks reduced trigger-point pain and increased grip strength in a study of 45 clients with fibromyalgia. As noted in the disclaimer in Table 35-9, nurses should instruct clients to consult with their prescribing practitioners before using any of the herbal remedies because of possible drug interactions.

ENVIRONMENT The environment can influence the perception of pain; therefore, changes in one's environment may reduce pain levels. Pet therapy, consisting of interactive sessions between clients and animals, is helpful for some people experiencing chronic pain. Horticultural therapy (treatment that includes looking at, touching, and growing plants) has several therapeutic benefits, including pain reduction, relaxation, and improved energy level. Participation in gardening can provide distraction from chronic pain. Music therapy may help ease pain by producing relaxation and providing distraction; see Chapter 31 for discussion of music therapy.

Many clients experiencing pain receive health care in their homes. The accompanying Community Considerations display on home care pain management offers recommendations for the home health nurse to use with clients experiencing pain.

EVALUATION

When trying to determine if an intervention works for a particular condition, search the literature and use the best evidence. Use a pain intensity rating scale to determine if the interventions are controlling the pain. Evaluating the efficacy of pain management interventions is ongoing, with client input throughout the process. Evaluation focuses primarily on the client's subjective reports.

Critical to the evaluative process is the complete documentation of pain assessment and client outcomes to facilitate regular reassessment and follow-up. Data should be documented regarding the appropriateness and effectiveness of pain management, including the client's comment, pain location, type of pain, intensity or duration of the pain (pain scale), pain behavior, quality of pain, pain patterns, the factors that increase pain, and the degree of relief due to an intervention within a defined time period.

Regular reassessment is an integral part of effective pain management. In addition to client self-report and nursing observation, family input is a valuable source of information for evaluating the effectiveness of care.

COMMUNITY CONSIDERATIONS

Pain Management Concepts in Home Care

- During each visit, evaluate the client's pain.
- Assess factors influencing effective pain management (e.g., motor, cognitive, and functional alterations).
- Teach clients and family members adjunctive therapies to be used with analgesics to decrease pain (i.e., encourage warm baths or compresses)
- Identify barriers that hinder pain control.
- Encourage the homebound client to use around-the-clock dosing of analgesics.

REST AND SLEEP

Rest and sleep are fundamental components of well-being. All individuals require certain periods of calm and lesser activity so that their bodies can regain energy and rebuild stamina. The need for rest and sleep varies with age, devel-

opmental level, health status, activity level, and cultural norms. Pain and impaired sleep are closely related in most people. Sleep disruption and/or deprivation can impair one's ability to think clearly and respond quickly; it can also compromise the cardiovascular and immune systems. Clients can sleep despite pain, especially those who have

been living with pain for a long time and are exhausted (D'Arcy, 2008).

Rest refers to a state of relaxation and calmness, both mental and physical. Activity during rest periods can range from lying down to reading a book to taking a quiet walk. When discussing a client's rest patterns, the nurse should try to understand which activities and environments the client defines as restful.

Sleep refers to a state of altered consciousness during which an individual experiences minimal physical activity and a general slowing of the body's physiological processes. Sleep generally occurs in a periodic cycle and usually lasts for several hours at a time; disruptions in the usual sleep routine can be distressing to clients and will most likely impair sleep further. As a restorative function, sleep is necessary for physiological and psychological healing to occur. It is important

for clients, their significant others, and health care providers to understand the normal sleep-wake cycle and how sleep affects mood and healing.

PHYSIOLOGY OF REST AND SLEEP

The cycles of wakefulness and sleep are controlled by centers in the brain and influenced by routines and environmental factors. An individual's biological clock also helps determine the specific cycles that will be followed for wakefulness and sleep.

Stages of Sleep

Electroencephalograph (EEG) patterns, eye movements, and muscle activity are used to identify stages of sleep. The stages of sleep are classified in two categories: non-rapid eye movement (NREM) and rapid eye movement (REM) sleep.

NURSING CARE PLAN

The Client with Chronic Pain

CASE PRESENTATION

Sally Atkinson, a 48-year-old woman, injured her back 3 years ago while lifting some boxes of paper at work. Since that time, she has had four epidural steroidal injections for the pain associated with two ruptured discs. Her pain has been intermittent, with some alleviation from the epidural injections. Her last epidural was 3 months ago. She arrives at the clinic stating, "I just don't know how I can go on like this. The pain has been tolerable until last night. I'm hurting so bad!" She is tearful and pacing, saying, "It hurts too much when I sit down."

ASSESSMENT

- Verbalization of pain (9 on a 0 to 10 pain intensity scale)
- Anxious (as evidenced by pacing and tears)
- Blood pressure 148/90
- Pulse strong and regular at 92
- Guarded movement
- History of chronic pain

NURSING DIAGNOSIS 1: *Chronic pain* related to muscle spasm and ruptured discs

NOC: Pain control

NIC: Pain management

EXPECTED OUTCOMES

The client will:

1. Practice selected noninvasive pain relief measures.
2. Report uncontrolled symptoms to health care professionals.
3. Have increased ability to perform daily activities as evidenced by walking 1 mile every day and being able to work.

(Continues)

NURSING CARE PLAN (Continued)

INTERVENTIONS/RATIONALES

1. Assess the client's level of pain, determining the intensity at its best and worst. Determines a baseline for future assessment.
2. Listen to the client while she discusses the pain; acknowledge the presence of pain. Acknowledging the client's pain decreases anxiety by communicating acceptance and validating the client's perceptions.
3. Discuss reasons why pain may be increased or decreased. Helps the client determine a cause-and-effect relationship between pain and specific activities.
4. Teach relaxation techniques such as deep breathing, progressive muscle relaxation, and imagery. Reduces skeletal muscle tension and anxiety, which potentiates the perception of pain.
5. Teach the client and family about treatment approaches (biofeedback, hypnosis, massage therapy, physical therapy, acupuncture, and exercise). Makes the client and family aware of the availability of treatment options.
6. Teach the client about the use of medication for pain relief. Provide accurate information to reduce fear of addiction. Lack of knowledge and fear may prohibit client from taking analgesic medications as prescribed.
7. Encourage the client to rest at intervals during the day. Fatigue increases the perception of pain.
8. Explain the relationship between chronic pain and depression. Knowledge decreases anxiety.

EVALUATION

Ms. Atkinson demonstrates the use of deep breathing and progressive muscle relaxation. After practicing relaxation techniques, she rates her pain as a 2 to 3 on the pain intensity scale. Ms. Atkinson is able to walk for 1 mile, but she still has a backache while sitting at her computer for extended periods of time.

NURSING DIAGNOSIS 2: *Anxiety* related to chronic pain

NOC: Anxiety reduction

NIC: Coping

EXPECTED OUTCOMES

The client will:

1. Verbalize an increase in psychological and physiological comfort level.
2. Demonstrate ability to cope with anxiety as evidenced by normal vital signs and a verbalized reduction in pain intensity.

INTERVENTIONS/RATIONALES

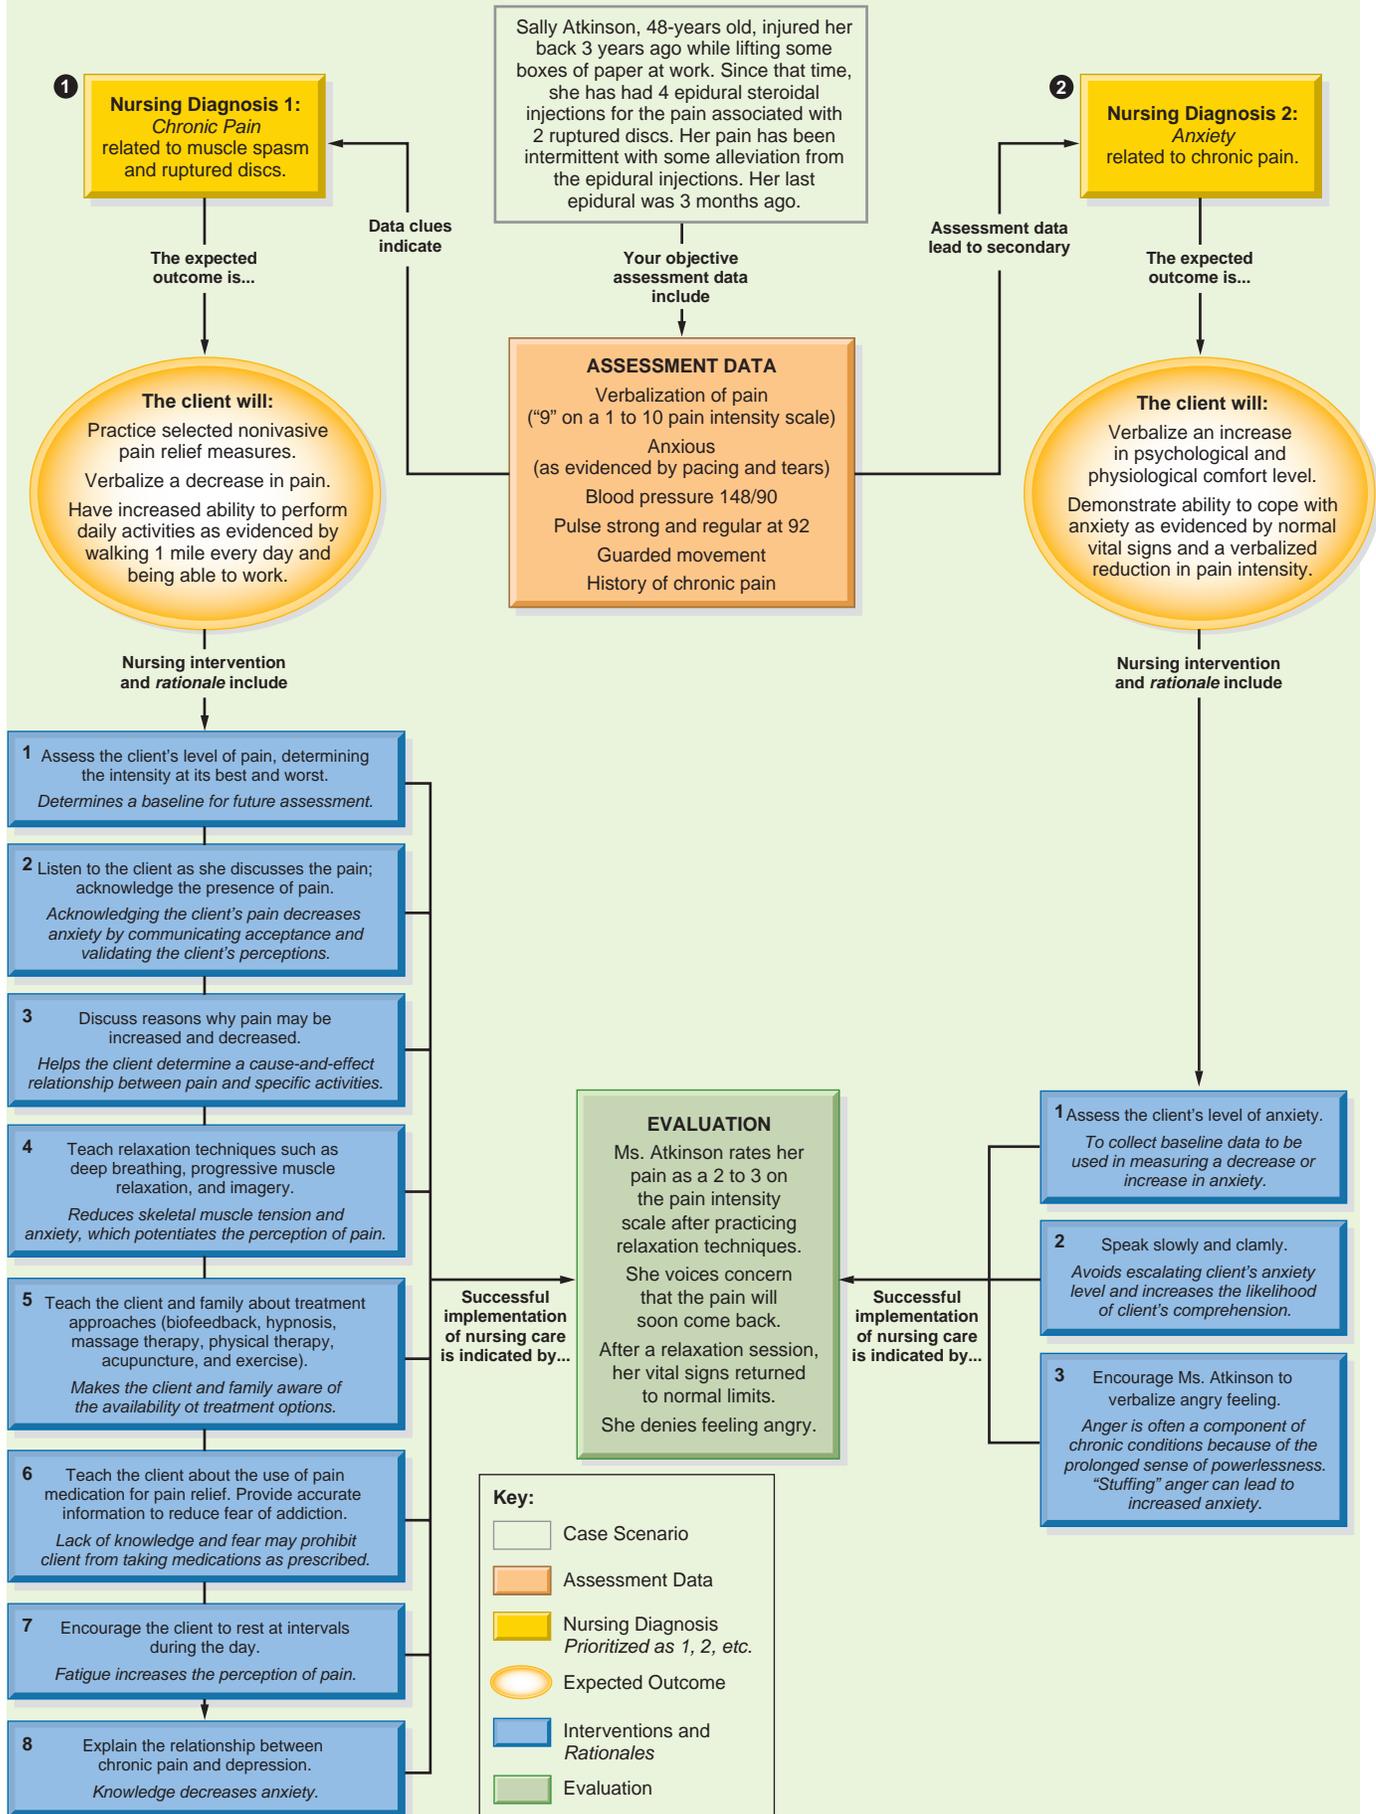

1. Assess the client's level of anxiety. To collect baseline data to be used in measuring a decrease or increase in anxiety level.
2. Speak slowly and calmly. Avoids escalating client's anxiety level and increases the likelihood of client's comprehension.
3. Encourage Ms. Atkinson to verbalize angry feelings. Anger is often a component of chronic conditions because of the prolonged sense of powerlessness. "Stuffing" anger can lead to increased anxiety.

EVALUATION

Ms. Atkinson rates her pain as a 2 to 3 on the pain intensity scale after practicing relaxation techniques. She voices concern that the pain will soon come back. After a relaxation session, her vital signs returned to normal limits. She denies feeling angry.

CONCEPT MAP

THE CLIENT WITH CHRONIC PLAN

NREM SLEEP With the onset of sleep, the heart rate and respiratory rate slow slightly and remain regular. This first phase of sleep is referred to as NREM sleep. NREM sleep consists of four different stages. As the client enters *stage 1 sleep*, there is a general slowing of EEG frequency but an appearance of wave spikes; the eyes tend to roll slowly from side to side, and muscle tension remains absent except in the facial and neck muscles. In adult clients with normal sleep patterns, stage 1 sleep usually lasts only 10 minutes or so. Stage 1 NREM sleep is of a very light quality, which means that during this stage a sleeper can be easily awakened.

Stage 2 sleep is still fairly light sleep, with a further slowing of EEG patterns and loss of slow rolling eye movements. Fifty percent of normal adult sleep may be spent in stage 2. After an initial 20 minutes or so of stage 2 sleep, a deep form of sleep called “stage 3 to 4” is entered.

Stage 3 and stage 4 sleep are frequently discussed together because of the difficulty of identifying and separating the two. Stage 3 refers to medium-depth sleep, and stage 4 signals the deepest sleep. During these stages, all cortical brain cells appear to be firing at the same time, resulting in large slow waves on the EEG. When roused from stage 3 to 4 sleep, an adult can take 15 seconds or so to become fully awake. This difficulty in awakening is even more pronounced in children. Stage 3 to 4 sleep is when most sleepwalking, sleeptalking, enuresis, and night terrors occur.

Stage 3 to 4 sleep is felt to have restorative value, necessary for physical recovery. After sleep deprivation studies, stage 3 to 4 sleep is the first to be regained. The majority of growth hormone is secreted at night, peaking during stage 3 to 4 sleep near the beginning of a sleep period. Growth hormone is required not only for growth but also for normal tissue repair in clients of all ages. Stage 3 to 4 sleep accounts for approximately 25% of sleep in children, declines slightly in young adulthood, and then gradually declines in middle age. It may be absent in older clients.

REM SLEEP After the initial 90 minutes or so of NREM sleep in adults, the client enters REM sleep. The EEG pattern resembles that of the awake state; there are rapid conjugate eye movements; heart rate and respiratory rate are irregular and often higher than when awake; and muscles, including those of the face and neck, are flaccid, leaving the body immobilized. Dreams occur 80% of the time clients are in REM sleep. Unlike stage 3 to 4 sleep, which is most abundant during the early portion of a sleep period, REM sleep periods become longer as the night progresses and the individual becomes more rested. An adult typically has four to six REM sleep periods through the night, accounting for 20% to 25% of sleep. REM sleep makes up 50% of sleep in the newborn, then gradually declines to 20% to 25% of sleep by early childhood. It remains fairly constant throughout the remainder of the life span.

Sleep Cycle

A **sleep cycle** refers to the sequence of sleep that begins with the four stages of NREM sleep in order, with a return

to stage 3, then 2, then passage into the first REM stage (Figure 35-8). The duration of a sleep cycle is generally between 70 and 90 minutes, and the typical sleeper will pass through four to six sleep cycles during an average sleep period of 7 to 8 hours.

The length of the NREM and REM periods of sleep will change as the overall sleep period progresses and the person becomes more relaxed and re-energized. There is less need for stage 3 to 4 sleep and more need for REM sleep as the sleep period progresses, and dreams during the REM phases of later sleep may become more vivid and intense. If the sleep cycle is broken at any point, a new sleep cycle will start, beginning again at stage 1 of NREM sleep and progressing through all of the stages to REM sleep.

BIOLOGICAL CLOCK

The **biological clock** (an endogenous mechanism that measures time) controls the daily fluctuations in hundreds of physiological processes, including body temperature, respiratory rate, performance, alertness, and hormone levels.

Chronobiology is a relatively new branch of science that studies these rhythms that are controlled by our biological clocks. The most widely studied are the **circadian rhythms**, or those that cycle on a daily basis. Other biological rhythms include:

- Ultradian—those much shorter than a day
- Infradian—those lasting a month or more
- Circannual—those requiring about 1 year to complete the cycle

When external time cues such as day-night, sleep-wake, and mealtimes are inconsistent, a desynchronization, or mismatching, of the circadian biological rhythms occurs. This

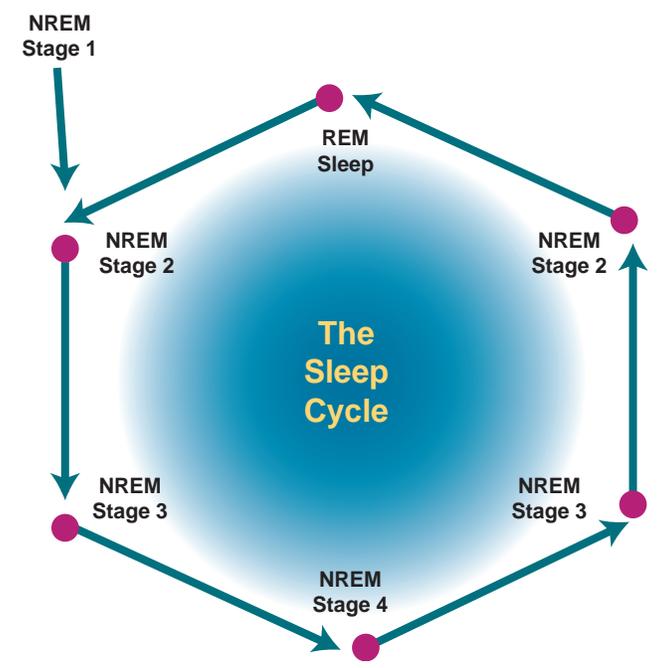

FIGURE 35-8 The Sleep Cycle DELMAR/CENGAGE LEARNING

internal desynchronization disrupts the timing of physiological and behavioral activity, which in turn causes chronic fatigue, disrupts sleep patterns, and causes decreased performance and coping abilities. An example of desynchronization is that of the newborn, whose biological rhythms are not established until 3 to 4 months of age. At this point, infants will start to develop longer sleep periods at night and become more predictable in their waking and sleeping patterns.

FACTORS AFFECTING REST AND SLEEP

Several factors can influence the quality and quantity of both sleep and rest. Often, sleep problems result from a combination of many factors.

Degree of Comfort

Comfort is a highly subjective experience. The nurse must assess the degree to which the client's physical and psychological needs have been met. Whenever basic needs are unmet, the person experiences discomfort, which leads to physiological tension, resultant anxiety, and potential impairments in sleep and rest.

Anxiety

A restless body and mind interfere with the ability to sleep. When trying to go to sleep, many individuals often have intrusive thoughts or muscular tension that will interfere with rest and sleep. Anxiety related to work pressures, family demands, and other stressors does not automatically cease when an individual attempts to go to sleep. Anxiety often results in difficulty falling asleep or staying asleep.

Environment

Environmental factors can either enhance or impair sleep. Lighting, temperature, odors, ventilation, and noise level can all interrupt the sleep process when they differ from the norms of the client's usual sleep environment.

Lifestyle

A fast-paced life filled with multiple stressors can result in a person's inability to relax easily or to fall asleep quickly. Relaxation precedes healthy sleep.

Another lifestyle factor that interferes with sleep is having a work schedule that does not coincide with an individual's biological clock (e.g., working at times other than the day shift). Individuals who frequently change work shifts have a real challenge trying to stabilize biological rhythms and rest comfortably.

Diet

The type of food consumed has an impact on the quality and quantity of sleep. Foods high in caffeine, such as coffee, cola, and chocolate, serve as stimulants and often disrupt the normal sleep cycle. Also, consuming a large, heavy, or spicy meal just before bedtime may cause indigestion, which will likely interfere with sleep. Conversely, going to bed when hungry

can also result in sleep problems because the individual may be preoccupied with food and hunger pangs instead of concentrating on sleep.

Drugs and Other Substances

Alcohol and nicotine use can impair sleep. Small amounts of alcohol may help some people fall asleep; however, in others alcohol may interfere with REM sleep, causing very restless and nonrefreshing sleep. Nicotine, which is a stimulant, can also impair the sleep cycle by stimulating the body, resulting in difficulty falling and staying asleep. Many medications (both prescription and over the counter) cause fatigue, sleepiness, restlessness, agitation, or insomnia, thus affecting the quality and quantity of rest and sleep.

Cultural Norms

Cultural and societal expectations also affect sleep. Some people perceive sleep as a luxury to be indulged in when they are not too busy with "important" activities. Others view sleep as an absolute necessity. The amount of sleep that a person considers necessary is partially determined by familial and cultural attitudes. See the Respecting Our Differences display.

Life Span Considerations

A person's need for sleep changes with age in a fairly predictable pattern. Although sleep and rest patterns are closely tied to lifestyle and other variables, there are some common variations:

- The *neonate* (birth to 1 month) sleeps in 3- to 4-hour intervals for a total of about 16 to 20 hours a day. The newborn usually is very passive, with little activity during sleep ("sleeping like a baby"), and typically sleeps very soundly. For the first few days or weeks of life, a baby's biological clock is not attuned to regular day-night patterns, so there is often no difference in sleep patterns between day and night.
- The *infant* averages about 12 to 16 hours of sleep a day. As the infant ages, the amount of sleep needed decreases. At approximately 2 months of age, infants can begin to sleep through the night and will typically nap two or three times during the day.

Cultural Norms and Sleep

Which of the two descriptions of sleep (a luxury or a necessity) do you think is most congruent with our society? Which view is closest to your own? Which approach would you take when discussing the rest and sleep needs of a client whose philosophy and views about sleep are in direct contrast to your own?

- During *toddlerhood* the daily average amount of sleep is 12 to 14 hours, which is usually broken down into 10 to 12 hours at night with one or two daytime naps. During this stage, bedtime rituals often develop and assume great importance in providing nighttime security. Repeated and predictable nighttime routines such as baths, brushing teeth, and reading books are helpful in establishing expectations and comfort.
- The *preschool child* sleeps approximately 10 to 12 hours a day. Daytime napping decreases or ceases, unless cultural norms dictate otherwise. Night sleep is often filled with vivid dreams and nightmares that will often awaken children several times during the night.
- A *school-age child* also averages about 10 to 12 hours of sleep daily. Resistance to bedtime and struggles for independence are hallmarks of the school-age child. During this time, the child may develop fear of the dark and will need reassurance and methods to handle this fear.
- *Adolescents* sleep about 8 to 10 hours a day and often decide their bedtime routines and hours. High activity levels often interfere with regular sleep patterns, and irregular sleeping habits often become the norm at this stage.
- The *young adult* averages about 8 hours of sleep a day. During this stage, sleep is often interrupted by young children in the home or work responsibilities. Lifestyle patterns cause many young adults to experience difficulties falling or staying asleep.
- The *middle-age adult* sleeps about 6 to 8 hours a day. Daily stressors may continue to result in insomnia, and the use of sleep-inducing medications is common.
- The sleep requirements for the *older adult* decrease to 5 to 7 hours a day and often include a daytime nap. The quality of sleep often diminishes due to frequent waking, physical pain, and shortened REM sleep. Many older adults misinterpret this decreased need for sleep as insomnia and are thus unduly concerned about not getting “enough” sleep.

ILLNESS OR HOSPITALIZATION

The stress imposed by illness usually disrupts sleep. Sleep is especially disrupted when a person is hospitalized. Some factors associated with hospitalization that lead to sleep impairment include:

- Physical or emotional pain
- Loss of familiar surroundings
- Loss of routine
- Fear of the unknown
- Timing of procedures and treatments
- Noise level (especially unfamiliar noises)
- Loss of privacy

ALTERATION IN SLEEP PATTERNS

Sleep disturbances can take many forms and are quite common. Alterations in sleep patterns are generally viewed as either primary sleep disorders (those in which the sleep

alteration is the fundamental problem) or secondary sleep disorders (those in which the alteration has a medical or clinical cause that results in or contributes to the sleep alteration). The most common sleep alterations include insomnia, hypersomnia or narcolepsy, sleep apnea, sleep deprivation, and parasomnias. Problems associated with sleep disturbances are as follows:

- Decreased work productivity (more missed days of work)
- Increased utilization of health care services
- Greater risk of accidents
- Short-term memory problems
- Cognitive and motor performance impairments

Insomnia

Insomnia refers to the chronic inability to sleep or inadequate quality of sleep due to sleep that prematurely ends or is interrupted by periods of wakefulness. Insomnia is *not* a disease, but it may be a manifestation of many illnesses. The person experiencing insomnia often gets caught up in a vicious cycle of not being able to sleep, trying harder to fall asleep, and increasing anxiety about not sleeping, which in turn increases the inability to fall asleep. Perception of sleep quantity can also be important; many insomniacs actually sleep significantly more than they think they do, so there is a discrepancy between perception and reality.

Sleep disturbances are common for individuals experiencing chronic pain. Sleep impairment can exacerbate pain; thus, a vicious cycle is established. The consequences of poor, nonrestorative sleep during the wake time may include change in physical activity, headaches or pain, GI malfunctions, and fibromyalgia. Treatment for insomnia is best directed at modifying those factors or behaviors that are causing it. It is impossible to force sleep.

Hypersomnia or Narcolepsy

Hypersomnia is an alteration in sleep pattern characterized by excessive sleep, especially in the daytime. Persons suffering from hypersomnia often feel that they cannot get enough sleep at night; therefore, they sleep very late into the morning and nap several times throughout the day. Causes of hypersomnia can be physical or psychological; treatment depends on addressing the underlying cause.

Narcolepsy, another sleep alteration, manifests as sudden uncontrollable urges to fall asleep during the daytime. Individuals suffering from narcolepsy often achieve adequate sleep at night but are overwhelmed by sleepiness at unexpected and unpredictable periods during the day. Effective treatments for narcolepsy include avoiding substances or activities that cause sleepiness, taking short daytime naps, or taking prescribed stimulant medications.

Sleep Apnea

Sleep apnea refers to periods of sleep during which airflow stops for 10 seconds or more. Sleep apnea gives rise to complications as a result of oxygen desaturation and carbon dioxide retention. Short-term consequences may include cognitive

impairment (including memory changes), personality changes, and impotence. A major problem is daytime sleepiness, which may interfere with functional abilities such as driving and working. If untreated, sleep apnea may contribute to the development of the following cardiovascular disorders: hypertension, coronary heart disease, and heart failure.

The first line of defense against apnea is treating its cause (emotional, cardiac, or respiratory alteration). Use of a nasal continuous positive airway pressure (CPAP) device may also give relief. With some individuals, surgical intervention is required to correct the cause of the apnea.

Sleep Deprivation

Sleep deprivation is a term used to describe prolonged inadequate quality and quantity of sleep, either of the REM or the NREM type. Sleep deprivation can result from age, prolonged hospitalization, drug and substance use, illness, and frequent changes in lifestyle patterns. Sleep and dreaming have a restorative value necessary for mental and emotional recovery and enhance the ability to cope with emotional problems. Therefore, sleep deprivation can cause symptoms ranging from irritability, hypersensitivity, and confusion to apathy, sleepiness, and diminished reflexes. Treating or minimizing the factors that cause the sleep deprivation is the most effective resolution.

Parasomnia

Parasomnia refers to sleep alterations resulting from “an activation of physiological systems at inappropriate times during the sleep-wake cycle” (American Psychiatric Association, 2000, p. 630). **Somnambulism** (sleepwalking), sleep-talking, bedwetting, and **bruxism** (teeth grinding) are the most common parasomnias. Treatment for parasomnias varies, and care should be focused on helping the client and family understand the disorder and its potential safety risks.

ASSESSMENT

Discussion of sleep and activity patterns is included as part of the regular health history. Any client acknowledging a sleep disturbance should be thoroughly assessed to determine sleep routines, sleep alterations, type of disturbances, and impact of sleep problems. Typically the client is a reliable source for this information, but a spouse or partner who shares sleeping arrangements may be able to add valuable information to the client’s report. Questions regarding the client’s usual sleep patterns should include:

1. Nature of sleep (restful, uninterrupted)
2. Quality of sleep (usual sleep pattern, schedules, hours of sleep, feeling upon awakening)
3. Sleep environment (description of room, temperature, noise level)
4. Associated factors (bedtime routines, use of sleep medications or any other sleep inducers)
5. Opinion of sleep (adequate, restores energy adequately, inadequate, problematic)

Questions regarding altered sleep patterns are intended to reveal such information as:

1. Nature of the problem (inability to fall asleep, difficulty remaining asleep, inability to fall asleep after awakening, restless sleep, daytime sleepiness)
2. Quality of the problem (number of hours of sleep versus number of hours spent trying to sleep, number of hours of sleep a night, duration and frequency of naps or other compensatory measures, number of wakings per sleep period)
3. Environmental factors (lighting, bed, noise level, surrounding stimulation, sleep partner)
4. Associated factors (relation to meals eaten, activity before retiring, life and work stressors, anxiety level, pain, recent illness or surgery)
5. Alleviating factors (mild diet, warm drink before retiring, reading a book, listening to quiet music, taking a hot bath, taking sleeping pills)
6. Effect of problem (fatigue, irritability, confusion)

For clients whose sleep problems do not seem to be well defined, a daily journal of sleep patterns may prove useful. This written account can mirror the preceding outline.

NURSING DIAGNOSIS

After information about the sleep impairment has been collected, data need to be analyzed to formulate appropriate nursing diagnoses. The primary diagnosis for individuals experiencing sleep problems is *insomnia*. According to Carpenito-Moyet (2008), insomnia is defined as “a state in which a person experiences a change in the quantity or quality of his rest pattern that causes discomfort or interferes with desired lifestyle” (p. 387). Alterations in sleep can manifest through verbal complaints of the client, physical signs such as yawning or dark circles under the eyes, or alterations in mood such as apathy or irritability.

If the client presents with problems in addition to the sleep disturbance, the nurse must be alert to the possibility that the sleep disturbance is the *cause* (not the effect) of another problem. For example, a client may be experiencing *activity intolerance* related to lack of sleep as evidenced by verbal complaint, extreme fatigue, disorientation, confusion, and lack of energy.

PLANNING AND OUTCOMES

The plan of care for the sleep-disordered client must be individualized. For the nursing care to be effective, client input should be incorporated when developing expected outcomes. It is important to tailor the outcomes and plan of care to the true cause related to the sleep disturbance or alteration. For example, if the client is experiencing *insomnia* because of bedwetting, then the bedwetting should be targeted for intervention.

Effective outcome identification and planning must consider the fact that many sleep disturbances will require extended periods of time (weeks or months) to correct.

Sleep patterns are by nature habitual and intertwined with lifestyle patterns, and these types of disturbances typically require interventions that have long-term goals. When planning care, the nurse should remember to perform procedures and treatments in a manner that disturbs sleep time and routines as little as possible.

IMPLEMENTATION

Several interventions can promote rest and sleep in clients. The interventions range from simple (e.g., correct bed-making techniques) to complex (teaching clients about necessary lifestyle modifications). The NIC system defines nursing actions that facilitate regular sleep and wake cycles (see the accompanying display on sleep enhancement activities). Several interventions that facilitate sleep are discussed here.

Establish a Trusting Nurse-Client Relationship

The quality of the nurse-client relationship can enhance a client's ability to rest and sleep. Knowing that the nurse is a trustworthy individual allows the client to relax and feel secure. The Nursing Checklist on page 1078 provides guidelines for communicating with the sleep-impaired client. Anxiety can be decreased by the nurse's use of therapeutic communication skills. The *therapeutic use of self* helps allay client anxiety.

Create a Relaxing Environment

Arranging the immediate surroundings to promote sleep is important for the sleep-impaired client. A place to sleep should be inviting. Determine the type of environment the client finds relaxing, then provide this environment in the inpatient setting, or help the client establish this type of environment in the home setting. See the Community Considerations display on page 1078.

Initiate Relaxation Techniques

The client's mood before sleep is of utmost importance. The *belief* that one can—and will—sleep greatly affects sleep quality and quantity. The client who is calm and relaxed is likely to fall asleep quickly and stay asleep all night. Relaxation techniques are useful sleep aids. Progressive muscle relaxation is especially therapeutic for the person who needs to lessen muscular tension and quiet the mind. A recent study (Kim & Sok, 2007) showed a positive response to auricular acupuncture for improving quality of sleep.

See the Respecting Our Differences display on page 1078 for a listing of herbal remedies used in some cultures to promote sleep.

Ensure Appropriate Nutrition

Certain foods can actually enhance sleep. Tryptophan, a substance in milk, promotes sleep by stimulating the brain's production of the neurotransmitter serotonin. The old wives'

NIC SLEEP ENHANCEMENT ACTIVITIES

- Determine the effects of the client's medications on sleep pattern, and adjust medication administration schedule to support client's sleep and wake cycles.
- Monitor and record client's sleep pattern and number of hours of sleep, and note physical (e.g., sleep apnea obstructed airway, pain and discomfort, and urinary frequency) and/or psychological (e.g., fear or anxiety) circumstances that interrupt sleep.
- Adjust environment (e.g., light, noise, temperature, mattress, and bed) to promote sleep.
- Facilitate maintenance of client's usual bedtime routines, presleep cues and props, and familiar objects (e.g., for children, a favorite blanket or toy, rocking, pacifier, or story; for adults, a book to read) as appropriate.
- Assist to eliminate stressful situations before bedtime, and instruct client to avoid bedtime foods and beverages that interfere with sleep.
- Instruct client how to perform autogenic muscle relaxation, and discuss other nonpharmacological forms of sleep inducement, such as massage, positioning, and touch.
- Instruct the client and significant others about factors (e.g., physiological, psychological, lifestyle, frequent work shift changes, rapid time zone changes, excessively long work hours, and other environmental factors) that contribute to sleep pattern disturbances.
- Provide pamphlet with information about sleep enhancement techniques.

Bulechek, G., Butcher, H., & Dochterman, J. (2008). *Nursing interventions classification (NIC)* (5th ed.). St. Louis, MO: Mosby Elsevier Health Sciences.

tale that drinking warm milk promotes sleep is supported by scientific data. Other dietary considerations include avoiding large or heavy meals close to bedtime, refraining from eating spicy or other foods that cause GI distress, and avoiding caffeine after noon.

Initiate Pharmacologic Interventions

If unrelieved pain is a factor in the client's sleep disturbance, then pain management should be the focus of initial interventions. Many of the nonpharmacologic relaxation and imagery interventions can be effective in clients with sleep disturbances.

Pharmacologic agents that may be therapeutic for clients with sleep disturbances include tricyclic antidepressants, antihistamines, and short-acting hypnotics. The tricyclic

**NURSING CHECKLIST****Communicating with the Sleep-Impaired Client**

- Thoroughly explain procedures before implementation.
- Encourage client and significant others to verbalize feelings and ask questions.
- Answer questions honestly and completely.
- Identify and support coping mechanisms of client and family.
- Spend adequate time with client to facilitate communication.
- Ascertain and incorporate client preferences as much as possible into plan of care.

**COMMUNITY CONSIDERATIONS****Relaxing Environment**

Observe a client care area. Which environmental factors encourage sleep? Which factors interfere with sleep? If you were to design the ideal client care environment, how would you address these variables?

- Colors
- Fabrics
- Lighting
- Noises
- Temperature
- Odors

**RESPECTING OUR DIFFERENCES****Complementary and Alternative Modalities That Promote Sleep**

- Massage
- Imagery
- Meditation
- Herbal: chamomile, hops, lavender, kava, passion flower, skullcap, valerian
- Aromatherapy: chamomile oil, lavender oil

antidepressants of choice are amitriptyline (Elavil) or doxepin (Sinequan). Amitriptyline improves the client's ability to fall asleep and stay asleep by causing sedation when given 1 to 3 hours before bedtime. Doses of amitriptyline for sleep disturbances are significantly lower than doses for treatment of depression, starting at 10 to 25 mg at bedtime and titrating up by 10 to 25 mg every 2 or 3 days until therapeutic effect is achieved.

Antihistamines such as hydroxyzine (Vistaril, Atarax) and diphenhydramine (Benadryl) have mild sedative effects that could promote sleep if given at bedtime. If anxiety throughout the day is of concern, low doses of these medications at regular intervals throughout the day may be effective.

The final group of pharmacologic interventions for sleep disturbances is the short-acting hypnotics. These medications are *not* recommended for routine or long-term use, but they may be effective for short-term intervention. When they are chosen, it is recommended that one with a short half-life be used.

Provide Client Education

Educating clients about sleep-promoting activities is a good investment of the nurse's time. By empowering clients to help themselves relax, the nurse helps them gain a sense of control over their sleep disturbance and boosts their confidence so that they can successfully meet their sleep and rest needs. See the Client Teaching Checklist for managing sleep disturbances.

**CLIENT TEACHING CHECKLIST****Managing Sleep Disturbance**

To facilitate rest and sleep, the client should be encouraged to:

- Avoid stimulating activities such as strenuous exercise or demanding intellectual activity during the hour before bedtime. Use the time instead to wind down with relaxing activities such as taking a warm bath, reading a book, or sitting by the fire.
- Use bedtime rituals on a consistent basis.
- Practice relaxation techniques such as neck rolls and muscle relaxation to release tensions before going to bed.
- Refrain from watching television, studying, or talking on the phone while lying in bed; use the bed for sleeping only.
- Follow dietary guidelines to avoid caffeine, spicy foods, and heavy meals several hours before bedtime.

NURSING CARE PLAN

The Client Experiencing Altered Sleep Patterns

CASE PRESENTATION

Jacques Porcheron, 6 years old, is brought to your clinic by his father, who states that Jacques has trouble sleeping at night. In the evenings after a dinner of hot dogs, corn or baked beans, and chocolate milk, Jacques reads some books, then watches his favorite superhero video. Afterward, he runs and plays, mimics the actions he sees in the video, and refuses to take a bath or cooperate when getting dressed for bed. Once put to bed at 9:00 p.m., he is up several times for any number of reasons and often is not asleep until midnight. When his father wakes him at 7:00 a.m. for school, Jacques is disagreeable, tired, and difficult to get moving.

ASSESSMENT

Client is experiencing:

- Inability to fall asleep
- Inability to remain asleep
- Inconsistent bedtime rituals that interfere with calm time needed before retiring

NURSING DIAGNOSIS: *Insomnia* related to lack of sleep and disruption in lifestyle as evidenced by parental complaint, ineffective bedtime rituals, and insufficient hours of sleep for developmental age.

NOC: Sleep

NIC: Sleep enhancement

EXPECTED OUTCOMES

The client will:

1. Identify behaviors that are helpful before bedtime.
2. Develop appropriate bedtime rituals to help Jacques wind down from the day.
3. Ensure that Jacques gets 10 to 12 hours of sleep a night.

INTERVENTIONS/RATIONALES

1. Determine from the father and child which sleeping behaviors they would like to achieve. Asking for client input in the desired outcomes will make the plan of care more effective and realistic.
2. Teach family members about effect certain foods can have on digestion and sleep habits, and list with them foods that are good choices for dinners. Educating family members about the potential adverse effects of certain foods will help them plan meals more appropriately.
3. Help client understand which bedtime activities can be detrimental to sleep induction. Understanding which behaviors can interfere with falling asleep will help client and family identify and therefore modify prebedtime behaviors.
4. Explain why overstimulation close to bedtime, such as watching superhero movies and engaging in rowdy play, will prevent the body and mind from slowing down and preparing for sleep. Understanding the psychological and physical implications of overstimulation before bedtime will help clients choose more appropriate bedtime activities.
5. Emphasize the importance of establishing a calming bedtime routine that is followed every night, especially for the school-age child. Children Jacques's age are helped by ritual and knowing what is expected of them, and they need guidance in practicing routines that are appropriate for bedtime.
6. Suggest appropriate bedtime rituals, such as taking a bath, brushing the teeth, reading a book, or listening to calming music. Focusing on quiet activities and routine will help the body and mind prepare for bedtime.
7. Help the family ensure an appropriate sleep environment for Jacques, such as a calm room at a comfortable temperature, lit only by a night light. Promotes sleep and does not interfere with falling back asleep once awake.

(Continues)

NURSING CARE PLAN (Continued)

8. Encourage the family through the preceding steps to work toward having Jacques get at least 10 to 12 hours of sleep a day, which is the normal requirement for a child his age. Helping family members understand which factors may be interfering with Jacques' sleep habits, such as excessive daytime napping or repetitive waking during the night, and also ensuring that they understand his sleep requirements will help them be more effective in their management of his bedtime and sleeping habits.

EVALUATION

After 2 weeks, the father reports that Jacques eats the same type of meals but is no longer allowed to watch stimulating videos after 7:00 p.m. Together they have established bedtime rituals that begin with quiet tablework (reading, arts and crafts, writing) or talks about the day, followed by a warm bath and reading three books together in the recliner in the living room. After this, they put on pajamas and brush teeth, and then Jacques goes up to bed by himself. The father would like to modify Jacques's diet somewhat and is planning this as his goal for the next 2 weeks.

EVALUATION

The plan of care must be individualized for and negotiated with the client. It must be updated on a regular schedule and additional interventions initiated as needed. One of the strongest supportive activities nurses can perform is to make sure clients understand that there is help for sleep problems and that they are not alone in having difficulty successfully managing their sleep patterns. The Nursing Process Highlight lists variables to be considered when evaluating the care of the sleep-disturbed client.

NURSING PROCESS HIGHLIGHT

Evaluation

When evaluating the care of the sleep-disordered client, consider the following variables:

- The client's basic needs were met.
- Client education included the family or significant others.
- An environment conducive to rest was maintained.
- Therapeutic activities were balanced with the client's need for rest and sleep.
- The client's bedtime rituals were followed as closely as possible.
- Anxiety reduction techniques were used appropriately.

PROCEDURE 35-1

Administering Patient-Controlled Analgesia (PCA)

EQUIPMENT

- A patent indwelling subcutaneous (SC), intravenous (IV), or epidural line installed as the prescribed route of administration.
- A PCA pump with manufacturer's instruction guide for operation: PCA pumps usually consist of a programmable infusion pump with syringe inside, a button linked to a timing unit that is activated by the client when demanded, and a tube that can be connected to an indwelling catheter (e.g., IV line).
- Pain medication as ordered by the health care provider
- Label for drug identification
- Adhesive tape
- Disposable gloves
- Naloxone solution (0.4 mg in 10 mL of saline) if giving opioid agonists (e.g., morphine)

(Continues)

PROCEDURE 35-1 Administering Patient-Controlled Analgesia (PCA) (Continued)

ACTION	RATIONALE
<ol style="list-style-type: none"> 1. Wash hands/hand hygiene. 2. Assess the client's comfort level: pain location, intensity, characteristics, pattern, and factors that increase or decrease the pain. 3. Assess the client's consciousness level and ability to understand the instruction. 4. Check the PCA (see Figure 35-9) order for drug, concentration, route, basal infusion rate, bolus dose, lockout interval, maximum dose, and any loading dose. 5. Check the PCA medication label against the prescribing practitioner's order, and follow the "five rights" principle. PCA medication usually has been placed in the PCA syringe at the pharmacy. Have a second nurse sign when therapy is initiated and with all dosing changes. 6. Read the manufacturer's instruction guide before assembling and programming the PCA pump. 7. Place the filled PCA syringe into the chamber in the PCA pump, and detect any leaking or damage to the system (see Figure 35-10 and Figures 35-11 and 35-12 on page 1082). 8. Program the pump according to the prescribed parameters, usually including basal infusion rate (mg/h), bolus dose (mg), lockout interval (min), and maximum dose limit (mg/h) (see Figure 35-13 on page 1082). 	<ol style="list-style-type: none"> 1. Prevents the spread of microorganisms. 2. Identifies pain problem, purpose of pain therapy, and other adjuvant therapies. Establishes baseline to measure improvement. 3. PCA is contraindicated for sedated and confused clients. 4. Opioid administration requires a prescribing practitioner's order. Dosing parameters are necessary for programming a PCA pump. 5. Minimizes medication error and harm to client. 6. Different manufacturers or models may require different operation. Follow the manufacturer's instructions to ensure proper operation of the pump. 7. Assemble PCA pump and inspect for damage of the system to avoid medication error and harm to client. 8. Avoids overmedication and ensures accuracy of the medication given.

delegation tip

The skill of medication administration is not delegated to ancillary personnel in acute care settings. This may vary in state or federal institutions. Ancillary personnel are generally informed about the medications the client is receiving if adverse effects are anticipated or are being monitored.

nursing tips

- Periodically assess pain intensity, pain relief, and side effects.
- Remember, if the medication is discontinued, any narcotic left in the pump must be wasted. Another nurse must witness the wasting procedure, and the amount, reason, time, and date of the wasting must be documented.
- Program the PCA pump with the actual dose; input the drug concentration so that the pump can calculate the volume needed to deliver the dose. The programmed concentration should match what is in the bag or syringe. For example, the client is to receive 1 mg of morphine with each demanded dose from the PCA pump. If the concentration is programmed as 0.1 mg/mL, the pump must deliver 10 mL of solution to achieve the 1 mg dose.

KEY CONCEPTS

- Pain is a subjective and an individualized experience.
- Pain is defined as whatever the client says it is.
- Pain is increased by anxiety and fatigue.
- Several factors influence the perception of pain, including developmental level, culture, and previous experience.
- The amount of sleep required differs according to developmental stage.
- Nonpharmacologic interventions may be used in managing pain and promoting rest and sleep.
- Pharmacologic agents can be therapeutic for clients experiencing pain or sleep pattern disturbances. However, the medications should not be the only interventions used.

REVIEW QUESTIONS

1. Which of the following is the best way for a nurse to assess for pain in a communicative client?
 - a. Note the frequency of pain medication administration.
 - b. Observe for changes in the client's vital signs.
 - c. Ask the client.
 - d. Assess the client's level of anxiety.
2. Which statement regarding IM injections of analgesia is true?
 - a. It is the gold standard for relieving acute pain.
 - b. It is discouraged in current practice.
 - c. It provides for consistent medication absorption.
 - d. It rarely causes damage to muscle tissue.
3. Which statement regarding pain and sleep is most correct?
 - a. A client may sleep despite being in pain.
 - b. A sleeping client is resting comfortably.
 - c. The brain shuts down during sleep, and the client does not feel pain.
 - d. Clients in pain are not able to fall asleep.
4. Which statement best describes clients with chronic pain?
 - a. They become chronic complainers.
 - b. They often experience depression.
 - c. They rarely become suicide risks.
 - d. They have a very high incidence of addiction.
5. The nurse is preparing to teach a class to a group of new graduate nurses on substance use disorders. Which statement should the nurse include in the class?
 - a. A client with a substance dependence must take the same drug to relieve withdrawal symptoms.
 - b. Substance abuse is both a physical and psychological disorder.
 - c. A client who is motivated and has a substance dependence can overcome the addiction by stopping the substance.
 - d. A substance must be abused over a long period of time before an addiction develops.
6. Which actions are required to ensure safe use of PCAs? Select all that apply.
 - a. Standard order sets are required.
 - b. Two nurses must sign when therapy is initiated and with all dosing orders.
 - c. PCA solutions and concentrations are standardized.
 - d. Competency of all nurses who use PCA in their practice must be documented annually.
 - e. A second nurse must witness the wasting of any narcotic left in the pump.
 - f. Nurses can activate PCA.
7. When is it appropriate to administer a placebo for pain?
 - a. Never
 - b. When the prescribing practitioner orders a placebo
 - c. When the client is a substance addict and the nurse needs to assess the client's "real" pain
 - d. When the client is participating in research and has given informed consent
8. Which factors can impair sleep and rest? Select all that apply.
 - a. Discomfort
 - b. Anxiety
 - c. Noise level
 - d. A change in one's normal bedtime
 - e. Decaffeinated foods and beverages
 - f. Alcohol and nicotine

—ANCIENT PROVERB IN TRADITIONAL CHINESE MEDICINE

CHAPTER 36

Mobility

COMPETENCIES

1. Explain the physiology of mobility.
2. Identify factors affecting mobility.
3. Identify health problems related to immobility.
4. Describe the process of activity and mobility assessment.
5. Discuss nursing diagnoses relevant to clients experiencing mobility impairments.
6. Develop client expected outcomes related to activity and mobility in terms of lifestyle, age, and health promotion.
7. Develop specific nursing interventions that promote mobility and prevent complications due to immobility.
8. Discuss evaluation of client activity and mobility status.

KEY TERMS

abduction	flexion	myoneural junction
active range of motion	functional assessment	opposition
adduction	gait belt	orthostatic hypotension
ambulation	hypertrophy	passive range of motion
atrophy	hypotonicity	proprioception
balance	incontinence	range of motion
base of support	kyphosis	skin shear
body alignment	line of gravity	spasticity
body mechanics	logrolling	thrombi
contracture	mobility	
extension	muscle tone	

Movement is an activity most people take for granted. The ability to move and be active improves health status, whereas immobility presents a threat to one's physical, mental, and social well-being. This chapter explores nursing responses to individuals with impaired ability to move.

OVERVIEW OF MOBILITY

Mobility refers to the ability to engage in activity and unrestricted movement that includes walking, running, sitting, standing, lifting, pushing, pulling, and performing activities of daily living (ADL). Mobility is often considered an indicator of health status because it influences the correct functioning of many body systems, especially the respiratory, gastrointestinal, and urinary systems. Mobility enhances muscle tone, increases energy level, and is associated with psychological benefits such as independence and freedom.

BODY ALIGNMENT

Body alignment refers to the position of body parts in relation to each other. Proper body alignment results in **balance**, which is an individual's ability to maintain postural equilibrium. When the body is in correct posture, the center of gravity (the center point of an object's mass) is evenly distributed over the foundation points. Correct posture promotes balance, reduces strain and injury to support structures, facilitates respiratory effort, enhances gastrointestinal processes, and gives an appearance of confidence and health. A correct postural stance is maintained by a well-functioning musculoskeletal system. The normal alignment of the spine has a cervical concavity, a thoracic convexity, and a lumbar concavity; see Figure 36-1 on page 1089.

Proper standing body alignment (see Figure 36-2 on page 1089) is characterized by the following:

- Head upright
- Face forward
- Shoulders squared
- Back straight

- Abdominal muscles tucked in
- Arms straight at side
- Hands palm forward
- Legs straight
- Feet forward

The sitting position in proper alignment has similar characteristics; however, the hips and knees are flexed. Figure 36-3 on page 1089 shows proper alignment and posture for the sitting position.

Proper alignment and posture of the client lying in bed appear similar to the standing position; however, the client is supine, as shown in Figure 36-4 on page 1090.

The benefits of proper alignment and posture include (1) client comfort; (2) prevention of contractures; (3) promotion of circulation; (4) less stress on muscles, tendons, nerves, and joints; and (5) prevention of foot drop (plantar flexion).

In a person standing upright, the center of gravity is located in the middle of the pelvis about halfway between the umbilicus and the symphysis pubis. The **line of gravity** (vertical line passing through the center of gravity) is shown in Figures 36-3 and 36-4. The **base of support** is the foundation on which a person or object rests. Stability of one's balance is promoted by a steady base of support and a low center of gravity.

Muscle tone and bone strength allow a person to maintain an erect posture. Muscle contour is affected by the individual's exercise and activity patterns. **Muscle tone** is the normal state of balanced tension present in the body; it allows a muscle to respond quickly to stimuli. Two aberrations of muscle tone include **hypotonicity** (flaccidity), which is a decrease in muscle tone, and **spasticity**, which is an increase in muscle tension and is often noted with extreme flexion or extension.

Muscle shape should be symmetrical. There may be **hypertrophy** (increased muscle size and shape due to an increase in muscle fibers) or **atrophy** (a reduction in muscle size and shape), which manifests as thin, flabby muscles with indistinct contour (see Figure 36-5 on page 1090). Atrophy is usually a result of disuse, whereas hypertrophy occurs when the muscle is overworked.

BODY MECHANICS

Functional mobility is governed by **body mechanics**, the purposeful and coordinated use of body parts and positions during activity. Use of proper body mechanics maximizes the effectiveness of the efforts of the musculoskeletal and neurological systems.

Proper body mechanics are as important to the nurse as to the client. The purpose of proper body mechanics is prevention of strain and injury to the muscles, joints, and tendons. The clinical application of body mechanics is described in the implementation section of this chapter.

Range of motion reflects the extent to which a joint can move. The ranges vary with each joint and are affected by several factors, including age, physical condition, and heredity. When performing ROM exercises, it is important that the nurse put the joint through its complete range. In order to do so, the nurse may place an extremity into **abduction** (to move a body part away from the midline) or **adduction** (to move a body part toward the midline). A body part may also be placed in a state of **extension** (be straightened) or **flexion** (bending the joint). **Opposition** (a body part being across from another part at nearly a 180° angle) is also used when performing ROM exercises.

PHYSIOLOGY OF MOBILITY

Mobility is regulated by the coordinated effort of the musculoskeletal and neurological systems. The major functions of the musculoskeletal system are to maintain body alignment and to facilitate mobility.

MUSCULOSKELETAL SYSTEM

The musculoskeletal system (comprised of bones, cartilage, joints, tendons, ligaments, bursa, and muscles) serves several functions, as described in Table 36-1 on page 1091.

Bone is the foundation of the musculoskeletal system. Mobility and weight-bearing capacity are directly related to the bone's size and shape. Joints work with muscles to provide motion and flexibility. Skeletal muscles overlying the joint exert opposing forces and, therefore, cause movement.

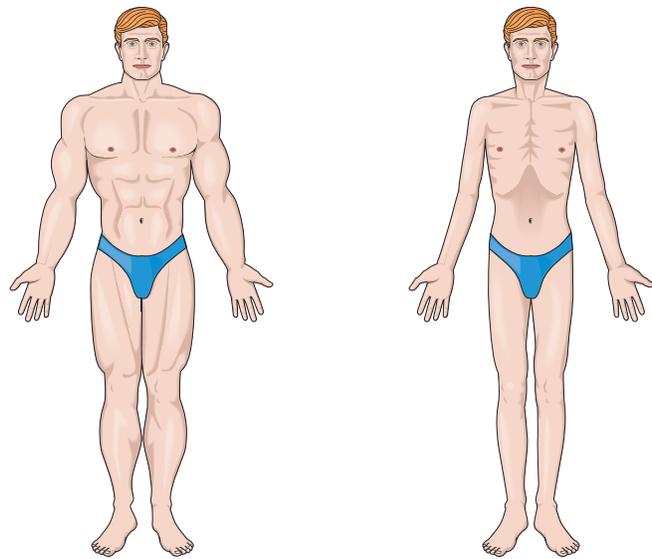

FIGURE 36-5 Variances of Muscle Size and Shape: A. Hypertrophy; B. Atrophy
DELMAR/CENGAGE LEARNING

Muscles are basically machines that convert energy into mechanical work. Contractility is the common property among the three types of muscles: smooth, cardiac, and skeletal. Skeletal muscle fibers are innervated by somatic nerves and, therefore, are generally under voluntary control.

The muscles work in cooperation with the nervous system to maintain body alignment and cause movement. Muscles act in pairs to perform work. One muscle of the pair produces movement in a single direction. The other muscle of the pair produces movement in the opposite direction. When one muscle of the pair is contracted, the other is relaxed. The opposing actions of contraction and relaxation make motion possible. The position of the tendons upon the bones and the articulation of the bones make possible types of motion such as flexion, extension, circumduction, rotation, and gliding.

Muscles that maintain body alignment work together to stabilize surrounding body parts and to support the body's weight. Posture is maintained primarily by the muscles in the back, neck, trunk, and lower extremities.

NEUROLOGICAL SYSTEM

Muscle contraction is controlled by the central nervous system (CNS) and is influenced by the transport of nutrients and oxygen and by the removal of waste products. An intact CNS is essential for coordinated movement to occur because nerve impulses stimulate the muscles to contract. The **myoneural junction** is the point at which nerve endings come into contact with muscle cells. The afferent pathway conveys information from sensory receptors to the CNS; these neurons conduct impulses throughout the body. The CNS processes the sensory input and determines a response. The efferent pathway transmits the desired response to skeletal muscles via the somatic nervous system. If the nerve

TABLE 36-1 Musculoskeletal System Components

ANATOMICAL STRUCTURE	DESCRIPTION	FUNCTIONS
Bones	Ossified connective tissue	Facilitates mobility, protects body structures (e.g., brain, spinal cord), and produces blood cells
Joints	The site of a union between two bones	Facilitates motion and allows flexibility
Tendons	Cord or band of inelastic connective tissue	Causes movement of muscles
Ligaments	Band of fibrous tissue connecting bones or cartilages	Supports and strengthens joints, facilitates mobility, and protects structures (e.g., knee, hip)
Bursa	Fluid-filled sac or cavity	Prevents friction between bones and cartilage and facilitates gliding of muscles or tendons over bony surfaces
Cartilage	Dense connective tissue	Facilitates mobility

Delmar/Cengage Learning

impulses are interrupted, the muscle becomes paralyzed and is unable to contract.

Proprioception

Proprioception is the awareness of posture, movement, and changes in equilibrium and the knowledge of position, weight, and resistance of objects in relation to the body. Nerve endings (proprioceptors) in muscles, tendons, and joints continuously provide input to the brain, which, in turn, regulates smooth, coordinated involuntary movement.

Postural Reflexes

Postural tonus is maintained by postural or righting reflexes. Table 36-2 describes the major reflexes involved in maintaining posture.

EXERCISE

Exercise is any physical activity involving muscles that elevates the heart rate above its resting level. Exercise reduces joint pain and stiffness and increases flexibility. Not only does exercise make bones stronger, thereby reducing the risk of osteoporosis and fractures, it also improves muscle strength, coordination, and balance. As a result, overall health status is improved (National Institute of Arthritis and Musculoskeletal and Skin Diseases, 2008). According to the Centers for Disease Control and Prevention (CDC, 2008b), approximately 51% of adults in the United States do not get enough physical exercise to benefit health; 24% of adults are not active in their leisure time.

The U.S. Surgeon General's report *Physical Activity Guidelines for Americans* (U.S. Department of Health and

TABLE 36-2 Reflexes That Maintain Postural Tonus

REFLEX	DESCRIPTION
Labyrinthine sense	Sensory organs in the inner ear activate impulses when the head is turned; impulses are transmitted to cerebellum.
Tonic neck-righting reflexes	Affected by movement of head from side to side; neck muscle tonus is affected most when neck is hyperextended.
Optic reflexes	Visual sensations affect posture by helping the person establish spatial relationships with surrounding objects.
Proprioceptor or kinesthetic sense	Activated when nerve endings in muscles and tendons are stimulated by movements of the joints; informs the brain of the location of a body part.
Antigravity (extensor) reflexes	When extensor muscles are stretched beyond a certain point, their stimulation causes a reflex contraction that counteracts the gravitational pull.
Plantar reflexes	Reflexive contraction of the extensor muscles of the lower legs in response to pressure against the sole of the foot by the floor or ground.

Delmar/Cengage Learning

Human Services, 2008) lists the following health benefits of exercise:

- Lower risk of:
 - Early death
 - Heart disease
 - Stroke
 - Type 2 diabetes
 - High blood pressure
 - Increased lipid levels
 - Colon and breast cancers
- Better health function in older adults
- Reduced abdominal obesity
- Weight maintenance after weight loss
- Lower risk of hip fracture
- Increased bone density
- Improved sleep quality

See the Respecting Our Differences display, which lists the CDC’s (2008a) recommended amounts of exercise for various age groups.

Vigorous exercise stimulates an increased production of endorphins, which promote a sense of well-being. However, it is important to caution people not to overdo the exercise, especially when first starting a new regimen. The following may be signs of too much exercise: unusual or persistent fatigue, increased weakness, decreased range of motion, joint swelling, or continuing pain (pain that lasts more than 1 hour after exercising). Instruct clients, especially those with sedentary lifestyles or chronic illness, to consult their prescribing practitioner before beginning an exercise program. See the Safety First display on page 1097.

TYPES OF EXERCISE

There are several types of exercise that promote physical and psychological health; see Table 36-3.

RESPECTING OUR DIFFERENCES

Physical Activity Recommendations for Age Groups

- Children and adolescents: 60 minutes or more of physical activity per day
- Adults: 150 minutes of moderately intense aerobic activity (i.e., brisk walking) each week and muscle-strength activities on 2 or more days per week
- Older adults: same activities and amounts as for other adults

Data from Centers for Disease Control and Prevention. (2008a). *Physical activity for everyone*. Atlanta, GA: Author. Retrieved January 8, 2009, from <http://www.cdc.gov/physicalactivity/everyone/guidelines>.

Range-of-Motion Exercise

Active range-of-motion (ROM) activities are performed independently by the client; see Table 36-4 on page 1093. During active ROM exercises, the client moves various muscle groups. **Passive ROM** exercises are done by the nurse to help maintain or restore a client’s mobility by achieving several outcomes, including the following:

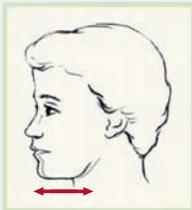

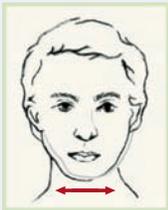

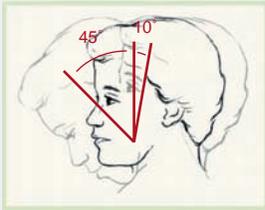

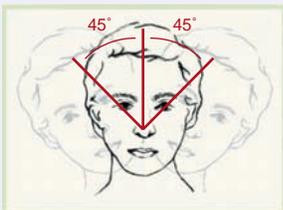

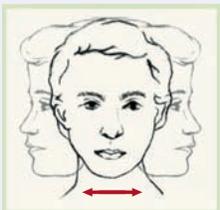

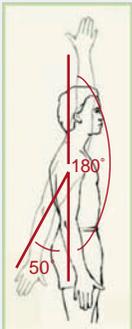

- Prevent contractures
- Improve muscle strength and tone
- Increase circulation
- Decrease vascular complications of immobility
- Facilitate client comfort

TABLE 36-3 Types of Exercise

EXERCISE TYPE	FUNCTION	EXAMPLES
Aerobic	Improve cardiovascular fitness; assist with weight control; improve general functional ability	Rowing, jumping rope, walking, running
Strengthening	Maintain or increase muscle strength	Weight training, calisthenics, physical labor
Isometric	Maintain muscle tone and strength	Quadriceps setting, gluteal setting, triceps setting
Isotonic	Increase and maintain muscle tone and strength; shape muscles; maintain joint mobility; improve cardiovascular fitness	Weight lifting, working with pulleys, ROM exercises, performance of activities of daily living (ADL)
Isokinetic	Condition muscle groups	Exercise equipment and resistive water exercises
Range-of-motion (ROM)	Maintain joint movement; maintain or increase flexibility	Adduction and abduction; flexion and contraction

Delmar/Cengage Learning

TABLE 36-4 Joint Range of Motion

JOINT AND MOVEMENT	EXAMPLE	MUSCLE GROUP(S)	RANGE*
1. Temporomandibular joint (TMJ) (synovial joint) a. Open mouth. b. Close mouth. c. <i>Protrusion</i> : Push out lower jaw. d. <i>Retrusion</i> : Tuck in lower jaw. e. <i>Lateral motion</i> : Slide jaw from side to side.	 	Masseter, temporalis Pterygoid lateralis Pterygoid lateralis, pterygoid medialis	1–2.5 in. Complete closure 0.5 in. 0.5 in. 0.5 in.
2. Cervical spine (pivot joint) a. <i>Flexion</i> : Rest chin on chest. b. <i>Extension</i> : Return head to midline. c. <i>Hyperextension</i> : Tilt head back.		Sternocleidomastoid Trapezius Trapezius	45° each side 45° 10°
d. <i>Lateral flexion</i> : Move head to touch ear to shoulder.		Sternocleidomastoid	45° each side
e. <i>Rotation</i> : Turn head to look to side.		Sternocleidomastoid, trapezius	90° each side
3. Shoulder (ball-and-socket joint) a. <i>Flexion</i> : Raise straight arm forward to a position above the head. b. <i>Extension</i> : Return straight arm forward and down to side of body. c. <i>Hyperextension</i> : Move straight arm behind body.		Pectoralis major, coracobrachialis, deltoid, biceps brachii Latissimus dorsi, deltoid, triceps brachii, teres major Latissimus dorsi, deltoid, teres major	180° 180° 50°

Delmar/Cengage Learning

SAFETY FIRST

Individuals with cardiovascular problems should be cautioned to exhale when performing isometric exercises in order to avoid increasing blood pressure.

PHYSICAL FITNESS

The goal of regular physical activity is physical fitness that affects an individual's functional ability. There are four components of physical fitness: endurance and strength, joint flexibility, cardiorespiratory fitness, and body composition.

Endurance and Strength

Endurance is the ability to withstand movement in terms of duration and absence of fatigue. A physically fit individual has adequate muscular strength and endurance to accomplish one's goals.

Muscle strength is the amount of force exerted by the muscles against resistance. Good muscle strength allows an individual to lift safely.

Joint Flexibility

The ability to use a muscle through its complete range of motion is referred to as flexibility; see Table 36-4 for a complete description of joint movement. People with limited

flexibility are likely to experience shortened muscles and tendons with resulting loss of muscle strength and joint injury. Flexibility can be improved by stretching exercises such as yoga, tai chi, and dancing. Performance of ADL also helps maintain flexibility. Walking, stooping, and lifting activities can promote and maintain flexibility.

Cardiorespiratory Fitness

Exercises that improve cardiorespiratory fitness are discussed in Table 36-3. To improve cardiorespiratory function, physical activity must be maintained for at least 20 minutes in order to raise the heart rate to the target level.

Body Composition

The proportion of fat to lean body tissue is referred to as body composition. Having a body that falls within the normal range of body weight and percentage of body fat depends on balancing caloric intake and expenditure. Any type of physical activity can be useful in developing and maintaining physical fitness; see Table 36-5 on page 1098.

Fitness in Older Adults

Physical fitness is essential for older adults for maintenance of well-being and injury prevention. Muscle strength, coordination, and endurance are affected by the physiological changes of aging. Diminished muscle strength is a result of age-related loss of muscle mass. Muscle coordination and endurance decline due to changes in the CNS and muscles (Miller, 2009).

TABLE 36-5 Steps for Maintaining Ideal Body Weight

ACTION	IMPACT ON ENERGY BALANCE
Decrease amount of time spent in sedentary activities (e.g., watching television), and build physical activity into regular routines.	Increases physical activity; increases calorie consumption
Select foods that are low in fat, calories, and added sugars.	Decreases excessive calorie consumption
Create more opportunities for physical activity in workplaces.	Increases physical activity; increases amount of calories used

Data from National Center for Chronic Disease Prevention and Health Promotion. (2008). *Overweight and obesity: Contributing factors*. Atlanta, GA: Author. Retrieved January 10, 2009, from http://www.cdc.gov/nccdphp/dnpa/obesity/contributing_factors.htm

Such physiological changes can increase the risk of falls. Falls are the greatest cause of injury in people over the age of 70 (Fulmer, Wallace, & Edelman, 2006). Regular exercise, especially weight-bearing exercise (e.g., walking), improves endurance and strengthens bones. Decreased bone density results in osteoporosis, which makes a person more vulnerable to fractures; see the Respecting Our Differences display.

Some benefits of physical exercise in older adults are the following:

- Improves gait and balance
- Improves cardiovascular function
- Increases energy
- Promotes bone density
- Improves mobility
- Promotes weight loss

RESPECTING OUR DIFFERENCES

Osteoporosis in Diverse Groups

Rates of Osteoporosis (listed in groups ranging from highest to lowest risk):

- Asians, Alaska Natives, Native Americans
- White non-Hispanic women
- Hispanic groups
- White men
- African American men

Miller, C. (2009). *Nursing for wellness in older adults* (5th ed.). Philadelphia: Wolters Kluwer/Lippincott Williams & Wilkins, p. 463.

FACTORS AFFECTING MOBILITY

Mobility and activity level can be influenced by many factors, including overall health status, developmental stage, environment, attitudes, beliefs, and lifestyle.

HEALTH STATUS

An individual's general health status will influence exercise and activity tolerance. Compromised status of any of the body systems may affect an individual's mobility and may, in turn, be affected by a lack of activity. Physical conditioning will also influence mobility and stamina. Physical factors interfering with mobility or exercise include fatigue, muscle cramping, dyspnea, neuromuscular or perceptual deficits, and chest pain.

Mental status is often manifested as changes in mobility or appearance. For instance, a client who shuffles into the room and slumps down into a chair may be sending a message of depression through low activity levels and poor posture.

DEVELOPMENTAL STAGE

An individual's developmental stage will affect mobility and functional ability. See Table 36-6 for examples of common age-related musculoskeletal trauma.

Children

Developmental norms related to mobility have been established for the infant and toddler. Childhood development is monitored through achievement of milestones such as sitting, crawling, walking, running, and hopping. See Chapter 18 for discussion of developmental milestones. For *infants*, mobility involves gross motor behaviors such as posture, head balance, grasping, sitting, creeping, and standing. *Toddlers* are more

TABLE 36-6 Common Age-Related Musculoskeletal Trauma

AGE RANGE	COMMON TRAUMAS
0 to 18 months	Falls
18 months to 6 years	Falls
6 to 20 years	Sports-related injuries, motorcycle accidents, high-impact falls (e.g., cycling, skiing)
20 to 50 years	Sports-related injuries, stress or overuse injuries (e.g., tendonitis), pedestrian injuries
50 to 65 years	Recreation-related injuries, falls, pathological fractures, pedestrian injuries
65+ years	Falls

Delmar/Cengage Learning

active, with walking, running, jumping, kicking, and going up and down stairs. Activity and mobility parameters for the toddler include gross and fine motor behaviors, manual dexterity, and exploration within environmental safety parameters. The preschooler increases strength and refines skills by walking, running, and jumping. During *middle childhood* (from 6 to 12 years of age), children have improved posture and locomotion abilities and increased muscle efficiency of the extremities and trunk; these children also have an increase in muscle tissue with a decrease of fat. For both preschool and middle childhood, activity and mobility expectations are centered on development of strength, coordination, and physical capacities.

Adolescents

The *adolescent* years (approximately ages 12 to 18) begin with onset of puberty and end with cessation of somatic growth. Changes are dramatic at this stage, with rapid physical growth and development of secondary sex characteristics. Activity and mobility landmarks are development of muscles plus cardiac, respiratory, and metabolic functions through physical conditioning.

Adults

Adulthood is divided into young, middle, and older age groups. The *young adult* has well-developed musculoskeletal and nervous systems that ideally function at peak efficiency. The *middle-aged* adult has a gradual decrease in muscle mass, strength, and agility. The focus of activity and mobility for both these groups is on maintaining or developing tone, strength, and coordination of the musculoskeletal system.

Older adults experience progressive changes in the physiological systems. The rate of calcium reabsorption, which affects bone density, increases with aging. Bone density loss accelerates in postmenopausal females due to decreased amounts of estrogen. Decreased bone density makes a person more vulnerable to fractures, **kypnosis** (abnormally increased convexity in the curvature of the spine), and a reduction in height.

Aging also negatively affects muscles and connective tissue. The development of muscle atrophy is a gradual process in which muscle fibers deteriorate and are replaced by fibrous connective tissue. Muscle atrophy is accompanied by reduced muscle mass, a loss of muscle strength, and a reduction in overall body mass. The degree of muscle atrophy will be affected by the person's activity level. Staying physically active helps prevent disuse muscle atrophy and helps maximize muscle strength.

Cartilage ages better than bone or muscle; however, some changes occur that do affect joint flexibility. Aging leads to a loss of water content of hyaline cartilage and a reduction in the ability of cartilage to regenerate following trauma. Articulating cartilage may slightly deteriorate as a result of lifetime wear and tear. Aging also affects the health of intervertebral disks. For example, the water content of the disks decreases, which leads to less vertebral flexibility. Thinning of the disks causes older individuals to be more vulnerable to back pain and injury.

As a result of the age-related physical changes, older people often experience some functional alterations in mobility. Ambulation may be altered as a result of joint inflexibility and decreased muscle strength; such alterations are noticed as a

reduction in step height and length, as demonstrated in a shuffling gait. Vertebral inflexibility and reduced muscle strength may cause difficulty with client transfers in and out of a sitting position. The elderly client may need assistance in rising from a chair, ambulating, or climbing stairs. Table 36-7 provides an overview of age-related effects on mobility. Aging also affects the cardiovascular and respiratory systems, which directly affect endurance and stamina. Activity and mobility goals focus on maintenance of functional status and safety.

ENVIRONMENT

Environment can influence activity levels in several ways. Home environments, for instance, can be considered safe and "mobility friendly" if they are free of hazards that can disrupt or endanger mobility and activity. Work environments can also affect mobility; repetitive handwork (e.g., key-stroking, sewing) can impair mobility and worsen arthritis.

ATTITUDES AND BELIEFS

Influential factors related to exercise are one's attitudes and beliefs, which are greatly affected by culture and family. Leisure activities provide a clue to the person's value system. Individuals who engage in hiking, bicycle riding, or swimming for recreation value an active lifestyle. On the other hand, individuals who consider work to be the dominant area of life may view exercise as "a waste of time." See the Nursing Process Highlight on page 1100. Activities enjoyed by the individual are less likely to produce fatigue than are activities that hold no interest for the person. Thus, individual preferences should be matched with capabilities when planning an exercise program.

LIFESTYLE

Modern lifestyles require little physical activity; thus, few adults in America are naturally fit. The use of many convenience items (e.g., automobiles, fast food, remote controls) encourages little

TABLE 36-7 Effects of Aging on Musculoskeletal System

AGE-RELATED CHANGES	HEALTH IMPLICATIONS
Osteoporosis	Risk of fracture
Decreased muscle size and tone	Impaired physical ability
Stiffening of joints	Decreased range of motion leading to: Decreased mobility Increased fall risk
Kyphosis	Shifting center of gravity (fall risk) Decreased self-esteem

Data from Clark, M. J. (2008). *Community health nursing: Advocacy for population health* (5th ed.). Upper Saddle River, NJ: Pearson Prentice Hall.

NURSING PROCESS HIGHLIGHT

Assessment

Assessing Attitudes and Beliefs about Exercise

Asking these questions helps determine the client's perception of physical activity:

Do you routinely climb stairs or use elevators?

Do you usually go everywhere in a car or walk for transportation?

Is exercise a part of your daily routine?

What activities do you enjoy doing in your leisure time?

physical exertion. The sedentary lifestyles of many Americans result in loss of muscle strength, decreased endurance, inadequate cardiorespiratory function, and obesity. A sedentary lifestyle can lead to muscle atrophy, weakened bones, and a lack of motivation and energy to engage in physical activity. Individuals with active lifestyles value exercise and, therefore, are more likely to experience its therapeutic outcomes.

PHYSIOLOGICAL EFFECTS OF MOBILITY AND IMMOBILITY

Maintaining functional mobility and desired activity levels is important for both psychological and physiological reasons. Mobility and lack thereof will both affect the various systems of the body. Table 36-8 summarizes the major complications associated with immobility.

NEUROLOGICAL EFFECTS AND MENTAL STATUS

Mobility and activity can increase an individual's energy levels and sense of well-being. Activity and exercise are excellent means to relieve tension and reduce stress, which result in better sleep patterns and an enhanced sense of well-being.

Client inactivity and immobility are stressors that can lead to frustration, lower self-esteem, anxiety, helplessness, depression, general dissatisfaction, restlessness, unhappiness, and decreased competency self-rating. Immobility affects cognitive abilities, affect, lifestyle, and social and family responsibilities. The fear of falls, pain, and sensory deficits such as visual problems, fatigue, and weakness are compounding factors that increase inactivity and immobility.

CARDIOVASCULAR EFFECTS

The cardiovascular system reaps many benefits from mobility and exercise. The heart becomes more efficient as it adapts to increased demands for oxygen, and cardiac output increases.

TABLE 36-8 Negative Outcomes of Immobility

Neurologic	Gastrointestinal
Sensory deprivation	Decreased appetite Stress ulcers Constipation Fecal impaction
Cardiovascular	Urinary
Increased cardiac workload Orthostatic hypotension Formation of thrombus	Urinary stasis Urinary tract infection Calculi
Respiratory	Integumentary
Increased respiratory effort Hypostatic pneumonia Altered gas exchange	Skin shearing Pressure ulcers
Musculoskeletal	Psychological
Decreased bone density (increased risk of fracture) Contractures Muscle atrophy Increased pain	Anxiety Depression Helplessness, hopelessness Increased dependency

Delmar/Cengage Learning

A healthy heart muscle leads to a decreased resting heart rate and decreased resting blood pressure. Thus, the heart does not have to work as hard in an individual who exercises regularly as it does in an individual who leads a sedentary lifestyle. Activity increases the oxygen supply to the heart and muscles and thereby benefits overall health.

Immobility increases the workload on the heart as the supine position increases the volume of blood circulating to the heart. This fluid shift increases central venous pressure along with left ventricular diastolic volume and stroke volume, and the cardiac workload increases. The cardiovascular system is prone to form **thrombi** (blood clots) due to venous stasis related to lack of muscle contractions of the legs and pressure on veins, especially the popliteal areas (see Figure 36-6 on page 1101). Thrombi are caused by increased coagulation of the blood due to free calcium from bone demineralization, stasis of venous blood, and intimal damage to veins (as from venipuncture). See the Safety First display on page 1101.

Another cardiovascular problem related to immobility is **orthostatic hypotension**, a decrease in blood pressure resulting from sudden position changes, caused by decreased vessel tone. In orthostatic hypotension, the blood pressure parameters drop at least 25 mm systolic and 10 mm diastolic with postural changes. Orthostatic hypotension is a result of several factors associated with immobility, including:

FIGURE 36-6 Effect of Immobility on the Cardiovascular System DELMAR/CENGAGE LEARNING

SAFETY FIRST

DEEPVEIN THROMBOSIS (DVT)

Deep vein thrombi have the potential of becoming pulmonary emboli, which are life-threatening. Individuals who are immobile (e.g., on bedrest) are at greater risk of developing DVT.

- Decreased circulating fluid volume
- Decreased autonomic nervous system response
- Blood pooling in lower extremities

These factors lead to decreased venous return, which negatively affects cardiac output; thus, the blood pressure is lowered. Orthostatic hypotension is an indication that the heart is working harder and less efficiently.

Clients who have experienced immobility (e.g., with bed rest) need to have blood pressure checked lying down, sitting, and then standing. This is done to establish baseline parameters to assist in determining the presence of postural-related changes in blood pressure.

RESPIRATORY EFFECTS

The respiratory response to activity is increased intake of oxygen, which results in increased overall respiratory capacity and easier breathing. The effects of oxygenation to the tissues are enhanced, and pooling of secretions in the bronchioles is less likely.

Immobility from sitting or lying limits chest expansion, which is compounded by the effects of respiratory muscle atrophy and ineffective cough (see Figure 36-7). Stasis of respiratory secretions can be worsened by the use of CNS-depressant

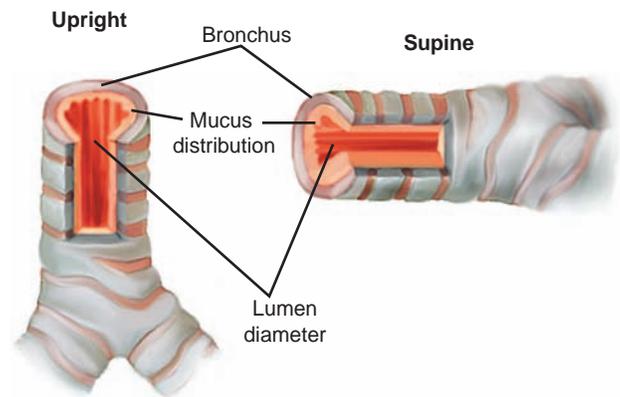

FIGURE 36-7 Effect of Immobility on the Respiratory System DELMAR/CENGAGE LEARNING

medications and dehydration and can lead to hypostatic pneumonia and atelectasis.

MUSCULOSKELETAL EFFECTS

Musculoskeletal responses to activity are numerous, including stronger and better-defined muscles, stronger bones, and increased mobility and joint range of motion. Exercise can enhance endurance and tolerance of the muscle groups. Weight-bearing exercises such as walking (as opposed to swimming) are especially beneficial in preventing osteoporosis, or loss of strength and minerals in the bones.

Decreased physical mobility results in gross musculoskeletal impairment, especially when muscular atrophy occurs. Decreased mobilization alters muscle structure by reducing muscle mass and decreasing muscle cell diameter and the actual number of muscle cells. Clients experience rapid fatigue, decreased muscle strength and tone, decreased endurance, decreased mobility of joints, muscle stiffness, joint contracture, and negative nitrogen balance due to protein catabolism. Loss of calcium is a response to immobility and indicates an imbalance between bone formation and breakdown. The lack of pressure (e.g., weight bearing) on bones triggers calcium loss. Bone demineralization occurs as early as 2 or 3 days after onset of immobility and may lead to pathological fractures, renal calculi, and osteoporosis.

DIGESTIVE EFFECTS

Digestive responses to activity include increased appetite and thirst, which indicate that the body's rate of processing nutritional intake is increased. Exercise increases metabolism with resultant absorption of nutrients and excretion of wastes.

Loss of appetite is commonly related to lack of activity, negative nitrogen balance, and altered elimination patterns. Negative nitrogen balance occurs when the nitrogen output exceeds nitrogen intake. The causes of negative nitrogen balance include the increased need for protein in situations of extensive tissue damage, such as surgery and extended immobility. Extended periods of immobility cause muscle atrophy or muscle wasting; thus, there is a need for extra protein intake to provide for muscle repair.

ELIMINATION EFFECTS

Elimination patterns are facilitated by mobility in that retention of wastes is usually prevented and the risk of constipation is reduced or avoided. Activity causes the muscles to become stronger and more efficient, thus enhancing the overall efficiency of elimination.

Constipation and fecal impaction are frequent complications of immobility. Variables contributing to these elimination problems are:

- Lack of activity, which decreases peristalsis
- Lack of privacy
- Inability to sit upright
- Improper diet
- Inadequate fluid intake
- Use of some medications, especially narcotics

Urinary stasis and urinary infections are related to the recumbent position of the immobile person. Decreased peristalsis of the ureters leads to stasis of urine, which is the etiology of urinary calculi (stones) and infection. Bladder distention occurs due to difficult relaxation of the external sphincter and decreased intraabdominal pressure, thus causing overflow **incontinence** (loss of bladder control) and infection. The combination of increased urinary calcium, urinary stasis, and urinary tract infection leads to calculi formation.

INTEGUMENTARY EFFECTS

The integumentary system benefits from activity and exercise in that increased circulation and blood flow enhance oxygenation of tissues. As a result, the turgor and luster of the skin and hair are maintained.

Pressure ulcers are serious problems related to immobility. Prolonged pressure, shearing force, friction (rubbing), and moisture lead to tissue ischemia (impaired blood circulation), causing skin breakdown and pressure ulcers. Moisture in the form of urine, feces, perspiration, and wound drainage can also lead to skin softening, which increases risk for pressure ulcers. Secondary factors contributing to pressure ulcer development are decreased nutrition, decreased arterial pressure, increased age, and edema. Refer to Chapter 37 for a discussion of pressure ulcers.

ASSESSMENT

During the assessment phase of the nursing process, data regarding activity and mobility of the client are gathered. Assessment data are used to initiate, individualize, plan, evaluate, and modify care on the basis of the client's strengths and limitations. Assessment of mobility status includes a health history and physical examination.

HEALTH HISTORY

Determining a client's health history is the first step in assessing the mobility needs and concerns of a client. Basic information about ADL, exercise patterns (type, frequency),

lifestyle (active, sedentary), activity tolerance, and use of medications should be discussed. If an alteration or recent change in status is noted, then a detailed health history is in order. The nurse should ask what impact the mobility impairment has had on the client's ADL and should have the client describe the exact nature of the problem (onset, duration, associated factors, aggravating factors, alleviating factors). The nurse should ask clients about the use (past and current) of medications, both prescription and over the counter, with the explanation that many drugs negatively affect the musculoskeletal system. It is also important to ask about the use of calcium supplements and estrogen replacement medication.

PHYSICAL EXAMINATION

The physical examination of mobility status typically covers three basic areas: musculoskeletal assessment, neurological assessment, and functional assessment.

Musculoskeletal Assessment

The nurse observes musculoskeletal functioning during every interaction with the client. The accompanying Nursing Process Highlight on page 1103 lists steps in assessing musculoskeletal status. Specific factors for objective assessment include the following:

- Body alignment
- Body mechanics
- Posture (sitting and standing)
- Range of motion
- Strength of muscles
- Endurance
- Muscle tone
- Size and contour of joints
- Inspection of the skin
- Palpation of skin, muscles, and joints

Subjective data include assessment of the client's pain, joint stiffness, muscle cramping, fatigue, weakness, exercise habits, and environmental variables. Children should be evaluated by comparing physical development and abilities with normal values for the age. Older adults should be assessed for functional abilities, strengths, weaknesses, joint limitations, and use of assistive devices such as canes or walkers that are necessary for self-care activities. A complete musculoskeletal assessment includes data related to client weakness, stiffness, and pain related to movement.

Movement and Gait

Gait, the way that one walks, is assessed to determine a baseline. Normal gait is characterized by a smooth, rhythmic movement of muscles when walking. Step height and length are symmetrical for each foot, and the arms swing freely at each side of the torso in opposite movement of the legs. Normally, the lower limbs are able to bear full body weight during standing and ambulation. Gait is described in terms of smoothness, balance, arm movement, effectiveness, and the length and width of the step.

NURSING PROCESS HIGHLIGHT

Assessment

Assessing Musculoskeletal Status

1. Wash hands.
2. Provide an explanation to the client of the assessment procedure.
3. Assist the client to a comfortable position.
4. Use pillows or folded blankets to support painful body parts.
5. Provide assistance with disrobing as needed.
6. Adjust room temperature for client comfort.
7. Provide clear instructions to client (e.g., assuming a certain body position or performing a certain body movement).
8. Inform client before touching or moving a painful body part.
9. Assess skeletal muscles and joints in a cephalocaudal, proximal-to-distal manner. Always compare paired muscles and joints.
10. Examine unaffected body parts before examining affected ones.
11. Avoid unnecessary or excessive manipulation of a painful body part. If the client verbalizes pain, stop the aggravating motion.
12. If needed, assist client in dressing after the physical examination is completed.

Data adapted from Estes, M. E. Z. (2010). *Health assessment and physical examination* (4th ed.). Clifton Park, NY: Delmar/Cengage Learning.

Body Alignment

When assessing body alignment, the nurse seeks to determine whether the movement results in fatigue, muscle stress, or strain. Structural deformities may interfere with body alignment and functional ability; see Table 36-9 on page 1104.

Endurance

When assessing a client's endurance during physical activity, look for reactions such as mood changes, indicators of pain, presence of fatigue, and changes in respiratory and circulatory status. Oxygen consumption increases during muscle activity; thus, assessment of vital signs is essential. The time required for vital signs to return to the normal (baseline) resting values is a significant factor to include in the assessment of mobility.

Pathological Alterations

Assessment to determine the presence of pathological alterations—such as bone disorders, joint impairment, impaired muscle development, postural abnormalities, musculoskeletal trauma, and neurological damage—can offer important data for the determination of mobility limitations.

MUSCLE IMPAIRMENTS Overuse injuries are a common type of musculoskeletal problem, especially in people who exercise too much or incorrectly. Common overuse injuries are listed in Table 36-10 on page 1106.

CONTRACTURES A **contracture**, a condition of fixed resistance to the passive stretch of a muscle, develops when the muscle fibers become unable to flex; see Figure 36-8 on page 1106. Each muscle has an antagonist that works in the opposite direction. If a muscle group is not moved for a period of time or if proper body alignment is not maintained, the stronger muscle will predominate, causing contracture deformities.

Once a contracture occurs, the only corrective action is surgical release of the fibrous tissue. Prevention of contractures is a major nursing focus with immobile clients. Nursing interventions to prevent a muscle contracture include:

- Encouraging clients to be as active as possible
- Performing ROM exercises
- Positioning to maintain proper body alignment
- Repositioning every 2 hours or more often as needed

MUSCULOSKELETAL TRAUMA Trauma to musculoskeletal tissues can result in many types of impairments (such as those described in Table 36-10). Other common types of musculoskeletal trauma are fractures (broken bones) and surgical amputation.

FRACTURES Hip fractures are disabling injuries that occur in many older people. Hip fractures are usually a result of falls, with complications that lead to the deaths of many of the fallers (Clark, 2008). Hip fracture complications result from immobility and include pressure ulcers, pneumonia, and sepsis from urinary tract infections. When a fracture is suspected, the nurse should assess the area for mobility, pain, color, temperature, pulse, and sensation.

AMPUTATION Any condition in which circulation is inadequate for cellular function may lead to amputation. For example, lower limb amputations are often required as a result of infection, peripheral vascular disease (PVD), neoplasm, and trauma. Pressure ulcers, if inadequately treated, can also lead to the loss of a limb. When pressure ulcers do not heal, infection and gangrene develop. Gangrene first manifests as a blackened area and is often accompanied by pain.

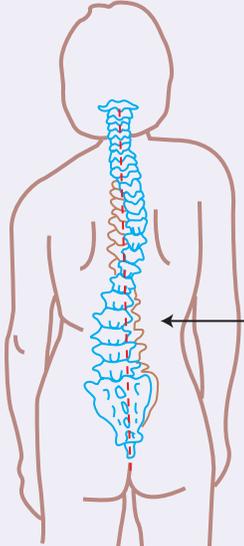

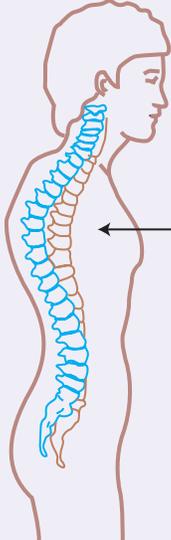

Lower limb amputation is either above or below the knee; the level of amputation depends on the extent of the disease process. Below-the-knee amputation is the most commonly performed type. The goal of the surgery is to preserve the length of the extremity in order to assist with prosthetic fitting. Therefore, as much limb as possible is salvaged.

CENTRAL NERVOUS SYSTEM DAMAGE As movement is a result of coordination between muscles and nerves, an intact CNS is necessary for mobility. Any disruption in the CNS, such as those occurring with spinal cord injury, can impair mobility. Spinal cord injury can lead to partial paralysis or complete loss of mobility.

SPINAL CORD INJURY (SCI) Damage to the spinal cord can be a result of hyperextension or compression. With hyperextension, the spinal cord is overstretched, leading to dislocation of the vertebrae or discs and possible compression of the spinal cord. Hyperextension can also completely dissect the spinal cord. In a complete spinal cord injury, voluntary motor activity, sensory function, and proprioception below the level of the injury are absent.

Compression injuries occur when the force of impact fractures the vertebrae or ruptures the discs, forcing bony fragments or discs into the spinal canal. These particles can lacerate or compress the spinal cord, resulting in paralysis below the level of the injury. Prevention of SCI is a major concern of nurses and may be addressed through educating the public on safety precautions related to driving, participation in sports, and leisure activities.

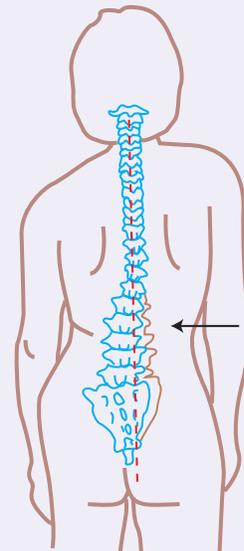

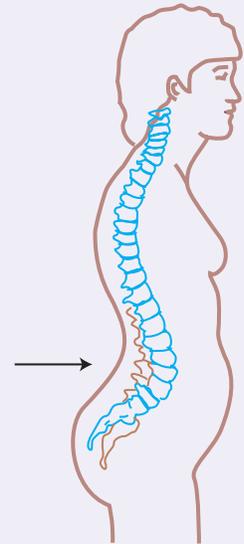

TABLE 36-9 Spinal Misalignment

ANOMALY	DESCRIPTION	CLINICAL IMPLICATIONS
<p>Scoliosis</p> <ul style="list-style-type: none"> • <i>Postural scoliosis</i>: no fixed rotation of vertebrae; can be corrected with exercise • <i>Structural scoliosis</i>: fixed rotation of the vertebrae in the direction of the convexity of the curve 	<ul style="list-style-type: none"> • Lateral deviation in the normally straight vertical line of the spine • More common in females, especially during adolescence • Some indicators: <ul style="list-style-type: none"> — One side of body higher than the other or one shoulder blade more prominent — Abnormal waistline tilt with more indentation on one side — Tilting of the hips with one hip more prominent — A prominence of the posterior chest or the shoulder when bending over 	<ul style="list-style-type: none"> • Can progress to a severe curvature in a short period of time if untreated 
<p>Kyphosis</p>	<ul style="list-style-type: none"> • Abnormally increased convexity in the curvature of the spine • Chin tilts downward onto chest with abdominal protrusion • Decreased interval between lower rib cage and iliac crests 	<ul style="list-style-type: none"> • In advanced stages, can interfere with lung expansion • Commonly seen in: <ul style="list-style-type: none"> — Older clients — Osteoporosis

List	<ul style="list-style-type: none"> • Lateral tilt of the spine • Iliac crests unequal in height • Decreased ROM, usually accompanied by pain 	<ul style="list-style-type: none"> • Commonly present in: <ul style="list-style-type: none"> – Back injury – Osteoarthritis – Herniated vertebral disc

Delmar/Cengage Learning

NEUROLOGICAL ASSESSMENT

An intact neurological system is essential for activity and mobility. A complete neurological assessment includes (1) cranial nerves, (2) the motor system, (3) the sensory system, and (4) reflexes. The nurse assesses the motor system for the following variables:

- Size, strength, and tone of muscles
- Presence of involuntary movements

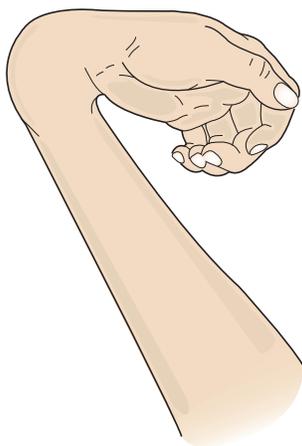

- Balance
- Gait
- Coordination
- Proprioception
- Fine motor function
- Gross motor function

The sensory system is assessed for integrity of peripheral nerves, pain, tactile discrimination (fine touch), and sensation of vibration. Assessment of deep tendon or stretch

TABLE 36-10 Musculoskeletal Trauma and Common Overuse Injuries

Strain	Commonly referred to as “pulled muscles”; caused by overstretching, tearing, or ripping of a muscle or its tendon
Tendonitis	Inflammation of a tendon; caused by chronic, low-grade strain of a muscle-tendon unit
Bursitis	Inflammation of the bursa (lubricating sac surrounding a joint); caused by repeated, low-grade strain of the joint’s supporting tissues
Sprain	Overstretching or tearing of ligaments

Delmar/Cengage Learning

**FIGURE 36-8 Hand-Wrist Contracture** DELMAR/CENGAGE LEARNING

reflexes focuses on the biceps, triceps, brachioradialis, quadriceps, and Achilles reflexes. Refer to Chapter 27 for further details on physical assessment.

Functional Assessment

Functional assessment focuses on the client’s abilities to perform ADL. The client’s functional status is assessed in terms of the ability to feed, dress, toilet, move, transfer, and ambulate himself or herself independently or with some degree of required assistance; see Figure 36-9. Functional assessment data are used for initial care planning, for discharge planning, for planning continuity of care in a nursing home or private home, and to provide baseline and ongoing data for rehabilitation.

**FIGURE 36-9** Some mobility impairments significantly limit a person’s ability to perform ADL. DELMAR/CENGAGE LEARNING

Clients at high risk for falls include those with prolonged hospitalization, those taking sedatives or tranquilizers, confused clients, and those with a history of physical restraint use. A great majority of falls:

- Occur in the evening
- Occur in the client’s room
- Involve wheelchairs
- Involve unattended clients
- Involve clients with poor footwear
- Occur with poor lighting
- Involve clients with poor vision
- Occur with clients experiencing neuromuscular impairment
- Occur when toileting needs arise

Awareness of these risk factors for falls allows the nurse to prevent many client injuries.

The nurse continually evaluates the client’s strength and endurance during the entire ambulation process. The Risk Assessment Tool (RAT) for falls was developed to identify clients at high risk for falls and to individualize care (Brians, Alexander, Grota, Chen, & Dumas, 1991). See the accompanying Nursing Checklist on page 1107 for the RAT and Chapter 29 for further discussion of fall prevention.

NURSING DIAGNOSIS

Nursing diagnoses related to mobility focus primarily on activity and mobility levels and the psychosocial impact that alterations in mobility can have on a client and family. Common nursing diagnoses, established by the North American Nursing Diagnosis Association (NANDA, 2009), related to

Text not available due to copyright restrictions

the physical adaptations or risks resulting from altered mobility include:

- *Activity intolerance* related to bed rest and immobility, generalized weakness, sedentary lifestyle, and imbalance between oxygen supply and demand (see Table 36-11 on page 1108)
- *Impaired physical mobility* related to intolerance to activity or decreased strength and endurance, pain, perceptual or cognitive impairment, neuromuscular impairment, musculoskeletal impairment, and depression or severe anxiety (see Table 36-11)
- *Risk for disuse syndrome* per risk factors of paralysis, mechanical immobilization, prescribed immobilization, and severe pain
- *Self-care deficits* related to inability to wash body or body parts, inability to obtain or get to water source, activity intolerance, decreased strength and endurance, pain, or impaired transfer ability
- *Ineffective health maintenance* related to lack of or significant alteration in communication skills (written, nonverbal)
- *Risk for falls* related to impaired mobility

Alterations in family and social processes may also result from immobility and inactivity. Disruption in activity and

mobility leads to impairment of the ability to perform one's usual social, vocational, educational, and family roles. There are often changes in the client's perception of his or her roles. *Disturbed body image* and *Situational low self-esteem* can result from (NANDA, 2009):

1. Changes in physical abilities
2. Changes in family responsibilities
3. Lack of knowledge regarding rehabilitation
4. Denial of abilities and strengths
5. Social insecurity
6. Feelings of worthlessness, hopelessness, or depression

PLANNING AND OUTCOME IDENTIFICATION

Client involvement is essential in the development of outcomes related to mobility needs. Realistic outcomes can be targeted by considering the client's (1) understanding of mobility status; (2) values, thoughts, and concerns regarding mobility problems; (3) general health status; and (4) ability to solve problems.

Text not available due to copyright restrictions

COLLABORATION

The goal of the interdisciplinary health team during acute hospitalization and rehabilitation is to restore function, thus maximizing the level of the client's independence. Maximal independence includes the ability to perform ADL (eating, dressing, bathing, and moving). Independence in these activities contributes to self-reliance, self-care, self-determination, self-direction, and personal control. Personal client variables that determine the maximal level of independence include extent of disability, competence, age, self-confidence, cognitive ability, knowledge level, and mood state. It is important to develop short-term goals that encourage clients to gain a sense of accomplishment. The nurse should recognize and praise the client's accomplishments that increase mobility.

The level of independence and ability for performance of ADL is enhanced or inhibited by the physical environment. Collaboration of the client, family, caregivers, nurses, physical therapists, and occupational therapists is essential for individualizing the physical environment to permit optimal activity and mobilization. Adaptive devices, such as those that follow, enhance independence for personal activities:

- Eating (e.g., plate guards and hand splints to hold utensils)
- Bathing (e.g., shower chairs and long-handled bath sponges)
- Dressing (e.g., Velcro closures and zipper pulls)
- Toileting (e.g., elevated toilet seats)
- Mobility (e.g., walkers)

Continued practice in self-care activities with adaptive devices promotes confidence. Interdisciplinary cooperation can be used to plan modifications for the home for activity and mobility, especially in the bathroom and kitchen. Physical modifications with adaptive equipment in home environments maximize client activity and mobility.

BED REST

Bed rest is a therapeutic intervention that achieves several objectives, including the following:

- Provides rest for clients who are exhausted
- Decreases the body's oxygen consumption
- Reduces pain and discomfort

The planned duration of bed rest depends on the client's physical condition and ability to move.

Even though implemented for therapeutic reasons, bed rest can be counterproductive to a client's recovery. The inactivity imposed by bed rest causes structural changes in joints and muscles, such as shortening of muscles, decreased range of motion, and contractures. To prevent such complications, bed rest should be avoided as much as possible. For clients whose medical condition necessitates bed rest, ROM exercises must be implemented.

RESTORATIVE NURSING CARE

Being able to move about independently is an important part of the recovery process and can determine whether the client is cared for at home or in a health care facility. Environmental evaluation is particularly important, with the focus on ease and safety of mobility. Promotion of activity through environmental modification increases the quality of life for the client whether injured, ill, or aging. Increased accessibility and mobility can be achieved through planning home modifications such as:

- Ramps
- Wide doorways
- Open-ended door handles replacing doorknobs
- Remote-controlled lighting

- Spacious room arrangements
- Bare floor or low-level pile carpeting
- Grab bars for bathrooms

Efforts by the client and the rehabilitation team to promote activity and mobility can be negated quickly by environmental barriers such as stairs and narrow passageways.

Clients who have limited mobility may be at risk for falls. To decrease the probability of falls at home, client education should focus on creating a safe environment for ambulation; see the Client Teaching Checklist. The accompanying Community Considerations display lists some assistive devices for clients receiving care in the home setting; see Figure 36-10.

HEALTH PROMOTION AND FITNESS

Client expected outcomes include the promotion of activity, mobility, and fitness. Therapeutic exercises maintain flexibility, strength of muscles, range of motion, and energy and increase endurance and the sense of well-being. Factors affecting targeted health promotion outcomes include perceived health status, perceived benefits of exercise, and perceived barriers to exercise as well as attitudes toward exercise. Perceived benefits of exercise and exercise attitudes held by the client have been identified as critical in health promotion and fitness.

IMPLEMENTATION

Interventions for clients with impaired mobility include meeting psychosocial needs, using body mechanics, maintaining body alignment, performing ROM exercises, transferring clients, assisting with ambulation, promoting wellness, using complementary treatment approaches, and documentation.

CLIENT TEACHING CHECKLIST

Promoting Safety at Home

- Avoid unsecured or loose rugs.
- Use banisters on stairways.
- Install bright lights near steps and stairways.
- Avoid wearing shoes that are ill-fitting, unlaced, or high-heeled or have slippery soles.
- Keep all walkways unobstructed (remove clutter).
- Use caution with telephone lines; use a cordless phone if available to avoid tripping danger.
- Do not walk on wet or waxed floors.
- Use nonskid mats in shower and bathtub.
- Use grab bars near toilet and in shower and bathtub.
- Keep commonly used objects within easy reach.

FIGURE 36-10 Assistive devices, such as those shown here, help clients dress independently. DELMAR/CENGAGE LEARNING

MEETING PSYCHOSOCIAL NEEDS

Nursing interventions directed at role changes due to deficits in activity and mobility include (1) fostering open family communication, (2) providing opportunities for family role resumption, (3) prioritizing family roles and responsibilities,

COMMUNITY CONSIDERATIONS

Home Health Care: Assistive Devices in the Home

The following devices may be rented and may qualify for reimbursement from Medicare or private insurance.

- Electric hospital bed with overhead trapeze (gives client more control of environment)
- Portable commode (extends client's independence)
- Lifting device (assists with transferring dependent client from bed to chair)
- Portable telephone (for client safety and convenience)
- Shower chair and hand-held shower for bathtub (promotes client independence and safety)
- Special mattresses for bed and cushions for chairs (promotes comfort and help maintain skin integrity)
- Overbed table for eating or hand activities (promotes client's ability to perform ADL)
- Comfortable chairs close to the bed (promotes socialization by facilitating visits of family and friends)
- Remote control for client who enjoys television (provides leisure/diversion activity)

and (4) modifying family roles and responsibilities. The accompanying Nursing Process Highlight lists nursing interventions that encourage socialization.

APPLYING PRINCIPLES OF BODY MECHANICS

Often nurses are required to have physical strength in order to assist clients in achieving mobility. Carrying, pulling, pushing, and lifting clients and equipment are all activities involved in the delivery of nursing care. Nurses' implementation of correct body mechanics helps minimize the following:

- Client injury
- Nurse work-related musculoskeletal injury
- Nurse fatigue

The following variables can increase the risk of nurse injury:

- Client weight
- Client weight-bearing ability
- Client combativeness and unpredictability
- Height of bed
- Confined workspace
- Wheelchairs without adjustable arms

Educating staff about the use of proper body mechanics is essential in preventing injury; see Procedure 36-1. The National Institute for Occupational Safety and Health (NIOSH, 2008) is studying methods for reducing injury to health care workers as well as improving client safety. A major recommendation of the NIOSH is to avoid the manual transfer of clients by using mechanical lifts whenever possible. As a result, many health care facilities have implemented no-lift policies and use no-lift teams consisting of those who have been specially trained in the use of transfer devices. "The use of patient-moving equipment appears to reduce the risk of injury and chronic pain ... [and] regular equipment use is associated with a 23% reduction in the incidence of chronic pain and injury in health care professionals" (Hart, 2006). Musculoskeletal disorders (MSD) are injuries and disorders of the muscles, nerves, tendons, ligaments, joints, cartilage, and spinal discs. Examples of MSD include carpal tunnel

syndrome, tendonitis, sciatica, herniated disc, and low back pain.

MSD are preventable by educating workers and modifying the work environment, such as providing transfer equipment, and assessing clients. See the Nursing Process Highlight for information that should be assessed prior to moving a client and the Spotlight On display.

MAINTAINING BODY ALIGNMENT: POSITIONING

Clients cannot always move independently and reposition themselves in bed. In such instances, nurses must use proper turning and positioning techniques in order to achieve the following outcomes:

- Increase client comfort
- Prevent contractures
- Prevent pressure sores
- Make portions of the client's body accessible for procedures
- Help clients access their environment

Clients who cannot move independently must be repositioned every 2 hours. Repositioning must be done more often for clients who are uncomfortable or incontinent or who have

NURSING PROCESS HIGHLIGHT

Assessment

Factors That Influence Transfer Technique Type

- Client size and weight
- Level of assistance required by client
- Client willingness and ability to cooperate
- Client health status and medical condition

NURSING PROCESS HIGHLIGHT

Implementation

Promoting Socialization

- Foster client autonomy
- Encourage activities in collaboration with recreational therapist
- Involve client with successful role models
- Inform client of vocational, educational, recreational, and social resources
- Involve client and family in support groups
- Facilitate transportation resources

SPOTLIGHT ON...

Professionalism

Preventing MSD Versus Client Needs

A newly hired nursing assistant is assigned to help move a client in order to change the linens. The charge nurse overhears the nursing assistant say that she is not going to move the client because he is too heavy and "I don't want to hurt myself!" What should the nurse do to promote meeting the client's needs and protecting the staff from injury?

fragile skin, poor circulation, decreased sensation, poor nutritional status, or impaired mental status. See Figure 36-11, which provides an algorithm for assistance in planning client repositioning.

Nurses need to be aware of three essential concepts when positioning clients: pressure, friction, and skin shear. A pressure site is any skin surface area on which the client is lying or sitting. The force of the pressure can compromise circulation and lead to skin breakdown and ulceration. Tissue areas over bony prominences are more likely to experience impaired skin integrity. It is important to always inspect the skin under increased pressure areas for signs of irritation (i.e., redness).

Friction is caused when the skin is dragged across a rough surface such as bedsheets or stretcher surfaces. Friction causes heat, which damages the skin and may lead to decreased skin integrity with resultant infection or skin breakdown.

Skin shear is the result of dragging skin across a hard surface. The force of resistance to being dragged tears the deep layers of skin, which can lead to skin ulceration; see the Safety First display.

For clients in bed, limit the number of pillows under the head in order to avoid neck flexion. Arms should be abducted from the body and straight with slight flexion. Hands should rest comfortably in a flat position with fingers open. The knees and hips should be aligned; use sandbags or pillows to prevent external hip rotation. Avoid flexing the knees by the use of pillows placed behind the knees.

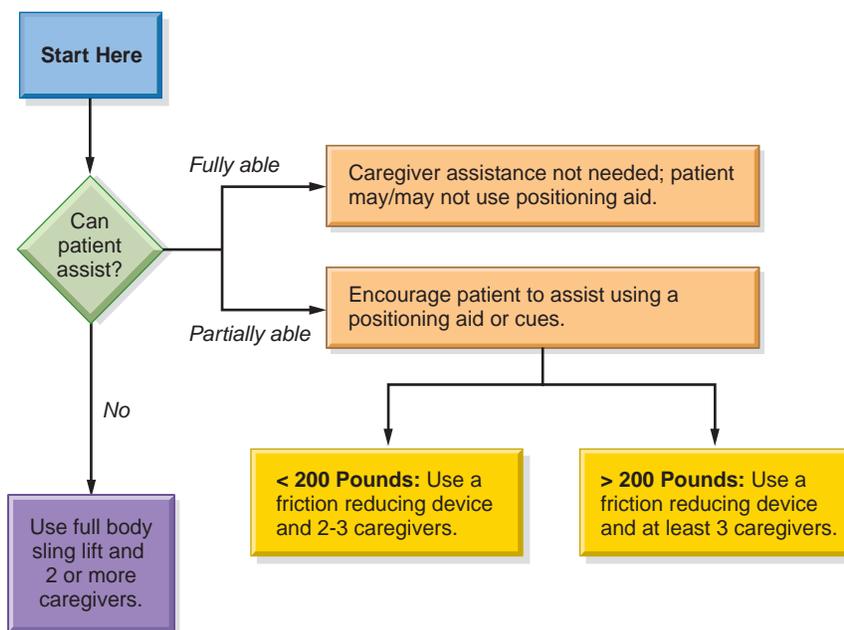

Ankles should be flexed at 90°; use pillows or footboard if necessary.

To maintain proper positioning for a client seated in a chair, be sure the head is straight without bending the neck or dangling the head. The trunk should be upright without bending or curving. Arms and hands are to be supported on armrests or the tabletop; avoid dangling the arms. The hands should be in a flat position with the fingers open. Hips and knees should be flexed. The feet are to be flat on the floor or footrest with the ankles at a 90° angle. If the legs are supported on leg rests and are straight, keep the ankles flexed at a 90° angle.

Table 36-12 on page 1112 provides a description of the most commonly used positions: Fowler's (elevated head and trunk), dorsal recumbent (back-lying with slight elevation of head and shoulders), prone (face down), lateral (side-lying), and Sims' (semi-prone).

SAFETY FIRST

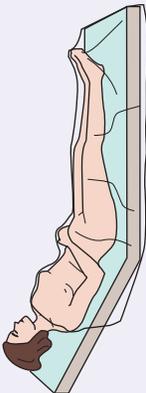

To prevent skin shear, avoid dragging a client across the bed or stretcher. Instead, lift the client or use assistive devices such as turn sheets (drawsheets) or transfer boards.

- This is not a one person task: **DO NOT PULL FROM HEAD OF BED.**
- When pulling a patient up in bed, patient should be flat or in a Trendelenburg position (when tolerated) to aid in gravity, with side rail down.
- For patients with stage III or IV pressure ulcers, care should be taken to avoid shearing force.
- The height of the bed should be appropriate for staff safety (at the elbows).
- If the patient can assist when repositioning "up in bed," ask the patient to flex the knees and push on the count of three.
- During any patient handling task, if the caregiver is required to lift more than 35 lbs. of a patient's weight, then the patient should be considered to be fully dependent and assistive devices should be used.

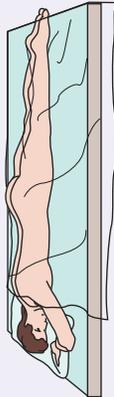

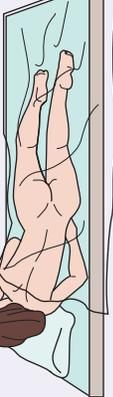

FIGURE 36-11 Algorithm: Reposition in Bed, Side-to-Side, Up in Bed NELSON, A. (2006). *SAFE PATIENT HANDLING AND MOVEMENT ALGORITHMS*. TAMPA, FL: VISN 8 VA SUNSHINE HEALTHCARE NETWORK. RETRIEVED JANUARY 8, 2009, FROM [HTTP://WWW.VISN8.MED.VA.GOV/PATIENTSAFETYCENTER](http://www.visn8.med.va.gov/patientsafetycenter).

TABLE 36-12 Positioning

POSITION	DESCRIPTION	INDICATIONS	POTENTIAL COMPLICATIONS	CORRECTIVE MEASURES
Fowler's	Semirecumbent position; head of bed elevated to 45°–60°; knees slightly elevated.	Promotes comfort; improves respiratory problems (e.g., dyspnea, pneumonia); encourages postoperative drainage.	Flexion contracture of cervical spine Exaggerated flexion of lumbar spine	Rest head directly on mattress or support with small pillow only. Firm support to back; pillow to support lower back.
Dorsal recumbent (supine)	 <p>Back-lying position; head and shoulders may be slightly raised.</p>	Promotes comfort. NOTE: Head and shoulders are kept flat after procedures involving spinal anesthetics.	Dislocation of shoulder	Elevate forearms on pillows to avoid tension on shoulders.
			Flexion contracture of wrist	Support hands on pillows to maintain natural alignment
			Finger contractures and thumb abduction	Hand-wrist splints.
			External hip rotation	Trochanter roll.
			Hyperextension of knees	Flex knees with small pillow under the thighs.
			Foot drop (plantar flexion)	Maintain dorsal flexion with footboard or high-top tennis shoes.
			Cervical hyperextension	Maintain correct alignment with pillows under upper shoulders, neck, and head.
			Posterior flexion of lumbar spine	Small pillow or roll under lumbar curvature.
			Clawhand deformities (extension of fingers and abduction of thumbs)	Hand-wrist splints.
			Hyperextension of knees	Pillow under lower legs from below the knees to ankles or small pillow under thighs to slightly flex knees.
Foot drop (plantar flexion)	Maintain dorsal flexion with footboard or high-top tennis shoes.

<p>Lateral</p> 	<p>Side-lying position; lateral aspects of lower scapula and lower ilium support most of body weight.</p>	<p>Promotes comfort; relieves pressure on sacrum and heels.</p>	<p>Foot drop Lateral flexion of neck Internal rotation of arm; limited chest expansion leading to respiratory impairment Extension of fingers and abduction of thumbs Internal rotation and abduction of femur Twisting of spine</p>	<p>Allow feet to dangle over end of mattress, or place lower legs on pillow to keep toes from resting on bed. Pillow under head and neck. Maintain alignment of upper arm with pillow underneath. Slightly flex lower arm. Hand-wrist splints. Pillows to support leg from groin to foot. Align both shoulders with both hips.</p>
<p>Sims'</p>	<p>Semi-prone position; upper arm is flexed at shoulder and elbow while lower arm is positioned behind client; both legs flexed in front of client with more flexion in upper leg.</p>	<p>Promotes drainage from mouth; prevents aspiration; reduces pressure on sacrum and greater trochanter of hip; promotes comfort, especially in pregnant clients.</p>	<p>Lateral flexion of cervical spine Damaged nerves and blood vessels of lower arm axillae Internal shoulder rotation and abduction Internal rotation and adduction of hip and leg; lumbar lordosis Foot drop</p>	<p>Support head with pillow unless drainage from mouth is necessary. Position lower arm behind and away from the back. Pillow between chest and upper arm. Pillow under upper flexed leg from groin to foot. Sandbag to dorsiflex lower foot.</p>

Delmar/Cengage Learning

Assisting clients to comfortable therapeutic positions requires much skill. Often the client is unable to assist in repositioning; in such cases, it is best to use two or more staff members to reposition the client in order to prevent injury to clients and staff.

Equipment used for client positioning includes pillows, foam wedges, trochanter rolls, footboards, bed boards, hand-wrist splints, traction, side rails, restraints, and trapeze bars. Table 36-13 describes devices used to help maintain proper positioning.

Hand-wrist splints can facilitate extension of the wrist, hand, and fingers as well as prevent contracture and reduce spasticity. The goal for splint use is to maintain a functional hand. Figure 36-12 shows hand-wrist splints. Clients must be taught the correct way to put on the device, as incorrect use of a splint or brace can cause joint damage, stiffness, or pain.

Side Rails

Falls are common types of injuries in hospitals and long-term care facilities. Side rails, also referred to as bed rails, which are placed on the sides of beds and stretchers to prevent falls, can be raised, lowered, and locked into place; see Figure 36-13 on page 1115. Side rails should not give nurses a sense of security because they increase the likelihood of fall injuries if clients climb over the rails. There have also been incidences in which clients experienced strangulation or death as a result of entrapment in the rails or between the rails and the mattress (Minnick, Mion, Johnson, Catrambone, & Leipzig, 2008). Beds must be placed in the lowest position to reduce the force of a possible fall, should one occur. Also, clients identified as being at risk for falls should be closely monitored.

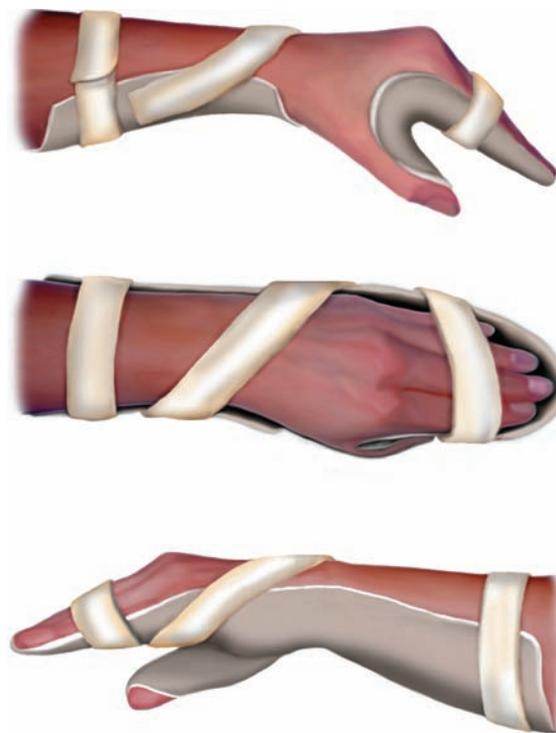

FIGURE 36-12 Hand-Wrist Splints DELMAR/CENGAGE LEARNING

Some clients resist the use of side rails because they feel their independence is altered. It is important that the nurse teach clients and families the purpose of side rails, focusing on safety promotion. Note that some health care agencies require signed notification consenting to the use of raised side rails.

TABLE 36-13 Maintaining Proper Position: Assistive Devices

Bed board	Plywood board placed under entire mattress; improves spinal alignment by providing support
Footboard	Board placed at end of bed to provide support for feet to maintain dorsiflexion; prevents foot drop (dorsiflexion)
Hand-wrist splint	Individually contoured for each client; maintains thumb adduction and opposition to fingers
Pillow	Available in various thicknesses; provides support; elevates body parts
Restraint	Variety of types available (jacket or vest, wrist belt, ankle belt, waist belt); provides immobilization
Side rails	Bars attached to the sides of the bed; assist with mobility and prevent falls
Traction	Used for immobilization and to promote healing of fractures
Trapeze bar	Triangular device hanging from above-bed bar that is secured to bed frame; used by clients with upper extremity function to assist in repositioning and transferring
Trochanter roll	Folded blanket placed under client's buttocks and rolled inward toward client to place thigh in a neutral position; used when client is supine to avoid external rotation of hips and legs

Delmar/Cengage Learning

FIGURE 36-13 The use of side rails promotes safety. DELMAR/CENGAGE LEARNING

Restraints

Restraints are protective devices used to limit physical activity or to immobilize a client or body part. Restraints are used for the following purposes: to protect the client from falls, to protect a body part, to prevent the client from interfering with therapies (e.g., pulling out tubes or catheters), and to reduce the risk of injury to others. See Chapter 29 for a complete discussion of restraints and the procedure for applying restraints; see the Spotlight On display.

Traction

Traction may be used to maintain body alignment, especially following injury or surgery. There are several traction techniques, including manual, skin, and skeletal; see Figure 36-14. See the accompanying Nursing Process Highlight on page 1116 for a listing of key assessment data for clients using skeletal and skin traction. The nurse must document assessment findings to promote continuity of care.

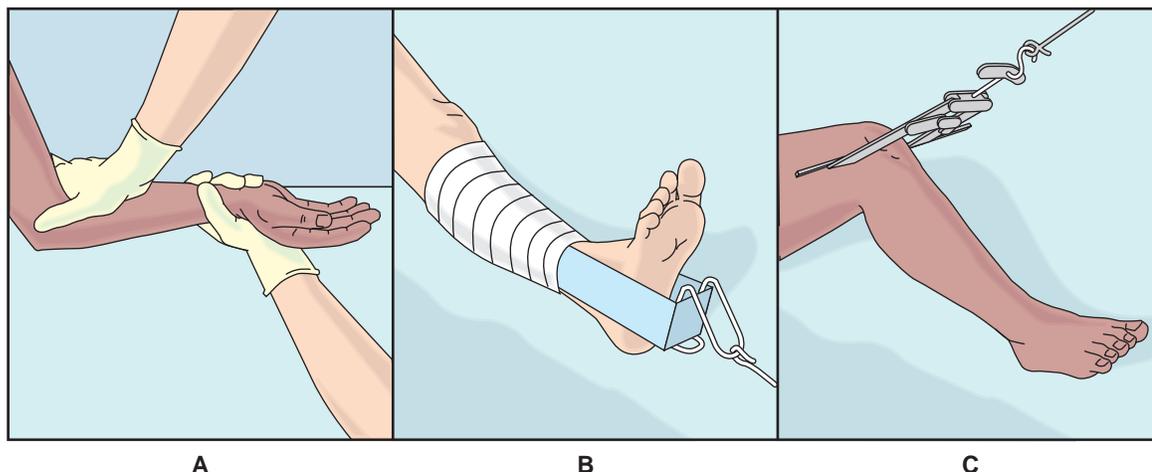

FIGURE 36-14 Traction Techniques: A. Manual; B. Skin; and C. Skeletal DELMAR/CENGAGE LEARNING

SPOTLIGHT ON...

Legal/Ethical

To Restrain or Not?

You are the charge nurse working nights at a long-term care facility. Two staff members called in sick at the beginning of the shift; therefore, you are very short staffed. Mrs. Ellington, an 84-year-old woman who is very confused, keeps trying to climb out of her bed. She almost fell twice while trying to climb over the bed rails. In an attempt to prevent Mrs. Ellington from falling, you have decided to place her in restraints until you can get more staff to come to work. What are the ethical implications of your actions? The legal ones? Would you change your actions if Mrs. Ellington were your grandmother?

PERFORMING RANGE-OF-MOTION EXERCISES

ROM exercises are performed several times a day by placing each joint through its full functional motion. The purposes of ROM exercises are to maintain full flexibility, maintain muscle tone and strength, prevent contractures, and improve circulation. See Procedure 36-2 and the Uncovering the Evidence display on page 1116.

TRANSFER TECHNIQUES

Planning plays a major role in safe, effective client transfers; the nurse must determine to what extent the client is able to help with the transfer. If the client is totally dependent or is heavy, the nurse will need other staff members to help. Table 36-14 lists potential hazards involved in client transfers with corresponding nursing interventions to promote safety.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Effects of a Range-of-Motion Exercise Programme”

AUTHORS

C. N. Tseng, C. C. Chen, S. C. Wu, and L. C. Lin

PURPOSE

To examine the effects of a nurse-led range-of-motion (ROM) exercise program on functional abilities of stroke survivors in long-term care facilities.

METHODS

A randomized, controlled trial was conducted with bedridden older stroke survivors in residential care. Participants were randomly assigned to one of three groups: a usual care group, Intervention Group I, or Intervention Group II. Intervention Group I had a registered nurse to supervise participants performing exercises. In Intervention Group II, a registered nurse provided physical assistance for participants in performing ROM exercises.

RESULTS

Both intervention groups had a statistically significant improvement in joint range, activity function, depressive symptoms, and perception of pain compared with the usual care group.

IMPLICATIONS

A nurse-led ROM exercise program can improve the physical and psychological function of bedridden older people with stroke.

Tseng, C. N., Chen, C. C., Wu, S. C., & Lin, L. C. (2007). Effects of a range-of-motion exercise programme. *Journal of Advanced Nursing*, 57(2), 181–191.

NURSING PROCESS HIGHLIGHT

Assessment

Skeletal and Skin Traction: Assessment Factors

Skeletal Traction

- Location of traction
- Amount of traction being applied
- Countertraction applied
- Body position to be maintained
- Duration of application (continuous, intermittent, or as-needed basis)
- Traction weights free falling
- Traction rope intact, taut, and unobstructed through the pulley
- Immobilized body part in alignment with rest of body
- Appearance of the skeletal pin or wire sites (e.g., dry, encrusted, reddened, edematous)
- Presence of drainage from the skeletal pin or wire sites
- Evidence of skin breakdown

Skin Traction

- Location of traction
- Type of traction (e.g., cervical, Buck’s, Russell’s)
- Amount of traction weight being applied to the affected body part
- Body position to be maintained
- Duration of application (continuous, intermittent, or as-needed basis)
- Traction weights free falling
- Traction rope intact, taut, and unobstructed through the pulley
- Immobilized body part in alignment with rest of body

Moving Clients

Prolonged immobility can cause discomfort, muscle wasting, thrombus formation, and skin breakdown. Also, the client who slides down toward the foot of the bed while the head is elevated can experience reduced lung capacity and impaired respiratory effort. Nurses often must move clients up in the bed or reposition them. Moving a client may sometimes be done by one person but often requires two staff members to ensure safe transfer; see Procedures 36-3 and 36-4.

LOGROLLING THE CLIENT **Logrolling** is a technique for moving a client whose body must remain in straight alignment. Situations requiring total alignment of the spine include spinal injury or recovery from spinal surgery. Logrolling is accomplished by two or three nurses working in a coordinated fashion.

Transferring from Bed to Chair

A client may need to be moved from the bed to a chair, commode, or wheelchair. Procedure 36-5 describes the steps involved in safely assisting a client from bed to chair. This procedure discusses moving a client to a wheelchair; however, the process is the same for transferring to a regular chair or bedside commode. Figure 36-15 on page 1118 provides an algorithm for planning safe bed-to-chair transfers. See the Nursing Checklist on page 1117 for guidelines on the safe use of wheelchairs.

A wheelchair is a means of transportation for clients unable to support their weight while standing. Safety instructions for use of a wheelchair include the need to keep the wheels locked when not deliberately moving and to move the footrests out of the way when getting in and out of the wheelchair; see the Safety First display on page 1117.

TABLE 36-14 Client Transfer: Hazards and Safety Measures

POTENTIAL HAZARD	PREVENTIVE MEASURES
Falling	<ul style="list-style-type: none"> Assess client's size and ability to assist. Ask for help from other staff members if needed. If client starts to fall, lower gently to the floor while protecting the head. If client has fallen, assess thoroughly for signs of injury.
Skin damage	<ul style="list-style-type: none"> Use a transfer board or drawsheet. Lift client instead of sliding across surfaces. Pad surfaces that may cause injury (e.g., bed rails).
Foot injury	<ul style="list-style-type: none"> Place nonskid slippers on client. Do not tuck sheets and blankets tightly over feet. Ensure that feet do not become tangled in side rails, chair legs, or other equipment.
Dislodging client care equipment	<ul style="list-style-type: none"> Assess for presence of all tubes and lines (e.g., catheters, IV lines). Determine if equipment must be temporarily disconnected during the transfer. Reconnect equipment promptly when transfer is completed. Keep the urinary drainage bag at a level lower than the bladder.

Delmar/Cengage Learning

Transferring from Bed to Stretcher

Some clients (e.g., those who are too weak to sit upright, those who are unconscious, or those with injuries prohibiting the erect position) must lie flat during transfers. In such situations, a stretcher (gurney) is used to facilitate client transfer. See Figure 36-16 on page 1119 for an algorithm for bed-to-stretcher transfers. Stretchers have several safety features, including side rails, safety belts and straps, and locking wheels. The nurse should caution clients to move carefully while on the stretcher as it is more narrow than the bed. Reassure the client that side rails will be used to prevent falls. See Procedure 36-6 for instructions on moving clients who need minimal and maximal assistance. See the Nursing Checklist on page 1118 on stretcher transport safety.

Assistive Devices

Nurses must educate clients about the use of assistive devices; see Figure 36-17 on page 1119. There are several devices

NURSING CHECKLIST

Wheelchair Safety

- When moving a client in a wheelchair, back into and out of elevators.
- Back slowly down wheelchair ramps.
- Push the wheelchair ahead of you when going up ramps.
- If going through a self-closing door, back the wheelchair out of the room. You can keep the door open by backing against the door. The wheelchair can then be guided out of the room.
- Lock brakes when the wheelchair is stationary.
- Intravenous infusion bags can be placed on portable IV poles attached to the wheelchair during transport.
- Urinary drainage bags can be placed on the lower body of the wheelchair during transport. Coil the drainage tubing so the catheter is not tugged during transport. Empty bag prior to wheelchair transfer. Keep the bag below the level of the client's urinary bladder.

▼ SAFETY FIRST ▼

WHEELCHAIR SAFETY

Caution client to avoid leaning forward in the wheelchair because leaning forward can cause tipping and falling.

available for helping with client transfers. Slide boards (transfer boards) assist the bed-wheelchair transfer by bridging the space between the bed and the wheelchair. Note that specialized wheelchairs with removable armrests are used with slide boards. As the client becomes more independent, the slide board can be used to transfer from the wheelchair to a car. Figure 36-18 on page 1119 shows a slide board transfer to a car.

The hydraulic (mechanical) lift is used for moving immobile clients who are heavy; see Procedure 36-7. A client may be transferred to a chair, wheelchair, bedside commode, stretcher, or scale using a hydraulic lift. The manufacturer's equipment instructions should be followed, and the weight limits must not exceed the manufacturer's specifications. Two staff members are needed to safely operate a hydraulic lift. Hydraulic lifts are not for use with clients who have spinal cord injury, as spinal alignment is not maintained during use of the lift. See the Safety First display on page 1118 for a warning about any type of transfer involving a client with a closed chest drainage system.

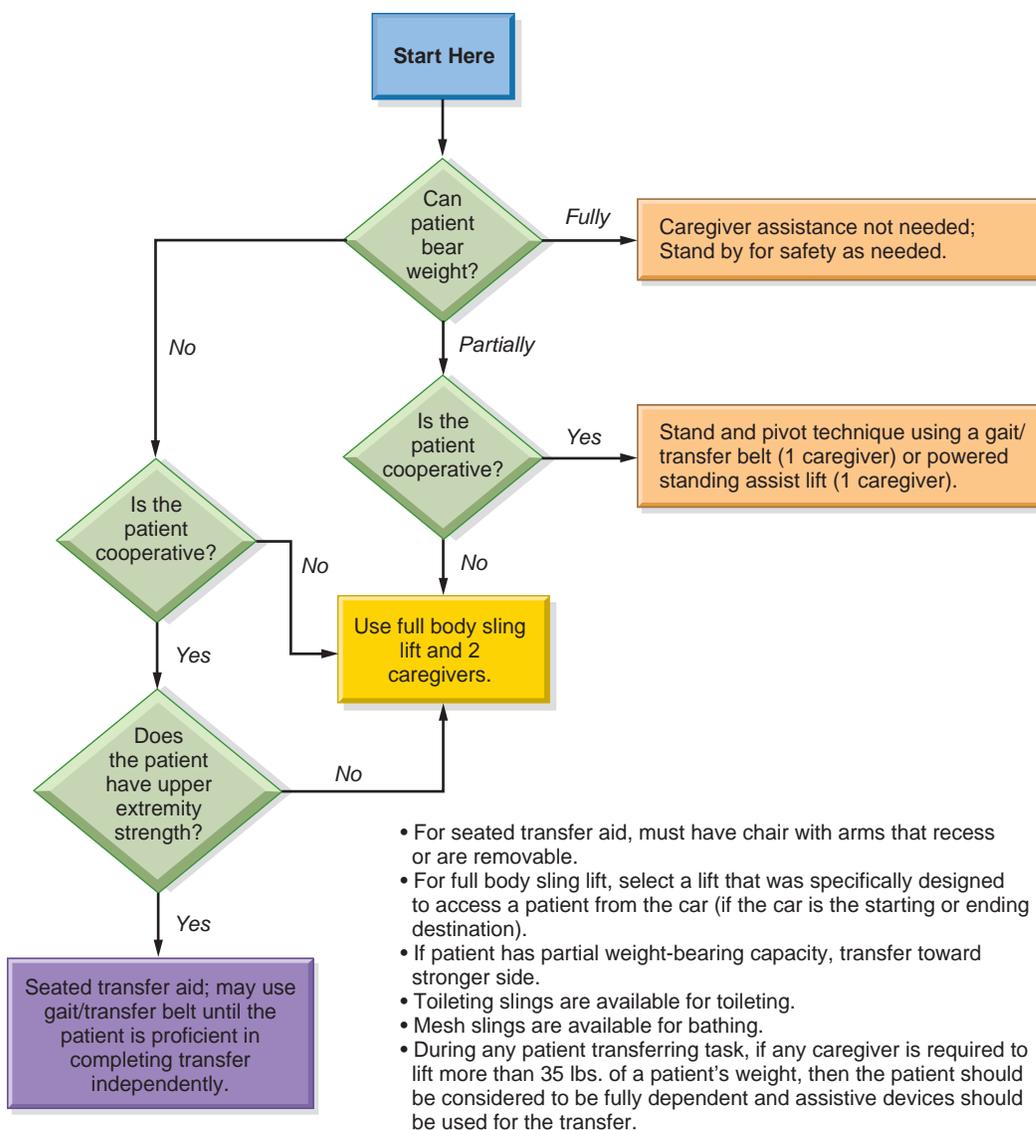

FIGURE 36-15 Algorithm: Transfer to and from Bed to Chair, Chair to Toilet, Chair to Chair, or Car to Chair NELSON, A. (2006). SAFE PATIENT HANDLING AND MOVEMENT ALGORITHMS. TAMPA, FL: VISN 8 PATIENT SAFETY CENTER. RETRIEVED JANUARY 8, 2009, FROM [HTTP://WWW.VISN8.MED.VA.GOV/PATIENTSAFETYCENTER](http://www.visn8.med.va.gov/patientsafetycenter).

✓ NURSING CHECKLIST

Stretcher Transport Safety

- Use hall ceiling mirrors at intersections before turning corners.
- Lock elevator door open when entering or exiting.
- Stand at head of stretcher to push stretcher up a ramp.
- Back down a steep ramp while positioned at head of stretcher.
- Lock stretcher brakes when standing still.

▼ SAFETY FIRST ▼

TRANSFERS AND CLOSED CHEST DRAINAGE SYSTEM

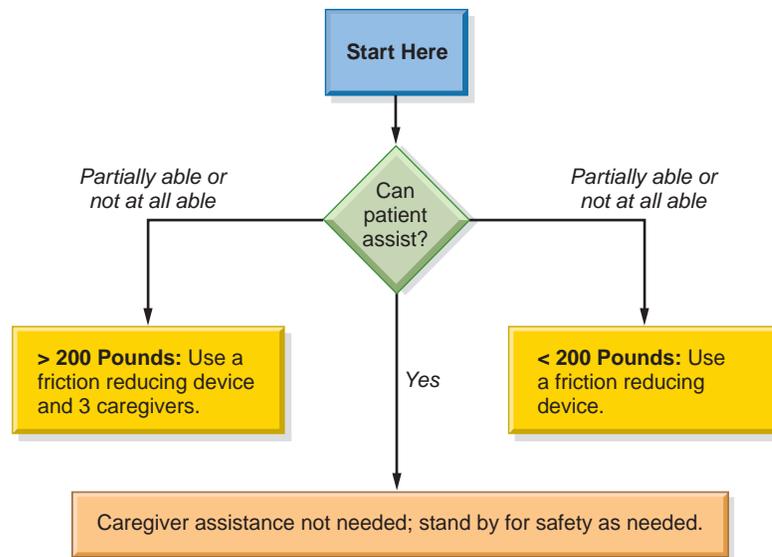

The closed chest drainage system must remain vertical at all times, including during transfers, to maintain the water seal.

ASSISTING WITH AMBULATION

Client **ambulation** (assisted or unassisted walking) is encouraged soon after the onset of illness, injury, or surgery

to prevent the complications of immobility. In planning ambulation, the nurse assesses the client's strength, endurance, and mobility status. Can the client walk alone, or is assistance needed? The presence of equipment (e.g., urinary catheters, IV infusions, drainage tubes) requires assistance; see the accompanying Nursing Checklist on page 1120.

In order to maintain client safety, ambulation must occur in progressive stages. First, the client should be able to tolerate

- Surfaces should be even for all lateral patient moves.
- For patients with stage III or IV pressure ulcers, care must be taken to avoid shearing force.
- During any patient transferring task, if any caregiver is required to lift more than 35 lbs. of a patient's weight, then the patient should be considered to be fully dependent and assistive devices should be used for the transfer.

FIGURE 36-16 Algorithm for Lateral Transfer to and from Bed to Stretcher, Trolley NELSON, A. (2006). *SAFE PATIENT HANDLING AND MOVEMENT ALGORITHMS*. TAMPA, FL: VISN 8 PATIENT SAFETY CENTER. RETRIEVED JANUARY 8, 2009, FROM [HTTP://WWW.VISN8.MED.VA.GOV/PATIENTSAFETYCENTER](http://www.visn8.med.va.gov/patientsafetycenter).

FIGURE 36-17 Both client and family members need education regarding wheelchair safety. DELMAR/CENGAGE LEARNING

FIGURE 36-18 Slide Board Transfer DELMAR/CENGAGE LEARNING

sitting on the bedside and dangling the feet. The next step is client tolerance of standing at the side of the bed. Then progressive ambulation can be initiated; see Procedure 36-8. Sometimes it may be necessary to use a **gait belt** (a two-inch wide webbed belt worn by the client for the purpose of stabilization during transfers and ambulation) to promote client safety.

As ambulation activities are initiated, it is important to assess the client's blood pressure, respiratory rate, pulse, skin

NURSING CHECKLIST

Assisting with Client Ambulation

- Determine the client's activity level and tolerance for physical exertion.
- Assess for factors that may negatively affect ambulation (e.g., mental status, fatigue, pain, medications).
- Evaluate the environment for safety (e.g., presence of obstacles in walkway, adequate lighting, nonslip floor, handrails).
- Check assistive devices for safety hazards.
- Check client's clothing (e.g., nonslip shoes, adequate covering for privacy and warmth).
- During ambulation, assess client's tolerance of activity.
- Postambulation, assess client's recovery from the activity.

color and moisture, and subjective responses. While the client is walking, observe for signs of exertion, including diaphoresis, shortness of breath, or weakness.

It is also important to assess for the presence of orthostatic hypotension in order to prevent falls. Depending on the client's physical conditioning and the effects of orthostatic hypotension, the client may need to slowly progress to independent ambulation. Once the activity is completed, the nurse evaluates the client, focusing on progression of activity. Continuous evaluation of the client's strength and endurance is performed by the nurse.

Preparing the Client to Walk

One of the best ways to encourage ambulation is to help the client become and remain as independent as possible while lying in bed. This includes urging clients to participate in ROM exercises and perform self-care activities as much as possible.

Independent mobility, the goal of most clients, is the ability to walk, run, sit, and turn without mechanical or personal aid. Progressive exercises and activities that promote independent mobility include:

1. *Turning.* The client turns in bed using side rails for stabilization and leverage.
2. *Sitting.* The client raises the head of the bed and lowers the height of the bed. Then the client turns to the side of the bed and swings legs over the side of the bed to assume the dangling position. Arms placed in the tripod position give balance to the sitting position.
3. *Standing.* The client dangles for a few minutes to ensure balance and then bears weight with both feet at the side of the bed. For additional stability and balance, the client can perch on the edge of the bed for several minutes before standing.

4. *Walking.* The client assesses strength and balance while walking, thus allowing a gradual progression of the duration of walking. Instruct clients to rest by sitting or standing still while stabilized with a guide rail if fatigued; see Figure 36-19.

CLIENT EDUCATION Prior to ambulation, clients who have been immobile need to be prepared adequately in order to prevent injury. Listing the therapeutic outcomes of ambulation is one way to teach clients the importance of ambulation. Clients should also be taught to sit down or use side rails if dizziness occurs.

Teach clients the technique for safe falling in order to minimize risk of injury; see Figure 36-20 on page 1121. Clients should be told that if they begin to feel faint, they should fall toward the affected side of the body and use the unaffected side to raise self from the floor or chair.

PREAMBULATORY EXERCISE Helping immobile clients to prepare for ambulation includes instruction of preambulatory exercises in order to strengthen and tone muscles. The quadriceps femoris is the major muscle used for walking; thus, clients should be directed to gently contract and release the leg muscles several times a day. Clients who will be walking with the assistance of walkers and crutches need upper body strength. Instruction in the safe use of ambulatory assistive devices is also necessary for many clients with impaired mobility.

FIGURE 36-19 The use of handrails promotes safety and independence in ambulating. DELMAR/CENGAGE LEARNING

FIGURE 36-20 Support for Falling Client DELMAR/CENGAGE LEARNING

Assistive Devices

Clients who are unable to ambulate independently can use devices designed to help them walk safely. Determination of which device to use is based on the following:

- Upper arm strength
- Endurance (stamina)
- Presence or absence of one-sided weakness
- Weight-bearing ability; see Table 36-15

See Table 36-16 on page 1122 for a comparison of the three most common devices used to assist in walking: canes, walkers, and crutches.

CANES A cane is to be used by the client who can bear weight on both legs but has some weakness in one leg or hip. The straight (standard) cane is used most often; canes with three or four legs are used with clients who need more stability than provided by the straight cane. Quad canes provide more stability but are sometimes more awkward to use than the straight cane; see Figure 36-21 on page 1122, Procedure 36-9, and the Safety First display.

WALKERS A walker is a waist-high, metal, tubular device with a handgrip and four legs. Some walkers have rubber tips on all four legs, whereas others have wheels on the two front legs. The advantages of using a walker include provision of extra support, provision of a sense of security, and independ-

TABLE 36-15 Weight-Bearing Status

DEGREE OF WEIGHT BEARING	DESCRIPTION
Non-weight bearing	Patient does not bear weight on the affected extremity. The affected extremity does not touch the floor.
Touchdown weight bearing	Patient's foot of the affected extremity may rest on the floor, but no weight is distributed through that extremity.
Partial weight bearing	Patient bears 30%–50% of his or her weight on the affected extremity.
Weight bearing as tolerated	Patient bears as much weight as can be tolerated on the affected extremity without undue strain or pain.
Full weight bearing	Patient bears weight fully on the affected extremity.

Reprinted with permission from Maher, A. (1994). *Orthopedic nursing*. Philadelphia: Saunders.

ence. The client first moves the walker forward and then takes a step while balancing his or her weight on the walker; see Procedure 36-9.

A walker is used by clients who need more support than that provided by a cane. Walkers are available with and without wheels. The walker without wheels provides more stability but also requires more client stamina in order to lift the walker. Walkers with wheels are intended for use by clients with limited upper body strength. The nurse should determine the following for clients using walkers:

1. Amount of weight bearing allowed on lower limb
2. Appropriateness for client's height
3. Type of walker (pick-up or rolling)
4. With pick-up walker: client's ability to grip, lift, and propel the walker forward

SAFETY FIRST

To promote safe ambulation using a cane, be sure that:

- The cane is appropriate for the client's height and has suction grips to prevent falls.
- The client is wearing flat shoes with nonskid soles.

TABLE 36-16 Assistive Devices for Ambulation

EQUIPMENT	DESCRIPTION	DIRECTIONS FOR USE
Cane	<ul style="list-style-type: none"> Widens base of support Various styles: (1) regular (straight)—gives minimal support for balance; (2) three-point—provides broader base of support, is more cumbersome; (3) four-point (quad)—broader base of support, more cumbersome 	<ul style="list-style-type: none"> Use on unaffected side. Advance cane simultaneously with affected limb. Hold close to body; do not move cane forward beyond toes of affected foot.
Walker	<ul style="list-style-type: none"> Provides more stability than canes due to broader base of support Various styles: (1) pickup—assists with weight bearing, though lifting may cause some strain for client; (2) rolling—pushed on wheels, which reduces physical strain on client 	<ul style="list-style-type: none"> For clients with weight-bearing status: Advance walker and step normally. For partial or non-weight bearing on one limb: Thrust weight forward, then lift walker and replace all four legs on floor.
Crutches	<ul style="list-style-type: none"> Less stable than canes and walkers Requires upper body strength and ability to maintain balance 	<ul style="list-style-type: none"> Use good posture. Maintain proper foot position on affected side (foot drop can result from walking on toes or ball of foot). Eliminate obstacles in ambulatory path.

Data from Miller, C. A. (2009). *Nursing for wellness in older adults* (5th ed.). Philadelphia: Wolters Kluwer/Lippincott Williams & Wilkins; Mincer, A. B. (2007). Assistive devices for the adult patient with orthopaedic dysfunction. *Orthopaedic Nursing*, 26(4), 226–233.

FIGURE 36-21 Nurse promotes safety of a client using a quad cane. Note the use of the gait belt for added safety. DELMAR/CENGAGE LEARNING

5. With rolling walker: client’s ability to grip and propel the walker forward

When educating clients about the use of walkers, inform them that when transferring from chair or commode, they should back the walker to the chair or toilet seat and use arms of chair or commode to assist in sitting and standing. Teach clients to always use both hands when using a walker to transfer from standing to sitting; see Figure 36-22.

FIGURE 36-22 Client Using a Walker DELMAR/CENGAGE LEARNING

CRUTCHES A crutch is a wooden or metal staff used to increase client mobility. There are two types of crutches: axillary and forearm. The most commonly used type, the axillary crutch, fits under the axilla with the weight being placed on the handgrips. The forearm crutch, which has a handgrip and a metal cuff that fits around the arm, is more convenient but provides less stability than the axillary crutch.

To prevent slipping, crutches have rubber tips, which must be kept dry. If the tips are worn or loose, they must be replaced. The crutch must be regularly inspected because if cracks or bends are present, the person's weight will not be properly supported; see the Client Teaching Checklist.

Crutches can be used by clients who are unable to bear any weight on one leg, clients who can bear partial weight on one leg, and clients who have full weight bearing on both legs. Several gaits are used with crutches: the four-point

gait, three-point gait, two-point gait, and swing-through gait.

The *four-point gait* for weight bearing with both legs follows the pattern of right crutch forward, left foot forward, left crutch forward, then right foot forward. The four-point gait with crutches is very stable but slow. The *two-point gait* for weight bearing with both legs has the pattern of right crutch and left foot forward together, then left crutch and right foot forward together. The two-point gait requires more balance but is a faster gait. The *three-point gait* for weight bearing with one leg has the pattern of crutches and weak leg forward together, then weight-bearing leg forward. The *swing-through gait* has the pattern of crutches forward, then legs swing forward together. The swing-through gait has the advantage of speed; however, it requires good balance. See Procedure 36-9 for a description of crutchwalking techniques.

CLIENT TEACHING CHECKLIST

Crutchwalking

Climbing Stairs

This method of climbing stairs provides a broad base of support and stability for the weaker leg:

- Climb stairs using the stronger leg first.
- Bring the crutches to the level of the stronger leg.
- Bring the weaker leg to the level of the crutches and the stronger leg.
- Repeat to climb stairs. This requires time, balance, and strength.

Descending Stairs

This method of descending stairs provides a broad base of support and stability for the weaker leg:

- Support the body with the stronger leg.
- Move the crutches down to the first descending step.
- Move the stronger leg to the first descending step.
- Repeat to descend the staircase. This requires time, balance, and strength.

Sitting in a Chair

The client has greater stability using the stronger leg and chair arm for support:

- Stand in front of a chair.
- Hold the crutches on the side with the weaker leg.
- Grasp the chair arm using the arm on the side of the stronger leg.
- Flex knees and hips to sit in chair.
- Reposition self in chair using arms and stronger leg while sitting.

Rising from the Chair

The client has greater strength using the stronger leg to rise. More stability is provided by the chair arm and crutches for support. Rising requires more strength than sitting:

- Move forward in chair, placing strongest leg on the floor.
- Grasp the chair arm on the same side as the stronger leg.
- Hold the crutches with the hand on the side of the weaker leg.
- Use the chair arm and crutches for support while rising.
- Once standing, place the crutches in the position for ambulation.
- Weak clients may need assistance. The gait belt is useful in such situations.

WELLNESS PROMOTION

Wellness promotion emphasizes the need for physical fitness, which increases well-being, increases sympathetic nervous system activity, improves cardiovascular functioning, and produces and maintains weight loss. The nurse should identify physical activities enjoyed by the client and encourage increased participation. When planning an exercise program, the following elements need to be considered:

- Health status (existing medical conditions)
- Physical condition
- Age
- Preferences for types of activities

See the Safety First display.

COMPLEMENTARY AND ALTERNATIVE TREATMENT MODALITIES

There are numerous complementary and alternative modalities that help improve musculoskeletal health; see the accompanying Respecting Our Differences display. Also, physical activity and relaxation exercises help reduce muscular tension and improve functional abilities. Healing Touch (see Chapter 31) has been shown to reduce pain and inflexibility in muscles and joints, thereby improving mobility for many people (Umbreit, 2006). Therapeutic touch (see Chapter 31) has been found to be effective with clients experiencing musculoskeletal problems, such as sprains, strains, muscle spasms, and fractures (Quinn, 2006). Tai chi (see Chapter 31) has been shown to reduce fall risk by improving balance (Mitty & Flores, 2007).

EVALUATION

A client with activity or mobility deficits must maintain a balance between independence and dependence, which is necessary for positive self-esteem and confidence. This healthy balance can be influenced by support from the client's family and friends. Encouragement, positive acceptance, and affection are ways in which significant others can demonstrate support.

Family members are often unaware of the client's potential to improve. Thus, they may give unnecessary assistance in activities and mobility rather than allow the client to function independently. The client then becomes resentful because there is a loss of self-control. Resentment can also occur with the family who has accepted the heavy responsibilities of

Evaluating Client Activity in the Home Setting

- Mobility status
- Ability to perform ADL
- Use of appropriate adaptive devices
- Use of activities as a basis for building competence and achievement

caregiving. For clients who overestimate their own cognitive and physical capabilities and energy level, safety becomes an important issue.

Long-term activity is the focus of evaluation as the client transfers skills and knowledge from the acute care hospital or rehabilitation facility to home. See the Community Considerations display for areas that need to be evaluated in the home setting. Measures of physical assessment, functional assessment, and performance of ADL are used for follow-up evaluation of the client's status for activity and mobility.

Ongoing assessment of the client's mobility is important because compliance with home exercise programs may lessen over time after discharge. When evaluating long-term activity and mobility goal achievement, the nurse should observe clients in the home setting in order to note their ability to function within their own environment.

Complementary and Alternative Therapy

- The herb *ginkgo biloba* may be used to promote circulation.
- Acupuncture is a traditional Chinese medicine (TCM) method of pain relief in which a qualified practitioner inserts needles in certain body sites to promote the release of endorphins (i.e., natural painkillers).
- Acupressure is a technique similar to acupuncture; pressure instead of needles is applied to the acupuncture sites to relieve pain.
- Massage protects skin integrity by promoting circulation.
- Moist heat (warm towels, hot packs, bath or shower) promotes circulation.
- Cold (ice bag) helps reduce swelling.
- Transcutaneous electrical nerve stimulation (TENS) is used to decrease pain.
- Biofeedback is used to help clients decrease muscular tension.

SAFETY FIRST

EXERCISE AND CLIMATE

Caution clients to consider the climate when exercising and replenish fluids accordingly. Dehydration affects mobility by increasing joint and back pain and may also lead to client collapse.

NURSING CARE PLAN

The Client with a Fractured Leg

CASE PRESENTATION

Magda Constantin is a 15-year-old high school student recovering from a closed fracture of her right tibia suffered in a soccer game. She states that she is having trouble using crutches and getting around school, especially up and down the stairs. She is unhappy about not being able to play soccer and states, “People stare at me when I walk down the hall.”

ASSESSMENT

- Difficulty ambulating due to cast and crutches
- Verbalizations of discomfort about altered mobility and body image

NURSING DIAGNOSIS: *Impaired physical mobility* related to inability to use legs normally and difficulty using crutches.

NOC: Coordinated movement

NIC: Exercise therapy: Ambulation

EXPECTED OUTCOMES

Client will:

1. Understand and demonstrate proper crutch technique.
2. Verbalize a more positive self-image and acceptance of her temporary condition.

INTERVENTIONS/RATIONALES

1. Measure crutch height and fit for client. Determines proper fit, which will relieve pressure, if any, and promotes safe ambulation.
2. Watch client as she walks across the room using the crutches. Provides baseline assessment of crutchwalking skills.
3. Demonstrate correct mechanics of crutch walking using three-point gait. Allows for partial or non-weight-bearing ambulation.
4. Ask client to return demonstrate crutchwalking technique. Shows client’s understanding and ability to execute technique.
5. Suggest ways that crutchwalking can be facilitated, such as wearing soft-soled, flat shoes; carrying a backpack strapped over both shoulders; wearing nonbulky shirts to minimize clothing under arms; and taking frequent rest stops while walking. Tips on facilitating crutch gait will help remove barriers to effective walking and increase client comfort and confidence in technique.
6. Help client understand that cast and crutches are a temporary measure to promote proper healing and are not a reflection of overall body health. Client should learn to view situation as temporary and keep in mind that the broken leg is only one part of the whole person and need not detract from other positive qualities.

EVALUATION

Goal met. Magda successfully demonstrates correct crutchwalking technique and decides to purchase a backpack to replace her shoulder bag. She is still somewhat shy about “people staring at me” but seems to be starting to accept the fact that the cast and crutches are temporary. She even jokes that “maybe this is an easy way to get noticed at school.”

CONCEPT MAP

The Client with a Fractured Leg

Magda Constantin, a 15-year-old high school student, has a fracture of her right tibia suffered in a soccer game. She states she is having trouble using crutches and getting around school, especially up and down the stairs. She is unhappy about not being able to play soccer and states, "People stare at me when I walk down the hall."

Your assessment data includes

ASSESSMENT DATA
 Difficulty ambulating due to cast and crutches
 Verbalizations of discomfort about the altered mobility and body image.

Data clues indicate

Nursing Diagnosis:
Risk for Injury
 related to sensory dysfunction and altered level of consciousness.

The expected outcome is...

The client will:
 be protected from injury during hospitalization.

Nursing Interventions and Rationales

- 1 Initiate the fall prevention protocol.
Identifies and reduces risk for injury.
- 2 Reassess the client's injury status every 4 hours.
Identifies changes and highlights need to modify plan of care.
- 3 Place the client in a room as close as possible to the nurse's station.
Facilitates faster response time to client's needs.
- 4 Place fall alert signs on the client's door and head of bed.
Alerts other health care workers to client's risk status.
- 5 Put the bed alarm on.
Helps monitor client status and facilitates prompt response if client tries to get out of bed unassisted.
- 6 Monitor the client and the environment every 2 hours and whenever a caregiver goes by the client's room.
Provides information on status, progress, and needs of client; encourages team approach to client care.
- 7 Instruct all caregivers to respond promptly to call light.
Ensures rapid response to client's needs.
- 8 Teach the client to use the call light; reinforce teaching each time before leaving the client alone.
Ensures that client has means and knowledge to call for assistance if necessary.

Successful implementation of nursing care is indicated by...

Fall prevention protocol implemented; client discharged on third day of hospitalization free from injury.

PROCEDURE
36-1
Body Mechanics, Lifting, and Transferring
EQUIPMENT

- Transfer or gait belt(s)
- Wheelchair with locks
- Transfer board
- Draw or lift sheet
- Gloves (when contact with body fluids is possible)
- Nonslip shoes or slippers
- Stretcher with locks
- Hydraulic lift

ACTION	RATIONALE
1. Wash hands/hand hygiene. Don gloves if contact with body fluids is possible.	1. Reduces the transmission of microorganisms.
2. Assess the situation for obstacles, heavy clients, poor handholds, or equipment or objects in the way. Reduce or remove safety hazards prior to lifting the client or object. Assess for any tubing or equipment connected to the client.	2. Good planning helps prevent accidental injury.
3. Assess for slippery surfaces, including wet floors; slippery shoes on client, helper, or nurse; and towels, linen, or paper on the floor. Resolve the slippery surface prior to lifting the client or object.	3. Removes the cause of many falls.
4. Assess for hidden risks, including client confusion, combativeness, orthostatic hypotension, medication effects, pain, or fear.	4. Allows the nurse to anticipate and plan for unexpected events.
5. Maintain low center of gravity by bending at the hips and knees, not the waist. Squat down rather than bend over to lift.	5. Provides for the equal distribution of body weight and assists in maintaining safe balance.
6. Establish a wide support base with feet spread apart.	6. Provides stability and lowers the center of gravity.
7. Use feet to move. Avoid twisting or bending from the waist.	7. Assists in maintaining correct body alignment, which increases strength to lift, push, pull, and carry.
8. When pushing or pulling, stand near the object and place one foot partially ahead of the other.	8. Helps avoid back injuries.
9. When pushing a client or an object, lean into the client or object and apply continuous light pressure. When pulling a client or an object, lean away and grasp with light pressure. Never jerk or twist your body to move weight.	9. Firm pressure will provide continuous movement of the object and will avoid abrupt movements that require the expenditure of increased energy.
10. When stooping to move an object, maintain a wide base of support with feet, flex knees to lower body, and maintain straight upper body.	10. Provides the appropriate mechanics for the strength and endurance to achieve the task and to stand up straight upon completion.

(Continues)

PROCEDURE 36-1 Body Mechanics, Lifting, and Transferring (Continued)

ACTION	RATIONALE
11. When lifting or carrying an object, bend the knees in front of the object, take a firm hold, and assume a standing position by using the leg muscles and keeping the back straight.	11. This stance will avoid the use of the back, diminish the potential for spinal twisting, and provide the lifter with a firm center of gravity and strength to lift the required weight.
12. When rising up from a squatting position, arch your back slightly. Keep the buttocks and abdomen tucked in and rise up with your head first.	12. Keeps the back from bowing and increasing the strain on the back muscles.
13. When lifting or carrying heavy objects, keep the weight as close to your center of gravity as possible (see Figure 36-23).	13. Reduces the strain on arm, leg, and back muscles.
14. When reaching for a client or an object, keep the back straight. If the client or object is heavy, do not try to lift the client or object without repositioning yourself closer to the weight (see Figure 36-24).	14. Avoids straining the back and arm muscles.
15. Use safety aids and equipment. Use gait belts, drawsheets, and other transfer assistive devices (see Figure 36-25 on page 1129). Encourage clients to use handrails and grab bars. Wheelchair, cart, and stretcher wheels should be locked when they are stationary.	15. Reduces strain on the nurse and improves safety for the client.
16. Wash hands/hand hygiene.	16. Reduces the transmission of microorganisms.

FIGURE 36-23 Hold weight close to your center of gravity.

(Continues)

PROCEDURE 36-1
Body Mechanics, Lifting, and Transferring (Continued)

FIGURE 36-25 Use transfer boards to reduce shearing forces and to reduce the effort needed to move the client. DELMAR/CENGAGE LEARNING

delegation tip

- Personnel must be taught how to utilize body mechanics in order to protect themselves as well as clients.
- A professional nurse must supervise ancillary personnel when the client requires complex turning or the use of assistive devices.

nursing tips

- Ancillary personnel must be taught how to safely lift and transfer clients.
- The nurse must verify the ancillary personnel's competency in performing the skills.

PROCEDURE
36-2

Administering Passive Range-of-Motion (ROM) Exercises

EQUIPMENT

- Gloves (when contact with body fluids is possible)

ACTION	RATIONALE
<ol style="list-style-type: none"> 1. Wash hands/hand hygiene. Wear gloves if contact with body fluids is possible. 2. Explain procedure to client, including estimated duration. 3. Provide for privacy by exposing only the extremity to be exercised. 	<ol style="list-style-type: none"> 1. Reduces the transmission of microorganisms. 2. Decreases anxiety and encourages compliance and participation. 3. Decreases embarrassment.

(Continues)

PROCEDURE 36-2 Administering Passive Range-of-Motion (ROM) Exercises (Continued)

ACTION	RATIONALE
4. Adjust bed to comfortable height for performing ROM. 5. Lower bed rail only on the side where you are working. 6. Describe the passive ROM exercises you are performing, or verbally cue client to perform ROM exercises with your assistance. When possible, demonstrate movement. 7. Start at the client's head and perform ROM exercises down each side of the body. Begin exercise on client's stronger (or unaffected) side.	4. Prevents muscle strain and discomfort for nurse. 5. Prevents client falls. 6. Encourages client participation and cooperation. 7. Provides a systematic method to ensure that all body parts are exercised. Working on client's unaffected side first promotes comfort and allows nurse to assess limitations or restrictions.
8. Repeat each ROM exercise as the client tolerates, to a maximum of 5 times. Perform each motion in a slow, firm manner. Encourage full joint movement, but do not go beyond the point of pain, resistance, or fatigue. 9. Head Perform these movements with the client in a sitting position, if possible. <ul style="list-style-type: none"> • Rotation: Turn the head from side to side. • Flexion and extension: Tilt the head toward the chest and then tilt slightly upward (Figure 36-26). • Lateral flexion: Tilt the head to each side so as to almost touch the ear to the shoulder. 	8. Provides exercise to the client's tolerance or to a level that will maintain the joint function. 9. <ul style="list-style-type: none"> • Optimizes the performance of the movements. • Preserves muscle tone and joint flexibility.

DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 36-2 Administering Passive Range-of-Motion (ROM) Exercises (Continued)

ACTION	RATIONALE
<ul style="list-style-type: none"> Adduction and abduction: Slide the leg away from the client's midline and then back to the midline. 	
18. Knee <ul style="list-style-type: none"> Flexion and extension: Supporting the lower leg, flex and extend the knee. 	18. Preserves muscle tone and joint flexibility.
19. Ankle <ul style="list-style-type: none"> Flexion and extension: Supporting the lower leg, flex and extend the ankle. 	19. Preserves muscle tone and joint flexibility.
20. Foot <ul style="list-style-type: none"> Adduction and abduction: Supporting the ankle, spread the toes apart and then bring them close together. Flexion and extension: Supporting the ankle, extend the toes upward and then flex the toes downward. 	20. Preserves muscle tone and joint flexibility.
21. Observe client for signs of exertion, pain, or fatigue during movement.	21. Alerts nurse to discontinue exercise.
22. Replace covers and position client in proper body alignment.	22. Promotes comfort.
23. Place side rails in original position. Adjust bed to lowest position.	23. Prevents falls.
24. Place call light within reach.	24. Facilitates communication.
25. Wash hands/hand hygiene.	25. Reduces the transmission of microorganisms.

delegation tip

- Administering passive ROM may be delegated to trained ancillary personnel.
- Outcomes of the activity must be reported to the nurse.

nursing tips

- Continuously assess client's pain level during the ROM exercises.
- Do not move a joint beyond the client's comfort level.
- Exercise client's unaffected side first.
- Document client's ability (e.g., "ROM on left side greater than on right.").
- Avoid documenting only client limitations; be sure to record progress in functional abilities.

PROCEDURE
36-3
Turning and Positioning a Client
EQUIPMENT

- Pillows
- Heel protectors
- Rolled blankets or towels
- Hand rolls
- Footboard
- Gloves (when contact with body fluids is possible)

ACTION	RATIONALE
1. Wash hands/hand hygiene. Don gloves if contact with body fluids is possible.	1. Reduces the transmission of microorganisms.
2. Explain procedure to client.	2. Decreases anxiety. Improves client compliance and cooperation.
3. Gather all necessary equipment. Provide for client privacy.	3. Promotes client dignity and allows for a smooth procedure.
4. Secure adequate assistance to safely complete task.	4. Prevents caregiver muscle strain and provides for client safety.
5. Adjust bed to comfortable working height. Lower side rail on side of bed from which you are assisting client.	5. Prevents caregiver back and muscle strain and promotes client safety.
6. Follow proper body mechanics guidelines: <ul style="list-style-type: none"> • When moving a client in bed, position the bed so that your legs are slightly bent at the knees and hips. • Maintain the natural curves in your back while lifting. • Position one foot slightly in front of the other and spread feet apart to create a wide base for balance. • When your arms are placed under the client, slowly lean backward onto your back leg using your body weight to help you lift the client to one side of the bed. Do not extend or rotate your back to move a client in bed. • If you cannot move the client easily, always obtain assistance (see Figure 36-29 on page 1135). • Be sure the floor is not slippery and that the bed is locked. • Always use a turn (draw) sheet when moving a client (see Figure 36-30 on page 1135). 	6. Prevents caregiver back injury and muscle strain and promotes client safety. <ul style="list-style-type: none"> • Spreading feet to create a wide base helps prevent loss of balance. • Use of a drawsheet promotes support and control of the client.
7. Position drains, tubes, and IVs to accommodate for new client position.	7. Prevents accidental dislodgment or discomfort from movement by reducing mechanical tension.
8. Place or assist client into appropriate starting position. Monitor client status, and provide adequate rest breaks or support as necessary.	8. Prevents client injury.

(Continues)

PROCEDURE 36-3 Turning and Positioning a Client (Continued)

ACTION

FIGURE 36-29 If the client is heavy or unable to assist, always obtain assistance for both the client's and your safety. DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 36-30 When moving a client, use a turn (draw) sheet for better support and control. DELMAR/CENGAGE LEARNING

MOVING FROM SUPINE TO SIDE-LYING POSITION

9. Slide your hands underneath the client.
 - Move the client to one side of the bed by lifting the client's body toward you in stages—first the upper trunk, then the lower trunk, and finally the legs.
 - Lift the client's body; do not drag the client across the sheets.
 - Roll the client to side-lying position by placing the client's inside arm next to the client's body with the palm of the hand against the hip.
 - Cross the client's outside arm and leg toward midline and logroll the client toward you using the client's outside shoulder and hip for leverage while maintaining stability and control of top arm and leg.

MAINTAINING SIDE-LYING POSITION

10. Repeat Actions 1–8.
11. Pillows may be placed to support the client's head and arms (see Figure 36-31 on page 1136). An additional pillow may be used to support the topside leg and fully and equally support the thigh, knee, ankle, and foot (see Figure 36-32 on page 1136). Move the lower arm forward slightly at the shoulder, and bend the elbow for comfort. If the client is unstable, a pillow placed against the back will provide additional support and keep the client from rolling to supine position.

9. Maintains client body alignment and prevents client injury. Protects caregiver's back and prevents muscle strain.
 - Prevents skin shearing.

10. See Rationales 1–8.
11. Provides support and comfort.

(Continues)

PROCEDURE 36-3 Turning and Positioning a Client (Continued)

ACTION

FIGURE 36-31 Place pillows to support the head and arms.
DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 36-32 Place pillows to support the leg, ankle, and foot.
DELMAR/CENGAGE LEARNING

MOVING FROM SIDE-LYING TO PRONE POSITION

12. Repeat Actions 1–8.
13. Remove positioning towels, pillows, or other support devices.
 - Assess whether the client's position in bed needs to be adjusted to accommodate the continued movement into prone position.
 - Move the client's inside arm next to the client's body with palm against hip.
 - Roll the client onto the stomach using the shoulder and hip as key points of control.
 - The head must be placed in a comfortable position to one side without excessive pressure to sensitive areas.
 - Pillows under the trunk are placed as needed to relieve pressure and increase comfort.
 - The client's arms are placed comfortably at the client's side, and the legs are uncrossed with the feet approximately a foot apart.

MAINTAINING PRONE POSITION

14. A shallow pillow or a folded towel may be used to support the client's head comfortably as well as a pillow placed under the abdomen to support the back. An additional pillow may be placed under the lower leg to reduce the pressure of the toes and forefoot against the bed.

12. See Rationales 1–8.
13. Ensures comfort and safety in movement.

14. Provides support and comfort.

(Continues)

PROCEDURE 36-3 Turning and Positioning a Client (Continued)

ACTION	RATIONALE
MOVING FROM PRONE TO SUPINE POSITION	
15. Repeat Actions 1–8. 16. Remove positioning towels, pillows, or other supporting devices. <ul style="list-style-type: none"> • Slide your hands underneath the client. • Move the client segmentally to one side of the bed to accommodate the new position. • Position the inside arm next to the client's body with the client's palm next to the hip. • Roll the client to supine by logrolling the client toward you using the client's outside shoulder and hip for leverage. • Have the client's face positioned away from the direction of the roll to prevent undue pressure to the face or neck. • When the client reaches supine position, uncross the client's arms and legs and place them in comfortable positions. 	15. See Rationales 1–8. 16. Provides support and comfort.
MAINTAINING SUPINE POSITION	
17. A footboard may be used to support the foot as well as heel protectors or a pillow placed between the heel and gastrocnemius muscle to reduce the pressure on the heels. <ul style="list-style-type: none"> • Assess and compare warmth, sensation, color, and movement of feet. • To prevent excessive external rotation of the lower extremity, a trochanter roll may be used. • For comfort, additional pillows may be used to support the client's head, arms, or lower back. 18. Be sure to replace side rails to upright position and lower the bed. 19. Place call light within reach of the client. 20. Move bedside table close to bed, and place items of frequent use within reach of the client. 21. Wash hands/hand hygiene.	17. Provides support and comfort. Heel protectors and routine assessment of the feet help to prevent pressure sores. Trochanter rolls and pillows help to prevent displacement of the acetabulum (hip joint). 18. Provides for client safety. 19. Provides for client safety. 20. Provides for client safety. 21. Reduces the transmission of microorganisms.

delegation tip

- *Turning and positioning are routinely delegated to ancillary personnel who have been appropriately trained.*
- *Ancillary personnel must report the client's response to the activity to the nurse.*

nursing tips

- *Safety is of utmost importance when turning and repositioning the client.*
- *Maintain client comfort as much as possible when moving the client.*
- *Assess the color and integrity of skin at bony prominences.*
- *Provide skin care as needed.*

PROCEDURE
36-4
Moving a Client in Bed
EQUIPMENT

- Hospital bed with side rails
- Turn sheet or drawsheet
- Trapeze if required
- Gloves (when contact with body fluids is possible)

ACTION
RATIONALE
MOVING UP A CLIENT IN BED WITH ONE NURSE

- | | |
|--|--|
| <ol style="list-style-type: none"> 1. Wash hands/hand hygiene. Don gloves if contact with body fluids is possible. 2. Inform client of reason for the move and how to assist (if able). 3. Raise bed to just below waist height. Lower head of bed if tolerated by client. Lower side rails on the side where you are standing. 4. Remove pillow and place it against the headboard. 5. Have the client fold arms across the chest. 6. Have the client hold on to the overhead trapeze, if available (see Figure 36-33). | <ol style="list-style-type: none"> 1. Reduces the transmission of microorganisms. 2. Reduces anxiety; helps increase comprehension and cooperation; promotes client autonomy. 3. Decreases fall risk. Lessens strain on nurse's back muscles. 4. Prevents having to move against the pillow. Protects client's head. 5. Prevents getting the client's arms trapped or injured during the move. 6. Promotes client autonomy by allowing the client to assist with the move. |
|--|--|

FIGURE 36-33 Have the client hold on to the overhead trapeze to assist in the move. DELMAR/CENGAGE LEARNING

- | | |
|--|---|
| <ol style="list-style-type: none"> 7. Have the client bend the knees and place the feet flat on the bed if able. 8. Stand at an angle to the head of the bed, feet apart, knees bent, feet toward the head of the bed. 9. Slide one hand and arm under the client's shoulder, the other under the client's thigh. | <ol style="list-style-type: none"> 7. Allows the client to assist in the move; promotes client autonomy. 8. Promotes good body mechanics. 9. Distributes the client's weight more evenly. Promotes good lifting technique. |
|--|---|

(Continues)

PROCEDURE 36-4 Moving a Client in Bed (Continued)

ACTION	RATIONALE
10. Rock forward toward the head of the bed, lifting the client with you. Simultaneously have the client push with the legs.	10. Allows a smooth motion to lift the client. Client assistance lessens strain on nurse's back muscles; promotes client autonomy.
11. Have the client pull up holding onto the trapeze (if available) as you move the client upward in bed.	11. Client assistance lessens strain on nurse's back muscles; promotes client autonomy.
12. Repeat these steps until the client is moved up high enough in bed.	12. Large or very immobile clients are often not moved far enough in one step.
13. Return the client's pillow under the head.	13. Promotes client comfort.
14. Elevate head of bed, if tolerated by client.	14. Promotes comfort; facilitates eating and drinking; facilitates communication.
15. Assess client for comfort.	15. Comfort is subjective.
16. Adjust the client's bedclothes as needed.	16. Promotes comfort and privacy.
17. Lower bed and elevate side rails.	17. Promotes client safety.
18. Wash hands/hand hygiene.	18. Reduces the transmission of microorganisms.
MOVING UP A CLIENT IN BED WITH TWO OR MORE NURSES	
19. Wash hands/hand hygiene. Apply gloves if needed.	19. Reduces the transmission of microorganisms.
20. Inform client of reason for the move and how to assist (if able).	20. Reduces anxiety; helps increase comprehension and cooperation; promotes client autonomy.
21. Elevate bed to just below waist height. Lower head of bed if tolerated by client. Lower side rails.	21. Lessens strain on nurses' back muscles.
22. With two nurses, place turn (draw) sheet under client's back and head.	22. Reduces shearing force, which can precipitate skin breakdown.
23. Roll up the drawsheet on each side until it is next to the client.	23. Provides support under the heavy parts of the body and places the nurses' hands close to the weight to be moved.
24. Follow Actions 4–7.	24. See Rationales 4–7.
25. The nurses stand on either side of the bed, at an angle to the head of the bed. They stand with knees flexed, feet apart in a wide stance.	25. Promotes good body mechanics.
26. The nurses hold their elbows as closely as possible to their bodies.	26. Allows the muscles of the torso to assist the arm muscles in bearing and moving the weight of the client.
27. The lead nurse will give the signal to move: 1-2-3 go. The nurses will lift up (off the bed) on the turn sheet and forward (toward the head of the bed) in one smooth motion. The move is coordinated to transfer the client toward the head of the bed. Simultaneously, have the client push with the legs or pull using the trapeze (see Figure 36-34 on page 1140).	27. Allows a smooth motion to lift the client. Client assistance lessens strain on the nurses' back muscles; promotes client autonomy.
28. Repeat until the client is moved up high enough in bed to be comfortable.	28. Large or very immobile clients are often not moved far enough in one step.
29. Return the client's pillow under the head.	29. Promotes client comfort.
30. Elevate head of bed, if tolerated by client.	30. Promotes comfort; facilitates eating and drinking; facilitates communication.

(Continues)

PROCEDURE 36-4
Moving a Client in Bed (Continued)

ACTION

RATIONALE

FIGURE 36-34 Moving Client in Bed: Client Positioned with Knees Flexed DELMAR/CENGAGE LEARNING

- 31. Assess client for comfort.
- 32. Adjust the client's bedclothes.
- 33. Lower bed and elevate side rails.
- 34. Wash hands/hand hygiene.

- 31. Comfort is subjective.
- 32. Promotes comfort and privacy.
- 33. Promotes client safety.
- 34. Reduces the transmission of microorganisms.

delegation tip

- Moving a client in bed is routinely delegated to ancillary personnel who have received appropriate training.
- Ancillary personnel must report the client's response to the activity to the nurse.

nursing tips

- Safety is of utmost importance when repositioning the client.
- Maintain client comfort as much as possible when moving the client.

PROCEDURE
36-5

Assisting from Bed to Wheelchair, Commode, or Chair

EQUIPMENT

- Bed
- Wheelchair, commode, or chair
- Splints, braces, or other assistive devices needed by the client
- Gloves (when contact with body fluids is possible)
- Shoes or slippers with nonskid soles
- Gait belt
- Transfer board (if needed)

(Continues)

PROCEDURE 36-5 Assisting from Bed to Wheelchair, Commode, or Chair (Continued)

ACTION	RATIONALE
<ol style="list-style-type: none"> 1. Inform client about desired purpose and destination. 2. Assess client for ability to assist with the transfer and for presence of cognitive or sensory deficits. 3. Lock the bed in position. 4. Wash hands/hand hygiene. Don gloves if contact with body fluids is possible. 5. Place any splints, braces, or other devices on the client. 6. Place shoes or slippers on the client's feet. 7. Lower the height of the bed to lowest possible position. 8. Slowly raise the head of the bed if not contraindicated by the client's condition. 9. Place one arm under the client's legs and one arm behind the client's back. Slowly pivot the client so the client's legs are dangling over the edge of the bed and the client is in a sitting position on the edge of the bed (see Figure 36-35). 10. Allow client to dangle for 2–5 minutes. Help support client if necessary (see Figure 36-36). 11. Bring the chair or wheelchair close to the side of the bed. Place it at a 45° angle to the bed. If the client has a weaker side, place the chair or wheelchair on the client's strong side. 	<ol style="list-style-type: none"> 1. Reduces client anxiety and increases cooperation. 2. Allows planning regarding the amount of assistance and cooperation to expect from the client. 3. Prevents the bed from rolling during the procedure. 4. Reduces the transmission of microorganisms. 5. Provides support and prevents injury to the client. 6. Provides a nonslip surface for stability. 7. Reduces distance client has to step down, thus decreasing risk of injury. 8. Minimizes lifting. 9. Supports client while sitting upright. 10. Allows time for assessing client's response to sitting; reduces possibility of orthostatic hypotension. 11. Minimizes transfer distance. Allows the client to pivot on the stronger leg.

FIGURE 36-35 Pivot the client to a sitting position on the edge of the bed. DELMAR/CENGAGE LEARNING

FIGURE 36-36 Support the client, if needed, while the client adjusts to the sitting position. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 36-5 Assisting from Bed to Wheelchair, Commode, or Chair (Continued)

ACTION	RATIONALE
12. Lock wheelchair brakes and elevate the foot pedals. For chairs, lock brakes if available.	12. Provides stability.
13. If you will be using a gait belt to assist the client, place it around the client's waist.	13. Provides a secure handhold for the nurse during the transfer.
14. Assist client to side of bed until feet are firmly on the floor and slightly apart.	14. Moves client into proper position for transfer. Provides stable footing for client.
15. Grasp the sides of the gait belt or place your hands just below the client's axillae. Using a wide stance, bend your knees and assist the client to a standing position.	15. Avoids putting pressure directly on the axillae and risking nerve damage or shoulder subluxation. Wide stance increases nurse stability and minimizes strain on the back.
16. Standing close to the client, pivot until the client's back is toward the chair.	16. Moves client into proper position to be seated.
17. Instruct the client to place hands on the arm supports, or place the client's hands on the arm supports of the chair.	17. Allows client to gain balance and judge distance to seat.
18. Bend at the knees, and ease the client into a sitting position.	18. Increases stability and minimizes strain on back.
19. Assist client to maintain proper posture. Support weak side with pillow if needed.	19. Increases client comfort.
20. Secure the safety belt, place client's feet on foot pedals (see Figure 36-37), and release brakes if you will be moving the client immediately. Make sure tubes and lines, arms, and hands are not pinched or caught between the client and the chair. If the client is sitting in a chair, offer a footstool if available.	20. Ensures client safety; prepares client for movement.
21. Wash hands/hand hygiene.	21. Reduces the transmission of microorganisms.

FIGURE 36-37 Position the wheelchair footrests or use a footstool if the client is sitting in a chair. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 36-5
Assisting from Bed to Wheelchair, Commode, or Chair (Continued)

delegation tip

- Moving a client from the bed is routinely delegated to ancillary personnel who have received appropriate training.
- Ancillary personnel must report the client's response to the activity to the nurse.

nursing tips

- Safety is of utmost importance when turning and repositioning the client.
- Maintain client comfort as much as possible when moving the client.
- Place the chair on the client's unaffected, or stronger, side.
- Brace your knees against the client's knees to keep legs from buckling.
- Assess the client's tolerance of the activity.

PROCEDURE
36-6

Assisting from Bed to Stretcher

EQUIPMENT

- Bed
- Transfer or slider boards
- Gloves (when contact with body fluids is possible)
- Stretcher
- Lift sheet
- Pillows
- Other qualified personnel to assist

ACTION

RATIONALE

TRANSFERRING A CLIENT WITH MINIMUM ASSISTANCE

- | | |
|--|---|
| <ol style="list-style-type: none"> 1. Inform client about desired purpose and destination. 2. Wash hands/hand hygiene. Don gloves if contact with body fluids is possible. 3. Raise the height of bed to 1 inch higher than the stretcher and lock brakes of bed. 4. Instruct client to move to side of bed close to stretcher. Lower side rails of bed and stretcher. Leave side rails on opposite side up. 5. Stand at outer side of stretcher and push it toward bed. Lock the stretcher brakes. 6. Instruct client to move onto stretcher with assistance as needed. 7. Cover client with sheet or bath blanket. 8. Elevate side rails on stretcher and secure safety belts about client. Release brakes of stretcher. | <ol style="list-style-type: none"> 1. Reduces client anxiety and increases cooperation. 2. Reduces the transmission of microorganisms. 3. Reduces distance nurse must bend, thus preventing back strain; prevents bed from moving. 4. Decreases risk of client falling. 5. Diminishes the gap between bed and stretcher; secures the stretcher position. 6. Promotes client independence. 7. Promotes comfort; protects privacy. 8. Prevents falls. |
|--|---|

(Continues)

PROCEDURE 36-6 Assisting from Bed to Stretcher (Continued)

ACTION	RATIONALE
9. Stand at head of stretcher to guide it when pushing.	9. Pushing, not pulling, ensures proper body mechanics.
10. Wash hands/hand hygiene.	10. Reduces the transmission of microorganisms.
TRANSFERRING A CLIENT WITH MAXIMUM ASSISTANCE	
11. Repeat Actions 1–3.	11. See Rationales 1–3.
12. Assess amount of assistance required for transfer. Usually 2–4 staff members are required for the maximum-assisted transfer.	12. Promotes client independence; ensures that enough staff are present before beginning transfer.
13. Lock wheels of bed and stretcher.	13. Prevents falls.
14. Have one nurse stand close to client's head.	14. Supports client's head during the move.
15. Logroll the client (keep in straight alignment) and place a lift sheet under the client's back, trunk, and upper legs. The lift sheet can extend under the head if client lacks head control abilities.	15. Prevents flexion and rotation of client's hips and spine; maintains correct body alignment.
16. Empty all drainage bags (e.g., T-tube, Hemovac, Jackson-Pratt). Record amounts. Secure drainage system to client's gown prior to transfer.	16. Decreases possibility of spills; prevents dislodging of tubes.
17. Move client to edge of bed near stretcher. Lift up and over to avoid dragging.	17. Prevents dragging, which causes shearing force.
18. Because the client is now on the side of the bed, without the side rail up, the nurse on nonstretcher side of bed holds the stretcher side of the lift sheet up (by reaching across the client's chest) to prevent the client from falling onto the stretcher or off the bed.	18. Protects the client from falling.
19. Place pillow or slider board overlapping the bed and stretcher (see Figure 36-38).	19. Protects head from injury. Slider board eases movement of the client.
20. Have staff members grasp edges of lift sheet. Be sure to use good body mechanics (see Figure 36-39).	20. Provides surface for client to slide on. Prevents dragging and shearing.

FIGURE 36-38 Place pillow or slider board overlapping the bed and stretcher. DELMAR/CENGAGE LEARNING

FIGURE 36-39 Firmly grasp edges of lift sheet. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 36-6 Assisting from Bed to Stretcher (Continued)

ACTION	RATIONALE
21. On the count of three, have staff members pull lift sheet and the client onto the stretcher.	21. Working in unison makes the overall job easier and prevents staff injury.
22. Position client on stretcher, place pillow under head, and cover with a sheet or bath blanket.	22. Promotes comfort and provides for privacy.
23. Secure safety belts and elevate side rails of stretcher.	23. Prevents falls.
24. If IV bag is present, move it from bed IV pole to stretcher IV pole after client transfer.	24. Prevents tubing from being pulled and IV from being dislodged.
25. Wash hands/hand hygiene.	25. Reduces the transmission of microorganisms.

delegation tip

- Moving a client from the bed to a stretcher is routinely delegated to ancillary personnel who have received appropriate training.
- The client's response to the activity must be reported to the nurse by ancillary personnel.

nursing tips

- Place the stretcher on the client's unaffected or stronger side.
- Remind the client that the stretcher is narrow and to move about carefully when on it.
- Access which devices can be safely removed and disconnected from the client prior to the transfer.
- Be sure to get enough help when transferring clients with complex needs. It may take one or two staff members just to watch the lines and tubes in order to promote a safe transfer.

PROCEDURE 36-7

Using a Hydraulic Lift

EQUIPMENT

- Mechanical lift
- Equipment should include lift, canvas or mesh sheet, and bars to slide into sheet
- Protective disposable cover or disinfectant to clean canvas
- Gloves (when applicable)

ACTION	RATIONALE
1. Wash hands/hand hygiene. Don gloves if contact with body fluids is possible.	1. Reduces the transmission of microorganisms.
2. Check the prescribing practitioner's order to determine the length of time the client may sit.	2. The prescribing practitioner may want the client to sit only for a specified length of time or for as long as tolerated.
3. Check the client's medical diagnosis and any other medical problems.	3. Assists in determining any problems that sitting may cause or any necessary restrictions.

(Continues)

PROCEDURE 36-7 Using a Hydraulic Lift (Continued)

ACTION	RATIONALE
4. Ask the client how long ago he or she last sat.	4. If the client has been in the bed several days, he or she may complain of dizziness or faintness.
5. Lock the wheels of the bed.	5. Prevents the bed from rolling when the client is moved; helps prevent falls.
6. Position the chair close to the bed.	6. Always transfer the client the shortest possible distance to conserve energy of client and nurse.
7. Position urine drainage, nasogastric (NG), and IV tubing on the side of the bed where the chair will be placed. Allow slack in the tubing.	7. Prevents the tubing from being dislodged when the client is moved.
8. Clamp and disconnect any tubing if condition allows.	8. NG suction tubing and feeding tubing are often allowed to be clamped. This makes moving the client easier.
9. Roll client on side, and position the sling on bed behind the client.	9. The sling is positioned behind the client so the client can be turned in the opposite direction and the sling can be pulled through.
10. Roll client on opposite side, pull the sling through, and position the sling smoothly on the bed.	10. Prevents skin breakdown.
11. Roll the client back onto the sling, and fold the arms over the chest (see Figure 36-40).	11. Prevents injury to the client's arms during the transfer.
12. Make sure the sling is centered under client.	12. Evenly distributes the client's weight.
13. Lower the side rail, and position the lift on the side of the bed with the chair. Be sure to spread the base of the hydraulic lift as indicated in manufacturer's instructions to provide stability (see Figure 36-41). Protect the client from falls while the side rail is down.	13. The side rail must be down to use the lift. Always transfer the client the shortest possible distance. The wheels and base of the lift should be spread to provide a wide, stable base to prevent the lift from tipping.

FIGURE 36-40 Roll the client back onto the sling. Position the client's arms across the chest. DELMAR/CENGAGE LEARNING

FIGURE 36-41 Spread the base of the hydraulic lift to provide stability. DELMAR/CENGAGE LEARNING

14. Lift the frame, and pass it over the client. Carefully lower the frame, and attach the hooks to the sling (see Figure 36-42 on page 1147).

14. Safely attaches sling to frame.

(Continues)

PROCEDURE 36-7 Using a Hydraulic Lift (Continued)

ACTION

RATIONALE

FIGURE 36-42 Attach the hooks to the sling. DELMAR/CENGAGE LEARNING

- | | |
|---|--|
| <p>15. Raise the client from the bed by activating the lift.</p> <p>16. Secure the client with a safety belt, and cover the client with a blanket.</p> <p>17. Steer the client away from the bed, and slide a chair through the base of the lift.</p> <p>18. The sling can be disconnected, and the lift can be moved out of the way while the client is sitting in the chair. If the lift will be used to return the client to bed, the sling may be left in place beneath the client.</p> <p>19. Reposition and reconnect tubing.</p> <p>20. Assess how well the client tolerated the move and whether any dizziness was experienced.</p> <p>21. Place call light, appropriate covers, and padding as needed after transfer. Place protective restraints as needed. Cover feet with slippers if in sitting position.</p> <p>22. Reverse the procedure to return the client to the bed.</p> <p>23. Lower the bed, and place the call light within reach.</p> <p>24. Wash hands/hand hygiene.</p> | <p>15. Read the manufacturer's directions to determine the mechanism for raising the particular lift you are using. The various models do not operate in the same manner.</p> <p>16. Provides safety and comfort.</p> <p>17. It is safer to slide the chair through the base than to slide the base around the chair.</p> <p>18. Provides safety and comfort.</p> <p>19. Tubing should not be left disconnected. The client may sit for a while and will need all the equipment to function properly.</p> <p>20. The data are necessary for charting whether the client experienced any problems.</p> <p>21. Ensures privacy and protection.</p> <p>22. Transfers client safely and comfortably.</p> <p>23. Promotes client safety.</p> <p>24. Reduces the transmission of microorganisms.</p> |
|---|--|

(Continues)

PROCEDURE 36-7 Using a Hydraulic Lift (Continued)

delegation tip

- Moving a client from the bed to a chair is routinely delegated to ancillary personnel who have received appropriate training.
- Supervision by a professional nurse may be required if the client has multiple devices or invasive lines.

nursing tips

- Provide reassurance to the client to reduce anxiety associated with being temporarily suspended in the air.
- Instruct the client to keep hands crossed over the chest and to sit still during the move.

PROCEDURE 36-8

Assisting with Ambulation

EQUIPMENT

- Gait belt (as needed)
- Gloves (when contact with body fluids is possible)

ACTION	RATIONALE
1. Wash hands/hand hygiene. Don gloves if contact with body fluids is possible.	1. Prevents transmission of microorganisms.
2. Encourage the client to void before ambulating, especially with elderly clients.	2. Prevents need to interrupt ambulation. Restroom may not be readily available.
3. When assisting a client with an intravenous (IV) infusion, place the IV pole with wheels at the head of the bed before having the client dangle the legs so there is room to swing the legs from the bed to the floor. If orders allow, place a saline lock on the IV.	3. Prevents the client's legs from becoming tangled in the IV pole or tubing, causing a fall or causing the tubing to become dislodged. Provides more freedom of movement.
4. Transfer the IV infusion from the bed IV pole to the portable IV pole. The client or the nurse can guide the portable IV pole ahead during ambulation (see Figure 36-43 on page 1149).	4. Supports the IV while the client ambulates.
5. When assisting the client who has a urinary drainage bag, empty the drainage bag prior to ambulation. <ul style="list-style-type: none"> • Have the client sit on the side of the bed with legs dangling. 	5. Emptying the bag reduces the weight of the bag. An empty bag kept below the level of the bladder reduces the risk of urine flowing back into the bladder and, hence, reduces risk of contamination.

(Continues)

PROCEDURE 36-8 Assisting with Ambulation (Continued)

ACTION

FIGURE 36-43 Ambulating Client with an IV DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 36-44 Ambulating Client with a Urinary Drainage Bag DELMAR/CENGAGE LEARNING

- Remove the urinary drainage bag from the bed. The nurse or client can hold the urinary drainage bag during ambulation.
 - Make sure the drainage bag remains below the level of the bladder (see Figure 36-44).
6. When the client has a drainage tube (such as a T-tube, Hemovac, or Jackson-Pratt drainage system), be sure to secure the drainage tube and bag prior to ambulation. Place a rubber band around the drainage tube near the drainage bag. Secure the drainage tube and bag with a safety pin through the rubber band to allow slack. The safety pin can be secured to the client's gown or robe (see Figure 36-45).

6. Prevents the tubing from becoming dislodged or tangled in clothing or other tubes.

FIGURE 36-45 Secure tubes and drainage bags prior to ambulation so they do not become dislodged. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 36-8 Assisting with Ambulation (Continued)

ACTION	RATIONALE
<p>7. Ambulating the client with a closed chest tube drainage system often requires two nurses, one assisting the client and one nurse managing the closed chest tube drainage system.</p> <ul style="list-style-type: none"> • While the client is sitting on the edge of the bed with feet dangling, remove the hangers from the drainage system. • Hold the closed chest tube drainage system upright at all times to maintain the water seal. • Do not pull or tug on the chest tubes; they may not be sutured into place. 	<p>7. Two nurses allow one to focus on the client's safety and ambulation while the other focuses on maintaining the chest drainage system and keeping tubes from becoming dislodged.</p>
<p>8. Use a transfer belt or gait belt when ambulating a client who is weak (see Figure 36-46). For additional safety, a wheelchair can be pushed alongside the client for ready access if the client feels weak, tired, or faint.</p>	<p>8. The transfer belt is worn by the client for the purposes of stabilization during transfers and ambulation. It provides more support for the client by having the nurse hold the back of the belt.</p>

FIGURE 36-46 Ambulating the client using a gait belt for better grip and control. DELMAR/CENGAGE LEARNING

<p>9. If a client feels faint or dizzy during dangling, return the client to a supine position in bed and lower the head of the bed. Monitor the client's blood pressure and pulse.</p>	<p>9. Keeps the client from falling from the bed. Lowering the head of the bed will allow gravity to support blood flow to the brain in the hypotensive client.</p>
<p>10. If the client feels dizzy during ambulation, allow the client to sit in a chair. Stay with the client for safety. Request another staff member to secure a wheelchair, if not already available, to return the client to bed.</p>	<p>10. May stop the client from progressing to full syncope.</p>
<p>11. If the client starts to fall, ease the client to the floor while supporting and protecting the client's head. Position yourself next to and slightly behind the client, and safely ease the client to the floor. Ask other personnel to assist you in returning the client to bed. Assess orthostatic blood pressures.</p>	<p>11. Easing the client to the floor prevents injury to the client.</p>

(Continues)

PROCEDURE 36-8
Assisting with Ambulation (Continued)

delegation tip

- *Assisting a client with ambulation is routinely delegated to ancillary personnel who have received appropriate training.*
- *The client's response to ambulation must be reported to the nurse by ancillary personnel.*

nursing tips

Be sure the client understands the need to have assistance during the first few times of ambulation.

PROCEDURE
36-9

Assisting with Crutches, Cane, or Walker

EQUIPMENT

- Gait belt
- Assistive device: crutches, cane, or walker
- Tape measure
- Nonslip footwear

ACTION

RATIONALE

CRUTCHWALKING

- | | |
|--|---|
| <ol style="list-style-type: none"> 1. Inform client that you will be assisting with ambulation using the device chosen. 2. Wash hands/hand hygiene. 3. Assess client for strength, mobility, range of motion, visual acuity, perceptual difficulties, and balance. <i>Note:</i> The nurse and physical therapist often work together on assessment and choosing the correct assistive equipment for ambulation. 4. Measure client for size of crutches, and adjust crutches to fit. While supine, measure client from heel to axilla. 5. Provide a robe and nonslip foot coverings or shoes. 6. Lower the height of the bed. | <ol style="list-style-type: none"> 1. Reduces anxiety and helps increase comprehension and cooperation. 2. Reduces the transmission of microorganisms. 3. Helps determine the client's capabilities and amount of assistance required. 4. Correct fit increases client safety and comfort. 5. Provides for privacy and safety. 6. Allows client to sit with feet on the floor and increases safety. |
|--|---|

(Continues)

PROCEDURE 36-9 Assisting with Crutches, Cane, or Walker (Continued)

ACTION	RATIONALE
7. Allow the client to dangle the legs at the side of the bed for several minutes. Assess for vertigo or nausea.	7. Allows for stabilization of blood pressure, thus preventing orthostatic hypotension; also increases client comfort.
8. Apply gait belt around the client's waist if balance is not steady. It is good practice to use a gait belt the first time the client is out of bed.	8. Provides support and promotes safety.
9. Instruct client on method of holding crutches while client remains seated. This should be with elbows bent 30° while hands are on the hand grips and pads 1.5–2 inches below the axillae (see Figure 36-47). Instruct client to position crutches 4–5 inches laterally and 4–6 inches in front of feet. This skill can be demonstrated on yourself.	9. Increases comprehension and cooperation; decreases anxiety.
10. Assist the client to a standing position by placing both crutches in the nondominant hand. Then, using the dominant hand, push off from the bed while using the crutches for balance. Once erect, the extra crutch can be moved into the dominant hand.	10. Allows for stability while promoting independence.

FIGURE 36-47 Adjusting the crutches to fit the client will increase comfort and stability. DELMAR/CENGAGE LEARNING

- | | |
|--|---|
| 11. Instruct the client to remain still for a few seconds while assessing for vertigo or nausea. Stand close to the client to support as needed. While client remains standing, check for correct fit of the crutches. | 11. Promotes client comfort, support, and safety. If the client becomes dizzy, sit client back down and wait before trying again. |
|--|---|

(Continues)

PROCEDURE 36-9 Assisting with Crutches, Cane, or Walker (Continued)

ACTION	RATIONALE
Four-Point Gait (see Figure 36-48)	
<p>12. Position the crutches 4.5–6 inches to the side and in front of each foot. Move the right crutch forward 4–6 inches and move the left foot forward, even with the left crutch. Move the left crutch forward 4–6 inches and move the right foot forward, even with the right crutch. Repeat the four-point gait.</p>	<p>12. The four-point gait (used for partial or full weight bearing) provides greater stability. Weight bearing is on three points (two crutches and one foot or two feet and one crutch) at all times. The client must be able to bear weight with both legs.</p>
	
A	B
<p>FIGURE 36-48 Crutchwalking, four-point gait: A. Moving right crutch forward and left foot forward; B. Moving left crutch forward and right foot forward, even with right crutch. DELMAR/CENGAGE LEARNING</p>	
Three-Point Gait (see Figure 36-49 on page 1148)	
<p>13. Advance both crutches and the weaker leg forward together 4–6 inches. Move the stronger leg forward, even with the crutches. Repeat the three-point gait.</p>	<p>13. The three-point gait (used for partial or non-weight bearing) provides a strong base of support. This gait can be used if the client has a weak or non-weight-bearing leg.</p>
Two-Point Gait	
<p>14. Move the left crutch and right leg forward 4–6 inches. Move the right crutch and left leg forward 4–6 inches. Repeat the two-point gait.</p>	<p>14. The two-point gait (used for partial weight bearing) provides a strong base of support. The client must be able to bear weight on both legs.</p>
Swing-Through Gait (see Figure 36-50 on page 1148)	
<p>15. This step is basically the same as the three-point gait. The difference is that on the swing, whichever leg is moving will go past the stationary point and set down in front.</p>	<p>15. The swing-through gait permits a faster pace. This gait requires greater balance, strength, and more practice.</p>

(Continues)

PROCEDURE 36-9 Assisting with Crutches, Cane, or Walker (Continued)

ACTION

RATIONALE

FIGURE 36-49 Crutchwalking, three-point gait: Advancing both crutches and weaker leg forward together. DELMAR/CENGAGE LEARNING

FIGURE 36-50 Crutchwalking: swing-through gait. DELMAR/CENGAGE LEARNING

Walking Upstairs

16. Stand beside and slightly behind client. Instruct client to position the crutches as if walking. Place body weight on hands. Place the strong leg on the first step. Pull the weak leg up and move the crutches up to the first step. Repeat for all steps.

Walking Downstairs

17. Position the crutches as if walking. Place weight on the strong leg.
 - Move the crutches down to the next lower step.
 - Place partial weight on hands and crutches.
 - Move the weak leg down to the step with the crutches.
 - Put total weight on arms and crutches.
 - Move strong leg to same step as weak leg and crutches.
 - Repeat for all steps.
 - A second caregiver standing behind the client holding on to the gait belt will further decrease the risk of falling.
18. Set realistic goals and opportunities for progressive ambulation using crutches.
19. Consult with a physical therapist for clients learning to walk with crutches.
20. Wash hands/hand hygiene.

Sitting with Crutches

21. Instruct client to back up to chair until it is felt with the back of the legs.
22. Place both crutches in the nondominant hand and use the dominant hand to reach back to the chair.
23. Instruct client to lower slowly into the chair.

16. Prevents weight bearing on the weaker leg. When ascending stairs, crutches should follow the legs, thereby allowing stability if the client's weight shifts down the stairs while moving. This allows the client to catch himself or herself instead of falling backward.
17. Prevents weight bearing on the weaker leg. Crutches in front of the legs while descending stairs allow the client more forward stability if client's weight shifts down the stairs while moving. This allows client to catch himself or herself before falling forward.
18. Crutch walking takes up to 10 times the energy required for unassisted ambulation.
19. The physical therapist is the expert for the health care team on crutchwalking techniques.
20. Reduces the transmission of microorganisms.

21. Allows for less turning, better stability, and increased safety.
22. Increases safety by giving client an idea of how far away client is from the seat.
23. Lowering slowly decreases possible injuries.

(Continues)

PROCEDURE 36-9 Assisting with Crutches, Cane, or Walker (Continued)

ACTION	RATIONALE
WALKING WITH A CANE	
24. Repeat Actions 1–10.	24. See Rationales 1–10.
25. Have the client hold the cane in the hand opposite the affected leg. Explain the safety and body mechanics underlying use of a cane on the strong side.	25. Promotes safety and cooperation. Promotes client autonomy. By holding the cane on the stronger side, the client has more control and strength for using it.
26. Have the client push up from the sitting position while pushing down on the bed with arms.	26. Promotes autonomy as well as increases upper body strength.
27. Have the client stand at the bedside for a few moments.	27. Allows the client to gain balance. The nurse can check for strength and balance.
28. Assess the height of the cane. With the cane placed 6 inches ahead of the client's body, the top of the cane should be at wrist level with the arm bent 25%–30% at the elbow.	28. A 25%–30% bend at the elbow provides for better muscle strength and support than if the arm is straight.
29. Walk to the side and slightly behind the client, holding the gait belt if needed for stability.	29. Provides stability or assistance to the client.
The Cane Gait	
30. Move the cane and the weaker leg forward at the same time for the same distance (see Figure 36-51). Place weight on the weaker leg and the cane. Move the strong leg forward. Place weight on the strong leg.	30. The cane helps to provide a wide base of support for the body when the weight is on the weaker leg.
Sitting with a Cane	
31. Have client turn around and back up to the chair. Have client grasp the arm of the chair with the free hand and lower himself or herself into the chair. Be sure to place the cane out of the way but within reach.	31. The cane provides additional support as client lowers himself or herself into the chair.
32. Set realistic goals and opportunities for progressive ambulation using a cane.	32. Walking with a cane takes practice.

FIGURE 36-51 Move the cane and the weaker leg forward. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 36-9 Assisting with Crutches, Cane, or Walker (Continued)

ACTION	RATIONALE
33. Consult with a physical therapist for clients learning to walk with a cane.	33. The physical therapist is the expert for the health care team on cane-walking techniques.
34. Wash hands/hand hygiene.	34. Reduces the transmission of microorganisms.
WALKING WITH A WALKER	
35. Repeat Actions 1–10.	35. See Rationales 1–10.
36. Place the walker in front of the client.	36. Positions the walker for use and allows for stability when the client is standing.
37. Have the client put the nondominant hand on the front bar of the walker or on the handgrip for that hand, whichever is more comfortable. Then, using the dominant hand to push off from the bed and the nondominant hand for stabilization, help the client to an erect position.	37. Uses upper body strength and encourages independence.
38. Have the client transfer hand to the walker handgrips.	38. Allows the client to maintain balance while transferring weight.
39. Be sure the walker is adjusted so the handgrips are just below waist level and the client's arms are slightly bent at the elbow.	39. Provides maximum support from the arms while ambulating.
40. Walk to the side and slightly behind the client, holding the gait belt if needed for stability.	40. Allows the nurse to provide stability or assistance if the client needs it.

Walker Gait

41. Move the walker and the weaker leg forward at the same time (see Figure 36-52). Place as much weight as possible or as allowed on the weaker leg, using the arms for supporting the rest of the weight. Move the strong leg forward, and shift the weight to the strong leg (see Figure 36-53).

FIGURE 36-52 Move the walker and the weaker leg forward. DELMAR/CENGAGE LEARNING

FIGURE 36-53 Use the arms to support the rest of the weight and move the strong leg forward. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 36-9 Assisting with Crutches, Cane, or Walker (Continued)

ACTION	RATIONALE
<i>Sitting with a Walker</i>	
42. Have the client turn around in front of the chair and back up until the back of the legs touch the chair. Have client place hands on the chair armrests, one hand at a time, then lower himself or herself into the chair using the armrests for support.	42. Using the armrests of the chair is a more stable support than using the walker.
43. Set realistic goals and opportunities for progressive ambulation using a walker.	43. Walking with a walker takes practice.
44. Consult with a physical therapist for clients learning to walk with a walker.	44. The physical therapist is the expert for the health care team on walker techniques.
45. Wash hands/hand hygiene.	45. Reduces the transmission of microorganisms.

delegation tip

- Client ambulation is routinely delegated to ancillary personnel who have received appropriate training.
- The initial teaching and the ongoing assessment of proper use of the assistive device are not delegated. The nurse or physical therapist is responsible for observing the client's technique and providing further education as needed.

nursing tips

Determine client's confidence in ability to use assistive device safely.

KEY CONCEPTS

- The nurse must assess the client's activity and mobility on an ongoing basis during acute hospitalization, rehabilitation, and postdischarge.
- Collaboration between client, family, and members of the interdisciplinary health care team is essential for establishing and modifying goals for activity and mobility.
- Nursing interventions are individualized to maximize client activity, mobility, and independence.
- The nurse should be aware of the home environment and lifestyle of the client.
- The family or caregivers should be included in educational sessions regarding activity and mobility.
- The need for adaptive equipment should be assessed and acquisition of equipment facilitated.
- The client and family should be informed of community resources to maximize activity, mobility, and independence.
- The nurse should be available to assist the client with problem solving after discharge.

REVIEW QUESTIONS

1. Which action should nurses perform to prevent injury when lifting clients?
 - a. Keep the client away from the nurse's body.
 - b. Lean to one side when lifting with one hand.
 - c. Position feet together.
 - d. Use legs to lift.
2. Which of the following best explains why the nurse should use a drawsheet when moving a client up in bed with wet linens?
 - a. Decrease possible skin shearing
 - b. Increase the client's mobility
 - c. Keep the bed linens clean
 - d. Keep the client's skin dry
3. When assisting a postoperative client to get out of bed the first time, which of the following must the nurse do?
 - a. Have the client bend the knees and push up in the bed.
 - b. Instruct the client to sit on the side of the bed before standing.
 - c. Place the foot of the bed in a high position so it is easier for the client to get out of bed.
 - d. Raise all four side rails to assist the client in getting into a seated position.
4. In order to flex the clients' fingers during range-of-motion (ROM) exercises, which of the following should the nurse instruct the client to do?
 - a. Straighten the fingers.
 - b. Bring the wrist up toward the elbow.
 - c. Make a fist.
 - d. Gently shake the wrist downward.
5. Which action by the nurse demonstrates inappropriate body mechanics?
 - a. Bending from the waist when making a bed
 - b. Flexing the knees when lifting an object from the floor
 - c. Holding heavy equipment close to the body when walking
 - d. Placing the feet apart when transferring a client
6. A client will be ambulating for the first time since surgery. Which of the following should the nurse consider when assisting the client?
 - a. Clients who are fearful of walking should be told to look at their feet when walking to ensure correct positioning.
 - b. Clients who can lift their legs only 1 to 2 inches off the bed do not have sufficient muscle power to permit walking.
 - c. If a client begins to fall, the nurse should slide the client down his or her own body to the floor.
 - d. Nurses should have a physical therapist present when ambulating a client for the first time.
7. A client has been bedridden for 5 days. The nurse will expect the client to exhibit which of the following?
 - a. Eupnea
 - b. High energy level
 - c. Hunger
 - d. Pressure ulcers
8. Which of the following positions is most likely to contribute to the development of a pressure ulcer in the sacral area?
 - a. Fowler's position
 - b. Lateral position
 - c. Prone position
 - d. Sims' position
9. To prevent the formation of pressure ulcers, the bottom sheet on the client's bed should be _____.
 - a. changed every day
 - b. covered by a drawsheet
 - c. kept free of wrinkles
 - d. made with mitered corners
10. The nurse is caring for a client who has weakness of the right arm and leg following a cerebrovascular accident (stroke). When setting up the client's hygiene supplies, where should the nurse place the items?
 - a. On the bedside table in front of the client
 - b. On the client's lap
 - c. Within the client's reach on his left side
 - d. Within the client's reach on his right side

“In dwelling upon the vital importance of sound observation, it must never be lost sight of what observation is for. It is not for the sake of piling up miscellaneous information or curious facts, but for the sake of saving life and increasing health and comfort.”

—NIGHTINGALE (IN SKRETKOWICZ, 1992)

CHAPTER 37

Skin Integrity and Wound Healing

COMPETENCIES

1. Describe the normal process of tissue healing.
2. Differentiate between primary, secondary, and tertiary wound healing.
3. Discuss factors that may impair or promote wound healing.
4. Discuss common complications of wound healing.
5. Discuss the risk factors and pathogenesis of pressure ulcers.
6. Identify preventive and early treatment measures in clients at risk for pressure ulcer development.
7. Utilize the nursing process for a client with impaired skin integrity by:
 - a. Identifying appropriate assessment data
 - b. Formulating relevant nursing diagnoses
 - c. Developing a plan of care and identifying outcome criteria
 - d. Implementing appropriate nursing interventions
 - e. Evaluating a plan of care according to outcome criteria
8. Describe the principles of wound assessment and care.
9. Outline dressing products used to treat wounds.
10. Discuss the therapeutic uses of heat and cold therapy and their methods of application.

KEY TERMS

angiogenesis	full-thickness	red wounds
black wounds	hematoma	secondary intention healing
blanching	hemorrhage	serous exudate
clean wounds	hemorrhagic exudate	shearing
clean-contaminated wounds	hemostasis	sloughing
closed suction drainage systems	homeostasis	superficial
collagen	inflammation	suppuration
contaminated wounds	intentional wounds	sutures
debridement	ischemia	tertiary intention healing
dehiscence	partial-thickness	unintentional wounds
dirty and infected wounds	penrose drains	vasoconstriction
epithelialization	phagocytosis	vasodilation
eschar	pressure ulcer	wound
evisceration	primary intention healing	yellow wounds
exudate	purulent exudate	
friction	pyogenic bacteria	

Maintaining skin integrity is a primary responsibility of nursing personnel. Impaired skin integrity, such as wounds, may occur as a result of trauma or surgery. The potential for skin breakdown and eventual pressure ulcer formation also exists whenever factors such as prolonged pressure, constant irritation of the skin, and immobility are present. Nurses, through constant and timely observations and interventions, can prevent or minimize skin breakdown. Prevention, early intervention, and treatment programs are essential strategies to decrease the prevalence of pressure ulcers and pain related to inflammation and infection.

WOUNDS

The skin is the body's largest organ and is the primary defense against infection. The body's complex physiological processes promote skin and wound healing, restoring the function and structure of the skin. A disruption in the integrity of body tissue is called a **wound**.

PHYSIOLOGY OF WOUND HEALING

When an injury is sustained, a complex set of responses is set in motion, and the body begins a three-phase process of wound healing: defensive (hemostasis and inflammatory), reconstructive (proliferative), and maturation. The wound healing process is also defined as having four main phases. When this occurs, the defensive phase is considered two separate phases: hemostasis and inflammation. Regardless of how the healing process is defined, these phases overlap and can take months or years to complete. Understanding these physiological responses will assist the nurse in caring for clients with impaired skin integrity and promoting optimal wound healing.

Defensive (Hemostasis and Inflammatory) Phase

The defensive phase occurs immediately after injury and lasts about 3 to 4 days. The major events that occur in this phase are hemostasis and inflammation. **Hemostasis**, or cessation of bleeding, occurs by vasoconstriction of large blood vessels in the affected area. Platelets, activated by the injury, aggregate to form a platelet plug and stop the bleeding. Activation of the clotting cascade results in the eventual formation of fibrin and a fibrinous meshwork, which further entraps platelets and other cells. The result is fibrin clot formation, which provides initial wound closure, prevents excessive loss of blood and body fluids, and inhibits contamination of the wound by microorganisms.

Inflammation is the body's defensive adaptation to tissue injury and involves both vascular and cellular responses. During the vascular response, tissue injury and activation of plasma protein systems stimulate the release of various chemical mediators, such as histamine (from mast cells), serotonin (from platelets), complement, and kinins. These vasoactive substances cause blood vessels to dilate and become more permeable, resulting in increased blood flow and leakage of serous fluid into the surrounding tissues. The increased blood supply carries nutrients and oxygen, which are essential for wound healing, and transports leukocytes to the area to participate in **phagocytosis**, or the envelopment and disposal of microorganisms. The increased blood supply also removes the "debris of battle," which includes dead cells, bacteria, and **exudate**, or material and cells discharged from blood vessels. The area is red, edematous, and warm to touch, and it has varying amounts of exudate as a result.

During the cellular response, leukocytes move out of the blood vessel into the interstitial space. Neutrophils are the first cells to arrive at the injured site and begin phagocytosis.

They subsequently die and are replaced by macrophages, which arise from blood monocytes. Macrophages perform the same function as neutrophils but remain for a longer time. In addition to being the primary phagocyte of debridement, macrophages are important cells in wound healing because they secrete several factors, including fibroblast activating factor (FAF) and angiogenesis factor (AGF). FAF attracts fibroblasts, which form collagen or collagen precursors. AGF stimulates the formation of new blood vessels. The development of this new microcirculation supports and sustains the wound and the healing process.

Reconstructive (Proliferative) Phase

The reconstructive phase begins on the third or fourth day after injury and lasts 2 to 3 weeks. This phase contains the process of collagen deposition, angiogenesis, granulation tissue development, and wound contraction.

Fibroblasts, normally found in connective tissue, migrate into the wound because of various cellular mediators. They are the most important cells in this phase because they synthesize and secrete collagen. **Collagen** is the most abundant protein in the body and is the material of tissue repair. Initially, collagen is gel-like, but within several months it cross-links to form collagen fibrils and adds tensile strength to the wound. As the wound gains strength, the risk of wound separation or rupture is less likely. The wound can resist normal stress such as tension or twisting after 15 to 20 days. During this time, a raised “healing ridge” may be visible under the injury or suture line.

Angiogenesis, the formation of new blood vessels, begins within hours after the injury. The endothelial cells in preexisting vessels begin to produce enzymes that break down the basement membrane. The membrane opens, and new endothelial cells build a new vessel. These capillaries grow across the wound, increasing blood flow, which increases the supply of nutrients and oxygen needed for wound healing.

Repair begins as granulation tissue, or new tissue, grows inward from surrounding healthy connective tissue. Granulation tissue is filled with new capillaries that are fragile and bleed easily, thus giving the healing area a red, translucent, granular appearance. As granulation tissue is formed, **epithelialization**, or growth of epithelial tissue, begins. Epithelial cells migrate into the wound from the wound margins. Eventually, the migrating cells contact similar cells that have migrated from the outer edges. Contact stops migration. The cells then begin to differentiate into the various cells that compose the different layers of the epidermis.

Wound contraction is the final step of the reconstructive phase of wound healing. Contraction is noticeable 6 to 12 days after injury and is necessary for closure of all wounds. The edges of the wound are drawn together by the action of myofibroblasts, specialized cells that contain bundles of parallel fibers in their cytoplasm. These myofibroblasts bridge across a wound and then contract to pull the wound closed.

Maturation Phase

Maturation, the final stage of healing, begins about the 21st day and may continue for up to 2 years or more, depending

on the depth and extent of the wound. During this phase, the scar tissue is remodeled (reshaped or reconstructed by collagen deposition and lysis and debridement of wound edges). Although the scar tissue continues to gain strength, it remains weaker than the tissue it replaces. Capillaries eventually disappear, leaving an avascular scar (a scar that is white because it lacks a blood supply).

Types of Healing

Tissue may heal by one of three methods, which are characterized by the degree of tissue loss. **Primary intention healing** occurs in wounds that have minimal tissue loss and edges that are well approximated (closed). If there are no complications, such as infection, necrosis, or abnormal scar formation, wound healing occurs with minimal granulation tissue and scarring.

Secondary intention healing is seen in wounds with extensive tissue loss and wounds in which the edges cannot be approximated. The wound is left open, and granulation tissue gradually fills in the deficit. Repair time is longer, tissue replacement and scarring are greater, and the susceptibility to infection is increased because of the lack of an epidermal barrier to microorganisms.

Tertiary intention healing, also known as delayed or secondary closure, is indicated when primary closure of a wound is undesirable. Conditions in which healing by tertiary intention may occur include poor circulation or infection. Suturing of the wound is delayed until the problems resolve and more favorable conditions exist for wound healing.

Kinds of Wound Drainage

Chemical mediators released during the inflammatory response cause vascular changes and exudation of fluid and cells from blood vessels into tissues. Exudates may vary in composition but all have similar functions. These functions include:

1. Dilution of toxins produced by bacteria and dying cells
2. Transport of leukocytes and plasma proteins, including antibodies, to the site
3. Transport of bacterial toxins, dead cells, debris, and other products of inflammation away from the site

The nature and amount of exudate vary depending on the tissue involved, the intensity and duration of the inflammation, and the presence of microorganisms.

Serous exudate is composed primarily of serum (the clear portion of blood), is watery in appearance, and has a low protein count. This type of exudate is seen with mild inflammation resulting in minimal capillary permeability changes and minimal protein molecule escape (e.g., seen in blister formation after a burn).

Purulent exudate is also called pus. It generally occurs with severe inflammation accompanied by infection. Purulent exudate is thicker than serous exudate because of the presence of leukocytes (particularly neutrophils), liquefied dead tissue debris, and dead and living bacteria. The process of pus formation is called **suppuration**, and bacteria that produce pus are referred to as **pyogenic bacteria**. Purulent exudates may

vary in color (e.g., yellow, green, brown), depending on the causative organism.

Hemorrhagic exudate has a large component of red blood cells (RBCs) due to capillary damage, which allows RBCs to escape. This type of exudate is usually present with severe inflammation. The color of the exudate (bright red versus dark red) reflects whether the bleeding is fresh or old.

Mixed types of exudates may also be seen, depending on the type of wound. For example, a serosanguineous exudate is clear with some blood tinge and is seen with surgical incisions.

FACTORS AFFECTING WOUND HEALING

Wound healing is dependent on multiple influences, both intrinsic and extrinsic. Wounds may fail to heal or may require a longer healing period when unfavorable conditions exist. Factors that may negatively influence healing include age, nutrition, oxygenation, smoking, drug therapy, and diseases such as diabetes. Such factors reduce local blood supply and therefore impair wound healing. Nutrition and diet can also have an impact on the healing process. See Table 37-1

and Table 37-2 (on page 1165) for a summary of factors that affect wound healing.

Hemorrhage

Some bleeding from a wound is normal during and immediately after initial trauma and surgery, but hemostasis usually occurs within a few minutes. **Hemorrhage** (persistent bleeding) is abnormal and may indicate a slipped surgical suture, a dislodged clot, or erosion of a blood vessel. Swelling in the area around the wound or affected body part and the presence of sanguineous drainage from the surgical drain may indicate internal bleeding. Other evidence of bleeding may include the signs and symptoms seen in hypovolemic shock (decreased blood pressure, rapid thready pulse, increased respiratory rate, diaphoresis, restlessness, and cool, clammy skin). A **hematoma**, a localized collection of blood underneath the tissues, may also be seen and appear as a reddish-blue swelling or mass. External hemorrhaging is detected when the surgical dressing becomes saturated with sanguineous drainage. It is also important to assess the linen under the client's wound site because it is possible for blood to seep out from under the sides of the dressing and pool

TABLE 37-1 Factors Affecting Wound Healing

FACTOR	EFFECT
Age	Blood circulation and oxygen delivery to the wound, clotting, inflammatory response, and phagocytosis may be impaired in the very young and in older adults; thus, the risk of infection is greater. Rate of cell growth and epithelialization of open wounds is lower with advancing age, so wound healing is slowed.
Nutrition	A balanced diet with adequate amounts of protein, carbohydrates, fats, vitamins, and minerals is needed to increase the body's resistance to pathogens and to decrease the susceptibility of skin and mucous membranes to infection and trauma. Surgery, severe wounds and infections, stress from burns and trauma, and preexisting nutritional deficits increase nutritional requirements. Malnutrition reduces humoral and cell-mediated factors, leading to immunocompromise, thus impairing wound healing and increasing the risk for infection. Obesity leads to fatty tissue, which has a decreased supply of blood vessels that impairs delivery of nutrients and other elements needed for healing; also, suturing of fatty tissue is more difficult, and complications such as dehiscence or evisceration with subsequent infection may occur.
Oxygenation	Decreased arterial oxygen tension alters the synthesis of collagen and the formation of epithelial cells, causing wounds to heal more slowly. Reduced hemoglobin levels (anemia) decrease oxygen delivery to the tissues and interfere with tissue repair.
Smoking	Functional hemoglobin levels decrease, impairing oxygenation to tissues.
Drug therapy	Steroids reduce the inflammatory response and slow collagen synthesis. Anti-inflammatory drugs suppress protein synthesis, wound contraction, epithelialization, and inflammation. Prolonged antibiotic use, with development of resistant strains of bacteria, may increase the risk of superinfection.
Diabetes mellitus	Small-vessel disease (microvascular changes) can impair tissue perfusion and oxygen delivery. Hemoglobin in poorly controlled diabetes has an increased affinity for oxygen, allowing less to be released to the wound bed. Elevated blood glucose levels impair leukocyte function and phagocytosis. The high-glucose environment is an excellent medium for the growth of bacterial, fungal, and yeast infections.

Adapted from Doughty, D. B. (2007). Wound-healing physiology. In R. A. Bryant & D. P. Nix (Eds.), *Acute and chronic wounds: Current management concepts* (3rd ed.). St. Louis, MO: Mosby Elsevier Health Sciences; and Sussman, C., & Bates-Jensen, B. M. (2005). *Wound care: A collaborative practice manual for physical therapists and nurses* (2nd ed.). Gaithersburg, MD: Lippincott Williams & Wilkins.

under the client. The risk for hemorrhage is greatest during the first 24 to 48 hours after surgery.

Infection

Bacterial wound contamination is one of the most common causes of altered wound healing. A wound can become infected with microorganisms preoperatively, intraoperatively, or postoperatively. During the preoperative period, the wound may become exposed to pathogens because of the manner in which the wound was inflicted, such as in traumatic injuries. Nicks or abrasions created during preoperative shaving may also be a source of pathogens. The risk for intraoperative exposure to pathogens increases when the respiratory, gastrointestinal, genitourinary, and oropharyngeal tracts are opened.

If the amount of bacteria in the wound is sufficient or the client's immune defenses are compromised, clinical infection may result and become apparent 2 to 11 days postoperatively. Infection slows healing by prolonging the inflammatory phase of healing, competing for nutrients, and producing chemicals and enzymes that are damaging to the tissues.

Dehiscence and Evisceration

Wound healing may be disrupted by **dehiscence**, the partial or complete separation of the wound edges and the layers below the skin. **Evisceration** occurs when the client's viscera protrude through the disrupted wound. Factors that may predispose a wound to dehiscence include obesity, poor nutrition, problems with suturing, excessive coughing, vomiting, straining, and infection. Wound dehiscence is most likely to occur 4 to 5 days postoperatively, before extensive collagen is deposited in the wound. It may be preceded by sudden straining, such as that associated with coughing, sneezing, or sitting up in bed. Signs of impending dehiscence may include the sensation of "something giving way" and an increased flow of serosanguineous drainage on the wound dressing.

WOUND CLASSIFICATION

Various terms are used to describe and classify wounds. Wounds are usually described based on their etiology, since the treatment for the wound varies depending on the underlying disease process. Wound classification systems describe the cause of the wound, status of skin integrity, extent of tissue damage, cleanliness of the wound, or descriptive qualities of the wound, such as color. Commonly used classification systems follow.

Cause of Wound

- **Intentional wounds** occur during treatment or therapy. These wounds are usually made under aseptic conditions. Examples include surgical incisions and venipunctures.
- **Unintentional wounds** are unanticipated and are often the result of trauma or an accident. These wounds are created in an unsterile environment and therefore pose a greater risk of infection.

TABLE 37-2 Nutrients That Enhance Wound Healing

NUTRIENT	FUNCTION IN WOUND REPAIR
Proteins	
Amino acids	Neovascularization, lymphocyte formation, fibroblast proliferation, collagen synthesis, wound remodeling, and cell-mediated responses (phagocytosis)
Albumin	Osmotic equilibrium control and edema prevention
Carbohydrates	Cellular energy and protein sparing
Fats	Cellular energy, component of cell membrane, and prostaglandin production
Minerals	
Copper	Collagen cross-linking for scar strength
Iron	Collagen synthesis and enhanced leukocytic bacterial activity
Zinc	Cell proliferation and cell membrane stabilization
Vitamins	
A	Collagen synthesis and epithelialization
Pyridoxine, riboflavin, thiamine	Antibody and white blood cell formation; cofactors of enzyme systems
C	Resistance to infection, collagen synthesis, and capillary formation and stabilization
K	Coagulation

Adapted from Doughty, D. B. (2007). Wound-healing physiology. In R. A. Bryant & D. P. Nix (Eds.), *Acute and chronic wounds: Current management concepts* (3rd ed.). St. Louis, MO: Mosby Elsevier Health Sciences; and Sussman, C., & Bates-Jensen, B. M. (2005). *Wound care: A collaborative practice manual for physical therapists and nurses* (2nd ed.). Gaithersburg, MD: Lippincott Williams & Wilkins.

Cleanliness of Wound

This classification system ranks the wound according to its contamination by bacteria and risk for infection (Sussman & Bates-Jensen, 2005).

- **Clean wounds** are intentional wounds that were created under conditions in which no inflammation was encountered, and the respiratory, alimentary, genitourinary, and oropharyngeal tracts were not entered.
- **Clean-contaminated wounds** are intentional wounds that were created by entry into the alimentary, respiratory,

genitourinary, or oropharyngeal tract under controlled conditions.

- **Contaminated wounds** are open, traumatic wounds or intentional wounds in which there was a major break in aseptic technique, spillage from the gastrointestinal tract, or incision into infected urinary or biliary tracts. These wounds have acute nonpurulent inflammation present.
- **Dirty and infected wounds** are traumatic wounds with retained dead tissue or intentional wounds created in situations where purulent drainage was present.

Examples of classification systems that describe wound severity for different wound etiologies are the National Pressure Ulcer Advisory Panel (NPUAP) method, discussed later in this chapter; the Wagner staging system; the partial-thickness and full-thickness skin loss criteria; and Marion Laboratories' red/yellow/black (RYB) color system.

Wagner Ulcer Grade Classification

The Wagner staging system measures the depth and infection in a wound, mainly the dysvascular foot. It is the primary assessment tool used to evaluate diabetic foot ulcers. The classification ranges from 0 to 5, with 0 identifying the predisposing factors that may lead to grades 1 to 3 (superficial ulcer, deep ulcer, abscess osteitis). Grades 4 and 5, respectively, describe gangrene of the forefoot and gangrene of the whole foot.

Classification by Thickness of Skin Loss

The thickness classification system is based on the depth of the wound (see Figure 37-1) and is used for wounds whose etiology is other than pressure wounds, such as skin tears, donor sites, vascular ulcers, surgical wounds, or burns.

Superficial epidermal (first-degree) wounds are confined to the epidermis layer, which comprises the four outermost layers of skin. **Partial-thickness** (first- to second-degree) wounds involve the epidermis and upper dermis, the layer of skin beneath the epidermis. Deep (second-degree) wounds involve the epidermis and deep dermis. **Full-thickness** (third-degree) wounds refer to skin loss that extends through the epidermis and the dermis and into subcutaneous fat and deeper

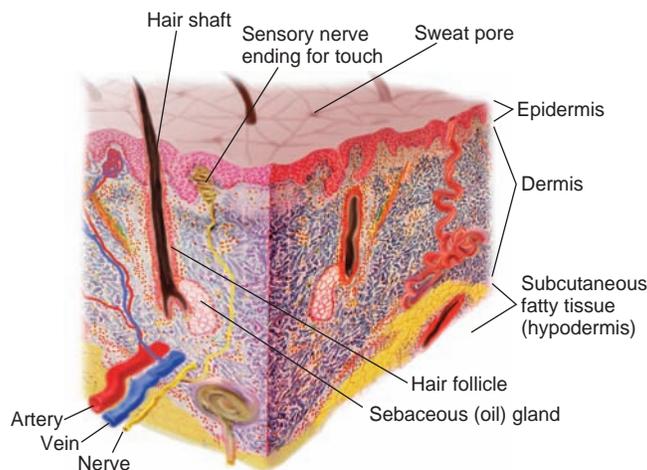

FIGURE 37-1 Structures of the Skin DELMAR/CENGAGE LEARNING

SPOTLIGHT ON...

Legal and Ethical

Impaired Skin Integrity Resulting from Abuse

A woman presents to your clinic with multiple bruises on her breasts, thighs, and abdomen; fresh abrasions on her hands and knees, with gravel mixed in; and two puncture wounds on her left shoulder blade, surrounded by streaks of blue ink. Her injuries are highly suggestive of abuse, especially the puncture wounds, because these could not have been self-inflicted.

How do you feel about caring for this client? What are the skin care priorities? What other issues should be addressed with this client once her wounds have been evaluated and any immediate physical needs attended to? What are the procedures for reporting suspected abuse at your clinical agency?

structures. Fourth-degree wounds are deeper than full-thickness loss, extending into the muscle and bone.

Types of wounds are described and illustrated in Figure 37-2 on page 1167, and burns are shown in Figure 37-3 on page 1168.

The RYB Wound Classification System

In 1988, the RYB classification system was introduced for use in conjunction with the other classification systems to assist the nurse in assessing the wound surface color. The three-color system is a tool to direct treatment of open wounds, with each color corresponding to specific therapy needs.

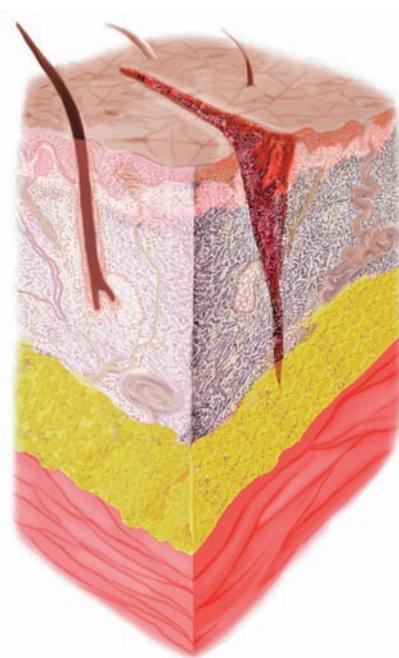

Red wounds are the color of normal granulation tissue and are in the proliferative phase of wound repair. These wounds need to be protected and kept moist and clean. **Yellow wounds** have either fibrinous slough or purulent exudate from bacteria. These wounds need to be cleansed of the purulent exudate, and nonviable slough needs to be removed. **Black wounds** contain necrotic tissue (**eschar**). Eschar may be either black, gray, brown, or tan. These wounds need debridement, which is the removal of nonviable necrotic tissue. Mixed-color wounds often occur. The rule for treatment is to treat the worst color first. For example, a red and black wound would be debrided first, and then moisture and protection would be provided for the red portion.

ASSESSMENT

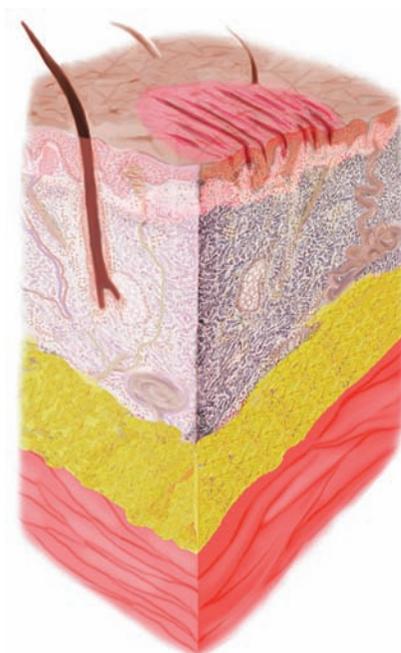

When it comes to wound care, the nurse is confronted with wounds that are extremely diverse. According to Doughty (2007), accurate assessment of wound healing is a critical component of effective wound management because it drives topical therapy and signals progress or problems in the healing process. The wound may have occurred traumatically just before the client presents to the emergency room, or the

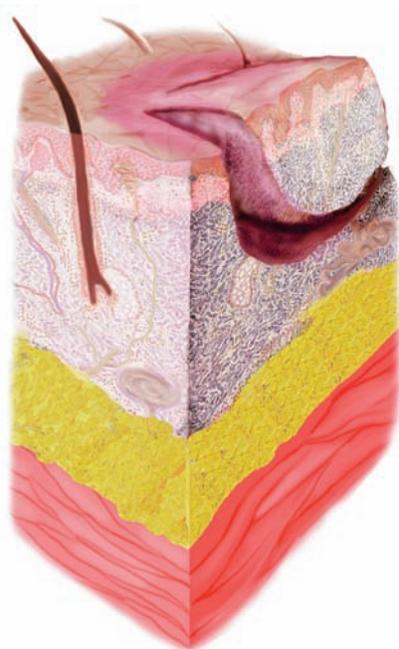

A. **Bruise**, also known as a contusion, results from damage to the soft tissues and blood vessels, which causes bleeding beneath the skin surface. A bruise in a light-skinned individual will change from red to purple to greenish yellow before fading; in a dark-skinned person, the bruise will first look dark red then darker red, brown, or purple, and slowly fade.

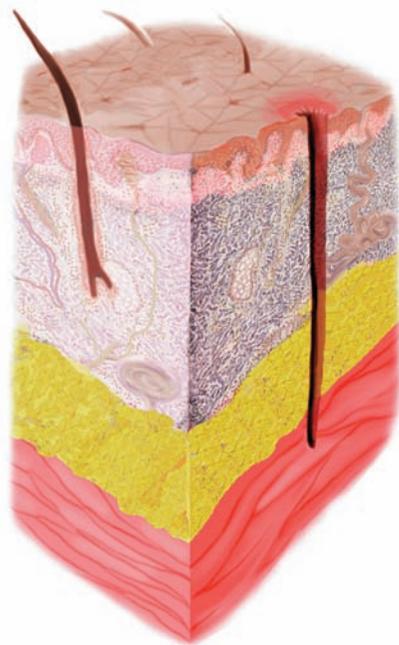

C. **Laceration**, cut, or incision is caused by sharp objects such as knives or glass or from trauma due to a strike from a blunt object that opens the skin, such as a baseball bat. If the wound is deep, the cut may bleed profusely; if nerve endings are exposed, it may also be painful.

B. **Abrasion**, also known as a scrape or rug burn, results when the outer layer of skin is scraped or rubbed away. Exposure of nerve endings makes this type of wound painful, and the presence of debris from the scraped surface (rug fibers, gravel, sand) makes abrasions highly susceptible to infection.

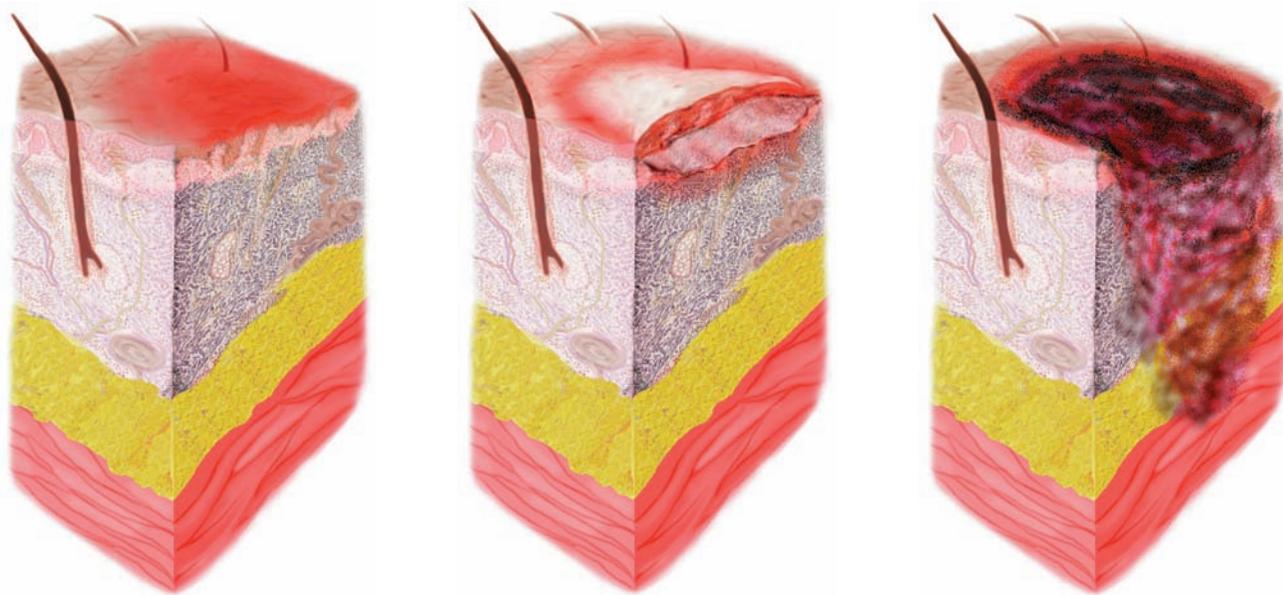

D. **Avulsion** results when the skin or tissue is torn away from the body, either partially or completely. The bleeding and pain will depend on the depth of tissue affected.

E. **Puncture** results when the skin is pierced by a sharp object such as a pencil, nail, or bullet. If a piece of the object remains in the skin, or if there is little bleeding due to the depth and location of the puncture, infection is likely.

FIGURE 37-2 Types of Wounds: A. Bruise; B. Abrasion; C. Laceration; D. Avulsion; E. Puncture DELMAR/CENGAGE LEARNING

A. **Superficial epidermal** (first-degree burn): Injury to the epidermis; skin is red, dry, and painful.

B. **Deep** (second-degree burn): Injury to the epidermis and upper layers of the dermis; skin is red, is moist or has dry blisters, and is extremely painful; exudate and swelling usually occur.

C. **Full-thickness** (third-degree burn): Injury to the epidermis, dermis, and subcutaneous tissue; skin is dry, pearly white to charred, inelastic, and leathery.

FIGURE 37-3 Types of Burns DELMAR/CENGAGE LEARNING

wound may be a slow-healing chronic ulcer. Despite all this diversity, the nurse should approach assessment of the wound in a systematic manner, evaluating the wound's stage in the healing process. The nurse also needs to show sensitivity to the client's pain and tolerance levels during assessment and must always follow Standard Precautions to prevent the transfer of pathogens. Basic criteria for wound assessment follow.

Health History

The health history is conducted to elicit information regarding medical conditions or disease processes that are often associated with delayed or disrupted healing, such as cardiovascular disease, diabetes, renal failure, immunosuppression, gastrointestinal disorders, collagen disorders, malignancy, septic shock, trauma, infection, liver disease, pulmonary disease, musculoskeletal disease, and depression and psychosis. It is important to obtain the data in chronological order: when and how the wound occurred, the initial location and size, and all associated symptoms, such as pain and itching. The history should include aggravating and alleviating factors, such as radiation at the site of the wound, which can influence the healing process. The nurse should document allergies to tape, latex, medications, or other substances. An assessment of the client's nutritional status should evaluate albumin and prealbumin levels, the client's weight trend, and the client's current nutrient intake (Doughty, 2007).

A personal and social history and a functional ability assessment are done to determine the client's ability to provide self-care and to identify support systems present in the home. A risk assessment tool, such as the Braden or Norton scale to assess the risk for pressure ulcers, is a part of the history.

Physical Examination

Although the focus of the assessment will be to accurately describe and/or stage the wound, the physical effects of any existing concurrent condition are evaluated. Three common types of ulcers include:

Vascular ulcers—Evaluate the skin, nails, hair, color, capillary refill, temperature, pulses, edema of the extremity, and hemosiderin (an iron pigment that is a product of RBC hemolysis) in the periulcer area.

Arterial ulcers—Evaluate for weak or absent pulses, thin skin, and lack of hair on the affected extremity.

Neuropathic ulcers—Use the Wagner staging system, previously discussed, to evaluate diabetic ulcers.

Wound Assessment

The following discussion will describe how to assess a wound, documenting location and size and noting length, width, and depth in centimeters. The appearance of the wound bed and surrounding skin is assessed for sinus tracts, undermining, tunneling, exudate, drainage, necrotic tissue, and signs of infection. Some agencies may require a photograph of the wound on admission and documentation of the client's response to therapy.

Location

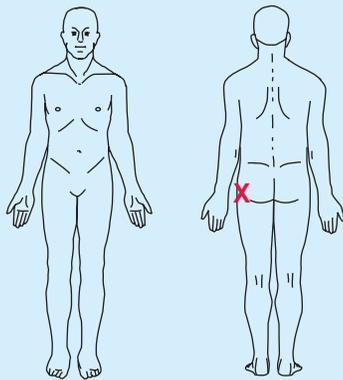

Assessment begins with a description of the anatomical location of the wound; for example, "5-inch suture line on the right lower quadrant of the abdomen." This task often becomes difficult if the client has multiple wounds close to each other, as is common in burn or multiple-trauma victims. Use of a skin

documentation form that incorporates drawings of the body (see Figure 37-4) allows the nurse to draw circles and write numbers to depict the locations of the various wounds.

Size

The length (head to toe), width (side to side), and depth of a wound are measured in centimeters. Single-use measurement guides (tape measures) often come with dressing supplies. To determine the depth of a wound, insert a sterile cotton swab into the deepest point of the wound and mark it at the skin surface level. Then the swab can be measured and the wound depth in centimeters can be documented. Tunneling, also called undermining, can be measured by using a cotton swab to gently probe the wound margins. If tunneling is noted, the location and depth are documented. For clarity in describing the location of the tunneling, refer to the tunnel location using the hands of the clock as a guide, with 12 o'clock pointing at the client's head. Example: "Tunneling occurs at 1 o'clock and its depth is 2 cm."

For extremely irregularly shaped wounds, the wound edges can be traced on a plastic surface. A plastic bag or piece of plastic sheeting folded in half is placed on the wound, and the wound margins are traced. The side of the plastic that has been placed against the skin is cut off and discarded. The rest of the plastic can be placed in the chart.

Mark the location of the skin wound, lesions, breakdown, or incision on the above diagram. Describe the character of the wound or lesions below. (If there are multiple wounds, number the areas on figure and provide a description according to the corresponding number.)

X The left trochanter has a stage IV pressure ulcer measuring 4.5 cm X 5.5 cm X 4.6 cm. The wound bed has 20% granulation tissue and 80% loosely attached slough. Undermining is present and extends 3.5 cm from the 2 o'clock to the 6 o'clock position. A large amount of thick, green, foul-smelling exudate is present.

FIGURE 37-4 Documenting the Location and Character of Wounds DELMAR/CENGAGE LEARNING

General Appearance and Drainage

A general description of the color of the wound and surrounding area helps determine the wound's present phase of healing. Gently palpate the edges of the wound for swelling. Document the amount, color, location, odor, and consistency of any drainage.

Nurses who care for the client in the home must demonstrate the need for skilled nursing services by accurately describing all wounds. Document a clear, concise, and accurate picture of the client's wound: size, depth, and location of the wound; nature of drainage; condition and appearance of surrounding skin; and specific individualized instructions for treatment. For example, for Medicare to reimburse for nursing care, the care must be reasonable, be necessary, and reflect a plan of care appropriate for the client's diagnosis, prognosis, and rehabilitative potential.

Pain

Document and notify the prescribing practitioner of any pain or tenderness at the wound site. Pain may indicate infection or bleeding. It is normal to experience pain at the incision site of a surgical wound for approximately 3 days. If there is any sudden increase in pain accompanied by changes in the appearance of the wound, be sure to notify the prescribing practitioner immediately. See Chapter 35 for more information on assessing pain.

Laboratory Data

Cultures of the wound drainage are used to determine the presence of infection and to identify the causative organism. The sensitivity results list the antibiotics that will effectively treat the infection. An elevated white blood cell (WBC) count is indicative of an infectious process. A decreased leukocyte count may indicate that the client is at increased risk for developing an infection related to decreased defense mechanisms. Albumin is a measure of the client's protein reserves; if decreased, there are decreased resources of protein for wound healing. Procedure 37-2 outlines the correct techniques for culturing a wound.

NURSING DIAGNOSES

Nursing diagnoses for clients with wounds focus on prevention of complications and promotion of the healing process through proper wound care and client teaching. The following are NANDA (2009)–approved nursing diagnoses with a partial list of related factors:

1. *Impaired skin integrity* (altered epidermis and/or dermis) related to skeletal prominence; chemical substances; mechanical factors such as shearing forces, pressure, restraint, or physical immobilization; extremes in age; altered nutritional state, such as obesity or emaciation; altered circulation and/or fluid states; alterations in turgor; and medications
2. *Impaired tissue integrity* related to surgical incision; decreased blood flow; immobility; mechanical irritants (pressure, shear, friction); radiation; nutritional deficit

- or excess; thermal factors; irritants, including body excretions and secretions; and medications
3. *Risk for infection* related to malnutrition and decreased defense mechanisms
 4. *Acute pain* related to inflammation and infection
 5. *Disturbed body image* related to changes in body appearance secondary to scars, drains, and removal of body parts
 6. *Deficient knowledge* (wound care) related to lack of exposure to information, misinterpretation, and lack of interest in learning (NANDA, 2009)

Nursing diagnoses for clients with wounds must consider the psychosocial aspects of nursing care. Because the skin is a visible organ, variations can cause intense psychological reactions from the client. It is important to remember that in addition to the physical risks of infection and further tissue damage, clients with wounds, pressure ulcers, and burns often have significant psychosocial needs that could benefit from competent nursing attention. *Disturbed body image* is a common reaction to a severe alteration in one's appearance and needs to be managed sensitively and effectively through honest evaluation and prognosis. The nurse may want to encourage a client to look at the wound and learn to accept it as only one part of the body; if that is too upsetting, encourage the client not to look at the wound until it is in more advanced stages of healing.

If *Deficient knowledge* is a primary diagnosis, as is usually the case in first-time wound sufferers, then educating the client about wound care and health promotion is among the nurse's priorities. Make sure the client understands the healing process, the stages of recovery that the wound will go through, and what to expect in terms of pain and regrowth. Encourage the client to follow a healthy diet to provide the body with maximum ammunition for wound repair and to get plenty of rest to allow the body's recuperative elements to do their work.

PLANNING AND OUTCOMES

After identifying the nursing diagnoses, the nurse establishes targeted outcomes for wound healing. When formulating outcomes, the nurse must keep in mind that they should be based on the client's identified needs and should be individualized on the basis of the client's condition. Changes in the health care delivery system have brought about early discharge from the hospital, so clients are often sent home with wounds that need continued care. The *Nursing Outcomes Classification* (NOC) (Moorhead, Johnson, Swanson, & Maas, 2008) addresses two wound healing outcomes in the physiological health (II) domain: Wound Healing: Primary Intention and Wound Healing: Secondary Intention. Wound Healing: Primary Intention ("extent of regeneration of cells and tissues following intentional closure" [Moorhead et al., p. 565]) provides two scales that are used for both Wound Healing outcomes. The first scale (none to extensive) measures the indicators of skin approximation, wound edge approximation, and scar formation. The second scale (extensive to none) is for drainage indicators such as purulent and serosanguineous, surrounding skin (erythema, bruising), periwound edema, skin temperature elevation, and foul wound odor (p. 565).

Wound Healing: Secondary Intention is defined by NOC as the "extent or regeneration of cells and tissues in an open wound" (p. 567); the first set of indicators measures granulation, scar formation, and decreased wound size. The second set of indicators provides for monitoring drainage, surrounding skin erythema, wound inflammation, periwound edema, and other specific wound alterations.

Wound healing is the goal for most clients; however, when wound healing is impossible because of chronic ischemia, malnutrition, or the client's inability to adhere to the treatment regimen, the treatment goal becomes maintenance (e.g., developing an effective system for wound management and transferring responsibility for wound care to the client and caregiver) (Rolstad, Ovington, & Harris, 2007). Based on the client's overall health status and the wound, the nurse should decide with the client and family whether the goal is to promote healing or maintain the wound and the client's comfort. If the client chooses palliative care, then the goal might be to prevent further deterioration of the wound and avoid painful treatments. Ayello and Cuddigan (2004) discuss palliative wound care from the perspective that some palliative care clients may benefit from active treatment to promote healing (e.g., some minimally invasive treatments may reduce wound size, drainage, and pain, thus improving quality of life [p. 13]).

The goals for clients with wounds generally focus on promoting wound healing, preventing infection, and educating the client. An example of a goal for debilitated clients would be demonstrating no signs of infection and preventing pressure to certain skin areas for extended periods of time.

Collaboration

Wound management often requires the collaborative strategies of interdisciplinary teams. Interdisciplinary teams may be composed of a wound ostomy clinician, dietitian, physical therapist, registered nurses, and the client's prescribing practitioner. Doughty (2007) addresses the need for accurately identifying and correcting etiologic factors and working collaboratively with other health team members to ensure appropriate nutrition and glucose control, topical therapy, and management of a nonhealing wound. The challenges in wound care are twofold: the need to incorporate the client and caregiver as active team members and the need to provide both outcomes-oriented and cost-effective care.

In order to achieve client outcomes, each discipline must contribute its unique perspective and knowledge to promote wound healing and prevent wound complications. Nurses must have information regarding their interventions and outcomes to share with other disciplines. The use of NOC and *Nursing Interventions Classification* (NIC) provides for professional nursing language that encourages systemic planning among all of the disciplines.

IMPLEMENTATION

Nursing interventions to promote wound healing and prevent infection include emergency measures to maintain **homeostasis** (state of internal constancy of the body) and cleansing and dressing of the wound. NIC (Bulechek, Butcher,

& Dochterman, 2008) identifies nursing measures regarding the prevention and promotion of wound healing: Skin Care: Donor Site, Skin Care: Graft Site, Skin Care: Topical Treatment, and Skin Surveillance. Wound Healing is the “prevention of wound complications and the promotion of wound healing” (p. 777) and provides for such activities as monitoring the characteristics of the wound, including drainage, color, size, and odor; dressing changes; cleansing the wound; applying an appropriate ointment; referrals; and instruction.

Initiate Emergency Measures

The nurse assesses the type and extent of injury that the client has sustained. If hemorrhage is detected, then sterile dressings and pressure should be applied to stop the bleeding. Standard Precautions are always implemented. The client’s vital signs should be monitored frequently and the prescribing practitioner notified immediately.

When dehiscence or evisceration occurs, the client should be instructed to remain quiet and to avoid coughing or straining. The client should be positioned to prevent further stress on the wound. Sterile dressings, such as ABD pads soaked with sterile normal saline, should be used to cover the wound and abdominal contents. This will reduce the risk of bacterial contamination and drying of the viscera. The surgeon should be notified immediately and the client prepared for surgical repair of the area.

Comfort Measures

Depending on the extent of tissue damage, a wound is usually painful. Several nursing measures may be used to minimize discomfort during dressing changes. Tape should be removed by carefully freeing all edges and lifting straight up to prevent stress on sensitive tissue. Position the client to decrease strain on the wound. Administer prescribed analgesics 30 to 60 minutes prior to dressing changes, depending on the drug’s time of peak action.

In a large international study, among six symptoms associated with chronic wounds, clients rated pain as the greatest concern. The researchers found that clients with venous, mixed, and arterial leg ulcers reported experiencing more frequent pain during dressing changes than those with other wound types (Price et al., 2008). Sixty-five percent of the participants took some type of analgesic to manage wound-related pain, but 21% reported that it usually was not effective (Price et al., 2008).

Cleanse the Wound

The goal of cleansing the wound is to remove debris and bacteria from the wound bed with as little trauma to the healthy granulation tissue as possible. Choice of cleansing agent depends on the prescribing practitioner as well as agency protocol. It is recommended that isotonic solutions such as normal saline or lactated Ringer’s be used to preserve healthy tissue. Much research has been conducted on the proper use of antiseptic solutions in open wounds. The results remain debatable, and continued research is needed to investigate the effects of antiseptic agents on leukocytes and fibroblasts. Studies suggest that some of these antiseptic solutions at dilute concentrations remain bactericidal yet not cytotoxic to healthy fibroblasts.

The major principles to keep in mind when cleansing a wound are:

1. Use Standard Precautions at all times.
2. When using a swab or gauze to cleanse a wound, work from the clean area out toward the dirtier area. For example, when cleaning a surgical incision, start over the incision line, and swab downward from top to bottom. Change the swab and proceed again on either side of the incision, using a new swab each time (see Figure 37-5).
3. When irrigating a wound, warm the solution to room temperature, preferably to body temperature, to prevent lowering of the tissue temperature. Be sure to allow the irrigant to flow from the cleanest area to the contaminated area to avoid spreading pathogens (see Procedure 37-1).

Dressing the Wound

The three purposes of a wound dressing are to:

1. Keep the wound moist and therefore enhance epithelialization
2. Clean the wound or keep it clean
3. Protect the wound from physical trauma or bacterial invasion

Keeping these three purposes in mind, the nurse and prescribing practitioner are confronted with the daunting task of determining the appropriate dressing for the client’s wound. Choosing the right dressing depends on the nurse’s wound assessment and the characteristics of the wound bed (Baranoski, 2008a, 2008b). In order to make an appropriate dressing choice, the nurse needs to be familiar with the proper use and indications for each dressing category and to select the one that meets the client’s wound healing needs (see Table 37-3 on page 1172).

TABLE 37-3 (Continued)

DRESSING TYPE AND EXAMPLES*	INDICATIONS	ADVANTAGES	DISADVANTAGES	TIPS FOR USING
Gauze dressings (numerous products available)	<ul style="list-style-type: none"> Exudative wounds Wounds with dead space, tunneling, or sinus tracts Wounds with combination exudate or necrotic debris 	<ul style="list-style-type: none"> Readily available Can be used with appropriate solutions such as gels, normal saline, or topical antimicrobials to keep wounds moist Can be used on infected wounds Effective for packing wounds with tunnels, tracts, or undermining 	<ul style="list-style-type: none"> Will disrupt wound healing if allowed to dry Require secondary dressing Fibers may shed or adhere to wound bed 	<ul style="list-style-type: none"> Change schedule varies with amount of exudate Pack loosely into wound; tight packing compromises blood flow and delays wound closure If too wet, dressing will macerate surrounding skin; protect surrounding skin with moisture barrier ointment or skin sealant as needed

*The products listed are representative of type; this list is not meant to be all-inclusive. Refer to manufacturers' directions for product usage. Adapted from Baranoski, S. (2008a). Wound & skin care: Choosing a wound dressing, Part I. *Nursing 2008*, 38(1), 60–61. Baranoski, S. (2008b). Wound & skin care: Choosing a wound dressing, Part II. *Nursing 2008*, 38(2), 14–15.

Wounds and ulcers are either granular and partial or full thickness, or stage II; or necrotic and full-thickness, or stages III or IV. Granular wounds that are nondraining usually require one of the following dressings: transparent; hydrocolloid; hydrogel; composite, which is a combination of two or more different products such as a foam, hydrocolloid, or hydrogel; growth factor; and moist gauze. For a granular draining wound, one of the following dressings may be used: foam, calcium alginate, hydrocolloid, composite, collagen, and gauze. Necrotic wounds that are nondraining usually require one of the following dressings: transparent, hydrogel, hydrocolloid, and moist gauze. A draining necrotic wound may require one of the following: foam, alginate, collagen, composite, gauze, and contact layer. Besides the different types of dressing, there are other wound products such as lubricating sprays and emollients, which provide moisture to the wound bed and stimulate local circulation, and enzymatic debriders that are used on full-thickness necrotic wounds and infected wounds.

In addition, it is important to remember that the dressing plans must be modified as the wound changes. An excellent guide to help the nurse in the decision-making process is the RYB color code. Procedures 37-3 and 37-4 explain the proper technique for dry sterile dressing and wet-to-damp dressing changes. The properties of the dressing and the wound determine the length of time a dressing is left in place.

Monitor Drainage of Wounds

During the inflammatory response, exudates develop within a wound. When excessive drainage accumulates in the wound bed, tissue healing is delayed. If the outer surface is allowed to heal while the drainage remains entrapped within the wound, infection and abscess formation may occur. To facilitate drainage of any excess fluid, the prescribing practitioner may insert a tube or drain.

When the drain is inserted by the surgeon at the time of surgery, one end of the drain is placed in the operative site and the other end is usually passed through a separate small stab wound near the main incision. Various types of drains exist on the market. Some flexible drains such as **Penrose drains** function by gravity and have an open end that drains onto dressings. **Closed suction drainage systems** commonly have a reservoir that is capable of creating negative pressure or a vacuum. The gentle suction that is created draws exudate from the wound into the reservoir. As fluid enters the reservoir, suction is lost; therefore, the nurse must empty the reservoir when it is half full. Hemovac and Jackson-Pratt drains are examples of closed suction drainage systems (see Figure 37-6 on page 1175).

Nurses are responsible for maintaining the patency of the system and for assessing the amount, type, and color of the drainage. It is important for the nurse to be cautious when changing wound dressings to prevent accidental removal or dislodgement of drains.

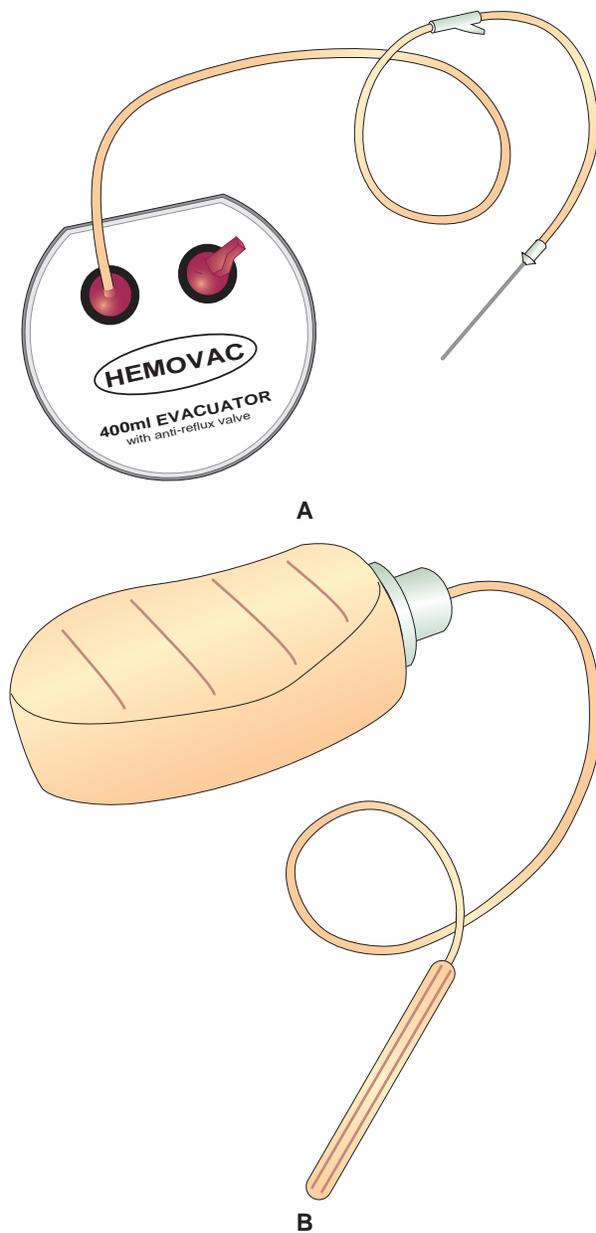

FIGURE 37-6 Drainage Systems: A. Closed System (Hemovac); B. Tube and Reservoir System (Jackson-Pratt) DELMAR/CENGAGE LEARNING

Provide Suture Care

Sutures are a surgical means of closing a wound by sewing, wiring, or stapling the edges of the wound together. When placed deep within the tissue layers, sutures made of absorbable material are used so that the sutures will not need to be removed but rather can dissolve into the tissue. For surface closures, steel staples or sutures made of wire, nylon, cotton, or other materials are used; these need to be removed as the wound heals.

Nurses are often responsible for removing sutures and should therefore be familiar with different suturing methods (see Figure 37-7). Continuous sutures are made with one thread, tied at the beginning and end of the suture line. Intermittent sutures are each tied individually. In blanket continuous sutures,

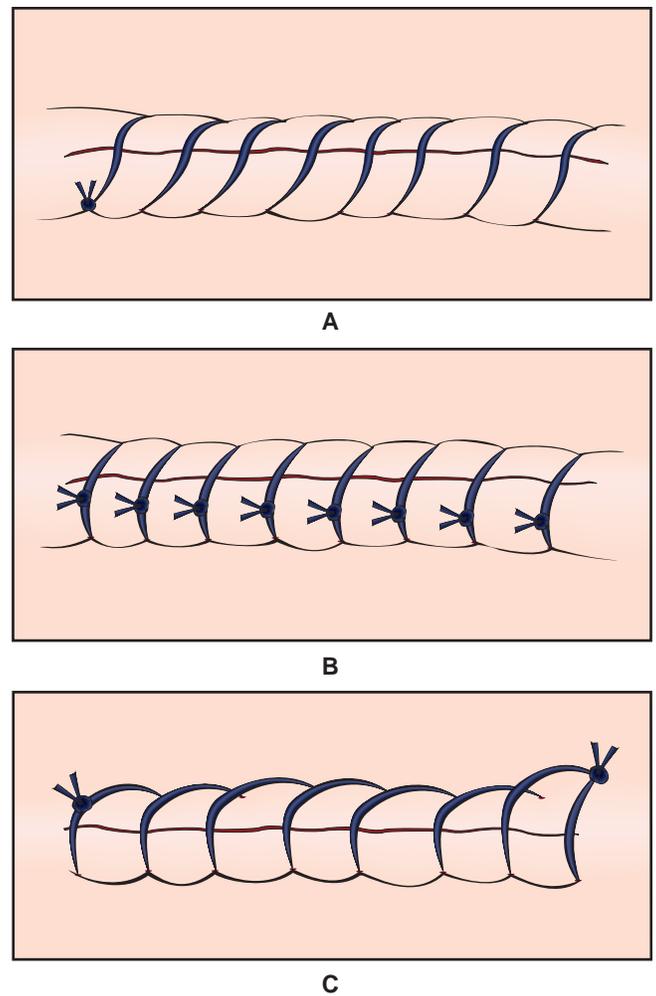

FIGURE 37-7 Selected Suturing Methods: A. Continuous; B. Intermittent; C. Blanket Continuous DELMAR/CENGAGE LEARNING

the single thread is grounded again in the last suture exit. When removing sutures, never pull a suture back through the skin. Sutures beneath tissue are sterile, but those that are visible are considered contaminated, and pulling them through the tissue introduces a risk of infection. Instead, cut the suture as close to the skin as possible on one side, then pull it through the skin from the other side.

To remove staples, the nurse inserts the end tips of the stapler remover under each wire staple. The end tips are placed in the middle of the staple; then the nurse slowly squeezes together the handles of the stapler remover, freeing the staple from the skin.

Checking Bandages, Binders, and Slings

Bandages and binders are applied over wound dressing sites to secure, immobilize, or support a body part; to hold a dressing in place; or to prevent or minimize swelling of a body part. Bandages are long rolls of material, such as gauze, webbing, or muslin, designed to be wrapped around body parts. Figure 37-8 on page 1176 illustrates several different methods of bandaging.

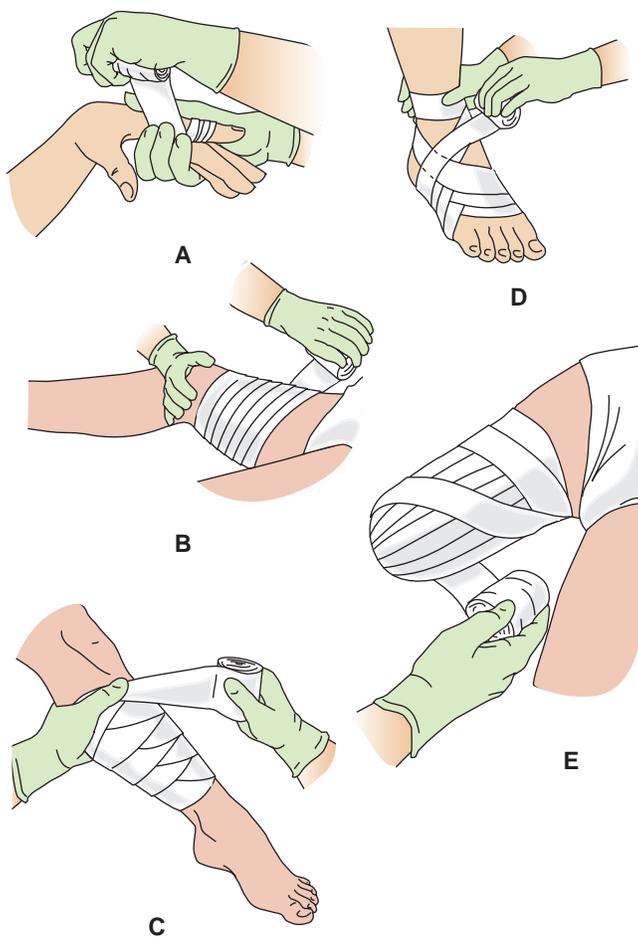

FIGURE 37-8 Common Bandaging Methods: A. Circular turns are wrapped around a body part several times to anchor the bandage or supply support. B. Spiral turns begin with two circular turns that anchor the bandage, then proceed up the body part, with each turn covering two-thirds the width of the preceding turn. C. Spiral reverse turns begin with a circular turn. Then the bandage is reversed, or twisted, once each turn to accommodate a limb that gets larger as the bandaging progresses. D. Figure-eight turns crisscross in the shape of a figure eight and are used on a joint that requires movement. E. Recurrent turns are anchored with circular turns and follow a back-and-forth motion, and they are completed with circular turns. They are used to cover a fingertip, head, or amputated stump. DELMAR/CENGAGE LEARNING

Binders are bandages made for specific body parts, usually the abdomen, perineal area, or arm (sling) (see Figure 37-9). Abdominal binders support the abdomen and are used following abdominal surgery or childbirth. Perineal binders, called T binders, are used to hold pads or dressings in the perineal area. Because of the urination and defecation needs of clients, T binders must be changed regularly. A sling is a cloth support for an injured arm that wraps around the back of the neck to maintain the arm in a set position. See the Nursing Checklist on page 1177.

Administer Heat and Cold Therapy

Cells in the hypothalamus act as a thermostat to regulate body temperature. When the hypothalamic thermostat detects that

CLINICAL APPLICATION

Home Care

Early discharge is one of the latest trends in health care. Clients are often being sent home with wounds that need special dressings. To facilitate an easy transition for the client from the hospital to the home, the nurse begins discharge planning during the admission assessment. At this time, the nurse determines the client's support system and availability to assist as caregivers, the home environment, and resources available to the client. Ongoing assessments provide data for the identification of physical care and home environment needs. At times, a referral for home care nursing is necessary. Common areas for health teaching include:

- Wound care
- Diet therapy
- Medications
- Signs and symptoms of complications of wound healing

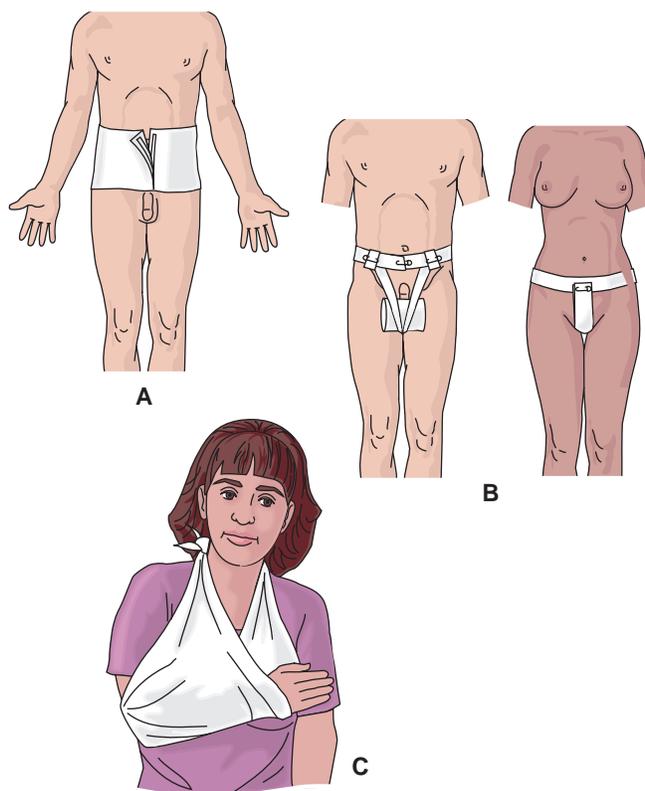

FIGURE 37-9 Common Binders: A. Abdominal; B. T Binders: Male and Female; C. Arm Sling DELMAR/CENGAGE LEARNING

the body temperature is either too high or too low, it responds systemically by instituting appropriate temperature-decreasing (vasodilation, sweating) or temperature-increasing (vasoconstriction, shivering) mechanisms to restore body temperature to the normal level.

Local responses to heat and cold occur through stimulation of temperature-sensitive receptors in the skin. Impulses travel from the periphery to the hypothalamus and the cerebral cortex. The hypothalamus then initiates heat-producing or heat-reducing reactions of the body. The conscious sensations of temperature are aroused in the cerebral cortex.

Heat and cold receptors adapt to changes in temperature. Upon initial exposure, receptors are strongly stimulated by extremes in temperature, but within a short time, this response declines as the receptors adapt to the new temperature variations. This adaptive ability of the body to temperature variations can be dangerous to clients insensitive to heat and cold extremes and may predispose them to serious injury. Nurses and clients need to understand this adaptive response when applying heat and cold.

Heat is one of the oldest nursing measures used to reduce pain and promote healing. Heat causes **vasodilation** and increases blood flow to the affected area, producing skin redness and warmth. Heat produces maximum vasodilation in 20 to 30 minutes; after this period, reflex vasoconstriction occurs along with tissue congestion. Periodic removal and reapplication of heat will restore vasodilation. Prolonged exposure to heat damages epithelial cells and results in redness, tenderness, and even blister formation.

The application of cold lowers the temperature of the skin and underlying tissues and causes **vasoconstriction**. Vasoconstriction reduces blood flow to the affected area and

produces skin pallor or a bluish discoloration and coolness. Maximum vasoconstriction is achieved at 15°C (60°F); at temperatures below 15°C, the vessels begin to dilate. Prolonged exposure to cold results in a reflex vasodilation. Initially the skin is reddened, but later it takes on a bluish-purple, mottled appearance with numbness and pain because of impaired circulation and tissue ischemia. Vasodilation and vasoconstriction of the blood vessels in the skin result primarily from increased sensitivity of the vessels to nerve stimulation but also from a protective reflex response that passes to the spinal cord and then back to the vessels. The therapeutic effects of heat and cold applications are outlined in Table 37-4 on page 1178.

The body's response to the application of heat and cold is influenced by a number of factors. These factors affect tolerance to heat and cold:

- **Body part:** Certain areas of the skin have a sensitivity to temperature variations. The inner aspect of the wrist and forearm, the neck, and the perineal area are temperature sensitive, while the backs of the hands and the feet are not as sensitive.
- **Duration of application:** Therapeutic benefits of heat and cold applications are achieved with short periods of exposure to temperature variations. Tolerance increases as the length of exposure increases.
- **Area of body exposed:** The larger the area exposed to heat and cold, the lower the tolerance to temperature changes.
- **Damage to body surface area:** Injured skin areas are more sensitive than intact areas to temperature variations.
- **Individual tolerance:** Tolerance to temperature variations is affected by age and physical condition. The young and older adults are especially susceptible to heat and cold. Neurosensory impairments may interfere with the reception and perception of stimuli, increasing the risk of injury.
- **Age:** Thinner skin layers in children and older adults increase the risk for burns from heat and cold applications. Older adults have a decreased sensitivity to pain.

The following conditions necessitate precautions in the use of heat and cold applications:

- **Neurosensory impairment:** Clients with reduced perception of sensory or painful stimuli (e.g., spinal cord injuries) are at an increased risk for tissue injury.
- **Impaired mental status:** Clients who are confused or unconscious need to be monitored and assessed frequently to ensure safety.
- **Impaired circulation:** Clients with cardiovascular and peripheral vascular problems or diabetes may not have the ability to dissipate heat through dilation of blood vessels and are at an increased risk for tissue injury.
- **Skin and tissue integrity (open wounds, broken skin, scar formation, edema):** Subcutaneous tissues are more sensitive to temperature variations than are superficial tissues (e.g., cold can decrease blood flow to an open wound, thereby inhibiting healing).

Heat and cold can be applied in dry and moist forms (see Figure 37-10 on page 1178). The type of wound or injury, location, and presence of drainage or inflammation

NURSINGCHECKLIST

Applying Bandages and Binders

When applying bandages and binders:

- Determine which type of support is needed for the wound and dressing.
- Note the appearance and condition of the skin and surrounding area, especially swelling, redness, excessive warmth, exudate, irritation, or uncovered wound areas.
- Ensure that the wound has a fresh sterile dressing before applying a bandage or binder to minimize intrusion and discomfort of the client for unnecessary dressing changes.
- Document the appearance of the skin that will be outside the bandage or binder to monitor changes in circulation, temperature, color, or swelling that occur once the bandage or binder is in place.
- Replace soiled or damp bandages and binders promptly.

TABLE 37-4 Therapeutic Effects of Heat and Cold Applications

PHYSIOLOGICAL RESPONSES	THERAPEUTIC BENEFITS
Heat therapy	
<ul style="list-style-type: none"> Promotes vasodilation. Decreases blood viscosity. Increases tissue metabolism. Increases capillary permeability. Reduces muscle tension. 	<ul style="list-style-type: none"> Improves blood flow. Increases delivery of oxygen and nutrients, leukocytes, and antibodies to facilitate the inflammatory process. Facilitates removal of wastes and toxins. Produces a local warming effect. Decreases venous congestion in injured tissues. Increases absorption of fluid by capillaries and promotes removal of excess fluid from interstitial spaces, thereby reducing edema. Promotes muscle relaxation and decreases pain from spasm or stiffness.
Cold therapy	
<ul style="list-style-type: none"> Promotes vasoconstriction. Increases blood viscosity. Decreases tissue metabolism. Has a local anesthetic effect. Decreases muscle tension. 	<ul style="list-style-type: none"> Decreases blood flow to site of injury, thereby decreasing inflammation and edema formation. Decreases blood flow, facilitating clotting and control of bleeding. Reduces the tissues' oxygen consumption. Raises the threshold of pain receptors, thereby decreasing pain.

Delmar/Cengage Learning

are considered when selecting moist or dry applications. See Table 37-5 on page 1179 for a discussion about the various forms of dry and moist heat and cold, their therapeutic effects, and general guidelines for their application. See the Nursing Checklist on page 1181.

EVALUATION

The nurse needs to evaluate the client's achievement of the goals established during the planning phase to achieve or

A

B

FIGURE 37-10 Types of Heat and Cold Applications: A. Aquathermal Heating Unit; B. Cold Packs DELMAR/CENGAGE LEARNING

maintain skin integrity. Goals for clients with wounds generally focus on wound healing, prevention of infection, and client education. If goals are not achieved, the nurse will need to examine the nursing interventions and strategies that were employed and revise the nursing care plan accordingly. Reviewing techniques and procedures, especially those performed by the client or other caregivers in the client's support system, is especially important.

PRESSURE ULCERS

Pressure ulcer, pressure sore, decubitus ulcer, and bedsore are terms used to describe impaired skin integrity related to mechanical factors such as unrelieved, prolonged pressure; shearing forces; and restraint (NANDA, 2009). The pressure causes **ischemia**, which is a temporary deficiency of blood supply to tissue or an organ. The unrelieved pressure or pressure in combination with shearing and/or friction results in localized damage that causes tissue necrosis when the soft tissue and blood supply are compressed between a bony prominence and an external surface for a prolonged period of time.

Pressure ulcers have plagued the nursing profession for years as a major health care problem in terms of a client's suffering and financial cost and have increased in occurrence by 63% from 1993 to 2003 in hospitalized clients (Wurster, 2007). This increase in occurrence has initiated many actions and regulations by national organizations. The NPUAP (2004) was instrumental in getting the Healthy People

TABLE 37-5 Overview of Heat and Cold Applications

DRY HEAT	DRY COLD
<p>Hot water bag</p> <ul style="list-style-type: none"> • Fill two-thirds full with warm water, and remove air at top so bag is easier to mold over body part. • Cover bag with towel or pillowcase (never apply directly on skin surface). • Keep bag in place 20–30 minutes, then remove. • Do not allow client to lie on hot water bag. 	<p>Ice bag, ice collar</p> <ul style="list-style-type: none"> • Fill two-thirds full with crushed ice so bag is easier to mold over body part. • Cover bag with towel or pillowcase, and apply to affected area for 30 minutes. • Provides cold to localized area (e.g., muscle sprain, hematoma) to prevent edema formation, control bleeding, and anesthetize body part.
<p>Hot packs</p> <ul style="list-style-type: none"> • Commercially prepared, disposable hot packs supply warm dry heat to injured area. • Striking or squeezing the pack releases chemicals that create heat. 	<p>Cold packs</p> <ul style="list-style-type: none"> • Commercially prepared single-use ice packs provide cold for designated period of time. • When pack is squeezed or kneaded, an alcohol-based solution is released, creating the cold temperature.
<p>Aquathermia pads</p> <ul style="list-style-type: none"> • Useful in treating muscle sprains and for areas with mild inflammation or edema. • Unit consists of a waterproof plastic or rubber pad connected by two hoses to an electrical control unit that has a heating element and a motor. The reservoir of the unit is filled two-thirds full with distilled water. • The desired temperature is usually set with a key at 45°C or 113°F for adults. • Cover the pad with a thin cloth or pillowcase prior to application. • Treatment usually continues for 20–30 minutes. • Do not have client lie on pad. 	
<p>Electrical heating pads</p> <ul style="list-style-type: none"> • Provide constant, even heat, are lightweight, and can easily be molded to a body part. • Unit composed of electrical coil enclosed within a waterproof pad covered with cotton or flannel cloth. • Instruct client to avoid using high setting to prevent burns. • Do not insert sharp objects into pad. • Do not allow client to lie directly on the pad because heat will not dissipate and the client may be burned. 	
MOIST HEAT	MOIST COLD
<p>Warm compresses (gauze dressing moistened in a prescribed warmed solution)</p> <ul style="list-style-type: none"> • Applied to improve circulation, relieve edema, and hasten the suppurative process and healing. • For an open wound, use sterile technique. • Solution to moisten gauze can be heated first to 40.5°C (105°F) or according to agency protocol. Procedure is similar to application of a wet-to-dry dressing and the use of a hot water bag or a heating pad to cover the dressing. 	<p>Cold compresses</p> <ul style="list-style-type: none"> • Applied to either decrease or prevent bleeding and reduce inflammation. • Procedure similar to that for warm compresses, except cold compresses applied for 20 minutes at a temperature of 15°C (59°F). • Observe for signs and symptoms of burning or numbness, mottling of skin, redness, extreme paleness, or bluish skin discoloration.

(Continues)

TABLE 37-5 (Continued)

MOIST HEAT

- Technique may be clean or sterile.
- Remove compress after 20–30 minutes and redress wound.

Warm soaks

- Immersion of body part in warmed solution promotes circulation, decreases edema, increases muscle relaxation, and provides a means to debride wounds and apply medicated solution.
- Can also be accomplished by wrapping body parts in dressings and saturating them with warmed solution.
- Position client comfortably. Place waterproof pads under area to be treated.
- Sterile technique is generally indicated for open wounds, such as a burn. Check agency protocol regarding the temperature of the solution.

Sitz bath

- Used for clients who have had rectal surgeries, episiotomy during childbirth, painful hemorrhoids, or vaginal inflammation.
- Only client's pelvic area is immersed in warm fluid; client sits in a special tub or chair or in a basin placed on toilet seat so legs and feet remain out of water (immersing the entire body causes widespread vasodilation, negating the effect of local heat to perineum or pelvic area).
- Water temperature should be from 40°–43°C (105°–110°F).
- Duration of bath is usually 15–20 minutes.
- Prevent overexposure and chilling by draping a bath blanket over client's shoulders and thighs, and prevent drafts.
- Assess client during bath for extensive vasodilation, faintness, dizziness, weakness, increased pulse rate, and pallor.

MOIST COLD

Cold soaks

- Procedure similar to that for warm soaks.
- Desired temperature for 20-minute soak is 15°C (59°F).
- Take precautions (such as preventing drafts and draping shoulders) to prevent client from chilling.

Adapted from Lehmann, J. F. (Ed.). (1982). *Therapeutic heat and cold* (3rd ed.). Baltimore, MD: Williams & Wilkins.

Consortium to include an objective that specifically addresses pressure ulcers in the Healthy People 2010 objectives.

The Centers for Medicare and Medicaid Services (CMS, 2008) has instituted ways to reduce or eliminate the occurrence of “never events”; refer to Chapter 29 for a discussion of never events. According to the National Quality Forum, never events are errors in medical care that are clearly identifiable, preventable, and serious in their consequences for clients and that indicate a real problem in the safety and credibility of a health care facility. The CMS has included stage III and IV pressure ulcers acquired after admission to a health care facility as never events.

The Joint Commission (2008) has a broader definition of pressure ulcer that includes decubitus ulcers and any other areas of ulceration associated with pressure such as prosthetic limbs or dental prostheses. Any client experiencing urinary or fecal incontinence, malnutrition, paralysis, or physical deformity is at risk for pressure ulcer development.

PHYSIOLOGY OF PRESSURE ULCERS

The reduction of blood flow causes **blanching** (white color) of the skin when pressure is applied. When pressure is relieved, the skin takes on a brighter color (reactive hyperemia) due to

NURSING CHECKLIST

Heat and Cold Applications

General guidelines to follow when using heat and cold applications include:

- Obtain a prescribing practitioner's order that details the site to be treated, the type of therapy, and the frequency and duration of application.
- Select temperature on the basis of client status and agency policy.
- Thoroughly explain procedure and expected benefits to client.
- Assess client's status before, during, and after treatment is performed to prevent injury.
- Document effects of therapy.

vasodilation, the body's normal compensatory response to the absence of blood flow. If this area blanches with fingertip pressure or if the redness disappears within an hour, no tissue damage is anticipated. If, however, the redness persists and no blanching occurs, then tissue damage is present.

Other forces acting in conjunction with pressure contribute to pressure ulcer formation. **Shearing** is the force exerted against the skin when a client is moved or repositioned in bed by being pulled or allowed to slide down in bed. The skin and subcutaneous tissue tend to adhere to the bed surface and remain stationary, while deeper underlying tissues pull away and slide in the direction of movement. This action results in the stretching and tearing of blood vessels, reduced blood flow, and necrosis. Shearing forces account for the high incidence of sacral ulcers.

Friction is the force of two surfaces moving across one another. When a client moves or is pulled up in bed, rubbing of the skin against the sheets creates friction. Friction can remove the superficial layers of the skin, making it more prone to breakdown.

RISK FACTORS FOR PRESSURE ULCERS

Pressure ulcers can be prevented if at-risk individuals and the specific factors placing them at risk can be identified. Many risk factors have been associated with pressure ulcer formation, including immobility and inactivity, incontinence, malnutrition, decreased mental status, diminished sensation, and age-related changes. Validated risk assessment tools such as the Braden scale (Braden, 2001) or the Norton scale (Norton, 1989) can be used to predict who will or will not develop pressure ulcers (see Table 37-6 on page 1182 and Table 37-7 on page 1184).

ASSESSMENT

The Joint Commission (2008) encourages the use of a valid risk assessment tool such as the Braden scale or the Norton scale to be used to identify clients at risk for developing

pressure ulcers upon admission to a facility. All clients admitted to a health care facility should be thoroughly assessed, and the status of any existing pressure ulcers must be clearly documented on admission. The nursing plan of care for clients at risk for pressure ulcers should include skin care; nutritional support; avoidance of skin injury from friction and shearing when repositioning, transferring, and turning; using repositioning devices when appropriate; and maintaining appropriate levels of activity and mobility. The Joint Commission also addresses the need for staff educational programs on the assessment, prevention, and treatment protocols for clients at risk for developing a pressure ulcer.

Pressure ulcers are staged to classify the degree of tissue damage (see Figure 37-11 on page 1184). The revised NPUAP (2007) statement recommends the following staging system:

- **Stage I.** Nonblanchable erythema of intact skin, the heralding lesion of skin ulceration. In individuals with darker skin, discoloration of the skin, warmth, edema, induration, or hardness may also be indicators.
- **Stage II.** Partial-thickness skin loss involving the epidermis, dermis, or both. The ulcer is superficial and presents clinically as an abrasion, a blister, or a shallow crater.
- **Stage III.** Full-thickness skin loss involving damage or necrosis of subcutaneous tissue that may extend down to, but not through, underlying fascia. The ulcer presents clinically as a deep crater with or without undermining of adjacent tissue.
- **Stage IV.** Full-thickness skin loss with extensive destruction, tissue necrosis, or damage to muscle, bone, or supporting structures. Undermining and sinus tracts may also be associated with stage IV pressure ulcers.

When eschar (scab or dry crust that results from death of the skin) is present, it should be described, since accurate staging of the ulcer is not possible until **sloughing** (shedding of dead tissue as a result of skin ulceration) and **debridement** (removal of necrotic tissue to foster the regeneration of healthy tissue) occur (NPUAP, 2007).

NURSING DIAGNOSES

Nursing diagnoses for clients with pressure ulcers will be similar to those for clients with wounds because the type of injury and its consequences are similar. The emphasis is on gentle client care and client teaching to promote healing of the ulcer and to prevent its recurrence. Identifying the client's psychological needs as well, in terms of diagnoses such as *Disturbed body image*, risk for *Social isolation*, alterations in *Self-esteem* related to the body image disturbance, and *Anxiety*, will ensure that the client's symptoms are addressed holistically.

PLANNING AND OUTCOMES

As with nursing diagnoses, the planning and outcomes phase of the nursing process for relieving pressure ulcers is similar to that for clients with wounds. Individualized outcomes based on the client's overall physical condition, the stage of

TABLE 37-6 Braden’s Scale for Predicting Pressure Sore Risk

Patient’s Name _____		Evaluator’s Name _____		Date of Assessment _____	
<p>Sensory perception Ability to respond to discomfort</p>	<p>1. Completely limited: Unresponsive to painful stimuli, either because of state of unconsciousness or severe sensory impairment, which limits ability to feel pain over most of body surface.</p> <p>2. Very limited: Responds only to painful stimuli (but not verbal commands) by opening eyes or flexing extremities. Cannot communicate discomfort verbally, OR has a sensory impairment that limits the ability to feel pain or discomfort over one-half of body surface.</p> <p>3. Slightly limited: Responds to verbal commands by opening eyes and obeying some commands, but cannot always communicate discomfort or need to be turned, OR has some sensory impairment that limits ability to feel pain or discomfort in one or two extremities.</p> <p>4. No impairment: Responds to verbal commands by obeying. Can communicate needs accurately. Has no sensory deficit that would limit ability to feel pain or discomfort.</p>				
<p>Moisture Degree to which skin is exposed to moisture</p>	<p>1. Very moist: Skin is kept moist almost constantly by perspiration and urine. Dampness is detected every time patient is moved or turned. Linen must be changed more than one time each shift.</p> <p>2. Occasionally moist: Skin is frequently, but not always, kept moist; linen must be changed two to three times every 24 hours.</p> <p>3. Rarely moist: Skin is rarely moist more than three to four times a week, but linen does require changing at that time.</p> <p>4. Never moist: Perspiration and incontinence are never a problem; linen changed at routine intervals only.</p>				
<p>Activity Degree of physical activity</p>	<p>1. Bedfast: Confined to bed.</p> <p>2. Chairfast: Ability to walk severely impaired or nonexistent and must be assisted into chair or wheelchair. Is confined to chair or wheelchair when not in bed.</p> <p>3. Walks occasionally: Walks occasionally during day, but for very short distances, with or without assistance. Spends majority of each shift in bed or chair.</p> <p>4. Walks frequently: Walks a moderate distance at least once every 1 to 2 hours during waking hours.</p>				
<p>Mobility Ability to change and control body position</p>	<p>1. Completely immobile: Unable to make even slight changes in position without assistance.</p> <p>2. Very limited: Makes occasional slight changes in position without help but unable to make frequent or significant changes in position independently.</p> <p>3. Slightly limited: Makes frequent though slight changes in position without assistance but unable to make major changes in or maintain position independently.</p> <p>4. No limitations: Makes major and frequent changes in position without assistance.</p>				

(Continues)

TABLE 37-6 (Continued)

<p>Nutrition Usual food intake pattern</p>	<p>1. Very poor: Never eats a complete meal. Rarely eats more than one-third of any food offered. Intake of protein is negligible. Takes even fluids poorly. Does not take a liquid dietary supplement, OR is NPO and/or maintained on clear liquids or IV for more than 5 days.</p>	<p>2. Probably inadequate: Rarely eats a complete meal and generally eats only about one-half of any food offered. Protein intake is poor. Occasionally will take a liquid dietary supplement, OR receiving less than optimum amount of liquid diet or tube feeding.</p>	<p>3. Adequate: Eats over half of most meals. Eats moderate amount of protein source one to two times daily. Occasionally will refuse a meal. Will usually take a dietary supplement if offered, OR is on a tube feeding or TPN regimen that probably meets most nutritional needs.</p>	<p>4. Excellent: Eats most of every meal. Never refuses a meal. Frequently eats between meals. Does not require a dietary supplementation.</p>			
<p>Friction and shear</p>	<p>1. Problem: Requires moderate to maximum assistance in moving. Complete lifting without sliding against sheets is impossible. Frequently slides down in bed or chair, requiring frequent repositioning with maximum assistance. Either spasticity, contraction, or agitation leads to almost constant friction.</p>	<p>2. Potential problem: Moves feebly independently or requires minimum assistance. Skin probably slides against bedsheets or chair to some extent when movement occurs. Maintains relatively good position in chair or bed most of time but occasionally slides down.</p>	<p>3. No apparent problem: Moves in bed and in chair independently and has sufficient muscle strength to lift up completely during move. Maintains good position in bed or chair at all times.</p>				
<p>Total score</p>							

Key: 16, minimum risk; 13–14, moderate risk; 12 or less, high risk; NPO, nothing by mouth; IV, intravenously; TPN, total parenteral nutrition. Braden, B. J. (1989). Clinical utility of the Braden scale for predicting pressure sore risk. *Decubitus*, 2(3), 44–46, 50–51. Copyright 1988 by Barbara Braden and Nancy Bergstrom. Text not available due to copyright restrictions

the wound, and the client's risk factors will help in identifying priority interventions. The outcomes as defined by NOC, previously addressed in the section on wounds, provide indicators that measure size and wound edge approximations, granulation, scar formation, and decreased wound size. Client teaching should be included as an integral part of the planning process; if the client desires, family and support persons should be brought into the learning circle as well.

IMPLEMENTATION

Pressure ulcers can be prevented through a variety of measures. Early identification of high-risk individuals and contributing risk factors and an ongoing assessment of risk factors and skin integrity should be done to decrease the possibility of pressure ulcer formation. NIC (Bulechek et al., 2008) identifies the following nursing measures regarding prevention and

A

C

B

D

FIGURE 37-11 Four Stages of Pressure Ulcers: A. Stage I; B. Stage II; C. Stage III; D. Stage IV PERMISSION TO REPRODUCE THIS COPYRIGHTED MATERIAL HAS BEEN GRANTED BY THE OWNER, HOLLISTER INCORPORATED.

pressure management and care: Pressure Ulcer Prevention, Pressure Management, and Pressure Ulcer Care. Nursing care is focused on preventive measures, such as the application of protective barriers, repositioning and monitoring pressure points, and monitoring the client's nutritional and circulatory status. The management and care of pressure ulcers require many of the aforementioned preventive activities, in addition to keeping the ulcer clean and moist to promote healing and teaching the caregiver wound care procedures.

Other areas to focus on in the prevention of pressure ulcers include nutritional status, hygiene and skin care, positioning, and the use of support surface therapy. The following interventions may be used as guidelines by the nurse in caring for adult clients at risk for pressure ulcer development. They are based on recommendations developed by the Agency for Health Care Policy and Research (AHCPR, 1996).

Monitor Nutritional Status

The nurse should monitor the nutritional status of clients at risk for or who have a pressure ulcer. Nutrients provide the needed substrates for the tissue metabolism that is necessary for healing. Adequate nutrition helps decrease the incidence of pressure ulcers and contributes to the healing process. Clients with a pressure ulcer should have a total caloric intake of at least 30–35 calories/kg/day and a protein intake of 1.25–1.5 g/kg/day, or enough to maintain a positive nitrogen balance; a client with a draining ulcer may require as much as 2.5 g/kg/day of protein (Schmidt, 2002). Fluid intake must be adequate, at a minimum of 30–35 mL/kg/day, with water being the main fluid.

Other recommended nutrients include an intake of vitamin C at 60–120 mg/kg/day and zinc at 12–15 mg/kg/day if the client is deficient in this mineral (Makelbust & Sieggreen, 2001). Zinc must be used with caution. If given in large doses, it can be toxic; also, it should not be taken longer than 2 to 3 weeks. See Chapters 33 and 34 for a complete discussion of fluid and electrolytes and nutrition.

Ensure Proper Hygiene and Skin Care

Proper skin care is essential to preventing skin breakdown. To maintain and improve tissue tolerance to pressure, the nurse should perform the following interventions:

- Assess the skin at least once a day, paying particular attention to bony prominences.
- Cleanse the skin at routine intervals and at time of soiling. Keep the client's skin clean, dry, and free of irritation and maceration by urine, feces, and sweat. A moisture-barrier cream can also be applied to the perineal area to protect the skin from moisture and toxins from urine and stool.
- Use warm water and mild cleansing agents so as not to irritate and dry the skin. Avoid the use of soaps and alcohol-based lotions, which may cause drying and leave an alkaline residue that discourages normal skin bacteria, leading to growth of opportunistic bacteria. Minimize the force and friction applied to the skin during cleansing so as not to disrupt the "natural barrier" to the skin.

SPOTLIGHT ON...

Caring and Compassion

Caring for Clients with Pressure Ulcers

Advanced-stage pressure ulcers can have extensive necrotic tissue, significant drainage, and a very strong odor. Have you ever seen skin in an advanced stage of tissue deterioration? How would you feel about caring for a client with a stage IV pressure ulcer? Would your opinion be different if the client were an 8-year-old comatose child or an 80-year-old bedridden client?

- If the skin is dry, use moisturizing lotions and minimize exposure to cold and low humidity, which can cause dryness of the skin.
- Avoid massage over bony prominences. Current evidence suggests that massage may be harmful and cause deep tissue trauma (Makelbust & Sieggreen, 2001; U.S. Department of Health and Human Services, 1992).

Debridement

Nursing care for pressure ulcers requires cleansing, debridement, and dressing the wound (see Table 37-3 for wound dressing guidelines). In order to properly assess and stage a wound, the wound must be clean. Wounds that are covered with necrosis or foreign debris prohibiting visual inspection and identification of tissue depth involvement cannot be staged. The AHCPR guidelines do not recommend the debridement of a dry, stable eschar ulcer on the heel without signs of edema, erythema, fluctuance (fluid wave), or drainage because the eschar serves as a natural barrier to infection. Necrotic ulcers on the heel or toe should be wrapped in a soft dressing material to prevent trauma and monitored for signs of infection.

Baranoski and Thimsen (2003) describe eschar as brown to black tissue that covers a wound that may be loose, firmly adherent, hard, soft, or boggy. Wounds deprived of moisture will have eschar that is hard and firmly adhered to the wound bed. Slough is described as a "soft, moist avascular (devitalized) tissue that may be white, yellow-tan, or green [and] may be loose or firmly adherent to the wound base" (Baranoski & Thimsen, 2003, p. 8).

In healthy individuals the body's natural defenses keep a wound debrided; however, in malnourished clients or clients who have medical conditions, such as diabetes, or certain types of wounds, such as pressure ulcers, the accumulation of necrotic tissue cannot keep pace with the body's natural debridement process (Ayello, Cuddigan, & Kerstein, 2002). Debridement is essential to wound healing because necrotic tissue retards healing and is a medium for bacterial growth; removing the necrotic tissue restores circulation to the wound. Failure to remove necrotic tissue from a large open

wound causes loss of large amounts of protein and places the client at risk for osteomyelitis, generalized infection, septicemia, and death.

In Europe, maggots or larval therapy and some newer debridement technologies are being used, but four common debridement methods are used in the United States and Canada: surgical or sharp, mechanical, enzymatic, and autolytic (Ayello et al., 2002); see Table 37-8 for debridement methods. In the absence of a severe infection, the prescribing practitioner has time to consider the most appropriate method of debridement. Primary or initial debridement is based on knowledge of wound characteristics, client characteristics, the debridement method, and the biology of chronic wound healing (Baranoski & Thimsen, 2003). “Maintenance debridement should be repeated until the causative agent of the wound is removed or controlled” (Ayello & Cuddigan, 2004, p. 13).

Provide Proper Positioning

Positioning interventions prevent the adverse effects of pressure, friction, and shear. For most clients, maintaining current activity levels, mobility, and range of motion is sufficient to prevent pressure ulcers. For the immobilized client, the following interventions may help prevent the development of pressure ulcers:

- Turn and reposition the client at least every 1 to 2 hours so ischemic areas can recover. If a reddened area does not blanch when pressed, turn the client more often.
- When positioning, pay attention to body alignment. The position shown in Figure 37-12 relieves pressure on the sacrum and trochanters. There should be a 30° angle between the client’s trochanters and the surface of the bed. The hips and knees should be flexed. To maintain this position,

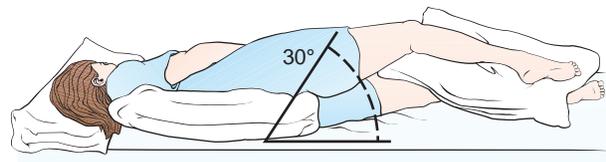

FIGURE 37-12 Avoiding Pressure Points with the 30° Lateral Position DELMAR/CENGAGE LEARNING

- support the client’s back with a pillow or foam wedge, and put a pillow between the knees.
- When turning the client, remove the pillows and wedges, lower the head of the bed, and use a draw sheet to lift, not drag, the client to a new position. Maintain the head of the bed at 30° or less to prevent shearing.
- If the client is supine, make sure the heels are not resting on the mattress. Suspend them by placing a pillow or foam pad lengthwise under the lower legs.
- Place at-risk clients on pressure-reducing surfaces.
- Have clients who are able to sit up shift their weight every 15 minutes; those who cannot do so need to be repositioned at least every hour.
- Use a pressure-reducing device such as a foam overlay on the seating surface to reduce pressure on the ischial tuberosities by redistributing weight over a much larger surface area. Do not use donut-shaped cushions, which reduce blood supply to the affected area, leading to even more ischemia.

Employ Support Surfaces

Various support surfaces are available to support the entire body and evenly distribute pressure. These devices can be

TABLE 37-8 Debridement Methods

METHOD	DEFINITION
Surgical or sharp debridement	The fastest way to remove dead tissue, used for all levels of bacterial load; first choice in treating worsening cellulitis or wound-related sepsis.
Mechanical debridement	Wet-to-dry dressings, hydrotherapy (whirlpool), and wound irrigation (pulsed lavage); caution should be used when infection is starting to spread.
Enzymatic or chemical debridement	Topical biologic enzyme, such as proteolytics, fibrinolytics, and collagenases, to selectively break down necrotic tissue; can be used in infected wounds but is most effective when used in conjunction with mechanical or surgical debridement.
Autolytic debridement	Enhances the body’s own enzymes and moisture to soften and break down necrotic tissue using a semiocclusive or occlusive dressing, such as a transparent or hydrocolloid dressing, to cover the wound; however, it is not a very effective method for removing hard, black necrotic tissue. Used with caution for contaminated, colonized, or critically colonized wounds.

Adapted from Ayello, E., Cuddigan, J., & Kerstein, M. (2002). Skip the knife: Debriding wounds without surgery. *Nursing 2002*, 32(9), 58–64; Ayello, E., & Cuddigan, J. (2004). Conquer chronic wounds with wound bed preparation. *Nurse Practitioner*, 29(3), 8–27.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Reducing Hospital-Acquired Heel Ulcer Rates in an Acute Care Facility: An Evaluation of a Nurse-Driven Performance Improvement Project”

AUTHORS

M. L. McElhinny and C. Hooper

PURPOSE

To reduce the incidence of hospital-acquired ulcers of the heel in an acute care setting with a nurse-driven performance improvement project.

METHOD

This was a descriptive, evaluative study using secondary data analysis in a 172-bed facility. The prevalence and incidence of heel pressure ulcers were obtained through skin surveys prior to implementation of the prevention program in 2004 and following its implementation in 2006 after introduction of the Braden Scale for Predicting Pressure Sore Risk. Heel pressure ulcers were staged using the National Pressure Ulcer Advisory Panel staging system and recommendations provided by the Agency for Health Care Quality Research clinical practice guidelines.

FINDINGS

The incidence of hospital-acquired heel pressure ulcers in 2004 was 13.5% (4 of 37 clients), compared to 2006, when there was an incidence of hospital-acquired heel pressure ulcers of 13.8% (5 of 36 clients).

IMPLICATIONS

The intervention did not appear to have adequate staff support in the following areas: educational method used; development of organization-approved, evidence-based, standardized protocols for prevention and treatment of heel ulcers; and assistance of facility management in conveying the importance of as well as their support for the project.

McElhinny, M. L., & Hooper, C. (2008). Reducing hospital-acquired heel ulcer rates in an acute care facility: An evaluation of a nurse-driven performance improvement project. *Journal of Wound Ostomy Continence Nursing*, 35(1), 79–83.

used as adjunct therapy to help reduce pressure and prevent ulcers, but they are no substitute for frequent positioning, and there is no scientific evidence that any one support surface works consistently better than another.

In addition to pressure reduction or relief, many support surfaces reduce shear and friction and control moisture. Pressure-reducing support surfaces include overlays filled with

foam, gel, water, or air (e.g., eggcrate mattresses, alternating air-filled mattresses) and replacement mattresses (replace standard mattresses). Pressure-relieving devices include specialty beds that replace hospital beds. Examples are low-air-loss (LAL) beds (e.g., Flexicair), air-fluidized beds (e.g., Clinitron), and beds that provide kinetic therapy. Kinetic beds (e.g., RotoRest) provide continuous passive motion or oscillation to counteract the effects of immobility. See Chapter 36 for a complete discussion of beds used to counteract the effects of immobility. See Table 37-9 on page 1188 for a list of selected support devices.

Complementary Therapies

Nature is rich in plants that promote the healing of cuts, burns, and wounds. Herbalists recognize that skin problems may reflect a variety of internal conditions; therefore, herbs used to treat wounds are selected based on their internal and external actions. Herbs that create the following actions are particularly useful for wound healing: vulneraries (promote healing of wounds and ulcers), alteratives (restore proper bodily function), diaphoretics (promote sweating and capillary dilation), antimicrobials (resist pathogenic microorganisms, usually by strengthening the immune system), and nervines (act on the nervous system as either tonics, relaxants, or stimulants). Some of the vulnerary herbs discussed next also work as astringents (bind to skin and mucous tissue, reduce irritation and inflammation, protect against infections) to arrest bleeding and to condense tissue.

Chickweed, a common garden weed, is a vulnerary and antimicrobial. It may be applied directly to an insect bite to relieve itching and irritation or used as an ointment in combination with marshmallow for cuts and wounds (Tierra & Lust, 2008).

Comfrey contains a chemical, allantoin, that stimulates cell proliferation and promotes wound healing both inside and out. Although it can be used internally to treat gastric and duodenal ulcers, comfrey is often used externally as a compress or poultice to speed the healing of wounds and fractures and reduce scarring. *Caution should be exercised when using comfrey to treat deep wounds, since it can lead to tissue forming over the wound before the wound heals from within, creating a risk for an abscess to form* (Tierra & Lust, 2008). The anticancer action of this herb has been reputed, and the herb should be used with caution in anyone with a family history of cancer.

Aloe vera is a common household plant. The juice from the plant is used externally to treat minor cuts and burns, sunburn, and insect bites. It has been used effectively to decrease the scarring from acne. Aloe is primarily a vulnerary herb that promotes wound healing and has an antimicrobial action. Internally this herb is used as a cathartic and an emmenagogue (normalize and tone the female reproductive system) and *should be used with caution during pregnancy and should be avoided during breastfeeding, since it is excreted in the mother's milk. Caution also should be exercised when taking dieter's teas containing aloe and other substances, as they act as laxatives when consumed in large quantities and*

TABLE 37-9 Support Surfaces

TYPE	EXAMPLES (MANUFACTURER)	INDICATIONS	ADVANTAGES	DISADVANTAGES
Foam overlay	Biogard (Bio Clinic) Geo-Matt (Span-America) First Wave (Pegasus Airwave)	Pressure reduction, comfort	Low cost, easy to use	Hot; traps moisture; pressure reduction lost with continued use; easily contaminated by body fluids
Static air mattress (air overlay)	Sof-Care (Gaymar Industries) Roho (Roho) First Step (Kinetic Concepts International [KCI])	Pressure relief		Damaged by sharp objects; inflation has to be monitored
Fluid overlay (water mattress)	Medline Water Overlay (Medline) MedRite Water Flotation Mattress (MedRite International)	Pressure reduction, comfort	Easy to clean, multiple-use	Leaks with puncture
Static, low air loss	Flexicair (Support Systems International) Kin Air (KCI) Prime-Air (Hill-Rom) Silk-Air (Hill-Rom)	Pressure relief when repositioning is difficult or contraindicated	Bed adjusts to variety of positions; filter reduces risk of airborne contamination; cushions provide pressure relief	Bed does not absorb fluid
Active, low air loss (oscillating)	Biodyne (KCI) TheraPulse (KCI) TotalCare SpO2RT (Hill-Rom) V-Cue (Hill-Rom)	Clients who are unstable and cannot tolerate sudden changes in position; clients with pneumonia changes to mobilize secretions	Protects skin integrity; promotes removal of pulmonary secretions	Limited motion
Air fluidized	Clinitron (Hill-Rom) Fluid Air (KCI) Rite Hite (Hill-Rom) Clinitron At-Home (Hill-Rom)	Clients who require minimal movement to prevent skin damage by shearing forces; pressure relief	Minimum pressure on bony prominences; fluidization makes turning easy; facilitates drainage and substance in beads reduces risk of infection	Heavy transport difficult; foam backrest provides limited head elevation; drying effect may inhibit cough and may dehydrate
Rotation	Tilt and Turn (SMI Patient Care) RotoRest (KCI)	Clients who require frequent turning but have unstable spines; movement, skeletal stability	Provides skeletal stability; mobilizes secretions; supports traction	Movement increases risk of friction and shearing and may cause motion sickness
Bariatric	Burke (KCI) Barimagnum (Hill-Rom) Total Care Bari Sport (Hill-Rom)	Management of morbidly obese	Supports independence; converts to chair	Not wide enough to facilitate repositioning

Delmar/Cengage Learning

Client with Impaired Skin Integrity

CASE PRESENTATION

Mr. Short is a 48-year-old client who was involved in a motor vehicle accident. Three days after abdominal surgery, he develops fever, tenderness around the incision, and purulent drainage from the wound. The prescribing practitioner opens the incision and orders normal saline wet-to-dry dressing changes three times a day.

ASSESSMENT

- Temperature 38°C or 101.8°F
- Pulse 110
- Respirations 20
- BP 130/70
- Incision—red, tender to touch, yellow, purulent drainage
- Labs—WBC ↑

NURSING DIAGNOSIS: *Impaired skin integrity* related to presence of contaminants

NOC: Wound healing

NIC: Wound care

EXPECTED OUTCOMES

1. Within 1 week the client's wound will be free of infection as evidenced by:
 - a. Absence of fever
 - b. Absence of redness, exudate
 - c. Normal WBC count
2. Within 1–2 weeks the client's wound will exhibit signs of healing as evidenced by:
 - a. Presence of granulation tissue
 - b. Wound being closed and without drainage

INTERVENTIONS/RATIONALES

- 1a.** Assess and document the wound for presence of redness, pain, and exudate with every dressing change. Exudate indicates infection.
- 1b.** Assess VS q4h. VS reflect client's overall condition.
- 1c.** Assess WBC count. WBC counts show progression of infection.
- 2a.** Apply wet-to-dry dressing changes tid utilizing sterile technique. Promotes clean environment, which encourages wound healing.
- 2b.** Ensure good hand washing before and after all dressing changes. Limits exposure of incision to pathogens.

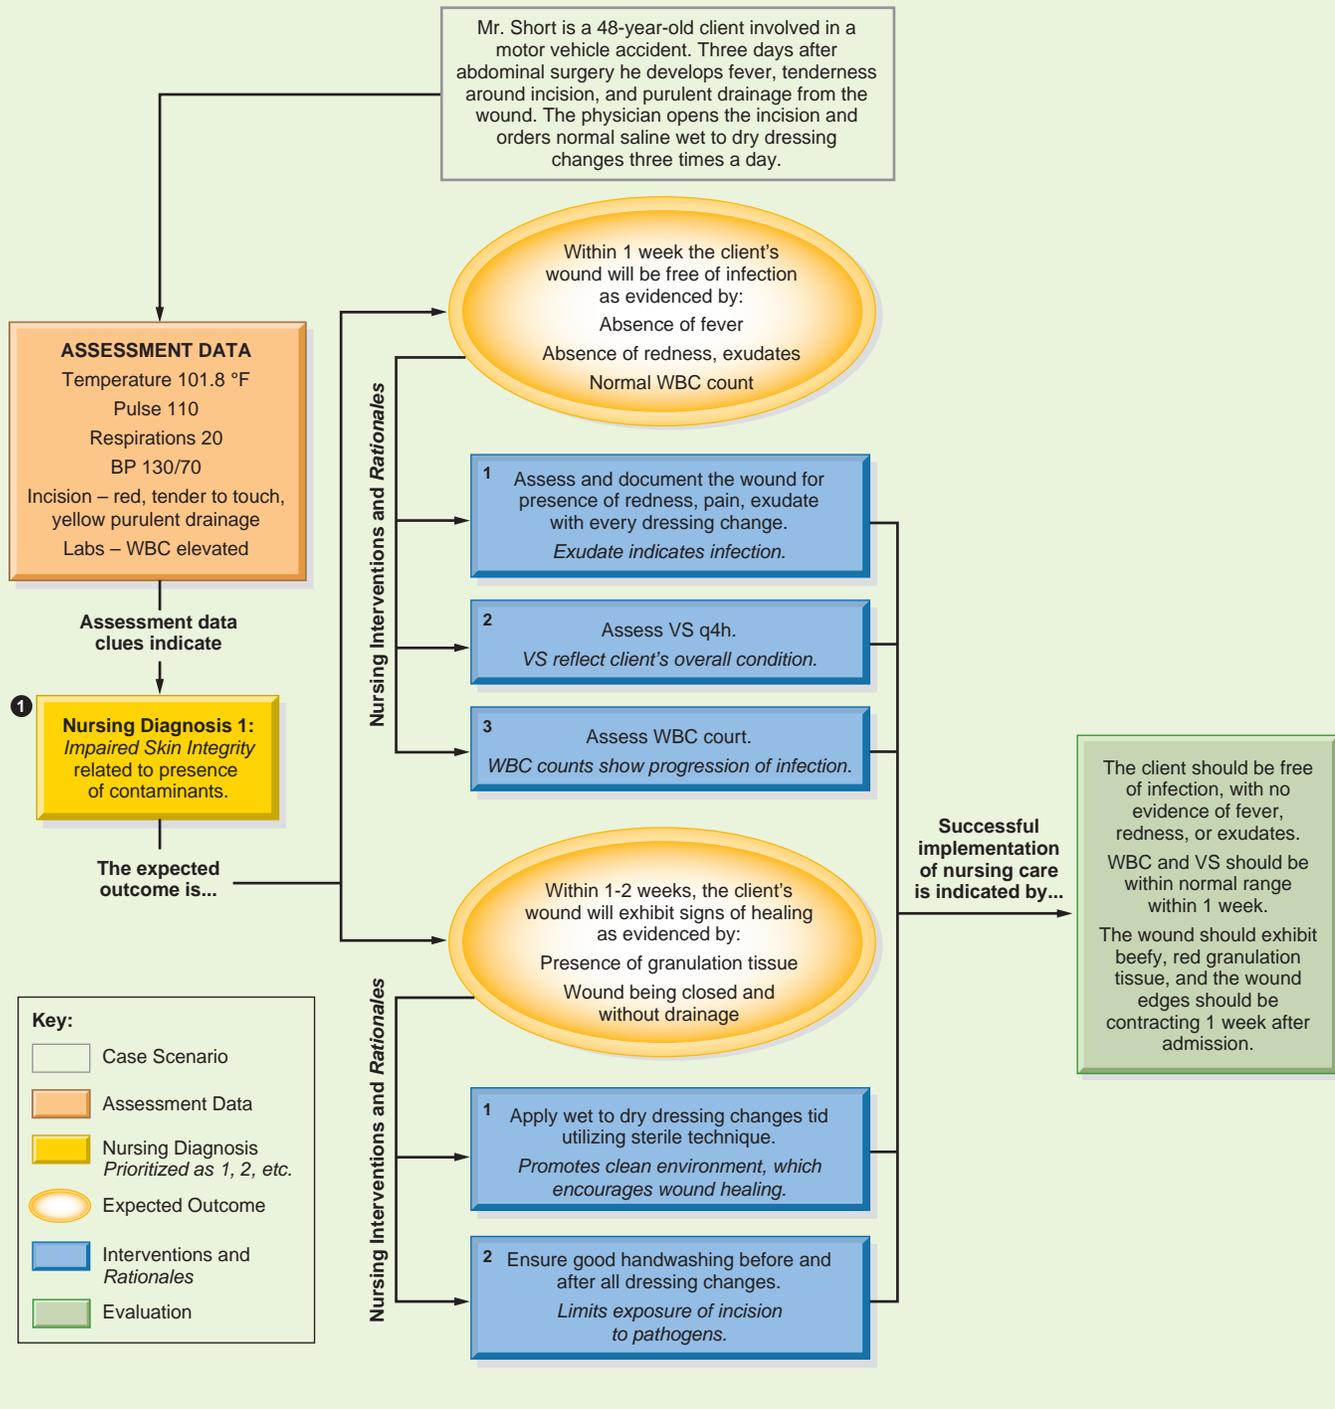

EVALUATION

The client should be free of infection, with no evidence of fever, redness, or exudate. WBC count and VS should be within normal range within 1 week. The wound should exhibit beefy-red granulation tissue, and the wound's edges should be contracting 1 week after admission.

(Continues)

CONCEPT MAP

THE CLIENT WITH IMPAIRED SKIN INTEGRITY

can disrupt potassium levels and contribute to cardiac arrhythmias (Fontaine, 2000).

Woundwort is a vulnerary, an antiseptic, an antispasmodic, and an astringent used primarily as a wound healer. It is equivalent to comfrey as a wound healer and may be used directly on the wound or as an ointment or a compress (Tierra & Lust, 2008).

Other herbs that may be used to promote wound healing and relieve irritation and pain associated with an ulcer or a wound are tea tree oil, lavender oil, colloid silver, *Echinacea*, golden seal (refer to Chapter 31 for a complete discussion of their antimicrobial action), slippery elm, knitbone, and self-heal.

Although most wounds heal with a well-balanced diet, special attention should be given to the diet when wounds are at risk for infection. Avoid stressor foods such as refined sugars, excess caffeine, and alcoholic beverages because they may decrease the body's immune function and healing. The diet should be rich in essential fatty acids, vitamin A, zinc, and vitamin C to promote the skin's healing. Foods rich in these essential elements are green and yellow vegetables, eggs, cold-water fish, raw seeds and nuts, and oysters.

EVALUATION

Evaluation of the plan of care for a client with a pressure ulcer will consider the physical signs of healing and the status of the pressure ulcer as well as the client's adaptation to the altered skin integrity. Each intervention should be evaluated for its effectiveness and the plan of care revised to reflect those actions that have proven the most beneficial in realizing the expected outcomes of care.

PROCEDURE 37-1

Irrigating a Wound

EQUIPMENT

- Sterile gloves
- Disposable gloves
- Sterile irrigation kit (basin, piston irrigation syringe, solution container)
- Moisture-proof container or bag for use after the irrigation procedure
- Irrigation solution (per health care provider's order)
- Waterproof pad
- Sterile dressing material to redress the wound

ACTION

RATIONALE

- | | |
|---|---|
| <ol style="list-style-type: none"> 1. Confirm the health care provider's order for wound irrigation, and note the type and strength of the ordered irrigation solution. 2. Assess the client's pain level and medicate if needed with analgesic 30 minutes before procedure if the medication is to be given PO or IM. 3. Explain the procedure to the client. Wash hands/hand hygiene. 4. Place a waterproof pad on the bed. Assist the client onto the pad and into a position that will allow the irrigant to flow through the wound and into the basin from the cleanest to dirtiest area of the wound. 5. Wash hands/hand hygiene, and apply the disposable gloves; remove and discard the old dressing. 6. Assess the wound's appearance and note quality, quantity, color, and odor of drainage. 7. Remove and discard the disposable gloves. Wash hands/hand hygiene. 8. Prepare the sterile irrigation tray and dressing supplies. Pour the room-temperature irrigation solution into the solution container. 9. Apply sterile gloves (and goggles, if needed). | <ol style="list-style-type: none"> 1. Wound irrigation is a dependent nursing action that requires a medical order stating the type of solution to be used. 2. Allows time for medication to be absorbed to increase the analgesic effect. 3. Helps decrease the client's anxiety and increase the client's cooperation. Prevents the spread of microorganisms. 4. Positioning of the client and placement of a waterproof pad will decrease contamination of bed linen. 5. Prevents the spread of microorganisms. 6. Provides assessment of the status of the wound. 7. Prevents the spread of microorganisms. 8. Aseptic technique is used to prevent introduction of microorganisms into the wound. Room-temperature solution reduces the client's discomfort. 9. Promotes sterile environment. |
|---|---|

(Continues)

PROCEDURE 37-1 Irrigating a Wound (Continued)

ACTION	RATIONALE
10. Position the sterile basin below the wound so the irrigant will flow from the cleanest area to the dirtiest area and into the basin.	10. Decreases possibility of wound contamination.
11. Fill the piston or bulb syringe with irrigant and gently flush the wound. Hold the syringe approximately 1 inch above the wound bed to irrigate. Refill the syringe and continue to flush the wound until the solution returns clear and no exudate is noted or until the prescribed amount of fluid has been used (see Figures 37-13 and 37-14).	11. Gently irrigating the wound decreases trauma to granulation tissue. This provides the ideal pressure for cleansing and removal of debris.
12. Dry the edges of the wound with sterile gauze (see Figure 37-15).	12. Drying the edges of the wound prevents maceration of tissues caused by excess moisture.
13. Assess the wound's appearance and drainage.	13. Provides indication of change in wound status.
14. Apply a sterile dressing. Remove sterile gloves and dispose of properly. Wash hands/hand hygiene.	14. Protects the wound from microorganisms; prevents the spread of microorganisms.
15. Document all assessment findings and actions taken.	15. Records information for evaluation.

FIGURE 37-13 Gently flush the wound. DELMAR/CENGAGE LEARNING

FIGURE 37-14 Hold the syringe close to the wound, but be careful not to touch the wound with the syringe. DELMAR/CENGAGE LEARNING

FIGURE 37-15 Dry the edges of the wound with sterile gauze. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 37-1
Irrigating a Wound (Continued)

delegation tip

Wound irrigation requires nursing assessment, aseptic technique, and monitoring of wound healing. This procedure is not delegated to ancillary personnel.

nursing tips

- Be sure the irrigant is at room temperature, or ideally body temperature, to avoid traumatizing the granulating tissues and to avoid client discomfort.
- A small wound can be irrigated with a syringe and solution poured into a sterile specimen cup.

PROCEDURE
37-2

Obtaining a Wound Drainage Specimen for Culturing

EQUIPMENT

- Disposable gloves
- Sterile gloves and dressing supplies
- Normal saline and irrigation tray
- Culture tube and swab
- Moisture-proof container or bag

ACTION

RATIONALE

ACTION	RATIONALE
1. Wash hands/hand hygiene, apply disposable gloves, and remove old dressing. Place old dressing in moisture-proof container, and remove and discard gloves. Wash hands/hand hygiene again.	1. Prevents the spread of microorganisms. Makes the wound accessible for obtaining the culture.
2. Open the dressing supplies using sterile technique and apply gloves.	2. Maintains sterile environment.
3. Assess the wound's appearance; note quality, quantity, color, and odor of discharge.	3. Provides assessment of the amount and character of the wound's drainage prior to irrigation. Reddened areas and heavy drainage suggest infection.
4. Irrigate the wound with normal saline prior to culturing the wound; do not irrigate with antiseptic.	4. Irrigation decreases the risk of culturing normal flora and other exudates such as protein; irrigating with an antiseptic prior to culturing may destroy the bacteria.
5. Using a sterile gauze pad, absorb the excess saline, and then discard the pad.	5. Removal of excess irrigant prevents maceration of tissue caused by excess moisture.
6. Remove the culture tube from the packaging (see Figure 37-16 on page 1194). Remove the culture swab from the culture tube, and gently roll the swab over the granulation tissue. Avoid eschar and wound edges (see Figure 37-17 on page 1194).	6. Decreases the chance of collecting superficial skin microorganisms.

(Continues)

PROCEDURE 37-2 Obtaining a Wound Drainage Specimen for Culturing (Continued)

ACTION

RATIONALE

FIGURE 37-16 Remove the culture tube from the packaging. DELMAR/CENGAGE LEARNING

7. Replace the swab into the culture tube, being careful not to touch the swab to the outside of the tube. Recap the tube. Crush the ampule of medium located in the bottom or cap of the tube (see Figure 37-18).

FIGURE 37-17 Roll the swab over the area to be cultured. DELMAR/CENGAGE LEARNING

7. Avoids contamination with microorganisms. Releases the medium to surround the swab.

FIGURE 37-18 Crush the ampule to release the medium inside the culture tube. DELMAR/CENGAGE LEARNING

8. Remove gloves, wash hands/hand hygiene, and apply sterile gloves. Dress the wound with sterile dressing.
 9. Label the specimen, place in biohazard transport bag, and arrange to transport the specimen to the laboratory according to institutional policy.
8. Prevents the spread of microorganisms and contamination of the wound.
 9. Ensures proper handling of specimen.

(Continues)

PROCEDURE 37-2
Obtaining a Wound Drainage Specimen for Culturing (Continued)

ACTION	RATIONALE
10. Remove gloves. Wash hands/hand hygiene.	10. Prevents the spread of microorganisms.
11. Document all assessment findings and actions taken. Document that a specimen was obtained.	11. Records information for evaluation and promotes continuity of care.

delegation tip

Obtaining a wound culture requires nursing assessment and aseptic technique and is potentially an invasive procedure; therefore, delegation to ancillary personnel is not appropriate.

nursing tips

- Do not irrigate the wound with anything except sterile saline or sterile water prior to obtaining the specimen.
- Be aware of what you are doing while holding the culture swab. Touching the swab to anything but the area to be cultured and sterile surfaces contaminates the swab and invalidates the test.
- In anaerobic cultures, be sure the specimen is immersed in the medium at the bottom of the tube.

PROCEDURE
37-3

Applying a Dry Dressing

EQUIPMENT

- Clean exam gloves
- Container for proper disposal of soiled dressing
- Sterile 4 × 4 gauze pads
- Washcloth (optional)
- ABD pads (optional)
- 2-inch tape (foam or paper)

ACTION	RATIONALE
1. Gather supplies (see Figure 37-19 on page 1196).	1. Promotes a smooth work flow.
2. Provide privacy; draw curtains; close door.	2. Maintains client comfort and privacy while body is exposed during procedure.
3. Explain procedure to client.	3. Provides information about the procedure.
4. Wash hands/hand hygiene.	4. Prevents the spread of microorganisms.
5. Apply clean exam gloves.	5. Promotes infection control and protection from body fluids.
6. Remove dressing and place in appropriate receptacle. Remove soiled gloves with contaminated surfaces inward and discard in appropriate receptacle; apply clean gloves.	6. Dressings and gloves soiled with body fluids are considered contaminated and subject to biohazard disposal in the correct manner per institution protocol.

It is standard for the surgeon to do the first postoperative dressing change. The initial dressing is maintained for 24 to 48 hours post-operatively, unless conditions of the dressing

(Continues)

PROCEDURE 37-3 Applying a Dry Dressing (Continued)

ACTION

RATIONALE

FIGURE 37-19 Gauze sponges, clean gloves, tape, and antiseptic solution are used to change a dry dressing. DELMAR/CENGAGE LEARNING

- | | |
|--|--|
| <ol style="list-style-type: none"> 7. Assess the appearance of the undressed wound bed for healing. 8. Cleanse the skin around the incision if necessary with a clean, warm, wet washcloth. <ul style="list-style-type: none"> • If the suture line requires cleansing, it should be done gently. Use normal saline, half-strength hydrogen peroxide, or Beta-dine swab (consult orders of health care provider and/or institution policy regarding antiseptic agents) and cotton-tip applicators using a rolling motion. • Used applicators should not be reintroduced into the sterile solution (see Figure 37-20 on page 1197). 9. Remove used exam gloves. 10. Wash hands/hand hygiene. 11. Set up supplies. | <p>call for contacting the health care provider for a dressing change order. Until the removal of the initial dressing, the nurse will reinforce the dressing as needed.</p> <p>The frequency of the dressing change depends upon the particular wound and the preference of the health care provider. This will usually be specified in the orders.</p> <ol style="list-style-type: none"> 7. Assess for signs of redness, foul odor, swelling, irritation, drainage, dehiscence, bleeding, or skin breakdown. 8. Dried blood or drainage on the surrounding skin can be an irritant and a medium for microbes. <ul style="list-style-type: none"> • The suture line itself should not be disturbed unnecessarily. • Avoid Betadine if client has an iodine allergy. • Reintroduction of the soiled applicator into sterile solution will contaminate the solution. 9. Exam gloves used to remove the old dressing are considered dirty and should be removed and discarded appropriately. 10. Hands should be washed prior to setting up dressing supplies to prevent the spread of microorganisms. 11. Following removal of the dressing, the nurse will have a better idea of which supplies are needed and in what amount. |
|--|--|

(Continues)

PROCEDURE 37-3 Applying a Dry Dressing (Continued)

ACTION

FIGURE 37-20 Clean the suture lines gently, as appropriate.
DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 37-21 Apply 4 × 4 gauze pads, folded in half.
Tape the gauze in place. DELMAR/CENGAGE LEARNING

- | | |
|---|--|
| <p>12. Apply a new pair of clean exam gloves.</p> <p>13. Grasping just the edges, apply a new dressing using 4 × 4 gauze pads folded in half to the 2 × 4 size. Place the folded gauze pad lengthwise on wound and tape lightly, or apply tubular mesh for those with sensitive skin (see Figure 37-21). Initial the dressing, citing date and time changed.
Optional: An ABD pad may be applied on top of the dressing for added protection over sutures or for the client's comfort.</p> <p>14. Remove gloves and dispose of appropriately, then wash hands/hand hygiene.</p> <p>15. Conduct client and family education session about the dressing, which may include teaching the dressing technique to the client and family.</p> | <p>12. This is considered a clean procedure after the initial dressing is removed if the skin margins are approximated with the skin closures.</p> <p>13. A light dressing of 4 × 4 pads may be the only dressing that is needed to protect the incision from clothing or to collect a small amount of tissue drainage. This maintains a record of the dressing change for the next nurse.</p> <p>14. Prevents the spread of microorganisms.</p> <p>15. Educates the client and family and prepares for discharge.</p> |
|---|--|

delegation tip

The application of bandages to the client is not delegated to ancillary personnel. Family members may be taught this skill prior to the client's discharge. Occasionally, ancillary personnel will be delegated the task of applying a clean dry gauze as skin protection, but the nurse is responsible for the assessment of the integrity of the client's skin.

nursing tips

- Do not overdress the wound.
- Check the room for supplies before bringing more into the room.
- Order specially needed supplies in advance of the procedure; do not wait until the last minute.
- Client and family education and preparation for discharge begin upon admission.

PROCEDURE
37-4
Applying a Wet-to-Damp Dressing (Wet-to-Moist Dressing)
EQUIPMENT

- Clean exam gloves
- Container for proper disposal of soiled dressing
- Sterile gloves
- Moisture-proof gown (optional)
- Sterile towel
- Normal saline or ordered solution
- Sterile bowl
- Sterile 4 × 4 gauze pads, multiple
- Cover sponges or fluffs (optional)
- ABD dressing pads
- 2-inch tape (foam or paper)
- Tubular mesh (optional)
- Montgomery straps (optional)

ACTION
RATIONALE

- | ACTION | RATIONALE |
|---|---|
| 1. Review order of health care provider for wound care and gather supplies. | 1. Promotes a smooth work flow. |
| 2. Provide privacy; draw curtains; close door. | 2. Maintains client's comfort and privacy while body is exposed during procedure. |
| 3. Assess need for pain medication. Pain is rated on a scale from 0 (lowest) to 10 (greatest). Assess need based on quality, pain pattern, location, and last pain medication received. | 3. Removal of a wet-to-damp or moist dressing may be painful to the client, so careful assessment of pain medication needs prior to the dressing change is important. |
| 4. Explain procedure to client. | 4. Provides information about the procedure. |
| 5. Wash hands/hand hygiene. | 5. Prevents the spread of microorganisms. |
| 6. Apply clean exam gloves, a moisture-proof gown, mask, and eye protection, as appropriate. | 6. Provides infection control and protection from body fluids. If there is copious drainage or the wound is infected, a gown, a mask, and eye protection should be worn. A mask will also help the nurse if the drainage is foul smelling. |
| 7. Inform client that the dressing is going to be removed. | 7. Helps prepare client and alleviates anxiety. |
| 8. Remove wet-to-damp dressing, noting number of gauze pads used, and place in appropriate receptacle (see Figure 37-22 on page 1199). | 8. The dressing should be removed slowly yet deliberately. Moistening the dressing with saline is not recommended because this defeats the purpose of the debriding and cleaning action. If it is found that the dressing is extremely dry and removal will result in injury, a small amount of saline to loosen that portion of the dressing is indicated (see Figure 37-23 on page 1199). To counteract the problem of an extremely dry dressing, increase the wetness of the dressing or increase the frequency of dressing changes. Count the number of gauze pads so you know how many to use when replacing the dressing. |
| 9. Observe the undressed wound for healing (granulation and approximation of edges), signs of infection (inflammation, edema, warmth, pain), and drainage. | 9. Allows for evaluation of effectiveness of treatment. |

(Continues)

PROCEDURE 37-4 Applying a Wet-to-Damp Dressing (Wet-to-Moist Dressing) (Continued)

ACTION

RATIONALE

FIGURE 37-22 Carefully remove the old dressing, allowing it to debride the wound as you pull it away. DELMAR/CENGAGE LEARNING

FIGURE 37-23 If the dressing is too dry and removing it will cause injury, use a small amount of saline to loosen the portion of the dressing that adheres too tightly to the wound. DELMAR/CENGAGE LEARNING

10. Cleanse the skin around the incision if necessary with a clean, warm, wet washcloth.
11. Remove used exam gloves.
12. Wash hands/hand hygiene.
13. Set up supplies in a sterile field, including pouring ordered solutions into appropriate containers if indicated for the dressing change (see Figure 37-24).

10. Dried blood or drainage on the surrounding skin can be an irritant and a medium for microbes.
11. Exam gloves used to remove the old dressing are considered dirty and should be removed and discarded appropriately.
12. Prevents the spread of microorganisms.
13. Following removal of the dressing, the nurse will have a better idea of which supplies are needed and in what amount.

FIGURE 37-24 Place the gauze on the wound. DELMAR/CENGAGE LEARNING

14. Apply sterile gloves.
15. Place gauze or packing material to be moistened in the bowl with the normal saline or other solution.
 - Wring gauze or packing of saline until damp.
 - Gently place damp gauze over the area (see Figure 37-24).

14. This is a sterile dressing change.
15. If a solution is not specified, then normal saline is used. Wounds considered dirty or contaminated may call for special solutions ordered by the health care provider to moisten the wound packing. Alternative solutions

(Continues)

PROCEDURE 37-4 Applying a Wet-to-Damp Dressing (Wet-to-Moist Dressing) (Continued)

ACTION	RATIONALE
<p>16. Apply external dressing of dry 4 × 4 gauze pads, cover sponges, fluffs, or ABD pads.</p> <ul style="list-style-type: none"> Secure dressing in place with tape, Montgomery straps, or tubular mesh (see Figure 37-25). 	<p>include dilute povidone-iodine and dilute acetic acid. Follow institutional guidelines.</p> <ul style="list-style-type: none"> Avoid overwringing of the dressing to prevent excessive drying. The dressing should be wet to damp, depending upon the depth and size of the wound and the interval of the dressing change. Dresses the wound. <p>16. The external dressing is determined by the size and shape of the wound.</p> <ul style="list-style-type: none"> Tape for short-term dressings in clients who are not sensitive to adhesives is the method of choice for securing dressings. For long-term dressings or for those clients who are sensitive to tape, use Montgomery straps or tubular mesh. <p>Tubular mesh is a nice alternative to hold the dressing in place because tape is not involved—the mesh is simply pulled up or down to accommodate the dressing change.</p>

FIGURE 37-25 Wrap the wet gauze with an external dressing of dry gauze bandages. DELMAR/CENGAGE LEARNING

17. Remove gloves and wash hands/hand hygiene.	17. Prevents the spread of microorganisms. Be sure to discard gloves in appropriate receptacle.
18. Mark the dressing with the date and time it was changed, and initial it.	18. This maintains a record of the dressing change for the next nurse and provides for continuity of care.
19. Conduct client and family education session about the dressing, which may include teaching the dressing technique to the client and family.	19. Educates the client and family and prepares for discharge.

(Continues)

PROCEDURE 37-4 Applying a Wet-to-Damp Dressing (Wet-to-Moist Dressing) (Continued)

delegation tip

Applying a wet-to-damp dressing requires sterile technique and professional assessment skills and cannot be delegated to ancillary personnel.

nursing tips

- Make a list, if necessary, of needed supplies to take into the room.
- If you are going to be in a client's room for some time, let others know so that they can cover your call lights and you can devote your attention to the dressing change.
- When doing very small wet-to-damp dressing changes, the normal saline can be carefully poured on open packets of sterile 4×4 pads, thus bypassing the need for a sterile bowl.
- Order specially needed supplies in advance of the procedure; do not wait until the last minute.
- Client and family education and preparation for discharge begin upon admission.
- Carefully evaluate and communicate client's wound healing response to dressing treatments. Consult wound specialist and change treatment as recommended or as ordered.

PROCEDURE 37-5

Preventing and Managing the Pressure Ulcer

EQUIPMENT

- Pillows
- Rolled-up blankets or towels
- Egg-crate mattress
- Specialty beds if ordered by prescribing practitioner or qualified practitioner
- Heel and elbow protectors
- Lotion or powder as needed
- Soap and water

ACTION

1. Check the health care provider's order for specific positioning of client and dressing change instructions.
2. Gather all the equipment you will need.
3. Identify the client and explain the procedure to the client.
4. Wash hands/hand hygiene.
5. Provide for client privacy and apply gloves.

RATIONALE

1. Because of the client's medical condition, the health care provider may want the client in a specific position and/or may have ordered dressing changes for a pressure ulcer.
2. Having all your equipment in the room will increase the consistency of client care.
3. Providing explanations to the client will employ the client's cooperation and provide time for client education.
4. Prevents the spread of microorganisms.
5. Shows respect for the client's privacy. Gloves protect both the client and the nurse from potential body fluid contact.

(Continues)

PROCEDURE 37-5 Preventing and Managing the Pressure Ulcer (Continued)

ACTION	RATIONALE
6. Adjust the bed to your level and lower the side rail nearest you without leaving client unattended.	6. Adjusting the bed to your level will make the procedure easier on your back. Lowering the side rails will allow you closer contact with the client to provide care.
7. Assess client's risk for developing pressure ulcers by using the Braden scale or a similar risk chart (see Table 37-6).	7. Informs the nurse about the extent of the client's education of risk factors and the preventive care needs to be instituted immediately.
8. Assess client's skin over all pressure points, such as sacrum (see Figure 37-26), ischial tuberosities, feet, heels (see Figure 37-27), elbows (see Figure 37-28), and back of head.	8. A reddened area in light-skinned clients and a bluish or purple area in dark-skinned clients indicate that the tissue was under pressure.

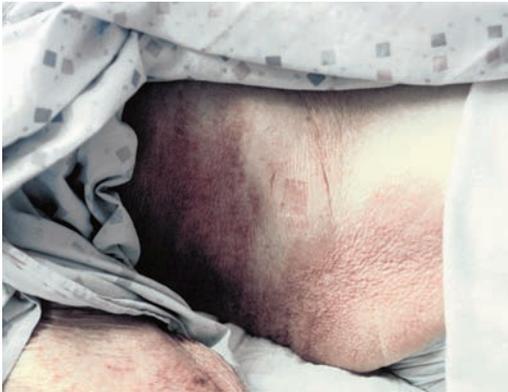

FIGURE 37-26 Assess the sacrum. DELMAR/CENGAGE LEARNING

FIGURE 37-27 Assess the feet and heels. DELMAR/CENGAGE LEARNING

FIGURE 37-28 Assess the elbows. DELMAR/CENGAGE LEARNING

- | | |
|---|---|
| 9. Assess other sites for potential areas of pressure points. | 9. Other potential sites and causes of pressure include the NG tube and tape on the tip of the nose, IV dressing tape, a Foley catheter touching the labia or taped area of skin, endotracheal tube and tape, and side rails touching the skin. |
|---|---|

(Continues)

PROCEDURE 37-5 Preventing and Managing the Pressure Ulcer (Continued)

ACTION	RATIONALE
10. Change client's position.	10. Increases client comfort and prevents contractures and decubiti.
11. Keep client's position at 30° or less.	11. A position of 30° or lower will limit the pressure on the sacrum.
12. Provide skin care if area is soiled or sweaty, but do not massage pressure points.	12. Skin care keeps skin clean and dry, and new preliminary evidence documents that massaging bony prominences may actually cause deep tissue trauma.
13. Use support devices such as special beds (see Figure 37-29), egg-crate mattresses, pillows (see Figures 37-30 and 37-31), towels, blankets, and heel protectors (see Figure 37-32) to support the body.	13. Lifting the heels and elbows off of the bed will limit the pressure to these areas. Also, providing support between the legs will limit the pressure.
14. Perform dressing change to a pressure ulcer as ordered or per agency policy (see Figures 37-33 and 37-34 on page 1204), remembering aseptic or sterile technique.	14. Providing wound care to existing pressure ulcers will facilitate wound healing and begin to protect the client from a potential infection.
15. Return side rail to the upright position and lower the bed.	15. Provides for client safety.

FIGURE 37-29 Special beds have air- or fluid-filled mattresses and are used to reduce the pressure on bony prominences. DELMAR/CENGAGE LEARNING

FIGURE 37-30 Pillows are used to take the pressure off the heels and feet. DELMAR/CENGAGE LEARNING

PROCEDURE 37-5 Preventing and Managing the Pressure Ulcer (Continued)

ACTION

FIGURE 37-33 This client's heels and feet have been protected from pressure with a special bed and pillow support. An existing pressure ulcer wound on the right foot has been cleaned and dressed. DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 37-34 A dressing change is performed on a large pressure ulcer. DELMAR/CENGAGE LEARNING

16. Remove gloves and wash hands/hand hygiene.
17. Document appearance of pressure points and/or ulcers, including skin care and wound care provided and position changes.
18. Create an every-2-hours turning schedule if one is not available.

16. Prevents the spread of microorganisms.
17. Provides a picture of skin surface and interventions instituted to prevent pressure points and/or to provide for tissue healing.
18. A turning schedule helps promote further compliance with preventive measures for providing care.

delegation tip

Assessment of pressure ulcers is the role of the nurse. Licensed and ancillary personnel may observe the wound for improvement or deterioration during daily care and report that information to the nurse.

nursing tips

- Look at the client's skin, especially the pressure areas, at least every 2 hours, and reposition the client as often as possible.
- Do not massage the skin over the site. Recent research has discouraged massaging the area because of the potential to cause deep tissue trauma.
- Look for pressure ulcers in unexpected places such as under any area that has tape on it, including the nasogastric tube, IV dressing, and wound dressing. Inspect the back of the head, ears, and elbows as well.
- When taking dressings off a pressure ulcer, note the sequence, size, and type of dressings used so you can repeat the sequence when reapplying the dressings. Be familiar with the health care provider's order.
- Avoid elastic bandages if the client has a history of latex allergy.

KEY CONCEPTS

- A wound is a disruption in the integrity of the body tissue that puts an individual at risk for infection.
- Wounds go through a three-step healing process that includes a defensive (inflammatory) phase, a reconstructive (proliferative) phase, and a maturation phase.
- The type of exudate from a wound can help determine the pathology of the infectious process.

- Wounds are often classified by their cause, level of cleanliness, depth, or color.
- Nursing diagnoses for clients with wounds and pressure ulcers focus on both the physical (*Acute pain, Risk for infection, Chronic pain, Impaired tissue integrity*) and the psychosocial (*Anxiety, Deficient knowledge, Disturbed body image*) aspects.
- A significant nursing intervention in all cases of *Impaired skin integrity* is client education on wound care and promotion of healing; the client's support people are often included in this teaching.
- Heat and cold applications help the body's own systems respond to and therefore relieve the pain that accompanies wounds.
- Pressure ulcers, or bedsores, are a common problem in acute and chronic care settings, resulting in longer stays for clients and increased costs of health care.
- Pressure ulcers are classified into four stages, depending on the depth of tissue damage.
- Proper positioning is the most effective preventive measure for pressure ulcers.

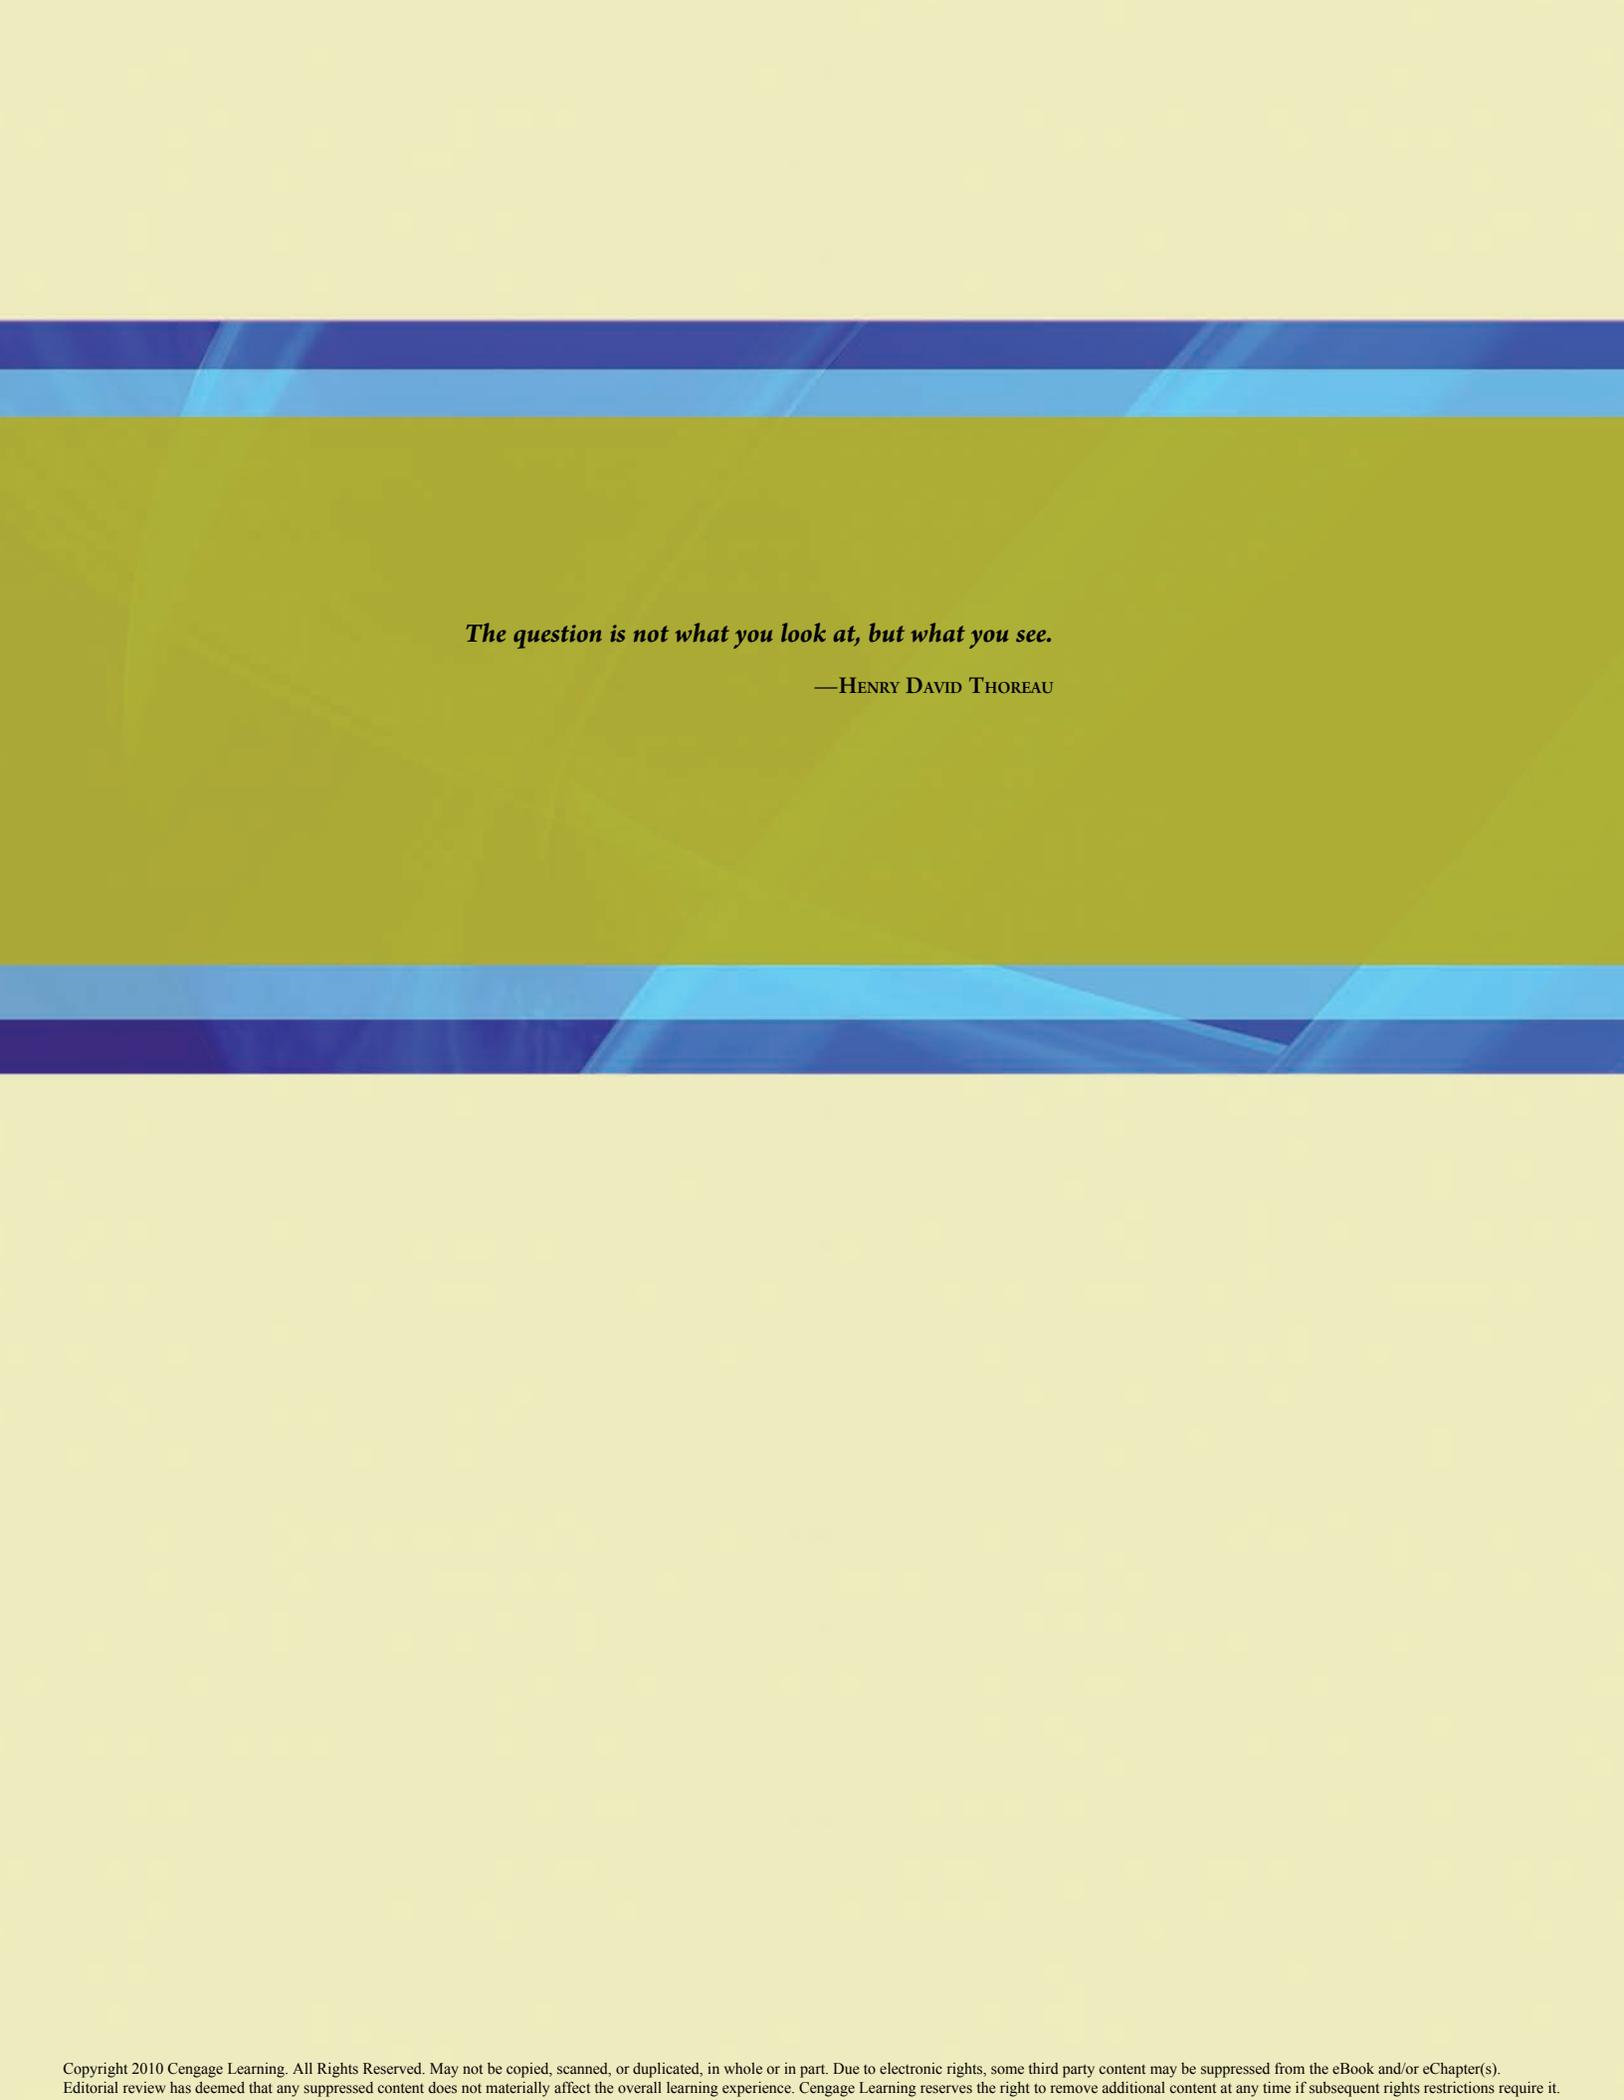

REVIEW QUESTIONS

- The nurse has to apply a bandage on a joint. Which bandaging method should be used?
 - Circular turns
 - Spiral turns
 - Spiral reverse turns
 - Figure-eight turns
- Proper technique for performing a wound culture is to _____.
 - cleanse the wound with normal saline prior to obtaining the specimen
 - swab the wound drainage
 - remove crust from the necrotic tissue and then swab
 - obtain the specimen from drainage on the dressing
- Which intervention is most appropriate for a client with a muscle sprain and hematoma?
 - Binder
 - Ace bandage
 - Ice bag
 - Polyurethane foam
- The appropriate nursing action for a client with a Braden scale score of 16 is to _____.
 - assess the client according to agency policy
 - implement a turning schedule
 - apply a transparent wound dressing on the coccyx
 - request an order for physical therapy
- Which wound care instruction should be given to a client being discharged from the hospital with a skin tear?
 - Cover the skin tear with a transparent dressing.
 - Use a nonadherent dressing over the wound.
 - Eat a high-fat diet to promote wound healing.
 - Drink 3000 mL of water every day to keep the skin hydrated.
- Which client is at the greatest risk for a pressure ulcer?
 - A 52-year-old obese female, 2 days postoperative for a knee replacement, who has an indwelling urinary catheter
 - A 74-year-old thin male who is awaiting surgery for a fractured hip
 - A 91-year-old emaciated female with a blood sugar of 160 mg/dL who is sitting in a wheelchair
 - A 67-year-old obese male who has cellulitis of his right lower leg
- A superficial abrasion with partial-thickness skin loss involving the epidermis and dermis would be staged as what degree of ulceration?
 - Stage I
 - Stage II
 - Stage III
 - Stage IV
- Which nursing activity should the registered nurse delegate to a licensed practical nurse?
 - Instruct a client on irrigation for a chronic wound.
 - Develop a plan of care for the irrigation of a skin ulcer.
 - Obtain a health history from a client admitted with a pressure sore on the coccyx.
 - Monitor the vital signs of a client with cellulitis for evidence of sepsis.

CHAPTER 38

Sensation, Perception, and Cognition

COMPETENCIES

1. Describe normal cognitive and sensory perceptual functioning.
2. Describe cognitive development across the life span.
3. Identify responses to sensory deprivation and overload.
4. Describe the learning needs of clients experiencing alterations in cognition and sensory perception.
5. Explain use of the nursing process with clients experiencing alterations in cognition and sensory perception.

KEY TERMS

affect	efferent nerve pathways	prosody
afferent nerve pathways	fluency	recent memory
aphasia	fluid intelligence	remote memory
arousal	hallucination	sensation
awareness	illusion	sensory deficit
cognition	immediate memory	sensory deprivation
consciousness	judgment	sensory overload
crystallized intelligence	orientation	sensory perception
disorientation	perception	

Making sense of one's situation, learning new information, and recalling memories of the past are activities that make each person a unique individual. Performance of these activities relies on intact cognition, sensation, and perceptual abilities.

This chapter discusses the physiology of sensation, perception, and cognition and the common alterations in each functional area. Information on the nurse's role in caring for individuals with sensory, perceptual, or cognitive alterations is presented.

PHYSIOLOGY OF SENSATION, PERCEPTION, AND COGNITION

Sensation is the ability to receive and process stimuli through the sensory organs. There are two types of stimuli: external and internal. External stimuli are received and processed through the sight (visual), hearing (auditory), smell (olfactory), taste (gustatory), and touch (tactile) modes. Internal stimuli are received and processed through kinesthetic (an awareness of the position of the body) and visceral (feelings originating from large organs within the body) modes.

Perception is the ability to experience, recognize, organize, and interpret sensory stimuli. **Sensory perception** is the ability to receive sensory impressions and, through cortical association, relate the stimuli to past experiences and to form impressions of the nature of the stimuli.

Perception is closely associated with **cognition**, the intellectual ability to think. The processes of organizing and interpreting stimuli are dependent on a person's level of intellectual functioning. Cognition includes the elements of memory, judgment, and orientation. The well-being of an individual is dependent on the functions of sensation, perception, and cognition because it is through these mechanisms that the person fully experiences and interacts with the environment.

Sensory, perceptual, and cognitive alterations can be either temporary or progressive in their manifestations and can result from disease or trauma. Whatever the cause of the alterations, these conditions usually lead to social isolation and increased dependence on others. In addition, impairment in sensory, perceptual, and cognitive functions can place the individual at risk for injury to himself or herself or to others.

Sensation, perception, and cognition are neurological functions. The nervous system is composed of two major subsystems: the central nervous system (CNS) and the peripheral nervous system (PNS), which consists of the somatic and autonomic nervous systems (see Figure 38-1).

The CNS and PNS act in unison to accomplish three purposes: collection of stimuli from the receptors at the end of the peripheral nerves, transport of the stimuli to the brain for integration and cognitive processing, and conduction of responses to the stimuli from the brain to responsive motor centers in the body.

The CNS is composed of the brain and spinal cord, which are protected by the bony structures of the skull and vertebral column. The brain, the most complex of the body's organs, is composed of three basic structures: the cerebrum (which consists of the temporal, frontal, parietal, and occipital lobes), the cerebellum, and the brain stem (see Figure 38-2 on page 1209). Table 38-1 on page 1209 describes each of these structures. The structures of the brain serve as both receptors and reactors by collecting stimuli and effecting responses to those stimuli. The spinal cord links the advanced neurosensory mechanisms that occur in the brain to the rest of the body via a coordinated pathway of neurons.

Sensory perception involves the function of both the cranial and peripheral nerves. The cranial nerves arise from the three structures of the brain and govern the movement and function of various muscles and nerves throughout the body (see Figure 38-3 on page 1210). The peripheral

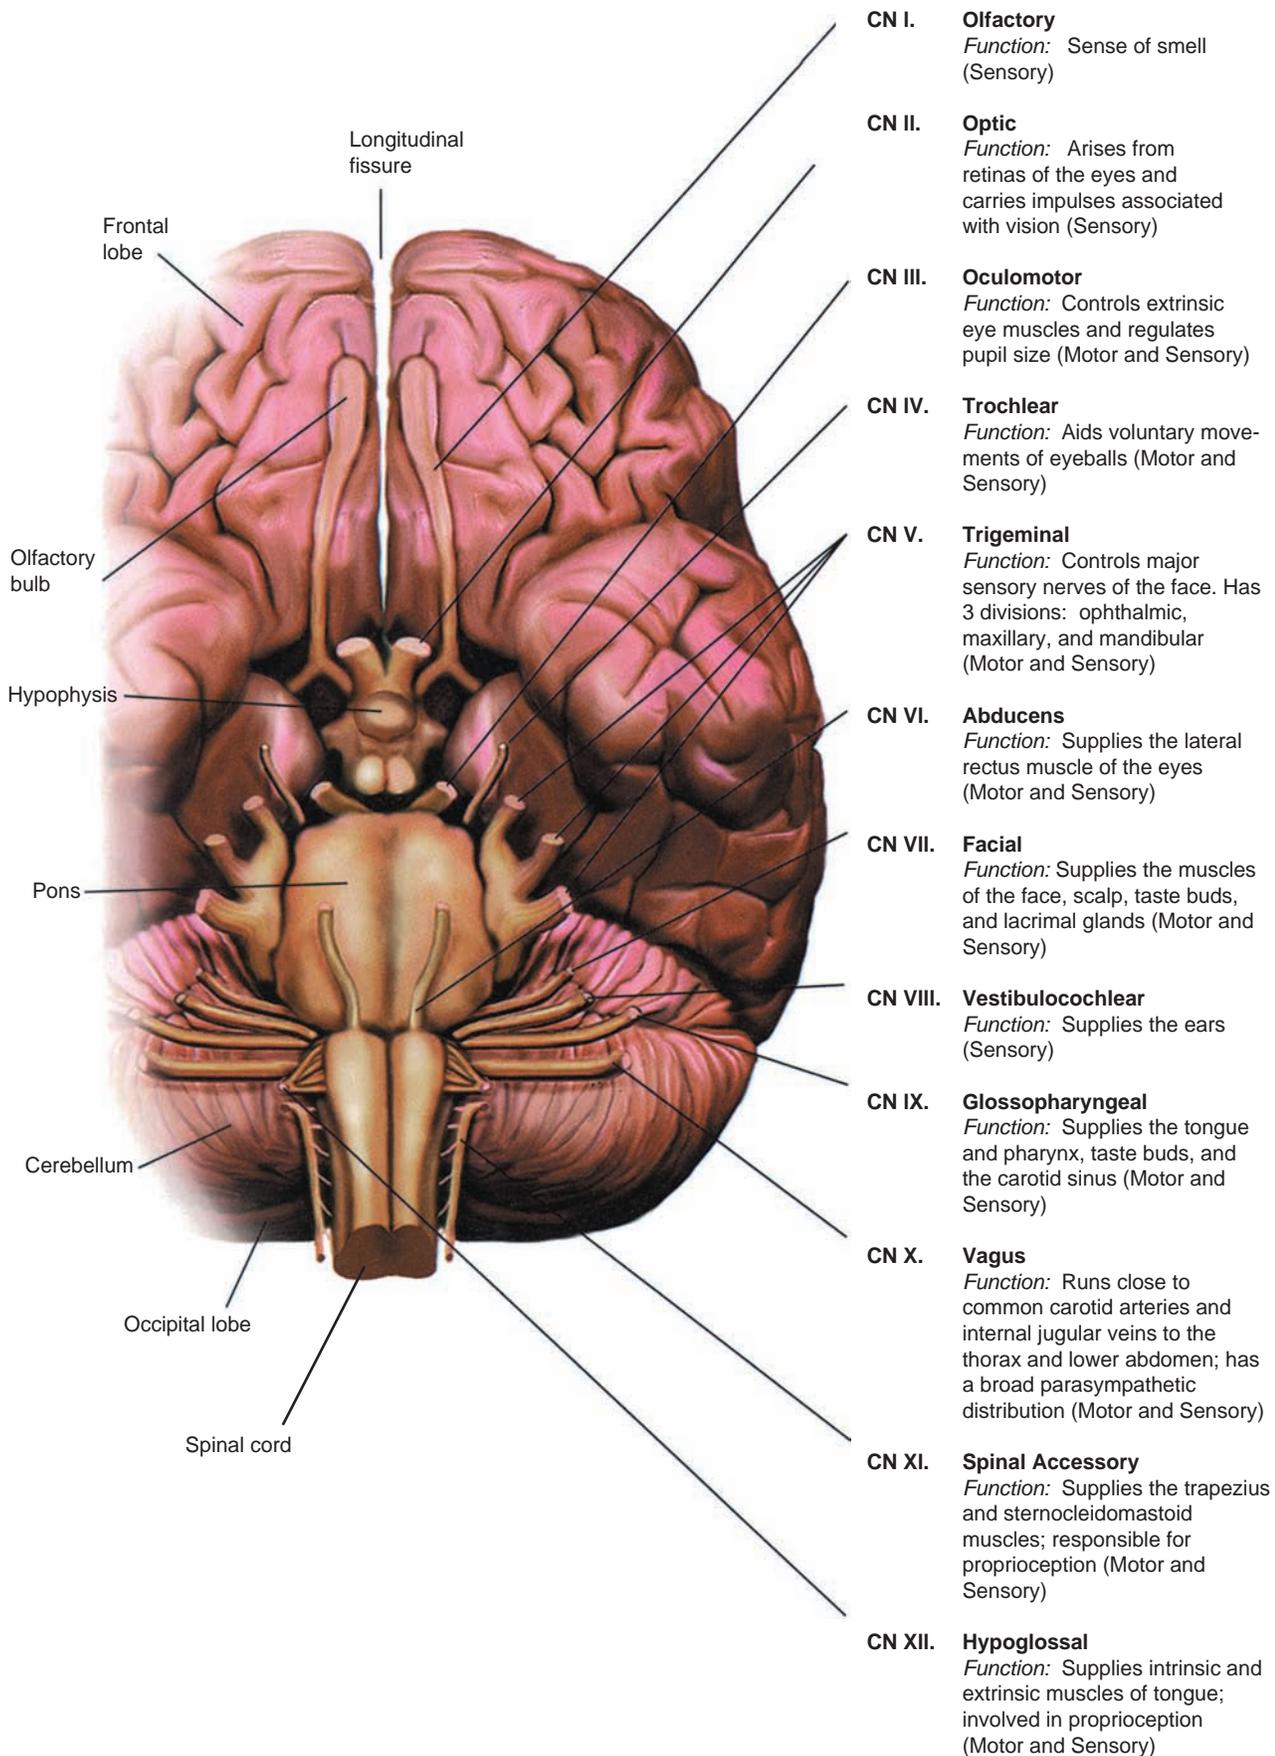

FIGURE 38-3 The Cranial Nerves DELMAR/CENGAGE LEARNING

nerves connect the CNS to other parts of the body (see Figure 38-4).

COMPONENTS OF SENSATION AND PERCEPTION

The sensory system is a complex network that consists of **afferent nerve pathways** (ascending pathways that transmit sensory impulses to the brain), **efferent nerve pathways** (descending pathways that send sensory impulses from the brain), the spinal cord, the brain stem, and the higher cortex (cerebral lobes). Figure 38-5 shows the major sensory pathways.

COMPONENTS OF COGNITION

Cognition includes the cerebral functions of memory, judgment, and emotion. In order for higher functions (e.g.,

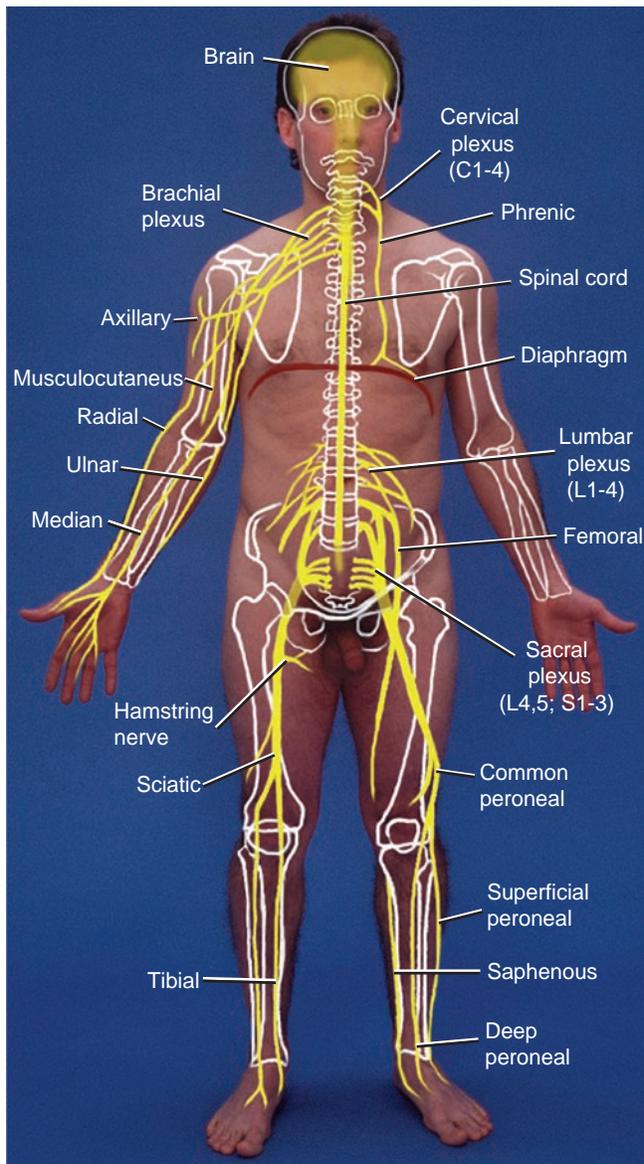

FIGURE 38-4 The Peripheral Nerves DELMAR/CENGAGE LEARNING

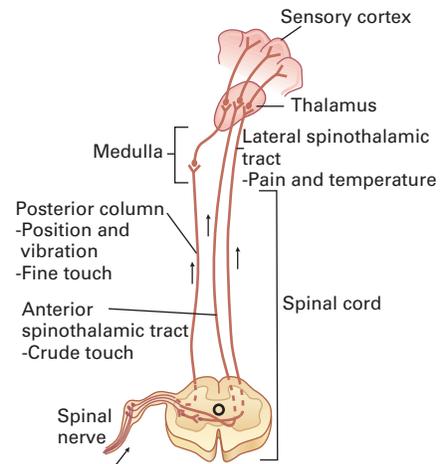

FIGURE 38-5 Major Sensory Pathways DELMAR/CENGAGE LEARNING

memory, affect, judgment, perception, and language) to occur, consciousness must be present.

Consciousness

Consciousness is a state of awareness of self, others, and the surrounding environment. It affects both cognitive (intellectual) and affective (emotional) functions. An alert individual (one who is aware of self and stimuli) is able to perceive reality accurately and to base behavior on those perceptions. The components of consciousness provide a foundation for behavior and emotional expression, thereby contributing to the uniqueness of each individual's personality.

Consciousness depends on the functioning of the reticular activating system (RAS), which is located within the mid-brain and thalamus, as well as connective fibers between these structures and areas within the cerebral cortex. The RAS controls activities such as sleep and wakefulness and monitors the selective transmission of stimuli to other parts of the neurosensory system. Consciousness may be altered by various metabolic, traumatic, or other factors such as the pharmacological actions of drugs that affect mental status. The primary components of consciousness are arousal and awareness, both of which must be present before higher cognitive functioning occurs.

AROUSAL The degree of **arousal**, a component linked closely to the appearance of wakefulness and alertness, is indicated by a person's general response and reaction to the environment. People exhibit arousal, the state of being prepared to act, by behaving in an alert, aware manner and by experiencing periods of wakefulness. The degree of an individual's arousal is indicated by the general response and reaction to the environment. Impaired arousal can exist when a sleep deficit is experienced; there may be an inability to take advantage of opportunities for activity because of limited periods of rest.

AWARENESS **Awareness** is the capacity to perceive sensory impressions and react appropriately through thoughts and actions. An essential element in awareness is

orientation, the perception of self in relation to the surrounding environment. When awareness is impaired, orientation to time is frequently the first area affected. The degree of disorientation is worse when the individual loses awareness of place and self (person). Changes in a client's orientation to time, place, and person are often early indicators of an altered level of consciousness (LOC). Several tools have been developed to measure LOC, which includes a measure of orientation.

Memory

There are three types of memory: immediate, recent, and remote. **Immediate memory** is the retention of information for a specified and usually short period of time. An example of this function is the recall of a telephone number long enough to dial it. **Recent memory** is the result of events that have occurred over the past 24 hours. An example of recent memory is the remembrance of foods eaten for dinner the previous night. **Remote memory** is the retention of experiences that occurred during earlier periods of life, such as an adult's memories of childhood. The ability to learn is dependent on remote memory.

Affect

Affect (mood or feeling) is an important component of cognition in that variations of mood can influence one's thinking ability. For example, depression may affect the client's concentration and attention. Also, anxiety narrows the perceptual field and interferes with the ability to concentrate by decreasing attention span.

Judgment

Judgment, the ability to compare or evaluate alternatives to life situations and arrive at an appropriate course of action, is closely related to reality testing and depends on effective cognitive functioning. When assessing logic and judgment, it is important to decide whether the client is answering questions appropriately. The assessment goal is to determine the use of reasoning and decision-making ability. It may be assessed by asking a question such as "What would you do if you were inside a burning building?" Answers that indicate impaired judgment may be given by clients experiencing frontal lobe damage, dementia, mental retardation, or psychosis. Behaviors indicative of impaired judgment include impulsiveness, unrealistic decision making, and inadequate problem-solving ability.

Perception

Cognitive perceptions are considered in the context of the individual's awareness of reality. Misperceptions of reality can occur in the form of an **illusion** (an inaccurate perception or misinterpretation of sensory stimuli) or a **hallucination** (a sensory perception that occurs in the absence of external stimuli and is not based on reality).

Clients who are anxious and fearful or who are taking certain medications may experience misperceptions of environmental stimuli. For example, a postoperative client, after receiving analgesic medication for pain, sees a belt from his

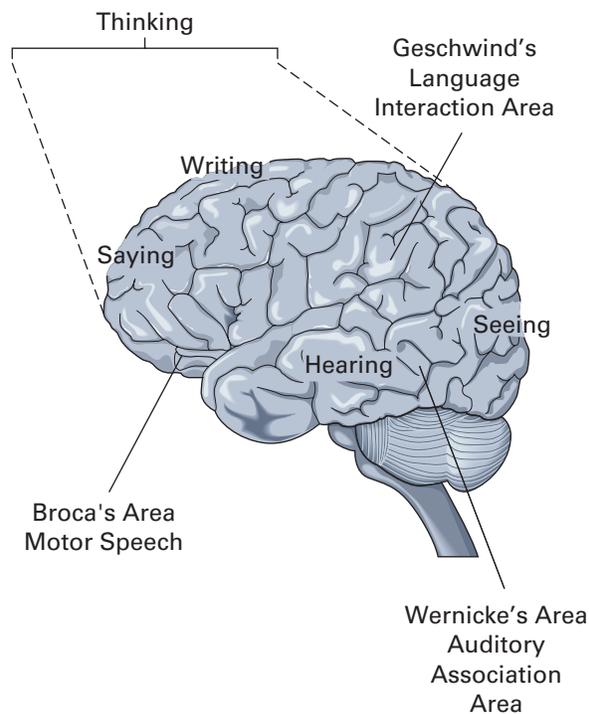

FIGURE 38-6 Language Perception Areas of the Brain. Note Broca's motor speech area in the frontal lobe, Wernicke's auditory association area in the temporal lobe, and Geschwind's language interaction area in the parietal lobe. DELMAR/CENGAGE LEARNING

bathrobe lying on the floor and thinks there is a snake in the room. Once the nurse determines that the client is experiencing an illusion, appropriate reassurance and reality orientation can be implemented to reduce the client's anxiety.

Language

Language is one of the most complex cognitive functions, involving not only the spoken word but also reading, writing, and comprehension. Each of these skills is controlled by specific areas located in the cerebral cortex (see Figure 38-6).

Characteristics of speech are **fluency** (ability to talk in a steady manner), **prosody** (melody of speech that conveys meaning through changes in the tempo, rhythm, and intonation), and content.

FACTORS AFFECTING SENSATION, PERCEPTION, AND COGNITION

The functions of sensation, perception, and cognition are influenced by many factors, including age, environment, lifestyle, stress, illness, and medications.

AGE

Neurosensory pathways in infants and children are immature and do not allow for sophisticated discrimination among stimuli. As children mature they learn to apply their perceptions of the environment to different situations and can thus

modify their behaviors accordingly. This process continues throughout the life cycle. For young adults, cognitive functioning is generally more advanced than during adolescence.

Intelligence is difficult to measure; intelligence quotient (IQ) tests, which are intended to predict academic achievement, are not very reliable indicators of adult intelligence. The measurement of intelligence in middle-aged adults is affected by several variables, including motivation, risk taking and caution, and anxiety.

Intellectual functioning is maintained in part by a stimulating environment. **Crystallized intelligence** (acquired knowledge) develops over time as individuals apply life experiences and previously learned skills in order to solve problems. However, **fluid intelligence**, the ability to acquire new concepts in order to adapt to unfamiliar situations, decreases over time (Jaeggi, Buschkuhl, Jonides, & Perrig, 2008).

Cognitive development in older adults shows no decline in intellectual function. Memory loss is an area of concern for many older adults. Research suggests that there is a gradual, age-related reduction in the ability to perform memory tasks (Grady, Springer, Hongwanishkul, McIntosh, & Winocur, 2006). Strategies such as list making and posting reminder notes can be helpful in compensating for minor memory losses. Some activities that encourage cognitive development in older people are reading, studying a new topic (e.g., language, computer skills), solving mathematical problems, and working word puzzles.

ENVIRONMENT

The amount and type of environmental stimuli affect sensation, perception, and cognition. Excessive stimuli in the form of visual impressions and noise can create feelings of anxiety and disorientation within clients. Too few relevant stimuli decrease the client's response to people and the environment, thus leading to isolation.

Crowded living conditions, traffic congestion, and living where sound levels are high are stressors associated with negative physical and psychological health outcomes. Prolonged exposure to loud sounds may impair hearing acuity. Hearing loss affects quality of life and health. In addition to noise-induced hearing loss, which may be permanent, other effects of exposure to noise include tension headaches, lack of concentration, anxiety, hypertension, and insomnia (Belojević, Jakovljević, Stojanov, Slepčević, & Paunović, 2008; Rhee, Kim, Roh, Kim, & Kwon, 2008; Riethmuller, Muller-Wenk, Knoblauch, & Schoch, 2008).

LIFESTYLE

The amount and quality of sensory information that people feel comfortable in processing are based on their work and leisure habits. Some people may prefer quiet environments in which to think, whereas others derive energy and productivity from the activity around them.

Stress

Stress and anxiety can exert a negative influence on a person's behavior and thought patterns. Depending on the type and degree of stress, the person either finds ways to cope

SPOTLIGHT ON...

Caring

Improving Cerebral Blood Flow

It is important for people to maintain an adequate flow of oxygenated blood to the brain. The following activities are helpful: controlling hypertension, monitoring and treating hyperlipidemia and diabetes, and smoking cessation.

with the situation or becomes overwhelmed with the stimuli being received. Individuals experiencing high anxiety levels may become disoriented.

Health Status

Specific conditions, such as diabetes mellitus and atherosclerosis, can impair neurosensory pathways and result in deficits in sensation, perception, and cognition. Diseases of the CNS can result in loss of sensory function and paralysis. Decreased hemoglobin levels generally result in impaired cognition; see the Spotlight On display. Cerebral vascular accidents (strokes) result in cognitive impairments, which may be transient or long term (Lee et al., 2008). "Cognitive impairment is common in the first weeks after stroke ... and premonitory moderate alcohol consumption is associated with acute cognitive impairment" (Nys et al., 2007, p. 416). Individuals who experience chronic stress are also at risk of experiencing cognitive impairment (Öhman, Nordin, Bergdahl, Slunga Birgander, & Stigsdotter Neely, 2007).

A person admitted to a health care agency experiences stimuli that are different from those usually encountered in the everyday routine. A change in environment can overwhelm one's ability to perceive and interpret sensory input. As a result, the treatment milieu itself can become a stressor that negatively affects sensory, perceptual, and cognitive functions.

Medications

Certain medications have the potential to alter or depress the neurosensory system. For example, sedatives and narcotics can alter the perception of sensory stimuli. Medications that alter LOC include:

- Analgesics
- Antidepressants
- Antidiuretics
- Antihypertensives
- Benzodiazepines
- Sedatives

SENSORY, PERCEPTUAL, AND COGNITIVE ALTERATIONS

An individual usually experiences discomfort and anxiety when subjected to a change in the type or amount of incoming stimuli. A person can become confused as a result of either

overstimulation or understimulation. According to the individual's ability to process the stimuli, confusion (or disorientation) may occur. **Disorientation** is a mentally confused state in which the person's awareness of time, place, self, or situation is impaired; when awareness of these four factors is accurate, a person is said to be "oriented \times 4."

Sensory overstimulation and sensory deprivation can lead to cognitive alterations in healthy adults. Such alterations may include physical symptoms (e.g., nausea), altered time perceptions, paranoid ideation, and visual, auditory, and olfactory distortions (similar to hallucinations). The three types of alterations are sensory deficits, sensory deprivation, and sensory overload.

SENSORY DEFICITS

A **sensory deficit** is a change in the perception of sensory stimuli. These deficits can affect all five senses. Examples of sensory deficits are vision and hearing losses such as those caused by cataracts, glaucoma, and presbycusis (steady loss of hearing acuity that occurs with aging).

The client's response to these losses usually depends on the time of onset and severity of the condition. If the problem occurs suddenly and without warning, the client may have difficulty in adjusting to the loss of sensory and perceptual function. If the alteration occurs gradually, the client may be able to accommodate the change and actually compensate for it by strengthening one or more of the other senses.

The effects of illness or intensive medical treatments can exacerbate the problems related to sensory deficits. For example, a client with acute hearing loss can feel alone and vulnerable when faced with an environment that does not provide an effective means (such as interpreters who sign) through which communication can occur. Because of these responses, clients with sensory deficits are at serious risk of experiencing either sensory deprivation or sensory overload.

SENSORY DEPRIVATION

Sensory deprivation is a state of reduced sensory input from the internal or external environment, manifested by alterations in sensory perception. Individuals can experience sensory deprivation as a result of illness, trauma, or isolation. A person experiencing sensory deprivation misinterprets the limited stimuli with a resultant impairment of thoughts and feelings.

The following are factors contributing to sensory deprivation:

- Visual or auditory impairments that limit or prohibit perception of stimuli
- Drugs that produce a sedative effect on the CNS and interfere with the interpretation of stimuli
- Trauma that results in brain damage and decreased cognitive function
- Isolation, either physical or social, that results in the creation of a nonstimulating environment

Some contributing factors (e.g., brain damage or blindness) result in chronic sensory deprivation, whereas others lead to acute, transient states of deprivation (e.g., an individual receiving analgesic medications). Individuals who are sensory deprived may exhibit any of the following characteristics:

- Inability to concentrate
- Poor memory
- Impaired problem-solving ability
- Confusion
- Irritability
- Emotional lability (mood swings)
- Depression
- Boredom and apathy
- Drowsiness
- Hallucinations (see Table 38-2)

TABLE 38-2 Types of Hallucinations

HALLUCINATION	DEFINITION	EXAMPLE
Visual	Perception of sights that are not actually present in the environment	"I see a little pink elephant at the foot of my bed."
Auditory	Perception of sounds that are not present in the environment	"I hear the space aliens telling me that I'll be in outer space soon."
Tactile	Perception of being touched by things not actually present in the environment	"I feel bugs crawling on my skin."
Olfactory	Perception of odors not present in the environment	"I smell old rubber tires burning all the time."
Gustatory	Perception of tastes that do not actually correspond to the foods being eaten	"That bitter taste is in all the food."

Delmar/Cengage Learning

SENSORY OVERLOAD

Sensory overload is a state of excessive and sustained multisensory stimulation manifested by behavioral change and perceptual distortion. The individual experiencing this alteration is unable to process the amount or intensity of stimuli being received. Individuals experiencing sensory overload may exhibit any of the following characteristics:

- Anxiety and restlessness
- Irritability
- Disorientation
- Insomnia
- Fatigue
- Impaired problem-solving ability

Some factors that contribute to sensory overload are:

- Pain originating from a heightened quality or quantity of internal stimuli
- Invasive procedures that result in an increased amount of external stimuli
- Activity-filled, busy environment that contributes to the amount of stimuli being perceived
- Medications that stimulate the CNS and prohibit client from ignoring selective stimuli

- Presence of strangers, both health care professionals and others, who contribute to the quantity of stimuli
- Diseases that affect the CNS and that maximize the perception of stimuli

A common type of stimulus that clients often experience is excessive noise; exposure to high noise levels interferes with the following:

- Ability to shift attention
- Ability to perform complex tasks requiring sustained attention
- Verbal learning and memory
- Ability to make verbal associations

ASSESSMENT

When caring for clients with sensory, perceptual, and cognitive alterations, the nurse must conduct a thorough health history and perform a complete physical examination of the client in order to identify existing or potential problems. See Table 38-3 for an overview of assessing cognition and sensory perception.

TABLE 38-3 Neurological Screening Assessment

ASSESSMENT PARAMETER	ASSESSMENT SKILL	COMMENTS
Mental status, level of consciousness	<ul style="list-style-type: none"> • Note general appearance, speech content, memory, logic, judgment, and speech patterns during history taking. • Perform Glasgow Coma Scale (GCS) with motor assessment component and pupil assessment. 	<ul style="list-style-type: none"> • If any abnormalities or inconsistencies are evident, perform full mental status assessment. • If GCS is <15, perform full assessment of mental status and consciousness. If motor assessment is abnormal or asymmetrical, perform complete motor and sensory assessment.
Sensation	<ul style="list-style-type: none"> • Assess pain and vibration in the hands and feet, light touch on the limbs. 	<ul style="list-style-type: none"> • If deficits are identified, perform a complete sensory assessment.
Cranial nerves	<ul style="list-style-type: none"> • Assess CN II, III, IV, VI: visual acuity, gross visual fields, fundoscopic examination, pupillary reactions, and extraocular movements. • Assess CN VII, VIII, IX, X, XII: facial expression, gross hearing, voice, and tongue. 	<ul style="list-style-type: none"> • If any abnormalities exist, perform a complete assessment of all 12 cranial nerves.
Cerebellar function	<ul style="list-style-type: none"> • Observe the client's initial gait. • Observe the client's ability to (a) walk heel to toe, (b) walk on toes, (c) walk on heels, (d) hop in place, and (e) perform shallow knee bends. 	<ul style="list-style-type: none"> • If any abnormalities exist, perform a complete cerebellar assessment.
Reflexes	<ul style="list-style-type: none"> • Assess the muscle stretch reflexes and the plantar response. 	<ul style="list-style-type: none"> • If an abnormal response is elicited, perform a complete reflex assessment.

Delmar/Cengage Learning

HEALTH HISTORY

In order to collect data that are used to develop the plan of care, the nurse performs a health history on the client experiencing alterations in sensation, perception, and cognition. Elements of the health history include the client's usual level of functioning, current sensory problems, and potential alterations. The nurse should also explore issues such as the client's current occupation, home environment, and ability to perform both daily routines and self-care activities. The accompanying Nursing Process Highlight presents examples of questions that the nurse can ask the client during the health history.

PHYSICAL EXAMINATION

During the physical examination, the nurse evaluates the client's visual, auditory, gustatory, olfactory, and tactile status. Physical examination focuses specifically on the client's ability to see, hear, taste, smell, perceive heat and cold, and perceive pain. See Chapter 27 for a complete discussion of assessing sensory and neurological status. Table 38-4 provides some guidelines helpful in assessing sensory perceptual status.

NURSING PROCESS HIGHLIGHT

Assessment

Health History: Sample Questions

- Are you experiencing any difficulty in seeing objects, either near or far from you?
- Do you currently wear eyeglasses, bifocals, or contacts?
- Have you recently experienced any changes in your vision—for example, blurred vision, pain, sensitivity to light, or eye fatigue?
- Are you experiencing any changes in your hearing?
- Do you currently wear a hearing aid?
- Have you experienced any unusual sensations in the ears, such as a buzzing or ringing noise?
- Has your appetite or preference for certain foods changed recently?
- Are you experiencing any difficulty in your ability to smell particular odors?
- Do you experience unusual heat or cold in any of your extremities?
- Are you having any problems performing activities such as eating, brushing your hair, bathing, or toileting?
- Have you been exposed to loud noises or chemicals in your work environment or neighborhood?

TABLE 38-4 Assessing Sensory Perceptual Status

SENSATION BEING ASSESSED	ASSESSMENT FOCUS
Visual	<ul style="list-style-type: none"> • Presence of visual problems, including: <ul style="list-style-type: none"> — Blurred vision — Double vision — Blind spots — Rainbows or halos around objects — Photosensitivity • Difficulty seeing far or near • Family history of visual problems (such as glaucoma, cataracts) • Use of contact lenses or eyeglasses • Date of last eye examination
Auditory	<ul style="list-style-type: none"> • Presence of hearing problems • Recent changes in hearing ability • Ability to distinguish sounds (tone and pitch) • Presence of buzzing or ringing noises • Use of a hearing aid
Gustatory	<ul style="list-style-type: none"> • Changes in ability to taste • Difficulty in differentiating salty, sweet, sour, and bitter tastes • Changes in appetite
Olfactory	<ul style="list-style-type: none"> • Changes in ability to smell • Ability to distinguish common smells (such as food, perfume, flowers)
Tactile	<ul style="list-style-type: none"> • Difficulty in feeling temperature changes in extremities • Impairment of pain perception in extremities • Presence of unusual sensations in extremities (such as tingling or numbness)

Delmar/Cengage Learning

Assessment of Cranial Nerves

There are 12 pairs of cranial nerves, most of which have both sensory and motor functions (see Figure 38-3). Assessment of the cranial nerves is done to determine the presence of any neurological deficits. Chapter 27 provides a detailed discussion on assessing the cranial nerves.

MENTAL STATUS ASSESSMENT

A thorough mental status examination includes a systematic assessment of all the emotional and cognitive

functions. Changes in LOC provide clues for underlying disorders, which must be identified and treated early; see the Safety First display. Mental status is usually assessed during the health history interview. See the Nursing Checklist for general guidelines on conducting a mental status assessment.

The Mini-Mental Status Examination (MMSE) (Folstein, Folstein, & McHugh, 1975) was developed to determine one’s baseline mental status; it includes several questions that assess orientation. The MMSE can be administered as a screening tool for clients in all settings. It is not intended to be used as a diagnostic tool but rather to screen clients for the cognitive aspects of mental functioning: orientation, registration, attention and recall, and language (Folstein et al., 1975). The highest possible score is 30, with a score of 21 or less usually indicating cognitive impairment. A more detailed mental status assessment is warranted if the client presents with any of the following: memory deficit, confusion, **aphasia** (impairment in language functioning), mood swings, irritability, excessive headaches, behavioral changes, or seizures.

Levels of Consciousness

When assessing clients for sensory, perceptual, and cognitive alterations, the nurse should evaluate the LOC. When describing assessment data relative to LOC, the nurse should include a brief description of the type of stimuli used to test LOC and the client’s response. The accompanying Respecting Our Differences display on page 1218 gives a list of terms commonly used in describing LOC.

The Glasgow Coma Scale (GCS) was developed as a standardized tool to assess LOC objectively (Table 38-5). The tool may be used in a variety of clinical situations and is meant to be used in conjunction with a complete neurological assessment. There is a revised version of the GCS for use with children or other individuals who communicate at the preverbal level; see Table 38-6 on page 1218.

FUNCTIONAL ABILITIES

The nurse needs to have an understanding of the client’s ability to conduct self-care activities. Any sensory, perceptual, or cognitive impairments may interfere with the client’s

▼ SAFETY FIRST ▼

LEVEL OF CONSCIOUSNESS AND RESPIRATORY FUNCTION

Deterioration in a client’s level of consciousness may indicate that intracranial pressure is increasing. This is a life-threatening condition that requires immediate intervention because it depresses respirations.

NURSING CHECKLIST

Assessment of Mental Status

- Assessment begins as the client approaches. Observe gait, posture, mode of dress, involuntary movements, and voice to refine assessment priorities.
- The history should be holistic because neurological disorders can affect all body systems.
- The history should be age-sensitive:
 - Utilize other family members when client is a child.
 - Acknowledge adolescents’ ability to speak for themselves.
 - Do not make assumptions regarding older clients’ ability to relate their own health history.
- Allow the client to remain clothed during the history and mental status assessment.
- Consider language and cultural norms when obtaining the history and performing the mental status assessment.

TABLE 38-5 Glasgow Coma Scale

BEHAVIOR	RESPONSE	SCORE
Best eye-opening response	Spontaneous	4
	To verbal command	3
	To pain	2
	No response	1
Best verbal response	Oriented, conversing	5
	Disoriented, conversing	4
	Use of inappropriate words	3
	Incomprehensible sounds	2
	No response	1
Best motor response	Obeys verbal commands	6
	Moves to localized pain	5
	Flexion withdrawal to pain	4
	Abnormal posturing—decorticate	3
	Abnormal posturing—decerebrate	2
	No response	1
Total		3 to 15

Note: With the GCS, a score of 15 indicates a fully oriented person. A score of 7 or less is considered a state of coma. A score of 3 is the lowest possible score and is indicative of deep coma.

Delmar/Cengage Learning

TABLE 38-6 Pediatric Glasgow Coma Scale

BEHAVIOR	RESPONSE	SCORE
Best eye-opening response	Eyes open spontaneously	4
	Eye opening to speech	3
	Eye opening to pain	2
	No eye opening	1
Best verbal response	Coos or babbles (normal activity)	5
	Is irritable and continually cries	4
	Cries to pain	3
	Moans to pain	2
	No verbal response	1
Best motor response	Spontaneous or purposeful movement	6
	Withdraws from touch	5
	Withdraws from pain	4
	Abnormal flexion to pain—decorticate	3
	Extension to pain—decerebrate	2
	No response	1

Note: Any score of less than 8 represents a significant risk to mortality. Delmar/Cengage Learning

ability to perform activities of daily living (ADL). Functional impairments can interfere with the client's ability to keep the home environment clean and safe. A thorough assessment of self-care abilities includes assessment of skills related to dressing, grooming, bathing, feeding, and toileting. See the accompanying Nursing Process Highlight for hints on assessing potential hearing loss.

ENVIRONMENT

A person's environment can affect sensory, perceptual, and cognitive status in a variety of ways. For example, a nonstimulating environment can lead to sensory deprivation, whereas an environment that is excessively stimulating can result in sensory overload.

People who are at increased risk for sensory perceptual deficits include those who are:

- Older
- Living alone
- Institutionalized
- Homebound
- Experiencing chronic illness or physical handicaps
- Mentally ill
- Affected by a developmental delay

The nurse assesses the type and quantity of stimuli in the client's environment (the health care facility or the home). See the accompanying Community Considerations display on page 1219 for information on assessing the client's home environment.

People with sensory, perceptual, and cognitive alterations are at increased risk of injury. See the Spotlight On display on page 1219. Also see Table 38-7 on page 1219, which lists hazards associated with impairment of sensory, perceptual, and cognitive abilities.

RESPECTING OUR DIFFERENCES

Descriptive Terms for Levels of Consciousness

- **Alert.** Oriented and aware of stimuli; responds appropriately.
- **Lethargic.** Responds appropriately to stimuli but may be slow to respond; may be drowsy and may drift off to sleep when not stimulated.
- **Obtunded.** Sleeps most of the time; difficult to arouse with minimal response; requires constant stimulation; inconsistently follows commands.
- **Semicomatose.** Responds with purposeful movements when stimulated, but does not follow commands and is nonverbal.
- **Comatose.** Unconscious with no meaningful response to stimuli. Light coma may include reflex motor response to painful stimuli (decorticate or decerebrate posturing); deep coma includes no motor response to any stimuli.

NURSING PROCESS HIGHLIGHT

Assessment

Potential Hearing Loss

Any of the following could be an indicator of hearing loss:

- Experiences tinnitus (ringing in the ears)
- Has a sensation of "stiffness" or fullness in the ear
- Experiences dullness of hearing (even if temporary)
- Needs to lip-read in order to "hear"
- Fails to respond when spoken to
- Gives inappropriate answers to questions
- Turns head to the side to hear better
- Speaks too loudly or too softly

TABLE 38-7 Safety Hazards Associated with Sensory Perceptual Impairments

SENSORY IMPAIRMENT	SAFETY RISK
Visual	Tripping, falling
Auditory	Lack of awareness of warning sounds (i.e., automobile horns, sirens, smoke detectors)
Olfactory	Inability to perceive warning odors (i.e., burning food, escaping gas)
Gustatory	Lack of awareness of spoiled or contaminated food or beverages
Tactile	Lack of awareness of excessive pressure on a body part Risk of exposure to extreme temperature (i.e., frostbite, burns)

Delmar/Cengage Learning

COMMUNITY CONSIDERATIONS

Assessing the Client's Home for Environmental Stimuli

To determine the presence of sensory stimuli, the nurse assesses the presence of the following in the home:

- Adequate lighting
- Clock and calendar
- Odors
- Noise
- Other people (family members or frequency of visitors)
- Television or radio
- Books, magazines, newspapers

DIAGNOSIS

Several nursing diagnoses are applicable to clients experiencing sensory, perceptual, and cognitive alterations. The nurse needs to establish a diagnosis that is most closely related to the client's priority needs. The North American Nursing Diagnosis Association International (NANDA) diagnostic label that is applicable for many clients experiencing altered sensory perception and cognition is *Disturbed sensory perception (specify: visual, auditory, kinesthetic, gustatory, tactile, olfactory)*. This condition occurs whenever stimuli are misinterpreted

SPOTLIGHT ON...

Legal/Ethical

Safety of the General Public Versus Individual Liberty

Your 72-year-old neighbor, Mrs. Stafford, confides in you one afternoon at her home that she is becoming "more deaf by the minute." She tells you, "Next week when I go in for my driver's license renewal, I am not going to tell them about my little problem." Your neighborhood has several small children who run into and out of the street while playing. How do you respond to Mrs. Stafford?

through exaggeration or distortion (NANDA, 2009). See Table 38-8 on page 1220 for other relevant diagnoses, with defining characteristics and related factors.

PLANNING AND OUTCOME IDENTIFICATION

Nurses understand the importance of promoting optimal sensory stimulation for clients in every practice setting. The following goals will promote supportive, restorative care for clients experiencing sensory, perceptual, or cognitive alterations:

The client will:

- Remain safe and free from injury
- Experience a level of arousal that promotes the meaningful perception of stimuli
- Remain oriented to time, place, person, and situation
- Demonstrate intact functioning of senses (using assistive devices if necessary)
- Perform self-care activities appropriate to own functional capability

The current trend is to provide care for individuals experiencing cognitive deficits at home. See the accompanying Nursing Process Highlight on page 1221 for guidelines on planning the delivery of care in a long-term care facility.

The American Psychiatric Association (2000) has identified the following as skills to be encouraged in order to promote cognitive functioning: stability, consistency, self-identification, and active participation. Table 38-9 on page 1221 lists nursing interventions that enhance the development of these four essential skills.

IMPLEMENTATION

Safety is a major concern of nurses caring for clients with sensory, perceptual, and cognitive alterations. Actions must be taken to ensure that the client's environment is hazard free and, at the same time, that it provides adequate stimulation. This section describes nursing interventions that promote

Text not available due to copyright restrictions

TABLE 38-9 Nursing Interventions to Promote Cognitive Function

INTERVENTION	EXAMPLES
Memory retraining	Supporting reality orientation
Social skills therapy	Reinforcing behaviors to be used when interacting with others
Communication therapy	Improving speech patterns or words to complete a thought
	Minimizing sensory deprivation
Stress management therapy	Identifying and using factors that minimize stress
Reminiscence therapy	Using storytelling and memory recall to identify with past experiences
Behavioral therapy	Maintaining consistency and stability to specify expected behaviors
	Recognizing and controlling environmental stressors
	Using written schedules and directions to assist with activities
Medication administration	Using pharmacologic agents to manage disruptive behaviors

Data from American Psychiatric Association. (2000). *Diagnostic and statistical manual of mental disorders* (4th ed., text rev.). Washington, DC: Author.

appropriate sensory, perceptual, and cognitive functioning. Care of clients with visual and hearing impairments is discussed. Also presented is information on communicating with a confused client and a client who is unconscious.

MANAGING SENSORY DEFICITS

Clients with sensory deficits, including tactile, auditory, and visual impairments, need sensitive nursing care to best adapt to their environments and specific challenges. Safety and appropriate sensory stimulation are major areas of concern; see the Safety First display. Education is very effective in preventing accidents, such as spinal cord injury. In addition to working with clients in the acute phase of illness or injury, nurses also provide restorative care.

Tactile Alterations

The client with impaired tactile sensation is placed at an increased risk for development of skin breakdown. Therefore, it is important to encourage a safe living environment and to educate the individual and significant others in injury preven-

NURSING PROCESS HIGHLIGHT

Planning

Long-Term Care: Promoting Sensory Stimulation

- Call the client by name.
- Introduce yourself by name.
- On every shift, inform the client of the year, month, day of month, day of week, name of facility, and name of health care provider.
- Have a calendar and clock that are easy to see near the client's bed.
- Explain all procedures prior to implementation.
- Name and state the purpose of medications before administration.
- Have all necessary assistive devices (eye-glasses, dentures, hearing aid) accessible.
- Encourage client and family to personalize immediate environment with personal items (clothing, family photos, and personal possessions, such as quilts or furniture from home, if feasible).

tion measures. For more information on preventing tissue and skin breakdown, refer to Chapter 37. See the Client Teaching Checklist on page 1222, which describes therapeutic approaches for maintaining skin integrity of clients with altered touch sensation.

Hearing Deficit

In addition to safety hazards, individuals with impaired hearing are also at risk for social isolation because of the difficulty communicating with others. Nurses must ensure that they spend time with hearing-impaired clients, focus on nonverbal communication, and face the client when speaking. Check all assistive devices used by clients to ensure that they are working properly. Use an interpreter when one is available for signing. If an interpreter is available, the nurse must talk to the client, not to the interpreter; see the accompanying Respecting Our Differences display on page 1222 for more information on communicating through an interpreter. Other communication aids include finger spelling, communication boards, and the use of paper and pen for writing messages. Refer to

SAFETY FIRST

SENSORY ALTERATIONS AND SAFETY

The client with impaired level of consciousness, weak memory, altered judgment, or confusion is at high risk for injury. It is essential to create a living environment that is safe for people experiencing sensory, perceptual, and cognitive deficits.

**CLIENT TEACHING CHECKLIST****The Client with a Tactile Deficit**

Teach the client and family that burns can occur not only from heat but also from friction, chemicals, or tape. It is important for the client to inspect skin daily and to avoid the following:

- Sun exposure
- Hot bath water
- Hot water bottles, heating pads
- Placing containers of hot food or liquids in lap
- Eating hot foods or other items that maintain heat for extended periods (e.g., pizza) without first testing the temperature
- Sitting on objects that may be hot (heaters, concrete or rocks in sunlight)
- Walking on hot surfaces (pavement or sand) without shoes
- Contact with items in or on an automobile that are hot from exhaust or sunlight (e.g., tailpipe, heater vents directed at feet, seatbelt buckles, steering wheel, and leather or vinyl upholstery)
- Overexposure to very low temperatures (cold weather or ice packs) without proper protection

Chapters 15 and 21 for more information on communicating with clients who are hearing impaired.

Visual Impairment

Clients with visual impairments often have developed the other senses to a high degree. The nurse can, therefore, use a variety of ways to enhance communication with such clients. For example, the nurse should do the following:

- Ask the client to explain what is helpful (e.g., preferred means of communicating, usual routine).
- Look directly at the client while speaking.
- Encourage the client to handle items and objects; use objects that can be identified by other senses.
- Keep furniture and other items in their usual places; orient the client to the environment by using clock hours to indicate the position of items in relation to the client.
- Use your normal tone, volume, and rate of speaking.
- Inform the client when you are entering or leaving the room.
- Ask for permission before touching the client.

See Chapters 15 and 21 for discussion of communicating with visually impaired clients.

MANAGING SENSORY DEPRIVATION

It is important to provide an adequate amount of sensory stimulation to those clients who are at risk for developing

**RESPECTING OUR DIFFERENCES****Communicating through an Interpreter**

- Plan what you intend to say ahead of time; this avoids confusing the interpreter by having to back up, restate, or revise previous statements.
- Use short sentences and questions.
- Avoid the use of ambiguous statements and questions.
- Avoid the use of technical and medical jargon.

sensory deprivation. The nurse should provide multisensory stimuli for 5–10-minute intervals throughout the day. Examples of appropriate stimuli are:

- Taped voices of family or friends
- Music (familiar to clients)
- Television
- Touch (applying lotions, different textures to skin)
- Frequent position changes
- Familiar visual stimuli (pictures, personal items)

Allow rest periods with no stimulation (e.g., 30 minutes to 1 hour of uninterrupted sleep every 2–4 hours) to avoid sensory overload.

MANAGING SENSORY OVERLOAD

Caring for clients experiencing sensory overload can be very challenging for nurses, especially in critical care areas (e.g., the emergency department, intensive care unit). It is important to reduce environmental stimuli as much as possible. Reorient clients frequently by talking to them, stating their names, and informing them of the day and time. Also, the nurse should promote social stimulation by encouraging visitors as appropriate to the client's health needs. The accompanying Nursing Checklist on page 1223 provides guidelines for nursing interventions for clients experiencing sensory overload. See also the Uncovering the Evidence display on page 1223.

Assisting the Confused Client

Nurses need to be sensitive and supportive when communicating with a client who is confused because many clients are aware of their cognitive deficit and become frustrated about their inability to process environmental stimuli correctly. The nurse must ask about the client's preferred means of communication and tailor the interaction accordingly. The accompanying Respecting Our Differences display on page 1223 lists some hints for communicating with confused clients.

Sensitive nursing care includes allowing additional time for the client to respond to questions, speaking directly to the client in uncomplicated language, repeating information

UNCOVERING THE

Evidence

TITLE OF STUDY

“Effects of Intensive Care Unit Noise on Patients: A Study on Coronary Artery Bypass Graft Surgery Patients”

AUTHORS

N. Akansel and S. Kaymakçi

PURPOSE

(1) To measure the noise levels in specific locations of an intensive care unit (ICU) and (2) to determine disturbance levels of clients owing to noise.

METHODS

The study was conducted with 35 clients who had coronary artery bypass graft surgery. The noise level was measured next to the bed of each client. Each client was questioned about disturbance owing to the ICU noise.

FINDINGS

Noises created by other clients who were admitted for the emergency department and operating room, monitor alarms, and conversations among staff members were the most disturbing noise sources for participants. Clients who were located in beds that were closer to the nurses’ station were more affected by the noise than other clients.

IMPLICATIONS

Nurses are in key positions to identify stressors that affect clients during hospitalization. Planned nursing activities and proper design of the ICU may help alleviate the negative effects of noise on client well-being.

Akansel, N., & Kaymakçi, S. (2008). Effects of intensive care unit noise on patients: A study on coronary artery bypass graft surgery patients. *Journal of Clinical Nursing, 17*(12), 1581–1590.

as needed, and using visual clues and body language to reinforce verbal messages. It is also important to address only one topic at a time and to give simple directions in sequence. For example, “First, sit up in bed. Then slide your legs over the edge of the bed.” Other interventions that are therapeutic for confused clients include the following:

- Written schedule of activities
- Written checklists for performing ADL
- Written directions for medication self-administration
- Active participation in activities

The accompanying Community Considerations display on page 1224 provides information to share with significant others who are caring for a confused client.

NURSING CHECKLIST

Care of the Client Experiencing Sensory Overload

- Address the client by name.
- Provide explanations of all procedures prior to implementation.
- Modify environment to reduce excessive multi-sensory stimulation; reduce distractions, loud noise, and excessive light.
- Use a calm, unhurried manner when communicating with the client.
- Provide a private room whenever feasible.
- Plan the delivery of care to allow for rest periods with no stimulation.
- Use soft background music.
- Keep the environment free of strong odors (including perfume or aftershave lotion).
- Limit the number and frequency of visitors.

RESPECTING OUR DIFFERENCES

Communicating with the Confused Client

- Choose simple words and short sentences.
- Use a calm tone of voice.
- Avoid talking down to the client.
- Avoid talking about clients as if they were not present.
- Minimize noise and distractions to help the client focus.
- Call the client by name.
- Allow enough time for a response, being careful not to interrupt.

CARING FOR THE UNCONSCIOUS CLIENT

Individuals who are unconscious can often hear what is spoken even though they are unable to respond. Thus, it is important for the nurse to be cautious of what is said in the presence of an unconscious client. Nurses should talk in a normal conversational tone while providing care. Also, remember the value of nonverbal communication, and touch the unconscious client. See the accompanying Nursing Checklist on page 1224 for additional guidelines in communicating with a client who is unconscious.

COMMUNITY CONSIDERATIONS

The Confused Client at Home

- Keep clutter in traffic areas at a minimum; remove small rugs that can cause tripping.
- Make sure that bed is low and that there is proper lighting to help prevent falls.
- Keep dangerous objects (e.g., matches, firearms, knives) from client's reach.
- Keep medications out of client's reach.
- Lock doors to areas that could be potentially dangerous if client wandered there.
- Assist in dressing appropriately for the season.
- Do not allow the client to stay alone; have a responsible adult provide supervision.
- Try to keep daily activities as routine as possible.
- Keep activities simple and uncomplicated.
- Provide signs, posters, clocks, and calendars as memory aids.
- Encourage client to be independent while providing assistance as needed.
- Always treat the client with respect and dignity.

USE OF RESTRAINTS

Restraints, both physical and chemical, are sometimes used with clients experiencing cognitive or sensory perceptual alterations. Even though restraints are used to protect cognitively impaired clients from harm, there are some risks of using restraints. Some of the risks associated with the use of restraints include strangulation, impaired circulation, increased risk of falls, and perception that one is being punished.

Therefore, the Centers for Medicare and Medicaid Services and the Joint Commission are mandating the reduced use of restraints in all health care facilities. Minimizing the use of restraints must be done in order to respect client dignity while, at the same time, promoting safety of clients and staff members. See Chapter 29 for guidelines on the safe use of restraints.

COMPLEMENTARY AND ALTERNATIVE THERAPIES

Natural therapies can play an essential role in maintaining a healthy CNS. This section discusses the use of herbs and aromatherapy as methods for enhancing mental well-being. Refer to Chapter 31 for a complete discussion of complementary and alternative treatment approaches.

Herbals

There are four groups of herbs that especially benefit the nervous system: tonics, sedatives, demulcents, and stimulants; see Table 38-10 on page 1225.

NURSING CHECKLIST

Communicating with an Unconscious Client

- Orient the client to self, situation, place, and time.
- Address the client by name and explain all procedures prior to implementation.
- Maintain a routine to increase the client's sense of security.
- Use touch deliberately.
- Actively listen to significant others.
- Encourage significant others to talk to and touch the client often.
- Treat the client with the same respect and dignity you display to all clients.

Aromatherapy

Aromatherapy can be used to relax or stimulate the CNS. Aromatic molecules emit signals that travel to the limbic system, the emotional switchboard of the brain. The aromas of essential oils serve as catalysts for psychological and physiological changes within the brain. The accompanying Nursing Process Highlight lists some essential oils used to promote a healthy CNS.

EVALUATION

Evaluating the care of the client with sensory, perceptual, and cognitive alterations is dependent on individualized expected outcomes for each client. Evaluation of outcome achievement is performed through the nurse's use of observation and communication skills. An important component of evaluation is determination of clients' ability to meet their own needs. Evaluation of the client's self-care abilities provides information for discharge planning, including follow-up care or placement in a long-term care facility, if necessary.

NURSING PROCESS HIGHLIGHT

Implementation

Essential Oils and CNS Health

- **Chamomile (*Anthemis nobilis*):** Alleviates physical and mental stress
- **Lavender (*Lavandula angustifolia*):** Calming, sedative effect
- **Mandarin (*Citrus reticulata*):** Relieves anxiety
- **Peppermint (*Mentha piperita*):** Stimulant; strengthens adrenal cortex
- **Yarrow (*Achillea millefolium*):** Promotes sleep

NURSING CARE PLAN

The Client with Impaired Memory

CASE PRESENTATION

Mr. Brown, a 53-year-old male, arrives at the clinic with his son, who had found Mr. Brown wandering aimlessly along a road in his community. The son is worried that his father is becoming "more and more forgetful every day." This was first noticed 1 month ago, when Mr. Brown forgot his phone number when completing a job application. Since then, the memory lapses have become more frequent and are now interfering with daily routines (he forgets to take his blood pressure medicine and gets lost returning home). Mr. Brown is currently unemployed and has no health care insurance. He denies that there is any problem and reluctantly agreed to come in today after hearing on the radio about free blood pressure screenings offered by the clinic.

ASSESSMENT

- Impaired memory
- Disorientation (occasionally)

(Continues)

NURSING CARE PLAN (Continued)

- Impaired judgment
- Impaired problem solving or decision making

NURSING DIAGNOSIS 1: *Acute confusion* related to unknown etiology as evidenced by fluctuations in cognition and level of consciousness (LOC) and memory disturbances

NOC: Cognitive orientation

NIC: Reality orientation

EXPECTED OUTCOME

The client will maintain current LOC with no demonstrated deterioration.

INTERVENTIONS/RATIONALES

1. Assess LOC. Establishes a baseline of data in order to intervene quickly if mental status changes.
2. Tell Mr. Brown your name and why you are meeting with him. Keeps client oriented to reality.
3. Talk to Mr. Brown while providing care. Maintains reality orientation.
4. Whenever possible, avoid the use of drugs that may cause drowsiness or sedation. Increased drowsiness or sedation will make it difficult to determine changes in neurological function.
5. Encourage physical and mental activity, daily exercise, and interaction (e.g., with family or friends, newspaper, TV). Improves memory, attention, and orientation.
6. Prepare the client for changes in activity or routines. Reduces confusion and creates a routine to improve orientation.

EVALUATION

Goal partially met. Mr. Brown was oriented to self and place when he arrived at the clinic.

NURSING DIAGNOSIS 2: *Risk for injury* related to cognitive deficits

NOC: Risk control

NIC: Risk identification

EXPECTED OUTCOME

Mr. Brown will remain free of injury.

INTERVENTIONS/RATIONALES

1. Assess environment and make alterations to enhance safety if necessary. Alterations will lessen likelihood of injury.
2. Provide support to significant others and supervision for tasks deemed potentially harmful to client, discouraging tasks as appropriate (e.g., cooking, smoking). Prevents physical injury to client and danger to others.
3. Provide a list of community resources and cost of services (e.g., day treatment centers, home health agencies) and encourage utilization of resources as appropriate. A list will promote access to available resources that offer a safe environment through part- or full-time supervised care.

EVALUATION

Goal partially met. Mr. Brown remained free of injury while at the clinic. He stated he was not interested in the list of community resources.

KEY CONCEPTS

- The well-being of an individual is dependent upon the functions of sensation, perception, and cognition, which are controlled by the central nervous system.
- Primary components of consciousness include arousal and awareness.
- Cognitive and perceptual functioning is inferred through assessment of the client's behaviors (e.g., consciousness, orientation, speech, thought processes, and perceptions).
- The sensory system is made up of a complex network of afferent fibers within the peripheral nerves, efferent tracts located in the spinal cord and brain stem, and the higher cortex (cerebral lobes).
- Consciousness is a state of awareness of one's self, others, and the surrounding environment, and it affects intellect and emotions.
- Consciousness is controlled by the reticular activating system located within the midbrain and thalamus as well as connective fibers between these structures and areas within the cerebral cortex.
- The degree of arousal (alertness) is indicated by a person's general response to the environment.
- Orientation refers to awareness of self in relation to the surrounding environment; an individual who is "oriented \times 4" is aware of time, place, person, and situation.
- There are three distinct types of memory: immediate, recent, and remote.
- An individual's affect (mood or feeling tone) can influence thinking ability.
- Judgment is the ability to compare or evaluate alternatives to life situations and arrive at an appropriate course of action.
- There are two types of perceptual distortions: illusions and hallucinations.
- Language is one of the most complex of cognitive functions, involving the ability to speak, read, write, and comprehend.
- A person can become confused as a result of either overstimulation or understimulation.
- Sensory deprivation, a state of reduced sensory input, can occur as a result of illness, trauma, or isolation.
- Sensory overload is a state of excessive and sustained multisensory stimulation manifested by behavior change and perceptual distortion.

REVIEW QUESTIONS

1. Which nursing activities are most therapeutic for a client with a visual impairment?
 - a. Face the client's interpreter to avoid confusion.
 - b. Inform the client when you are entering the room.
 - c. Speak in a high-pitched tone of voice.
 - d. Talk rapidly to help the client quickly process information.
2. The nurse should be especially alert for the possibility of burns in clients with which sensory perceptual deficits?
 - a. Auditory
 - b. Olfactory
 - c. Tactile
 - d. Visual
3. A client is admitted to the intensive care unit following surgery. Which potential problem should be a priority for the nurse who is planning to care for this client?
 - a. Decreased anxiety
 - b. Impaired mobility
 - c. Sensory deprivation
 - d. Sensory overload
4. A client has been started on benzodiazepine therapy for treatment of anxiety. When assessing the client, the nurse will know that the client will most likely exhibit _____.
 - a. bloating and flatulence
 - b. confusion
 - c. headache
 - d. nausea
5. A client is admitted to the emergency department following an automobile accident in which he was driving under the influence of alcohol. The client says, "There are ants crawling on my arms!" This client is likely experiencing which type of hallucination?
 - a. Auditory
 - b. Gustatory
 - c. Olfactory
 - d. Tactile
6. The nurse must assess a client experiencing a sensory deficit for development of which of the following?
 - a. Back pain
 - b. Pneumonia
 - c. Polyuria
 - d. Pressure ulcers

7. A client with an impaired gustatory sensory perception is being treated in the home. When teaching family members how to care for the client, which of the following should have the highest priority?
 - a. Buying a hearing aid
 - b. Checking expiration dates on food packages
 - c. Providing large-print reading materials
 - d. Repositioning the client frequently
8. A client is exhibiting signs of confusion. Which nursing actions will promote a safe environment for this client? Select all that apply.
 - a. Apply restraints to prevent falls.
 - b. Keep the ambient noise level high.
 - c. Keep the bed in a low position, and close to the floor.
 - d. Keep the room clean and organized.
 - e. Perform all ADL for the client in order to conserve his or her energy.
 - f. Place the client in a quiet area with no visitors.
9. Which action by the nurse is therapeutic for an unconscious client?
 - a. Explain procedures to the client in a normal tone of voice.
 - b. Perform nursing tasks quickly and quietly in order not to disturb the client.
 - c. Place the client in a quiet room far away from the nurse's station.
 - d. Request that family members leave the client alone until consciousness is regained.

CHAPTER 39

Elimination

COMPETENCIES

1. Describe the normal urinary elimination process.
2. Explain age-related changes that affect elimination.
3. Assess the critical elements of urinary structures.
4. Relate the principles of asepsis to urinary catheterization.
5. Discuss normal bowel elimination.
6. Assess the critical elements of bowel function.
7. Describe the expected outcomes of nursing interventions that promote normal elimination.
8. Discuss nursing interventions for selected alterations in bowel function.

KEY TERMS

bacteriuria	functional incontinence	stoma
constipation	hematuria	stool
defecation	hemorrhoids	stress urinary incontinence
detrusor muscle	impaction	urge urinary incontinence

dysuria	nocturia	urinary incontinence
extraurethral incontinence	peristalsis	urinary retention
fecal incontinence	pyuria	voiding
flatulence	specific gravity	

Elimination patterns are essential to maintain health. The urinary and gastrointestinal (GI) systems together provide for the elimination of body wastes. The urinary system filters and excretes urine from the body, thereby maintaining fluid, electrolyte, and acid-base balance. Normal bowel function provides for the regular elimination of solid wastes.

During periods of stress and illness, clients experience alterations in elimination patterns. Nurses assess for changes, identify problems, and intervene to assist clients with maintaining proper elimination patterns. The nurse's role encompasses teaching clients self-care activities to promote independence and health.

PHYSIOLOGY OF ELIMINATION

The urinary system is composed of the kidneys, ureters, bladder, and urethra. The kidneys form the urine, the ureters carry urine to the bladder, the bladder acts as a reservoir for the urine, and the urethra is the passageway for the urine to exit the body.

The GI tract is composed of the stomach, small intestine, large intestine, and rectum. The small intestine absorbs nutrients, the large intestine absorbs fluids and the remaining nutrients, and the distal portion of the large intestine collects and stores the remaining solid waste until elimination occurs.

URINARY ELIMINATION

The physiological mechanisms that govern urinary elimination are complex and not yet completely understood. Continence in the adult requires anatomic integrity of the urinary system, nervous control of the detrusor muscle, and a competent sphincter mechanism. **Urinary incontinence** occurs when abnormalities of one or more of these factors cause an uncontrolled loss of urine that produces social, physiological, or hygienic difficulties for the client.

Structures of the Urinary Tract

The urinary system is typically divided into upper and lower tracts. The upper urinary tract includes the kidneys, renal pelvis, and ureters; the lower urinary tract includes the

urinary bladder, urethra, and pelvic muscles (see Figure 39-1 on page 1233).

UPPER URINARY TRACT The kidneys are a pair of reddish brown, bean-shaped organs located in the retroperitoneal space, adjacent to vertebral bones T12 to L2. The right kidney lies slightly lower than the left because of the presence of the liver. The periphery of the kidney contains approximately 1 million nephrons; collectively this aspect of the organ is called the parenchyma. The hilum of the kidney (its convex surface) contains the renal pelvis and the ureters, which connect the kidneys and the bladder. The primary function of the kidney is to maintain internal homeostasis through filtration of the blood and production of urine. In addition, the kidney is an endocrine organ (producing erythropoietin, a hormone that aids in the production of red blood cells), and it plays a role in vitamin D synthesis.

After production within the nephron, urine passes through the calyceal system of the kidneys into the renal pelvis. The renal pelvis is shaped like a funnel, holds approximately 15 mL of urine, and serves as a temporary storage area for urine before transport to the lower urinary tract. The ureter is a long tube, shaped like an inverted S, that begins at the renal pelvis, passes under the psoas muscle of the back, and enters the pelvis near the sacroiliac junction. When entering the pelvis, the ureters curve medially to end in the base of the bladder. The union between bladder and ureter is called the ureterovesical junction.

Both the renal pelvis and ureters consist primarily of smooth muscle, and they move urine from the upper to the lower urinary tract by muscular contraction. This process is called **peristalsis**, and it is similar to the peristaltic waves of the GI system used to digest food and produce fecal waste. The process of peristalsis occurs during the prolonged phases of bladder filling and storage, but it is temporarily interrupted during micturition.

LOWER URINARY TRACT The bladder is a hollow, muscular organ located in the pelvis. It has a fixed base and a distensible upper portion composed of multiple bundles of smooth muscle. Collectively, the smooth muscle bundles are called the detrusor muscle.

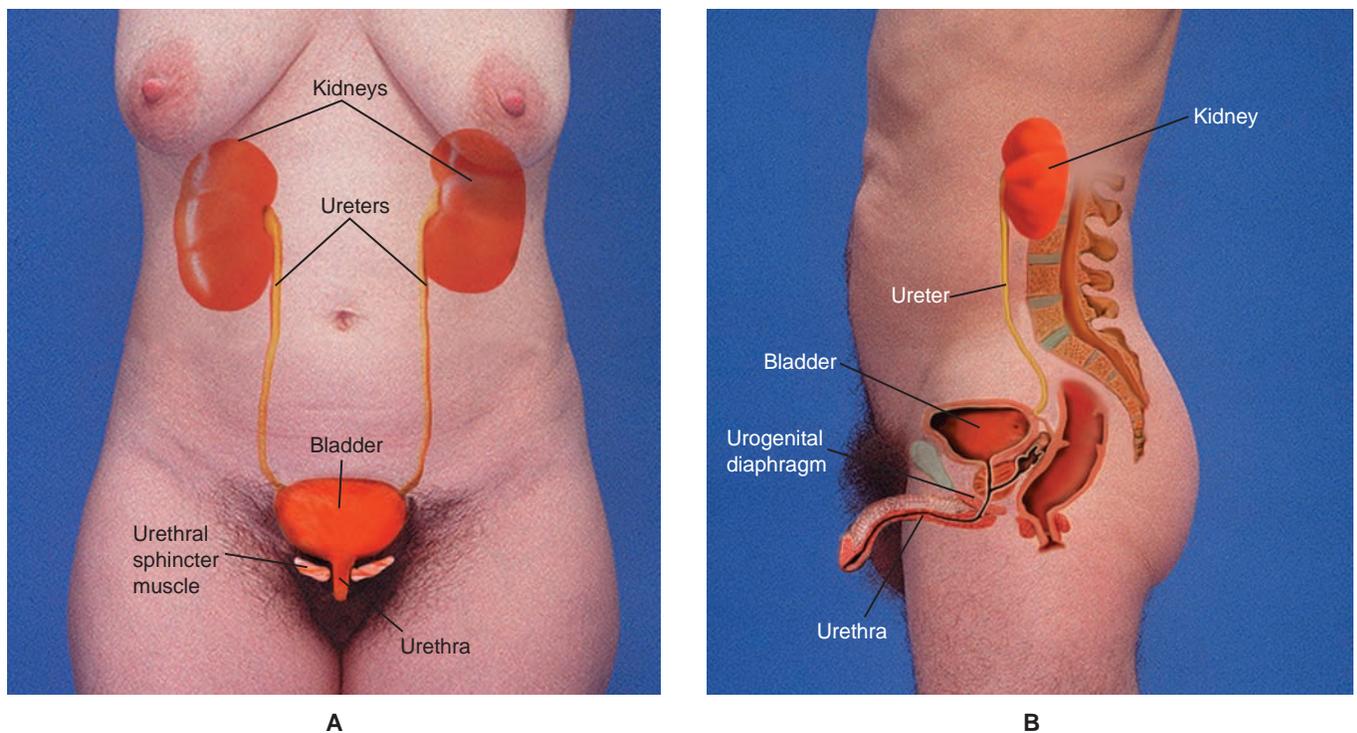

FIGURE 39-1 Urinary Tract: A. Female; B. Male DELMAR/CENGAGE LEARNING

The urethra is a tube that is a conduit for urinary elimination. The urethra differs significantly in women and men. In women, the urethra exits the bladder base and travels at a 16° angle to the external meatus located at the vestibule. The female urethra is approximately 3.5 to 5.5 cm long, and the distal third is histologically fused with the vaginal wall (see Figure 39-1). The entire length of the urethra forms a sphincter mechanism with elements of compression and elements of tension.

In men, the urethra is approximately 23 cm long. It begins at the bladder base, pierces the anterior portion of the prostate, and turns to exit the body through the penis. The proximal third of the male urethra forms a sphincter mechanism comparable to the female urethra. The distal two-thirds is a conduit for the expulsion of urine or semen.

The pelvic muscles connect the anterior and posterior aspects of the bony pelvis, support the organs of the true pelvis, and contribute to the urethral sphincter mechanism in both women and men. The pelvic muscles contain primarily slow-twitch fibers that are physiologically suited for prolonged periods of tone. In addition, fast-twitch fibers within the pelvic muscles respond rapidly to sudden increases in abdominal pressure, although they soon fatigue. Fibers from the pelvic muscles surround the membranous urethra of the male and the proximal two-thirds of the female urethra. In both sexes, the urethra pierces the muscular diaphragm of the pelvic muscles.

Nervous Control of the Detrusor Muscle

The **detrusor muscle**, the smooth muscle of the bladder, is under indirect voluntary control, allowing the continent adult

to postpone urination until a socially appropriate time and location for bladder evacuation is identified. Specific areas of the brain, spinal cord, and peripheral nervous system modulate the reflex activity of the detrusor muscle.

Central nervous control of the bladder begins in several modulatory centers in the brain. A neurologic lesion affecting one or more of these areas causes hyperactive detrusor contractions and a loss of bladder control. The primary areas in the brain that modulate the detrusor muscle are located in the frontal lobes, thalamus, hypothalamus, basal ganglia, and cerebellum. The limbic system, which controls many aspects of autonomic nervous function, also influences continence.

A micturition center, located near the base of the brain, has two groups of neurons that mark the origin of the urination (micturition), the evacuation of urine from the bladder. In the infant, urinary elimination is controlled entirely by the micturition center, which evacuates the bladder when a specific “threshold” volume is reached or when the bladder is stimulated in another way. In the adult, however, the micturition center is controlled by the multiple centers of the brain, and urination usually occurs when the individual wishes to empty the bladder.

Reticulospinal tracts in the spinal cord transmit messages from the brain and brain stem to the peripheral nerves of the bladder. Bladder filling and urinary storage are promoted by excitation of the sympathetic nervous system via efferent, sympathetic spinal nuclei at spinal segments T10 to L2. Excitation of these neurons relaxes the detrusor muscle and contracts the muscular elements of the sphincter mechanism. Urinary evacuation is accomplished through the parasympathetic nervous system. Excitation of neurons located at

segments S2 to S4 causes **voiding** (urination) by contraction of the detrusor muscle and relaxation of muscular elements of the sphincter mechanism.

Two peripheral nerves transmit messages from the central nervous system to the detrusor muscle. The pelvic plexus transmits parasympathetic impulses to the smooth muscle of the detrusor. Nervous excitation of the parasympathetic nerves causes release of a neurotransmitter, acetylcholine, which produces contraction of detrusor muscle cells. Other substances also affect contraction of the detrusor muscle, but all act under the influence of the central nervous system.

The inferior hypogastric nerves provide the majority of sympathetic tone to the bladder wall and sphincter mechanism. In the detrusor muscle, excitation of β -adrenergic receptors causes release of norepinephrine, which inhibits detrusor muscle contraction. In addition, stimulation of α -adrenergic (excitatory) receptors at the bladder neck, in the proximal urethra, and in the prostatic urethra in men causes contraction of muscular components of the sphincter mechanism, promoting urethral closure and continence.

Urethral Sphincter Mechanism

The urethral sphincter is traditionally divided into two muscles, an internal (smooth muscle) and external (striated) sphincter. Unfortunately, this schema leads to more confusion than it addresses, and it should be discarded for a conceptualization of the sphincter as a single mechanism, comprising elements of compression and elements of tone, with essential supportive structures.

Urethral compression relies on three components: urethral mucosa softness, mucous secretions, and a vascular cushion. During bladder filling and urinary storage, the epithelium must fill in the gaps of the collapsed (closed) urethral lumen, creating a watertight seal through which no urine can escape. Coaptation requires a pliable, soft, and unscarred urethra, with adequate mucous secretions to reduce surface tension and to fill in the microscopic gaps left by the epithelium. These elements of compression are supplemented by a rich network of vascular connections in the submucosal space. This vascular network promotes urethral closure by nourishing the epithelium and mucous production cells and by serving as a cushion for the transmission of force exerted by the muscular elements of the sphincter mechanism. In women, all the elements of compression are directly influenced by the presence of estrogens.

Elements of urethral tension protect the individual from urinary leakage during physical exercise or exertion. Smooth muscle bundles at the bladder neck and proximal urethra (and prostatic urethra of the male) close the urethra during bladder filling and urinary storage. The urethral wall also contains a set of highly specialized, triple-innervated striated muscle fibers that form a rhabdosphincter. It is crucial for maintaining continence during normal exertion. Striated muscle fibers from the pelvic muscle surround the urethra and contribute to the sphincter. These muscles are particularly needed when abdominal pressure changes from sneezing, coughing, or lifting a heavy object.

The muscular elements of the urethra rely on supportive structures to provide an optimal configuration allowing them to contract and relax efficiently. Loss of support interferes with efficient urethral sphincter function.

BOWEL ELIMINATION

The process of normal fecal elimination is not completely understood. Continence primarily relies on the consistency of the **stool** (fecal material), intestinal motility, compliance and contractility of the rectum, and competence of the anal sphincters.

Structures of the Gastrointestinal Tract

The GI system (alimentary canal) begins at the mouth and ends at the anus. The small intestine in the adult is approximately 22 feet long. The small intestine is primarily responsible for the digestion and absorption of nutrients, vitamins, minerals, fluids, and electrolytes. The digestive chyme (mixture of partially digested food and secretions) travels through the small bowel by a combination of segmental contractions and peristaltic waves. Substances that are well tolerated move through the bowel relatively slowly; foods or drugs that are toxic or irritable to the small bowel are evacuated rapidly. The small intestine joins the large bowel (colon) at the ileocecal valve. This valve works in conjunction with the ileocecal sphincter to control emptying of contents from the small intestine into the colon and to prevent regurgitation of digestive chyme from the large to small bowel (see Figure 39-2).

The colon is approximately 5 to 6 feet long in adults. It is divided into six segments: the cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and anal canal. The primary functions of the colon are to collect, concentrate, transport, and eliminate waste materials (feces). The anal

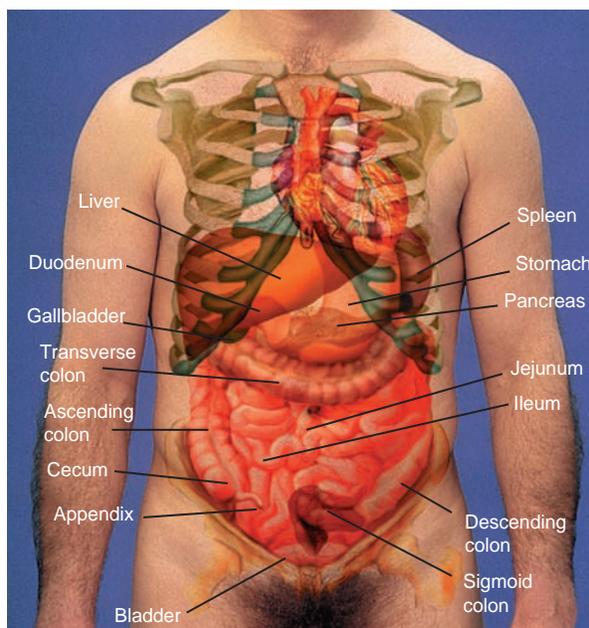

FIGURE 39-2 Gastrointestinal Tract DELMAR/CENGAGE LEARNING

sphincter consists of smooth and skeletal muscles that line the distal portion of the anal canal. It works with the anus to store and to eliminate feces under voluntary control.

Intestinal Motility and Rectal Accommodation

Fecal continence relies on regular delivery of small boluses of stool that are stored in the rectum before elimination. The transit time from ingestion of food to passage of stool from the bowels varies. Typically, at least 80% of intake that is not absorbed by the body is excreted from the bowel within 5 days following ingestion. Transit time is significantly affected by the type of foods ingested, subsequent dietary intake, exercise, and stress-related factors.

Filling of the rectum causes a growing awareness of the presence of stool, which is stored until an appropriate opportunity for **defecation**, the evacuation of stool from the rectum, is identified. In the continent individual, an initial awareness of stool in the rectum is identified at 150 mL. The desire to defecate is typically transient, diminishing as the rectum accommodates larger volumes of stool. When 400 mL or more of stool is collected in the rectum, this urge becomes strong, and the call to defecate becomes more persistent. Failure to heed the call to defecate may lead to overdistension of the rectum with hardening of the stool and subsequent constipation.

Anal Sphincter Mechanism

The anal sphincter is divided into two mechanisms called the internal and external sphincters (see Figure 39-3). An internal anal sphincter is primarily made up of smooth muscle bundles that are connected to the smooth muscle of the rectum. It begins in the distal portion of the rectum and extends approximately 3 cm into the anal canal. The internal sphincter mechanism is primarily innervated by sympathetic nerves

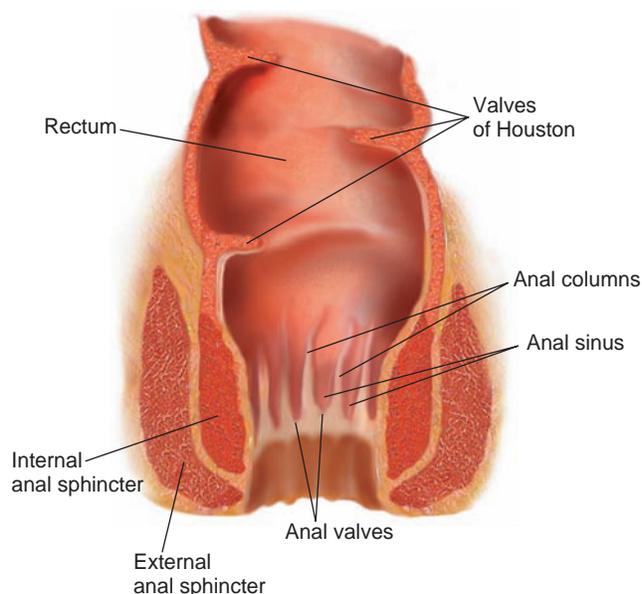

FIGURE 39-3 Anal Sphincter DELMAR/CENGAGE LEARNING

that promote smooth muscle contraction and by parasympathetic nerves that cause sphincter relaxation.

The external sphincter is composed of striated muscle fibers that are divided into deep and superficial components. The deep portion of the external anal sphincter comprises muscle fibers that encircle the proximal aspect of the anal canal and attach to the symphysis pubis, forming a U shape. The superficial portion of the anal sphincter also encircles the anal canal, forming a U shape; however, it attaches to the coccyx and postanal plate rather than to the anterior aspect of the pelvis. Like the periurethral muscles, the striated component of the external anal sphincter contains both fast- and slow-twitch fibers that allow sustained tone over a period of time before voluntary defecation.

Sensory receptors located at the proximal anal canal affect anal function. These specialized sensory receptors are able to “sample” fecal contents, allowing the individual to differentiate among solid stool, liquid stool, and gas.

Distension of the rectum causes a reflex inhibition of the internal anal sphincter and contraction of the external sphincter. The proximal anal sphincter then samples the contents of the rectum, and the individual perceives the desire to defecate. If the person postpones defecation, rectal accommodation occurs and the desire to defecate is postponed. If the desire to defecate is heeded, the person voluntarily relaxes the external anal sphincter and evacuates the bowel of feces.

The significance of rectal contractions during defecation remains unclear. Many persons strain to defecate, and abdominal force is readily transmitted to the rectum, creating an effective expulsive force. The continent individual is able to simultaneously increase abdominal pressure by straining and maintain external anal sphincter relaxation, allowing effective evacuation of feces from the bowel.

FACTORS AFFECTING ELIMINATION

AGE

A client’s age or developmental level will affect control over urinary and bowel patterns. Infants initially lack a pattern to their elimination. Control over bladder and bowel movements can begin as early as 18 months of age but is typically not mastered until age 4. Nighttime control usually takes longer to achieve, and boys typically take longer to develop control over elimination than girls.

Control of elimination is generally constant throughout the adult years, with the exception of illness and pregnancy stages, when temporary loss of control, urgency, and retention may develop. With increasing age comes loss of muscle tone and therefore bladder control; this is usually accompanied by the urge to void more frequently.

DIET

Adequate fluid and fiber intake are critical factors to a client’s urinary and bowel health. Inadequate fluid intake is a primary

cause of constipation, as is ingestion of constipating foods such as certain dairy products. Diarrhea and **flatulence** (discharge of gas from the rectum) are a direct result of foods ingested, and clients need to be educated as to which foods and fluids promote healthy elimination and which foods may inhibit it.

EXERCISE

Exercise enhances muscle tone, which leads to better bladder and sphincter control. Peristalsis is also aided by activity, thus promoting healthy bowel elimination patterns.

MEDICATIONS

Medications can have an impact on a client's elimination health and patterns and should be assessed during the health history interview. Cardiac clients, for instance, are commonly prescribed diuretics, which increase urine production. Antidepressants and antihypertensives may lead to urinary retention. Some over-the-counter (OTC) cold remedies, especially antihistamines, may also result in urinary retention. Other OTC medications are designed specifically to promote bowel elimination or to soften stools; the nurse needs to inquire about all medications being taken in order to provide proper care for a client experiencing alterations in elimination patterns.

COMMON ALTERATIONS IN ELIMINATION

URINARY ELIMINATION

Urinary incontinence and urinary retention are the most common causes of altered urinary elimination patterns. Urinary incontinence is the uncontrolled loss of urine that constitutes a social or hygienic problem. Urinary incontinence is

prevalent in men and women across the life span, affecting an estimated 13 million Americans. "It affects approximately 30 percent of the elderly and 50 percent of nursing home residents. Depending on the case mix, rates can be 70 percent and higher in nursing home facilities with a frail, functionally impaired population" (Newman, 2004, p. 17).

Urinary retention is the inability to completely evacuate urine from the bladder during micturition. There are two primary types of urinary incontinence, acute and chronic. In addition, chronic urinary incontinence can be subdivided into several distinctive types. Because each has its own etiology and management, it is important to determine the type of incontinence before subjecting the client to the expense, potential risks, and rigors of a treatment program.

Acute Urinary Incontinence

Acute urinary incontinence is a transient and reversible loss of urine. It may occur during an acute illness or after an injury. Common causes of acute urinary incontinence include urinary tract infection, atrophic vaginitis, polyuria related to diabetes, acute confusion, immobility, and sedation. Medications that increase or decrease bladder or urethral sphincter tone also may contribute to acute incontinence.

Chronic Urinary Incontinence

Acute incontinence is distinguished from established or chronic incontinence. There are four predominant types of chronic urine loss: stress urinary incontinence, instability incontinence, functional incontinence, and extraurethral incontinence.

STRESS URINARY INCONTINENCE **Stress urinary incontinence** (SUI) is the uncontrolled loss of urine caused by physical exertion in the absence of a detrusor muscle contraction. SUI is associated with urethral hypermobility or with intrinsic sphincter deficiency. According to Weiss and Newman (2002), there is consistent evidence that the frequency of SUI in women increases with age. The relaxation of the pelvic muscle accelerates rapidly after menopause and may progress with aging. These changes may cause the prolapse of pelvic organs.

Urethral hypermobility is the abnormal movement of the bladder base and urethra during physical exertion. The relationship between urethral hypermobility and SUI is not entirely understood, although several mechanisms have been proposed. Descent of the urethra into the lower portion of the pelvis may cause a loss of abdominal pressure transmission when compared with forces that affect the bladder. In addition, muscular contraction is compromised in the hypermobile urethra. Loss of the normal anatomical relationships between the urethral sphincter and related structures also may contribute to SUI by reducing the efficiency of the muscular elements of the sphincter. The contribution of estrogen deficiency, which compromises the elements of urethral coaptation in the woman, accelerates the rate of atrophy of the mucosal tissue that lines the urethra and vagina. Because of the atrophy and a decline in mucus production within the urethra, the urethra's ability to maintain a tight seal is

SPOTLIGHT ON...

Caring and Compassion

Sensitivity During the Genital Exam

Assessment of the genital area can produce feelings of anxiety and embarrassment in both clients and nurses. Before beginning the genital examination, consider your client's cultural background and what beliefs or attitudes the client may have about having the examination. Does the client's culture prohibit a female nurse from examining a male client? Does the client's culture prohibit a male nurse from examining a male client? Remember that you are assessing a person, not just a body part.

weakened, especially when intra-abdominal pressure increases with the Valsalva maneuver (Weiss & Newman, 2002). Table 39-1 identifies common factors that contribute to SUI.

Intrinsic sphincter deficiency is a disorder of the muscular components of the urethral sphincter. Sphincter closure is compromised, and urinary leakage is often severe. Severe urine loss caused by intrinsic sphincter deficiency is defined as *total incontinence* by the North American Nursing Diagnosis Association (NANDA, 2009) system. Unlike urethral hypermobility, which is a women’s health concern, intrinsic sphincter deficiency occurs in both genders and is related primarily to iatrogenic or neuropathic causes. Table 39-1 identifies common causes of intrinsic sphincter deficiency. It is important to note that intrinsic sphincter deficiency and urethral hypermobility frequently coexist in women.

INSTABILITY INCONTINENCE *Instability incontinence* is the loss of urine caused by a premature or hyperactive contraction of the detrusor. In the person with normal sensations of the lower urinary tract, these unstable detrusor contractions initially cause a precipitous desire to urinate, followed by urinary leakage unless the opportunity to toilet is immediately available. In those without sensations of bladder filling and impending urination, the contraction is followed by urinary incontinence that is often described as unpredictable. The NANDA (2009) classification schema divides this type of incontinence into two forms: *urge incontinence* and *reflex incontinence*. This distinction is clinically relevant because reflex incontinence is commonly associated with detrusor sphincter dyssynergia, an uncontrolled contraction

of striated muscle of the sphincter mechanism during micturition. Dyssynergia, or a loss of coordination between the bladder and sphincter mechanism, causes a functional obstruction of the bladder outlet and urinary retention. Table 39-2 outlines common causes of instability incontinence of urine.

FUNCTIONAL INCONTINENCE *Functional incontinence* is the loss of urine caused by altered mobility, dexterity, access to the toilet, or changes in mentation. Altered mobility and dexterity produce incontinence when the individual is unable to reach the toilet within a reasonable time after the onset of the urge to urinate. These conditions are worsened in an unfamiliar environment, such as a hospital, where side rails are raised on beds and sedatives are used to enhance sleep. Difficulty in reaching the toilet due to environmental

factors (e.g., stairs, poor lighting, toilet height, narrow doors that are impassable to wheelchairs or walkers) also produces functional incontinence when the obstacles render the person unable to enter the bathroom with reasonable ease. Acute confusion or dementia causes urinary incontinence when the signals to toilet become unclear. Functional incontinence exists as a separate entity from stress or instability urinary leakage. Nonetheless, it is important to remember that functional limitations also exacerbate these forms of urine loss.

Functional incontinence related to dementia may be managed by a prompted voiding technique. Prompted voiding is a technique of providing the opportunity to toilet on the basis of an individualized prompted urge response toileting (PURT) program or using a routine schedule. A PURT program is based on knowledge of the individual's typical voiding pattern. The client's voiding pattern is assessed by the use of a specially designed device to monitor urinary elimination patterns or by routine assessment of containment devices for wetness. The client is then placed on a prompted voiding schedule requiring the nurse or other caregiver to approach the client, offer the opportunity to urinate, and assist with toileting. Voiding is praised, as is dryness during the period before voiding. PURT is limited to clients with adequate cognitive awareness to respond to the prompted voiding and to those with caregivers willing to comply with the demands of this ongoing program. Prompted voiding programs also may be instituted using a more arbitrary schedule for toileting, usually every 2 to 3 hours.

EXTRAURETHRAL INCONTINENCE *Extraurethral incontinence* is the uncontrolled loss of urine that exists when the sphincter mechanism has been bypassed. According to the NANDA (2007) classification system, extraurethral leakage is termed *total incontinence*, although that term is also applied to severe SUI. The three causes of extraurethral incontinence are ectopia, a congenital defect in which leaks occur from a source outside the urethra; a fistula, an acquired passage allowing urinary leakage; or a surgical bypass of the urinary bladder, such as the ileal conduit. The severity of extraurethral incontinence varies from a dribbling leakage superimposed on an otherwise normal voiding pattern to a continuous urine loss that replaces any recognizable voiding pattern.

Urinary Retention

Urinary retention is caused by two conditions: bladder outlet obstruction and deficient detrusor muscle contraction strength. Bladder outlet obstruction causes incomplete bladder evacuation by blocking the outflow of urine through the sphincter mechanism or the urethra. Deficient detrusor muscle contraction strength occurs when contractions are insufficient to maintain urethral opening long enough for complete emptying of the bladder's contents. Because the management of each condition is different, it is important to differentiate between these disorders during evaluation. Table 39-3 describes common causes of urinary retention.

Delmar/Cengage Learning

BOWEL ELIMINATION

Many diseases and conditions affect bowel function. Although many alterations in bowel elimination patterns may be observed, this discussion is limited to three common alterations: constipation, diarrhea, and fecal incontinence.

Constipation

Colonic **constipation** is the infrequent and difficult passage of hardened stool. (Perceived constipation, influenced by psychological and emotional stress, is not included in this discussion.)

Dietary factors may contribute to constipation. Dehydration causes drying of the stool as the body increases the reabsorption of water and sodium from the bowel. Inadequate dietary bulk also dehydrates the stool. Diverticular disease, a common problem in older adults, also reduces colonic transit, further increasing the risk of constipation.

Neuropathic conditions promote constipation by diminishing the efficiency of gastric motility. They also weaken the abdominal muscles, reducing the efficiency of straining and rectal evacuation. Lesions of the brain (e.g., cerebrovascular accident, spinal disorders, disc problems, spinal stenosis) contribute to constipation by reducing mobility, weakening the abdominal muscles, and diminishing the motility of the smooth muscle of the colon and rectum. Functional limitations, particularly impaired mobility, predispose older adult clients to constipation; they perceive a diminished desire to defecate and have a prolonged colonic transit time. Multiple medications, particularly narcotics, sedatives, anticholinergics, antidepressants, antiparkinsonian drugs, and iron, also contribute to constipation.

In women, mechanical factors may exacerbate constipation. A rectocele is the herniation of the rectum and surrounding tissues into the potential space of the vagina (see Figure 39-4). A significant rectocele causes a mechanical obstruction to defecation and subsequent constipation. Both women and men may experience constipation because of incomplete control of the anal sphincter. In this case, failure of complete relaxation of the anal sphincter causes fecal retention, drying of stool, and constipation.

In severe cases, the hardened stool may consolidate into an **impaction**. This bolus of stool serves as a nidus for bacterial overgrowth and produces an obstruction that further slows colonic transit time and the passage of further fecal contents.

Diarrhea

Diarrhea is the passage of liquefied stool that, because of its increased frequency and consistency, represents a change in the person's bowel habits. The primary causes of diarrhea include infectious agents, malabsorption disorders, inflammatory bowel disease, short bowel syndrome, side effects of drugs, and laxative or enema misuse.

Infectious diarrhea occurs when overgrowth of a pathogen produces osmotic diarrhea via toxins or reduced absorptive ability due to mucosal damage. Common pathogens include *Clostridium difficile* (*C. difficile*), enterotoxigenic *Escherichia coli*, *Salmonella*, *Shigella*, *Entamoeba histolytica*, and *Giardia* (see Chapter 29 for additional information regarding *C. difficile*).

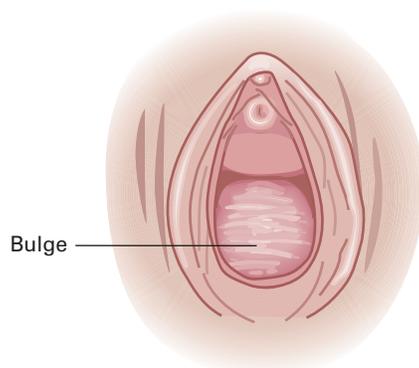

FIGURE 39-4 Rectocele DELMAR/CENGAGE LEARNING

Malabsorption syndromes produce diarrhea when unabsorbed substances in the diet create an osmotic imbalance and liquefaction of the stool. Lactose intolerance, sorbitol intolerance, and celiac sprue syndrome are examples of common malabsorption syndromes that predispose clients to diarrhea. Persons with inflammatory bowel disease (IBD) or short bowel syndrome are predisposed toward diarrhea because of a reduced surface area for reabsorption. IBD refers to one of two disorders: Crohn's disease or ulcerative colitis. These diseases cause diarrhea, abdominal pain, fever, arthritis of the spine and large joints of the arms and legs, and anorexia, and both can be debilitating and even life threatening (Day, 2008).

Specific drugs may cause diarrhea as a side effect. Administration of multiple antimicrobial agents may indirectly predispose the client to diarrhea by promoting an overgrowth of *C. difficile* in the bowel. Cholinergic drugs increase motility and reduce reabsorption of water and electrolytes from the stool. Other drugs produce osmotic diarrhea, primarily because of the vehicle for delivery, which frequently contains sorbitol and a high osmolality.

Enteral feedings contain a relatively high osmolality that frequently predisposes the client to diarrhea. These formulas may contain lactose, which causes intolerance in some people. The risk of diarrhea is further enhanced in the critically ill who have highly catabolic states and decreased absorptive ability and among those receiving bolus administration of intravenous fluids.

The misuse of laxatives and enemas is frequently associated with diarrhea among clients living at home. Overuse of saline cathartics may produce osmotic diarrhea, and the chronic misuse of laxatives may alter motility patterns and cause an osmotic shift in the bowel.

Secretory diarrhea occurs when the normal mechanisms that produce intestinal fluid are hyperactivated, causing excessive production and movement of food through the intestinal system. Zollinger-Ellison syndrome, pancreatic cholera, carcinoid syndrome, and villous adenoma may produce severe, chronic diarrhea.

Fecal Incontinence

Fecal incontinence is the involuntary loss of stool of sufficient magnitude to create a social or hygienic problem. The primary mechanisms that predispose the adult to incontinence of stool are dysfunction of the anal sphincter, disorders of the delivery of stool to the rectum, disorders of rectal storage, and anatomic defects.

A disorder of stool volume and consistency is typically not enough to produce fecal incontinence in the otherwise normal individual. Instead, the person is likely to perceive a precipitous urgency to defecate, an impulse that is heeded rapidly. However, if the volume of stool is sufficient and the storage capacity of the rectum is compromised or sphincter function is suboptimal, fecal incontinence may result. When severe constipation leads to an impaction of stool, bacteria in the rectum overgrow, producing a liquefied medium. The toxins produced by this liquefied stool are likely to stimulate

the bowel and may produce transient seepage of stool in the normally continent client.

Low compliance of the rectum also predisposes the client to fecal incontinence. In the normal individual, the rectum is able to accommodate 400 mL of feces at low pressure. However, clients with radiation proctitis, rectal wall fibrosis due to inflammatory disorders, infectious proctitis, chronic obstruction, or malignancies store lower volumes of stool at higher pressures. Low rectal compliance diminishes storage capacity and causes greater than normal urgency to defecate when stool enters the rectum. When a large volume of stool enters the rectum rapidly, the urgency to defecate is likely to be overwhelming, and the risk of incontinence is significant.

Anal sphincter dysfunction is likely to cause incontinence when both the internal and external mechanisms are compromised. Neurologic lesions are the most common cause of anal sphincter dysfunction. Typically, the client is able to compensate for sphincter weakness, provided the rectum is presented with a normal delivery of solid stool. However, in the presence of diarrhea, significant fecal incontinence may occur.

Sensory disorders also predispose the client to fecal incontinence. Loss of the sensitive epithelium in the proximal anal canal interferes with the client's ability to differentiate gas and solid and liquid contents in the rectum. In addition, loss of proprioception in the rectum disturbs the client's ability to detect rectal fullness. These individuals are particularly prone to incontinence when a large bolus of stool enters the rectum rapidly or when an impaction occurs.

Anatomic disorders also may compromise sphincter function and predispose the individual to fecal incontinence. Among women, the most common risk factor is obstetric trauma. Vaginal deliveries, particularly those requiring the use of forceps and those complicated by third-degree tearing, are likely to damage the anal sphincter mechanism.

ASSESSMENT

The nursing assessment of elimination is based on a client interview and history, evaluation of an objective log or record of urinary or fecal elimination patterns, focused physical examination, and review of diagnostic laboratory data. When altered patterns of elimination indicate a significant health problem, additional diagnostic information is used to formulate a plan of care.

HEALTH HISTORY

Because issues of elimination may produce feelings of anxiety, guilt, or shame among clients, the interview must be instigated by the nurse and conducted in a setting that provides adequate privacy. Clients are asked to describe their usual elimination habits. Table 39-4 on page 1241 presents the typical questions asked when assessing urinary and fecal elimination patterns.

When screening questions concerning altered patterns of elimination reveal significant findings, the interview should be expanded to include specific questions about the nature of the elimination disorder. These questions explore the type of incontinence, complicating factors, and bladder (see Table 39-5 on page 1242) and bowel management strategies currently used by the client. Nurses need to speak freely with clients regarding continence problems since they may have a negative effect on a client's self-image and self-esteem.

SPOTLIGHT ON...

Caring and Compassion

Assessment of Elimination Patterns

Consider your feelings about urinary and fecal incontinence. Many people, including health care professionals, consider incontinence to be a hygienic rather than a health concern. Parents may view incontinence in children to be a form of misbehavior. Some adults consider incontinence to be a form of childlike or infantile behavior, or they may believe that urinary or fecal leakage is an inevitable consequence of aging. Consider your feelings if you lost control of your bowels or your bladder. Would you not wish your health care providers to consider this a significant problem worthy of aggressive treatment? Would you feel embarrassed about bringing up this problem to a nurse or prescribing practitioner? Would you be relieved when a nurse or prescribing practitioner asked you about this problem? Would you desire privacy when discussing this health care issue?

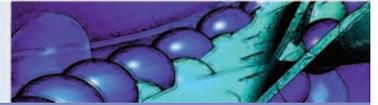

SPOTLIGHT ON...

Legal and Ethical

Spotting Sexual Abuse

Suspect abuse if you note any of the following during inspection of a client's genital area: bruises, cuts, tears, or bleeding, especially around the genitals, anus, buttocks, hips, and thighs. Emotional signs such as refusing a rectal examination, lack of eye contact during the examination, or extreme anxiety or guarding of body parts during the assessment may all be indicators of abuse. Document all signs of suspected abuse, and know your state's and institution's policies regarding reporting abuse. Remember that no client, regardless of age or gender, should be excluded from evaluation for sexual abuse.

TABLE 39-4 Health History Questions for Clients with Altered Elimination

AREA OF INQUIRY	SAMPLE QUESTION	SIGNIFICANT FINDINGS
Determine duration of problem	<ul style="list-style-type: none"> • How long have you been bothered with problems controlling your bladder or bowel? 	<ul style="list-style-type: none"> • Association of onset of urinary or fecal incontinence with injury; disorder of central nervous system, brain, or spine; pelvic trauma; vaginal delivery; onset of climacteric.
Determine type of urinary incontinence	<ul style="list-style-type: none"> • What activities make you leak? • Do you leak when you cough, sneeze, laugh, exercise, or walk? • Do you leak with a strong urge to urinate? • Do you leak with no sensation or warning? • How much do you typically leak? • Is it enough to dampen your underclothing? • Is it enough to saturate your underclothing, dress, or pants? • Is it enough to run down your legs and require a change of clothing? 	<ul style="list-style-type: none"> • Leakage with physical exertion is related to SUI. • Leakage associated with a sudden urge to urinate is related to detrusor hyperactivity (urge incontinence). • Leakage associated with no sensation or warning is generally associated with bypassing of sphincter (extraurethral incontinence). • SUI is typically associated with smaller volumes of leakage with each episode. • Urge incontinence often produces larger-volume leakage.
Determine type of fecal incontinence	<ul style="list-style-type: none"> • Do you have trouble controlling gas or liquid stool? 	<ul style="list-style-type: none"> • Fecal incontinence associated with motility disorders (dietary intolerance), low compliance of the rectal vault, or rectal urgency is associated with diarrhea. • Intermittent fecal incontinence associated with mild anal sphincter intolerance may cause loss of control only when coping with liquid stool or gas. Regular loss of solid stool is typically associated with central nervous system disorders or significant dysfunction of the anal sphincter mechanism.
Identify complicating factors of urinary incontinence	<ul style="list-style-type: none"> • Do you ever experience bladder (urine or urinary tract) infections? • Do you feel you completely empty your bladder? • Do you ever lose control of your bowels? • Do you ever seep stool? 	<ul style="list-style-type: none"> • Urinary tract infections are commonly associated with incontinence complicated by obstruction or urinary retention. • Combined fecal and urinary incontinence typically implies neurologic disorders, including altered mentation.
Identify complicating factors of fecal incontinence	<ul style="list-style-type: none"> • Are there any foods that routinely cause you to experience nausea, vomiting, or diarrhea? • Do you experience constipation? • Do you pass hardened stool? • How frequently do you move your bowels? 	<ul style="list-style-type: none"> • Intolerance of specific dietary elements (e.g., lactose) increases small bowel motility and the subsequent risk of incontinence. • The infrequent, difficult passage of hardened stool (constipation) increases the bacterial load within the rectum, creating a liquid stool around the hardened stool. This bacteria-laden, liquefied stool increases both rectal urgency and the risk of fecal incontinence.

(Continues)

TABLE 39-4 (Continued)

AREA OF INQUIRY	SAMPLE QUESTION	SIGNIFICANT FINDINGS
Identify bladder management program	<ul style="list-style-type: none"> How do you manage your leakage? 	<ul style="list-style-type: none"> Clients often experience complications of urinary incontinence, including altered skin integrity, shame, and humiliation. These can be prevented by using better containment devices.
Identify bowel management program	<ul style="list-style-type: none"> How do you evacuate (move) your bowels? Do you regularly use laxatives, suppositories or other stool softeners, or an enema to assist with a bowel movement? 	<ul style="list-style-type: none"> The normal individual may move the bowels as frequently as once each day or as little as once every 2–3 days. Clients with perceived or organic constipation frequently use laxatives, stool softeners, or enemas to assist with bowel movements. Clients with paralyzing neurologic lesions often must use a digital stimulation, an enema, or a suppository to stimulate a bowel movement.

Delmar/Cengage Learning

TABLE 39-5 Questions for Clients with Altered Patterns of Urinary Elimination

AREA OF INQUIRY	SAMPLE QUESTION	SIGNIFICANT FINDINGS
Diurnal voiding habits	<ul style="list-style-type: none"> How long can you postpone urination? Can you postpone urination for 2 hours? 	<ul style="list-style-type: none"> Diurnal frequency greater than every 2 hours
Nocturia (awakening from sleep to urinate)	<ul style="list-style-type: none"> How many times do you wake up at night and urinate? Does the urge to urinate interrupt your sleep? 	<ul style="list-style-type: none"> Nocturia greater than once per night in adults younger than 65 years old Nocturia greater than twice per night in older adults
Urinary incontinence	<ul style="list-style-type: none"> Do you leak urine or lose bladder control? Does this leakage cause any problems for you? 	<ul style="list-style-type: none"> Any leakage sufficient to be defined as a problem by the client or significant others
Urinary retention	<ul style="list-style-type: none"> Do you feel you completely empty your bladder? Have you ever been unable to urinate at all? 	<ul style="list-style-type: none"> Any episode of acute urinary retention; suspicion of chronic retention (incomplete emptying) significant when complicated by urinary tract infections or incontinence

Delmar/Cengage Learning

PHYSICAL EXAMINATION

The physical examination for elimination patterns focuses on functional issues associated with urinary or fecal incontinence and assesses the perineal and perianal areas. Functional evaluation begins with the interview and continues throughout the physical examination. Mental status can be evaluated by listen-

ing to the client's responses to questions and by observing interactions with others. When mental assessment reveals changes from normal or expected function, a more specific tool, such as the Mini-Mental Status Examination, may be administered (see Chapter 38 for a complete discussion of the Mini-Mental Status Examination).

Mobility and dexterity are evaluated by observation or by asking the client to perform simple tasks. Mobility may be evaluated by observing the client undress or move onto a table, chair, or bed. Dexterity is assessed by observing the client remove clothing; particular attention is paid to the manipulation of zippers, buttons, shoestrings, and snaps.

Inspect all four abdominal quadrants for symmetry, contour, shape, and skin color, noting masses, peristaltic waves, scars, venous patterns, stomas, and lesions. Peristaltic waves are normally not visible; however, observable peristalsis may be a sign of small or large bowel obstruction. Bowel obstructions may be caused by intrinsic or extrinsic compression of the bowel from a tumor, postsurgical adhesions, an ileus (obstruction of the bowel), or a volvulus (twisting of the intestine). Physical assessment findings may also include nausea followed by vomiting when the bowel obstructs, distended abdomen with hyperactive bowel sounds on auscultation above the obstruction, and acute spasms of pain lasting 5 to 15 minutes; with time, bowel sounds become hypoactive (Held-Warmkessel & Schiech, 2008). If the client is experiencing abdominal pain, the client may guard (tighten the abdominal muscles) on palpation; if this occurs, have the client flex the knees to relax the abdomen to provide for a complete palpation of the abdomen. Constipation or obstipation (intractable constipation) develops because the intestinal contents above the obstruction are not being passed.

The perineum is initially inspected for skin integrity. Among clients with severe urinary leakage, the characteristic odor of urine may be present, and the skin may show signs of a monilial rash (maculopapular, red rash with satellite lesions) or an ammonia contact dermatitis (papular rash with saturated, macerated skin). Among clients with severe fecal incontinence, the skin is frequently denuded, red, and painful to touch, particularly if it has been exposed to liquid stool. The integrity of the skin typically remains intact with mild to moderate fecal or urinary incontinence, although a monilial rash may be present. This monilial rash may involve the inner aspect of the thighs, and it frequently extends throughout the skin surface covered by a containment device.

The vaginal vault of the woman is inspected for signs of atrophic vaginitis and for bladder and urethral support. The atrophic vagina has a dry, thin, friable mucosa with a loss of rugae (regular folds of tissue observed in the normal vagina). It is tender to touch, pale, and cracks or bleeds easily. The vaginal introitus and vault may be quite small, and the client may be intolerant of even gentle efforts to distend the vagina for examination. Atrophic vaginal changes are important to assess because they are associated with SUI, irritative voiding symptoms, and urge incontinence.

Pelvic support is assessed in the woman because it is associated with pelvic muscle weakness. Loss of pelvic muscle tone is associated with pelvic descent, increasing the risk of urethral hypermobility or intrinsic sphincter deficiency. Both can lead to SUI or defects of the anal sphincter or rectocele, causing chronic constipation and incomplete evacuation of stool with defecation. Paravaginal support is assessed using a gloved hand or speculum. The posterior vaginal wall is supported using either a Sims speculum or a gloved finger

gently inserted into the vagina. The woman is asked to cough or strain down, and movement of the posterior vaginal wall is evaluated. Bulging of the anterior wall indicates a cystocele or loss of support of the bladder base. This maneuver is repeated, and the posterior vaginal wall is evaluated for the presence of a rectocele. Uterine prolapse is noted when the uterus or cervix migrates toward the vaginal introitus in response to physical exertion.

The sensations of the perineal area are assessed, using a small needle to evaluate sharp versus dull stimuli and using two probes to determine one- versus two-point discrimination. The bulbocavernosus reflex (BCR) is evaluated by gently tapping on the clitoris while observing the anal sphincter. A positive reflex will produce an anal “wink” or contraction of the perianal muscle. A weaker response is assessed by placing a gloved finger at the anus or by pelvic muscle electromyogram using patch or needle electrodes. Loss of sensations or absence of the BCR indicates neurologic damage associated with urinary incontinence or retention.

Careful inspection of the perianal area and a digital rectal examination are particularly important for men and women. The cheeks of the buttocks should be pulled apart and the anus and surrounding area visually inspected. The client may be asked to bear down and the anus inspected for prolapse or for gaping, indicating significant weakness of the anal sphincter. In both genders, the anal sphincter is assessed for tone and symmetry. The gloved, lubricated finger is gently inserted into the anal sphincter. The finger is rotated 360° and the tone of the external sphincter is assessed. In addition, the rectum is palpated for evidence of stool or the hardened, large mass of feces characteristic of fecal impaction. **Hemorrhoids**, perianal varicosities of the hemorrhoidal veins, may also be identified. The prostate is examined for size, consistency, and induration when urinary retention is suspected. Benign prostatic hyperplasia, a common cause of urinary retention in older men, produces a uniform enlargement of the prostate. In contrast, prostate cancer causes asymmetric enlargement or discrete, hard nodules.

When altered patterns of urinary or fecal elimination are suspected from the health history, a log or diary should be completed. The simple bladder log is kept over a long period of time to determine patterns of urinary elimination and patterns of incontinence. A more detailed log allows the nurse to evaluate fluid intake, client responses to prompted toileting, functional bladder capacity, and the estimated volume of an incontinent episode.

DIAGNOSTIC AND LABORATORY DATA

When significant urinary or fecal elimination problems are observed, further testing is needed to evaluate the underlying cause of the condition and to determine treatment options. When urinary incontinence exists, a dipstick **urinalysis** is obtained and evaluated for nitrites, leukocytes, hemoglobin, glucose, and specific gravity. When nitrites or leukocytes are present, a microscopic analysis is completed to determine the presence of white blood cells in the urine (**pyuria**) and bacteria in the urine (**bacteriuria**). Urine culture and

SPOTLIGHT ON...

Professionalism

Professionalism During the Rectal Assessment

The rectal examination may cause the client to feel uncomfortable or embarrassed. How would you handle the following situations if they were to occur during the rectal assessment?

- The client has an erection during the examination.
- The client loses bowel control.
- The client passes flatus during the examination.

sensitivity testing are completed and the client is treated for a urinary tract infection. If glucose is noted in the urine, the client may undergo further evaluation for diabetes mellitus, or methods of glucose control may be reviewed and adjusted in the client with known diabetes. If the **specific gravity** (the weight of urine compared with the weight of distilled water) of the urine is abnormally low (below 1.010), the volume of fluid consumed by the client over a 24-hour period is evaluated further. **Hematuria** (blood in the urine) may be noted.

More detailed diagnostic testing of lower urinary tract function may be obtained in cases of complex urinary retention or incontinence. Urodynamics is a set of tests that measure bladder and surrounding abdominal pressures. Pressure data are combined with electromyography of the pelvic muscles and urinary flow rate to determine lower urinary tract function during bladder filling and micturition.

Laboratory tests also may be obtained for select cases of fecal incontinence. A stool culture may be analyzed for ova and parasites, electrolytes, or culture when dietary intolerance or a GI infection is thought to be causing diarrhea and related incontinence. When anal sphincter weakness is suspected as a cause of fecal incontinence, anorectal manometry may be completed to further evaluate anal sphincter and rectal vault function. When pelvic muscle weakness and descent are thought to cause fecal incontinence, defecography (x-ray images of the rectal vault and anal sphincter obtained during defecation) or anorectal ultrasonography may be completed.

Although colonoscopy is the gold standard for colorectal cancer screening, there are several other screening tests available for colorectal cancer, including the fecal occult blood test, the immunochemical fecal occult blood test, flexible sigmoidoscopy, double-contrast barium enema, and computed tomography colonography. The American Cancer Society has developed colorectal screening guidelines based on risk factors; see Chapter 27 for additional information regarding colorectal screening and Chapter 28 for endoscopy procedures.

NURSING DIAGNOSIS

The following nursing diagnoses are frequently encountered in clients experiencing changes in urinary and bowel habits. These nursing diagnoses are based on NANDA's (2009) classification.

IMPAIRED URINARY ELIMINATION

Impaired urinary elimination is the state in which the individual experiences a disturbance in urine elimination. Defining characteristics include **dysuria** (painful urination), frequency, hesitancy, incontinence, nocturia, retention, and urgency. Altered urinary elimination patterns can result from multiple causes, including anatomic obstruction, sensory motor impairment, and urinary tract infection.

STRESS URINARY INCONTINENCE

Stress urinary incontinence is the state in which an individual experiences a loss of urine less than 50 mL occurring with increased abdominal pressure. Major characteristics include reported or observed dribbling with increased abdominal pressure. Minor characteristics may include urinary urgency and urinary frequency (more often than every 2 hours). The client may also be experiencing related factors such as degenerative changes in pelvic muscles and structural supports associated with increased age, high intra-abdominal pressure (e.g., obesity, gravid uterus), incompetent bladder outlet, overdistension between voidings, or weak pelvic muscles and structural supports.

REFLEX URINARY INCONTINENCE

The state in which an individual experiences an involuntary loss of urine, occurring at somewhat predictable intervals when a specific bladder volume is reached, is known as *Reflex urinary incontinence*. Major characteristics include no awareness of bladder filling, no urge to void or feelings of bladder fullness, and uninhibited bladder contraction or spasm at regular intervals. Related factors include a neurologic impairment (e.g., spinal cord lesion that interferes with conduction of cerebral messages above the level of the reflex arc).

URGE URINARY INCONTINENCE

Urge urinary incontinence is the state in which an individual experiences involuntary passage of urine occurring soon after a strong sense of urgency to void. Major characteristics include urinary urgency, frequency (voiding more often than every 2 hours), and bladder contracture or spasm. Minor characteristics include nocturia (more than two times per night), voiding small amounts (less than 100 mL) or large amounts (more than 550 mL), and inability to reach the toilet in time. Urge incontinence may be related to decreased bladder capacity (e.g., history of pelvic inflammatory disease, abdominal surgeries, indwelling urinary catheter), irritation of bladder stretch receptors causing spasm (e.g., bladder infection),

alcohol, caffeine, increased fluids, increased urine concentration, or overdistension of the bladder.

FUNCTIONAL URINARY INCONTINENCE

The state in which an individual experiences an involuntary, unpredictable passage of urine is called *Functional urinary incontinence*. Major characteristics include the urge to void or bladder contractions sufficiently strong to result in loss of urine before reaching an appropriate receptacle. Altered environment and sensory, cognitive, or mobility deficits may contribute to functional incontinence.

TOTAL URINARY INCONTINENCE

Total urinary incontinence is the state in which an individual experiences a continuous and unpredictable loss of urine. Major characteristics include constant flow of urine occurring at unpredictable times without distension, uninhibited bladder contractions or spasms, unsuccessful incontinence refractory treatments, and nocturia. Related factors include neuropathy that prevents transmission of the reflex that indicates bladder fullness; neurologic dysfunction causing triggering of micturition at unpredictable times; independent contraction of the detrusor reflex owing to surgery, trauma, or disease that affects spinal cord nerves; or anatomy (fistula).

URINARY RETENTION

The state in which the individual experiences incomplete emptying of the bladder is known as *Urinary retention*. Major characteristics for urinary retention include bladder distension and small, frequent voiding or absence of urine output. Minor characteristics include sensation of bladder fullness, dribbling, residual urine, dysuria, and overflow incontinence. High urethral pressure caused by a weak detrusor, inhibition of the reflex arc, a strong sphincter, and blockage are related factors for urinary retention.

CONSTIPATION

A state in which an individual experiences a change in normal bowel habits characterized by a decrease in frequency or passage of hard, dry stools is called *Constipation*. Defining characteristics include decreased activity level, frequency of less than the usual pattern, hard-formed stools, a palpable mass, reported feelings of pressure and fullness in rectum, and straining at stool. Other possible characteristics include abdominal pain, appetite impairment, back pain, headache, interference with daily living, and use of laxatives. Related factors for constipation are still under development by NANDA; some possible considerations may be change in daily routine and less than adequate fluid and dietary intake.

PERCEIVED CONSTIPATION

Perceived constipation is the state in which an individual makes a self-diagnosis of constipation and ensures a daily

bowel movement through abuse of laxatives, enemas, and suppositories. Major characteristics include expectation of daily bowel movement, with the resulting overuse of laxatives, enemas, and suppositories, and expected passage of stool at the same time every day. Related factors may include cultural or family health beliefs, faulty appraisal, or impaired thought processes.

DIARRHEA

Diarrhea is the state in which an individual experiences a change in normal bowel habits characterized by the frequent passage of loose, fluid, unformed stools. Defining characteristics include abdominal pain, cramping, increased frequency, increased frequency of bowel sounds, loose or liquid stools, and urgency. Other possible characteristics include change in the color of stools. GI, metabolic, nutritional, or endocrine disorders; infectious processes; tube feedings; fecal impaction; change in dietary intake; adverse effects of medications; and high stress levels may all contribute to diarrhea.

BOWEL INCONTINENCE

A state in which an individual experiences a change in normal bowel habits characterized by involuntary passage of stool is called *Bowel incontinence*. Related factors may include GI and neuromuscular disorders, colostomy, loss of rectal sphincter control, and impaired cognition.

OTHER DIAGNOSES

Other nursing diagnoses that may be important for clients experiencing alterations in elimination patterns include *Situational low self-esteem*, *Deficient knowledge*, *Risk for infection*, *Risk for impaired skin integrity*, and *Toileting self-care deficit*. Nursing diagnoses and the resulting plan of care need to be developed to ensure delivery of thoughtful nursing care for both the physical and psychosocial aspects of altered elimination patterns that may affect a client's well-being.

PLANNING AND OUTCOMES

The targeted outcomes for clients with alterations in elimination patterns center around restoring and maintaining regular elimination habits and preventing potential associated complications such as infections and altered skin integrity. Interventions that respond to the client's physical needs relating to maintaining skin health and fluid volume balance need to be developed, as well as strategies to address the client's psychosocial needs, such as countering deficient knowledge, enhancing self-esteem, and reducing or controlling anxiety.

The Nursing Outcomes Classification (NOC) (Moorhead, Johnson, Swanson, & Mass, 2008) presents nursing sets for *urinary continence*, *urinary elimination*, *bowel continence*, and *bowel elimination*. Each of the NOC sets is in the physiological health (I) domain. The primary continence scales span from never demonstrated to consistently demonstrated while

the primary elimination scales go from severely compromised to not compromised. *Urinary continence* (control of elimination of urine from the bladder) includes recognizing the urge to void, voiding greater than 150 mL each time in an appropriate receptacle, starting and stopping the stream, and emptying the bladder completely. *Urinary elimination* (collection and discharge of urine) refers to the elimination pattern and the urine odor, amount, color, and clarity. *Bowel continence* (control of passage of stool from the bowel) includes recognizing the urge to defecate, maintaining a predictable pattern of stool evacuation with adequate sphincter tone to control defecation, ingesting an adequate amount of fiber; and toileting independently. *Bowel elimination* (formation and evacuation of stool) refers to the elimination pattern, stool color and amount for the client's diet, and the passage of stool without aids.

The secondary scales go from severe to none to allow for rating the severity of important complications or symptoms. For example, the secondary scale for a urinary tract infection (<100,000 white blood count) refers to visible urine particles, pain with urination, urinary frequency, retention, and incontinence (stress, urge, and functional).

Client teaching is also a critical factor in planning care for clients with urinary and fecal complications. The nurse's role in educating clients concerning proper diet and exercise regimens to maintain urinary and fecal health is an important aspect of planning care. When ostomies are involved, clients and their families will need instruction on and demonstration of proper care and the warning signs of infection.

IMPLEMENTATION

The Nursing Interventions Classification (NIC) (Bulechek, Butcher, & Dochterman, 2008) for clients with alterations in urinary continence and elimination are as follows: bladder and habit training, catheterization, elimination management, incontinence care, retention care, and bladder irrigation. NIC interventions for clients with alterations in bowel continence and elimination include bowel incontinence care, bowel irrigation, management, and training.

MAINTAIN ELIMINATION HEALTH

The nursing management of altered patterns of urinary and bowel elimination begins with an understanding of the principles for general bladder and bowel health and by primary prevention of problems whenever feasible. All clients should be taught basic principles of fluid intake and urinary output, regular bowel evacuation, stool consistency, and altered patterns of elimination. The Client Teaching Checklists offer suggestions for maintaining urinary and bowel elimination patterns.

Fluid Intake

Clients should be taught to drink an adequate volume of fluid each day. The recommended daily allowance (RDA) for fluids is 30 mL/kg body weight, or roughly 1/2 oz/lb

CLIENT TEACHING CHECKLIST

Managing Altered Urinary Elimination

- Ensure adequate daily fluid intake (15 mL/lb body weight).
- Reduce or avoid bladder irritants.
- Reduce alcohol consumption.
- Stop smoking.
- Teach pelvic muscle exercises to women (Kegel exercises).

CLIENT TEACHING CHECKLIST

Managing Altered Fecal Elimination

- Understand the relationship between dietary and fluid intake and stool consistency.
- Understand the relationship between altered stool consistency and altered patterns of bowel elimination, including incontinence.
- Ensure adequate daily fluid intake (15 mL/lb body weight).
- Ensure adequate intake of dietary fiber.
- Establish regular schedule of defecation.
- Heed the urge to defecate.

body weight. In the average-sized adult, this equals 1500 to 2000 mL/d, although obese and thin individuals will vary from this range. Manipulation of the volume of fluid intake showed only a weak correlation with voluntary or incontinent episodes in the classical research regarding older women (Wyman, Elswick, Ory, Wilson, & Fantl, 1993). A person who experiences altered patterns of urinary elimination, particularly incontinence, is likely to reduce fluid intake in an attempt to manage the problem. Many clients reason that curtailing fluid intake will reduce urinary output and the risk of incontinence. Unfortunately, it will not. Systematic dehydration may increase rather than diminish the risk of urinary incontinence by promoting bacteriuria and by concentrating the urine, thereby enhancing its irritative properties when stored in the bladder. Dehydration also causes the body to compensate for a shortage of available fluids by reabsorbing fluids and sodium from the bowel, causing drying of the stool and constipation.

Diet

Persons with urinary incontinence or frequent urination associated with urgency should be taught to recognize potential bladder irritants. Specific foods and beverages irritate the bladder and produce frequent urination and bladder

discomfort in certain persons, while exerting relatively little effect among others. Foods or substances that may irritate the bladder are:

- Caffeinated beverages, carbonated drinks, and acidic fluids (including coffee and tea)
- Aspartame, particularly when added to a caffeinated or carbonated beverage
- Citrus fruits or juices
- Foods containing tomatoes or tomato-based sauces
- Chocolate
- Greasy or spicy foods

Dietary fiber may prevent constipation and increase the desire to defecate. The client is advised to increase the amount of fiber-rich foods in the diet, including grains, fruits, and vegetables (see Table 39-6). Remind the client that dietary fiber should be increased gradually; a sudden increase in fiber may produce bloating and abdominal discomfort. Clients with either chronic constipation or diarrhea may have to avoid certain foods that trigger symptoms. For example, clients with irritable bowel syndrome (IBS) may benefit from avoiding alcohol, caffeine, high-fat foods, excess fruit, sorbitol, and gas-producing vegetables, which may aggravate IBS symptoms (Brown-Guttovz, 2008).

Lifestyle and Prevention

For many clients, lifestyle and habits affect normal elimination patterns. Individual, social, family, and cultural variables play an important role in elimination. Proper nutrition, adequate rest and sleep, and regular exercise help maintain healthy elimination patterns. Clients with elimination problems can take measures to correct or alter the problem by modifying their lifestyle.

TABLE 39-6 Common Dietary Fiber Sources

Whole grains	Wheat, rye, oat, millet, buckwheat All-Bran cereal Shredded wheat cereal Popcorn Brown rice
Fruits	Apples, pears Blackberries, raspberries, strawberries Peaches, apricots Bananas
Vegetables	Beans Asparagus, broccoli, Brussels sprouts Carrots Garlic Acorn squash, zucchini squash
Delmar/Cengage Learning	

ALCOHOL AND TOBACCO USE Consumption of alcohol exerts significant effects on the bladder. Alcohol suppresses antidiuretic hormone (ADH) excretion by the hypothalamus, causing polyuria and increasing the risk of urinary leakage. In addition, the sedative effects of alcohol increase the risk of urinary incontinence, both while awake and during sleep. Alcohol irritates the intestines and bowels, causing inflammation. The irritant effect causes increased elimination of fluid in the stool, resulting in diarrhea. With chronic use of alcohol, inflammation results, causing enteritis or colitis.

Cigarette smoking also may irritate the bladder. Cigarette smoke may increase the risk of SUI because of its association with a chronic cough, and smoking is a significant risk factor for the development of bladder cancer. Smoking stimulates the bowel through the action of nicotine, present in tobacco, causing increased bowel tone and motility. The result is diarrhea.

STRESS MANAGEMENT Managing stress promotes healthy bowel and urinary elimination patterns. Acute and chronic stress affect both elimination systems. According to Hertig's (2007) study of IBS, stress has been implicated in contributing to the initiation and exacerbation of bowel discomfort symptoms in clients with IBS; in order to reduce GI symptoms, the treatment protocols for IBS should incorporate strategies that decrease stress and psychological distress. The bowel responds by increasing activity when the parasympathetic nervous system is stimulated. However, the longer lasting effect of norepinephrine causes slowing of the GI tract. In response to the effect of ADH, the kidneys retain fluid. The effect of ADH in combination with the effect of norepinephrine and epinephrine elevates the blood pressure. Using education and support, nurses can help clients manage stress.

Elimination Habits

The client is urged to establish a regular schedule of bowel elimination and to answer the desire to defecate. In the normal individual, the desire to move the bowel is transient and lost when avoided or ignored. Although occasional avoidance of the urge to defecate is a useful tool for continence, routine avoidance may predispose the client to constipation and reduce the efficiency of bowel evacuation. The urge to defecate is typically greatest after a meal, and it may be enhanced by dietary stimulants such as fiber or a caffeinated beverage or by light exercise. In an unfamiliar setting, such as the hospital, it is important to provide adequate privacy so that the client can heed the urge to defecate without undue interruption or embarrassment.

Encourage the client to establish a regular elimination pattern to prevent urinary incontinence. This can be successfully accomplished by using techniques such as relaxation and timing. The client, with the assistance of the nurse, establishes a voiding schedule. Once the client has met the goal of staying continent for the established time period, the interval between voidings can be lengthened. Within the interval between urinations, the client can use relaxation exercises to help manage the feelings of urgency.

UNCOVERING THE

Evidence

TITLE OF STUDY

“Daily Stress and Gastrointestinal Symptoms in Women with Irritable Bowel Syndrome”

AUTHOR

Vicky Hertig

PURPOSE

To examine the relationship of daily self-reported stress to gastrointestinal (GI) and psychological distress symptoms both across women and within a woman in a comparison group of women with IBS.

METHODS

Women with IBS were divided into subgroups based on bowel pattern and compared to a group of women without IBS. Self-reported stress measures; abdominal symptoms, bowel pattern, and intestinal gas; and psychological distress symptoms were obtained daily for 1 month. Across-women and within-woman analyses were used.

FINDINGS

There were significant across-women correlations among mean daily stress, psychological distress, and GI symptoms in the total IBS group and IBS bowel pattern subgroups. The across-women relationships between daily stress and GI symptoms were diminished when anxiety and depression were controlled in the analyses. Within-woman analyses showed little evidence of a relationship between day-to-day variations in stress; however, stress was strongly related to anxiety and depression.

IMPLICATIONS

GI symptom distress is associated with self-reported stress in women with IBS. Psychological distress moderates the effects of stress on GI symptoms. IBS treatment protocols that incorporate strategies that decrease stress and psychological distress are likely to reduce GI symptoms.

Hertig, V. (2007). Daily stress and gastrointestinal symptoms in women with irritable bowel syndrome. *Nursing Research*, 56(6), 399–406.

Positioning

Positioning of the client plays an important role in elimination. Sitting is the usual position for both men and women for bowel elimination. Sitting is also the usual position for women to urinate; standing is the position preferred by some men. Clients unable to use the toilet require assistance in accomplishing elimination. Devices such as the bedpan, commode, or urinal can be substituted (see Figures 39-5 and 39-6).

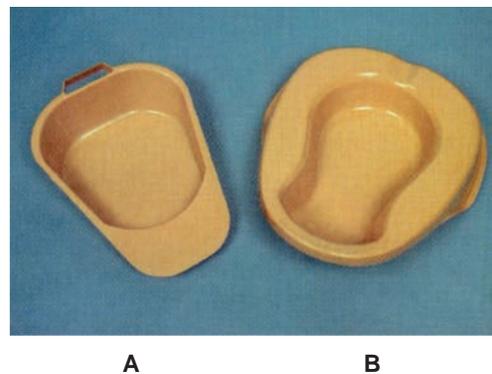

FIGURE 39-5 Types of Bedpans: A. Fracture; B. Regular
DELMAR/CENGAGE LEARNING

FIGURE 39-6 Male Urinal
DELMAR/CENGAGE LEARNING

Clients who use a bedpan need as comfortable a setting as possible; therefore, after placement of the bedpan, the head of the bed should be elevated to a 45° angle, unless contraindicated. The nurse may need to assist the client to cross the legs in order to create somewhat of a sitting position. Male clients who are unable to stand should have the head of the bed elevated to a 45° angle, unless contraindicated, while using the urinal. Procedure 39-1 outlines the steps in positioning and removing a bedpan.

Clients who are able to get out of bed but are unable to ambulate to the toilet can use a bedside commode, which resembles a toilet but is portable. Typically, the client is assisted to stand and pivot to the commode from the bed.

INITIATE EXERCISE REGIMEN

Regular exercise leads to good muscle tone and body metabolism. Exercise also stimulates the bowels to move regularly and leads to good urine production. Poor muscle tone can lead to impaired bladder muscle contraction and poor urination control. Pelvic muscle exercises are taught to manage SUI, and a strength training program is begun using principles of exercise physiology. Clients are taught to identify, isolate, and contract the pelvic muscles and to avoid contraction of distant muscle groups such as the thigh or abdominal muscles. Because clients frequently have difficulty isolating the pelvic muscles, biofeedback may be helpful. The nurse

teaches the client to perform a single exercise that combines maximal strength and endurance. The client is asked to perform a maximal strength contraction of the muscles “surrounding the urethra and vagina or rectum” for a count of 10, or approximately 6 seconds, followed by a rest period of equal length. The program begins with few contractions (typically 10 or fewer), and the number of repetitions is increased to a maximum of 35 to 50. The exercise regimen must be integrated into activities of daily living for maximal effectiveness. Pelvic muscle exercises, particularly when combined with biofeedback techniques, are typically taught by a specialty practice or advanced practice nurse with specific education in the management of the client with SUI.

Other management techniques are administered by the advanced practice or specialty practice nurse. These include transvaginal or transrectal electrical stimulation and placement of a vaginal pessary (a supportive device).

Inadequate tone in the abdominal muscles, diaphragm, and perineal muscles can cause difficulty in defecating. If a client is suffering from constipation, a regimen of walking or light recreational exercise should be recommended to promote peristalsis and defecation.

SUGGEST ENVIRONMENTAL MODIFICATIONS

Functional incontinence is managed by removing the barriers to toileting. The environment is manipulated to maximize opportunities for toileting, to minimize the impact of poor mobility, and to remove any environmental barriers. Clothing is carefully evaluated, and buttons, zippers, and multiple layers of clothing are exchanged for items that are simpler to remove. Mobility is maximized by selection of shoes with nonskid soles, and Velcro straps are preferred over strings when dexterity is compromised. The accompanying Community Considerations display on home care describes the effectiveness of environmental modifications in managing functional incontinence.

The nursing management of fecal incontinence begins with measures to normalize stool consistency because constipation and diarrhea increase the risk of incontinent episodes. The environment is also manipulated to minimize functional limitations to bowel elimination. Mobility is enhanced by assistive devices (canes, walkers) as needed and by altering seating and toilets to a height that allows optimal ease when transferring. Clothing is altered to minimize the time required for removal in preparation for defecation. Environmental barriers including poor lighting, narrow doorways, and slippery flooring are removed, or portable toileting facilities are made available.

INITIATE BEHAVIORAL INTERVENTIONS

A scheduled defecation program is used for clients with either a diminished ability to sense rectal distension or altered cognition who are unable to adequately respond to the presence of a bolus of stool in the rectum. The colon is cleansed of any excess stool, using an oral laxative or enema. The diet

Home Care

Mr. M is a 79-year-old with Parkinson's disease and altered cognition. His home health care nurse was consulted for management of his incontinence. A recent medical evaluation showed mild sensory urgency but failed to demonstrate significant urge or SUI. He is cared for primarily by Mrs. M, his 70-year-old wife. She reports using paper towels and baby diapers to contain his urinary leakage. She notes that he is wet every 2 to 3 hours and that he awakens her at night to urinate, but he is unable to postpone voiding long enough to reach the toilet.

On the basis of this health history, his home health care nurse diagnosed functional incontinence. She inspected the home and found that the bathroom was 35 steps from the couch and 15 steps from the bed. Mr. M walks with some difficulty, requiring a walker for assistance. He usually wears slick-soled shoes and trousers with two buttons and a zipper. The home health nurse recommended alterations in clothing and the addition of a handheld urinal for rapid urination. Mr. M has begun to wear stretch-band trousers that can be easily lowered for urination. A handheld urinal was offered when the urge to urinate was perceived, thereby dramatically reducing the number of incontinent episodes. Because of these interventions, no containment device was required for urination, and his incontinent episodes were reduced from two to three per day to fewer than one per week.

is altered to enhance the formation of a soft, solid stool, and supplemental bulk is added if indicated. Patterns of bowel elimination are evaluated, and the client is encouraged to defecate on this schedule if feasible. Otherwise, bowel elimination is scheduled after either a meal or another stimulant, such as a caffeinated beverage or a pharmacologic agent. The importance of heeding the urge to defecate is emphasized, and the client with altered cognition is prompted to defecate.

Clients with significant sensory and motor deficits of the rectum and anus typically require a scheduled defecation program combined with vigorous stimulation of defecation. Persons with a paralyzing neurologic disorder have significant loss of anal sphincter control, poor abdominal muscle control, and altered colonic mobility. As a result, defecation must be scheduled and vigorously stimulated to avoid impaction and fecal incontinence. The colon is cleansed and stool consistency is normalized at the outset of the program. A timetable for bowel elimination is identified. Because of the need for an extensive process for effective defecation, this program must consider the schedule of the client and significant

others as well as premonitory defecation patterns. The bowel is stimulated by a pharmacologic device, such as bisacodyl or a mini-enema.

Behavioral interventions play a primary role in the management of urge incontinence. Methods of biofeedback are used to teach the client to perform either a “quick flick” maneuver or a sustained contraction in response to an episode of precipitous urgency. The quick flick is a rapid, maximal contraction of the pelvic muscles held for 3 to 4 seconds, and a sustained contraction is held for 6 to 10 seconds. The client is instructed to stop, rather than rush to the bathroom, thus decreasing the risk of falling. Several quick flicks or a sustained contraction are then performed until the precipitous urge is controlled. At this point, the client is instructed to proceed to the bathroom at a normal pace, but without further delays.

Other techniques, including electrical stimulation and more extensive biofeedback training, also may be used for urge incontinence. These treatment programs are typically managed by the advanced practice or specialty practice continence nurse.

The management of urinary retention is influenced by the underlying cause and the severity of the symptom. Mild urinary retention caused by poor detrusor contractility or obstruction may be managed by timed voiding or by double voiding. Timed voiding is a strategy to reduce overdistension and loss of muscle tone in clients with diminished sensations of urinary urgency. The client is taught to urinate at specific intervals, typically every 3 to 4 hours. Double voiding is an attempt to increase the efficiency of urine evacuation by contracting the detrusor twice during micturition. The client is taught to void, rest on the toilet for 2 to 5 minutes, and void again.

Intermittent catheterization is used for moderate to severe urinary retention, when the residual urine volume is 50% or more of the total bladder capacity. Intermittent self-catheterization is taught using a clean technique. The client is taught to wash the hands and to locate and catheterize the urethra using a water-based soluble lubricant. Catheters may be cleaned and reused, and the client or significant other may catheterize without applying sterile gloves.

MONITOR SKIN INTEGRITY

Because problems with urinary functioning may result in disturbances in hydration and excretion of body wastes, the skin should be carefully assessed for color, texture, turgor, and the excretion of any wastes. The integrity of the skin in the perineal area also should be assessed. Problems with incontinence may result in severe excoriation.

The risk of altered skin integrity is significant. The client is taught to regularly clean and thoroughly dry the skin. Clients with fragile skin are advised to use a skin cleanser; otherwise, use of soap and water is adequate. After cleansing, the skin should be dried thoroughly. A hair dryer set on the low (cool) setting may be recommended.

When monitoring a client with diarrhea, the nurse should assess the perineal skin for altered integrity. After each defecation, the skin is routinely cleansed with tap water or a gentle

cleanser specifically designed for incontinence. Soap and water and abrasive cleaning techniques are avoided because they increase discomfort and the risk of altered skin integrity. The skin is then protected by application of a sealant or moisture barrier. Denuded skin is first treated with a pectin-based powder, followed by a skin sealant or moisture barrier.

APPLY A CONTAINMENT DEVICE

Condom Catheter

The condom catheter is a device that resembles a condom with a large-caliber connector at its distal end (see Figure 39-7). This is connected to a drainage bag via a leg bag or bedside container for urinary containment. Procedure 39-2 discusses the application of a condom catheter. Several types of condom catheters are available. The ideal device adheres to the penile skin without producing irritation and has sufficient elasticity to maintain its watertight seal whether the penis is in an erect or a flaccid state. Because of the potential for altered skin integrity, the condom catheter is reserved for severe SUI.

Men without adequate upper extremity dexterity may manage urine containment using a condom catheter. The bladder outlet resistance caused by detrusor sphincter dyssynergia must be managed by pharmacotherapy or by transurethral or laser sphincterotomy. A special device, the UroLume, also may be inserted. This device consists of a wire mesh that is inserted into the urethra via a special cystoscopic device and expanded at the membranous urethra. The wire mesh of the UroLume gently holds the sphincter open, promoting urine evacuation and preventing the deleterious effects of sphincter dyssynergia.

Incontinent and Dribble Pads

Many women attempt to contain urine with feminine hygiene pads. Although these pads effectively contain menstrual flow, they are not designed for urine loss. As a result, they must be changed frequently, and the risk of odor and soiling outer clothing is enhanced. Women with mild SUI typically benefit from a small incontinent pad that adheres to the undergarments. Unlike the feminine hygiene pad, the ideal incontinent pad contains Superabsorbents® that increase the product’s absorptive ability. Women with more

FIGURE 39-7 Condom Catheter DELMAR/CENGAGE LEARNING

severe SUI also may use a device that adheres to the undergarments. However, larger pads that are capable of absorbing up to 500 mL are recommended (see Figure 39-8). Only women with very severe leakage are advised to use an incontinent brief. It is important to remember that containment devices are considered temporary, and the ultimate goal is reduction or ablation of urinary leakage so that pads are not needed.

Men with mild SUI may use a “dribble pad,” a device that adheres to the undergarments and holds the penis in a specially designed pouch. More absorptive pads or incontinent briefs are reserved for severe cases. Two additional devices, the penile clamp and condom catheter, are also used for men with SUI. The penile clamp is a constrictive device that mechanically closes the pendulous urethra. The device is worn for a brief period and removed to prevent ischemia to local tissues. Because of the risk of necrosis and discomfort associated with the clamp, its use is limited.

Rectal Pouch and Rectal Tube

Severe diarrhea may justify the use of a rectal pouch or rectal tube to contain leakage and to protect the surrounding skin. The rectal pouch is a drainable pouch attached to an adhesive skin barrier that conforms to the perianal region. The pouch is attached to the perianal area, and any exposed skin

surfaces are carefully protected with a skin sealant. Attachment to intact skin is relatively straightforward; however, application to denuded skin is difficult, and consultation with an enterostomal therapist or incontinence nurse specialist is recommended.

The rectal tube is an alternative to the rectal pouch. A larger catheter (30 French) is passed into the rectum and attached to a large bedside drainage bag. Although the rectal tube is effective for short-term use, its safety when used over longer periods of time is uncertain.

INITIATE DIET AND FLUID THERAPY

It is important to remember that foods and beverages affect each client differently and that a very restrictive diet, designed to remove all potential irritants, is not reasonable for most clients. Therefore, nurses can teach the client to eliminate potential irritants one at a time and to judge the effects on patterns of voiding and urinary leakage.

Dietary fiber and fluid intake can be increased to promote the passage of soft, hydrated stool. The client who is unable or unwilling to obtain adequate fiber from the diet may be given a bulk laxative (such as Metamucil) or a bran mixture as a specific dietary supplement. The nurse should present options for taking this supplement, honoring the client’s preferences whenever feasible. Initially, 3 to 6 g of the supplement is administered, and the dosage is gradually increased until a soft, well-formed stool is obtained.

The initial management of diarrhea involves the removal of factors that predispose the individual to the condition and the maintenance of adequate fluid and electrolyte balance. The nurse collaborates with the client, prescribing practitioner, and dietitian to determine foods that contribute to diarrhea by malabsorption or inflammation of the GI tract. These foods are then eliminated from the diet or given with a substance (such as Lactaid) that renders them tolerable to the client. Persons with infectious diarrhea are given antimicrobials to destroy the pathogens that produce diarrhea. Anti-inflammatory drugs are administered as directed for diarrhea caused by inflammatory disorders of the bowel (see the accompanying Nursing Checklist on page 1252 on managing diarrhea).

Bulking agents may be used for clients with watery diarrhea. These agents absorb water in the stool and improve the consistency of feces. Antidiarrheal drugs, including diphenoxylate and loperamide, may be administered to reduce intestinal motility and increase absorption of water from the stool. However, these drugs are contraindicated in clients with infectious diarrhea because the diminished motility would enhance overgrowth of pathogens in the GI tract.

Clients who have significant diarrhea may experience mild to severe dehydration and electrolyte imbalances. Oral fluids are given as tolerated; beverages containing glucose and electrolytes are encouraged. In contrast, beverages that contain caffeine are avoided because they stimulate colonic motility. Individuals with severe fluid volume deficits and large-volume diarrhea may require intravenous fluid and electrolyte support until the diarrhea subsides.

NURSING PROCESS HIGHLIGHT

Implementation

Client Teaching

Teach the client and significant others to remove and reapply the condom. Teach skin inspection and care during routine changes for the hospitalized client. Advise the client to seek care if erosions, rashes, or other lesions are noted on the penis.

FIGURE 39-8 Incontinent Pads DELMAR/CENGAGE LEARNING

**NURSING CHECKLIST****Managing Diarrhea**

- Eliminate from the diet foods and beverages that contain malabsorbed substances.
- Administer antimicrobials for infectious diarrhea.
- Administer anti-inflammatory agents for irritative disorders of the bowel.
- Administer bulking agents for watery stools.
- Provide oral fluids as tolerated; offer fluids rich in electrolytes.
- Administer intravenous fluids and electrolytes as directed for clients unable to tolerate oral fluids.
- Monitor perianal skin for integrity.
- Apply skin barriers for altered integrity.
- Apply a rectal pouch or insert a rectal tube for severe, large-volume diarrhea.

ADMINISTER MEDICATIONS

Constipation is initially managed by assisting the individual to pass hardened stool or by removing any impacted feces (see the accompanying Nursing Checklist on managing constipation). Bowel evacuation is encouraged by an oral laxative, such as psyllium, a bulk-forming agent. Constipation resulting in an impaction requires mechanical disruption and removal, followed by a cleansing enema or an oral laxative. As an alternative, a pulsed irrigation enhanced evacuation (PIEE) system can be used to remove severe impaction. The PIEE uses gravity to deliver intermittent pulses of warmed saline to break up and remove hardened and impacted fecal material.

The medical management of SUI includes both OTC and prescription drugs. OTC medications such as Dexatrim without caffeine and Sudafed contain the α -adrenergic agonists phenylpropanolamine and pseudoephedrine, respectively,

**NURSING CHECKLIST****Managing Constipation**

- Remove hardened or impacted stool by mechanical means, cleansing enema, stimulant or laxative, or pulsed irrigation enhanced evacuation (PIEE).
- Increase dietary fiber and fluid until soft, formed stool is obtained.
- Administer supplemental bulk laxative for client intolerant of dietary fiber.
- Encourage light exercise to stimulate defecation.
- Encourage regular pattern of defecation.
- Teach client to stimulate defecation by mini-enema, oral laxative or stimulant, or digital stimulation as needed.

which increase urethral sphincter tone and relieve urinary leakage. Nurses teach the client the specific purpose of these medications, and they advise clients to ignore the dosage and scheduling recommendations on the medication container. Instead, the client is taught to take the medication only during waking hours rather than around the clock to reduce the risk of associated insomnia. Potential side effects associated with these medications, such as restlessness and hypertension, are discussed with the client, and blood pressure is monitored regularly.

SUI also may be managed by prescription medications including imipramine (Tofranil) and topical estrogens, often administered in combination. The client is taught the dosage and administration of each of these agents. Because imipramine has anticholinergic as well as α -adrenergic effects, clients are advised of additional side effects including dry mouth, the potential for constipation, and mydriasis. Women who are placed on topical or systemic estrogens are advised to seek ongoing care from their gynecologist, including routine vaginal examinations and Papanicolaou (Pap) smears.

Medications are often prescribed for urge urinary incontinence. Anticholinergics or antispasmodics relax detrusor muscle contractions by blocking the action of acetylcholine, by a local anesthetic effect, or by a direct effect on the detrusor muscle. Common agents, their actions, and potential side effects are described in Table 39-7 on page 1253. None of these agents will be effective unless the client is taught to adhere to a timed voiding schedule and to identify and limit the intake of bladder irritants.

Several pharmacologic agents may be used in the management of urinary retention. Finasteride, a 5- α -reductase inhibitor, is used to reduce prostatic size and related urinary retention. Men who take finasteride are taught the dosage and administration of the drug and its potential side effects, including impotence and loss of libido. Caregivers are cautioned to refrain from handling the drug without gloves because transdermal absorption and irritation of the skin have been reported.

α -Adrenergic blocking agents also may be used to manage urinary retention caused by prostatic hyperplasia, bladder neck dyssynergia, or detrusor-striated sphincter dyssynergia. Because of the risk of postural hypotension when the medication reaches a peak plasma level, the client is taught to take these drugs before bedtime. Clients are also taught to monitor for medication side effects, including postural dizziness during waking hours, fatigue, and headache. The significance of titrating the dosage of an α -blocking agent is emphasized, and the client is reminded that the dosage must be retitrated if the medication is inadvertently stopped for a period of more than 72 hours.

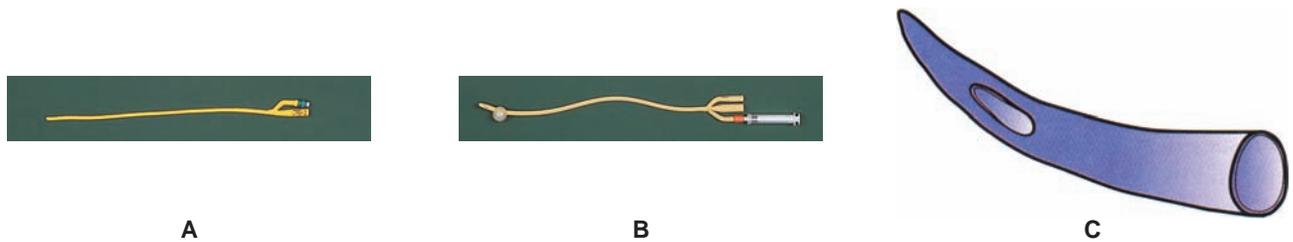

PERFORM CATHETERIZATION

Occasionally, an indwelling urethral or suprapubic catheter may be used to provide continuous drainage for reflex incontinence (see Figure 39-9 on page 1253). An indwelling catheter may be inserted for an acute episode of urinary retention or when other strategies to manage retention are ineffective.

TABLE 39-7 Common Anticholinergic and Antispasmodic Medications

AGENT	EFFECT	COMMON SIDE EFFECTS
Oxybutynin (Ditropan)	Relaxation of unstable detrusor contractions; reduces urgency; maximal therapeutic response requires 5–7 days	Dry mouth, slightly blurred vision, constipation, nightmares; confusion may occur in older adult clients
Propantheline (Pro-Banthine)	Relaxation of unstable detrusor contractions; maximal therapeutic response requires 3–5 days	Similar to oxybutynin effects
Hyoscyamine (Levsin)	Relaxation of unstable detrusor	Similar to oxybutynin effects, but dry mouth less pronounced

Delmar/Cengage Learning

**FIGURE 39-9** Types of Catheters: A. Foley Catheter; B. Three-Way Foley Catheter with Balloon Inflated; C. Coudé Catheter DELMAR/CENGAGE LEARNING

A catheter is chosen that minimizes urethral irritation and maximizes drainage from the bladder. A silicone or other inert-material catheter is preferred over a Silastic catheter coated with Teflon. A Lubricious-coated catheter (Bard Urological, Covington, GA) also may be used because of its hydrophilic nature and its low friction coefficient. The client is provided with a drainage bag with adequate storage capacity for overnight use (typically 2000 mL) and a leg bag with nonlatex straps when indicated.

The use of a coudé catheter is indicated when intermittent catheterization is needed. The coudé catheter works much like the other catheters; however, a distinguishing feature is that the tip of the catheter is more pointed and curved. The coudé catheter does not have a balloon; therefore, it cannot be used for a procedure requiring an indwelling catheter. Procedures 39-3 and 39-4 discuss catheterization. Procedures 39-5 and 39-6 discuss irrigation of catheters.

Intermittent Self-Catheterization

Women with reflex incontinence have more limited options for management because no effective condom device has been designed for women. Intermittent self-catheterization is chosen whenever feasible. This option is typically used in combination with pharmacotherapy for detrusor hyperreflexia. Indwelling catheterization is used only when other means of bladder management are not feasible.

Of the bladder management programs available for the client with a spinal injury or multiple sclerosis and reflex incontinence, intermittent self-catheterization is preferred when feasible. The nurse teaches the client with adequate upper extremity dexterity to perform self-catheterization, and the skill is also taught to significant others. Pharmacotherapy, consisting of an anticholinergic agent, imipramine, or (rarely) a calcium channel blocker, is frequently required to control hyperreflexic detrusor contractions.

ADMINISTER ENEMAS

Enema administration is a procedure used to introduce fluid into the lower bowel. The purpose of an enema is to cleanse the lower bowel, to assist in the evacuation of stool or flatus, or to instill medication. Table 39-8 on page 1254 outlines four types of enemas, along with the solutions and the indications for use of each.

Enemas can be large or small, depending on their purpose. Large-volume enemas, which typically contain 500 to 1000 mL fluid, are administered to cleanse the bowel. Small-volume enemas are used for the purpose of evacuating stool or instilling medications in the lower bowel. These are usually found as prepackaged solutions, which contain 150 to 240 mL fluid. Refer to Procedures 39-7 and 39-8 for guidelines on enema administration.

TABLE 39-8 Types of Enemas

TYPE	SOLUTION	INDICATION
Cleansing	Tap water Soap suds Normal saline	Evacuates lower bowel before diagnostic studies or surgery
Retention (should be retained for at least 30 min)	Emollient (oil)	Softens and lubricates stool for easy evacuation
Carminative (return flow)	Tap water Normal saline	Relieves distension due to flatus
Medication	Normal saline Sterile water mixed with prescribed medication	Depends on what medication is introduced

Delmar/Cengage Learning

TABLE 39-9 Solutions Used for Enemas

SOLUTION	ACTION	CLASS
Tap water	Stimulates and dilates bowel	Hypotonic
Soap suds	Dilates, stimulates, and irritates bowel	Hypotonic
Normal saline	Dilates, stimulates, and irritates bowel	0.9% (isotonic), <0.9% (hypotonic), >0.9% (hypertonic)
Oil	Lubricates, softens	Lubricant
Sodium polystyrene sulfonate (Kayexalate)	Reduces serum potassium	Hypertonic
Antibiotic	Cleansing	Antibacterial; may be hypertonic or hypotonic

Delmar/Cengage Learning

SAFETY FIRST

ENEMA ADMINISTRATION

If “enema till clear” is ordered, no more than 3 L fluid should be administered in any one series of enemas. Repeated enemas produce irritation of the bowel mucosa and perianal area as well as electrolyte loss and exhaustion. If returns are not clear, consult prescribing practitioner for further instructions.

Caution should be used when administering large-volume enemas because fluid and electrolyte imbalance can occur. This is related to the volume, frequency, and type of solution used. Large-volume enemas disrupt the normal flora of the bowel, predisposing the client to diarrhea as the bowels recover from this traumatic event. Provide yogurt with active cultures or buttermilk to help the client restore normal flora. Antibiotic enemas may disrupt vitamin K synthesis by intestinal flora. Supplemental vitamin K may be required until normal intestinal flora is restored. Table 39-9 lists the types of enema solutions and their effects.

INITIATE RECTAL STIMULATION

As an alternative to a scheduled defecation program, digital rectal stimulation may be used to regulate fecal elimination patterns. This process requires circular palpation of the anal sphincter and distal anus for 2 to 3 minutes. This process is

repeated in 20 minutes if defecation does not occur. Deep breathing is encouraged during defecation because it drops the diaphragm and partially compensates for the client’s inability to effectively strain.

Persons with chronic fecal incontinence due to anal sphincter incompetence may be managed with biofeedback techniques. These techniques are typically taught by a specialty or advanced practice nurse with specific training in the field of GI disorders and biofeedback techniques.

MONITOR ELIMINATION DIVERSIONS

When certain disease conditions cause a disruption to the normal flow of either urine or feces, the treatment is a temporary or permanent artificial opening (stoma) in the abdominal wall. Altered body image is a significant issue for clients with a urinary or bowel diversion. Client teaching should begin as soon as possible. Show the client the stoma and the associated equipment to care for the stoma so that this new situation can be integrated into the client’s body image. Nursing care should be provided in an open, accepting manner and encourage the client and family to express their feelings regarding the stoma.

Urinary Diversions

Surgically created extraurethral incontinence is managed by a pouch. The ileal conduit is, by design, an incontinent stoma constructed from a 10-cm segment of ileum. The ileum is

isolated from the fecal stream and connected to the ureters using a refluxing end-to-end anastomosis. A small incision is made in the abdominal wall, and a stoma is constructed from the distal portion of the ileal segment. An enterostomal nurse is consulted to advise the surgeon on stoma site selection and to assist the client to adapt to and learn to manage the stoma.

The continent urinary diversion is an alternative to the ileal conduit. It contains a reservoir for urinary storage and gains continence from various mechanisms. The urinary reservoir may be created from small or large bowel. The Kock Indiana and Florida pouches are types of pouches created from intestinal material. Continence is obtained by forming an abdominal reservoir. Continence also may be preserved by the Mitrofanoff technique, which uses a segment of appendix or ureter to create a continent stoma. Evacuation of urine from the reservoir relies on intermittent catheterization of these continent mechanisms. Orthotopic urinary diversions have been described in which the bladder is attached to the urethra, and its sphincter mechanism is relied on for continence. Urine may be evacuated from the urinary reservoir by catheterization of the urethra or by strain voiding.

Bowel Diversions

The fecal stream is diverted when tissue damage from trauma or inflammation necessitates the temporary bypassing of a segment of bowel or when permanent resection of malignant or irreversibly damaged tissue is necessary. Several techniques are used to create a fecal diversion; some require a pouch to contain fecal contents, whereas others maintain continence. Continent diversions rely on catheterization of an abdominal stoma or evacuation of stool from a pouch reservoir reattached to the anal sphincter.

Virtually any portion of the large and small intestine can be diverted or used to form a fecal reservoir. Some diversions rely on a **stoma**, a surgically created opening, for the evacuation of fecal contents. Stomas are primarily constructed in three ways. An *end stoma* is created by dividing the bowel and bringing the proximal segment to the abdominal wall. The end is rolled and attached to the skin of the abdomen, creating a red rosette of intestinal mucosa. A *double-barrel stoma* is constructed by dividing the bowel and bringing both the proximal and distal ends to the abdominal wall. The proximal end is used to evacuate stool. The distal stoma is typically referred to as a mucous fistula. The double-barrel stoma is designed for temporary diversion of the fecal stream. A *loop stoma* is created by opening the anterior aspect of the bowel either longitudinally or transversely. The resulting stoma has both proximal and distal openings that are separated by the posterior wall of the bowel loop. It is designed for temporary fecal diversion.

The fecal stream is diverted at the most distal point possible to maximize the absorption of food, fluid, and electrolytes and to preserve continence. The *ileostomy*, a diversion of the bowel at the level of the ileum, is more uncommon than it was during earlier decades. A permanent ileostomy is typically reserved for clients with severe Crohn's colitis, familial adenomatous polyposis, or chronic ulcerative colitis. A loop (temporary) ileostomy may be created as one stage in

an ileoanal reservoir procedure or as a staged procedure for the relief of obstruction of the ascending colon.

The colostomy is created as a permanent or temporary fecal diversion (see Figure 39-10). Among adults, it may be created in cases of severe diverticulitis or trauma. The most common indication for a permanent colostomy among adults is an abdominoperineal resection for lower rectal cancer. A temporary colostomy may be created from the transverse colon or (rarely) from the cecum. The descending or sigmoid colon may be temporarily diverted because of radiation proctitis or low rectal carcinoma. "Getting good adhesion of the skin barrier is vital to changing an ostomy pouch" (Kent, 2008). Procedure 39-9 outlines steps for changing a colostomy pouch.

Continent diversions of the bowel may incorporate the anus and sphincter or may be constructed with an abdominal stoma. The ileoanal reservoir is created in a staged approach. In the first stage an abdominal colectomy is completed, followed by a rectal mucosectomy, creation of a J- or S-shaped pouch comprising the anus and ileum, and a temporary end or loop ileostomy. In the second stage the temporary ileostomy is taken down and the ileoanal reservoir is reattached to the rectal stream.

The Kock continent ileostomy is performed as a single procedure. A colectomy and proctectomy are performed, and the distal 45 cm of the ileum is used to form the reservoir for the ileostomy and the abdominal stoma. The abdominal stoma is rendered continent by intussusception of the bowel that is stabilized to the abdominal wall by stapling or suturing the nipple valve. A polyglycolic acid mesh may be incorporated to provide further support if necessary. Effluent gathered in the reservoir is evacuated by catheterization through the abdominal stoma.

MONITOR SURGICAL MANAGEMENT

The surgical management for SUI differs for urethral hypermobility as compared with intrinsic sphincter deficiency. Urethral hypermobility is managed by a bladder suspension designed to prevent descent of the bladder base and urine loss during physical exertion. The selection of the procedure depends on the severity of the incontinence and client and surgeon preference.

FIGURE 39-10 Colostomy. What are some major nursing implications when caring for this client? DELMAR/CENGAGE LEARNING

Clients with adequate urethral support and intrinsic sphincter deficiency may be managed with a urethral bulking agent, such as Contigen (Bard Urological, Covington, GA). This product is a glutaraldehyde cross-linked collagen that improves continence by enhancing compressive elements of the urethral sphincter mechanism. It is injected transurethral, and local anesthesia with systemic sedation is often used in preference to general anesthesia. Women with a combination of urethral hypermobility and intrinsic sphincter deficiency may undergo a suburethral sling procedure, in which the proximal third of the urethra is supported with fascia or a synthetic material.

An artificial urinary sphincter device also may be used to manage intrinsic sphincter deficiency. This mechanical device allows the client to mechanically inflate and deflate a cuff that compresses underlying urethral tissues. Each of these procedures requires specific nursing care and instruction. See a urologic nursing text for a detailed discussion of the nursing care for urologic surgery.

Surgery plays only a limited role in the management of urge incontinence. Surgical procedures designed to denervate the bladder (sever nerves needed for contraction of the detrusor muscle) have had little success because of significant complications, including fecal incontinence and impotence among men. A surgically implanted device designed to deliver electrical stimulation to the lower urinary tract has been approved for use in the United States.

The management of reflex incontinence is complicated by the combination of urine leakage and urinary retention caused by detrusor sphincter dyssynergia. A bladder management program is chosen that both protects the upper urinary tracts from serious damage and maximizes continence.

Surgical reconstruction is sometimes used in the long-term management of reflex incontinence. An augmentation enterocystoplasty enlarges bladder capacity and alleviates reflex incontinence by converting the hyperreflexic bladder into a large, atonic bladder with improved storage ability. Unfortunately,

the augmented bladder rarely empties efficiently, and clients are advised that lifelong intermittent self-catheterization will be necessary after augmentation surgery. A continent or incontinent urinary diversion is occasionally used to manage urine elimination in the client with reflex incontinence. However, urinary diversion is completed only when bladder function threatens the normal function of the upper urinary tracts.

Fistulae and ectopia are managed by surgical closure whenever possible. When surgery is not feasible, a fistula may be treated by careful application of a sclerosing agent, such as tetracycline or doxycycline in suspension. The solution is applied monthly, and a skin barrier is used on the area surrounding the fistula to prevent scarring. The fistula that cannot be closed surgically or by sclerosing therapy must be managed by application of a urinary containment device and a preventive skin program.

Surgery or endoscopic procedures alleviate urinary retention caused by bladder outlet obstruction. Transurethral resection of the prostate, open prostatectomy, VaporTrode, visual ablation of the prostate, and other procedures are used to alleviate obstruction caused by benign prostatic hyperplasia. Transurethral incision of the bladder neck or transurethral sphincterotomy may be used for bladder neck or striated sphincter dyssynergia. Refer to a textbook of urologic nursing for the care following these specialized procedures.

COMPLEMENTARY AND ALTERNATIVE THERAPIES

“One of the largest health problems in the western world is in the area of elimination” (Barney, 1996, p. 57). When the body fails to eliminate waste that is full of toxic substances, other systems are compromised and the person becomes prone to illness. Herbalists view the role of the kidneys and the intestines in a holistic manner. The proper function of any part of the body is dependent on the effective elimination of waste products and toxins.

NURSING CARE PLAN

The Client Experiencing Constipation

CASE PRESENTATION

Mrs. M is a 30-year-old woman who sustained a complete spinal cord injury of the seventh cervical vertebra 2 years before this hospital admission. She currently manages her bowels by enemas every 5 to 7 days when she notes pressure and distension of her abdomen. She has frequent episodes of fecal incontinence, described as passage of moderate amounts of black, watery stool. She manages these episodes by administering one or two enemas, followed by passage of a large volume of odorous, dark feces. She denies any problems with bowel control before her spinal injury, stating that she moved her bowels every other day, typically after breakfast. Currently, she reports fluid intake of 3 to 4 glasses per day. She eats primarily meats, white breads, some pastas, and one portion of vegetables per day. She does not routinely eat cereals or fruits or supplement her diet with bulk laxatives.

(Continues)

NURSING CARE PLAN (Continued)

ASSESSMENT

- Inadequate fluid intake
- Inadequate fiber intake
- Presence of large impaction in the rectum

NURSING DIAGNOSIS 1: *Constipation* related to spinal cord injury and neurogenic bowel

NOC: Bowel elimination

NIC: Constipation/impaction management

NURSING DIAGNOSIS 2: *Bowel incontinence* related to fecal impaction, altered stool consistency, and neurogenic bowel

NOC: Bowel continence

NIC: Bowel training

EXPECTED OUTCOME

The rectum will be cleansed of impaction.

INTERVENTION/RATIONALE

1. Administer PIEE until impaction is disrupted. Bowel is clear of impacted stool as assessed by digital examination.

EXPECTED OUTCOME

Stool will be soft and formed.

INTERVENTIONS/RATIONALES

1. Encourage dietary intake of fiber-rich foods, including one serving of cereal per day, one serving of fruit, and two servings of vegetables.
2. Increase fluid intake to 15 mL/lb body weight; encourage water intake to equal at least 50% of fluids.
3. Administer supplemental bulk laxatives (Metamucil) if client is unable to alter diet to meet needs for fiber.

Stool will be soft, formed feces without impacted or dry, hardened material.

EXPECTED OUTCOME

A regular routine for bowel elimination will be established.

INTERVENTIONS/RATIONALES

1. Begin a bowel program every other day.
2. Determine time for evacuation with client; encourage defecation after breakfast, based on premorbid bowel elimination pattern.
3. Encourage bowel evacuation program after meal if premorbid schedule is not feasible with current activities.

Bowel evacuation will occur every other day after a meal, based on client's activities of daily living, preferences, and premorbid bowel elimination patterns.

EXPECTED OUTCOME

Bowel management program will cause completed elimination of feces from rectum.

INTERVENTIONS/RATIONALES

1. Begin stimulated, scheduled bowel evacuation program using an oral laxative, mini-enema, and digital stimulation program.
2. Discuss program with client and significant others, giving description of each stimulation program, time required, cost implications, and advantages and disadvantages.

(Continues)

NURSING CARE PLAN (Continued)

Client will completely evacuate the bowel using a stimulation or timed management program.

EXPECTED OUTCOME

Fecal incontinent episodes will be alleviated.

INTERVENTIONS/RATIONALES

1. Teach client relationship among stool consistency, regularity of evacuation, fecal impaction, and fecal continence.
2. Advise client to consult nurse specialist or gastroenterologist if fecal incontinent episodes persist despite regulation of bowel management program.
3. Warn client that occurrence of diarrhea may predispose to acute transient fecal incontinence.

Fecal incontinent episodes will be reduced by greater than 50%.

Gladstar (2001) states that “longevity herbs are not life extenders; what they will do is increase quality of life, so that you feel better and better as you grow older” (p. 19). Dandelion leaf and nettle are considered longevity herbs that maintain the health and vitality of the kidneys. Herbs that aid the functions of the urinary system are:

- *Diuretics*: dandelion root and leaf (refer to Chapter 34 for a full discussion of this herb) and cleavers
- *Antiseptics*: bearberry, birch, boldo, buchu, celery seed, couch grass, juniper, and yarrow
- *Antimicrobials*: echinacea root (refer to Chapter 32 for a full discussion of this herb) and wild indigo root
- *Demulcents*: corn silk, couch grass, and marshmallow leaf

Herbs that possess other properties may also be used. For example, urinary astringents (Beth root, horsetail, and plantain tormentil) can be used to treat blood in the urine caused by minor problems and to aid the healing of lesions. Antilithics (gravel root, hydrangea, and stone root) can be used to prevent the formation of or aid in the removal of calculi (stones or gravel) in the urinary system.

Both urinary and fecal elimination are reliant upon sufficient amounts of fiber and fluids in the diet. Poor nutrition is the most common cause of chronic constipation (Barney, 1996). These herbs are helpful in relieving constipation: *Cascara sagrada* bark, senna, ginger root, butternut root bark, and burdock root. Also, milk thistle, a cholagogue, may be used to aid liver function and to enhance bile flow to soften stools.

Cascara sagrada bark is an old Indian remedy to encourage peristalsis and tone relaxed muscles of the digestive tract. Senna is the most widely used stimulant laxative when compared to synthetic drugs (Barney, 1996). *Cascara* and senna should be combined with aromatics and carminatives such as

licorice and ginger root to increase palatability and reduce gripping. Ginger root aids in digestion and enhances bile flow from the liver. Burdock root is a mild laxative and an effective diuretic; its cleansing effect goes beyond its diuretic and laxative properties as it promotes perspiration and strengthens the liver.

Psyllium seed and flaxseed are also helpful for constipation. Psyllium seed must be taken with a full glass of water. Mineral oil should not be taken on a regular basis because, if inhaled, it can damage the lungs, and it reduces the absorption of fat-soluble vitamins (Balch, 2006).

EVALUATION

Evaluating the effectiveness of the nursing interventions is an ongoing process. The client’s level of maintenance or restoration of elimination patterns and return to an appropriate level of independence are indicators of success. When evaluating these aspects, it is important for the nurse to reassess how realistic the original identified outcomes were, especially for goals that were not met, and to modify the target outcomes accordingly. Prevention of skin breakdown and infection can also be used to determine the appropriateness of the plan of care. Client understanding of procedures and self-care should be evaluated to determine the effectiveness of teaching plans, and modifications should be made to address deficiencies and ongoing learning needs. If support persons were included in the teaching process, their understanding of skills and competence with procedures should also be measured. If additional care or teaching is deemed necessary, clients should be given referrals for community and other resources to support their continuing learning needs.

PROCEDURE 39-1

Assisting with a Bedpan or Urinal

EQUIPMENT

- Bedpan (regular or fracture) or urinal
- Disposable gloves
- Bedpan cover
- Toilet paper
- Washcloth and towel

ACTION

RATIONALE

POSITIONING A BEDPAN

1. Close curtain or door.
2. Wash hands/hand hygiene; apply gloves.
3. Lower head of bed so client is in supine position.
4. Elevate bed.
5. Assist client to side-lying position using side rail for support.
6. Place bedpan under buttocks. Place a fracture pan with the lower end near the client's lower back region. Place large bedpans with the opening near the client's thighs.
7. While holding the bedpan with one hand, help the client roll onto his or her back, while pushing against the bedpan (toward the center of the bed) to hold it in place (see Figure 39-11).
8. Alternative: Help the client raise the hips using the overbed trapeze, and slide the pan in place. Alternative: If the client is unable to turn or raise hips, use a fracture pan instead of a bedpan. With a fracture pan, the flat side is placed toward the client's head (see Figure 39-12).

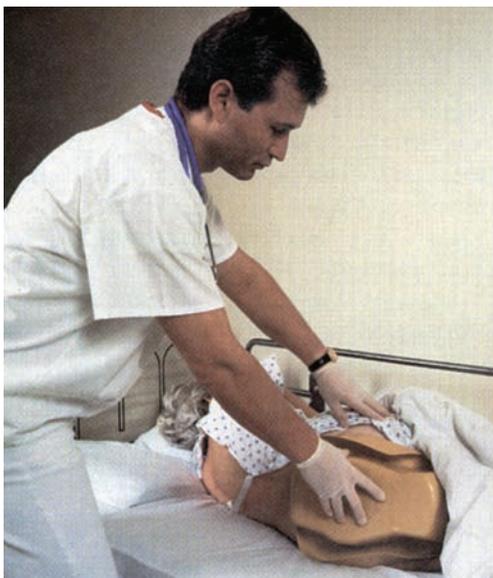

FIGURE 39-11 Place the bedpan against the client's buttocks while rolling client to side. DELMAR/CENGAGE LEARNING

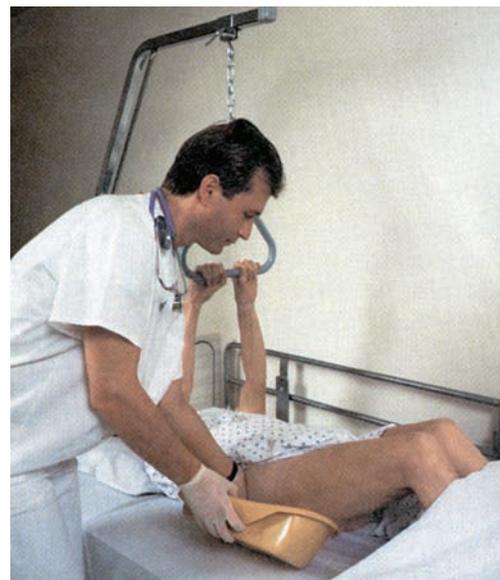

FIGURE 39-12 Slip the bedpan under the client's buttocks while client lifts himself or herself with the trapeze. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 39-1 Assisting with a Bedpan or Urinal (Continued)

ACTION	RATIONALE
9. Check placement of bedpan by looking between client's legs. 10. If indicated, elevate head of bed to 45° angle or higher for comfort.	9. May prevent spillage from misalignment of bedpan. 10. Check order of prescribing or qualified practitioner; bed remains flat if client has a spinal cord injury or spinal surgery. Elevating the head of bed creates a more normal elimination position.
11. Place call light within reach of client; place side rails in upright position, lower bed, and provide privacy. 12. Remove gloves; wash hands/hand hygiene.	11. Privacy allows for a more comfortable elimination environment; elevated side rails provide for safety. 12. Reduces transmission of microorganisms.
POSITIONING A URINAL	
13. Repeat Actions 1 and 2. 14. Lift the covers and place the urinal so the client may grasp the handle and position it. If the client cannot do this, you must position the urinal and place the penis into the opening (see Figures 39-13 and 39-14). 15. Remove gloves; wash hands/hand hygiene.	13. See Rationales 1 and 2. 14. Ensures proper placement of the urinal and reduces the risk of spillage. 15. Reduces transmission of microorganisms.
REMOVING A BEDPAN	
16. Wash hands; apply gloves/hand hygiene. 17. Gather toilet paper and washing supplies. 18. Lower head of bed to supine position. 19. While holding bedpan with one hand, roll client to side and remove the pan, being careful not to pull or shear skin sticking to the pan and being careful not to spill contents. 20. Assist with cleaning or wiping; always wipe with a front to back motion.	16. Reduces transmission of microorganisms. 17. Having supplies at the bedside allows smooth and safe completion of the procedure. 18. Increases client's ability to move to side-lying position. 19. Prevents possible spillage of bedpan contents. 20. Client may not be able to clean self; wiping from front to back decreases chances of cross-contamination from anus to urethra.

FIGURE 39-13 Lift the covers and place the urinal. Allow the client to adjust the position. DELMAR/CENGAGE LEARNING

FIGURE 39-14 If the client is unable to assist, place the penis into the opening of the urinal. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 39-1 Assisting with a Bedpan or Urinal (Continued)

ACTION	RATIONALE
21. Empty bedpan (observe and measure urine output and check for occult blood if ordered), clean bedpan, and store it in proper place; if bedpan is to be emptied outside client's room, cover it during transport.	21. Promotes privacy and decreases the chance of spilling contents. Assessment of types of stool evaluates for constipation and diarrhea.
22. Remove soiled gloves; wash hands.	22. Reduces transmission of microorganisms.
23. Allow client to wash hands.	23. Provides for physical hygiene and comfort.
24. Place call light within reach; recheck that side rails are in the upright position.	24. Ensures client safety and comfort.
25. Wash hands/hand hygiene.	25. Reduces transmission of microorganisms.
REMOVING A URINAL	
26. Wash hands/hand hygiene; apply gloves.	26. Reduces transmission of microorganisms.
27. Empty the urinal, measuring urine output if ordered, rinse the urinal, and replace it within client's reach. Observe odor and color of urine before discarding.	27. Provides a way to measure client's output. Keeping the urinal within reach promotes client autonomy. Helps evaluate for concentrated urine, infection, and renal problems.
28. Remove soiled gloves; wash hands.	28. Reduces transmission of microorganisms.
29. Allow client to wash hands.	29. Provides for physical hygiene and comfort.
30. Place call light within reach; recheck that side rails are in the upright position.	30. Ensures client safety and comfort.
31. Wash hands/hand hygiene.	31. Reduces transmission of microorganisms.

delegation tip

This skill is routinely delegated to ancillary personnel who have been trained in Standard Precautions and proper body positioning and to report color, odor, and amount of output to the nurse.

nursing tips

Elimination is normally a private function done without assistance. However, during periods of immobility and illness, assistance is needed. The main focus of the nurse is to provide maximum comfort and privacy to lessen the client's embarrassment.

PROCEDURE 39-2

Applying a Condom Catheter

EQUIPMENT

- Condom catheter kit with adhesive strip
- Urinary drainage bag
- Clean gloves
- Basin with warm water and soap
- Towel and washcloth

(Continues)

PROCEDURE 39-2

Applying a Condom Catheter (Continued)

ACTION	RATIONALE
<ol style="list-style-type: none"> 1. Wash hands/hand hygiene. 2. Protect the client's privacy by closing the door and pulling curtains around the bed. 3. Position the client in a comfortable position, preferably a supine position, if tolerated by the client. Raise the bed to a comfortable height for the nurse. 	<ol style="list-style-type: none"> 1. Reduces transmission of microorganisms. 2. Allows privacy for the client. 3. The client will be more comfortable and tolerate the procedure more readily; a supine position facilitates the cleaning and application of the catheter. Raising the bed to a comfortable height promotes good body mechanics.
<ol style="list-style-type: none"> 4. Apply latex-free gloves. 	<ol style="list-style-type: none"> 4. Gloves should be worn to prevent the possible transmission of microorganisms when there is a chance of coming into contact with any body fluid.
<ol style="list-style-type: none"> 5. Fold the client's gown across the abdomen, and pull the sheet up over the client's legs. 6. Assess the client's penis for any signs of redness, irritation, or skin breakdown. 	<ol style="list-style-type: none"> 5. Provides minimal exposure of the client, thereby reducing the client's embarrassment. 6. The client may require an indwelling catheter if there is a significant amount of skin breakdown. Assessment will give baseline data for comparison with future assessments.
<ol style="list-style-type: none"> 7. Clean the client's penis with warm soapy water. Retract the foreskin on the uncircumcised male and clean thoroughly in folds. 	<ol style="list-style-type: none"> 7. Removes microorganisms present in any drainage or feces that could enter the urinary meatus and cause a urinary tract infection. Avoids trapping microorganisms in folds around the meatus.
<ol style="list-style-type: none"> 8. Return the client's foreskin to its normal position. 	<ol style="list-style-type: none"> 8. Failure to return the foreskin to a normal position can lead to swelling of the penis and possible constriction.
<ol style="list-style-type: none"> 9. Shave any excess hair around the base of the penis if required by institutional policy. 	<ol style="list-style-type: none"> 9. Prevents additional discomfort from the adhesive strip when the condom catheter is removed. Also prevents hair from catching on the adhesive strip, causing discomfort.
<ol style="list-style-type: none"> 10. Rinse and dry the area. 	<ol style="list-style-type: none"> 10. Moist warm environment can lead to the growth of microorganisms.
<ol style="list-style-type: none"> 11. If a condom kit is used, open the package containing the skin preparation. Wipe and apply skin preparation solution to the shaft of the penis. If the client has an erection, wait for termination of erection before applying the catheter. 	<ol style="list-style-type: none"> 11. Preparation solutions protect the client's skin from irritation. An erection may occur from manipulation of the penis while cleaning the area. This is a normal reaction and will terminate in a few minutes.
<ol style="list-style-type: none"> 12. Apply the double-sided adhesive strip around the base of the client's penis in a spiral fashion. The strip is applied 1 inch from the proximal end of the penis. Do not completely encircle the penis or tightly encompass penis. 	<ol style="list-style-type: none"> 12. Applying the adhesive in a spiral fashion does not compromise circulation of the penis. Encircling the penis can constrict the penis, impair circulation, and cause edema.
<ol style="list-style-type: none"> 13. Position the rolled condom at the distal portion of the penis and unroll it, covering the penis and the double-sided strip of adhesive. Leave a 1- to 2-inch space between the tip of the penis and the end of the condom (see Figure 39-15 on page 1263). 	<ol style="list-style-type: none"> 13. The condom sticks to the adhesive and remains in place. The extra spacing prevents pressure and erosion of the tip of the penis.

(Continues)

PROCEDURE 39-2 Applying a Condom Catheter (Continued)

ACTION

FIGURE 39-15 Unroll condom catheter to the base of the penis. DELMAR/CENGAGE LEARNING

14. Gently press the condom to the adhesive strip (see Figure 39-16).
15. Attach the drainage bag tubing to the catheter tubing. Make sure the tubing lies over the client's legs, not under. Secure the drainage bag to the side of the bed below the level of the client's bladder or to the client's leg.
16. Determine that the condom and tubing are not twisted.
17. Cover the client.
18. Dispose of the used equipment in appropriate receptacle and wash hands.
19. Return the client's bed to the lowest position, and reposition client to comfortable or appropriate position.
20. Empty the bag, measure the client's urinary output, and record every 4 hours. After procedure, remove gloves; wash hands/hand hygiene.
21. Remove the condom once a day to clean the area and assess the skin for signs of impaired skin integrity.

delegation tip

Application of a condom catheter may be delegated to properly trained ancillary personnel. The need for condom drainage and the ongoing assessment of the client's skin condition should be followed up by the nurse.

nursing tips

- *If the client gets an erection, assure him that it is not unusual when applying a condom catheter.*
- *Wrap the adhesive strip in a spiral fashion to avoid constricting the penis and causing skin breakdown.*

RATIONALE

FIGURE 39-16 Secure the condom catheter with the adhesive strip. DELMAR/CENGAGE LEARNING

14. Enables the condom to adhere evenly to the adhesive strip.
15. The drainage bag is positioned below the level of the client's bladder to prevent reflux of the urine onto the penis and microorganisms from entering the penis. The tubing is placed over the leg to promote urine flow away from the client. Constant exposure to urine and moisture can irritate the penis.
16. If the condom or tubing is twisted, the urine cannot flow out and the condom will leak or fall off.
17. Maintains privacy of the client.
18. Reduces transmission of microorganisms.
19. Reduces potential injury from falls.
20. Records output and prevents bag from becoming overly full or too heavy. Reduces transmission of microorganisms.
21. Promotes hygiene and reduces the possibility of skin breakdown.

PROCEDURE 39-3

Inserting an Indwelling Catheter: Male

EQUIPMENT

- Indwelling or straight catheter with drainage system
- Sterile catheterization kit
- Adequate lighting source
- Disposable gloves
- Blanket or drape
- Soap and washcloth
- Warm water
- Towel
- Forceps

ACTION

RATIONALE

PERFORMING URINARY CATHETERIZATION: MALE CLIENT

- | | |
|--|---|
| <ol style="list-style-type: none"> 1. Gather the equipment needed (see Figure 39-17). Read the label on the catheterization kit. Note if the catheter is included in the kit and, if so, what type it is. Gather any supplies you will need that are not in the prepackaged kit. Wash hands/hand hygiene. 2. Provide for privacy and explain procedure to client. 3. Set the bed to a comfortable height to work, and raise the side rail on the side opposite you. 4. Assist the client to a supine position with legs slightly spread (see Figure 39-18). 5. Drape the client's abdomen and thighs if needed. 6. Ensure adequate lighting of the penis and perineal area. 7. Wash hands/hand hygiene; apply latex-free disposable gloves; and wash perineal area. 8. Remove gloves and wash hands/hand hygiene. 9. Open the catheterization kit, using aseptic technique. Use the wrapper to establish a sterile field (see Figure 39-19 on page 1265). | <ol style="list-style-type: none"> 1. Promotes efficiency in the procedure. Kits from various manufacturers come with different equipment. The catheter may or may not be packaged in the kit. Sterile gloves and the urine drainage bag may also need to be gathered separately. 2. Promotes cooperation and client dignity. 3. Promotes proper body mechanics and ensures client safety. 4. Relaxes muscles and allows visualization of the area to facilitate insertion of the catheter. 5. Promotes client comfort and warmth. 6. Facilitates proper execution of technique. 7. Reduces transfer of microorganisms. Avoids reaction to latex. 8. Reduces transfer of microorganisms. 9. Provides an area for the sterile equipment to be laid out and assembled. Establish the sterile field close to the client. If the client is able to cooperate, the sterile field can sometimes be established in the open area between the client's legs. |
|--|---|

FIGURE 39-17 Catheterization Kit DELMAR/CENGAGE LEARNING

FIGURE 39-18 Assist the client to a supine position with legs spread. This allows visualization of the area and relaxes muscles. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 39-3 Inserting an Indwelling Catheter: Male (Continued)

ACTION

FIGURE 39-19 Open the catheterization kit, using the wrapper to establish a sterile field between the client's legs. DELMAR/CENGAGE LEARNING

10. If the catheter is not included in the kit, carefully drop the sterile catheter onto the field using aseptic technique. Add any other items needed.
11. Apply sterile gloves. These may be included in the kit.
12. Place the fenestrated drape from the catheterization kit over the client's perineal area with the penis extending through the opening.
13. If inserting a retention catheter, attach the syringe filled with sterile water to the Luer-Lok tail of the catheter. Inflate and deflate the retention balloon. Detach the water-filled syringe (see Figure 39-20).
14. Attach the catheter to the urine drainage bag if it is not preconnected.
15. Generously coat the distal portion of the catheter with water-soluble, sterile lubricant and place it nearby on the sterile field.
16. With your nondominant hand, gently grasp the penis and retract the foreskin (if present). With your dominant hand, cleanse the glans penis with a povidone-iodine solution or other antimicrobial cleanser (see Figure 39-21 on page 1266).
17. Hold the penis perpendicular to the body and pull up gently.
18. Inject 10 mL sterile, water-soluble lubricant (use a 2% Xylocaine lubricant whenever feasible) into the urethra.

RATIONALE

FIGURE 39-20 Inflate and deflate the retention balloon to test its patency. DELMAR/CENGAGE LEARNING

10. Prevents contamination of the sterile equipment and the sterile field.
11. Prevents contamination of the sterile equipment and the sterile field.
12. Provides a sterile field at the procedural site. Prevents accidental contamination from adjacent areas.
13. Tests the patency of the retention balloon. Detaching the syringe prevents accidental inflation during catheter insertion.
14. The catheter and drainage system may be preconnected; otherwise, it is connected before catheterization to avoid exposing the client to ascending infection from an open-ended catheter.
15. Facilitates catheter insertion.
16. Removes dirt and minimizes the risk of urinary tract infection by removing surface pathogens.
17. Facilitates catheter insertion by straightening urethra.
18. Avoids urethral trauma and discomfort during catheter insertion and facilitates insertion.

(Continues)

PROCEDURE 39-3 Inserting an Indwelling Catheter: Male (Continued)

ACTION

FIGURE 39-21 Cleanse the glans penis with a povidone-iodine solution. DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 39-22 Steadily insert the catheter. DELMAR/CENGAGE LEARNING

19. Holding the catheter in the dominant hand, steadily insert the catheter about 8 inches, until urine is noted in the drainage bag or tubing (see Figure 39-22).
20. If the catheter will be removed as soon as the client's bladder is empty, insert the catheter another inch, place the penis in a comfortable position, and hold the catheter in place as the bladder drains.
21. If the catheter will be indwelling with a retention balloon, continue inserting until the hub of the catheter (bifurcation between drainage port and retention balloon arm) is met (see Figure 39-23).
22. Reattach the water-filled syringe to the inflation port.

19. Provides a visual confirmation that the catheter tip is in the bladder.
20. The catheter needs to be inserted far enough to allow complete bladder drainage but not so far as to possibly irritate the bladder, causing spasms.
21. Ensures adequate catheter insertion before retention balloon is inflated.
22. Provides a sterile method of inflating the retention balloon.

FIGURE 39-23 Continue inserting the catheter until the bifurcation between the drainage port and the retention balloon reaches the end of the penis. This ensures the retention balloon will be fully in the bladder prior to inflation.

DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 39-3 Inserting an Indwelling Catheter: Male (Continued)

ACTION

FIGURE 39-24 Inflate the retention balloon. DELMAR/CENGAGE LEARNING

23. Inflate the retention balloon with sterile water per manufacturer's recommendations or the prescribing practitioner's orders (see Figure 39-24).
24. Instruct the client to immediately report discomfort or pressure during balloon inflation; if pain occurs, discontinue the procedure, deflate the balloon, and insert the catheter farther into the bladder. If the client continues to complain of pain with balloon inflation, remove the catheter and notify the client's health care provider.
25. Once the balloon has been inflated, gently pull the catheter until the retention balloon is resting snug against the bladder neck (resistance will be felt when the balloon is properly seated).
26. Secure the catheter according to institutional policy. Securing it to either the client's thigh or abdomen is generally acceptable.
27. Place the drainage bag below the level of the bladder. Do not let it rest on the floor (see Figure 39-25 and Figure 39-26 on page 1268). Secure the drainage tubing to prevent pulling on the tubing and the catheter.
28. Remove gloves; dispose of equipment. Wash hands/hand hygiene.
29. Help client adjust position. Lower the bed.
30. Assess and document the amount, color, odor, and quality of urine.

RATIONALE

FIGURE 39-25 Place the drainage bag tubing over the leg. DELMAR/CENGAGE LEARNING

23. Ensures retention of the balloon. Retention catheters are available with a variety of balloon sizes. Use a catheter with the appropriate size balloon.
24. Pain or pressure indicates inflation of the balloon in the urethra; further insertion will prevent misplacement and further pain or bleeding.
25. Maximizes continuous bladder drainage and prevents urine leakage around the catheter.
26. Prevents excessive traction from the balloon rubbing against the bladder neck, inadvertent catheter removal, or urethral erosion.
27. Maximizes continuous drainage of urine from the bladder (drainage is prevented when the drainage bag is placed above the abdomen).
28. Prevents transfer of microorganisms.
29. Promotes client comfort and safety.
30. Monitors urinary status.

(Continues)

PROCEDURE 39-3
Inserting an Indwelling Catheter: Male (Continued)

FIGURE 39-26 Place the drainage bag below the level of the bladder, but do not rest it on the floor. DELMAR/CENGAGE LEARNING

delegation tip

The skill of male urinary catheterization may be delegated to properly trained ancillary personnel depending on institution policies. The nurse is responsible to evaluate the client for contraindications to delegating this procedure, such as the risk for a difficult or traumatic insertion. The nurse may then decide to perform the procedure or to defer to the prescribing practitioner.

nursing tips

If the client suddenly complains of sharp pain, pull the catheter back and notify the prescribing practitioner.

PROCEDURE
39-4

Inserting an Indwelling Catheter: Female

EQUIPMENT

- Indwelling or straight catheter with drainage system
- Sterile catheterization kit
- Adequate lighting source
- Disposable gloves
- Blanket or drape
- Soap and washcloth
- Warm water
- Towel

ACTION

RATIONALE

PERFORMING URINARY CATHETERIZATION: FEMALE CLIENT

1. Gather the equipment needed (see Figure 39-27 on page 1269). Read the label on the catheterization kit. Note if the catheter is included in the kit and, if so, what type it is. Gather any supplies you will need that are not in the prepackaged kit.

1. Promotes efficiency in the procedure. Kits from various manufacturers come with different equipment. The catheter may or may not be packaged in the kit. Sterile gloves and the urine drainage bag may also need to be gathered separately.

(Continues)

PROCEDURE 39-4 Inserting an Indwelling Catheter: Female (Continued)

ACTION

FIGURE 39-27 Catheterization Kit DELMAR/CENGAGE LEARNING

2. Provide for privacy and explain procedure to client. Assess for allergy to povidone-iodine. Wash hands/hand hygiene.
3. Set the bed to a comfortable height to work, and raise the side rail on the side opposite you.
4. Assist the client to a supine position with legs spread and feet together or to a side-lying position with upper leg flexed (see Figure 39-28).
5. Drape the client's abdomen and thighs for warmth if needed.
6. Ensure adequate lighting of the perineal area.
7. Wash hands/hand hygiene; apply disposable gloves.
8. Wash perineal area.
9. Remove gloves and wash hands.
10. Open the catheterization kit, using aseptic technique. Use the wrapper to establish a sterile field (see Figure 39-29).

FIGURE 39-29 Open the catheterization kit, using the wrapper to establish a sterile field between the client's legs. DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 39-28 Position the client supine with legs spread. DELMAR/CENGAGE LEARNING

2. Promotes cooperation and client dignity.
3. Promotes proper body mechanics and ensures client safety.
4. Relaxes muscles and allows visualization of the area to facilitate insertion of the catheter.
5. Promotes client comfort and warmth.
6. Facilitates proper execution of technique.
7. Reduces transfer of microorganisms.
8. Reduces transfer of microorganisms.
9. Reduces transfer of microorganisms.
10. Provides an area for the sterile equipment to be laid out and assembled. Establish the sterile field close to the client. If the client is able to cooperate, the sterile field can sometimes be established in the open area between the client's legs.

(Continues)

PROCEDURE 39-4 Inserting an Indwelling Catheter: Female (Continued)

ACTION	RATIONALE
11. If the catheter is not included in the kit, drop the sterile catheter onto the field using aseptic technique. Add any other items needed.	11. Prevents contamination of the sterile equipment and the sterile field.
12. Apply sterile gloves. These may be included in the kit.	12. Prevents contamination of the sterile equipment and the sterile field.
13. If inserting a retention catheter, attach the syringe filled with sterile water to the Luer-Lok tail of the catheter. Inflate and deflate the retention balloon. Detach the water-filled syringe.	13. Tests the patency of the retention balloon. Detaching the syringe prevents accidental inflation during catheter insertion.
14. Attach the catheter to the urine drainage bag if it is not preconnected.	14. The catheter and drainage system may be preconnected; otherwise, connect it before catheterization to avoid exposing the client to ascending infection from an open-ended catheter.
15. Generously coat the distal portion of the catheter with water-soluble, sterile lubricant and place it nearby on the sterile field (see Figure 39-30).	15. Facilitates catheter insertion.
16. Place the fenestrated drape from the catheterization kit over the client's perineal area with the labia visible through the opening.	16. Provides a sterile field at the procedural site. Prevents accidental contamination from adjacent areas.
17. Gently spread the labia minora with the fingers of your nondominant hand and visualize the urinary meatus (see Figure 39-31).	17. Helps locate the meatus, so the catheter can be placed in the correct spot.
18. Holding the labia apart with your nondominant hand, use the forceps to pick up a cotton ball soaked in povidone-iodine, and cleanse the periurethral mucosa. Use one downward stroke for each cotton ball and dispose. Keep the labia separated with your nondominant hand until you insert the catheter (see Figure 39-32 on page 1271).	18. Cleans the area and minimizes the risk of urinary tract infection by removing surface pathogens.

FIGURE 39-30 Open the lubrication package and squeeze lubricant onto the sterile field, where it will be used to lubricate the catheter. DELMAR/CENGAGE LEARNING

FIGURE 39-31 Spread the labia minora and visualize the urinary meatus. DELMAR/CENGAGE LEARNING

PROCEDURE 39-4 Inserting an Indwelling Catheter: Female (Continued)

ACTION

FIGURE 39-32 Using forceps, pick up a cotton ball soaked in povidone-iodine. Cleanse the periurethral mucosa. DELMAR/CENGAGE LEARNING

19. Holding the catheter in the dominant hand, steadily insert the catheter into the meatus until urine is noted in the drainage bag or tubing (see Figure 39-33).
20. If the catheter will be removed as soon as the client's bladder is empty, insert the catheter another inch and hold the catheter in place as the bladder drains.
21. If the catheter will be indwelling with a retention balloon, continue inserting another 1 to 3 inches.
22. Reattach the water-filled syringe to the inflation port.
23. Inflate the retention balloon using manufacturer's recommendations or according to the prescribing practitioner's orders (see Figure 39-34).

RATIONALE

FIGURE 39-33 Steadily insert the catheter into the meatus. DELMAR/CENGAGE LEARNING

19. Provides a visual confirmation that the catheter tip is in the bladder.
20. The catheter needs to be inserted far enough to allow complete bladder drainage, but not so far as to possibly irritate the bladder, causing spasms.
21. Ensures adequate catheter insertion before retention balloon is inflated.
22. Provides a sterile method of inflating the retention balloon.
23. Ensures retention of the balloon. Retention catheters are available with a variety of balloon sizes. Use a catheter with the appropriate size balloon.

FIGURE 39-34 Inflate the retention balloon. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 39-4 Inserting an Indwelling Catheter: Female (Continued)

ACTION

FIGURE 39-35 Tape the catheter to the client's thigh.
DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 39-36 Monitor the urinary status. Assess and document the amount, color, and quality of urine. DELMAR/CENGAGE LEARNING

- | | |
|--|--|
| <p>24. Instruct the client to immediately report discomfort or pressure during balloon inflation; if pain occurs, discontinue the procedure, deflate the balloon, and insert the catheter farther into the bladder. If the client continues to complain of pain with balloon inflation, remove the catheter and notify the client's health care provider.</p> <p>25. Once the balloon has been inflated, gently pull the catheter until the retention balloon is resting snugly against the bladder neck (resistance will be felt when the balloon is properly seated).</p> <p>26. Tape the catheter to the abdomen or thigh snugly, yet with enough slack so it will not pull on the bladder (see Figure 39-35).</p> <p>27. Place the drainage bag below the level of the bladder. Do not let it rest on the floor. Make sure the tubing lies over, not under, the leg.</p> <p>28. Remove gloves, dispose of equipment, and wash hands.</p> <p>29. Help client adjust position. Lower the bed.</p> <p>30. Assess and document the amount, color, odor, and quality of urine (see Figure 39-36).</p> <p>31. Wash hands/hand hygiene.</p> | <p>24. Pain or pressure indicates inflation of the balloon in the urethra; further insertion will prevent misplacement and further pain or bleeding.</p> <p>25. Maximizes continuous bladder drainage and prevents urine leakage around the catheter.</p> <p>26. Prevents excessive traction from the balloon rubbing against the bladder neck, inadvertent catheter removal, or urethral erosion.</p> <p>27. Maximizes continuous drainage of urine from the bladder (drainage is prevented when the drainage bag is placed above the abdomen).</p> <p>28. Prevents transfer of microorganisms.</p> <p>29. Promotes client comfort and safety.</p> <p>30. Monitors urinary status.</p> <p>31. Reduces transmission of microorganisms.</p> |
|--|--|

delegation tip

Insertion of an indwelling catheter in a female client is generally not delegated to ancillary personnel. The delegation of this skill depends on institution policy and the availability of licensed staff versus properly trained ancillary personnel.

nursing tips

- If you miss and insert the catheter in the vagina, leave it there so you can use it as a landmark to find the meatus on the next try.
- If the client is unable to tolerate lying supine with her legs spread, attempt to visualize the meatus with the client in the side-lying position.
- Be aware that a client with a history of sexual assault or trauma may be anxious or apprehensive about the procedure.
- The lithotomy position can be used for women with a history of knee or hip disease or surgery.

PROCEDURE
39-5
Irrigating an Open Urinary Catheter
EQUIPMENT

- Sterile gloves
- Sterile cover for the end of the drainage tubing
- Disposable, water-resistant drape or towel
- Sterile Asepto or Toomey syringe with container for irrigant
- Sterile antiseptic swabs
- Sterile irrigating solution (labeled with date and time of opening, if opened)

ACTION
RATIONALE

- | | |
|--|---|
| <ol style="list-style-type: none"> 1. Verify the need for bladder or catheter irrigation. 2. For prn catheter irrigation, palpate for full bladder and check current output against previous totals. 3. Verify prescribing practitioner's orders for type of irrigation and irrigant as well as amount. 4. If repeat procedure, read previous documentation in the record. 5. Assemble all supplies (see Figure 39-37). Wash hands/hand hygiene. 6. Premedicate client if ordered or needed. 7. Provide teaching to the client as needed, based on what client already knows. 8. Assist the client to a dorsal recumbent position. 9. Wash hands/hand hygiene. 10. Provide for client privacy with a closed door or curtain. 11. Empty the collection bag of urine. | <ol style="list-style-type: none"> 1. Ensures that procedure is being applied correctly; reduces unnecessary opening of the system and risk of infection. 2. If irrigation is on a prn basis, it may not be needed currently. 3. Ensures accuracy in the provision of treatment. 4. Establishes prior client responses to prior teaching done by staff. 5. Having all supplies in room enables the nurse to maintain sterility of supplies once they are opened and laid out. 6. Increases comfort for the procedure. 7. Knowledge will increase client cooperation and decrease anxiety. 8. Facilitates the flow of irrigant into the bladder. 9. Decreases transmission of microorganisms. 10. Decreases client anxiety. 11. Starting with an empty collection bag makes it easier to identify clots or sediment passed as a result of irrigation. |

PROCEDURE 39-5 Irrigating an Open Urinary Catheter (Continued)

ACTION

FIGURE 39-38 Expose the retention catheter. DELMAR/CENGAGE LEARNING

RATIONALE

FIGURE 39-39 Place a water-resistant drape under the retention catheter. DELMAR/CENGAGE LEARNING

- | | |
|---|---|
| <ol style="list-style-type: none"> 12. Expose the retention catheter, and place the water-resistant drape underneath it (see Figures 39-38 and 39-39). 13. Open the sterile syringe and container. Stand it up carefully in or on the wrapper and add 100 to 200 cc sterile diluent without touching or contaminating the tip of the syringe or the inside of the receptacle. 14. Open the end of the antiseptic swab package, exposing the swab sticks. 15. Open the sterile cover for drainage tube. 16. Apply the sterile gloves. 17. Disinfect the connection between the catheter and the drainage tubing. 18. After the disinfectant dries, loosen the ends of the connection. 19. Grasp the catheter and tubing 1 to 2 inches from their ends, with catheter in the nondominant hand. 20. Fold the catheter to pinch it closed between the palm and last three fingers; use the thumb and first finger to hold the sterile cap for the drainage tube. 21. Separate the catheter and tube, covering the tube tightly with the sterile cap. 22. Fill the syringe with 30 cc for catheter irrigation or 60 cc for bladder irrigation. Insert the tip of the syringe into the catheter and gently instill the solution into the catheter (see Figures 39-40 and 39-41 on page 1275). 23. Clamp catheter if ordered (medicated solution). If not clamped, irrigant may be released into a collection container or aspirated back into the syringe (see Figure 39-42 on page 1275). 24. If the bladder or catheter is being irrigated to clear solid material, repeat irrigation until return is clear. | <ol style="list-style-type: none"> 12. Protects the bedclothes and client from urine and body fluids. 13. Enables nurse to maintain sterility of gloves once they are applied. 14. Enables nurse to maintain sterility of gloves once they are applied. 15. Enables nurse to maintain sterility of gloves once they are applied. 16. Maintains sterility of the procedure. 17. Minimizes risk of contaminating the system. 18. Enables the nurse to open the connection without accidentally contaminating either end. 19. Maintains sterility of the procedure and allows the nurse to be positioned to use the dominant hand for the syringe. 20. Allows for one nurse to handle all equipment simultaneously, thus maintaining sterility. 21. Maintains sterility of equipment. 22. Catheter can be irrigated with 30 cc of solution, minimizing bladder discomfort, while irrigating a bladder takes 60 cc. 23. Fine sediment or clear irrigant with medication can run freely; material with more solids (sediment or clots) may need gentle aspiration. 24. Clearing the catheter completely in this irrigation means a lower total number of irrigations and less opening of the system, thus decreasing the risk of infection. |
|---|---|

(Continues)

PROCEDURE 39-5 Irrigating an Open Urinary Catheter (Continued)

ACTION

FIGURE 39-40 Separate the catheter and tube. DELMAR/CENGAGE LEARNING

FIGURE 39-42 Irrigant is released into a collection container. DELMAR/CENGAGE LEARNING

25. Reconnect system and remove sterile gloves. Wash hands (see Figure 39-43).
26. When irrigation is finished, record type of returns and total amount of irrigation fluid used.
27. Monitor client for pain, urine color and clarity, any solid material passed, and total intake and output.
28. Wash hands/hand hygiene.

delegation tip

The task of irrigating a urinary catheter cannot be delegated, as it requires the skills and problem-solving abilities of a nurse.

nursing tips

Never try to force irrigation of any tube. If the tube does not irrigate smoothly, stop and assess the situation.

RATIONALE

FIGURE 39-41 Insert the tip of the syringe into the catheter, and gently instill the solution. DELMAR/CENGAGE LEARNING

FIGURE 39-43 Reconnect the tubing to the catheter. DELMAR/CENGAGE LEARNING

25. Maintains sterility of system and reduces transmission of microorganisms.
26. This information can be compared to evaluate status of the urinary tract and catheter. A catheter that is being frequently irrigated for sediment, for instance, may need to be changed, or medications may need to be adjusted.
27. Monitoring output after irrigation evaluates the efficacy of the treatment.
28. Reduces transmission of microorganisms.

PROCEDURE
39-6
Irrigating the Bladder Using a Closed-System Catheter
EQUIPMENT

- Three-way indwelling catheter or Y adapter
- IV pole
- Ordered irrigation solution
- Sterile gloves
- Closed-irrigation tubing
- Large urine collection bag
- Antiseptic swabs

ACTION
RATIONALE
INTERMITTENT BLADDER IRRIGATION USING A STANDARD RETENTION CATHETER AND A Y ADAPTER

- | | |
|--|---|
| <ol style="list-style-type: none"> 1. Wash hands/hand hygiene. 2. Close privacy curtain or door. 3. Hang the prescribed irrigation solution from an IV pole. 4. Insert the clamped irrigation tubing into the bottle of irrigant and prime the tubing with fluid, expelling all air and reclamping the tube. 5. Prepare sterile antiseptic swabs and sterile Y connector if one will be used. 6. Apply sterile gloves. 7. Clamp the urinary catheter. 8. Unhook the drainage bag from the retention catheter. 9. While holding the drainage tubing and the drainage port of the catheter in your nondominant hand, cleanse both the tubing and the port with antiseptic swabs. 10. Connect one port of the Y connector to the drainage port of the retention catheter. 11. Connect another port of the Y adapter to the drainage tubing and bag. 12. Attach the third port of the Y adapter to the irrigant tubing. 13. Unclamp the urinary catheter and establish that urine is draining through the catheter into the drainage bag. 14. To irrigate the catheter and bladder, clamp the drainage tubing distal to the Y adapter. | <ol style="list-style-type: none"> 1. Prevents spread of microorganisms. 2. Provides privacy. 3. Different solutions may be ordered depending on the results the prescribing practitioner desires. Bladder irrigant is generally packaged in 2000- to 4000-mL bottles. 4. Prevents introduction of air into the bladder. 5. Prevents contamination of sterile gloves and field. 6. Minimizes the client's risk of infection when connecting the irrigant to the catheter and drainage system. 7. Prevents urine leakage onto the bed linens. 8. Allows the Y adapter to be inserted into the system. 9. Reduces risk of contamination and infection. 10. Provides a bifurcation for irrigant to instill as well as urine to drain. 11. Collects the urine and drained irrigant. This may be the established urine collection bag or a new sterile bag that is large enough to hold the increased volume of drainage. 12. Instills the irrigant into the closed system. 13. If the urine does not flow freely after unclamping, the catheter may have become clogged with a clot or debris. Notify the client's prescribing practitioner of the lack of urine drainage. 14. Prevents the irrigant from bypassing the bladder and flowing directly into the drainage bag. |

ACTION

RATIONALE

FIGURE 39-44 Clamp the irrigant tubing. DELMAR/CENGAGE LEARNING

- | | |
|---|---|
| <p>15. Instill the prescribed amount of irrigant.</p> <p>16. Clamp the irrigant tubing (see Figure 39-44).</p> <p>17. If the prescribing practitioner has ordered the irrigant to remain in the bladder for a measured length of time, wait the prescribed length of time.</p> <p>18. Unclamp the drainage tubing and monitor the drainage as it flows into the drainage bag.</p> | <p>15. The bladder normally feels full when it contains approximately 300 cc of urine. If a prescribed amount of irrigant was not ordered, do not instill more than 150 cc of irrigant. If the client has undergone bladder surgery, do not instill irrigant without knowing the specific amount ordered.</p> <p>16. Prevents further instillation of irrigant.</p> <p>17. Some irrigation solutions contain medication and are meant to remain in contact with the bladder wall for a prescribed length of time.</p> <p>18. Assess the drainage for volume, color, clarity, and the presence of any clots or debris.</p> |
|---|---|

CLOSED BLADDER IRRIGATION USING A THREE-WAY CATHETER

- | | |
|--|--|
| <p>19. Wash hands/hand hygiene.</p> <p>20. Close privacy curtain or door.</p> <p>21. Explain procedure to the client. Answer questions and provide support.</p> <p>22. Hang prescribed irrigation solution from an IV pole.</p> <p>23. Insert the clamped irrigation tubing into the bottle of irrigant and prime the tubing with fluid, expelling all air and reclamping the tube (see Figure 39-45 on page 1278).</p> <p>24. Prepare sterile antiseptic swabs and any other sterile equipment needed.</p> <p>25. Apply sterile gloves (see Figure 39-46 on page 1278).</p> | <p>19. Reduces transmission of microorganisms.</p> <p>20. Provides privacy.</p> <p>21. Reduces anxiety and uncertainty associated with the procedure.</p> <p>22. Different solutions may be ordered depending on the results desired. Bladder irrigant is generally packaged in 2000- to 4000-mL bottles.</p> <p>23. Prevents introduction of air into the bladder.</p> <p>24. Prevents contamination of sterile gloves and field.</p> <p>25. Minimizes the client's risk of infection when connecting the irrigant to the catheter and drainage system.</p> |
|--|--|

(Continues)

PROCEDURE 39-6 Irrigating the Bladder Using a Closed-System Catheter (Continued)

ACTION

RATIONALE

FIGURE 39-45 Insert the clamped irrigation tubing into the bottle of irrigant. DELMAR/CENGAGE LEARNING

FIGURE 39-46 Apply sterile gloves. DELMAR/CENGAGE LEARNING

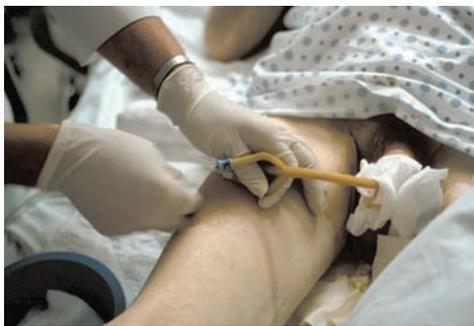

FIGURE 39-47 Remove the cap from the irrigation port of the three-way catheter. DELMAR/CENGAGE LEARNING

FIGURE 39-48 Attach the irrigation tubing, remove the clamp from the catheter, and observe for urine drainage. Carefully observe the drainage for color, clarity, and the presence of debris. DELMAR/CENGAGE LEARNING

26. Clamp the urinary catheter.
27. Remove the cap from the irrigation port of the three-way catheter (see Figure 39-47).
28. Cleanse the irrigation port with the sterile antiseptic swabs.
29. Attach the irrigation tubing to the irrigation port of the three-way catheter.
30. Remove the clamp from the catheter and observe for urine drainage (see Figure 39-48).

IF INTERMITTENT IRRIGATION HAS BEEN ORDERED

31. Instill the prescribed amount of irrigant.
32. Clamp the irrigant tubing.

26. Prevents leakage of urine onto the bedclothes.
27. Allows access for the irrigant tubing.
28. Minimizes the risk of infection.
29. Introduces the irrigant into the system.
30. Ensures catheter remains patent after being clamped. Some surgical procedures can cause bleeding and clotting of the catheter.

31. The bladder normally feels full when it contains approximately 300 cc of urine. If a prescribed amount of irrigant was not ordered, do not instill more than 150 cc of irrigant. If the client has undergone bladder surgery, do not instill irrigant without knowing the specific amount ordered.
32. Prevents further instillation of irrigant.

Reduces transmission of microorganisms.</p> |
| <p>If Continuous Bladder Irrigation Has Been Ordered</p> | |
| <p>37. Adjust the clamp on the irrigation tubing to allow the prescribed rate of irrigant to flow into the catheter and bladder.</p> <p>38. Monitor the drainage for color, clarity, debris, and volume as it flows back into the drainage bag.</p> <p>39. Tape the catheter securely to the thigh (see Figure 39-49).</p> <p>40. Wash hands/hand hygiene.</p> | <p>37. Regulates the amount of irrigant flowing in and out of the bladder to prevent distention or damage to any surgical site.</p> <p>38. Assesses for bleeding, clotting, and blockage of urine drainage or other complications.</p> <p>39. Prevents the catheter from becoming dislodged.</p> <p>40. Reduces transmission of microorganisms.</p> |

delegation tip

This task cannot be delegated. Bladder irrigation using a closed-system catheter requires the skills of a nurse.

nursing tips

- Do not slow a continuous irrigation without specific orders from the client's prescribing practitioner, obvious signs of bladder distention, or a plugged catheter.
- Be sure to track the amount of irrigant instilled and the amount of drainage. The drainage must always equal or exceed the amount instilled.
- Be sure to note the amount of irrigant instilled in the intake and output record so the amount instilled can be subtracted from the output to determine the urine output. Negative amounts must be reported.

PROCEDURE 39-7

Administering an Enema

EQUIPMENT

Large-Volume Cleansing Enema

- Absorbent pad for the bed
- Disposable gloves
- Bedside commode or bedpan if client will not be able to ambulate to bathroom
- Lubricant
- Enema container
- Tubing with clamp and nozzle
- Thermometer for enema solution
- Toilet tissue
- IV pole
- Washcloth, towel, and basin

Small-Volume Prepackaged Enema

- Prescribed prepackaged enema
- Lubricant if the tip is not prelubricated
- Toilet tissue
- Bedpan or commode if the client cannot use the bathroom
- Absorbent pad for bed
- Gloves

Return-Flow Enema

- Absorbent pad for the bed
- Disposable gloves
- Bedside commode or bedpan if client will not be able to ambulate to bathroom
- Prescribed solution
- Lubricant
- Enema container
- Tubing with clamp and nozzle
- Thermometer
- Toilet tissue

ACTION

RATIONALE

LARGE-VOLUME CLEANSING ENEMA

1. Wash hands/hand hygiene.
 2. Assess client's understanding of procedure and provide privacy.
 3. Apply gloves.
 4. Prepare equipment (see Figure 39-50).
 5. Place absorbent pad on bed under client. Assist client in attaining left lateral position with right leg flexed as sharply as possible. If there is a question regarding the client's ability to hold the solution, place a bedpan on the bed nearby (see Figure 39-51).
1. Reduces transmission of microorganisms.
 2. Prepares client for procedure.
 3. Prevents contact with feces.
 4. Ensures a smooth procedure.
 5. Facilitates flow of solution into the rectum and colon. The flexed leg provides the best exposure of the anus.

FIGURE 39-50 Assemble the equipment at the bedside.

DELMAR/CENGAGE LEARNING

FIGURE 39-51 Position the client in the left lateral position with the right leg sharply flexed.

DELMAR/CENGAGE LEARNING
(Continues)

PROCEDURE 39-7 Administering an Enema (Continued)

ACTION	RATIONALE
<p>6. If specified, heat solution to desired temperature using thermometer to measure. Enemas administered to adults are usually given at 105°F to 110°F (40.5°F to 43°C), and those administered to children are usually administered at 100°F (37.7°C). Solution should be at least body temperature to prevent cramping and discomfort.</p> <p>7. Pour solution into the bag or bucket; add water if needed (see Figure 39-52). Open clamp and allow solution to prime tubing. Clamp tubing when primed.</p> <p>8. Lubricate 5 cm (2 in) of the rectal tube unless the tube is part of a prelubricated enema set (see Figure 39-53).</p> <p>9. Holding the enema container level with the rectum, have the client take a deep breath. Slowly and smoothly insert rectal tube into rectum approximately 7 to 10 cm in an adult. The rectum of an adult is usually 10 to 20 cm (4 to 6 in). The tube should be inserted beyond the internal sphincter. Aim the rectal tube toward the client's umbilicus (see Figure 39-54).</p>	<p>6. Enemas work best when solution is warm. If enemas are too hot, damage can be done to the bowel mucosa. If enemas are too cold, spasms may occur.</p> <p>7. Expels air from the tubing, which could cause intestinal distention and discomfort.</p> <p>8. Minimizes trauma to the anal sphincter during insertion of the rectal tube.</p> <p>9. A deep breath helps to relax the sphincter. Insertion of rectal tube toward the umbilicus guides tube along rectum.</p>

FIGURE 39-52 Place solution into the bucket and add water as needed. DELMAR/CENGAGE LEARNING

FIGURE 39-53 Lubricate 2 inches of the rectal tube with lubricant. DELMAR/CENGAGE LEARNING

FIGURE 39-54 Gently and smoothly insert the rectal tube into the rectum. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 39-7 Administering an Enema (Continued)

ACTION	RATIONALE
10. Raise the container holding the solution and open clamp. (If using an enema set, squeeze the container holding solution.) The solution should be 30 to 45 cm (12 to 18 in) above the rectum for an adult, and 7.5 cm (3 in) above the rectum for an infant. The solution may be placed on an IV pole at the proper height.	10. Solution should be at a height above rectum that allows gravity flow of solution into the rectum but does not cause damage to the rectal lining because of a too rapid increase in rectal pressure.
11. Slowly administer the fluid.	11. Administering enema slowly with momentary pauses decreases the incidence of intestinal spasms and cramps.
12. When solution has been completely administered or when the client cannot hold any more fluid, clamp the tubing, remove the rectal tube, and dispose of it properly.	12. The urge to defecate indicates that a sufficient amount of fluid has been administered.
13. Clean lubricant, any solution, and any feces from the anus with toilet tissue (see Figure 39-55).	13. Minimizes skin irritation.
14. Have the client continue to lie on the left side for the prescribed length of time.	14. Certain types of enemas are more effective when retained for a specified amount of time. It is easier for the client to retain the enema in a lying position, where gravity can be resisted.
15. When the client has retained the enema for the prescribed amount of time, assist to the bedside commode or toilet or onto the bedpan. If the client is using the bathroom, instruct not to flush the toilet when finished.	15. Client will be prepared to expel fluid and feces.
16. When the client is finished expelling the enema, assist to clean the perineal area if needed.	16. Prevents skin breakdown and excoriation.
17. Return the client to a comfortable position. Place a clean, dry protective pad under the client to catch any solution or feces that may continue to be expelled.	17. Provides comfort for the client and protects the linen from potential soiling.
18. Observe feces and document data.	18. Provides a record of the results.
19. Remove gloves; wash hands/hand hygiene.	19. Reduces transmission of microorganisms.

FIGURE 39-55 Clean the anal area to remove excess lubricant. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 39-7 Administering an Enema (Continued)

ACTION	RATIONALE
SMALL-VOLUME PREPACKAGED ENEMA	
<p>20. Wash hands/hand hygiene.</p> <p>21. Remove prepackaged enema from packaging. Be familiar with any special instructions included with the enema. The packaged enema may be stood in a basin of warm water to warm the fluid prior to use (see Figure 39-56).</p> <p>22. Apply gloves.</p> <p>23. Place absorbent pad on bed under client. Assist client in attaining left lateral position with right leg flexed as sharply as possible (see Figure 39-57), or you may use the knee-chest position (see Figure 39-58). If there is a question regarding the client's ability to hold the solution, place a bedpan on the bed nearby.</p> <p>24. Remove the protective cap from the nozzle, and inspect the nozzle for lubrication. If the lubrication is not adequate, add more.</p>	<p>20. Reduces transmission of microorganisms.</p> <p>21. Prepares the enema for use.</p> <p>22. Protects hands from exposure to feces.</p> <p>23. Facilitates flow of solution into the rectum and colon. The flexed leg provides the best exposure of the anus. The knee-chest position provides good exposure and allows gravity to aid in retention of the enema.</p> <p>24. Prevents trauma to the rectal mucosa.</p>

FIGURE 39-56 A Commercial Enema DELMAR/CENGAGE LEARNING

FIGURE 39-57 Position the client in the left lateral position with the right leg sharply flexed. DELMAR/CENGAGE LEARNING

FIGURE 39-58 Alternately, you may position the client in the knee-chest position. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 39-7 Administering an Enema (Continued)

ACTION

FIGURE 39-59 After inserting the nozzle into the anus, squeeze the container until all the solution is instilled. DELMAR/CENGAGE LEARNING

25. Squeeze the container gently to remove any air, and prime the nozzle.
26. Have the client take a deep breath. Simultaneously gently insert the enema nozzle into the anus, pointing the nozzle toward the umbilicus.
27. Squeeze the container until all the solution is instilled (see Figure 39-59).
28. Remove the nozzle from the anus, and dispose of the empty container in a trash receptacle (see Figure 39-60).
29. Clean lubricant, any solution, and any feces from the anus with toilet tissue.
30. Have the client continue to lie on the left side for the prescribed length of time.
31. When the client has retained the enema for the prescribed amount of time, assist to the bedside commode or toilet or onto the bedpan. If the client is using the bathroom, instruct not to flush the toilet when finished.
32. When the client is finished expelling the enema, assist to clean the perineal area if needed.
33. Return the client to a comfortable position. Place a clean, dry protective pad under the client to catch any solution or feces that may continue to be expelled.
34. Observe feces and document data.
35. Remove gloves; wash hands/hand hygiene.

RETURN-FLOW ENEMA

36. Wash hands/hand hygiene.
37. Assess if client understands procedure.

RATIONALE

FIGURE 39-60 Remove the nozzle and container, and have the client continue to lie on the left side for the prescribed length of time. Dispose of the empty container in a trash receptacle. DELMAR/CENGAGE LEARNING

25. Reduces introduction of air into the rectum.
26. Relaxes the rectal sphincter. Pointing the nozzle toward the umbilicus positions the nozzle away from the rectal walls.
27. Allows the client to get the full benefit of the solution.
28. Prevents the spread of microorganisms.
29. Minimizes skin irritation.
30. Certain types of enemas are more effective when retained for a specified amount of time. It is easier for the client to retain the enema in a lying position, where gravity can be resisted.
31. Client will be prepared to expel fluid and feces.
32. Prevents skin breakdown and excoriation.
33. Provides comfort for the client and protects the linen from potential soiling.
34. Provides a record of the results.
35. Reduces transmission of microorganisms.
36. Practices clean technique.
37. Prepares client for procedure.

(Continues)

PROCEDURE 39-7 Administering an Enema (Continued)

ACTION	RATIONALE
<p>38. Apply gloves.</p> <p>39. Place absorbent pad on bed under client. Assist client in attaining left lateral position with right leg flexed as sharply as possible.</p> <p>40. If specified, heat solution to desired temperature using thermometer to measure. Enemas administered to adults are usually given at 105°F to 110°F (40.5°C to 43°C), and those administered to children are usually administered at 100°F (37.7°C). Solution should be at least body temperature to prevent cramping and discomfort.</p> <p>41. Pour solution into the bag or bucket, open clamp, and allow solution to prime tubing. Clamp tubing when primed.</p> <p>42. Lubricate 5 cm (2 in) of the rectal tube unless the tube is part of a prelubricated enema set.</p> <p>43. Holding the enema container level with the rectum, have the client take a deep breath. Simultaneously, slowly and smoothly insert rectal tube into rectum approximately 7 to 10 cm in an adult. Rectum of an adult is usually 10 to 20 cm (4 to 6 in). The tube should be inserted beyond the internal sphincter. Aim the rectal tube toward the client's umbilicus.</p> <p>44. Raise the container holding the solution and open clamp. The solution should be 30 to 45 cm (12 to 18 in) above the rectum for an adult and 7.5 cm (3 in) above the rectum for an infant (see Figure 39-61).</p> <p>45. Slowly administer approximately 200 cc of solution.</p> <p>46. Clamp the tubing and lower the enema container 12 to 18 inches below the client's rectum. Open the clamp (see Figure 39-62).</p>	<p>38. Prevents contact with feces.</p> <p>39. Facilitates flow of solution into the rectum and colon. The flexed leg provides the best exposure of the anus.</p> <p>40. Enemas work best when solution is warm. If enemas are too hot, damage can be done to the bowel mucosa. If enemas are too cold, spasms may occur.</p> <p>41. Expels air from the tubing that could cause intestinal distention and discomfort.</p> <p>42. Minimizes trauma to the anal sphincter during insertion of the rectal tube.</p> <p>43. A deep breath helps to relax the sphincter. Insertion of rectal tube toward the umbilicus guides tube along rectum.</p> <p>44. Solution should be at a height that allows gravity flow of solution into the rectum but does not cause damage to the rectal lining because of a too rapid increase in rectal pressure.</p> <p>45. Administering enema slowly with momentary pauses decreases the incidence of intestinal spasms and cramps.</p> <p>46. Allows the solution to flow back out of the rectum.</p>

FIGURE 39-61 Raise the container 12 to 18 inches above the rectum and instill 200 cc of solution. DELMAR/CENGAGE LEARNING

FIGURE 39-62 Lower the container 12 to 18 inches below the client's rectum. Observe for air bubbles as the solution returns. DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 39-7 Administering an Enema (Continued)

ACTION	RATIONALE
47. Observe the solution container for air bubbles as the solution returns. Note any fecal particles that may be returned.	47. Assesses the effectiveness of the procedure. Air bubbles in the container indicate flatus being passed from the rectum.
48. When no further solution is returned to the container, clamp the tubing and raise the enema container 12 to 18 inches above the client's rectum. Open the clamp and instill approximately 200 cc of fluid.	48. Continues to stimulate peristalsis and remove flatus.
49. Repeat raising and lowering the solution container until no further flatus is seen. Most institutions have guidelines regarding the number of returns to perform. A good rule of thumb is not more than 3 times.	49. Limiting the number of returns prevents unduly tiring or stressing the client.
50. After the final return of fluid, clamp the tubing and gently remove it from the client's anus. Clean the anus with tissue to remove any lubricant or solution.	50. Prevents skin irritation.
51. If the client feels the need to empty rectum, assist onto the bedpan or up to the bathroom or commode.	51. Allows any retained solution to be expelled. Stimulates peristalsis.
52. When the client is finished expelling any retained solution, assist to clean the perineal area if needed.	52. Prevents skin breakdown and excoriation.
53. Return client to a comfortable position. Place a clean, dry protective pad under the client to catch any solution or feces that may continue to be expelled.	53. Provides comfort for the client and protects the linen from potential soiling.
54. Observe any expelled solution, and document the results of the enema.	54. Provides a record of the results.
55. Remove gloves; wash hands/hand hygiene.	55. Reduces transmission of microorganisms.

delegation tip

Administering an enema is a procedure that ancillary personnel are able to perform after proper instruction and supervision. Instruct ancillary personnel to notify the nurse if any difficulty in administering or negative reactions such as severe cramping or inability to retain the enema occur. Results should be documented and reported to the nurse.

nursing tips

Instruct the client that lying on the back with knees and hips flexed toward the chest may make it easier to self-administer an enema.

PROCEDURE 39-8

Irrigating and Cleaning a Stoma

EQUIPMENT

- Colostomy irrigation kit
- Tape, if gauze is used
- Ostomy odor eliminator
- 4 × 4 gauze or stoma cover
- Clean gloves
- Bedpan, toilet, or basin

(Continues)

PROCEDURE 39-8 Irrigating and Cleaning a Stoma (Continued)

ACTION

FIGURE 39-63 Colostomy Irrigation Kit DELMAR/CENGAGE LEARNING

1. Wash hands/hand hygiene.
2. Apply clean gloves.
3. Assemble irrigation kit (see Figure 39-63): Attach cone or catheter to irrigation bag tubing.
4. Fill irrigation bag with 1000 cc tepid tap water (see Figure 39-64).
5. Open clamp and let water from the irrigation bag fill the tubing.
6. Hang bottom of irrigation bag at height of client's shoulder, or 18 inches above the stoma if the client is supine.
7. Check direction of intestine by inserting a gloved finger into orifice of stoma.
8. Place irrigation sleeve over stoma and hold in place with belt (see Figure 39-65 on page 1288).
9. Spray inside of irrigation sleeve and bathroom with odor eliminator (usual dose is 2 sprays).
10. Cuff end of irrigation sleeve and place into toilet bowl (if client is in bathroom) or bedpan (if client is in bed or on chair) (see Figure 39-66 on page 1288).
11. Lubricate the cone end of the irrigation tubing (see Figure 39-67 on page 1288) and insert into orifice of stoma through the top opening of irrigation sleeve (see Figure 39-68 on page 1288).
12. Close top of irrigation sleeve over the tubing.

RATIONALE

FIGURE 39-64 Colostomy irrigation solution may be administered using a bag or bucket. Fill with tepid tap water. DELMAR/CENGAGE LEARNING

1. Reduces transmission of microorganisms.
2. Practices clean technique.
3. Ensures that all equipment is ready to use.
4. The colon is already filled with microorganisms, so the use of sterile water is not necessary.
5. This eliminates any air bubbles, which can cause intestinal cramping.
6. Hanging the irrigation bag too high will cause increased intestinal cramping, and hanging the irrigation bag below shoulder level will cause poor results. This height provides resistance of back pressure from flatus.
7. Determining direction of stoma prior to irrigation of colostomy prevents trauma to mucosa and conduit.
8. Irrigant and stool need a vehicle for containment.
9. Helps to decrease or eliminate odor from stool as it is passed from the bowel.
10. Facilitates drainage of water and stool into a suitable container.
11. Prevents cone from causing trauma to intestinal lumen.
12. Prevents water and stool from splashing outside the irrigation sleeve.

(Continues)

PROCEDURE 39-8
Irrigating and Cleaning a Stoma (Continued)

ACTION

RATIONALE

FIGURE 39-65 Place the irrigation sleeve over the stoma.
 DELMAR/CENGAGE LEARNING

FIGURE 39-66 Place the end of the irrigation sleeve into a basin, bedpan, or toilet bowl.
 DELMAR/CENGAGE LEARNING

FIGURE 39-67 Lubricate the cone end of the irrigation tubing.
 DELMAR/CENGAGE LEARNING

FIGURE 39-68 Insert the cone into the orifice of the stoma.
 DELMAR/CENGAGE LEARNING

- 13. Slowly run water through tubing into colon (see Figure 39-69).
- 14. Remove cone after all water has emptied out of irrigation bag.

- 13. Alleviates intestinal cramping. If cramping should start, immediately stop and allow client to rest for a few minutes.
- 14. Irrigation of colostomy has been completed.

FIGURE 39-69 Gently instill 500 to 1000 cc of tepid water.
 DELMAR/CENGAGE LEARNING

(Continues)

PROCEDURE 39-8
Irrigating and Cleaning a Stoma (Continued)

ACTION	RATIONALE
15. Close end of irrigation sleeve by attaching it to the top of the sleeve.	15. This maintains a closed system for any remaining stool and irrigant to empty into.
16. Encourage client to ambulate to facilitate emptying of remaining stool from colon.	16. Ambulating influences peristalsis.
17. Remove irrigation sleeve after 20 to 30 minutes or when stool is no longer emptying from colon.	17. Practices clean technique.
18. Cleanse stoma and skin with warm tap water. Pat dry.	18. Gentle care of the stoma prevents injury to the mucosa, which has no nerve endings and is very friable.
19. Place gauze pad over stoma to absorb mucus from stoma.	19. Protects both the client's clothing and the stoma from irritation.
20. Secure gauze with hypoallergenic tape.	20. Ensures that the gauze remains in place.
21. Remove gloves and wash hands/hand hygiene.	21. Reduces transmission of microorganisms.

delegation tip

This task cannot be delegated to ancillary personnel. Colostomy irrigation and cleaning require the skills of a nurse.

nursing tips

- Assess skin integrity when performing stoma care. A healthy stoma should be red and moist but not painful; a dusky appearance, cyanosis, or pallor indicates a compromised blood supply. Document any sign of skin breakdown.
- Change the stoma pouch frequently if the skin underneath the appliance appears irritated.

PROCEDURE
39-9

Changing a Colostomy Pouch

EQUIPMENT

- Appropriate pouch
- Skin barrier
- Pouch clip or rubber band
- Skin paste
- Disposable gloves
- Soap and washcloth
- Warm water

ACTION	RATIONALE
1. Gather equipment (see Figure 39-70 on page 1290). Explain the procedure to client and provide for privacy. Include caregivers in instruction if indicated.	1. Promotes cooperation and boosts caregiver confidence in ability to perform procedure.
2. Assist client to a standing (preferable) or sitting position.	2. Facilitates application of pouch by reducing wrinkles.

(Continues)

PROCEDURE 39-9 Changing a Colostomy Pouch (Continued)

CENGAGE LEARNING

RATIONALE

FIGURE 39-71 Measure the stoma for the colostomy
pouch. DELMAR/CENGAGE LEARNING

3. Wash hands/hand hygiene; don gloves.
4. Remove the soiled pouch by gently pressing on the skin while pulling the pouch.
5. Dispose of the pouch in a plastic bag after removing the clip used to seal the pouch.
6. Cleanse the skin with soap and water.
7. Inspect the peristomal skin for redness, altered skin integrity, or rashes; consult the enterostomal nurse if lesions of the peristomal skin are observed.
8. Remove excessive hair with a safety razor or electric razor.
9. Inspect the pouch opening and ensure that it fits the stoma; use a pouch pattern to customize the fit if indicated (see Figure 39-71).
10. Apply a skin sealant or skin paste if indicated; apply skin barrier (see Figure 39-72).
11. Gently apply the pouch and press into place (see Figure 39-73). Seal the inferior opening with the clip or a rubber band.

3. Reduces risk of contamination.
4. Avoids trauma to the peristomal skin.
5. Minimizes odor associated with the pouch change.
6. Removes fecal material and pathogens and prepares the skin for pouch reapplication.
7. Peristomal skin conditions cause morbidity and problems with pouch application unless managed promptly.
8. Promotes the seal between pouch adhesive and peristomal skin.
9. Ensures appropriate-sized pouch and protects the peristomal skin.
10. Promotes an effective seal and protects the peristomal skin.
11. Prevents leakage of effluent from the pouch.

FIGURE 39-72 Apply the skin barrier to the stoma. DELMAR/
CENGAGE LEARNING

FIGURE 39-73 Press the pouch into place. DELMAR/CENGAGE
LEARNING

(Continues)

PROCEDURE 39-9 Changing a Colostomy Pouch (Continued)

ACTION	RATIONALE
12. Remove gloves and discard; wash hands/hand hygiene.	12. Reduces risk of transfer of microorganisms.
13. Note type and size of pouch, condition of stoma (drainage amount and odor; surrounding skin), and client response.	13. Documents client status and condition of stoma.

delegation tip

This task cannot be delegated to ancillary personnel. Changing a colostomy pouch requires the skills of a nurse.

nursing tips

- Assess skin integrity when performing stoma care. Document any sign of skin breakdown. An ischemic stoma usually appears dark red or black.
- Use latex-free gloves and pouches if history of allergy or contact dermatitis.
- Change the stoma pouch frequently if the skin underneath the appliance appears irritated.

KEY CONCEPTS

- Normal urination requires anatomic integrity of the lower urinary tract, nervous control of the detrusor muscle, and competence of the urethral sphincter mechanism.
- Normal bowel evacuation relies on motility factors, the storage abilities of the rectum, and competence of the internal and external sphincter mechanisms.
- Common alterations in urinary elimination include SUI, instability incontinence (urge and reflex incontinence), functional urinary incontinence, extraurethral incontinence, and urinary retention.
- Constipation and diarrhea are common alterations in stool consistency that cause changes in fecal elimination patterns and predispose clients to bowel incontinence.
- Clients with altered patterns of urinary and bowel elimination are evaluated with a detailed historical interview, focused physical examination, record of bladder and bowel elimination patterns, and review of laboratory values.
- Multiple options, including behavioral management strategies, pharmacotherapy, and surgical interventions, are used to manage clients with altered patterns of elimination.
- Altered stool consistency is prevented or alleviated by managing malabsorption syndromes, maintaining a regular pattern of elimination, ensuring dietary intake of adequate fluid and fiber, and heeding the urge to defecate.
- Bowel incontinence is managed by normalization of stool consistency, maximization of rectal storage abilities, and management of anal sphincter incompetence.

REVIEW QUESTIONS

1. Anticholinergic and antispasmodic medications, such as oxybutynin and propantheline, may be used to treat _____.
 - a. stress urinary incontinence
 - b. reflex urinary incontinence
 - c. urge urinary incontinence
 - d. urinary retention
2. When assessing the abdomen of a client with abdominal guarding, _____.
 - a. stop the assessment and report the findings
 - b. flex the client's knees
 - c. position the client on the left side
 - d. position the client on the right side
3. A permanent colostomy is usually performed to treat _____.
 - a. lower rectal cancer
 - b. Crohn's colitis
 - c. prostate cancer
 - d. urinary retention
4. Dandelion root and leaf are considered _____.
 - a. diuretics
 - b. antiseptics
 - c. antimicrobials
 - d. demulcents
5. A healthy stoma should appear _____.
 - a. dusky
 - b. moist
 - c. pale
 - d. cyanotic
6. Which of the following procedures may not be delegated to trained ancillary personnel?
 - a. Assisting a client with a bedpan or urinal
 - b. Application of a condom catheter
 - c. Inserting an indwelling catheter in a male
 - d. Irrigating and cleaning a stoma
7. Which of the following should the nurse include in the procedure for female urinary catheterization?
 - a. Expose the urinary meatus with the dominant hand.
 - b. Lubricate 2 inches of the catheter.
 - c. Insert the catheter 8 inches with the sterile, gloved hand.
 - d. Allow the labia to relax after the meatus is cleansed.

CHAPTER 40

Nursing Care of the Perioperative Client

COMPETENCIES

1. Discuss the three phases of the perioperative experience in relation to the client's expected outcomes and the major functional roles of the nurse.
2. Assess the physiological, psychological, social, cultural, spiritual, and age-related aspects of the perioperative client's health status.
3. Recognize sociocultural and ethical factors that affect decision making in planning care with the perioperative client.
4. Demonstrate an awareness of age-related functions and values when assessing and teaching clients.
5. Plan, implement, and evaluate the nursing care outcomes for perioperative clients in various health care settings.
6. Document nursing interventions that achieve the individualized expected outcomes for perioperative clients.
7. Describe essential components of discharge teaching for the perioperative client.

urgency

Perioperative refers to the management and treatment of the client during the three phases of surgery: preoperative, intraoperative, and postoperative. The three perioperative phases are designated by time intervals, interventions, and settings, using the word roots of *pre*—before, *intra*—during, and *post*—after. **Preoperative** (before surgery) refers to the time interval that begins when the decision is made for surgery until the client is transferred to the operating room (OR). The **intraoperative** (during surgery) phase begins when the client is transferred to the OR and ends with client transfer to a postanesthesia care unit (PACU). When the client leaves the OR and is taken to a PACU, the **postoperative** (after surgery) phase begins; this phase continues until the client is discharged from the care of the surgeon. The perioperative nurse manages, teaches, and studies the care of clients undergoing operative and other invasive procedures.

Changes have occurred in perioperative services as a result of advances in technology (such as lasers), laparoscopic and minimally invasive endoscopic surgeries, and limited resources such as cost-containment measures in health care. These changes have challenged health care providers to be more responsive and cost-effective in delivering perioperative services. Wherever procedures occur, all clients deserve to be treated with the same standard of care.

Surgery is a major source of a hospital's income. Although major surgical interventions still occur in the hospital setting, the 1980s introduced a trend to perform surgery in ambulatory settings. Many of the services of the hospital's perioperative departments are now performed in outpatient settings. This change has had a positive impact on decreasing health care costs related to surgery. At the same time, health care providers are challenged to work in greater collaboration to decrease the client's length of stay in the hospital, increase satisfaction with the services, and prevent complications.

Ambulatory surgery clinics (free-standing facilities) also began in the 1980s as an outgrowth of federally regulated reforms from the Health Care Financing Administration (HCFA). The HCFA's goal in health care reform was to decrease inpatient costs of services. Except for inpatient hospitalization, ambulatory surgery clinics provide all the services offered by hospitals.

In 1989, the HCFA developed a listing of urgent and elective surgeries that require preauthorization for Medicare clients. Preauthorization means the surgery must be approved

before surgery is performed to ensure that Medicare and other third-party payers will reimburse the facility for incurred surgical costs.

SURGICAL INTERVENTIONS

Surgery is performed to correct anatomical or physiological defects and to provide therapeutic interventions. Surgeries are categorized according to the degree of **urgency** (timely intervention of surgery):

1. Emergency surgery requires immediate intervention to sustain life. Emergency cases take precedence over urgent and electively scheduled procedures.
2. Urgent surgery dictates intervention as necessary to maintain health in situations that are not life threatening. These cases are usually added to the surgical schedule rather than replacing a previously scheduled procedure.
3. Elective cases are nonemergent, nonurgent procedures, prescheduled at the convenience of the client and the surgeon because the delay presents no physiological harm. The procedure usually occurs within days or months of the diagnosis.

Once the degree of urgency is established, the reason for performing the surgical intervention is categorized according to the expected outcome (see Table 40-1 on page 1297).

In a true emergency, saving the client's life is the primary goal. Stat blood work, including a type and crossmatch, is performed while the client and the OR are prepared for the surgery. Urgent and elective surgeries allow the client and prescribing practitioner time to discuss the setting and scheduling of the surgery.

SETTING

Ambulatory care centers and prescribing practitioner offices are the usual settings for minor surgical procedures, such as removal of skin lesions and laparoscopy for inspection and biopsy. Outpatient surgery areas (1-day surgery centers or free-standing ambulatory clinics) provide the client and prescribing practitioner with alternative services for urgent and elective surgeries.

TABLE 40-1 Surgical Interventions Based on Expected Outcomes

INTERVENTION	EXPECTED OUTCOME
Diagnostic/exploratory	Determine the origin of presenting symptoms and extent of a disease process (e.g., biopsy)
Reconstructive	Correct a disease process or improve cosmetic appearance (e.g., arthroplasty and rhinoplasty)
Curative	Repair or remove a diseased organ or restore normal physiological functioning (e.g., amputation or aneurysm repair)
Palliative	Decrease the spread of the disease process to prolong life or to alleviate pain (e.g., colostomy or partial tumor removal)
Transplant	Remove diseased tissue or organ and replace with functioning tissue or organ (e.g., kidney)

Delmar/Cengage Learning

Outpatient surgical units focus on the needs of the client and strive to expedite the rendering of services with a preadmission visit. Preadmission documents for Medicare or third-party insurance payers should be processed and approved before the preadmission visit.

During the preadmission visit, the circulating nurse and anesthesia provider perform the preoperative assessment and initiate teaching. Diagnostic tests are performed in the outpatient surgical unit as opposed to the traditional process of having a client go to the various hospital departments for testing. Performing diagnostic testing in this fashion promotes a sense of caring for the client's needs and decreases the preadmission time.

On the day of surgery, clients who have been preadmitted go directly to an outpatient surgical unit, where they are prepared for surgery. Family members are encouraged to remain with the client while the client awaits transfer to the operative area.

Perioperative care is initiated for the hospitalized client when the decision is made for surgery. The client is reassessed and the nurse collaborates with the client in planning the care. Client and family teaching is begun as soon as possible to allow time to reinforce the teaching.

Preparing a client for a surgical procedure requires the collaboration of many professionals. Specific role responsibilities focus on assessment, client and family teaching, and interventions to promote client achievement of expected outcomes.

CLIENT SAFETY

Safety is a major concern for the surgical client. Surgeries and procedures involving the wrong site, client, and procedure continue despite national efforts by regulators and professional organizations (Michaels, 2007). In support of the national effort to create a safe health care environment and to prevent surgical errors, the Joint Commission established its National Patient Safety Goals (NPSGs) program in 2002, and the first set of goals was effective in 2003. The NPSGs were established to help accredited organizations address specific areas of concern regarding client safety. The development and annual updating of the NPSGs and requirements are overseen by an expert panel of widely recognized safety experts as well as nurses, prescribing practitioners, pharmacists, risk managers, and other professionals who have hands-on experience in addressing client safety issues in a wide variety of health care settings. The Joint Commission's 2009 NPSGs (2008) for all procedures and surgeries are summarized as follows:

1. Implement best practices for preventing surgical infections, to be phased in during 2009 with full implementation in 2010:
 - Prior to all surgical procedures, the hospital educates clients and their families, implements policies and practices, and conducts periodic risk assessments regarding surgical site infection prevention.
 - Antimicrobial agents for prophylaxis used for specific procedures or diseases are administered according to evidence-based standards and best practice guidelines.
 - The appropriate method of hair removal is by clippers or depilatories; shaving is an inappropriate method of hair removal.
2. Clearly identify the intended site for the procedure:
 - The practitioner performing the procedure marks the procedure site while the client is awake and aware of the marking, if possible.
 - The site marking has the following characteristics:
 - It is made near the site.
 - It includes the practitioner's initials.
 - It is made with a marker that remains visible after the skin prep, final positioning, and sterile draping (adhesive site markers are not acceptable).
 - In addition to preoperative skin marking for spinal procedures, special intraoperative radiographic techniques are used for marking the exact vertebral level.
 - Have in place an alternative process for clients who refuse site marking or who cannot easily be marked under the following conditions:
 - Cases in which it is technically or anatomically impossible to mark the site, such as the perineum or with premature infants
 - Minimal access procedures that intend to treat a lateralized internal organ, for which the intended site is indicated by a mark at or near the insertion site and remains visible after completion of skin prep and sterile draping

- Interventional procedures such as cardiac catheterization, in which the catheter/instrument insertion site is not predetermined
 - Tooth extraction, for which the site is documented on the dental radiographs or dental diagram and is available in the procedure room prior to the start of the procedure
 - Premature infants, for whom the mark may cause a permanent tattoo
3. Time-out is performed immediately prior to starting the procedure to conduct a final assessment that the correct client, site, positioning, and procedure are identified and that all relevant documents, related information, and necessary equipment are available.
- The time-out has the following characteristics:
 - It is standardized, as defined by the hospital.
 - It is initiated by a designated member of the team.
 - It involves the immediate members of the procedure team.
 - It involves interactive verbal communication between all team members, with all members having the opportunity to express concerns about the procedure verification.
 - It includes a defined process for reconciling differences in responses.
 - During the time-out, all other activities are suspended without compromising client safety.
 - When two or more procedures are being performed on the same client, a time-out is called to confirm each subsequent procedure before it is initiated.
 - The time-out addresses the following:
 - Correct client identity
 - Confirmation of the correct site and site marking
 - An accurate procedure consent form
 - An agreement of the procedure to be performed
 - Correct client position
 - Proper labeling and display of relevant images and results
 - The need to administer antibiotics or fluids for irrigation purposes
 - Safety precautions based on client history or medication use
 - The completed components of the Universal Protocol and time-out are documented.

The Joint Commission goals require the collaborative efforts of all surgical personnel and the client to ensure a safe experience.

To facilitate the implementation of its safety goals, the Joint Commission also issued in 2004 the *Universal Protocol for Preventing Wrong Site, Wrong Procedure, Wrong Person Surgery*. The universal protocol is based on the consensus of clinical experts and endorsed by more than 40 professional health care associations and organizations. The Association of periOperative Registered Nurses (AORN), formerly called the Association of Operating Room Nurses, has a position statement regarding “Correct Site Surgery” that endorses the

Joint Commission’s *Universal Protocol for Preventing Wrong Site, Wrong Procedure, Wrong Person Surgery*.

ANESTHESIA

Anesthesia means the absence of pain. Anesthetic agents render a person insensible to pain during surgical, obstetric, and therapeutic or diagnostic procedures. Anesthesia requires a balancing of several agents to provide sedation, analgesia, muscle relaxation, and anesthesia for procedures of varying complexity. The types of anesthesia and their effects are listed in Table 40-2 on page 1299.

GENERAL ANESTHESIA

General anesthesia refers to the drug-induced state of analgesia, amnesia, muscle relaxation, and unconsciousness. General anesthesia represents a critical experience for surgical clients. The needs of these clients require that perioperative nurses possess knowledge of the basic principles of general anesthesia.

The common routes for administering general anesthetics are inhalation and parenteral; other routes used less frequently are oral and rectal. Inhalation agents are administered in the form of gases or as vapors of volatile liquids through an anesthesia delivery system and a face mask, endotracheal tube, or laryngeal mask airway (LMA) that may be inserted without a muscle relaxant. Commonly used inhalation agents that can produce all of the elements of general anesthesia are listed in the accompanying display on page 1299; these agents are absorbed by the lungs. Nitrous oxide (compressed gas) is both absorbed and eliminated by the lungs, whereas percentages of different volatile liquids vary in excretion between the lungs and kidneys.

Although anesthesia is administered parenterally, it takes several intravenous drugs to produce all the elements of general anesthesia. Injectable agents used for induction or maintenance of anesthesia are from one of the following drug classifications: barbiturates, benzodiazepines, narcotics, and neuromuscular blocking agents. See the accompanying display on page 1300 for common drugs in each of these classifications.

Barbiturates provide a rapid induction of short duration and are therefore used for invasive diagnostic and obstetric procedures and minor surgery. When barbiturates are contraindicated, other short-acting agents are used: ketamine or a nonbarbiturate drug (etomidate or propofol). Neuromuscular blocking agents produce muscle relaxation required for select surgical procedures; these drugs vary in their duration of action.

The client’s individualized plan for balanced anesthesia may involve the concurrent or sequential use of many agents. For instance, thoracic muscle relaxation that is required for lung surgery can be provided by intravenous administration of a neuromuscular blocking agent. During the surgery, various types of vapors and gases may also be administered with oxygen to provide anesthesia. For abdominal surgery, muscle relaxation can be achieved by injecting a local anesthetic into the cerebrospinal fluid; after the abdominal anesthesia level

TABLE 40-2 Effects of Anesthetic Agents

TYPE OF ANESTHESIA	EXPECTED RESULT	TECHNIQUE	RISKS
General anesthesia	Total unconscious state, placement of a tube into the trachea	Drug injected into the bloodstream, breathed into the lungs, or administered by other routes	Mouth or throat pain, hoarseness, injury to mouth or teeth, awareness under anesthesia, injury to blood vessels, aspiration, pneumonia
Spinal or epidural analgesic/ anesthesia (with and without sedation)	Temporary decreased sensation or loss of feeling and movement to lower part of the body	Drug injected through a needle/catheter placed either directly into the spinal canal (spinal or subarachnoid) or immediately outside the spinal canal (epidural)	Headache, backache, buzzing in the ears, convulsions, infection, persistent weakness, numbness, residual pain, injury to blood vessels, “total spinal”
Major/minor nerve block (with and without sedation)	Temporary loss of feeling or movement of a specific limb or area	Drug injected near multiple nerves or a plexus (major) or into or around a nerve or small nerve group (minor), providing loss of sensation to the area of the operation	Infection, convulsions, weakness, persistent numbness, residual pain, injury to blood vessels
Intravenous regional anesthesia (with and without sedation)	Temporary loss of feeling and/ or movement of an extremity	Drug injected into veins of arms or legs while using a tourniquet	Infection, convulsions, persistent numbness, residual pain, injury to blood vessels
Monitored anesthesia care (with sedation)	Reduced anxiety and pain, partial or total anesthesia	Drug injected into the bloodstream, breathed into the lungs, or administered by other routes, producing a semiconscious state	Unconscious state, depressed breathing, injury to blood vessels
Monitored anesthesia care (without sedation)	Measurement of vital signs, availability of anesthesia provider for further intervention	None	Increased awareness, anxiety, and/or discomfort

INHALATION GENERAL ANESTHETIC AGENTS

VOLATILE LIQUIDS

- Halothane (Fluothane, Somnothane)
- Methoxyflurane (Penthrane)
- Enflurane (Ethrane)
- Isoflurane (Forane)

is established, a short-acting barbiturate may be infused to provide general anesthesia during the surgical procedure. Although the incidence of drug toxicity in anesthesia is rare, clients need to be informed about these inherent risk factors.

REGIONAL ANESTHESIA

The increased use of balanced anesthesia for surgical procedures has made it increasingly important for perioperative nurses to be knowledgeable about regional and local anesthetic agents. Regional anesthesia blocks nerve impulse conduction to a specific area or region of the body to decrease intractable pain or to produce an anesthetic field without the loss of consciousness.

An analgesic or anesthetic state is obtained by injecting a local anesthetic solution along a specific nerve path (see the accompanying display for a list of commonly used local anesthetic agents). Regional anesthesia can be administered with or without sedation (see Table 40-2 for the various techniques used in administering regional anesthesia).

LOCAL ANESTHESIA

Local anesthesia refers to use of an anesthetic agent that disrupts sensation at the nerve endings. The two techniques used for administering local anesthesia are topical and infiltration. Topical anesthesia is the direct application of local anesthetics to tissues in the form of ointments, lotions, solutions, or sprays. After the use of oral anesthetic solutions (e.g., viscous lidocaine), *fluids and foods must be withheld until the gag reflex returns.*

Infiltrate anesthesia refers to intradermal, subcutaneous, or submucosal injection to provide a circumscribed area of anesthesia. This technique provides a local nerve block that is used for suturing lacerations or extracting teeth.

COMMON INTRAVENOUS AGENTS USED FOR GENERAL ANESTHESIA

- Barbiturates: methohexital sodium, thiamylal sodium, thiopental sodium propofol
- Benzodiazepines: diazepam and midazolam
- Narcotics: alfentanil hydrochloride, fentanyl, and sufentanil citrate
- Neuromuscular blocking agents: atracurium besylate, doxacurium chloride, gallamine triethiodide, metocurine iodide, mivacurium chloride, pancuronium bromide, pipecuronium bromide, succinylcholine chloride, tubocurarine chloride, and vecuronium bromide

COMMONLY USED LOCAL ANESTHETIC AGENTS

- Bupivacaine hydrochloride (Marcaine, Sensorcaine)
- Chloroprocaine (Nesacaine, Nesacaine-MPF)
- Etidocaine hydrochloride (Duranest)
- Lidocaine hydrochloride (Xylocaine)
- Mepivacaine hydrochloride (Carbocaine, Polocaine)
- Procaine hydrochloride (Novocain)
- Tetracaine hydrochloride (Pontocaine)

PREOPERATIVE PHASE

The primary goal of preoperative nursing care is to place the client in the best possible condition for surgery through careful assessment and thorough preparation. Assessment of the client's status before surgery establishes baseline data to direct interventions throughout the perioperative phases. Each member of the health care team has identified functions relating to the assessment of the client's physiological, psychological, social, cultural, and spiritual status. *The findings from the client's assessment must be documented throughout the surgical experience.*

ASSESSMENT

Assessment of the perioperative client includes a nursing history and physical examination. A complete assessment is performed at the outpatient clinic during the preadmission visit. On the day of surgery, the nurse conducts a focused assessment to ensure current, accurate data.

During the assessment process, the nurse evaluates the client's level of anxiety and fear. Bulechek, Butcher, and Dochterman (2008) describe these feelings:

- Anxiety is a vague, uneasy feeling whose source is often nonspecific or unknown to the client.
- Fear is a feeling of dread related to an identifiable source that the client validates.

Anxiety is accompanied by well-defined physiological changes, such as an increased heart rate, clammy hands, muscular tension (especially in the neck muscles), and behavioral manifestations, such as rapid speech and irritability.

Nursing History

The perioperative nursing history provides information relative to factors that can increase a client's risk or influence the expected surgical outcomes. Pertinent data are obtained from the client interview: medical history, including family history of anesthesia complications (malignant hypertension); medications; allergies; age-related factors; social, cultural, and spiritual concerns; and psychological status. See Chapter 6 for more details.

Nurses should conduct the interview in a quiet room, free from background noise. Many older adult clients have some degree of high-tone hearing loss, so it is necessary to speak in a strong, clear voice.

Clients who have difficulty comprehending the surgical procedure should have a responsible family member present during the interview. A third person can help clarify precisely what the nurse said and can interpret such instructions for other family members.

Medical History

The nurse reviews the client's medical record. The surgeon's history and physical findings provide pertinent data regarding the reasons for surgery. If the client was previously hospitalized, the nurse obtains the previous medical records to have available on the nursing unit. Hospitalization records are

reviewed to gain an overview of the client's health status because preexisting medical conditions can increase the client's surgical risks.

During the preoperative interview, the registered nurse (RN) (or circulating nurse) reviews the client's information regarding past illnesses and the main reason for seeking surgical treatment. The surgeon's history and physical findings provide a comprehensive review of the client's current information within a prescribed period of time (usually within 7 days) and pertinent data regarding the reasons for the surgery. Any complications from a previous surgery or anesthesia should be recorded.

It is important to note if the client has had prior blood transfusions or reactions. At this time the nurse can ascertain whether the client has objections to receiving blood or blood products or has made arrangements for blood replacement. Some clients prefer to donate their own blood in advance so that it can be held in reserve if the need for it arises during surgery. Family members or friends may also donate blood to decrease the cost to the client.

Medications

During the nursing history, the nurse needs to assess exactly what drugs the client has been taking. The client's response to questions about the use of alcohol, tobacco, "street drugs," prescriptions, over-the-counter (OTC) drugs, and herbs should be documented because these substances have surgical implications.

Certain prescription drugs (antihypertensives, tranquilizers, steroids, and diuretics), as well as certain OTC medications and herbal preparations, can increase the client's anesthesia risks. Some medications must be stopped at least 2 weeks prior to surgery, or the surgery may be canceled. Clients with chronic diseases are likely to be taking numerous medications that can cause complications during the perioperative period (see the accompanying display on drugs that place surgical clients at risk).

HERBS Question clients regarding their use of herbal products and supplements as part of the preoperative assessment. Certain herbal products and supplements (e.g., *Ephedra sinica*, or Chinese ephedra or ma huang; St. John's wort; feverfew) may place the client at risk if taken before surgery.

Ephedra can produce the same side effects as ephedrine (e.g., increased blood pressure and heart rate, insomnia, anxiety). St. John's wort is used widely as a mild to moderate antidepressant because of its ability to inhibit monoamine oxidase (MAO). MAO inhibitors may interact with various types of anesthetic agents. Feverfew inhibits platelet aggregation and may affect the client's clotting time.

Although some herbal products may place the client at risk during surgery, other herbs, such as *bromelain*, can reduce healing time and pain following various surgical procedures. Bromelain is obtained from the pineapple plant and refers to a group of sulfur-containing enzymes that digest protein (proteolytic enzymes or proteases). Bromelain reduces edema, inflammation, and pain when taken preoperatively.

DRUGS THAT PLACE SURGICAL CLIENTS AT RISK

- Aspirin: May increase bleeding
- Antidepressants: May lower blood pressure during anesthesia
- Bromide in medications (e.g., Sominex): Can accumulate and produce signs and symptoms of dementia
- Drugs with anticholinergic effects: Increase the potential for confusion
- Steroids: Suppress immunity
- Nonsteroidal anti-inflammatory medications: Increase the risk of stress ulcers and displace other drugs from blood proteins

ALLERGIES Allergies and sensitivities to foods, drugs, or other substances should be documented on the assessment record. Of special importance is questioning the client about allergies to iodine. Povidone-iodine, a common antiseptic, is used to prepare the skin for surgery. The nurse places a note regarding the client's allergies on the front of the chart to alert perioperative team members.

Age-Related Considerations

Age-related considerations are critical aspects of assessment. The client's age and developmental stage can influence the ability to cope with surgery. Age-related factors can also influence existing health care problems and the client's response to surgery. For instance, infants are at risk during surgical interventions because their physiological functions are immature. The infant's ability to respond to stress is also altered.

Morbidity and mortality rates for surgical clients over the age of 90 are much higher than for those in the 70 to 75 age group. Older clients may be fearful of death, especially if this is their first hospitalization or surgery. The risk of surgery for many older clients is complicated by chronic disease processes. Age-related risk factors for the older adult should be assessed on an individual basis. When older adult clients are adequately prepared for a noncomplicated surgical procedure, they can tolerate many types of surgeries as well as younger clients. However, studies have shown that when older adult clients are subjected to emergency surgeries or long, complicated surgeries, their decreased ability to adapt to physical and psychological stress may have a negative surgical outcome.

Social and Cultural Considerations

Data relative to the client's social and cultural orientation are incorporated into care. In our multicultural world, our communities are diverse, requiring that the nurse incorporate these data into the plan of care and utilize appropriate teaching methods. Many facilities provide interpreters to prevent language from being a communication barrier.

Cultural beliefs can influence a client's perception of surgery. Listen to the concerns a client expresses during the interview. Surgeries that cause changes in body image can alter self-esteem. The client may worry about being sexually attractive or active after surgery. The nurse may initiate discussion regarding sexual outcomes of surgery; encourage the client to verbalize fears in order to increase adaptive coping. As always, the nurse is cognizant of the client's comfort level when broaching any topic that could be considered sensitive in nature.

Spiritual Considerations

Clients must be provided the opportunity to express their spiritual values and beliefs. Religious beliefs are discussed and incorporated into the client's plan of care. A client may ask to see a member of the clergy before surgery. The beliefs of the client should be respected. The client has the right to refuse certain types of interventions. For example, some religions do not allow the administration of blood products as treatment. When the client indicates that religious beliefs prevent blood administration, the health care team should identify alternative methods of treatment and discuss these with the client during the preoperative phase. Collaborating with the client preoperatively helps prevent ethical dilemmas from arising during the other perioperative phases in the event that the client loses a large quantity of blood.

Psychosocial Status

A psychosocial evaluation is conducted with the client and family by assessing their degree of understanding and anxiety regarding the surgical procedure (see the accompanying display on assessment questions). Assess the client's knowledge of the surgical procedure and the expected surgical outcomes. It is important that the client express agreement with the surgical plan of care.

ASSESSMENT QUESTIONS: PSYCHOSOCIAL STATUS

- Why are you having surgery?
- When did this problem start?
- What do you think caused this problem?
- Has this caused any problems with your relationships with others?
- Has your problem prevented you from working?
- Are you able to take care of your own needs?
- Are you experiencing any discomfort or pain?
- What are you expecting from this surgery?
- Is there anything that you do not understand regarding your surgery?
- Are you worried about anything?
- Will someone be available to assist you when you return home?

Physical Assessment

The perioperative nursing assessment includes the review of medical records, a client interview, and a partial or complete physical examination. Key points include, but are not limited to, the following: age, height, weight, skin condition, preexisting conditions, nutritional status, and physical or mobility limitations. The decision to conduct a partial or complete physical depends on the client's health status relative to the surgical procedure, the setting, and the amount of time available to gather pertinent data.

The nurse in an outpatient setting, on the day of surgery, usually performs a partial examination. The client's medical record should be reviewed to ensure that a complete nursing physical was conducted during the preadmission visit. The nurse should focus on obtaining pertinent assessment data to establish baseline parameters for prioritizing the client's care. The client's neurologic assessment is integrated throughout the interview and physical examination.

GENERAL SURVEY Observe the client's condition starting with the initial contact. For instance, if the client walks into the unit, observe and note the client's gait; note if assistance is needed with ambulation. Does the client need assistance when transferred to a bed? When shaking the client's hand, note the strength and sensation of the hand grasp and the skin temperature. Coldness of the hand may indicate impaired circulation.

During the interview, assess the level of consciousness and orientation. Does the client respond appropriately to questions? Observe for signs of hearing impairment or loss of vision. Note if the client is wearing glasses.

HEAD AND NECK While talking with the client, assess if eye contact is maintained. Note the color of the sclera and

SPOTLIGHT ON...

Caring and Compassion

Responding to a Client's Altered Self-Image

As a student nurse, how can you assist the client in verbalizing fears about alterations in body image that have sexual implications? A 30-year-old woman is admitted for removal of a cancerous breast. Her mother died at age 30 from breast cancer. The client has been married for 5 years and has a 3-week-old infant. Her husband is with her. You have to admit and interview the client for the nursing history. How would you approach the medical diagnosis? Would you feel comfortable helping this client verbalize her fears?

inspect for drainage from the eyes. Inspect the general condition of the scalp, noting alopecia or seborrheic dermatitis. Inspect the oral cavity, check for any loose teeth, and assess the tongue and mucous membranes (note color and moisture). Observe the client's lips and tongue, especially if client has a history of cardiac disease. Note if the client has dentures.

Inspect the neck and verify the strength of the carotid pulses, one at a time; palpate jugular veins for distension. If the client is a child or has cancer, palpate the cervical lymph nodes. Assess for range of motion.

UPPER EXTREMITIES Palpate the client's brachial and radial pulses bilaterally; note the rate and character of each pulse. Check the capillary refill. Assess the skin; note the temperature, texture, and integrity. Assess for range of motion. For instance, if the client is scheduled for a neurosurgical procedure, the perioperative RN (or circulating nurse) assesses the strength and character of the client's handgrips and dorsal/plantar flexion ("push-pulls") with resistance.

ANTERIOR AND POSTERIOR CHEST AND ABDOMEN

Inspect and palpate the chest wall, noting the breathing pattern and expansion of the chest wall. Auscultate heart sounds, and listen to anterior and posterior breath sounds; note crackles, gurgles, or wheezing.

Inspect the abdomen for distension, and listen for bowel sounds in all four quadrants. Palpate the abdomen for rigidity, enlarged organs, or rebound tenderness.

LOWER EXTREMITIES Assess the length and position of each leg. Palpate the bilateral strength of femoral, popliteal, and pedal pulses, noting the rate and character of each pulse. Assess the skin; note the temperature, texture, integrity, and presence of edema. Check the capillary refill. Inspect the bony prominences of the ankles and feet. Assess for strength and sensation by having the client bend the leg and push the foot against the nurse's hand. Assess for range of motion. Clients scheduled for spinal anesthesia should be assessed for gross motor function and strength.

The nurse documents on the medical record and communicates to the health care team all significant assessment data. This information establishes baseline parameters to direct decision making throughout the perioperative phases. Spinal anesthesia causes temporary paralysis of the lower extremities. Preoperative weakness or impaired movement of the lower extremities should be reported to nurses caring for clients recovering from spinal anesthesia; postoperatively this report prevents the recovery nurse from making the wrong decisions when full motor function fails to return.

DIAGNOSIS

The nursing diagnosis is a concise clinical judgment of a client problem formulated to direct nursing actions to achieve the expected outcome (AORN, 2007). The nurse formulates nursing diagnoses based on an analysis of assessment data and the nature of surgery. Physical assessment findings are compared against diagnostic test results; for example, cardiovascular

findings are analyzed with blood chemistry and electrocardiogram (ECG) results.

Selection of the most appropriate nursing diagnosis should focus on the specific perioperative phase (see Table 40-3 on page 1304). The diagnosis may be pertinent to all three perioperative phases or to one or more phases.

For instance, as described in the Nursing Process Highlight, Mrs. Broussard is experiencing pain that is caused by the degenerative changes in the hip joint as a result of arthritis. Although the surgeon will remove the diseased joint, Mrs. Broussard will continue to experience pain. In fact, the pain may worsen for several weeks postoperatively. The most appropriate diagnosis for Mrs. Broussard is *Pain*. Preoperatively, the pain is related to the degeneration of the hip joint; postoperatively, the pain is related to swelling at the surgery site.

Common nursing diagnoses for the preoperative client are *Deficient knowledge* related to the surgery, *Anxiety*, and *Fear*. Clients and families view the perioperative experience differently on the basis of prior experiences and coping skills. Some clients are threatened; others consider the experience to be a challenge. Some clients are highly anxious, whereas others experience a moderate degree of anxiety. Besides the primary threat of surgery, clients also have to deal with separation from family and loss of independence.

Associated nursing diagnoses address the client's preexisting health condition. For instance, an associated diagnosis for Mrs. Broussard is *Impaired physical mobility* related to musculoskeletal impairment. This nursing diagnosis would be initiated preoperatively and throughout the perioperative experience.

NURSING PROCESS HIGHLIGHT

Assessment

Mrs. Broussard, 69, was admitted to an outpatient surgical unit for a total hip replacement (**arthroplasty**). The surgeon explained the surgical procedure during her last office visit. Preauthorization has been granted for the surgery. Diagnostic testing, a comprehensive history and physical examination, and postoperative exercise instructions were performed during the preadmission visit. Mrs. Broussard has been suffering for 10 years with chronic degenerative arthritis. She has experienced increasing pain and loss of mobility in her left hip for the past 6 months.

- In collecting data from Mrs. Broussard during the focused assessment, what types of information are essential for the development of a plan of care for her on the day of surgery?
- Which baseline data should be obtained from Mrs. Broussard during the partial physical examination?
- What further data should be collected at this time?

Text not available due to copyright restrictions

PLANNING AND OUTCOMES

Outcomes are positive statements, the anticipated goals that clients are expected to achieve at the close of the perioperative experience based on the nursing diagnoses. The nurse develops goals with client-focused expected outcomes based on the relevant nursing diagnoses. Nurses collaborate with other health care team members and the client in establishing the goals and outcomes. The overall goal is to protect the client from injury related to anesthesia and surgery. The plan of care directs the selection of specific nursing interventions that promote the client's achievement of expected outcomes, for example, client teaching.

The current health care system challenges the perioperative nurse to be responsible to surgical clients who may enter and exit the diverse health care settings at various points along the continuum of care with different experiences. Some clients are admitted to the hospital the day of surgery and some the evening before; some have surgery as an outpatient and some in the prescribing practitioner's office. Some clients with general anesthesia may be discharged the day of surgery.

Discharge planning needs are incorporated into the plan of care on admission and ideally include family and client education. The following considerations are included in discharge planning:

- Psychosocial and spiritual support systems and community resources
- Financial aspects of the illness
- The degree of illness or disability
- Rehabilitation
- Preventive care
- Client teaching needs

Some clients need the services of a home health agency on discharge. The perioperative nurse usually coordinates home care with the social worker.

Collaboration

Effective perioperative management is directed by a multidisciplinary team in accordance with recognized standards of care and individualized expected client outcomes. Institutional protocol, which defines how procedures will be performed, is initiated in the preoperative phase and continues throughout the other phases.

Each member of the health care team (surgeon, anesthesia provider, and nurse) has a specific role and responsibility toward the perioperative client. Collaboration between all health care providers is essential in planning client care. "Collaboration means that people with different areas of expertise are working as equals to define issues, design solutions, and achieve high quality outcome" (Rubinfeld & Scheffer, 1999, p. 352).

SURGEON Prescribing practitioners are credentialed by health care facilities to perform surgery. The surgeon is the

primary prescribing practitioner the nurse communicates with regarding client care needs. Before surgery, the surgeon:

- Determines the need for the surgical intervention on the basis of the client's medical diagnosis and findings from the medical history and physical examination
- Determines the surgical setting in collaboration with the client
- Orders diagnostic tests only if directly correlated to the procedure or client diagnosis (see the accompanying display on common preoperative diagnostic tests)
- Obtains client's consent for the surgical procedure
- Teaches the client about the outcomes and risks of the procedure

A major role function of the surgeon is *explaining and documenting evidence that the client understands the nature of the surgical procedure, the risk factors, and expected outcomes of the surgery*. This is done with a surgical consent form, the client's written permission to allow the surgeon to provide surgery. Many states, through statutory provisions, require prescribing practitioners to perform and document client teaching. Once the client demonstrates understanding, the client signs the form, giving permission for the specific surgical intervention.

ANESTHESIA PROVIDER The anesthesia provider (anesthesiologist or certified RN anesthetist) actively participates in each perioperative phase. The main role of the anesthesia provider is to ensure client safety relative to the administration of anesthesia. The anesthesia provider:

- Obtains informed consent for anesthesia services
- Performs a preanesthesia evaluation that includes a thorough history, such as complications from previous anesthesia, and physical examination
- Selects anesthetic agents

COMMON PREOPERATIVE DIAGNOSTIC TESTS

- Urinalysis
- Complete blood count (CBC)
- Prothrombin time (PT) and partial thromboplastin time (PTT): Clients with known or suspected coagulation defects or to establish baseline information
- Chemistry profile: Clients with diseases that can alter electrolytes
- Electrocardiogram (ECG)
- Human immunodeficiency virus (HIV) testing: In accordance with agency policy
- Chest x-ray films: Clients over 60 years of age, smokers, or those scheduled for general anesthesia

- Teaches the client regarding the anesthetic medications, their side effects, and risk factors
- Performs **intubation** (the insertion of an endotracheal tube into the bronchus through the nose or mouth to ensure an airway) and **extubation** (the removal of an endotracheal tube)

Most surgical procedures have predetermined anesthetic agents based on policy; if there is a variance from the norm, the anesthesia provider seeks agreement with the surgeon. The decision to use particular anesthetic agents is based on the client's health status, the surgical procedure, and the anticipated duration of the surgery.

During the client interview, the anesthesiologist inquires about previous anesthesia experiences that can place the client at risk, such as connective tissue abnormalities that suggest the presence of the autosomal dominant malignant hyperthermia (MH) gene. **Malignant hyperthermia** is a potentially lethal syndrome caused by a hypermetabolic state that is precipitated by the administration of certain anesthetic agents, for example, succinylcholine. When appropriate and feasible, medical records from previous surgeries are reviewed as part of the preanesthesia examination.

REGISTERED NURSE The AORN promotes client care through the development of standards, guidelines, and recommended practices of perioperative nursing. The AORN has also developed the Perioperative Nursing Data Set (PNDS) to standardize nursing terminology regarding the perioperative client experience from preadmission until discharge to promote evidence-based practice. The PNDS is the first nursing language developed by a specialty organization that has been recognized by the American Nurses Association. The PNDS is composed of 4 domains, 74 nursing diagnoses, 133 interventions, and 28 outcomes unique to the role of the perioperative nurse.

Perioperative nurses perform critical functions that vary with specific surgical procedures and the unique needs of individual clients to achieve positive client outcomes (Parker, Mimick, & Kee, 1999). Rubenfeld and Scheffer (1999) identified three guiding principles for implementing care based on professional standards: maintain client safety; provide effective care; and provide care as efficiently as possible. These principles are incorporated into each phase of the perioperative standards of nursing practice.

The nurse coordinates the client's care in a timely fashion to ensure safety and avoid surgical delays. Activities include:

- Scheduling the diagnostic tests.
- Verifying that all the necessary documents (e.g., signed consent form) are in the client's medical record.
- Reporting abnormal diagnostic results to the surgeon. Depending on the test results, treatment may be instituted to correct any abnormalities, or the surgery may be canceled.

A major part of the nurse's time is spent in preparing and teaching the client. Preoperative teaching is structured to provide planned educational activities to presurgical clients and

UNCOVERING THE

Evidence

TITLE OF STUDY

"Operating Theater Culture: Implications for Nurse Retention"

AUTHORS

Bridget Gillespie, Marianne Wallis, and Wendy Chaboyer

PURPOSE

To explore characteristics of the organizational culture of the operating theater and how this culture is communicated and sustained.

METHODS

This study was a mini-ethnography of three themes related to primacy of knowledge and competence, social order, and situational control, which are important cultural indicators in the operating theater.

FINDINGS

The level to which members are able to assimilate and meet role expectations depends on the amount of knowledge and experience they possess.

IMPLICATIONS

A lack of acceptance has the potential to affect members' willingness to continue working in the operating theater and, consequently, may contribute to existing nursing shortages in this specialty.

Gillespie, B., Wallis, M., & Chaboyer, W. (2008). Operating theater culture: Implications for nurse retention. *Western Journal of Nursing Research, 30*(2), 259–277.

family (significant others) according to assessed anxiety and fear levels, as discussed later in this chapter. See Table 40-4 on page 1307 for the roles of the RN in the perioperative environment.

As technology becomes more sophisticated and health care resources become more limited, ethical issues have become more complex (Schroeter, 1999). Ethical dilemmas are inherent in perioperative nursing; for example, lack of respect for the client's dignity, withholding information or lying to clients, inadequate consents, incompetent health care providers, and do-not-resuscitate (DNR) orders are all issues that have implications for the management of care in perioperative settings. Schroeter (1999) studied the aspects of informed consent and the impaired or incompetent colleague in the perioperative practice setting and determined that perioperative nurses can accurately identify ethical situations occurring in the environment and that the majority of the participants reported that they would take action. The ethical competency of perioperative nurses is paramount to ensure that safe, competent, and ethical care is provided to all surgical clients.

TABLE 40-4 Roles for the RN in the Perioperative Environment

Scrub person (Phillips, 2004)	Staff member of the sterile team. The RN, licensed vocational nurse (LVN), or surgical technologist is responsible for establishing and maintaining the safety, efficiency, and integrity of the sterile field throughout the surgical or invasive procedure.
Circulating nurse (Phillips, 2004)	Registered nurse member of the nonsterile team who coordinates and directs the activities of the intraoperative environment during the surgical procedure. The RN continually assesses and manages client safety needs and the sterile team utilizing critical thinking skills.
RN first assistant (RNFA) (Rothrock, 1999)	As an expanded perioperative role, the RN who has received additional educational preparation assists the surgeon in performing the surgical procedure throughout the perioperative course of client care. The RNFA is prescribing practitioner based, hospital based, or entrepreneurial in practice and is credentialed by the facility in which the RNFA performs first-assisting duties.

Delmar/Cengage Learning

IMPLEMENTATION

Preparing the client for surgery requires the nurse to perform multiple interventions within specific time constraints. However, the nurse must remain responsive to the client's needs, demonstrating a caring attitude (see Figure 40-1). Documentation tools (e.g., consent form, preoperative checklist) are available to assist the nurse in providing safe, timely preoperative care. Throughout the perioperative experience, active planning, intervention, and evaluation are essential elements to reduce the risk of complication. See the accompanying display for the *Nursing Interventions Classification* (NIC) recommendations regarding preoperative coordination for facilitating preadmission diagnostic testing and preparation of the surgical client.

Surgical Consent Form

Although surgeons are responsible for obtaining informed consent, nurses should verify that consent has been obtained before treatment begins. Consent is given only for the extent

FIGURE 40-1 The nurse prepares a client for surgery. While the nurse was performing preoperative assessment, the client demonstrated pain through facial expression. What implications might the client's pain have for the surgery? What actions should the nurse take, considering the potential effects on the client's perioperative experience? DELMAR/CENGAGE LEARNING

of action documented on the informed consent. Nurses can identify problems with consent when the client:

- Cannot explain the procedure or identify the risks
- Signed the form more than 30 days before surgery
- Had an unauthorized person sign the consent form
- Did not sign the consent form
- Signed a consent form that identified an incorrect surgical site
- Signed a consent form that identified a procedure incongruent with that now identified

NIC: PREOPERATIVE COORDINATION

- Review planned surgery and prescribing practitioner orders.
- Obtain client history, physical assessment, and blood and urine specimens; notify prescribing practitioner of abnormal diagnostic test results, as appropriate.
- Describe and explain preadmission treatments and diagnostic tests; inform client and significant others of the date and time of surgery, time of arrival, admission procedure, and locations of receiving unit, surgery area, and waiting area; and allow time for client and significant others to ask questions and voice concerns.
- Discuss postoperative discharge plans and determine ability of caretakers.

Adapted from Bulechek, G., Butcher, H., & Dochterman, J. (2008). *Nursing interventions classification (NIC)* (5th ed., p. 578). St. Louis, MO: Mosby Elsevier Health Sciences.

The nurse should notify the surgeon in the event that any problems with consent are identified.

If the surgeon proceeds without appropriate consent, nursing administration should be notified and the nurse should make personal notations outside the medical record. This practice protects the nurse should the situation be brought to court. If the client reverses a decision and decides against surgery, the nurse is obligated to inform the surgeon in order to prevent unwanted treatment.

Preoperative Checklist

A checklist is a form that allows the nurse to insert a check mark (✓) beside symptoms or to fill in one or two words in answer to a cue or a question. Although some variations exist in how agencies format the preoperative checklist, the forms usually have similar content. Nursing activities are usually designated by time intervals: “night before surgery” and “day of surgery.” Time designations help to prevent surgical delays that can increase the client’s anxiety and the agency’s costs. Table 40-5 on page 1309 presents a sample preoperative checklist that incorporates most of the intervention activities described in NIC—Surgical Preparation (2930).

Although clients in outpatient settings arrive the day of surgery, the nurse prepares the client’s medical record the day before for necessary documentation as itemized in Table 40-5. This preparation ensures that assessment, diagnostic tests, and teaching were done on the preadmission visit and allows time to obtain missing information and to assess the need for reinforcement or reevaluation as necessary.

On the day of surgery, the nurse focuses on the immediate physical interventions to prepare the client for surgery. While admitting and preparing the client for surgery, the nurse uses this time to encourage the client to verbalize any concerns. Allowance should be made for family members or significant others to remain with the client as the client awaits transfer to the OR.

Client Teaching

Most clients view surgery as a threatening and anxiety-provoking event. Client teaching reduces anxiety. The risks of surgical complications are decreased when the client knows what to expect and receives instruction in postoperative exercises (Bulechek et al., 2008; Lindeman & Van Aernam, 1971).

Teaching the client and family members (significant others) is the responsibility of the multidisciplinary team. The nurse verifies that the client or family member is able to describe, in his or her own words, the reason for the surgery, what will be done during the surgical procedure, the side effects of the anesthetic agents, and the possible complications of both the surgery and the anesthesia.

The nurse plays a major role in relieving the client’s anxiety by facilitating communication between prescribing practitioners and the client and family and by reinforcing teaching regarding preoperative care. The client’s family should be involved in the teaching sessions. Table 40-6 on page 1311 presents an overview to perioperative teaching activities with the client’s expected outcomes.

Teaching aids (videotapes and pamphlets) are resources for client instruction during the perioperative processes. The nurse selects teaching materials based on the client’s ability to read and understand. The nurse provides accurate, consistent information throughout the teaching process. The teaching aids must reinforce the verbal instructions of the nurse, anesthesiologist, and surgeon. Informational materials should explain what will happen in each of the perioperative areas (such as the holding area) to foster client cooperation. Refer to Chapter 21 for additional information on client teaching and NIC intervention, Teaching: Preoperative (S610).

TYPES OF SURGICAL INCISIONS Nurses need to be knowledgeable about common surgical incisions to reinforce the surgeon’s teaching and to answer the client’s questions. Two main factors govern incisions: direction and location. Incisions may be vertical, horizontal, transverse, or oblique. For minimally invasive surgeries, such as laparoscopic cholecystectomy, small incisions are strategically placed to facilitate access to the gall bladder utilizing laparoscopic instrumentation and video equipment. Placement of trocars will vary in size and placement according to the procedure to be performed. Figure 40-2 on page 1312 illustrates and describes the location of common surgical incisions.

POSTOPERATIVE EXERCISE INSTRUCTION As early as 1941, nurses were challenged to participate in preoperative instruction. In 1983, Leventhal and his colleagues suggested that the effectiveness of existing preoperative instruction could be increased by assisting clients to assume self-regulation after surgery.

Preoperative teaching of postoperative exercises prepares the client physically and emotionally for the impending surgery. Language barriers, identified during assessment, are considered when teaching the client. The goal of instruction is to have the client demonstrate the performance of exercises while verbalizing why the exercises are used during the postoperative phase (see Procedure 40-1).

Clients may experience their worst postoperative pain while coughing, deep breathing, and exercising. Clients with abdominal or chest surgery may avoid using muscles in the affected areas to take deep breaths or to cough effectively. Deep breathing and coughing facilitate removal of accumulated pulmonary secretions. Certain anesthetic agents depress the central nervous system, causing some clients to experience shallow respirations. Inhaled gases and oxygen have a direct drying effect on the respiratory mucosa, which increases the viscosity of mucus, making the secretions difficult to raise with coughing. These factors place the client at risk for respiratory complications (see the accompanying display on common respiratory complications after surgery on page 1310).

To prevent respiratory complications, the nurse teaches clients to use a breathing technique in which the client turns, coughs, and deep breathes to achieve sustained maximum inspiration (SMI). SMI promotes the reinflation of the alveoli and the removal of mucus secretions.

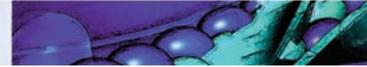

Several devices help encourage clients to perform SMI exercises. The breathing devices, called **incentive spirometers**,

measure the client’s ventilatory volume and provide the user with a tangible reward for generating an adequate respiratory flow. Devices range from simple types, such as a Ping-Pong ball in a plastic tube, to sophisticated models. When the client takes a deep breath, the ball moves upward and the amount of air is measured, making the results visible to the client.

Turning, deep breathing, coughing, and using spirometry prevent respiratory complications by:

- Promoting pulmonary circulation
- Promoting the exchange of gases by increasing lung compliance
- Facilitating the removal of mucus secretions from the tracheobronchial tree

Postoperatively the client is encouraged to move in bed and perform leg exercises as explained in Procedure 40-1. These exercises assist in preventing circulatory complications that can arise from anesthetic agents that depress the metabolic and heart rates; see the accompanying display on page 1311. Early ambulation also increases respiratory function and the return of peristalsis.

COMMON RESPIRATORY COMPLICATIONS AFTER SURGERY AND ANESTHESIA

- Pulmonary embolism: A blood clot that has moved to the lungs, causing pulmonary obstruction
- Atelectasis: Decreased ventilation caused by the pooling of secretions in dependent areas of the bronchiole
- Pneumonia: Inflammation of lung tissue
- Hypoxemia: Lowered oxygen level in the blood

OTHER DEVICES Besides exercises, other devices are used to prevent postoperative circulatory complications, namely, antiembolism stockings and pneumatic compression. Another device, continuous passive motion, increases range of motion for immobilized clients after surgery. The CPM device also

TABLE 40-6 Preoperative Teaching Interventions and Expected Client Outcomes

INTERVENTION	EXPECTED CLIENT OUTCOMES
Preparation activities	The client can: <ul style="list-style-type: none"> • Describe in own terms the purpose, risk factors, and outcomes of surgery and anesthesia. • Explain restrictions on food the evening before, identifying the time frame (6–8 h) of NPO, when no food and drink are allowed by mouth. • Explain the meaning and purpose of skin and bowel preps. • Identify medications to be taken or omitted the day of surgery. • Describe activities that will occur in each perioperative area: holding area, fluids will be started in a vein; position on the operating room table; stay in recovery until awake, then be transferred to an intensive care unit.
Postoperative exercise instructions	The client can demonstrate on two consecutive occasions postoperative exercises: deep breathing, coughing and pillow splinting, turning and proper body alignment; leg and foot exercises; and out-of-bed transfers.
Proper application and usage of medical devices	For example, the client can demonstrate proper use of incentive spirometer, application of TED hose, and self-medicating pain infusion pump.
Physical or environmental changes following surgery	The client can demonstrate knowledge of the rehabilitation process: daily physical therapy for 2 weeks and a home health nurse for 10 days to administer prophylactic antibiotics and to monitor and refill the patient-controlled analgesia pump.

TED, thromboembolic disorder.

Delmar/Cengage Learning

COMMON CIRCULATORY COMPLICATIONS AFTER SURGERY AND ANESTHESIA

- Thrombophlebitis: Inflammation of a vein with the formation of a blood clot
- Thrombus: A blood clot in the circulatory system
- Embolus: A blood clot or air that moves in the circulatory system from its place of origin

stimulates healing of articular cartilage by reducing swelling and adhesions.

Pain is managed with devices such as transcutaneous electrical nerve stimulation and patient-controlled analgesia. The client needs to be informed about the use of such devices preoperatively to promote achievement of postoperative pain outcomes. All medical devices require a prescribing practitioner's order.

Antiembolism stockings are elastic hose that compress leg veins to facilitate the return of venous blood. Depending on the surgical site, these stockings can be applied preoperatively (e.g., abdominal surgery) and utilized throughout the perioperative course at the direction of the surgeon.

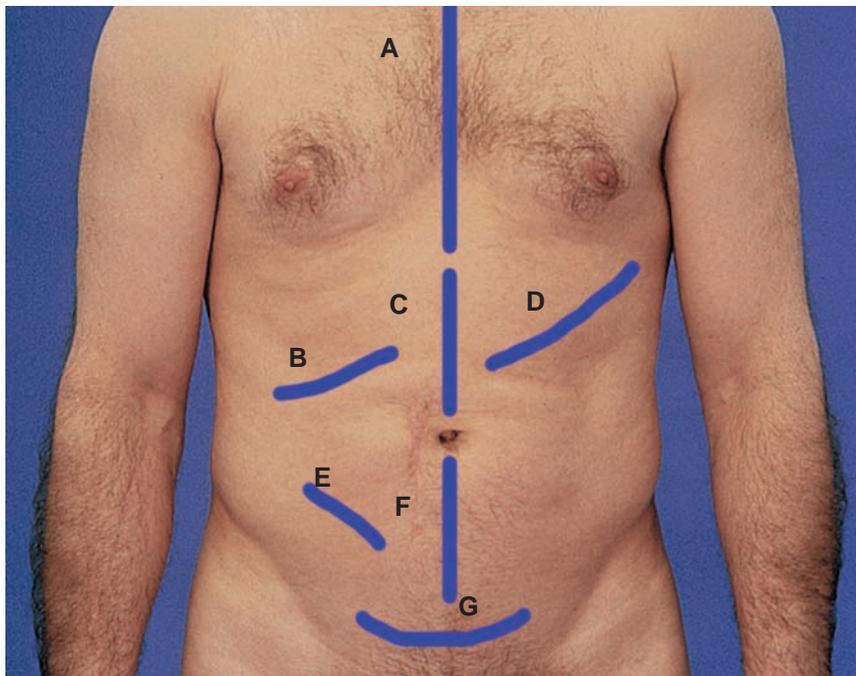

Elastic stockings are available in a variety of lengths, colors, and sizes to accommodate specific needs. One type of

hose goes from the foot to the knee; another type goes from the foot to midhigh. Some stockings have partial openings on the foot to expose either the toes or heel so that the nurse can assess circulation.

The prescribing practitioner usually specifies the size and style of the hose and the frequency of application. If the prescribing practitioner does not indicate the size, the nurse uses a tape to measure the circumference of the calf and thigh and the length of the client's leg from the heel to the gluteal furrow. Stockings are removed for 20 to 30 minutes three times a day to allow for assessment and hygienic care. Assessment should include inspection for redness, palpation for tenderness or increased temperature, and testing for Homans' sign. (See the Nursing Checklist on application of antiembolism stockings on page 1313.)

A **pneumatic compression device** provides intermittent compression cycles to the veins of the extremities to promote circulation. The device consists of either vinyl surgical sleeves that slide over each calf or Velcro-secured vinyl compression hoses that are applied under the thigh and leg with a knee-opening site that is placed over each popliteal area (see Figure 40-3 on page 1312). Both types of vinyl appliances have tube connectors that attach to an air pump machine. Observe the client applying the stockings, connecting the tubes to the air pump, and setting the correct pressure.

The air pump has an on-off switch and a dial to set the desired pressure. Turning on the pump initiates compression cycles, which cause the vinyl sleeves to inflate and deflate automatically. The nurse assesses the circulation to the extremities

INCISION	LOCATION	ORGAN
A. Sternal split	Begins at the top of the sternum and extends downward to the sternal notch	Heart
B. Oblique subcostal	Begins in the epigastric area and extends laterally and obliquely below the lower costal margin	Right side: Gallbladder, biliary Left side: Spleen
C. Upper vertical midline	Begins below the sternal notch and extends distally around the umbilicus	Stomach, duodenum, pancreas
D. Thoracoabdominal	Begins midway between the xiphoid process and the umbilicus and extends across the seventh or eighth intercostal space to the midscapular line	Thorax, heart
E. McBurney	Begins below the umbilicus, goes through McBurney's point, and extends toward the right flank	Appendix
F. Lower vertical midline	Begins below the umbilicus and extends downward toward the symphysis pubis	Bladder, uterus
G. Pfannenstiel	Begins 1.5 inches above the symphysis pubis with a curved transverse cut across the lower abdomen	Uterus, fallopian tubes, ovaries

FIGURE 40-2 Location of Common Surgical Incisions DELMAR/CENGAGE LEARNING

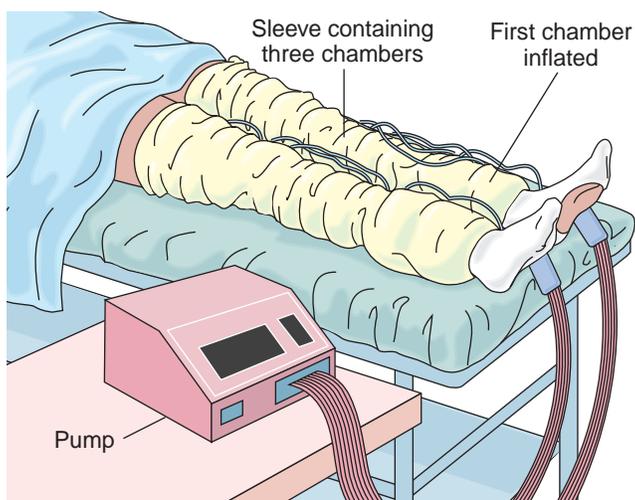

FIGURE 40-3 Pneumatic Compression Device DELMAR/CENGAGE LEARNING

and placement of the stockings every 2 to 3 hours. The stockings are removed three times a day for 20- to 30-minute intervals to allow for hygiene care. Instruct the client on how to clean the vinyl stockings by disconnecting the stockings from the air pump and wiping off with tepid, soapy water.

The **continuous passive motion (CPM) device** increases range of motion and stimulates healing of the articular cartilage by decreasing swelling and the formation of adhesions. It is used for clients with a nursing diagnosis of either *Impaired physical mobility* related to the surgical intervention or *Altered tissue perfusion* related to surgical intervention and immobility. The goal is to increase tolerance of the CPM device. The expected client outcome is to maintain maximum mobility of the joint.

Before initiating CPM, the nurse:

- Assesses the neurovascular status (skin color and temperature, pulses, capillary refill, sensation, and movement) of the client's extremity

NURSINGCHECKLIST

Application of Antiembolism Stockings

- Wash hands and obtain the stockings, making sure the type and size are correct.
- Check the client's identification band.
- Show the client the stockings and explain the procedure to elicit cooperation. Make sure the client knows that the stockings are to be removed routinely and washed daily according to package directions.
- Provide for privacy. The client should be in a comfortable position to observe your technique while you apply one of the stockings.
- Wash, rinse, and dry the legs; stockings should be applied only to clean, dry skin.
- Talcum powder can be applied to the feet and legs to allow the stocking to move more easily over the skin.
- Turn the stocking inside out, except the foot portion.
- Place the foot of the stocking over the client's toes and on the foot; with your nondominant hand supporting the client's ankle, use your dominant hand to pull the heel pocket over the client's heel (see Figure 40-4).

FIGURE 40-4 When applying antiembolism stockings, support client's ankle while pulling stocking up. DELMAR/CENGAGE LEARNING

- Slide the stocking up the leg, straightening as you apply; make sure that kinks and wrinkles are smoothed out to provide even pressure.
- Knee-length stockings should end 1 in (2.5 cm) below the knees.
- If the stocking goes to midthigh, have the client flex the knee while you pull the stocking over the knee and thigh; the stocking should be 1 to 3 in (2.5 to 7.5 cm) from the groin.
- The top of the stockings should not be folded over because additional constriction can occur.
- Have the client apply the other stocking, and assess the client's learning.
- Document client learning.

NURSINGCHECKLIST

Instructing the Client on the Use of the TENS Device

- Place electrodes on the skin in the area of pain (e.g., on both sides of an incision).
- Connect the lead wires to the electrodes and portable battery-powered transmitter.
- Turn on and regulate for comfort by working with one lead at a time, beginning with a zero setting.
- Gradually increase the level of stimulation until the client feels discomfort, indicating that maximum stimulation has been achieved to block pain sensation; then reduce the volume slightly to prevent continued contraction of muscles.
- Repeat the same process with the other lead; this time allow the client to perform the actions.
- Ensure that the client knows to apply the electrodes to clean, unbroken skin.

- Applies the disposable soft goods to the CPM device according to the manufacturer's instructions
- Sets the machine to provide the degree of flexion and extension according to the prescribing practitioner's orders (e.g., 0° extension and 35° flexion)
- Adjusts the speed to control movement

When the device is readied, the client is positioned in the middle of the bed to accommodate the CPM unit. The nurse places the client's legs in the padded CPM device, making sure that the knees are at the hinged joint of the machine. The nurse measures the angle of flexion with a goniometer when the device has reached its greatest height. The client is taught how to operate the "go/stop" button and is instructed to report any discomfort or pain that occurs with motion.

Postprocedure, clients experience pain, a subjective experience that may or may not be verbalized. Postoperative pain should be discussed with the client preoperatively so that clinical practice guidelines can be used to assess the severity of pain using either a verbal rating scale or a visual analog scale; refer to Chapter 35 for a discussion of pain scales. It is important to understand that all clients respond to pain in a different manner.

A **transcutaneous electrical nerve stimulation (TENS)** unit controls pain by delivering electrical impulses to nerve endings that block the passage of pain signals from entering the dorsal spinal root. (See the Nursing Checklist on instructing a client on the use of the TENS device.) The TENS unit is effective in reducing pain and the amount of pain medication required to maintain comfort after surgery. The unit consists of a transmitter, lead wires, and electrodes (see Figure 40-5 on page 1314).

The **patient-controlled analgesia (PCA)** pump is a device that allows the client to control the delivery of

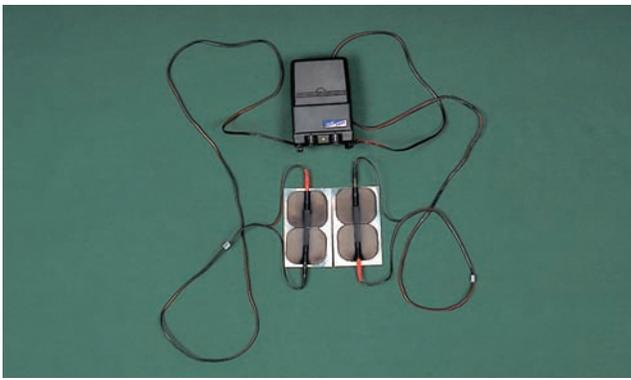

FIGURE 40-5 Transcutaneous Electrical Nerve Stimulation (TENS) Unit DELMAR/CENGAGE LEARNING

intravenous or subcutaneous pain medication in a safe, effective manner. The client self-regulates the delivery of the medication. Several different types of PCA devices are available; the manufacturers provide instructions for setting up the infusion pump. The pain medication is contained within an infusion pump and set according to the prescribing practitioner's order: type and concentration of pain medication, loading dosage, and **lock-out interval** (minimum time allowed between doses for the client to self-medicate).

Before initiating the PCA pump, the nurse assesses the client's level of consciousness, orientation, reading ability, and ability to learn and comprehend. PCA is used most frequently in adolescents and adults. Family members are also taught how to recognize the signs of drug overdose in homebound clients. Instruct the client on the PCA unit:

- To self-administer the medication as needed
- That the amount of the drug the machine delivers within a particular time frame is regulated to prevent overdose
- On the use of the control button

The advantages of a PCA unit are rapid pain relief, increased client satisfaction, and often the use of less medication than with the traditional intramuscular analgesia method.

Physical Preparation

Physical preparation should be discussed with the client to ensure that the client is mentally and physically prepared for surgery. These nursing functions are individualized to the client's needs as determined by health status and the type of surgical procedure scheduled. Activities such as restricting fluids, bowel preparation, or the removal of nail polish are done the evening before, regardless of the setting. Other activities occur the day of surgery in various perioperative settings.

SKIN PREPARATION The skin and hair follicles harbor microorganisms that can contaminate a surgical wound. The skin around the operative site is prepared to reduce the number of organisms present and to inhibit rebound growth. Preparation of the skin to reduce contamination of the surgical wound occurs in two phases. The evening before or the day of surgery, the client washes the area involved in the surgical procedure with an antimicrobial soap. The client is

usually instructed to wash the surgical area vigorously several times to decrease the chance of wound infection.

Most agencies follow the recommendations of the Centers for Disease Control and Prevention (CDC), the Joint Commission, and AORN regarding the second phase. During the second phase, the skin is surgically prepared by removing hair in the operative site. The CDC and AORN recommend that this be done in the OR. Prior to the Joint Commission's 2009 NPSGs, shaving with a razor was done in the OR immediately before surgery; however, this technique for preparing the skin is no longer acceptable because of the increased risk for infection caused by razor cuts and nicks in the skin. As stated earlier in this chapter, effective January 1, 2010, when hair removal is necessary, the appropriate method is clippers or depilatories. Methods used to prep the skin are discussed in the section on the intraoperative phase later in this chapter.

NUTRITION Nutrition and fluid considerations are determined by the client's health status and the nature of the surgical procedure and anesthesia. Clients scheduled for surgical procedures requiring only local anesthetic agents may be allowed a light breakfast or clear liquids the day of surgery. However, clients scheduled for regional or general anesthesia are instructed not to eat or drink (NPO) for 6 to 8 hours before surgery. Restricting food and fluids decreases the risk of aspiration of gastric contents into the lungs during anesthesia.

Clients at risk for dehydration are infants, older adults, those with preexisting nutritional imbalances, and those having surgical procedures that cause extensive loss of blood and other body fluids. These clients are usually given intravenous fluids preoperatively to maintain fluid and electrolyte balances. Measurement of intake and output allows the nurse to monitor the client's fluid and electrolyte status.

GASTROINTESTINAL PREPARATION Gastrointestinal surgeries may require special procedures to prepare the stomach or intestines. These special procedures are performed to decrease the risk of complications such as aspiration or infection.

Nasogastric Tube Some clients may require a nasogastric tube to facilitate stomach decompression to prevent postoperative abdominal distension. Insertion of a nasogastric tube causes client discomfort and can increase apprehension regarding surgery; therefore, the tube is usually inserted during the intraoperative phase when the client is under anesthesia (see Chapter 34). Inform clients that the tube can cause irritation to the nasal mucosa and may result in a sore throat.

Bowel Preparation The surgeon prescribes the type of bowel preparation on the basis of the surgical procedure. Enemas and laxatives are not routinely administered unless the client is having abdominal surgery. Intestinal surgeries require a bowel preparation to cleanse the intestines of fecal material by administering either a cathartic or enema to empty the bowel (see Chapter 39). Antibiotics are given to

reduce the bacterial content. Cleansing the bowel is necessary because surgical manipulation of the intestines interrupts normal peristalsis. Also, incision of any portion of the gastrointestinal tract places the client at risk for peritonitis if fecal material enters the abdominal cavity.

The client is usually instructed to eat a light meal the evening before, avoiding high-fat foods, and is given a laxative. The morning of surgery, enemas may be given. If the surgeon orders “enemas until clear” (no fecal return), refer to the agency’s policy. Administering enemas until clear can place the NPO client at risk for fluid and electrolyte imbalances. The client’s stress response may already be compromised by the fear of surgery; administering repeated enemas may further decrease the client’s coping mechanisms.

URINARY ELIMINATION The client is instructed to void before receiving the preoperative medication or being transferred to the OR. The bladder needs to be empty to prevent distension and incontinence during the surgery.

Some surgeries can require continuous decompression of the bladder; the OR nurse usually inserts a Foley catheter before or during surgery. See Chapter 39 for details on catheterization. If this occurs, the client should be informed about the catheter and how long the catheter will be left in place. Inform the client that a Foley catheter causes a sensation of pressure and an urge to urinate.

SAFETY PRECAUTIONS Outpatient clients are instructed to leave their jewelry at home and to avoid the use of makeup the day of surgery for safety reasons. Jewelry and other metal objects can cause burns when electrocautery is used during surgery. Rings can compromise circulation. Hairpins can injure the scalp when the head is positioned for anesthesia. Makeup and nail polish can interfere with the practitioner’s assessment of oxygenation.

Unnecessary prosthetic devices should also be left at home to prevent client injury or loss. Outpatient areas have limited space to secure valuables. Contact lenses should always be removed and stored before surgery to avoid cor-

neal ulceration and displacement. Partial dentures and other orthodontic devices must be removed to prevent displacement into the throat during anesthesia.

If the client feels helpless without certain devices, such as glasses and hearing aids, it should be documented on the preoperative checklist that the client is wearing such devices. The OR nurse removes such devices immediately before or after anesthesia induction.

Hospitalized clients are usually instructed to give their valuables to a family member before surgery. Otherwise, these items are removed from the client’s room and placed in a safe area according to hospital policy. The nurse documents on the preoperative checklist the disposition of valuables and prosthetic devices.

MEDICATIONS Efforts are made to continue routine medications throughout the perioperative experience. The surgeon instructs outpatient clients on which medications to take the day of surgery. The nurse is responsible on the day of surgery to document which medications were taken and to notify the surgeon when drugs were omitted.

Clients scheduled to receive only local anesthesia are usually instructed to wait until after the procedure to take their medications unless there may be a time delay that could have a negative effect on the client. The following medications that increase client risk are withheld:

- Anticoagulants, ibuprofen, and aspirin: May increase blood loss. Clients routinely taking oral anticoagulants are given subcutaneous heparin to ensure prompt reversal with intravenous protamine sulfate should the need arise; oral anticoagulants are not reversed by protamine sulfate.
- MAO inhibitors: May interact with anesthetic agents and are discontinued 2 weeks before surgery.
- Aminoglycosides: Potentiate the effect of neuromuscular blockers.
- Oral hypoglycemic agents: Are continued until the evening before surgery except for chlorpropamide, which is discontinued 48 hours before surgery. To prevent intraoperative fluctuations in blood sugar, an intravenous infusion of glucose and insulin is begun before surgery.
- OTC medications and herbal preparations that are contraindicated for anesthesia are ceased as long as 2 weeks prior to surgery.

The client should always disclose all medications currently in use to the prescribing practitioner when a surgical procedure is scheduled. The medication dosage can be adjusted preoperatively for certain drugs. For instance, corticosteroid therapy should be continued when clients have been maintained on the drug for 2 months or more; the dose to be given on the day of surgery depends on the client’s daily therapy.

Medications to reduce anxiety and facilitate the induction of anesthesia are administered as prescribed. To prevent client discomfort with traditional intramuscular preanesthetic injections, facilities with a holding area use this setting to initiate intravenous therapy and administer the preanesthetic drugs intravenously.

SPOTLIGHT ON...

Legal and Ethical

Nursing Intervention

What should a nurse do if a client refuses a treatment? You are caring for a 16-year-old boy who was in an automobile accident and is scheduled for bladder surgery. The parents are present for perioperative teaching. You explain what will happen during the surgical procedure and that the boy will have a catheter after surgery. The boy gets upset, saying he does not want a tube. What type of age-related teaching materials might you use in this situation?

EVALUATION

Evaluation of actual and expected outcomes of the perioperative client is done over the three phases. Preoperative evaluation focuses on the client's ability to verbalize and demonstrate the exercises. The outcome is evaluated when the client successfully performs the exercises after surgery. Measurement of the client's ability to perform postoperative exercises should first be assessed during the teaching session and again an hour later to evaluate learning. If the client needs coaching to perform the exercises, reinforce teaching until the client demonstrates the exercises appropriately.

Assessment of the client's knowledge regarding the nature, purpose, and risks of the surgical procedure is measured preoperatively. Likewise, the nurse listens to the client's comments and monitors physiological indicators (e.g., vital signs) to measure fears and anxieties regarding the surgery.

The evaluation of a client's preoperative preparation for surgery should include understanding of the procedure, verbalization and return demonstration of postoperative exercises, and postoperative expectations resulting from the surgery. Refer to the accompanying Nursing Process Highlight to understand how the nurse evaluates achievement of client expected outcomes.

Documentation

Documentation of preoperative activities must be entered in the client's medical record on the appropriate forms. The preoperative checklist is used to document accurate comple-

tion of preoperative activities. Documentation on this form means that all aspects of care have been performed as ordered. When the OR personnel come to transfer the client, the preoperative nurse signs the checklist, entering the time and mode of transportation to the OR (e.g., by stretcher).

INTRAOPERATIVE PHASE

The intraoperative phase begins when the client is transferred to the OR and ends with the client's discharge from the OR. The goal of nursing care during this phase is to ensure client safety. Maintaining a safe environment includes protecting the client from injury, infection, and complications arising from anesthetic agents, hazards, and the surgical procedure. The nursing interventions are based on the AORN's (2008) preoperative standards and recommended practices.

SURGICAL ENVIRONMENT

The surgical area usually consists of three zones: unrestricted, semirestricted, and restricted. The unrestricted area is designed for personnel to enter in street clothes: receiving desk, holding area, and locker rooms. Surgical attire (scrub clothes, disposable shoe covers, and caps) is required in the semirestricted and restricted zones. Personal protective equipment (PPE) (e.g., goggles, gloves, gowns) is utilized as part of the Occupational Safety and Health Administration (OSHA) and Joint Commission guidelines. Evidence-based practice has shown that shoe covers are no longer required as a conduction precaution; however, OR personnel may still wear shoe covers to keep their shoes clean. Hallways and storage areas constitute the semirestricted area. Restricted zones (controlled and germ-free areas) include the OR and rooms where sterile instruments are prepared.

Holding Area

The holding area is a unit where the surgical team prepares the client for surgery (see Figure 40-6 on page 1317). The anesthesia provider usually starts the intravenous infusion and administers the preoperative intravenous medication. The nurse confirms that aspects of care on the preoperative checklist have been performed. A family member is usually encouraged to remain with the client while the client awaits transfer to the OR.

Occupational Hazards

Perioperative personnel are at risk of exposure to harmful pathogens and other dangers. Dangers of a particular concern to perioperative nurses are latex allergies, needlesticks, eye splashes, back injuries, and indoor pollution. Precautions should be in place that are in compliance with OSHA standards regarding bloodborne pathogens, medical waste and hazards materials (including personal protection devices), disposal of needles and syringes, and contaminated supplies.

NURSING PROCESS HIGHLIGHT

Evaluation

Achievement of Expected Outcomes

In evaluating the nursing care of Mrs. Broussard during the preoperative phase of her total hip replacement surgery, the following questions should be considered:

- What methods can be used to determine whether Mrs. Broussard understands the events that will occur during the surgery?
- What postoperative exercises should Mrs. Broussard be asked to demonstrate for the evaluation of her ability to perform these measures?
- What types of information should Mrs. Broussard be able to share about the postoperative course of treatment?
- What methods can be implemented to elicit Mrs. Broussard's concern or anxiety about the surgery itself or the expectations for her recovery?

FIGURE 40-6 Holding Area. What is this nurse doing to prepare this client for surgery? DELMAR/CENGAGE LEARNING

See Chapter 29 for a complete discussion of latex allergy and OSHA's standards.

Health care agencies need to have a process in place to document compliance with OSHA requirements. Akduman et al. (1999) studied the compliance of OR personnel with universal precautions during surgical procedures in four specialties: orthopedic, gynecologic, cardiothoracic, and general surgery. Personnel were informed in advance about data collection regarding the use of protective equipment. The study revealed that only 39% of the personnel wore protective goggles, 5% wore face shields, 32% wore regular glasses, and nearly 25% wore no eye protection. Although double-gloving was higher in orthopedics than other areas, only 28% of the observed personnel double-gloved. A 22% rate of exposure was observed during 76 cases, with 3 percutaneous injuries (2 scalpel, 1 needlestick) and 14 cutaneous blood and bodily fluid exposures. The study proposed the need for consistent training in and reinforcement of OSHA's guidelines.

Slattery (1998) refers to the hospital environment as a "chemical soup" and addresses the agents that compromise the quality of indoor air. Pollution in the OR is caused by fumes from high levels of disinfectants; surgical smoke from tissue being cut, vaporized, or coagulated; and waste gases from anesthetic agents. Disinfectants such as glutaraldehyde used to sterilize instruments are not regulated, and the fumes may cause serious respiratory and dermatologic problems. OR nurses are also at risk with respect to laser plume or surgical smoke, which can lead to respiratory problems, burning, watery eyes, nausea, and viral contamination and regrowth. To decrease the exposure to these dangerous pollutants, agencies should have policies in place that require clients and personnel to wear high-filtration masks and should provide rooms with smoke evacuators.

ASSESSMENT

The first activity of assessment for the OR nurse is to check the client's identification band and confirm the surgical site. Agency protocol and standards of care from the AORN

establish the focus areas of assessment for the client and the environment.

Assessment of proper positioning to ensure comfort and safety includes:

- Checking for client alterations that can affect positioning during the procedure, such as previous skeletal or joint surgery, presence of a joint or vascular prosthesis, poor nutrition, and compromised skin integrity
- Making sure the OR bed is prepared to receive the client: for example, warming mattress on bed, proper orientation of bed, bed wheels locked
- Ensuring that accessories are clean and readily available for a specific position: for example, Wilson frame, chest rolls, pillows, headrest

Throughout the surgical procedure, the nurse assesses for pressure areas of the extremities, joints, or any body surface; skin discoloration; and temperature. Whenever the client's position is changed during surgery, the nurse reassesses for signs of circulatory impairment from positioning and equipment in contact with the skin.

NURSING DIAGNOSES

Common intraoperative nursing diagnoses promote client comfort, safety, and support during the surgical procedure. See the previous Table 40-3 on perioperative nursing diagnoses.

PLANNING AND OUTCOMES

The focus of intraoperative care planning is on nursing activities that promote the client's achievement of expected intraoperative outcomes (see the accompanying display on page 1318). These outcomes are directed at placing the client in a safe environment free from injury. The OR team monitors the client throughout the surgical procedure for complications.

Specific nursing care is planned to encompass the surgeon's specifications for positioning and to alleviate or prevent any individual client problem. Surgeons have preference cards that identify the type of equipment and instruments for various surgical procedures (e.g., indications and use of electrical equipment). Planning also involves determining the appropriate mode of client transfer, equipment and positioning aids, and need for ancillary personnel to accomplish the positioning. The plan of care should be individualized to include needs relative to the client's health status such as diabetes, malnourishment, or paralysis.

Collaboration

The surgical team consists of the surgeon, anesthesia provider, RN, surgical technologist, RN first assistant (RNFA) or physician assistant (PA), and other members of the health care team.

The roles and responsibilities of the surgeon and anesthesia provider have already been discussed. The OR team usually consists of:

- Surgeon: Scrubbed and in surgical attire to perform the surgery

COMMON INTRAOPERATIVE CLIENT OUTCOMES

- The client demonstrates knowledge related to the physical environment and surgical intervention.
- The client's needs are met while in a dependent state from the anesthesia.
- The client is maintained in a safe, germ-free environment during the surgical procedure.
- The client is free from infection 72 hours postoperatively.
- The client's skin integrity is maintained by proper positioning on the operating room table.
- The client is maintained in proper body alignment to prevent injury from positioning.
- The client is free from injury related to exposure from heat loss.
- The client is free from injury related to chemical, electrical, and physical hazards.
- The client's fluid and electrolyte balance is maintained.

- Anesthesia provider: Masked and in clean scrub attire to administer the anesthesia
- Surgical assistant (first assistant): Can be another prescribing practitioner, RNFA, or PA who is scrubbed, is in sterile attire, and assists the surgeon to ligate, suction, and suture
- Scrub nurse or technologist: Scrubbed and in sterile attire; prepares the instrument tray and passes the instruments, sponges, needles, and sutures to the surgeon
- Circulating nurse: In clean scrub attire and mask; obtains supplies, delivers materials, pours solutions, handles specimens, positions the client and surgical drapes, disposes of soiled items, and coordinates care of the client

Both the scrub and circulating nurses are responsible for counting the number of used instruments, needles, and sponges. Before the surgeon closes the incision, these items are counted to ensure that nothing is being left in the operative site.

INTERVENTIONS

Nursing interventions are selected to facilitate caring and to achieve the expected outcomes, such as the client is free from infection 72 hours postoperatively. Because anesthesia inhibits the client's ability to protect himself or herself, the OR staff implements surgical asepsis, safe positioning, and other interventions that promote client safety (e.g., the client is never left unattended).

Nursing care includes communication skills to reduce the client's anxiety. The OR staff communicates a caring

COMMUNITY CONSIDERATIONS

Nursing Care and Client Populations

What options are available to nurses who have personal objections to caring for certain client populations?

The Special Committee on Ethics of the AORN conducted a study to elicit acquired immunodeficiency syndrome (AIDS)-related knowledge, attitudes, and practices of perioperative nurses. The findings revealed that:

Nurses continue to be reluctant to provide care to HIV-positive clients if given a choice. Sixty percent of perioperative nurse respondents said they "somewhat agreed" or "strongly agreed" with this sentiment compared with 62% of the respondents in the original study. One AORN respondent said, "I don't believe anyone should be legally required to care for any patient with any illness/disease" (Reeder, Hamlet, Killen, King, & Uruburu, 1994, p. 456).

What is your reaction to the AORN respondent? Read the American Nurses Association Code of Ethics in reviewing your own values toward HIV-positive clients.

attitude, functioning under the assumption that anesthetized clients will be able to recall comments made during surgery.

Surgical Asepsis

Surgical asepsis is used to decrease the client's risk for an infection. Surgical asepsis refers to handwashing, wearing surgical attire, handling sterile instruments and equipment, and establishing and maintaining sterile fields. The sterile field is free of microorganisms, and only sterile items can be placed inside the field.

Surgical handwashing is performed to remove soil and microorganisms from the skin. The skin on the hands and arms should be intact (free of lesions). Agency policy determines how the scrub is to be performed (e.g., method and timing); see Chapter 29.

Once the scrub nurse is properly attired for surgery, strict adherence to aseptic principles guides all actions. The hands and arms are held above the waist at all times. Only attire from the waist to the gown's collar and the anterior surface of the sleeves is considered sterile. The scrub nurse sets up the instrument table, using sterile drapes and instruments. Only the tops of instrument tables are considered sterile. Items placed within a sterile field are opened, dispensed, and transferred using techniques to maintain their sterility. Soiled or contaminated

articles are removed immediately from the room by the circulating nurse.

Skin Preparation

Skin preparation (prep) is performed to decrease the risk for infection by reducing the resident microbial count on the skin and inhibiting rebound growth of microbes when the skin is incised during surgery. The second phase of the surgical skin prep is usually done by OR personnel before surgery to prevent the growth of microorganisms.

Guidelines for when and where the skin is to be prepped for the surgical procedure differ according to agency policy, surgeon preference, and incision site. The preference card usually indicates the type of preparation. The OR nurse ensures that the operative site is clean.

The skin prep should comply with the CDC and Joint Commission recommendations to avoid unnecessary hair removal. Hair can be removed by clipping and depilatory. A dry shave refers to the removal of hair by clipping or the use of a depilatory. Figure 40-7 designates the body surfaces to be prepared for surgical procedures involving the head, neck, ear, and upper thorax. Preparation of the upper extremities, chest, and abdomen are illustrated in Figure 40-8 on page 1320.

When performing a skin prep, the nurse should provide the client with an explanation of the procedure, privacy, comfort, and safety. Common agents for prepping the skin include povidone-iodine, chlorhexidine, alcohol, and hexachlorophene. If the client has any adverse reactions to the prep, the nature of the reaction should be documented and the prescribing practitioner notified.

Positioning and Draping

The surgical client is usually sedated or anesthetized and therefore is unable to communicate any discomfort. Proper positioning ensures client comfort and safety, preserves vascular supply, and prevents neuromuscular damage to tissue; refer to NIC, Positioning: Intraoperative (0842). At the same time, positioning also provides access to the surgical site, airway, intravenous lines, and all monitoring devices.

All sharp surfaces in contact with the client's skin are padded to prevent injury from positioning. Bony prominences (e.g., sacrum, elbows, and heels) are padded to avoid excessive pressure on these points. The nurse ensures that skin surfaces are insulated from metal bed attachments (e.g., padded arm boards, headrest, stirrups). Appropriate devices

SAFETY FIRST

CHEMICAL BURNS

After the skin preparation, remove all solution that has pooled under the client; chemical skin burns can result from prolonged exposure to antiseptic solutions.

are made available to support extremities to prevent compression of vital structures, such as the ulnar nerve or Achilles tendons.

The circulating nurse ensures that at least four persons are available for positioning clients under general anesthesia. Restraints (or belts) are available to secure the client to the operating bed; sufficient soft padding is used to maintain anatomical alignment of the head and neck with the spine.

FIGURE 40-8 Surgical Preparation of Upper Extremities and Trunk for Surgery, Anterior and Posterior Views DELMAR/CENGAGE LEARNING

Once the client is positioned properly and the site has been prepped, the sterile team applies the sterile drapes. OR drapes are designed to expose specific operative sites. The staff keeps the sterile drapes dry and in place.

Electrical Hazards

During surgery the client can be exposed to an electrical surgical generator (electrocautery device to eliminate bleeding and reduce contamination); refer to NIC, Surgical Precautions (2920). Electricity cannot flow unless a circuit is complete; thus, electricity introduced into the body has to find a pathway back to the generator. A ground pad is provided for that purpose.

Proper grounding technique is essential for the safe and effective use of the generator. The circulating nurse ensures that the selected ground site is free of skinfolds, scar tissue, erythema, skin lesions, or bony protuberances. The site should be as close as possible to the operative area. Throughout the surgery, the circulating nurse monitors the electrocautery for signs of improper function. At the end of the procedure, when drapes are removed, the circulating nurse inspects the ground site for any unusual skin discoloration, burns, or skin reaction.

Lasers provide another method for cutting and coagulating tissue during surgical procedures. Lasers deliver high-energy beams directly onto the tissue and reduce tissue damage and scarring that can inhibit healing. To prevent injury to the skin and eyes, the conscious client and staff wear special high-filtration masks to protect them from surgical smoke. All wear protective eyewear dependent upon the type of laser in use during the procedure. Appropriate signage designating the proper attire and precautions needed to safely enter the OR is posted to inform staff that the laser is in use.

Heat Loss

Injury from hypothermia is prevented by measures implemented to minimize heat loss. During surgery, body heat is lost by positioning on a cold OR table (conduction); administration of cold gases (convection); exposure of large operative sites, such as thoracic and abdominal areas (evaporation); and exposure to cold OR temperatures (radiation). Anesthetic agents can also alter thermoregulation and lower metabolism. Body temperature is maintained by applying warming mattresses or warmed blankets, warming and humidifying inhaled gases, warming irrigating and intravenous solutions, and increasing room temperature when the client is exposed (e.g., during skin prep and positioning).

Monitoring Physiological Functioning

After intubation and induction of anesthesia, the client is monitored for:

- Ventilation and circulation
- ECG and oxygen analyzer alterations
- Fluid intake, urinary output, and calculated blood loss

- Behavioral changes
- Body temperature
- Diagnostic testing (collection of specimens and cultures, x-rays, and fluoroscopy)
- Placement of medical devices (ground pad, position support, drains, catheters, implants, packings, and dressings)

These measures assist in identifying and correcting any serious problems before they can result in client injury.

EVALUATION

Before the client is transferred to the PACU, the circulating nurse evaluates and documents achievement of client outcomes. Evaluation is based on reassessment of findings for the client during and after surgery. The circulating nurse documents the specific data on the OR record, which usually reflects AORN standards of intraoperative care and other direct care issues pertinent to client outcomes.

TRANSFER TO POSTANESTHESIA CARE UNIT

While the surgeon is closing the incision, the circulating nurse gives a telephone report to a recovery room or PACU nurse regarding the client's health status, surgical outcomes, special equipment needs, and nursing interventions. This information allows the PACU staff time to prepare to receive the client.

Planning for personnel and equipment needed to safely transfer the client is usually handled by the circulating nurse. Moving the semianesthetized client from the OR table to the PACU stretcher for transport requires the coordinated effort of at least four persons. Assurance is made that a sufficient number of staff are available to move the client while maintaining proper body alignment and preventing the dislodgement of any tubes, drains, or monitoring devices.

Safety measures are implemented to prevent injury to both client and staff members. The staff uses good body mechanics and assistive devices, such as drawsheets or body rollers, to allow proper weight distribution of the client. The stretcher wheels are locked to prevent movement. The client is always lifted from the table, as opposed to being dragged or pulled with drawsheets, to prevent skin irritation or shearing. The nurse applies stretcher belts (restraints) prior to transport. Also, the head of the stretcher is elevated, side rails are raised, and the placement of tubes and drains is confirmed.

Once on the stretcher, the client is quickly transported by the circulating nurse and the anesthesia provider to the PACU. The client at this time is at high risk for injury related to the effects of residual anesthesia: airway distress, vomiting and aspiration, and circulatory alterations. The anesthesia provider stays with the client while the circulating nurse gives a report to the PACU nurse assigned to the client. The report should include all pertinent anesthesia and surgery information (see the Nursing Checklist).

After giving the report, the circulating nurse documents the time of discharge, method and disposition of transfer, and

NURSING CHECKLIST

Preparing the Postanesthesia Report

- Brief history of client's health status: preexisting conditions and medical diagnoses requiring surgery
- Baseline and OR vital signs
- Results of diagnostic testing (e.g., blood gases)
- Administration of anesthetic agents and other medications
- Estimated blood loss
- Total volume of output from all tubes and drains
- Total volume of infused intravenous fluids and blood products
- Presence and status of devices (e.g., tubes, drains, antiembolism hose)
- Any other problems treated during the surgery or other special nursing interventions

a general statement regarding the client's status. The client usually remains on the same PACU stretcher throughout the stay in the unit.

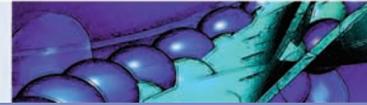

POSTOPERATIVE PHASE

The primary goal of nursing care during the immediate postoperative phase is to maintain the "A-B-Cs": airway, breathing, and circulation. Ongoing care is directed toward restoring the client to the preoperative health status. Clients receiving local anesthetics, without sedation, are usually transferred to the outpatient ambulatory care setting for observation while awaiting discharge. Their postoperative care is usually nonemergent in nature and is discussed later in the section titled Ongoing Postoperative Care.

General anesthesia requires intubation. Extubation is performed by the anesthesia provider before the client leaves the OR or in the PACU when assessment data confirm adequate gas perfusion. Clients with heart and other major surgeries are not extubated immediately. The endotracheal tube is usually removed on the first postoperative day. Intubated clients are usually transferred to intensive care units for 2 or 3 days.

ASSESSMENT

Following the initial assessment of the client's respiratory status, the nurse performs a total assessment (see Table 40-7 on page 1322). The postoperative nursing care protocol, based on AORN standards of care and guidelines from the American Society of PeriAnesthesia Nurses (ASPAN), is initiated. The protocol identifies those areas requiring immediate assessment and reassessment as discussed in Table 40-7.

TABLE 40-7 Initial Postoperative Assessment: Normal and Abnormal Findings

AREA OF ASSESSMENT	NORMAL FINDINGS	ABNORMAL FINDINGS
Airway and respiratory status <ul style="list-style-type: none"> • Adequacy of airway and return of gag, cough, and swallowing reflexes • Type of artificial airway • Rate, rhythm, and depth of respirations • Symmetry of chest wall movements and use of accessory muscles • Breath sounds • Color of mucous membranes • Pulse oximeter readings • Amount and method of oxygen administration • If awake, ability to breathe deeply and cough 	The client is able to: <ul style="list-style-type: none"> • Expel an oral airway; exhibit return of gag reflex • Breathe deeply and cough freely with normal rate for age, even without use of accessory muscles, and exhibit chest wall symmetry; show breath sounds present in all lobes; show pink mucous membranes • Show pulse oximeter reading between 95% and 100% • Demonstrate proper use of incentive spirometer, if awake 	<ul style="list-style-type: none"> • Upper airway obstruction: stridor, retractions, asymmetrical chest movement • Laryngospasm: high-pitched squeaky sounds • Dyspnea: shortness of breath or difficulty in breathing • Diminished breath sounds, wheezing, rales, or rhonchi • Residual neuromuscular blockage: weak inspiratory effort, inability to lift head, or inadequate muscle strength
Circulatory status <ul style="list-style-type: none"> • Apical and peripheral pulses • Blood pressure (BP) • Nail bed and skin color and temperature • Capillary refill • Homans' sign Monitoring devices: <ul style="list-style-type: none"> • Cardiac monitor (ECG) • Pressure readings (arterial BP or central venous pressure) 	The client has: <ul style="list-style-type: none"> • Normal apical rate and peripheral pulses • BP within 20 mm HG of baseline measurements • Pink nail beds; warm and dry skin • Capillary refill < 3 s • Negative Homans' sign • Normal ECG rhythm 	<ul style="list-style-type: none"> • Hypotension: BP < 20 mm of baseline; rapid, weak pulse; bluish nail beds; capillary refill < 3 s • Hemorrhage/hypovolemic shock: rapid, weak pulse; increasing respirations; restlessness hypotension; cold, clammy skin; pallor; urinary output < 30 mL/h • Positive Homans' sign (calf pain present on dorsiflexion of foot) • ECG pattern: dysrhythmias; signs of cardiac ischemia
Neurologic status <ul style="list-style-type: none"> • Level of consciousness (Glasgow Coma Scale) • Eye opening • Verbal response • Motor response 	The client: <ul style="list-style-type: none"> • Spontaneously opens eyes • Is orientated • Obeys commands (Glasgow Coma Scale of 15, highest rating) 	Glasgow Coma Scale score of 15 indicates some alteration in consciousness; a score of 7 is considered coma
Fluid and metabolic status <ul style="list-style-type: none"> • Intake and output • Palpate for bladder distention • Patency of intravenous (IV) infusion (type, rate, and amount) • Signs of dehydration (skin integrity and turgor) or overload (edema) • Patency, amount, and character of drainage (catheters, drains, or tubes) • Inspect operative dressing (type, color, and amount of drainage) • Auscultate for bowel tones in all four quadrants and inspect for abdominal distension 	Fluid intake balanced with total output and electrolytes within normal limits, considering replacement of blood volume lost during surgery: <ul style="list-style-type: none"> • IV fluids infusing per surgeon's order • Absence of bladder distension • Good skin turgor • Absence of edema • Drains and other tubing patent and intact • Dressing dry and intact • Bowel tones faint or absent during the immediate recovery phase • Absence of nausea and vomiting 	<ul style="list-style-type: none"> • Signs of deficient fluid volume (thirst, poor skin turgor, low-grade temperature, tachycardia, respirations \geq 30, a 10–15 mm Hg decrease in systolic BP, slow venous filling, urinary output < 25 mL/h) • Bright red blood on operative dressing • Signs of excess fluid volume (increased central venous pressure and edema, pulmonary or peripheral)

Level of discomfort or pain <ul style="list-style-type: none"> • Location, intensity, and duration • Type, amount of analgesia administered and client's response 	Client free from pain	Pain not relieved by analgesia
Wound management <ul style="list-style-type: none"> • Inspect the dressing • Type and amount of analgesia administered and client's response • If drainage is present, reassess in 15-min intervals 	Dressing dry and intact	Clot dislodged: bright red drainage on the dressing

Delmar/Cengage Learning

Focused assessment is performed relative to the surgical procedure as discussed in the Nursing Process Highlight.

NURSING DIAGNOSIS

Refer to the earlier Table 40-3 listing perioperative nursing diagnoses. Clients with preexisting conditions, identified during the preoperative period, will continue to require special nursing care. Depending on the individual client's needs, other nursing diagnoses can be included in the plan of care.

Some surgeries have unpleasant outcomes. The loss of an extremity or other body part or function can cause the client and family to experience ineffective coping. These situations require compassion and consideration to assist those involved to work through and express their feelings. Support needs to be given not only to the client but also to the family. Physical healing can occur before emotional or spiritual healing does. Learning to cope with a loss sometimes extends beyond the postoperative phase. See Chapters 14 and 25 for more information.

PLANNING AND OUTCOMES

Planning the care for postanesthesia clients addresses the development of nursing interventions to achieve the client's expected outcomes during recovery from anesthesia and surgery. Care planning is done in two parts: immediate care rendered in the PACU area and ongoing post-PACU care. Nursing care in the PACU usually lasts 1 to 3 hours and is directed toward returning the client to a safe physiological level of functioning after anesthesia. Care is prioritized according to the type of anesthesia and surgical interventions through the assistance of appropriate agency protocols (e.g., care of the client following extubation). See the accompanying

display on page 1324 for a sample of *Nursing Outcomes Classification* (NOC) measurements regarding postanesthesia care.

After discharge from the PACU, the nurse ensures that the client is knowledgeable about home care. Post-PACU care is begun for outpatients in the ambulatory setting. The

NURSING PROCESS HIGHLIGHT

Assessment

Client Specific (Focused)

During surgery Mrs. Broussard was placed in a lateral position and given a general anesthetic. She was extubated before leaving the OR with an oral airway in place on arrival to the PACU. Following assessment and management of the "A-B-Cs," the nurse assessed alignment of the left hip; the client's level of pain; incision dressing for drainage, inspecting posteriorly where drainage can pool; and circulatory, motor, and sensory status below the site of surgery.

- What immediate assessment parameters must the nurse address to ascertain the status of the postoperative client?
- What priority areas must the nurse assess?
- What measures should be implemented to determine the client's level of pain?
- What are the nurse's priorities when inspecting the incision?
- What signs or manifestations should the nurse be alert for regarding the incision?

NOC: POSTPROCEDURE RECOVERY STATUS

- Definition: Extent to which an individual returns to baseline function following a procedure requiring anesthesia or sedation
- Scales: Severe deviation from normal range to no deviation from normal range, and severe to none
- Indicators: Patent airway; spontaneous respirations; forceful cough; systolic blood pressure within 20 mm Hg of baseline; gag reflex; retaining oral fluids; fully awake; moving extremities on command; thermoregulation; urine output; voiding; drainage from tube or drain; drainage on dressing; nausea; vomiting; shivering; pain

Adapted from Moorhead, S., Johnson, M., Swanson, M., & Maas, M. (2008). *Nursing outcomes classification (NOC)* (4th ed., p. 448). St. Louis, MO: Mosby Elsevier Health Sciences.

nursing interventions reinforce client safety and teaching for discharge. For clients who are hospitalized postoperatively, the nursing care plan encompasses both inpatient and discharge needs.

INTERVENTIONS

Care in the recovery unit is directed by standards of care and protocols. These tools assist the nurse in determining the most effective interventions for specific client populations, type of anesthesia, and surgical procedure. Postoperative nursing interventions are based on assessment and reassessment findings.

Safety measures are initiated immediately on arrival into the recovery unit (see Figure 40-9). Intubated clients require the constant attendance of a nurse at the bedside. The head of

FIGURE 40-9 Postanesthesia care unit (PACU). What is the most essential action the nurse should implement with the client in this situation? DELMAR/CENGAGE LEARNING

the stretcher is maintained in a high Fowler's position. Stretcher belts and side rails are left in place from transfer; wheels on the stretcher are locked. Lifesaving equipment is at the client's bedside. The following is a discussion of nursing interventions for the postoperative client that incorporates nursing activities as defined by NIC, Postanesthesia Care (2870).

Monitor Respiratory Status

On arrival in the recovery area, the client is placed on high-humidity oxygen and attached to a **pulse oximeter**, a sensor device to measure the oxygen saturation level of the blood; see Procedure 40-2. The client is at risk for ineffective breathing patterns resulting from the anesthesia. At least every 15 minutes the nurse monitors the reading on the pulse oximeter along with respirations. A patent airway can be maintained with an endotracheal tube, nasal or oral airways, and suctioning when needed. See Chapter 32 for a complete discussion of airway devices.

If the client is extubated and experiences difficulty in breathing, reestablish the upper airway: Bring the chin forward, hyperextend the neck, and turn the head to the side. If the obstruction is unrelieved, insert either a nasal or an oral airway and suction. If these measures fail to relieve the obstruction, notify the anesthesia provider. The anesthesia provider is responsible for treating any physiological impairments related to anesthesia.

The nurse tapes the endotracheal tube on intubated clients to ensure proper placement. The client is maintained in a high Fowler's position to optimize breathing and lung expansion, unless contraindicated. Bronchial secretions are removed by suctioning the intubated client. Suctioning is performed on the basis of assessment findings:

- Rhonchi (low-pitched gurgling sounds in large airways)
- Low-pitched, musical wheezes despite bronchodilator therapy
- Increased peak airway pressure in clients receiving mechanical ventilation

The lungs are usually hyperinflated and hyperoxygenated before, between, and after suctioning to prevent hypoxemia and cardiac dysrhythmias. The nurse observes the ECG monitor while suctioning to observe for signs of hypoxemia.

Hypoxemia can be caused by inadequate lung ventilation from the depressant effects of anesthesia or narcotics. The PACU client is at risk for hypoxemia from the effects of general anesthesia, which reduces the inspiratory effort, and the presence of pain, which reduces ventilatory effort. Older or obese clients are especially vulnerable to postoperative hypoxemia.

The early symptoms of hypoxemia are drowsiness and confusion. These symptoms are usually present in PACU clients recovering from anesthesia. A blood oxygen level measurement less than 95% is an indication of hypoxemia.

EXTUBATION The agency's protocol is implemented to determine the parameters for extubation, such as the client being able to lift the head for 5 seconds and produce strong bilateral hand grasps. The nurse obtains a tidal volume,

negative inspiratory force, and vital capacity (if the client can cooperate) before extubation. See Chapter 32 for further discussion. The anesthesia provider is notified when the oxygen saturation percentage is within safe limits to allow extubation.

The nurse confirms the presence of bilateral breath sounds immediately before and after extubation by auscultation. The procedure is explained to elicit client cooperation and to allay anxiety. Before extubation, the pharynx and trachea are suctioned. The client is instructed to inhale deeply while the anesthesia provider deflates the cuff and removes the endotracheal tube at maximal lung inflation to encourage initial gas flux outward, allowing the forceful exhaling of secretions.

The client is placed immediately on humidified oxygen for at least 30 minutes and monitored with a pulse oximeter for an hour after extubation. Ventilation is maintained by encouraging deep breathing, coughing, turning, and taking deep breaths every 5 to 10 minutes.

Monitor Circulatory Status

The client is monitored carefully for the signs of hypotension (see Table 40-7), which can occur from the myocardial depressant effects of residual anesthesia or hypovolemia. The cardiac monitor displays the client's heart rhythm; it is used to detect and treat tachycardia, bradycardia, dysrhythmias, and cardiac ischemia.

Hypovolemic shock, the marked reduction in circulating blood volume, is caused by hemorrhage. The symptoms of hemorrhage are presented in Table 40-7. A rapid pulse rate can indicate pain, bleeding, dehydration, or shock. Impaired capillary refill indicates inadequate tissue perfusion to extremities.

Passive range of motion and the application of antiembolism hose or other devices promote circulation of the intubated or semiconscious client. Postoperative leg exercises are begun as soon as the client recovers from the effects of anesthesia. These measures prevent circulatory complications such as thrombophlebitis, thrombus, and embolus formation.

Monitor Neurologic Status

Monitoring the client's level of consciousness is done in relation to how the airway is maintained:

- The unconscious client with an absence of the cough and gag reflex will have an endotracheal tube or airway.
- The semiconscious client with partial return of all reflexes will have an oral or nasal airway.
- The conscious client with full return of all reflexes will breathe without assistance from an artificial airway.

The Glasgow Coma Scale is used to measure the client's level of response. See Chapter 38 for a description of the Glasgow Coma Scale.

The nurse monitors clients who had spinal anesthesia for return of reflexes, sensation, and movement of extremities below the level of anesthesia. Extremities are assessed for color, temperature, and pedal pulses.

Nursing care of clients with spinal anesthesia includes the prevention of a postspinal headache. The postspinal headache is thought to be caused by the leakage of cerebrospinal fluid from the puncture site in the dura. Measures to prevent a headache include strict bed rest for 24 to 48 hours, adequate hydration with intravenous saline, and injection of 5 to 20 mL autologous blood into the epidural space at the puncture site.

Monitor Fluid and Metabolic Status

During the immediate postoperative phase, gastrointestinal and genitourinary assessment and interventions are considered from a fluid and metabolic perspective. The client is maintained on intravenous infusions as prescribed by the surgeon. The goal of intravenous therapy is to maintain the circulating fluid volume. Infusion sites are inspected for patency immediately when the client arrives in the PACU. Frequent inspection of these sites is necessary throughout recovery; intravenous access must be maintained in the event of complications (e.g., hemorrhage) that warrant emergency administration of intravenous fluids or medications. Secretions from tubes, drains, and the incision site are measured to determine output. The client's total output is compared against the volume of intravenous replacement fluids.

After surgery, the muscle tone of the bladder is compromised by analgesic or anesthetic agents. Assess for bladder distension by palpating the contour of the lower abdomen for a rounded mass above the symphysis pubis. When clients cannot void within 8 hours, the surgeon is notified for an order to catheterize. If the client has a Foley catheter, it should flow freely with urine.

Postoperative nausea and vomiting can be caused by multiple factors. Anesthetic agents and opiates can stimulate the chemoreceptors of the inner ear and the vomiting center in the brain. Deficient fluid volume, electrolyte imbalances, drugs, and general anesthesia by mask technique can also cause nausea and vomiting. Nausea and vomiting are treated with antiemetics.

Anesthetic agents can decrease peristalsis, resulting in diminished or absent bowel tones. Manipulation of the intestines further decreases the loss of bowel tones. The nurse auscultates for bowel tones and inspects for abdominal distension. A nasogastric tube is usually in place for clients with abdominal surgery and clients at risk for nausea and vomiting postoperatively.

With abdominal surgery, the nurse also monitors for abdominal distension to detect internal hemorrhage. When clients with abdominal surgery develop abdominal distension, inspect the tape over the incision dressing; tension on the tape can cause disruption of skin integrity (irritation and blisters). This can also increase the client's risk for a wound infection. **Cullen's sign**, a bluish discoloration around the umbilicus in postoperative clients, can indicate intra-abdominal or perineal bleeding.

Clients are kept on an NPO status until the gag reflex returns, they are free from nausea, and the presence of bowel tones is detected. Certain drugs, such as analgesic and

anesthetic agents, have a drying effect on the oral mucous membranes. Dehydration from loss of body fluids also causes dryness and thirst. Oral hygiene is performed frequently to promote comfort and prevent infections.

Manage Pain

Nurses assess for pain by allowing the client to rate the intensity of pain. Studies comparing nurses' and clients' ratings of pain have found little similarity between the two (Pasero, 2008). One study compared the pain ratings of 119 postoperative clients and their nurses. The ratings matched only 35% of the time; nurses underassessed pain in 45% of the cases and overassessed pain in 20% of the cases.

Pain management is monitored and treated by intravenous narcotics in titrated doses until the client is fully conscious. Once the client is fully conscious, pain is managed according to prescribing practitioner order: PCA, continuous epidural anesthesia, intravenous or intramuscular injection, or TENS. See Chapter 35 for a complete discussion of pain management.

The nurse should institute comfort measures such as splinting the incision line and positional changes to decrease the client's pain response. Besides incisional pain, the client can experience pain for other reasons, such as positioning during surgery, presence of tubes (endotracheal, nasogastric, chest, or Foley), and tight dressings or casts. Skin care and back rubs are done to promote comfort and circulation.

The Agency for Healthcare Research and Quality has clinically relevant practice guidelines for the management of postoperative pain. Three interdisciplinary panels, chaired by nurses, developed guidelines to inform the public on pain management:

- The provider should anticipate the pain.
- It is least therapeutic to be medicated when in pain.
- There are alternatives to pharmacologic management of pain.

Relaxation techniques, distraction, environmental manipulation, massage, and positioning are optional therapies. See Chapter 31 for additional information on complementary therapies for pain management.

EVALUATION AND DISCHARGE FROM THE PACU

The anesthesia provider is responsible for releasing the client from the PACU. Agencies have specific standards of care that have to be met before discharge. These standards address achievement of specific client outcomes with inherent parameters for evaluation, such as:

- The client is conscious, oriented, and can move all extremities.
- The client demonstrates full return of reflexes.
- The client can clear the airway and cough effectively.
- Vital signs have been stable or within baseline ranges for 30 minutes.
- Intake and urinary output are adequate to maintain the circulating blood volume.

- The client is afebrile, or a febrile condition has been treated accordingly.
- Dressings are dry or have only minimal drainage.

The surgeon manages the client's treatment throughout the remainder of the postoperative phase.

ONGOING POSTOPERATIVE CARE

The postoperative phase continues until the client is released from the surgeon's care. The primary goal during this phase is to restore physiological functioning, promote healing, and prevent complications. When the client is discharged from the PACU, the client goes either directly to an inpatient hospital bed or to the outpatient ambulatory unit for observation. The surgeon will later decide whether to admit the client to an inpatient 24-hour observation room or to discharge the client. When clients are discharged to their residence, they often require the services of a home health nurse to assist with their postoperative care. The home health nurse will continue to assess and provide necessary care until the client achieves the expected outcomes.

Postoperative nursing care after discharge is based on the nursing diagnoses and expected outcomes that still have not been met (see the accompanying display on discharge teaching). Clients who are discharged without the services of a home health agency assume their own care or have a family member or significant other serve as the care provider. In this situation, specific written discharge instructions are explained to the client or care provider.

Ineffective Airway Clearance

Ineffective airway clearance during this phase can result from a diminished cough reflex or increased pulmonary congestion. The nurse monitors skin color and respiratory rate and depth and auscultates breath sounds to determine the adequacy of

DISCHARGE TEACHING

CLIENT EXPECTED OUTCOMES

Before discharge, the client can:

- List the symptoms to be reported to the prescribing practitioner on occurrence.
- Describe limitations in activity.
- Explain dietary limitations.
- Explain the meaning and purpose of medications.
- Explain potential food or drug interactions.
- Describe the use of Standard Precautions as appropriate.
- Demonstrate aseptic technique in changing dressings.
- Demonstrate use or application of prescribed medical devices (identify appropriate device).

oxygenation and to identify complications (e.g., atelectasis). Deep breathing, coughing, and the use of the incentive spirometer are continued until the client demonstrates achievement of respiratory outcomes.

Ineffective Tissue Perfusion

Ineffective tissue perfusion (cardiopulmonary) related to inadequate circulation is a possible nursing diagnosis. The nurse monitors pulse rate and quality, blood pressure, skin and nail bed color and condition, and temperature for indications of decreased oxygenation at the cellular level. Capillary refill and peripheral pulses are checked for adequate circulation to the extremities. The nurse monitors the lower extremities for signs of superficial vein thrombosis (local warmth, swelling, pain, redness) and deep vein thrombosis (a positive Homans' sign).

Postoperative leg exercises are performed until the client is able to ambulate and resume activities of daily living. Anti-embolism hose are usually worn until the client returns for the first office visit. At that time the surgeon assesses the need to continue use of the hose.

Other devices, pneumatic compression, and CPM are maintained according to the prescribing practitioner's order. Clients are encouraged to ambulate while these devices are in place to promote respiratory, circulatory, and gastrointestinal functions. The CPM device is used until signs of incision swelling have decreased, healing is evident, and range of motion is achieved.

Deficient Fluid Volume

Deficient fluid volume can be related to active fluid volume loss, inadequate fluid intake from being NPO, or nausea and vomiting. The client is monitored for intake and output that includes secretions from drainage tubes, drains, and dressings. If oral fluids are restricted, the client is maintained on intravenous infusions as ordered by the surgeon. The nurse monitors the patency of the intravenous line, observes for signs of infiltration, and records the amount and type of fluids infused. The nurse assesses for signs of dehydration or fluid overload. See Chapter 33 for a discussion of fluid balance.

Home health clients with continuous intravenous therapy are maintained on an infusion pump. The caregiver is taught how to add infusions to the line under sterile technique. The home health nurse visits the client daily to assess for intravenous patency. A nurse is usually on call 24 hours for clients receiving continuous infusions.

Imbalanced Nutrition

Imbalanced nutrition: less than body requirements is usually related to anesthesia or surgical manipulation of the intestines. Until peristalsis returns and nausea, anorexia, or vomiting subsides, the client is maintained on intravenous therapy to preserve fluid and electrolyte balance. Nasogastric tube drainage is measured, and color and consistency are documented. See Chapter 34 for more information.

Clients with abdominal surgery can take up to 2 to 3 days or longer for return of normal gastrointestinal function. The nurse auscultates the abdomen for gurgling and rumbling sounds in all four quadrants to indicate return of peristalsis.

Early ambulation promotes the return of peristalsis. When bowel tones return and nausea subsides, the client's diet is progressive: First, ice chips are offered, then clear to full liquids; if tolerated, the diet is progressed to soft or regular. Some clients are on a regular diet within hours after surgery. See Chapter 34 for a discussion of types of modified diets.

Urinary Retention

Urinary retention is related to anesthesia or surgical manipulation that causes temporary loss of bladder tone. Efforts are made to promote urination (e.g., male clients are more prone to void if they can stand). If the client does not void within 8 hours after surgery, assess for bladder distension and notify the surgeon. The surgeon can order a straight or Foley catheter. *Clients must void before they can be released from the ambulatory setting.*

Acute Pain

Position changes and splinting are continued to relieve pain. Clients can be discharged to home with a PCA pump. Before discharge the nurse ensures that the client is able to correctly self-administer using the PCA. Efforts are made to provide adequate rest by scheduling procedures that do not interfere with sleep.

Risk for Infection

The client with a surgical incision is at risk for infection. Wound healing begins as early as 2 hours after surgery. The nurse ensures that the dressing is clean, dry, and intact; dressings promote rapid reepithelialization and protect against infection. Various types of dressings are used: conventional absorbent nonocclusive, semioclusive hydroactive, and occlusive hydrocolloid.

Nurses use Standard Precautions while caring for clients and sterile technique when changing a dressing. The incision line is assessed when the nurse changes the dressing. For some clients, the surgeon usually orders prophylactic antibiotics and removes any catheters or drains as soon as possible to prevent an infection. If the client were to develop a deep wound infection, it could necessitate prosthesis removal.

To monitor for signs of an infection, the nurse notes the type and amount of drainage on the dressing and the stage of wound healing. Vital signs are measured, recorded, and analyzed against laboratory results, especially the white blood cell count and differential. The client is taught to care for the wound and to observe for the complications of wound healing: hemorrhage, hematoma formation, infection, dehiscence, and evisceration. See Chapter 37 for a discussion of these complications.

EVALUATION

Evaluation is based on client-specific postoperative nursing diagnoses and achievement of outcomes. The time frame for the client's achieving the outcomes can vary with the client's health status, surgical procedure, and other factors, such as age. The nurse documents achievement of outcome criteria data (see the Nursing Checklist on postoperative documentation on page 1328).

**NURSING CHECKLIST****Postoperative Documentation**

- The client's respiratory function has returned to baseline level within 1 week after surgery as demonstrated by respirations 16 to 20/minute, deep and regular; skin color pink; lungs sounds clear on auscultation; and oxygen saturation greater than 95%.
- The client's cardiopulmonary function has returned to baseline level within 1 week after surgery as demonstrated by blood pressure with 10 to 20 mm Hg of baseline measurement; absence of dysrhythmias; pulse rate 60 to 90 beats per minute; skin pink, warm, and dry; capillary refill less than 3 seconds; peripheral pulses present; negative Homans' sign; and output within 500 mL of intake.
- The client is free from signs of a wound infection within 72 hours after surgery as demonstrated by normal temperature; pulse and respirations at baseline level; sutures intact; incision line without swelling, redness, or purulent exudate; and scab sloughing.

**PROCEDURE
40-1****Postoperative Exercise Instruction****EQUIPMENT**

- Educational materials
- Tissues
- Pillow
- Nonsterile gloves
- Disposable volume-oriented incentive spirometer

ACTION**RATIONALE**

- | | |
|---|---|
| <ol style="list-style-type: none"> 1. Wash hands/hand hygiene; organize equipment. 2. Check the client's identification band. 3. Place client in a sitting position. 4. Demonstrate deep breathing exercise. 5. Have client return demonstrate deep breathing: <ul style="list-style-type: none"> • Place one hand on abdomen (umbilical area) during inhalation. • Expand the abdomen and rib cage on inspiration. • Inhale slowly and evenly through your nose until you achieve maximum chest expansion. • Hold breath for 2 to 3 seconds. • Slowly exhale through your mouth until maximum chest contraction has been achieved. • Repeat the exercise three or four times; allow client to rest. 6. The nurse demonstrates splinting and coughing. 7. Don gloves. 8. Keep the client in a sitting position, head slightly flexed, shoulders relaxed and slightly forward, and feet supported on the floor. | <ol style="list-style-type: none"> 1. Reduces transmission of microorganisms and promotes efficiency. 2. Facilitates proper identification of client. 3. Promotes full chest expansion. 4. Shows client how to breathe deeply. 5. Fosters learning. <ul style="list-style-type: none"> • Exerts counterpressure during inhalation. • Promotes maximum chest expansion. • Maintains full expansion of the alveoli. • Increases the pressure, preventing immediate collapse of the alveoli. • Promotes maximum chest contraction. • Enforces learning. 6. Shows the client how to raise mucus secretions from the tracheobronchial tree. 7. Reduces transmission of microorganisms. 8. Promotes full expansion of chest cage and use of accessory muscles to produce a deep, productive cough. |
|---|---|

(Continues)

PROCEDURE 40-1 Postoperative Exercise Instruction (Continued)

ACTION	RATIONALE
<p>9. Have the client return demonstrate splinting and coughing:</p> <ul style="list-style-type: none"> • Have the client slowly raise head and sniff the air. • Have the client slowly bend forward and exhale slowly through pursed lips. • Repeat breathing two to three times. • When the client is ready to cough, have client place a folded pillow against the abdomen; have the client grasp the pillow against the abdomen with clasped hands (see Figure 40-10). • Have client take a deep breath and begin coughing immediately after inspiration is completed by bending forward slightly and producing a series of soft, staccato coughs. • Have a tissue ready. 	<p>9. Fosters learning.</p> <ul style="list-style-type: none"> • Increases the amount of air and helps to aerate the base of the lungs. • Dries the tracheal mucosa as air flows over it; there is a slight increase in the carbon dioxide level, which stimulates deeper breathing. • Loosens mucus plugs and moves secretions to the main bronchus. • Elevates the diaphragm and expels air in a more forceful cough; supports the abdominal muscles and reduces pain when coughing if the client has an abdominal incision. • Removes secretions from the main bronchus. • Provides a tissue for sputum disposal.
<p>10. Instruct the client on the use of an incentive spirometer (see Figure 40-11). Have the client:</p> <ul style="list-style-type: none"> • Hold a volume-oriented incentive spirometer upright. 	<p>10. Reinflates the alveoli and removes mucous secretions.</p> <ul style="list-style-type: none"> • Promotes proper functioning of the device.

FIGURE 40-10 Splinting DELMAR/CENGAGE LEARNING

- Take a normal breath and exhale, then seal lips tightly around the mouthpiece; take a slow, deep breath to elevate the balls in the plastic tube, and hold the inspiration for at least 3 seconds.
- The client simultaneously measures the amount of inspired air volume on the calibrated plastic tube.

FIGURE 40-11 Incentive Spirometer DELMAR/CENGAGE LEARNING

- Allows for greater lung expansion; holding the inspiration increases the pressure, preventing immediate collapse of the alveoli.
- Encourages the client to do respiratory exercises.
- Allows normal expiration.
- Provides client the opportunity to relax.
- Encourages sustained maximal inspiration and loosens secretions. *(Continues)*

PROCEDURE 40-1 Postoperative Exercise Instruction (Continued)

ACTION	RATIONALE
<ul style="list-style-type: none"> Remove the mouthpiece, and exhale normally. Take several normal breaths. Repeat the procedure four to five times. Have the client cough after the incentive effort; repeat Action 9. Have a tissue ready. Have client clean mouthpiece under running water and place in clean container (disposable mouthpiece changed every 24 hours). <p>11. The nurse explains leg and foot exercises (see Figure 40-12).</p> <p>12. Instruct client to return demonstrate in bed:</p> <ul style="list-style-type: none"> Have the client, with heels on bed, push the toes of both feet toward the foot of the bed until the calf muscles tighten; then relax feet. Pull the toes toward the chin until calf muscles tighten; then relax feet (see Figure 40-12B). With heels on bed, lift and circle both ankles, first to the right and then to the left; repeat three times, and relax. Flex and extend each knee alternately, sliding foot up along the bed; relax (see Figure 40-12C). 	<ul style="list-style-type: none"> Facilitates removal of secretions. Prevents transmission of microorganisms. <p>11. Elicits client cooperation.</p> <p>12. Fosters learning of how to improve venous blood return:</p> <ul style="list-style-type: none"> Causes contraction and relaxation of the calf muscles. Causes contraction and relaxation of the quadriceps muscles. Causes contraction and relaxation of the quadriceps muscles.

PROCEDURE 40-1 Postoperative Exercise Instruction (Continued)

ACTION	RATIONALE
13. The nurse shows the client how to turn in bed and get out of bed.	13. Elicits client cooperation.
14. Instruct the client who will have a left-sided abdominal or chest incision to turn to the right side of bed and sit up as follows: <ul style="list-style-type: none"> • Flex the knees. • With the right hand, splint the incision with hand or small pillow. • Turn toward right side by pushing with the left foot and grasping the shoulder of the nurse or partial foot rail of the bed with the left hand. • Raise up to a sitting position on the side of the bed by using the left arm and hand to push down against the mattress (see Figure 40-13). 	14. Fosters learning how to turn and get out of bed without putting pressure on the incision line.

FIGURE 40-13 Out-of-Bed Transfers DELMAR/CENGAGE LEARNING

15. Reverse instructions (use left side instead of right) for the client with a right-sided incision according to Action 14.	15. Same as Rationale 14.
16. Instruct clients with orthopedic surgery (e.g., hip surgery) how to use a trapeze bar.	16. Facilitates movement in bed without putting pressure on a leg or hip joint.

(Continues)

PROCEDURE 40-1 Postoperative Exercise Instruction (Continued)

delegation tip

It is the registered nurse's responsibility to initiate client teaching after completing an assessment that validates the need for the intervention. Follow-up assessment regarding the effectiveness of these exercises is also the registered nurse's responsibility; however, ancillary personnel should be instructed to encourage these activities, to assist clients into the proper positions, and to report results. Ancillary personnel may assist clients to perform coughing and deep breathing exercises, incentive spirometer exercises, and leg exercises.

nursing tips

- *The best time to teach postoperative exercises is before surgery. Remember to assess the client's motivation to learn and ability to pay attention.*
- *Encourage the client to use a pillow or other splinting method to ease the discomfort of coughing, turning, and deep breathing.*
- *Keep the incentive spirometer close to the client to encourage its use.*

PROCEDURE 40-2

Administering Pulse Oximetry

EQUIPMENT

- Pulse oximeter
- Alcohol wipe or soap and water
- Proper sensor
- Nail polish remover if necessary

ACTION

RATIONALE

- | | |
|--|---|
| <ol style="list-style-type: none"> 1. Wash hands/hand hygiene. 2. Select an appropriate sensor. Sensors are commonly used for the fingertips. 3. Select an appropriate site for the sensor. Fingers are most commonly used; however, toes (see Figure 40-14 on page 1333), ear lobes, nose, forehead (see Figure 40-15 on page 1333), hands, and feet can be used. Assess for capillary refill and proximal pulse. If the client has poor circulation, use an earlobe, forehead, or nasal sensor instead. In children, sensors may be used on the hand, foot, or trunk. If older adult clients have thickened nails, pick another site. 4. Clean the site with an alcohol wipe. Remove artificial nails or nail polish if present, or select another site. Clean any tape adhesive. Use soap and water if necessary to clean the site. | <ol style="list-style-type: none"> 1. Reduces transmission of microorganisms. 2. The sensor should be selected based on the size of the person and the site to be used. 3. Decreased circulation alters the O₂ saturation measurement. 4. Polish and artificial fingernails alter the results. |
|--|---|

(Continues)

PROCEDURE 40-2 Administering Pulse Oximetry (Continued)

ACTION

RATIONALE

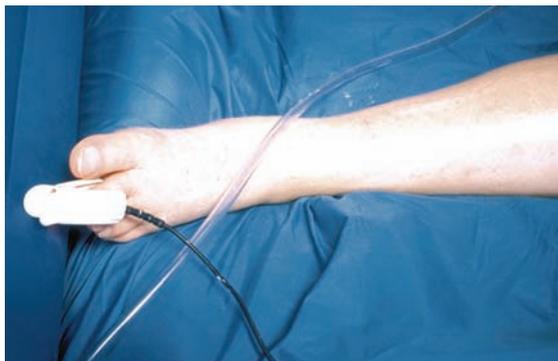

FIGURE 40-14 Pulse Oximeter Sensor Placed on a Toe DELMAR/CENGAGE LEARNING

5. Apply the sensor. Make sure the photon detectors are aligned on opposite sides of the selected site (see Figure 40-16).
6. Connect the sensor to the oximeter with a sensor cable. Turn on the machine. Initially a tone can be heard, followed by an arterial wave-form fluctuation with each arterial pulse. In most oximeters if the battery is low, a low-battery light illuminates when 15 minutes of battery life are remaining. Oximeters should remain plugged in even when not in use (see Figure 40-17).

FIGURE 40-16 Apply the sensor to the selected site. DELMAR/CENGAGE LEARNING

7. Adjust the alarm limits for high and low O_2 saturation levels according to the manufacturer's directions. Pulse rate limits most often can also be set. Adjust volume.

FIGURE 40-15 Pulse Oximeter Sensor Placed on the Forehead DELMAR/CENGAGE LEARNING

5. Proper application is necessary for accurate results.
6. The tone and wave-form fluctuation indicate that the machine is detecting blood flow with each arterial pulsation.

FIGURE 40-17 Follow the manufacturer's instructions when taking an oximetry reading. DELMAR/CENGAGE LEARNING

7. The alarms indicate that the saturation levels or pulse rates are outside the designated levels and alert the nurse of abnormal O_2 saturation levels and pulse rates.

(Continues)

PROCEDURE 40-2 Administering Pulse Oximetry (Continued)

ACTION	RATIONALE
8. If taking a reading, note the results (see Figure 40-18). If the oximeter is being used for constant monitoring, move the site of spring sensors every 2 hours and adhesive sensors every 4 hours.	8. Prevents skin breakdown from pressure and skin irritation from the adhesive.
9. Cover the sensor with a sheet or towel to protect it from exposure to bright light.	9. Ambient light sources such as sunlight or warming lights may interfere with the sensor and alter the SaO_2 results.
10. Notify the prescribing practitioner of abnormal results.	10. Low SaO_2 levels require medical attention because permanent tissue damage may result from low oxygen saturation.
11. Record the results of O_2 saturation measurements according to prescribing practitioner's order or protocol. Include in the documentation the type of sensor used, the site of application, the hemoglobin levels, and your assessment of the client's skin at the sensor site.	11. Communicates the findings to the other members of the health care team and contributes to the legal record by documenting the care given to the client.

FIGURE 40-18 Note the results on the oximeter. DELMAR/CENGAGE LEARNING

delegation tip

Ancillary personnel routinely perform pulse oximetry. They should be instructed on acceptable parameters and to report any abnormal findings to the nurse.

nursing tips

- If the client has a chronic lung disease, then the highest attainable value might be 90% (or even lower [65% to 80%]) instead of 92% to 100%. Know the client's normal values and carefully evaluate changes in respiratory, cardiac, and mental status.
- The client with diabetes, peripheral vascular disease, or hypothyroidism may have thickened or discolored nail beds. Assess the client and move the sensor to an alternate site if required.
- Always remember to treat the client and not the machine. If the alarm goes off frequently, yet the client is asymptomatic, then move or secure the sensor, or change the machine.

KEY CONCEPTS

- The major role of nursing functions in caring for the perioperative client is to foster the achievement of expected outcomes of care.
- Outpatient surgical clinics decrease the client's length of stay in the hospital and health care costs.
- Management of the perioperative client occurs in various health care settings.
- Ensuring the safety of the surgical client requires the collaborative efforts of all surgical personnel.
- Effective perioperative management is directed by a multidisciplinary team on the basis of recognized standards of care, protocols, and individualized expected client outcomes.
- Assessment of the client's status before surgery establishes baseline data to direct interventions throughout the perioperative phases.
- The NIC identifies one of the major preoperative roles of the registered nurse as coordinator, ensuring the obtainment of baseline data and communication among the surgical team members.
- Interventions of the health care team focus on decreasing the perioperative client's risks for complications.
- The first intervention for the OR nurse is to check the client's identification band and confirm the surgical site.
- Prior to release from the OR, the circulating nurse evaluates and documents the achievement of client outcomes during the intraoperative phase.
- NOC indicators provide an inclusive listing of identifiers to monitor the postoperative client's return to normal (baseline) function.
- Documentation of the client's response to interventions and achievement of expected outcomes provides the framework for evaluation.
- Coordination of discharge care begins in the preoperative phase and is reinforced throughout the other two phases.

REVIEW QUESTIONS

- Which drugs place the surgical client at risk for perioperative complications? Select all that apply.
 - Acetaminophen (Tylenol)
 - Acetylsalicylic acid (aspirin)
 - Omeprazole (Prilosec)
 - Diphenhydramine (Sominex)
 - Ibuprofen (Motrin)
 - Sertraline (Zoloft)
- Preoperative client teaching regarding an upcoming outpatient surgery should include _____.
 - postoperative nursing interventions
 - risk for postoperative complications
 - risks and benefits of the proposed surgical procedure
 - risks and benefits of anesthesia choices
- Which is the greatest risk factor for a client scheduled for general anesthesia?
 - Expresses concern about the scheduled procedure
 - Ate a pack of cookies within the last 2 hours
 - Has a history of smoking and had the last cigarette 24 hours ago
 - Has a history of hypertension that is controlled by diet and exercise
- Which is a priority nursing intervention used to prevent infection in the perioperative client?
 - Preparation of the skin overlying the surgical site
 - Maintenance of hemodynamic status
 - Maintenance of client's temperature
 - Determination of estimated blood loss
- During assessment of a client scheduled for a procedure to rule out cancer, the nurse observes tears in the client's eyes. Which response by the nurse is the most therapeutic intervention?
 - Contact the surgeon to speak with the client.
 - Ask the client to describe his or her feelings.
 - Medicate the client with a preoperative analgesic.
 - Reassure the client that there is nothing to worry about.
- Which is the priority nursing intervention to be performed by the nurse for a client during the postoperative phase?
 - Establish a patent airway.
 - Maintain adequate blood pressure.
 - Establish level of consciousness.
 - Assess level of pain.
- A postoperative client is experiencing impaired capillary refill to the lower extremities. The most appropriate nursing diagnosis is _____.
 - Ineffective breathing pattern*
 - Ineffective airway clearance*
 - Ineffective tissue perfusion*
 - Infection*

8. The postoperative phase begins when the client is transferred from the operating room and ends when _____.
- the client's vital signs are stable
 - the client is fully alert and responsive
 - the client is discharged from the agency
 - the client is discharged from the surgeon's care

online companion

GLOSSARY

A

abduction To move a body part away from the midline.

absorption Process by which the end products of digestion pass through the epithelial membranes in the small and large intestines into the blood or lymph system; passage of a drug from the site of administration into the bloodstream.

abstract Summary statement of a research article that identifies the purpose, methodology, findings, and conclusions.

accommodation Component of cognitive development that allows for readjustment of the cognitive structure (mind-set) in order to take in new information.

accountability Process that mandates that individuals are answerable for their actions and have an obligation (or duty) to act.

accreditation Process by which a voluntary, nongovernmental agency or organization appraises and grants accredited status to institutions and programs or services that meet predetermined structure, process, and outcome criteria.

acculturation Process that consists of learning norms, beliefs, and behavioral expectations of a group through which people of a subculture assume the characteristics of the dominant culture.

acid A molecule or an ion that can function as a hydrogen ion donor.

acid-base balance Regulation of hydrogen ion concentration.

acid-base buffer system A solution containing two or more chemical compounds that prevents marked changes

in the hydrogen ion concentration when either an acid or a base is added to a solution.

acidosis A condition that occurs when there is an excessive number of hydrogen ions in a solution.

acquired immunity Formation of antibodies that protect the individual against invading agents such as lethal bacteria, viruses, toxins, and foreign tissues from other animals.

active euthanasia Process of taking deliberate action that will hasten the client's death.

active listening Listening that focuses on the feelings of the individual who is speaking.

active range of motion Range-of-motion exercises performed independently by the client.

actual nursing diagnosis Nursing diagnosis that indicates that a problem exists; composed of the diagnostic label, related factors, and signs and symptoms.

acupressure The use of finger pressure applied to specific points (energy pathways) on the body to promote healing.

acupuncture The use of needles inserted at specific points on the body (energy pathways) to promote healing.

acute illness Disruption (usually reversible) in functional ability characterized by a rapid onset, intense manifestations, and a relatively short duration.

acute pain Discomfort identified by sudden onset and relatively short duration, mild to severe intensity, and a steady decrease in intensity over several days or weeks.

adaptation Component of cognitive development that refers to the changes that occur as a result of assimilation and accommodation; ongoing process by which an individual adjusts to stressors in order to achieve homeostasis.

addiction Physiological and psychological dependence upon a substance.

adduction To move a body part toward the midline.

adjuvant medication Drugs used to enhance the analgesic efficacy of opioids, treat concurrent symptoms that exacerbate pain, and provide independent analgesia for specific types of pain.

administrative law Laws developed by groups that are appointed to governmental administrative agencies and entrusted with enforcing the statutory laws passed by the legislature.

adolescence Developmental stage from the ages of 12 to 20 years that begins with the appearance of the secondary sex characteristics (puberty).

advance care medical directive Document in which an individual, in consultation with the prescribing practitioner, relatives, or other personal advisers, provides precise instructions for the type of health care the client wants or does not want in a number of scenarios (e.g., end-of-life decisions).

advance directive Written instruction for health care that is recognized under state law and is related to the provision of such care when the individual is incapacitated.

advanced practice nursing Practice of nursing at a level requiring an expanded knowledge base and clinical expertise in a specialty area.

adventitious breath sounds Superimposed sounds on the normal vesicular, bronchovesicular, and bronchial breath sounds.

adverse reaction Any drug effect other than what is therapeutically intended.

aerobic metabolism Metabolism of nutrients in the presence of oxygen; a metabolic pathway that uses oxygen to convert glucose into cellular energy.

affect Mood or feeling.

affective domain Area of learning that involves attitudes, beliefs, and emotions.

afferent nerve pathway Ascending pathways that transmit sensory impulses to the brain.

afferent pain pathway Ascending the spinal cord.

ageism Imposition of age stereotypes and discrimination.

agent An entity that is capable of causing disease.

agglutination Clumping together of red blood cells.

agglutinin A specific kind of antibody whose interaction with antigens is manifested as agglutination.

agglutinogen Any antigenic substance that causes agglutination by the production of agglutinin.

aggregates Individuals, families, and other subgroupings of people who are associated because of similar social, personal, or health care needs; a defined group or population.

airborne transmission Occurs when a susceptible host contacts droplet nuclei or dust particles that are suspended in the air.

algor mortis Lack of skin elasticity as a result of death.

alkalosis Excessive removal of hydrogen ions from a solution.

Allen test Assessment procedure that measures the collateral circulation to the radial artery.

allodynia Pain caused by a stimulus that does not normally evoke pain.

allopathic That which is recognized by a specific culture as being traditional, conventional, or mainstream (e.g., Western medicine).

alternative therapies Treatment approaches that are not accepted by mainstream medical practice.

ambulation Assisted or unassisted walking.

amniocentesis Withdrawal of amniotic fluid to obtain a sample for specimen examination.

anabolism Constructive phase of metabolism.

anaerobic metabolism Metabolism of nutrients in the absence of oxygen; a metabolic pathway that converts glucose into energy in the absence of oxygen.

analysis Breaking the whole down into parts that can be examined.

analyte A substance dissolved in a solution; also called a solute.

anemia Reduction in the amount of hemoglobin in the blood, thus decreasing the oxygen-carrying capacity of the blood.

anesthesia Absence of pain.

aneurysm Weakness in the wall of a blood vessel.

angina Pain in the chest, neck, or arm resulting from myocardial ischemia.

angina pectoris Pain caused by tissue ischemia in the heart.

angiocatheter An intracatheter with a metal stylet.

angiogenesis The formation of new blood vessels.

angiography Visualization of the vascular structures through the use of fluoroscopy with a contrast medium.

anions Ions with a negative charge.

anorexia nervosa Self-imposed starvation that results in a 15% or more loss of body weight.

anthropogenic Reflecting changes in the relationship between humans and their environments.

anthropometric measurements Measurement of the size, weight, and proportions of the body.

antibody An immunoglobulin produced by the body in response to bacteria, viruses, or other antigenic substances; counteracts and neutralizes the effects of antigens and destroys bacteria and other cells. Agglutinin is one type of antibody.

anticipatory grief Occurrence of grief work before an expected loss.

antigens A substance, usually a protein, that causes the formation of an antibody and reacts specifically with that antibody (e.g., agglutinin).

antioxidants Substances that block or inhibit destructive oxidation reactions.

antiseptic hand rub Applying an antiseptic hand cleanser to the hands in order to reduce the number of microorganisms

antiseptic handwash “Washing hands with water and soap or other detergents containing an antiseptic agent” (CDC, 2002, p. 4).

anxiety Subjective response that occurs when a person experiences a threat to well-being; a diverse feeling of dread or apprehension.

aphasia Impairment or absence of language function.

apnea monitor Machine with chest leads that monitors the movement of the chest.

appetite Desire for specific foods instead of food in general (hunger); involves a psychological desire or craving.

aromatherapy Therapeutic use of concentrated essences or essential oils that have been extracted from plants and flowers.

arousal A component linked closely to the appearance of wakefulness and alertness.

arterial blood gases (ABGs) Measurement of levels of oxygen and carbon dioxide, as well as pH and bicarbonate ion, in arterial blood.

arthritis Inflammation of the joints that causes pain and swelling.

arthroplasty Total hip replacement.

artifact Specific type of nonverbal message that includes items in the client’s environment, grooming, or use of clothing and jewelry.

ascites Accumulation of fluid in the abdomen.

asepsis Absence of microorganisms.

aseptic technique Infection control practice used to prevent the transmission of pathogens.

aspiration Procedure performed to withdraw fluid that has abnormally collected or to obtain a specimen.

assault Intentional and unlawful offer to touch a person in an offensive, insulting, or physically intimidating manner.

assessment First step in the nursing process; includes collection, verification, organization, interpretation, and documentation of data.

assessment model Framework that provides a systematic method for organizing data.

assimilation Component of cognitive development that involves taking in new experiences or information.

assisted suicide Situation in which a health care professional provides a client with the means to end his or her own life.

atelectasis Collapsed alveoli.

atherosclerosis Disease characterized by narrowing and eventual occlusion of the lumen (opening of the arteries)

by deposits of lipids, fibrin, and calcium on the interior walls of the arteries.

atherosclerotic plaque A thick, hard deposit on the walls of the inner arteries that can clog the arteries in the heart and the brain.

atrophy Thinning of skin surface and loss of markings; thin, flabby muscles due to a reduction in muscle size and shape.

attending behaviors A set of nonverbal listening skills that conveys interest in what the other person is saying.

auditory channel Transmission of messages through spoken words and by cues.

auditory learner Style of learning in which an individual learns by hearing.

auscultation Physical examination technique that involves listening to sounds in the body that are created by movement of air or fluid.

auscultatory gap The temporary disappearance of sounds at the end of Korotkoff phase I and beginning of phase II.

autocratic leadership style Style of leadership in which the leader maintains strong control, makes the decisions, and solves all the problems.

autoimmune disorder A malfunction of the body’s immune system that causes the body to attack its own tissues.

autonomy Being self-directed and taking initiative instead of waiting for direction from others; ethical principle that refers to the individual’s right to choose for oneself and the ability to act on that choice.

autopsy Postmortem examination to determine the cause of death.

autoregulation Redistribution of blood flow to areas of greatest need.

awareness The capacity to perceive sensory impressions and react appropriately through thoughts and actions.

Ayurveda A healing system based on Hindu philosophy and Indian philosophy that embraces the concept of an energy force in the body that seeks to maintain balance or harmony.

B

bacteriuria Bacteria in the urine.

balance The body’s ability to maintain postural equilibrium.

basal metabolic rate (BMR) Energy needed to maintain essential physiological functions when a person is at complete rest both physically and mentally.

base A molecule or an ion that will combine with hydrogen ions.

baseline values Establish the norm against which subsequent vital sign measurements can be compared.

base of support Foundation on which a person or object rests.

basic human need Need that must be met for survival.

battery Touching another person without consent.

behavior Observable response of an individual to external stimuli.

beneficence Ethical principle regarding the duty to promote good and prevent harm.

bereavement Period of grieving following the death of a loved one.

bioavailability Readiness to produce a drug effect.

bioethics Application of general ethical principles to health care.

biofeedback Measurement of physiological responses that yields information about the relationship between the mind and body and helps clients learn how to manipulate these responses through mental activity.

biological agent Living organisms that invade the host, such as bacteria, viruses, fungi, and protozoa.

biological clock Endogenous mechanism capable of measuring time in a living organism.

biopsy Excision of a small amount of tissue.

bisexuality Having an equal or almost equal preference for sexual partners of either gender.

black wound Contains necrotic tissue (eschar).

blanching Reduction of blood flow causing the skin to turn white when pressure is applied.

blood pressure Measurement of pressure pulsations exerted against the blood vessel walls during systole and diastole.

body alignment Position of body parts in relation to each other.

body image Individual's perception of physical self, including appearance, function, and ability.

body mass index (BMI) Determines whether a person's weight is appropriate for height by dividing the weight in kilograms by the height in meters squared.

body mechanics Purposeful and coordinated use of body parts and positions during activity.

bodymind Inseparable connection and operation of thoughts, feelings, and physiological functions.

bonding Formation of attachment between parent and child.

bradycardia A heart rate less than 60 beats per minute in an adult.

bradypnea Respiratory rate of 10 or fewer breaths per minute.

bronchial sounds Loud and high-pitched sounds with a hollow quality heard longer on expiration than inspiration from air moving through the trachea.

bronchovesicular sounds Medium-pitched and blowing sounds heard equally on inspiration and expiration from air moving through the large airways, posteriorly between the scapula and anteriorly over bronchioles lateral to the sternum at the first and second intercostal spaces.

bruits Blowing sounds that are heard when the blood flow becomes turbulent as it rushes past an obstruction.

bruxism Teeth grinding during sleep.

buccal Pertaining to the inside cheek.

bulimia Insatiable appetite.

bulimia nervosa An eating disorder characterized by episodic binge eating followed by purging.

burnout State of physical and emotional exhaustion that occurs when caregivers deplete their adaptive energy; characterized by fatigue, depersonalization, and decreased feelings of personal accomplishment.

butterfly needle Winged-tipped needle.

C

cachexia Weight loss marked by weakness and emaciation that usually occurs with a chronic illness such as tuberculosis or cancer.

calorie Quantity of heat required to raise the temperature of 1 g of water 1°C.

capitated rate Preset fees based on membership, not services provided; payment system used in managed care.

carbohydrate Organic compound composed of carbon, hydrogen, and oxygen.

cardiac catheterization Radiographic study with the use of a contrast medium injected into a vascular catheter that is threaded into the heart, coronary, or pulmonary vessels.

cardiac conduction system Specialized cells in the heart that generate and conduct electrical impulses; consists of the sinoatrial node, internodal pathways, atrioventricular node, bundle of His, right and left bundle branches, and Purkinje fibers.

cardiac cycle Series of electrical and mechanical events resulting in a cycle of atrial and ventricular contraction and relaxation.

cardiac output Measurement of blood pumped by the heart in 1 minute; measured by multiplying the heart rate by the ventricle's stroke volume.

cardiopulmonary resuscitation (CPR) Technique of applying respiration and chest compressions to support oxygenation in the event of cardiac and respiratory arrest.

case management Methodology for organizing client care through an episode of illnesses so that specific clinical and financial outcomes are achieved within an allotted time frame.

catabolism Destructive phase of metabolism.

categorical imperative Concept that states that one should act only if the action is based on a principle that is universal.

catharsis Process of talking out one's feelings; "getting things off the chest" through verbalization.

cations Ions with a positive charge.

cavities Dental caries.

ceiling effect As the dose of medication is increased above a certain level, the analgesic effect remains the same.

centering Process of bringing oneself to an inward focus of serenity that is done before beginning an energetic touch therapy treatment.

central line Venous catheter inserted into the superior vena cava through the subclavian, internal, or external jugular vein.

certification Process by which a nongovernmental agency or association certifies that an individual licensed to practice a profession has met predetermined standards specified by that profession for specialty practice.

chain of infection Phenomenon of developing an infectious process.

chakra A concentrated area of energy that influences the physical body, emotions, mental patterns, and spiritual awareness.

change Dynamic process in which an individual's response to a stressor leads to an alteration in behavior.

change agent Individual who intentionally creates and implements change.

channel Medium through which a message is transmitted.

charting by exception (CBE) Charting method that requires the nurse to document only deviations from preestablished norms.

chemical agent Substances that can interact with the body, such as pesticides, food additives, medications, and industrial chemicals.

chemical restraint Medications used to control the client's behavior.

chest physiotherapy (CPT) Technique of percussing or vibrating the chest wall in an effort to mobilize pulmonary secretions; usually accompanies postural drainage.

chiropractic Promotion of healing through manipulation of the spinal column.

cholesterol Lipid that is produced by the body and used in the synthesis of steroid hormones. Cholesterol is excreted in bile.

cholinesterase Enzyme manufactured in the liver that is responsible for the breakdown of acetylcholine and other choline esters.

chronemics Study of the effects of time on the communication process.

chronic acute pain Discomfort that occurs almost daily over a long period, has the potential for lasting months or years, and has a high probability of ending.

chronic illness Disruption in functional ability usually characterized by a gradual, insidious onset with lifelong changes that are usually irreversible.

chronic nonmalignant pain Discomfort that occurs almost daily and lasts for at least 6 months, with intensity ranging from mild to severe.

chronic obstructive pulmonary disease (COPD)

Category of alterations in ventilation including emphysema, asthma, and chronic bronchitis.

chronic persistent pain Discomfort that is persistent, nearly constant, and long lasting (6 months or longer); or recurrent pain that produces significant negative changes in a person's life.

chronobiology A relatively new branch of science that studies rhythms that are controlled by our biological clocks.

chronological age Exact age of a person from birth.

chylomicrons Lipoproteins synthesized in the intestines that transport triglycerides to the liver.

circadian rhythms Biological rhythms that cycle on a daily basis.

civil law Law that deals with relations between individuals.

clean-contaminated wound Intentional wound created by entry into the alimentary, respiratory, genitourinary, or oropharyngeal tract under controlled conditions.

clean object Object considered to have the presence of some microorganisms that are usually not pathogenic.

cleansing Removal of soil or organic material from instruments and equipment used in providing client care.

clean wound Intentional wound created under conditions in which no inflammation was encountered, and the respiratory, alimentary, genitourinary, and oropharyngeal tracts were not entered.

client advocate Person who speaks up or acts on behalf of the client.

client behavior accident When the client's behavior or actions precipitate the incident, for example, poisonings, burns, and self-inflicted cuts and bruises.

closed question Interviewing technique that consists of questions that can be answered briefly with one-word responses.

closed suction drainage system Fluid-draining method that commonly has a reservoir capable of creating negative pressure or a vacuum.

cluster Set of data cues in which relationships between and among cues are established to identify a specific health state or condition.

cognition The intellectual ability to think.

cognitive domain Area of learning that involves intellectual understanding.

cognitive reframing Stress management technique in which the individual changes his or her own negative perception of a situation or event to a more positive, less threatening perspective.

cohesiveness Bonding of group members with one another.

colic Acute abdominal pain.

collaboration A partnership in which all parties are valued for their contribution.

collaborative problems Certain physiological complications that nurses monitor to detect onset of changes in status.

collagen The most abundant protein in the body and the material of tissue repair.

colloid Nondiffusible substances.

colonization Multiplication of microorganisms on or within a host that does not result in cellular injury.

communicable agent Infectious agents that are capable of being transmitted to a client by direct or indirect contact through a vehicle (or vector) or airborne route.

communicable disease Diseases produced by infectious agents.

communication Dynamic, continuous, and multidimensional process for sharing information as determined by standards or policies.

community Group of people united by some common element or shared interest.

community health nursing Nursing specialty that is divided into two sections: public health and home health care nursing.

comorbidity Existence of simultaneous disease processes within an individual.

competency Ability, qualities, and capacity to function in a particular way.

complementary therapies Treatment approaches that can be used in conjunction with conventional medical therapies.

complicated grief Associated with traumatic death such as death by homicide, suicide, or an accident.

comprehensive assessment Type of assessment that provides baseline client data, including a complete health history and current needs assessment.

compromised host Person whose normal defense mechanisms are impaired and who is therefore susceptible to infection.

computed tomography Radiological scanning of the body with x-ray beams and radiation detectors that transmit data to a computer that transcribes the data into quantitative measurement and multidimensional images of the internal structures.

computer literacy Familiarity with the use of personal computers, including the use of software tools.

concept Vehicle of thought.

conceptual framework Structure that links global concepts together to form a unified whole.

conceptualization Process of developing and refining abstract ideas.

conduction Loss of heat to an object in contact with the body.

consciousness State of awareness of self, others, and the surrounding environment.

conscious procedural sedation Minimally depressed level of consciousness during which the client retains the ability to maintain a continuously patent airway and to respond appropriately to physical stimulation or verbal commands.

constipation Infrequent and difficult passage of hard stool.

construct Abstraction or mental representation inferred from situations, events, or behaviors.

consultation Method of soliciting help from a specialist in order to resolve diagnoses.

contact transmission Direct physical transfer of an agent from an infected person to a host through direct contact with a contaminated object or close contact with contaminated secretions.

contaminated wound Open, traumatic wound or intentional wound in which there was a major break in aseptic technique, spillage from the gastrointestinal tract, or incision into infected urinary or biliary tracts.

continuous passive motion device (CPM) Device that increases range of motion and stimulates healing of the articular cartilage by decreasing swelling and the formation of adhesions.

continuous quality improvement Approach to quality management in which scientific, data-driven approaches are used to study work processes that lead to long-term system improvements.

contract law Enforcement of agreements among private individuals.

contracture A condition of fixed resistance to the passive stretch of a muscle.

contrast medium Radiopaque substance that facilitates roentgen imaging of the body's internal structures.

convalescent stage Period of time from the beginning of the disappearance of acute symptoms until the client returns to the previous state of health.

convection Movement of heat away from the body's surface.

costal (thoracic) breathing Occurs when the external intercostal muscles are used to move the chest upward and outward.

counterstimulation Techniques believed to activate the endogenous opioid and monoamine analgesia systems.

crackles Heard predominantly on inspiration over the base of the lungs as an interrupted fine crackle (dry, high-pitched crackling, popping sound of short duration) that sounds like a piece of hair being rolled between the fingers in front of the ear or a coarse crackle (moist, low-pitched crackling, gurgling sound of long duration) that sounds like water going down the drain after the plug has been pulled on a full tub of water.

crepitus Grating or crackling sensation caused by two rough surfaces rubbing together.

criminal law Acts or offenses against the welfare or safety of the public.

crisis Acute state of disorganization that occurs when the individual's usual coping mechanisms are no longer effective.

crisis intervention Specific technique used to assist clients in regaining equilibrium.

criteria Standards that are used to evaluate whether the behavior demonstrated indicates accomplishment of the goal.

critical pathway Abbreviated summary of key elements from the case management plan.

critical period Time of the most rapid growth or development in a particular stage of the life cycle in which an individual is most vulnerable to stressors of any type.

critical thinking Disciplined, deliberate method of thinking used to search for meaning; employs strategies such as asking questions, evaluating evidence, identifying assumptions, examining alternatives, and seeking to understand various points of view.

cross-functional team Interdepartmental, multidisciplinary group that is assigned to study an organization-wide process.

crystallized intelligence The application of life experiences and learned skills to solve problems.

crystalloid Electrolyte solution with the potential to form crystals.

cues Small amounts of data that are applied to the decision-making process.

Cullen's sign Bluish discoloration around the umbilicus in postoperative clients; can indicate intra-abdominal or perineal bleeding.

cultural assimilation Process by which individuals from a minority group are absorbed by the dominant culture and take on the characteristics of the dominant culture.

cultural competence Process through which the nurse provides care that is appropriate to the client's cultural context.

cultural diversity Individual differences among people that result from racial, ethnic, and cultural variables.

culture Dynamic and integrated structures of knowledge, beliefs, behaviors, ideas, attitudes, values, habits, customs, languages, symbols, rituals, ceremonies, and practices that are unique to a particular group of people; growing microorganisms to identify a pathogen.

customer Anyone who uses the products, services, or processes provided by an organization.

cutaneous pain Caused by stimulation of the cutaneous nerve endings in the skin and results in a well-localized "burning" or "prickling" sensation.

cyanosis Blue or gray discoloration of the skin resulting from reduced oxygen levels in the arterial blood.

cystocele Protrusion of the urinary bladder through the wall of the vagina.

cytomegalovirus (CMV) DNA virus that causes intranuclear and intracytoplasmic changes in infected cells.

D

data clustering Process of grouping significant cues together according to a specific assessment model to establish a nursing diagnosis.

data interpretation Recognition of patterns in data to determine nursing diagnoses.

data verification Process through which data are validated as being complete and accurate.

deadspace Condition in which lung tissue is well ventilated but poorly perfused.

deamination Removal of the amino groups from the amino acids.

debridement Removal of necrotic tissue to foster the regeneration of healthy tissue.

decision making The consideration and selection of interventions that facilitate the achievement of a desired outcome.

declarative knowledge Specific facts or information and an understanding of the nature of that knowledge.

defamation Act that occurs when information that damages an individual's reputation is communicated to a third party either in writing (libel) or verbally (slander).

defecation Evacuation of feces from the rectum.

defendant Person being sued in a lawsuit.

defense mechanisms Unconscious operations that protect the mind from anxiety.

defining characteristics Observable cues/inferences that cluster as manifestations of an actual or wellness diagnosis.

definition Clear description of diagnosis that differentiates it from other similar diagnoses.

deglutition Swallowing of food.

degrees Units that measure the heat of the body.

dehiscence Partial or complete separation of a wound's edges and the layers below the skin.

delegation Process of transferring a selected nursing task in a situation to an individual who is competent to perform that task.

democratic leadership style Style of leadership that is based on the belief that every group member should have input into the development of goals and problem solving; also called participative leadership.

deontology Ethical theory that considers the intrinsic moral significance of an act itself as the criterion for determination of good.

dependence Reliance on or need to take a drug.

dependent nursing intervention Nursing action that requires an order from a prescribing practitioner or other health care professional.

dependent variable Outcome variable of interest.

depersonalization Treating an individual as an object rather than as a person.

dermatome map Cutaneous area whose sensory receptors and axons feed into a single dorsal root of the spinal cord.

detrusor muscle Smooth muscle of the bladder wall.

development Behavioral changes in functional abilities and skills.

developmental tasks Certain goals that must be achieved during each developmental stage of the life cycle.

diabetes mellitus A disease in which the pancreas fails to secrete adequate levels of insulin to accommodate blood glucose levels.

diagnosis Science and art of identifying problems or conditions.

diagnostic label (concept) One or more nouns (may also include an adjective) that name the diagnosis; can be a word or a phrase that describes the pattern or related cues.

diaphragmatic (abdominal) breathing Occurs when the diaphragm contracts and relaxes, as observed by the movement of the abdomen.

diarrhea Passage of liquified stool (increased frequency and decreased consistency of stool sufficient to represent a change in bowel habits).

diastole Process of cardiac chamber filling.

dietary fiber The part of food that body enzymes cannot digest and absorb.

diffusion Movement of molecules in a solution or a gas from an area of high concentration to one of low concentration.

diffusion defect Decrease in efficiency of gas diffusion from the alveolar space into the pulmonary capillary blood.

digestion Mechanical and chemical processes that convert nutrients into a physically absorbable state.

digital subtraction angiography Computerized imaging of the vasculature with visualization on a monitor screen following the intravenous injection of iodine through a catheter.

dirty and infected wound Traumatic wound with retained dead tissue or intentional wound created in situations where purulent drainage was present.

dirty object Object considered to have a high number of microorganisms, with some that are potentially pathogenic.

disaccharide Double sugar.

disaster Any event (human-made or natural) that causes destruction that cannot be relieved without assistance.

discharge planning Planning that involves critical anticipation and planning for the client's needs after discharge; the client begins to resume self-care activities before leaving the health care environment.

discipline Field of study.

disinfectant Chemical solutions used to clean inanimate objects.

disinfection Elimination of pathogens, except spores, from inanimate objects.

disorientation A mentally confused state in which the person's awareness of time, place, self, and situation is impaired.

disseminated intravascular coagulation (DIC) An acquired hemorrhagic syndrome characterized by uncontrollable formation and deposition of thrombi.

dissolution Rate at which a drug becomes a solution.

distraction Focusing attention on stimuli other than pain.

distress Experienced when stressors evoke an ineffective response.

distribution Movement of drugs from the blood into various body fluids and tissues.

documentation Written evidence of the interactions between and among health care professionals, clients and their families, and health care organizations; the administration of tests, procedures, treatments, and client education; the result or client's response to these diagnostic tests and interventions.

dominant culture Group whose values prevail within a society.

Doppler Handheld transducer.

drug allergy Hypersensitivity to a drug.

drug incompatibility Undesired chemical or physical reaction between a drug and a solution, between two drugs, or between a drug and the container or tubing.

drug tolerance Reaction that occurs when the body becomes accustomed to a specific drug and requires larger doses of the drug to produce the desired therapeutic effect.

dullness A muffled thudlike sound that occurs over dense tissue.

durable power of attorney Document or legal status that enables any competent individual to name someone to exercise health-related decision-making authority, under specific circumstances, on the individual's behalf when the client is incapable of making decisions for himself or herself.

duration The time a drug remains in the system in a concentration great enough to have a therapeutic effect.

duty Obligation created either by law, contract, or any voluntary action.

dysfunctional grief Failure to progress through the stages of overwhelming emotions associated with grief or

failure to demonstrate any behaviors commonly associated with grief.

dyspnea Difficulty in breathing as observed by labored or forced respirations through the use of accessory muscles in the chest and neck to breathe.

dysrhythmia Irregular heartbeat.

dysuria Painful urination.

E

echocardiogram Ultrasonic procedure used to reveal abnormal structure or motion of the heart wall and thrombi.

edema Detectable accumulation of increased interstitial fluid.

efferent nerve pathway Descending pathways that send sensory impulses from the brain.

efferent pain pathway Descending the spinal cord.

effleurage Massage technique consisting of long, smooth strokes used at the beginning and end of treatment and between other movements.

electrocardiogram Graphic recording of the heart's electrical activity.

electrochemical gradient Sum of all the diffusion forces acting on the membrane.

electroencephalogram Graphic recording of the brain's electrical activity.

electrolyte Element or compound that, when dissolved in water or another solvent, dissociates (separates) into ions (electrically charged particles) and provides for cellular reactions.

embryonic stage Developmental stage that occurs during the first 2–8 weeks after fertilization of a human egg.

empathy Understanding another person's perception of a situation.

empowerment Process of enabling others to do for themselves.

encoding Use of language and other specific signs and symbols for sending messages.

endorphins Group of opiate-like substances produced naturally by the brain; these substances raise the pain threshold, produce sedation and euphoria, and promote a sense of well-being.

endoscopy Visualization of a body organ or cavity through a scope.

energetic-touch therapies Techniques in which the hands are used to direct or redirect the flow of the body's energy fields to enhance balance within the fields.

enmeshment Overinvolvement or lack of separateness of family members; occurs as a result of unhealthy boundaries within the family unit.

enteral instillation Administration of drugs through a gastrointestinal tube.

enteral nutrition The nonvolitional delivery of nutrients through a gastrointestinal tube.

enzyme Protein produced in the body that catalyzes chemical reactions in organic matter.

epidemiology The study of the distribution and determinants of health-related states or events in populations.

epithelialization Growth of epithelial tissue.

e-prescribing The electronic transmission of drug prescriptions to a pharmacy from a hospital-based inpatient ordering system, personal digital assistants, wireless computers, or other handheld devices.

equipment accident Results from the malfunction or improper use of medical equipment, for example, electrocution and fire.

erythema Increased blood flow to an inflamed area.

erythrocytes Red blood cells.

eschar The scab or dry crust resulting from death of the skin.

essential amino acids Amino acids that are required for growth and development and must be obtained from food.

ethical dilemma Situation that occurs when there is a conflict between two or more ethical principles.

ethical principles Beliefs that govern actions.

ethical reasoning Process of thinking through what one ought to do in an orderly, systematic manner in order to provide justification of actions based on principles.

ethics Branch of philosophy concerned with determining right from wrong on the basis of a body of knowledge.

ethnicity Cultural group members' perception of themselves (group identity) and others' perception of them.

ethnocentrism Assumption of cultural superiority and an inability to accept other cultures' ways of organizing reality.

etiology Related cause of or contributor to a problem.

eupnea Easy respirations with a normal breath rate of breaths per minute that are age specific.

eustress Type of stress that results in positive outcomes.

euthanasia Intentional action or lack of action causing the merciful death of someone suffering from a terminal illness or incurable condition; derived from the Greek word *euthanatos*, which literally means "good or gentle death."

evaluation Fifth step in the nursing process; involves determining whether client goals have been met, partially met, or not met.

evaporation Continuous insensible heat loss from the skin and lungs when water is converted from a liquid to a gas.

evidence-based practice The application of the best available empirical evidence, including recent research

findings, to clinical practice in order to aid clinical decision making.

evisceration Occurs when the client's viscera protrude through the disrupted wound.

exclusive provider organization Organization in which care must be delivered by the plan in order for clients to receive reimbursement for health care services.

excretion Elimination of drugs from the body.

existentialism Movement that is centered on individual existence in an incomprehensible world and the role that free will plays in it.

expected outcome Detailed, specific statement that describes the methods through which a goal will be achieved and includes aspects such as direct nursing care, client teaching, and continuity of care.

expert witness Person called by parties in a malpractice suit who is a member of the same profession as the party being sued and who is qualified to testify to the expected behaviors usually employed by members of the profession when in a similar situation.

expiration (exhalation) Movement of gases from the lungs to the atmosphere.

expressed contract Conditions and terms of a contract given in writing by the concerned parties.

extension To straighten a joint.

external respiration See *oxygen uptake*.

extinction Ability to discriminate the points of distance when two body parts are simultaneously touched.

extraurethral incontinence Uncontrolled loss of urine caused when the sphincter mechanism has been bypassed.

extubation Removal of an endotracheal tube.

exudate Material and cells discharged from blood vessels.

F

faith Belief in and relationship with a higher power.

false imprisonment Situation that occurs when clients are made to wrongfully believe they cannot leave a place.

family A dynamic system of people living together who are united by significant emotional bonds.

family functions Roles that allow family members to adapt in order to develop as individuals and as members of the family unit.

family roles Behaviors expected of family members.

family structure Form a family takes in adapting and maintaining itself as a dynamic system of people living together who are united by significant emotional bonds.

fat-soluble vitamins Vitamins that require the presence of fats for their absorption from the gastrointestinal tract and for cellular metabolism.

fatty acids Basic structural units of most lipids that contain carbon chains and hydrogen.

fecal incontinence Involuntary loss of stool of sufficient duration and volume to create a social or hygienic problem.

feedback Information the sender receives about the receiver's reaction to a message.

fee-for-service Health care recipient directly pays the provider for services as they are provided.

felony Crime of a serious nature usually punishable by imprisonment in a state penitentiary or by death.

fetal alcohol syndrome Condition in which fetal development is impaired by maternal consumption of alcohol.

fetal stage Intrauterine developmental period from 8 weeks to birth.

fidelity Ethical concept that means faithfulness and keeping promises.

fight-or-flight response State in which the body becomes physiologically ready to respond to a stressor by either fighting or running away from the danger (which may be actual or perceived).

fixation Inadequate mastery or failure to achieve a developmental task that inhibits healthy progression through subsequent stages.

flashback Rush of blood back into intravenous tubing when a negative pressure is created on the tubing.

flatulence Discharge of gas from the rectum.

flexion To bend a joint.

floras Microorganisms on the human body.

flow rate Volume of fluid to infuse over a set period of time.

fluency Ability to talk in a steady manner.

fluid intelligence Ability to acquire new concepts and adapt to unfamiliar situations; mental activities based on organizing information.

focus charting Documentation method using a columnar format to chart data, action, and response.

focused assessment Type of assessment that is limited in scope in order to focus on a particular need, health care problem, or potential health care risk.

formal contract Written contract that cannot be changed legally by an oral agreement.

fraud Wrong that results from a deliberate deception intended to produce unlawful gain.

free radicals Atoms or groups of atoms that can cause damage to cells.

free radical scavengers Substances that remove or destroy free radicals.

friction Force of two surfaces moving against one another; massage technique whereby the heels of the hands or the thumb pads are used to apply deep penetrating pressure on knotted muscles.

full disclosure Communication of complete information to potential research subjects regarding the nature of the

study, the subject's right to refuse participation, and the likely risks and benefits that will be incurred.

full-thickness wound Skin loss that extends through the epidermis and dermis and into subcutaneous fat and deeper structures.

functional assessment Assessment of the client's ability to perform activities of daily living.

functional incontinence Loss of urine caused by altered mobility or dexterity, access to the toilet, or changes in mentation.

functional nursing Type of care delivery system in which nursing care is divided into tasks to be completed; various levels of personnel provide care depending on the complexity of the task.

functional team Departmental or unit-specific group whose scope is limited to departmental or work area processes.

G

gait or transfer belt Two-inch wide webbed belt worn by the client for the purpose of stabilization during transfers and ambulation.

gallop Extra heart sounds.

gate control pain theory Combines cognitive, sensory, and emotional components—in addition to the physiological aspects—and proposes that they can act on a gate control system to block the individual's perception of pain.

gender identity View of one's self as male or female in relationship to others.

general adaptation syndrome Physiological response that occurs when a person experiences a stressor.

general anesthesia Anesthesia that causes the client to lose all sensation and consciousness; used for major surgical procedures.

germicide Chemical that can be applied to both animate and inanimate objects to eliminate pathogens.

germinal stage Developmental stage that begins with conception and lasts approximately 10 to 14 days.

gingivitis Inflammation of the gums.

Glasgow Coma Scale International scale used in grading neurologic responses to determine the client's level of consciousness.

gluconeogenesis Conversion of amino acids into glucose or glycogen.

glycolysis Breakdown of glucose by enzymes located inside the cell's cytoplasm.

goal Aim, intent, or end.

goniometer Protractor with two movable arms used to measure the angle of a skeletal joint during range of motion.

Good Samaritan acts Laws that provide protection to health care providers by ensuring immunity from civil

liability when the caregiver provides assistance at the scene of an emergency and does not intentionally or recklessly cause the client injury.

grand theory Theory composed of concepts representing global and complex phenomena.

graphesthesia Ability to identify numbers, letters, or shapes drawn on the skin.

grief Series of intense physical and psychological responses that occur following a loss.

grief work Phrase coined from Lindemann; it describes the process experienced by the bereaved. It consists of freedom from attachment to the deceased, becoming reoriented to the environment in which the deceased is no longer present, and establishing new relationships.

group communication A complex level of communication that occurs when three or more people meet in face-to-face encounters or through another communication medium, such as a conference call.

group dynamics Study of the events that take place during small-group interaction and the development of subgroups.

groupthink Going along with the majority opinion while personally having another viewpoint.

growth Quantitative (measurable) changes in the physical size of the body and its parts.

guided imagery A process in which the person uses all the senses to experience the sensation of relaxation.

H

half-life Time it takes the body to eliminate half of the blood concentration level of the original drug dose.

halitosis Bad breath.

hallucination A sensory perception that occurs in the absence of external stimuli and is not based on reality.

hand hygiene "A general term that applies to either handwashing, antiseptic handwash, antiseptic hand rub or surgical antiseptic handwash" (CDC. [2002]. *Guideline for hand hygiene in healthcare settings*. Retrieved November 10, 2005, from <http://www.cdc.gov/handhygiene>)

handwashing "Washing hands with plain (i.e., nonantimicrobial) soap and water" (CDC, 2002, p. 4).

healing Process of recovery from illness, accident, or disability.

healing touch Energy-based therapeutic modality that alters the energy fields through the use of touch, thereby affecting physical, mental, emotional, and spiritual health.

health Process through which the person seeks to maintain an equilibrium that promotes stability and comfort; includes physiological, psychological, sociocultural, intellectual, and spiritual well-being.

health care-associated infections Infections acquired in the hospital or other health care facilities that were not present or incubating at the time of admission.

health care delivery system Mechanism for providing services that meet the health-related needs of individuals.

health history Review of the client's functional health patterns prior to the current contact with a health care agency.

health maintenance organization Prepaid health plan that provides primary health care services for a preset fee and focuses on cost-effective treatment methods.

health-promoting behaviors Actions that increase well-being or quality of life.

health promotion Process undertaken to increase levels of wellness in individuals, families, and communities.

health-seeking behaviors Activities that are directed toward attaining and maintaining a state of well-being.

heart failure Inability of the heart to pump enough blood to meet the metabolic needs of the body; often accompanied by a backup of blood in the venous circuits (congestive heart failure).

heaves Lifting of the cardiac area secondary to an increased workload and force of left ventricular contraction.

Heimlich maneuver Application of sharp, upward thrusts to the abdomen in order to remove an airway obstruction.

hematoma Localized collection of blood underneath the tissues that may appear as a reddish-blue swelling or mass.

hematuria Blood in the urine; *microscopic hematuria* is the presence of blood noted on microscopic examination of the urine; *gross hematuria* is the presence of blood visible to the naked eye.

hemoconcentration Reduced volume of plasma water and the increased concentration of blood cells, plasma proteins, and protein-bound constituents; occurs with increased capillary hydrostatic pressure, which causes water to shift from the intravascular into the interstitial space.

hemodynamic regulation Physiological function of blood circulating to maintain an appropriate environment in tissue fluids.

hemoglobin electrophoresis A laboratory test that uses an electromagnetic field to identify various types of hemolytic anemia.

hemolysis A breakdown of red cells and the release of hemoglobin.

hemorrhage Persistent bleeding.

hemorrhagic exudate Has a large component of red blood cells due to capillary damage, which allows red blood cells to escape.

hemorrhoids Perianal varicosity of the hemorrhoidal veins.

hemostasis Cessation of bleeding that occurs by vasoconstriction of large blood vessels in the affected area.

heterosexuality Sexual activity between a man and a woman.

high-biological-value proteins (complete proteins) Proteins that contain all of the essential amino acids.

high-level wellness State in which individuals function at their maximum health potential while remaining in balance with the environment.

history Study of the past, including events, situations, and individuals.

homeostasis Equilibrium (balance) between physiological, psychological, sociocultural, intellectual, and spiritual needs.

homosexuality Sexual activity between two members of the same sex.

hope Factor that enables one to cope with distressing events.

hospice Type of care for the terminally ill founded on the concept of allowing individuals to die with dignity and surrounded by those who love them.

hospital-acquired condition Also called a "never event" because it is an event that should never happen in a hospital, such as a pressure ulcer or fall.

humoral immunity Stimulation of B cells and antibody production.

hydrostatic pressure Pressure that a liquid exerts on the sides of the container that holds it; also called filtration force.

hygiene The science of health.

hyperalgesia Extreme sensitivity to pain.

hypercalcemia Excess in the extracellular level of calcium.

hypercapnia Elevation of carbon dioxide levels in the blood indicating inadequate alveolar ventilation.

hyperchloremia Excess in the extracellular level of chloride.

hyperglycemia Condition characterized by a blood glucose level greater than 110 mg/dL.

hyperkalemia Excess in the extracellular level of potassium.

hypermagnesemia Excess in the extracellular level of magnesium.

hypernatremia Excess in the extracellular level of sodium.

hyperphosphatemia Excess in the extracellular level of phosphorus.

hypersomnia An alteration in sleep pattern characterized by excessive sleep, especially in the daytime.

hypertension Refers to a persistent systolic pressure greater than 135 to 140 mm Hg and a diastolic pressure greater than 90 mm Hg.

hyperthyroidism Increased secretion of thyroid hormones, which increases the rate of metabolism.

hypertonic Solution with more solutes in proportion to the volume of body water; also called a hyperosmolar solution.

hypertonicity Increased muscle tone.

hypertrophy Increase in muscle size and shape due to an increase in muscle fiber.

hyperventilation Characterized by deep, rapid ventilations.

hypervolemia Increased circulating fluid volume.

hypocalcemia Deficit in the extracellular level of calcium.

hypochloremia Deficit in the extracellular level of chloride.

hypoglycemia Condition characterized by a blood glucose level less than 80 mg/dL.

hypokalemia Deficit in the extracellular level of potassium.

hypomagnesemia Deficit in the extracellular level of magnesium.

hyponatremia Deficit in the extracellular level of sodium.

hypophosphatemia Deficit in the extracellular level of phosphorus.

hypotension A systolic blood pressure less than 90 mm Hg or 20 to 30 mm Hg below the client's normal blood pressure.

hypothesis Statement of an asserted relationship between dependent variables.

hypothyroidism Decreased secretion of thyroid hormones, which decreases the metabolic rate.

hypotonic Solution with less solute in proportion to the volume of water; also called a hypo-osmolar solution.

hypotonicity Flabby muscle with poor tone.

hypoventilation Characterized by shallow respirations.

hypoxemia Decreased oxygen level in the blood.

hypoxia Oxygen deprivation of the body's cells.

I

identity What sets one person apart as a unique individual; may include a person's name, gender, ethnic identity, family status, occupation, and various roles.

idiosyncratic reaction Reaction of overresponse, underresponse, or an atypical response.

illness Inability of an individual's adaptive responses to maintain physical and emotional balance that subsequently results in an impairment in functional abilities.

illness stage When the client is manifesting specific symptoms of an infectious process.

illusion An inaccurate perception or misinterpretation of sensory stimuli.

imagery Relaxation technique in which the individual uses the imagination to visualize a pleasant, soothing image.

immediate memory The retention of information for a specified and usually short period of time.

impaction Hard bolus of stool that obstructs the fecal stream.

impaired nurse Nurse who is habitually intemperate or is addicted to the use of alcohol or habit-forming drugs.

implantable port Device with a radiopaque silicone catheter and a plastic or stainless steel injection port with a self-sealing silicone-rubber septum.

implementation Fourth step in the nursing process; involves the execution of the nursing plan of care formulated during the planning phase of the nursing process.

implied contract Contract that recognizes a relationship between parties for services.

incentive spirometers Breathing devices that measure the client's ventilatory volumes.

incidence Refers to the prevalence of a disease in a population or community. The predictive value of the same test can be different when applied to people of differing ages, genders, and geographic locations.

incident report Documentation of an unusual occurrence or an accident in delivery of client care.

incontinence Loss of the ability to initiate, control, or inhibit elimination.

independent nursing intervention Nursing action initiated by the nurse that does not require direction or an order from another health care professional.

independent variable Variable that is believed to cause or influence the dependent variable.

infancy Developmental stage from the first month to the first year of life.

infarction Death (necrosis) of an area of tissue caused by oxygen deprivation.

infection Invasion and a multiplication of microorganisms in body tissue that result in cellular injury.

infectious agent Microorganism that causes infections.

infiltration Seepage of foreign substances into the interstitial tissue.

inflammation Nonspecific cellular response to tissue injury or infection.

informatics The science of turning data into information.

information technology The management and processing of information with the assistance of computers.

informed consent Client understands the reason for the proposed intervention, knows its benefits and risks, and agrees to the treatment by signing a consent form.

initial planning Development of the beginning of care by the nurse who performs the admission assessment and gathers the comprehensive admission assessment data.

insensible heat loss Heat that is lost through the continuous, unnoticed water loss that occurs with evaporation.

insomnia Refers to the chronic inability to sleep or inadequate quality of sleep due to sleep that prematurely ends or is interrupted by periods of wakefulness.

inspection Physical examination technique that involves careful visual observation.

inspiration (inhalation) Intake of air into the lungs.

instability incontinence Loss of urine caused by a premature or hyperactive contraction of the detrusor.

insulin Pancreatic hormone that aids in the diffusion of glucose into the liver and muscle cells and the synthesis of glycogen.

integrative therapy A clinical approach that combines Western technological medicine with techniques from Eastern medicine.

integumentary system Skin, hair, scalp, and nails.

intentional wound Occurs during treatment or therapy, usually under aseptic conditions, such as surgical incisions and venipunctures.

interdependent nursing intervention Actions that are implemented in a collaborative manner by the nurse with other health care professionals.

intermittent claudication Ischemia to the extremities usually brought on by activity and relieved by rest.

internal respiration Process of gas exchange between capillary blood and the body's cells, in which the cells receive oxygen and carbon dioxide is removed.

interpersonal communication Process that occurs between two people either in face-to-face encounters, over the telephone, or through other communication media.

interview Therapeutic interaction that has a specific purpose.

intracath Plastic tube for insertion into a vein.

intra dermal (ID) Injection into the dermis.

intramuscular (IM) Injection into the muscle.

intraoperative (during surgery) Phase that begins when the client is transferred to the operating room and ends when the client is transferred to a postanesthesia care unit.

intrapersonal communication Messages one sends to oneself, including "self-talk," or communication with oneself.

intrapsychic theory Theory that focuses on an individual's unconscious processes. Feelings, needs, conflicts, and drives are considered to be motivators of behavior.

intravenous (IV) Injection into a vein.

intravenous (IV) therapy Administration of nutrients, fluids, electrolytes, or medications by the venous route.

intubation Insertion of an endotracheal tube into the bronchus through the nose or mouth to ensure an airway.

invasive Accessing the body tissues, organs, or cavities through some type of instrumentation procedure.

ischemia Oxygen deprivation, usually caused by poor perfusion, that is usually temporary and localized.

ischemic pain Pain occurring when the blood supply of an area is restricted or cut off completely.

isotonic Solution with body water and solutes (sodium) in equal amounts; also called an isosmolar solution.

J

judgment The ability to compare or evaluate alternatives to life situations and arrive at an appropriate course of action.

jurisprudence Body of judge-made law.

justice Ethical principle based on the concept of fairness that is extended to each individual.

K

Kardex Summary worksheet reference of basic client care information.

ketogenesis Conversion of amino acids into keto acids or fatty acids.

ketones Products of incomplete fat metabolism.

kilocalorie Equivalent to 1000 calories.

kinesthetic channel Transmission of messages through sensation of touch.

kinesthetic learner Learning style in which a person processes information by experiencing the information or by touching and feeling.

kyphosis Abnormally increased convexity in the curvature of the spine.

L

laissez-faire leadership style Style of leadership in which the leader assumes a passive, nondirective, and inactive style.

lancinating Piercing or stabbing pain.

late potentials Electrical activity that occurs after normal depolarization of the ventricles.

laws Rules or regulations that are enacted by legal entities.

leadership Interpersonal process that involves motivating and guiding others to achieve goals.

learning Process of assimilating information, with a resultant change in behavior.

learning plateau Peak in effectiveness of teaching and depth of learning.

learning style Way in which an individual incorporates new information.

legal regulation Process by which the state attests to the public that the individual licensed to practice is competent to do so.

lentigo senilis Benign brown-pigmented areas on the face, hands, and arms of older people.

leukocytes White blood cells.

liability Obligation one has incurred or might incur through any act or failure to act.

licensure Method by which a state holds the nurse accountable for safe practice to citizens of that state.

licensure by endorsement Process by which an individual who is duly licensed as a registered nurse under the laws of one state or country has his or her credentials accepted and approved by another state or country.

licensure by examination Process by which an individual who has completed an approved program of studies leading to registered nurse licensure seeks initial licensure by successfully passing a standardized competency examination.

line of gravity Vertical line passing through the center of gravity.

lipids Organic compounds that are insoluble in water but soluble in organic solvents such as ether and alcohol; also known as fats.

lipoproteins Blood lipids bound to protein.

liver mortis Bluish purple discoloration that is a by-product of red blood cell destruction.

living will Document prepared by a competent adult that provides direction regarding medical care should the person become incapacitated or otherwise unable to make decisions personally.

local adaptation syndrome Physiological response to a stressor (e.g., trauma, illness) affecting a specific part of the body.

local anesthesia Anesthesia that causes the client to lose sensation to a localized body part (e.g., spraying the back of the throat with lidocaine decreases the gag reflex).

localized infection Limited to a defined area or single organ with symptoms that resemble inflammation (redness, tenderness, and swelling).

lock-out interval Minimum time allowed between doses for the client to self-medicate; feature found in infusion pumps used for patient-controlled analgesia.

locus of control A person's perception of the source of control over events and situations affecting the person's life.

logrolling Technique for moving a client whose cervical spine must stay in alignment with the entire vertebral column.

long-term goal Statement written in objective format demonstrating an expectation to be achieved in resolution of the nursing diagnosis over a long period of time, usually over weeks or months.

lordosis Abnormal forward curvature of the lumbar spine.

loss Any situation in which a valued object is changed or is no longer accessible to an individual.

low-biological-value proteins (incomplete proteins) Proteins lacking in one or more of the essential amino acids.

lumbar puncture Aspiration of cerebrospinal fluid from the subarachnoid space.

lymphokine A substance of low molecular weight that is not an antibody, is secreted by T cells in response to stimulation by antigens, and has a role in cell-mediated immunity.

M

magnetic resonance imaging An imaging technique that uses radio waves and a strong magnetic field to make continuous cross-sectional images of the body.

maladaptation Process of ineffective coping with stressors.

malignant hyperthermia (MH) A potentially lethal syndrome caused by a hypermetabolic state that is precipitated by the administration of certain anesthetic agents.

malnutrition Nutritional alterations related to inadequate intake, disorders of digestion or absorption, or overeating.

malpractice Professional person's wrongful conduct, improper discharge of professional duties, or failure to meet the standards of acceptable care that results in harm to another person.

mammography A low-dose radiographic study of the breast tissue.

managed care System of providing and monitoring care in which access, cost, and quality are controlled before or during delivery of services. These networks "manage" or control costs in many ways (e.g., by limiting referrals to costly specialists). HMOs are a common form of managed care.

management Accomplishment of tasks either by oneself or by directing others.

mandatory licensure laws Legislation that prohibits any individual from practicing as a registered nurse without a current license.

mastication Chewing into fine particles and then mixing the food with enzymes in saliva.

material principle of justice Rationale for determining when there can be unequal allocation of scarce resources.

maturation Process of becoming fully grown and developed; involves physiological and behavioral aspects.

maturational loss Adolescent who loses the younger child's freedom from responsibility.

medical asepsis Practices to reduce the number, growth, and spread of microorganisms.

medical diagnosis Clinical judgment by the prescribing practitioner that identifies or determines a specific disease, condition, or pathologic state.

meditation Quieting the mind by focusing one's attention.

menarche Onset of the first menstrual period.

message Stimulus produced by a sender and responded to by a receiver.

metabolic rate Rate of heat liberated during chemical reactions.

metabolism Aggregate of all chemical reactions in every body cell.

metacommunication Relationship aspect of communication that refers to the message about the message.

metaparadigm Unifying force in a discipline that names the phenomena of concern to that discipline.

micro-range theory Theory that explains a specific phenomenon of concern to a discipline.

middle adulthood Developmental stage from the ages of 40 to 65 years.

middle-range theory Theory that addresses more concrete and more narrowly defined phenomena than a grand theory but does not cover the full range of phenomena of concern to a discipline.

mid-upper-arm circumference (MAC) Measures skeletal muscle mass and serves as an indicator of protein reserve.

mindfulness Form of meditation in which one focuses only on the present moment.

minerals Inorganic elements.

minority group Group of people who constitute less than a numerical majority of the population and who, because of their cultural or physical characteristics, are labeled and treated differently than others in the society.

misdemeanor Offense less serious than a felony that may be punished by a fine or sentence to a local prison for less than 1 year.

mixed agonist-antagonist Compound that blocks opioid effects on one receptor type while producing opioid effects on a second receptor type.

mobility Ability to engage in activity and free movement.

mode of transmission Process that bridges the gap between the portal of exit of the biological agent from the reservoir or source and the portal of entry of the susceptible “new” host.

modular nursing Care delivery system in which caregivers are assigned to a small segment of clients in close geographical proximity.

modulation The changing of pain impulses.

monosaccharides Simple sugars.

monounsaturated fatty acids Fatty acids with one double or triple bond.

morality Behavior in accordance with custom or tradition that usually reflects personal or religious beliefs.

moral maturity Ability to decide for oneself what is “right.”

mourning Period of time during which grief is expressed and resolution and integration of the loss occur.

multidimensionality Acting based on the belief that we live at many realms of the universe all at once.

murmur Swishing or blowing sounds of long duration heard during the systolic and diastolic phases created by turbulent blood flow through a valve.

muscle tone Normal state of balanced tension present in the body that allows muscles to respond quickly to stimuli.

music-thanatology Holistic and palliative method for use of music with dying clients; solely concerned with dissipating any obstacle to a peaceful passage.

myocardial infarction Necrosis of the heart muscle.

myofascial pain syndromes A group of muscle disorders characterized by pain, muscle spasm, tenderness, stiffness, and limited motion.

myoneural junction Point at which nerve endings come in contact with muscle cells.

N

narcolepsy A sleep alteration that manifests as sudden uncontrollable urges to fall asleep during the daytime.

narrative charting A story format of documentation that describes the client’s status, interventions and treatments, and the response to treatments.

necrosis Tissue death as the result of disease or injury.

need Anything that is absolutely essential for existence.

negative nitrogen balance Condition that exists when nitrogen output exceeds intake and protein catabolism exceeds anabolism.

negligence Failure of an individual to provide the care in a situation that a reasonable person would ordinarily provide in a similar circumstance.

neonatal period First 28 days of life following birth.

networking Process of building connections with others.

neuralgia Paroxysmal pain that extends along the course of one or more nerves.

neurogenic fever Long-term elevation of body temperature thought to result from a disruption of the normal body temperature set point as a result of damage to the hypothalamus.

neuropathic pain Arises from damage to portions of the peripheral or central nervous system.

neuropeptides Amino acids produced in the brain and other sites in the body that act as chemical communicators.

neurotransmitters Chemical substances produced by the body that facilitate nerve impulse transmission.

nitrogen balance Net result of intake and loss of nitrogen that measures protein anabolism and catabolism.

nociception The process by which an individual becomes consciously aware of pain.

nociceptors Receptive neurons for painful sensations that, together with the axons of neurons, convey information to the spinal cord where reflexes are activated.

nocturia Awakening from sleep to urinate.

nonessential amino acids Amino acids that can be synthesized in the adult body.

noninvasive The body is not entered with any type of instrument.

nonmaleficence Ethical principle that means the duty to cause no harm to others.

nonverbal message Message communicated without words.

nurse Stems from the Latin word *nutrix*, or *nutrio*, which means to nourish.

nurse-client relationship One-to-one interactive process between client and nurse that is directed at improving the client's health status or assisting in problem solving.

nurse practice act Law determined by each state governing the practice of nursing.

nursing audit Process of collecting and analyzing data to evaluate the effectiveness of nursing interventions.

nursing diagnosis Second step in the nursing process and includes clinical judgments made about wellness states, illness states and syndromes, and the readiness to enhance current states of wellness experienced by individuals, families, and aggregate populations (communities).

nursing informatics The use of information and computer technology to support all aspects of nursing practice.

nursing intervention Action performed by a nurse that helps the client achieve the results specified by the goals and expected outcomes.

Nursing Interventions Classification (NIC) Standardized language for nursing interventions.

Nursing Minimum Data Set (NMDS) Elements contained in clinical records and abstracted for studies on the effectiveness and costs of nursing care.

nursing order Statement written by the nurse that is within the scope of nursing practice to plan and initiate.

Nursing Outcomes Classification (NOC) Classification system of nurse-sensitive outcomes.

nursing process Systematic method of providing care to clients; consists of five steps: assessment, diagnosis, outcome identification and planning, implementation, and evaluation.

nursing research Systematic application of formalized methods for generating valid and dependable information about the phenomena of concern to the discipline of nursing.

nutraceuticals Natural substances found in plant or animal foods that act as protective or healing agents.

nutrition Process by which the body metabolizes and utilizes nutrients.

nystagmus Involuntary rhythmical oscillation of eyes.

O

obesity Weight that is 20% or more above the ideal body weight.

objective data Observable and measurable data that are obtained through both standard assessment techniques performed during the physical examination and laboratory and diagnostic tests.

obligatory loss of proteins Degradation of the body's own proteins into amino acids in response to inadequate protein intake.

observation Skill of watching carefully and attentively.

obstructive pulmonary disease Category of lung diseases characterized by obstruction of the airways and trapping of air distal to the obstruction.

occult Blood in the stool that can be detected only through a microscope or by chemical means.

older adulthood Developmental stage occurring from the age of 65 and beyond.

ongoing assessment Type of assessment that includes systematic monitoring and observation related to specific problems.

ongoing planning Planning that entails continuous updating of the client's plan of care.

onset of action Time it takes the body to respond to a drug after administration.

open-ended questions Interview technique that encourages the client to elaborate about a particular concern or problem.

operative knowledge An understanding of the nature of knowledge (knowing the "how" or "why").

opposition One body part being across from another part at nearly 180°.

oppression Condition in which the rules, modes, and ideals of one group are imposed on another group.

organization Means by which members of a profession join together to promote and protect the profession as a valuable service to society.

organizational culture Commonly held beliefs, values, norms, and expectations that drive the workforce.

orientation Perception of self in relation to the surrounding environment.

orientation phase First stage of the therapeutic relationship, in which the nurse and client become acquainted, establish trust, and determine the expectations of each other.

orthostatic hypotension (postural hypotension) Refers to a sudden drop of 25 mm Hg in systolic pressure and 10 mm Hg in diastolic pressure when the client moves from a lying to a sitting or a sitting to a standing position.

osmolality Measurement of the total concentration of dissolved particles (solutes) per kilogram of water.

osmolarity Concentration of solutes per liter of cellular fluid.

osmole Unit of measure of osmotic pressure.

osmosis Process caused by a concentration difference of water.

osmotic pressure Force that develops when two solutions of different strengths are separated by a selectively permeable membrane.

osteoarthritis Most common type of degenerative arthritis, in which the joints become stiff and tender to touch.

osteoporosis Process in which reabsorption exceeds accretion of bone.

outcome evaluation Process of comparing the client's current status with the expected outcomes.

oximeter Machine that measures the oxygen saturation of the blood through a probe clipped to the fingernail or earlobe.

oxygen uptake Process of oxygen diffusing from the alveolar space into the pulmonary capillary blood; also called external respiration.

oxyhemoglobin dissociation curve Graphic representation of the relationship between partial pressure of oxygen and oxygen saturation.

P

pain A universal human experience defined as “a state in which an individual experiences and reports the presence of severe discomfort or an uncomfortable sensation” (Carpenito, 2003, p. 58).

pain threshold The level of intensity at which pain becomes appreciable or perceptible; varies with each individual and type of pain.

pain tolerance The level of intensity or duration of pain the client is willing or able to endure.

palliative care Control of the symptoms rather than cure.

palpation Physical examination technique that uses the sense of touch to assess texture, temperature, moisture, organ location and size, vibrations and pulsations, swelling, masses, and tenderness.

Papanicolaou test Smear method of examining stained exfoliative cells.

paracentesis Aspiration of fluid from the abdominal cavity.

paradigm Pattern, model, or mind-set that strongly influences one's decisions and behaviors.

paradigm revolution Turmoil experienced by a discipline when a competing paradigm gains acceptance over the dominant, prevailing paradigm.

paradigm shift Acceptance of a competing paradigm over the prevailing paradigm.

parasomnia Refers to sleep alterations resulting from “an activation of physiological systems at inappropriate times during the sleep-wake cycle” (American Psychiatric Association, 1994, p. 579).

paraverbal communication The way in which a person speaks, including voice tone, pitch, and inflection.

paraverbal cues Verbal messages accompanied by cues, such as tone and pitch of voice, speed, inflection, volume, and other nonlanguage vocalizations.

parenteral Introducing a medication into the system by any route other than the oral-gastrointestinal tract.

parenteral nutrition Nutrients bypass the small intestine and enter the blood directly.

paresthesia Abnormal sensation such as burning, prickling, or tingling.

paroxysmal nocturnal dyspnea Episode of sudden shortness of breath occurring during sleep.

partial-thickness wound Involves the epidermis and upper dermis, the layer of skin beneath the epidermis.

passive euthanasia Process of cooperating with the client's dying process.

passive range of motion Range-of-motion exercises performed by the nurse for the dependent client.

patency Openness of tube lock or bodily passageway.

paternalism Practice by which health care providers decide what is “best” for clients and then attempt to coerce clients to act against their own choices.

pathogen Microorganisms that cause diseases in humans.

pathogenicity Ability of a microorganism to produce disease.

patient-controlled analgesia (PCA) Device that allows the client to control the delivery of intravenous or subcutaneous pain medication in a safe, effective manner through a programmable pump.

peak plasma level Achievement of the highest blood concentration of a single drug dose until the elimination rate equals the rate of absorption.

peer evaluation Process by which professionals provide critical performance appraisal and feedback that is geared toward corrective action.

Penrose drain Functions by gravity and has an open end that drains onto dressings.

perception Person's sense and understanding of the world; conscious awareness of pain.

percussion Physical examination technique that uses short, tapping strokes on the surface of the skin to create vibrations of underlying organs.

performance improvement Activities and behaviors that each individual does to meet customers' expectations.

perineal care Cleansing of the external genitalia, perineum, and surrounding area.

perioperative Refers to the management and treatment of the surgical client during the three phases of surgery: preoperative, intraoperative, and postoperative.

peristalsis Coordinated, rhythmic, serial contraction of the smooth muscles of the gastrointestinal tract.

permeability Capability of a substance, molecule, or ion to diffuse through a membrane.

petrissage Massage technique using squeezing, kneading, and rolling movements to release muscle tension and stimulate circulation.

phagocytosis Process by which certain cells engulf and dispose of foreign bodies.

phantom limb pain Neuropathic pain in which pain sensations are referred to an area from which an extremity has been amputated.

pharmacognosy The study of the biochemical aspects of natural products.

pharmacokinetics Study of the absorption, distribution, metabolism, and excretion of drugs.

phenomenon Observable fact or event that can be perceived through the senses and is susceptible to description and explanation.

philosophy Statement of beliefs that is the foundation for one's thoughts and actions.

phlebitis Inflammation of a vein.

phlebotomist Individual who performs venipuncture.

phospholipids Composed of one or more fatty acid molecules and one phosphoric acid radical and usually contain a nitrogenous base.

physical agents Factors in the environment that are capable of causing disease, such as heat, light, noise, radiation, and machinery.

physical dependence Reaction of the body, commonly known as withdrawal syndrome, to abrupt discontinuation of an opioid after repeated use.

physical restraints Reduce the client's movement through the application of a device.

phytonutrients Chemicals found in plants.

PIE charting Documentation method using problem, intervention, evaluation (PIE) format.

piggybacked Addition of an intravenous solution to infuse concurrently with another infusion.

piloerection Hairs standing on end as a result of the body's decrease in body temperature.

plaintiff Party who initiates a lawsuit that seeks damages or other relief.

planning Third step of the nursing process; includes the formulation of guidelines that establish the proposed course of nursing action in the resolution of nursing diagnoses and the development of the client's plan of care.

plan of care Written guide that organizes data about a client's care into a formal statement of the strategies that will be implemented to help the client achieve optimal health.

plateau Level at which a drug's blood concentration is maintained.

pleura Lining of the chest cavity.

pleural friction rub Heard on either inspiration or expiration over the anterior lateral lungs as a continuous creaking, grating sound.

pneumatic compression device Device that provides intermittent compression cycles to the veins of the extremities to promote circulation.

pneumothorax Collection of air or gas in the pleural space, causing the lungs to collapse.

point-of-care charting Documentation system that allows health care providers to gain immediate access to client information at the bedside.

poison Any substance that causes an alteration in the client's health, such as injury or death, when inhaled, injected, ingested, or absorbed by the body.

politics Way in which people try to influence decision making, especially decisions about the use of resources.

polyp A small, abnormal growth of tissue.

polypharmacy Concurrent use of several different medications.

polysaccharide Complex sugar.

polyunsaturated fatty acids Fatty acids that have many carbons unbonded to hydrogen atoms.

Port-a-Cath A port that has been implanted under the skin with a catheter inserted into the superior vena cava or right atrium through the subclavian or internal jugular vein.

positive nitrogen balance Condition that exists when nitrogen intake exceeds output and protein anabolism exceeds catabolism.

possible nursing diagnosis Nursing diagnosis that indicates a situation exists in which a problem could arise unless preventive action is taken or a "hunch" or intuition by the nurse that cannot be confirmed or eliminated until more data have been collected. It is composed of the diagnostic label and related factors.

postoperative (after surgery) Begins when the client leaves the operating room and is taken to a postanesthesia care unit; this phase continues until the client is discharged from the care of the surgeon.

postural drainage A technique of positioning that promotes gravitational drainage of specific lung lobes.

power Ability to do or act, resulting in the achievement of desired results.

preadolescence Developmental stage from the ages of approximately 10 to 12 years.

prealbumin Precursor of albumin.

precapillary sphincters Smooth muscles surrounding the smallest arterioles that control blood flow through the capillary beds.

predictive value The ability of screening test results to correctly identify the disease state, such as a true positive

correctly identifies persons who actually have the disease, whereas a true negative correctly identifies persons who do not actually have the disease (Fischbach, 2000).

preferred provider organization Type of managed care model in which member choice is limited to providers within the system.

prenatal period Developmental stage beginning with conception and ending with birth.

preoperative (before surgery) Refers to the time interval that begins when the decision is made for surgery until the client is transferred to the operating room.

presbycusis Hearing loss associated with old age.

preschool stage Developmental stage from the ages of 3 to 6 years.

presence The process of just being with another; a therapeutic nursing intervention.

pressure ulcer Impaired skin integrity related to mechanical factors such as unrelieved, prolonged pressure; shearing forces; and restraint.

primary care provider Health care provider whom a client sees first for health care; typically, a family practitioner (prescribing practitioner/nurse), internist, or pediatrician.

primary health care Client's point of entry into the health care system; includes assessment, diagnosis, treatment, coordination of care, education, preventive services, and surveillance.

primary intention healing Occurs in wounds that have minimal tissue loss and edges that are well approximated (closed).

primary nursing Nursing management system in which the professional nurse assumes complete responsibility for total care for a small number of clients.

primary source Major provider of information about a client; research article written by one or more researchers.

prn orders Drug orders that are administered as needed.

proactive Initiating change rather than responding to change imposed by others.

problem-oriented medical record (POMR) Documentation focused on the client's problem with a structured, logical format to narrative charting called SOAP (subjective and objective data, assessment, plan).

process Series of steps or acts that lead to accomplishment of a goal or purpose.

process evaluation Measurement of nursing actions by examination of each phase of the nursing process.

process improvement Process that examines the flow of client care between departments in order to ensure that the processes work as they were designed and that acceptable levels of performance are achieved.

prodromal stage Time interval from the onset of nonspecific symptoms until specific symptoms of the infectious process begin to manifest.

profession Group (vocational or occupational) that requires specialized education and intellectual knowledge.

professional regulation Process by which nursing ensures that its members act in the public interest by providing a unique service that society has entrusted to them.

professional standards Authoritative statements developed by the profession by which quality of practice, service, and education can be judged.

progressive muscle relaxation Stress management technique involving tensing and relaxing muscles.

proposition Statement that proposes a relationship between concepts.

proprioception Awareness of posture, movement, and changes in equilibrium and knowledge of position, weight, and resistance of objects in relation to the body.

prosody Melody of speech that conveys meaning through changes in the tempo, rhythm, and intonation.

proteins Organic compounds of amino acid polymers connected by peptide bonds that contain carbon, hydrogen, oxygen, and nitrogen.

protocol Series of standing orders or procedures that should be followed under certain specific conditions.

proxemics Study of the distance between people and objects.

psychomotor domain Area of learning that involves performance of motor skills.

psychoneuroimmunology Study of the complex relationship between the cognitive, affective, and physical aspects of humans.

puberty Appearance of secondary sex characteristics that signals the beginning of adolescence.

public law Law that deals with an individual's relationship to the state.

pulse Bounding of blood flow in an artery that is palpable at various points on the body.

pulse deficit Condition in which the apical pulse rate is greater than the radial pulse rate.

pulse oximeter Sensor device used to measure the oxygen saturation level of the blood.

pulse pressure Measurement of the ratio of stroke volume to compliance (total distensibility) of the arterial system.

pulse quality Refers to the "feel" of the pulse, its rhythm and forcefulness.

pulse rate Indirect measurement of cardiac output obtained by counting the number of apical or peripheral pulse waves over a pulse point.

pulse rhythm Regularity of the heartbeat.

pulse volume Measurement of the strength or amplitude of the force exerted by the ejected blood against the arterial wall with each contraction.

purulent exudate Pus, generally occurring with severe inflammation accompanied by infection.

pyogenic bacteria Bacteria that produce pus.

pyorrhea Periodontal disease.

pyrexia When heat production exceeds heat loss and body temperature rises above the normal range.

pyrogens Bacteria, viruses, fungi, and some antigens.

pyuria Pus (white blood cells) in the urine.

Q

qualitative analysis Integration and synthesis of narrative, nonnumerical data.

qualitative research Systematic collection and analysis of subjective narrative materials, using procedures for which there tends to be a minimum of research-imposed control.

quality Meeting or exceeding requirements of the client.

quality assurance Traditional approach to quality management in which monitoring and evaluation focus on individual performance, deviation from standards, and problem solving.

quantitative research Systematic collection of numerical information, often under conditions of considerable control.

R

race Grouping of people based on biological similarities such as physical characteristics.

racism Discrimination directed toward individuals who are misperceived to be inferior because of biological factors.

radiation Loss of heat in the form of infrared rays.

radiofrequency ablation The delivery of low-voltage, high-frequency alternating electrical current to cauterize the abnormal myocardial tissue.

radiography Study of x-rays or gamma ray–exposed film through the action of ionizing radiation.

range of motion Extent to which a joint can move.

rapport Bond or connection between two people that is based on mutual trust.

rationale Explanation based on the theories and scientific principles of natural and behavioral sciences and the humanities.

readiness for learning Evidence of willingness to learn.

receiver Person who intercepts the sender's message.

recent memory The result of events that have occurred over the past 24 hours.

recommended dietary allowances (RDA)

Recommended allowances of essential nutrients

established by the Food and Nutrition Board of the Academy of Sciences–National Research Council.

reconstitution Adaptation to a stressor.

recontextualizing Exploration of a developed theory in terms of its applicability to other settings or groups.

recurrent acute pain Identified by repetitive painful episodes that may recur over a prolonged period or throughout the client's lifetime.

red cell indices Laboratory measurement of the size and hemoglobin content of the red cells.

red wound Wound that is the color of normal granulation tissue and in the proliferative phase of wound repair.

referred pain The sensation of pain is not felt in the organ itself but instead is perceived at the spot where the organs were located during fetal development.

reframing A technique that teaches clients to monitor their negative thoughts and replace them with ones that are more positive.

regional anesthesia Anesthesia that causes the client to lose sensation in a particular area of the body (e.g., laparoscopy for a tubal sterilization).

regurgitation Backward flow of blood through a diseased heart valve, also known as insufficiency.

related factors Elements that can precede, be associated with, contribute to, or be related to nursing diagnoses in some type of patterned relationship.

relaxation response State of increased arousal of the parasympathetic nervous system that leads to a relaxed physiological state.

relaxation techniques A variety of methods used to decrease anxiety and muscle tension.

religion Set of beliefs associated with a formal organized group, such as a church, synagogue, mosque, or temple.

remote memory The retention of experiences that occurred during earlier periods of life.

research Systematic method of exploring, describing, explaining, relating, or establishing the existence of a phenomenon, the factors that cause changes in the phenomenon, and how the phenomenon influences other phenomena.

research design Overall plan used to conduct research.

resident floras Microorganisms that are always present, usually without altering the client's health.

respiration The act of breathing.

rest A state of relaxation and calmness, both mental and physical.

restorative nursing care Nursing care provided to clients who have residual impairment as a result of disease or injury; seeks to increase the client's independence and ability to perform self-care.

restraints Protective devices used to limit the physical activity of a client or to immobilize a client or extremity.

restrictive pulmonary disease A category of lung diseases characterized by impaired mobility or elasticity of the lungs or chest wall.

review of systems A brief account of any recent signs or symptoms related to any body system.

rhonchi Heard predominantly on expiration over the trachea and bronchi as a continuous, low-pitched musical sound.

rigor mortis Stiffening of the body after death caused by contraction of the skeletal and smooth muscles.

risk factors Elements that increase the chances of an individual, family, or community being susceptible to a disease state or life event affecting health.

risk for infection State in which an individual is at increased risk for being invaded by pathogenic organisms.

risk nursing diagnosis Nursing diagnosis that indicates that a problem does not yet exist but specific risk factors are present; composed of the diagnostic label preceded by the phrase “risk for” with the specific risk factors listed.

role Set of expected behaviors associated with a person’s status or position.

role conflict When the expectations of one role compete with the expectations of other roles.

S

saccharides Sugar units.

satiety Feeling of fulfillment from food.

saturated fatty acids Glycerol esters of organic acids whose atoms are joined by a single-valence bond.

school-age period Developmental stage from the ages of 6 to 12 years.

scoliosis Lateral deviation of the vertical line of the spine.

scope of practice Legal boundaries of practice for health care providers as defined in state statutes.

sebum Produced by the skin and contains fatty acids that kill some bacteria.

secondary gain Outcomes of the sick role other than alleviation of anxiety (primary gain); examples include gaining attention and sympathy, avoiding responsibilities, and receiving financial compensation or reward.

secondary intention healing Seen in wounds with extensive tissue loss and wounds in which the edges cannot be approximated.

secondary source Source of data other than the client, such as family members, other health care providers, or medical records; article in which an author addresses the research of someone else.

self-care Learned behavior and a deliberate action in response to a need.

self-care deficit Exists when the client is not able to perform one or more of the activities of daily living.

self-concept Individual’s perception of self; includes self-esteem, body image, and ideal self.

self-efficacy Belief in one’s ability to succeed; according to social cognitive theory of learning, serves as an internal motivator for change.

self-esteem Individual’s perception of self-worth; includes judgments about one’s self and one’s capabilities.

semipermeable Selective permeability of membranes.

sender Person who generates a message.

sensation The ability to receive and process stimuli received through the sensory organs.

sensitivity Determines the susceptibility of a pathogen to an antibiotic; the ability of a test to correctly identify those individuals who have the disease.

sensory deficit A change in the perception of sensory stimuli.

sensory deprivation A state of reduced sensory input from the internal or external environment, manifested by alterations in sensory perceptions.

sensory overload Increased perception of the intensity of auditory and visual stimuli.

sensory perception The ability to receive sensory impressions and, through cortical association, relate the stimuli to past experiences to form an impression of the nature of the stimulus.

serous exudate Exudate that is composed primarily of serum (the clear portion of blood), is watery in appearance, and has a low protein count.

sex roles Culturally determined patterns associated with being male or female.

sexuality Human characteristic that refers not just to gender but to all the aspects of being male or female, including feelings, attitudes, beliefs, and behavior.

sexual orientation Individual’s preference for ways of expressing sexual feelings.

shaman Folk healer–priest who uses natural and supernatural forces to help others.

shamanism Practice of entering altered states of consciousness with the intent of helping others.

shearing The force exerted against the skin when a client is moved or repositioned in bed by being pulled or allowed to slide down in bed.

short-term goal Statement written in objective format demonstrating an expectation to be achieved in resolution of the nursing diagnosis in a short period of time, usually a few hours or days.

shunting Condition in which alveolar regions are well perfused but not adequately ventilated.

side effects Mild nontherapeutic drug effects.

signal-averaged ECG Surface electrocardiogram that amplifies late potentials.

simultaneity paradigm Nursing viewpoint that focuses on the quality of life from the client’s perspective and

conceptualizes the interaction between person and environment as mutual and simultaneous.

single-payer system Health care delivery model in which the government is the only entity to reimburse.

single point of entry Entry into the health care system is required through a point designated by the plan.

situational leadership Style of leadership in which there is a blending of styles based on current circumstances and events.

situational loss Occurs in response to external events, usually beyond the individual's control (e.g., death of a significant other).

skinfold measurement Measures the amount of body fat.

skin shear Result of dragging skin across a hard surface.

skin turgor Normal resiliency of the skin.

sleep A state of altered consciousness during which an individual experiences minimal physical activity and a general slowing of the body's physiological processes.

sleep apnea A syndrome in which breathing periodically ceases during sleep, often associated with heavy snoring.

sleep cycle The sequence of sleep that begins with the four stages of non-rapid eye movement sleep in order, with a return to stage 3, then 2, then passage into the first rapid eye movement stage.

sleep deprivation A term used to describe prolonged inadequate quality and quantity of sleep, either of the rapid eye movement or the non-rapid eye movement type.

sloughing Shedding of dead tissue as a result of skin ulceration.

small-group ecology Study of proxemics in small-group situations.

Snellen chart Chart that contains various-sized letters with standardized numbers at the end of each line of letters.

SOAP charting Documentation method using subjective data, objective data, assessment, and plan.

solute A substance dissolved in a solution; also called an analyte.

solvent A liquid with a substance in solution.

somatic pain Nonlocalized pain originating in support structures such as tendons, ligaments, and nerves; may be a deep pain.

somnambulism Sleepwalking.

source-oriented (SO) charting Narrative recording by each member (source) of the health care team on a separate record.

spasticity Increase in muscle tension.

specific gravity Weight of urine compared with weight of distilled water; a specific gravity greater than 1.0 indicates solutes in the urine.

specificity The ability of a test to correctly identify those individuals who do not have the disease.

spherocytes Small, thick red cells.

spiritual distress State experienced when an individual perceives that his or her belief system, or that person's place within it, is threatened.

spirituality Multidimensional aspect of self that refers to one's relationship with oneself, a sense of connection with others, and a relationship with a higher power or divine source.

spiritual well-being Sense of connectedness between the self, others, nature, and a higher power that can be accessed through prayer or other means.

spores Single-celled microorganisms or microorganisms in the resting or inactive stage.

standing order Standardized intervention written, approved, and signed by a prescribing practitioner that is kept on file within health care agencies to be used in predictable situations or in circumstances requiring immediate attention.

stat order An order for a single dose of medication to be given immediately.

statutory law Laws enacted by legislative bodies.

stenosis Narrowing or constriction of a blood vessel or valve.

stereognosis Ability to identify objects by manipulation and touch.

stereotyping Belief that all people within the same racial, ethnic, or cultural group act alike and share the same beliefs and attitudes.

sterilization The total elimination of all microorganisms, including spores.

stock supply Medications dispensed and labeled in large quantities for storage in the medication room or nursing unit.

stoma Surgically created opening.

stomatitis Inflammation of the oral mucosa.

stool Fecal material.

stress Body's reaction to any stimulus.

stressor Any stimulus encountered by an individual; leads to the need to adapt.

stress test Measures the client's cardiovascular response to exercise tolerance.

stress urinary incontinence Uncontrolled loss of urine caused by physical exertion in the absence of a bladder contraction.

striae Red or silvery-white streaks due to rapid stretching of skin with resultant damage to elastic fibers of dermis.

stridor Heard predominantly on inspiration as a continuous crowing sound.

stroke volume Measurement of blood that enters the aorta with each ventricular contraction.

structure evaluation Determination of the health care agency's ability to provide the services offered to its client population.

subcutaneous Injection into the subcutaneous tissue.

subjective data Data from the client's point of view, including feelings, perceptions, and concerns.

sublingual Under the tongue.

superficial wound Confined to the epidermis layer, which comprises the four outermost layers of skin.

supernumerary nipples Extra nipples that appear as pigmented moles along the "milk line" of the breast.

suppression Conscious defense mechanism whereby a person decides to avoid dealing with a stressor at the present time.

suppuration The process of pus formation.

surfactant Phospholipid secreted by type II alveolar cells that reduces the alveolar surface tension and thus helps prevent alveolar collapse.

surgical asepsis Sterile technique; consists of those practices that eliminate all microorganisms and spores from an object or area.

surgical hand antisepsis "Antiseptic handwash or antiseptic hand rub performed preoperatively by surgical personnel to eliminate transient and reduce resident hand flora. Antiseptic detergent preparations often have persistent antimicrobial activity" (CDC. [2002]. *Guideline for hand hygiene in healthcare settings*. Retrieved November 10, 2005, from <http://www.cdc.gov/Handhygiene>)

susceptible host Person who lacks resistance to an agent and is thus vulnerable to disease.

suture Surgical means of closing a wound by sewing, wiring, or stapling the edges of the wound together.

synergy Combined power of many people.

synthesis Putting data together in a new way.

systemic infection Affects the entire body and involves multiple organs.

systole Process of cardiac chamber emptying or ejecting blood.

T

tachycardia A heart rate in excess of 100 beats per minute in an adult.

tachypnea Respiratory rate greater than 24 breaths per minute.

tactile fremitus Vibrations created by sound waves.

tapotement Massage technique using a light tapping of the fingers that stimulates movement in tired muscles.

taxonomy of nursing diagnoses Classifies diagnostic labels based on which human responses the client is demonstrating in response to the actual or perceived stressor.

teaching Active process in which one individual shares information with another as a means to facilitate behavioral changes.

teaching-learning process Planned interaction that promotes a behavioral change that is not a result of maturation or coincidence.

teaching strategies Techniques employed by the teacher to promote learning.

team Group of individuals who work together to achieve a common goal.

team nursing Type of nursing care delivery system in which a variety of personnel (professional, technical, and unlicensed) provide care.

teleology Ethical theory that states that the moral value of a situation is determined by its consequences.

teratogenic substance Substance that can cross the placental barrier and impair normal growth and development.

termination phase Third and final stage of the therapeutic relationship; focuses on evaluation of goal achievement and effectiveness of treatment.

tertiary intention healing Also known as delayed or secondary closure, it is indicated when primary closure of a wound is undesirable.

testimony Written or verbal evidence given by a qualified expert in an area.

thallium Radionuclide that is the physiological analogue of potassium.

theory Set of concepts and propositions that provide an orderly way to view phenomena.

therapeutic Describes actions that are beneficial to the client.

therapeutic communication Use of communication for the purpose of creating a beneficial outcome for the client.

therapeutic massage Application of pressure and motion by the hands with the intent of improving the recipient's well-being.

therapeutic procedure accidents Occur during the delivery of medical or nursing interventions.

therapeutic range Achievement of a constant therapeutic blood level of a medication within a safe range.

therapeutic relationship A relationship that benefits the client's health status.

therapeutic touch Holistic technique that consists of assessing alterations in a person's energy fields and using the hands to direct energy to achieve a balanced state.

therapeutic use of self Process in which nurses deliberately plan their actions and approach the relationship with a specific goal in mind before interacting with the client.

thermoregulation Body's physiological function of heat regulation to maintain a constant internal body temperature.

thoracentesis The aspiration of fluids from the pleural cavity.

thrills Vibrations that feel similar to a purring cat.

thrombus Blood clot.

toddler Developmental stage beginning at approximately 12 to 18 months of age, when a child begins to walk, and ending at approximately age 3.

tolerance Can occur after repeated administration of an opioid analgesic, when a specific dose loses its effectiveness and the client requires larger and larger doses to produce the same level of analgesia.

tort Civil wrong committed upon a person or property stemming from a direct invasion of some legal right of the person, the infraction of some public duty, or the violation of some private obligation by which damages accrue to the person.

tort law Enforcement of duties and rights among individuals independent of contractual agreements.

total client care Variation of the primary nursing management system in which responsibility for client care changes from shift to shift with the assigned caregiver.

totality paradigm Nursing viewpoint that conceptualizes the interaction between person and environment as constant in order to accomplish goals and maintain balance.

total parenteral nutrition (TPN) Intravenous infusion of a solution containing dextrose, amino acids, fats, essential fatty acids, vitamins, and minerals.

total quality management Method of management and system operation that is used to achieve continuous quality improvement.

touch Means of perceiving or experiencing through tactile sensation.

toxic effect Reaction that occurs when the body cannot metabolize a drug, causing the drug to accumulate in the blood.

tracheotomy A surgical procedure in which an opening (stoma) is made through the anterior neck into the trachea; an artificial airway (tracheostomy tube) is placed into the stoma.

transcultural nursing Formal area of study and practice focused on comparative analysis of different cultures and subcultures with respect to cultural care, health and illness beliefs, values, and practices, with the goal of providing health care within the context of the client's culture.

transcutaneous electrical nerve stimulation (TENS) Method of applying minute amounts of electrical stimulation to large-diameter nerve fibers via electrodes placed on the skin to block the passage of pain to the dorsal spinal root.

transducer Instrument that converts electrical energy to sound waves.

transduction The changing of noxious stimuli in sensory nerve endings to energy impulses.

transferrin (nonheme iron) Combination of a blood protein and iron.

transient floras Microorganisms that are episodic.

transmission Movement of impulses from the site of origin to the brain.

transsexuality Belief that one is psychologically of the sex opposite one's anatomic gender.

trigger point A hypersensitive point that when stimulated causes a local twitch or "jump" response.

triglycerides Lipid compounds consisting of three fatty acids and a glycerol molecule.

trocac Large-bored abdominal paracentesis needle.

trough The lowest blood serum concentration of a drug in a person's system.

tympany Musical drumlike sound that occurs over air-filled cavities.

type and cross-match Laboratory test that identifies the client's blood type (e.g., A or B) and determines the compatibility of the blood between potential donor and recipient.

U

ultrasound Use of high-frequency sound waves instead of x-ray film to visualize deep body structures; also called an echogram.

uncomplicated grief A fairly predictable grief reaction following a significant loss, ending with the relinquishing of the lost object and resumption of the previous life.

unintentional wound Unanticipated wound and often the result of trauma or an accident.

unit dose form System of packaging and labeling each dose of medication, usually for a 24-hour period.

unprofessional conduct Conduct that could adversely affect the health and welfare of the public.

unsaturated fatty acids Glycerol esters of organic acids whose atoms are joined by double- or triple-valence bonds.

urgency Timely intervention of surgery.

urge urinary incontinence Uncontrolled discharge of urine caused by hyperactive (unstable) contractions of the detrusor muscle.

urinalysis Laboratory analysis of the urine.

urinary incontinence Uncontrolled loss of urine of sufficient duration and volume to create a social or hygienic problem.

urinary retention Inability to completely evacuate the bladder.

urobilinogen Derived from the normal bacterial action of intestinal floras on bilirubin.

utility Ethical principle that states that an act must result in the greatest amount of good for the greatest number of people involved in a situation.

V

vaccination Provides acquired immunity against specific diseases.

value Variation of the variable.

values Principles that influence the development of beliefs and attitudes.

values clarification Process of analyzing one's own values to better understand what is truly important to oneself.

variable Anything that may differ from the norm.

variations Goals not met or interventions not performed according to the time frame; also called variance.

vasoconstriction The narrowing of the vessels, usually leading to reduced blood flow.

vasodilation The widening of the vessels, usually leading to increased blood flow.

vectorborne transmission Occurs when an agent is transferred to a susceptible host by animate means such as mosquitoes, fleas, ticks, lice, and other animals.

vehicle transmission Occurs when an agent is transferred to a susceptible host by contaminated inanimate objects such as water, food, milk, drugs, and blood.

venipuncture Puncturing of a vein with a needle to aspirate blood.

ventilation Movement of air into and out of the lungs for the purpose of delivering fresh air to the alveoli.

ventilation-perfusion (V/Q) mismatching Condition in which perfusion and ventilation of the lung areas are not adequately balanced.

veracity Ethical principle that means that one should be truthful, neither lying nor deceiving others.

verbal message Message communicated through words or language, both spoken and written.

vesicant Medication that causes blisters and tissue injury when it escapes into surrounding tissue.

vesicular sounds Soft, breezy, and low-pitched sounds heard longer on inspiration than expiration that result from air moving through the smaller airways over the lung's periphery, with the exception of the scapular area.

vibration Massage technique using rapid movements that stimulate or relax muscles.

virulence Degree of pathogenicity of an infectious microorganism (pathogen).

visceral pain Discomfort in the internal organs that is less localized and more slowly transmitted than cutaneous pain.

visual channel Transmission of messages through sight, observation, and perception.

visual learner Style of learning in which people learn by processing information by seeing.

vital capacity Amount of air exhaled from the lungs after a minimal full inspiration.

vital signs Measurement of the client's body temperature (T), pulse (P) and respiratory (R) rates, and blood pressure (BP).

vitamins Organic compounds.

voiding Process of urine evacuation.

W

walking rounds Reporting method used when the members of the care team walk to each client's room and discuss care and progress with each other and the client.

water-soluble vitamins Vitamins that require daily ingestion in normal quantities because they are not stored in the body.

wellness Condition in which an individual functions at optimal levels.

wellness nursing diagnosis Nursing diagnosis that indicates the client's expression of a desire to obtain a higher level of wellness in some area of function. It is composed of the diagnostic label preceded by the phrase "potential for enhanced."

wheezes Heard predominantly on expiration all over the lungs as a continuous sonorous wheeze (low-pitched snoring) or sibilant wheeze (high-pitched musical sound).

whistle-blowing Calling attention to the unethical, illegal, or incompetent actions of others.

working phase Second stage of the therapeutic relationship in which problems are identified, goals are established, and problem-solving methods are selected.

work of breathing Amount of muscular energy (work) required to accomplish ventilation.

wound Disruption in the integrity of body tissue.

Y

yellow wound Has either fibrinous slough or purulent exudate from bacteria.

young adulthood Developmental stage from the ages of 21 to approximately 40 years.

Z

Z-track (zigzag) technique Method of intramuscular injection to seal the medication in the muscle, preventing the drug from irritating the subcutaneous tissue.

StudyWare™ to Accompany Fundamentals of Nursing: Standards and Practice, Fourth Edition

MINIMUM SYSTEM REQUIREMENTS

- Operating systems: Microsoft Windows XP w/SP 2, Windows Vista w/SP 1, Windows 7
- Processor: Minimum required by Operating System
- Memory: Minimum required by Operating System
- Hard Drive Space: 500MB
- Screen resolution: 1024 × 768 pixels
- CD-ROM drive
- Sound card & listening device required for audio features
- Flash Player 10. The Adobe Flash Player is free, and can be downloaded from <http://www.adobe.com/products/flashplayer/>

SETUP INSTRUCTIONS

1. Insert disc into CD-ROM drive. The StudyWare™ installation program should start automatically. If it does not, go to step 2.

2. From My Computer, double-click the icon for the CD drive.
3. Double-click the *setup.exe* file to start the program.

TECHNICAL SUPPORT

Telephone: 1-800-648-7450

8:30 A.M.–6:30 P.M. Eastern Time

E-mail: delmar.help@cengage.com
